    PollReceiver.scheduleInexactAlarm(this, alarms, period,
        download.isChecked());
  }
  else {
    PollReceiver.cancelAlarm(this, alarms);
  }
}
```

It uses the same recipe as manageExact(), except that it calls scheduleInexactAlarm() on PollReceiver. scheduleInexactAlarm(), in turn, uses setInexactRepeating() on AlarmManager to arrange to get control every so often.

Pondering Backoff Criteria

Sometimes, even with the Internet-availability checks offered by JobScheduler, you find that you cannot actually do the job you scheduled. Perhaps the server is down for maintenance, or has been replaced by a honeycomb frame, or something. In this case, while you failed to do the job now, you may want to try again later.

Sometimes, "later" can just be handled by your existing JobScheduler setup. If the job in question is a periodic job, and missing a whole period is not a big problem, you might just continue on normally.

However, sometimes you will want the job to be retried, either because:

- it was a one-shot job, not a periodic one, or

- the period of the job is fairly long (e.g., once per day) and you want to retry well before the job is scheduled to happen again

Requesting that a job be retried is handled by the `boolean` parameter to `jobFinished()` or the `boolean` return value from `onStopJob()`. `true` means that you want the job to be rescheduled; `false` means that it is OK to skip the job entirely.

Given that you use `true` for either `jobFinished()` or `onStopJob()`, there are three possible options for how to request and retry a failed job:

- What happens for a job which you requested only run when the device is idle
- What happens for other jobs by default
- How you can influence the timing of when the job is retried, known as the "backoff criteria"

Idle Jobs

If you requested idle-only jobs, if the user wakes up the device while the job is going on, you will be called with `onStopJob()`. Ideally, you then stop the background work and return `true` or `false` from `onStopJob()` to determine if the job should be rescheduled.

If you request a job be rescheduled, when that job is set up to only run when the device is idle, the job is simply "put back in the queue" to be tried again during the next idle window.

Default Behavior

If, for a non-idle-only job, you use `true` for `jobFinished()` or `onStopJob()`, the next time to try will be calculated using the default backoff criteria, which has a time of 30 seconds and a policy of `BACKOFF_POLICY_EXPONENTIAL`.

What this means is that the first time you use `true`, your job will be tried again 30 seconds later. If you use `true` again for that job, it will be tried again 60 seconds later. If you use `true` again, it would be tried 120 seconds later — in other words, each job failure will reschedule using the formula `2^(n-1)*t`, where `n` is the number of failures and `t` is 30 seconds.

However, there is a cap of 18,000,000 milliseconds, or what normal people would refer to as “5 hours”. That is the most your job will be delayed, regardless of how many failures you have.

Custom Backoff Criteria

You can change the backoff criteria for non-idle-only jobs via a call to `setBackoffCriteria()` on your `JobInfo.Builder`, where you provide your own time (measured in milliseconds) and policy (`BACKOFF_POLICY_EXPONENTIAL` or `BACKOFF_POLICY_LINEAR`).

As noted above, the formula for exponential backoff rescheduling is **2[sup>n-1</sup]t**, where `n` is the number of failures and `t` is your chosen time.

The formula for linear backoff rescheduling is `n*t`, where `n` is the number of failures and `t` is your chosen time.

Other JobScheduler Features

There are a few other options for scheduling jobs that may be of use to you in select circumstances:

- `JobInfo.Builder` has `setOverrideDeadline()`, which indicates a maximum delay for this job before it will be executed even if other criteria (e.g., idleness) have been met. Note that this is only available on one-shot jobs, not periodic jobs.
- The `JobParameters` passed to `onStartJob()` has an `isOverrideDeadlineExpired()` method. This will return `true` if the job was executed early due to a `setOverrideDeadline()` value being met. This will indicate to you that your requirements may not be met (e.g., Internet access) and you will need to double-check those things yourself.
- `JobInfo.Builder` has `setMinimumLatency()` which sets a minimum delay time; the job will not be considered until at least this amount of time has elapsed. Note that this is only available on one-shot jobs, not periodic jobs.

Also, `JobScheduler` has a `getAllPendingJobs()` method, that returns a `List` of `JobInfo` objects representing “the jobs registered by this package that have not yet been executed”. Presumably, this includes the next occurrence of any periodic jobs and any jobs that are blocked pending a backoff delay, though the documentation is unclear on this point.

Android 6.0 and "the War on Background Processing"

Google has been increasingly aggressive about trying to prevent background work, particularly while the device is deemed to be idle, in an effort to improve battery life. In Android 4.4 (API Level 19), we were given a strong "nudge" to use inexact alarms. In Android 5.0 (API Level 21), we were given `JobScheduler` as a smarter `AlarmManager`, but one that also emphasizes inexact schedules.

In Android 6.0, Google broke out more serious weaponry in the war against background work, in ways that are going to cause a fair bit of pain and confusion for users.

Doze Mode

If the device's screen is off, the device is not being charged, and the device does not appear to be moving (as determined via sensors, like the accelerometer), an Android 6.0+ device will go into "Doze mode". This mode is reminiscent of similar modes used by specific device manufacturers, such as SONY's STAMINA mode.

While in "Doze mode", your scheduled alarms (with `AlarmManager`), jobs (with `JobScheduler`), and syncs (with `SyncManager`) will be ignored by default, except during occasional "idle maintenance windows". In short, much of what your user thinks will happen in the background will not happen.

App Standby Mode

Further compounding the problem from "Doze mode" is "app standby".

After some undefined period of time, an app that has not been in the foreground (or is showing a `Notification`) will be put into "standby" state. While the app is in "standby":

- If the device is unplugged, the app behaves as though the device is in "Doze mode", with background access degrading over time to a point where the app will only get network access in the background around once per day
- If the device is plugged in, the app behaves normally

How to Win the War

The vision behind "the war on background processing" is to improve battery life, particularly while the device is not being used (Doze mode) or for apps that are not being used (app standby). However, any number of apps will have their behavior severely compromised by these changes.

Here are some techniques for helping your app behave better on Android 6.0+.

GCM

If you are using Google Cloud Messaging (GCM), and you send a "high-priority tickle" to the app on a device, that may allow you to run then, despite being in Doze mode or app standby mode. However, this implies that you have all the plumbing set up for GCM, that the device has an active network connection, etc. Also, this requires you to adopt GCM, which has its issues (no service-level agreement, Google has access to all of the messages, etc.).

…AndAllowWhileIdle()

`AlarmManager` now has two additional methods:

- `setAndAllowWhileIdle()`
- `setExactAndAllowWhileIdle()`

These work better in Doze mode and app standby mode, allowing you to get control briefly even if otherwise you would not. However:

- While in those modes, these alarms will occur at most once every 15 minutes, except during the aforementioned "idle maintenance windows"
- There is no guarantee of how long you will be able to keep the device awake
- There is no guarantee that you can access the Internet

Use a Foreground Service

While not officially documented, Dianne Hackborn (a core Android developer) wrote in a comment on a Google+ post:

> Apps that have been running foreground services (with the associated notification) are not restricted by doze.

The Whitelist

Users have the ability to disable these “battery optimizations” for an individual app, allowing it to run closer to normally. On the “Apps” screen in Settings, there is now a gear icon in the action bar:

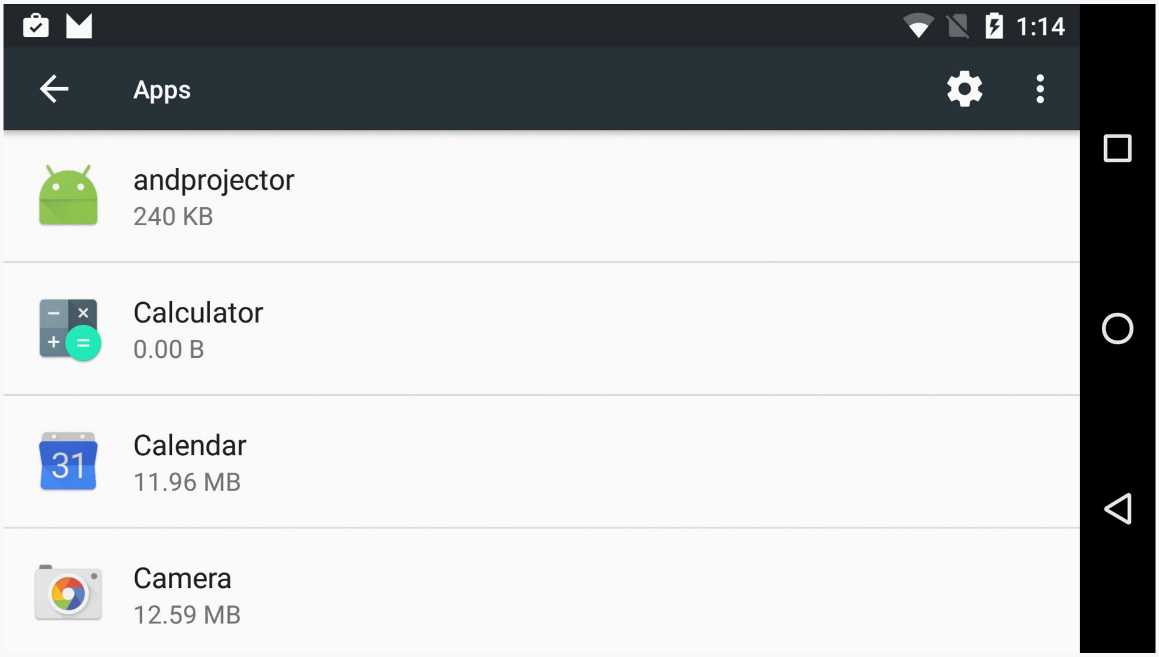

Figure 746: Android 6.0, Settings App, Apps Screen

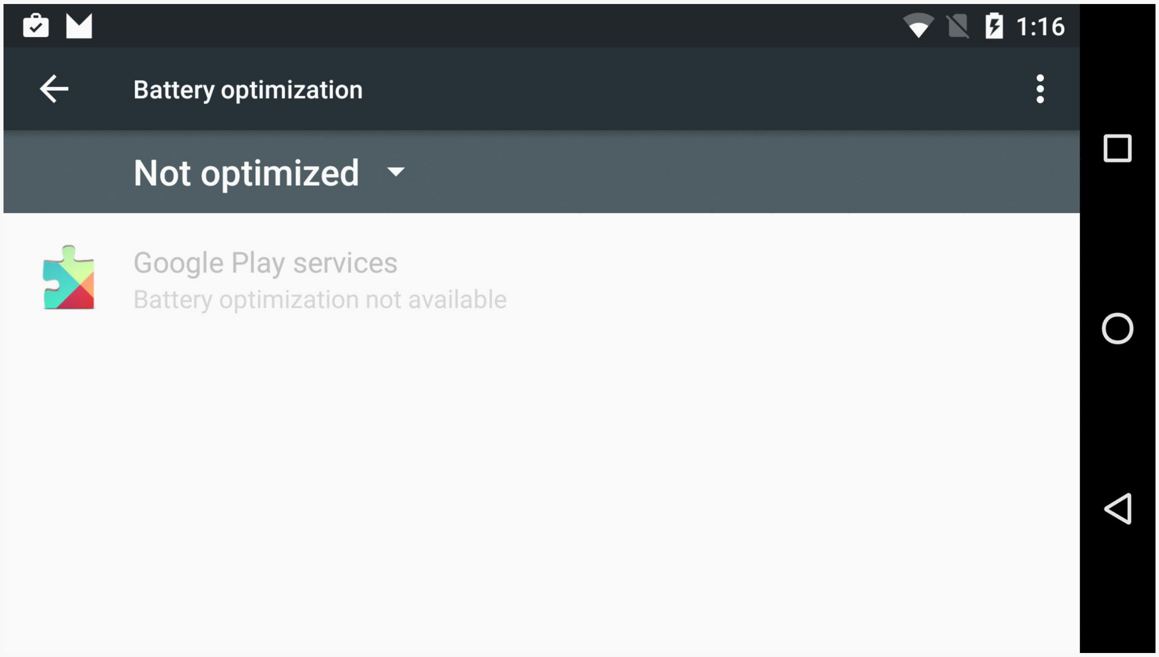
Tapping that brings up a “Configure apps” screen. On there is a “Battery optimization” entry. Tapping on that will initially show the apps for which battery optimizations will be ignored (a.k.a., “Not optimized”):



Battery optimization

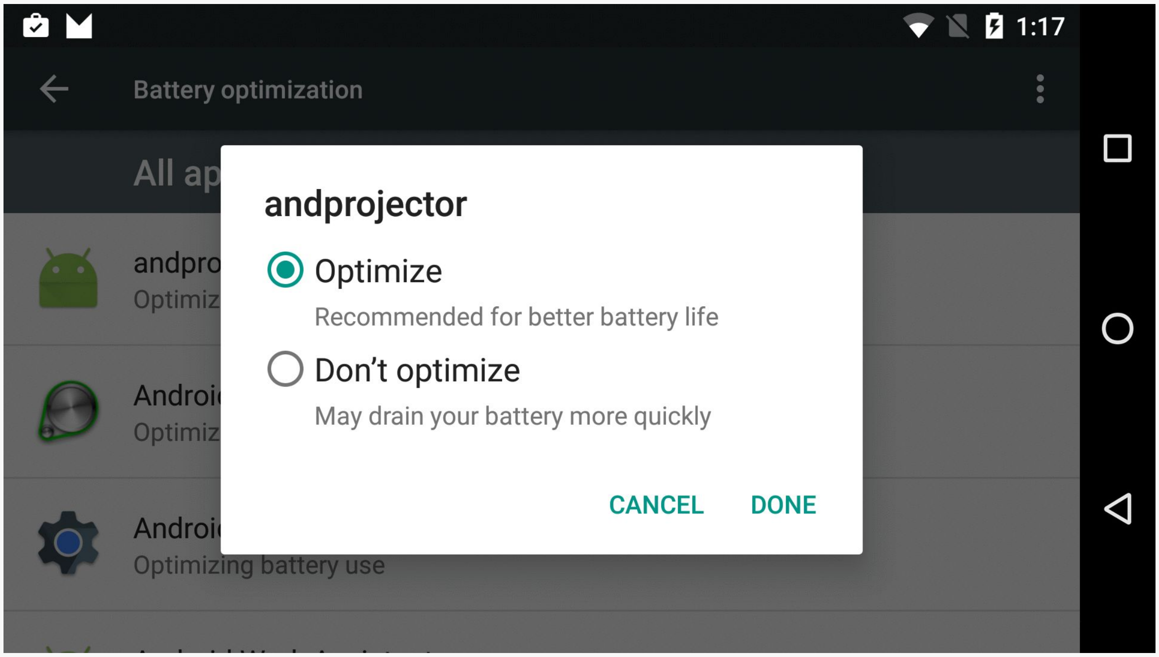
Not optimized

Google Play services

Battery optimization not available

Figure 747: Android 6.0, Settings App, Battery Optimization Screen

If the user toggles the "Not optimized" drop-down to "All apps" and taps on one of those apps, the user can elect to decide whether to "optimize" the app (and cause app standby to trigger) or not:



andprojector

● Optimize

Recommended for better battery life

○ Don't optimize

May drain your battery more quickly

Figure 748: Android 6.0, Settings App, Battery Optimization Options Dialog

This "whitelist" of apps allows you to hold wakelocks and access the network. It does *not* change the behavior of `AlarmManager`, `JobScheduler`, or `SyncManager` — those things will still fire far less frequently in Doze mode or in app standby.

To determine if your app is already on the whitelist, you can call `isIgnoringBatteryOptimizations()` on a `PowerManager` instance.

If you would like to lead the user over to the screen where they can generally configure the whitelist, use an `ACTION_IGNORE_BATTERY_OPTIMIZATION_SETTINGS` `Intent` with `startActivity()`:

```
startActivity(new Intent(Settings.ACTION_IGNORE_BATTERY_OPTIMIZATION_SETTINGS));
```

If you would like to drive the user straight to the screen where they can add your specific app to the whitelist:

- Request the `REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` permission via a `<uses-permission>` element in the manifest
- Create a `package:` `Uri` pointing to your app
- Wrap that `Uri` in an `ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` `Intent`
- Call `startActivity()` with that `Intent`

```
Intent i=new Intent(Settings.ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS,
                    Uri.parse("package:" + getPackageName()));

startActivity(intent);
```

Note, though, that using this may cause your app to be banned on the Play Store, even though it is a legitimate part of the Android SDK.

While the whitelist existed in the first developer preview of Android 6.0, its role was expanded very late in the process, as originally it did not affect Doze mode. The rationale appears to be for apps that cannot use GCM as the trigger mechanism to do background work, particularly if they need something else network-based as the trigger. For example, SIP clients, XMPP clients, MQTT clients, and so on are idle until a message comes in on an open network connection, yet none of those can be readily converted to use GCM. The whitelist allows apps to behave as they did prior to Android 6.0, though it requires user involvement.

However, any app can use this whitelist approach to return to more-normal behavior. The biggest limitation is for apps that relied upon `AlarmManager`, `JobScheduler`, or `SyncAdapter` as their triggers, as those are still crippled, regardless of whitelist status. The best you can get is ~15 minute periods, via `setExactAndAllowWhileIdle()`.

If you are sure that you need polling more frequently than that, and you are sure that the user will value that polling, your primary option is to use a foreground `Service` (or whitelisted app) and Java's `ScheduledExecutorService` to get control every so often, using a partial wakelock to keep the CPU powered on *all the time*. From a battery standpoint, this is horrible, far worse than the behavior you would get on Android 5.1 and earlier using `AlarmManager`. But, it's the ultimate workaround, which is why it is demonstrated in the `AlarmManager/AntiDoze` sample application.

The AntiDoze sample is based off of the greenrobot's EventBus sample from the chapter on event bus alternatives. In that app, we used `AlarmManager` to get control every 15 seconds to either update a fragment (if the UI was in the foreground) or show a `Notification` (if not). AntiDoze gets rid of the every-event `Notification`, replacing it with appending an entry to a log file. And, it replaces `AlarmManager` with `ScheduledExecutorService` inside of a foreground `Service`, trying to run forever and get control every 15 seconds along the way.

This app has two product flavors defined in its `app/build.gradle` file, `normal` and `foreground`:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.android.support:support-v13:23.0.1'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.1"

  defaultConfig {
        minSdkVersion 19
    targetSdkVersion 23
  }

    productFlavors {
        foreground {
            buildConfigField "boolean", "IS_FOREGROUND", "true"
        }

        normal {
            buildConfigField "boolean", "IS_FOREGROUND", "false"
        }
    }
}
```

A `normal` build will use a regular `Service`; a `foreground` build will use a foreground `Service`.

The launcher activity is `EventDemoActivity`. Its `onCreate()` method will do three things:

1. If we are on Android 6.0 or higher, it will use `isIgnoringBatteryOptimizations()` on `PowerManager` to see if we are already on the battery optimization whitelist, and if not, display a system-supplied dialog-themed activity to ask the user to add our app to the whitelist
2. If we do not already have the `EventLogFragment`, add it
3. If we do not already have the `EventLogFragment`, also start up the `ScheduledService`, as probably it is not already running

```
package com.commonsware.android.antidoze;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Build;
import android.os.Bundle;
import android.os.PowerManager;
import android.provider.Settings;
```

```
public class EventDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (Build.VERSION.SDK_INT>Build.VERSION_CODES.LOLLIPOP_MR1) {
      String pkg=getPackageName();
      PowerManager pm=getSystemService(PowerManager.class);

      if (!pm.isIgnoringBatteryOptimizations(pkg)) {
        Intent i=
          new Intent(Settings.ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS)
            .setData(Uri.parse("package:"+pkg));

        startActivity(i);
      }
    }

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      getFragmentManager().beginTransaction()
        .add(android.R.id.content,
          new EventLogFragment()).commit();
      startService(new Intent(this, ScheduledService.class));
    }
  }
}
```

To be able to use `ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS`, we need to request and hold the `REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` permission, which we handle in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonsware.android.antidoze"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.WAKE_LOCK"/>
  <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>
  <uses-permission
android:name="android.permission.REQUEST_IGNORE_BATTERY_OPTIMIZATIONS" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
      android:name="EventDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <receiver android:name="PollReceiver">
      <intent-filter>
        <action android:name="android.intent.action.BOOT_COMPLETED"/>
      </intent-filter>
    </receiver>

    <receiver android:name="StopReceiver"/>

    <service android:name="ScheduledService"/>
  </application>

</manifest>
```

The rest of the UI layer is unchanged. Where the differences really creep in is with `ScheduledService`. This used to be a `WakefulIntentService`, triggered by an alarm event. Now, it is a regular service, designed to run all the time.

As part of initializing the `ScheduledService` class, we create an instance of `ScheduledExecutorService`, through the `newSingleThreadScheduledExecutor()` static method on the `Executors` utility class:

```
  private ScheduledExecutorService sched=
    Executors.newSingleThreadScheduledExecutor();
```

In `onCreate()`, we:

- Acquire a partial wakelock
- Call a private `foregroundify()` method to make our service be a foreground service with a suitable `Notification`, if our `IS_FOREGROUND` value is `true` based upon on our product flavor
- Set up a `File` for use with logging (named `log`), including creating the directory for it if needed
- Call `scheduleAtFixedRate()` on the `ScheduledExecutorService` to get control every 15 seconds

```
  @Override
  public void onCreate() {
    super.onCreate();

    PowerManager mgr=(PowerManager)getSystemService(POWER_SERVICE);

    wakeLock=mgr.newWakeLock(PowerManager.PARTIAL_WAKE_LOCK,
      getClass().getSimpleName());
    wakeLock.acquire();

    if (BuildConfig.IS_FOREGROUND) {
      foregroundify();
    }

    log=new File(getExternalFilesDir(null), "antidoze-log.txt");
    log.getParentFile().mkdirs();
    sched.scheduleAtFixedRate(this, 0, 15, TimeUnit.SECONDS);
  }
```

We can pass the service itself to `scheduleAtFixedRate()` because it implements the `Runnable` interface. Its `run()` method uses greenrobot's EventBus to tell the UI layer about our event, plus it calls an `append()` method to log that event to our `log` file:

```
  @Override
  public void run() {
    RandomEvent event=new RandomEvent(rng.nextInt());

    EventBus.getDefault().post(event);
    append(log, event);
  }
```

`append()` simply uses Java file I/O to append a line to the `log` file:

```
  private void append(File f, RandomEvent event) {
    try {
      FileOutputStream fos=new FileOutputStream(f, true);
      Writer osw=new OutputStreamWriter(fos);

      osw.write(event.when.toString());
      osw.write(" : ");
      osw.write(Integer.toHexString(event.value));
      osw.write('\n');
      osw.flush();
      fos.flush();
      fos.getFD().sync();
      fos.close();

      Log.d(getClass().getSimpleName(),
        "logged to "+f.getAbsolutePath());
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(),
        "Exception writing to file", e);
    }
  }
```

The `foregroundify()` method, called from `onCreate()`, creates a `Notification` and calls `startForeground()` to make the service be a foreground service:

```
  private void foregroundify() {
    NotificationCompat.Builder b=
      new NotificationCompat.Builder(this);
    Intent iActivity=new Intent(this, EventDemoActivity.class);
    PendingIntent piActivity=
      PendingIntent.getActivity(this, 0, iActivity, 0);
    Intent iReceiver=new Intent(this, StopReceiver.class);
    PendingIntent piReceiver=
      PendingIntent.getBroadcast(this, 0, iReceiver, 0);
    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(getString(R.string.app_name))
      .setContentIntent(piActivity)
      .setSmallIcon(R.drawable.ic_launcher)
      .setTicker(getString(R.string.app_name))
      .addAction(R.drawable.ic_stop_white_24dp,
        getString(R.string.notif_stop),
        piReceiver);

    startForeground(NOTIFY_ID, b.build());
  }
```

The `Notification` includes a "stop" action, pointing to a `StopReceiver`, which just uses `stopService()` to stop the service. This allows the user to shut down our background service at any point, just via the `Notification`.

When the service is stopped, `onDestroy()` tidies things up, notably releasing the wakelock:

```
  @Override
  public void onDestroy() {
    sched.shutdownNow();
    wakeLock.release();
    stopForeground(true);

    super.onDestroy();
  }
```

Running this overnight on an Android 6.0 device shows that, indeed, we get control every 15 seconds, as desired. The device's battery drains commensurately, considering that we are keeping the CPU powered on all of the time. Either the whitelist keeps us going (`normal` flavor) or the foreground service keeps us going (`foreground` flavor).

setAlarmClock()

`AlarmManager` also has a `setAlarmClock()` method, added in API Level 21. This works a bit like `setExact()` (and, hence, `setExactAndAllowWhileIdle()`), in that you provide a time to get control and a `PendingIntent` to be invoked at that time. From the standpoint of power management, Doze mode leaves `setAlarmClock()` events alone, and so they are executed at the appropriate time regardless of device state. However, at the same time, `setAlarmClock()` has some user-visible impacts that make it suitable for certain apps (e.g., calendar reminders) and unsuitable for others (e.g., polling).

The AlarmManager/AlarmClock sample application demonstrates the use of setAlarmClock() as an alternative to setExactAndAllowWhileIdle().

This app is reminiscent of the AntiDoze sample from earlier in this chapter. Once again, we have a fork off of an earlier demo of using greenrobot's EventBus to handle notifications from periodic work. In this case, rather than using AlarmManager and setRepeating() (as the original demo used) or using ScheduledExecutorService (as AntiDoze used), we use setAlarmClock() on AlarmManager.

PollReceiver now has a substantially different scheduleAlarms() implementation, along with a slightly different onReceive() implementation:

```
package com.commonsware.android.alarmclock;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonsware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
  private static final int PERIOD=15000; // 15 seconds

  @Override
  public void onReceive(Context ctxt, Intent i) {
    if (i.getAction()==null) {
      WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
    }

    scheduleAlarms(ctxt);
  }

  static void scheduleAlarms(Context ctxt) {
    AlarmManager mgr=
      (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);
    Intent i2=new Intent(ctxt, EventDemoActivity.class);
    PendingIntent pi2=PendingIntent.getActivity(ctxt, 0, i2, 0);

    AlarmManager.AlarmClockInfo ac=
      new AlarmManager.AlarmClockInfo(System.currentTimeMillis()+PERIOD,
        pi2);

    mgr.setAlarmClock(ac, pi);
  }
}
```

scheduleAlarms() creates a PendingIntent identifying the PollReceiver itself, as was done in the original demo. This sample app is using WakefulIntentService, and the rules for wakeup-style alarms is that you should have the PendingIntent be a broadcast one. While it is unclear if setAlarmClock() has the same requirement, it seems reasonably likely.

However, scheduleAlarms() then creates a *second* PendingIntent, one pointing to the EventDemoActivity. That PendingIntent is supplied to the constructor to AlarmManager.AlarmClockInfo, along with the time we want the alarm to go off, expressed in the RTC-style timebase (i.e., milliseconds since the Unix epoch, System.currentTimeMillis()). We will see in a bit where that PendingIntent gets used.

Then, we call setAlarmClock() on AlarmManager, providing the AlarmClockInfo object and the first PendingIntent, to be invoked at the time indicated in the AlarmClockInfo.

As with the original example, onReceive() is used both for ACTION_BOOT_COMPLETED and for the one AlarmManager PendingIntent. To distinguish between these cases, onReceive() examines the action string of the incoming Intent — if this is not null, it must be the ACTION_BOOT_COMPLETED broadcast, as we did not put an action string in the Intent used to create the PendingIntent in scheduleAlarms(). If the Intent action is null, though, this is our PendingIntent invocation, so we call sendWakefulWork() to have the ScheduledService do something (in this case, log a message to a file and use EventBus to let the UI layer know about the event). However, in either case (Intent action is null or not), we call scheduleAlarms() to set up the next event, as setAlarmClock() is a one-shot alarm, not a recurring alarm.

The net effect is that if you run this app, your code gets control every 15 seconds, updating the fragment (via the event bus) and logging a line to a log file (using an append() method akin to the one from AntiDoze). More importantly, this will continue working despite Doze mode, even without your app being on the whitelist.

The biggest issue with setAlarmClock() is that it is visible to the user:

- The user will see the alarm clock icon in their status bar, as if they had set an alarm with their device's built-in alarm clock app
- The user will see the time of the alarm when they fully slide open their notification shade

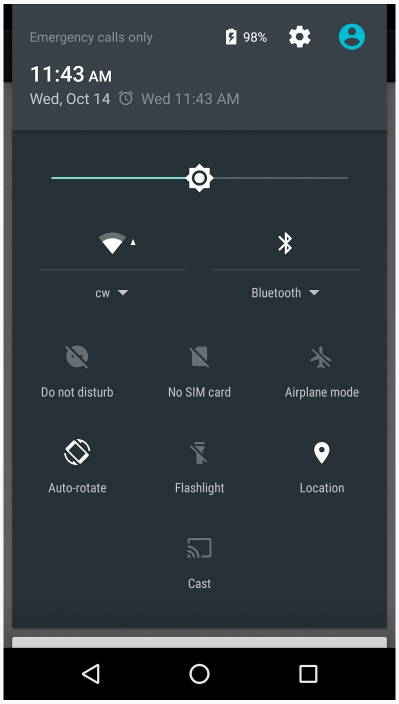


Figure 749: Notification Shade, Showing Upcoming Alarm

- Tapping on the alarm time in the notification shade will invoke the `PendingIntent` that you put into the `AlarmClockInfo` object

By default, executing this `PendingIntent` will start up the activity in a new task, and so you will need to consider using `android:launchMode` or `android:taskAffinity` to redirect the activity back to your original task.

For an app offering calendar-style reminders, none of this is necessarily a bad thing. You would tie the `PendingIntent` for the `AlarmClockInfo` object to the activity that shows details of that particular appointment, so the user can review the details, remove the reminder request, etc.

For an app looking to do periodic work, the ever-present icon may aggravate some users, particularly those using alarm clock apps for actual alarm clock work and wondering why an alarm is set.

Also note that the manual rescheduling means that you are likely to have a bit of drift for periodic work. In the case of the sample app, each event will occur at least 15000 milliseconds apart. In reality, it will be slightly more, reflecting the execution time between when the system recognizes that it is time to invoke the alarm and the time when we call `setAlarmClock()` again. Many apps can just live with the drift. If this is an issue for you, you can try to minimize the drift by doing a more elaborate calculation of the next alarm time, one that cancels out previous drift.

Hope Somebody Else Does Something

Doze mode is for the entire device. Hence, your app may wind up getting control more frequently than you might expect, even without any code changes, simply because *somebody else* is doing something to get control more frequently.

GCM Network Manager

As noted earlier in this chapter, Android 5.0 added `JobScheduler`. However, Google did not release any sort of backport of this, as that would be difficult to do on a whole-device basis. They did not even implement a `JobSchedulerCompat`, hampering adoption.

Google Cloud Messaging (GCM) now has a `GcmNetworkManager` that, despite the name, is basically a backport of `JobScheduler`. In fact, it will delegate to `JobScheduler` on Android 5.0+ devices. It is unclear how old of an Android OS version `GcmNetworkManager` supports, but it is likely to work on more devices than does `JobScheduler`.

Trail: Hardware and System Services

Accessing Location-Based Services

A popular feature on current-era mobile devices is GPS capability, so the device can tell you where you are at any point in time. While the most popular use of GPS service is mapping and directions, there are other things you can do if you know your location. For example, you might set up a dynamic chat application where the people you can chat with are based on physical location, so you are chatting with those you are nearest. Or, you could automatically "geotag" posts to Twitter or similar services.

GPS is not the only way a mobile device can identify your location. Alternatives include:

1. Cell tower triangulation, where your position is determined based on signal strength to nearby cell towers
2. Proximity to public WiFi "hotspots" that have known geographic locations
3. GPS alternatives, such as GLONASS (Russia), Galileo (European Union, still under development), and Compass (China, still under development)

Android devices may have one or more of these services available to them. You, as a developer, can ask the device for your location, plus details on what providers are available. There are even ways for you to simulate your location in the emulator, for use in testing your location-enabled applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on threads.

Location Providers: They Know Where You're Hiding

Android devices can have access to several different means of determining your location. Some will have better accuracy than others. Some may be free, while others may have a cost associated with them. Some may be able to tell you more than just your current position, such as your elevation over sea level, or your current speed.

Android, therefore, has abstracted all this out into a set of `LocationProvider` objects. Your Android environment will have zero or more `LocationProvider` instances, one for each distinct locating service that is available on the device. Providers know not only your location, but also their own characteristics, in terms of accuracy, cost, etc.

You, as a developer, will use a `LocationManager`, which holds the `LocationProvider` set, to figure out which `LocationProvider` is right for your particular circumstance. You will also need a permission in your application, or the various location APIs will fail due to a security violation. Depending on which location providers you wish to use, you may need `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. Note that `ACCESS_COARSE_LOCATION` may intentionally "fuzz" or filter out location fixes that are "too good" (i.e., more accurate than a city block).

Finding Yourself

The obvious thing to do with a location service is to figure out where you are right now.

To do that, you need to get a `LocationManager` — call `getSystemService(LOCATION_SERVICE)` from your activity or service and cast it to be a `LocationManager`.

The next step to find out where you are is to get the name of the `LocationProvider` you want to use. Here, you have two main options:

- Ask the user to pick a provider
- Find the best-match provider based on a set of criteria

If you want the user to pick a provider, calling `getProviders()` on the `LocationManager` will give you a `List` of providers, which you can then present to the user for selection.

Or, you can create and populate a `Criteria` object, stating the particulars of what you want out of a `LocationProvider`, such as:

1. `setAltitudeRequired()` to indicate if you need the current altitude or not
2. `setAccuracy()` to set a minimum level of accuracy, in meters, for the position
3. `setCostAllowed()` to control if the provider must be free or if it can incur a cost on behalf of the device user

Given a filled-in `Criteria` object, call `getBestProvider()` on your `LocationManager`, and Android will sift through the criteria and give you the best answer. Note that not all of your criteria may be met – all but the monetary cost criterion might be relaxed if nothing matches.

You are also welcome to hard-wire in a `LocationProvider` name (e.g., `GPS_PROVIDER`), perhaps just for testing purposes.

Once you know the name of the `LocationProvider`, you can call `getLastKnownLocation()` to find out where you were recently. However, unless something else is causing the desired provider to collect fixes (e.g., unless the GPS radio is on), `getLastKnownLocation()` will return `null`, indicating that there is no known position. On the other hand, `getLastKnownLocation()` incurs no monetary or power cost, since the provider does not need to be activated to get the value.

This method returns a `Location` object, which can give you the latitude and longitude of the device in degrees as a Java `double`. If the particular location provider offers other data, you can get at that as well:

1. For altitude, `hasAltitude()` will tell you if there is an altitude value, and `getAltitude()` will return the altitude in meters.
2. For bearing (i.e., compass-style direction), `hasBearing()` will tell you if there is a bearing available, and `getBearing()` will return it as degrees east of true north.
3. For speed, `hasSpeed()` will tell you if the speed is known and `getSpeed()` will return the speed in meters per second.

A more likely approach to getting the Location from a LocationProvider, though, is to register for updates, as described in the next section.

On the Move

Not all location providers are necessarily immediately responsive. GPS, for example, requires activating a radio and getting a fix from the satellites before you get a location. That is why Android does not offer a getMeMyCurrentLocationNow() method. Combine that with the fact that your users may well want their movements to be reflected in your application, and you are probably best off registering for location updates and using that as your means of getting the current location.

The Internet/Weather sample application shows how to register for updates — call requestLocationUpdates() on your LocationManager instance. This takes four parameters:

- The name of the location provider you wish to use
- How long, in milliseconds, *should* have elapsed before we might get a location update
- How far, in meters, must the device have moved before we might get a location update
- An implementation of the LocationListener interface that will be notified of key location-related events

LocationListener requires four methods, the big one being onLocationChanged(), where you will receive your Location object when an update is ready:

```
@Override
public void onLocationChanged(Location location) {
  FetchForecastTask task=new FetchForecastTask();

  task.execute(location);
}
```

Bear in mind that the time parameter is only a guide to help steer Android from a power consumption standpoint. You may get many more location updates than this. To get the maximum number of location updates, supply 0 for both the time and distance constraints.

When you no longer need the updates, call removeUpdates() with the LocationListener you registered. If you fail to do this, your application will continue receiving location updates even after all activities and such are closed up, which will also prevent Android from reclaiming your application's memory.

There is another version of `requestLocationUpdates()` that takes a `PendingIntent` rather than a `LocationListener`. This is useful if you want to be notified of changes in your position even when your code is not running. For example, if you are logging movements, you could use a `PendingIntent` that triggers a `BroadcastReceiver` (`getBroadcast()`) and have the `BroadcastReceiver` add the entry to the log. This way, your code is only in memory when the position changes, so you do not tie up system resources while the device is not moving.

Are We There Yet? Are We There Yet? Are We There Yet?

Sometimes, you want to know not where you are now, or even when you move, but when you get to where you are going. This could be an end destination, or it could be getting to the next step on a set of directions, so you can give the user the next turn.

To accomplish this, `LocationManager` offers `addProximityAlert()`. This registers a `PendingIntent`, which will be fired off when the device gets within a certain distance of a certain location. The `addProximityAlert()` method takes, as parameters:

1. The latitude and longitude of the position that you are interested in
2. A radius, specifying how close you should be to that position for the `Intent` to be raised
3. A duration for the registration, in milliseconds — after this period, the registration automatically lapses. A value of `-1` means the registration lasts until you manually remove it via `removeProximityAlert()`.
4. The `PendingIntent` to be raised when the device is within the "target zone" expressed by the position and radius

Note that it is not guaranteed that you will actually receive an `Intent`, if there is an interruption in location services, or if the device is not in the target zone during the period of time the proximity alert is active. For example, if the position is off by a bit, and the radius is a little too tight, the device might only skirt the edge of the target zone, or go by so quickly that the device's location isn't sampled while in the target zone.

It is up to you to arrange for an activity or receiver to respond to the Intent you register with the proximity alert. What you then do when the Intent arrives is up to you: set up a notification (e.g., vibrate the device), log the information to a content provider, post a message to a Web site, etc. Note that you will receive the Intent whenever the position is sampled and you are within the target zone – not just upon entering the zone. Hence, you will get the Intent several times, perhaps quite a few times depending on the size of the target zone and the speed of the device's movement.

Testing… Testing…

The Android emulator does not have the ability to get a fix from GPS, triangulate your position from cell towers, or identify your location by some nearby WiFi signal. So, if you want to simulate a moving device, you will need to have some means of providing mock location data to the emulator.

You can send location fixes via telnet to an emulator. The port number is in your emulator's title bar (usually 5554 for the first running emulator instance). You can then run:

```
telnet localhost 5554
```

to access the Android Console within the emulator. Running the geo fix NNN NNN command, where NNN NNN is your latitude and longitude, will have the emulator respond as if those coordinates came from GPS.

Alternative Flavors of Updates

There are more ways to get updates from LocationManager than the versions of requestLocationUpdates() we have seen so far. There are four major axes of difference:

1. Some versions of requestLocationUpdates() take a Criteria object, having Android give you fixes based on the best-available provider given the requirements stipulated in the Criteria
2. Some versions of requestLocationUpdates() take a Looper as a parameter, allowing you to receive updates on a background HandlerThread instead of the main application thread
3. Some versions of requestLocationUpdates() take a PendingIntent which will be executed, instead of calling your LocationListener

4. There are a few flavors of `requestSingleUpdate()`, which, as the name suggests, gives you just one location fix, rather than a stream until you remove the request for updates

For the `Criteria`-flavored versions of `requestLocationUpdates()` and `requestSingleUpdate()`, bear in mind that your code will still crash if there are no possible providers for your `Criteria`. For example, even if you use an empty `Criteria` object (for maximum possible matches), but GPS is disabled and the device lacks telephony (e.g., a tablet), you can get a crash like this one:

```
02-09 13:29:21.549: E/AndroidRuntime(2236): FATAL EXCEPTION: main

```

Hence, you will still want to use `getProviders()` or `getBestProvider()` to ensure that your `Criteria` will resolve to *something* before you try using the `Criteria` to actually request fixes.

The Fused Option

Google Play Services — the proprietary API set supported by many Android devices – offers a fused location provider that simplifies location tracking. This capability is covered in the next chapter.

The Fused Location Provider

At the 2013 Google I|O conference, Google announced an update to Google Play Services that offers a "fused location provider", one that seamlessly uses all available location data to give you as accurate of a location as possible, as quickly as possible, with as little power consumption as possible. This serves as an adjunct to the traditional `LocationManager` approach for finding one's position. The fused location provider has a different API, though one that is similar in some respects to the `LocationManager` API.

In this chapter, we will examine how to use the fused location provider.

Prerequisites

This chapter assumes that you have read the preceding chapter on location-based services, along with that chapter's prerequisites.

Why Use the Fused Location Provider?

The traditional recipes for using location providers are a bit complicated, if you want to maximize results. Simply asking for a GPS fix is not that hard, but:

- What if GPS is disabled?
- What if GPS signals are unavailable (e.g., the device is indoors)?
- What about the GPS power drain?

The fused location provider is designed to address these sorts of concerns. Its implementation will blend data from GPS, cell tower triangulation, and WiFi hotspot proximity to determine the device's location, without your having to manually set all of that up. The fused location provider will also take advantage of sensor data, so it does not try to update your location as frequently if the accelerometer indicates that you are not moving.

The net result is better location data, delivered more quickly, with (reportedly) less power consumption.

Why Not Use the Fused Location Provider?

The fused location provider is part of Google Play Services. Google Play Services is available on hundreds of millions of Android devices. However:

- It is closed source, and so we do not know what the Play Services all do, and whether anything that it does might be detrimental.
- It is proprietary, and so Play Services will not be available on the Kindle Fire series and other devices working solely from the Android open source project.
- Play Services is only available on devices that have the Play Store, as opposed to the old Android Market, and so older devices (e.g., Android 2.2 and older) are far less likely to have Play Services available.

If you are aiming to distribute your app solely through the Play Store, relying upon the Play Services framework is reasonable. If, however, you are distributing through other channels, you will either need to *conditionally* use the fused location provider on devices that offer it, or *avoid* the fused location provider entirely, falling back to the traditional `LocationManager` solution.

Finding Our Location, Once

The fused location provider requires a fair bit of setup, because of its dependence upon the Play Services framework. However, once that is established, the fused location provider is as easy to use, if not easier, than is `LocationManager`.

This section will review the `Location/FusedNew` sample application, which is a clone of the `Internet/Weather` sample application from the previous chapter, revised to use the fused location provider to get a one-off weather forecast.

Installing and Attaching Google Play Services

If you have not done so already (e.g., for Maps V2), you will need to install the Play Services framework in your development environment.

Android Studio users should install the "Google Repository" entry in the SDK Manager. At that point, you can add a dependency upon the `com.google.android.gms:play-services-location` artifact for some appropriate version, such as `com.google.android.gms:play-services-location:7.8.0`.

Eclipse users will need to install the "Google Play services" entry in the SDK Manager, then add to your project a reference to the Android library project found in the `extras/google/google_play_services/libproject/google-play-services_lib/` directory in your Android SDK installation.

Checking for Google Play Services

There is a fair bit of programming overhead to check for whether or not the Play Services Framework exists on the user's device and is up to date. Much of this will be the same for any app that uses Play Services, particularly for apps that use the `GoogleApiClient` as we will here.

The chapter on Play Services has an extensive section covering this overhead.

Permissions

To use the fused location provider, you still need the `ACCESS_FINE_LOCATION` or `ACCESS_COARSE_LOCATION` permissions. If you only hold `ACCESS_COARSE_LOCATION`, the data you get back will be limited to data that is sufficiently "fuzzy". Typically, if you are bothering using this provider, you will request `ACCESS_FINE_LOCATION` — if coarse location data is all you need, using `LocationManager` should be just as good and is compatible with more devices.

For Android 6.0+ devices, if your `targetSdkVersion` is 23 or higher, you are going to need to deal with the runtime permissions model. Both `ACCESS_FINE_LOCATION` and `ACCESS_COARSE_LOCATION` are considered to be `dangerous` permissions. You will need both the `<uses-permission>` elements *and* specifically ask for user permission at runtime.

The previously-mentioned section on setting up Play Services also covers requesting runtime permissions.

Clients, Connections, and Callbacks

Play Services runs in its own process, one that appears to be continuously monitoring the user's location. In order to get location data from this process, we need to establish some sort of IPC (inter-process communication) with it. The low-level implementation of this is handled by the Play Services Android library project. However, we do need to set some things up ourselves.

Specifically, we need to create and use an instance of `GoogleApiClient`, our gateway to the Play Services SDK. The `AbstractGoogleApiClientActivity` — described in the section on setting up Play Services — handles a lot of this for us. What we need to do is override a few methods in our concrete `WeatherDemo` subclass of `AbstractGoogleApiClientActivity`:

```
package com.commonsware.android.weather2;

import android.Manifest;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import com.google.android.gms.common.api.GoogleApiClient;
import com.google.android.gms.location.LocationServices;

public class WeatherDemo extends AbstractGoogleApiClientActivity {
  private static final String[] PERMS=
    {Manifest.permission.ACCESS_FINE_LOCATION};

  @Override
  protected GoogleApiClient.Builder configureApiClientBuilder(
    GoogleApiClient.Builder b) {
    return(b.addApi(LocationServices.API));
  }

  @Override
  protected String[] getDesiredPermissions() {
    return(PERMS);
  }

  @Override
  protected void handlePermissionDenied() {
    Toast
      .makeText(this, R.string.msg_no_perm, Toast.LENGTH_LONG)
      .show();
    finish();
  }

  @Override
  public void onConnected(Bundle bundle) {
    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
        .add(android.R.id.content,
          new WeatherFragment()).commit();
    }
  }

  @Override
  public void onConnectionSuspended(int i) {
    Log.w(((Object)this).getClass().getSimpleName(),
      "onConnectionSuspended() called, whatever that means");
  }
}
```

Specifically:

- `configureApiClientBuilder()` needs to flesh out the details of what sorts of APIs we are looking to use in this app. In this case, we call `addApi()` on the supplied `GoogleApiClient.Builder`, requesting the `LocationServices.API`, to be able to get at the relevant portion of the Play Services SDK.
- `getDesiredPermissions()` returns an array of the names of the runtime permissions that we need in order to use this API. In this case, we are asking for `ACCESS_FINE_LOCATION` (though, in truth, `ACCESS_COARSE_LOCATION` would suffice for getting weather forecasts). The manifest also has the `<uses-permission>` element for `ACCESS_FINE_LOCATION`.
- `handlePermissionDenied()` will be called if we request the permission and we do not have it when we get control back. This means that either the user denied it now or the user denied it earlier and checked the "Don't ask again" checkbox to stop being bothered about runtime permissions. We could use `shouldShowPermissionRequestRationale()` and perhaps take some steps to educate the user. This is a book example, so we just `finish()` the activity and move along with our day.
- `onConnected()`, from the `GoogleApiClient.ConnectionCallbacks`, will be called if we now have access to the `LocationServices.API` that we requested. At this point, it is safe for us to show a `WeatherFragment` that will use this API to go get the location and, from that, get the weather forecast.
- `onConnectionSuspended()`, also from the `GoogleApiClient.ConnectionCallbacks`, might get called, for uncertain reasons. Here, we are largely ignoring this condition.

The upshot is that, if things go as expected, we will show the `WeatherFragment` when we can get the location and the subsequent forecast.

Finding the Current Location

Given all that setup, actually getting the location is almost anti-climactic.

To find the current location, given a connected `GoogleApiClient`, just call the static `getLastLocation()` method on `LocationServices.FusedLocationApi`, passing in the `GoogleApiClient` instance as a parameter. This usually will return a non-`null` `Location` object, using the same `Location` class that you would use with `LocationManager`.

In the sample, the `run()` method checks to see if `getLastLocation()` returns `null` or not. If the location is `null`, it schedules `run()` to be invoked again in one second, using `postDelayed()` on some suitable `View` (in this case, the `WebView` for displaying the results). If, however, we do have a valid location, `run()` invokes a `FetchForecastTask`, as did the original version of this sample:

```
@Override
public void run() {
  Location loc=LocationServices.FusedLocationApi
                .getLastLocation(getPlayServices());

  if (loc == null) {
    getListView().postDelayed(this, 1000);
  }
  else {
    FetchForecastTask task=new FetchForecastTask();

    task.execute(loc);
  }
}
```

The fact that we are using `postDelayed()` here is why we use `removeCallbacks()` in `onPause()`, to stop polling for `getLastLocation()` when we are disconnecting from the `LocationClient`.

Note that the documentation for `getLastLocation()` states “If a location is not available, which should happen very rarely, `null` will be returned.” The “very rarely” part indicates that Play Services is constantly checking for the user’s location, possibly because location providers are not available.

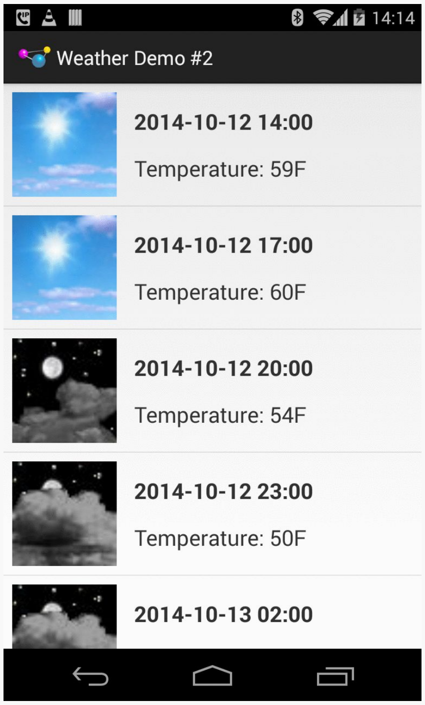
The Rest of the Sample

The rest of the sample follows some examples from earlier in the book for fetching data and displaying it.

`run()`, once it gets a location from `getLastLocation()`, executes a `FetchForecastTask`, which is a subclass of `AsyncTask`. This task, in `doInBackground()`, calls `getForecastXML()`, which uses `HttpUrlConnection` to retrieve the weather forecast XML. The task also calls `buildForecasts()`, which parses that XML using the Java DOM and builds an `ArrayList` of `Forecast` objects, where each `Forecast` holds a time, the predicted temperature, and a code indicating the expected cloud cover and precipitation.

In the task's `onPostExecute()` method, it creates a `ForecastAdapter`, wrapped around our list of `Forecast` objects, and puts that adapter in the `ListView` for our `ListFragment`. `ForecastAdapter` follows the same pattern as was seen in the Picasso sample, using Picasso to load in icons associated with each cloud cover/precipitation prediction and show those alongside the time and temperature.

The result looks like:



14:14

Weather Demo #2

2014-10-12 14:00
Temperature: 59F

2014-10-12 17:00
Temperature: 60F

2014-10-12 20:00
Temperature: 54F

2014-10-12 23:00
Temperature: 50F

2014-10-13 02:00

Figure 750: The FusedNew Sample Application

Requesting Location Updates

As with LocationManager, you can use LocationClient to be delivered location updates as the device moves, via requestLocationUpdates(). There are two major axes of control you have over these updates: the way the locations are delivered to you, and the LocationRequest that configures what updates you receive.

Delivery Options

A foreground application would use forms of requestLocationUpdates() that take a LocationListener as a parameter. Despite the class being named the same, this is a separate implementation of the LocationListener interface. The Play Services one (com.google.android.gms.location.LocationListener) only requires a single method: onLocationChanged(), which is handed a Location object representing a location fix.

A background application would use the requestLocationUpdates() that takes a PendingIntent instead of a LocationListener, where that PendingIntent can do whatever you wish (start an activity, start a service, send a broadcast). The location itself is delivered in the form of an Intent extra, keyed as KEY_LOCATION_CHANGED, with a value in the form of a Location object.

Request Options

All forms of requestLocationUpdates() take a LocationRequest object describing what you want in terms of updates. Unlike with LocationManager, you do not specify specific location technologies (e.g., GPS). You also lack the fine-grained control of the Criteria object (e.g., to require the location to have speed data). However, you do have some measure of control, via various setters on LocationRequest.

Frequency

Calling setInterval() indicates approximately how frequently you wish to receive location updates. The key word here is “approximately”, as you will receive updates more or less frequently than the number of milliseconds you specify as the desired interval. However, your requested interval is taken into account, and the longer of an interval you provide, the less power your app will consume.

To help prevent being flooded with location data, you can also call `setFastestInterval()`, which will throttle the actual updates to be no more frequent than the number of milliseconds that you state.

Priority

`setPriority()` allows you to control the accuracy and power consumption of your app's request, by specifying one of four possible priority levels:

- `PRIORITY_HIGH_ACCURACY` will tend to use GPS and therefore will consume more power
- `PRIORITY_BALANCED_POWER_ACCURACY` will try to consume somewhat less power
- `PRIORITY_LOW_POWER` will try to consume even less power
- `PRIORITY_NO_POWER` indicates that you want to consume no additional power over any other requests, but to get what you can (akin to the "passive provider" available with `LocationManager`)

Duration

You can proactively cancel receiving further updates by calling `removeUpdates()`, passing in your delivery option from `requestLocationUpdates()`:

- The same `LocationListener` as you used to request the updates, or
- An equivalent `PendingIntent` to the one that you used to request the updates

You can also automatically expire your requested updates by one of three means:

- `setNumUpdates()` indicates exactly how many location fixes that you want to receive (e.g., 1) and discontinues the updates after that number
- `setExpirationDuration()` indicates how long you wish to receive updates, expressed as a number of milliseconds from now
- `setExpirationTime()` indicates when you wish to discontinue updates, expressed in the form of the number of milliseconds since the device turned on (e.g., the same time base as is used by `elapsedRealtime()` on the `SystemClock` class)

For example, an improved version of the sample shown in this chapter would use a `LocationRequest` with `setNumUpdates(1)`, instead of the one-second polling of `getLastLocation()`. In fact, we will see such an improved version in the next section.

I Can Haz Location?

One common complaint among Android developers is that there is no way for developers to enable location providers, like GPS. This is for privacy reasons. Users should be able to control whether apps can track their movements. However, to enable location providers, the user had to go into the Settings app, which was aggravating.

In early 2015, Google added `SettingsApi` to the fused location provider portion of the Play Services SDK. This allows apps to find out if we are capable of using the fused location provider, and if not, pop up a dialog where the user can agree to enable location tracking.

The `Location/FusedPeriodic` sample application demonstrates this, plus the APIs used for periodic location updates. In truth, we will only get a single location fix, as hinted in the previous section, but this example could be extended to update more than once if needed.

The business logic, and some of the code, is the same as in the previous sample: fetch the location, then show a weather forecast for that location. What differs is in how we are fetching the location, as we use `SettingsApi` and `requestLocationUpdates()`.

Defining a Location Request

Core to both finding out whether we can use the fused location provider, and later getting location fixes, will be to define a `LocationRequest` object. Fortunately, this is a pure POJO, without any ties to any `Context` or other existing Play Services SDK objects. Hence, we can declare it as an ordinary data member and initialize it in `onCreate()` of the revised `WeatherFragment`:

```
public class WeatherFragment extends ListFragment implements
    ResultCallback<LocationSettingsResult>,
    LocationListener {
  static final int SETTINGS_REQUEST_ID=1338;
  private String template=null;
  private LocationRequest request=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);

    template=getActivity().getString(R.string.url);
    request=new LocationRequest()
              .setNumUpdates(1)
              .setExpirationDuration(60000)
              .setInterval(1000)
              .setPriority(LocationRequest.PRIORITY_LOW_POWER);
  }
```

(you will also notice that we are now implementing some new interfaces — more about those later in this section)

In `onCreate()`, we indicate that the `LocationRequest`:

- Only needs to provide us with a single location fix (`setNumUpdates(1)`)
- Can give up automatically if we do not get a location fix within the first minute (`setExpirationDuration(60000)`)
- Should start working fairly quickly to get us our fix (`setInterval(1000)`)
- Can optimize for power over accuracy (`setPriority(LocationRequest.PRIORITY_LOW_POWER)`)

The `setInterval()` call may seem odd, given that we are only seeking one fix. Leaving this out, though, means that you *never* get a fix, for unclear reasons.

Also, while we are requesting `PRIORITY_LOW_POWER`, and we do not need a particularly accurate fix just to get a weather forecast, we still request `ACCESS_FINE_LOCATION` in the manifest. Without this, once again we seem to never get a fix.

Another issue comes with the expiration value. The Play Services SDK is closed source, and so it is difficult to know the exact implementation. Based on testing, it feels as though `setExpirationDuration()` calculates the expiration time based on when the `LocationRequest` object is *created*, not when it is *used*. That's bad, and we will see where that can bite us a bit later in this chapter.

Requesting and Reacting to Settings Status

In the original example, once we were connected to the Play Services engine and our `WeatherFragment` was created, we would get the last-known location and try to fetch a forecast. If there was no location, we would just ask again every second. This is not a great solution:

- We might never get a location, because the user has disabled location tracking
- We might never get a location, because the environment is unsuitable (e.g., underground parking garage)
- It does not give Play Services much information about what we need in terms of a location fix

Therefore, this sample changes `onViewCreated()` to call a private `requestSettings()` method, so we can find out if location tracking is enabled and, if not, perhaps ask the user to enable it:

```
private void requestSettings() {
  LocationSettingsRequest.Builder b=
      new LocationSettingsRequest.Builder()
            .addLocationRequest(request);
  PendingResult<LocationSettingsResult> result=
      LocationServices.SettingsApi.checkLocationSettings(getPlayServices(),
                                                          b.build());

  result.setResultCallback(this);
}
```

Here, we create a `LocationSettingsRequest.Builder` and pass it our already-defined `LocationRequest` via `addLocationRequest()`. This way, Play Services will know the sort of location data that we will be looking for later and can tell us whether or not that is presently possible.

We then `build()` the `LocationSettingsRequest` and pass it to `checkLocationSettings()` on the `LocationServices.SettingsApi` class. This returns a `PendingResult`, specifically of a `LocationSettingsResult` type. We call `setResultCallback()` to indicate that the fragment itself should be notified about the results of this request. That is why `WeatherFragment` now implements the `ResultCallback` interface for `LocationSettingsResult`, which in turn requires us to implement an `onResult()` method that takes a `LocationSettingsResult` as a parameter:

```
@Override
public void onResult(LocationSettingsResult result) {
  boolean thingsPlumbBusted=true;

  switch(result.getStatus().getStatusCode()) {
    case LocationSettingsStatusCodes.SUCCESS:
      requestLocations();
      thingsPlumbBusted=false;
      break;

    case LocationSettingsStatusCodes.RESOLUTION_REQUIRED:
      try {
        result
          .getStatus()
          .startResolutionForResult(getActivity(),
                                    SETTINGS_REQUEST_ID);
        thingsPlumbBusted=false;
      }
      catch (IntentSender.SendIntentException e) {
        // oops
      }
      break;

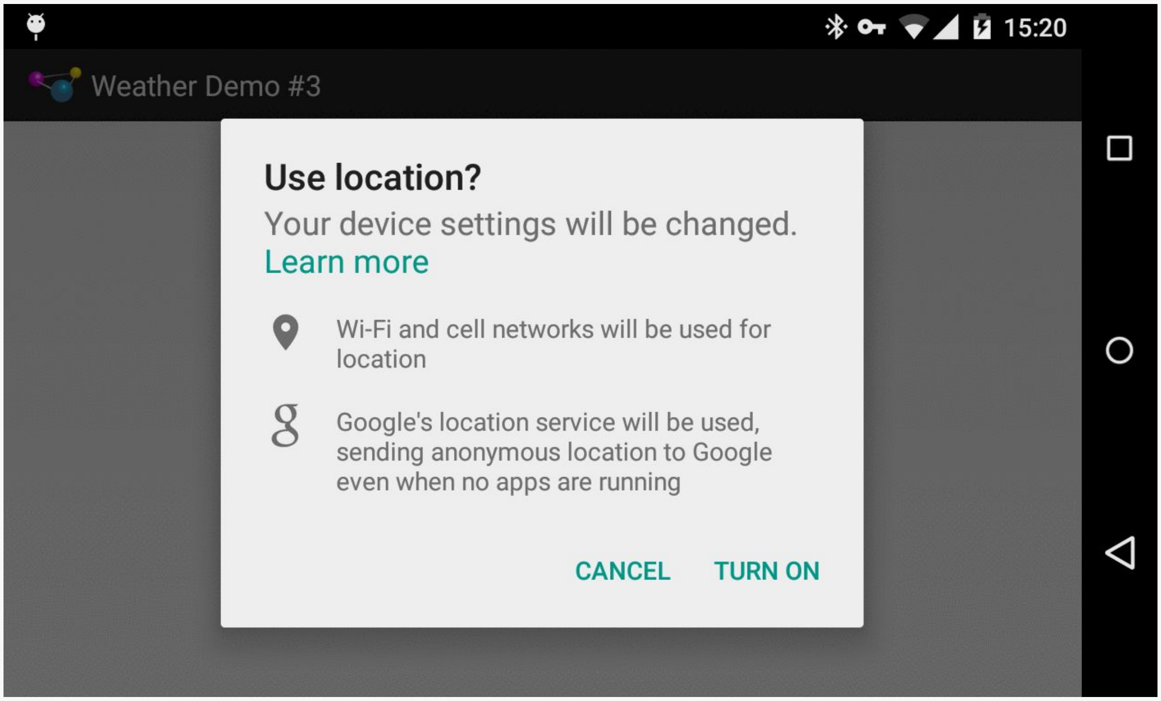
    case LocationSettingsStatusCodes.SETTINGS_CHANGE_UNAVAILABLE:
      // more oops
      break;
  }

  if (thingsPlumbBusted) {
    Toast
      .makeText(getActivity(),
                R.string.settings_resolution_fail_msg,
                Toast.LENGTH_LONG)
      .show();
    getActivity().finish();
  }
}
```

What we are hoping for is `LocationSettingsStatusCodes.SUCCESS` as the status code out of the result's `Status` object (obtained via `getStatus()`). This means that our proposed location updates should succeed, and we can go ahead and make that request. We do that via a call to a private `requestLocations()` method that we will explore a bit later.

However, instead we might get `LocationSettingsStatusCodes.RESOLUTION_REQUIRED`. This means that the user has disabled location providers necessary to fulfill the request, but that we could prompt the user to enable location tracking. To do this, we call `startResolutionForResult()` on that `Status` object, passing in our `Activity` along with a locally-unique integer.

This will display the following dialog-themed `Activity`:



Weather Demo #3

Use location?

Your device settings will be changed.
Learn more

Wi-Fi and cell networks will be used for location

Google's location service will be used, sending anonymous location to Google even when no apps are running

Figure 751: Location Enable Dialog

Google Maps users will recognize it as being akin to the one that appears if you try using certain Maps features (e.g., navigation) and do not have location tracking enabled in Settings.

That should eventually trigger a call to `onActivityResult()` *on the activity* – `startResolutionForResult()` knows nothing about fragments. There are two possibilities here: the user accepts our request to enable location tracking, or the user denies it. If the user accepts our request, `onResult()` will be called again with `LocationSettingsStatusCodes.SUCCESS`, at which time we can request location updates. If the user rejects the request, we need to arrange to stop asking. By default, if we do nothing, if the user rejects the request, we will be called with `LocationSettingsStatusCodes.RESOLUTION_REQUIRED` again and will pop up the dialog again. That is why, in the `WeatherDemo` activity, we have an `onActivityResult()` to catch when the user completes the dialog triggered by `startResolutionForResult()`:

```
@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
  if (requestCode==WeatherFragment.SETTINGS_REQUEST_ID) {
    if (resultCode==Activity.RESULT_CANCELED) {
      finish();
    }
```

```
      else {
        // this should not be needed, but apparently is in 8.1
        WeatherFragment f=
          (WeatherFragment)getFragmentManager().findFragmentById(android.R.id.content);
        f.requestLocations();
      }
    }
  }
```

The locally-unique integer provided to `startResolutionForResult()`, under the covers, is used for a `startActivityForResult()` call, which is why we get control in `onActivityResult()`. If the request is for this settings dialog, and if the user canceled our request, we `finish()` the activity, as we cannot do anything anymore and may as well close up shop. There are probably other ways of handling this condition that will prevent `onResult()` from getting called again.

If the `resultCode` is `Activity.RESULT_OK`, though, then the user presumably is allowing us to request locations. For some reason, on version 8.1 of the Play Services SDK, this does *not* trigger a fresh call to the `onResult()` method, the way it used to. So, we have to get our `WeatherFragment` and call `requestLocations()` from `onActivityResult()` instead.

Speaking of `onResult()`, it is possible that the status code is neither of those values. In those cases, we are also stuck — Play Services is indicating that we will not be able to get the locations that we are requesting. So, there, we show a `Toast` and `finish()` the activity.

Requesting "Periodic Locations"

The `requestLocations()` method will be triggered once `SettingsApi` gives us "the go-ahead" via the `onResult()` method:

```
  void requestLocations() {
    PendingResult<Status> result=
        LocationServices.FusedLocationApi
          .requestLocationUpdates(getPlayServices(), request, this);

    result.setResultCallback(new ResultCallback<Status>() {
      @Override
      public void onResult(Status status) {
        if (status.isSuccess()) {
          Toast
              .makeText(getActivity(),
                  R.string.location_req_success_msg,
                  Toast.LENGTH_LONG)
              .show();
        } else {
          Toast
```

```
            .makeText(getActivity(), status.getStatusMessage(),
                Toast.LENGTH_LONG)
            .show();
        getActivity().finish();
      }
    }
  });
}
```

Here, we start off by calling `requestLocationUpdates()`, passing in the `LocationRequest` that we created before, along with our `LocationListener` implementation, which happens to be the fragment itself.

We can, if we want, attach another `ResultCallback` object to the `PendingResult` returned by `requestLocationUpdates()`. This way, we can find out if our request for location updates was successfully queued or not. Here, we do that, using an instance of an anonymous inner class of `PendingResult`. We show a `Toast` regardless of success or failure; we also `finish()` the method on failure.

What should happen, if the request was successful, is that we will get one fix delivered to `onLocationChanged()` on our `LocationListener`. There, we kick off the `FetchForecastTask`, this time using `executeOnExecutor()`:

```
@Override
public void onLocationChanged(Location location) {
  new FetchForecastTask()
      .executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, location);
}
```

If, after a minute of trying, we do not get the location fix, Play Services will stop trying, based on our `setExpirationDuration()` value on the `LocationRequest` object.

However, this is where we run into a problem with using that `LocationRequest` created originally. It appears that the `LocationRequest` calculates the time to give up based on when the `LocationRequest` is created. It is not based on the time when we call `requestLocationUpdates()`. In many cases, there will be little delay between those two points in time, and so the different is negligible. But if the user gets the enable-location dialog and leaves it open for a minute, when we call `requestLocationUpdates()`, *we are already expired*. However, we do not find out about this, and we just never get a location fix. Hence, rather than creating a single instance of `LocationRequest`, have a `buildLocationRequest()` method that can return the instance to you, newly created, so you have the full expiration time to work with.

Also, in `onPause()`, we call `removeLocationUpdates()`, so that we minimize power drain while we are not in the foreground.

This sample app is less-than-optimal in its handling of configuration changes. Everything works, but we wind up re-requesting location updates on each configuration change. A better implementation would note if we already have our location fix and therefore no longer need to request location updates.

Working with the Clipboard

Being able to copy and paste is something that mobile device users seem to want almost as much as their desktop brethren. Most of the time, we think of this as copying and pasting text, and for a long time that was all that was possible on Android. Android 3.0 added in new clipboard capabilities for more rich content, which application developers can choose to support as well. This section will cover both of these techniques.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Using the Clipboard on Android 1.x/2.x

Android has a `ClipboardManager` that allows you to interact with the clipboard manually, in addition to built-in clipboard facilities for users (e.g., copy/paste context menus on `EditText`). `ClipboardManager`, like `AudioManager`, is obtained via a call to `getSystemService()`:

From there, you have three simple methods:

1. `getText()` to retrieve the current clipboard contents
2. `hasText()`, to determine if there are any clipboard contents, so you can react accordingly (e.g., disable "paste" menus when there is nothing to paste)
3. `setText()`, to put text on the clipboard

For example, the SystemServices/ClipIP sample project contains a little application that puts your current IP address on the clipboard, for pasting into some `EditText` of an application.

The `IPClipper` activity's `onCreate()` does the work of putting text onto the clipboard via `setText()` and notifying the user via a `Toast`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  try {
    String addr=getLocalIPAddress();

    if (addr == null) {
      Toast.makeText(this,
                     "IP address not available -- are you online?",
                     Toast.LENGTH_LONG).show();
    }
    else {
      ClipboardManager cm=
          (ClipboardManager)getSystemService(CLIPBOARD_SERVICE);

      try {
        cm.setText(addr);

        Toast.makeText(this, "IP Address clipped!",
                       Toast.LENGTH_SHORT).show();
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(), "Exception clipping IP", e);
        Toast.makeText(this, "Exception: " + e.getMessage(),
                       Toast.LENGTH_SHORT).show();
      }
    }
  }
  catch (Exception e) {
    Log.e("IPClipper", "Exception getting IP address", e);
    Toast.makeText(this, "Could not obtain IP address",
                   Toast.LENGTH_LONG).show();
  }

  finish();
}
```

The work of figuring out what the IP address is can be found in the `getLocalIPAddress()` method:

```
public String getLocalIPAddress() throws SocketException {
  Enumeration<NetworkInterface> nics=
      NetworkInterface.getNetworkInterfaces();

  while (nics.hasMoreElements()) {
    NetworkInterface intf=nics.nextElement();
```

```
      Enumeration<InetAddress> addrs=intf.getInetAddresses();

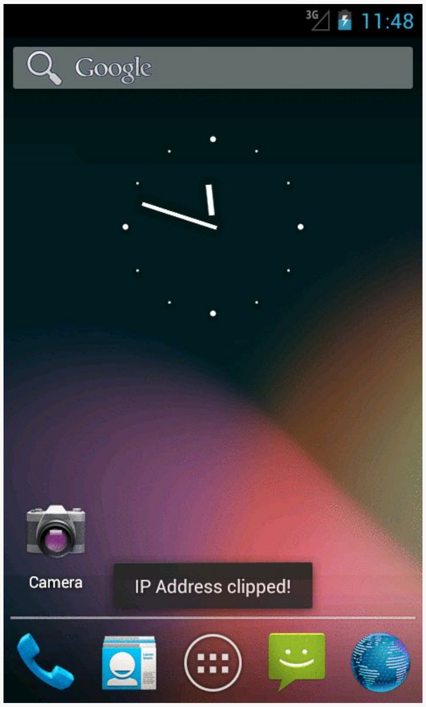
      while (addrs.hasMoreElements()) {
        InetAddress addr=addrs.nextElement();

        if (!addr.isLoopbackAddress()) {
          return(addr.getHostAddress().toString());
        }
      }
    }

    return(null);
  }
```

This uses the `NetworkInterface` and `InetAddress` classes from the `java.net` package to loop through all network interfaces and find the first one that has a non-localhost (loopback) IP address. The emulator will return 10.0.2.15 all of the time; your device will return whatever IP address it has from WiFi, 3G, etc. If no such address is available, it returns `null`.

The activity itself has no UI, as the application uses `Theme.NoDisplay`. The activity avoids a call to `setContentView()`, and calls `finish()` when all the work is done in `onCreate()`. Hence after starting the activity, the user will hopefully see the "successful" `Toast`, and nothing else:



IP Address clipped!

Figure 752: The IPClipper, shortly after launching

Then, if the user long-taps on an `EditText` and chooses Paste, the IP address is added to the `EditText` contents. Note that the clipboard is system-wide, not merely application-wide, which is why you can successfully paste the IP address into any application's fields.

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setText()` call wrapped in a `try/catch` blog, even though `setText()` does not throw a checked exception. The rationale for this will be discussed later in this chapter.

Advanced Clipboard on Android 3.x and Higher

Android 3.0 added in new ways of working with `ClipboardManager` to clip things that transcend simple text. In part, this is expected to be used for advanced copy and paste features between applications. However, this also forms the foundation for a rich drag-and-drop model within an application.

Note that they also moved `ClipboardManager` to the `android.content` package. You can still refer to it via the `android.text` package, for backwards compatibility. However, if your project will be on API Level 11 or higher only, you might consider using the new `android.content` package edition of the class.

Copying Rich Data to the Clipboard

In addition to methods like `setText()` to put a piece of plain text on the clipboard, `ClipboardManager` (as of API Level 11) offers `setPrimaryClip()`, which allows you to put a `ClipData` object on the clipboard.

What's a `ClipData`? In some respects, it is whatever you want. It can hold:

1. plain text
2. a `Uri` (e.g., to a piece of music)
3. an `Intent`

The `Uri` means that you can put anything on the clipboard that can be referenced by a `Uri`… and if there is nothing in Android that lets you reference some data via a `Uri`, you can invent your own content provider to handle that chore for you. Furthermore, a single `ClipData` can actually hold as many of these as you want, each represented as individual `ClipData.Item` objects. As such, the possibilities are endless.

There are static factory methods on `ClipData`, such as `newUri()`, that you can use to create your `ClipData` objects. In fact, that is what we use in the [SystemServices/ClipMusic]() sample project and the `MusicClipper` activity.

`MusicClipper` has the classic two-big-button layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="horizontal"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button android:id="@+id/pick"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="Pick"
    android:onClick="pickMusic"
  />
  <Button android:id="@+id/view"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="Play"
    android:onClick="playMusic"
  />
</LinearLayout>
```

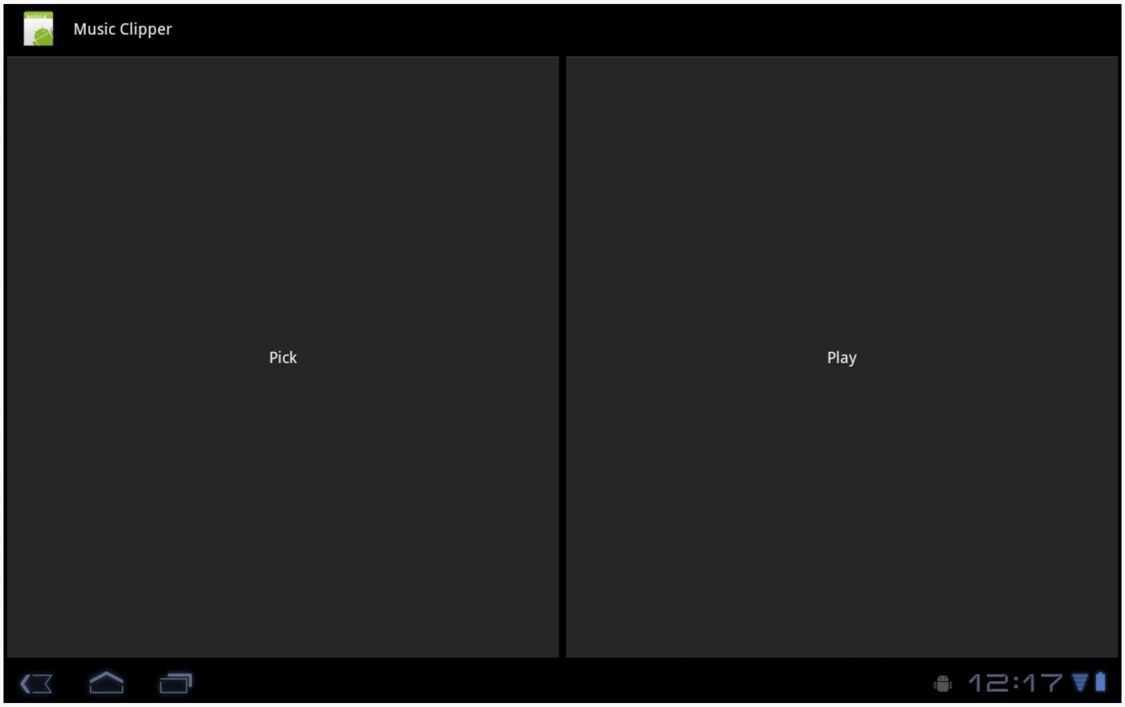


Figure 753: The Music Clipper main screen

In `onCreate()`, we get our hands on our `ClipboardManager` system service:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

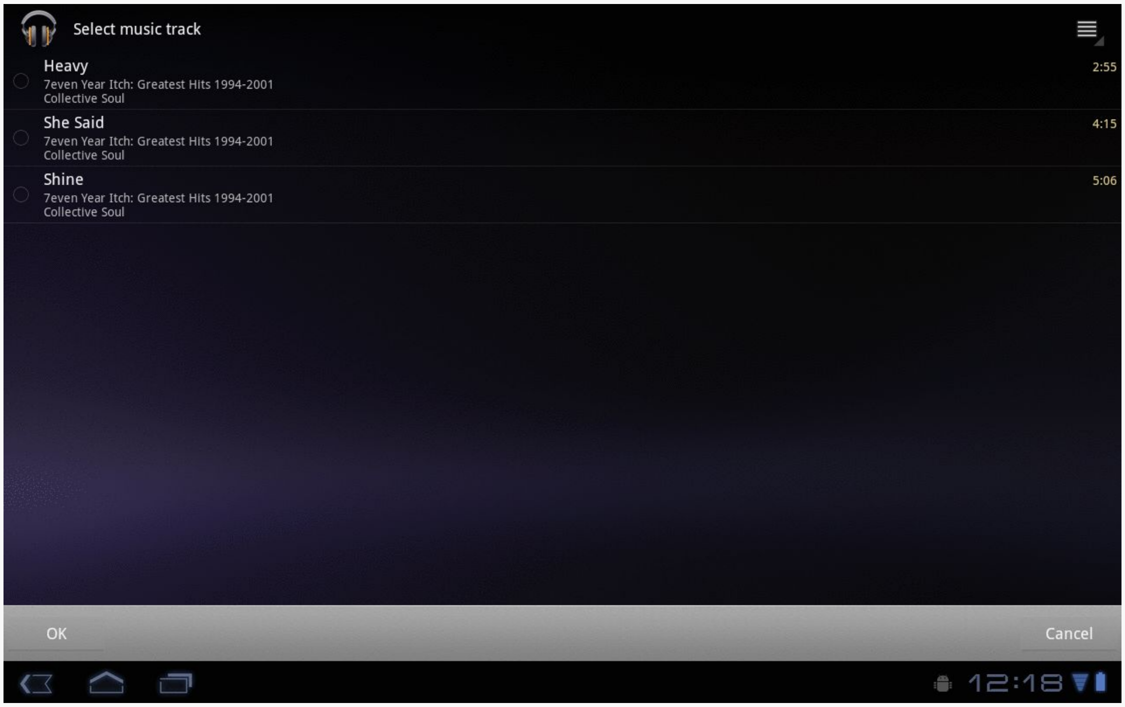
  clipboard=(ClipboardManager)getSystemService(CLIPBOARD_SERVICE);
}
```

Tapping the "Pick" button will let you pick a piece of music, courtesy of the `pickMusic()` method wired to that `Button` object:

```
public void pickMusic(View v) {
  Intent i=new Intent(Intent.ACTION_GET_CONTENT);

  i.setType("audio/*");
  startActivityForResult(i, PICK_REQUEST);
}
```

Here, we tell Android to let us pick a piece of music from any available audio MIME type (`audio/*`). Fortunately, Android has an activity that lets us do that:



Select music track

Heavy 2:55
7even Year Itch: Greatest Hits 1994-2001
Collective Soul

She Said 4:15
7even Year Itch: Greatest Hits 1994-2001
Collective Soul

Shine 5:06
7even Year Itch: Greatest Hits 1994-2001
Collective Soul

Figure 754: The XOOM tablet's music track picker

We get the result in `onActivityResult()`, since we used `startActivityForResult()` to pick the music. There, we package up the `content://` `Uri` to the music into a `ClipData` object and put it on the clipboard:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
  if (requestCode == PICK_REQUEST) {
    if (resultCode == RESULT_OK) {
      ClipData clip=
          ClipData.newUri(getContentResolver(), "Some music",
                          data.getData());

      try {
        clipboard.setPrimaryClip(clip);
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(), "Exception clipping Uri", e);
        Toast.makeText(this, "Exception: " + e.getMessage(),
                       Toast.LENGTH_SHORT).show();
      }
    }
  }
}
```

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setPrimaryClip()` call wrapped in a `try/catch` blog, even though `setPrimaryClip()` does not throw a checked exception. The rationale for this will be discussed [later in this chapter](#).

Pasting Rich Data from the Clipboard

The catch with rich data on the clipboard is that somebody has to know about the sort of information you are placing on the clipboard. Eventually, the Android development community will work out common practices in this area. Right now, though, you can certainly use it within your own application (e.g., clipping a note and pasting it into another folder).

Since putting `ClipData` onto the clipboard involves a call to `setPrimaryClip()`, it should not be surprising that the reverse operation — getting a `ClipData` from the clipboard — uses `getPrimaryClip()`. However, since you do not know where this clip came from, you need to validate that it has what you expect and to let the user know when the clipboard contents are not something you can leverage.

The "Play" button in our UI is wired to a `playMusic()` method. This will only work when we have pasted a `Uri ClipData` to the clipboard pointing to a piece of music. Since we cannot be sure that the user has done that, we have to sniff around:

```
public void playMusic(View v) {
  ClipData clip=clipboard.getPrimaryClip();

  if (clip == null) {
    Toast.makeText(this, "There is no clip!", Toast.LENGTH_LONG)
         .show();
  }
  else {
    ClipData.Item item=clip.getItemAt(0);
    Uri song=item.getUri();

    if (song != null
        && getContentResolver().getType(song).startsWith("audio/")) {
      startActivity(new Intent(Intent.ACTION_VIEW, song));
    }
    else {
      Toast.makeText(this, "There is no song!", Toast.LENGTH_LONG)
           .show();
    }
  }
}
```

First, there may be nothing on the clipboard, in which case the `ClipData` returned by `getPrimaryClip()` would be `null`. Or, there may be stuff on the clipboard, but it may not have a `Uri` associated with it (`getUri()` on `ClipData`). Even then, the `Uri` may point to something other than music, so even if we get a `Uri`, we need to use a `ContentResolver` to check the MIME type (`getContentResolver().getType()`) and make sure it seems like it is music (e.g., starts with `audio/`). Then, and only then, does it make sense to try to start an `ACTION_VIEW` activity on that `Uri` and hope that something useful happens. Assuming you clipped a piece of music with the “Pick” button, “Play” will kick off playback of that song.

ClipData and Drag-and-Drop

Android 3.0 also introduced Android’s first built-in drag-and-drop framework. One might expect that this would be related entirely to `View` and `ViewGroup` objects and have nothing to do with the clipboard. In reality, the drag-and-drop framework leverages `ClipData` to say what it is that is being dragged and dropped. You call `startDrag()` on a `View`, supplying a `ClipData` object, along with some objects to help render the “shadow” that is the visual representation of this drag operation. A `View` that can receive objects “dropped” via drag-and-drop needs to register an `OnDragListener` to receive drag events as the user slides the shadow over the top of the `View` in question. If the user lifts their finger, thereby dropping the shadow, the recipient `View` will get an `ACTION_DROP` drag event, and can get the `ClipData` out of the event.

Monitoring the Clipboard

Android 3.0 added the capability for an app to monitor what is put on the clipboard, including things put on the clipboard by other apps.

This is a somewhat esoteric feature, but one that perhaps has some valid use cases. Mostly, it would be used by something *not* in the foreground, since the foreground activity is probably what is adding material to the clipboard. A service, or perhaps an activity that has moved to the background, could use this feature to find out about new clipboard entries.

To monitor the clipboard, you simply call `addPrimaryClipChangedListener()` on `ClipboardMonitor`, passing an implementation of an `OnPrimaryClipChangedListener` interface. That object, in turn, will be called with `onPrimaryClipChanged()` whenever there is a new clipboard entry. Later on, you can call `removePrimaryClipChangedListener()` to stop being notified about new clipboard entries.

For example, here is `MainActivity` from the SystemServices/ClipboardMonitor sample project:

```
package com.commonsware.android.clipmon;

import android.app.Activity;
import android.content.ClipboardManager;
import android.content.ClipboardManager.OnPrimaryClipChangedListener;
import android.os.Bundle;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnPrimaryClipChangedListener {
  private ClipboardManager cm=null;
  private TextView lastClip=null;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    lastClip=(TextView)findViewById(R.id.last_clip);
    cm=(ClipboardManager)getSystemService(CLIPBOARD_SERVICE);
  }

  @Override
  public void onResume() {
    super.onResume();
    cm.addPrimaryClipChangedListener(this);
  }

  @Override
  public void onPause() {
    cm.removePrimaryClipChangedListener(this);
    super.onPause();
  }

  @Override
  public void onPrimaryClipChanged() {
    lastClip.setText(cm.getPrimaryClip().getItemAt(0)
                       .coerceToText(this));
  }
}
```

Here, we:

- Retrieve the `ClipboardManager` in `onCreate()`
- Register for clipboard events via `addPrimaryClipChangedListener()` in `onResume()`

- Unregister from clipboard events via `removePrimaryClipChangedListener()` in `onPause()`
- Convert the first item (`getItemAt(0)`) of the primary clip (`getPrimaryClip()`) to text (`coerceToText(this)`), and stuff the results into a `TextView`

In theory, this activity will display new clipboard entries as they arrive. In practice, it will only do so while it is in the foreground, and so it would require something in the background to add something to the clipboard. That is not a particularly useful example… except to test the bug outlined in the next section.

The Android 4.3 Clipboard Bug

AndroidPolice reported on a fairly unpleasant bug in Android 4.3. While this bug was fixed in Android 4.4, there is little evidence that Google will be releasing a fix for Android 4.3 devices, which means that this problem will plague developers into 2015 and perhaps beyond.

The bug stems from the clipboard monitoring facility. If an app has used `addPrimaryClipChangedListener()`, *any other app* that tries to paste to the clipboard will crash.

The first crash will be a `SecurityException`:

```
java.lang.SecurityException: uid ... does not have
android.permission.UPDATE_APP_OPS_STATS
```

The second and subsequent times this occurs on the device, it will be an `IllegalStateException`:

```
java.lang.IllegalStateException: beginBroadcast() called while already
in a broadcast
```

The only resolution is to unregister the clipboard listener… and hope that the first crash has not occurred. If it has, a **full reboot of the device is required** to fix the broken system.

If Your App Monitors the Clipboard…

If you have a component, such as a long-running service, that is monitoring the clipboard, please ensure that the users have an easy way to stop that behavior, even if it means stopping your whole service. While this may mean that your app has seriously degraded functionality, the alternative is that the user has to keep rebooting their device while your app is installed.

If Your App Pastes to the Clipboard…

If you are pasting to the clipboard, with `setPrimaryClip()` or the older `setText()`, you will want to throw a `try/catch` block around those calls, so you catch the `RuntimeExceptions` that will be thrown.

However, you will need to tell your users that they are now fairly well screwed, needing to both find the clipboard-monitoring app and learn how to control it (or uninstall/disable it, if needed), plus reboot their device, in order to paste to the clipboard again.

Telephony

Many, if not most, Android devices will be phones. As such, not only will users be expecting to place and receive calls using Android, but you will have the opportunity to help them place calls, if you wish.

Why might you want to?

1. Maybe you are writing an Android interface to a sales management application (a la Salesforce.com) and you want to offer users the ability to call prospects with a single button click, and without them having to keep those contacts both in your application and in the phone's contacts application
2. Maybe you are writing a social networking application, and the roster of phone numbers that you can access shifts constantly, so rather than try to "sync" the social network contacts with the phone's contact database, you let people place calls directly from your application
3. Maybe you are creating an alternative interface to the existing contacts system, perhaps for users with reduced motor control (e.g., the elderly), sporting big buttons and the like to make it easier for them to place calls

Whatever the reason, Android has the means to let you manipulate the phone just like any other piece of the Android system.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on working with multiple activities.

Report To The Manager

To get at much of the phone API, you use the `TelephonyManager`. That class lets you do things like:

1. Determine if the phone is in use via `getCallState()`, with return values of `CALL_STATE_IDLE` (phone not in use), `CALL_STATE_RINGING` (call requested but still being connected), and `CALL_STATE_OFFHOOK` (call in progress)
2. Find out the SIM ID (IMSI) via `getSubscriberId()`
3. Find out the phone type (e.g., GSM) via `getPhoneType()` or find out the data connection type (e.g., GPRS, EDGE) via `getNetworkType()`

You Make the Call!

You can also initiate a call from your application, such as from a phone number you obtained through your own Web service. To do this, simply craft an `ACTION_DIAL` `Intent` with a `Uri` of the form `tel:NNNNN` (where `NNNNN` is the phone number to dial) and use that `Intent` with `startActivity()`. This will not actually dial the phone; rather, it activates the dialer activity, from which the user can then press a button to place the call.

For example, let's look at the `Phone/Dialer` sample application. Here's the crude-but-effective layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
  <LinearLayout
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    >
    <TextView
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="Number to dial:"
      />
    <EditText android:id="@+id/number"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:cursorVisible="true"
      android:editable="true"
      android:singleLine="true"
    />
  </LinearLayout>
  <Button android:id="@+id/dial"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:text="Dial It!"
    android:onClick="dial"
  />
</LinearLayout>
```

We have a labeled field for typing in a phone number, plus a button for dialing said number.

The Java code simply launches the dialer using the phone number from the field:

```
package com.commonsware.android.dialer;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class DialerDemo extends Activity {
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);
  }

  public void dial(View v) {
    EditText number=(EditText)findViewById(R.id.number);
    String toDial="tel:"+number.getText().toString();

    startActivity(new Intent(Intent.ACTION_DIAL, Uri.parse(toDial)));
  }
}
```

The activity's own UI is not that impressive:

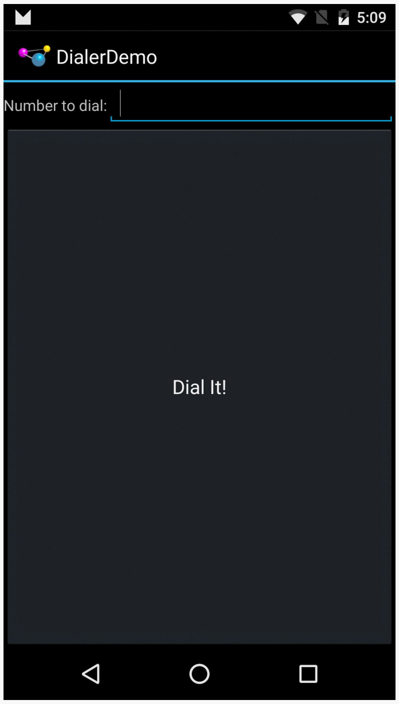


Figure 755: The DialerDemo sample application, as initially launched

However, the dialer you get from clicking the dial button is better, showing you the number you are about to dial:

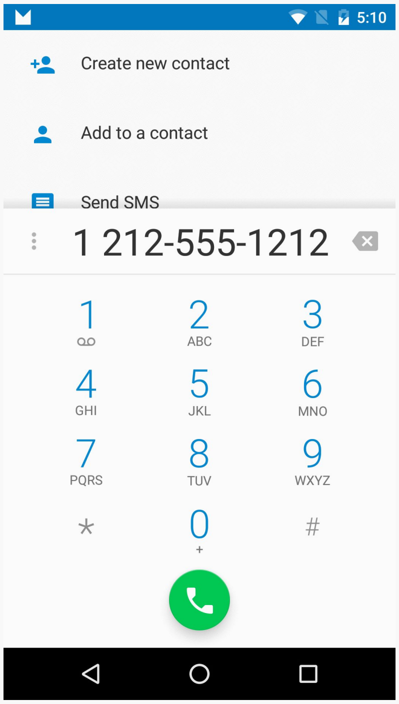

Figure 756: The Android Dialer activity, as launched from DialerDemo

No, Really, You Make the Call!

The good news is that `ACTION_DIAL` works without any special permissions. The bad news is that it only takes the user to the Dialer – the user still has to take action (pressing the green call button) to actually place the phone call.

An alternative approach is to use `ACTION_CALL` instead of `ACTION_DIAL`. Calling `startActivity()` on an `ACTION_CALL` `Intent` will immediately place the phone call, without any other UI steps required. However, you need the `CALL_PHONE` permission in order to use `ACTION_CALL`.

Working With SMS

Oh, what a tangled web we weave

When first we practice to work with SMS on Android, Eve

(with apologies to Sir Walter Scott)

Android devices have had SMS capability since Android 1.0. However, from a programming standpoint, for years, SMS and Android were intensely frustrating. When the Android SDK was developed, some aspects of working with SMS were put into the SDK, while others were held back. This, of course, did not stop many an intrepid developer from working with the undocumented, unsupported SMS APIs, with varying degrees of success.

After much wailing and gnashing of teeth by developers, Google finally formalized a more complete SMS API in Android 4.4. However, this too has its issues, where some apps that worked fine with the undocumented API will now fail outright, in irreparable fashion, on Android 4.4+.

This chapter starts with the one thing you can do reasonably reliably across Android device versions – send an SMS, either directly or by invoking the user's choice of SMS client. The chapter then examines how to monitor or receive SMS messages (both pre-4.4 and 4.4+) and the SMS-related `ContentProvider` (both pre-4.4 and 4.4+).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on broadcast `Intents`. One of the samples uses the

ContactsContract provider, so reading that chapter will help you understand that particular sample.

Sending Out an SOS, Give or Take a Letter

While much of Android's SMS capabilities are not in the SDK, sending an SMS is. You have two major choices for doing this:

- Invoke the user's choice of SMS client application, so they can compose a message, track its progress, and so forth using that tool
- Send the SMS directly yourself, bypassing any existing client

Which of these is best for you depends on what your desired user experience is. If you are composing the message totally within your application, you may want to just send it. However, as we will see, that comes at a price: an extra permission.

Sending Via the SMS Client

Sending an SMS via the user's choice of SMS client is very similar to the use of ACTION_SEND described elsewhere in this book. You craft an appropriate Intent, then call startActivity() on that Intent to bring up an SMS client (or allow the user to choose between clients).

The Intent differs a bit from the ACTION_SEND example:

1. You use ACTION_SENDTO, rather than ACTION_SEND
2. Your Uri needs to begin with smsto:, followed by the mobile number you want to send the message to
3. Your text message goes in an sms_body extra on the Intent

For example, here is a snippet of code from the SMS/Sender sample project:

```
    Intent sms=new Intent(Intent.ACTION_SENDTO,
                          Uri.parse("smsto:"+c.getString(2)));

    sms.putExtra("sms_body", msg.getText().toString());

    startActivity(sms);
```

Here, our phone number is coming out of the third column of a Cursor, and the text message is coming from an EditText — more on how this works later in this section, when we review the Sender sample more closely.

Sending SMS Directly

If you wish to bypass the UI and send an SMS directly, you can do so through the SmsManager class, in the android.telephony package. Unlike most Android classes ending in Manager, you obtain an SmsManager via a static getDefault() method on the SmsManager class. You can then call sendTextMessage(), supplying:

1. The phone number to send the text message to
2. The "service center" address — leave this null unless you know what you are doing
3. The actual text message
4. A pair of PendingIntent objects to be executed when the SMS has been sent and delivered, respectively

If you are concerned that your message may be too long, use divideMessage() on SmsManager to take your message and split it into individual pieces. Then, you can use sendMultipartTextMessage() to send the entire ArrayList of message pieces.

For this to work, your application needs to hold the SEND_SMS permission, via a child element of your <manifest> element in your AndroidManifest.xml file.

For example, here is code from Sender that uses SmsManager to send the same message that the previous section sent via the user's choice of SMS client:

```
      SmsManager
        .getDefault()
        .sendTextMessage(c.getString(2), null,
                         msg.getText().toString(),
                         null, null);
```

Inside the Sender Sample

The Sender example application is fairly straightforward, given the aforementioned techniques.

The manifest has both the SEND_SMS and READ_CONTACTS permissions, because we want to allow the user to pick a mobile phone number from their list of contacts, rather than type one in by hand:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.sms.sender"
  android:installLocation="preferExternal"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.READ_CONTACTS"/>
  <uses-permission android:name="android.permission.SEND_SMS"/>

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="Sender"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

If you noticed the `android:installLocation` attribute in the root element, that is to allow this application to be installed onto external storage, such as an SD card.

The layout has a `Spinner` (for a drop-down of available mobile phone numbers), a pair of `RadioButton` widgets (to indicate which way to send the message), an `EditText` (for the text message), and a "Send" `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>
  <Spinner android:id="@+id/spinner"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:drawSelectorOnTop="true"
  />
  <RadioGroup android:id="@+id/means"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    >
      <RadioButton android:id="@+id/client"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:checked="true"
        android:text="Via Client" />
      <RadioButton android:id="@+id/direct"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Direct" />
  </RadioGroup>
  <EditText
    android:id="@+id/msg"
    android:layout_width="match_parent"
    android:layout_height="0px"
    android:layout_weight="1"
    android:singleLine="false"
    android:gravity="top|left"
  />
  <Button
    android:id="@+id/send"
    android:text="Send!"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="sendTheMessage"
  />
</LinearLayout>
```

`Sender` uses the same technique for obtaining mobile phone numbers from our contacts as is seen in the chapter on contacts. To support Android 1.x and Android 2.x devices, we implement an abstract class and two concrete implementations, one for the old API and one for the new. The abstract class then has a static method to get at an instance suitable for the device the code is running on:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.os.Build;
import android.widget.SpinnerAdapter;

abstract class ContactsAdapterBridge {
  abstract SpinnerAdapter buildPhonesAdapter(Activity a);

  public static final ContactsAdapterBridge INSTANCE=buildBridge();

  private static ContactsAdapterBridge buildBridge() {
    int sdk=new Integer(Build.VERSION.SDK).intValue();

    if (sdk<5) {
      return(new OldContactsAdapterBridge());
    }

    return(new NewContactsAdapterBridge());
  }
}
```

The Android 2.x edition uses `ContactsContract` to find just the mobile numbers:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.CommonDataKinds.Phone;
import android.widget.SpinnerAdapter;
import android.widget.SimpleCursorAdapter;

class NewContactsAdapterBridge extends ContactsAdapterBridge {
  SpinnerAdapter buildPhonesAdapter(Activity a) {
    String[] PROJECTION=new String[] { Contacts._ID,
                                        Contacts.DISPLAY_NAME,
                                        Phone.NUMBER
                                      };
    String[] ARGS={String.valueOf(Phone.TYPE_MOBILE)};
    Cursor c=a.managedQuery(Phone.CONTENT_URI,
                            PROJECTION, Phone.TYPE+"=?",
                            ARGS, Contacts.DISPLAY_NAME);

    SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
                                    android.R.layout.simple_spinner_item,
                                    c,
                                    new String[] {
                                      Contacts.DISPLAY_NAME
                                    },
                                    new int[] {
                                      android.R.id.text1
                                    });

    adapter.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);

    return(adapter);
  }
}
```

… while the Android 1.x edition uses the older `Contacts` provider to find the mobile numbers:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.Contacts;
import android.widget.SimpleCursorAdapter;
import android.widget.SpinnerAdapter;

@SuppressWarnings("deprecation")
class OldContactsAdapterBridge extends ContactsAdapterBridge {
  SpinnerAdapter buildPhonesAdapter(Activity a) {
    String[] PROJECTION=new String[] {  Contacts.Phones._ID,
                                        Contacts.Phones.NAME,
                                        Contacts.Phones.NUMBER
                                      };
    String[] ARGS={String.valueOf(Contacts.Phones.TYPE_MOBILE)};
    Cursor c=a.managedQuery(Contacts.Phones.CONTENT_URI,
                            PROJECTION,
                            Contacts.Phones.TYPE+"=?", ARGS,
                            Contacts.Phones.NAME);

    SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
                                    android.R.layout.simple_spinner_item,
                                    c,
                                    new String[] {
                                      Contacts.Phones.NAME
                                    },
                                    new int[] {
                                      android.R.id.text1
                                    });

    adapter.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);

    return(adapter);
  }
}
```

For more details on how those providers work, please see the chapter on contacts.

The activity then loads up the `Spinner` with the appropriate list of contacts. When the user taps the Send button, the `sendTheMessage()` method is invoked (courtesy of the `android:onClick` attribute in the layout). That method looks at the radio buttons, sees which one is selected, and routes the text message accordingly:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.os.Bundle;
import android.telephony.SmsManager;
import android.view.View;
import android.widget.EditText;
import android.widget.RadioGroup;
import android.widget.Spinner;

public class Sender extends Activity {
  Spinner contacts=null;
  RadioGroup means=null;
  EditText msg=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    contacts=(Spinner)findViewById(R.id.spinner);

    contacts.setAdapter(ContactsAdapterBridge
                        .INSTANCE
                        .buildPhonesAdapter(this));
    means=(RadioGroup)findViewById(R.id.means);
    msg=(EditText)findViewById(R.id.msg);
  }

  public void sendTheMessage(View v) {
    Cursor c=(Cursor)contacts.getSelectedItem();

    if (means.getCheckedRadioButtonId()==R.id.client) {
      Intent sms=new Intent(Intent.ACTION_SENDTO,
                            Uri.parse("smsto:"+c.getString(2)));

      sms.putExtra("sms_body", msg.getText().toString());

      startActivity(sms);
    }
    else {
      SmsManager
        .getDefault()
        .sendTextMessage(c.getString(2), null,
                         msg.getText().toString(),
                         null, null);
    }
  }
}
```

SMS Sending Limitations

Apps running on Android 1.x and 2.x devices are limited to sending 100 SMS messages an hour, before the user starts getting prompted with each SMS message request to confirm that they do indeed wish to send it.

Apps running on Android 4.x devices, the limits are now 30 SMS messages in 30 minutes, according to some source code analysis by Al Sutton.

Monitoring and Receiving SMS

For the purposes of this section, “monitoring” refers to the ability to inspect incoming SMS messages, including reading their contents. In contrast, “receiving” SMS messages is actually consuming the message and storing it somewhere for the user to use.

As it turns out, “monitoring” and “receiving” are much the same thing prior to Android 4.4, but are significantly different in the new API made available in Android 4.4

The Undocumented, Unsupported, Pre-Android 4.4 Way

It is possible for an application to monitor or receive an incoming SMS message… if you are willing to listen on the undocumented `android.provider.Telephony.SMS_RECEIVED` broadcast `Intent`. That is sent by Android whenever an SMS arrives, and it is up to an application to implement a `BroadcastReceiver` to respond to that `Intent` and do something with the message. The Android open source project has such an application — Messaging — and device manufacturers can replace it with something else.

Note that to listen for this broadcast, your app must hold the `RECEIVE_SMS` permission.

The `BroadcastReceiver` can then turn around and use the `SmsMessage` class, in the `android.telephony` package, to get at the message itself, through the following undocumented recipe:

1. Given the received `Intent` (`intent`), call `intent.getExtras().get("pdus")` to get an `Object` array representing the raw portions of the message
2. For each of those "pdus" objects, call `SmsMessage.createFromPdu()` to convert the `Object` into an `SmsMessage` — though to make this work, you need to cast the `Object` to a `byte` array as part of passing it to the `createFromPdu()` static method

The resulting `SmsMessage` object gets you access to the text of the message, the sending phone number, etc.

The `SMS_RECEIVED` broadcast `Intent` is broadcast a bit differently than most others in Android. It is an "ordered broadcast", meaning the `Intent` will be delivered to one `BroadcastReceiver` at a time. This has two impacts of note:

- In your receiver's `<intent-filter>` element, you can have an `android:priority` attribute. Higher priority values get access to the broadcast `Intent` earlier than will lower priority values. The standard Messaging application has the default priority (undocumented, appears to be `0` or `1`), so you can arrange to get access to the SMS before the application does.
- Your `BroadcastReceiver` can call `abortBroadcast()` on itself to prevent the `Intent` from being broadcast to other receivers of lower priority. In effect, this causes your receiver to consume the SMS — the Messaging application will not receive it. So, aborting the broadcast means that your app chose to

"receive" the SMS; not aborting the broadcast means that your app is merely "monitoring" the SMS messages that come in.

However, just because the Messaging application has the default priority does not mean all SMS clients will, and so you cannot reliably intercept SMS messages this way. That, plus the undocumented nature of all of this, means that applications you write to receive SMS messages are likely to be fragile in production, breaking on various devices due to device manufacturer-installed apps, third-party apps, or changes to Android itself… such as the changes that came about in Android 4.4.

The Android 4.4+ Way: Monitoring SMS

The code described above still works on Android 4.4, though the formerly-hidden `android.provider.Telephony` class is now part of the SDK.

The biggest difference, though, is that even if you call `abortBroadcast()`, the user's chosen SMS messaging client will still receive the message. It is not possible for an app listening for `SMS_RECEIVED` broadcasts to prevent the user's chosen SMS messaging client from receiving those same messages. This is a substantial change, one that will break or make obsolete many Android applications.

Regardless, if monitoring SMS fits your needs, `SMS_RECEIVED` can do it.

So, for example, the [`SMS/Monitor`]() sample project implements a `BroadcastReceiver` for `SMS_RECEIVED`, one with slightly elevated priority:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.sms.monitor"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <uses-permission android:name="android.permission.RECEIVE_SMS"/>

  <uses-sdk
    android:minSdkVersion="3"
    android:targetSdkVersion="19"/>

  <application
    android:icon="@drawable/cw"
    android:label="@string/app_name">
    <receiver
      android:name="Monitor"
      android:permission="android.permission.BROADCAST_SMS">
      <intent-filter android:priority="2">
        <action android:name="android.provider.Telephony.SMS_RECEIVED"/>
      </intent-filter>
    </receiver>

    <activity
      android:name="BootstrapActivity"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

You will notice that the BroadcastReceiver not only has the slightly-elevated priority (android:priority="2"), but also a required permission (android:permission="android.permission.BROADCAST_SMS"). Only apps that hold this permission can send this broadcast in a way that will be picked up by the receiver. Since this permission can only be held by the device firmware, you are protected from "spoof" SMS messages from rogue apps on the device, sending the SMS_RECEIVED themselves.

The app also has a do-nothing activity, solely there to activate the manifest-registered BroadcastReceiver, which will not work until some component of the app is manually started.

The bulk of the business logic — what little there is of it — lies in the Monitor class that is the BroadcastReceiver:

```
package com.commonsware.android.sms.monitor;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.telephony.SmsMessage;
import android.util.Log;

public class Monitor extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    Object[] rawMsgs=(Object[])intent.getExtras().get("pdus");

    for (Object raw : rawMsgs) {
      SmsMessage msg=SmsMessage.createFromPdu((byte[])raw);

      if (msg.getMessageBody().toUpperCase().contains("SEKRIT")) {
        Log.w("SMS:"+msg.getOriginatingAddress(),
              msg.getMessageBody());

        abortBroadcast();
      }
    }
  }
}
```

Here, we retrieve the raw messages from the Intent extra, iterate over them, and convert each to an SmsMessage. Those that have the magic word in their message body will result in the message being dumped to LogCat, plus the broadcast is aborted. On Android 4.3 and below, this will prevent lower-priority receivers from receiving the SMS. On Android 4.4, the abort request is ignored.

The Android 4.4+ Way: Receiving SMS

Receiving SMS messages, on Android 4.4+, means that you are implementing an SMS client application, one the user might be willing to set as their default SMS client application in Settings. There are other sorts of apps that may temporarily want to be the default SMS client, such as a backup/restore utility, as only the default SMS client will be able to work with the SMS ContentProvider suite, such as the inbox.

Receiving the Broadcasts

The default SMS client should be able to handle both SMS and MMS. This is a problem, as while supporting SMS is poorly documented, supporting MMS has almost no documentation whatsoever. However, unless the default SMS client handles MMS, nobody else can (at least, while saving MMS details to the ContentProvider suite.

Hence, Google is expecting you to have two BroadcastReceivers registered in the manifest: one for SMS and one for MMS. Unfortunately, these cannot readily be combined into a single receiver, because each has its own permission requirement:

- the SMS receiver should require senders to hold BROADCAST_SMS
- the MMS receiver should require senders to hold BROADCAST_WAP_PUSH

In practice, probably both are held by the OS component that is sending these broadcasts in response to incoming messages of either type. In principle, though, they could be separate, and an individual <receiver> can only specify one such permission.

The Android documentation illustrates the `<receiver>` elements that Google expects your SMS client application to have:

```
<!-- BroadcastReceiver that listens for incoming SMS messages -->
<receiver android:name=".SmsReceiver"
        android:permission="android.permission.BROADCAST_SMS">
    <intent-filter>
        <action android:name="android.provider.Telephony.SMS_DELIVER" />
    </intent-filter>
</receiver>

<!-- BroadcastReceiver that listens for incoming MMS messages -->
<receiver android:name=".MmsReceiver"
    android:permission="android.permission.BROADCAST_WAP_PUSH">
    <intent-filter>
        <action android:name="android.provider.Telephony.WAP_PUSH_DELIVER" />
        <data android:mimeType="application/vnd.wap.mms-message" />
    </intent-filter>
</receiver>
```

Notice that the MMS receiver has both an `<action>` and a `<data>` element in its `<intent-filter>`, which is rather unusual.

On the SMS side, the `Intent` you receive should be the same as the `Intent` you would receive for the `SMS_RECEIVED` broadcast, where you can decode the message(s) and deal with them as you see fit. On the MMS side… there is little documentation.

Other Expectations

Google expects the default SMS client to be able to handle `ACTION_SEND` and `ACTION_SENDTO` for relevant schemes:

```
<!-- Activity that allows the user to send new SMS/MMS messages -->
<activity android:name=".ComposeSmsActivity" >
    <intent-filter>
        <action android:name="android.intent.action.SEND" />
        <action android:name="android.intent.action.SENDTO" />
        <category android:name="android.intent.category.DEFAULT" />
        <category android:name="android.intent.category.BROWSABLE" />
        <data android:scheme="sms" />
        <data android:scheme="smsto" />
        <data android:scheme="mms" />
        <data android:scheme="mmsto" />
    </intent-filter>
</activity>
```

That may not be terribly surprising. What *is* surprising is that Google also expects you to have an exported *service* for handling “quick response” requests. These requests come when the user receives a phone call and taps on an icon to reply with a text message, rather than accept the call. In those cases, Android will invoke a service in the default SMS client, with an action of `android.intent.action.RESPOND_VIA_MESSAGE`. The `Intent` that you receive in `onStartCommand()` (or `onHandleIntent()`, if you elect to use an `IntentService`) will have an `EXTRA_TEXT` and optionally an `EXTRA_SUBJECT` as extras, representing the message to be sent. The `Uri` in the `Intent` will indicate the intended recipient of the message. Your job is to use `SmsManager` to actually send the message.

The Android documentation cites this as the relevant `<service>` element:

```
<!-- Service that delivers messages from the phone "quick response" -->
<service android:name=".HeadlessSmsSendService"
         android:permission="android.permission.SEND_RESPOND_VIA_MESSAGE"
         android:exported="true" >
    <intent-filter>
        <action android:name="android.intent.action.RESPOND_VIA_MESSAGE" />
        <category android:name="android.intent.category.DEFAULT" />
        <data android:scheme="sms" />
        <data android:scheme="smsto" />
        <data android:scheme="mms" />
        <data android:scheme="mmsto" />
    </intent-filter>
</service>
```

Note:

- The `<service>` requires that the sender have the `SEND_RESPOND_VIA_MESSAGE` permission, to reduce spoofing
- The `android:exported="true"` shown in the sample should be superfluous, as since the `<service>` has an `<intent-filter>`, it should be exported by default
- The `<category>`, and possibly the `<data>`, elements may be erroneous… and since the author cannot find anything in the OS that uses `RESPOND_VIA_MESSAGE`, the author cannot validate that these elements should be here or represent copy-and-paste errors in the documentation

Handling Both Receive Options

If you want to support receiving SMS using both the legacy approach and the Android 4.4+ approach, you can have two `BroadcastReceiver` implementations, one for `android.provider.Telephony.SMS_RECEIVED` and one for `android.provider.Telephony.SMS_DELIVER`. However, you will only need the latter one on Android 4.4, and by default you would receive both broadcasts.

To handle that, you can define a boolean resource in the `res/values-v19/` directory (e.g., `isPreKitKat`) to be `false`, with a default definition in `res/values/` of `true` for the same resource. Then, in your manifest, you can have `android:enabled="@bool/isPreKitKat"` on your `SMS_RECEIVED` `<receiver>` element. This will only enable this component on API Level 18 and below, disabling it on API Level 19+.

You can also define a counterpart resource for the positive case (e.g., `@bool/isKitKat`), and use that to selectively enable the SMS and MMS receivers, if desired.

The SMS Inbox

Many users keep their text messages around, at least for a while. These are stored in an "inbox", represented by a `ContentProvider`. How you work with this `ContentProvider` — or if you can work with it at all, varies upon whether you are running on Android 4.4+ or not.

The Undocumented, Unsupported, Pre-Android 4.4 Way

When perusing the Internet, you will find various blog posts and such referring to the SMS inbox `ContentProvider`, represented by the `content://sms/inbox` `Uri`.

This `ContentProvider` is undocumented and is not part of the Android SDK, because it is not part of the Android OS.

Rather, this `ContentProvider` is used by the aforementioned Messaging application, for storing saved SMS messages. And, as noted, this application may or may not exist on any given Android device. If a device manufacturer replaces Messaging with their own application, there may be nothing on that device that responds to that `Uri`, or the schemas may be totally different. Plus, Android may well change or even remove this `ContentProvider` in future editions of Android.

For all those reasons, developers should not be relying upon this `ContentProvider`.

The Android 4.4+ Way

Android 4.4 has exposed a series of `ContentProviders`, in the `android.provider.Telephony` namespace, for storing SMS and MMS messages. These include:

- the `Inbox` for received messages
- the `Outbox` for a log of sent messages
- the `Draft` for messages that were written but have not yet been sent

- etc.

Some are duplicated, such as separate providers for the SMS inbox versus the MMS inbox. Some are distinct, such as `Sms.Conversations` and `Mms.Rate`.

All are largely undocumented.

The user's chosen default SMS client can write to these providers. Apps with `READ_SMS` permission should be able to read from them.

Asking to Change the Default

There are many areas in Android where the user must do two things to use an app:

1. Install the app (from the Play Store or elsewhere)
2. Go into Settings (or sometimes elsewhere) and indicate that a certain capability of the newly-installed app should become active

You see this with app widgets, input method editors, device administrators, and many others.

On Android 4.4+, you also see this with SMS/MMS clients. Devices usually ship with one. If the user wants a replacement, the user must indicate in Settings that this new SMS/MMS client should be the default, so it can write to the SMS/MMS `ContentProvider` suite.

Your app can determine what the default client is by calling `getDefaultSmsPackage()` on the `Telephony.Sms` class. This will return the package name of the current default client.

If this is not your package, and you would like the user to make you the default, you can start an activity to request this change:

```
Intent i = new Intent(Sms.Intents.ACTION_CHANGE_DEFAULT);
i.putExtra(Sms.Intents.EXTRA_PACKAGE_NAME, getPackageName());
startActivity(i);
```

The `EXTRA_PACKAGE_NAME` will trigger the UI to ask the user if the user wishes to change the current default to your package (versus anything else on the device that might also be a possible SMS/MMS client).

Hence, the recommended flow for a backup/restore app is to:

- Make note of the current default, via getDefaultSmsPackage()
- Request to the user to make you the default, via ACTION_CHANGE_DEFAULT
- Confirm that they did this, via getDefaultSmsPackage()
- If they did, do your backup or restore work
- Request to the user to restore the original default, via ACTION_CHANGE_DEFAULT

SMS and the Emulator

The “Emulator Control” view in DDMS allows you to send fake SMS messages to a running emulator. This is very useful for light testing.

You can also send fake SMS messages to an emulator via the emulator console. This can be accessed via telnet, where the console is available on localhost on your development machine, via the port number that appears in the title bar of your emulator window (e.g., 5554). In the telnet session, you can enter sms send [sendingNumber> <txt>, replacing <sendingNumber> with the phone number of the pretend sender of the SMS, and replacing <txt> with the text message itself.

NFC

NFC, courtesy of high-profile boosters like Google Wallet, is poised to be a significant new capability in Android devices. While at the time of this writing, only a handful of Android devices have NFC built in, other handsets are slated to be NFC-capable in the coming months. Google is hoping that developers will write NFC-aware applications to help further drive adoption of this technology by device manufacturers.

This, of course, raises the question: what is NFC? Besides being where the Green Bay Packers play, that is?

(For those of you from outside of the United States, that was an American football joke. We now return you to your regularly-scheduled chapter.)

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on broadcast `Intents` and services.

What Is NFC?

NFC stands for Near-Field Communications. It is a wireless standard for data exchange, aimed at very short range transmissions — on the order of a couple of centimeters. NFC is in wide use today, for everything from credit cards to passports. Typically, the NFC data exchange is for simple data — contact information, URLs, and the like.

In particular, NFC tends to be widely used where one side of the communications channel is “passive”, or unpowered. The other side (the “initiator”) broadcasts a signal, which the passive side converts into power enough to send back its response. As such, NFC “tags” containing such passive targets can be made fairly small and can be embedded in a wide range of containers, from stickers to cards to hats.

The objective is “low friction” interaction — no pairing like with Bluetooth, no IP address shenanigans as with WiFi. The user just taps and goes.

… Compared to RFID?

NFC is often confused with or compared to RFID. It is simplest to think of RFID as being an umbrella term, under which NFC falls. Not every RFID technology is NFC, but many things that you hear of being “RFID” may actually be NFC-compliant devices or tags.

… Compared to QR Codes?

In many places, NFC will be used in ways you might consider using QR codes. For example, a restaurant could use either technology, or both, on a sign to lead patrons to the restaurant’s Yelp page, as a way of soliciting reviews. Somebody with a capable device could either tap the NFC tag on the sign to bring up Yelp or take a picture of the QR code and use that to bring up Yelp.

NFC’s primary advantage over QR codes is that it requires no user intervention beyond physically moving their device in close proximity to the tag. QR codes, on the other hand, require the user to launch a barcode scanning application, center the barcode in the viewfinder, and then get the results. The net effect is that NFC will be faster.

QR’s advantages include:

1. No need for any special hardware to generate the code, as opposed to needing a tag and something to write information into the tag for NFC
2. The ability to display QR codes in distant locations (e.g., via Web sites), whereas NFC requires physical proximity

To NDEF, Or Not to NDEF

RFID is a concept, not a standard. As such, different vendors created their own ways of structuring data on these tags or chips, making one vendor's tags incompatible with another vendor's readers or writers. While various standards bodies, like ISO, have gotten involved, it's still a bit of a rat's nest of conflicting formats and approaches.

The NFC offshoot of RFID has had somewhat greater success in establishing standards. NFC itself is an ISO and ECMA standard, covering things like transport protocols and transfer speeds. And a consortium called the NFC Forum created NDEF — the NFC Data Exchange Format — for specifying the content of tags.

However, not all NFC tags necessarily support NDEF. NDEF is much newer than NFC, and so lots of NFC tags are out in the wild that were distributed before NDEF even existed.

You can roughly divide NFC tags into three buckets:

- Those that support NDEF "out of the box"
- Those that can be "formatted" as NDEF
- Those that use other content schemes

Android has some support for non-NDEF tags, such as the MIFARE Classic. However, the hope and expectation going forward is that NFC tags will coalesce around NDEF.

NDEF, as it turns out, maps neatly to Android's `Intent` system, as you will see as we proceed through this chapter.

NDEF Modalities

Most developers interested in NFC will be interested in reading NFC tags and retrieving the NDEF data off of them. In Android, tapping an NDEF tag with an NFC-capable device will trigger an activity to be started, based on a certain `IntentFilter`.

Some developers will be interested in writing to NFC tags, putting URLs, vCards, or other information on them. This may or may not be possible for any given tag.

And while the "traditional" thinking around NFC has been that one side of the communication is a passive tag, Android will help promote the "peer-to-peer" approach — having two Android devices exchange data via NFC and NDEF. Basically, putting the two devices back-to-back will cause each to detect the other device's "tag", and each can read and write to the other via this means. This is referred to as "Android Beam" and will be discussed later in this chapter.

Of course, all of these are only available on hardware. At the present time, there is no emulator for NFC, nor any means of accessing a USB NFC reader or writer from the emulator.

NDEF Structure and Android's Translation

NDEF is made up of messages, themselves made up of a series of records. From Android's standpoint, each tag consists of one such message.

Each record consists of a binary (byte array) payload plus metadata to describe the nature of the payload. The metadata primarily consists of a type and a subtype. There are quite a few combinations of these, but the big three for new Android NFC uses are:

- A type of TNF_WELL_KNOWN and a subtype of RTD_TEXT, indicating that the payload is simply plain text
- A type of TNF_WELL_KNOWN and a subtype of RTD_URI, indicating that the payload is a URI, such as a URL to a Web page
- A type of TNF_MIME_MEDIA, where the subtype is a standard MIME type, indicating that the payload is of that MIME type

When Android scans an NDEF tag, it will use this information to construct a suitable Intent to use with startActivity(). The action will be android.nfc.action.NDEF_DISCOVERED, to distinguish the scanned-tag case from, say, something simply asking to view some content. The MIME type in the Intent will be text/plain for the first scenario above or the supplied MIME type for the third scenario above. The data (Uri) in the Intent will be the supplied URI for the second scenario above. Once constructed, Android will invoke startActivity() on that Intent, bringing up an activity or an activity chooser, as appropriate.

NFC-capable Android devices have a Tags application pre-installed that will handle any NFC tag not handled by some other app. So, for example, an NDEF tag with an

HTTP URL will fire up the Tags application, which in turn will allow the user to open up a Web browser on that URL.

The Reality of NDEF

The enthusiasm that some have with regards to Android and NFC technology needs to be tempered by the reality of NDEF, NFC tags in general, and Android's support for NFC. It is easy to imagine all sorts of possibilities that may or may not be practical when current limitations are reached.

Some Tags are Read-Only

Some tags come "from the factory" read-only. Either you arrange for the distributor to write data onto them (e.g., blast a certain URL onto a bunch of NFC stickers to paste onto signs), or they come with some other pre-established data. Touchatag, for example, distributes NFC tags that have Touchatag URLs on them — they then help you set up redirects from their supplied URL to ones you supply.

While these tags will be of interest to consumers and businesses, they are unlikely to be of interest to Android developers, since their use cases are already established and typically do not need custom Android application support. Android developers seeking customizable tags will want ones that are read-write, or at least write-once.

Some Tags Can't Be Read-Only

Conversely, some tags lack any sort of read-only flag. An ideal tag for developers is one that is write-once: putting an NDEF message on the tag and flagging it read-only in one operation. Some tags do not support this, or making the tag read-only at any later point. The MIFARE Classic 1K tag is an example — while technically it can be made read-only, it requires a key known only to the tag manufacturer.

Some Tags Need to be Formatted

The MIFARE Classic 1K NFC tag is NDEF-capable, but must be "formatted" first, supplying the initial NDEF message contents. You have the option of formatting it read-write or read-only (turning the Classic 1K a write-once tag).

This is not a problem — in fact, the write-once option may be compelling. However, it is something to keep in mind.

Also, note that the MIFARE Classic 1K, while it can be formatted as NDEF, uses a proprietary protocol "under the covers". Not all Android devices will support the Classic 1K, as the device manufacturers elect not to pay the licensing fee. Where possible, try to stick to tags that are natively NDEF-compliant (so-called "NFC Forum Tag Types 1-4").

Tags Have Limited Storage

The "1K" in the name "MIFARE Classic 1K" refers to the amount of storage on the tag: 1 kilobyte of information.

And that's far larger than other tags, such as the MIFARE Ultralight C, some of which have ~64 bytes of storage.

Clearly, you will not be writing an MP3 file or JPEG photo to these tags. Rather, the tags will tend to either be a "launcher" into something with richer communications (e.g., URL to a Web site) or will use the sorts of data you may be used to from QR codes, such as a vCard or iCalendar for contact and event data, respectively.

NDEF Data Structures Are Documented Elsewhere

The Android developer documentation is focused on the Android classes related to NFC and on the `Intent` mechanism used for scanned tags. It does not focus on the actual structure of the payloads.

For `TNF_MIME_MEDIA` and `RTD_TEXT`, the payload is whatever you want. For `RTD_URI`, however, the byte array has a bit more structure to it, as the NDEF specification calls for a single byte to represent the URI prefix (e.g., `http://www.` versus `http://` versus `https://www.`). The objective, presumably, is to support incrementally longer URLs on tags with minuscule storage. Hence, you will need to convert your URLs into this sort of byte array if you are writing them out to a tag.

Generally speaking, the rules surrounding the structure of NDEF messages and records is found at the NFC Forum site.

Tag and Device Compatibility

Different devices will have different NFC chipsets. Not all NFC chipsets can read and write all tags. The expectation is that NDEF-formatted tags will work on all devices, but if you wander away from that, things get dicier. For example, NXP's Mifare Classic tag can only be read and written by NXP's NFC chip.

This is increasingly a challenge for Android developers, as a Broadcom NFC chip is becoming significantly more popular. Many new major Android devices, such as the Samsung Galaxy S4, the Nexus 4, the Nexus 10, and the 2013/2nd generation version of the Nexus 7, all use the Broadcom chip. Those devices are incompatible with the Mifare tags, such as the popular Mifare Classic 1K.

That is because NXP is the maker of the Mifare Classic series, and those tags broke the NFC Forum's standards to create a tag that was NXP-specific.

Right now, NTAG203 and Topaz tags (like the Topaz 512), are likely candidate tags that will work across all NFC-capable Android devices, due to their adherence to NFC standard protocols.

Sources of Tags

NFC tags are not the sort of thing you will find on your grocer's shelves. In fact, few, if any, mainstream firms sell them today.

Here are some online sites from which you can order rewritable NFC tags, listed here in alphabetical order:

1. Andytags
2. Buy NFC Tags
3. Smartcard Focus
4. tagstand

Note that not all may ship to your locale.

Writing to a Tag

So, let's see what it takes to write an NDEF message to a tag, formatting it if needed. The code samples shown in this chapter are from the `NFC/URLTagger` sample application. This application will set up an activity to respond to `ACTION_SEND` activity `Intents`, with an eye towards receiving a URL from a browser, then waiting for a tag and writing the URL to that tag. The idea is that this sort of application could be used by non-technical people to populate tags containing URLs to their company's Web site, etc.

Getting a URL

First, we need to get a URL from the browser. As we saw in the chapter on integration, the standard Android browser uses `ACTION_SEND` of `text/plain` contents when the user chooses the "Share Page" menu. So, we have one activity, `URLTagger`, that will respond to such an `Intent`:

```
    <activity
      android:name="URLTagger"
      android:label="@string/app_name">
      <intent-filter android:label="@string/app_name">
        <action android:name="android.intent.action.SEND"/>

        <data android:mimeType="text/plain"/>

        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
```

Of course, lots of other applications support `ACTION_SEND` of `text/plain` contents that are not URLs. A production-grade version of this application would want to validate the `EXTRA_TEXT` `Intent` extra to confirm that, indeed, this is a URL, before putting in an NDEF message claiming that it is a URL.

Detecting a Tag

When the user shares a URL with our application, our activity is launched. At that point, we need to go into "detect a tag" mode – the user should then tap their device to a tag, so we can write out the URL.

First, in `onCreate()`, we get access to the `NfcAdapter`, which is our gateway to much of the NFC functionality in Android:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    nfc=NfcAdapter.getDefaultAdapter(this);
  }
```

We use a boolean data member — `inWriteMode` — to keep track of whether or not we are set up to write to a tag. Initially, of course, that is set to be `false`. Hence, when we are first launched, by the time we get to `onResume()`, we can go ahead and register our interest in future tags:

```
@Override
public void onResume() {
  super.onResume();

  if (!inWriteMode) {
    IntentFilter discovery=new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
    IntentFilter[] tagFilters=new IntentFilter[] { discovery };
    Intent i=new Intent(this, getClass())
              .addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP|
                        Intent.FLAG_ACTIVITY_CLEAR_TOP);
    PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

    inWriteMode=true;
    nfc.enableForegroundDispatch(this, pi, tagFilters, null);
  }
}
```

When an NDEF-capable tag is within signal range of the device, Android will invoke `startActivity()` for the `NfcAdapter.ACTION_TAG_DISCOVERED` `Intent` action. However, it can do this in one of two ways:

- Normally, it will use a chooser (via `Intent.createChooser()`) to allow the user to pick from any activities that claim to support this action.
- The foreground application can request via `enableForegroundDispatch()` for it to handle all tag events while it is in the foreground, superseding the normal `startActivity()` flow. In this case, while Android still will invoke an activity, it will be our activity, not any other one.

We want the second approach right now, so the next tag brought in range is the one we will try writing to.

To do that, we need to create an array of `IntentFilter` objects, identifying the NFC-related actions that we want to capture in the foreground. In this case, we only care about `ACTION_TAG_DISCOVERED` – if we were supporting non-NDEF NFC tags, we might also need to watch for `ACTION_TECH_DISCOVERED`.

We also need a `PendingIntent` identifying the activity that should be invoked when such a tag is encountered while we are in the foreground. Typically, this will be the current activity. By adding `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to the `Intent` as flags, we ensure that our current specific instance of the activity will be given control again via `onNewIntent()`.

Armed with those two values, we can call `enableForegroundDispatch()` on the `NfcAdapter` to register our request to process tags via the current activity instance.

In onPause(), if the activity is finishing, we call disableForegroundDispatch() to undo the work done in onResume():

```
@Override
public void onPause() {
  if (isFinishing()) {
    nfc.disableForegroundDispatch(this);
    inWriteMode=false;
  }

  super.onPause();
}
```

We have to see if we are finishing, because even though our activity never leaves the screen, Android still calls onPause() and onResume() as part of delivering the Intent to onNewIntent(). Our approach, though, has flaws — if the user presses HOME, for example, we never disable the NFC dispatch logic. A production-grade application would need to handle this better.

For any of this code to work, we need to hold the NFC permission via an appropriate line in the manifest:

```
<uses-permission android:name="android.permission.NFC"/>
```

Also note that if you have several activities that the user can reach while you are trying to also capture NFC tag events, you will need to call enableForegroundDispatch() in each activity — it's a per-activity request, not a per-application request.

Reacting to a Tag

Once the user brings a tag in range, onNewIntent() will be invoked with the ACTION_TAG_DISCOVERED Intent action:

```
@Override
protected void onNewIntent(Intent intent) {
  if (inWriteMode &&
      NfcAdapter.ACTION_TAG_DISCOVERED.equals(intent.getAction())) {
    Tag tag=intent.getParcelableExtra(NfcAdapter.EXTRA_TAG);
    byte[] url=buildUrlBytes(getIntent().getStringExtra(Intent.EXTRA_TEXT));
    NdefRecord record=new NdefRecord(NdefRecord.TNF_WELL_KNOWN,
                                     NdefRecord.RTD_URI,
                                     new byte[] {}, url);
    NdefMessage msg=new NdefMessage(new NdefRecord[] {record});

    new WriteTask(this, msg, tag).execute();
  }
}
```

If we are in write mode and the delivered Intent is indeed an ACTION_TAG_DISCOVERED one, we can get at the Tag object associated with the user's NFC tag via the NfcAdapter.EXTRA_TAG Parcelable extra on the Intent.

Writing an NDEF message to the tag, therefore, is a matter of crafting the message and actually writing it. An NDEF message consists of one or more records (though, typically, only one record is used), with each record wrapping around a byte array of payload data.

Getting the Shared URL

We did not do anything to get the URL out of the Intent back in onCreate(), when our activity was first started up. Now, of course, we need that URL. You might think it is too late to get it, since our activity was effectively started again due to the tag and onNewIntent().

However, getIntent() on an Activity always returns the Intent used to create the activity in the first place. The getIntent() value is not replaced when onNewIntent() is called.

Hence, as part of the buildUrlBytes() method to create the binary payload, we can go and call getIntent().getStringExtra(Intent.EXTRA_TEXT) to retrieve the URL.

Creating the Byte Array

Given the URL, we need to convert it into a byte array suitable for use in a TNF_WELL_KNOWN, RTD_URI NDEF record. Ordinarily, you would just call toByteArray() on the String and be done with it. However, the byte array we need uses a single byte to indicate the URL prefix, with the rest of the byte array for the characters after this prefix.

This is efficient. This is understandable. This is annoying.

First, we need the roster of prefixes, defined in URLTagger as a static data member cunningly named PREFIXES:

```
  static private final String[] PREFIXES={"http://www.", "https://www.",
                                          "http://", "https://",
                                          "tel:", "mailto:",
                                          "ftp://anonymous:anonymous@",
                                          "ftp://ftp.", "ftps://",
                                          "sftp://", "smb://",
                                          "nfs://", "ftp://",
                                          "dav://", "news:",
                                          "telnet://", "imap:",
                                          "rtsp://", "urn:",
                                          "pop:", "sip:", "sips:",
                                          "tftp:", "btspp://",
                                          "btl2cap://", "btgoep://",
                                          "tcpobex://",
                                          "irdaobex://",
                                          "file://", "urn:epc:id:",
                                          "urn:epc:tag:",
                                          "urn:epc:pat:",
                                          "urn:epc:raw:",
                                          "urn:epc:", "urn:nfc:"};
```

Then, in `buildUrlBytes()`, we need to find the prefix (if any) and use it:

```
private byte[] buildUrlBytes(String url) {
  byte prefixByte=0;
  String subset=url;
  int bestPrefixLength=0;

  for (int i=0;i<PREFIXES.length;i++) {
    String prefix = PREFIXES[i];

    if (url.startsWith(prefix) && prefix.length() > bestPrefixLength) {
      prefixByte=(byte)(i+1);
      bestPrefixLength=prefix.length();
      subset=url.substring(bestPrefixLength);
    }
  }

  final byte[] subsetBytes = subset.getBytes();
  final byte[] result = new byte[subsetBytes.length+1];

  result[0]=prefixByte;
  System.arraycopy(subsetBytes, 0, result, 1, subsetBytes.length);

  return(result);
}
```

We iterate over the `PREFIXES` array and find a match, if any, and the best possible match if there is more than one. If there is a match, we record the NDEF value for the first byte (our `PREFIXES` index plus one) and create a subset string containing the characters after the prefix. If there is no matching prefix, the prefix byte is `0` and we will include the full URL.

Given that, we construct a byte array containing our prefix byte in the first slot, and the rest taken up by the byte array of the subset of our URL.

Creating the NDEF Record and Message

Given the result of `buildUrlBytes()`, our `onNewIntent()` implementation creates a `TNF_WELL_KNOWN`, `RTD_URI` `NdefRecord` object, and pours that into an `NdefMessage` object.

The third parameter to the `NdefRecord` constructor is a byte array representing the optional “ID” of this record, which is not necessary here.

Finally, we delegate the actual writing to a `WriteTask` subclass of `AsyncTask`, as writing the `NdefMessage` to the `Tag` is… interesting.

Writing to a Tag

Here is the aforementioned `WriteTask` static inner class:

```
static class WriteTask extends AsyncTask<Void, Void, Void> {
  Activity host=null;
  NdefMessage msg=null;
  Tag tag=null;
  String text=null;

  WriteTask(Activity host, NdefMessage msg, Tag tag) {
    this.host=host;
    this.msg=msg;
    this.tag=tag;
  }

  @Override
  protected Void doInBackground(Void... arg0) {
    int size=msg.toByteArray().length;

    try {
      Ndef ndef=Ndef.get(tag);

      if (ndef==null) {
        NdefFormatable formatable=NdefFormatable.get(tag);

        if (formatable!=null) {
          try {
            formatable.connect();

            try {
              formatable.format(msg);
            }
            catch (Exception e) {
              text="Tag refused to format";
            }
          }
          catch (Exception e) {
            text="Tag refused to connect";
          }
          finally {
            formatable.close();
          }
        }
        else {
          text="Tag does not support NDEF";
        }
      }
      else {
        ndef.connect();

        try {
          if (!ndef.isWritable()) {
            text="Tag is read-only";
          }
          else if (ndef.getMaxSize()<size) {
            text="Message is too big for tag";
          }
          else {
            ndef.writeNdefMessage(msg);
          }
        }
        catch (Exception e) {
          text="Tag refused to connect";
        }
        finally {
          ndef.close();
        }
      }
    }
    catch (Exception e) {
      Log.e("URLTagger", "Exception when writing tag", e);
      text="General exception: "+e.getMessage();
    }

    return(null);
  }

  @Override
  protected void onPostExecute(Void unused) {
    if (text!=null) {
      Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }

    host.finish();
  }
}
```

In `doInBackground()`, after making note of how big the message is in bytes, we first try to get the `Ndef` aspect of the `Tag` object, by calling the static `get()` method on the `Ndef` class. If the tag is an NDEF tag, this should return an `Ndef` instance. If it does not, we try to get an `NdefFormatable` aspect by calling `get()` on the `NdefFormatable` class. If the tag is not NDEF now but can be formatted as NDEF, this should give us an `NdefFormatable` object. If both aspect attempts fail, we bail out, displaying a

Toast to let the user know that while the tag they used is NFC, it is not NDEF-compliant.

If the tag turned out to be NdefFormatable, to put the NdefMessage on it, we first connect() to the tag, then format() it, supplying the message. NdefFormatable also supports formatReadOnly() for tags that support that mode — this will write the message on the tag, then block it from further updates. When we are done, we close() the connection.

If the tag turned out to be Ndef already, we connect() to it, then see if it is writable and has enough room. If it meets both of those criteria, we can emit the message via writeNdefMessage(), which overwrites the NDEF message that had already existed on the tag (if any). If the tag supported it, a call to makeReadOnly() would block further updates to the tag. Again, when we are done, we close() the connection.

All of the actual NFC I/O is performed in doInBackground(), because this I/O may take some time, and we do not want to block the main application thread while doing it.

Responding to a Tag

Writing to a tag is a bit complicated. Responding to an NDEF message on a tag is significantly easier.

If the foreground activity is not consuming NFC events — as URLTagger does in write mode — then Android will use normal Intent resolution with startActivity() to handle the tag. To respond to the tag, all you need to do is have an activity set up to watch for an android.nfc.action.NDEF_DISCOVERED Intent. To get control ahead of the built-in Tags application, also have a <data> element that describes the sort of content or URL you are expecting to find on the tag.

For example, suppose you used the Android browser to visit some page on the CommonsWare Web site, and you wrote that to a tag using URLTagger. The URLTagger application has another activity, URLHandler, that will respond when you tap the newly-written tag from the home screen or anywhere else. It accomplishes this via a suitable <intent-filter>:

```
    <activity
      android:name="URLHandler"
      android:label="@string/app_name">
      <intent-filter android:label="@string/app_name">
        <action android:name="android.nfc.action.NDEF_DISCOVERED"/>
        <data
          android:host="commonsware.com"
          android:scheme="http"/>

        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
```

The `URLHandler` activity can then use `getIntent()` to retrieve the key pieces of data from the tag itself, if needed. In particular, the `EXTRA_NDEF_MESSAGES` `Parcelable` array extra will return an array of `NdefMessage` objects. Typically, there will only be one of these. You can call `getRecords()` on the `NdefMessage` to get at the array of `NdefRecord` objects (again, typically only one). Methods like `getPayload()` will allow you to get at the individual portions of the record.

The nice thing is that the URL still works, even if URLTagger is not on the device. In that case, the Tags application would react to the tag, and the user could tap on it to bring up a browser on this URL. A production application might create a Web page that tells the user about this great and wonderful app she can install, and provide links to the Play Store (or elsewhere) to go get the app.

Expected Pattern: Bootstrap

Tags tend to have limited capacity. Even in peer-to-peer settings, the effective bandwidth of NFC is paltry compared to anything outside of dial-up Internet access.

As a result, NFC will be used infrequently as the complete communications solution between a publisher and a device. Sometimes it will, when the content is specifically small, such as a contact (vCard) or event (iCalendar). But, for anything bigger than that, NFC will serve more as a convenient bootstrap for more conventional communications options:

1. Embedding a URL in a tag, as the previous sample showed, allows an installed application to run or a Web site to be browsed
2. Embedding a Play Store URL in a tag allows for easy access to some specialized app (e.g., menu for a restaurant)
3. A multi-player game might use peer-to-peer NFC to allow local participants to rapidly connect into the same shared game area, where the game is played over the Internet or Bluetooth
4. And so on.

Mobile Devices are Mobile

Reading and writing NFC tags is a relatively slow process, mostly due to low bandwidth. It may take a second or two to actually complete the operation.

Users, however, are not known for their patience.

If a user moves their device out of range of the tag while Android is attempting to read it, Android simply will skip the dispatch. If, however, the tag leaves the signal area of the device while you are writing to it, you will get an `IOException`. At this point, the state of the tag is unknown.

You may wish to incorporate something into your UI to let the user know that you are working with the tag, encouraging them to leave the phone in place until you are done.

Enabled and Disabled

There are two separate system settings that control NFC behavior:

- The user could have NFC disabled outright, which you would detect by calling `isEnabled()` on your `NfcAdapter`
- The user could have NFC enabled but have Android Beam disabled, which you would detect by calling `isNdefPushEnabled()` on your `NfcAdapter`

As with most enabled/disabled settings, you cannot change these values yourself. On newer Android SDK versions, though, you can try to bring up the relevant Settings screens for the user to enable these features, by using the following activity action strings from the `android.provider.Settings` class:

- `ACTION_NFC_SETTINGS` for the main NFC settings screen (added in API Level 16)
- `ACTION_NFCSHARING_SETTINGS` for the Android Beam settings screen (added in API Level 14)

Android Beam

Android Beam is Google's moniker for peer-to-peer NFC messaging, with an emphasis — obviously — on Android apps. Rather than you tapping your NFC-capable Android device on a smart tag, you put it back-to-back with another NFC-capable Android device, and romance ensues.

Partially, this is simply one side of the exchange "pushing" an NDEF record, in a fashion that makes the other side of the exchange think that it is picking up a smart tag.

Partially, this is the concept of the "Android Application Record" (AAR), another NDEF record you can place in the NDEF message being pushed. This will identify the app you are trying to push the message to. If nothing on the device can handle the rest of the NDEF message, the AAR will lead Android to start up an app, or even lead the user to the Play Store to go download said app.

As the basis for explaining further how this all works, let's take a look at the NFC/WebBeam sample application. The UI consists of a WebViewFragment, in which we can browse to some Web page. Then, running this app on two NFC-capable devices, one app can "push" the URL of the currently-viewed Web page to the other app, which will respond by displaying that page. In this fashion, we are "sharing" a URL, without one side having to type it in by hand. And, while we are using this to share a URL, you could use Android Beam to share any sort of bootstrapping data, such as the user IDs of each person, for use in connecting to some common game server.

The Fragment

The fragment that implements our UI, BeamFragment, extends from WebViewFragment. In onActivityCreated(), we configure the WebView, load up Google's home page, and indicate that would like to participate in the action bar (via a call to setHasOptionsMenu()):

```
@SuppressLint("SetJavaScriptEnabled")
@Override
public void onActivityCreated(Bundle savedInstanceState) {
  super.onActivityCreated(savedInstanceState);

  getWebView().setWebViewClient(new BeamClient());
  getWebView().getSettings().setJavaScriptEnabled(true);
  loadUrl("http://google.com");
  setHasOptionsMenu(true);
}
```

To keep all links within the WebView, we attached a WebViewClient implementation, named BeamClient, that just loads all requested URLs back into the WebView:

```
class BeamClient extends WebViewClient {
  @Override
```

```
    public boolean shouldOverrideUrlLoading(WebView wv, String url) {
      wv.loadUrl(url);

      return(true);
    }
  }
```

We add one item to the action bar: a toolbar button (`R.id.beam`) that will be used to indicate we wish to beam the URL in our `WebView` to another copy of this application running on another NFC-capable Android device:

```
  @Override
  public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    if (getContract().hasNFC()) {
      inflater.inflate(R.menu.actions, menu);
    }

    super.onCreateOptionsMenu(menu, inflater);
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.beam) {
      getContract().enablePush();

      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

So, when the app is initially launched, it will look something like this:

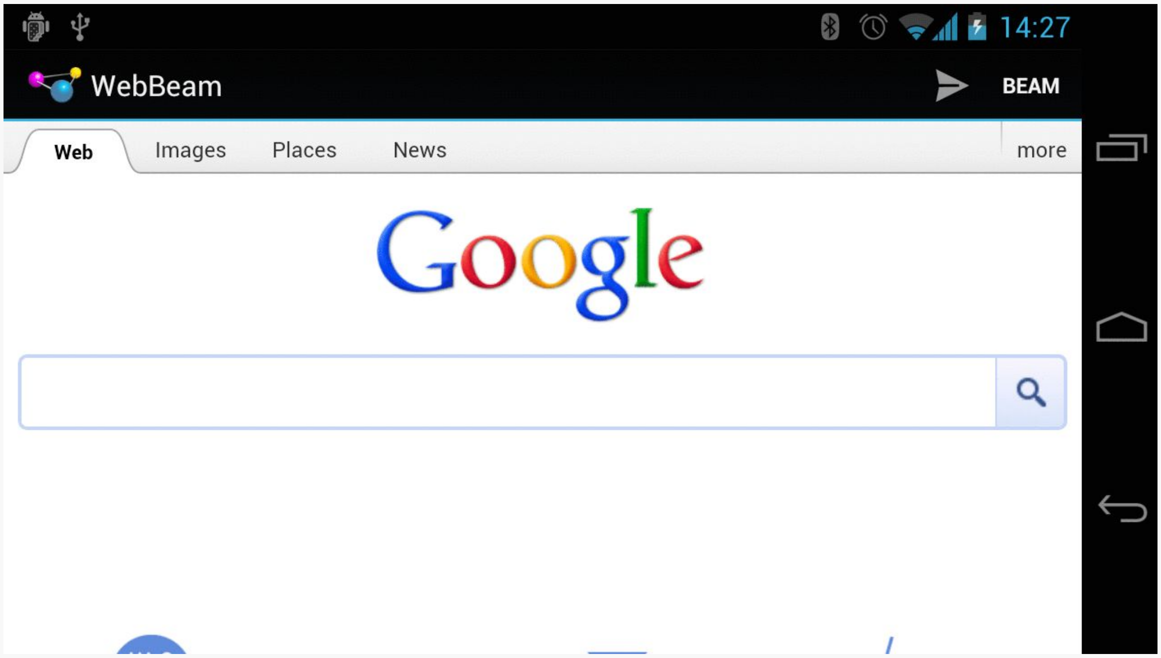

Figure 757: The WebBeam UI

The user can use Google to find a Web page worth beaming.

Requesting the Beam

Our hosting activity, `WebBeamActivity`, gets access to our `NfcAdapter`, as we did in the previous example:

```
    adapter=NfcAdapter.getDefaultAdapter(this);
```

When the user taps on our action bar item, the fragment calls `enablePush()` on the activity. `WebBeamActivity`, in turn, calls `setNdefPushMessageCallback()` on the `NfcAdapter`, supplying two parameters:

1. An implementation of the `NfcAdapter.CreateNdefMessageCallback` interface, used to let us know when another device is in range for us to beam to (in our case, `WebBeamActivity` implements this interface)
2. Our activity that is participating in this push

If something else comes to the foreground, `onStop()` will call a corresponding `disablePush()`, which also calls `setNdefPushMessageCallback()`, specifying a `null` first parameter, to turn off our request to beam:

```
  void enablePush() {
    adapter.setNdefPushMessageCallback(this, this);
  }

  void disablePush() {
    adapter.setNdefPushMessageCallback(null, this);
  }
```

In between the calls to `enablePush()` and `disablePush()`, if another NFC device comes in range that supports the NDEF push protocols, we're beamin'.

Sending the Beam

When our beam-enabled device encounters another beam-capable device, our `NfcAdapter.CreateNdefMessageCallback` is called with `createNdefMessage()`, where we need to prepare the `NfcMessage` to beam to the other party:

```
  @Override
  public NdefMessage createNdefMessage(NfcEvent arg0) {
    NdefRecord uriRecord=
        new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
                       MIME_TYPE.getBytes(Charset.forName("US-ASCII")),
                       new byte[0],
                       beamFragment.getUrl()
                           .getBytes(Charset.forName("US-ASCII")));
    NdefMessage msg=
        new NdefMessage(
                        new NdefRecord[] {
                            uriRecord,

NdefRecord.createApplicationRecord("com.commonsware.android.webbeam") });

    return(msg);
  }
```

We first create a typical `NfcRecord`, in this case of `TNF_MIME_MEDIA`, with a MIME type defined in a static data member and payload consisting of the URL from our `WebView`:

```
  private static final String MIME_TYPE=
      "application/vnd.commonsware.sample.webbeam";
```

You might wonder why we are using `TNF_MIME_MEDIA`, instead of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, since our payload is a URL. The reason is that we need to have a unique MIME type for our message for the whole beam process to work properly, and `TNF_WELL_KNOWN` does not support MIME types. This is also why the MIME type is something distinctive, and not just `text/plain` — it has to be something only we will pick up.

Our NfcMessage then consists of *two* NfcRecord objects: the one we just created, and one created via the static createApplicationRecord() method on NfcRecord. This helper method creates an AAR record, identifying our application by its Android package name. This record must go last – Android will try to find an app to work with based on the other records first, before “failing over” to use the AAR.

Receiving the Beam

To receive our beam, our WebBeamActivity must be configured in the manifest to respond to NDEF_DISCOVERED actions with our unique MIME type:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.webbeam"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="14"/>

  <uses-permission android:name="android.permission.INTERNET"/>
  <uses-permission android:name="android.permission.NFC"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
      android:name=".WebBeamActivity"
      android:label="@string/app_name"
      android:launchMode="singleTask"
      android:screenOrientation="landscape">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
      <intent-filter>
        <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

        <category android:name="android.intent.category.DEFAULT"/>

        <data android:mimeType="application/vnd.commonsware.sample.webbeam"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

You will also notice that we set android:launchMode="singleTask" on this activity. That is so we will only have one instance of this activity, regardless of whether it is in the foreground or not. Otherwise, if we already have an instance of this activity, and we receive a beam, Android will create a *second* instance of this activity — when the user later presses BACK, they return to our first instance, and wonder why our app is broken.

If we receive the beam, we will get the `Intent` for the `NDEF_DISCOVERED` action *either* in `onCreate()` (if we were not already running) or `onNewIntent()` (if we were). In either case, we want to handle it the same way: pass the URL from the first record's payload to our `BeamFragment`. However, we cannot do that from `onCreate()` — the fragment will not have created the `WebView` yet. So, we use a trick: calling `post()` with a `Runnable` puts that `Runnable` on the *end* of the work queue for the main application thread. We can delay our processing of the `Intent` by this mechanism, so we can safely assume the `WebView` exists.

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  beamFragment=
      (BeamFragment)getFragmentManager().findFragmentById(android.R.id.content);

  if (beamFragment == null) {
    beamFragment=new BeamFragment();

    getFragmentManager().beginTransaction()
                               .add(android.R.id.content, beamFragment)
                               .commit();
  }

  adapter=NfcAdapter.getDefaultAdapter(this);

  findViewById(android.R.id.content).post(new Runnable() {
    public void run() {
      handleIntent(getIntent());
    }
  });
}

@Override
public void onNewIntent(Intent i) {
  handleIntent(i);
}
```

```
private void handleIntent(Intent i) {
  if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
    Parcelable[] rawMsgs=
        i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);
    NdefMessage msg=(NdefMessage)rawMsgs[0];
    String url=new String(msg.getRecords()[0].getPayload());

    beamFragment.loadUrl(url);
    }
  }
```

The Scenarios

There are three possible scenarios, when we try beaming from one device to another:

1. The other device has our application installed, and it is running. In that case, our activity is brought to the foreground and the `Intent` is delivered to it, courtesy of our `NDEF_DISCOVERED` `<intent-filter>` with our unique MIME type.
2. The other device has our application installed, but it is not running. Android's `Intent` system handles this in the same general fashion as the first scenario, though it starts up a process for us and creates our activity instance anew in this case.
3. The other device does not have our application installed. Since nothing (hopefully) claims to support our unique MIME type, the AAR takes effect, and the user is led to the Play Store to go download our app (or, in this case, display an error message, as `WebBeam` is not in the Play Store).

Beaming Files

Android 4.1 (a.k.a., Jelly Bean) added in a far simpler facility for an app to beam a file to another device using the Android Beam system. You can use `setBeamPushUris()` or `setBeamPushUrisCallback()` on an `NfcAdapter` to hand Android one or more `Uri` objects representing files to be transferred. While the initial connection will be made via NFC and Android Beam, the actual data transfer will be via Bluetooth or WiFi, much more suitable than NFC for bulk data.

The difference between the two approaches is mostly when you provide the array of `Uri` objects. With `setBeamPushUris()`, you initiate the beam operation and supply the `Uri` values immediately. With `setBeamPushUrisCallback()`, you initiate the beam but do not supply the `Uri` values until the beam connection is established with the peer app.

The `NFC/FileBeam` sample application shows file-based beaming in action.

In our activity (`MainActivity`), in `onCreate()`, we check to make sure that Android Beam is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`. If it is, then we use ACTION_GET_CONTENT to retrieve some file from the user (MIME type wildcard of */*):

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  adapter=NfcAdapter.getDefaultAdapter(this);

  if (!adapter.isNdefPushEnabled()) {
    Toast.makeText(this, R.string.sorry, Toast.LENGTH_LONG).show();
    finish();
  }
  else {
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);

    i.setType("*/*");
    startActivityForResult(i, 0);
  }
}
```

In onActivityResult(), if we actually got a file (e.g., the result is ACTION_OK), we turn around and call setBeamPushUris() to pass that file to some peer device. We also set up a Button as our UI — clicking the Button will finish() the activity:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
  if (requestCode==0 && resultCode==RESULT_OK) {
    adapter.setBeamPushUris(new Uri[] {data.getData()}, this);

    Button btn=new Button(this);

    btn.setText(R.string.over);
    btn.setOnClickListener(this);
    setContentView(btn);
  }
}
```

That is all there is to it. If you run this app and pick a file, then hold the device up to another Android 4.1+ device, you will be prompted to “Touch to Beam” — doing so will kick off the transfer. Once the transfer is shown on the receiving device, you can pull the devices apart a bit, as the transfer will be proceeding over Bluetooth or WiFi. However, while Bluetooth ranges are much longer than NFC, you still need to keep the devices within a handful of meters of one another.

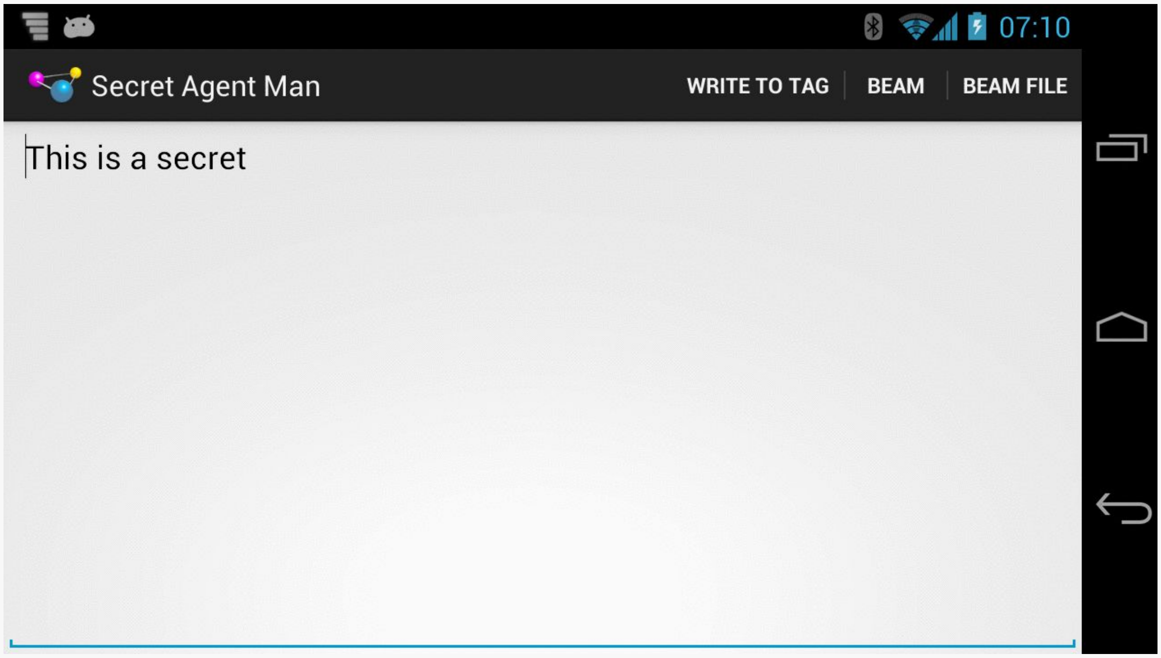
Note that the receiving device is not running our app. The OS handles the receipt of the transferred file, not our code. Similarly, the OS on the sending device is really the one responsible for the file transfer, so our app does not need the INTERNET or BLUETOOTH permissions. The downside is that we have no control over anything on the receiving side — the file is stored wherever the OS elects to put it, and the

Notification it displays when complete will simply launch ACTION_VIEW on the pushed file.

Another Sample: SecretAgentMan

To provide another take on using these features of NfcAdapter, let's examine the NFC/SecretAgentMan sample application, originally written for a presentation at the 2012 droidcon UK conference. This combines writing to tags, directly beaming text to another device, and using Uri-based beaming, all in one app.

The UI of the app is a large EditText widget with an action bar:



This is a secret

Figure 758: The SecretAgentMan UI

There are three action bar items, one each for the three operations: writing to a tag, directly beaming to another device, and beaming a file (represented via a Uri).

Configuration and Initialization

Our app is comprised of a single activity, named MainActivity. As part of our manifest setup, we request the NFC permission. And, since the app needs NFC to be useful, we also have a <uses-feature> element, stipulating that the device needs to have NFC, otherwise the app should not be shown in the Play Store:

```
<uses-permission android:name="android.permission.NFC"/>

<uses-feature
  android:name="android.hardware.nfc"
  android:required="true"/>
```

In onCreate() of MainActivity, we can then safely get access to an NfcAdapter, since the NFC hardware should exist and we have rights to use NFC:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.activity_main);

  nfc=NfcAdapter.getDefaultAdapter(this);
  secretMessage=(EditText)findViewById(R.id.secretMessage);

  nfc.setOnNdefPushCompleteCallback(this, this);

  if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(getIntent().getAction())) {
    readFromTag(getIntent());
  }
}
```

We also get our hands on the EditText widget, storing a reference to it in a data member named secretMessage. We will cover the rest of the initialization work in onCreate() later in this section, as we cover the code that needs that initialization.

Writing to the Tag

If the user chooses the “Write to Tag” action bar item, we call a setUpWriteMode() method from onOptionsItemSelected() of MainActivity. We maintain an inWriteMode boolean data member to track whether or not we are already trying to write to an NFC tag. If inWriteMode is false, we go ahead and take control over the NFC hardware to attempt to write to the next tag we see:

```
void setUpWriteMode() {
  if (!inWriteMode) {
    IntentFilter discovery=
        new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
    IntentFilter[] tagFilters=new IntentFilter[] { discovery };
    Intent i=
        new Intent(this, getClass()).addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP
            | Intent.FLAG_ACTIVITY_CLEAR_TOP);
    PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

    inWriteMode=true;
```

```
      nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
  }
```

To do that, we:

- Create an `IntentFilter` for `ACTION_TAG_DISCOVERED`
- Create a `PendingIntent` for an `Intent` pointing back to this same activity instance (using `getClass()` to identify the instance, plus `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to route control back to our running instance)
- Call `enableForegroundDispatch()` on our `NfcAdapter`, to route newly-discovered tags to us, with the `IntentFilter` identifying the tag-related events we are interested in, and the `PendingIntent` identifying what to do when such a tag is encountered

Once our activity is finishing (e.g., the user presses BACK), we need to clean up our write-to-tag logic. This is kicked off in `onPause()` of `MainActivity`:

```
  @Override
  public void onPause() {
    if (isFinishing()) {
      cleanUpWritingToTag();
    }

    super.onPause();
```

All we do in `cleanUpWritingToTag()` is discontinue our foreground control over the NFC hardware:

```
  void cleanUpWritingToTag() {
    nfc.disableForegroundDispatch(this);
    inWriteMode=false;
  }
```

If, before that occurs, the device is tapped on a tag, our activity should regain control in `onNewIntent()` as a result of our `PendingIntent` having been executed:

```
  @Override
  protected void onNewIntent(Intent i) {
    if (inWriteMode
        && NfcAdapter.ACTION_TAG_DISCOVERED.equals(i.getAction())) {
      writeToTag(i);
    }
    else if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
      readFromTag(i);
    }
  }
```

If we are in write mode, and if the Intent that was just used with startActivity() was ACTION_TAG_DISCOVERED, we call our writeToTag() method to actually start writing information to the tag:

```
void writeToTag(Intent i) {
  Tag tag=i.getParcelableExtra(NfcAdapter.EXTRA_TAG);
  NdefMessage msg=
      new NdefMessage(new NdefRecord[] { buildNdefRecord() });

  new WriteTagTask(this, msg, tag).execute();
}
```

To write to the tag, we get our Tag out of its Intent extra (keyed by EXTRA_TAG). Then, we build an NfcMessage to write to the tag, getting its NfcRecord from buildNdefRecord():

```
NdefRecord buildNdefRecord() {
  return(new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
                        MIME_TYPE.getBytes(), new byte[] {},
                        secretMessage.getText().toString().getBytes()));
}
```

Our NDEF record will be of a specific MIME type, represented by a static data member named MIME_TYPE:

```
private static final String MIME_TYPE="vnd.secret/agent.man";
```

The payload of the NDEF record is our “secret message” from the secretMessage EditText widget.

The writeToTag() method then kicks off the same WriteTagTask that we used earlier in this chapter:

```
package com.commonsware.android.jimmyb;

import android.nfc.NdefMessage;
import android.nfc.Tag;
import android.nfc.tech.Ndef;
import android.nfc.tech.NdefFormatable;
import android.os.AsyncTask;
import android.util.Log;
import android.widget.Toast;

class WriteTagTask extends AsyncTask<Void, Void, Void> {
  MainActivity host=null;
  NdefMessage msg=null;
  Tag tag=null;
  String text=null;

  WriteTagTask(MainActivity host, NdefMessage msg, Tag tag) {
    this.host=host;
    this.msg=msg;
    this.tag=tag;
  }

  @Override
  protected Void doInBackground(Void... arg0) {
    int size=msg.toByteArray().length;

    try {
      Ndef ndef=Ndef.get(tag);

      if (ndef == null) {
        NdefFormatable formatable=NdefFormatable.get(tag);

        if (formatable != null) {
          try {
            formatable.connect();

            try {
              formatable.format(msg);
            }
            catch (Exception e) {
              text=host.getString(R.string.tag_refused_to_format);
            }
          }
          catch (Exception e) {
            text=host.getString(R.string.tag_refused_to_connect);
          }
          finally {
            formatable.close();
          }
        }
        else {
          text=host.getString(R.string.tag_does_not_support_ndef);
        }
      }
      else {
        ndef.connect();

        try {
          if (!ndef.isWritable()) {
            text=host.getString(R.string.tag_is_read_only);
          }
          else if (ndef.getMaxSize() < size) {
            text=host.getString(R.string.message_is_too_big_for_tag);
          }
          else {
            ndef.writeNdefMessage(msg);
            text=host.getString(R.string.success);
          }
        }
        catch (Exception e) {
          text=host.getString(R.string.tag_refused_to_connect);
        }
        finally {
          ndef.close();
        }
      }
    }
```

```
    catch (Exception e) {
      Log.e("URLTagger", "Exception when writing tag", e);
      text=host.getString(R.string.general_exception) + e.getMessage();
    }

    return(null);
  }

  @Override
  protected void onPostExecute(Void unused) {
    host.cleanUpWritingToTag();

    if (text != null) {
      Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }
  }
}
```

The net result is that if the user taps the “Write to Tag” action bar item, then taps and holds the device to a tag, we will write a message to the tag and display a `Toast` when we are done.

And, yes, this is a surprising amount of code for what really should be a simple operation…

Reading from the Tag

We can set up `MainActivity` to respond to tags similar to the one we wrote — ones that have the desired MIME Type — via an `android.nfc.action.NDEF_DISCOVERED` `<intent-filter>`:

```
      <intent-filter android:label="@string/app_name">
        <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

        <data android:mimeType="vnd.secret/agent.man"/>

        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
```

In both `onCreate()` and `onNewIntent()`, if the `Intent` that started our activity is an `NDEF_DISCOVERED` `Intent`, we route control to a `readFromTag()` method:

```
  void readFromTag(Intent i) {
    Parcelable[] msgs=
        (Parcelable[])i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);

    if (msgs.length > 0) {
      NdefMessage msg=(NdefMessage)msgs[0];

      if (msg.getRecords().length > 0) {
        NdefRecord rec=msg.getRecords()[0];
        secretMessage.setText(new String(rec.getPayload(), US_ASCII));
      }
    }
  }
```

In principle, there could be several NDEF messages on the tag, but we only pay attention to the first element, if any, of the EXTRA_NDEF_MESSAGES array of Parcelable objects on the Intent. Similarly, in principle, there could be several NDEF records in the first message, but we only examine the first element out of the array of NdefRecord objects contained in the NdefMessage. From there, we extract our secret message and display it by means of putting it in the EditText widget.

Beaming the Text

This sample only supports beaming — whether of NDEF messages directly or of a file — if we are on API Level 16 or higher. Hence, in onCreateOptionsMenu(), we check our version and only enable our default-disabled beam action bar items if:

- We are on API Level 16 or higher, and
- NDEF push mode is enabled, via a call to isNdefPushEnabled() on our NfcAdapter:

```
  @TargetApi(16)
  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_main, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN) {
      menu.findItem(R.id.simple_beam)
          .setEnabled(nfc.isNdefPushEnabled());
      menu.findItem(R.id.file_beam).setEnabled(nfc.isNdefPushEnabled());
    }

    return(super.onCreateOptionsMenu(menu));
  }
```

If the user taps on the "Beam" action bar item, we call an enablePush() method from onOptionsItemSelected(), which simply enables push mode:

```
  void enablePush() {
    nfc.setNdefPushMessageCallback(this, this);
  }
```

We arrange for the activity itself to be the CreateNdefMessageCallback necessary for push mode. That requires us to implement createNdefMessage(), which will be called if we are in push mode and a push-compliant device comes within range:

```
  @Override
  public NdefMessage createNdefMessage(NfcEvent event) {
    return(new NdefMessage(
                               new NdefRecord[] {
                                   buildNdefRecord(),

NdefRecord.createApplicationRecord("com.commonsware.android.jimmyb") }));
  }
```

Here, we create an `NdefMessage` similar to the one we wrote to the tag earlier in this sample. However, we also attach an Android Application Record (AAR), by means of the static `createApplicationRecord()` method on `NdefRecord`. This, in theory, will help route the push to our app on the other device, including downloading it from the Play Store if needed (and, of course, if it actually existed on the Play Store, which it does not).

Back up in `onCreate()`, we call `setOnNdefPushCompleteCallback()`, to be notified of when a push operation is completed. Once again, we set up `MainActivity` to be the callback, this time by implementing the `OnNdefPushCompleteCallback` interface. That, in turn, requires us to implement `onNdefPushComplete()`, where we disable push mode via a call to `setNdefPushMessageCallback()` with a `null` listener:

```
  @Override
  public void onNdefPushComplete(NfcEvent event) {
    nfc.setNdefPushMessageCallback(null, this);
  }
```

To receive the beam, we only need our existing logic to read from the tag, as on the receiving side, a push is indistinguishable from reading a tag, and we are using the same MIME type for both the message written to the tag and the message we are pushing.

Beaming the File

If the user taps the “Beam File” action bar item, we find some file to beam, by means of an `ACTION_GET_CONTENT` request and `startActivityForResult()`:

```
      case R.id.file_beam:
        Intent i=new Intent(Intent.ACTION_GET_CONTENT);

        i.setType("*/*");
        startActivityForResult(i, 0);
        return(true);
```

In `onActivityResult()`, if the request succeeded, we use `setBeamPushUris()` to tell Android to beam the selected file to another device. Nothing more is needed on our side, and the receipt of the file is handled entirely by the OS, not our application code, so there is nothing to be written for that.

This code assumes the NFC adapter is enabled. We could check that via a call to `isEnabled()` on our `NfcAdapter`. If it is not enabled, we could — on user request — bring up the Settings activity for configuring NFC, via `startActivity(new Intent(Settings.ACTION_NFC_SETTINGS))`. However, oddly, this `Intent` action is only available on Android 4.1 (API Level 16) and higher, despite NFC having been available for some time previously.

This code ignores the possibility of doing the simple beam (not the file-based beam) on Android 4.0.x devices. That is because the `isNdefPushEnabled()` method was not added until Android 4.1, and therefore we do not know whether or not we can actually do a beam.

If `isNdefPushEnabled()` returns `false`, we simply disable some action bar items. Alternatively, we could use `startActivity(new Intent(Settings.ACTION_NFCSHARING_SETTINGS))`, on API Level 14 and higher, to bring up the beam screen in Settings, to allow the user to toggle beam support on.

Additional Resources

To help make sense of the tags that you are trying to use with your app, you may wish to grab the NFC TagInfo application off of the Google Play Store. This application simply scans a tag and allows you to peruse all the details of that tag, including the supported technologies (e.g., does it support NDEF? is it `NdefFormatable`?), the NDEF records, and so on.

To learn more about NFC on Android — beyond this chapter or the Android developer documentation – this Google I|O 2011 presentation is recommended.

Device Administration

Balding authors of Android books often point out that enterprises and malware authors have the same interests: they want to take control of a device away from the person that is holding it and give that control to some other party. Android, being a consumer operating system, is designed to defend against malware, and so enterprises can run into issues.

However, Android does have a growing area of device administration APIs, that allow carefully-constructed and installed applications to exert some degree of control over the device, how it is configured, and how it operates.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on broadcast `Intents`.

Objectives and Scope

One might read the phrase "device administration" and assume that somebody, using these APIs, could do anything they want on the device.

That's not quite what "device administration" means in this case.

Rather, the device administration APIs serve three main roles:

1. They allow an application to dictate how well a device is secured, from the password required in the OS lock screen to whether the device should have full-disk encryption

2. They allow an application to find out when security issues might arise, notably failed password attempts
3. They allow an application to lock the device, disable its cameras, or even perform a "wipe" (i.e., factory reset)

The user, however, has to agree to enable a device administration app. It does not magically get all these powers simply by being installed. What the user gets from agreeing to this is access to something that otherwise would be denied (e.g., to use Enterprise App X, you must agree to allow it to be a device administrator).

Defining and Registering an Admin Component

There are four pieces for defining and registering a device administration app: creating the metadata, adding the `<receiver>` to the manifest, implementing that `BroadcastReceiver`, and telling Android to ask the user to agree to allow the app to a device administrator.

Here, we will take a peek at the `DeviceAdmin/LockMeNow` sample application.

The Feature

Apps implementing device administrators should add a `<uses-feature>` element with a name of `android.software.device_admin`, indicating whether or not they require this device feature to exist. This can be used by the Play Store to filter your app from being available on devices that, for one reason or another, do not offer this capability.

The Metadata

As with app widgets and other Android facilities, you will need to define a metadata file as an XML resource, describing in greater detail what your device administration app wishes to do. This information will determine what you will be allowed to do once the user approves your app, and what you list here will be displayed to the user when you request such approval.

The `DeviceAdminInfo` class has a series of static data members (e.g., `USES_ENCRYPTED_STORAGE`) that represent specific policies that your device administrator app could use. The documentation for each of those static data members lists the corresponding element that goes in this XML metadata file (e.g., `<encrypted-storage>`). These elements are wrapped in a `<uses-policies>` element, which itself is wrapped in a `<device-admin>` element. The range of possible policies is shown in the following sample XML metadata file:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-camera />
    <encrypted-storage />
    <expire-password />
    <force-lock />
    <limit-password />
    <reset-password />
    <watch-login />
    <wipe-data />
  </uses-policies>
</device-admin>
```

Here, we:

- Intend to disable the cameras, if needed
- Will ask the user to encrypt their device storage, if it has not been done already
- Will set an expiration time for the user's password, after which they will need to set up a new one
- Intend to lock the device, if needed
- Will set criteria for password quality, such as minimum length
- Intend to forcibly reset the user's password, if needed
- Intend to monitor for failed and successful login attempts
- Intend to wipe the device, if needed

Choose which of those policies you need — the fewer you request, the more likely it is the user will not wonder about your intentions. In your project's `res/xml/` directory, create a file that looks like the above with the policies you wish. You can name this file whatever you want (e.g., `device_admin.xml`), within standard Android resource naming rules.

The Manifest

In the manifest, you will need to declare a `<receiver>` element for the `DeviceAdminReceiver` component that you will write. This component not only is the embodiment of the device admin capabilities of your app, but it will be the one notified of failed logins and other events.

For example, here is the `<receiver>` element from the `LockMeNow` sample app:

```
    <receiver
      android:name="AdminReceiver"
      android:permission="android.permission.BIND_DEVICE_ADMIN">
      <meta-data
        android:name="android.app.device_admin"
        android:resource="@xml/device_admin"/>

      <intent-filter>
        <action android:name="android.app.action.DEVICE_ADMIN_ENABLED"/>
      </intent-filter>
    </receiver>
```

There are three things distinctive about this element compared to your usual `<receiver>` element:

1. It requires that whoever sends broadcasts to it hold the `BIND_DEVICE_ADMIN` permission. Since that permission is protected and can only be held by apps signed with the firmware's signing key, you can be reasonably assured that any events sent to you are real.
2. It has the `<meta-data>` child element pointing to our device administration metadata from the previous section.
3. It registers for `android.app.action.DEVICE_ADMIN_ENABLED` broadcasts via its `<intent-filter>` — this is the broadcast that will be used to notify you about failed logins or other events.

The Receiver

The `DeviceAdminReceiver` itself needs to exist as a component in your app, registered in the manifest as shown above. At minimum, though, it does not need to override any methods, such as the implementation from the `LockMeNow` sample app:

```
package com.commonsware.android.lockme;

import android.app.admin.DeviceAdminReceiver;

public class AdminReceiver extends DeviceAdminReceiver {
}
```

By requesting the `DEVICE_ADMIN_ENABLED` broadcasts, we could get control when we are enabled by overriding an `onEnabled()` method. We could also register for other broadcasts (e.g., `ACTION_PASSWORD_FAILED`) and implement the corresponding callback method on our `DeviceAdminReceiver` (e.g., `onPasswordFailed()`).

The Demand for Device Domination

Simply having this component in our manifest, though, is insufficient. The user must proactively agree to allow us to administer their device. And, since this is potentially very dangerous, a simple permission was deemed to also be insufficient. Instead, we need to ask the user to approve us as a device administrator from our app, typically from an activity.

In the case of LockMeNow, the UI is just a really big button, tied to a lockMeNow() method on our LockMeNowActivity:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <Button
    android:id="@+id/Button1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:onClick="lockMeNow"
    android:text="@string/lock_me"
    android:textColor="#FFFF0000"
    android:textSize="40sp"
    android:textStyle="bold"/>

</LinearLayout>
```

In onCreate() of the activity, in addition to loading up the UI via setContentView(), we create a ComponentName object identifying our AdminReceiver component. We also request access to the DevicePolicyManager, via a call to getSystemService(). DevicePolicyManager is our gateway for making direct requests for device administration operations, such as locking the device:

```
package com.commonsware.android.lockme;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class LockMeNowActivity extends Activity {
  private DevicePolicyManager mgr=null;
  private ComponentName cn=null;

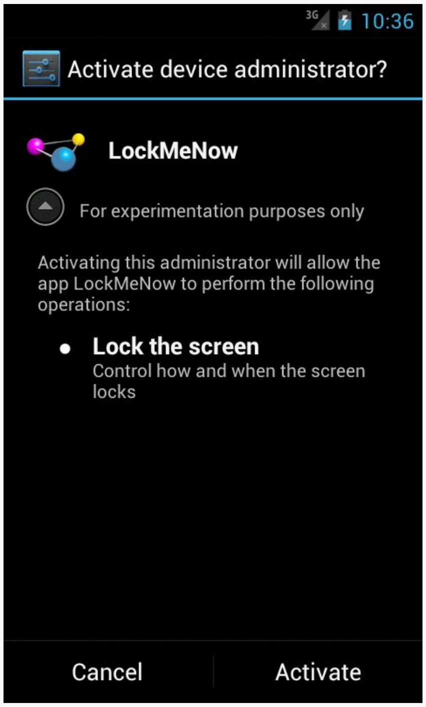
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
    cn=new ComponentName(this, AdminReceiver.class);
    mgr=(DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);
  }

  public void lockMeNow(View v) {
    if (mgr.isAdminActive(cn)) {
      mgr.lockNow();
    }
    else {
      Intent intent=
          new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
      intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
      intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
                      getString(R.string.device_admin_explanation));
      startActivity(intent);
    }
  }
}
```

In lockMeNow(), we ask the DevicePolicyManager if we have already been registered as a device administrator, by calling isAdminActive(), supplying the ComponentName of our DeviceAdminReceiver that should be so registered. If that returns false, then the user has not approved us as a device administrator yet, so we need to ask them to do so. To do that, you:

- Create an Intent for the DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN action
- Add the ComponentName of our DeviceAdminReceiver as an extra, keyed as DevicePolicyManager.EXTRA_DEVICE_ADMIN
- Add another extra, DevicePolicyManager.EXTRA_ADD_EXPLANATION, which is some text to show the user as part of the authorization screen, to explain why we need to be a device admin
- Start up an activity using that Intent, via startActivity()

If you run this on a device, then tap the button, the first time you do so the user will be prompted to agree to making the app be a device administrator:



10:36

Activate device administrator?

LockMeNow

For experimentation purposes only

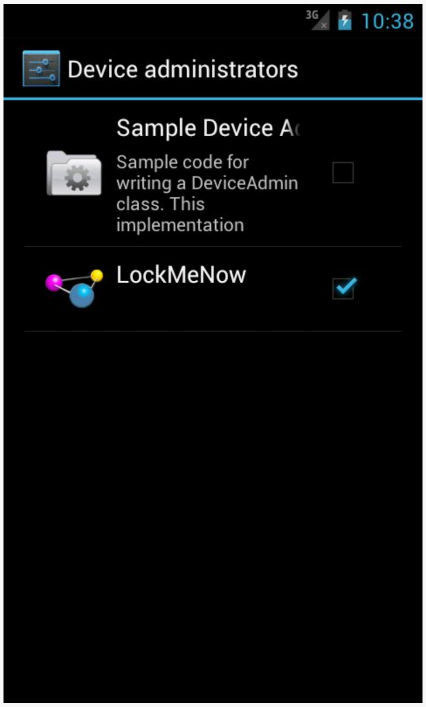
Activating this administrator will allow the app LockMeNow to perform the following operations:

- **Lock the screen**
  Control how and when the screen locks

Figure 759: The Activate Device Administrator Screen

The "For experimentation purposes only" is the value of our `DevicePolicyManager.EXTRA_ADD_EXPLANATION` extra, loaded from a string resource.

If the user clicks "Activate", and you overrode `onEnabled()` in your `DeviceAdminReceiver`, that will be called to let you know that you have been approved and can perform device administration functions. Your component will also appear in the list of device administrators in the Settings app:



10:38
Device administrators
Sample Device A
Sample code for writing a DeviceAdmin class. This implementation
LockMeNow

Figure 760: The Device Administrator List

The user can, at any time, uncheck you in this list and disable you. You can find out about this by having your `DeviceAdminReceiver` listen for `ACTION_DEVICE_ADMIN_DISABLE_REQUESTED` broadcasts and overriding the `onDisableRequested()` method, where you can return the text of a message to be displayed to the user confirming that they do indeed wish to go ahead with the disable operation. To find out if they go through with it, your `DeviceAdminReceiver` can listen for `ACTION_DEVICE_ADMIN_DISABLED` broadcasts and override `onDisabled()`.

Going Into Lockdown

Given that the user has approved your device administration request, and given that you requested `<force-lock>` in your metadata, you can call `lockNow()` on a `DevicePolicyManager`. That will immediately lock the device and (generally) turn off the screen. It is as if the user pressed the POWER button on the device.

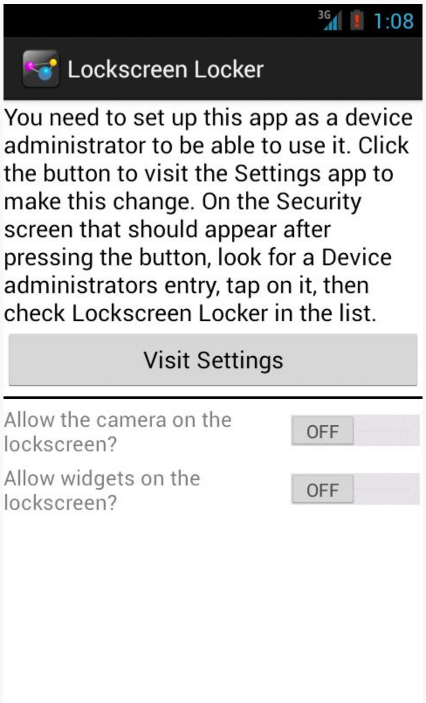
The `LockItNow` sample app does this if, when the user clicks the really big button, it detects that it is already a device administrator. If you test this on a device, it will behave as though the user pressed POWER; on an emulator, you will need to press the HOME button to "power on" the screen and be able to re-enter your emulator.

You can also call:

- `setCameraDisabled()` to disable all cameras, if you requested `<disable-camera>` in the metadata. Note that this disables all cameras; there is no provision at this time to disable individual cameras separately.
- `wipeData()`, which performs what amounts to a factory reset — it leaves external storage alone but wipes the contents of internal storage as part of a reboot. This requires the `<wipe-data>` policy in the metadata.
- `setKeyguardDisabledFeatures()`, to control whether or not the lockscreen allows direct access to the camera and/or app widgets (lockscreen app widgets are described in the chapter on app widgets)

For example, the latter feature, while available in the Android SDK, is not built into the Settings app of Android 4.2. As a result, users need a third-party app to toggle on or off lockscreen access to the camera and app widgets. One such third-party app is LockscreenLocker, released as open source by the author of this book.

Basically, the app presents you with two `Switch` widgets to control the camera and app widgets on the lock screen. First, though, it shows you a message and a `Button`, if the app is not set up as a device administrator:



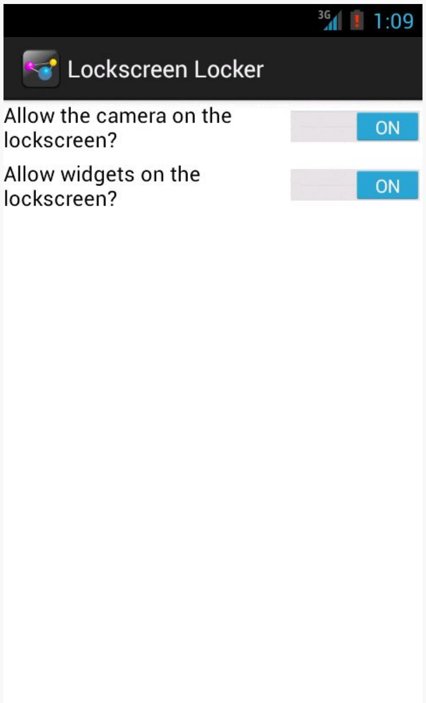
You need to set up this app as a device administrator to be able to use it. Click the button to visit the Settings app to make this change. On the Security screen that should appear after pressing the button, look for a Device administrators entry, tap on it, then check Lockscreen Locker in the list.

Allow the camera on the lockscreen? OFF

Allow widgets on the lockscreen? OFF

Figure 761: LockscreenLocker, On Initial Run

Once that is complete, the `Switch` widgets become enabled and usable:



Lockscreen Locker

Allow the camera on the lockscreen? ON

Allow widgets on the lockscreen? ON

Figure 762: LockscreenLocker, After Being Made a Device Admin

The device admin metadata for this app specifies that we want to control keyguard features:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">

  <uses-policies>
    <disable-keyguard-features/>
  </uses-policies>

</device-admin>
```

Note that, at the time of this writing, there is a flaw in the Android developer documentation — the correct element to have in the metadata is `<disable-keyguard-features/>`, not `<disable-keyguard-widgets>`. You can track this issue to see when this documentation bug has been repaired.

Our device admin component, `LockscreenAdminReceiver`, is empty, because there are no events that we are trying to listen to:

```
public class LockscreenAdminReceiver extends DeviceAdminReceiver {
}
```

However, we still need the LockscreenAdminReceiver, as it is the component that is tied to our device admin metadata and indicates to the system that we should be an option in Settings for available device administrators.

Our activity layout contains all the requisite widgets: a TextView for the message, a Button to jump to the Settings app, a View to serve as a divider, and a pair of Switch widgets to manage the lockscreen settings:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <TextView
    android:id="@+id/setupMessage"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/setup_message"
    android:textAppearance="?android:attr/textAppearanceMedium"
    android:visibility="gone"/>

  <Button
    android:id="@+id/setup"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showSettings"
    android:text="@string/visit_settings"
    android:visibility="gone"/>

  <View
    android:id="@+id/divider"
    android:layout_width="match_parent"
    android:layout_height="2dip"
    android:layout_marginBottom="4dip"
    android:layout_marginTop="4dip"
    android:background="#FF000000"
    android:visibility="gone"/>

  <Switch
    android:id="@+id/camera"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/allow_camera"/>

  <Switch
    android:id="@+id/widgets"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="4dip"
    android:text="@string/allow_widgets"/>

</LinearLayout>
```

In onCreate() of our activity (MainActivity), we request a DevicePolicyManager, set up a ComponentName identifying our DeviceAdminReceiver implementation (LockscreenAdminReceiver), and hook up the activity to know about changes in the state of the Switch widgets:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.activity_main);

  mgr=(DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);
  cn=new ComponentName(this, LockscreenAdminReceiver.class);

  camera=(CompoundButton)findViewById(R.id.camera);
  camera.setOnCheckedChangeListener(this);

  widgets=(CompoundButton)findViewById(R.id.widgets);
  widgets.setOnCheckedChangeListener(this);
}
```

In onResume(), we check to see if our DeviceAdminReceiver is active — in other words, whether the user has set us up as being a device administrator or not:

```
@Override
public void onResume() {
  super.onResume();

  if (mgr.isAdminActive(cn)) {
    toggleWidgets(true);

    int status=mgr.getKeyguardDisabledFeatures(cn);

    camera.setChecked(!((status & DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA)
== DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA));
    widgets.setChecked(!((status & DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL)
== DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL));
  }
  else {
    toggleWidgets(false);
  }
}
```

We toggle the visibility and enabled settings of our widgets based upon whether we are a device administrator or not, in a toggleWidgets() private method:

```
private void toggleWidgets(boolean enable) {
  int visibility=(enable ? View.GONE : View.VISIBLE);

  camera.setEnabled(enable);
  widgets.setEnabled(enable);

  findViewById(R.id.divider).setVisibility(visibility);
  findViewById(R.id.setup).setVisibility(visibility);
```

```
    findViewById(R.id.setupMessage).setVisibility(visibility);
  }
```

onResume() also sets the state of our Switch widgets based upon the current state of the keyguard features, by calling getKeyguardDisabledFeatures() on the DevicePolicyManager. This returns a bit set of which features are disabled, with DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA and/or DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL possibly being set.

At the outset, after being installed, we will not be a device administrator, so the Switch widgets will be disabled and the Button will be visible. We simply send the user to the security screen in the Settings app if they click that button:

```
  public void showSettings(View v) {
    startActivity(new Intent(Settings.ACTION_SECURITY_SETTINGS));
  }
```

When the user toggles a Switch, our activity will be called with onCheckedChanged(). There, we need to call setKeyguardDisabledFeatures() with a new bit set, toggling on or off a bit based on the user's chosen values in the UI:

```
  @Override
  public void onCheckedChanged(CompoundButton buttonView,
                               boolean isChecked) {
    int status=mgr.getKeyguardDisabledFeatures(cn);

    if (buttonView == camera) {
      if (isChecked) {
        mgr.setKeyguardDisabledFeatures(cn, status
            & ~DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
      }
      else {
        mgr.setKeyguardDisabledFeatures(cn, status
            | DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
      }
    }
    else {
      if (isChecked) {
        mgr.setKeyguardDisabledFeatures(cn, status
            & ~DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
      }
      else {
        mgr.setKeyguardDisabledFeatures(cn, status
            | DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
      }
    }
  }
```

Note that we have the Switch widgets set up for positive statements (e.g., "enable the camera"), while the bit set uses negative statements (e.g., "disable the camera").

That makes toggling the bit set a "bit" more complicated, to ensure that we are applying the user's choices correctly.

Passwords and Device Administration

One popular facet of the device administration APIs is for an app to mandate a certain degree of password quality. The app might then fail to operate if the current password does not meet the requested quality standard.

Mandating Quality of Security

You can call various setters on `DevicePolicyManager` to dictate your minimum requirements for the password that the user uses to get past the lock screen. Examples include:

- `setPasswordMinimumLength()`
- `setPasswordQuality()` (with an integer flag describing the type of "quality" you seek, such as `PASSWORD_QUALITY_NUMERIC` if a PIN is OK, or `PASSWORD_QUALITY_COMPLEX` if you require mixed case and numbers and such)
- `setPasswordMinimumLowerCase()` (indicating how many lowercase letters are required at minimum in the user's password)

All of these require the `<limit-password>` policy be requested in the metadata.

Then, you can call `isActivePasswordSufficient()` to determine if the current password meets your requirements. If it does not, you might elect to disable certain functionality. Or, if you requested the `<reset-password>` policy in the metadata, you can call `resetPassword()` to force the user to come up with a password meeting your requirements.

Similarly, you can also call `getStorageEncryptionStatus()` on `DevicePolicyManager` to find out whether full-disk encryption is active, inactive, or unavailable on this particular device. If it is inactive, and you requested the `<encrypted-storage>` policy in your metadata, you can call `setStorageEncryption()` to demand it, and start the encryption process via starting the `ACTION_START_ENCRYPTION` activity.

Establishing Password Requirements

To see password quality enforcement in action, let us examine the DeviceAdmin/PasswordEnforcer sample application.

The activity (MainActivity) is fairly short, and much of its code is based on the earlier LockMeNow sample:

```
package com.commonsware.android.pwenforce;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.widget.Toast;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    ComponentName cn=new ComponentName(this, AdminReceiver.class);
    DevicePolicyManager mgr=
        (DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);

    if (mgr.isAdminActive(cn)) {
      int msgId;

      if (mgr.isActivePasswordSufficient()) {
        msgId=R.string.compliant;
      }
      else {
        msgId=R.string.not_compliant;
      }

      Toast.makeText(this, msgId, Toast.LENGTH_LONG).show();
    }
    else {
      Intent intent=
          new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
      intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
      intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
                      getString(R.string.device_admin_explanation));
      startActivity(intent);
    }

    finish();
  }
}
```

In onCreate(), after obtaining a DevicePolicyManager, we see if our app has been designated by the user as a device administrator. If not — which will be the case when the app is first installed — we use an ACTION_ADD_DEVICE_ADMIN Intent and startActivity() to steer the user towards making our app be a device administrator.

If the user does make our app be a device administrator, our AdminReceiver will get control in onEnabled(), as we have registered it for DEVICE_ADMIN_ENABLED broadcasts in the manifest. In onEnabled(), we mandate that the password for the device must be alphanumeric, via a call to setPasswordQuality() on the DevicePolicyManager:

```
@Override
public void onEnabled(Context ctxt, Intent intent) {
  ComponentName cn=new ComponentName(ctxt, AdminReceiver.class);
  DevicePolicyManager mgr=
      (DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);

  mgr.setPasswordQuality(cn,
                         DevicePolicyManager.PASSWORD_QUALITY_ALPHANUMERIC);

  onPasswordChanged(ctxt, intent);
}
```

We will see the role of the onPasswordChanged() method, called late in onEnabled(), later in this chapter.

Back in onCreate() of our MainActivity, if we *are* a device administrator, then we know that the setPasswordQuality() call has been made, and so we can check to see if the current password meets our standards via a call to isActivePasswordSufficient() on the DevicePolicyManager. The app displays a Toast showing whether the password is or is not currently “sufficient”.

Password-Related Events

Via appropriate actions in our <intent-filter> for our DeviceAdminReceiver, and associated callback methods, we can find out other things that go on with respect to the password:

- ACTION_PASSWORD_CHANGED informs us when the user has changed her password
- ACTION_PASSWORD_FAILED informs us when somebody tries to enter a password, and the password was incorrect
- ACTION_PASSWORD_SUCCEEDED informs us when the user has successfully entered the password and unlocked the device… after an attempt had previously failed

The PasswordEnforcer sample registers for all of these in the manifest:

```
  <receiver
    android:name="AdminReceiver"
    android:permission="android.permission.BIND_DEVICE_ADMIN">
    <meta-data
      android:name="android.app.device_admin"
      android:resource="@xml/device_admin"/>

    <intent-filter>
      <action android:name="android.app.action.DEVICE_ADMIN_ENABLED"/>
      <action android:name="android.app.action.ACTION_PASSWORD_CHANGED"/>
      <action android:name="android.app.action.ACTION_PASSWORD_FAILED"/>
      <action android:name="android.app.action.ACTION_PASSWORD_SUCCEEDED"/>
    </intent-filter>
  </receiver>
```

The implementations of the corresponding onPasswordChanged(), onPasswordFailed(), and onPasswordSucceeded() methods simply display Toast messages about those events:

```
@Override
public void onPasswordChanged(Context ctxt, Intent intent) {
  DevicePolicyManager mgr=
      (DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);
  int msgId;

  if (mgr.isActivePasswordSufficient()) {
    msgId=R.string.compliant;
  }
  else {
    msgId=R.string.not_compliant;
  }

  Toast.makeText(ctxt, msgId, Toast.LENGTH_LONG).show();
}

@Override
public void onPasswordFailed(Context ctxt, Intent intent) {
  Toast.makeText(ctxt, R.string.password_failed, Toast.LENGTH_LONG)
       .show();
}

@Override
public void onPasswordSucceeded(Context ctxt, Intent intent) {
  Toast.makeText(ctxt, R.string.password_success, Toast.LENGTH_LONG)
       .show();
}
```

However, these will illustrate some quirks in the behavior of the device administration APIs:

- onPasswordSucceeded() is not called on *every* successful password entry, only those that come after a prior onPasswordFailed() call. One imagines that perhaps `onPasswordSucceededAfterItHadFailedBefore()` was deemed to be too wordy.

- `isActivePasswordSufficient()` will return a value based on the *previous* password in `onPasswordChanged()`, not the newly-changed password. Since the system will prevent the user from entering a new password that is insufficient, you should not need to call `isActivePasswordSufficient()` from `onPasswordChanged()`.
- A `Toast` cannot display over the lockscreen, and so the `onPasswordFailed()` `Toast` will never be seen.

Getting Along with Others

Bear in mind that you might not be the only device administrator on any given device. If there are multiple administrators, the most secure requirements are in force. So, for example, if Admin A requests a minimum password length of 7, and Admin B requests a minimum password length of 10, the user will have to supply a password that is at least 10 characters long, to meet both device administrators' requirements.

This also means that certain requests you make may fail. For example, if you decide to say that you do *not* need encryption (`setStorageEncryption()` with a value of `false`), if something *else* needs encryption, the user will still need to encrypt their device.

Basic Use of Sensors

“Sensors” is Android’s overall term for ways that Android can detect elements of the physical world around it, from magnetic flux to the movement of the device. Not all devices will have all possible sensors, and other sensors are likely to be added over time. In this chapter, we will explore the general concept of Android sensors and how to receive data from them.

Note, however, that this chapter will not get into details of detecting movement via the accelerometer, etc.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on threads. Having experience with other system-service-and-listener patterns, such as fetching locations with `LocationManager`, is helpful but not strictly required.

The Sensor Abstraction Model

When fetching locations from `LocationManager`, you do not have dedicated APIs per location-finding technology (e.g., GPS vs. WiFi hotspot proximity vs. cell-tower triangulation vs. …). Instead, you work with a `LocationManager` system service, asking for locations using a single API, where location technologies are identified by name (e.g., `GPS_PROVIDER`).

Similarly, when working with sensors, you do not have dedicated APIs to get sensor readings from each sensor. Instead, you work with a `SensorManager` system service, asking for sensor events using a single API, where sensors are identified by name (e.g., `TYPE_LINEAR_ACCELERATION`).

Note, though, that there are some dedicated methods on `SensorManager` to help you *interpret* some of the sensors, particularly the accelerometer. However, those are merely helper methods; getting at the actual accelerometer data uses the same APIs that you would use to, say, access the barometer for atmospheric pressure.

Considering Rates

Usually, when working with sensors, you want to find out about changes in the sensor reading over a period of time. For example, in a driving game, where the user holds their device like a steering wheel and uses it to “turn” their virtual car, you need to know information about acceleration and positioning so long as game play is going on.

Hence, when you request a feed of sensor readings from `SensorManager`, you will specify a desired rate at which you should receive those readings. You do that by specifying an amount of delay in between readings; Android will drop sensor readings that arrive before the delay period has elapsed.

There are four standard delay periods, defined as constants on the `SensorManager` class:

1. `SENSOR_DELAY_NORMAL`, which is what most apps would use for broad changes, such as detecting a screen rotating from portrait to landscape
2. `SENSOR_DELAY_UI`, for non-game cases where you want to update the UI continuously based upon sensor readings
3. `SENSOR_DELAY_GAME`, which is faster (less delay) than `SENSOR_DELAY_UI`, to try to drive a higher frame rate
4. `SENSOR_DELAY_FASTEST`, which is the “firehose” of sensor readings, without delay

The more sensor readings you get, the faster your code has to be for using those readings, lest you take too long and starve your thread of time to do anything else. This is particularly important given that you receive these sensor events on the main application thread, and therefore the time you spend processing these events is time unavailable for screen updates. Hence, choose the slowest rate that you can that will give you acceptable granularity of output.

Reading Sensors

Sensors are event-driven. You cannot ask Android for the value of a sensor at a point in time. Rather, you register a listener for a sensor, then process the sensor events as they come in. You can unregister the listener when you are done, either because you have the reading that you need, or the user has done something (like move to another activity) that indicates that you no longer need the sensor events.

To demonstrate this, we will examine the Sensor/Monitor sample application, which will list all of the available sensors, plus show the incoming readings from a selected sensor.

Obtaining a SensorManager

The gateway to the sensor roster on the device is the SensorManager system service. You obtain one of these by calling getSystemService() on any Context, asking for the SENSOR_SERVICE, and casting the result to be a SensorManager, as seen in the onCreate() method of our MainActivity:

```
    mgr=(SensorManager)getSystemService(Context.SENSOR_SERVICE);
```

Identifying a Sensor of Interest

There are sensor types, and then there are sensors.

You might think that there would be a one-to-one mapping between these. In truth, there might be more than one sensor for a given type, the way the SensorManager API is set up. Regardless, somewhere along the line, you will need to identify the Sensor that you want to work with.

The most common pattern, if you know the type of sensor that you want, is to call getDefaultSensor() on SensorManager, supplying the type of the sensor (e.g., TYPE_ACCELEROMETER, TYPE_GYROSCOPE), where the type names are constants defined on the Sensor class. If there is more than one possible Sensor for that type, Android will give you the “default” one, which is usually a reasonable choice.

Another approach, and the one used by this sample application, is to call getSensorList() on SensorManager, which returns a List of all Sensor objects available on this device. The sample’s MainActivity has a getSensorList() that returns this list, after a bit of manipulation:

```
@Override
public List<Sensor> getSensorList() {
  List<Sensor> unfiltered=
      new ArrayList<Sensor>(mgr.getSensorList(Sensor.TYPE_ALL));
  List<Sensor> result=new ArrayList<Sensor>();

  for (Sensor s : unfiltered) {
    if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT
        || !isTriggerSensor(s)) {
      result.add(s);
    }
  }

  Collections.sort(result, new Comparator<Sensor>() {
    @Override
    public int compare(final Sensor a, final Sensor b) {
      return(a.toString().compareTo(b.toString()));
    }
  });

  return(result);
}
```

Android 4.4 started introducing some "trigger sensors", ones that are designed to deliver a single reading, then automatically become unregistered. This sample app is designed to display results from more traditional sensors that provide ongoing readings. So, `getSensorList()` calls an `isTriggerSensor()` method on API Level 19+ devices, and throws out sensors that are trigger sensors. The `isTriggerSensor()` method simply checks the sensor type against a list of trigger sensors:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isTriggerSensor(Sensor s) {
  int[] triggers=
      { Sensor.TYPE_SIGNIFICANT_MOTION, Sensor.TYPE_STEP_DETECTOR,
          Sensor.TYPE_STEP_COUNTER };

  return(Arrays.binarySearch(triggers, s.getType()) >= 0);
}
```

The reason for isolating `isTriggerSensor()` into a separate method, and not having the array of sensor types as a `static final` array, is because these sensor types are not available in all Android versions. Having the array of sensor types as a `static final` data member would require putting the `@TargetApi` annotation on the entire class, which is unwise if the class will be used on older devices. This way, we can isolate the new-target code into a dedicated method, with a more locally-scoped `@TargetApi` annotation.

Getting Sensor Events

To get sensor events, you need a SensorEventListener. This is an interface, calling for two method implementations:

1. onAccuracyChanged(), where you are informed about a significant change in the accuracy of the readings that you are going to get from the sensor
2. onSensorChanged(), where you are passed a SensorEvent representing one of those readings

To receive events for a given Sensor, you call registerListener() on the SensorManager, supplying the Sensor, the SensorEventListener, and one of the SENSOR_DELAY_* values to control the rate of events. Later on, you need to call unregisterListener(), supplying the same SensorEventListener, to break the connection. **Failing to unregister the listener is bad**. The sensor subsystem is oblivious to things like activity lifecycles, and so if you leak a listener, not only will you perhaps leak the component that registered the listener, but you will continue to get sensor events until the process is terminated. As active sensors do consume power, users will not appreciate the battery drain your leaked listener will incur.

The List of Sensor objects from that getSensorList() method shown previously will be used to populate a ListView. When the user taps on a Sensor in the list, an onSensorSelected() method is called on the MainActivity. Here, we unregister our listener (a SensorLogFragment that we will discuss more in a bit), in case we were registered for a prior Sensor choice, before registering for the newly-selected Sensor:

```
@Override
public void onSensorSelected(Sensor s) {
  mgr.unregisterListener(log);
  mgr.registerListener(log, s, SensorManager.SENSOR_DELAY_NORMAL);
  log.init(isXYZ(s));
  panes.closePane();
}
```

We will discuss the remainder of the onSensorSelected() method a bit later in this chapter.

Since SensorLogFragment implements SensorEventListener — so we can use it with registerListener() — we need to implement onAccuracyChanged() and onSensorChanged():

```
@Override
public void onAccuracyChanged(Sensor sensor, int accuracy) {
  // unused
}

@Override
public void onSensorChanged(SensorEvent e) {
  Float[] values=new Float[3];

  values[0]=e.values[0];
  values[1]=e.values[1];
  values[2]=e.values[2];

  adapter.add(values);
}
```

Once again, we will get into the implementation of `onSensorChanged()` a bit later in this chapter.

The big thing to note now about `onSensorChanged()`, though, is that **the `SensorEvent` object comes from an object pool and gets recycled**. It is not safe for you to hold onto this `SensorEvent` object past the call to `onSensorChanged()`. Hence, you need to do something with the data in the `SensorEvent`, then let go of the `SensorEvent` itself, so that instance can be used again later. This is to help prevent excessive garbage collection, particularly for low-delay requests for sensor readings (e.g., `SENSOR_DELAY_FASTEST`).

Interpreting Sensor Events

The key piece of data in the `SensorEvent` object is `values`. This is a six-element `float` array containing the actual sensor reading. What those values *mean* will vary by sensor. For example:

- For accelerometer readings (e.g., `TYPE_ACCELEROMETER`), the first three elements of the array represent the reported acceleration, in m/s^2, along the X, Y, and Z axes respectively (X = out the right side of the device, Y = out the top edge of the device, Z = out the screen towards the user's eyes)
- `TYPE_PRESSURE` uses the first element of the `values` array to report the barometric pressure in millibars
- `TYPE_LIGHT` uses the first element of the `values` array to report the light level in lux

And so on.

The `SensorEvent` documentation contains instructions on how to interpret these events on a per-sensor-type basis.

That being said, sensors can be roughly divided into two groups:

1. Sensors whose readings take into account three axes (X/Y/Z). These include TYPE_ACCELEROMETER, TYPE_GRAVITY, TYPE_GYROSCOPE, TYPE_LINEAR_ACCELERATION, and TYPE_MAGNETIC_FIELD.
2. Sensors that have simple single-value readings, such as TYPE_PRESSURE and TYPE_LIGHT

The isXYZ() method on MainActivity simply returns a boolean indicating whether or not this particular Sensor is one that uses all three axes (true) or not (false). As the roster of sensors has changed over the years, it also does some checks based on API level:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isXYZ(Sensor s) {
  switch (s.getType()) {
    case Sensor.TYPE_ACCELEROMETER:
    case Sensor.TYPE_GRAVITY:
    case Sensor.TYPE_GYROSCOPE:
    case Sensor.TYPE_LINEAR_ACCELERATION:
    case Sensor.TYPE_MAGNETIC_FIELD:
    case Sensor.TYPE_ROTATION_VECTOR:
      return(true);
  }

  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR2) {
    if (s.getType() == Sensor.TYPE_GAME_ROTATION_VECTOR
        || s.getType() == Sensor.TYPE_GYROSCOPE_UNCALIBRATED
        || s.getType() == Sensor.TYPE_MAGNETIC_FIELD_UNCALIBRATED) {
      return(true);
    }
  }

  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
    if (s.getType() == Sensor.TYPE_GEOMAGNETIC_ROTATION_VECTOR) {
      return(true);
    }
  }

  return(false);
}
```

Wiring Together the Sample

Overall, this sample app uses the SlidingPaneLayout first seen back in the chapter on large-screen support. We have two fragments, in a master-detail pattern, where the "master" will be a list of all available sensors, and the "detail" will be a log of sensor readings from a selected sensor.

Our layout (`res/layout/activity_main.xml`) wires in a `SensorsFragment` (master) and `SensorLogFragment` (detail) in a `SlidingPaneLayout`:

```
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/
apk/res/android"
  android:id="@+id/panes"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <fragment
    android:id="@+id/sensors"
    android:name="com.commonsware.android.sensor.monitor.SensorsFragment"
    android:layout_width="300sp"
    android:layout_height="match_parent"/>

  <fragment
    android:id="@+id/log"
    android:name="com.commonsware.android.sensor.monitor.SensorLogFragment"
    android:layout_width="400dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

</android.support.v4.widget.SlidingPaneLayout>
```

The `SensorsFragment` is reminiscent of `CountriesFragment` from the `SlidingPaneLayout` variant of the `EU4You` sample. The biggest differences are that we use a `SensorListAdapter` for representing the list of sensors, that we use `getSensorList()` on our `SensorsFragment.Contract` class to retrieve the model data, and that we call `onSensorSelected()` on the contract to report of selections:

```
package com.commonsware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Bundle;
import android.view.View;
import android.widget.ListView;
import java.util.List;

public class SensorsFragment extends
    ContractListFragment<SensorsFragment.Contract> {
  static private final String STATE_CHECKED=
      "com.commonsware.android.sensor.monitor.STATE_CHECKED";
  private SensorListAdapter adapter=null;

  @Override
  public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    adapter=new SensorListAdapter(this);
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    setListAdapter(adapter);

    if (state != null) {
      int position=state.getInt(STATE_CHECKED, -1);
      if (position > -1) {
        getListView().setItemChecked(position, true);
        getContract().onSensorSelected(adapter.getItem(position));
      }
    }
  }

  @Override
  public void onListItemClick(ListView l, View v, int position, long id) {
    l.setItemChecked(position, true);

    getContract().onSensorSelected(adapter.getItem(position));
  }

  @Override
  public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    state.putInt(STATE_CHECKED, getListView().getCheckedItemPosition());
  }

  interface Contract {
    void onSensorSelected(Sensor s);

    List<Sensor> getSensorList();
  }
}
```

`SensorListAdapter` illustrates another approach for handling the difference in "activated" row support. The `EU4You` samples used an `activated` style to apply the "activated" support on Android 3.0 and higher. Here, our custom `ArrayAdapter` subclass dynamically chooses between `android.R.layout.simple_list_item_activated_1` (an activated-capable built-in row layout) and the classic `android.R.layout.simple_list_item_1` based upon API level:

```
package com.commonsware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Build;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.TextView;

class SensorListAdapter extends ArrayAdapter<Sensor> {
  SensorListAdapter(SensorsFragment sensorsFragment) {
    super(sensorsFragment.getActivity(), getRowResourceId(),
          sensorsFragment.getContract().getSensorList());
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    View result=super.getView(position, convertView, parent);
    ((TextView)result).setText(getItem(position).getName());

    return(result);
  }

  private static int getRowResourceId() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {
      return(android.R.layout.simple_list_item_activated_1);
    }

    return(android.R.layout.simple_list_item_1);
  }
}
```

We also have to override `getView()`, as our model is `Sensor`, whose `toString()` is not what we want, so we have to manually populate the list row with `getName()` instead.

`SensorLogFragment` is another `ListFragment`. In particular, though, we set it up for `TRANSCRIPT_MODE_NORMAL`, which means that Android will automatically scroll the `ListView` to the bottom if we add new rows to the list *and* the user has not scrolled up in the list to view past data:

```
  @Override
  public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);
  }
```

However, we do not initialize our `ListAdapter` in `onActivityCreated()`, as we might normally do. Instead, we have a dedicated `init()` method, to be called by `MainActivity`, where we set up the `SensorLogAdapter` and keep track of whether the `Sensor` that we are logging is designed to report three-dimensional values (`isXYZ` is `true`) or not:

```
  void init(boolean isXYZ) {
    this.isXYZ=isXYZ;
    adapter=new SensorLogAdapter(this);
    setListAdapter(adapter);
  }
```

The `init()` method, in turn, was called by `onSensorSelected()` of `MainActivity`. Hence, whenever the user taps on a sensor, we set up a fresh log. `init()` can do this because `MainActivity` retrieved our `SensorLogFragment` up in `onCreate()`, stashing it in a `log` data member:

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(SensorManager)getSystemService(Context.SENSOR_SERVICE);
    log=
        (SensorLogFragment)getFragmentManager().findFragmentById(R.id.log);

    panes=(SlidingPaneLayout)findViewById(R.id.panes);
    panes.openPane();
  }
```

Our `onSensorChanged()` method in `SensorLogFragment` copies the `values` from the `SensorEvent` into a separate `Float` array that is our list's model data:

```
  @Override
  public void onSensorChanged(SensorEvent e) {
    Float[] values=new Float[3];

    values[0]=e.values[0];
    values[1]=e.values[1];
    values[2]=e.values[2];

    adapter.add(values);
  }
```

`SensorLogAdapter` uses the `isXYZ` value to determine how it should format the rows:

- For single-value sensors, we just show the first `Float` from the array
- For three-dimensional sensors, we show all three dimensions, plus the "net" (square root of the sum of the squares), separated by slashes

```
  class SensorLogAdapter extends ArrayAdapter<Float[]> {
    public SensorLogAdapter(SensorLogFragment sensorLogFragment) {
      super(sensorLogFragment.getActivity(),
            android.R.layout.simple_list_item_1,
            new ArrayList<Float[]>());
    }

    @SuppressLint("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
      TextView row=
          (TextView)super.getView(position, convertView, parent);
      String content=null;
      Float[] values=getItem(position);

      if (isXYZ) {
        content=
            String.format("%7.3f / %7.3f / %7.3f / %7.3f",
                          values[0],
                          values[1],
                          values[2],
                          Math.sqrt(values[0] * values[0] + values[1]
                              * values[1] + values[2] * values[2]));
      }
      else {
        content=String.format("%7.3f", values[0]);
      }

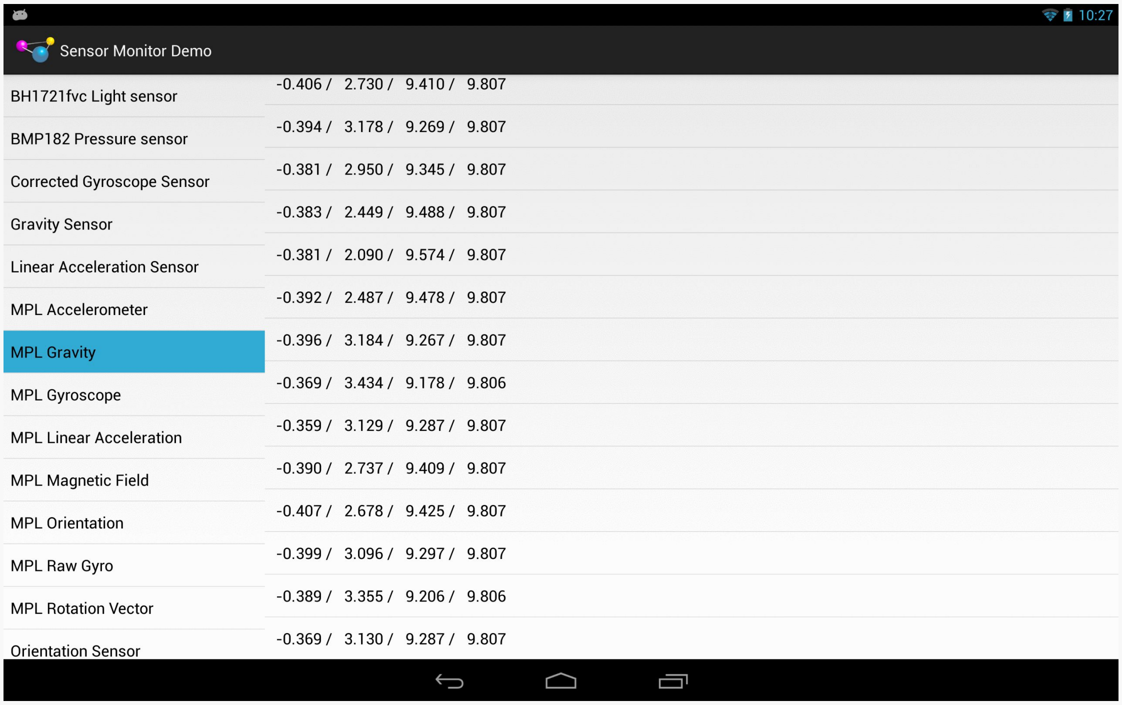
      row.setText(content);

      return(row);
    }
  }
```

The rest of `MainActivity` simply manages the `SlidingPaneLayout`, much like the `EU4YouSlidingPane` sample did.

The Results

When the user taps on a sensor in the list, we get a log of readings:



- BH1721fvc Light sensor
- BMP182 Pressure sensor
- Corrected Gyroscope Sensor
- Gravity Sensor
- Linear Acceleration Sensor
- MPL Accelerometer
- MPL Gravity
- MPL Gyroscope
- MPL Linear Acceleration
- MPL Magnetic Field
- MPL Orientation
- MPL Raw Gyro
- MPL Rotation Vector
- Orientation Sensor

Batching Sensor Readings

API Level 19 (Android 4.4) added a new feature to the sensor subsystem: batched sensor events. Now, `registerListener()` can take a batch period in microseconds, and Android may elect to deliver events to you delayed by up to that amount of time. The objective will be to reduce the power draw of the sensors, for sensor hardware that supports this sort of batching behavior. Not all hardware will, in which case your requested batch latency will be ignored.

Printing and Document Generation

Mobile devices are continuing to close the gap on capabilities that had formerly been the sole province of desktop systems or servers. After all, if the vision is that people should be able to use phones and tablets *instead of* desktops and notebooks, phones and tablets need to do whatever it is that those people need to have done.

One such capability is the ability to print to networked printers. While various third-party printing options had been available for some time, it is only startig with the Android 4.4 release that the OS and framework itself has support for printing. Hence, at this time, a significant majority of Android devices will be natively capable of printing, and so users will be more likely to expect that your app supports such printing.

As it turns out, the print engine in Android is centered upon the PDF document format, and Android supports converting HTML into PDF, albeit on a somewhat limited basis.

The API seems simple and clean. It actually *is* simple and clean… so long as you are printing very simple contents (bitmaps or HTML). Once you get into anything more complicated than that, the threading alone starts to make things rather messy.

This chapter describes how to use the Android 4.4 print system, including how to print HTML and PDF files. It will also cover how to generate HTML and PDF files, whether for printing or for other purposes (e.g., reports to be emailed or uploaded somewhere).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on advanced uses of `WebView`.

The Android Print System

Writing programs that print on desktop operating systems historically has been tedious. The fine-grained control that is needed for high-quality output makes the APIs complicated, and these tend to be only partially masked by high-level wrappers to simplify common scenarios.

Android's print system is no different.

Starting with Android 4.4, you can request access to a `PrintManager` system service (via `getSystemService()`, called on any `Context`). It offers a `print()` method that lets you describe what should be printed, in the form of a `PrintAttributes` (e.g., what size paper are you looking for?) and a `PrintDocumentAdapter`. The latter is responsible for working with Android to actually create the content to be printed.

`print()` returns a `PrintJob`, which you can use to examine the status of the print request. `PrintManager` also offers a `getPrintJobs()` method that returns all of *your* outstanding print requests. Note that you cannot access print jobs from other applications.

Hence, the real complexity of printing lies in the `PrintDocumentAdapter` implementation. This class is responsible for generating a PDF that represents the content to be printed. This leads to four basic ways of working with a `PrintDocumentAdapter`:

1. Have one created for you, such as via a `WebView` for printing HTML content
2. Create one that takes a PDF generated elsewhere and uses it for the output
3. Create one that uses Android's `Canvas`-based PDF generation class, called `PrintedPdfDocument`
4. Use APIs that avoid all of this entirely, such as `printBitmap()` on `PrintHelper`

About the Sample App

The Printing/PrintManager sample project demonstrates all but the `Canvas` option.

The UI is just a large `EditText`, designed for you to type in a message.

The action bar overflow contains four options:

- "Bitmap", to print an image from your device or emulator
- "Web Page", to print the Web page for this book
- "TPS Report", which prints a report containing the message from the `EditText`
- "PDF", which prints a copy of the cover of Version 5.8 of this book, which is packaged in the app as an asset

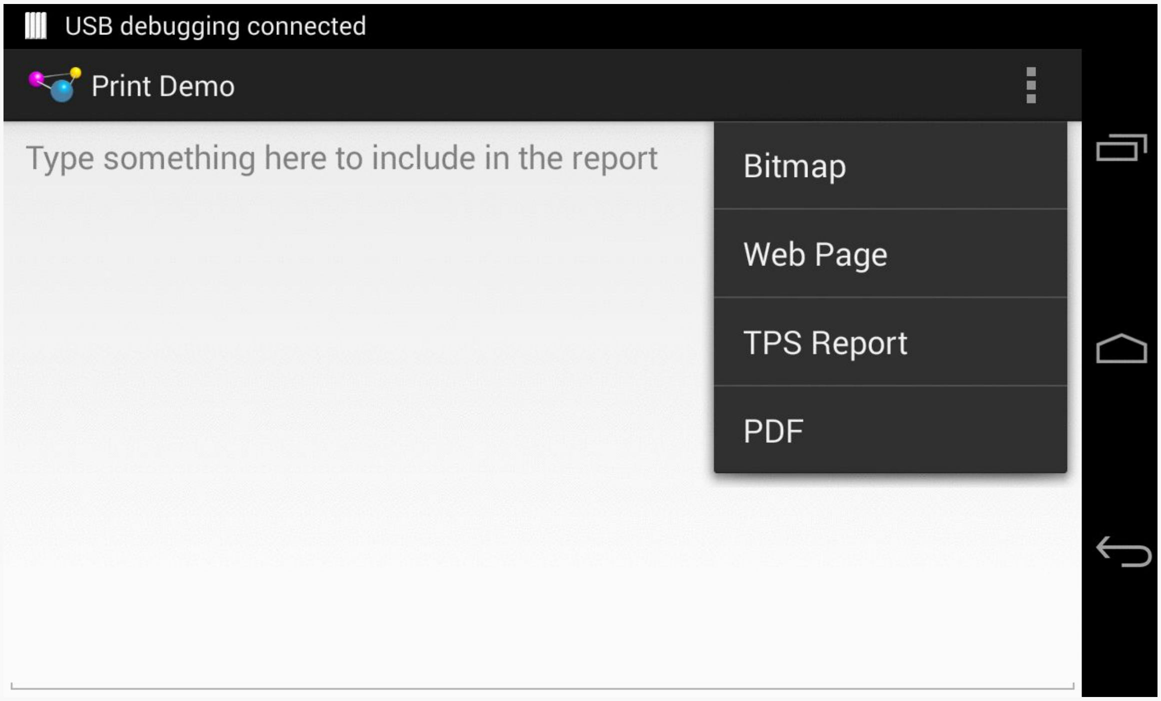

Figure 764: Print Demo App, Showing Overflow

Printing a Bitmap

Google helpfully supplies a PrintHelper class in the Android Support package that makes it trivially easy to print a bitmap. Just call printBitmap() on the PrintHelper, after some minor configuration, and it takes over from there.

In onOptionsItemSelected() of the sample app's MainActivity, when the user chooses the "Bitmap" item, we call startActivityForResult() on an ACTION_GET_CONTENT Intent, to allow the user to pick an image from the device or emulator:

```
        Intent i=
            new Intent(Intent.ACTION_GET_CONTENT).setType("image/*");

        startActivityForResult(i, IMAGE_REQUEST_ID);
```

This, in turn, will trigger a call to onActivityResult(), once the user has (presumably) chosen an image:

```
  @Override
  protected void onActivityResult(int requestCode, int resultCode,
                                  Intent data) {
    if (requestCode == IMAGE_REQUEST_ID
        && resultCode == Activity.RESULT_OK) {
      try {
        PrintHelper help=new PrintHelper(this);

        help.setScaleMode(PrintHelper.SCALE_MODE_FIT);
        help.printBitmap("Photo!", data.getData());
      }
      catch (FileNotFoundException e) {
        Log.e(getClass().getSimpleName(), "Exception printing bitmap",
              e);
      }
    }
  }
```

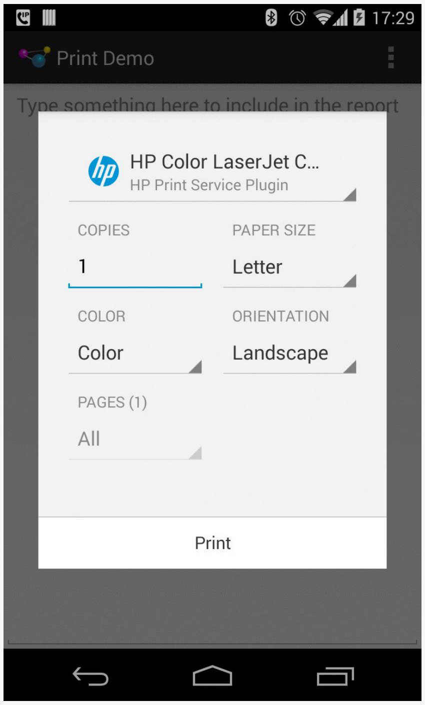
If the user did indeed choose an image, we create an instance of PrintHelper, call setScaleMode() to tell it fit the image to the page, and then call printBitmap() to print the image.

setScaleMode() takes one of two values:

1. SCALE_MODE_FIT will show the entire image, blown up as big as possible
2. SCALE_MODE_FILL will fill the entire page, at the cost of cropping the image along one axis, if the image's aspect ratio does not match the paper's aspect ratio

printBitmap() takes the name of the print job (so the user, when reviewing the outstanding print jobs, knows what it is) and either a Uri or a Bitmap for the image itself. In the case of a Uri, the Uri could be malformed, in which case the FileNotFoundException may be thrown, which is why we catch it.

What the user sees, after choosing an image to print (and a printer, if the user has more than one available), is a print configuration dialog appear, much like those you might see in a desktop OS:



HP Color LaserJet C…
HP Print Service Plugin

COPIES: 1
PAPER SIZE: Letter
COLOR: Color
ORIENTATION: Landscape
PAGES (1): All

Figure 765: HP Print Configuration Dialog

The dialog itself is provided by Android; the contents of the dialog is provided by a PrintService that is responsible for taking our print job and actually dispatching it to the printer.

Here, the user can make typical changes, like portrait/landscape printing and the number of copies, before pressing the "Print" button. At that point, the user's chosen image will be printed.

Note that, in Android 4.4, the print dialog does not work especially well in landscape on smaller screen sizes, forcing the user to scroll to get to all of the widgets, including the "Print" button.

Printing an HTML Document

Printing a bitmap is nice. It is not especially useful, as it implies that we have a bitmap worth printing by itself. That is certainly possible, but it is unlikely. Even in the case where we want to print a photo, there is a very good chance that we will need to print some additional information along with the photo (caption, date when photo was taken, etc.).

Being able to print something over which we have greater control of the rendering would be more useful. The easiest way to do that is to print some HTML. Later in this chapter we will cover how to generate some dynamic HTML representing what you want to print. For the moment, though, let's focus on the printing itself.

Printing and WebView

Starting in API Level 19, `WebView` is capable of participating in the print process. You can load up a `WebView` with your desired content, then print that content.

Some apps will already be using a `WebView` as part of the UI, and that `WebView` will contain what needs to be printed. For example, a Web browser can easily add a "Print" action bar overflow item that would print the contents of the active `WebView` in the browser.

For cases where you want to print something, but you are not using the `WebView` for anything but printing, you do *not* need to add the `WebView` to the UI. You can create a `WebView` instance via its constructor, passing in your `Activity` as the `Context` required by that constructor. You can then populate that `WebView` with what needs to be printed, then print it. That is the technique that the sample application demonstrates, in part because it is likely to be the more common scenario — only so many apps use a `WebView` in the UI, and more are likely to need to print.

Printing a URL

The sample app's "Web Page" action bar overflow item is tied to an `R.id.web` `MenuItem`. When that is tapped by the user, `onOptionsItemSelected()` calls `printWebPage()` to print a Web page loaded from a URL:

```
private void printWebPage() {
  WebView print=prepPrintWebView(getString(R.string.web_page));

  print.loadUrl("https://commonsware.com/Android");
}
```

Here, `getString(R.string.web_page)` is returning a string resource that will be used for the name of a print job. `prepPrintWebView()` returns the `WebView` that will be used for printing. `loadUrl()` is the standard `WebView` method for populating the `WebView` from a URL. Note that this causes the sample app to need the `INTERNET` permission, since we are downloading a Web page and its related assets (CSS, images) from the Internet.

You will notice that we are not actually printing anything directly in `printWebPage()`, which may seem a bit odd given the name of the method. That is because we cannot print anything until the page is loaded — after all, it is only then that we have what we want to print.

The job of `prepPrintWebView()` is to arrange to get control when the page is loaded and actually print the desired page:

```
private WebView prepPrintWebView(final String name) {
  WebView result=getWebView();

  result.setWebViewClient(new WebViewClient() {
    @Override
    public void onPageFinished(WebView view, String url) {
      print(name, view.createPrintDocumentAdapter(),
            new PrintAttributes.Builder().build());
    }
  });

  return(result);
}
```

`getWebView()` is just a lazy-initialization method, populating a `wv` data member of the activity with a `WebView`. This way, we avoid creating the `WebView` up front, as if the user does not elect to print any HTML, we do not need the `WebView`, and a `WebView` is expensive to initialize:

```
private WebView getWebView() {
  if (wv == null) {
    wv=new WebView(this);
  }

  return(wv);
}
```

We are holding onto the `WebView` in a data member to ensure that it will not be garbage-collected. A `WebView` that is part of our UI is being strongly held by its parent in the `View` hierarchy, so we do not normally need to worry about this. However, in this case, we are creating a `WebView` dynamically and are *not* adding it to the UI, so we are responsible for holding onto it, at least as long as is needed. In this sample, we just hold onto it for the rest of the life of the activity.

Back in prepPrintWebView(), we call setWebViewClient(), to attach an anonymous inner class extending WebViewClient to the WebView. Back in the chapter introducing WebView, we saw WebViewClient in the context of shouldOverrideUrlLoading(). Another popular method to override on a WebViewClient is onPageFinished(). This is called when the HTML and related assets (CSS, images, etc.) have been loaded and rendered within the WebView. At this point, for the particular URL we are loading, it is safe to print the page.

In onPageFinished(), we call a print() method on MainActivity itself:

```
private PrintJob print(String name, PrintDocumentAdapter adapter,
                       PrintAttributes attrs) {
  startService(new Intent(this, PrintJobMonitorService.class));

  return(mgr.print(name, adapter, attrs));
}
```

The first line of print() calls startService() to start a PrintJobMonitorService. We will see more about why we are doing that later in this chapter. For the moment, take it on faith that this service will help ensure that our process stays around long enough for our print job to finish.

The second line of print() calls a print() method on a mgr data member. Here, mgr is a PrintManager, initialized up in onCreate() of the activity, by calling getSystemService(), asking for the PRINT_SERVICE, and casting the result to be a PrintManager.

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);
  prose=(EditText)findViewById(R.id.prose);
  mgr=(PrintManager)getSystemService(PRINT_SERVICE);
}
```

The print() method tells the PrintManager to go print something. print() takes three parameters:

1. The name of the print job, which is kept along with the print job itself in case something (e.g., the print driver) wishes to show the user a roster of print jobs. In our case, this is that string resource passed in as the name parameter to prepPrintWebView(). That parameter is marked final, so the

call to `setWebViewClient()` will include the value of that parameter in the anonymous inner class' implementation of `onPageFinished()`.

2. A `PrintDocumentAdapter`. For the case of printing HTML, we get one of those by calling `createPrintDocumentAdapter()` on our populated `WebView`.
3. A `PrintAttributes` object, describing any particular requirements that you have for the printed output (e.g., media size, margins, color/monochrome). If you will let the user control all of that via the print dialog, an empty `PrintAttributes` is fine to use with `print()`. You typically create a `PrintAttributes` by creating a `PrintAttributes.Builder`, calling setters on the `Builder` to configure the `PrintAttributes`, and getting the resulting `PrintAttributes` via a call to `build()`.

And that's it. Android — in particular, `WebView` and its `PrintDocumentAdapter` – takes over from here and prints the Web page.

Limitations and Concerns

Alas, we do not have infinite flexibility with printing HTML from a `WebView`. Here are some limitations and potential problem areas that you will encounter:

- While you can use JavaScript in the loaded HTML, it cannot trigger the print itself using any standard DOM methods.
- Also, if your JavaScript is going to fire off some asynchronous operations, like an AJAX request, bear in mind that `onPageFinished()` does *not* take those operations into account. You will need to use `addJavascriptInterface()` to inject a Java object into the JavaScript realm, then have your asynchronous work arrange to call some method on that Java object, to signal to you that the document is ready for printing.
- Print CSS rules, like headers, footers, page numbers, landscape properties, and the like are ignored at present.
- A `WebView` can only do one print job at a time. Printing occurs asynchronously, and so you have to be careful that you do not accidentally start off a second print job while an earlier one is in process. The `print()` method returns a `PrintJob` that you can use to monitor the print job status, and this object will be covered in a bit more detail later in this chapter. You may wish to set up a `WebView` pool, where you reuse an existing `WebView` only if its associated `PrintJob` is completed, creating a new `WebView` instance if there is no available `WebView` at the moment. Or, you might disable printing options in the UI until the `PrintJob` is done, so you can reuse the `WebView`. The sample app does none of this, to keep things simpler.

- Printing HTML is "an all-or-nothing affair". You cannot print a subset of the HTML, whether denoted by HTML constructs (e.g., `<div>` IDs) or by page numbers. Hence, you need to load into the `WebView` *exactly* what you want to print, no more, no less.

Also, any direct use of `PrintManager` will only work on API Level 19. You will need to ensure that you only try using it on API Level 19+ devices, using Java version guard blocks. You will also need to set your build target (i.e., `compileSdkVersion` in Android Studio) to at least API Level 19 to be able to reference the `PrintManager` and related classes.

Finally, while loading and printing HTML are both intrinsically asynchronous, *generating* HTML locally is not. We will discuss this issue a bit more later in this chapter.

Printing a PDF File

As will be seen in the next section, even if we "hand-roll" our printed output using a `Canvas`, the result seems to be a PDF file. Hence, you would think that the printing framework would provide convenience code to print a PDF file that we obtained by other means.

Alas, that is not the case.

The sample app contains some code demonstrating how this is possible, inspired by this Stack Overflow answer, though it may cut a few corners that Google would prefer not be cut. However, it also illustrates how to create your own `PrintDocumentHandler`, which you will need for any print job not involving a bitmap or HTML.

The PrintDocumentAdapter Protocol

We supply a `PrintDocumentAdapter` to the `print()` method on `PrintManager`. In the HTML case, we got a `PrintDocumentAdapter` from the `WebView`, and so it is Google's job to implement that adapter. Similarly, `PrintHelper` has its own internal implementation of a `PrintDocumentAdapter` that it uses for printing the bitmap.

For anything else, you need to create your own `PrintDocumentAdapter`, or find a third-party implementation that you can perhaps reuse.

PrintDocumentAdapter's job is to supply the PrintManager with the content to be printed, in the form of a PDF file. To do that, there are four callback methods that PrintManager (and related classes) will call on the PrintDocumentAdapter:

1. onStart() is called first. If you are planning on using the same PrintDocumentAdapter instance for multiple print jobs, this would be a spot to initialize the work for a new job. Otherwise, if you were only planning on using a PrintDocumentAdapter instance once, you may as well just put your initialization logic in the constructor.
2. onLayout() is called next. Here is where you do enough work to determine what the resulting output will be later on as printing continues. In particular, if you want to provide an accurate page count, this is where you will need to perform the necessary calculations to determine that.
3. onWrite() is called next, asking you to write one or more PDF pages out to a supplied ParcelFileDescriptor (on which you can create an OutputStream).
4. onFinish() is called last, when the printing request is completed, so you can free up any necessary resources.

Introducing ThreadedPrintDocumentAdapter

All four of those callback methods are called on the main application thread. Your onStart() and onFinish() methods need to be fast enough to complete their work on that thread, and that may not be a problem. The work that onLayout() and onWrite() do may take a while, though, and so the protocol is designed to allow you to do that work on a background thread. Both methods are passed a callback object that you use to pass along the results of your work, and both are passed a CancellationSignal to indicate if the user cancels the print job while you are doing the work.

What PrintDocumentAdapter does *not* do is actually give you a thread to use.

So, the sample app contains a ThreadedPrintDocumentAdapter that moves the onLayout() and onFinish() work to a background thread:

```
package com.commonsware.android.print;

import android.content.Context;
import android.os.Bundle;
import android.os.CancellationSignal;
import android.os.ParcelFileDescriptor;
import android.print.PageRange;
import android.print.PrintAttributes;
import android.print.PrintDocumentAdapter;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;

abstract class ThreadedPrintDocumentAdapter extends
    PrintDocumentAdapter {
  abstract LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
                                    PrintAttributes newAttributes,
                                    CancellationSignal cancellationSignal,
                                    LayoutResultCallback callback,
                                    Bundle extras);

  abstract WriteJob buildWriteJob(PageRange[] pages,
                                  ParcelFileDescriptor destination,
                                  CancellationSignal cancellationSignal,
                                  WriteResultCallback callback,
                                  Context ctxt);

  private Context ctxt=null;
  private ExecutorService threadPool=Executors.newFixedThreadPool(1);

  ThreadedPrintDocumentAdapter(Context ctxt) {
    this.ctxt=ctxt;
  }

  @Override
  public void onLayout(PrintAttributes oldAttributes,
                       PrintAttributes newAttributes,
                       CancellationSignal cancellationSignal,
                       LayoutResultCallback callback, Bundle extras) {
    threadPool.submit(buildLayoutJob(oldAttributes, newAttributes,
                                     cancellationSignal, callback,
                                     extras));
  }

  @Override
  public void onWrite(PageRange[] pages,
                      ParcelFileDescriptor destination,
                      CancellationSignal cancellationSignal,
                      WriteResultCallback callback) {
    threadPool.submit(buildWriteJob(pages, destination,
                                    cancellationSignal, callback, ctxt));
  }

  @Override
  public void onFinish() {
    threadPool.shutdown();

    super.onFinish();
  }

  protected abstract static class LayoutJob implements Runnable {
    PrintAttributes oldAttributes;
    PrintAttributes newAttributes;
    CancellationSignal cancellationSignal;
    LayoutResultCallback callback;
    Bundle extras;

    LayoutJob(PrintAttributes oldAttributes,
              PrintAttributes newAttributes,
              CancellationSignal cancellationSignal,
              LayoutResultCallback callback, Bundle extras) {
      this.oldAttributes=oldAttributes;
      this.newAttributes=newAttributes;
      this.cancellationSignal=cancellationSignal;
      this.callback=callback;
      this.extras=extras;
    }
  }

  protected abstract static class WriteJob implements Runnable {
    PageRange[] pages;
    ParcelFileDescriptor destination;
    CancellationSignal cancellationSignal;
    WriteResultCallback callback;
    Context ctxt;

    WriteJob(PageRange[] pages, ParcelFileDescriptor destination,
             CancellationSignal cancellationSignal,
             WriteResultCallback callback, Context ctxt) {
      this.pages=pages;
      this.destination=destination;
      this.cancellationSignal=cancellationSignal;
      this.callback=callback;
      this.ctxt=ctxt;
    }
  }
}
```

This class uses a single-thread thread pool, managed by an `ExecutorService`. In principle, a well-written `PrintDocumentAdapter` could handle multiple print jobs in parallel — if you attempt this and are using `ThreadedPrintDocumentAdapter` for inspiration, simply increase the size of the thread pool.

The `onLayout()` and `onWrite()` methods package up their parameters (described in the next section) into job objects. Those objects implement `Runnable`, and they are then handed to the `ExecutorService` to be run on the next-available thread. `onFinish()` shuts down the `ExecutorService`, though if you wanted to use the `ThreadedPrintDocumentAdapter` for multiple print jobs, you would come up with some other logic to clean up the `ExecutorService` when you were done with *all* of the jobs.

Subclasses of `ThreadedPrintDocumentAdapter` need to:

- Create subclasses of the `LayoutJob` and `WriteJob` static inner classes, implementing their respective `run()` methods, to do the work required of `onLayout()` and `onWrite()`
- Implement `buildLayoutJob()` and `buildWriteJob()` methods that return instances of those custom subclasses

(fans of dependency injection no doubt can find better solutions for wiring up a ThreadedPrintDocumentAdapter)

A PdfDocumentAdapter

However, we still need to actually be able to print a PDF, which ThreadedPrintDocumentAdapter does not do on its own. The sample app also has a PdfDocumentAdapter, which extends ThreadedPrintDocumentAdapter and demonstrates a crude way of printing a PDF through the PrintDocumentAdapter protocol.

PdfDocumentAdapter does not use onStart() or onFinish(). And, since the onLayout() and onWrite() methods are handled by ThreadedPrintDocumentAdapter, PdfDocumentAdapter does not have those either.

It does, however, have the buildLayoutJob() and buildWriteJob() methods required by ThreadedPrintDocumentAdapter. These return instances of a PdfLayoutJob and PdfWriteJob, respectively:

```
@Override
LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
                         PrintAttributes newAttributes,
                         CancellationSignal cancellationSignal,
                         LayoutResultCallback callback, Bundle extras) {
  return(new PdfLayoutJob(oldAttributes, newAttributes,
                          cancellationSignal, callback, extras));
}

@Override
WriteJob buildWriteJob(PageRange[] pages,
                       ParcelFileDescriptor destination,
                       CancellationSignal cancellationSignal,
                       WriteResultCallback callback, Context ctxt) {
  return(new PdfWriteJob(pages, destination, cancellationSignal,
                         callback, ctxt));
}
```

PdfLayoutJob needs to fulfill the bulk of the onLayout() contract:

- Monitor the CancellationSignal and call onLayoutCancelled() on the supplied LayoutResultCallback if the job has been canceled
- Populate a PrintDocumentInfo object to provide metadata about the document to be printed, and pass that to onLayoutFinished() on the LayoutResultCallback

```
private static class PdfLayoutJob extends LayoutJob {
  PdfLayoutJob(PrintAttributes oldAttributes,
               PrintAttributes newAttributes,
               CancellationSignal cancellationSignal,
               LayoutResultCallback callback, Bundle extras) {
    super(oldAttributes, newAttributes, cancellationSignal, callback,
          extras);
  }

  @Override
  public void run() {
    if (cancellationSignal.isCanceled()) {
      callback.onLayoutCancelled();
    }
    else {
      PrintDocumentInfo.Builder builder=
          new PrintDocumentInfo.Builder("CHANGE ME PLEASE");

      builder.setContentType(PrintDocumentInfo.CONTENT_TYPE_DOCUMENT)
             .setPageCount(PrintDocumentInfo.PAGE_COUNT_UNKNOWN)
             .build();

      callback.onLayoutFinished(builder.build(),
                                !newAttributes.equals(oldAttributes));
    }
  }
}
```

PdfLayoutJob also has access to two PrintAttributes objects, the "old" attributes and the "new" attributes. In principle, onLayout() could be called a couple of times, perhaps based upon changes the user makes in the print dialog. These PrintAttributes objects describe the nature of the output, including things like page size and margins. PdfLayoutJob totally ignores these, because the PDF is a packaged asset in this case and cannot be changed. If you are dynamically generating a PDF file, you may wish to pay attention to the new PrintAttributes and take them into account.

PdfLayoutJob also has access to a Bundle of "extras", not unlike the "extras" associated with an Intent. At the present time, there is only one semi-documented "extra", EXTRA_PRINT_PREVIEW, which will be true if onLayout() is being called to generate a print preview of the printed output, false otherwise.

What PdfLayoutJob does do is create a PrintDocumentInfo.Builder to set up a PrintDocumentInfo object indicating that:

- The output is a "document" (CONTENT_TYPE_DOCUMENT) versus a "photo" (CONTENT_TYPE_PHOTO) or "unknown" (CONTENT_TYPE_UNKNOWN). This information is passed to the PrintService that functions as a bridge between PrintManager and the printer, and the PrintService might optimize output based upon this setting (e.g., lower quality print output for a "document" instead of a "photo").

- The page count of the output is unknown (PAGE_COUNT_UNKNOWN). In principle, the page count is known, insofar as the PDF that will be printed is an asset baked into the app, and so we could hard-code the page count in addition to hard-coding other details (like the asset's filename).

The boolean second parameter to onLayoutFinished() is supposed to be true if the layout changed, false otherwise. In practice, the value does not seem to matter on the first onLayout() call. The implementation here compares the two PrintAttributes objects using equals().

The last piece is the PdfWriteJob, which performs the work required of the onWrite() callback:

```
private static class PdfWriteJob extends WriteJob {
  PdfWriteJob(PageRange[] pages, ParcelFileDescriptor destination,
              CancellationSignal cancellationSignal,
              WriteResultCallback callback, Context ctxt) {
    super(pages, destination, cancellationSignal, callback, ctxt);
  }

  @Override
  public void run() {
    InputStream in=null;
    OutputStream out=null;

    try {
      in=ctxt.getAssets().open("cover.pdf");
      out=new FileOutputStream(destination.getFileDescriptor());

      byte[] buf=new byte[16384];
      int size;

      while ((size=in.read(buf)) >= 0
          && !cancellationSignal.isCanceled()) {
        out.write(buf, 0, size);
      }

      if (cancellationSignal.isCanceled()) {
        callback.onWriteCancelled();
      }
      else {
        callback.onWriteFinished(new PageRange[] { PageRange.ALL_PAGES });
      }
    }
    catch (Exception e) {
      callback.onWriteFailed(e.getMessage());
      Log.e(getClass().getSimpleName(), "Exception printing PDF", e);
    }
    finally {
      try {
        in.close();
        out.close();
      }
```

```
        catch (IOException e) {
          Log.e(getClass().getSimpleName(),
                "Exception cleaning up from printing PDF", e);
        }
      }
    }
  }
```

At its core, `PdfWriteJob` simply writes our PDF (culled from a `cover.pdf` asset) to an `OutputStream`. The `OutputStream` is built from the `ParcelFileDescriptor`, indicating where the PDF content should be written to.

The `InputStream`-to-`OutputStream` "bucket brigade" is augmented with checks on the `CancellationSignal`, to abandon the loop if the print job was canceled by the user. At the end, we call one of three methods on the `WriteResultCallback`:

- `onWriteCancelled()` if the `CancellationSignal` indicates that the job was canceled
- `onWriteFinished()` if everything succeeded
- `onWriteFailed()` (with an error message) if there was some problem, such as failed I/O

`PdfWriteJob` has access to a `PageRange` array, representing the particular pages out of a larger document to be printed. The parameter to `onWriteFinished()` is another `PageRange` array that should indicate what pages were printed. Once again, since the PDF is fixed, `PdfWriteJob` ignores the input `PageRange` array, and it indicates that we wrote all pages (`PageRange.ALL_PAGES`) in the output. In principle, if you have more control over your environment, you should only print the requested pages, in which case the output parameter to `onWriteFinished()` might be the same array as was passed into `onWrite()`.

Using PdfDocumentAdapter

Back in `MainActivity`, the "PDF" action bar overflow item triggers a call to `print()` on the `PrintManager`, supplying our `PdfDocumentAdapter` and another empty `PrintAttributes`:

```
        print("Test PDF",
              new PdfDocumentAdapter(getApplicationContext()),
              new PrintAttributes.Builder().build());
```

The `PdfDocumentAdapter` needs a `Context`, in order to access the `cover.pdf` asset. If your PDF file is being generated, or is saved as a file on external storage, you would not need this. Since it is theoretically possible that our activity could be destroyed while the printing is going on in background threads, rather that briefly leak an Activity, we provide the Application Context to PdfDocumentAdapter, as that is a singleton and cannot be leaked.

The result of all of this is that when the user chooses the "PDF" action bar overflow item, the book cover copy is printed.

Printing Using a Canvas

What Google *really* wants you to do — if bitmaps and HTML are insufficient – is to create PDF documents using PdfPrintedDocument and a Canvas.

The concept is simple:

- Create a PrintedPdfDocument instance, given a PrintAttributes that describes the page size, margins, etc.
- Call startPage() to add a page to the document, which returns a PdfDocument.Page
- Call getCanvas() on the Page and use the standard Android 2D drawing APIs to draw lines, text, shaded areas, and so forth
- Call finishPage() on the PdfPrintedDocument when you are done rendering that page
- Repeat the preceding three steps for all needed pages
- Call writeTo() on the PrintedPdfDocument to write the PDF to an OutputStream, such as the one you get from the ParcelFileDescriptor in the onWrite() callback of your PrintDocumentAdapter
- Call close() on the PrintedPdfDocument when you are done

For example, let's look at the onWrite() implementation used by PrintHelper to print a bitmap:

```
@Override
public void onWrite(PageRange[] pageRanges, ParcelFileDescriptor fileDescriptor,
                    CancellationSignal cancellationSignal,
                    WriteResultCallback writeResultCallback) {
    PrintedPdfDocument pdfDocument = new PrintedPdfDocument(mContext,
            mAttributes);
    try {

        Page page = pdfDocument.startPage(1);
        RectF content = new RectF(page.getInfo().getContentRect());

        // Compute and apply scale to fill the page.
        Matrix matrix = getMatrix(mBitmap.getWidth(), mBitmap.getHeight(),
                content, fittingMode);
        // Draw the bitmap.
        page.getCanvas().drawBitmap(mBitmap, matrix, null);

        // Finish the page.
        pdfDocument.finishPage(page);

        try {
            // Write the document.
            pdfDocument.writeTo(new FileOutputStream(
                    fileDescriptor.getFileDescriptor()));
            // Done.
            writeResultCallback.onWriteFinished(
                    new PageRange[]{PageRange.ALL_PAGES});
        } catch (IOException ioe) {
            // Failed.
            Log.e(LOG_TAG, "Error writing printed content", ioe);
            writeResultCallback.onWriteFailed(null);
        }
    } finally {
        if (pdfDocument != null) {
            pdfDocument.close();
        }
        if (fileDescriptor != null) {
            try {
                fileDescriptor.close();
            } catch (IOException ioe) {
                /* ignore */
            }
        }
    }
}
```

(note: the preceding code snippet is Copyright (C) 2013 The Android Open Source Project)

Here, they:

- Create the `PrintedPdfDocument`
- Add a page using `startPage()`
- Calculate a scaling `Matrix` based upon the image size, the page size, and the scale type (`FIT` or `FILL`)
- Draw the bitmap on the `Canvas` using that `Matrix`
- Finish the page
- Write the result to an `OutputStream` for the supplied `ParcelFileDescriptor`
- Close the document

Curiously, they do not do this work in a background thread, though the `onLayout()` implementation does use a background thread (since the image `Uri` may require an Internet download).

If you are comfortable with the `Canvas` API, writing PDF pages is much the same as drawing to your custom `View`. On the other hand, Android's `Canvas` API is not the same as any other drawing system's API, so there will be distinct differences from any other 2D drawing API that you might have used previously.

Print Jobs

The `print()` method that we have been calling on `PrintManager` returns a `PrintJob`, representing the print job. This object has a number of status inquiry methods, including (in rough order of when the events occur):

- `isStarted()`
- `isQueued()` (i.e., waiting for the print system to process it)
- `isBlocked()` (i.e., permanently stuck, but needs to be canceled)
- `isCompleted()`
- `isFailed()`
- `isCancelled()`

It also has a `cancel()` method that you can call to cancel the print job (e.g., based on user request). `PrintJob` also offers a `restart()` method that you can use to re-try a failed (but not canceled) print job.

What `PrintJob` does not have is a listener interface to be proactively notified when the job changes state.

`PrintManager` also has `getPrintJobs()`, which will return a list of the `PrintJob` objects representing the jobs you have requested in this process, rather than having to keep track of all of those yourself.

Printing, Threads, and Services

If you are going to create a report in HTML, you will want to consider doing that work in an `AsyncTask`'s `doInBackground()` method, so the I/O involved in creating the report happens in the background. However, `PrintManager` requires that `print()` be called on the main application thread, so you would call `print()` from `onPostExecute()` of the `AsyncTask`.

Similarly, if you are creating your own `PrintDocumentAdapter`, you will want to consider moving the `onLayout()` and `onWrite()` work into background threads, such as is illustrated in the sample app via `ThreadedPrintDocumentAdapter`.

The problem with bare threads or an AsyncTask is that they do not indicate to Android that your process is still doing some work. It is possible that the user could request that you print something, then switch to another app (e.g., HOME, recent-tasks list). Android might consider your process to be relatively low priority and could terminate it before your print job completes.

The obvious solution is to involve a service, perhaps even a foreground service, to indicate to Android that your process is doing work that the user will notice if it does not complete. You could start the service when you do the print job, and then stop the service when the print job is completed, to return your process to normal priority.

However, actually having a service do the printing is a serious pain:

- WebView's PrintDocumentAdapter really wants the Context that created the WebView to be an Activity
- The key parameters to onLayout() and onWrite() are not Parcelable and so cannot be passed in Intent extras via startService() to the service

One possibility would be to create a PrintJobMonitorService, which is what the sample app does. PrintJobMonitorService takes advantage of that listPrintJobs() method on PrintManager to keep tabs on all of our requested print jobs. So long as there is one or more print jobs in an active state, the service keeps running. Otherwise, the service stops. Hence, while the service is not actually doing the printing, it is running while the printing is going on, flagging to the OS to leave our process alone during this critical juncture.

```
package com.commonsware.android.print;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.os.SystemClock;
import android.print.PrintJob;
import android.print.PrintJobInfo;
import android.print.PrintManager;
import java.util.concurrent.Executors;
import java.util.concurrent.ScheduledExecutorService;
import java.util.concurrent.TimeUnit;

public class PrintJobMonitorService extends Service implements Runnable {
  private static final int POLL_PERIOD=3;
  private PrintManager mgr=null;
  private ScheduledExecutorService executor=
      Executors.newSingleThreadScheduledExecutor();
  private long lastPrintJobTime=SystemClock.elapsedRealtime();
  @Override
  public void onCreate() {
    super.onCreate();

    mgr=(PrintManager)getSystemService(PRINT_SERVICE);
    executor.scheduleAtFixedRate(this, POLL_PERIOD, POLL_PERIOD,
                                 TimeUnit.SECONDS);
  }

  @Override
  public int onStartCommand(Intent intent, int flags, int startId) {
    return(super.onStartCommand(intent, flags, startId));
  }

  @Override
  public void onDestroy() {
    executor.shutdown();

    super.onDestroy();
  }

  @Override
  public void run() {
    for (PrintJob job : mgr.getPrintJobs()) {
      if (job.getInfo().getState() == PrintJobInfo.STATE_CREATED
          || job.isQueued() || job.isStarted()) {
        lastPrintJobTime=SystemClock.elapsedRealtime();
      }
    }

    long delta=SystemClock.elapsedRealtime() - lastPrintJobTime;

    if (delta > POLL_PERIOD * 2) {
      stopSelf();
    }
  }

  @Override
  public IBinder onBind(Intent intent) {
    return(null);
  }
}
```

`PrintJobMonitorService` uses a single-thread `ScheduledExecutorService`, to get control every three seconds in its `run()` method. The `run()` method iterates over the `PrintJob` objects associated with our app and looks for any that are in one of three states:

- "started", meaning that printing has begun
- "queued", meaning that the user has accepted the print dialog values, but printing has not yet started
- "created", meaning that the job has been created, but it is not yet considered queued, such as when the print dialog is up on the screen

The first two states have simple test methods on `PrintJob` (`isStarted()` and `isQueued()`). The "created" state does not, for some reason, so we have to get the underlying `PrintJobInfo` object and manually check its state (`getState()`) to see if it is started (`PrintJobInfo.STATE_STARTED`).

`PrintJobMonitorService` tracks the last time we saw an in-progress print job. If we have gone through two three-second polling periods without any in-progress print jobs, the service assumes that it is no longer needed and calls `stopSelf()`.

Printing Prior to Android 4.4

Before Android 4.4, printing in Android was limited and clunky.

The primary approach was to use Google Cloud Print. In effect, Google Cloud Print is a Web-managed print server. You would teach Google how to talk to your printers, and then any authorized device could print to those printers. By sharing your content (particularly PDFs) via `ACTION_SEND`, the user could choose Google Cloud Print as an option if they had Google Cloud Print set up for their device and printer. Note that the Android 4.4 printing framework includes a `PrintService` that works with Google Cloud Print, so users who have set up Google Cloud Print can still use it even with the new printing framework.

Various printer manufacturers or third parties also created their own apps that would fill a similar role, albeit perhaps working with printers on the local network. Or, you could write your own low-level code to talk to a network printer via relevant printing protocols like IPP, though this would be unpleasant at best.

HTML Generation

Earlier in this chapter, we saw how to print HTML. However, the HTML we printed was loaded from a URL. That is fine, but, as with printing bitmaps, it may not be a very popular scenario. What will be more likely is that you want to print some sort of report, generated on the device. And, since printing using the `Canvas` is a bit complicated, creating the report via HTML may be an easier route to take.

The typical approach for this involves creating an HTML template that sets up the basic page (e.g., references to CSS), then uses some sort of "macros" in the template to indicate portions that should be replaced dynamically with something from outside of the template.

This approach has been used since the early days of the original "dot-com revolution" of the 1990's, pioneered by tools like Cold Fusion. In Java, there are any number of available template engines.

However, for HTML, it is reasonably likely that a Web designer is going to want to get involved, to style the report. Ideally, you choose a template engine that is either something the designer is already using, or is one that is something the designer might wish to use elsewhere in the future. Forcing the designer to learn some new template syntax, just for the purposes of creating these reports, may not be the best use of the designer's time (or your time, for answering all of the designer's questions).

One of the more popular template structures used today use braces (a.k.a., curly brackets) as the macro delimiters (e.g., `{{ something }}`). In particular, the macro syntax popularized by mustache is used by many template engine implementations. There is a very good chance that your Web designer already has used mustache-style templates, or at least has heard about them.

And, conveniently enough, there is a Java implementation – jmustache — that is Android-friendly. The sample app in this chapter implements a "TPS Report" that is generated from a mustache template using jmustache.

Adding jmustache To Your App

The "Get It" section of the jmustache documentation contains up-to-date instructions for adding it to a project.

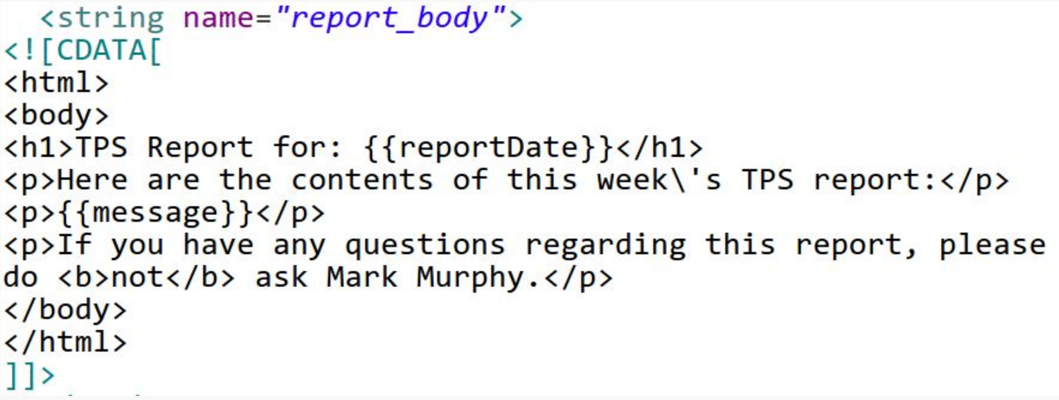
Developers using Gradle for Android — including Android Studio users – should reference the Maven Central artifact (`com.samskivert:jmustache`) from `build.gradle`.

Developers using Eclipse or Ant can download the JAR file and add it to their project's `libs/` directory.

Writing the Report Template

A report template for jmustache can be a `String` or a `Reader`, with the latter allowing you to pull in files, assets, or raw resources (the latter two via an `InputStreamReader`).

In the case of the sample app, the template is small, and is packaged as a string resource. However, since the template involves HTML tags, we have to use CDATA notation to allow those tags to be left alone within the XML of the string resource:



```
  <string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of this week\'s TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
```

Figure 766: TPS Report Mustache Template

The template contains {{reportDate}} and {{message}} variables to be replaced at runtime with dynamic data from our app. Also note that, despite the CDATA, we still need to escape the apostrophe with a leading backslash (\').

Creating a Report Context

What will fill in the {{reportDate}} and {{message}} variables will be values from a "context". Here, "context" is not referring to Context, but rather an object that we pass to jmustache to serve as the source of data to blend into the report.

jmustache has fairly flexible rules for how it can resolve template variables, including calling Java getter methods based on the variable names. Hence, we can create a "context" that has getReportDate() and getMessage() methods, such as the TpsReportContext class in the sample app:

```
private static class TpsReportContext {
  private static final SimpleDateFormat fmt=
      new SimpleDateFormat("yyyy-MM-dd", Locale.US);
  String msg;

  TpsReportContext(String msg) {
    this.msg=msg;
  }

  @SuppressWarnings("unused")
  String getReportDate() {
    return(fmt.format(new Date()));
  }
```

```
    @SuppressWarnings("unused")
    String getMessage() {
      return(msg);
    }
  }
```

Printing the Report

The "TPS Report" action bar overflow item eventually routes to a `printReport()` method on `MainActivity`:

```
  private void printReport() {
    Template tmpl=
        Mustache.compiler().compile(getString(R.string.report_body));
    WebView print=prepPrintWebView(getString(R.string.tps_report));

    print.loadData(tmpl.execute(new TpsReportContext(prose.getText()
                                                         .toString())),
                   "text/html", "UTF-8");
  }
```

The first statement creates a jmustache `Template` object representing the report template. This is created by getting the singleton `compiler()` from `Mustache`, and calling `compile()` on it to interpret the string resource. Note that since this `Template` only depends upon the string resource, we could cache the `Template`, rebuilding it only on configuration changes, if desired.

Note that we load the template on the main application thread, as `printReport()` is called from `onOptionsItemSelected()`. For a small string resource, that is OK. If you are loading a more complex report template, you will want to do that in a background thread.

The second statement mirrors one from printing the Web page from before, where we call `prepPrintWebView()` to lazy-create our `WebView` and set it up to print when the page is loaded. Here, we use a different print job name than before, one reflecting the fact that this is a TPS report.

Finally, we use `execute()` on the `Template` to generate our HTML for printing, then pass that HTML to the `loadData()` method on `WebView`. `execute()` takes our "context" `Object`, which in this case is an instance of our `TpsReportContext` class, with the value typed into the `EditText` widget in our UI as the "message" to go into the report.

Note that we execute() the Template on the main application thread as well as having loaded it on that thread in the first place. Once again, the more complex the report, the more likely it is that you will want to move this logic into a background thread. However, remember that print() needs to be called on the main application thread.

The result is that the user gets a printed TPS report, containing today's date and whatever message they typed into the EditText.

PDF Generation Options

Perhaps you feel that generating HTML does not give you enough control, yet using the Canvas options directly was *too* much control. Perhaps you then think that generating a PDF to print, using something other than PdfDocument, is the right answer. Or perhaps you are generating a PDF for other reasons, such as to use with ACTION_SEND as output from your app.

You have two basic options for getting this PDF: generate it on the device, or offload the generation to a server.

There are various open source and commercial libraries for generating PDF on Android. The best-known open source Java PDF library – iText — has as dedicated Android version (iTextG), though the AGPL license may make it unsuitable for your use case. The commercial libraries range from fixed-price to per-device licenses. How much advantage these have over using PrintedPdfDocument from the Android SDK depends upon your needs.

If the bulk of the data needed for generating the PDF resides on a server, rather than downloading that data and using an underpowered Android device to create the PDF, you could upload the device-specific data to the server, have it create the PDF, and download the result from the server. There are plenty of server-side PDF generation tools, ranging from open source (e.g., wkhtmltopdf, unoconv, prawn) to commercial (e.g., Prince, used to generate the PDF edition of this book). You also get to work in your preferred programming language, in case that is not Java, and perhaps leverage the PDF generation logic for other uses (e.g., generate reports from your Web app).

Dealing with Different Hardware

While a lot of focus is placed on screen sizes, there are many other possible hardware differences among different Android devices. For example, some have telephony features, while others do not.

There is a three-phase plan for dealing with these variations:

1. **Filter** out devices that cannot possibly run your app successfully, so your app will not appear to them in the Play Store and they will be unable to install your app if obtained by other means
2. **React** to varying hardware that you can support, but perhaps might support differently (e.g., choosing a particular flash mode for a device having a camera with a flash)
3. **Cope** with device bugs or regressions that impact your application

This chapter will go through each of these topics.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Filtering Out Devices

Elsewhere in the book, we discussed a few manifest entries that will serve to filter out devices that cannot run your app:

- android:minSdkVersion in the <uses-sdk> element, to stipulate that devices must run a certain version of Android (or higher)
- <supports-screens> and <compatible-screens>, which indicate which screens sizes and densities you are capable of supporting

This section outlines other "advertisements" that you can put in the manifest to restrict which devices run your app.

uses-feature

The <uses-feature> element restricts your app to devices that have certain hardware features. For each element, you supply the name of a feature (e.g., android.hardware.telephony) and whether or not it is required:

```
<uses-feature
  android:name="android.hardware.camera"
  android:required="false" />
```

By default, android:required is set to true, so typically you will only see it in a manifest when it is set to false.

You might wonder why we would bother ever setting android:required to false. After all, that should have the same effect as not listing it at all. In practice, though, it has two major uses.

First, markets like the Play Store might highlight the fact that you *can* use a particular hardware capability, even though you do not strictly require it.

More importantly, you can use android:required="false" to *undo* a *requirement* that Android infers from your permissions. Requesting some permissions causes Android to assume — for backwards-compatibility reasons — that your app needs the affiliated hardware. For example, requesting the CAMERA permission causes Android to assume that you need a camera (android.hardware.camera) *and* that the camera support auto-focus (android.hardware.camera.autofocus). If, however, you are requesting the permission because you would like to use the hardware if available, but can live without it, you need to expressly add a <uses-feature> element declaring that the hardware feature is not required.

For example, in February 2010, the Motorola XOOM tablet was released. This was the first Android device that had the Play Store on it and truly had no telephony capability. As such, the XOOM would be filtered out of the then-Android Market (now Play Store) for any app that required permissions like SEND_SMS. Many developers requested this permission, even though their apps could survive without SMS-sending capability. However, their apps were still filtered out if they did not have the `<uses-feature>` element declaring that telephony was not required.

You can find a table listing Android permissions and assumed hardware feature requirements in the Android developer documentation.

uses-configuration

The `<uses-configuration>` element is very reminiscent of `<uses-feature>`: it dictates hardware requirements. The difference is two-fold:

1. It focuses on hardware elements that represent different device configurations, meaning that you might use different resources for them
2. It allows you to specify *combinations* of capabilities that you need

There are three capabilities that you can require via `<uses-configuration>`:

1. The existence of a five-way navigation control, whether a specific type (D-pad, trackball, etc.) or any such control
2. The existence of a physical keyboard, whether a specific type (QWERTY, 12-key numeric keypad, etc.) or any such keyboard
3. A touchscreen

You can have as many `<uses-configuration>` elements as you need – any device that matches at least one such configuration will be eligible to install your app.

For example, the following `<uses-configuration>` element restricts your app to devices that have some sort of navigation control but do not necessarily have a touchscreen, such as a Android TV device:

```
<uses-configuration
  android:reqFiveWayNav="true"
  android:reqTouchScreen="notouch" />
```

uses-library

The `<uses-library>` element tells Android that your application wishes to use a particular *firmware*-supplied library. The most common case for this was Maps V1, which is shipped in the form of an SDK add-on and firmware library. This, however, has been deprecated for quite some time.

However, there are other firmware libraries that you might need. These will typically be manufacturer-specific libraries, allowing your application to take advantage of particular beyond-the-Android-SDK capabilities of a particular device. This is very uncommon nowadays.

The Google Play Store will filter out your application from devices that lack a firmware library that you require via `<uses-library>`. If the user tries installing your app by some other means (e.g., download from a Web site), your app will fail to install on devices that lack the firmware library.

If you conditionally want the firmware library — you will use it if available but can cope if it is not — you can add `android:required="false"` to your `<uses-library>` element. That will allow your app to install and run on devices missing the library in question. Detecting whether or not the library exists in your process at runtime is a matter if using `Class.forName()` to see if you have access to some class from that library, where a `ClassNotFoundException` means that you do not have the library.

Runtime Capability Detection

Reacting to device capabilities is the second phase of dealing with different devices. Some features you might want (e.g., telephony for sending SMSes) but can live without. Other features may have subtle variations that you cannot filter against and therefore need to adapt to at runtime (e.g., possible picture resolutions off of a camera).

This section will cover various techniques for determining what a device can do, at runtime, so you can react accordingly.

Features

Any feature you do not make required via `<uses-feature>` can be detected at runtime by calling `hasSystemFeature()` on `PackageManager`. For example, if you would like to send SMS messages, but only on telephony-capable devices, you could have the following `<uses-feature>` element:

```
<uses-feature
  android:name="android.hardware.telephony"
  android:required="false" />
```

Then, at runtime, you can call `hasSystemFeature(PackageManager.FEATURE_TELEPHONY)` on a `PackageManager` instance to find out if, indeed, the device has telephony capability and sending SMSes should work.

Other Capabilities

Various subsystems have their own means of helping you determine what is possible or not:

- The camera APIs can let you know the capabilities of a camera (e.g., whether or not it has a flash, and what specific flash modes are supported).
- The `LocationManager` will help you determine what location providers are available that meet your `Criteria`.
- The sensor subsystem lets you find out what sensors are installed, either overall or for a particular type (e.g., accelerometer).

Dealing with Device Bugs

Alas, devices are not perfect. Even though the Compatibility Test Suite attempts to ensure that all Android devices legitimately running the Play Store faithfully implement the Android SDK, some device manufacturers make changes that introduce bugs.

Just as Web developers can "sniff" on the `User-Agent` HTTP header to determine what sort of browser is requesting a page, you can use the `Build` class to determine what sort of device is running your app. If you encounter problems with a specific device, you may be able to use `Build` to identify that device at runtime and "route around the damage".

Trail: Integration and Introspection

Writing and Using Parcelables

Parcelable is a marker interface, reminiscent of Serializable, that shows up in many places in the Android SDK. Parcelable objects can be put into Intent extras or Bundle objects, for example. Making your own custom classes implement Parcelable greatly increases their flexibility.

At the same time, Parcelable is something that can be overused. In most Android apps, few if any custom classes really need to have Parcelable capabilities.

In this chapter, we will review how to modify classes to implement Parcelable and what the limitations are on using Parcelable.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

The Role of Parcelable

A Parcelable object is one that can be placed into a Parcel. A Parcel is the primary vehicle for passing data between processes in Android's inter-process communication (IPC) framework.

IPC abounds in Android, even in places where you may not expect it. Every time you call startActivity(), for example, IPC occurs, even if the activity that calls startActivity() and the activity to be started are in the same process. A core OS process is the one that is responsible for identifying the activity to be started and routing control to it, so startActivity() performs IPC from the original activity's process to a core OS process. The core OS process then eventually performs IPC to the target process for the activity to be started.

If you see an `Intent` or a `Bundle` in the Android SDK, odds are that those objects are involved in IPC. That is not always the case — `LocalBroadcastManager`, for example, uses `Intent` objects purely in-process — but it is a reasonable rule of thumb. Hence, there is keen interest in being able to implement `Parcelable` on specific classes, either to pass to other components via `Intent` extras, or to become part of the saved instance state `Bundle`.

`Parcelable` objects are also important for use with remote services via the binding pattern.

Writing a Parcelable

You have three major approaches for adding `Parcelable` capabilities to your classes in Android:

1. Use an annotation processor that will add in the appropriate bits of magic for you
2. Use a code generator site or tool that will take your existing class as input and give you the `Parcelable`-enabled rendition as output
3. Just do it yourself

By Annotations

Enterprising developers have created annotation processing libraries that can be used to add `Parcelable` capabilities to a Java class in an Android app.

One approach is used by Parceler. Here, you just add a `@Parcel` annotation to the Java class, and it code generates what is needed. However, it does *not* actually make the Java class `Parcelable`. Rather, it creates a runtime wrapper class that *is* `Parcelable` and that knows how to convert instances of your own Java class to and from the wrapper. You wind up calling static `wrap()` and `unwrap()` methods on a `Parcels` class to handle the conversion between your class and the generated `Parcelable` class.

AutoParcel takes a slightly different approach. In this case, you need to:

- Add the `@AutoParcel` annotation to the class

- Make the class abstract and have it implement Parcelable
- Write abstract method signatures for getters for the data members

AutoParcel then code-generates a Java class that implements the getters, data members, and Parcelable logic, along with other niceties like equals() and hashCode(). That Java class will be named AutoParcel_, followed by the name of the class with the @AutoParcel annotation (e.g., annotating a Foo class gives you an AutoParcel_Foo class). The AutoParcel-generated class is a concrete subclass of the abstract base class, and so you can just work with the abstract class' public API and let AutoParcel handle the details.

However, neither of these give you classes that play well with the other children. Other code that expects to work with your classes — whether that is passing a Parceler-defined Parcelable to a third-party app or using something like Gson to handle JSON parsing — will not like either Parceler or AutoParcel that much.

By Code Generator Sites and Tools

The Parcelabler Web site is a code generator. You paste in a simple Java class, with the class declaration and data members:

```
class Book {
    String isbn;
    String title;
    int pubYear;
}
```

and it gives you an output class that adds the Parcelable logic:

```
class Book implements Parcelable {
    String isbn;
    String title;
    int pubYear;

    protected Book(Parcel in) {
        isbn = in.readString();
        title = in.readString();
        pubYear = in.readInt();
    }

    @Override
    public int describeContents() {
        return 0;
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeString(isbn);
        dest.writeString(title);
        dest.writeInt(pubYear);
    }

    @SuppressWarnings("unused")
    public static final Parcelable.Creator<Book> CREATOR = new
Parcelable.Creator<Book>() {
        @Override
        public Book createFromParcel(Parcel in) {
            return new Book(in);
        }

        @Override
        public Book[] newArray(int size) {
            return new Book[size];
        }
    };
}
```

We will see in the next section what all of that code does for us, as part of understanding how to build it by hand.

However, the Parcelabler Web site has some limitations in its Java parsing, and so the more complex your Java class, the more likely it is that the Parcelabler site will have difficulty understanding it and blending in the `Parceable` logic.

The ParcelableCodeGenerator project implements a command-line code generator that takes a JSON schema and gives you a Java class that, among other things, has the `Parcelable` implementation.

By Hand

Adding `Parcelable` support yourself is not especially difficult, though it is a bit tedious.

The Parcelable Interface

The first steps is to add `implements Parcelable` to the class. Immediately, your IDE should start complaining that you need to implement two methods to satisfy the `Parcelable` interface.

The easier of the two methods is `describeContents()`, where you will return 0, most likely.

The other method you will need to implement is `writeToParcel()`. You are passed in two parameters: a very important `Parcel`, and a usually-ignored `int` named `flags`.

Your job, in writeToParcel(), is to call a series of write...() methods on the Parcel to write out all data members of this object that should be considered part of the object as it is passed across process boundaries. There are dozens of type-safe methods for writing data into the Parcel:

- methods that write individual primitives (e.g., writeInt()) or Java arrays of primitives (e.g., writeStringArray())
- writeBundle(), for writing out a Bundle
- writeParcelable() and writeParcelableArray(), for writing out other objects that implement Parcelable
- writeFileDescriptor(), for putting a FileDescriptor into the Parcel, with an eye towards allowing whoever reconstitutes the Parcelable to be able to read or write a stream based on that FileDescriptor
- methods to write other "active objects", such as IBinder objects from a remote service binding
- various specialized methods for particular data types (e.g., writeSizeF()) or interfaces (e.g., writeSerializable())

If, in writeToParcel(), you called writeFileDescriptor(), you will want to have describeContents() return CONTENTS_FILE_DESCRIPTOR instead of 0, as apparently the Parcelable support logic needs to know that a file descriptor is in the Parcel.

In the case of the generated Book code shown earlier in this chapter, writeToParcel() writes out the two String and one int data member:

```
@Override
public int describeContents() {
    return 0;
}

@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeString(isbn);
    dest.writeString(title);
    dest.writeInt(pubYear);
}
```

The CREATOR

When Android tries reading objects in from a Parcel, and it encounters an instance of your Parcelable class, it will retrieve a static CREATOR object that must be defined on that class. The CREATOR is an instance of Parcelable.Creator, using generics to tie it to the type of your class:

```
@SuppressWarnings("unused")
public static final Parcelable.Creator<Book> CREATOR = new Parcelable.Creator<Book>() {
    @Override
    public Book createFromParcel(Parcel in) {
        return new Book(in);
    }

    @Override
    public Book[] newArray(int size) {
        return new Book[size];
    }
};
```

The `@SuppressWarnings("unused")` annotation is because the IDE will think that this `CREATOR` instance is not referred to anywhere. That is because it will only be used via Java reflection.

The `CREATOR` will need two methods. `createFromParcel()`, given a `Parcel`, needs to return an instance of your class populated from that `Parcel`. `newArray()`, given a size, needs to return a type-safe array of your class.

The typical implementation of `createFromParcel()` will delegate the actual work to a `protected` or `private` constructor on your class that takes the `Parcel` as input:

```
protected Book(Parcel in) {
    isbn = in.readString();
    title = in.readString();
    pubYear = in.readInt();
}
```

You need to read in the *same* values that you wrote out to the `Parcel`, and in the same order.

By Hand, With a Little Bit of Help

Android Studio 1.3 and higher have a template for a new `Parcelable` class. Right-click over your desired Java package and choose New > Other > New Parcelable Type from the context menu. Fill in your class and the template will create a new standalone Java class, akin to this one:

```
import android.os.Parcel;
import android.os.Parcelable;

public class Item implements Parcelable {

  // TODO declare your real class members
  // Members must be either primitives, primitive arrays or parcelables
  private int mFoo;
  private String mBar;
  // TODO implement your constructors, getters & setters, methods

  private Item(Parcel in) {
    // TODO read your class members from the parcel
    // Note: order is important - you must read in the same order
    // you write in writeToParcel!
    mFoo=in.readInt();
    mBar=in.readString();
  }

  @Override
  public void writeToParcel(Parcel out, int flags) {
    // TODO write your class members to the parcel
    // Note: order is important - you must write in the same order
    // you read in your private parcelable constructor!
    out.writeInt(mFoo);
    out.writeString(mBar);
  }

  @Override
  public int describeContents() {
    // TODO return Parcelable.CONTENTS_FILE_DESCRIPTOR if your class members
    // include a FileDescriptor, otherwise you can simply return 0
    return 0;
  }

  public static final Parcelable.Creator<Item> CREATOR=new Parcelable.Creator<Item>() {
    public Item createFromParcel(Parcel in) {
      return new Item(in);
    }

    public Item[] newArray(int size) {
      return new Item[size];
    }
  };

}
```

You would have to adjust the stock fields (`mFoo`, `mBar`) to be what you need, and adjust the `writeToParcel()` and private constructor to match.

However, this template is designed for starting from scratch; it is not that useful when you have an existing class and wish to now make it be `Parcelable`.

The ParcelablePlease library saves you from having to do all of the reading and writing to and from the `Parcel` yourself. Putting the `@ParceablePlease` annotation on the class generates a class for you (your class name followed by `ParcelablePlease`, so `FooParcelablePlease` for a `Foo` class). This class *only* marshals your data members to and from a `Parcel`, via static `readFromParcel()` and `writeToParcel()` methods. You still have to have the rest of the `Parcelable` boilerplate. Hence, this library is not as powerful as the annotation processors mentioned earlier in this chapter, but you wind up with a "real" complete Java class that can work better with other annotation-based libraries like Gson. On the other hand, it still makes it difficult for you to distribute your code to third parties, as they will need to also have this annotation processing library in their project builds.

The Limitations of Parcelable

While the mechanics of writing a `Parcelable` are not hard, this does not mean that every model object or other POJO in your app should be made `Parcelable`. Overuse of `Parcelable` is a bit of a code smell, as it suggests that the developer is not necessarily considering all of the limitations and effects of the use of `Parcelable`.

The 1MB Limit

The biggest one (pun lightly intended) is the size limitation. A `Parcel` – the IPC structure that is used to pass `Parcelable` objects across process boundaries — has a 1MB size limit. If you get over this limit, you will likely crash with a "Failed Binder Transaction" message as part of the exception's stack trace.

There are two main ways you can reach this limit:

1. Have a `Parcelable` that individually is too large. A common case for this is wrapping a `Bitmap` or other large `byte` array in some `Parcelable` object.
2. Have too many `Parcelable` objects. For example, you might have performed a database query, converted the results into a collection of model objects, then tried to pass that collection to another activity via an `Intent` extra. Syntactically, this can work fine, if the collection and its model objects are all `Parcelable`. But now your risk of hitting the 1MB limit is determined by how many rows there are in the query's result set, and that can vary by user.

Large data like this need to be managed by singletons or other static data members and shared among your application components, rather than passed via `Parcelable` objects.

Pass-By-Value

Suppose we have two activities, A and B. Activity A calls `startActivity()`, identifying activity B in the `Intent`. The `Intent` also includes a custom `Parcelable` object, one that takes up 1KB of space.

Question: how much system RAM is taken up by that `Parcelable`?

Wrong Answer: 1KB.

Right Answer: At least 3KB, as there are at least three copies of the `Parcelable` data:

- One copy is the original `Parcelable` object, the one that is stored as an extra in the `Intent`
- Another copy is the one in the `Parcel` that is held by a core OS process, for handling things like configuration changes and the recent-tasks list, where that `Intent` (and its extras, including your `Parcelable`) are needed
- A third copy is the one in the `Intent` that Activity B receives

`Parcelable` is, in effect "pass-by-value", as the `Parceable` object is copied as part of getting it across the process boundary twice, once from your process to the core OS, and once from the core OS back to your process.

This means that modifications that Activity B makes to the `Parcelable` object will not be seen by Activity A, as they are working on separate copies of the object. Similarly, changes that Activity B makes to the `Parcelable` will not affect the copy held by the core OS process and re-delivered to Activity B on a configuration change.

The safest way to help defend against mistakes related to this is to consider a `Parcelable` object to be an immutable object. Only configure it through a constructor (possibly with the assistance of some `Builder` if you want a cleaner API). Offer getters for the values in the `Parcelable`, but do not offer any setters, so once the instance is created, it cannot be changed.

Also note that these copies magnify the effects of having a large `Parcelable` object, or too many `Parcelable` objects in a `Parcel`. A 900KB `Parcel` might fit within the 1MB size limit, but it would consume at least 2.7MB if the `Parcel` is part of some IPC.

Conversely, there are cases where `Intent` objects are not passed across process boundaries, such as `LocalBroadcastManager`. In those cases, neither the 1MB limit nor the pass-by-value effect are an issue. Only if the `Intent` is "flattened" into a `Parcel`, and later converted back into an `Intent`, do these extra copies and the 1MB limit come into play.

The ClassLoader Conundrum

Sometimes, weird stuff happens, particularly when trying to read in other Parcelable objects that you wrote to the Parcel. In this case, the Parcel system needs to use Java reflection to find the Java class associated with the Parcelable objects, and sometimes it gets a bit lost.

When you use readParcelable() to read in the Parcelable objects out of the Parcel, you may need to supply the ClassLoader that you know has those Parcelable classes.

For example, the CWAC-Pager project implements a PagerAdapter named ArrayPagerAdapter. The use of ArrayPagerAdapter is covered elsewhere in the book, but it makes it easier for you to add, insert, and remove pages on the fly from a ViewPager. To accomplish this, it holds onto a series of PageEntry objects, where PageEntry implements Parcelable. PageEntry, in turn, holds onto two other Parcelable objects:

1. a PageDescriptor named descriptor
2. a Fragment.SavedState named state

To reliably be able to read in these values from a Parcel, it was necessary to manually stipulate the ClassLoader to use:

```
PageEntry(Parcel in) {
  this.descriptor=in.readParcelable(getClass().getClassLoader());
  this.state=in.readParcelable(getClass().getClassLoader());
}
```

Here, we are using the same ClassLoader that has this PageEntry class.

Sharing Between Apps

Parcelable objects need to read and write the same values to and from the Parcel. This sounds simple, but it gets into some nasty issues when multiple code bases need to work with the Parcelable.

For example, suppose your app offers an SDK, such as a remote service. You have some custom Parcelable objects that you can either give to third-party clients of your app or get as input from those clients. Now, your SDK needs to ship implementations of the Parcelable classes; without them, clients cannot use you exposed service API.

What happens now, if you change the definition of the `Parcelable`? Bear in mind that:

- You may not be able to control when third-party developers take on some new version of your SDK
- You may not be able to control when end users update your app
- You may not be able to control when end users update third-party client apps

As a result, it is reasonably likely that your `Parcelable` implementations will be out of sync on a user's device, with your app having one implementation and a third-party app having another implementation. The results of this may not be pretty.

This is not a problem for purely internal uses of `Parcelable`, such as for holding onto data across a configuration change.

Responding to URLs

You may have noticed that Android supports a `market:` URL scheme. Web pages can use such URLs so that, if they are viewed on an Android device's browser, the user can be transported to a Play Store page, perhaps for a specific app or a list of apps for a publisher.

Fortunately, that mechanism is not limited to Android's code — you can get control for various other types of links as well. You do this by adding certain entries to an activity's `<intent-filter>` for an `ACTION_VIEW` `Intent`.

However, be forewarned that this capability is browser-specific. What works on the original Android "Browser" app and Google's Chrome may not necessarily work on Firefox for Android or other browsers.

Prerequisites

Understanding this chapter requires that you have read the chapter on `Intent` filters.

Manifest Modifications

First, any `<intent-filter>` designed to respond to browser links will need to have a `<category>` element with a name of `android.intent.category.BROWSABLE`. Just as the `LAUNCHER` category indicates an activity that should get an icon in the launcher, the `BROWSABLE` category indicates an activity that wishes to respond to browser links.

You will then need to further refine which links you wish to respond to, via a `<data>` element. This lets you describe the URL and/or MIME type that you wish to respond to. For example, here is the `AndroidManifest.xml` file from the [`Introspection/URLHandler`]() sample project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
          package="com.commonsware.android.urlhandler"
          android:versionCode="1"
          android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="19"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <application
    android:icon="@drawable/cw"
    android:label="@string/app_name">
    <activity
      android:name="URLHandler"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
      <intent-filter>
        <action android:name="android.intent.action.VIEW"/>

        <category android:name="android.intent.category.DEFAULT"/>
        <category android:name="android.intent.category.BROWSABLE"/>

        <data android:mimeType="application/pdf"/>
      </intent-filter>
      <intent-filter>
        <action android:name="android.intent.action.VIEW"/>

        <category android:name="android.intent.category.DEFAULT"/>
        <category android:name="android.intent.category.BROWSABLE"/>

        <data
          android:host="www.this-so-does-not-exist.com"
          android:path="/something"
          android:scheme="http"/>
      </intent-filter>
      <intent-filter>
        <action android:name="com.commonsware.android.MY_ACTION"/>

        <category android:name="android.intent.category.DEFAULT"/>
        <category android:name="android.intent.category.BROWSABLE"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Here, we have four <intent-filter> elements for our one activity:

- The first is a standard "put an icon for me in the launcher, please" filter, with the LAUNCHABLE category
- The second claims that we handle PDF files (MIME type of application/pdf), and that we will respond to browser links (BROWSABLE category)
- The third claims that we will handle any HTTP request (scheme of "http") for a certain Web site (host of "www.this-so-does-not-exist.com" and path of /something), and that we will respond to browser links (BROWSABLE category)
- The last is a custom action, for which we will generate a URL that Android will honor, and that we will respond to browser links (BROWSABLE category) — we will examine this more closely in the next section

What happens for the first two links varies based on browser.

The original Android "Browser" app, and Google Chrome, will do the following:

- Tapping the link to the PDF, on Android 2.3+, will trigger a download of the PDF. When the user taps on the downloaded file (e.g., from the Notification in the status bar), the user will have URLHandler as one of the options in the chooser to view the PDF file.
- Tapping the link to http://www.this-so-does-not-exist.com/something will bring up a chooser showing all available Web browser, plus URLHandler, as expected

Firefox for Android will treat the PDF link the same way. However, Firefox for Android does not check the URL for the second link to see if there is anything else supporting ACTION_VIEW for the URL, and so it always loads up the Web page. You see this effect with the link to Barcode Scanner as well — even though a device has Barcode Scanner installed, Firefox never offers that as an option.

Creating a Custom URL

Responding to MIME types makes complete sense… if we implement something designed to handle such a MIME type.

Responding to certain schemes, hosts, paths, or file extensions is certainly usable, but other than perhaps the file extension approach, it makes your application a bit fragile. If the site changes domain names (even a sub-domain) or reorganizes its site with different URL structures, your code will break.

If the goal is simply for you to be able to trigger your own application from your own Web pages, though, the safest approach is to use an `intent:` URL. These can be generated from an `Intent` object by calling `toUri(Intent.URI_INTENT_SCHEME)` on a properly-configured `Intent`, then calling `toString()` on the resulting `Uri`.

For example, the `intent:` URL for the fourth `<intent-filter>` from above is:

```
intent:#Intent;action=com.commonsware.android.MY_ACTION;end
```

This is not an official URL scheme, any more than `market:` is, but it works for Android devices. When the Android built-in Browser encounters this URL, it will create an `Intent` out of the URL-serialized form and call `startActivity()` on it, thereby starting your activity. Chrome also supports this URL structure. Firefox for Android does not, indicating instead that it cannot recognize the URL.

Reacting to the Link

Your activity can then examine the `Intent` that launched it to determine what to do. In particular, you will probably be interested in the `Uri` corresponding to the link — this is available via the `getData()` method. For example, here is the `URLHandler` activity for this sample project:

```
package com.commonsware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    TextView uri=(TextView)findViewById(R.id.uri);

    if (Intent.ACTION_MAIN.equals(getIntent().getAction())) {
      String intentUri=(new Intent("com.commonsware.android.MY_ACTION"))
                          .toUri(Intent.URI_INTENT_SCHEME)
                          .toString();
      uri.setText(intentUri);
      Log.w("URLHandler", intentUri);
    }
    else {
      Uri data=getIntent().getData();

      if (data==null) {
        uri.setText("Got com.commonsware.android.MY_ACTION Intent");
      }
      else {
        uri.setText(getIntent().getData().toString());
      }
    }
  }

  public void visitSample(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW,
                             Uri.parse("https://commonsware.com/sample")));
  }
}
```

This activity's layout has a `TextView` (uri) for showing a `Uri` and a `Button` to launch a page of links, found on the CommonsWare site (`https://commonsware.com/sample`). The `Button` is wired to call `visitSample()`, which just calls `startActivity()` using the aforementioned URL to display it in the user's chosen Web browser.

When the activity starts up, though, it first loads up the `TextView`. What goes in there depends on how the activity was launched:

1. If it was launched via the launcher (e.g., the action is `MAIN`), then we display in the `TextView` the `intent:` URL shown in the previous section, generated from an `Intent` object designed to trigger our fourth `<intent-filter>`. This also gets dumped to LogCat, and is how the author got this URL in the first place to put on the sample Web page of links.
2. If it was not launched via the launcher, it was launched from a Web link. If the `Uri` from the launching `Intent` is `null`, though, that means the activity was launched via the custom `intent:` URL (which only has an action string), so we put a message in the `TextView` to match.
3. Otherwise, the `Uri` from the launching `Intent` will have something we can use to process the link request. For the PDF file, it will be the local path to the downloaded PDF, so we can open it. For the `www.this-so-does-not-exist.com` URL, it will be the URL itself, so we can process it our own way.

Note that for the PDF case, clicking the PDF link in the Browser will download the file in the background, with a Notification indicating when it is complete. Tapping on the entry in the notification drawer will then trigger the URLHandler activity.

Also, bear in mind that the device may have multiple handlers for some URLs. For example, a device with a real PDF viewer will give the user a choice of whether to launch the downloaded PDF in the real view or URLHandler.

App Links

We have had the ability to have activities with <intent-filter> elements that support custom schemes (e.g., myapp://) since Android 1.0. The benefit over using a custom scheme is that, if it is unique on the device, an Intent for that custom scheme will go straight to the desired activity. However, this approach had a lot of flaws:

- There is no guarantee of uniqueness
- Few apps would recognize the custom scheme and issue an ACTION_VIEW Intent on the desired Uri
- If the user *did* encounter a link that would try to issue the ACTION_VIEW Intent, and the app handling that custom scheme was not installed, the request would simply fail

Using an <intent-filter> advertising support for some http or https URL would improve the results for the latter two issues, as many more apps would recognize the URL as being a URL, and usually the fallback would be to have a browser open up on that URL. However, now it is guaranteed that the scheme is *not* unique. Users would initially get a chooser, to determine what activity should handle the request. This can be confusing, particularly since the chooser does not really indicate the scope of the choice (would I be saying that XYZ app is now handling all Web links?).

Android 6.0 added an interesting solution for this. If you use a <intent-filter> for a domain that you control, you can publish a bit of metadata, as a JSON file, on the Web server. Android can be taught to sniff for that metadata and use it to validate that the app was developed by the same person or group that runs the server for the identified domain. In that case, Android will bypass the chooser and go straight to the activity with the domain-specific <intent-filter>. The cited example would be Twitter doing this, so any link click on a twitter.com URL would bring up the Twitter app, not a Web browser.

Of course, these links are only so useful. They are fine for when a link appears in an ordinary app. Web browsers, however, tend not to actually see whether a URL they encounter is handled by some on-device app. Android 6.0 does not change this behavior. So, links on Web pages viewed in 2015 versions of Firefox will not honor your desired `<intent-filter>` regardless of whether you are using this new app link system or not. Chrome's behavior varies by version.

That being said, app links still have their uses (e.g., responding to links from social media posts).

Setting Up the IntentFilter

Supporting an `<intent-filter>` for some `http` or `https` URL has been possible since Android 1.0. The only thing that is different is that now you can add an `android:autoVerify="true"` to the `<intent-filter>` element, to tell Android that you would like it to verify the connection between the app and the domain used in the `<intent-filter>`, to skip the chooser when URLs for that domain trigger your `<intent-filter>`.

For example, the [Introspection/URLHandlerMNC]() sample project is a revised version of the `URLHandler` sample, one that switches its `http` `<intent-filter>` to look for `https://commonsware.com` URLs, and it incorporates `android:autoVerify="true"`:

```
    <intent-filter android:autoVerify="true">
      <action android:name="android.intent.action.VIEW"/>

      <category android:name="android.intent.category.DEFAULT"/>
      <category android:name="android.intent.category.BROWSABLE"/>

      <data
        android:host="commonsware.com"
        android:scheme="https"/>
    </intent-filter>
```

On pre-Marshmallow versions of Android, this attribute will be ignored, as it will not be recognized. But, on Android 6.0+, this attribute will be used to attempt to validate that your app was written by somebody who owns the specified domain.

The author of this book owns the `commonsware.com` domain. To actually run this project and have the updated app linking work, you would need to switch this to be some domain that *you* control.

Note that while `android:autoVerify="true"` is written at the scope of a single `<intent-filter>`, it affects *all* activities and *all* `<intent-filter>` structures. *All* of them that use http or https as the android:scheme must support the app links protocol described in this chapter. You cannot have some filters supporting app links and others not — either they *all* support app links, or none will.

Setting Up the JSON

When Android installs an app that has one or more <intent-filter> elements with android:autoVerify="true", it will attempt to find a JSON file on the identified server. Specifically, for the sample app, the Android 6.0 will create a URL of the form:

```
https://commonsware.com/.well-known/assetlinks.json
```

In your app, commonsware.com would be replaced with the domain you have in your <intent-filter>.

This URL is part of a proposed IETF standard that unfortunately does not appear to be formally documented.

Android 6.0+ will use HTTPS to retrieve your assetlinks.json file, regardless of the scheme that you use in the <intent-filter>. Also, the JSON needs to be publicly accessible, without any forms of authentication.

The JSON content itself is an array of JSON objects, one object per application ID that you publish as an app:

```
[
  {
    "relation": ["delegate_permission/common.handle_all_urls"],
    "target": {
      "namespace": "android_app",
      "package_name": "com.commonsware.android.urlhandler",
      "sha256_cert_fingerprints": ["A9:99:84:D8:...:60:5B:CB:E3"]
    }
  }
]
```

(the sha256_cert_fingerprints value is shown truncated for easier reading)

Here, the only two variable bits are:

1. The package_name, which will be your application ID, and

2. The sha256_cert_fingerprints array, which will list the SHA256 hashes of your public signing keys, for whatever keystores you might be using for this app (e.g., your debug keystore and your production keystore)

To get the SHA256 hash of your public signing key, you will need to use the keytool command from your Java SDK (Java 7 or higher required):

```
keytool -list -v -keystore ...
```

where ... is the path to your keystore (e.g., ~/.android/debug.keystore for your debug keystore on OS X and Linux).

You will need to provide the password to the keystore. For the debug keystore, this is android.

As part of the output, you will get the SHA256 hash:

```
Keystore type: JKS
Keystore provider: SUN

Your keystore contains 1 entry

Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate[1]:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
   MD5:  98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
   SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
   SHA256: A9:99:84:D8:...:60:5B:CB:E3
   Signature algorithm name: SHA1withRSA
   Version: 3

*******************************************
*******************************************
```

(the SHA256 value is shown truncated for easier reading)

That long set of hex digits will need to go in the sha256_cert_fingerprints JSON array.

The rest of the JSON is fixed. Try not to introduce other JSON properties and such into this file, as they may cause your file to fail validation. However, you can have multiple JSON objects for multiple apps, each providing the relation and target properties.

According to this Google+ post, there are some undocumented things to note about the assetlinks.json file:

- The /.well-known/assetlinks.json for your scheme and host must return the result directly, not via a redirect (HTTP 30x) response. This was documented as being the case for the M Developer Preview; the official documentation does not mention this.
- To help overcome the above limitation, instead of having the actual JSON file at that path, you can have a stub JSON file that uses an include value to point to some other URL which will have the real assetlinks.json file:

```
[{ "include": "https://someother.com/this_is_my_boomstick.json" }]
```

Note that the author has not tested the include option, nor is the author presently in possession of a boomstick.

Results

Our URLHandler activity not only responds to http://misc.commonsware.com URLs, but it uses one if the user taps the "view-sample" button:

```
package com.commonsware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    if (Intent.ACTION_VIEW.equals(getIntent().getAction())) {
      findViewById(R.id.visit).setEnabled(false);
    }
  }

  public void visitSample(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW,
                             Uri.parse("https://commonsware.com/Android/")));
  }
}
```

There, we launch an ACTION_VIEW Intent on a http://commonsware.com/Android URL via startActivity().

On a pre-Marshmallow device, this startActivity() request will normally bring up a chooser, offering the URLHandler activity along with Web browsers and potentially other apps.

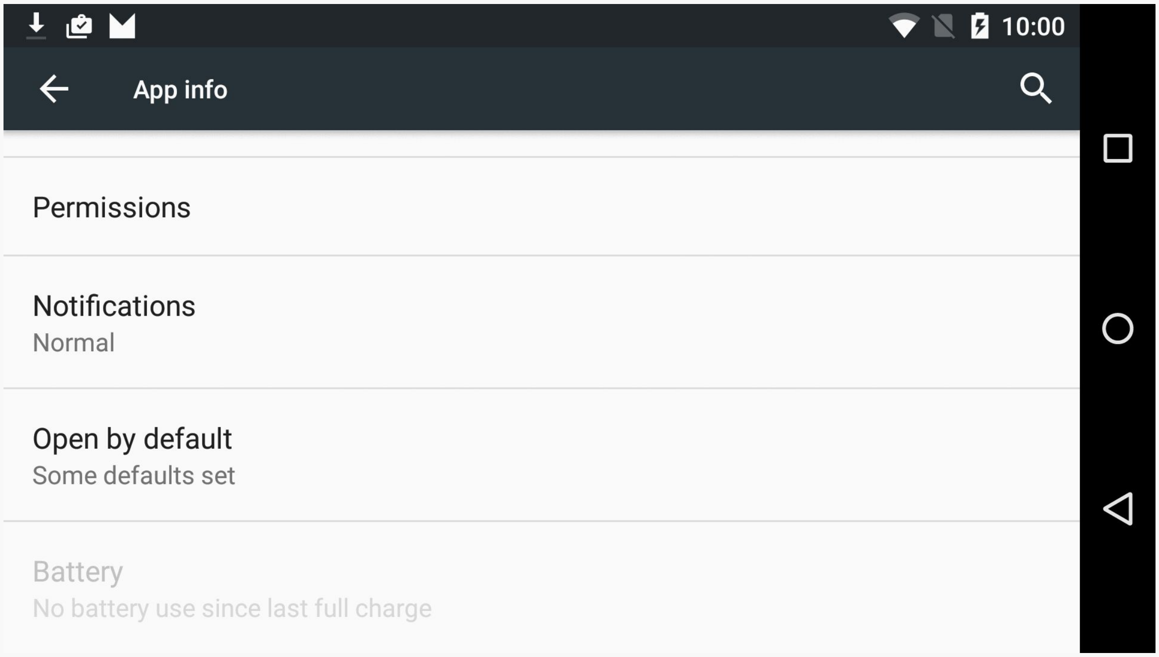
On an Android 6.0+ device, in the normal case, if the server is configured properly with the above JSON, and if the app was compiled by the author of this book, the chooser is bypassed, and the user gets another instance of URLHandler. The "another instance" part can be controlled via Intent flags or manifest entries, as is covered in the chapter on tasks.

However, this is not assured:

- If *you* compile and run the app, your signing key should not match the JSON-published fingerprint, and so the validation will fail and normal chooser behavior will return. You would have to substitute some URL of your own with a corresponding JSON file on that server that contains your hash.
- If the server is mis-configured (e.g., JSON not available via HTTPS), the validation will fail and normal chooser behavior will return.
- If the app is not signed with the correct signing key — such as the user is really running a copy of your app with injected malware and somebody else's signing key — the validation will fail and normal chooser behavior will return.
- If there is no connectivity at the time the user installs the app (e.g., they are side-loading it), the validation will fail and normal chooser behavior will return. The device may try to validate again in the future, though.

User Intervention

Another thing that can change the behavior to return is if the user revokes the app link. Users can do this by going to the app's screen in the Settings app and clicking the "Open by default" option:



10:00

App info

Permissions

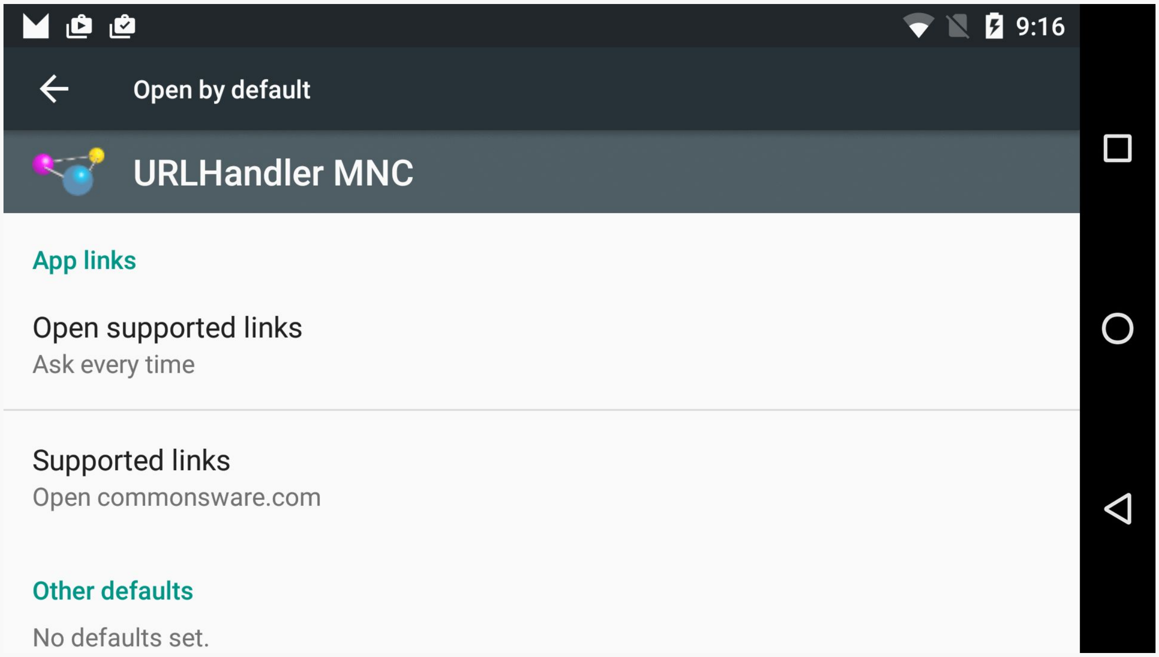
Notifications
Normal

Open by default
Some defaults set

Battery
No battery use since last full charge

Figure 767: URLHandlerMNC in Settings, "Open by default" Visible

If the user taps that entry, one section of the next screen is entitled "App links" and gives the user the option to toggle the app link behavior off:



Open by default

URLHandler MNC

App links

Open supported links
Ask every time

Supported links
Open commonsware.com

Other defaults

No defaults set.

Figure 768: URLHandlerMNC in Settings, "Open by default" Screen

Unfortunately, the labeling here does not seem to work properly. The "Ask every time" choice shown selected here actually bypasses the chooser. The available choices are "open in this app", "ask every time", and "don't open in this app":

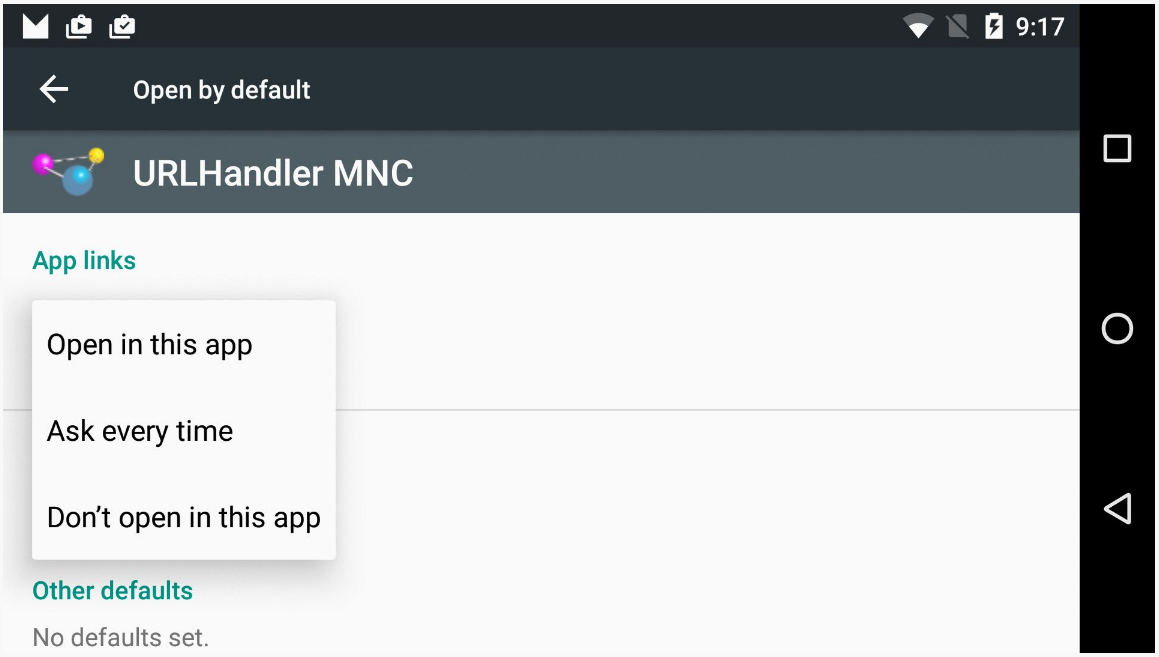


Figure 769: URLHandlerMNC in Settings, "Open supported links" Options

Testing Your Setup

You can confirm that other parties can see your `assetlinks.json` file by visiting the following URL:

```
https://digitalassetlinks.googleapis.com/v1/statements:list?
  source.web.site=https://DDDDD&
  relation=delegate_permission/common.handle_all_urls
```

(NOTE: the URL shown above is split across several lines for readability but should be all on one line when actually using the URL)

Replace `DDDDD` with the domain name for your site, and you should get a JSON document back that, among other things, contains the details from your `assetlinks.json` file:

```
{
  "statements": [
    {
      "source": {
        "web": {
          "site": "https://commonsware.com."
        }
      },
      "relation": "delegate_permission/common.handle_all_urls",
      "target": {
        "androidApp": {
          "packageName": "com.commonsware.android.urlhandler",
          "certificate": {
            "sha256Fingerprint": "A9:99:84:D8:...:60:5B:CB:E3"
          }
        }
      }
    }
  ],
  "maxAge": "3213.779933024s"
}
```

(sha256Fingerprint truncated for readability)

If you try visiting that URL, and there is no assetlinks.json file available for that domain, you will get a JSON response back containing a debugString indicating the nature of the problem.

You can see if an Android device in your lab has successfully performed the app link validation by running the **adb shell dumpsys package domain-preferred-apps** command. This will list all of the apps that have app links, and your app should appear among them, in a stanza like this one:

```
  Package: com.commonsware.android.urlhandler
  Domains: commonsware.com
  Status:  never
```

The status will reflect the user's choice of how to handle your app link inside of Settings (the never shown above indicates that the user decided to ignore your app link and have your app never handle such URLs).

Plugin Patterns

Plugins have historically been a popular model for extending the functionality of a base application. Browsers, for example, have long used plugins for everything from playing Flash animations to displaying calendars.

While Android does not have a specific "plugin framework", many techniques exist in Android to create plugins. Which of these patterns is appropriate for you will depend upon the nature of the host application and, more importantly, on the nature of the plugin. This chapter will explore some of these plugin patterns.

Prerequisites

Having read the chapters on app widgets (to be exposed to `RemoteViews`) and the `Loader` framework would be useful, though neither is essential for grasping the core concepts presented in this chapter. Similarly, this chapter has a case study that covers a lockscreen widget, so knowing a bit about those will help, but is not absolutely essential. Another sample involves the use of custom permissions, which are subject to a vulnerability covered in another chapter.

Definitions, Scenarios, and Scope

For the purposes of this chapter, a "plugin model" refers to an app (the plugin "host") that is being extended by other apps (the "plugins") that are largely dedicated to that job.

Certainly, there are plenty of ways that apps can work together without one being a plugin to another. The user's Web browser is not a plugin of your app when you call `startActivity()` to view a Web page, for example.

By contrast, the Locale app can be extended via plugins, written either by two forty four a.m. (the authors of Locale) or third parties. These plugins have no real value to the user other than by how they improve what Locale itself can do. This sort of structure, therefore, qualifies as a plugin model.

In particular, this chapter will focus on two general scenarios for wanting a plugin model, though others certainly exist:

1. You want to allow third parties to extend the capability of your app, much as two forty four a.m. wanted with Locale, or
2. You want to reduce the number of permissions in your core app by delegating some permissions to plugins, so users can "opt into" those permissions

The Keys to Any Plugin System

There are four essential ingredients for any plugin model:

1. Somehow, the user has to be able to find, download, and install plugins for the host.
2. Somehow, the host app has to know what plugins are installed and available for use.
3. Somehow, the host app and the plugin need to communicate, usually through one form or another of inter-process communication (IPC)
4. All of this needs to be done without compromising the user's privacy or security

Depending upon the nature of the host app and plugin system, there may need to be additional ingredients (e.g., allowing users to configure the behavior of plugins).

Discovery… By the User

A popular thought experiment is:

> If a tree falls in a forest and no one is around to hear it, does it make a sound?

The analog to plugins is:

> If an app offers a plugin model, and the user cannot find any plugins, is there really a plugin model?

Somehow, users need to know about available plugins, and frequently that means that *you* will need to help steer them towards those plugins.

If you are focused solely on distributing through the Play Store, you could invite all of your plugin authors to use some particular keyword or phrase, likely to be unique for your plugins, then use `market://search?q=...&c=apps` (with `...` replaced by your keyword or phrase) as a `Uri` for an `ACTION_VIEW` `Intent` passed to `startActivity()`. This will show the user a list of all apps on the Play Store with that keyword or phrase. For example, SONY suggested that developers writing extensions for the SONY SmartWatch use “smartwatch” as a keyword.

Of course, you are welcome to maintain your own roster of available plugins, where your app can download that roster as needed and display the candidates to your users. For example, you might have a JSON file on your Web server at a well-known URL that contains the current lineup of available plugins.

Or, you are welcome to simply offer this sort of information via your Web site, not from within your app. Depending upon how frequently users will be visiting your Web site, this may or may not be helpful to them, but it may be simpler than doing something custom built into your app. For example, you could maintain a simple static Web page with links to the plugins.

Discovery… By Your App

Once a user installs one or more plugins, your plugin host app needs to know that they are there. Continuing with the thought experiments:

> If an app offers a plugin model, but fails to recognize any plugins, is there really a plugin model?

Conversely, once a user *removes* a plugin, your host app needs to know about that as well, so that you do not try to use a plugin that no longer exists.

There are any number of possible strategies for finding available plugins; the following sections outline a few candidates.

Broadcast-and-Response

One approach is to send a custom broadcast `Intent`, at relevant points in time, that is an advertisement to plugins, saying "Hey! Tell me that you exist!". Plugins, as part of your instructions for writing a plugin, are obligated to respond to that broadcast by doing something to let you know about them, such as:

- Sending their own broadcast back to your host app, providing details about the plugin
- Inserting or updating an entry in a host-published `ContentProvider`
- Sending a command to a host-supplied `IntentService`
- Etc.

Any previously-existing plugins that do not respond within some specific period of time are considered "gone", possibly with the host app using `PackageManager` and `getPackageInfo()` to confirm that it is gone.

This is fairly easy to set up, but suffers from non-deterministic timing of broadcasts. The host app can only guess when the broadcast has had enough time to reach all of the plugins and gather responses. It also forces all of those plugin apps to run (to respond to the broadcast), which will cause Android to eject other apps from memory, possibly irritating the user.

Another limitation is that a newly-installed plugin will not respond to a broadcast, on Android 3.1+, until something manually runs one of that plugin's components, such as the user tapping on the plugin's activity in the launcher. Not only does this require the plugin to have such an activity (which might not otherwise be needed), but it means that the plugin is useless until this happens. We will discuss this issue a bit more later in this chapter.

Scanning with PackageManager

You could skip the broadcast and directly use `PackageManager` to find plugins. The benefit here is that the timing is deterministic — you know precisely when you are done with `PackageManager`. However, somehow, you will need to know what is and is not a plugin, in a way that you can determine by information returned from `PackageManager`.

If you happen to know the complete list of possible plugins, you could iterate over that list and use `getPackageInfo()` to see which ones exist and do not exist.

However, this reduces your flexibility, as it requires you to know up front the package names of all possible plugins.

Or, you could use `queryIntentActivities()`, `queryIntentServices()`, or `queryBroadcastReceivers()`, providing an `Intent` that identifies some operation a plugin is obligated to implement, to see what matches are found.

There is also a `queryContentProviders()`, but as it does not take an `Intent`, you would have to iterate over each returned `ProviderInfo` to try to determine if it is a `ContentProvider` representing a plugin.

Alternatively, you could call `getInstalledPackages()` on `PackageManager`, to find out about *everything* that is installed, then iterate over them looking for something.

Watching Package-Related Broadcasts

If using `PackageManager` to examine all possible plugins is still too slow, you could optimize things a bit by watching for `ACTION_PACKAGE_ADDED`, `ACTION_PACKAGE_REPLACED`, and `ACTION_PACKAGE_REMOVED` broadcasts, to monitor *changes* to the mix of installed packages. If a known plugin is removed, you can remove it from your roster of installed plugins. When packages are added or replaced, you could use `PackageManager` and `getPackageInfo()` to learn about that specific package, to determine if it represents one of your plugins.

This, however, increases the complexity of your app, as now you need to monitor these broadcasts and maintain your own roster of available plugins somewhere.

Discovery and Usage of the IPC Endpoints

Given that you know that you have a certain number of plugins, represented by a certain set of packages, you can work on actually communicating with them, using any of the available IPC mechanisms. Also, for static data, you have the option of using manifest metadata or well-known resources to publish that data.

No matter what you settle upon, though, you need to consider the impacts of changes to your host app, that might require changes to your interaction with plugins. Everything in this section qualifies as an API that your host app offers to plugins; changes to that API will require you to consider versioning and backwards compatibility.

Component IPC Options

Your plugin could:

- Have an activity, supporting an agreed-upon `Intent` structure, that your app opens as needed
- Have a service, supporting an agreed-upon `Intent` structure, that your app sends commands to or binds to as needed
- Have a `BroadcastReceiver`, supporting an agreed-upon `Intent` structure, that your app can send broadcasts to as needed

For any of those, you would use `setComponentName()` as part of the `Intent`, to specifically identify the plugin that you are talking to.

Your plugin could also have a `ContentProvider` that your host communicates with. That, however, requires that you somehow find out the appropriate authority to use. That authority might be obtained by an agreed-upon algorithm based upon the package name (e.g., the authority is the plugin's package name plus `.PROVIDER`). Or, that authority might be determined by some static data, techniques for which are described in the next section.

In any of these cases, your host's plugin model would document the expectations the host would have of the plugins:

- What `Intent` extras are supported, what their meanings are, and what the data types are for the extras' keys
- What the schema is for the `ContentProvider`
- Etc.

Your host could also be publishing activities, services, receivers, or providers for the plugin to use. So, for example, your host could send a command to a plugin's `IntentService`, that turns around and modifies data in your host's exported `ContentProvider`.

What data is transferred between the host and plugin, of course, is up to you. Bear in mind, though, that IPC cannot handle arbitrary objects. You will need to stick to primitives and basic collections, framework-supplied `Parcelable` classes (e.g., `Bundle`), or your own custom `Parcelable` classes.

Static Data Options

Some information that you might need about the plugin is static. In those cases, you do not need to use IPC to get the data, thereby saving the cost of loading the plugin into memory just to invoke some component inside of it.

One option for static data is to use manifest metadata. Any `<activity>`, `<service>`, or `<receiver>` element can have one or more child `<meta-data>` elements. These can hold static data that your host app can read in. There are two major flavors of `<meta-data>` elements:

- A simple key/value pair, where the key is provided by `android:name` and the value is provided by `android:value`
- A key pointing to a resource ID to some other resource, frequently an XML resource (i.e., file in `res/xml/`), providing more details, where the key is in `android:name` and the resource ID is `android:resource`

You will see this approach used in places like app widgets, which use a `<meta-data>` element to point to the app widget metadata, which resides in a separate XML resource.

Your app reads in these values — as literals or identifiers to resources — by retrieving an `ActivityInfo` or `ServiceInfo` object from `PackageManager` for the component (e.g., `getActivityInfo()`, `getReceiverInfo()`, `getServiceInfo()`), then examining the `Bundle` in the `metaData` field of that `...Info` object.

There is nothing stopping you from requiring your plugins implement certain resources or assets in agreed-upon paths. You could then access those resources — or ones from `android:resource` in a `<meta-data>` element — via a `Context` created from `createPackageContext()`. `createPackageContext()` is available on any `Context`, such as an `Activity` or `Service`. Given the package name of your plugin, it gives you a `Context` object that you can use to retrieve resources (`getResources()`) or assets (`getAssets()`) much as you do with one of your own contexts.

Versioning

Any time you are providing programmatic access to your app to others, or any time you are expecting others to provide programmatic access to their apps based upon your specification, you need to bear in mind that your needs may change over time. You may want additional extras, or new bits of static data, or new `Intent` actions. And while you can change your app to take into account your new requirements:

- You have no means of forcing third-party developers to update their apps in lock-step with yours
- You have no means of forcing users to update their plugins and such in lock-step with updating your host app

Hence, you are going to need to deal with versioning your plugin API and supporting older API versions, to offer backwards compatibility for not-yet-updated plugins.

A `<meta-data>` element is perhaps the easiest way to have plugins declare what API version they support. This way, you can find out what "language" the plugin speaks before you try talking to it.

When you then communicate via IPC to the plugins, you will need to take into account what API version the plugin speaks, and adjust your communications accordingly. For example, if you are binding to a plugin's service, you would need to make sure that you are using the right AIDL, to get the right client-side proxy object, one that has the methods and parameters that the plugin supports.

Conversely, if you are providing ways for plugins to initiate communications back to you, you will have to take into account that plugins could be using any outstanding API version. You might elect to use different `Intent` actions or provider authorities to help distinguish the API versions. For example, the plugin sending a command to your service might use `com.suchandso.app.ACTION_PLUGIN.V1` or `com.suchandso.app.ACTION_PLUGIN.V2` in its `Intent`, so you have the flexibility of having a single `Service` handle both of those operations, or splitting them into separate `Service` classes if you feel that will help improve maintainability.

On the whole:

- Be careful in what you send to the plugins. If you claim that certain extras are of certain data types, stick with that, trying to avoid sending other data types that the plugins might not expect.
- Be generous in what you accept from the plugins, particularly where you are changing what you accept from version to version of your API. If you declared that an extra sent to you was originally an `int` and now is a `String`, ideally your new-version code would accept *either* an `int` or a `String`, to help ease the transition.
- Be slow to discontinue support for old API versions. You might use analytics or other data collection mechanisms to get a sense for how many devices are using plugins that speak a particular API version, to give you an idea of how

much grief you will get from users if you drop support for that API version and therefore disable certain plugins in an upgrade to your app.

Security

Any time you have inter-process communication, you open up security risks. Hence, intentionally doing IPC means that you intentionally have to consider how best to secure that IPC, to reduce those risks.

Here are three areas of security for you to consider with your plugin model:

User Safe from Permission Leakage

Your plugins, and perhaps the plugin host, may hold various Android permissions, like `READ_CONTACTS` or `INTERNET`. It is incumbent upon you to make sure that either:

- You do not expose information tied to such permissions through your plugin model API (either the host talking to a plugin or vice versa) in a way that other apps could intercept, or
- You ensure that the other party holds the same permission, so that the user knows that the secured information is moving from point to point

For example, suppose that your host app does not hold `READ_CONTACTS`, but a plugin does, specifically to allow the host app to get access to contact information. You need to make sure that, while the host app can get this contact information from the plugin, nobody else can.

Ideally, a plugin developer can be confident that, when the plugin sends information via IPC to the host app, that it is *really* the host app that the plugin is talking to. If some other app can pretend to be the host app, and intercept that information, that other app could potentially use that information to nefarious ends.

Partially, this is an extension of the permission leakage issue described above. It's bad enough that a plugin might leak data to a host app that is not authorized for that data; it is worse if some other app can intercept that data as well.

However, it may be that the data being transferred is not covered by an explicit Android permission, yet might represent information that the user is expecting to keep secure. A financial planner host app using plugins to collect a user's financial data from various banks and brokerages should be taking steps to ensure that the plugin data *only* flows back to the host app, and not to any other apps. This comes despite the fact that Android does not have an `ACCESS_FINANCIAL_DATA` permission as part of the core operating system.

Mostly, this involves having the plugin explicitly state the component that it is communicating with via IPC, rather than relying upon Android derive that information via `Intent` resolution or similar approaches. So, for example, rather than calling `startService()` with just an `Intent` action identifying the host, also set the `ComponentName` on the `Intent` to specifically direct the command to the host app, not to something else advertising that same `Intent` action.

If the host and all its plugins are written by the same firm, you can also use signature-level permissions to restrict access, limiting the IPC to only apps signed by the same signing key.

Host Safe from Trojans

Conversely, if the host app supplies information to the plugins that might represent private or secure data, we need to make sure that the user is comfortable with that data being transferred.

Partially, this involves creating a custom permission that plugins must hold, letting the user know at the time of installing the plugin that this data will be transferred.

Partially, this is making sure that this data is only delivered to the plugins (and, if possible, only to the plugins that specifically need this data). Hence, rather than broadcast `Intents` — even ones where you require a specific permission be held by the receiver — consider using other IPC options that are more “point-to-point”, such as sending commands to a specific service identified by its `ComponentName`.

Case Study: DashClock

A Googler’s take on an app with a plugin model can be found in DashClock, written by Roman Nurik. DashClock is open source, making it easy to see how he elected to implement his plugin model.

What is DashClock?

Android 4.2 added the notion of lockscreen widgets, app widgets that can go on the lockscreen. DashClock is one such lockscreen widget, designed to replace the standard clock. But, more importantly, it offers a plugin model, so third-party apps can provide dynamic data to be displayed by DashClock, without themselves having to have a lockscreen widget. Similarly, the user can just add DashClock to the lockscreen, not a whole bunch of individual lockscreen widgets.

Discovery… By the User

DashClock helps users find extensions by linking to the Play Store via the following URL: `http://play.google.com/store/search?q=DashClock+Extension&c=apps`.

Anyone publishing a DashClock extension merely needs to describe their app as having (or being) a DashClock extension, and they will automatically show up when the user requests to get more extensions from within DashClock's configuration activity.

DashClock extensions do not *have* to be installed via the Play Store, but DashClock will not directly help improve the "findability" of extensions distributed by other means.

Discovery… By Your App

At its core, DashClock finds extensions by scanning via `PackageManager`. Each extension is obligated to implement a service that advertises an `<action>` of `com.google.android.apps.dashclock.Extension`. DashClock then uses `queryIntentServices()` on `PackageManager` to find these services.

DashClock, however, has the notion of installed versus active extensions. Just because a user installed some app that happens to implement a DashClock extension does not necessarily mean that the user *wants* that app's content cluttering up her DashClock lockscreen widget. Instead, the user not only has to install the app, but tell DashClock to activate that extension. Hence, DashClock has an activity that shows a list of all installed extensions and allows the user to toggle them between active and inactive states (plus order them, etc.).

It is conceivable that the user installs a DashClock extension while this extension-configuration activity is running. Hence, while this activity is running, DashClock registers a `BroadcastReceiver`, via `registerReceiver()`, for the package-management broadcasts (e.g., `ACTION_PACKAGE_ADDED`). Upon receipt of the broadcast, DashClock goes through the original logic to scan using `PackageManager` to find available extensions, then updates the list to match any changes (added extensions, removed extensions, etc.).

DashClock also monitors for the many of the same broadcasts via a manifest-registered receiver, so it knows when extensions are replaced or removed. In those cases, DashClock needs to determine whether the extension had been active, and if so, what is now required (e.g., removing the extension from the lockscreen widget once it is uninstalled).

Discovery and Usage of the IPC Endpoints

The DashClock app, serving as the plugin host, communicates with its plugins in three main ways:

- Via the aforementioned service, usually implemented as a `DashClockExtension`, which allows DashClock to proactively request that plugins publish updates to their data
- Via an optional "settings activity", which DashClock links to from the extension list, so users can configure the behavior of this specific extension
- Via metadata in the `<service>` element for the `DashClockExtension`

One of the key pieces of metadata is the `protocolVersion`, which tells DashClock what version of the DashClock plugin API the plugin supports.

The plugin turns around and communicates back to DashClock via a service, exported by DashClock under an agreed-upon action. The extension uses this service to publish updates to the data that should be shown for this extension in DashClock's lockscreen widget, much along the lines of how an `AppWidgetProvider` tells the `AppWidgetManager` to update an app widget.

Security

DashClock defines a custom `READ_EXTENSION_DATA` permission. Extensions protect their services by requiring this permission (`android:permission = "com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA"`), so that the user knows about apps seeking to communicate with the extension. Such apps need to hold the `READ_EXTENSION_DATA` permission, meaning that the user will be informed at installation time about the app wishing to speak with DashClock extensions.

Other Plugin Examples

DashClock shows one way of implementing a plugin model, but it is certainly not the only possible implementation. The following sections review some other approaches, to contrast with DashClock's approach.

Plugins by Remote

The biggest challenge with plugins comes at the UI level. While there are many ways to integrate applications for background work (remote services, broadcast Intents, etc.), blending user interfaces is a problem. It is unsafe to have an application execute some plugin's code in its own process, as the plugin may be malicious in nature. Yet, the plugin cannot directly add widgets to the host app's activities any other way.

The key word in that last sentence, of course, is "directly".

There is an indirect way of having one app supply UI components to another app, in the form of the `RemoteViews` object. This is used by app widgets and custom `Notifications`, covered elsewhere in this book.

The plugin can create a `RemoteViews` structure describing the desired UI and deliver that `RemoteViews` to the host app, which can then render that `RemoteViews` wherever it is needed.

This section will outline some of the mechanics behind creating such a UI-centric plugin mechanism.

RemoteViews, Beyond App Widgets

`RemoteViews` are used in a few other places besides app widgets, such as custom `Notification` views. However, you can use `RemoteViews` yourself easily enough. You create one as you would for any other circumstance, like an app widget. To display one, you can use the `apply()` method on the `RemoteViews` object. The `apply()` method takes two parameters:

1. Your `Context`, typically your `Activity`
2. The container into which the contents of the `RemoteViews` will eventually reside

The apply() method returns the View specified by the rules poured into the RemoteViews object… but it does not add it to the container specified in that second parameter. Hence, apply() is a bit like calling the three-parameter inflate() on a LayoutInflater and passing false for the third parameter — you are still responsible for actually adding the View to the parent when appropriate.

And that's pretty much it.

Since a RemoteViews object implements the Parcelable interface, you can store a RemoteViews in an Intent extra, a Bundle, or anything else that works with Parcelable (e.g., AIDL-defined remote service interfaces). This is what makes RemoteViews so valuable – you can pass one to another process, which can apply() it to its own UI.

As a result, RemoteViews are a secure way for a plugin to contribute to some host activity's UI. In fact, you can think of an app widget as being a "plugin" for the UI of the home screen.

Thinking About Plugins

So, what does our plugin implementation need?

You have one application (the host) that will be able to display the RemoteViews supplied by other applications (the plugins). Somehow, the host will need to know:

1. What plugins are installed
2. How to get RemoteViews from the plugins to the host
3. Whether there are plugins that are installed that the user does not want (e.g., app widgets not added to the home screen) or if the user wants to see multiple RemoteViews from the same plugin (e.g., multiple instances of an app widget)

As is discussed earlier in this chapter, there are any number of ways of implementing these. The sample shown below will use a broadcast Intent to find plugins and another broadcast Intent to retrieve RemoteViews on demand, while assuming that each plugin will deliver exactly one RemoteViews.

Similarly, the plugin will need to know:

1. How it will be activated by the host

2. How it is supposed to deliver RemoteViews to the host (broadcast Intent? remote service API? something else?)
3. When it is supposed to deliver RemoteViews to the host (pulled by the host? pushed to the host? both?)
4. How many distinct instances of the plugin does the user want (e.g., multiple instances of the app widget), and what is the configuration data for each instance that makes one distinct from the next?

Let's take a look at the RemoteViews/Host and RemoteViews/Plugin sample applications. These are two apps, each in their own package, implementing a host/plugin relationship, with RemoteViews being generated by the plugin and displayed by the host.

In this sample, the plugin will respond to a broadcast Intent from the host with a broadcast of its own, signaling that it wishes to serve as a plugin. When the host sends a broadcast to retrieve the RemoteViews, the plugin will send a broadcast in response that contains the RemoteViews. And, to keep things simple, each plugin will only have one instance (and we will only have one plugin).

Finding Available Plugins

Our host is a simple activity containing a TextView as its only content. The expectation is that when the user chooses a Refresh options menu item, we will pull a RemoteViews from the plugin and display it.

That, of course, assumes that we have a plugin.

To find plugins, we will send a broadcast, with a custom action, ACTION_CALL_FOR_PLUGINS. Any plugin implementation would need a BroadcastReceiver set up in the manifest to respond to such an action.

To keep things simple, the host will only have one plugin. The plugin itself will be represented by a ComponentName object, identifying the implementation of the plugin, held in a pluginCN data member:

```
private ComponentName pluginCN=null;
```

In onResume(), if we do not have a plugin yet, we send the broadcast to try to find one:

```
@Override
public void onResume() {
  super.onResume();

  IntentFilter pluginFilter=new IntentFilter();

  pluginFilter.addAction(ACTION_REGISTER_PLUGIN);
  pluginFilter.addAction(ACTION_DELIVER_CONTENT);

  registerReceiver(plugin, pluginFilter, PERM_ACT_AS_PLUGIN, null);

  if (pluginCN == null) {
    sendBroadcast(new Intent(ACTION_CALL_FOR_PLUGINS));
  }
}
```

Responding to the Call for Plugins

Over in our plugin implementation, we do indeed have a `BroadcastReceiver` — cunningly named `Plugin` — with a manifest entry set up to respond to our `ACTION_CALL_FOR_PLUGINS` broadcast.

What the host wants in response is to receive a broadcast from the plugin, with an action of `ACTION_REGISTER_PLUGIN`, and an extra of `EXTRA_COMPONENT`, containing the `ComponentName` of the `BroadcastReceiver` that is the plugin implementation. So, when `Plugin` receives an `ACTION_CALL_FOR_PLUGINS` broadcast, it does just that:

```
package com.commonsware.android.rv.plugin;

import android.content.BroadcastReceiver;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class Plugin extends BroadcastReceiver {
  public static final String ACTION_CALL_FOR_PLUGINS=
      "com.commonsware.android.rv.host.CALL_FOR_PLUGINS";
  public static final String ACTION_REGISTER_PLUGIN=
      "com.commonsware.android.rv.host.REGISTER_PLUGIN";
  public static final String ACTION_CALL_FOR_CONTENT=
      "com.commonsware.android.rv.host.CALL_FOR_CONTENT";
  public static final String ACTION_DELIVER_CONTENT=
      "com.commonsware.android.rv.host.DELIVER_CONTENT";
  public static final String EXTRA_COMPONENT="component";
  public static final String EXTRA_CONTENT="content";
  private static final String HOST_PACKAGE="com.commonsware.android.rv.host";

  @Override
  public void onReceive(Context ctxt, Intent i) {
    if (ACTION_CALL_FOR_PLUGINS.equals(i.getAction())) {
      Intent registration=new Intent(ACTION_REGISTER_PLUGIN);

      registration.setPackage(HOST_PACKAGE);
      registration.putExtra(EXTRA_COMPONENT,
                            new ComponentName(ctxt, getClass()));

      ctxt.sendBroadcast(registration);
    }
    else if (ACTION_CALL_FOR_CONTENT.equals(i.getAction())) {
      RemoteViews rv=
          new RemoteViews(ctxt.getPackageName(), R.layout.plugin);
      Intent update=new Intent(ACTION_DELIVER_CONTENT);

      update.setPackage(HOST_PACKAGE);
      update.putExtra(EXTRA_CONTENT, rv);
      ctxt.sendBroadcast(update);
    }
  }
}
```

For added security, we use `setPackage()` in the plugin, so the `ACTION_REGISTER_PLUGIN` broadcast can only be received by the host.

The host activity needs to receive `ACTION_REGISTER_PLUGIN` broadcasts. Hence, it has a `BroadcastReceiver` implementation, in the `plugin` data member, that it registers for `ACTION_REGISTER_PLUGIN` in `onResume()`. The `plugin` `BroadcastReceiver`, upon receiving an `ACTION_REGISTER_PLUGIN` broadcast, grabs the `ComponentName` out of the `EXTRA_COMPONENT` extra and stores it in `pluginCN`:

```
  private BroadcastReceiver plugin=new BroadcastReceiver() {
    @Override
    public void onReceive(Context ctxt, Intent i) {
      if (ACTION_REGISTER_PLUGIN.equals(i.getAction())) {
        pluginCN=(ComponentName)i.getParcelableExtra(EXTRA_COMPONENT);
      }
      else if (ACTION_DELIVER_CONTENT.equals(i.getAction())) {
        RemoteViews rv=(RemoteViews)i.getParcelableExtra(EXTRA_CONTENT);
        ViewGroup frame=(ViewGroup)findViewById(android.R.id.content);

        frame.removeAllViews();

        View pluginView=rv.apply(RemoteViewsHostActivity.this, frame);

        frame.addView(pluginView);
      }
    }
  };
```

At this point, we wait for the user to click the Refresh options menu item.

Requesting RemoteViews

When the user does indeed choose Refresh, we call a `refreshPlugin()` method on the host activity:

```
private void refreshPlugin() {
  Intent call=new Intent(ACTION_CALL_FOR_CONTENT);

  call.setComponent(pluginCN);
  sendBroadcast(call);
}
```

Here, we send an `ACTION_CALL_FOR_CONTENT` broadcast, with the target component set to be the plugin implementation, as identified by its `ComponentName`. This ensures that this broadcast will only go to that plugin app and nobody else.

Responding with RemoteViews

Our `Plugin` is also registered in the manifest to respond to `ACTION_CALL_FOR_CONTENT`. So, when that broadcast arrives, it can create the `RemoteViews` in response, sending it out via an `ACTION_DELIVER_CONTENT` broadcast back to the host. Once again, we use `setPackage()` to restrict the broadcast to be the host's package. The broadcast also has the `RemoteViews` tucked in an `EXTRA_CONTENT` extra.

Our host activity registered the `plugin` `BroadcastReceiver` for `ACTION_DELIVER_CONTENT` as well. So, when that broadcast arrives, it can utilize the `RemoteViews`. We find the `ViewGroup` that is the root of our content (`android.R.id.content`), wipe out whatever is in it now, `apply()` the `RemoteViews` to that `ViewGroup`, and add the resulting `View` to the `ViewGroup`. This has the net effect of getting rid of our original `TextView` content, replacing it with whatever the plugin poured into the `RemoteViews`. Or, if the user chooses Refresh again, the older `RemoteViews`-generated content is replaced with fresh content.

Dealing with Android 3.1+

To test this, install the Host application, followed by the Plugin application. On Android 3.0 and older, running the Host and choosing the Refresh options menu item will change the display from its original state to the one with the plugin's `RemoteViews`.

However, that will not work right away on Android 3.1 and higher.

On these versions of Android, applications are installed into a "stopped" state, where no `BroadcastReceiver` in the manifest will work, until the user manually runs the application. The simplest way to do that is via an activity. So, the Plugin project has a trivial activity that just displays a `Toast` and exits:

```java
package com.commonsware.android.rv.plugin;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class PluginActivationActivity extends Activity {
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);

    Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
    finish();
  }
}
```

You will need to run this activity on Android 3.1 and higher first, then run the Host project's activity, to get the plugin to work.

If you happen to install these on an Android 3.0 or older device, though, you may wonder if the author has lost his marbles. That is because you will not see any activity associated with the Plugin application.

Since the author has not owned marbles in a few decades, clearly there must be some other answer. In this case, we use a variation of a trick pointed out by Daniel Lew.

Our `<activity>` element in the manifest has an `android:enabled` attribute. A disabled activity does not show up in the launcher. But rather than have `android:enabled` specifically tied to `true` or `false` in the manifest, it references a boolean resource:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.rv.plugin"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk android:minSdkVersion="7"/>

  <uses-permission android:name="com.commonsware.android.rv.host.ACT_AS_PLUGIN"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver
      android:name="Plugin"
      android:permission="com.commonsware.android.rv.host.ACT_AS_HOST">
      <intent-filter>
        <action android:name="com.commonsware.android.rv.host.CALL_FOR_PLUGINS"/>
        <action android:name="com.commonsware.android.rv.host.CALL_FOR_CONTENT"/>
      </intent-filter>
    </receiver>

    <activity
      android:name="PluginActivationActivity"
      android:enabled="@bool/i_has_needs_activity"
      android:excludeFromRecents="true"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

In `res/values/bools.xml`, we define that boolean resource to be `false`, meaning the activity will not appear in the launcher:

```
<resources>

  <bool name="i_has_needs_activity">false</bool>

</resources>
```

But, in `res/values-v12/bools.xml`, we define that boolean resource to be `true`, causing the activity to appear on Android 3.1 and higher:

```
<resources>

  <bool name="i_has_needs_activity">true</bool>

</resources>
```

This way, our extraneous activity does not clutter up older devices where it is not needed. Mr. Lew's blog post on this subject points out that this trick can be used to have different implementations of an app widget for different Android versions (e.g., one that uses a `ListView` for API Level 11 and higher, plus one that does not for older devices).

The Permission Scheme

Another thing that these sample projects use are custom permissions, to help with security.

To serve as a plugin host, you must hold the `ACTS_AS_HOST` permission. To serve as a plugin implementation, you must hold the `ACTS_AS_PLUGIN` permission. These are defined in the Host project's manifest:

```
<permission
  android:name="com.commonsware.android.rv.host.ACT_AS_HOST"
  android:description="@string/host_desc"
  android:label="@string/host_label">
</permission>
<permission
  android:name="com.commonsware.android.rv.host.ACT_AS_PLUGIN"
  android:description="@string/plugin_desc"
  android:label="@string/plugin_label">
</permission>
```

Each application then has its appropriate `<uses-permission>` element for the role that it plays, such as the Plugin holding the `ACTS_AS_PLUGIN` permission:

```
<uses-permission android:name="com.commonsware.android.rv.host.ACT_AS_PLUGIN"/>
```

The `BroadcastReceiver` defined by the Plugin project has, in its `<receiver>` element, the `android:permission` attribute, indicating that whoever sends a broadcast to this receiver must holds `ACTS_AS_HOST`:

```
  <receiver
    android:name="Plugin"
    android:permission="com.commonsware.android.rv.host.ACT_AS_HOST">
    <intent-filter>
      <action android:name="com.commonsware.android.rv.host.CALL_FOR_PLUGINS"/>
      <action android:name="com.commonsware.android.rv.host.CALL_FOR_CONTENT"/>
    </intent-filter>
  </receiver>
```

Similarly, the `BroadcastReceiver` defined dynamically by the host activity uses a version of `registerReceiver()` that takes the permission the sender must hold:

```
  registerReceiver(plugin, pluginFilter, PERM_ACT_AS_PLUGIN, null);
```

That permission is defined in a static data member:

```
public static final String PERM_ACT_AS_PLUGIN=
    "com.commonsware.android.rv.host.ACT_AS_PLUGIN";
```

This way, the user is informed about the host/plugin relationship and can make appropriate decisions when they install plugins.

Note, though, that for this to work, the host application must be installed first, to define the custom permissions. If a plugin is installed before the host, there is no error, but the plugin will not be granted the as-yet-undefined custom permissions, and so the plugin will not work. The user would have to uninstall and reinstall the plugin after installing the host to fix this problem.

Other Plugin Features and Issues

It is possible for the `apply()` method on `RemoteViews` to throw a `RuntimeException`. For example, the `RemoteViews` might contain a reference to a widget ID that does not exist within the inflated views of the `RemoteViews` itself. Since `apply()` does not throw a checked exception, it is easy to do what we did in the sample app and assume `apply()` will succeed, but it very well may not. A robust implementation of this plugin system would wrap the `apply()` call in an exception handler that would do something useful if the plugin's `RemoteViews` has a bug.

You need to be a bit careful to make sure that a plugin can only update itself. The sample app assumes that the only thing that will send an `ACTION_DELIVER_CONTENT` broadcast to it will be the plugin, but that is not necessarily the case. In principle, anything that holds the `ACTS_AS_PLUGIN` permission could send an `ACTION_DELIVER_CONTENT` to the host, and thereby specify what the `RemoteViews` are. A robust plugin system would have some sort of shared secret, such as an identifier, between the host and the plugin, so another component cannot readily masquerade as being the plugin itself.

ContentProvider Plugins

Another way to extend your application at runtime is via plugins implemented via the `ContentProvider` framework. You could create new `ContentProvider` implementations that offer up data, perhaps using a consistent schema. Then, you could find those providers via a naming convention (e.g., for a main application with a package of `com.foo.abc`, your plugin apps would be `com.foo.abc.plugin.*`) and `PackageManager`, perhaps using a provider `Uri` naming convention to allow the host to know how to query the plugin.

However, there are other ways of employing a `ContentProvider` to help as a plugin, and this section explores one specific scenario: reducing the host app's permission requirements.

The Problem: Permission Creep

At the moment, for standard versions of Android, apps cannot request "conditional" or "optional" permissions, that the user could elect to opt out of. Instead, apps must request in their manifest all possible permissions that they could need. This is considered by many to be a significant limitation, but Google has stated repeatedly that they are not considering alternative strategies.

The net effect, though, is that an app often times needs a lot of permissions, or needs to add new permissions (requiring existing users to agree to the new permission list). Such lists of permissions can dissuade potential users from installing the app in the first place.

However, even though Android does not provide a simple and clean way for users to opt into (or out of) certain permissions for certain apps, plugins can offer a similar model. The base app can require some permissions for some features, with other features (and their respective permissions) added via plugins. Users can elect to install the plugins and agree to those permissions, or abandon or never install the plugins in the first place.

The hassle, of course, is in implementing the plugin APK and connecting to it from the main app. The plugin needs to have all the functionality that must directly use classes and methods secured by the permission. This can increase the complexity in maintaining the overall app.

A Solution: ContentProvider Proxies

Some permissions exist primarily to protect a `ContentProvider`, such as `READ_CONTACTS` and `WRITE_CONTACTS` for the `ContactsContract` provider.

The nice thing about the `ContentProvider` framework is that it is simply a contract. You use a `ContentResolver` and some magic values (`Uri`, "projection" of columns to return, etc.), and you get results. In fact, you can even change some of those magic values – any `Uri` supporting the same columns could be used with all the same client Java code, just by changing the `Uri` itself.

That allows us to create a proxy for `ContentProvider`. The proxy APK will hold the permission and call the real `ContentProvider` as needed. The proxy APK will expose its own `ContentProvider`, with a different `Uri`. Done properly — such that only the host app can use the proxy — the proxy will isolate the permission(s) for the real `ContentProvider` in the plugin. A `ContactsContract` proxy, for example, could hold `READ_CONTACTS` and `WRITE_CONTACTS`, proxying requests on behalf of a main app that lacks those permissions.

To secure the proxy, we need to ensure that only our apps can use the proxy, not anyone else's apps. Otherwise, those third-party apps could get at, say, contacts without the `READ_CONTACTS` permission.

The simplest way to accomplish this is to use a signature-level custom permission.

Any app can declare a new permission via the <permission> element in the manifest. Normally, any app can request to hold this permission via <uses-permission>, and the user will be able to grant or deny this request at install time, just like any system-defined permission.

However, it is possible to add an android:protectionLevel="signature" attribute to the <permission> element. In this case, only apps signed by the same signing key will be able to request the permission — everyone else is automatically denied. Furthermore, apps signed by the same signing key will automatically get the permission without the user having to approve it.

So, you can have the proxy require a signature-level custom permission, thereby limiting possible consumers of the proxy to be signed by the same signing key.

Let's look at a pair of projects that create and consume a proxy for the CallLog ContentProvider. These projects are located in the Introspection/CPProxy directory and are named Provider and Consumer, respectively.

Note that this sample works only on API Level 11 and higher, due to the consumer's use of the native implementation of the Loader framework.

Provider

Most of the logic for our provider proxy can be found in the AbstractCPProxy base class. It implements the mandatory methods for the ContentProvider contract — such as insert() — and simply turns around and forwards those requests along to another provider:

```
@Override
public Cursor query(Uri uri, String[] projection, String selection,
                    String[] selectionArgs, String sortOrder) {
  checkTainted();

  Cursor result=
      getContext().getContentResolver().query(convertUri(uri),
                                              projection, selection,
                                              selectionArgs,
                                              sortOrder);

  return(new CrossProcessCursorWrapper(result));
}

@Override
public Uri insert(Uri uri, ContentValues values) {
  checkTainted();

  return(getContext().getContentResolver().insert(convertUri(uri),
                                                  values));
}

@Override
public int update(Uri uri, ContentValues values, String selection,
                  String[] selectionArgs) {
  checkTainted();

  return(getContext().getContentResolver().update(convertUri(uri),
                                                  values, selection,
                                                  selectionArgs));
}

@Override
public int delete(Uri uri, String selection, String[] selectionArgs) {
  checkTainted();

  return(getContext().getContentResolver().delete(convertUri(uri),
                                                  selection,
                                                  selectionArgs));
}

@Override
public String getType(Uri uri) {
  checkTainted();

  return(getContext().getContentResolver().getType(convertUri(uri)));
}
```

The `checkTainted()` calls are part of our confirming that our custom permission is OK, and that is covered in the chapter on advanced permissions. For the purposes of this chapter, just ignore them (along with the `onCreate()` method not shown here).

It is up to a subclass of `AbstractCPProxy` to implement the `convertUri()` method, which takes the `Uri` supplied by the consumer and transforms it into the proper `Uri` to use for making the real request. In this case, our subclass is `CallLogProxy`:

```
package com.commonsware.android.cpproxy.provider;

import android.content.ContentUris;
import android.net.Uri;
import android.provider.CallLog;

public class CallLogProxy extends AbstractCPProxy {
  protected Uri convertUri(Uri uri) {
    long id=ContentUris.parseId(uri);

    if (id >= 0) {
      return(ContentUris.withAppendedId(CallLog.Calls.CONTENT_URI, id));
    }

    return(CallLog.Calls.CONTENT_URI);
  }
}
```

Here, we grab the instance ID off the end of the Uri (if it exists) and generate a new Uri based on CallLog.CONTENT_URI, indicating that we want to forward our requests to the CallLog.

The biggest complexity of the standard CRUD ContentProvider methods comes with query(). The Cursor returned by query() must implement the CrossProcessCursor interface. The SQLiteCursor implementation supports this interface, which is why typical providers do not worry about this requirement. However, the Cursor returned by query() on ContentResolver is not necessarily a CrossProcessCursor. Hence, we need to wrap it in a CursorWrapper that does implement CrossProcessCursor:

```
@Override
public Cursor query(Uri uri, String[] projection, String selection,
                    String[] selectionArgs, String sortOrder) {
  checkTainted();

  Cursor result=
      getContext().getContentResolver().query(convertUri(uri),
                                              projection, selection,
                                              selectionArgs,
                                              sortOrder);

  return(new CrossProcessCursorWrapper(result));
}
```

The resulting CrossProcessCursorWrapper, as originally shown in a Stack Overflow answer, looks like this:

```
// following from
// http://stackoverflow.com/a/5243978/115145

public class CrossProcessCursorWrapper extends CursorWrapper
    implements CrossProcessCursor {
  public CrossProcessCursorWrapper(Cursor cursor) {
    super(cursor);
  }

  @Override
  public CursorWindow getWindow() {
    return null;
  }

  @Override
  public void fillWindow(int position, CursorWindow window) {
    if (position < 0 || position > getCount()) {
      return;
    }
    window.acquireReference();
    try {
      moveToPosition(position - 1);
      window.clear();
```

```
        window.setStartPosition(position);
        int columnNum=getColumnCount();
        window.setNumColumns(columnNum);
        while (moveToNext() && window.allocRow()) {
          for (int i=0; i < columnNum; i++) {
            String field=getString(i);
            if (field != null) {
              if (!window.putString(field, getPosition(), i)) {
                window.freeLastRow();
                break;
              }
            }
            else {
              if (!window.putNull(getPosition(), i)) {
                window.freeLastRow();
                break;
              }
            }
          }
        }
      }
      catch (IllegalStateException e) {
        // simply ignore it
      }
      finally {
        window.releaseReference();
      }
    }

    @Override
    public boolean onMove(int oldPosition, int newPosition) {
      return true;
    }
  }
```

Note that this implementation has been largely untested by this book's author, though it appears to work.

The manifest for this project has three items of note:

- It has the `<uses-permission>` element for `READ_CONTACTS`, while our consumer project will not
- It has a `<permission>` element, defining a custom `com.commonsware.android.cpproxy.PLUGIN` permission that has signature-level protection
- It has our `<provider>`, requiring that custom permission, and declaring its authority to be `com.commonsware.android.cpproxy.CALL_LOG`

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.cpproxy.provider"
  android:versionCode="1"
  android:versionName="1.0">
  <uses-sdk
    android:minSdkVersion="9"
    android:targetSdkVersion="11"/>

  <uses-permission android:name="android.permission.READ_CONTACTS"/>

  <permission
    android:name="com.commonsware.android.cpproxy.PLUGIN"
    android:protectionLevel="signature">
  </permission>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <provider
      android:name=".CallLogProxy"
      android:authorities="com.commonsware.android.cpproxy.CALL_LOG"
      android:permission="com.commonsware.android.cpproxy.PLUGIN">
    </provider>
  </application>

</manifest>
```

Note that a complete `AbstractCPProxy` implementation should forward along all the other methods as well (e.g., `call()`).

Consumer

Our Consumer project is nearly identical to the `CalendarContract` sample from elsewhere in this book.

However, instead of the `READ_CONTACTS` permission, we declare that we need the `com.commonsware.android.cpproxy.PLUGIN` permission instead:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.cpproxy.consumer"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="11"
    android:targetSdkVersion="11"/>

  <uses-permission android:name="com.commonsware.android.cpproxy.PLUGIN"/>

  <permission
    android:name="com.commonsware.android.cpproxy.PLUGIN"
    android:protectionLevel="signature">
  </permission>

  <application
```

```
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".CPProxyConsumerActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Also, our CONTENT_URI is no longer the one found on CallLog, but rather one identifying our proxy:

```
  private static final Uri CONTENT_URI=
      Uri.parse("content://com.commonsware.android.cpproxy.CALL_LOG");
```

And there are minor changes because we are querying CallLog (indirectly) rather than CalendarContract, such as a change in the columns for our projection:

```
  private static final String[] PROJECTION=new String[] {
      CallLog.Calls._ID, CallLog.Calls.NUMBER, CallLog.Calls.DATE };
```

Otherwise, the consumer projects are the same. The difference is that our consumer project does not need the READ_CONTACTS permission the same way that the original needed the READ_CALENDAR permission.

In this case, the consumer project depends entirely upon the existence of the plugin — otherwise, the consumer project has no value. Hence, in this case, going the plugin route is silly. But an application that could use the CallLog but does not depend upon it could use this approach to isolate the READ_CONTACTS requirement in a plugin, so users could elect to install the plugin or not, and the main app would not need to request READ_CONTACTS and add to the roster of permissions the user must agree to up front.

Note that, in principle, the consumer should contain some of the same defenses against custom permission changes that the proxy does (in the form of those checkTainted() calls). This is covered in greater detail in the chapter on advanced permissions.

Limitations of the Approach

There will be additional overhead in using the proxy, which will hamper performance. Ideally, this plugin mechanism is only used for features that need light use of the protected `ContentProvider`, so the overhead will not be a burden to the user.

PackageManager Tricks

PackageManager is your primary means of introspection at the component level, to determine what else is installed on the device and what components they export (activities, etc.). As such, there are many ways you can use PackageManager to determine if something you want is possible or not, so you can modify your behavior accordingly (e.g., disable action bar items that are not possible).

This chapter will outline some ways you can use PackageManager to find out what components are available to you on a device.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Asking Around

The ways to find out whether there is an activity that will respond to a given Intent are by means of queryIntentActivityOptions() and the somewhat simpler queryIntentActivities().

The queryIntentActivityOptions() method takes the caller ComponentName, the "specifics" array of Intent instances, the overall Intent representing the actions you are seeking, and the set of flags. It returns a List of Intent instances matching the stated criteria, with the "specifics" ones first.

If you would like to offer alternative actions to users, but by means other than addIntentOptions(), you could call queryIntentActivityOptions(), get the Intent instances, then use them to populate some other user interface (e.g., a toolbar).

A simpler version of this method, queryIntentActivities(), is used by the Introspection/Launchalot sample application. This presents a "launcher" — an activity that starts other activities — but uses a ListView rather than a grid like the Android default home screen uses.

Here is the Java code for Launchalot itself:

```
package com.commonsware.android.launchalot;

import android.app.ListActivity;
import android.content.ComponentName;
import android.content.Intent;
import android.content.pm.ActivityInfo;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ImageView;
import android.widget.ListView;
import android.widget.TextView;
import java.util.Collections;
import java.util.List;

public class Launchalot extends ListActivity {
  AppAdapter adapter=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    PackageManager pm=getPackageManager();
    Intent main=new Intent(Intent.ACTION_MAIN, null);

    main.addCategory(Intent.CATEGORY_LAUNCHER);

    List<ResolveInfo> launchables=pm.queryIntentActivities(main, 0);

    Collections.sort(launchables,
                     new ResolveInfo.DisplayNameComparator(pm));

    adapter=new AppAdapter(pm, launchables);
    setListAdapter(adapter);
  }

  @Override
  protected void onListItemClick(ListView l, View v,
                                 int position, long id) {
```

```
    ResolveInfo launchable=adapter.getItem(position);
    ActivityInfo activity=launchable.activityInfo;
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);
    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
                Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
    i.setComponent(name);

    startActivity(i);
  }

  class AppAdapter extends ArrayAdapter<ResolveInfo> {
    private PackageManager pm=null;

    AppAdapter(PackageManager pm, List<ResolveInfo> apps) {
      super(Launchalot.this, R.layout.row, apps);
      this.pm=pm;
    }

    @Override
    public View getView(int position, View convertView,
                          ViewGroup parent) {
      if (convertView==null) {
        convertView=newView(parent);
      }

      bindView(position, convertView);

      return(convertView);
    }

    private View newView(ViewGroup parent) {
      return(getLayoutInflater().inflate(R.layout.row, parent, false));
    }

    private void bindView(int position, View row) {
      TextView label=(TextView)row.findViewById(R.id.label);

      label.setText(getItem(position).loadLabel(pm));

      ImageView icon=(ImageView)row.findViewById(R.id.icon);

      icon.setImageDrawable(getItem(position).loadIcon(pm));
    }
  }
}
```

In `onCreate()`, we:

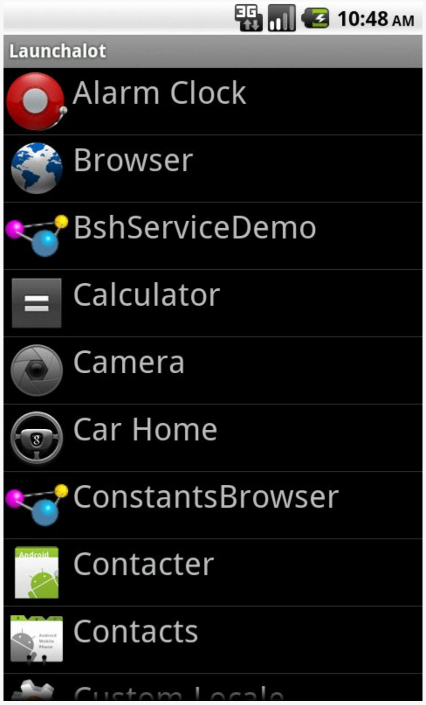
1. Get a `PackageManager` object via `getPackageManager()`
2. Create an `Intent` for `ACTION_MAIN` in `CATEGORY_LAUNCHER`, which identifies activities that wish to be considered "launchable"

3. Call `queryIntentActivities()` to get a `List` of `ResolveInfo` objects, each one representing one launchable activity
4. Sort those `ResolveInfo` objects via a `ResolveInfo.DisplayNameComparator` instance
5. Pour them into a custom `AppAdapter` and set that to be the contents of our `ListView`

`AppAdapter` is an `ArrayAdapter` subclass that maps the icon and name of the launchable `Activity` to a row in the `ListView`, using a custom row layout.

Finally, in `onListItemClick()`, we construct an `Intent` that will launch the clicked-upon `Activity`, given the information from the corresponding `ResolveInfo` object. Not only do we need to populate the `Intent` with `ACTION_MAIN` and `CATEGORY_LAUNCHER`, but we also need to set the component to be the desired `Activity`. We also set `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` flags, following Android's own launcher implementation from the Home sample project. Finally, we call `startActivity()` with that `Intent`, which opens up the activity selected by the user.

The result is a simple list of launchable activities:



Alarm Clock
Browser
BshServiceDemo
Calculator
Camera
Car Home
ConstantsBrowser
Contacter
Contacts
Custom Locale

Figure 770: The Launchalot sample application

There is also a `resolveActivity()` method that takes a template Intent, as do `queryIntentActivities()` and `queryIntentActivityOptions()`. However, `resolveActivity()` returns the single best match, rather than a list.

NOTE: On modern versions of Android, there is a `LauncherApps` class that simplifies a lot of this and takes things like Android Work profiles into account. For really implementing a home screen-style launcher, you will probably want to use `LauncherApps`. However, using `PackageManager` to find what can handle certain `Intent` structures is used for other purposes beyond home screen launchers.

Preferred Activities

Users, when presented with a default activity chooser, usually have the option to make their next choice be the default for this action for now on. The next time they do whatever they did to bring up the chooser, it should go straight to this default. This is known in the system as the "preferred activity" for an `Intent` structure, and is stored in the system as a set of pairs of `IntentFilter` objects and the corresponding `ComponentName` of the preferred activity.

To find out what the preferred activities are on a given device, you can ask `PackageManager` to `getPreferredActivities()`. You pass in a `List<IntentFilter>` and a `List<ComponentName>`, and Android fills in those lists with the preferred activity information.

To see this in action, take a look at the Introspection/PrefActivities sample application. This simply loads all of the information into a `ListView`, using `android.R.layout.simple_list_item_2` as a row layout for a title-and-description pattern.

The `PackageManager` logic is confined to `onCreate()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  PackageManager mgr=getPackageManager();

  mgr.getPreferredActivities(filters, names, null);
  setListAdapter(new IntentFilterAdapter());
}
```

In this case, the two lists are data members of the activity:

```
ArrayList<IntentFilter> filters=new ArrayList<IntentFilter>();
ArrayList<ComponentName> names=new ArrayList<ComponentName>();
```

Most of the logic is in formatting the `ListView` contents. `IntentFilter`, unfortunately, does not come with a method that gives us a human-readable dump of its definition. As a result, we need to roll that ourselves. Compounding the problem is that `IntentFilter` tends to return `Iterator` objects for its collections (e.g., roster of actions), rather than something `Iterable`. The activity leverages an `Iterator`-to-`Iterable` wrapper culled from a Stack Overflow answer to help with this. The `IntentFilterAdapter` and helper code looks like this:

```
// from http://stackoverflow.com/a/8555153/115145

public static <T> Iterable<T> in(final Iterator<T> iterator) {
  class SingleUseIterable implements Iterable<T> {
    private boolean used=false;

    @Override
    public Iterator<T> iterator() {
      if (used) {
        throw new IllegalStateException("Already invoked");
      }
      used=true;
      return iterator;
    }
  }
  return new SingleUseIterable();
}

class IntentFilterAdapter extends ArrayAdapter<IntentFilter> {
  IntentFilterAdapter() {
    super(PreferredActivitiesDemoActivity.this,
          android.R.layout.simple_list_item_2, android.R.id.text1,
          filters);
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    TextView filter=(TextView)row.findViewById(android.R.id.text1);
    TextView name=(TextView)row.findViewById(android.R.id.text2);

    filter.setText(buildTitle(getItem(position)));
    name.setText(names.get(position).getClassName());

    return(row);
  }

  String buildTitle(IntentFilter filter) {
    StringBuilder buf=new StringBuilder();
    boolean first=true;

    if (filter.countActions() > 0) {
      for (String action : in(filter.actionsIterator())) {
        if (first) {
          first=false;
        }
        else {
          buf.append('/');
        }

        buf.append(action.replaceAll("android.intent.action.", ""));
      }
    }

    if (filter.countDataTypes() > 0) {
      first=true;

      for (String type : in(filter.typesIterator())) {
        if (first) {
          buf.append(" : ");
          first=false;
        }
        else {
          buf.append('|');
        }

        buf.append(type);
      }
    }

    if (filter.countDataSchemes() > 0) {
      buf.append(" : ");
      buf.append(filter.getDataScheme(0));

      if (filter.countDataSchemes() > 1) {
        buf.append(" (other schemes)");
      }
    }

    if (filter.countDataPaths() > 0) {
      buf.append(" : ");
      buf.append(filter.getDataPath(0));

      if (filter.countDataPaths() > 1) {
        buf.append(" (other paths)");
      }
    }

    return(buf.toString());
  }
}
```

The resulting activity shows a simple description of the `IntentFilter` along with the class name of the corresponding activity in each row:

Figure 771: Preferred Activities on a Stock HTC One S

Another way to think about preferred activities is to determine what specific activity will handle a `startActivity()` call on some `Intent`. If there is only one alternative, or the user chose a preferred activity, that activity should handle the `Intent`. Otherwise, the activity handling the `Intent` *should* be one implementing a chooser. The `resolveActivity()` method on `PackageManager` can let us know what will handle the `Intent`.

To examine what `resolveActivity()` returns, take a look at the Introspection/Resolver sample application.

The activity — which uses `Theme.NoDisplay` and so has no UI of its own — is fairly short:

```
package com.commonsware.android.resolver;

import android.app.Activity;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.net.Uri;
import android.os.Bundle;
import android.widget.Toast;
```

```
public class ResolveActivityDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    PackageManager mgr=getPackageManager();
    Intent i=
        new Intent(Intent.ACTION_VIEW,
                   Uri.parse("https://commonsware.com"));
    ResolveInfo ri=
        mgr.resolveActivity(i, PackageManager.MATCH_DEFAULT_ONLY);

    Toast.makeText(this, ri.loadLabel(mgr), Toast.LENGTH_LONG).show();

    startActivity(i);
    finish();
  }
}
```

We get a PackageManager, create an Intent to test, and pass the Intent to resolveActivity(). We include MATCH_DEFAULT_ONLY so we only get activities that have CATEGORY_DEFAULT in their <intent-filter> elements. We then use loadLabel() on the resulting ResolveInfo object to get the display name of the activity, toss that in a Toast, and invoke startActivity() on the Intent to confirm the results.

On a device with only one option, or with a default chosen, the Toast will show the name of the preferred activity (e.g., Browser). On most devices with more than one option, the startActivity() call will display a chooser, and the Toast will show the display name of the chooser (e.g., “Android System”).

However, on some devices — notably newer models from HTC distributed in the US — resolveActivity() indicates that HTCLinkifyDispatcher is the one that will handle ACTION_VIEW on a URL… even if there is more than one browser installed and no default has been specified. This is part of a workaround that HTC added in 2012 to help deal with a patent dispute with Apple.

Middle Management

The PackageManager class offers much more than merely queryIntentActivities() and queryIntentActivityOptions(). It is your gateway to all sorts of analysis of what is installed and available on the device where your application is installed and available. If you want to be able to intelligently connect to third-party applications based on whether or not they are around, PackageManager is what you will want.

Finding Applications and Packages

Packages are what get installed on the device — a package is the in-device representation of an APK. An application is defined within a package's manifest. Between the two, you can find out all sorts of things about existing software installed on the device.

Specifically, `getInstalledPackages()` returns a `List` of `PackageInfo` objects, each of which describes a single package. Here, you can find out:

1. The version of the package, in terms of a monotonically increasing number (`versionCode`) and the display name (`versionName`)
2. Details about all of the components — activities, services, etc. — offered by this package
3. Details about the permissions the package requires

Similarly, `getInstalledApplications()` returns a `List` of `ApplicationInfo` objects, each providing data like:

1. The user ID that the application will run as
2. The path to the application's private data directory
3. Whether or not the application is enabled

In addition to those methods, you can call:

1. `getApplicationIcon()` and `getApplicationLabel()` to get the icon and display name for an application
2. `getLaunchIntentForPackage()` to get an `Intent` for something launchable within a named package
3. `setApplicationEnabledSetting()` to enable or disable an application

Finding Resources

You can access resources from another application, apparently without any security restrictions. This may be useful if you have multiple applications and wish to share resources for one reason or another.

The `getResourcesForActivity()` and `getResourcesForApplication()` methods on `PackageManager` return a `Resources` object. This is just like the one you get for your own application via `getResources()` on any `Context` (e.g., `Activity`). However, in this case, you identify what activity or application you wish to get the `Resources` from (e.g., supply the application's package name as a `String`).

There are also `getText()` and `getXml()` methods that dive into the `Resources` object for an application and pull out specific `String` or `XmlPullParser` objects. However, these require you to know the resource ID of the resource to be retrieved, and that may be difficult to manage between disparate applications.

Finding Components

Not only does Android offer "query" and "resolve" methods to find activities, but it offers similar methods to find other sorts of Android components:

1. `queryBroadcastReceivers()`
2. `queryContentProviders()`
3. `queryIntentServices()`
4. `resolveContentProvider()`
5. `resolveService()`

For example, you could use `resolveService()` to determine if a certain remote service is available, so you can disable certain UI elements if the service is not on the device. You could achieve the same end by calling `bindService()` and watching for a failure, but that may be later in the application flow than you would like.

There is also a `setComponentEnabledSetting()` to toggle a component (activity, service, etc.) on and off. While this may seem esoteric, there are a number of possible uses for this method, such as:

1. Flagging a launchable activity as disabled in your manifest, then enabling it programmatically after the user has entered a license key, achieved some level or standing in a game, or any other criteria
2. Controlling whether a `BroadcastReceiver` registered in the manifest is hooked into the system or not, replicating the level of control you have with `registerReceiver()` while still taking advantage of the fact that a manifest-registered `BroadcastReceiver` can be started even if no other component of your application is running

Remote Services and the Binding Pattern

Earlier in this book, we covered using services by sending commands to them to be processed. That "command pattern" is one of two primary means of interacting with a service — the binding pattern is the other. With the binding pattern, your service exposes a more traditional API, in the form of a "binder" object with methods of your choosing. On the plus side, you get a richer interface. However, it more tightly ties your activity to your service, which may cause you problems with configuration changes.

Either the command pattern or the binding pattern can be used, if desired, across process boundaries, with the client being some third-party application. In either case, you will need to export your service via an `<intent-filter>`. And, in the case of the binding pattern, your "binder" implementation will have some restrictions.

This chapter covers the binding pattern for local services, plus inter-process commands and binding (a.k.a., remote services).

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- broadcast Intents
- service theory

The Binding Pattern

Implementing the binding pattern requires work on both the service side and the client side. The service will need to have a full implementation of the `onBind()` method, which typically just returns `null` or throws some sort of runtime exception for a service solely implementing the command pattern. And, the client (e.g., an activity) will need to ask to bind to the service, instead of (or perhaps in addition to) starting the service.

What the Service Does

The service implements a subclass of `Binder` that represents the service's exposed API. For a local service, your `Binder` can have pretty much whatever methods you want: method names, parameters, return types, and exceptions thrown are up to you. When you get into remote services, your `Binder` implementation will be substantially more constrained, to support inter-process communication.

Then, your `onBind()` method returns an instance of the `Binder`.

What the Client Does

Clients call `bindService()`, supplying the `Intent` that identifies the service, a `ServiceConnection` object representing the client side of the binding, and an optional `BIND_AUTO_CREATE` flag. As with `startService()`, `bindService()` is asynchronous. The client will not know anything about the status of the binding until the `ServiceConnection` object is called with `onServiceConnected()`. This not only indicates the binding has been established, but for local services it provides the Binder object that the service returned via `onBind()`. At this point, the client can use the `Binder` to ask the service to do work on its behalf.

Note that if the service is not already running, and if you provide `BIND_AUTO_CREATE`, then the service will be created first before being bound to the client. If you skip `BIND_AUTO_CREATE`, and the service is not already running, `bindService()` is supposed to return `false`, indicating there was no existing service to bind to. However, in actuality, Android returns `true`, due to an apparent bug.

Eventually, the client will need to call `unbindService()`, to indicate it no longer needs to communicate with the service. For example, an activity might call `bindService()` in its `onCreate()` method, then call `unbindService()` in its `onDestroy()` method. Once you call `unbindService()`, your `Binder` object is no longer safe to be used by the client. If there are no other bound clients to the service, Android will shut down the service as well, releasing its memory. Hence, we do not need to call `stopService()` ourselves — Android handles that, if needed, as a side effect of unbinding.

Your `ServiceConnection` object will also need an `onServiceDisconnected()` method. This will be called only if there is an unexpected disconnection, such as the service crashing with an unhandled exception.

A Binding Sample

In the chapter introducing services, we saw a sample app that would download a file off of a Web server. That sample used the command pattern, telling the service what to download via an `Intent` extra. In this chapter, we will review a few variations of that sample, all of which use the binding pattern instead of the command pattern.

Right now, we are focused on local services, and so the `Binding/Local` sample project does the download via a local bound service.

We start by defining an interface that will serve as the "contract" between the client (fragment) and service. This interface, `IDownload`, contains a single `download()` method:

```
package com.commonsware.android.advservice.binding;

// Declare the interface.
interface IDownload {
  void download(String url);
}
```

Our service, `DownloadService`, implements just one method, `onBind()`, which returns an instance of a `DownloadBinder`:

```
package com.commonsware.android.advservice.binding;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Binder;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
```

```java
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
  @Override
  public IBinder onBind(Intent intent) {
    return(new DownloadBinder());
  }

  private static class DownloadBinder extends Binder implements IDownload {
    @Override
    public void download(String url) {
      new DownloadThread(url).start();
    }
  }

  private static class DownloadThread extends Thread {
    String url=null;

    DownloadThread(String url) {
      this.url=url;
    }

    @Override
    public void run() {
      try {
        File root=

Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

        root.mkdirs();

        File output=new File(root, Uri.parse(url).getLastPathSegment());

        if (output.exists()) {
          output.delete();
        }

        HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

        FileOutputStream fos=new FileOutputStream(output.getPath());
        BufferedOutputStream out=new BufferedOutputStream(fos);

        try {
          InputStream in=c.getInputStream();
          byte[] buffer=new byte[8192];
          int len=0;

          while ((len=in.read(buffer)) >= 0) {
            out.write(buffer, 0, len);
          }

          out.flush();
        }
        finally {
          fos.getFD().sync();
          out.close();
          c.disconnect();
        }
      }
      catch (IOException e2) {
        Log.e("DownloadJob", "Exception in download", e2);
      }
    }
  }
}
```

DownloadBinder implements the IDownload interface. Its download() method, in turn, forks a DownloadThread to perform the download in the background — remember, for local services, the methods you invoke on the Binder are executed on whatever thread you call them on.

Our fragment, DownloadFragment, loads our layout, res/layout/main.xml, containing a Button to trigger the download:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/go"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
    android:text="@string/go"/>
```

The implementation of onCreateView() simply loads that layout, gets the Button, sets up the fragment as being the click listener for the Button, and disables the Button:

```
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, container, false);

    btn=(Button)result.findViewById(R.id.go);
    btn.setOnClickListener(this);
    btn.setEnabled(binding!=null);

    return(result);
  }
```

The reason why we disable the Button is because we are not connected to our service at this point, and until we are, we cannot allow the user to try to download a file.

In onCreate() of our fragment, we mark the fragment as retained and bind to the service:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();
    appContext.bindService(new Intent(getActivity(),
        DownloadService.class),
      this, Context.BIND_AUTO_CREATE);
  }
```

You will notice something curious here: `getApplicationContext()`. Technically, we could bind to the service directly from the `Activity`, by calling `bindService()` on it, as `bindService()` is a method on `Context`. However, our service binding represents some state, and it is possible that this state will hold a reference to the `Context` that created the binding. In that case, we run the risk of leaking our original activity during a configuration change. The `getApplicationContext()` method returns the global `Application` singleton, which is a `Context` suitable for binding, but one that cannot be leaked, since it is already in a global scope. In effect, it is “pre-leaked”.

The call to `setRetainInstance()` allows the fragment – serving as our `ServiceConnection` — to survive a configuration change, so we can cleanly unbind from the service later on, when `onDestroy()` is called.

Some time after `onCreate()` is called and we call `bindService()`, our `onServiceConnected()` method will be called, as we designated our fragment to be the `ServiceConnection`. Here, we can cast the `IBinder` object we receive to be our `IDownload` interface to the service, and we can enable the `Button`:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
  binding=(IDownload)binder;
  btn.setEnabled(true);
}
```

Since we are implementing the `ServiceConnection` interface, our fragment also needs to implement the `onServiceDisconnected()` method, invoked if our service crashes. Here, we delegate responsibility to a `disconnect()` private method, which removes our link to the `IDownload` object and disables our `Button`:

```
@Override
public void onServiceDisconnected(ComponentName className) {
  disconnect();
}

private void disconnect() {
  binding=null;
  btn.setEnabled(false);
}
```

And, when our fragment is destroyed, we unbind from the service (using the same `Context` as before, from `getApplicationContext()`) and `disconnect()`:

```
  @Override
  public void onDestroy() {
    appContext.unbindService(this);
    disconnect();

    super.onDestroy();
  }
```

However, in between `onServiceConnected()` and either `onServiceDisconnected()` or `onDestroy()`, the user can click the `Button`, which will trigger the download via a call to `download()` on our `IDownload` instance:

```
  @Override
  public void onClick(View view) {
    binding.download(TO_DOWNLOAD);
  }
```

The `DownloadBindingDemo` activity adds our `DownloadFragment` via a `FragmentTransaction`:

```
package com.commonsware.android.advservice.binding;

import android.app.Activity;
import android.os.Bundle;

public class DownloadBindingDemo extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
                                 .add(android.R.id.content,
                                      new DownloadFragment()).commit();
    }
  }
}
```

Starting and Binding

Some developers will use *both* `startService()` and `bindService()` at the same time. The typical argument is that they need frequent updates from the service (e.g., percentage of progress, for updating a `ProgressBar`) in the client and are concerned about the overhead of sending broadcasts.

With the advent of LocalBroadcastManager and other event bus implementations, binding to a service you are using with startService() should no longer be necessary.

When IPC Attacks!

If you wish to extend the binding pattern to serve in the role of IPC, whereby other processes can get at your Binder and call its methods, you will need to use AIDL: the Android Interface Description Language. If you have used IPC mechanisms like SOAP, XML-RPC, DCOM, CORBA, or the like, you will recognize the notion of IDL. AIDL describes the public IPC interface, and Android supplies tools to build the client and server side of that interface.

With that in mind, let's take a look at AIDL and IPC.

Write the AIDL

IDLs are frequently written in a "language-neutral" syntax. AIDL, on the other hand, looks a lot like a Java interface file. For example, here is some AIDL:

```
package com.commonsware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
  void download(String url);
}
```

As you will notice, this looks suspiciously like the regular Java interface we used in the simple binding example earlier in this chapter.

As with a Java interface, you declare a package at the top. As with a Java interface, the methods are wrapped in an interface declaration (interface IDownload { ... }). And, as with a Java interface, you list the methods you are making available.

The differences, though, are critical.

First, not every Java type can be used as a parameter. Your choices are:

1. Primitive values (int, float, double, boolean, etc.)
2. String and CharSequence
3. List and Map (from java.util)
4. Any other AIDL-defined interfaces

5. Any Java classes that implement the Parcelable or Serializable interface

In the case of the latter two categories, you need to include import statements referencing the names of the classes or interfaces that you are using (e.g., import com.commonsware.android.ISomething). This is true even if these classes are in your own package — you have to import them anyway.

Next, parameters can be classified as in, out, or inout. Values that are out or inout can be changed by the service and those changes will be propagated back to the client. Primitives (e.g., int) can only be in.

Also, you cannot throw any exceptions. You will need to catch all exceptions in your code, deal with them, and return failure indications some other way (e.g., error code return values).

Name your AIDL files with the .aidl extension and place them in the proper directory based on the package name:

- For native Android Studio projects, this will be an aidl/ directory in your src/ sourceset, as a peer of your java/ directory, with the same sort of subdirectories-based-on-the-Java-package approach as you use for regular Java source code
- For Eclipse-compatible projects, the .aidl files will go alongside your .java files in the src/ directory tree

When you build your project, either via an IDE or via command-line build tools, the aidl utility from the Android SDK will translate your AIDL into a server stub and a client proxy.

Implement the Interface

Given the AIDL-created server stub, now you need to implement the service, either directly in the stub, or by routing the stub implementation to other methods you have already written.

The mechanics of this are fairly straightforward:

1. Create a subclass of the AIDL-generated .Stub class (e.g., IDownload.Stub)
2. Implement methods matching up with each of the methods you placed in the AIDL

3. Return an instance of this subclass from your `onBind()` method in the `Service` subclass

Note that AIDL IPC calls are synchronous, and so the caller is blocked until the IPC method returns. Hence, your services need to be quick about their work.

We will see examples of service stubs later in this chapter.

Service From Afar

So, given our AIDL description, let us examine a sample implementation, using AIDL for a remote service.

Our sample applications — shown in the `Binding/Remote/Service` and `Binding/Remote/Client` sample projects — simply move the service logic into a separate project from the client logic.

Service Names

To bind to a service's AIDL-defined API, you need to craft an `Intent` that can identify the service in question. In the case of a local service, that Intent can use the local approach of directly referencing the service class.

Obviously, that is not possible in a remote service case, where the service class is not in the same process, and may not even be known by name to the client.

When you define a service to be used by remote, you need to add an `<intent-filter>` element to your service declaration in the manifest, indicating how you want that service to be referred to by clients. The manifest for `RemoteService` is shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.advservice.remotebinding.svc"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET" />
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

  <application
```

```
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <service android:name=".DownloadService">
            <intent-filter>
                <action
android:name="com.commonsware.android.advservice.remotebinding.IDownload" />
            </intent-filter>
        </service>
  </application>

</manifest>
```

Here, we say that the service can be identified by the name `com.commonsware.android.advservice.IDownload`. So long as the client uses this name to identify the service, it can bind to that service's API.

In this case, the name is not an implementation, but the AIDL API, as you will see below. In effect, this means that so long as some service exists on the device that implements this API, the client will be able to bind to something.

Remote Services and Implicit Intents

We are used to a device having multiple activities that can respond to the same `<intent-filter>`. In that case, by default, the user will see a chooser if we try to start one of those activities.

We are used to a device having multiple `BroadcastReceiver` components that can respond to the same `<intent-filter>` (or `IntentFilter`). In that case, in a regular broadcast, all eligible receivers will receive it.

We are used to it being impossible to have multiple `ContentProvider` components with the same authority, as the second one fails on install with an `INSTALL_FAILED_CONFLICTING_PROVIDER` error.

What happens if there are *two* (or more) services installed on the device that claim to support the same `<intent-filter>`, but have different package names? You might think that this would fail on install, as happens with providers with duplicate authorities. Alas, it does not… prior to Android 5.0. Instead, the higher-priority `<intent-filter>` gets it (set via the `android:priority` attribute). If 2+ implementations have the same priority, the first one installed wins.

So, if we have `BadService` and `GoodService`, both responding to the same `<intent-filter>`, and a client app tries to communicate to `GoodService` via the implicit `Intent` matching that `<intent-filter>`, it might *actually* be communicating with BadService, simply because BadService was installed first. The user is oblivious to this.

Android 5.0 solves this by preventing binding using an implicit Intent. This, however, presents a conundrum:

- We cannot bind using an implicit Intent
- We do not know how to construct an explicit Intent identifying the desired service, as that might be from a third-party app

As you will see, when we examine the client side of this sample, we have to use PackageManager to convert an implicit Intent into a valid explicit Intent for our service. This not only allows us to comply with the Android 5.0 binding restriction, but it gives us an opportunity to detect and handle the cases where there is no matching service (e.g., the service app has not yet been installed) or when there is more than one matching service (e.g., BadService and GoodService). And the techniques that all of this uses works on pretty much any version of Android, so while we *need* them for Android 5.0 and higher, we can *use* them anywhere.

The Service

Beyond the manifest, the service implementation is not too unusual. There is the AIDL interface, IDownload:

```
package com.commonsware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
  void download(String url);
}
```

And there is the actual service class itself, DownloadService:

```
package com.commonsware.android.advservice.remotebinding.svc;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import com.commonsware.android.advservice.remotebinding.IDownload;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
  @Override
  public IBinder onBind(Intent intent) {
    return(new DownloadBinder());
  }

  private static class DownloadBinder extends IDownload.Stub {
    @Override
    public void download(String url) {
      new DownloadThread(url).start();
    }
  }

  private static class DownloadThread extends Thread {
    String url=null;

    DownloadThread(String url) {
      this.url=url;
    }

    @Override
    public void run() {
      try {
        File root=

Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

        root.mkdirs();

        File output=new File(root, Uri.parse(url).getLastPathSegment());

        if (output.exists()) {
          output.delete();
        }

        HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

        FileOutputStream fos=new FileOutputStream(output.getPath());
        BufferedOutputStream out=new BufferedOutputStream(fos);

        try {
          InputStream in=c.getInputStream();
          byte[] buffer=new byte[8192];
          int len=0;

          while ((len=in.read(buffer)) >= 0) {
            out.write(buffer, 0, len);
          }

          out.flush();
        }
        finally {
          fos.getFD().sync();
          out.close();
          c.disconnect();
        }
      }
      catch (IOException e2) {
        Log.e("DownloadJob", "Exception in download", e2);
      }
    }
  }
}
```

This is identical to the local binding example, with one key difference: `DownloadService` now extends `IDownload.Stub` rather than the generic `Binder` class.

The Client

The client — a revised version of `DownloadFragment` — connects to the remote service to ask it to download the file on the user's behalf. This has three changes of note over our original local implementation.

First, when we call `download()` on the `IDownload` object, we need to catch a `RemoteException`. This will thrown if the service crashes during our request or otherwise is unable to return properly:

```
  @Override
  public void onClick(View view) {
    try {
      binding.download(TO_DOWNLOAD);
    }
    catch (RemoteException e) {
      Log.e(getClass().getSimpleName(), "Exception requesting download", e);
      Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
    }
  }
```

Second, our `onServiceConnected()` uses `IDownload.Stub.asInterface()` to convert the raw `IBinder` into an `IDownload` object for use:

```
  @Override
  public void onServiceConnected(ComponentName className, IBinder binder) {
    binding=IDownload.Stub.asInterface(binder);
    btn.setEnabled(true);
  }
```

Third, our binding logic in `onCreate()` is significantly more complicated:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();
    Intent implicit=new Intent(IDownload.class.getName());
    List<ResolveInfo> matches=getActivity().getPackageManager()
      .queryIntentServices(implicit, 0);

    if (matches.size() == 0) {
      Toast.makeText(getActivity(), "Cannot find a matching service!",
        Toast.LENGTH_LONG).show();
    }
    else if (matches.size() > 1) {
      Toast.makeText(getActivity(), "Found multiple matching services!",
        Toast.LENGTH_LONG).show();
    }
    else {
      Intent explicit=new Intent(implicit);
      ServiceInfo svcInfo=matches.get(0).serviceInfo;
      ComponentName cn=new ComponentName(svcInfo.applicationInfo.packageName,
        svcInfo.name);

      explicit.setComponent(cn);
      appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
    }
  }
```

Here, we:

- Get the `Application` singleton `Context` as before
- Craft an implicit `Intent` for the service, using the appropriate action string (which, in this case, happens to be the fully-qualified name of the `IDownload` interface)
- Use `PackageManager` and `queryIntentServices()` to find out all services that implement a matching `<intent-filter>` for that implicit `Intent`
- Fail with a `Toast` if there is not exactly one such service
- Use the `ServiceInfo` object from our `queryIntentServices()` call to craft an explicit `Intent`, with the same structure as the implicit `Intent` had, but also with the actual matched component (via `setComponent()`)
- Use the explicit `Intent` to bind to the service

Note that the client needs its own copy of `IDownload.aidl`. After all, it is a totally separate application, and therefore does not share source code with the service. In a production environment, we might craft and distribute a JAR file that contains the `IDownload` classes, so both client and service can work off the same definition (see the upcoming chapter on reusable components). For now, we will just have a copy of the AIDL.

If you compile both applications and upload them to the device, then start up the client, you can have the service download the file.

Tightening Up the Security

The previous sample confirms that there is exactly one service that matches the desired `Intent`. This catches the zero-service scenario (requiring the user to install the other app) and catches the multiple-service scenario (where one service is an attacker, presumably).

However, what happens if there is only one service installed, and it is not the desired service, but rather is an attacker? The preceding binding code will still go ahead and bind with that service.

You might consider just examining the package name/application ID of the other service, to see if it matches an expected value. However, that will not help you if the attacker is a modified version of the real service, one that kept its original package name but changed the service to do evil things.

Checking the digital signature of the other service is a more robust check, as that cannot readily be forged. Even if somebody modifies and repackages the app with the service, that app would wind up being signed by a different signing key, which you can detect.

Moreover, this approach can be used in both directions: the client can validate the service, and the service can validate the client. For example, perhaps as part of a licensing scheme, your service can only be used by apps developed by certain firms, based upon their signing keys.

The `Binding/SigCheck/Client` sample project illustrates a client that will perform this signature check on the client side. The corresponding service project – `Binding/SigCheck/Service` – will perfom a signature check on the service side.

Adding the Dependency

Both projects use the CWAC-Security library, described elsewhere in this book, to do the signature checking. Hence, their Gradle build files have a dependency on that library:

```
buildscript {
    repositories {
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.2.3'
        // NOTE: Do not place your application dependencies here; they belong
        // in the individual module build.gradle files
    }
```

Adding the Signature Check: Client

The client's `DownloadFragment` is nearly the same as before, with an adjustment to `onCreate()` to check the signature if there is exactly one service that matches the `Intent`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  setRetainInstance(true);

  appContext=(Application)getActivity().getApplicationContext();

  Intent implicit=new Intent(IDownload.class.getName());
  List<ResolveInfo> matches=getActivity().getPackageManager()
    .queryIntentServices(implicit, 0);

  if (matches.size() == 0) {
    Toast.makeText(getActivity(), "Cannot find a matching service!",
      Toast.LENGTH_LONG).show();
  }
  else if (matches.size() > 1) {
    Toast.makeText(getActivity(), "Found multiple matching services!",
      Toast.LENGTH_LONG).show();
  }
  else {
    ServiceInfo svcInfo=matches.get(0).serviceInfo;

    try {
      String otherHash=SignatureUtils.getSignatureHash(getActivity(),
        svcInfo.applicationInfo.packageName);
      String expected=getActivity().getString(R.string.expected_sig_hash);

      if (expected.equals(otherHash)) {
        Intent explicit=new Intent(implicit);
        ComponentName cn=new ComponentName(svcInfo.applicationInfo.packageName,
          svcInfo.name);

        explicit.setComponent(cn);
        appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
      }
      else {
        Toast.makeText(getActivity(), "Unexpected signature found!",
          Toast.LENGTH_LONG).show();
      }
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(), "Exception trying to get signature hash", e);
    }
  }
}
```

In the one-match scenario, we get the signature of the other app, by using `getSignatureHash()` on `SignatureUtils`, passing in the package name of the other app. We then compare that with a hard-coded expected hash, pulled from a string resource, one that is unfortunately too long to represent in this book.

Only if those two match do we go ahead with the binding.

Adding the Signature Check: Service

This gets a bit more complicated, as we first need to figure out who the client *is*, before we can validate the signature. In the case of the client connecting to the service, we know the application ID of the service courtesy of the `queryIntentServices()` call. On the service side, we need to use a different approach to identify who the client is.

To do this work, `DownloadBinder` now needs a `Context` with which to work, so `onBind()` passes one to a revised `DownloadBinder` constructor:

```
@Override
public IBinder onBind(Intent intent) {
  return(new DownloadBinder(this));
}
```

The constructor holds on to three things:

- a `Context`, in this case the `Application` obtained from the `Service`
- a `PackageManager`, as we will need this for the signature lookup
- the expected hash of the client's signing key, pulled once again from a string resource

```
private static class DownloadBinder extends IDownload.Stub {
  private final PackageManager pm;
  private final String expectedHash;
  private final Context ctxt;

  public DownloadBinder(Context ctxt) {
    this.ctxt=ctxt.getApplicationContext();
    this.pm=this.ctxt.getPackageManager();
    this.expectedHash=this.ctxt.getString(
      R.string.expected_sig_hash);
  }
```

A `Binder` can find out who is invoking one of its exposed methods via `Binder.getCallingUid()`. This returns the Linux user ID (uid) that the client uses.

Normally, this will be tied to one application ID. However, it is possible for a suite of apps to share a Linux user ID, via the `android:sharedUserId` option in the manifest. Hence, the call to map the user ID to an application ID is `getPackagesForUid()` on `PackageManager`, which returns a *list* of application IDs.

So, the revised `download()` method iterates over those application IDs to see if any of them have the expected signature:

```
@Override
public void download(String url) {
  boolean ok=false;

  for (String pkg :
    pm.getPackagesForUid(Binder.getCallingUid())) {
    try {
      String otherHash=
        SignatureUtils.getSignatureHash(ctxt, pkg);

      if (expectedHash.equals(otherHash)) {
        ok=true;
        break;
      }
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(),
        "Exception finding signature hash", e);
    }
  }

  if (ok) {
    new DownloadThread(url).start();
  }
  else {
    Log.e(getClass().getSimpleName(),
      "Could not validate client signature");
  }
}
```

In practice, Android itself will ensure that if there are several application IDs sharing a Linux user ID, they will all be signed by the same signing key.

If and only if we find a signature match do we actually do the download; otherwise, we log an error.

This happens to be a very simple service with a single-method `Binder`. In a more complicated service, where there are several methods exposed by the `Binder`, the signature-check logic could be refactored into a common private method that the AIDL-defined Binder methods could all use to validate the client.

So, Where Do We Get the Expected Hash From?

Today, there are two main ways you can get the expected hash:

- Since this is really a hash of the public part of the app's signing key, the author of the other app might publish it as part of integration documentation, where the hash is generated via keytool
- You might call getSignatureHash() from your app and log the results, running it against a known good copy of the other app

Servicing the Service

However, we do not get any result back from the service to know if the download succeeded or failed. That is likely to be rather important information for the user.

In principle, download() could return some success-or-failure indication… but then we would have a blocking call. Neither the client nor the service could proceed until the download is completed. That would require the client to manage its own background thread, which is a minor hassle. It also means that the service ties up one of a limited number of "Binder threads", which is not a good idea.

Another approach would be to pass some sort of callback object with download(), such that the server could run the script asynchronously and invoke the callback on success or failure. This, though, implies that there is some way to have the client export an API to the service.

Fortunately, this is eminently doable, as you will see in this section, and the accompanying samples (Binding/Callback/Service and Binding/Callback/Client).

Callbacks via AIDL

AIDL does not have any concept of direction. It just knows interfaces, proxies, and stub implementations. In the preceding example, we used AIDL to have the service flesh out the stub implementation and have the client access the service via the AIDL-defined interface. However, there is nothing magic about services implementing interfaces and clients accessing them — it is equally possible to reverse matters and have the client implement something the service uses via an interface.

So, for example, we could create an `IDownloadCallback.aidl` file:

```
package com.commonsware.android.advservice.callbackbinding;

// Declare the interface.
interface IDownloadCallback {
  void onSuccess();
  void onFailure(String msg);
}
```

Then, we can augment `IDownload` itself, to pass an `IDownloadCallback` with `download()`:

```
package com.commonsware.android.advservice.callbackbinding;

import com.commonsware.android.advservice.callbackbinding.IDownloadCallback;

// Declare the interface.
interface IDownload {
  void download(String url, IDownloadCallback cb);
}
```

Notice that we need to specifically import `IDownloadCallback`, just like we might import some "regular" Java interface. And, as before, we need to make sure the client and the server are working off of the same AIDL definitions, so these two AIDL files need to be replicated across each project.

But other than that one little twist, this is all that is required, at the AIDL level, to have the client pass a callback object to the service: define the AIDL for the callback and add it as a parameter to some service API call.

Of course, there is a little more work to do on the client and server side to make use of this callback object.

Revising the Client

On the client, we need to implement an `IDownloadCallback`. In `onSuccess()` and `onFailure()` we can do something like raise a `Toast`.

The catch is that we cannot be certain we are being called on the UI thread in our callback object. In fact, it is almost assured that we are not. So, we need to get our work moved over to the main application thread. To do that, this sample uses greenrobot's EventBus, having the IDownloadCallback.Stub post a CallbackEvent indicating success or failure:

```
IDownloadCallback.Stub cb=new IDownloadCallback.Stub() {
  @Override
  public void onSuccess() throws RemoteException {
    EventBus.getDefault().post(new CallbackEvent(true, null));
  }

  @Override
  public void onFailure(String msg) throws RemoteException {
    EventBus.getDefault().post(new CallbackEvent(false, msg));
  }
};

static class CallbackEvent {
  boolean succeeded=false;
  String msg=null;

  CallbackEvent(boolean succeeded, String msg) {
    this.succeeded=succeeded;
    this.msg=msg;
  }
}
```

The fragment itself registers for the event bus, and in onEventMainThread(), it raises the Toast:

```
public void onEventMainThread(CallbackEvent event) {
  if (getActivity()!=null) {
    if (event.succeeded) {
      Toast.makeText(getActivity(), "Download successful!", Toast.LENGTH_LONG).show();
    }
    else {
      Toast.makeText(getActivity(), event.msg, Toast.LENGTH_LONG).show();
    }
  }
}
```

And, of course, we need to pass the IDownloadCallback object in our download() call:

```
@Override
public void onClick(View view) {
  try {
    binding.download(TO_DOWNLOAD, cb);
  }
  catch (RemoteException e) {
    Log.e(getClass().getSimpleName(), "Exception requesting download", e);
    Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
  }
}
```

Revising the Service

The service also needs changing, to use the supplied callback object for the end results of the download.

`DownloadBinder` now receives an `IDownloadCallback` proxy in its `download()` method, which it passes along to the `DownloadThread`:

```
private static class DownloadBinder extends IDownload.Stub {
  @Override
  public void download(String url, IDownloadCallback cb) {
    new DownloadThread(url, cb).start();
  }
}
```

Notice that the service's own API just needs the `IDownloadCallback` parameter, which can be passed around and used like any other Java object. The fact that it happens to cause calls to be made synchronously back to the remote client is invisible to the service.

`DownloadThread`, in turn, invokes `onSuccess()` or `onFailure()` as appropriate:

```
private static class DownloadThread extends Thread {
  String url=null;
  IDownloadCallback cb=null;

  DownloadThread(String url, IDownloadCallback cb) {
    this.url=url;
    this.cb=cb;
  }

  @Override
  public void run() {
    try {
      File root=
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

      root.mkdirs();

      File output=new File(root, Uri.parse(url).getLastPathSegment());

      if (output.exists()) {
        output.delete();
      }

      HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

      FileOutputStream fos=new FileOutputStream(output.getPath());
      BufferedOutputStream out=new BufferedOutputStream(fos);

      try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[8192];
        int len=0;

        while ((len=in.read(buffer)) >= 0) {
          out.write(buffer, 0, len);
        }

        out.flush();

        try {
          cb.onSuccess();
        }
        catch (RemoteException e) {
          Log.e("DownloadJob", "Exception when calling onSuccess()", e);
        }
      }
      finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
      }
    }
    catch (IOException e2) {
      Log.e("DownloadJob", "Exception in download", e2);

      try {
        cb.onFailure(e2.getMessage());
      }
      catch (RemoteException e) {
        Log.e("DownloadJob", "Exception when calling onFailure()", e2);
      }
    }
  }
}
```

Thinking About Security

Remote services, by definition, are available for anyone to connect to. This may or may not be a good idea.

If the only client of your remote service is some other app of yours, you could protect the service using a custom signature-level permission.

If you anticipate third-party apps communicating with your service, you should strongly consider protecting the service with an ordinary custom permission, so the *user* can vote on whether the communication is allowed.

For local services, the simplest way to secure the service is to not export it, typically by not having an `<intent-filter>` element for the `<service>` in the manifest. Then, your app is the only app that can work with the service.

The “Everlasting Service” Anti-Pattern

One anti-pattern that is all too prevalent in Android is the “everlasting service”. Such a service is started via `startService()` and never stops — the component starting it does not stop it and it does not stop itself via `stopSelf()`.

Why is this an anti-pattern?

1. The service takes up memory all of the time. This is bad in its own right if the service is not continuously delivering sufficient value to be worth the memory.
2. Users, fearing services that sap their device’s CPU or RAM, may attack the service with so-called “task killer” applications or may terminate the service via the Settings app, thereby defeating your original goal.
3. Android itself, due to user frustration with sloppy developers, will terminate services it deems ill-used, particularly ones that have run for quite some time.

Occasionally, an everlasting service is the right solution. Take a VOIP client, for example. A VOIP client usually needs to hold an open socket with the VOIP server to know about incoming calls. The only way to continuously watch for incoming calls is to continuously hold open the socket. The only component capable of doing that would be a service, so the service would have to continuously run.

However, in the case of a VOIP client, or a music player, the user is the one specifically requesting the service to run forever. By using `startForeground()`, a service can ensure it will not be stopped due to old age for cases like this.

As a counter-example, imagine an email client. The client wishes to check for new email messages periodically. The right solution for this is the `AlarmManager` pattern described elsewhere in this book. The anti-pattern would have a service running constantly, spending most of its time waiting for the polling period to elapse (e.g., via `Thread.sleep()`). There is no value to the user in taking up RAM to watch the clock tick. Such services should be rewritten to use `AlarmManager`.

Most of the time, though, it appears that services are simply leaked. That is one advantage of using `AlarmManager` and an `IntentService` – it is difficult to leak the service, causing it to run indefinitely. In fact, `IntentService` in general is a great implementation to use whenever you use the command pattern, as it ensures that the service will shut down eventually. If you use a regular service, be sure to shut it down when it is no longer actively delivering value to the user.

Advanced Manifest Tips

If you have been diligent about reading this book (versus having randomly jumped to this chapter), you will already have done a fair number of things with your project's `AndroidManifest.xml` file:

1. Used it to define components, like activities, services, content providers, and manifest-registered broadcast receivers
2. Used it to declare permissions your application requires, or possibly to define permissions that other applications need in order to integrate with your application
3. Used it to define what SDK level, screen sizes, and other device capabilities your application requires

In this chapter, we continue looking at things the manifest offers you, starting with a discussion of controlling where your application gets installed on a device, and wrapping up with a bit of information about activity aliases.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Just Looking For Some Elbow Room

On October 22, 2008, the HTC Dream was released, under the moniker of "T-Mobile G1", as the first production Android device.

Complaints about the lack of available storage space for applications probably started on October 23rd.

The Dream, while a solid first Android device, offered only 70MB of on-board flash for application storage. This storage had to include:

1. The Android application (APK) file
2. Any local files or databases the application created, particularly those deemed unsafe to put on the SD card (e.g., privacy)
3. Extra copies of some portions of the APK file, such as the compiled Dalvik bytecode, which get unpacked on installation for speed of access

It would not take long for a user to fill up 70MB of space, then have to start removing some applications to be able to try others.

Users and developers alike could not quite understand why the Dream had so little space compared to the available iPhone models, and they begged to at least allow applications to install to the SD card, where there would be more room. This, however, was not easy to implement in a secure fashion, and it took until Android 2.2 for the feature to become officially available.

If your app's `android:minSdkVersion` is 11 or higher, you can probably ignore all of this. At that time, what the Android SDK refers to as "internal storage" and "external storage" were moved to be part of one filesystem partition, and so there is no artificial division of space between the two.

But, if you are still supporting Android 2.2 and 2.3, you may wish to consider supporting having your app be installed to, or moved to, external storage.

Configuring Your App to Reside on External Storage

Indicating to Android that your application can reside on the SD card is easy… and necessary, if you want the feature. If you do not tell Android this is allowed, Android will *not* install your application to the SD card, nor allow the user to move the application to the SD card.

All you need to do is add an `android:installLocation` attribute to the root `<manifest>` element of your `AndroidManifest.xml` file. There are three possible values for this attribute:

- internalOnly, the default, meaning that the application cannot be installed to the SD card
- preferExternal, meaning the application would like to be installed on the SD card
- auto, meaning the application can be installed in either location

If you use preferExternal, then your application will be initially installed on the SD card in most cases. Android reserves the right to still install your application on internal storage in cases where that makes too much sense, such as there not being an SD card installed at the time.

If you use auto, then Android will make the decision as to the installation location, based on a variety of factors. In effect, this means that auto and preferExternal are functionally very similar – all you are doing with preferExternal is giving Android a hint as to your desired installation destination.

Because Android decides where your application is initially installed, and because the user has the option to move your application between the SD card and on-board flash, you cannot assume any given installation spot. The exception is if you choose internalOnly, in which case Android will honor your request, at the potential cost of not allowing the installation at all if there is no more room in on-board flash.

For example, here is the manifest from the SMS/Sender sample project, profiled in another chapter, showing the use of preferExternal:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.sms.sender"
  android:installLocation="preferExternal"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.READ_CONTACTS"/>
  <uses-permission android:name="android.permission.SEND_SMS"/>

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
```

```
      android:name="Sender"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Since this feature only became available in Android 2.2, to support older versions of Android, just have your build tools target API level 8 (e.g., `compileSdkVersion` of 8 or higher in `build.gradle` for Android Studio users, or Project > Properties > Android for those of you building with Eclipse) while having your `minSdkVersion` attribute in the manifest state the lowest Android version your application supports overall. Older versions of Android will ignore the `android:installLocation` attribute. So, for example, in the above manifest, the `Sender` application supports API level 4 and above (Android 1.6 and newer), but still can use `android:installLocation="preferExternal"`, because the build tools are targeting API level 8.

What the User Sees

On newer devices, such as those running Android 4.2, the user will see nothing different. That is because internal and external storage share a common pool of space, and therefore there is no advantage in having your application installed to external storage.

However, on, say, Android 2.3, you will see a difference in behavior.

For an application that wound up on external storage, courtesy of your choice of `preferExternal` or `auto`, the user will have an option to move it to the phone's internal storage. This can be done by choosing the application in the Manage Applications list in the Settings application, then clicking the "Move to phone" button.

Conversely, if your application is installed in on-board flash, and it is movable to external storage, they will be given that option with a "Move to SD card" button.

What the Pirate Sees

Ideally, the pirate sees nothing at all.

One of the major concerns with installing applications to the SD card is that the SD card is usually formatted FAT32 (`vfat`), offering no protection from prying eyes. The concern was that pirates could then just pluck the APK file off external storage and distribute it, even for paid apps from the Play Store.

Apparently, they solved this problem.

To quote the Android developer documentation:

> The unique container in which your application is stored is encrypted with a randomly generated key that can be decrypted only by the device that originally installed it. Thus, an application installed on an SD card works for only one device.

Moreover, this "unique container" is not normally mounted when the user mounts external storage on their host machine. The user mounts `/mnt/sdcard`; the "unique container" is `/mnt/asec`.

What Your App Sees… When External Storage is Inaccessible

So far, this has all seemed great for users and developers. Developers need to add a single attribute to the manifest, and Android 2.2+ users gain the flexibility of where the app gets stored.

Alas, there is a problem, and it is a big one: on Android 1.x and 2.x, either the host PC or the device can have access to the SD card, but not both. As a result, if the user makes the SD card available to the host PC, by plugging in the USB cable and mounting the SD card as a drive via a `Notification` or other means, that SD card becomes unavailable for running applications.

So, what happens?

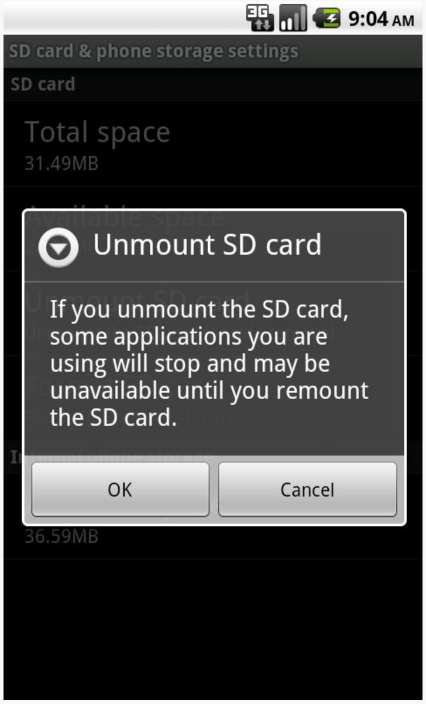
1. First, your application is terminated forcibly, as if your process was being closed due to low memory. Notably, your activities and services will not be called with `onDestroy()`, and instance state saved via `onSaveInstanceState()` is lost.
2. Second, your application is unhooked from the system. Users will not see your application in the launcher, your `AlarmManager` alarms will be canceled, and so on.

3. When the user makes external storage available to the phone again, your application will be hooked back into the system and will be once again available to the user (for example, your icon will reappear in the launcher)

The upshot: if your application is simply a collection of activities, otherwise not terribly connected to Android, the impact on your application is no different than if the user reboots the phone, kills your process via a so-called “task killer” application, etc. If, however, you are doing more than that, the impacts may be more dramatic.

Perhaps the most dramatic impact, from a user’s standpoint, will be if your application implements app widgets. If the user has your app widget on her home screen, that app widget will be removed when the SD card becomes unavailable to the phone. Worse, your app widget cannot be re-added to the home screen until the phone is rebooted (a limitation that hopefully will be lifted sometime after Android 2.2).

The user is warned about this happening, at least in general:



SD card & phone storage settings

SD card

Total space
31.49MB

Unmount SD card

If you unmount the SD card, some applications you are using will stop and may be unavailable until you remount the SD card.

36.59MB

Figure 772: Warning when unmounting the SD card

Two broadcast Intents are sent out related to this:

- `ACTION_EXTERNAL_APPLICATIONS_UNAVAILABLE`, when the SD card (and applications installed upon it) become unavailable
- `ACTION_EXTERNAL_APPLICATIONS_AVAILABLE`, when the SD card and its applications return to normal

Note that the documentation is unclear as to whether your own application, that had been on the SD card, can receive `ACTION_EXTERNAL_APPLICATIONS_AVAILABLE` once the SD card is back in action. There is an outstanding issue on this topic in the Android issue tracker.

Also note that all of these problems hold true for longer if the user physically removes the SD card from the device. If, for example, they replace the card with a different one — such as one with more space — your application will be largely lost. They will see a note in their applications list for your application, but the icon will indicate it is on external storage, and the only thing they can do is uninstall it:

Choosing Whether to Support External Storage

Given the huge problem from the previous section, the question of whether or not your application should support external storage is far from clear.

As the Android developer documentation states:

> Large games are more commonly the types of applications that should allow installation on external storage, because games don't typically provide additional services when inactive. When external storage becomes unavailable and a game process is killed, there should be no visible effect when the storage becomes available again and the user restarts the game (assuming that the game properly saved its state during the normal Activity lifecycle).

Conversely, if your application implements any of the following features, it may be best to not support external storage:

1. Polling of Web services or other Internet resources via a scheduled alarm
2. Account managers and their corresponding sync adapters, for custom sources of contact data
3. App widgets, as noted in the previous section
4. Device administration extensions
5. Live folders
6. Custom soft keyboards ("input method engines")
7. Live wallpapers
8. Custom search providers

But, as noted earlier, this is not even usually necessary on API Level 11+ devices. Hence, even if your app would otherwise qualify for being installed to external storage, you may not wish to bother. If few devices (Android 2.2 and Android 2.3) might need the capability, it may not be worth the extra testing burden.

Android 6.0 and "Adoption" of Removable Storage

When Android 3.0 did away with the required separate partitions for internal storage and external storage, the `android:installLocation` option fell out of use, as there was no particular value in having the apps on external storage. For single-partition devices — meaning, for most devices — users did not even have the option for moving their apps to external storage.

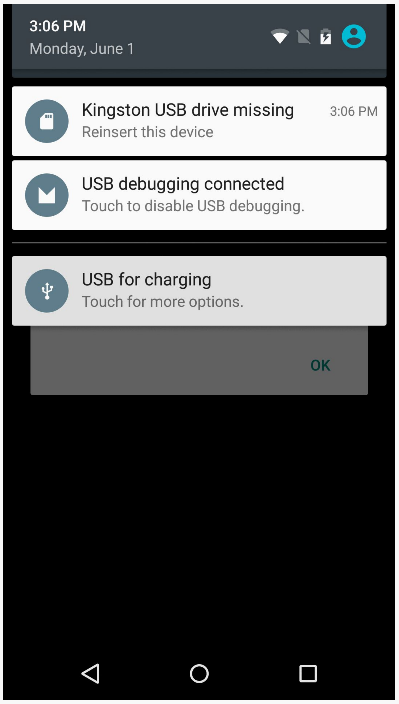
However, `android:installLocation` is returning to relevance, once again courtesy of removable media.

On Android 6.0+, users with removable storage options, such as micro SD card slots, have the option of "adopting" those as an extension of the device's internal storage. Once done, apps set with `auto` or `preferExternal` for `android:installLocation` can be moved to the removable media. However, there appears to be one key difference: not only is the APK on the removable media, but so is all of that app's portion of internal storage. The removable media is encrypted, so the material copied to the removable media should remain fairly inaccessible.

From the user's standpoint, for low-end devices with minimal on-board flash, they have additional storage space that they can use for apps.

However:

- Removable media tends to be slow, and some cards will be slower than others. For developers, this makes it all that much more important for you to move disk I/O off of the main application thread.
- Removable media tends to be removable. If the user removes the removable media, while your app is installed on that removable media, your app will no longer work.
- All the old rules for apps that allow themselves to be installed on external storage will still hold true. Basically, any app that does periodic work, or will respond to incoming GCM messages, or has an app widget, or is always possibly needed (e.g., custom soft keyboard), should not allow itself to be moved to removable media. If the user *does* eject the media, they will get a permanent `Notification` telling them to put it back:



3:06 PM
Monday, June 1

Kingston USB drive missing 3:06 PM
Reinsert this device

USB debugging connected
Touch to disable USB debugging.

USB for charging
Touch for more options.

Figure 774: Android 6.0, Ejected Adopted Removable Media Notification

The user does have an "Erase & Format" option that will reformat the removable media and allow it to be permanently removed from the device. It does not appear that this will automatically move any apps back to internal storage. The users would need to move those apps back to internal storage by means of the Apps list in Settings.

Normally, it appears this system will be limited to internal card slots for things like micro SD cards. While USB On-The-Go (OTG) allows Android devices to access thumb drives, those are likely to be accidentally removed by the user (not to mention they usually tie up the charging port). However, for development testing purposes, you can run the `adb shell sm set-force-adoptable true` command to allow the device to adopt USB OTG drives. Note though that once you do this, the drive is more or less owned by that Android device until you "Erase & Format" it, and you will lose everything on the drive as part of this whole process.

Using an Alias

As was mentioned in the chapter on integration, you can use the `PackageManager` class to enable and disable components in your application. This works at the component level, meaning you can enable and disable activities, services, content providers, and broadcast receivers. It does not support enabling or disabling individual `<intent-filter>` stanzas from a given component, though.

Why might you want to do this?

1. Perhaps you have an activity you want to be available for use, but not necessarily available in the launcher, depending on user configuration or unlocking “pro” features or something
2. Perhaps you want to add browser support for certain MIME types, but only if other third-party applications are not already installed on the device

While you cannot control individual `<intent-filter>` stanzas directly, you can have a similar effect via an activity alias.

An activity alias is another manifest element — `<activity-alias>` – that provides an alternative set of filters or other component settings for an already-defined activity. For example, here is the `AndroidManifest.xml` file from the `Manifest/Alias` sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
          android:versionName="1.0"
          package="com.commonsware.android.alias"
          xmlns:android="http://schemas.android.com/apk/res/android">

  <supports-screens android:largeScreens="true"
                    android:normalScreens="true"
                    android:smallScreens="false" />
  <application android:icon="@drawable/cw"
               android:label="@string/app_name">
    <activity android:label="@string/app_name"
              android:name="AliasActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
    <activity-alias android:label="@string/app_name2"
                    android:name="ThisIsTheAlias"
                    android:targetActivity="AliasActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity-alias>
  </application>
</manifest>
```

Here, we have one `<activity>` element, with an `<intent-filter>` to put the activity in the launcher. We also have an `<activity-alias>` element… which puts a second icon in the launcher for the same activity implementation.

An activity alias can be enabled and disabled independently of its underlying activity. Hence, you can have one activity class have several independent sets of intent filters and can choose which of those sets are enabled at any point in time.

For testing purposes, you can also enable and disable these from the command line. Use the **`adb shell pm disable`** command to disable a component:

```
adb shell pm disable
com.commonsware.android.alias/com.commonsware.android.alias.ThisIsTheAlias
```

… and the corresponding **`adb shell pm enable`** command to enable a component:

```
adb shell pm enable
com.commonsware.android.alias/com.commonsware.android.alias.ThisIsTheAlias
```

In each case, you supply the package of the application (`com.commonsware.android.alias`) and the class of the component to enable or disable (`com.commonsware.android.alias.ThisIsTheAlias`), separated by a slash.

Getting Meta (Data)

Sometimes, you may want to put more data in the manifest, associated with your components. You will frequently see this for use with libraries or plugin distribution models, where sharing some configuration data between parties could eliminate a bunch of API code that a reuser might need to implement.

To support this, Android offers a `<meta-data>` element as a child of `<activity>`, `<activity-alias>`, `<receiver>`, or `<service>`. Each `<meta-data>` element has an `android:name` attribute plus an associated value, supplied by either an `android:value` attribute (typically for literals) or an `android:resource` attribute (for references to resources).

Other parties can then get at this information via `PackageManager`. So, for example, the implementer of a plugin could have `<meta-data>` elements indicating details of how the plugin should be used (e.g., desired polling frequency), and the host of the plugin could then get that configuration data without the plugin author having to mess around with implementing some Java API for it.

For example, Roman Nurik's DashClock is a lockscreen app widget designed to serve as a replacement for the clock app widget that ships with many Android 4.2+ devices. Not only does it display the time, but it is a plugin host, allowing third party developers to supply "extensions" that can also display data in the app widget. This way, users can set up a single lockscreen app widget and get at a bunch of useful information.

DashClock's extension API makes use of `<meta-data>` to pass configuration data from the extension to DashClock itself. The implementation of a DashClock extension is a service, and so the extension's `<service>` element will have a batch of `<meta-data>` elements with this configuration data:

```
<service android:name=".ExampleExtension"
     android:icon="@drawable/ic_extension_example"
     android:label="@string/extension_title"

android:permission="com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA">
     <intent-filter>
         <action android:name="com.google.android.apps.dashclock.Extension" />
     </intent-filter>
     <meta-data android:name="protocolVersion" android:value="1" />
     <meta-data android:name="description"
         android:value="@string/extension_description" />
     <!-- A settings activity is optional -->
     <meta-data android:name="settingsActivity"
         android:value=".ExampleSettingsActivity" />
 </service>
```

(sample from the DashClock documentation)

Here, the developer can specify:

- What version of the communications protocol is supported, so DashClock can update its protocol over time yet remain backwards-compatible with older extensions, via the `protocolVersion` entry
- What the description is for the extension, used in DashClock's configuration screens to let the user know what available extensions there are, via the `description` entry
- What activity, if any, does the extension supply that allows the user to configure that extension, that DashClock should provide access to from its own settings activity, via the `settingsActivity` entry

In all three cases, DashClock uses `android:value`. Note that `android:value` *does* support the use of resources — the value of `description` is a reference to the `extension_description` string resource, for example.

To retrieve that metdata, an app can ask for `PackageManager.GET_META_DATA` as a flag on `PackageManager` methods for introspection, like `queryIntentActivities()`. In the case of DashClock, it retrieves all implementations of its plugin by asking Android what *services* have an `<intent-filter>` with an `<action>` of `com.google.android.apps.dashclock.Extension`, via `queryIntentServices()`, asking for `PackageManager` to also supply each service's metadata:

```
List<ResolveInfo> resolveInfos = pm.queryIntentServices(
                new Intent(DashClockExtension.ACTION_EXTENSION),
PackageManager.GET_META_DATA);
```

(from the `ExtensionManager.java` file in the DashClock source code)

Each `ResolveInfo` object that comes back in the list will have a `serviceInfo` field containing details of the service. Because `GET_META_DATA` was passed in as a flag, the `serviceInfo` will have a `Bundle` named `metaData` which will contain the key/value pairs specified by the `<meta-data>` elements. DashClock can then grab that data and use it to populate its own object model:

```
for (ResolveInfo resolveInfo : resolveInfos) {
    ExtensionListing listing = new ExtensionListing();
    listing.componentName = new ComponentName(resolveInfo.serviceInfo.packageName,
            resolveInfo.serviceInfo.name);
    listing.title = resolveInfo.loadLabel(pm).toString();
    Bundle metaData = resolveInfo.serviceInfo.metaData;
    if (metaData != null) {
        listing.protocolVersion = metaData.getInt("protocolVersion");
        listing.description = metaData.getString("description");
        String settingsActivity = metaData.getString("settingsActivity");
        if (!TextUtils.isEmpty(settingsActivity)) {
            listing.settingsActivity = ComponentName.unflattenFromString(
                    resolveInfo.serviceInfo.packageName + "/" + settingsActivity);
        }
    }
```

(from the `ExtensionManager.java` file in the DashClock source code)

The `<meta-data>` element supports five data types for `android:value`:

- String
- Integer
- Boolean (specified as `true` or `false` in the `android:value` attribute)
- Float

It also supports colors, specified in #AARRGGBB and similar formats, which, according to the documentation, is returned as a string.

In this fashion, extension developers can supply enough information for DashClock to allow the user to see the list of installed extensions, choose which one(s) they want, and configure those (where applicable). Actually getting the *content* to display will need to be done at runtime, in this case via making requests of the service to supply a `ExtensionData` structure with the messages, icon, and so forth to be displayed.

Miscellaneous Integration Tips

This chapter is a collection of other miscellaneous integration and introspection tips and techniques that you might find useful in your Android apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Take the Shortcut

Another way to integrate with Android is to offer custom shortcuts. Shortcuts are available from the home screen. Whereas app widgets allow you to draw on the home screen, shortcuts allow you to wrap a custom `Intent` with an icon and caption and put that on the home screen. You can use this to drive users not just to your application's "front door", like the launcher icon, but to some specific capability within your application, like a bookmark.

In our case, in the `Introspection/QuickSender` sample project, we will allow users to create shortcuts that use `ACTION_SEND` to send a pre-defined message, either to a specific address or anywhere, as we have seen before in this chapter.

Once again, the key is in the intent filter.

Registering a Shortcut Provider

Here is the manifest for `QuickSender`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonsware.android.qsender"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="15"
    android:targetSdkVersion="15"/>
  <application
    android:icon="@drawable/cw"
    android:label="@string/app_name">
    <activity
      android:name="QuickSender"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.CREATE_SHORTCUT"/>
        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

Our single activity does not implement a traditional launcher `<intent-filter>`. Rather, it has one that watches for a `CREATE_SHORTCUT` action. This does two things:

- It means that our activity will show up in the list of possible shortcuts a user can configure
- It means this activity will be the recipient of a `CREATE_SHORTCUT` Intent if the user chooses this application from the shortcuts list

Implementing a Shortcut Provider

The job of a shortcut-providing activity is to:

1. Create an `Intent` that will be what the shortcut launches
2. Return that `Intent` and other data to the activity that started the shortcut provider
3. Finally, `finish()`, so the caller gets control

You can see all of that in the `QuickSender` implementation:

```
package com.commonsware.android.qsender;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.widget.TextView;

public class QuickSender extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void save(View v) {
    Intent shortcut=new Intent(Intent.ACTION_SEND);
    TextView addr=(TextView)findViewById(R.id.addr);
    TextView subject=(TextView)findViewById(R.id.subject);
    TextView body=(TextView)findViewById(R.id.body);
    TextView name=(TextView)findViewById(R.id.name);

    if (!TextUtils.isEmpty(addr.getText())) {
      shortcut.putExtra(Intent.EXTRA_EMAIL,
                        new String[] { addr.getText().toString() });
    }

    if (!TextUtils.isEmpty(subject.getText())) {
      shortcut.putExtra(Intent.EXTRA_SUBJECT, subject.getText()
                                                .toString());
    }

    if (!TextUtils.isEmpty(body.getText())) {
      shortcut.putExtra(Intent.EXTRA_TEXT, body.getText().toString());
    }

    shortcut.setType("text/plain");

    Intent result=new Intent();

    result.putExtra(Intent.EXTRA_SHORTCUT_INTENT, shortcut);
    result.putExtra(Intent.EXTRA_SHORTCUT_NAME, name.getText()
                                              .toString());
    result.putExtra(Intent.EXTRA_SHORTCUT_ICON_RESOURCE,
                    Intent.ShortcutIconResource.fromContext(this,
                                                        R.drawable.icon));

    setResult(RESULT_OK, result);
    finish();
  }
}
```

The `shortcut` `Intent` is the one that will be launched when the user taps the shortcut icon on the home screen. The `result` `Intent` packages up shortcut plus the icon and caption, where the icon is converted into an `Intent.ShortcutIconResource` object. That `result` `Intent` is then used with the `setResult()` call, to pass that back to whatever called `startActivityForResult()` to open up `QuickSender`. Then, we `finish()`.

At this point, all the information about the shortcut is in the hands of Android (or, more accurately, the home screen application), which can add the icon to the home screen.

Using the Shortcuts

Exactly how `CREATE_SHORTCUT` implementations like this are handled depends on the home screen implementation. Some might not offer them at all. Other home screens might have dedicated options for shortcuts.

The Nexus series devices, running Android 6.0, lump `CREATE_SHORTCUT` implementations in with the app widgets. You can add one to your home screen by long-tapping on the home screen, choosing "Widgets", and scrolling down to the shortcut that you want:

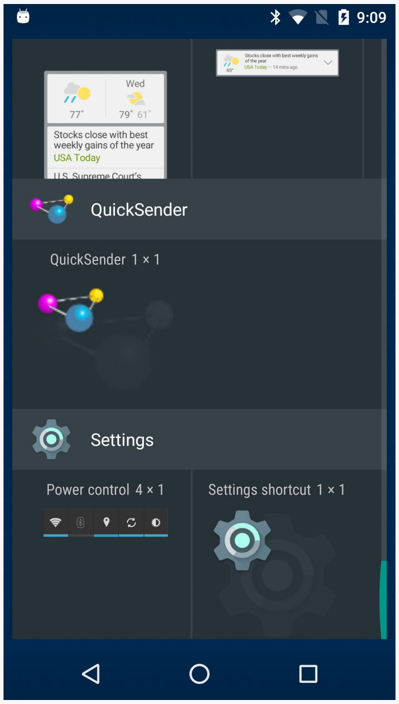


Figure 775: Android 6.0, Widgets List, Showing Sample App

Tap-and-hold on the "widget", and you will be able to place it on the screen. Once that is done, our activity will appear, with the form to define what to send:

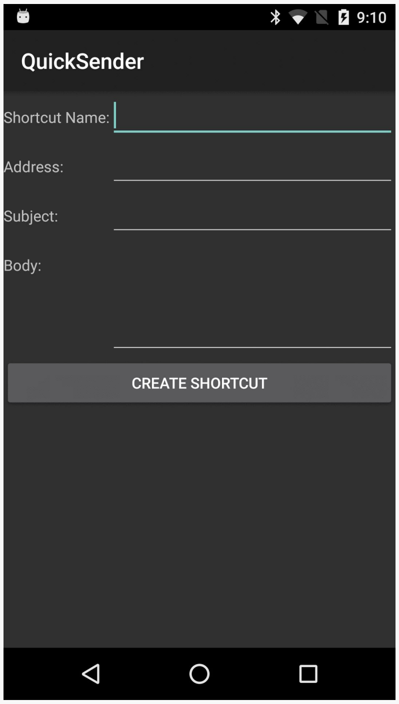

Figure 776: QuickSender Configuration Activity

Fill in the name, either the subject or body, and optionally the address. Then, click the Create Shortcut button, and you will find your shortcut sitting on your home screen, with your chosen shortcut name as the label:

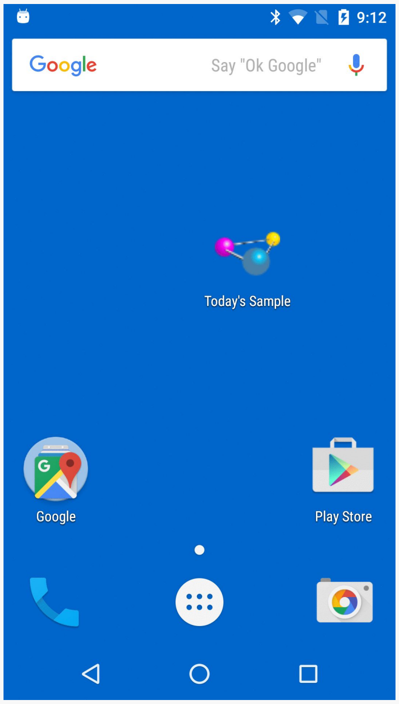

Figure 777: Home Screen, Showing QuickSender-Defined Shortcut

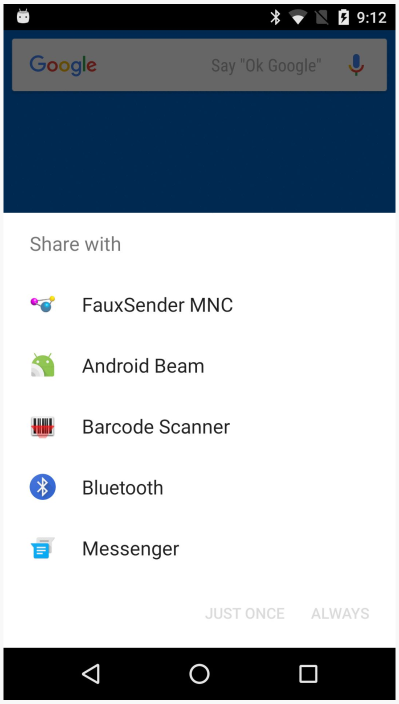
If you launch that shortcut, and if there is more than one application on the device set up to handle `ACTION_SEND`, Android will bring up a special chooser, to allow you to not only pick how to send the message, but optionally make that method the default for all future requests:



Share with

FauxSender MNC

Android Beam

Barcode Scanner

Bluetooth

Messenger

Figure 778: ACTION_SEND Request, As Triggered by Shortcut

Depending on what you choose, of course, will dictate how the message actually gets sent.

Homing Beacons for Intents

If you are encountering problems with `Intent` resolution — you create an `Intent` for something and try starting an `Activity` or `Service` with it, and it does not work — you can add the `FLAG_DEBUG_LOG_RESOLUTION` flag to the `Intent`. This will dump information to LogCat about how the `Intent` resolution occurred, so you can better diagnose what might be going wrong.

Integrating with Text Selection

On Android 6.0+, if you highlight text, you will see a new floating action mode, where cut, copy, and paste operations reside:

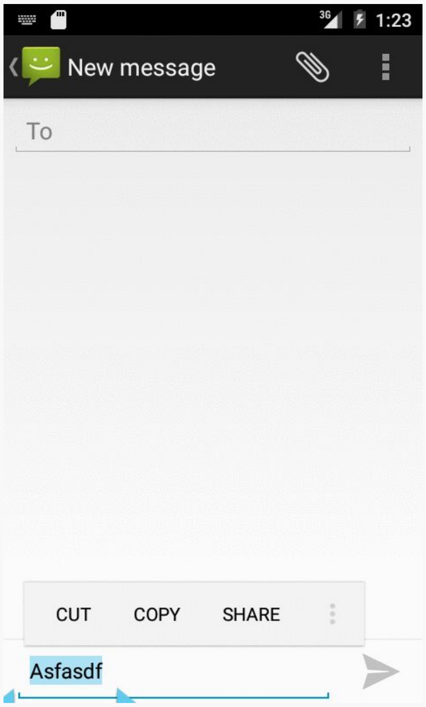


Figure 779: Floating Action Mode

If you tap that overflow indicator on the action mode, a fly-out menu will appear… one that contains arbitrary apps, in addition to system-supplied options:

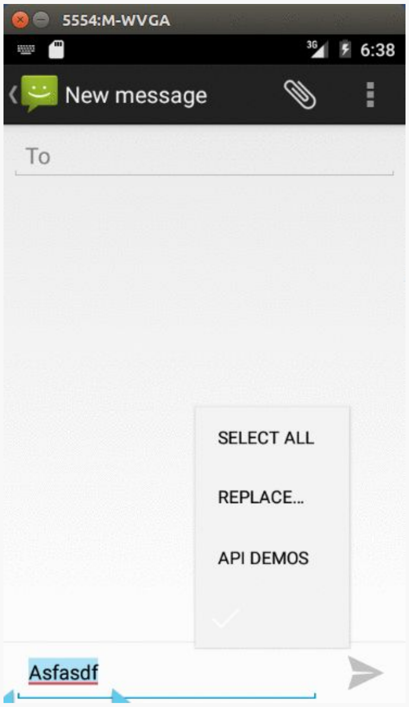

Figure 780: Floating Action Mode, Showing Overflow with Custom Apps

In this case, the Android 6.0 “API Demos” app appears as an option. Choosing it pops up an activity *that has access to the highlighted text from the preceding activity*:

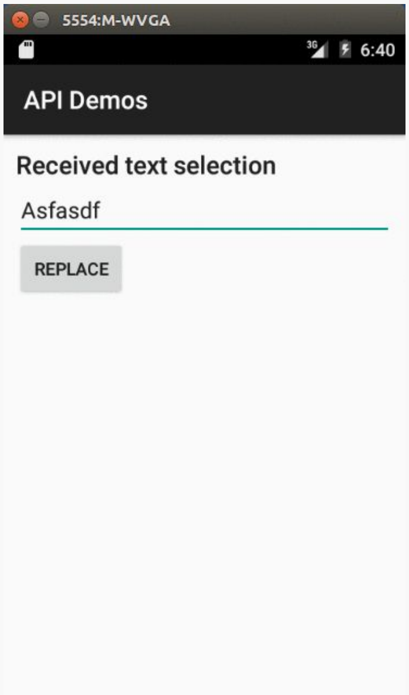

Figure 781: API Demos Application, Showing Text Selection

Replacing the value in the field and clicking the button puts your replacement text in as a replacement for whatever you had highlighted.

This is accomplished via the `ACTION_PROCESS_TEXT` `Intent` action. Apps can advertise activities that support this action, and they will be added (sometimes) to the floating action mode. Apps that have `EditText` widgets just automatically get these options in the floating action mode, with no additional required code.

Supporting ACTION_PROCESS_TEXT

Your app can offer an `ACTION_PROCESS_TEXT` activity, in which case you will appear in Android 6.0+ text-selection floating action modes. This is illustrated in the [`Introspection/ProcessText`]() sample application.

The Manifest

To be visible to these text-selection action modes, you need an activity with an `<intent-filter>` calling for `ACTION_PROCESS_TEXT` and a MIME type of `text/plain`:

```
    <activity
      android:name="MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
      <intent-filter >
        <action android:name="android.intent.action.PROCESS_TEXT"/>
        <category android:name="android.intent.category.DEFAULT" />
        <data android:mimeType="text/plain" />
      </intent-filter>
    </activity>
```

Exactly which MIME types are supported is not documented. At the time of this writing, the only examples showed `text/plain`. It is possible that other formats (e.g., `text/html`) might also be supported.

The Extras

You will get one of two extras attached to the `ACTION_PROCESS_TEXT` `Intent`:

- `EXTRA_PROCESS_TEXT` is the text to be processed, and also indicates that you can supply replacement text, if you wish
- `EXTRA_PROCESS_TEXT_READONLY` will be set if `EXTRA_PROCESS_TEXT` is not, and provides the text to be processed and an indication that you cannot supply replacement text

It is up to you to check for those string extras, grab the right value, and do something useful with it.

In the sample app, in `onCreate()` of the `MainActivity`, if we are starting fresh (i.e., there is no `QuestionsFragment` already), we get the search string and provide it to `QuestionsFragment` via a `newInstance()` factory method:

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      String search=null;

      if (Intent.ACTION_PROCESS_TEXT.equals(getIntent().getAction())) {
        search=getIntent().getStringExtra(Intent.EXTRA_PROCESS_TEXT);

        if (search==null) {
          search=getIntent()
            .getStringExtra(Intent.EXTRA_PROCESS_TEXT_READONLY);
        }
      }

      getFragmentManager()
        .beginTransaction()
        .add(android.R.id.content,
          QuestionsFragment.newInstance(search))
        .commit();
    }
  }
```

QuestionsFragment, in turn, stuffs that value into the arguments Bundle in newInstance():

```
public class QuestionsFragment extends ListFragment implements
    Callback<SOQuestions> {
  private static final String ARG_SEARCH="search";

  static QuestionsFragment newInstance(String search) {
    QuestionsFragment result=new QuestionsFragment();
    Bundle args=new Bundle();

    args.putString(ARG_SEARCH, search);
    result.setArguments(args);

    return(result);
  }
```

An expanded version of StackOverflowInterface offers not only the original questions() method, but also a search() method, the latter of which searches Stack Overflow for questions in the android tag that have a search term in the title:

```
package com.commonsware.android.processtext;

import retrofit.Callback;
import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
  @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
  void questions(@Query("tagged") String tags, Callback<SOQuestions> cb);
  @GET("/2.2/questions?order=desc&sort=creation&site=stackoverflow&tagged=android")
  void search(@Query("intitle") String search, Callback<SOQuestions> cb);
}
```

onCreateView() in QuestionsFragment then calls either questions() or search(), depending on whether or not we have a search string from ACTION_PROCESS_TEXT:

```
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=
        super.onCreateView(inflater, container, savedInstanceState);
    setRetainInstance(true);

    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
                                 .build();
    StackOverflowInterface so=
        restAdapter.create(StackOverflowInterface.class);
    String search=getArguments().getString(ARG_SEARCH);

    if (search==null) {
      so.questions("android", this);
    }
    else {
      so.search(search, this);
    }

    return(result);
  }
```

The Results (If Any)

If you got a value for EXTRA_PROCESS_TEXT and you wish to return a replacement string, you need to create an Intent with your own EXTRA_PROCESS_TEXT value that is the replacement text, then use that Intent with setResult(). MainActivity does this when the user taps on a list item in QuestionsFragment:

```
  }

  public void onEventMainThread(QuestionClickedEvent event) {
    if (Intent.ACTION_PROCESS_TEXT.equals(getIntent().getAction()) &&
      getIntent().getStringExtra(Intent.EXTRA_PROCESS_TEXT)!=null) {
      setResult(Activity.RESULT_OK,
        new Intent().putExtra(Intent.EXTRA_PROCESS_TEXT, event.item.link));
      finish();
    }
    else {
      startActivity(new Intent(Intent.ACTION_VIEW,
        Uri.parse(event.item.link)));
```

If the activity was started due to a replaceable bit of text to be processed, we return the URL to the question the user tapped on. In all other cases, we just start up some browser or other app to view that URL.

If you install this app on an Android 6.0+ device, then run some other app that has an EditText, type in some term in portrait mode, highlight it, and choose “PROCESS TEXT DEMO” from the floating action mode, you will be presented with a list of Stack Overflow questions in the android tag that refer to your search term in the title. If you tap on one, your search term will be replaced in the EditText widget by the URL of the question.

Limitations of ACTION_PROCESS_TEXT

Alas, `ACTION_PROCESS_TEXT` is "not all unicorns and rainbows". There are a few issues that you will need to take into account.

Security

There is no documented `android:permission` attribute to place on the `<activity>` that is offering `ACTION_PROCESS_TEXT`, to limit callers. Ideally, we could limit invocations of `ACTION_PROCESS_TEXT` only to the firmware itself. As it stands, any app can call `startActivity()` (or, worse, `startActivityForResult()`) for your `ACTION_PROCESS_TEXT` activity and have your code process the text (with user intervention). Please be sure that if you return data via `EXTRA_PROCESS_TEXT` that the data not include any private information or anything that needs to be secured.

With luck, this will be improved in a future version of Android.

Landscape

In Android 6.0, the text-selection floating action mode for an `EditText` does not appear in landscape mode, when the entire UI is dedicated to the text-entry screen with the input method editor:

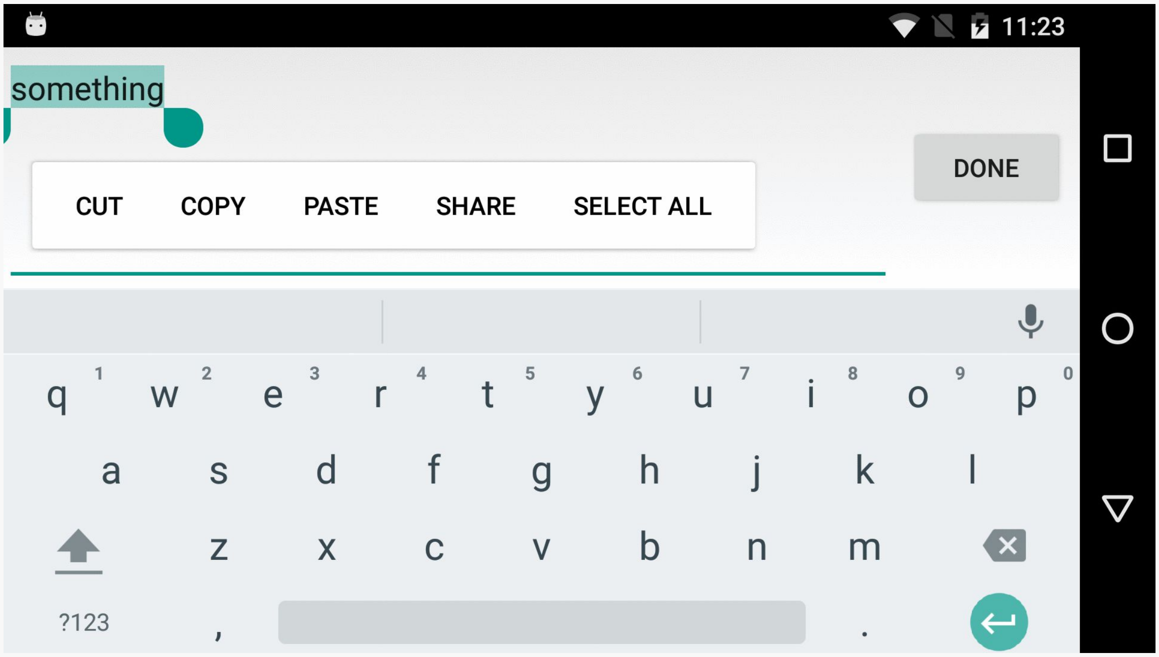

Figure 782: Landscape EditText, Sans ACTION_PROCESS_TEXT Options

With luck, this too will be fixed in a future version of Android.

Supporting ACTION_PROCESS_TEXT in Custom Views

`TextView` and its subclasses are already capable of offering the user `ACTION_PROCESS_TEXT` options. However, you may have custom `View` classes that have the notion of text selection, but where you are rendering the available actions to take upon that selection yourself. In that case, you will need to do the reverse: find the implementers of `ACTION_PROCESS_TEXT` and add them to your UI.

To do this:

- Create an `Intent` for `ACTION_PROCESS_TEXT` and a MIME type of `text/plain`
- Use `queryIntentActivities()` on `PackageManager` to find out the activities that handle that `Intent` structure
- Organize the results, such as sorting them alphabetically by label using `ResolveInfo.DisplayNameComparator`
- Create `Intent` objects for each resolved activity, also with `ACTION_PROCESS_TEXT` and `text/plain`, but also with `EXTRA_PROCESS_TEXT` *or* `EXTRA_PROCESS_TEXT_READONLY` filled in with your selection, and also call

setClassName() to provide the package name and activity class name to make the Intent explicit
- Add appropriate elements to your UI for each of those Intent objects
- If the user chooses one, call startActivity() (for EXTRA_PROCESS_TEXT_READONLY) or startActivityForResult() (for EXTRA_PROCESS_TEXT) to invoke the other activity
- In the case of EXTRA_PROCESS_TEXT, watch for your result in onActivityResult() and use the replacement text supplied in the result Intent and its EXTRA_PROCESS_TEXT string extra

The Android Developers Blog has a post that provides some code for this, assuming that you want to put items in an action bar or action mode for the various resolved activities.

Blocking ACTION_PROCESS_TEXT

There will be cases where you do not want ACTION_PROCESS_TEXT to be offered to your users. For example, perhaps the text contains sensitive information that should not be passed outside of your app.

The best solution, particularly for a TextView, is to mark the text as not being selectable. This is accomplished via android:textIsSelectable="false" in a layout file, or via setTextIsSelectable(false) in Java. false is the default value for TextView.

However, for an EditText widget, true is the default is-selectable state, and you cannot seem to override that with setTextIsSelectable(false).

There is no officially supported option for handling this case, though perhaps there will be one in the future.

One unsupported hack of a workaround relies upon the fact that EditText blocks the floating action mode for password fields. In the source code to EditText, TextView, and related classes, this is handled by seeing if the TransformationMethod associated with the widget is PasswordTransformationMethod. A TransformationMethod is responsible for on-the-fly adjustments between what the user types and what the user sees, such as PasswordTransformationMethod replacing typed-in characters with dots.

Making your EditText widget use PasswordTransformationMethod itself is fine for actual password fields. But suppose you have an EditText whose contents should be kept private but should not have the input-shrouding effect of PasswordTransformationMethod. To offer this, you would need to create a *subclass* of PasswordTransformationMethod (so the block-the-floating-action-mode logic works) that does not actually transform the text (to block the changes that PasswordTransformationMethod would ordinarily apply).

A proof-of-concept implementation of this can be found in the Introspection/ProcessTextBlocker sample application. This is a clone of the FilesEditor sample app from the chapter on files, with one change: the use of DummyTransformationMethod:

```
private static class DummyTransformationMethod
  extends PasswordTransformationMethod {
  @Override
  public CharSequence getTransformation(CharSequence source,
                                        View view) {
    return(source);
  }

  @Override
  public void onTextChanged(CharSequence s, int start,
                            int before, int count) {
    // no-op
  }

  @Override
  public void onFocusChanged(View view,
                             CharSequence sourceText,
                             boolean focused, int direction,
                             Rect previouslyFocusedRect) {
    // no-op
  }

  @Override
  public void afterTextChanged(Editable s) {
    // no-op
  }

  @Override
  public void beforeTextChanged(CharSequence s, int start,
                                int count, int after) {
    // no-op
  }
}
```

This is a do-nothing TransformationMethod. Ordinarily, this would be completely useless. However, it inherits from PasswordTransformationMethod, which is what we need to block the floating action mode.

In onCreateView() of the EditorFragment, we apply a DummyTransformationMethod via setTransformationMethod():

```
@Override
public View onCreateView(LayoutInflater inflater,
                         ViewGroup container,
                         Bundle savedInstanceState) {
  View result=inflater.inflate(R.layout.editor, container, false);

  editor=(EditText)result.findViewById(R.id.editor);
  editor.setTransformationMethod(new DummyTransformationMethod());

  return(result);
}
```

However, this approach has limitations:

- It only works in portrait, not landscape, for unclear reasons. Since `ACTION_PROCESS_TEXT` *also* only works in portrait, not landscape, we still succeed in blocking `ACTION_PROCESS_TEXT` options.
- It blocks the entire floating action mode (in portrait), clobbering the existing cut/copy/paste/select-all options that might ordinarily be there.
- Since it is tied to internal implementation (that the floating action mode is suppressed when using an `instanceof` a `PasswordTransformationMethod`), not only is this subject to change across Android versions, but also it is subject to change based on device manufacturer or custom ROM tweaks to the Android source code.

Reusable Components

In the world of Java outside of Android, reusable components rule the roost. Whether they are simple JARs, are tied in via inversion-of-control (IoC) containers like Spring, or rely on enterprise service buses like Mule, reusable Java components are a huge portion of the overall Java ecosystem. Even full-fledged applications, like Eclipse or NetBeans, are frequently made up of a number of inter-locking components, many of which are available for others to use in their own applications.

Android, too, supports this sort of reuse. In some cases, it follows standard Java approaches. However, in other cases, unique Android aspects, such as resources, steer developers in different directions for reuse.

This chapter will outline what reuse models are in use today and how you can package your own components for reuse.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Where Do I Find Them?

Android historically has not had a “go-to” place to find reusable components. The Android Arsenal is probably the largest collection at present. Beyond that, look for recommendations in Stack Overflow answers, blog posts, and the like.

How Are They Packaged?

There are three main ways that reusable code gets packaged on Android: as a traditional Java JAR, as an Android library project, or (technically) as an APK. The last approach is usually used by apps that have user value in their own right, but also expose some sort of integration API for use by other apps, that you can take advantage of.

JARs

Android code that is pure *code*, without requiring its own resources, can be packaged into a JAR, no differently than can regular Java code outside of Android.

As was covered earlier in the book, to use such a JAR, just drop it into `libs/`. Its contents will be added to your compile path (so you can reference classes from the library) and its contents will be packaged in your APK (so those references will work at runtime).

Library Projects

Android code that relies upon resources — such as many reusable UI components, such as custom widgets — cannot be packaged as a simple JAR, as there is no way of packaging the Android resources in that JAR. Instead, Google created the Android library project as the "unit of reuse" for such cases.

Android library projects are sometimes published in full source form (usually open source projects), and sometimes are published as AARs in an artifact repository. Eclipse users can readily use the full-source library projects, but have limited ability to use AARs. Android Studio users can use either, and AARs may be as simple as adding a single line to `build.gradle`.

APKs

Using JARs or library projects fits in the "traditional" model of compile-time reuse. Android's many IPC mechanisms offer plenty of options for run-time reuse, where your app communicates with another app, having that app do things on your behalf. In this case, the primary unit of reuse is not the JAR, or the library project, but the APK.

For example, the ZXing project publishes the Barcode Scanner app. This app not only allows *users* to scan barcodes, but allows *other apps* to scan barcodes, by asking Barcode Scanner to scan the barcodes and return results.

To integrate with such an app, you will need to find the instructions from the app's developers on how to do that. Sometimes, they will tell you things that you would use directly (e.g., "call `startActivityForResult()` with an `Intent` that contains…"). Sometimes, they will distribute a client-side JAR that you can use that wraps up the low-level IPC details into something a bit easier to consume. For example, ZXing distributes an `IntentIntegrator.java` class file that you can use that not only handles requesting the scans, but also helping the user install Barcode Scanner if it is not already installed.

How Do I Create Them?

To create a reusable component, you start by getting a working code base, one that implements whatever it is that you desire. From there, you need to choose which of those aforementioned distribution patterns you believe is appropriate:

- JAR
- Standard library project
- Eclipse-compatible binary-only library project
- APK (with optional client-side JAR)

That, in turn, will drive how you take your code and create such a package. The basics of how to do that for the different alternatives is described in the following sections.

JARs

Creating a JAR for a reusable chunk of Android-related code is not significantly different than is creating a JAR for a reusable chunk of "ordinary" Java code.

First, you need a project that represents the "resuable chunk of Android-related code". An easy way to do this is to just create a standard Android library project, but one where you do not bother creating any resources.

Once the code is ready for distribution, you can create a JAR from the compiled Java classes by your favorite traditional means. The author of this book, for example, adds custom Gradle tasks for this:

```
// from http://stackoverflow.com/a/19484146/115145

android.libraryVariants.all { variant ->
  def name = variant.buildType.name
  if (name.equals(com.android.builder.core.BuilderConstants.DEBUG)) {
    return; // Skip debug builds.
  }
  def task = project.tasks.create "jar${name.capitalize()}", Jar
  task.dependsOn variant.javaCompile
  task.from variant.javaCompile.destinationDir
  task.archiveName = "cwac-${task.archiveName}"
  task.exclude('com/commonsware/cwac/**/BuildConfig.**')
}
```

This will create JAR-building Gradle tasks for all non-debug build types, so you get Gradle tasks like `jarRelease`. It specifically excludes `BuildConfig`, which the CWAC libraries never use, but otherwise takes all of the library classes and packages them in a JAR, named after the library and version, with a `cwac-` prefix.

If your reusable code is pure Java, not involving Android at all, you are welcome to create a plain Java project and create your JAR from that. The only major recommendation would be to ensure that you are using some `android.jar` from the SDK, rather than a JDK `rt.jar`, to ensure that you are sticking with classes and methods that are in Android's subset of the Java SE class library.

Standard Library Projects

In many respects, distributing a standard Android library project is even easier: just ZIP it up. Or, if it is in a public source control repository (e.g., GitHub), reusers can obtain it from that repository.

Of course, this will distribute the source code along with the resources and everything else. This is typical for an open source library project.

Android Studio and Gradle users can create AARs from their library projects. The `assembleRelease` task will create an AAR for the library in `build/outputs/aar`, named after the library and version (e.g., `pager-0.2.3.jar`).

Eclipse-Compatible Binary-Only Library Projects

AARs do not ship Java source code, but rather only binaries. However, AARs are not readily consumable from Eclipse.

It is possible to create an Eclipse-Compatible binary-only library project, one where your source code is replaced by a JAR. This can be useful for proprietary library projects, for example. However, there is one noteworthy limitation with today's tools: the library project cannot itself depend upon a JAR or another library project.

For simpler library projects, the recipe is straightforward, given an already-existing Android library project:

1. Compile the Java source (e.g., via Ant) and turn it into a JAR file.
2. Create a copy of your original Android library project to serve as a distribution Android library project.
3. Place the compiled JAR from step #1 and put it in `libs/` of the distribution library project from step #2.
4. Delete everything in src/ of the distribution library project (but leave the now-empty `src/` directory there).
5. Distribute the distribution library project (e.g., ZIP it up)

For example, an Ant target to create a distribution ZIP might be:

```
<target name="jar" depends="release">
    <delete file="bin/WhateverYouWantToCallYourLibrary.jar" />
    <jar destfile="bin/WhateverYouWantToCallYourLibrary.jar">
      <fileset dir="bin/classes">
        <exclude name="**/BuildConfig.class" />
        <exclude name="**/R.class" />
        <exclude name="**/R$*.class" />
      </fileset>
    </jar>
</target>
<target name="dist" depends="jar">
  <copy todir="/tmp/WhateverYouWantToCallYourLibrary/libs">
    <fileset dir="libs/" />
  </copy>
  <copy todir="/tmp/WhateverYouWantToCallYourLibrary/res">
    <fileset dir="res/" />
  </copy>
  <copy
    file="bin/WhateverYouWantToCallYourLibrary.jar"
    todir="/tmp/WhateverYouWantToCallYourLibrary/libs" />
  <copy
    file="AndroidManifest.xml"
    todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy file="build.xml" todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy
    file="project.properties"
    todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy file="LICENSE" todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <mkdir dir="/tmp/WhateverYouWantToCallYourLibrary/src" />
  <zip
    destfile="/tmp/WhateverYouWantToCallYourLibrary.zip"
    basedir="/tmp/"
    includes="WhateverYouWantToCallYourLibrary/**"
    whenempty="create" />
  <delete dir="/tmp/WhateverYouWantToCallYourLibrary" />
</target>
```

Assuming the existence of a `/tmp/` directory (e.g., OS X or Linux), this will result in a `WhateverYouWantToCallYourLibrary.zip` file in `/tmp/`. Along the way, we:

- Copy the `libs/` and `res/` trees from your source library project to a temporary distribution directory
- Copy your compiled JAR into the `libs/` subdirectory of the temporary distribution directory
- Copy other miscellaneous files, like your `LICENSE` file for your software license terms, into the root of the temporary distribution directory
- Create an empty `src/` subdirectory in the temporary distribution directory
- ZIP up the temporary distribution directory to a ZIP file
- Delete the temporary distribution directory

APK

Most of your work for this distribution model is in writing and distributing the app to your end users, through the Play Store or your other chosen distribution channels.

In addition to that, you need to either document to reusers what sorts of IPC your app supports, or create a JAR or library project that reusers can use to perform that sort of integration. In the latter case, you would have a separate project representing that JAR or library project that you would distribute using any of the aforementioned approaches.

Other Considerations for Publishing Reusable Code

Of course, there is more to publishing a resuable component than code and perhaps Android resources. The following sections outline some other things to consider as you contemplate offering some code base up for reuse by third parties.

Licensing

Your reusable code should be accompanied by adequate licensing information.

Your License

The first license you should worry about is your own. Is your component open source? If so, you will want to ship a license file containing those terms. If your component is not open source, make sure there is a license agreement shipped with the component that lets the reuser know the terms of use.

Bear in mind that not all of your code necessarily has to have the same license. For example, you might have a proprietary license for the component itself, but have sample code be licensed under Apache License 2.0 for easy copy-and-paste.

Third-Party License Impacts

You may need to include licenses for third party libraries that you have to ship along with your own JAR. Obviously, those licenses would need to give you redistribution rights — otherwise, you cannot ship those libraries in the first place.

Sometimes, the third party licenses will impact your project more directly, such as:

1. Incorporating a GPL library may require your project to be licensed under the same license
2. Adding support for Facebook data may require you to limit your API or require reusers to supply API access keys, since you probably do not have rights to redistribute Facebook data

Documenting the Usage

If you are expecting people to reuse your code, you are going to have to tell them how to do that. Usually, these sorts of packages ship documentation with them, sometimes a clone of what is available online. That way, developers can choose the local or hosted edition of the documentation as they wish.

Note that generated documentation (e.g., Javadocs) may still need to be shipped or otherwise supplied to reusers, if you are not providing the source code in the package. Without the source code, reusers cannot regenerate the Javadocs.

Many open source projects eschew formal documentation in favor of simple JavaDocs, plus “documentation in the form of a test suite” or “documentation in the form of sample apps”. While test suites and sample apps are useful supplements, they are not always an effective replacement for written documentation. And, while

JavaDocs are useful for reference material, they are often difficult to comprehend for those trying to get started with the code and not knowing where to begin.

Naming Conventions

Make sure that your Java code is in a package that is likely to be distinct from any others that reusers might already have. Typically, this means that the package name is based on a domain name that you control, much like the package name for Android apps themselves. Whatever you do, please do not publish your own code as `android.*`, unless you are contributing this code to the Android open source project, as `android.*` is reserved for use by Android itself.

(The author of this book would also appreciate it if you would not use `com.commonsware.*`)

Also, be careful about the names of your resources. While your Java code resides in its own namespace, your resources are pooled with all other resources in use by the app. As a result, if you decide to reference `R.layout.main` thinking that it will be *your* `main.xml` layout resource, it might actually be replaced by a `main.xml` resource written by the app developer. You may wish to use some sort of a prefix convention on your resource names to reduce the odds of accidental collision:

- ActionBarSherlock uses `abs__`
- ViewPagerIndicator uses `vpi__`
- And so on

Android Studio Editors and Dialogs

Eclipse, with the ADT plugin, had many structured editors and specialized dialogs for modifying Android project files and otherwise configuring Android project behavior.

Android Studio has fewer of those, and they are generally less critical. The editors and dialogs presented in this chapter can be useful, at least in some cases, but you do not need to use any of them to be able to create your Android projects. However, some may speed up your Android development a bit over working with bare resource and Gradle files.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with the chapters on:

- the Gradle project structure
- Gradle dependencies

Project Structure

The Project Structure dialog allows you to configure many aspects of your `build.gradle` files from a tabbed property-style dialog, as opposed to having to work with the Gradle scripts directly. On the plus side, this can be easier. However, since Gradle is built on the Groovy scripting language, `build.gradle` files are not simple XML or JSON data structures. It remains to be seen how well the Project Structure dialog will be able to handle complex Gradle scripts.

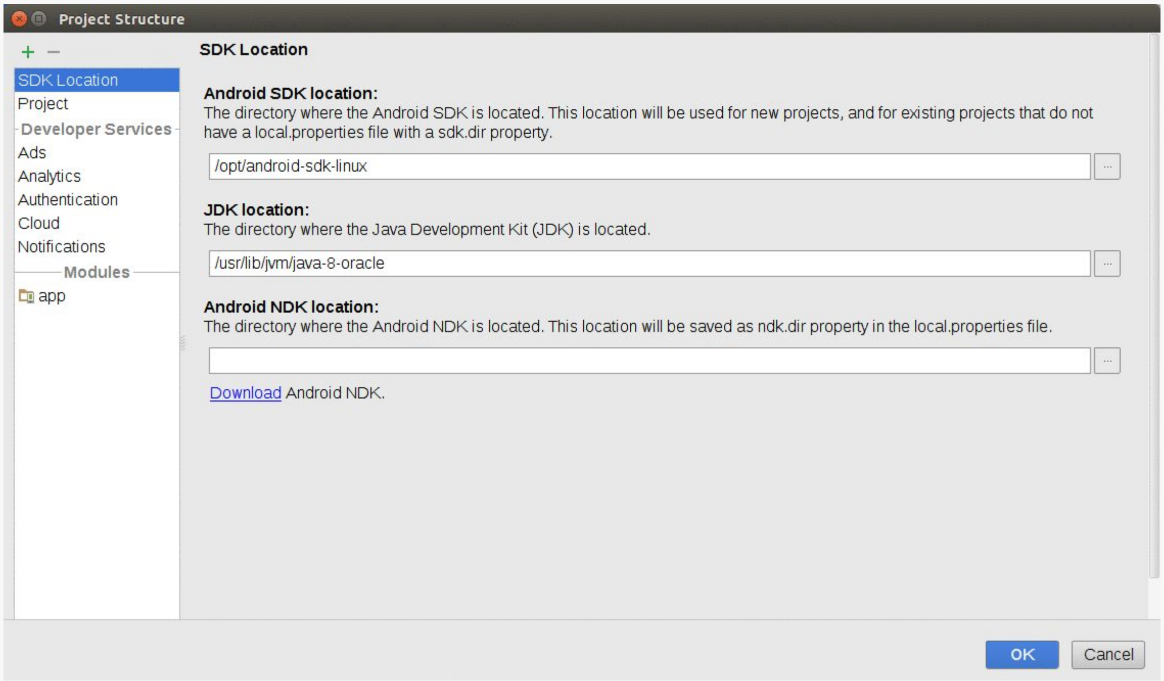
To access the Project Structure dialog, choose File > Project Structure from the main IDE menu.

The left-hand side lists major areas of the dialog; choosing one of those switches to that area's form on the right.

The sections that follow outline each of the major areas and what you can configure in them.

SDK Location

The Project Structure dialog opens up on the SDK Location area, where you can configure where your Android SDK is located, where your JDK is located, and where your NDK is located:



SDK Location

Android SDK location:
The directory where the Android SDK is located. This location will be used for new projects, and for existing projects that do not have a local.properties file with a sdk.dir property.

/opt/android-sdk-linux

JDK location:
The directory where the Java Development Kit (JDK) is located.

/usr/lib/jvm/java-8-oracle

Android NDK location:
The directory where the Android NDK is located. This location will be saved as ndk.dir property in the local.properties file.

Download Android NDK.

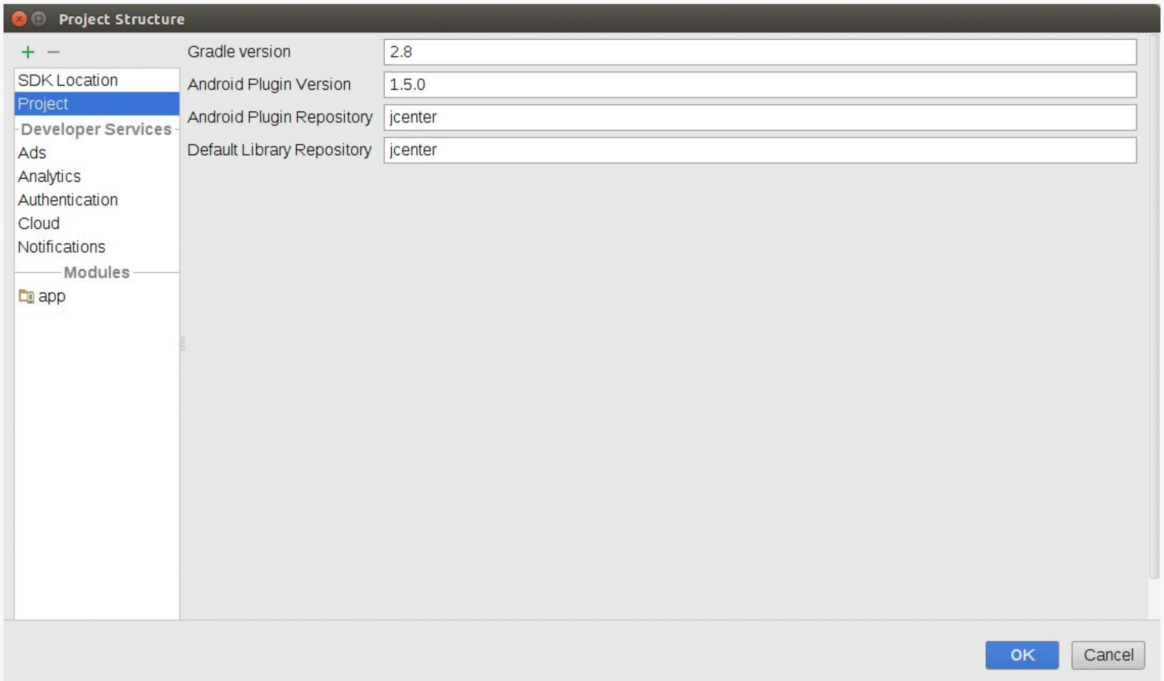
Figure 783: Project Structure Dialog, SDK Location Category

Adjusting these in Project Settings affects this specific project. There is also File > Other Settings > Default Project Structure, where you can edit the default values to be used for new projects and projects that you import in the future.

Project Settings

The second entry in the Project Structure dialog category list is “Project”. This allows you to configure four items found by default in the `build.gradle` file in your project root or in the `gradle-wrapper.properties` file:

- What version of Gradle you wish to use for the Gradle Wrapper
- What version of the Android Plugin for Gradle you wish to use
- What artifact repository should be used for pulling in the Gradle for Android plugin (and any other plugins you may be using)
- What artifact repository should be used by default for standard module artifacts (e.g., those you request via `compile` directives in your module’s `build.gradle` file)

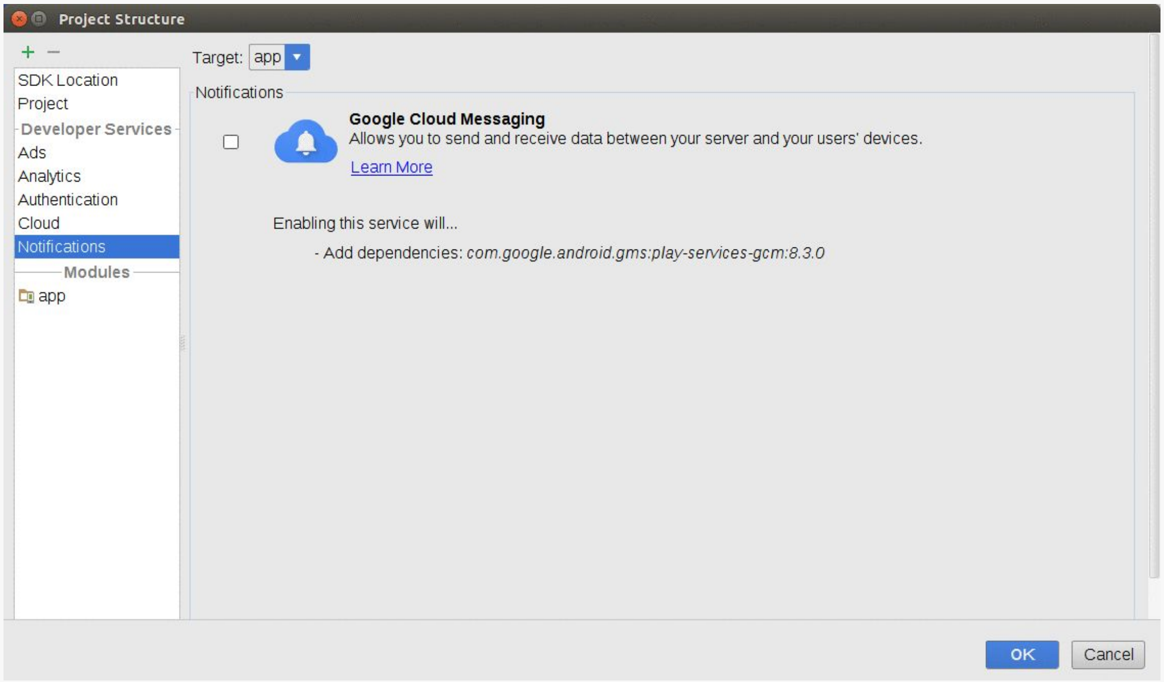


Gradle version: 2.8
Android Plugin Version: 1.5.0
Android Plugin Repository: jcenter
Default Library Repository: jcenter

Figure 784: Project Structure Dialog, Project Settings Category

Developer Services

If you are using select portions of the Play Services SDK, the items under the “Developer Services” divider allow you to configure those portions. By default, they amount to checkboxes, to enable certain features:



☐ **Google Cloud Messaging**
Allows you to send and receive data between your server and your users' devices.

Enabling this service will...

- Add dependencies: *com.google.android.gms:play-services-gcm:8.3.0*

Figure 785: Project Structure Dialog, Notifications Category

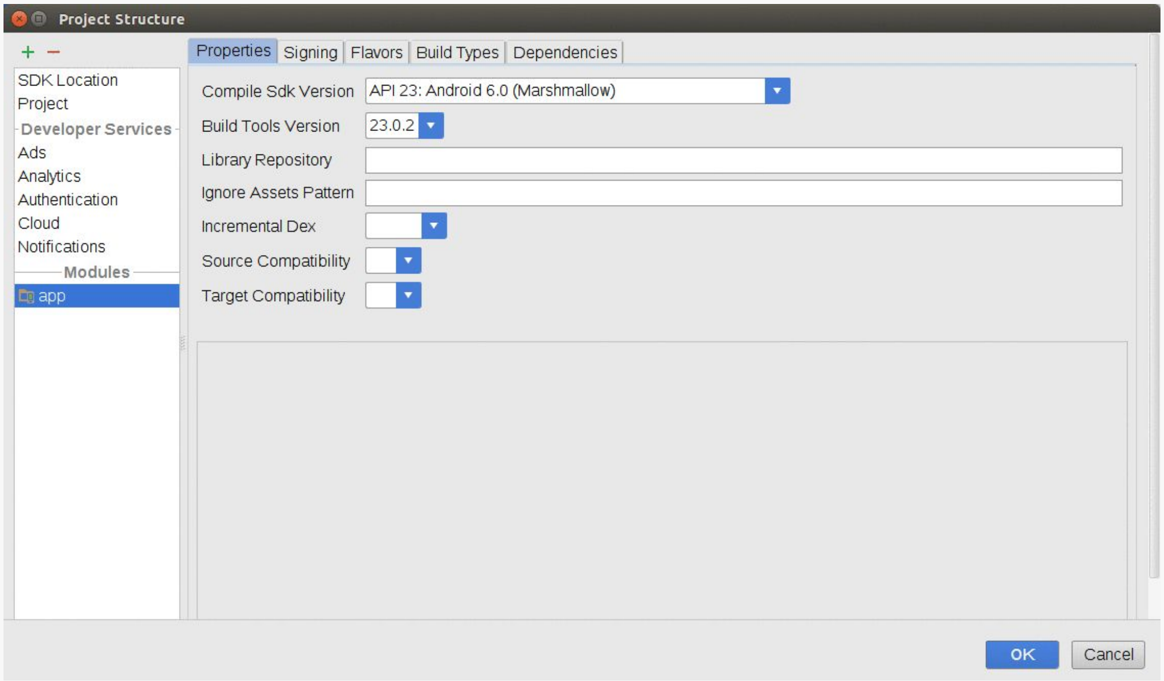
Module Settings

Below the "Modules" divider in the category list on the left will come all of your modules. If you are not using modules, there will be a single entry in the category list with the same name as your project, as a quasi-module.

Clicking on a module will bring up a set of tabs on the right to edit various properties of that module, independently of any other module in your project. The following sections outline the contents of those tabs.

Properties

The first tab is labeled "Properties" and allows you to adjust various top-level settings in your module's `build.gradle` file.



Compile Sdk Version: API 23: Android 6.0 (Marshmallow)
Build Tools Version: 23.0.2
Library Repository
Ignore Assets Pattern
Incremental Dex
Source Compatibility
Target Compatibility

Figure 786: Project Structure Dialog, Module Category, Properties Tab

These include:

- Your `compileSdkVersion` ("Compile Sdk Version" drop-down)
- Your `buildToolsVersion` ("Build Tools Version" drop-down)
- Another artifact repository to use for this module, added to your module's `repositories` closure ("Library Repository")
- The `ignoreAssetsPattern` property in `aaptOptions` ("Ignore Assets Pattern")
- The `incremental` property in `dexOptions` ("Incremental Dex")
- The `sourceCompatibility` in `compileOptions` ("Source Compatibility")
- The `targetCompatibility` in `compileOptions` ("Target Compatibility")

Signing

If your module's `build.gradle` file has a `signingConfigs` closure, the "Signing" tab will let you edit those signing configurations:

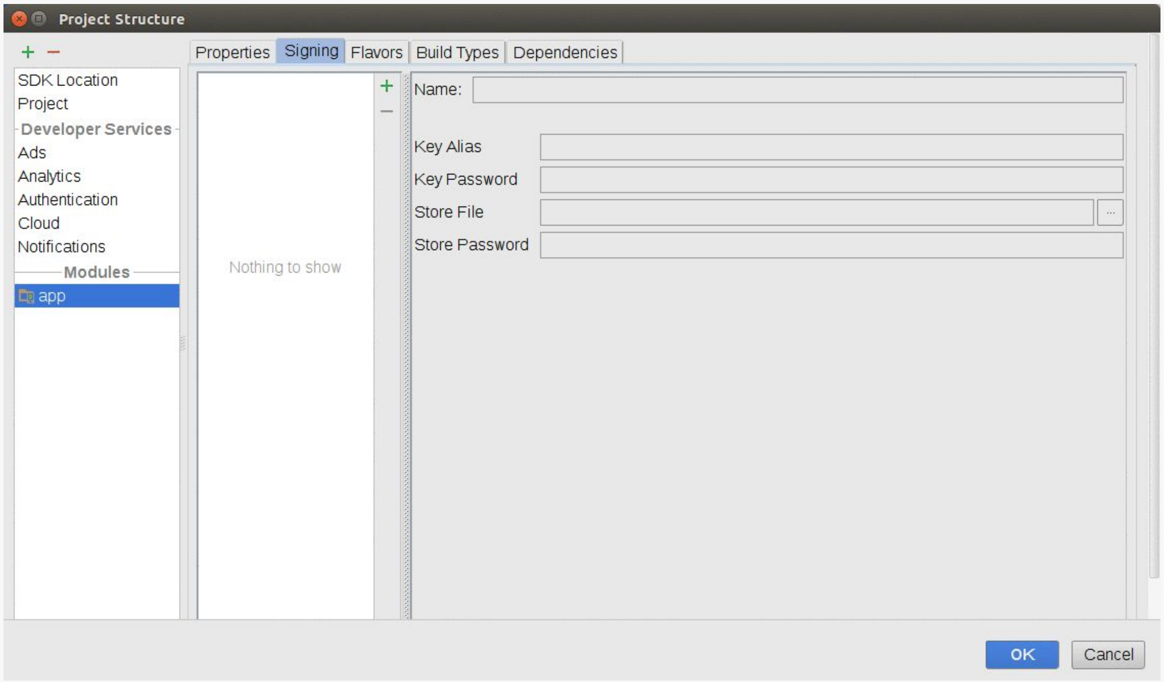


Figure 787: Project Structure Dialog, Module Category, Signing Tab

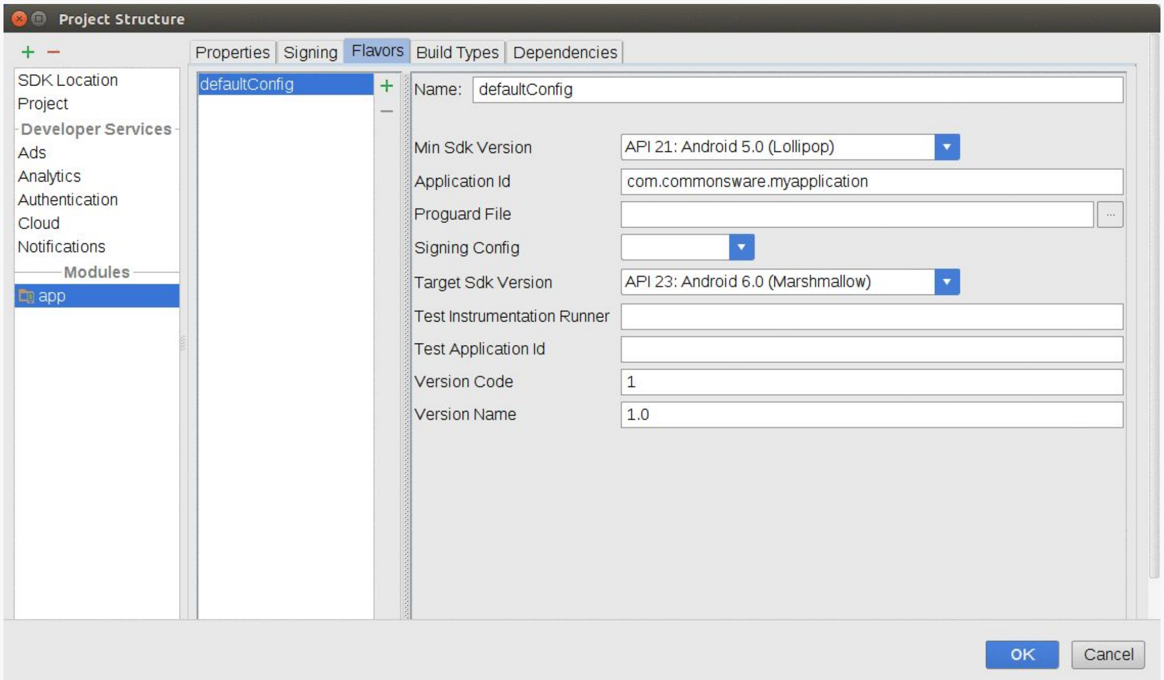
Each signing configuration that you have defined will appear in the list on the left side of the tab. On the right are fields for you to fill in the signing configuration name, the keystore file and key alias to use, and the passwords to use for accessing that file and alias.

The green plus ("+") icon on the right side of the list lets you define a new signing configuration, while the red minus ("-") icon lets you delete an existing signing configuration.

Flavors

The "Flavors" tab starts off with a single "flavor", representing your `build.gradle` file's `defaultConfig` settings. The green plus icon next to the list of flavors lets you define a new flavor, while the red minus icon lets you remove an existing flavor. Note that you cannot remove `defaultConfig`, as it is defined by the Gradle for Android plugin.



Name: defaultConfig

Min Sdk Version: API 21: Android 5.0 (Lollipop)

Application Id: com.commonsware.myapplication

Proguard File:

Signing Config:

Target Sdk Version: API 23: Android 6.0 (Marshmallow)

Test Instrumentation Runner:

Test Application Id:

Version Code: 1

Version Name: 1.0

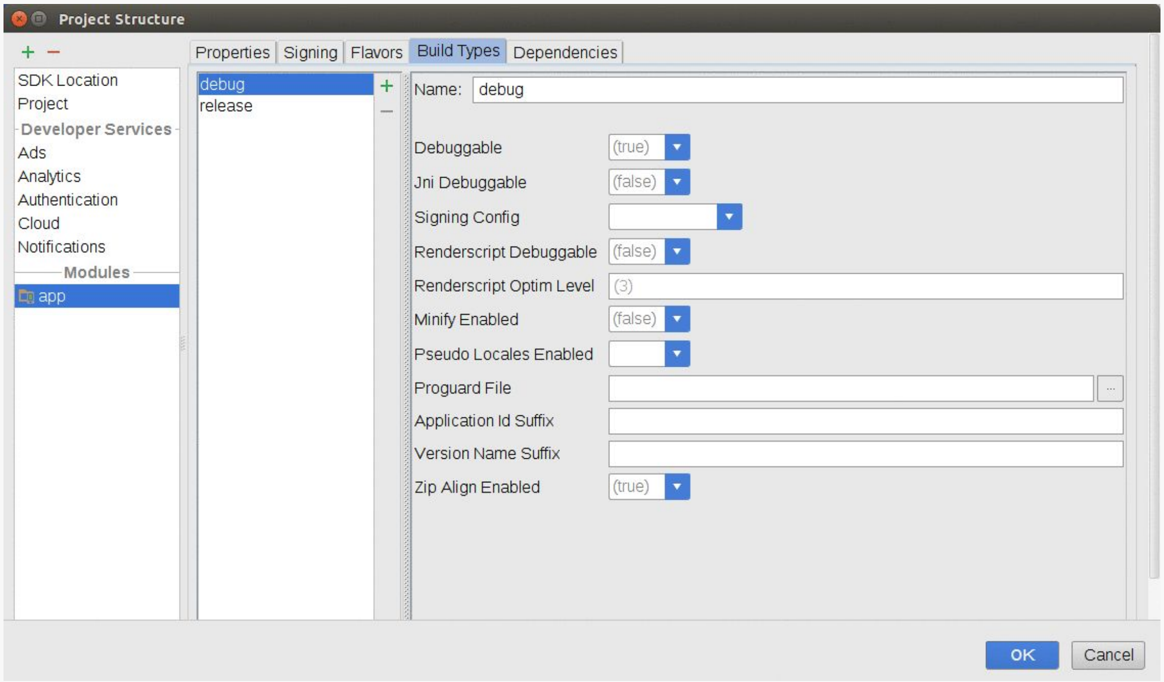
Figure 788: Project Structure Dialog, Module Category, Flavors Tab

On the right side of the tab, you can set or change the name of the flavor, plus you can adjust various flavor (or `defaultConfig`) settings, including:

- the `minSdkVersion` value ("Min Sdk Version" drop-down)
- the `applicationId` ("Application Id")
- the ProGuard rules file to use for builds ("Proguard File")
- which of your defined signing configurations to use ("Signing Config" drop-down)
- the `targetSdkVersion` value ("Target Sdk Version" drop-down)
- the `testInstrumentationRunner` to use for instrumentation testing ("Test Instrumentation Runner")
- the `testApplicationId` value for instrumentation testing ("Test Application Id")
- the `versionCode` and `versionName` to use ("Version Code" and "Version Name")

Build Types

The "Build Types" tab allows you to adjust settings for the `debug` and `release` build types. The green plus icon next to the list of build types lets you define a new build type, while the red minus icon lets you remove an existing build type. Note that you cannot remove `debug` or `release`, as they are defined by Gradle.



Name: debug

Debuggable (true)
Jni Debuggable (false)
Signing Config
Renderscript Debuggable (false)
Renderscript Optim Level (3)
Minify Enabled (false)
Pseudo Locales Enabled
Proguard File
Application Id Suffix
Version Name Suffix
Zip Align Enabled (true)

Figure 789: Project Structure Dialog, Module Category, Build Types Tab

On the right side of the tab, you can set or change the name of the build type, plus you can adjust various settings in your `buildTypes` closure, including:

- the value of `debuggable`, to control if the app is considered to be debuggable on production hardware ("Debuggable" drop-down)
- the value of the undocumented `jniDebuggable` flag ("Jni Debuggable")
- which signing configuration to use ("Signing Config" drop-down)
- the value of the undocumented `renderscriptDebuggable` flag ("Renderscript Debuggable")
- the value of the undocumented `renderscriptOptimLevel` property ("Renderscript Optim Level")

- the value of `minifyEnabled`, to control whether the build process should attempt to strip out unused code ("Minify Enabled" drop-down)
- the value of the undocumented `pseudoLocalesEnabled` flag ("Pseudo Locales Enabled")
- the ProGuard rules file to use for builds ("Proguard File")
- the suffix to append to the `applicationId` ("Application Id Suffix")
- the suffix to append to the `versionName` ("Version Name Suffix")
- whether the resulting APK should be processed by `zipalign` ("Zip Align Enabled")

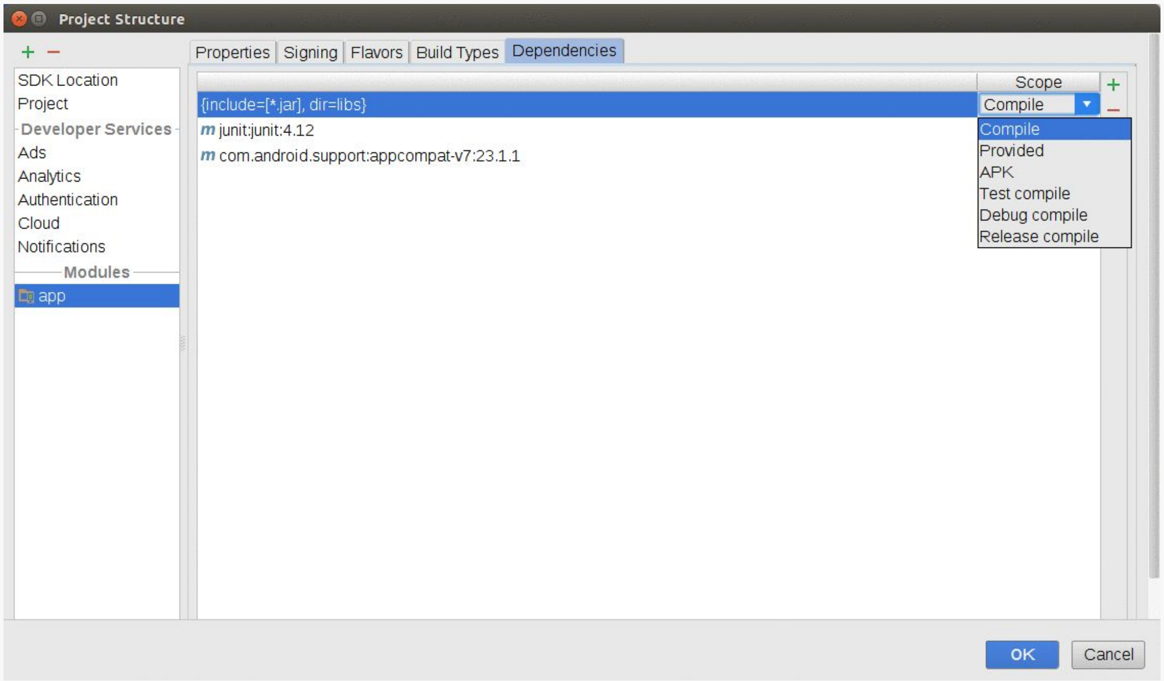
Dependencies

If your project has any defined dependencies in a `dependencies` closure, these will appear in the "Dependencies" tab:

	Scope
{include=[*.jar], dir=libs}	Compile
m junit:junit:4.12	Test compile
m com.android.support:appcompat-v7:23.1.1	Compile

Figure 790: Project Structure Dialog, Module Category, Dependencies Tab

The tab is dominated by a two-column table, where the left column is the dependency itself. The right column is the "scope", where the cell shows the current scope, and if you click on it, you get a drop-down list of available scopes:



{include=[*.jar], dir=libs} Compile
m junit:junit:4.12
m com.android.support:appcompat-v7:23.1.1

Figure 791: Dependencies Tab, Showing Scope Drop-Down

Those scopes include:

- “Compile”, for a `compile` dependency
- “Test compile” for an `androidTestCompile` dependency (i.e., one to be used only for instrumentation testing)
- Other “compile” scopes for your build variants (e.g., “Debug compile” for a `debugCompile` dependency)
- “Provided”, for a `provided` dependency (where the dependency is used only at compile time and its contents are not packaged into the APK file)
- “APK” for an `apk` dependency (where the dependency is not used at compile time, but its contents are packaged into the APK file)

The latter two scopes will be used infrequently.

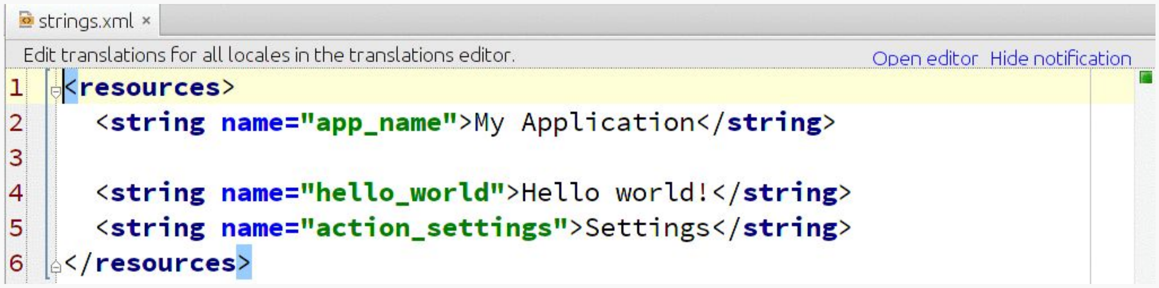
Translations Editor

On Android Studio, if you open a file containing string resources, you will find a notification banner atop the editor, offering a way for you to "Edit translations for all locales in the translations editor":



Edit translations for all locales in the translations editor.

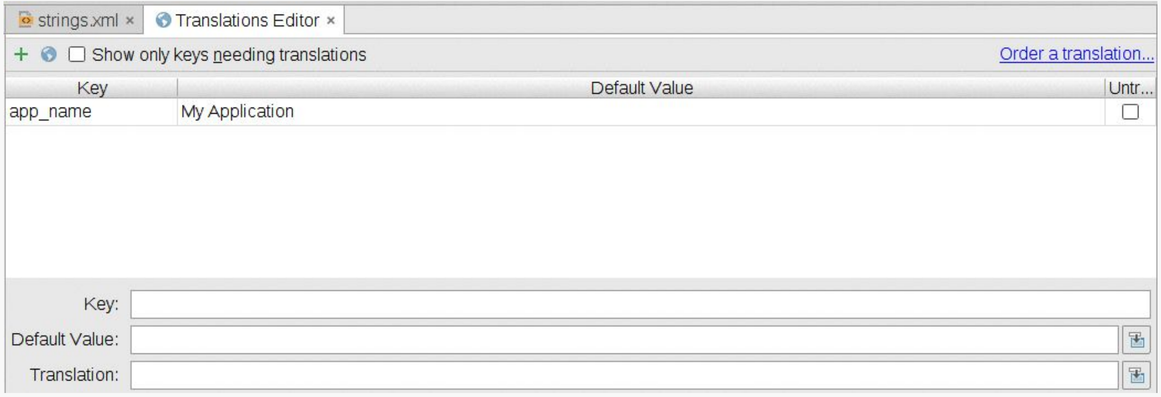
```
<resources>
  <string name="app_name">My Application</string>

  <string name="hello_world">Hello world!</string>
  <string name="action_settings">Settings</string>
</resources>
```

Figure 794: Notification Banner for Translations Editor

Clicking the “Open editor” link will open the Translations Editor. You can also get to this editor by right-clicking over the resource file in the Project or Android view on the left and choosing “Open Translation Editor” from the context menu.

For an un-translated project — such as one newly-created from the new-project wizard — when you open the Translations Editor, you will just see all of the existing strings:



Key	Default Value	Untr...
app_name	My Application	□

Key:
Default Value:
Translation:

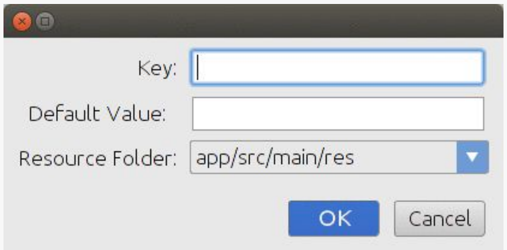
Figure 795: Translations Editor, As Initially Opened

These are labeled as “default value” because, in this case, the values are coming from the default resource set (`res/values/strings.xml`), not some specific language translation.

You can edit an existing default value either by clicking on the cell containing the default value (e.g., clicking the “My Application” cell), or by clicking anywhere on the row and then editing the value in the “Default Value” field towards the bottom of the editor. Note that you cannot edit keys via this editor.

The right-hand column of the table has checkboxes, with a column heading of “Untranslatable”. Checking one of those adds a `translatable="false"` attribute to the `<string>` element in the XML. The IDE and related tools can use this to not warn you that this string lacks translations. This would be good for strings that you elected to put in string resources yet are not user-facing and therefore do not need translation.

The + icon in the toolbar, when clicked, pops up a dialog where you can define a new string:



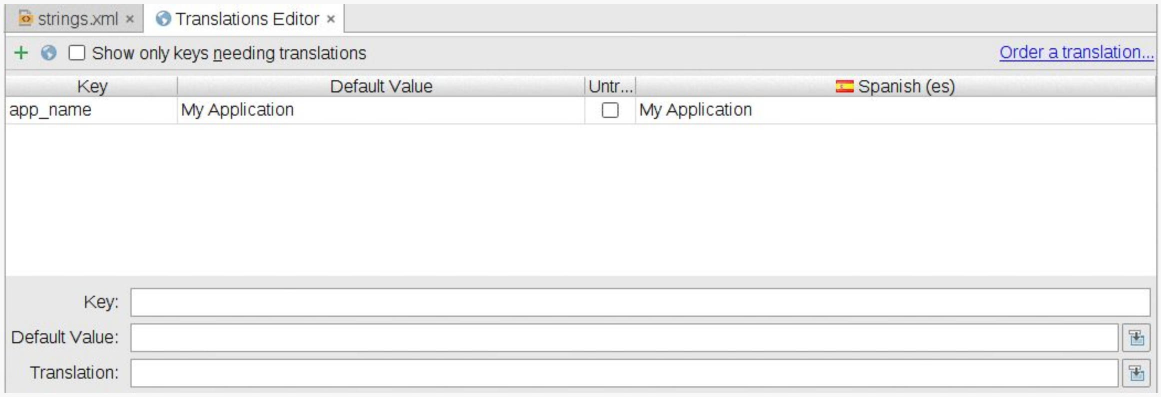
Key:

Default Value:

Resource Folder: app/src/main/res

Figure 796: Translations Editor, New-String Dialog

Where the fun begins, though, is if you click the globe icon in the toolbar. This displays a drop-down list of languages:



☐ Show only keys needing translations

Key	Default Value	Untr...	Spanish (es)
app_name	My Application	☐	My Application

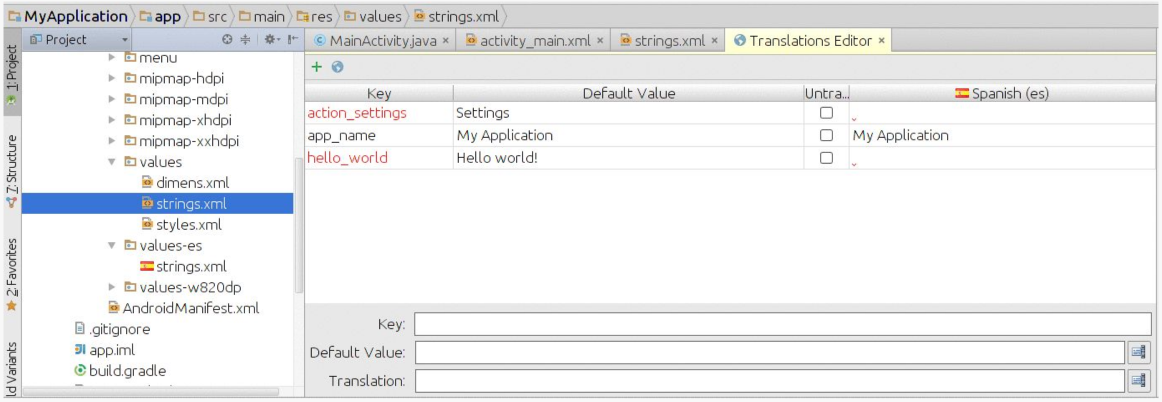
Key:

Default Value:

Translation:

Figure 797: Translations Editor, Showing Languages Drop-Down List

Choosing a language has two main effects. First, it creates a corresponding `res/values-*/` directory for your chosen language. Second, it adds a column to the Translations Editor for that language:



Key	Default Value	Untra...	Spanish (es)
action_settings	Settings	☐	
app_name	My Application	☐	My Application
hello_world	Hello world!	☐	

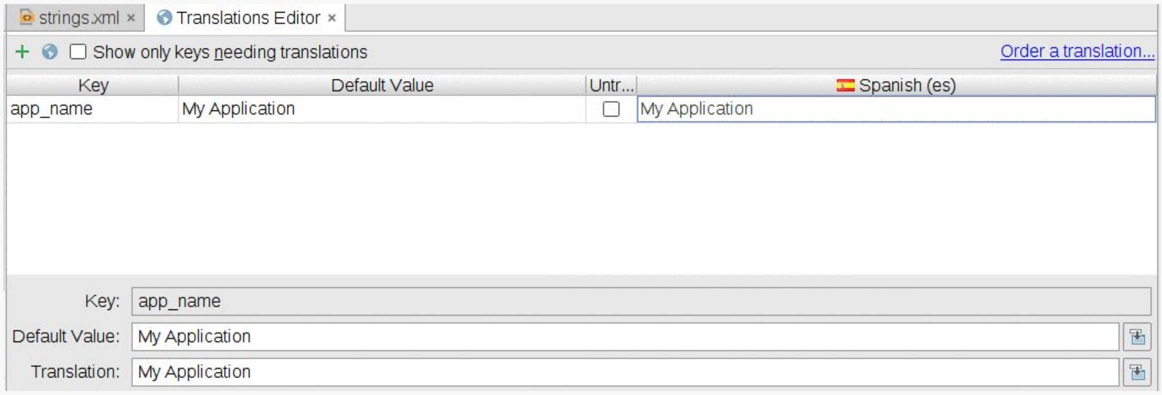
Key:

Default Value:

Translation:

Figure 798: Spanish Strings in Resource File and Translations Editor

You can then click on a cell representing a word and its language, and fill in the translation in the form:



Key	Default Value	Untr...	Spanish (es)
app_name	My Application	□	My Application

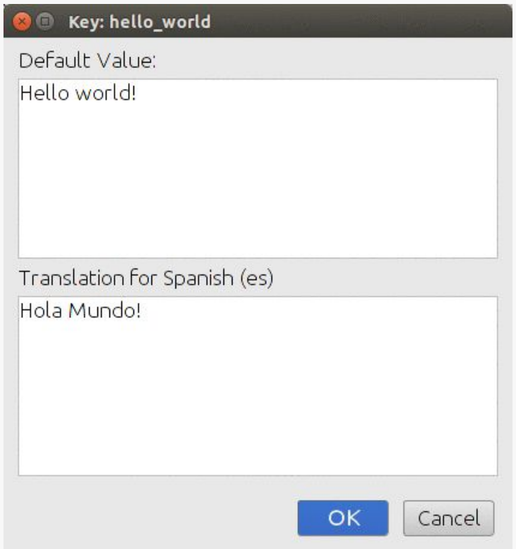
Key: app_name

Default Value: My Application

Translation: My Application

Figure 799: Translations Editor, Showing Spanish Translation

The icons to the right of the “Default Value” and “Translation” fields in the form simply pop up a dialog giving you a bit more room to type:



Default Value:

Hello world!

Translation for Spanish (es)

Hola Mundo!

Figure 800: Translations Editor, Values Edit Dialog

Keys rendered in red represent string resources for which you are missing one or more translations. The languages for which you are missing translations have a small red downward-pointing caret in them.

Trail: Other Tools

Advanced Emulator Capabilities

The Android emulator, at its core, is not that complex. Once you have one or more Android virtual devices (AVDs) defined, using them is a matter of launching the emulator and installing your app upon it. With Android Studio and Eclipse, those two steps can even be combined — the IDE will automatically start an emulator instance if one is needed.

However, there is much more to the Android emulator. This chapter will explore various advanced features of the emulator and how you can use them.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

x86 Images

Normally, the Android emulator emulates a device with an ARM-based CPU. That matches with most Android devices available to users today. However, most developers are developing on an x86-based development machine, not one powered by ARM. As a result, the normal Android emulator has to convert ARM instructions to x86 instructions before executing them, slowing down performance.

Some versions of the Android emulator, though, have an x86 version as well. Where available, these *can* run much more quickly than will their ARM counterparts on an x86 development machine.

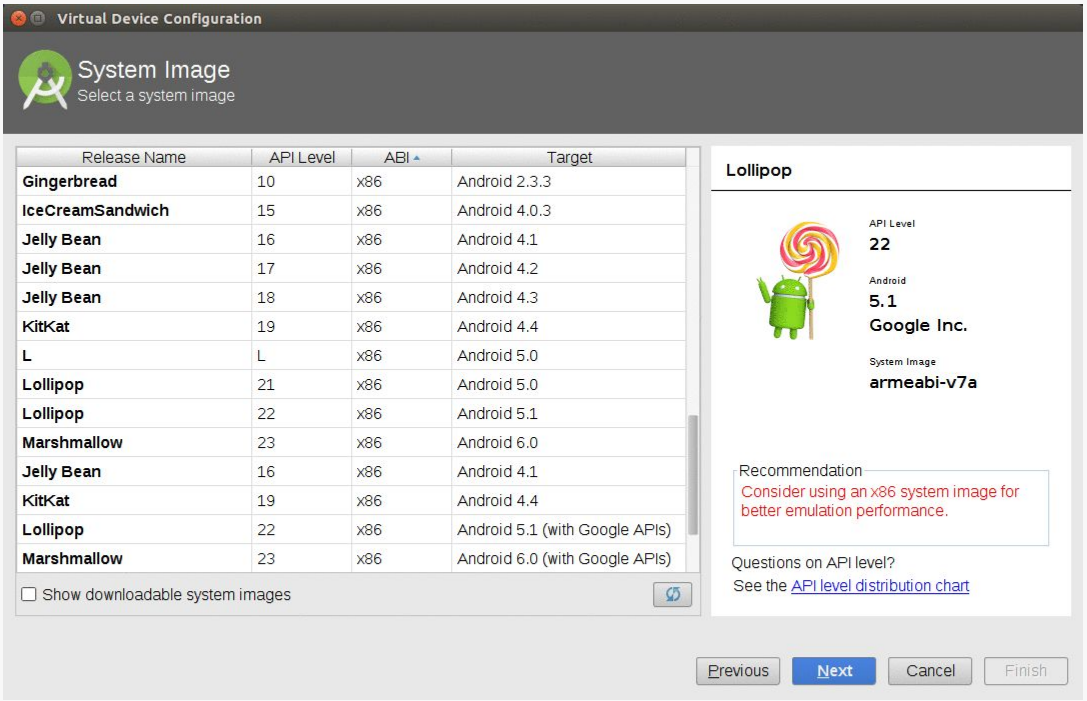
The emphasis on *can* is that your development machine must have things set up properly first. Linux users need KVM, while Mac and Windows users need the "Intel Hardware Accelerated Execution Manager" (available from the SDK Manager). The latter must be manually installed once downloaded — please consult the Android tools documentation for details.

Also, this only works for certain CPU architectures, ones that support virtualization in hardware:

- Intel Virtualization Technology (VT, VT-x, vmx) extensions
- AMD Virtualization (AMD-V, SVM) extensions (Linux only)

Those virtualization extensions must also be enabled in your device's BIOS, and other OS-specific modifications may be required.

When you are defining an AVD in the AVD Manager, you should see x86 entries in the "ABI" column. You can even sort on that column, to show all the x86-capable versions:



Release Name	API Level	ABI ▲	Target
Gingerbread	10	x86	Android 2.3.3
IceCreamSandwich	15	x86	Android 4.0.3
Jelly Bean	16	x86	Android 4.1
Jelly Bean	17	x86	Android 4.2
Jelly Bean	18	x86	Android 4.3
KitKat	19	x86	Android 4.4
L	L	x86	Android 5.0
Lollipop	21	x86	Android 5.0
Lollipop	22	x86	Android 5.1
Marshmallow	23	x86	Android 6.0
Jelly Bean	16	x86	Android 4.1
KitKat	19	x86	Android 4.4
Lollipop	22	x86	Android 5.1 (with Google APIs)
Marshmallow	23	x86	Android 6.0 (with Google APIs)

☐ Show downloadable system images

Lollipop

API Level
22

Android
5.1
Google Inc.

System Image
armeabi-v7a

Recommendation
Consider using an x86 system image for better emulation performance.

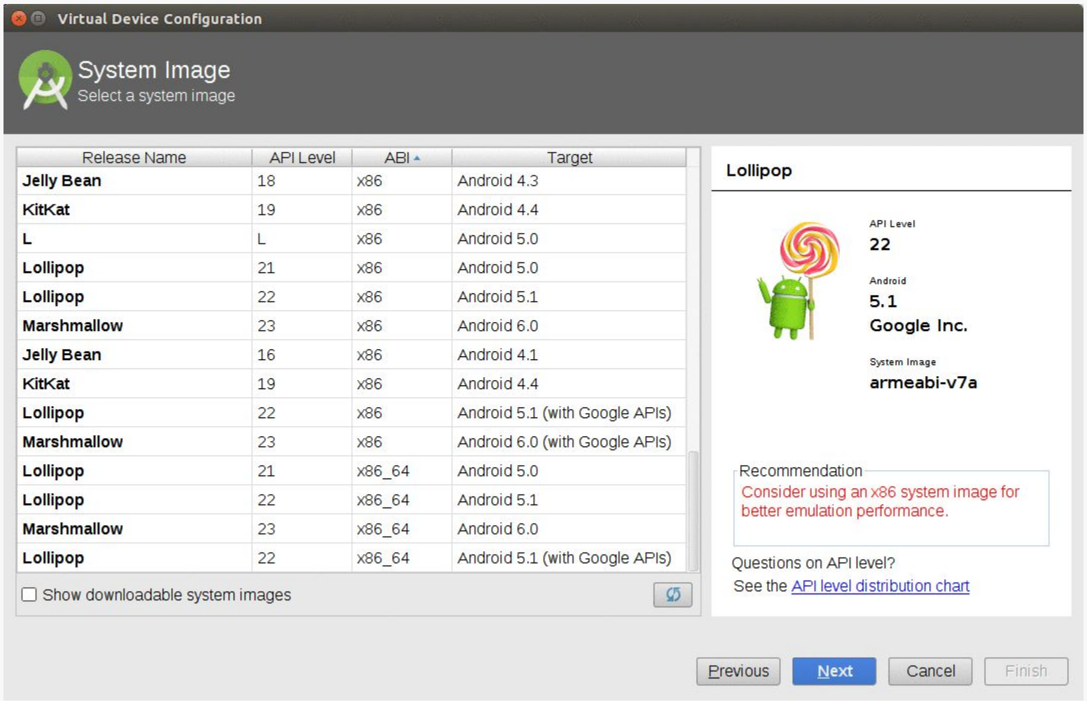
Figure 801: Android Studio AVD Manager, Showing x86 Emulator ABIs

You may need to download some images, if you do not already have them in your Android SDK. The AVD Manager will help you do that.

64-Bit Emulators

There are also emulators for 64-bit versions of Android, notably 64-bit x86:



Release Name	API Level	ABI ▴	Target
Jelly Bean	18	x86	Android 4.3
KitKat	19	x86	Android 4.4
L	L	x86	Android 5.0
Lollipop	21	x86	Android 5.0
Lollipop	22	x86	Android 5.1
Marshmallow	23	x86	Android 6.0
Jelly Bean	16	x86	Android 4.1
KitKat	19	x86	Android 4.4
Lollipop	22	x86	Android 5.1 (with Google APIs)
Marshmallow	23	x86	Android 6.0 (with Google APIs)
Lollipop	21	x86_64	Android 5.0
Lollipop	22	x86_64	Android 5.1
Marshmallow	23	x86_64	Android 6.0
Lollipop	22	x86_64	Android 5.1 (with Google APIs)

Figure 802: Android Studio AVD Manager, Showing x86-64 Emulator ABIs

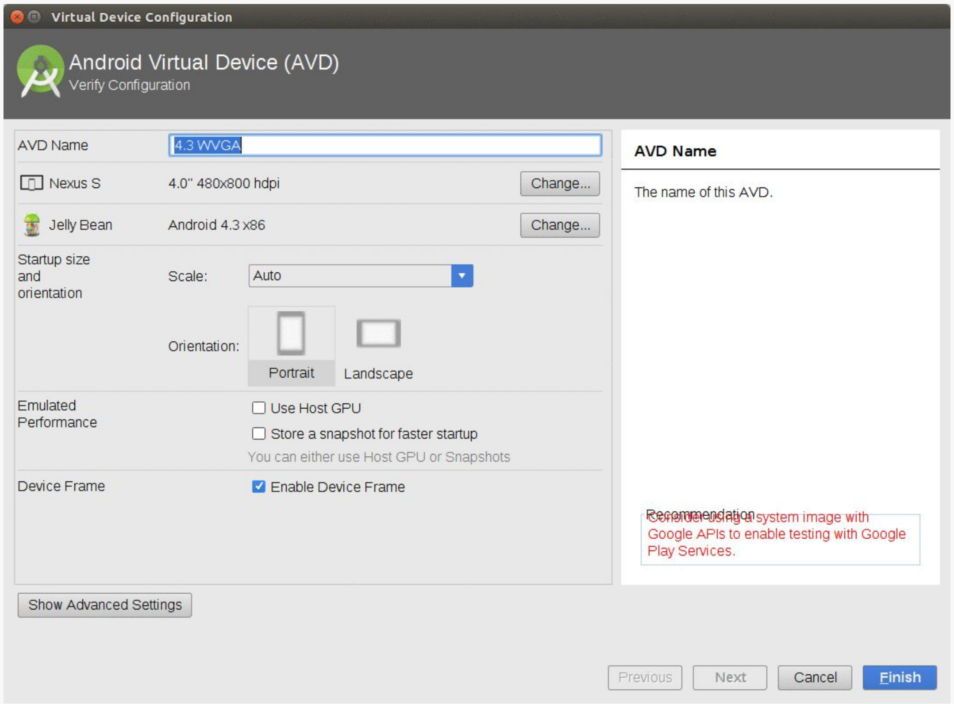
These have the same underlying system requirements as their 32-bit counterparts.

Hardware Graphics Acceleration

The other way to speed up the emulator is to have it use the graphic card or GPU of your development machine to accelerate the graphics rendering of the emulator window. By default, the emulator will use software-based rendering, without the GPU, which is slow in general and worse when running an ARM-based image.

Whether this will work or not for you will depend in part upon your graphics drivers of your development machine. Also, their use might conflict with other things you might want to do — on Linux, using Host GPU mode might break your ability to take screenshots, for example.

This setting is toggled within the AVD Manager, for new and existing AVDs, via the "Use Host GPU" checkbox in the "Emulated Performance" group:



Virtual Device Configuration

Android Virtual Device (AVD)

Verify Configuration

AVD Name: 4.3 WVGA

Nexus S: 4.0" 480x800 hdpi

Jelly Bean: Android 4.3 x86

Startup size and orientation: Scale: Auto; Orientation: Portrait

Emulated Performance:

☐ Use Host GPU

☐ Store a snapshot for faster startup

You can either use Host GPU or Snapshots

Device Frame: ☑ Enable Device Frame

AVD Name

The name of this AVD.

Recommendation: Consider using a system image with Google APIs to enable testing with Google Play Services.

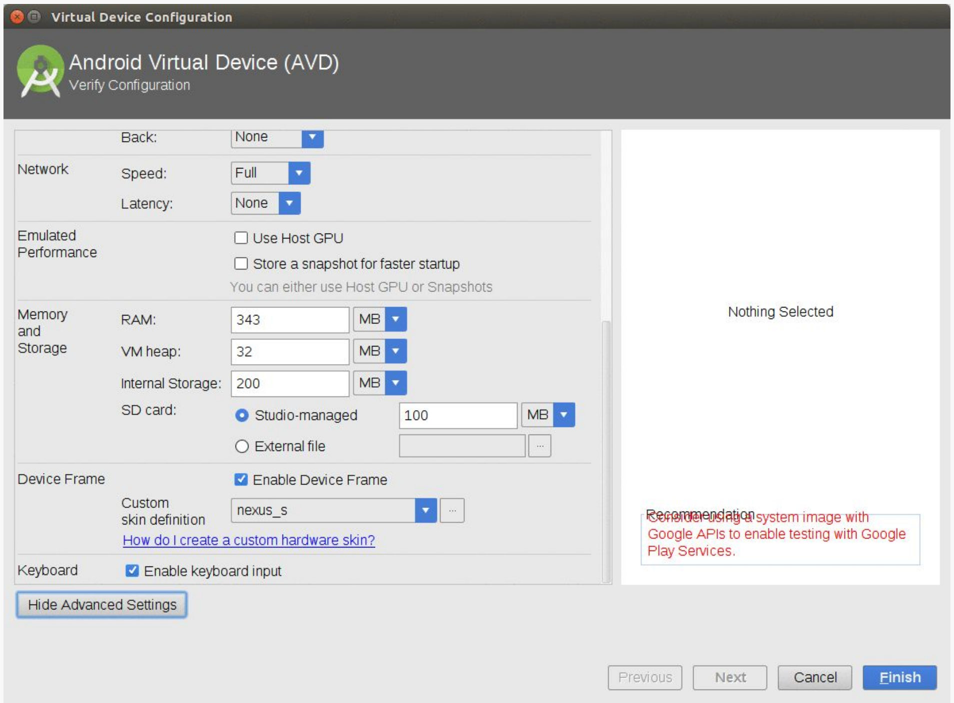
Figure 803: Virtual Device Configuration, Showing "Use Host GPU" Checkbox

Keyboard Behavior

The Android emulator can emulate devices that have, or do not have, a physical keyboard. Most Android devices do not have a physical keyboard, and so the emulator is set up to behave the same. However, this means that typing on your development machine's keyboard will not work in `EditText` widgets and the like — you have to tap out what you want to type on the on-screen keyboard.

If you wish to switch your emulator to emulate a device with a physical keyboard – either "for realz" or just to simplify working with the emulator on your development machine — you can do so.

In the Android Studio AVD Manager, in the "Advanced Settings" area, there is an "Enable keyboard input" checkbox that determines whether hardware keyboard input is honored in the AVD or not:



Virtual Device Configuration

Android Virtual Device (AVD)

How do I create a custom hardware skin?

Keyboard
☑ Enable keyboard input

Nothing Selected

Recommendation
Consider using a system image with Google APIs to enable testing with Google Play Services.

Figure 804: Virtual Device Configuration, Showing "Enable keyboard input" Checkbox

Headless Operation

Sometimes, you want an emulator without a GUI. Typically, this is used for continuous integration or some other server-based testing solution — you use the "headless" emulator to run tests, even on a machine that lacks any GUI capability.

To do this, you will need to run the emulator from the command-line. Run `emulator -no-window -avd ...`, where `...` is the name of your AVD (e.g., the value in the left column of the list of AVDs in the AVD Manager). To test this first in normal mode, run the command without the `-no-window` switch.

The simplest solution to get rid of the emulator instance is to `kill` its process.

There are many other command-line switches for the emulator that you may wish to investigate. While most of these have UI analogues in the AVD Manager, the switches would be necessary to replicate some of those for headless operation.

Lint and the Support Annotations

As C/C++ developers are well aware, `lint` is not merely something that collects in pockets and belly buttons.

`lint` is a long-standing C/C++ utility that points out issues in a code base that are not errors or warnings, but are still indicative of a likely flaw in the code. After all, what might be legal from a syntax standpoint may still be a bug when used.

Android Studio and the Android Plugin for Gradle have their own equivalent Lint tool, for reporting similar sorts of issues with an Android project's Java code, resources, and manifest. You can also get Lint reports from the command line, such as via Gradle for Android, perhaps as part of integrating your builds into a continuous integration server.

To help Lint catch problems stemming from your own code, Google has released the `support-annotations` library, to help catch things like passing a widget ID, instead of a layout ID, into `setContentView()`. You can also use these annotations to help those using your code – whether in the same project or in consumers of a library that you publish – make sure that they do not make similar mistakes.

This chapter will explore how you use Lint to detect problems and how you can add annotations to your code to help Lint catch even more problems.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

What It Is

Lint can be best described as “a pest, but a good pest”.

Normally, what stops you from building your app are compiler errors: bad Java syntax, malformed XML resource files, and the like. At the command line, these stop an in-progress build and dump error messages to the console. In Android Studio, these are noted in a log and also by notations in the source code. In Eclipse, these result in red “X” notations on the files in the Package Explorer, and frequently result in red sqiggle lines underneath the offending Java or XML when viewed in an editor. You also may get yellow squiggle lines for warnings — things the compiler will allow but the compiler thinks may be a problem.

However, there are many things that might be syntactically valid but are not a good idea from an Android standpoint. For example, if you specify a minimum SDK version of API Level 8, and you try using a class that only exists on API Level 11, that’s a problem if you are not handling it correctly and avoiding this class on the older-yet-supported devices. Yet, if your build target (i.e., `compileSdkVersion` in Android Studio) is API Level 11 or higher, it is perfectly valid syntax and would compile just fine.

Lint is designed to encapsulate rules that transcend syntax, to add more errors and warnings that reflect good Android practices beyond simple validity.

When It Runs

Running Lint sometimes happens automatically (e.g., from your IDE) or sometimes happens manually. The following sections outline the various possibilities.

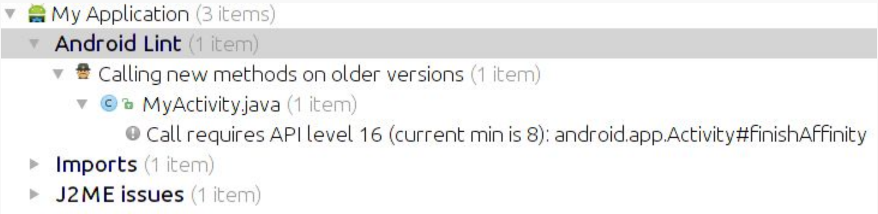
Android Studio

By default, in Android Studio, Lint will run when you save a file, giving you error (red) or warning (yellow) squiggles for things that run afoul of Lint rules:

```
finishAffinity();
```

Figure 805: Android Studio Lint Error

You can manually invoke it via Analyze > Inspect Code… from the main menu, though this also performs other analyses that are not necessarily relevant for you as an Android developer, such as "J2ME issues".



```
▼ My Application (3 items)
  ▼ Android Lint (1 item)
    ▼ Calling new methods on older versions (1 item)
      ▼ MyActivity.java (1 item)
          Call requires API level 16 (current min is 8): android.app.Activity#finishAffinity
  ► Imports (1 item)
  ► J2ME issues (1 item)
```

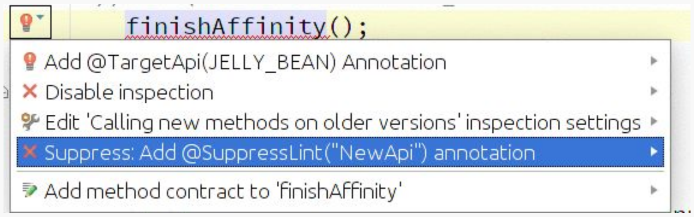
Figure 806: Android Studio Inspection Results

Command Line

You can also invoke Lint via `gradle lint` or a per-variant edition (e.g., `gradle lintRelease`). This will write results to an XML file in `build/outputs/` based upon product variant (e.g., `build/outputs/lint-results-release.xml` for a `gradle lintRelease` run). It will also emit an HTML file with the same base name in the same directory. These contain the same basic information as you get from the command-line output, with the XML in particular designed to be consumed by other tools, such as a continuous integration server.

What to Fix

In Android Studio, clicking on a red or yellow squiggle will pop up an adjacent "lightbulb" drop-down offering ways to fix the problem:



```
finishAffinity();
```

Add @TargetApi(JELLY_BEAN) Annotation
Disable inspection
Edit 'Calling new methods on older versions' inspection settings
Suppress: Add @SuppressLint("NewApi") annotation
Add method contract to 'finishAffinity'

Figure 807: Android Studio Lint Fix Suggestions

You can also bring up this "quick fixes" list via [kbd>Alt-`Enter</kbd]. For example:`

- Errors related to accessing classes or methods higher than your `minSdkVersion` have “quick fixes” to add the `@TargetApi` annotation to the class or method containing your code
- Warnings related to hard-coded strings in layouts or the manifest have “quick fixes” to convert those strings into string resources

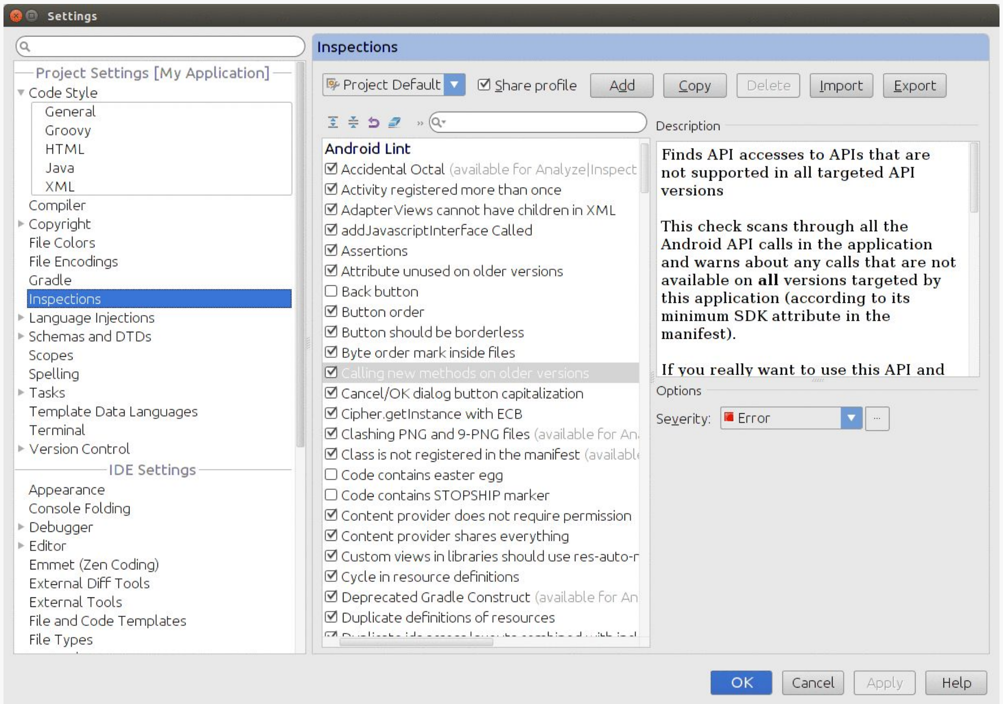
All warnings and errors will have “quick fixes” to suppress that warning or error in the future, by adding notations to the file to that effect.

What to Configure

You have some measure of control over Lint’s behavior, though the mechanics of doing this varies by tool.

Android Studio

In Android Studio, you can configure Lint’s behavior via the Project Settings dialog, accessible via File > Settings:



Project Default ☑ Share profile

Android Lint

☑ Accidental Octal (available for Analyze|Inspect
☑ Activity registered more than once
☑ AdapterViews cannot have children in XML
☑ addJavascriptInterface Called
☑ Assertions
☑ Attribute unused on older versions
☐ Back button
☑ Button order
☑ Button should be borderless
☑ Byte order mark inside files
☑ Calling new methods on older versions
☑ Cancel/OK dialog button capitalization
☑ Cipher.getInstance with ECB
☑ Clashing PNG and 9-PNG files (available for An
☑ Class is not registered in the manifest (available
☐ Code contains easter egg
☐ Code contains STOPSHIP marker
☑ Content provider does not require permission
☑ Content provider shares everything
☑ Custom views in libraries should use res-auto-r
☑ Cycle in resource definitions
☑ Deprecated Gradle Construct (available for An
☑ Duplicate definitions of resources

Description

Finds API accesses to APIs that are not supported in all targeted API versions

This check scans through all the Android API calls in the application and warns about any calls that are not available on **all** versions targeted by this application (according to its minimum SDK attribute in the manifest).

If you really want to use this API and

Options

Severity: Error

Figure 808: Android Studio Lint Error Checking Preferences

You can change some details about the specific checks that Lint makes:

- the severity of the issue, usually set to Warning or Error
- whether the specific issue should be ignored rather than executed

To do this, you may wish to create your own inspection profile, rather than modifying the stock “Project Default” profile. To do this, just click the “Copy” button in the Inspections page of the Settings dialog and supply a name for the new profile.

The above recipe changes the inspections for the individual project. To change them for new projects, go into File > Other Settings > Default Settings, and make your changes there.

Command Line

To block certain Lint checks in Gradle, you can create a `lint.xml` file, in the root directory of your project, containing information about which particular issues should be suppressed for that project. The benefit here is that you can configure suppression at a finer granularity, blocking issues for certain files or directories and allowing them for others. The sample `lint.xml` from [the Lint documentation]() looks like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<lint>
    <!-- Disable the given check in this project -->
    <issue id="IconMissingDensityFolder" severity="ignore" />

    <!-- Ignore the ObsoleteLayoutParam issue in the given files -->
    <issue id="ObsoleteLayoutParam">
        <ignore path="res/layout/activation.xml" />
        <ignore path="res/layout-xlarge/activation.xml" />
    </issue>

    <!-- Ignore the UselessLeaf issue in the given file -->
    <issue id="UselessLeaf">
        <ignore path="res/layout/main.xml" />
    </issue>

    <!-- Change the severity of hardcoded strings to "error" -->
    <issue id="HardcodedText" severity="error" />
</lint>
```

You can also configure lint via a `lintOptions` closure inside the `android` closure of your `build.gradle` file. In particular, you can have a `disable` statement to list the Lint checks that you would like to block:

```
android {
    lintOptions {
        disable 'IconMissingDensityFolder','InefficientWeight'
        ...
    }
}
```

The names used in `lint.xml` or `lintOptions` are the "issue IDs". You can get a roster of these by running `lint --list` for brief summaries:

```
Valid issue categories:
    Correctness
    Correctness:Messages
    Security
    Performance
    Usability:Typography
    Usability:Icons
    Usability
    Accessibility
    Internationalization
    Bi-directional Text

Valid issue id's:
"ContentDescription": Image without contentDescription
"AddJavascriptInterface": addJavascriptInterface Called
"ShortAlarm": Short or Frequent Alarm
"AlwaysShowAction": Usage of showAsAction=always
"ShiftFlags": Dangerous Flag Constant Declaration
"LocalSuppress": @SuppressLint on invalid element
"UniqueConstants": Overlapping Enumeration Constants
"InlinedApi": Using inlined constants on older versions
"Override": Method conflicts with new inherited method
"NewApi": Calling new methods on older versions
...
```

…or `lint --show` for a set of more elaborate descriptions:

```
Available issues:

Correctness
===========

AdapterViewChildren
-------------------
Summary: AdapterViews cannot have children in XML

Priority: 10 / 10
Severity: Warning
Category: Correctness

AdapterViews such as ListViews must be configured with data from Java code,
such as a ListAdapter.

More information:
http://developer.android.com/reference/android/widget/AdapterView.html
```

```
OnClick
-------
Summary: onClick method does not exist

Priority: 10 / 10
Severity: Error
Category: Correctness

The onClick attribute value should be the name of a method in this View's
context to invoke when the view is clicked. This name must correspond to a
public method that takes exactly one parameter of type View.

Must be a string value, using '\;' to escape characters such as '\n' or
'\uxxxx' for a unicode character.

StopShip
--------
Summary: Code contains STOPSHIP marker

Priority: 10 / 10
Severity: Warning
Category: Correctness
NOTE: This issue is disabled by default!
You can enable it by adding --enable StopShip

Using the comment // STOPSHIP can be used to flag code that is incomplete but
checked in. This comment marker can be used to indicate that the code should
not be shipped until the issue is addressed, and lint will look for these.

MissingPermission
-----------------
Summary: Missing Permissions

Priority: 9 / 10
Severity: Error
Category: Correctness

This check scans through your code and libraries and looks at the APIs being
used, and checks this against the set of permissions required to access those
APIs. If the code using those APIs is called at runtime, then the program will
crash.
...
```

The `lint` command can be found in the `tools/` directory of your Android SDK installation.

Support Annotations

The `support-annotations` library, from the Android Support set of libraries, offers a series of annotations that you can add to methods, method parameters, and the like to teach Lint certain types of bugs to check for. Some of the Android Support libraries use these annotations, so Lint can help catch problems when you use those public APIs. You, in turn, can add these annotations to *your* code, to catch certain problems at compile time that otherwise might be missed.

However, the important thing is that these are compile-time checks, not assertions at runtime. Lint will see if there is a likely bug at compile time and point it out to the developer, but there are many places where Lint simply has no way to know if everything is OK or not. These annotations are not a replacement for defensive programming. In fact, they not only help *users* of some API you publish to use it correctly, they help *you* by serving as a reminder that these should be checked at runtime as well.

Pretty much all of the Android Support libraries pull in `support-annotations`, courtesy of Gradle and transitive dependencies. If you do not seem to have `support-annotations` in your project, just add it to your `dependencies` closure, as you would any other of the Android Support libraries:

```
dependencies {
  compile 'com.android.support:support-annotations:23.1.0'
}
```

You may occasionally run into version conflicts over this library, where Library A wants one version and Library B wants another version. In those cases, you may need to teach Gradle to not try to load the `support-annotations` version that a particular library might want, so you can use a different version:

```
dependencies {
  compile 'com.android.support:support-annotations:23.1.0'
  compile('com.davemorrissey.labs:subsampling-scale-image-view:3.4.0') {
    exclude module: 'support-annotations'
  }
}
```

In this case, `com.davemorrissey.labs:subsampling-scale-image-view:3.4.0` wants version `20.0.0` of the `support-annotations`, which is rather old. Hence, we block that dependency and substitute our own, for version `23.1.0`. In general, newer versions of this library should be backwards-compatible with older versions of this library, so in case of conflict, use the newer version.

Permissions, Again

You can indicate that certain bits of your app require callers to hold certain permissions, using the `@RequiresPermission` annotation. This is mostly for libraries, where other projects might use the library.

Methods

The most common place to put this annotation will be on a method, to indicate that the method requires that callers hold a certain permission.

The simplest scenario is where the method requires that callers hold a single permission, in which case you just list the permission as a parameter to the annotation:

```
@RequiresPermission(Manifest.permission.CAMERA)
public void takeSelfie() {
  // do work here
}
```

If the caller does not have a `<uses-permission>` element for the `CAMERA` permission, Lint will complain at the point where the app calls `takeSelfie()`.

Sometimes, you may need callers to hold more than one permission. In that case, you can use `allOf` to list permissions; callers have to have requested all of them in the manifest:

```
@RequiresPermission(
  allOf = {
    Manifest.permission.CAMERA,
    Manifest.permission.WRITE_EXTERNAL_STORAGE
  }
)
public void takeSelfie() {
  // do work here
}
```

On occasion, you may need the caller to hold one of a set of possible permissions. The quintessential example here is location, where your code might dynamically adapt based upon whether the app has `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. In that case, you can use `anyOf` to list the possibilities; if the app has any of those permissions requested in the manifest, Lint will be happy:

```
@RequiresPermission(
  anyOf = {
    Manifest.permission.ACCESS_COARSE_LOCATION,
    Manifest.permission.ACCESS_FINE_LOCATION
  }
)
public void makeNoteOfWhereWeAt() {
  // do work here
}
```

It is unclear if there is a way to combine anyOf and allOf in a single annotation (e.g., a takeSelfie() method that wants to geotag the photo with the user's current location).

Intent Actions

If you have a custom Intent action string, and the operation tied to that action string requires a permission, you can teach Lint about that by putting a @RequiresPermission annotation on a static String for that action string:

```
@RequiresPermission(Manifest.permission.CAMERA)
public static final String ACTION_TAKE_SELFIE="com.commonsware.intent.action.SELFIE";
```

Basically, Lint keeps track of such strings, and if any Intent in the app is created using those strings as actions, Lint will check to see if the permission was requested.

ContentProviders

Similarly, you can annotate a static Uri that serves as the base Uri for a ContentProvider. Any calls to ContentObserver that have a Uri based on the static base will trigger Lint to check to see if permissions were requested.

Frequently, though, a ContentProvider will have separate read and write permissions. To handle that, you have to use some fairly clunky syntax, wrapping the @RequiresPermission annotation in @RequiresPermission.Read or @RequiresPermission.Write annotations. For example, the ContactsContract class could, in theory, have:

```
public static final String AUTHORITY = "com.android.contacts";
public static final Uri AUTHORITY_URI = Uri.parse("content://" + AUTHORITY);

@RequiresPermission.Read(@RequiresPermission(Manifest.permission.READ_CONTACTS))
@RequiresPermission.Write(@RequiresPermission(Manifest.permission.WRITE_CONTACTS))
public static final Uri CONTENT_URI = Uri.withAppendedPath(AUTHORITY_URI, "contacts");
```

(it actually does not have these; any Lint checks for this CONTENT_URI are being handled through rules internal to the tools, not through the support annotations)

What Permissions Should I Annotate?

If the method (or whatever) absolutely needs the permission, in all significant cases, then having the annotation will be useful.

However, there will be scenarios in which a permission may or may not be needed, depending upon circumstances.

For example, let's go back to:

```
@RequiresPermission(
  allOf = {
    Manifest.permission.CAMERA,
    Manifest.permission.WRITE_EXTERNAL_STORAGE
  }
)
public void takeSelfie() {
  // do work here
}
```

Here, we are implying that `takeSelfie()` will need both of those permissions, and probably all of the time. For example, perhaps the method is set up to write to `Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DCIM)`. That directory requires `WRITE_EXTERNAL_STORAGE` all of the time.

But, suppose the method were implemented where the destination was a `Uri`, instead? You would have:

```
@RequiresPermission(
  allOf = {
    Manifest.permission.CAMERA,
    Manifest.permission.WRITE_EXTERNAL_STORAGE
  }
)
public void takeSelfie(Uri dest) {
  // do work here
}
```

That `Uri` could point to any number of locations, only some of which might require `WRITE_EXTERNAL_STORAGE`. For example, the caller could provide a `file:` `Uri` pointing to `getExternalFilesDir()`, which does not need `WRITE_EXTERNAL_STORAGE` on API Level 19+.

There are two major strategies here, with respect to these annotations:

- Be conservative, and annotate for both permissions, as shown in the example above. The caller can always suppress the warning, if the caller is sure that `WRITE_EXTERNAL_STORAGE` is not required. However, this may confuse people not familiar with your API or with Android overall.
- Be liberal, and only annotate for the `CAMERA` permission (which `takeSelfies()` always needs). Here, you are relying on the caller to read the documentation for your library, use common sense, or perform adequate

testing to ensure that WRITE_EXTERNAL_STORAGE is requested in cases where it is needed.

A "middle ground" approach would be to be conservative in cases where the permission might require significant work, and liberal otherwise. For example, WRITE_EXTERNAL_STORAGE is a dangerous permission on Android 6.0+, and so the caller has to go through all of the runtime permission request stuff for that if the app's targetSdkVersion is 23 or higher. But, if takeSelfie() really needed CAMERA and VIBRATE (to shake the device once the selfie is taken, perhaps based on user preferences), requesting VIBRATE is merely a single line in the manifest, and so demanding it via the annotation when it might not be needed would be excessive.

Type Roles, and the War on Enums

In 2015, a kerfuffle erupted in the world of Android development, one that quickly got tagged with the label, "the War on Enums".

Google developer advocates started promoting the idea that using the Java enum construct was bad, and that you should use int constants instead, the way the Android SDK does. Core Android engineers slowly backed away from those developer advocates, but explained the reason why all through the Android SDK we are passing around int values.

In a nutshell, an enum reference will consume more heap space than will an int. If every place we passed around int flags or int resource IDs, we passed around enum objects, we would put greater pressure on our available heap space.

For most Android developers, for their own code, this particular concern is unimportant, compared to the type safety one gets from using an enum properly. However, the Android SDK team decided that, in general, they should use int values rather than enum values, so they would not be the ones to blame for consuming too much heap space.

However, this does bring us back to the core problem of passing the *wrong* int values into the *wrong* methods, such as:

- passing a widget ID or a string resource ID into setContentView()
- passing in Intent flags (e.g., FLAG_ACTIVITY_NEW_TASK) to PendingIntent methods like getActivity()
- passing in a color resource ID to a method that takes an actual ARGB color value

Instead, we get a convoluted set of annotations to try to help developers using public APIs to provide the smarts that ordinarily would be handled simply by `enum`.

Resources

Ideally, resource IDs would use Java's `enum`, so that you could not pass a string resource ID to a method that is expecting a menu resource ID. Alas, that is not the case.

Instead, if you accept resource IDs as parameters on methods or as return values from those methods, you can use a set of annotations to indicate what specific role the `int` values play.

- `@AnimatorRes`
- `@AnimRes`
- `@ArrayRes`
- `@AttrRes`
- `@BoolRes`
- `@ColorRes` (i.e., the `int` should be a color resource ID)
- `@DimenRes`
- `@DrawableRes` (i.e., the `int` should be a drawable resource ID)
- `@FractionRes`
- `@IdRes`
- `@InterpolatorRes`
- `@LayoutRes`
- `@MenuRes`
- `@PluralsRes`
- `@RawRes`
- `@StringRes` (i.e., the `int` should be a string resource ID)
- `@StyleableRes`
- `@StyleRes`
- `@TransitionRes`
- `@XmlRes`

Documentation for these, such as it is, can be found in the JavaDocs for the `android.support.annotation` package.

There is also `@AnyRes`, which indicates that the `int` needs to be a resource, but does not imply a particular type of resource.

So, for example, you could have:

```
public void loadConfig(@XmlRes xmlResId) {
  // do work here
}
```

If Lint is uncertain whether the parameter passed to `loadConfig()` is really an `R.xml` value, it can warn the caller.

Custom Enum Replacement

Sometimes, the `int` values are replacing what would have been a custom Java `enum`.

For example, the CWAC-Cam2 library has a `FlashMode` `enum`:

```
public enum FlashMode {
  OFF,
  ALWAYS,
  AUTO,
  REDEYE
}
```

Apparently, the author of that library is evil and therefore supports the use of an `enum`.

(note: the author of that library is also the author of this book)

An alternative would be to define those as a series of `int` flags:

```
public class FlashMode {
  public static final int OFF=0x0;
  public static final int ALWAYS=0x1;
  public static final int AUTO=0x2;
  public static final int REDEYE=0x3;
}
```

However, we are then back in the state where we do not know if some arbitrary `int` that we are passed as a parameter really is a `FlashMode`, as a method might expect. With the `enum`, we can have methods like:

```
public void setFlashMode(FlashMode mode) {
  // do work
}
```

The `support-annotations` library makes it possible to write a `setFlashMode()` that warns developers if they pass in the wrong `int`, but it takes a bit of work.

The documented recipe is:

```
public class FlashMode {
  @IntDef({OFF, ALWAYS, AUTO, REDEYE})
  @Retention(RetentionPolicy.SOURCE)
  public @interface FlashModeInt {}

  public static final int OFF=0x0;
  public static final int ALWAYS=0x1;
  public static final int AUTO=0x2;
  public static final int REDEYE=0x3;
}
```

Then, elsewhere, we could reference that custom `FlashModeInt` annotation:

```
public void setFlashMode(@FlashMode.FlashModeInt int mode) {
  // do work
}
```

Then, if Lint cannot confirm that the supplied `mode` is one of those constants, Lint can warn the caller.

Flags

One benefit of `int` over `enum` is that it is easier to implement parameters and return values that represent a combination of values rather than single values.

For example, there are a wide range of flags that you can put on an `Intent`, like `FLAG_ACTIVITY_CLEAR_TOP` and `FLAG_ACTIVITY_SINGLE_TOP`. An `Intent` can have zero, one, or several of these flags.

With an `enum` for those flags, you would need to be passing around a `Set` of `enum` instances. With `int` values, though, you can use bitfields, where each flag is assigned a bit within the `int`. For example, `FLAG_ACTIVITY_CLEAR_TOP` is `0x04000000` and `FLAG_ACTIVITY_SINGLE_TOP` is `0x20000000`. Having both of those on a single `Intent` is merely a matter of using a OR bit operation:

```
yourIntent.setFlags(Intent.FLAG_ACTIVITY_CLEAR_TOP|FLAG_ACTIVITY_SINGLE_TOP`)
```

This takes up a lot less space, and is more efficient from a CPU standpoint, than a `Set` of `enum` values. However, once again, type safety becomes a problem.

`@IntDef` also supports a “flag” mode, where Lint will validate that the value passed in is comprised of the designated constants, either used individually or in combination using boolean bit operators. For example, perhaps we can support several possible flash modes in a camera API, and the caller can indicate the various modes of interest using flags:

```
@IntDef(flag=true, value={
  FLAG_OFF,
  FLAG_ALWAYS,
  FLAG_ON,
  FLAG_REDEYE
})
@Retention(RetentionPolicy.SOURCE)
public @interface FlashModeOptions {}
```

Now, methods and parameters annotated with `@FlashModeOptions` will be validated to ensure they are passing valid flags and combinations of flags.

Does It Null?

The `@NonNull` annotation can be used for parameters that are not allowed to be `null`. If, at compile time, the caller is clearly passing a `null` value, the caller will be warned.

```
public void doSomethingContextual(@NonNull Context ctxt) {
  // do work here
}
```

This could also be used on methods where you are sure that the return value cannot be `null`. This is particularly important with abstract methods, methods you expect other developers to override, callbacks, and the like — putting `@NotNull` on return values for those methods indicate that *you* are requiring that the implementer not hand you back a `null` value.

Conversely, the `@Nullable` annotation can be used on methods that explicitly *can* return `null` as valid value:

```
@Nullable
public Context getContextIfWeHaveOne() {
  // do work here

  return(result);
}
```

Any caller of `getContextIfWeHaveOne()` will get a Lint warning, pointing out that they need to check for `null` results. That warning will remain there until the developer suppresses it or, in Lint's estimation, appears to check the result for a `null` value and handle that case.

This can be used to help find `@NonNull` violations elsewhere, by helping Lint see where things might be `null`.

Data Validation

A variety of other annotations can be used for checking parameter values at compile time, to perhaps catch bugs earlier.

Size

For parameters and return values that implement `java.util.Collection` – such as `ArrayList`, you can use the `@Size` annotation to provide some compile-time guidance with regards to your expectations for that collection. This also works for ordinary Java arrays.

A simple number in the `@Size` annotation means you are expecting exactly that number of items in the collection, no more, no less:

```
public void growPair(@Size(2) ArrayList<String> values) {
  // do something
}
```

You can use `min` and `max` to constrain the size, without tying it down to a particular value:

```
public void sortInPlace(@Size(min=1) List<Comparable> unsorted) {
  // do a sort
}

public @Size(min=1, max=6) float[] getReading(SensorEvent e) {
  return(e.values);
}
```

Occasionally, you might have a collection that does not have a specific size, but the size it *does* have has to be evenly divisible by some number. For that, there is the `multiple` option:

```
@RequiresPermission(Manifest.permission.VIBRATE)
public void shakeItOff(@Size(multiple=2) long[] vibrationPattern) {
  // use Vibrator system service
}
```

Ranges

`@IntRange` and `@FloatRange` help validate that

Colors

If you have a method that expects a color resource ID as a parameter or return value, use the @ColorRes annotation, as noted previously.

However, more often than not, you will be expecting *colors*, not color resource IDs, to give the other developers flexibility about where the colors come from. In that case, @ColorInt will help identify parameters and return values that are expected to be actual ARGB colors, not just arbitrary integers. In particular, this will catch when somebody tries using a color resource ID where you expect an actual color.

Thread Validation

If a method needs to be invoked on a certain type of thread (e.g., a background thread), you can use annotations to try to catch that sort of bug.

The simple one is @WorkerThread, which indicates that the method needs to be called on a background thread. If Lint thinks that the method is being invoked from something else (e.g., the main application thread), it will flag the caller with a warning.

```
@WorkerThread
public void thisIsGoingToTakeLikeForEVER() {
  // do something tedious
}
```

There are two possible converse annotations: @MainThread and @UiThread. In one bit of documentation, Google says they are interchangeable. In another bit of documentation, Google tries to point out a disparity between them

> There is one and only one main thread in the process. That's the @MainThread. That thread is also a @UiThread. This thread is what the main window of an activity runs on, for example. However it is also possible for applications to create other threads on which they run different windows. This will be very rare; really the main place this distinction matters is the system process. Generally you'll want to annotate methods associated with the life cycle with @MainThread, and methods associated with the view hierarchy with @UiThread. Since the @MainThread is a @UiThread, and since it's usually the case that a @UiThread is the @MainThread, the tools (lint, Android Studio, etc) treat these threads as interchangeable, so you can call @UiThread methods from @MainThread methods and vice versa.

Roughly speaking, if the method has to be run on the main application thread for lifecycle reasons, use `@MainThread`. If the method has to be run on a UI thread to avoid "cannot modify views from a non-UI thread" sorts of errors, use `@UiThread`. And, if you're not sure, flip a coin.

Other Annotations

If you have a `protected` or `public` method in a class that might be subclassed, and you want to help ensure that if the method is overridden that the developer calls through to your superclass implementation, use `@CallSuper`.

(note: this annotation will not call a building superintendent; it will only be honored by Superman if your name is on the whitelist, e.g., Lois Lane)

```
@CallSuper
protected int heyDontForgetAboutMe() {
  // do something

  return(somethingToo);
}
```

`@CheckResult` allows you to nag any caller of your method, to ensure that they actually look at the value you return, rather than ignore it.

Using Hierarchy View

Android comes with a Hierarchy View tool, designed to help you visualize your layouts as they are seen in a running activity in a running emulator. So, for example, you can determine how much space a certain widget is taking up, or try to find where a widget is hiding that does not appear on the screen.

Prerequisites

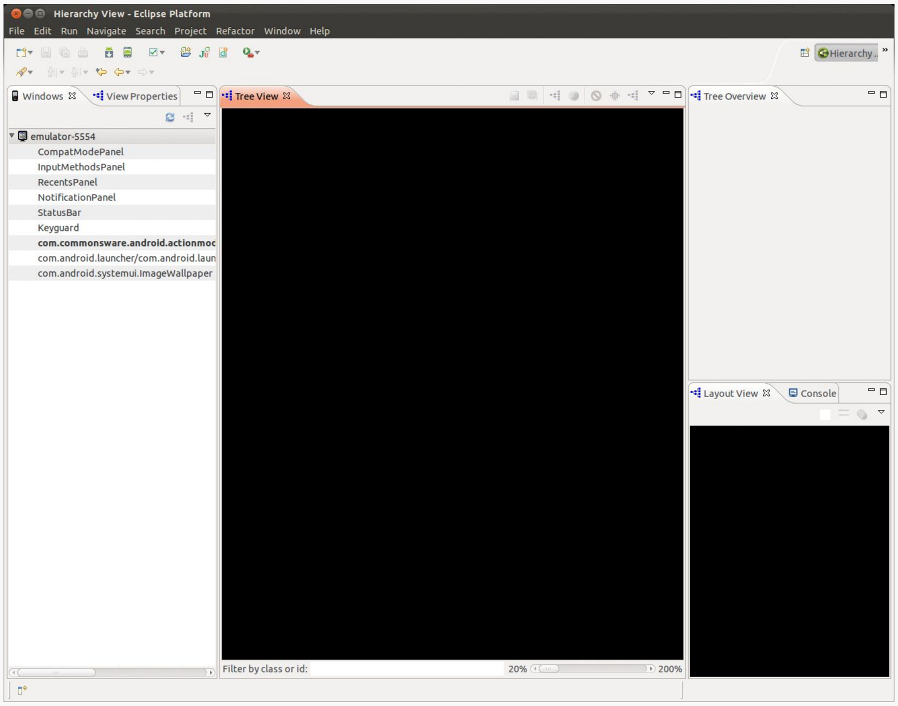
Understanding this chapter requires that you have read the core chapters of this book.

Launching Hierarchy View

To use the Hierarchy View, you first need to fire up your emulator, install your application, launch your activity, and navigate to the spot you wish to examine. Note that you cannot use Hierarchy View with a production Android device without some help.

To launch Hierarchy View, you have two options:

1. From Eclipse, open the Hierarchy View perspective
2. Use the Android Device Monitor. In Android Studio, this is available from the Tools > Android menu. From the command line, run the `monitor` program to bring up the Android Device Monitor. In the Android Device Monitor, choose Window > Open Perspective from the main menu, and open Hierarchy View:



Hierarchy View - Eclipse Platform
File Edit Run Navigate Search Project Refactor Window Help
Hierarchy
Windows
View Properties
Tree View
Tree Overview
emulator-5554
CompatModePanel
InputMethodsPanel
RecentsPanel
NotificationPanel
StatusBar
Keyguard
com.commonsware.android.actionmoc
com.android.launcher/com.android.laun
com.android.systemui.ImageWallpaper
Layout View
Console
Filter by class or id:
20%
200%

Figure 809: Hierarchy View, in Eclipse, As Originally Opened

The roots of the tree-table on the left show the emulator instances presently running on your development machine. The leaves represent applications running on that particular emulator. Your activity will be identified by application package and class (e.g., `com.commonsware.android.files/...`).

Viewing the View Hierarchy

Where things get interesting, though, is when you double-click on your activity in the tree-table. After a few seconds, the details spring into, er, view:

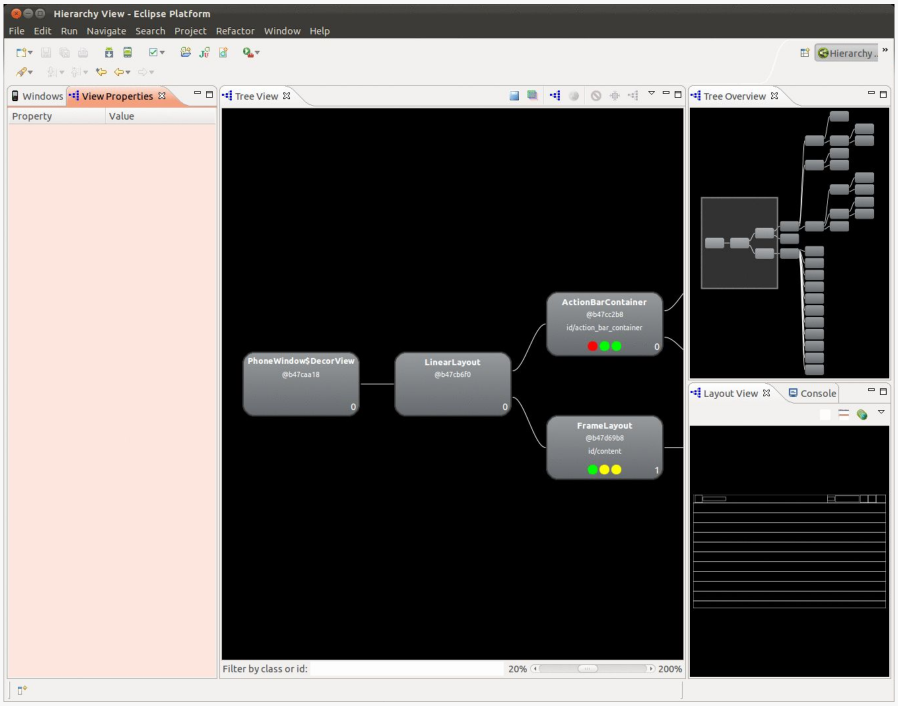


Figure 810: Hierarchy View, in Eclipse, Showing an Activity

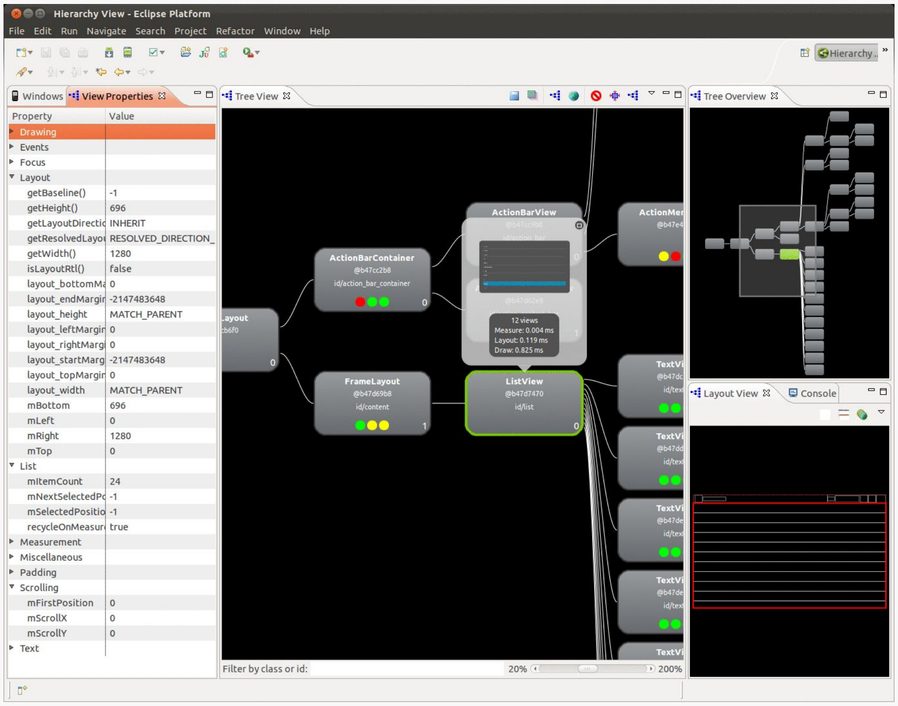
The main area of the Layout View shows a tree of the various widgets and stuff that make up your activity, starting from the overall system window and driving down into the individual UI widgets that users are supposed to interact with. This includes both widgets and containers defined by your application and others that are supplied by the system, including the title bar.

Clicking on one of the views adds more information to this perspective:



Property	Value
Drawing	
Events	
Focus	
Layout	
getBaseline()	-1
getHeight()	696
getLayoutDirectic	INHERIT
getResolvedLayou	RESOLVED_DIRECTION_

Text	

Figure 811: Hierarchy View, in Eclipse, Showing a View's Details

Now, we get:

- In the left region of the Viewer, we see the properties of the selected widget or container, in its own tree-table.
- In the Tree View in the middle, the selected widget or container has a pop-up bubble with what that particular `View` looks like on the screen, along with some performance timing data.
- In the Tree Overview in the upper-right portion of the tool, our selected `View` is highlighted in green.
- In the Layout View in the lower-right portion of the tool, our selected `View` is highlighted in red in the wireframe.

From the toolbar above the Tree View, you can:

- Save the tree diagram as a PNG file
- Save the UI as a Photoshop PSD file, with different layers for the different widgets and containers
- Force the UI to repaint in the emulator or re-load the hierarchy, in case you have made changes to a database or to the app's contents and need a fresh diagram

ViewServer

One major limitation of Hierarchy View is that it only works with the emulator by default. There is no means for it to pull information from random activities running on production hardware.

However, Romain Guy, one of the core Android engineers, has published a ViewServer open-source component that gets around this limitation.

If you add the ViewServer source code to your project, and register your activities as they are created (and remove them when they are destroyed), you will be able to use Hierarchy View with them. However, this is a bit dangerous on a production app, so you should strongly consider using BuildConfig.DEBUG to only enable this logic in debug builds.

Blending in the BuildConfig.DEBUG concept with Mr. Guy's supplied sample usage, we get something like this:

```
public class MyActivity extends Activity {
   public void onCreate(Bundle savedInstanceState) {
     super.onCreate(savedInstanceState);

     // Set content view, etc.

     if (BuildConfig.DEBUG) ViewServer.get(this).addWindow(this);
   }

   public void onDestroy() {
     if (BuildConfig.DEBUG) ViewServer.get(this).removeWindow(this);

     super.onDestroy();
   }

   public void onResume() {
     super.onResume();

     if (BuildConfig.DEBUG) ViewServer.get(this).setFocusedWindow(this);
   }
}
```

Also note that ViewServer requires that your application hold the INTERNET permission, which you may already have requested for other reasons.

Screenshots and Screencasts

They say that a picture is worth a thousand words.

If that were really true, this book would be a lot shorter, mostly consisting of a bunch of screenshots.

That being said, having screenshots of your app is essential for documentation, marketing, and other uses. You are going to want to collect screenshots from your app by one means or another.

Screencasts — videos recording the user's interaction with a device – are also very useful for the same purposes, even if their nature precludes their practical use in various mediums (e.g., PDFs). These are also a bit more complex to collect, though you have plenty of options for that.

This chapter will outline various ways to get screenshots and screencasts of your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Collecting from Android Studio

The Android Monitor tool has buttons to take a screenshot and record a screencast, in the outer toolbar:

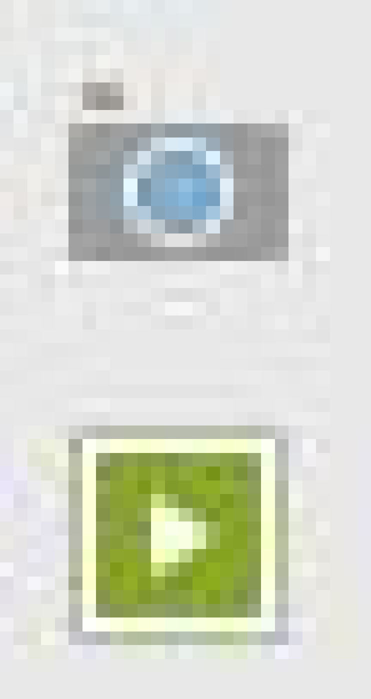

Figure 812: Android Studio Screenshot and Screencast Toolbar Buttons

Screenshots

The top one takes a screenshot, giving you a dialog to control what gets captured:

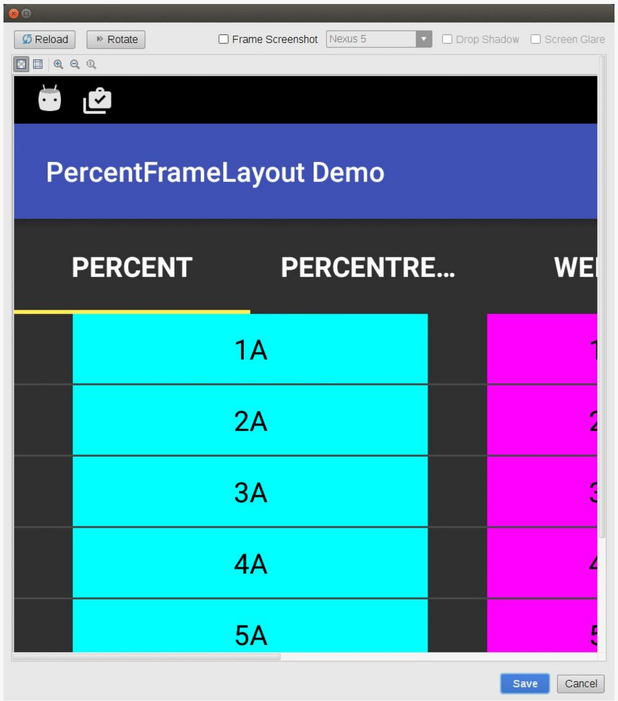

Figure 813: Android Studio Screenshot Dialog

The main area shows the screen at the time you clicked the screenshot toolbar button. Clicking the "Reload" button on the top of the dialog will update the dialog to show the now-current device (or emulator) contents.

Depending on Android Studio version and device characteristics, the dialog may open with the correct orientation. If not, click the "Rotate" button until the image is oriented as you would like it to be.

The "Frame Screenshot" checkbox, if checked, will wrap your screenshot in an image that resembles the hardware from the drop-down list:

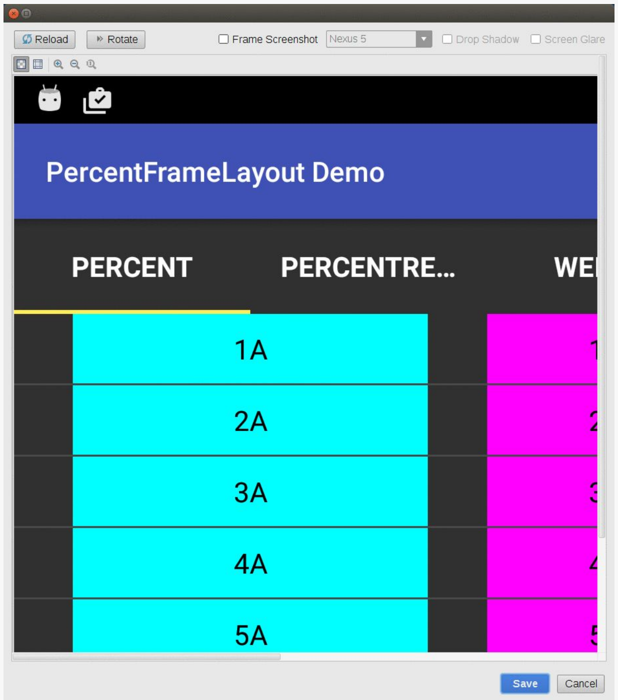

Figure 814: Android Studio Screenshot Dialog, Framing as Nexus 5

The "chessboard" on the outside edges of the image represent transparent areas in the PNG that will be created when you save the image.

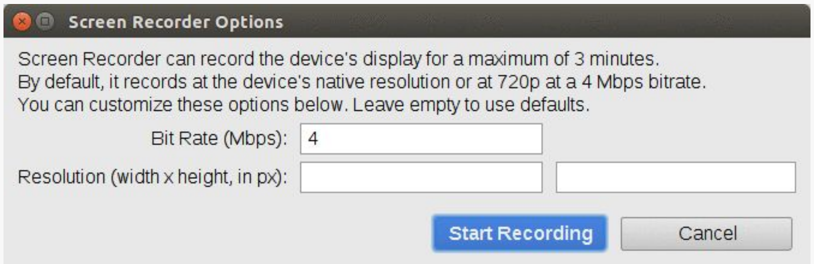
Checking the "Drop Shadow" checkbox updates the fake device frame to make it seem like the device is sitting on its edge on some horizontal surface, with a drop-shadow effect. Similarly, checking the "Screen Glare" checkbox adds a fake bit of lighting to the screenshot, as if a light from the upper right side is causing a glare on the fake glass of the fake device frame. Suffice it to say, none of this looks especially realistic.

When you have the screenshot set to your liking, click the "Save" button on the bottom of the dialog, to get a platform-specific "Save As" dialog for you to save your screenshot to wherever you like.

The resulting screenshot will then open in a tab in your IDE. This tab does not let you edit the picture, but it does have an "eyedropper" toolbar button that allows you to examine the image and identify the exact colors of various pixels.

Screencasts

Clicking the second of the two toolbar icons mentioned above brings up a dialog for configuring a screencast:



Screen Recorder can record the device's display for a maximum of 3 minutes.
By default, it records at the device's native resolution or at 720p at a 4 Mbps bitrate.
You can customize these options below. Leave empty to use defaults.

Bit Rate (Mbps): 4

Resolution (width x height, in px):

Figure 815: Android Studio Screen Recorder Options Dialog

The particular technique that Android Studio uses to record the screencast is capped at three minutes, which is one of the reasons why there are other alternatives that this chapter will explore.

The bit rate will determine the size of the resulting MP4 file, where a higher bit rate will give you a larger file. However, too low of a bit rate will degrade the quality of the recording, particularly if there is a lot of motion. You will need to experiment for yourself to see what bit rate value works best for you; 4Mbps is the default.

Similarly, normally, the screencast will be at the resolution of the device screen. However, there will be some low-end devices that are incapable of recording a video at that resolution, due to weak video recording support. For those devices, the screencast will be downgraded to 720p. Or, you can attempt to specify the resolution, though you get odd results from the IDE if you try to specify a resolution that is not supported.

Clicking the "Start Recording" button will then start the screencast recording. The dialog that appears has a corresponding "Stop Recording" button. After clicking that, you will be given a "Save As" dialog to save the video wherever you like.

Collecting from the Command Line

The same capabilities that Android Studio taps into to collect screenshots and screencasts graphically are also available to you from the command line, via `adb`. Since `adb` is in the `platform-tools/` directory of your Android SDK installation, if that directory is in your PATH, you can run adb from any likely directory on your development machine.

Screenshots

adb shell screencap captures a screenshot. This sounds easy enough.

The difficulty is that the screenshot is stored directly on the device or emulator, not on your development machine. This means that taking a screenshot is really a two-step process:

1. Capturing the screen to a PNG on the device
2. Moving that PNG from the device to your development machine

adb shell screencap takes the path for where the PNG should be saved on the device. Since we want to move that PNG to the development machine, it will be simplest if that path is pointing to external storage. What path you use will be tied to what version of Android you are running the screencap command on:

- Android 4.x/5.x: Use /mnt/shell/emulated/0 as the base, which points to the root of external storage
- Android 6.0+: Use /storage/emulated/0 as the base, which points to the root of external storage

You can then use adb pull to copy that PNG to your development machine, followed by adb shell rm to delete the copy that is on the device (to save space, remove clutter, etc.).

For example, the following script would take a screenshot on an Android 6.0 device or emulator and move it to your development machine into whatever the current working directory is:

```
adb shell screencap /storage/emulated/0/screenshot.png
adb pull /storage/emulated/0/screenshot.png .
adb shell rm /storage/emulated/0/screenshot.png
```

Note that the other effects handled by Android Studio, such as rotating the image, are not offered by the command-line interface. Instead, you would use your available image editing tools on your development machine to handle that.

Screencasts

Similarly, `adb shell screenrecord` will record a screencast, saving it as a MP4 file on your device or emulator. And, once again, you will need to use something like `adb pull` to copy that MP4 to your development machine, perhaps followed by `adb shell rm` to remove the copy from the device.

`adb shell screenrecord` is a bit more configurable, though. In addition to the device path to the MP4 file, you can use command-line switches to change the nature of the recording:

- `--size` sets your desired resolution, overriding the default of 1280x720 if your resolution is supported. For example, use `--size 1920x1080` for a 1080p recording.
- `--bit-rate` sets the bit rate, as discussed in the earlier section about screencasts in Android Studio. This is expressed in *bits per second*, so `--bit-rate 8000000` would save at ~8Mbps.
- `--time-limit` will automatically stop the recording after the stipulated number of seconds, capped at a maximum value of three minutes (the equivalent of `--time-limit 180`). Alternatively, while the screencast is recording, press [kbd>Ctrl-`C</kbd] to stop the recording.`

For example, the following script would record a 30-second 1080p screencast on an Android 6.0 device or emulator and move it to your development machine into whatever the current working directory is:

```
adb shell screenrecord --size 1920x1080 --time-limit 30 /storage/emulated/0/
screencast.mp4
adb pull /storage/emulated/0/screencast.mp4 .
adb shell rm /storage/emulated/0/screencast.mp4
```

Collecting from Another App

The three-minute limitation on screencasts, imposed by Android Studio and `adb shell screenrecord`, can be troublesome in some situations.

On Android 5.0 and higher devices, the media projection APIs allow authorized apps to take screenshots and record screencasts. These screencasts do not have an arbitrary time limitation. However, do bear in mind that the videos are stored on the device itself, so disk space can become an issue.

Various apps on the Play Store and elsewhere are available for “out of the box” screencast recording. On the open source front, Jake Wharton wrote and released Telecine, both in a GitHub repository and as an app on the Play Store.

Another chapter in this book shows how you can use the media projection APIs, and one of the sample apps (`andcorder`) can be used akin to how you would use Telecine or `adb shell screenrecorder`.

Tips and Tricks

Note that none of these approaches will record audio along with the video for the screencasts. You will need to use video editing software to add an audio track to the video, whether that comes in the form of a spoken-word voiceover, a soundtrack, or whatever.

While all of the techniques described here will work with devices and emulators, emulators need “Use Host GPU” enabled, at least for API Level 15+ emulators on Linux. Otherwise, your screenshots and screencasts turn out blank.

For screencasts designed to show users how to use an app, you may wish to enable “Show touches” in the Developer Options area of Settings. This will display a white dot where your finger touches the screen, to help illlustrate where you are tapping, sliding, etc. Otherwise, the user may or may not be able to follow exactly what you are doing to cause the app to behave as shown.

ADB Tips and Tricks

Several chapters in this book offer `adb` recipes for doing certain things at the command line. Having the `adb` binary in the `PATH` environment variable for your development machine is very handy, so you can run such commands from anywhere.

However, those other chapters only skim the surface of what sorts of `adb` commands there are and what they can be used for. Several others are presented here.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, and that you know how to work on the command line.

Installing and Uninstalling Apps

If you have an APK file that you wish to install — such as the APK edition of this book — you can do that at the command line via `adb install /path/to/the.apk`, where `/path/to/the.apk` is where the APK can be found on your development machine.

If the app already exists on the device or emulator, and you wish to replace it with this new APK, you will have to include the `-r` switch: `adb install -r /path/to/the.apk`. This indicates that you wish to reinstall the app.

Conversely, `adb uninstall your.application.id` will uninstall the app identified by the application ID (`your.application.id`).

Starting and Stopping Components

Given an installed app, you can trigger its activities, services, and broadcast receivers from the command line, using `adb shell` to run commands on the device or emulator.

The actual commands are simple:

- `adb shell am start ...` to start an activity
- `adb shell am startservice ...` to start a service
- `adb shell am broadcast ...` to send a broadcast

The challenge is in the `...` part, where you provide command-line switches to construct an `Intent` that will be used for those operations. Here are some common patterns:

- Simple explicit `Intent` with just an action string, use `-a` (e.g., `adb shell am start -a android.intent.action.VOICE_COMMAND`)
- Explicit `Intent` with a `Uri`, use `-a` and `-d` (e.g., `adb shell am start -a android.intent.action.VIEW -d https://commonsware.com`)
- Explicit `Intent` with a different category, use `-a` and `-c` (e.g., `adb shell am start -a android.intent.action.MAIN -c android.intent.category.HOME`)
- Implicit `Intent`: use `-n` (e.g., `adb shell am start -n your.app.id/.YourActivity`)

There are all sorts of command-line switches, for everything from flags to extras, that you can use to build up the `Intent`.

The chapter on the media projection APIs covers a sample screencast recorder, one that can be controlled using these sorts of commands. For example, to start the recording, the `record` shell script from the sample project uses:

```
adb shell am startservice -n
com.commonsware.android.andcorder/.RecorderService -a
com.commonsware.android.andcorder.RECORD
```

This starts the `RecorderService`, using an explicit `Intent` (`-n`) but also providing an action string (`-a`) to state what sort of command we are sending to the service.

Killing Processes and Clearing Data

`adb shell am kill ...` will kill all processes associated with the application ID (`...`).

`adb shell am force-stop ...` will force-stop the app associated with the application ID (`...`), as if the user went into Settings and clicked the "Force Stop" button for the identified app.

`adb shell pm clear ...` will clear the data associated with the application ID (`...`), as if the user went into Settings and clicked the "Clear Data" button for the identified app. This will erase that app's portion of internal storage, plus app-specific directories on external storage (e.g., `getExternalFilesDir()`).

Changing Display Metrics

One reason why developers use emulators is because they lack hardware for device scenarios that they wish to test. Two such scenarios are screen size and density. Many developers have only a device or two to test against, and they may need to try out screen sizes and densities that their hardware does not offer directly.

However, if you have a device with a *higher* resolution or density, you can use `adb` to have the device fake operating as a lower-resolution or lower-density device.

Specifically, on Android 4.3 and higher, `adb shell wm size 1280x800` would tell an Android device to pretend to have a WXGA800 display. You will see the smaller area centered within the overall device screen.

Note, though, that the device may no longer honor orientation changes by rotating the device. You will need to stipulate your size based upon the orientation that you are holding the device and the default orientation of the device itself.

For example, running the above command on a Nexus 9 gives you the following, regardless of whether the Nexus 9 is in portrait or landscape:

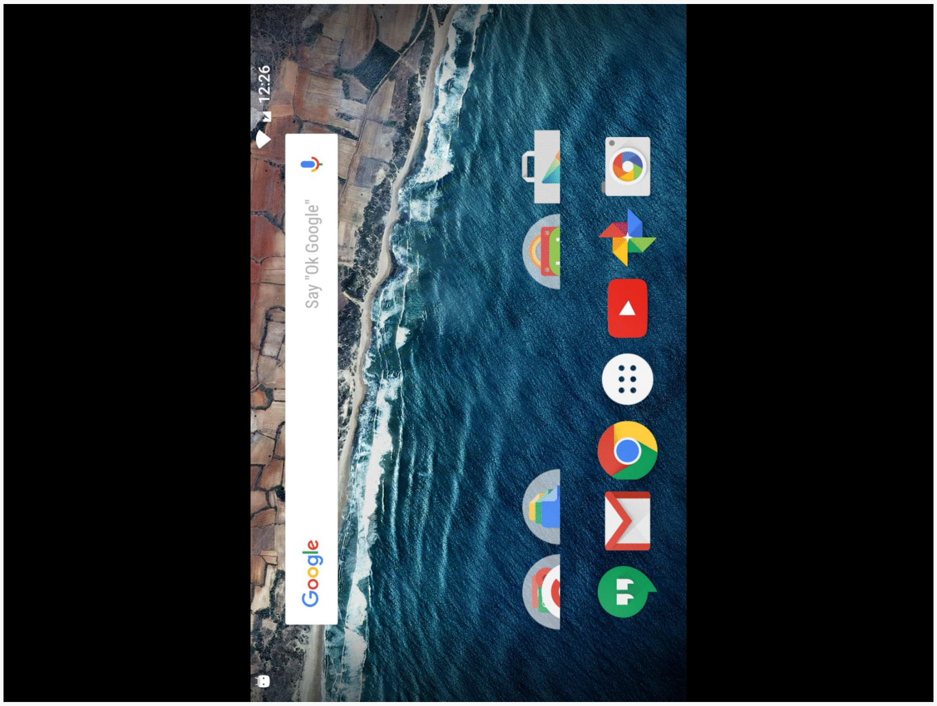


Figure 816: 1280x800 Display Size, On a Nexus 9, Held in Landscape

If you were planning on testing the Nexus 9 in portrait mode and wanted a landscape WXGA800 display, this is fine. More likely, you will need to change the order of your dimensions in the command. So, running `adb shell wm size 800x1280` gives you:

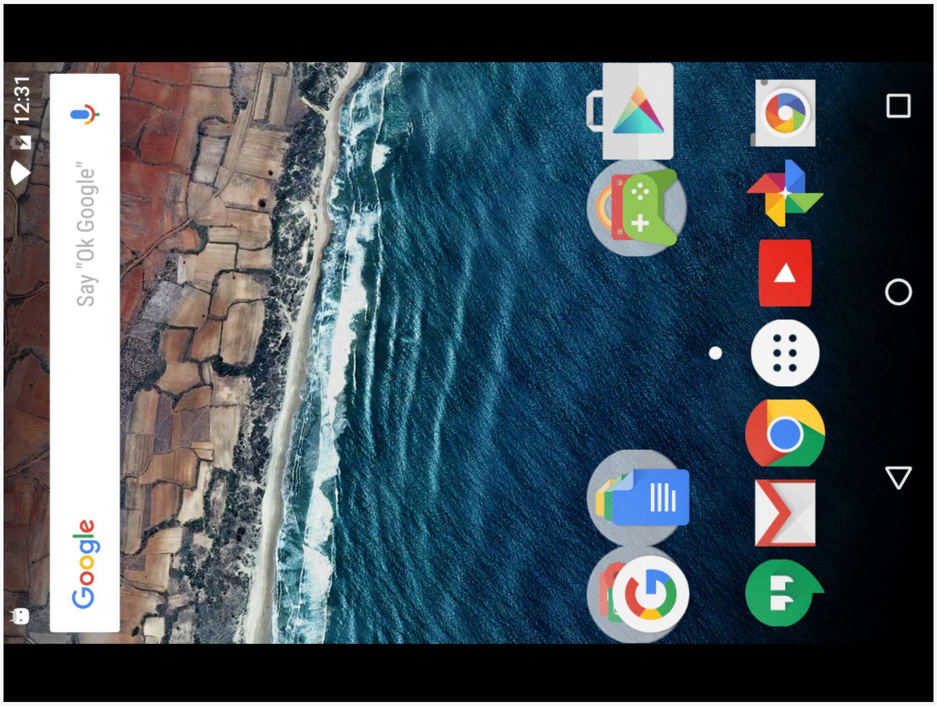

Figure 817: 800x1280 Display Size, On a Nexus 9, Held in Landscape

Here, at least, the device orientation matches the reduced-size screen orientation, if you were to hold the device in portrait mode.

If you prefer, you can use `dp` units instead, by appending `dp` after the values. Using `reset` instead of a resolution will return the device to its native resolution.

Trail: Tuning Android Applications

Issues with Speed

Mobile devices are never fast enough. Either they are slow in general (e.g., slow CPU) or they are slow for particular operations (e.g., advanced game graphics).

What you do not want is for your application to be unnecessarily slow, where the user determines what is and is not "necessary". Your opinion of what is "necessary", alas, is of secondary importance.

This part of the book will focus on speed, including how you can measure and reduce lag in your applications. First, though, let's take a look at some of the specific issues surrounding speed.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Getting Things Done

In some cases, you simply cannot seem to get the work done that you want to accomplish. Your database query seems slow. Your encryption algorithm seems slow. Your image processing logic seems slow. And so on.

The limits of the device will certainly make this more of a problem than it might otherwise be. Even a current-era multi-core device will be slow compared to your average notebook or desktop, as mobile CPUs cannot readily be directly compared to desktop and notebook CPUs. Also, this sort of speed issue is pervasive throughout computing, with decades of experience to help developers learn how to write leaner code.

This part of the book will aim to help you identify where the problem spots are, so you know what needs optimization, and then some Android-specific techniques for trying to improve matters.

Your UI Seems… Janky

Sometimes, the speed would be less of an issue for the user, if it was not freezing the UI or otherwise making it appear sluggish and "janky".

The Android widget framework operates in a single-threaded mode. All UI changes — from setting the text of a `TextView` to handling scrolling of a `GridView` — are processed as events on an event queue by the main application thread. That same thread is used for most UI callbacks, including activity lifecycle methods (e.g., `onCreate()`) and UI event methods (e.g., `onClick()` of a `Button`, `getView()` of an `Adapter`). Any time you take in those methods on the main application thread tie up that thread, preventing it from processing other GUI events or dispatching user input. For example, if your `getView()` processing in an `Adapter` takes too long, scrolling a `ListView` may appear slow compared to other `ListView` widgets in other applications.

Your objective is to identify where things are slow and move them into background operations. Some of this has been advised since the early days of Android, such as moving all network I/O to background threads. Lots of work has gone into providing libraries for you to be able to easily move common tasks, like loading images, onto background threads.

This part of the book will point out ways for you to find out where you may be doing unfortunate things on the main application thread and techniques for getting that work handled by a background thread, or possibly eliminated outright.

Not Far Enough in the Background

Sometimes, even work you are trying to do in the background will seem to impact the foreground.

For example, you might think that your `Service` is automatically in the background. An `IntentService` does indeed use a background thread for processing commands via `onHandleIntent()`. However, all lifecycle methods of any `Service`, including `onStartCommand()`, are called on the main application thread. Hence, any time you take in those lifecycle methods will steal time away from GUI processing for the main application thread. The same holds true for `onReceive()` of a `BroadcastReceiver` and all the main methods of a `ContentProvider` (e.g., `query()`).

Even your background threads may not be sufficiently in the background. A process runs with a certain priority, using Linux process management APIs, based upon its state (e.g., if there is an activity in the foreground, it runs at a higher priority than if the process solely hosts some service). This will help to cap the CPU utilization of the background work, but only to a point. Similarly, threads that you fork — directly or via something like `IntentService` — may run at default priority rather than a lower priority. Even with lower priorities for the thread or process, every CPU instruction executed in the background is one clock tick that cannot be utilized by the foreground.

This part of the book will help you identify where you are taking lots of time on various threads and will help you manually manage priorities to help minimize the foreground impact of those threads, in addition to helping you reduce the amount of work those threads have to do.

Playing with Speed

Games, more so than most other applications, are highly speed-dependent. Everyone is seeking the “holy grail” of 60 frames per second (FPS) necessary for smooth animated effects. Not achieving that frame rate overall may mean the application will not appear quite as smooth; sporadically falling below that frame rate will result in jerky animation effects, much like the “janky” UIs in a non-game Android application.

For example, a classic problem with Android game development is garbage collection (GC). The original Android garbage collector was a “stop the world” implementation, that would freeze the game long enough for a bit of GC work to be done before the game could continue. This behavior pretty much guaranteed sporadic failures to maintain a consistent frame rate. This caused game developers to have to take particular steps to avoid generating any garbage, such as maintaining its own object pools, to minimize or eliminate garbage collection pauses. While Android 2.3 and beyond have taken steps to have garbage collection be more concurrent, there are still short pauses (1-2ms, typically), where all threads have to be suspended to wrap up the GC run.

This book does not focus much on specific issues related to game development, though many of the techniques outlined here will be relevant for game developers.

Finding CPU Bottlenecks

CPU issues tend to manifest themselves in three ways:

- The user has a bad experience when using your app directly — scrolling is sluggish, activities take too long to display, etc.
- The user has a bad experience when your app is running in the background, such as having slower frame rates on their favorite game because you are doing something complex in a service
- The user has poor battery performance, driven by your excessive CPU utilization

Regardless of how the issue appears to the user, in the end, it is a matter of you using too much CPU time. That could be simply because your application is written to be constantly active (e.g., you have an everlasting service that uses `TimerTask` to wake up every second and do something). There is little anyone can do to help that short of totally rethinking the app's architecture (e.g., switch to `AlarmManager` and allow the user to configure the polling period).

However, in many cases, the problem is that you are using algorithms – yours or ones built into Android — that simply take too long when used improperly. This chapter will help you identify these bottlenecks, so you know what portions of your code need to be optimized in general or apply the techniques described in later chapters of this part of the book.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the introductory chapter to this trail is also a good idea.

Android Studio Monitors

In Android Studio, tabs inside the Android Monitor tool allow you to examine the real-time behavior of your app with respect to various system resources, such as the CPU and GPU. These tabs appear alongside the “logcat” tab, in a tab strip towards the top of the Android Monitor tool frame.

CPU

The CPU tab will show you a real-time graph of the CPU usage of your app, where your app is the one shown in the drop-down list at the top of the Android Monitor:

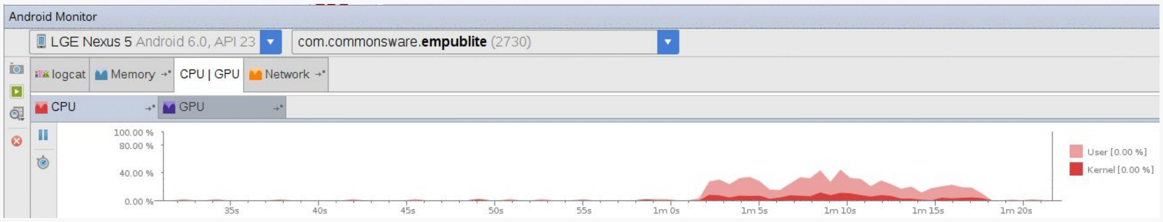

Figure 818: Android Studio, Android Monitor, CPU|GPU Tab, CPU Sub-Tab

The horizontal axis shows the time since the process started, and the vertical axis shows the percent of CPU utilization associated with your app. Within there, you are shown CPU utilization for “userland” operations (i.e., stuff in your app code) and “kernel” operations (e.g., time spent doing work related to I/O). Most Android apps should show much more time spent in the “User” light pink area.

Since this is a real-time graph, you can manipulate your app in the device or emulator and see the impacts of what you are doing on the CPU utilization. There is a slight lag between what you do to the device and when it shows up on the graph, though.

When you do something short in your UI, such as tap an action bar item, ideally you should see a short pulse of CPU utilization. When you do something continuously in your UI, such as scroll a `ListView` or `WebView`, you will see continuous CPU utilization.

The big thing that this graph can help you identify is when you do something in the UI that has longer-term CPU utilization. For example, tapping an action bar item that, in turn, uses an `AsyncTask` or `IntentService` to go download some data, parse it, and integrate it into your app's existing data, will take a chunk of CPU time. Your objectives are:

- The percentage of CPU utilization should be low while this is going on
- The window of time where you are using the CPU after user input ceases should be as short as you can manage

GPU

You may also be interested in the GPU sub-tab, which shows work related to rendering your app's UI:

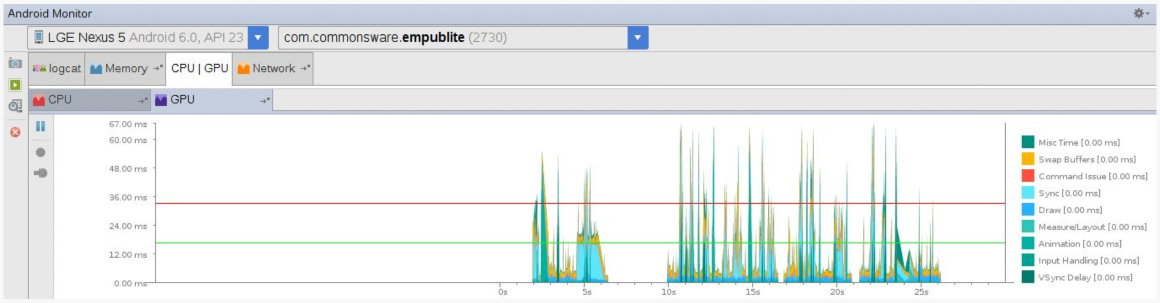

Figure 819: Android Studio, Android Monitor, CPU|GPU Tab, GPU Sub-Tab

While the sub-tab is labeled "GPU", really this is showing a mix of actual GPU processing and work done in your app in rendering the user interface.

Method Tracing

The #1 tool in your toolbox for finding out where bottlenecks are occurring in your application is method tracing. This will record your code and how long it takes your various methods to do their work. You can use this to look for outliers:

- Methods that are called way too frequently
- Methods that call other methods way too frequently
- Methods that take a lot of time in their own statements, including things like blocking on I/O

In the realm of Eclipse, the tool used to examine the results of method tracing is called Traceview, and so you will see that term pop up from time to time. Android Studio does not give it a particular name beyond "method tracing".

OK, What Is Method Tracing, Really?

Technically, the method tracing in Android is performed by the virtual machine, under the direction of either your IDE or requests from your application code. Dalvik or ART will write the "trace data" (call graphs showing methods, what they call, and the amount of time in each) to a file on external storage of the device or emulator. Your IDE then views these trace files in a GUI, allowing you to visualize "hot spots", drill down to find where the time is being taken, and so forth.

At the time of this writing, method tracing is designed for use on single-core devices. Results on multi-core devices may be difficult to interpret.

Collecting Trace Data

Hence, the first step for finding where your CPU bottlenecks lie comes in the form of collecting trace data for analysis. As mentioned, there are two approaches for requesting trace data be logged: using the `Debug` class, and using your IDE.

Debug Class

If you know what chunk of code you want to profile, one way to arrange for the profile is to call `startMethodTracing()` on the `Debug` class. This takes the name of a trace file as a parameter and will begin recording all activity to that file, stored in the root of your external storage. You need to call `stopMethodTracing()` at some point to stop the trace — failing to do so will leave you with a corrupt trace file in the end.

Note that your application will need the `WRITE_EXTERNAL_STORAGE` permission for this to work. If your application does not normally need this permission, make yourself a note to remove it before you ship the production edition of your product, as there is no sense asking for any more permissions than you absolutely need. Or, put this permission in a `debug` sourceset's manifest in Android Studio, and then it will only be included in debug builds.

Also, your device or emulator will need enough external storage to hold the file, which can get very large for long traces — 100MB a minute is well within reason.

Android Studio

After you run your app on your device or emulator, and after you get the app set up to the starting point where you want to collect tracing data, open up the Android tool and switch over to the CPU sub-tab, as shown earlier in the chapter:

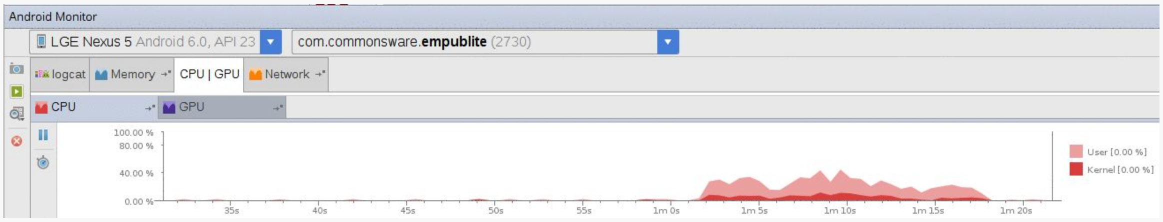

Figure 820: Android Studio, Android Tool, CPU|GPU Tab, CPU Sub-Tab

In there, tap the toolbar button that looks like a stopwatch, shown in the above screenshot in the right-most of the two vertical toolbars. The toolbar button will take on an "inset" sort of dark background, indicating that trace data is being collected. Do what you wanted to do in the GUI of your app, then tap the same toolbar button to stop the method tracing. The results will show up in a tab in the main editing area of your IDE, and we will explore those results later in this chapter.

Performance While Tracing

Writing out each method invocation to a trace file adds significant overhead to your application. Run times can easily double or more. Hence, absolute times while tracing is enabled are largely meaningless — instead, as you analyze the data generated by method tracing, the goal is to examine relative times (i.e., such-and-so method takes up X% of the CPU time shown in the trace).

Also, running method tracing disables the JIT engine in Dalvik, further harming performance. Notably, this will not affect any native code you have added via the NDK, so an application run while method tracing will give you unusual results (much worse Java performance, more normal native performance). It is unclear what method tracing does with respect to ART in this area.

Displaying Trace Data

Given that we have collected a trace file with data, the next step is to examine the results. These will pop up automatically for you in Android Studio, once the IDE is done parsing the trace data.

In addition to the results tab automatically showing up when the trace is completed, the results will also be added to the Captures tool, normally docked on the left:

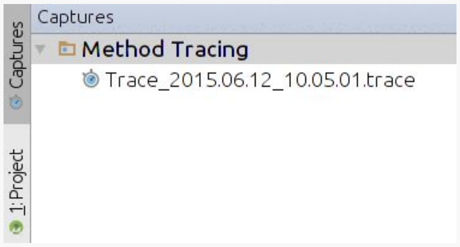

Figure 821: Android Studio, Captures Tool, Showing Method Tracing Result

You can use this to re-open the results tab whenever you wish, to look at the method tracing results in the future.

To remove previous trace results, just highlight the result to delete and choose Delete from the right-mouse context menu, or press the Delete key.

Interpreting Trace Data

Of course, the challenge is in making sense of what the IDE is trying to present.

For example, a classic performance bug in Java development is using string concatenation:

```
package com.commonsware.android.traceview;

import android.view.View;
import android.widget.TextView;

public class StringConcatActivity extends BaseActivity {
    StringConcatTask createTask(TextView msg, View v) {
      return(new StringConcatTask(msg, v));
    }

    class StringConcatTask extends BaseTask {
      StringConcatTask(TextView msg, View v) {
        super(msg, v);
```

```
   }

   protected String doTest() {
    String result="This is a string";

    result+=" -- that varies --";
    result+=" and also has ";
    result+=String.valueOf(4);
    result+=" hyphens in it";

    return(result);
   }
  }
}
```

Inclusive Time and Exclusive Time

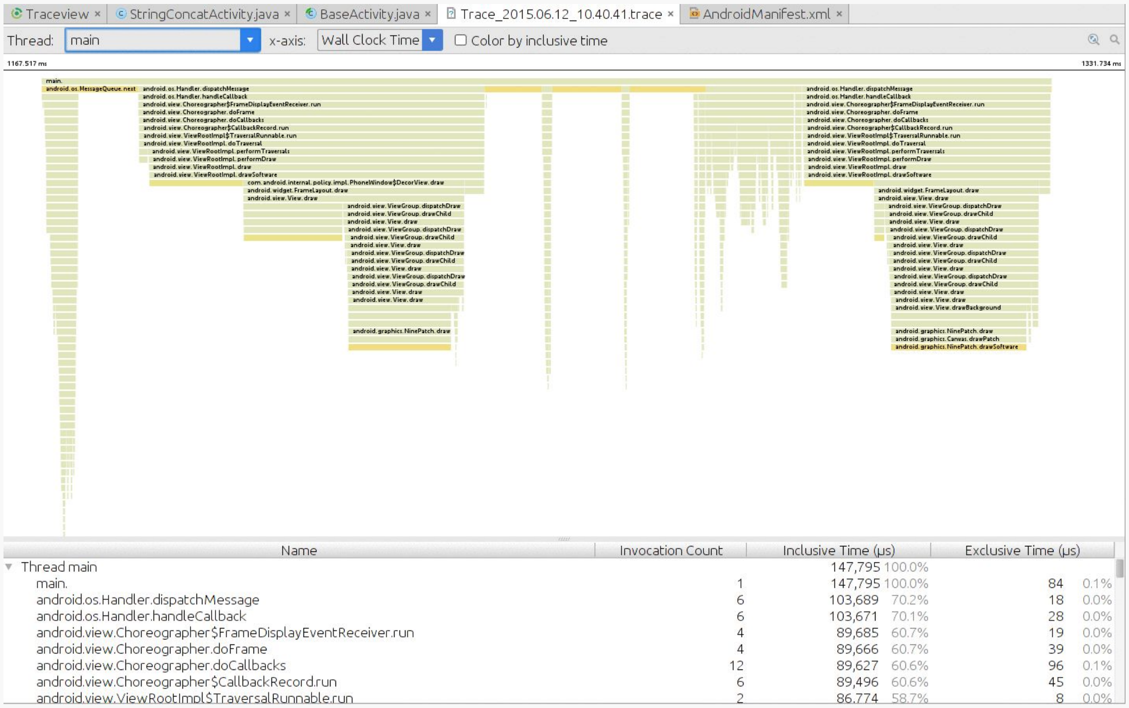
All method tracing results speak in terms of “inclusive time” and “exclusive time” for a method call. Exclusive time refers to the time spent solely in primitive operations within the method itself. This will include things like basic arithmetic, `if` and `switch` branches, and so forth. Inclusive time refers to the time spent in this method, including all other methods invoked from this method.

So, for example, suppose we have a method `foo()` that has a loop that, inside the loop, calls another method `bar()` on each pass. `bar()` on its own is not that expensive, but calling it lots of times in a loop will add up. Further suppose that `bar()` does not call any other methods.

What you would expect to see in method tracing results is:

- The exclusive time and the inclusive time of `bar()` to be about the same, as `bar()` is not calling anything else
- The inclusive time of `foo()` and the inclusive time of `bar()` to be about the same, if most of what `foo()` does is just call `bar()` lots of times in a loop
- The exclusive time of `foo()` to be very small, as it is not doing much other than calling `bar()`

The entire method tracing results tab will be difficult to render in this book due to its size and complexity:



Name	Invocation Count	Inclusive Time (µs)		Exclusive Time (µs)	
▼ Thread main		147,795	100.0%		
main.	1	147,795	100.0%	84	0.1%
android.os.Handler.dispatchMessage	6	103,689	70.2%	18	0.0%
android.os.Handler.handleCallback	6	103,671	70.1%	28	0.0%
android.view.Choreographer$FrameDisplayEventReceiver.run	4	89,685	60.7%	19	0.0%
android.view.Choreographer.doFrame	4	89,666	60.7%	39	0.0%
android.view.Choreographer.doCallbacks	12	89,627	60.6%	96	0.1%
android.view.Choreographer$CallbackRecord.run	6	89,496	60.6%	45	0.0%
android.view.ViewRootImpl$TraversalRunnable.run	2	86,774	58.7%	8	0.0%

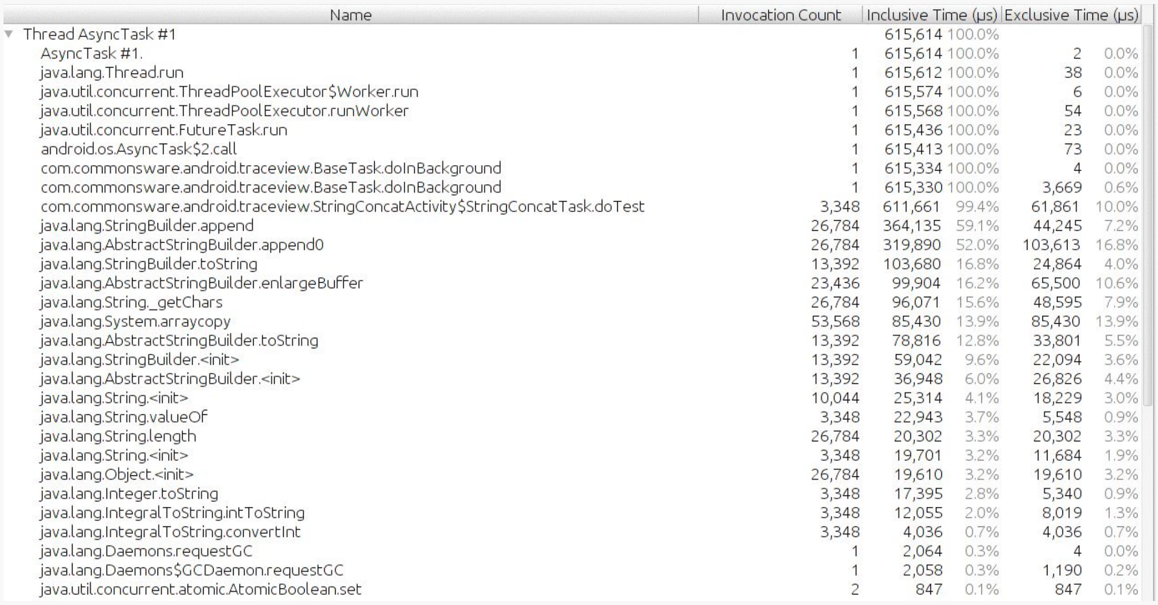
Figure 822: Android Studio, Trace Results Tab

The main portion of the output is a timeline of the processing on a thread. By default, it is the main application thread, and you can control what thread shows up via the Thread drop-down list in the tab's own toolbar.

Each "row" in that main output area represents a call, or a nested call from the higher-order call, within the calls made on that thread. The width of each "cell" indicates the time spent within that specific call. By default, the X axis represents "Wall Clock Time", or the time from when the tracing began until the tracing ended. Via the "x-axis" drop-down list in the tab's toolbar, you can switch this to be "Thread Time".

The bottom portion of the output shows the same call information for the selected thread, but in a tabular form instead of a timeline. Each method is denoted by how many times that method was called, how much inclusive time was spent in that call, and how much exclusive time was spent in that call. By default, the table is ordered by inclusive time, descending.

In the sample app, the string concatenation work is being done 100,000 times in an `AsyncTask` kicked off by a `StringConcatActivity` activity. To see its results in the trace results tab, we have to switch the Thread drop-down to “AsyncTask #1”, which gives us the following output table:



Name	Invocation Count	Inclusive Time (µs)		Exclusive Time (µs)	
▼ Thread AsyncTask #1		615,614	100.0%		
AsyncTask #1.	1	615,614	100.0%	2	0.0%
java.lang.Thread.run	1	615,612	100.0%	38	0.0%
java.util.concurrent.ThreadPoolExecutor$Worker.run	1	615,574	100.0%	6	0.0%
java.util.concurrent.ThreadPoolExecutor.runWorker	1	615,568	100.0%	54	0.0%
java.util.concurrent.FutureTask.run	1	615,436	100.0%	23	0.0%
android.os.AsyncTask$2.call	1	615,413	100.0%	73	0.0%
com.commonsware.android.traceview.BaseTask.doInBackground	1	615,334	100.0%	4	0.0%
com.commonsware.android.traceview.BaseTask.doInBackground	1	615,330	100.0%	3,669	0.6%
com.commonsware.android.traceview.StringConcatActivity$StringConcatTask.doTest	3,348	611,661	99.4%	61,861	10.0%
java.lang.StringBuilder.append	26,784	364,135	59.1%	44,245	7.2%
java.lang.AbstractStringBuilder.append0	26,784	319,890	52.0%	103,613	16.8%
java.lang.StringBuilder.toString	13,392	103,680	16.8%	24,864	4.0%

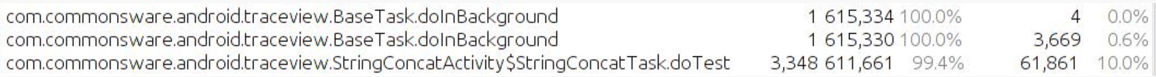
Figure 823: Android Studio, Trace Results Tab, Call Table

So, What Are We Learning Here?

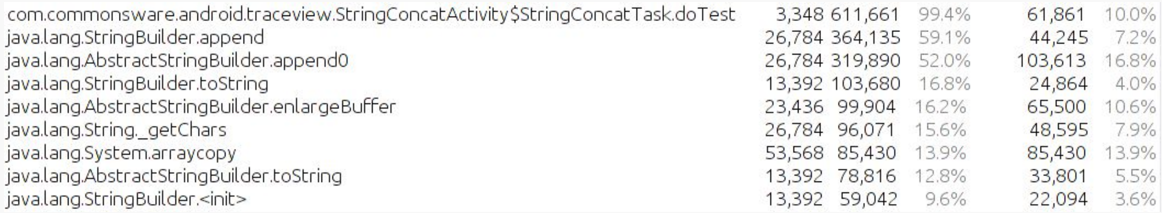
Typically, you want to find lines that reference your code. In this case, lines 7-9 are from the `com.commonsware` package. Let’s focus on those:



com.commonsware.android.traceview.BaseTask.doInBackground	1	615,334	100.0%	4	0.0%
com.commonsware.android.traceview.BaseTask.doInBackground	1	615,330	100.0%	3,669	0.6%
com.commonsware.android.traceview.StringConcatActivity$StringConcatTask.doTest	3,348	611,661	99.4%	61,861	10.0%

Figure 824: Trace Results, Showing Sample App Methods

Not surprisingly, 99.4% of our inclusive time is taken up in `doTest()`, where our loop is. To find out more of where we are spending our time, just look at the next few lines:



com.commonsware.android.traceview.StringConcatActivity$StringConcatTask.doTest	3,348	611,661	99.4%	61,861	10.0%
java.lang.StringBuilder.append	26,784	364,135	59.1%	44,245	7.2%
java.lang.AbstractStringBuilder.append0	26,784	319,890	52.0%	103,613	16.8%
java.lang.StringBuilder.toString	13,392	103,680	16.8%	24,864	4.0%
java.lang.AbstractStringBuilder.enlargeBuffer	23,436	99,904	16.2%	65,500	10.6%
java.lang.String._getChars	26,784	96,071	15.6%	48,595	7.9%
java.lang.System.arraycopy	53,568	85,430	13.9%	85,430	13.9%
java.lang.AbstractStringBuilder.toString	13,392	78,816	12.8%	33,801	5.5%
java.lang.StringBuilder.<init>	13,392	59,042	9.6%	22,094	3.6%

Figure 825: Trace Results, Showing Other Expensive Calls

We see chunks of time being devoted to `StringBuilder`. This is odd, as we are not using `StringBuilder` explicitly in our app.

It turns out that the `javac` compiler replaces string concatenation with `append()` calls on a `StringBuilder`, created on the fly for that specific concatenation. So, of the time taken up in the entire run by the `doTest()` method, much of it is taken up by creating these temporary `StringBuilder` objects, another chunk is consumed by calling `append()` on the `StringBuilder`, and yet another chunk is used by calling `toString()` to get the resulting `String` out of the `StringBuilder`.

This suggests an optimization: we could create our own `StringBuilder` and use it for concatenating the text, thereby saving us creating a few temporary ones and calling `toString()` extra times:

```java
package com.commonsware.android.traceview;

import android.view.View;
import android.widget.TextView;

public class StringBuilderActivity extends BaseActivity {
  StringBuilderTask createTask(TextView msg, View v) {
    return(new StringBuilderTask(msg, v));
  }

  class StringBuilderTask extends BaseTask {
    StringBuilderTask(TextView msg, View v) {
      super(msg, v);
    }

    protected String doTest() {
      StringBuilder result=new StringBuilder("This is a string");

      result.append(" -- that varies --");
      result.append(" and also has ");
      result.append(String.valueOf(4));
      result.append(" hyphens in it");

      return(result.toString());
    }
  }
}
```

This implementation of the algorithm runs about twice as fast as the first.

Other General CPU Measurement Techniques

While method tracing can be useful for narrowing down a general performance issue to a specific portion of code, it does assume that you know approximately where the problem is, or that you even have a problem in the first place. There are other approaches to help you identify if and (roughly) where you have problems, which you can then attack with method tracing to try to refine.

Logging

Method tracing can be useful, if you have a rough idea of where your performance problem lies and need to narrow it down further. If you have a large and complicated application, though, trying to sift through all of it in method tracing may be difficult.

However, there is nothing stopping you from using good old-fashioned logging to get a rough idea of where your problems lie, for further analysis via method tracing. Just sprinkle your code with `Log.d()` calls, logging `SystemClock.uptimeMillis()` with an appropriate label to identify where you were at that moment in time. "Eyeballing" the LogCat output can illustrate areas where unexpected delays are occurring — the areas in which you can focus more time using method tracing.

A useful utility class for this is `TimingLogger`, in the `android.util` package. It will collect a series of "splits" and can dump them to LogCat along with the overall time between the creation of the `TimingLogger` object and the corresponding `dumpToLog()` method call. Note, though, that this will only log to LogCat when you call `dumpToLog()` — all of the calls to `split()` to record intermediate times have their results buffered until `dumpToLog()` is called. Also note that logging needs to be set to VERBOSE for this information to actually be logged — use the command **`adb shell setprop log.tag.LOG_TAG VERBOSE`**, substituting your log tag (supplied to the `TimingLogger` constructor) for `LOG_TAG`.

FPS Calculations

Sometimes, it may not even be strictly obvious how bad the problem is. For example, consider scrolling a `ListView`. Some performance issues, like sporadic "hiccups" in the scrolling, will be visually apparent. However, absent those, it may be difficult to determine whether your particular ListView is behaving more slowly than you would expect.

A classic measurement for games is frames per second (FPS). Game developers aim for a high FPS value — 60 FPS is considered to be fairly smooth, for example. However, this sort of calculation can only really be done for applications that are continuously drawing – such as Romain Guy's WindowBackground sample application. Ordinary Android widget-based UIs are only drawing based upon user interaction or, possibly, upon background updates to data. In other words, if the UI will not even be trying to draw 60 times in a second, trying to measure FPS to get 60 FPS is pointless.

You may be able to achieve similar results, though, simply by logging how long it takes to, say, fling a list (use setOnScrollListener() and watch for SCROLL_STATE_FLING and other events).

UI "Jank" Measurement

A user interface is considered "janky" if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Sometimes, janky behavior is obvious to all. Sometimes, janky behavior is only noticeable to those sensitive to small hiccups in the UI.

This section will outline what "jank" is and how to determine, concretely, if your UI suffers from it.

What, Exactly, is Jank?

Prior to Android 4.0, it was difficult to come up with a concrete definition of jank. In effect, we were stuck with "I know it when I see it" ad-hoc analysis, rather than being able to rely on concrete measurements.

Project Butter changed that.

Android 4.0 ties all graphic operations to a 60 frames-per-second "vsync" frequency. If everything is working smoothly, your UI will update 60 times per second, uniformly (versus varying amounts of times between changes).

The converse is also true: if everything is not working smoothly, your UI will not update 60 times per second. This is the source of the term "dropped frames": when the time came around for an update, you were not ready, and that frame was skipped.

There are two main ways in which you will drop a frame:

1. You spend too much time on the main application thread, preventing Android from processing your requested UI updates in a timely fashion
2. Your UI changes are too complex to be rendered before time runs out for the current frame, causing your changes to spill over into the next frame

Each frame is ~16ms in duration on-screen (1/60th of a second). Hence, if we cause per-frame work to exceed 16ms, we will skip, or "drop", a frame.

So, what we need is some way to determine if our code is actually delivering frames on time.

Using gfxinfo

To determine if our problem is in the actual rendering of our UI updates, we can use the GPU profiling feature added in Android 4.2.

Enabling Developer Options

To toggle on GPU profiling, you will need to be able to get to the Developer Options portion of your Settings app. If you see this — typically towards the bottom of the list on the initial Settings screen — just tap on the entry.

If, however, Developer Options is missing, then you will need to use the super-secret trick for enabling Developer Options:

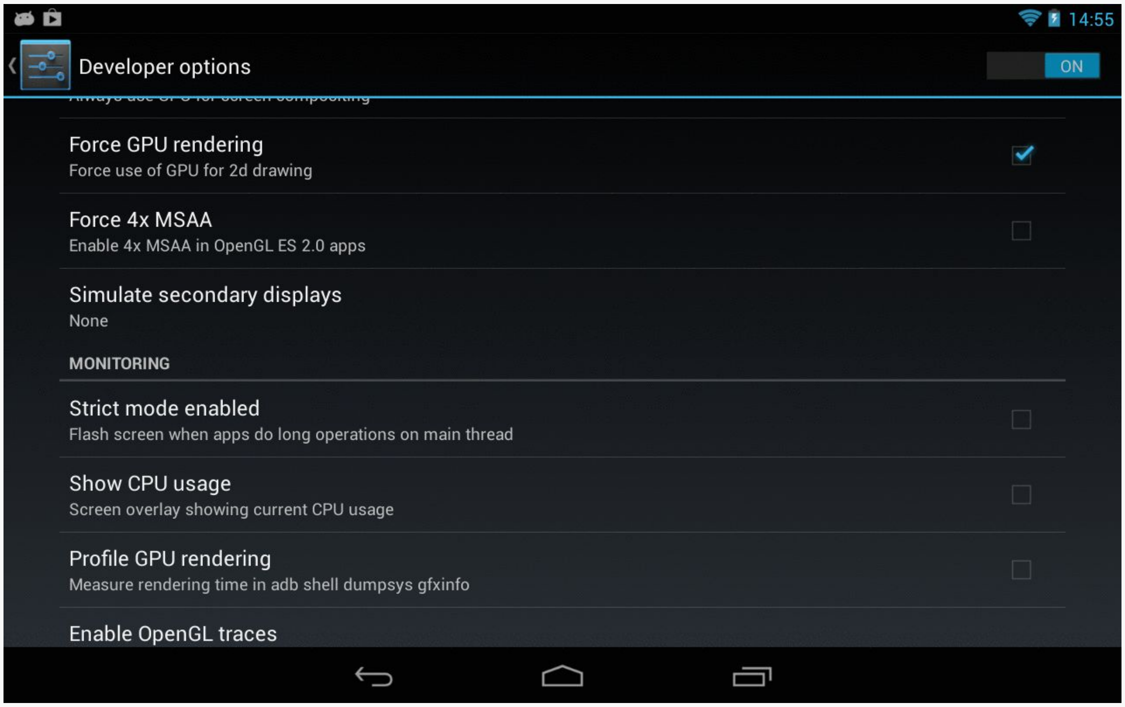
1. Tap on "About Phone", "About Tablet", or the equivalent at the bottom of your Settings list
2. Tap on the "Build Number" entry seven times in succession
3. Press BACK, and "Developer Options" should now be in the list

Toggling on GPU Profiling

There are two checkboxes in Developer Options that need to be checked for GPU profiling to be enabled.

The first is "Force GPU rendering", in the Drawing section. As the name suggests, this will force your application to use the GPU for drawing, even if your application may have requested that hardware acceleration be disabled. Since most applications do not force hardware acceleration to be disabled, this checkbox probably will have no real effect on your app. Note that if you disabled hardware acceleration due to specific rendering problems, this checkbox will probably cause those rendering artifacts to re-appear during your testing.

The second is "Profile GPU rendering", in the Monitoring section. This will cause the device to keep track of graphics performance on a per-process basis, in a way that we can dump later on.



Developer options ON

Force GPU rendering ☑
Force use of GPU for 2d drawing

Force 4x MSAA □
Enable 4x MSAA in OpenGL ES 2.0 apps

Simulate secondary displays
None

MONITORING

Strict mode enabled □
Flash screen when apps do long operations on main thread

Show CPU usage □
Screen overlay showing current CPU usage

Profile GPU rendering □
Measure rendering time in adb shell dumpsys gfxinfo

Enable OpenGL traces

Figure 826: Developer Options, Showing "Force GPU rendering" and "Profile GPU rendering"

If your app was already running, you will need to get rid of its process (e.g., via swiping it off the recent-tasks list) after you check the "Profile GPU rendering" checkbox. At the present time, whether or not this profiling takes effect is determined at process startup time and is not changed on the fly when you toggle the checkbox. Besides, as noted above, starting with a fresh process should give you more accurate results.

Collecting Data

At this point, you can run your app and conduct your specific test, whether manually or via instrumentation (e.g., a targeted JUnit test suite).

When complete, run `adb shell dumpsys gfxinfo ...` in a terminal window, where `...` is replaced by the package name of your app (e.g., `com.commonsware.android.anim.threepane`). This will dump a fair amount of information to the terminal display:

```
mmurphy@xps15:~$ adb shell dumpsys gfxinfo com.commonsware.android.anim.threepane
Applications Graphics Acceleration Info:
Uptime: 482460 Realtime: 482454

** Graphics info for pid 3469 [com.commonsware.android.anim.threepane] **

Total DisplayList:  4.48 kB
```

We will discuss what this means in just a bit.

Disabling GPU Profiling

When you are done with your test, it is a good idea to undo the settings changes you made, at least “Profile GPU rendering”. That way, the act of collecting this data does not itself add overhead to unrelated tests in the future.

Analyzing the Results

The key bit for our performance analysis is that long table labeled “Profile data in ms:”. This reports, for a series of UI requests, how much time is spent:

- drawing your UI changes (e.g., `onDraw()` calls to various widgets and containers)
- processing the low-level drawing commands created via the draw phase, to create the contents of the frame
- executing the frame, sending it to the compositor to display on the screen

One way to interpret this table is to paste it into your favorite spreadsheet program, then use that program to draw a stacked column chart of the data. You can [download a spreadsheet]() in ODS format (for use with LibreOffice, OpenOffice, or other tools that can handle that format) that contains the above table along with a stacked column chart:

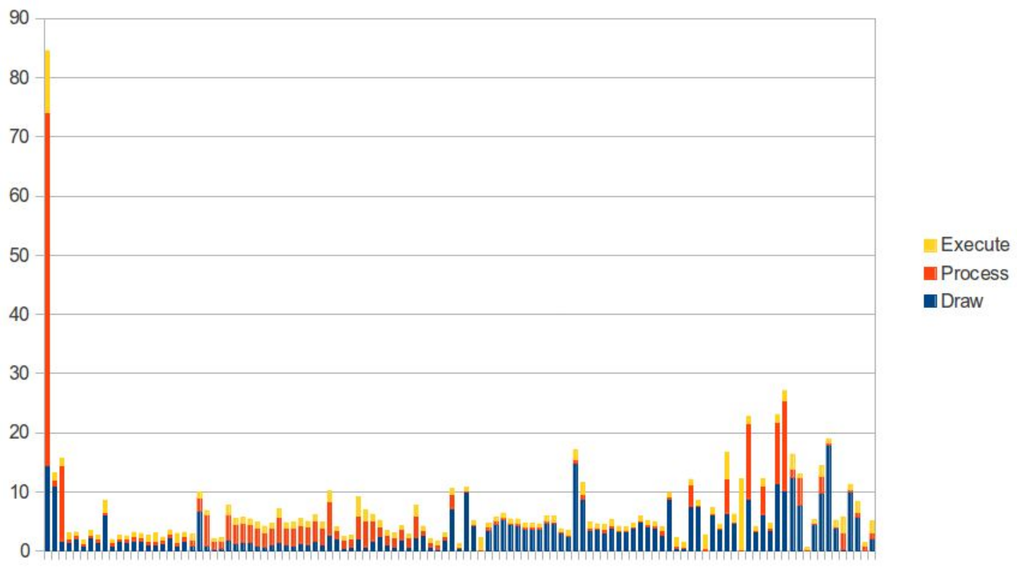

Figure 827: gfxinfo Output, In Stacked Column Chart

What you are looking for are columns that come close to, or exceed, the 16ms mark, with milliseconds on the Y axis. As you can see, many operations towards the end of the table are near or above 16ms, indicating that we are probably dropping some frames.

Using systrace

Another way we could determine whether or not we are dropping frames is to use `systrace` to collect system-level tracing information about the entire device, including our app.

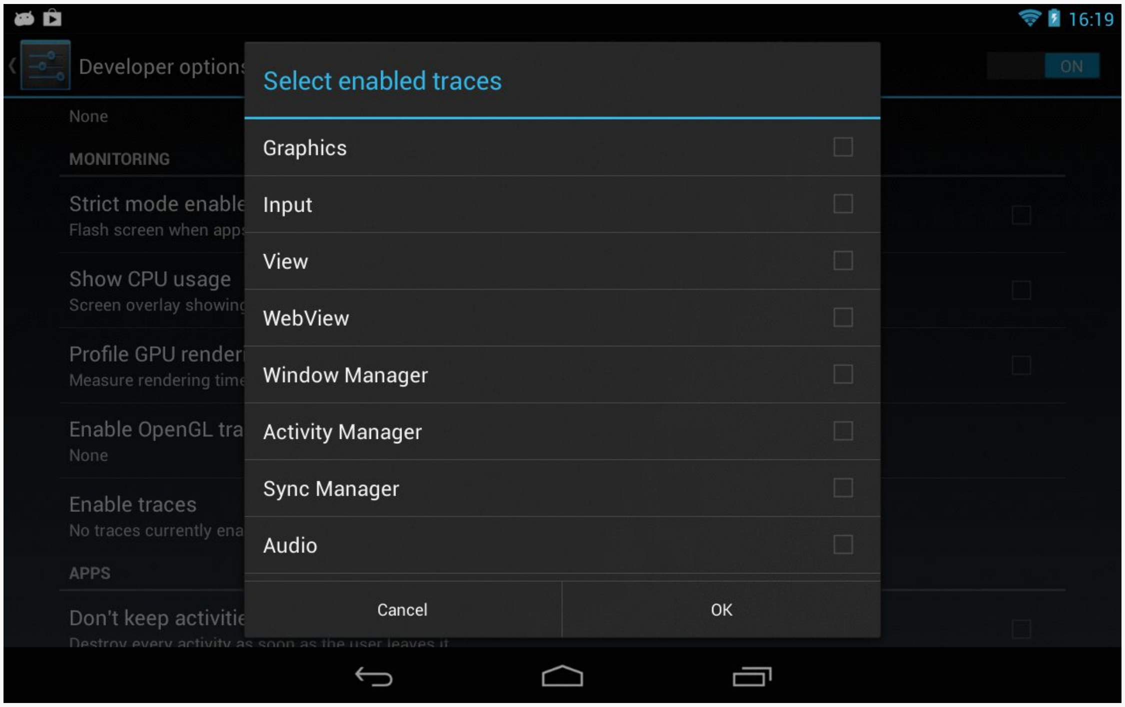
`systrace` is a very powerful tool, one that 20 or 30 people on the planet truly understand, due to cryptic output and limited documentation. Using `gfxinfo` for detecting dropped frames is simple by comparison. On the other hand, `systrace` works for Android 4.1 and higher, versus the Android 4.2 requirement of `gfxinfo`.

Using `systrace` involves collecting a trace, which is saved in the form of an HTML file. The HTML file is then used to determine what went on during the period of the trace itself.

Enabling and Collecting a Trace: Command-Line

The original means of using `systrace` was from the command line. There is a `systrace.py` Python script located in the `tools/systrace/` directory of your SDK installation. If you have a Python interpreter (e.g., your development machine does not run Windows), you can use this approach.

To indicate what specific bits of information to collect, on Android 4.2 and higher, you can tap the "Enable traces" entry in the Monitoring section of the Developer Options page in Settings. This displays a multi-select dialog of the possible major categories of information that `systrace` should collect:



Select enabled traces

- Graphics □
- Input □
- View □
- WebView □
- Window Manager □
- Activity Manager □
- Sync Manager □
- Audio □

Figure 828: "Enable traces" In Settings

Alternatively, when you run the `systrace.py` script, you can include the `--set-tags` switch, with a comma-delimited list of specific traces ("tags") that you want to collect. The list of available tag names can be found in [the developer documentation]().

To actually collect the trace, you run the `systrace.py` script, optionally with `--set-tags` or other command-line switches.

On Android 4.1 and 4.2, this would look like:

```
python systrace.py --set-tags gfx,view,wm
adb shell stop
adb shell start
python systrace.py --time=10 -o trace.html
```

The first `python` command runs `systrace.py` just to set the tags to collect. If you set them using Developer Options in Settings, this would not be required. Restarting `adb shell` is apparently needed, for unclear reasons. The second `systrace.py` run will actually collect the trace, for 10 seconds (`--time=10`), resulting in report written to `trace.html` in the current working directory (`-o trace.html`).

The syntax changed for Android 4.3 and higher to simplify matters, combining the two `systrace.py` commands into one:

```
python systrace.py --time=10 -o trace.html gfx view sched wm
```

Note that `--set-tags` is no longer used. Instead, all values not identified by a switch are considered to be tags.

Once you run the script, quickly go to your device and run your test scenario, as the trace starts immediately upon running the script.

Enabling and Collecting a Trace: Android Device Monitor

The Android Device Monitor also allows you to collect a trace using `systrace`. There is a "Capture system wide trace using systrace" button in the toolbar in the Devices view, typically found in the DDMS perspective:

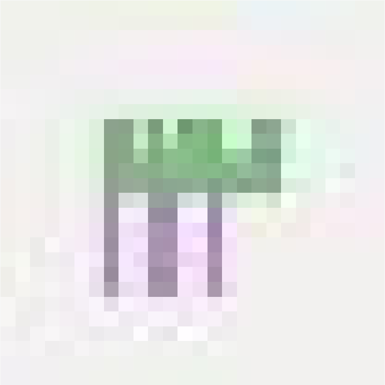


Figure 829: Systrace Toolbar Button in Devices View

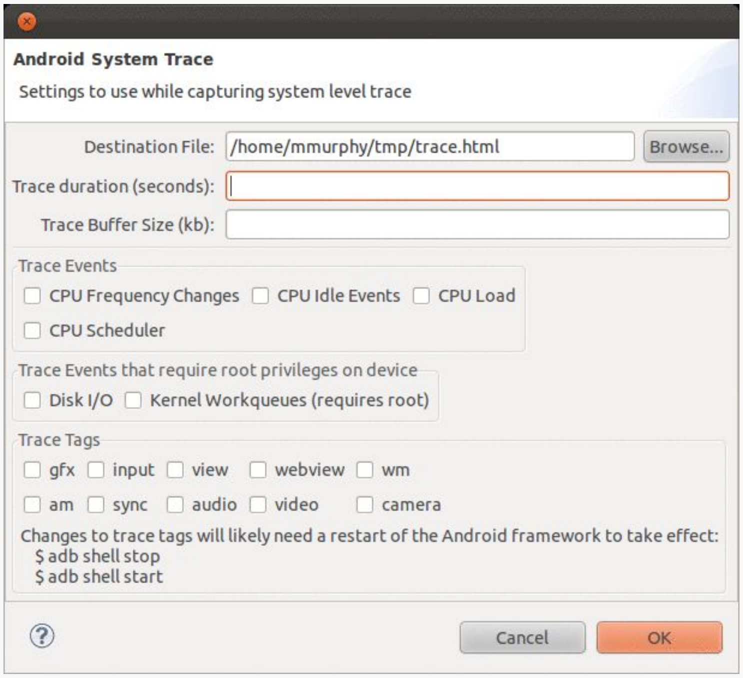
To get to the Android Device Monitor in Android Studio, choose Tools > Android > Android Device Monitor from the main menu.

Tapping that toolbar button brings up a dialog that allows you to configure the trace you wish to collect, with checkboxes and fields replacing the variety of command-line switches you might use manually with `systrace.py`:



Android System Trace
Settings to use while capturing system level trace
Browse...
Trace Events
□ CPU Frequency Changes □ CPU Idle Events □ CPU Load
□ CPU Scheduler
Trace Events that require root privileges on device
□ Disk I/O □ Kernel Workqueues (requires root)
Trace Tags
□ gfx □ input □ view □ webview □ wm
□ am □ sync □ audio □ video □ camera
Cancel
OK

Destination File: /home/mmurphy/tmp/trace.html

Trace duration (seconds):

Trace Buffer Size (kb):

Changes to trace tags will likely need a restart of the Android framework to take effect:

```
$ adb shell stop
$ adb shell start
```

Figure 830: Systrace Dialog in Android Device Monitor

Notable settings that you will wish to tailor include:

- Where the trace will be written (by default, as `trace.html` in your home or user directory)
- The duration of the trace
- Which trace tags you wish to use

Clicking OK will then initiate the trace collection, at which point you will want to go to your test device and run through your test scenario.

Choosing the Trace Tags

All of these instructions have been telling you to specify what `systrace` tags to collect when you collect the trace data. So, what should you collect?

The big four are:

- `sched` for CPU scheduling
- `gfx` for graphics
- `view` for widget rendering

- wm for window management

Apps using WebView might consider the webview tag. There are a variety of other tags as well that you might find useful for one analysis or another. However, be careful not to request "everything but the kitchen sink", as it may make your reports difficult to interpret.

Also note that not all devices support all tags. python systrace.py --list-categories should tell you what is possible for your connected device.

Augmenting the Trace from Java

You can effectively add your own tag to the output in Java code, to flag key sections of application processing and see where they fall in the report's timeline. To do this:

- Add calls to Trace.beginSection() and Trace.endSection() in your API Level 18+ app. Here, Trace is android.os.Trace, and beginSection() takes a String parameter that you would like to have logged. Note that these calls can nest, so you can have one section inside of another, but endSection() closes the last-begun section. Hence, make sure that your beginSection() and endSection() calls match up, typically by using try/finally exception handling. Also, your beginSection() and endSection() calls must match up in terms of threads — you cannot begin a section on one thread and end it on another.
- Add the --app switch to name your application's package if you are running systrace from the command line. Or, in DDMS, choose your application in the "Enable Application Traces from" drop-down list.

Viewing and Interpreting the Results

What you get as output is an HTML file that can be viewed in the Chrome browser, though you will tend to want to use a development machine for this instead of, say, an Android tablet. That is because the navigation of the Web page is designed for use with a hardware QWERTY keyboard, which most Android devices lack.

You can find a sample trace from a Nexus 7 online, though note that the HTML is a bit large and may take a few seconds to download. Initially, you will see something like this:

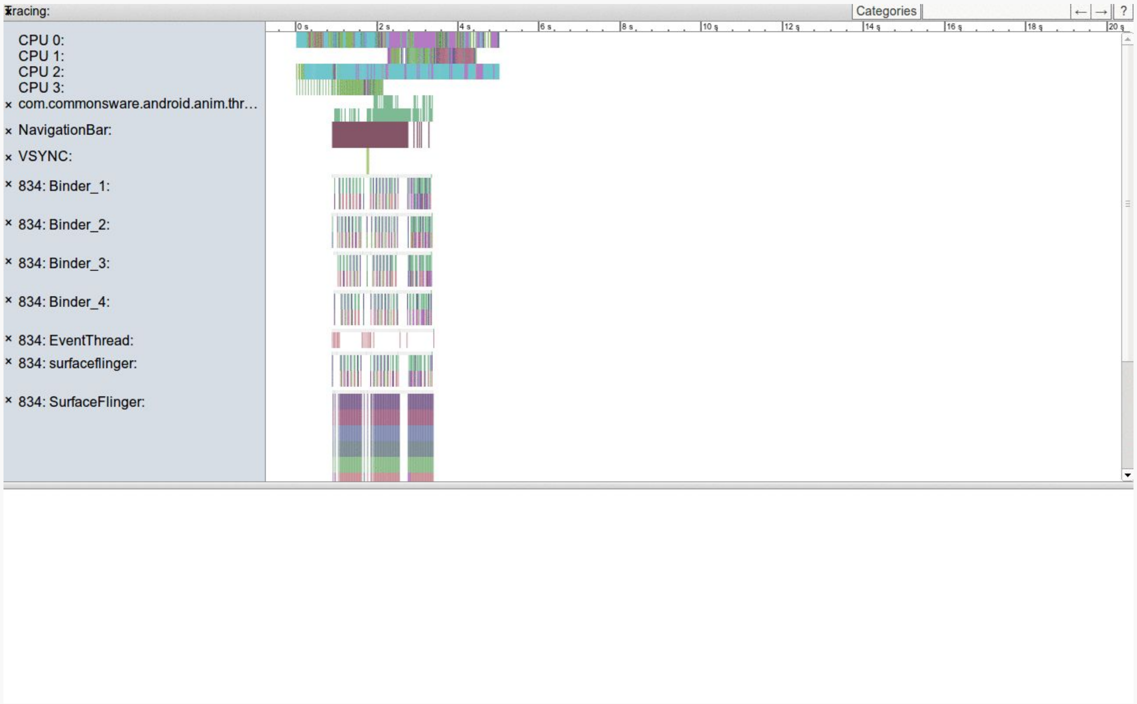


Figure 831: Systrace Output, As Initially Viewed

The left-hand sidebar represents various categories (or “slices” or “tags” or whatever) of data collected by `systrace`. The main area shows a timeline for the test, with rows corresponding to the sidebar entries for what was occurring at the various times for that particular category. The bottom pane will hold details that will appear when you click on various little blocks within that timeline.

Mostly, your navigation will use the W, A, S, and D keys, presumably chosen to make it appear as though you are playing a video game. Specifically:

- W will zoom in the timeline, while S will zoom out
- A and D will pane the timeline left and right

Jank will show up as gaps in the `SurfaceFlinger`:

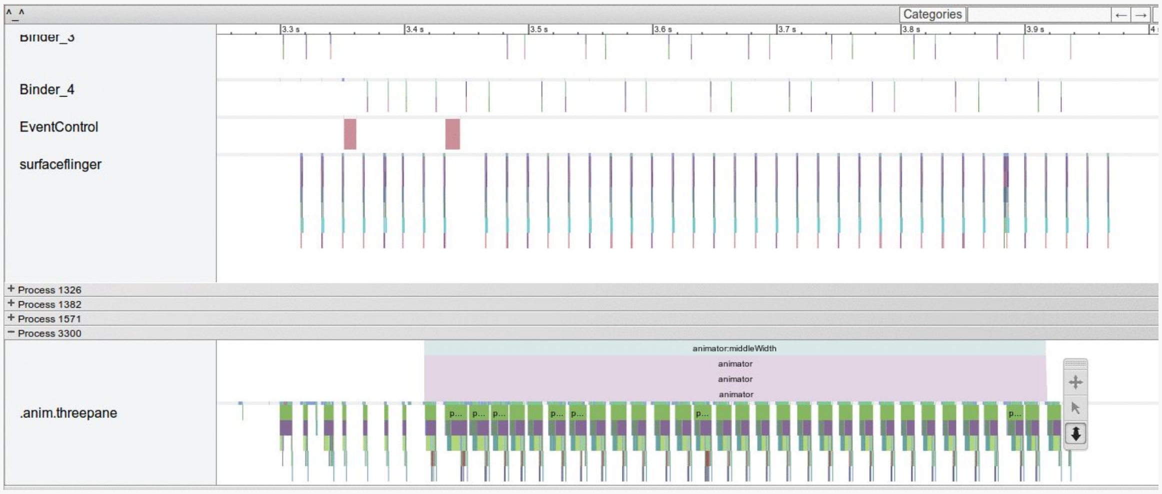

Figure 832: Systrace Output, Zoomed In on 0.7 Seconds of Profiling

Each of the major ticks across the timeline represents 0.1 seconds. There should be six frames in those seconds. However, we can see that in the 3.4-3.5 second range, there is a dropped frame, which shows up as a gap where there should be a pulse of `SurfaceFlinger` activity.

Zooming in further starts to bring up some detail for the threads in our process, showing methods within the view processing hierarchy that we were working on during this period of time:

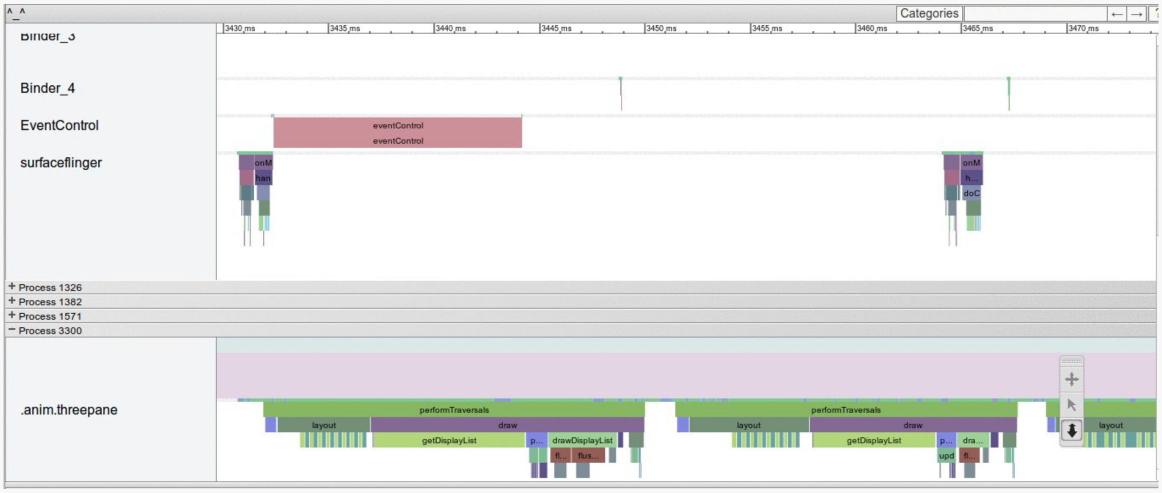

Figure 833: Systrace Output, Zoomed In on 40 Milliseconds of Profiling

In our `gfx/view` slice, we will see various blocks for different major operations in the rendering of our UI. Notably, you will see blocks labeled "performTraversals", referring to the private `performTraversals()` method on `ViewRootImpl`. It turns out that `performTraversals()` wraps around all of the work shown in the three columns of our `gfxinfo` output: draw, process, and execute. The widths of the "performTraversals" blocks in the `systrace` output shows us how long each of those takes. What we want are nice, short blocks. Instead, panning through our trace, you will see several that are too long. The chapter on "jank busting" will go into further analysis of where this particular sample application went wrong that caused this behavior.

Focus On: NDK

When Android was first released, many a developer wanted to run C/C++ code on it. There was little support for this, other than by distributing a binary executable and running it via a forked process. While this works, it is a bit cumbersome, and the process-based interface limits how cleanly your C/C++ code could interact with a Java-based UI. On top of all of that, the use of such binary executables is not well supported.

In June 2009, the core Android team released the Native Development Kit (NDK). This allows developers to write C/C++ for Android applications in a supported fashion, in the form of libraries linked to a hosting Java-based application via the Java Native Interface (JNI). This offers a wealth of opportunities for Android development, and this part of the book will explore how you can take advantage of the NDK to exploit those opportunities.

This chapter explains how to set up the NDK and apply it to your project. What it does not do is attempt to cover all possible uses of the NDK — game applications in particular have access to many frameworks, like OpenGL and OpenSL, that are beyond the scope of this book.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the introductory chapter to this trail is also a good idea.

This chapter also assumes that you know C/C++ programming.

The Role of the NDK

We start by examining Dalvik's primary limitation — speed. Next, we look at the reasons one might choose the NDK, speed among them. We wrap up with some reasons why the NDK may not be the right solution for every Android problem, despite its benefits.

Dalvik: Secure, Yes; Speedy, Not So Much

Dalvik was written with security as a high priority. Android's security architecture is built around Linux's user model, with each application getting its own user ID. With each application's process running under its own user ID, one process cannot readily affect other processes, helping to contain any single security flaw in an Android application or subsystem. This requires a fair number of processes. However, phones have limited RAM, and the Android project wanted to offer Java-based development. Multiple processes hosting their own Java virtual machines simply could not fit in a phone. Dalvik's virtual machine is designed to address this, maximizing the amount of the virtual machine that can be shared securely between processes (e.g., via "copy-on-write").

Of course, it is wonderful that Android has security so woven into the fabric of its implementation. However, inventing a new virtual machine required tradeoffs, and most of those are related to speed.

A fair amount of work has gone into making Java fast. Standard Java virtual machines do a remarkable job of optimizing applications on the fly, such that Java applications can perform at speeds near their C/C++ counterparts. This borders on the amazing and is a testament to the many engineers who put countless years into Java.

Dalvik, by comparison, is very young. Many of Java's performance optimization techniques — such as advanced garbage collection algorithms — simply have not been implemented to nearly the same level in Dalvik. This is not to say they will never exist, but it will take some time. Even then, though, there may be limits as to how fast Dalvik can operate, considering that it cannot "throw memory at the problem" to the extent Java can on the desktop or server.

ART has significantly improved matters, with ahead-of-time compilation (AOT) replacing just-in-time compilation (JIT) for getting native opcodes from the Dalvik bytecodes. However, that code may still be inefficient when compared with writing C/C++ by hand.

Going Native

Java-based Android development via Dalvik and the Android SDK is far and away the option with the best support from the core Android team. HTML5 application development is another option that was brought to you by the core Android development team. The third leg of the official Android development triad is the NDK, provided to developers to address some specific problems, outlined below.

Speed

Far and away the biggest reason for using the NDK is speed, pure and simple. Writing in C/C++ for the device's CPU will be a major speed improvement over writing the same algorithms in Java, despite Android's JIT compiler (Dalvik) and AOT compiler (ART).

There is overhead in reaching out to the C/C++ code from a hosting Java application, and so for the best performance, you will want a coarse interface, without a lot of calls back and forth between Java and the native opcodes. This may require some redesign of what might otherwise be the "natural" way of writing the C/C++ code, or you may just have to settle for less of a speed improvement. Regardless, for many types of algorithms — from cryptography to game AI to video format conversions — using C/C++ with the NDK will make your application perform much better, to the point where it can enable applications to be successful that would be entirely too slow if written solely in Java.

Bear in mind, though, that much of what you think is Java code in your app really is native "under the covers". Many of the built-in Android classes are thin shims over native implementations. Again, focus on applying the NDK where you are performing lots of work yourself in Java code that might benefit from the performance gains.

Porting

You may already have some C/C++ code, written for another environment, that you would like to use with Android. That might be for a desktop application. That might be for another mobile platform, such as iOS, where C/C++ is an option. That might be for mobile platform, such as Symbian, where C/C++ is the conventional solution, rather than some other language. Regardless, so long as that code is itself relatively platform-independent, it should be usable on Android.

This may significantly streamline your ability to support multiple platforms for your application, even if down-to-the-metal speed is not really something you necessarily need. This may also allow you to reuse existing C/C++ code written by others, for image processing or scripting languages or anything else.

Knowing Your Limits

Developers love silver bullets. Developers are forevermore seeking The One True Approach to development that will be problem-free. Sisyphus would approve, of course, as development always involves tradeoffs. So while the NDK's speed may make it tantalizing, it is not a solution for general Android application development, for several reasons, explored in this section.

Android APIs

The biggest issue with the NDK is that you have very limited access to Android itself. There are a few libraries bundled with Android that you can leverage, and a few other APIs offered specifically to the NDK, such as the ability to render OpenGL 3D graphics. But, generally speaking, the NDK has no access to the Android SDK, except by way of objects made available to it from the hosting application via JNI.

As such, it is best to view the NDK as a way of speeding up particular pieces of an SDK application — game physics, audio processing, OCR, and the like. All of those are algorithms that need to run on Android devices with data obtained from Android, but otherwise are independent of Android itself.

Cross-Platform Compatibility

While C/C++ *can* be written for cross-platform use, often it is not.

Sometimes, the disparity is one of APIs. Any time you use an API from a platform (e.g., iPhone) or a library (e.g., Qt) not available on Android, you introduce an incompatibility. This means that while a lot of your code — measured in terms of lines — may be fine for Android, there may be enough platform-specific bits woven throughout it that you would have a significant rewrite ahead of you to make it truly cross-platform.

Android itself, though, has a compatibility issue, in terms of CPUs. Android mostly runs on ARM devices today, since Android's initial focus was on smartphones, and ARM-powered smartphones at that. However, the focus on ARM will continue to waver, particularly as Android moves into other devices where other CPU architectures are more prevalent, such as Atom or MIPS for set-top boxes. While your code may be written in a fashion that works on all those architectures, the binaries that code produces will be specific to one architecture. The NDK gives you additional assistance in managing that, so that your application can simultaneously support multiple architectures.

Right now, the NDK supports ARM, x86, and MIPS CPU architectures. Of these, ARM CPUs power the *vast* majority of Android devices. The first generation of Google TV boxes, and a few other devices, use Intel x86 CPUs (usually Atom-based). MIPS is a relative newcomer to Android, with few devices using such CPUs at this time.

NDK Installation and Project Setup

The Android NDK is blissfully easy to install, in some ways even easier than is the Android SDK. Similarly, setting up an NDK-equipped project is rather straightforward. However, the documentation for the NDK is mostly a set of text files (`OVERVIEW.TXT` prominent among them). These are well-written but suffer from the limits of the plain-text form factor, plus are focused strictly on the NDK and not the larger issue of Android projects that use the NDK.

This chapter will fill in some of those gaps.

Installing the NDK

As with the Android SDK, the [Android NDK comes in the form of a ZIP or `tar.gz` file], containing everything you need to build NDK-enabled Android applications. Hence, setting up the NDK is fairly trivial, particularly if you are developing on Linux.

Prerequisites

You will need the GNU `make` and GNU `awk` packages installed. These may be part of your environment already. For example, in Ubuntu, run `sudo apt-get install make gawk`, or use the Software Center, to ensure you have these two packages.

While you can do NDK development directly on Linux or OS X, NDK development on Windows can only be done using the Cygwin environment. This gives you a Linux-style shell and Linux-style tools on a Windows PC. In addition to a base Cygwin 1.7 (or newer) installation, you will need the make and gawk Cygwin packages installed in Cygwin.

If you encounter difficulties with Cygwin, you may wish to consider whether running Linux in a virtualization environment (e.g., VirtualBox) might be a better solution for you.

Download and Unpack

The Android NDK per-platform (Linux/OS X/Windows) ZIP files can be downloaded from the NDK page on the Android Developers site. These ZIP files are not small (~500MB each), because they contain the entire toolchain — that is why there are so few prerequisites.

You are welcome to unpack the ZIP file anywhere it makes sense on your development machine. However, putting it *inside* the Android SDK directory may not be a wise move — a peer directory would be a safer choice. You are welcome to rename the directory if you choose.

Environment Variables

The NDK documentation will cite an NDK environment variable, set to point to the directory in which you unpacked the NDK. This is a documentation convention and does not appear to be required for actual use of the NDK, though it is not a bad idea. You could also consider adding the NDK directory to your PATH, though that too is not required.

Bear in mind that you will be using the NDK tools from the command line, and so being able to conveniently reference this directory is reasonably important.

Setting Up an NDK Project

At its core, an NDK-enhanced Android project is a regular Android project. You still need a manifest, layouts, Java source code, and all the other trappings of a regular Android application. The NDK simply enables you to add C/C++ code to that project and have it included in your builds, referenced from your Java code via the Java Native Interface (JNI).

The examples shown in this section are from the JNI/WeakBench sample project, which implements a pair of benchmarks in Java and C, to help demonstrate the performance differences between the environments.

Writing Your C/C++ Code

The first step towards adding NDK code to your project is to create a jni/ directory and place your C/C++ code inside of it. While there are ways to use a different base directory, it is unclear why you would need to. How you organize the code inside of jni/ is up to you. C++ code should use .cpp as file extensions, though this too is configurable.

Your C/C++ code will be made up of two facets:

- The code doing the real work
- The code implementing your JNI interface

If you have never used JNI before, JNI uses naming conventions to tie functions in a C/C++ library to their corresponding hooks in the Java code.

For example, in the WeakBench project, you will find jni/weakbench.c:

```
#include <stdlib.h>
#include <math.h>
#include <jni.h>

typedef unsigned char boolean;

static void nsieve(int m) {
    unsigned int count = 0, i, j;
    boolean * flags = (boolean *) malloc(m * sizeof(boolean));
    memset(flags, 1, m);

    for (i = 2; i < m; ++i)
        if (flags[i]) {
            ++count;
            for (j = i << 1; j < m; j += i)
//                  if (flags[j])
                   flags[j] = 0;
    }

    free(flags);
}

void
Java_com_commonsware_android_tuning_weakbench_WeakBench_nsievenative( JNIEnv* env,
                                                                      jobject thiz )
{
    int i=0;
    for (i = 0; i < 3; i++)
        nsieve(10000 << (9-i));
}

double eval_A(int i, int j) { return 1.0/((i+j)*(i+j+1)/2+i+1); }

void eval_A_times_u(int N, const double u[], double Au[])
{
  int i,j;
  for(i=0;i<N;i++)
    {
      Au[i]=0;
      for(j=0;j<N;j++) Au[i]+=eval_A(i,j)*u[j];
    }
}

void eval_At_times_u(int N, const double u[], double Au[])
{
  int i,j;
  for(i=0;i<N;i++)
    {
      Au[i]=0;
      for(j=0;j<N;j++) Au[i]+=eval_A(j,i)*u[j];
    }
}

void eval_AtA_times_u(int N, const double u[], double AtAu[])
{ double v[N]; eval_A_times_u(N,u,v); eval_At_times_u(N,v,AtAu); }

void
Java_com_commonsware_android_tuning_weakbench_WeakBench_specnative( JNIEnv* env,
                                                                     jobject thiz )
{
    int i;
    int N = 1000;
    double u[N],v[N],vBv,vv;
    for(i=0;i<N;i++) u[i]=1;
    for(i=0;i<10;i++)
      {
        eval_AtA_times_u(N,u,v);
        eval_AtA_times_u(N,v,u);
      }
    vBv=vv=0;
    for(i=0;i<N;i++) { vBv+=u[i]*v[i]; vv+=v[i]*v[i]; }
}
```

Much of the code shown here comes from the Great Language Benchmarks Game, specifically their `nsieve` and `spectral-norm` benchmarks. And, much of the code looks like normal C code.

Two functions, though, serve as JNI entry points:

- `Java_com_commonsware_abj_weakbench_WeakBench_nsievenative`
- `Java_com_commonsware_abj_weakbench_WeakBench_specnative`

As will be seen later in this section, these will map to nsievenative() and specnative() methods on a com.commonsware.abj.weakbench.WeakBench class. The Java class (with package) and method names are converted into a function call name, so JNI can identify the function at runtime.

The implementation of these methods do not make use of any Java objects, nor do they return anything — they just implement the benchmark.

Writing Your Makefile(s)

To tell the NDK tools how to build your code, you will need one or two makefiles.

Android.mk

This makefile will describe the "module" (library) that you are attempting to add to your Android project by way of the NDK. In it, you will specify the source files that should be compiled and linked into the module. This file, by default, resides in the root of your jni/ directory.

For example, here is jni/Android.mk from the WeakBench project:

```
LOCAL_PATH := $(call my-dir)

include $(CLEAR_VARS)

LOCAL_MODULE    := weakbench
LOCAL_SRC_FILES := weakbench.c

include $(BUILD_SHARED_LIBRARY)
```

Here, we give the module a name (weakbench) and identify the source files that go into it (weakbench.c).

It is possible for you to have multiple Android.mk files, in multiple subdirectories of jni/, to create multiple modules. There is an ANDROID-MK.TXT file in the NDK documentation directory that provides more detail on how you can configure complex scenarios like this one.

Application.mk

There is a separate, optional, makefile that you can have, Application.mk, in your jni/ directory. This is where you can provide compile flags for the build process, which CPU architectures (ARM, x86, etc.) you wish to support, and so on. By default, if you do not have such a file, the NDK build tools will include all modules defined in your Android.mk file(s) in your project, compiled for a generic ARM target with software support for floating-point operations.

For basic NDK applications, skipping Application.mk is a reasonable choice. Complex projects, or ones specifically aiming to support other CPU architectures (e.g., ARM-v7 CPUs with hardware floating-point support), will need an Application.mk file.

The WeakBench project has a one-line Application.mk file:

```
APP_ABI := all
```

This tells Android that we want to build the JNI code for all supported CPU architectures. At the time of this writing, that is ARMv5, ARMv7, and x86.

Building Your Library

Any time you modify your C/C++ code, or the makefiles, you will need to build your NDK library. To do that, from a command prompt in your project's root directory, run the **ndk-build** script found in the NDK's root directory. In other words, if you set up an NDK environment variable to point to where you have the NDK installed, execute **$NDK/ndk-build** from your project root.

This will compile and link your C/C++ code into a library (or conceivably several libraries, if you have a complex set of Android.mk files). These will wind up in your project's libs/ directory, in subdirectories based on your CPU architectures indicated by your Application.mk file.

For example, if you run **$NDK/ndk-build** from the WeakBench project root, you will wind up with a libs/armeabi/libweakbench.so file. The armeabi portion is because that is the default CPU architecture that the NDK supports, and WeakBench did not change the defaults via an Application.mk file. The "weakbench" portion of libweakbench.so is because our LOCAL_MODULE value in our Android.mk file is weakbench. The lib prefix is automatically added by the build tools. The .so file extension is because our Android.mk file indicated that we are building a shared library (via the BUILD_SHARED_LIBRARY directive), and .so is the standard file extension for shared libraries in Linux (and, hence, Android).

Note that you will also wind up with similar .so files in libs/armeabi-v7a/ and libs/x86 for those architectures.

You are welcome to add this to your build process, such as adding it to your Ant build script, though it is not automatically included in the build process as defined by Android.

Using Your Library Via JNI

Now that you have your base C/C++ code being successfully compiled by the NDK, you need to turn your attention towards crafting the bridge between the Dalvik VM and the C/C++ code, following in the conventions of the Java Native Interface (JNI).

This section, while explaining the various steps involved in using the JNI, is far from a complete treatise on the subject. If you are going to spend a lot of time working with JNI, you are encouraged to seek additional resources on this topic, such as Core Java: Volume II, which has a chapter on JNI.

We created two C functions for accessing benchmarks:

- `Java_com_commonsware_abj_weakbench_WeakBench_nsievenative`
- `Java_com_commonsware_abj_weakbench_WeakBench_specnative`

Those, in turn, need to be defined as static methods on a `com.commonsware.abj.weakbench.WeakBench` class. Moreover, these methods will need to have the `native` keyword, indicating that their implementation is not found in Java code, but in native C/C++ code. The naming convention of the C functions allows the Dalvik runtime to identify what function names should be used for those `native` method implementations.

However, that alone will be insufficient — we need to tell Dalvik where it can find the library in the first place. While naming conventions are good enough for the C function names, there is no corresponding naming convention for the library itself.

To do this, we use the `loadLibrary()` static method on the `System` class. A class implementing native methods should call `loadLibrary()` in a `static` block, so it is executed when the class is first referenced. For the NDK, all we need to do is supply the name we gave the library in the `Android.mk` file.

Here is the portion of the `WeakBench` class that has the `native` methods and the `loadLibrary()` call:

```
static {
  System.loadLibrary("weakbench");
}

public native void nsievenative();
public native void specnative();
```

Now, we can call our `nsievenative()` and `specnative()` methods on `WeakBench`, just as if they were regular Dalvik methods on a regular Dalvik class. The fact that they are really going off and invoking C functions is purely "implementation detail" that the consumers of those methods can be blissfully unaware of.

`WeakBench` itself is an `Activity`, invoking both Dalvik and native implementations of these two benchmarks. It uses a series of `AsyncTask` objects for executing the benchmarks on background threads, then updates `TextView` widgets in the UI to show the results:

```
package com.commonsware.android.tuning.weakbench;

import android.app.Activity;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.SystemClock;
import android.widget.TextView;

public class WeakBench extends Activity {
  static {
    System.loadLibrary("weakbench");
  }

  public native void nsievenative();
  public native void specnative();

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    new JavaSieveTask().execute();
  }

  /*
   * Code after this point is adapted from the Great Computer Language
   * Shootout. Copyrights are owned by whoever contributed this stuff,
   * or possibly the Shootout itself, since there isn't much information
   * on ownership there. Licensed under a modified BSD license.
   */

  private class JavaSieveTask extends AsyncTask<Void, Void, Void> {
    long start=0;
    TextView result=null;

    @Override
    protected void onPreExecute() {
      result=(TextView)findViewById(R.id.nsieve_java);
      result.setText("running...");
    }

     @Override
    protected Void doInBackground(Void... unused) {
      start=SystemClock.uptimeMillis();

      int n=9;
      int m=(1<<n)*10000;
      boolean[] flags=new boolean[m+1];

      nsieve(m,flags);

      m=(1<<n-1)*10000;
      nsieve(m,flags);

      m=(1<<n-2)*10000;
      nsieve(m,flags);

      return(null);
    }

    @Override
    protected void onPostExecute(Void unused) {
      long delta=SystemClock.uptimeMillis()-start;

      result.setText(String.valueOf(delta));
      new JavaSpecTask().execute();
    }
  }

  private class JavaSpecTask extends AsyncTask<Void, Void, Void> {
    long start=0;
    TextView result=null;

    @Override
    protected void onPreExecute() {
      result=(TextView)findViewById(R.id.spec_java);

      result.setText("running...");
    }

     @Override
    protected Void doInBackground(Void... unused) {
      start=SystemClock.uptimeMillis();

      Approximate(1000);

      return(null);
    }

    @Override
    protected void onPostExecute(Void unused) {
      long delta=SystemClock.uptimeMillis()-start;

      result.setText(String.valueOf(delta));
      new JNISieveTask().execute();
    }
  }
```

```
private class JNISieveTask extends AsyncTask<Void, Void, Void> {
  long start=0;
  TextView result=null;

  @Override
  protected void onPreExecute() {
    result=(TextView)findViewById(R.id.nsieve_jni);

    result.setText("running...");
  }

   @Override
  protected Void doInBackground(Void... unused) {
    start=SystemClock.uptimeMillis();

    nsievenative();

    return(null);
  }

  @Override
  protected void onPostExecute(Void unused) {
    long delta=SystemClock.uptimeMillis()-start;

    result.setText(String.valueOf(delta));
    new JNISpecTask().execute();
  }
}

private class JNISpecTask extends AsyncTask<Void, Void, Void> {
  long start=0;
  TextView result=null;

  @Override
  protected void onPreExecute() {
    result=(TextView)findViewById(R.id.spec_jni);

    result.setText("running...");
  }

   @Override
  protected Void doInBackground(Void... unused) {
    start=SystemClock.uptimeMillis();

    specnative();

    return(null);
  }

  @Override
  protected void onPostExecute(Void unused) {
    long delta=SystemClock.uptimeMillis()-start;

    result.setText(String.valueOf(delta));
  }
}

private static int nsieve(int m, boolean[] isPrime) {
    for (int i=2; i <= m; i++) isPrime[i] = true;
    int count = 0;

    for (int i=2; i <= m; i++) {
       if (isPrime[i]) {
          for (int k=i+i; k <= m; k+=i) isPrime[k] = false;
          count++;
       }
    }
    return count;
}

private final double Approximate(int n) {
  // create unit vector
  double[] u = new double[n];
  for (int i=0; i<n; i++) u[i] =  1;

  // 20 steps of the power method
  double[] v = new double[n];
  for (int i=0; i<n; i++) v[i] = 0;

  for (int i=0; i<10; i++) {
    MultiplyAtAv(n,u,v);
    MultiplyAtAv(n,v,u);
  }

  // B=AtA         A multiplied by A transposed
  // v.Bv /(v.v)   eigenvalue of v
  double vBv = 0, vv = 0;
  for (int i=0; i<n; i++) {
    vBv += u[i]*v[i];
    vv  += v[i]*v[i];
  }

  return Math.sqrt(vBv/vv);
}

/* return element i,j of infinite matrix A */
private final double A(int i, int j){
  return 1.0/((i+j)*(i+j+1)/2 +i+1);
}

/* multiply vector v by matrix A */
private final void MultiplyAv(int n, double[] v, double[] Av){
  for (int i=0; i<n; i++){
    Av[i] = 0;
    for (int j=0; j<n; j++) Av[i] += A(i,j)*v[j];
  }
}

/* multiply vector v by matrix A transposed */
private final void MultiplyAtv(int n, double[] v, double[] Atv){
  for (int i=0;i<n;i++){
    Atv[i] = 0;
    for (int j=0; j<n; j++) Atv[i] += A(j,i)*v[j];
  }
}
```

```
  /* multiply vector v by matrix A and then by matrix A transposed */
  private final void MultiplyAtAv(int n, double[] v, double[] AtAv){
    double[] u = new double[n];
    MultiplyAv(n,v,u);
    MultiplyAtv(n,u,AtAv);
  }
}
```

As with our C implementations of the benchmarks, the Java source code is derived from the Great Language Benchmarks Game.

Building and Deploying Your Project

Given that you have done all of this, the rest is perfectly normal – you build and deploy your Android project no differently than if you did not have any C/C++ code. Your native library is embedded in your APK file, so you do not have to worry about distributing it separately.

However, bear in mind that the more architectures you choose, the more `.so` files there are and the bigger your app will be. For tiny bits of C/C++ code, like the code in this app, this increase in file size will not be very noticeable. However, it is something to keep in mind for more elaborate NDK applications. Moreover, there are some ways to help reduce the impact of these extra architectures.

libhoudini and the NDK

`libhoudini` is a proprietary ARM translation layer for x86-powered Android devices. It allows an app that has NDK binaries for ARM, but not x86, to still run on x86 hardware, albeit not as quickly as it would with native x86 binaries.

Given ARM's current dominance in the Android ecosystem, `libhoudini` is hugely useful for Intel and hardware vendors interested in using Intel's mobile CPUs. Without it, only apps that ship x86 NDK binaries would be compatible with x86-powered devices like the Samsung Galaxy Tab 3 10.1" tablet. Some developers probably skip x86 NDK binaries, because they are not aware of popular x86-powered devices, or lack one for testing, or are concerned over APK size. The Play Store for x86 would shrink substantially from the million-plus apps available to ARM devices, to those that do not use the NDK or happen to ship x86 binaries. `libhoudini` makes ARM-only NDK binaries usable on x86, giving x86-powered Android devices access to more of the Play Store catalog.

However, it *is* slower. A test suite for SQLCipher for Android, run on an ASUS MeMO Pad FHD 10, ran about three times as long when using the ARM binaries and `libhoudini`, when compared to the same test run using x86 binaries. On the other hand, supporting x86 in addition to ARM adds another 5MB to the app, on top of the 6.5MB spent for ARM and the platform-neutral pieces. Being able to use SQLCipher for Android without the x86 binaries might be useful, particularly for apps bumping up against APK size limits, like the 50MB limit on the Play Store.

You may wish to do your own testing. Testing is easy enough: just temporarily move the `x86/` directory from `libs/` somewhere else, then recompile and test on `libhoudini`-equipped hardware. If you do not have your own `libhoudini`-equipped hardware, you may be able to take advantage of services like Samsung's Remote Test Lab, which recently added the Galaxy Tab 3 10.1 to its lineup.

If you have the space for it, include the x86 binaries for your NDK-compiled libraries. This will give you maximum speed for little incremental engineering cost. However, if space is at a premium, `libhoudini` may allow you to reach many of the same x86 devices, but be sure that your app will run acceptably given the performance overhead.

Gradle and the NDK

The Android Plugin for Gradle has preliminary support for the NDK. However, this support has its issues, and so you may wish to pursue other approaches, at least in the short term.

Official Support, for Externally-Built Binaries

Sometimes, you may have a project for which you want to use NDK-compiled binaries that somebody else supplies.

For example, at the time of this writing, SQLCipher for Android is not available as an AAR dependency from any repo. To use it, you need to include a handful of JARs in your project, along with NDK-compiled binaries for the core SQLCipher library and related libraries. Once this is available as an AAR, you could get all of that via a dependency; in the short term, you need to teach Gradle how to pick up the NDK-compiled binaries.

Using the Android Plugin for Gradle, you can have a `jniLibs/` directory in a sourceset. Underneath that directory would go your pre-compiled binaries, in the standard CPU architecture directories (e.g., `jniLibs/x86/`, `jniLibs/armeabi-v7a/`).

The [`Gradle/ConstantsSecure`]() sample project is a clone of the same-named project from the SQLCipher for Android chapter, but with the code reorganized into a Gradle sourceset:

```
ConstantsSecure
|── build.gradle
|── libs
|    |── commons-codec.jar
|    |── guava-r09.jar
|    |── sqlcipher.jar
|── local.properties
|── proguard.cfg
|── project.properties
|── src
    |── main
        |── AndroidManifest.xml
        |── assets
        |    |── icudt46l.zip
        |── java
        |    |── com
        |        └── commonsware

            |    |── eject.png
            |    |── ic_launcher.png
            |── drawable-xhdpi
            |    |── ic_launcher.png
            |── layout
            |    |── add_edit.xml
            |    |── main.xml
            |    |── row.xml
            └── values
              |── strings.xml
```

(note: above listing includes only files of relevance for the current discussion)

The JARs remain in `libs/`, but the associated NDK `.so` files go in `jniLibs/` of the `main` sourceset.

When organized this way, the `build.gradle` file needs no changes to incorporate the `.so` files. If you wanted to have the JNI `.so` files in some other directory, you can modify `jniLibs.srcDirs` of your sourceset to point to where you want the files to reside.

Official Support, for Building NDK Binaries

To use the official NDK support for invoking the NDK build process from your `build.gradle` file, you need to have a `local.properties` file, defining an `ndk.dir` property, pointing to where your NDK is installed. This needs to be in the project root directory, not in a module directory.

You can add an `ndk` closure to your `defaultConfig`, describing how your NDK code can be built:

```
defaultConfig {
    ndk {
        moduleName "anddown"
    }
}
```

In addition to `moduleName`, you can specify:

- `cFlags` for compiler flags
- `ldLibs` for libraries to link in

Your productFlavors can also have ndk closures with abiFilter properties, identifying a particular set of NDK binaries to be included in that flavor. For example, here is a build.gradle sample file from a test project for the Android Plugin for Gradle:

```
buildscript {
    repositories {
        maven { url '../../../../out/host/gradle/repo' }
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:0.7.0-SNAPSHOT'
    }
}
apply plugin: 'android'

android {
    compileSdkVersion 15
    buildToolsVersion "18.0.1"

    defaultConfig {
        ndk {
            moduleName "sanangeles"
            cFlags "-DANDROID_NDK -DDISABLE_IMPORTGL"
            ldLibs "GLESv1_CM", "dl", "log"
            stl "stlport_static"
        }
    }

    buildTypes.debug.jniDebugBuild true

    productFlavors {
        x86 {
            ndk {
                abiFilter "x86"
            }
        }
        arm {
            ndk {
                abiFilter "armeabi-v7a"
            }
        }
        mips {
            ndk {
                abiFilter "mips"
            }
        }
    }
}
```

Note that this sample is seriously out of date, as it uses Gradle for Android 0.7.0, but it helps to illustrate how the product flavors work.

In here, we define three product flavors, one each for x86, ARM, and MIPS. Each resulting binary will only contain that architecture's version of the compiled NDK code.

Also, you need to tell Gradle for Android where your C/C++ source code resides. The default location is a `jni/` directory in your sourcesets, such as the `main/` sourceset. However, you can override that using `jni.srcDirs` in your configuration of a sourceset.

Example: CWAC-AndDown

CWAC-AndDown is mentioned in passing in the chapter on rich text handling. It is an Android library that wraps hoedown, a C-based Markdown-to-HTML converter. The hoedown project itself is a fork of sundown, which itself was used by many sites, like GitHub, for their Markdown processing. CWAC-AndDown is great for projects that take in Markdown and want to render the results in a `WebView` (though you can use `Html.fromHtml()` to put the results in a `TextView` if you want).

Since CWAC-AndDown uses hoedown's C code, it has a `jni/` directory containing the JNI wrapper C code, the appropriate makefiles, plus a `src/` subdirectory containing the hoedown source code.

The classic way to build the project was to manually run the `ndk-build` script in the project root, then use Ant to compile the demo. CWAC-AndDown itself is an Android library project, designed to be used by apps like the demo app.

To get this library project to build using Ant and Eclipse, in addition to Gradle, we needed to leave the `jni/` directory in its original spot, alongside the `res/`, `src/`, and related directories and files. Since that is not where Gradle for Android goes looking for C/C++ files, we needed to teach Gradle for Android where our JNI code resides, by configuring `jni.srcDirs` for our `main` sourceset in `build.gradle`:

```
    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
            jni.srcDirs = ['jni', 'jni/src']
        }

        debug.setRoot('build-types/debug')
        release.setRoot('build-types/release')
    }
```

The CWAC-AndDown `build.gradle` file also contains the `ndk` closure shown earlier in this section, to name the module that we are generating.

Unofficial Support for Makefiles

We also needed to reorganize the CWAC-AndDown source code, due to some fundamental limitations in the current official Android support. Specifically, Gradle for Android *ignores* your own makefiles, preferring instead to generate its own. The generation algorithms are rather limited and make some assumptions about the organization of your code. Having all of your C/C++ source and header files in one big directory seems to work; having other structures may or may not work.

The fact that Gradle for Android ignores your makefiles means that if your makefiles do anything beyond very vanilla stuff, your build may well not work.

The alternative to using the built-in NDK support is to add in your own tasks that use the `ndk-build` command with your original makefiles. One such set of tasks was published by David Weinstein in a GitHub Gist. However, this recipe was written for an early beta version of the Gradle for Android plugin and therefore may require some modification.

Mostly, it involves adding the following to the bottom of your `build.gradle` file:

```
task packageNativeLibs_ARM(type: Jar) {
    baseName 'libtestlib'
    classifier 'armeabi'
    from(file('libs/armeabi/')) {
        include '**/*.so'
    }
    into('lib/armeabi')
    destinationDir(file('libs/'))
}

task packageNativeLibs_x86(type: Jar) {
    baseName 'libtestlib'
    classifier 'x86'
    from(file('libs/x86/')) {
        include '**/*.so'
    }
    into('lib/x86')
    destinationDir(file('libs/'))
}

task packageNativeLibs(description: "package native libraries") {
}

packageNativeLibs.dependsOn 'packageNativeLibs_ARM'
packageNativeLibs.dependsOn 'packageNativeLibs_x86'

task ndkBuild(type: Exec, description: "Task to run ndk-build") {
    commandLine ndkDir + '/ndk-build'
}

packageNativeLibs.dependsOn 'ndkBuild'

tasks.withType(JavaCompile) { compileTask -> compileTask.dependsOn packageNativeLibs }

clean.dependsOn 'cleanPackageNativeLibs'
```

This task also assumes that you have set an `ndkDir` property. To set properties in Gradle, add a `gradle.properties` file to your project, using the typical properties format:

```
ndkDir=/opt/android-ndk
```

The Gradle code snippet does several things:

1. It defines two tasks, one each to package the ARM and x86 version of the binaries. If you have a different mix of NDK build targets (e.g., ARMv7, MIPS), you could add or alter these tasks to suit.
2. It defines a `packageNativeLibs` task, that depends upon each of the CPU architecture-specific tasks from the previous point. If you add, change, or remove those architecture-specific tasks, you will need to add, change, or remove the corresponding `packageNativeLibs.dependsUpon` statements.
3. It defines an `ndkBuild` task, that simply executes the `ndk-build` script found in your NDK directory (defined by that `ndkDir` property).
4. It has `packageNativeLibs` depend upon `ndkBuild`.
5. It has all `JavaCompile` tasks in the build depend upon the `packageNativeLibs` task. This ensures that when we compile our Java code, we also compile the NDK code, if it is not already up to date.
6. It adds the auto-generated `cleanPackageNativeLibs` task as a dependency for the `clean` task, so **`gradle clean`** will clean the NDK build as well as cleaning everything else.

Gradle supports other ways of defining where the NDK directory is, such as depending upon an environment variable, so you have alternatives.

Improving CPU Performance in Java

Knowing that you have CPU-related issues in your app is one thing — doing something about it is the next challenge. In some respects, tuning an Android application is a "one-off" job, tied to the particulars of the application and what it is trying to accomplish. That being said, this chapter will outline some general-purpose ways of boosting performance that may counter issues that you are running into.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the introductory chapter to this trail is also a good idea.

Reduce CPU Utilization

One class of CPU-related problems come from purely sluggish code. These are the sorts of things you will see in Traceview, for example – methods or branches of code that seem to take an inordinately long time. These are also some of the most difficult to have general solutions for, as often times it comes down to what the application is trying to accomplish. However, the following sections provide suggestions for consuming fewer CPU instructions while getting the same work done.

These are presented in no particular order.

Standard Java Optimizations

Most of your algorithm fixes will be standard Java optimizations, no different than have been used by Java projects over the past decade and change. This section outlines a few of them. For more, consider reading *Effective Java* by Joshua Bloch or *Java Performance Tuning* by Jack Shirazi.

Avoid Excessive Synchronization

Few objects in `java.*` namespaces are intrinsically thread-safe, outside of `java.util.concurrent`. Typically, you need to perform your own synchronization if multiple threads will be accessing non-thread-safe objects. However, sometimes, Java classes have synchronization that you neither expect nor need. Synchronization adds unnecessary overhead.

The classic example here is `StringBuffer` and `StringBuilder`. `StringBuffer` was part of Java from early on, and, for whatever reason, was written to be thread-safe — two threads that append to the buffer will not cause any problems. However, most of the time, you are only using the `StringBuffer` from one thread, meaning all that synchronization overhead is a waste. Later on, Java added `StringBuilder`, with the same basic set of methods as has `StringBuffer`, but without the synchronization.

Similarly, in your own code, only synchronize where it is really needed. Do not toss the `synchronized` keyword around randomly, or use concurrent collections that will only be used by one thread, etc.

Avoid Floating-Point Math

The first generation of Android devices lacked a floating-point coprocessor on the ARM CPU package. As a result, floating-point math speed was atrocious. That is why the Google Maps add-on for Android uses `GeoPoint`, with latitude and longitude in integer microdegrees, rather than the standard Android `Location` class, which uses Java double variables holding decimal degrees.

While later Android devices do have floating-point coprocessor support, that does not mean that floating-point math is now as fast as integer math. If you find that your code is spending lots of time on floating-point calculations, consider whether a change in units would allow you to replace the floating-point calculations with integer equivalents. For example, microdegrees for latitude and longitude provide adequate granularity for most maps, yet allow Google Maps to do all of its calculations in integers.

Similarly, consider whether the full decimal accuracy of floating-point values is really needed. While it may be physically possible to perform distance calculations in meters with accuracy to a few decimal points, for example, in many cases the user will not need that degree of accuracy. If so, perhaps changing to fixed-point (integer) math can boost your performance.

Don’t Assume Built-In Algorithms are Best

Years upon years of work has gone into the implementation of various algorithms that underlie Java methods, like searching for substrings inside of strings.

Somewhat less work has gone into the implementation of the Apache Harmony versions of those methods, simply because the project is younger, and it is a modified version of the Harmony implementation that you will find in Android. While the core Android team has made many improvements to the original Harmony implementation, those improvements may be for optimizations that do not fit your needs (e.g., optimizing to reduce memory consumption at the expense of CPU time).

But beyond that, there are dozens of string-matching algorithms, some of which may be better for you depending on the string being searched and the string being searched for. Hence, you may wish to consider applying your own searching algorithm rather than relying on the built-in one, to boost performance. And, this same concept may hold for other algorithms as well (e.g., sorting).

Of course, this will also increase the complexity of your application, with long-term impacts in terms of maintenance cost. Hence, do not assume the built-in algorithms are the worst, either — optimize those algorithms that Traceview or logging suggest are where you are spending too much time.

Support Hardware-Accelerated Graphics

An easy “win” is to add `android:hardwareAccelerated="true"` to your `<application>` element in the manifest. This toggles on hardware acceleration for 2D graphics, including much of the stock widget framework. For maximum backwards compatibility, this hardware acceleration is off, but adding the aforementioned attribute will enable it for all activities in your application.

Note that this is only available starting with Android 3.0. It is safe to have the attribute in the manifest for older Android devices, as they simply will ignore your request.

You also should test your application thoroughly after enabling hardware acceleration, to make sure there are no unexpected issues. For ordinary widget-based applications, you should encounter no problems. Games or other applications that do their own drawing might have issues. If you find that some of your code runs into problems, you can override hardware acceleration on a per-activity basis by putting the `android:hardwareAccelerated` on `<activity>` elements in the manifest.

Minimize IPC

Calling a method on an object in your own process is fairly inexpensive. The overhead of the method invocation is fairly minuscule, and so the time involved is simply however long it takes for that method to do its work.

Invoking behaviors in another process, via inter-process communication (IPC), is considerably more expensive. Your request has to be converted into a byte array (e.g., via the `Parcelable` interface), made available to the other process, converted back into a regular request, then executed. This adds substantial CPU overhead.

There are three basic flavors of IPC in Android:

1. "Directly" invoking a third-party application's service's AIDL-published interface, to which you bound with `bindService()`
2. Performing operations on a content provider that is not part of your application (i.e., supplied by the OS or a third-party application)
3. Performing other operations that, under the covers, trigger IPC

Remote Bound Service

Using a remote service is fairly obvious when you do it — it is difficult to mistake copying the AIDL into your project and such. The proxy object generated from the AIDL converts all your method calls on the interface into IPC operations, and this is relatively expensive.

If you are exposing a service via AIDL, design your API to be coarse-grained. Do not require the client to make 1,000 method invocations to accomplish something that can be done in 1 via slightly more complex arguments and return values.

If you are consuming a remote service, try not to get into situations where you have to make lots of calls in a tight loop, or per row of a scrolled `AdapterView`, or anything else where the overhead may become troublesome.

For example, in the [`CPU-Java/AIDLOverhead`]() sample project, you will find a pair of projects implementing the same do-nothing method in equivalent services. One uses AIDL and is bound to remotely from a separate client application; the other is a local service in the client application itself. The client then calls the do-nothing method 1 million times for each of the two services. On average, on a Samsung Galaxy Tab 10.1, 1 million calls takes around 170 seconds for the remote service, while it takes around 170 *milliseconds* for the local service. Hence, the overhead of an individual remote method invocation is small (~170 microseconds), but doing lots of them in a loop, or as the user flings a `ListView`, might become noticeable.

Remote Content Provider

Using a content provider can be somewhat less obvious of a problem. Using `ContentResolver` or a `CursorLoader` looks the same whether it is your own content provider or someone else's. However, you know what content providers you wrote; anything else is probably running in another process.

As with remote services, try to aggregate operations with remote content providers, such as:

1. Use `bulkInsert()` rather than lots of individual `insert()` calls
2. Try to avoid calling `update()` or `delete()` in a tight loop – instead, if the content provider supports it, use a more complex "WHERE clause" to update or delete everything at once
3. Try to get all your data back in few queries, rather than lots of little ones… though this can then cause you issues in terms of memory consumption

Remote OS Operation

The content provider scenario is really a subset of the broader case where you request that Android do something for you and winds up performing IPC as part of that.

Sometimes, this is going to be obvious. If you are sending commands to a third-party service via `startService()`, by definition, this will involve IPC, since the third-party service will run in a third-party process. Try to avoid calling `startService()` lots of times in close succession.

However, there are plenty of cases that are less obvious:

1. All requests to `startActivity()`, `startService()`, and `sendBroadcast()` involve IPC, as it is a separate OS process that does the real work
2. Registering and unregistering a `BroadcastReceiver` (e.g., `registerReceiver()`) involves IPC
3. All of the "system services", such as `LocationManager`, are really rich interfaces to an AIDL-defined remote service, and so most operations on these system services require IPC

Once again, your objective should be to minimize calls that involve IPC, particularly where you are making those calls frequently in close succession, such as in a loop. For example, frequently calling `getLastKnownLocation()` will be expensive, as that involves IPC to a system process.

Android-Specific Java Optimizations

The way that the Dalvik VM was implemented and operates is subtly different than a traditional Java VM. Therefore, there are some optimizations that are more important on Android than you might find in regular desktop or server Java.

The Android developer documentation has a roster of such optimizations. Some of the highlights include:

1. Getters and setters, while perhaps useful for encapsulation, are significantly slower than direct field access. For simpler cases, such as `ViewHolder` objects for optimizing an Adapter, consider skipping the accessor methods and just use the fields directly.
2. Some popular method calls are replaced by hand-created assembler instructions rather than code generated via the JIT compiler. `indexOf()` on `String` and `arraycopy()` on `System` are two cited examples. These will run much faster than anything you might create yourself in Java.

Reduce Time on the Main Application Thread

Another class of CPU-related problem is when your code may be efficient, but it is occurring on the main application thread, causing your UI to react sluggishly. You might have tuned your decryption algorithm as best as is mathematically possible, but it may be that decrypting data on the main application thread simply takes too much time. Or, perhaps StrictMode complained about some disk or network I/O that you are performing on the main application thread.

The following sections recap some commonly-seen patterns for moving work off the main application thread, plus a few newer options that you may have missed.

Generate Less Garbage

Most developers think of having too many allocations as being solely an issue of heap space. That certainly has an impact, and depending on the nature of the allocations (e.g., bitmaps), it may be the dominant issue.

However, garbage has impacts from a CPU standpoint as well. Every object you create causes its constructor to be executed. Every object that is garbage-collected requires CPU time both to find the object in the heap and to actually clean it up (e.g., execute the finalizer, if any).

Worse still, on older versions of Android (e.g., Android 2.2 and down), the garbage collector interrupts the entire process to do its work, so the more garbage you generate, the more times you "stop the world". Game developers have had to deal with this since Android's inception. To maintain a 60 FPS refresh rate, you cannot afford *any* garbage collections on older devices, as a single GC run could easily take more than the ~16ms you have per drawing pass.

As a result of all of this, game developers have had to carefully manage their own object pools, pre-allocating a bunch of objects before game play begins, then using and recycling those objects themselves, only allowing them to become garbage after game play ends.

Most non-game Android applications may not have to go to quite that extreme across the board. However, there are cases where excessive allocation may cause you difficulty. For example, avoiding creating too much garbage is one aspect of view recycling with AdapterView, which is covered in greater detail in the next section.

If Traceview indicates that you are spending a lot of time in garbage collection, pay attention to your loops or things that may be invoked many times in rapid succession (e.g., accessing data from a custom Cursor implementation that is tied to a CursorAdapter). These are the most likely places where your own code might be creating lots of extra objects that are not needed. Examining the heap to see what is all being created (and eventually garbage collected) will be covered in an upcoming chapter of the book.

View Recycling

Perhaps the best-covered Android-specific optimization is view recycling with AdapterView.

In a nutshell, if you are extending BaseAdapter, or if you are overriding getView() in another adapter, please make use of the View parameter supplied to getView() (referred to here as convertView). If convertView is not null, it is one of your previous View objects you returned from getView() before, being offered to you for recycling purposes. Using convertView saves you from inflating or manually constructing a fresh View every time the user scrolls, and both of those operations are relatively expensive.

If you have been ignoring convertView because you have more than one type of View that getView() returns, your Adapter should be overriding getViewTypeCount() and getItemViewType(). These will allow Android to maintain separate object pools for each type of row from your Adapter, so getView() is guaranteed to be passed a convertView that matches the row type you are trying to create.

A somewhat more advanced optimization — caching all those findViewById() lookups — is also possible once your row recycling is in place. Often referred to as "the holder pattern", you do the findViewById() calls when you inflate a new row, then attach the findViewById() results to the row itself via some custom "holder" object and the setTag() method on View. When you recycle the row, you can get your "holder" back via getTag() and skip having to do the findViewById() calls again.

Background Threads

Of course, the backbone of any strategy to move work off the main application thread is to use background threads, in one form or fashion. You will want to apply these in places where StrictMode complains about network or disk I/O, or places where Traceview or logging indicate that you are taking too much time on the main application thread during GUI processing (e.g., converting downloaded bitmap images into Bitmap objects via BitmapFactory).

Sometimes, you will manually dictate where work should be done in the background, either by forking threads yourself or by using AsyncTask. AsyncTask is a nice framework, handling all of the inter-thread communication for you and neatly packaging up the work to be done in readily understood methods. However, `AsyncTask` does not fit every scenario — it is mostly designed for "transactional" work that is known to take a modest amount of time (milliseconds to seconds) then end. For cases where you need unbounded background processing, such as monitoring a socket for incoming data, forking your own thread will be the better approach.

Sometimes, you will use facilities supplied by Android to move work to the background. For example, many activities are backed by a `Cursor` obtained from a database or content provider. Classically, you would manage the cursor (via `startManagingCursor()`) or otherwise arrange to refresh that `Cursor` in `onResume()`, so when your activity returns to the foreground after having been gone for a while, you would have fresh data. However, this pattern tends to lead to database I/O on the main application thread, triggering complaints from `StrictMode`. Android 3.0 and the Android Compatibility Library offer a `Loader` framework designed to try to solve the core pattern of refreshing the data, while arranging for the work to be done asynchronously.

Asynchronous BroadcastReceiver Operations

99.44% of the time (approximately) that Android calls your code in some sort of event handler, you are being called on the main application thread. This includes manifest-registered `BroadcastReceiver` components — `onReceive()` is called on the main application thread. So any work you do in `onReceive()` ties up that thread (possibly impacting an activity of yours in the foreground), and if you take more than 10 seconds, Android will terminate your `BroadcastReceiver` with extreme prejudice.

Classically, manifest-registered `BroadcastReceiver` components only live as long as the `onReceive()` call does, meaning you can do very little work in the `BroadcastReceiver` itself. The typical pattern is to have it send a command to a service via `startService()`, where the service "does the heavy lifting".

Android 3.0 added a `goAsync()` method on `BroadcastReceiver` that can help a bit here. While under-documented, it tells Android that you need more time to complete the broadcast work, but that you can do that work on a background thread. This does not eliminate the 10-second rule, but it does mean that the `BroadcastReceiver` can do some amount of I/O without having to send a command to a service to do it while still not tying up the main application thread.

The CPU-Java/GoAsync sample project demonstrates goAsync() in use, as the project name might suggest.

Our activity's layout consists of two Button widgets and an EditText widget:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical" android:layout_width="match_parent"
  android:layout_height="match_parent">
  <EditText android:id="@+id/editText1" android:layout_width="match_parent"
    android:layout_height="wrap_content">
  </EditText>
  <Button android:layout_width="match_parent" android:id="@+id/button1"
    android:layout_height="wrap_content" android:text="@string/nonasync"
    android:onClick="sendNonAsync"></Button>
  <Button android:layout_width="match_parent" android:id="@+id/button2"
    android:layout_height="wrap_content" android:text="@string/async"
    android:onClick="sendAsync"></Button>
</LinearLayout>
```

The activity itself simply has sendAsync() and sendNonAsync() methods, each invoking sendBroadcast() to a different BroadcastReceiver implementation:

```
package com.commonsware.android.tuning.goasync;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class GoAsyncActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void sendAsync(View v) {
    sendBroadcast(new Intent(this, AsyncReceiver.class));
  }

  public void sendNonAsync(View v) {
    sendBroadcast(new Intent(this, NonAsyncReceiver.class));
  }
}
```

The NonAsyncReceiver simulates doing time-consuming work in onReceive() itself:

```
package com.commonsware.android.tuning.goasync;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
```

```
public class NonAsyncReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context arg0, Intent arg1) {
    SystemClock.sleep(7000);
  }
}
```

Hence, if you click the “Send Non-Async Broadcast” button, not only will the button fail to return to its normal state for seven seconds, but the `EditText` will not respond to user input either.

The `AsyncReceiver`, though, uses `goAsync()`:

```
package com.commonsware.android.tuning.goasync;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class AsyncReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    final BroadcastReceiver.PendingResult result=goAsync();

    (new Thread() {
      public void run() {
        SystemClock.sleep(7000);
        result.finish();
      }
    }).start();
  }
}
```

The `goAsync()` method returns a `PendingResult`, which supports a series of methods that you might ordinarily fire on the `BroadcastReceiver` itself (e.g., `abortBroadcast()`) but want to do on a background thread. You need your background thread to have access to the `PendingResult` — in this case, via a `final` local variable. When you are done with your work, call `finish()` on the `PendingResult`.

If you click the “Send Async Broadcast” button, even though we are still sleeping for 7 seconds, we are doing so on a background thread, and so our user interface is still responsive.

Saving SharedPreferences

The classic way to save SharedPreferences.Editor changes was via a call to commit(). This writes the preference information to an XML file on whatever thread you are on — another hidden source of disk I/O you might be doing on the main application thread.

If you are on API Level 9, and you are willing to blindly try saving the changes, use the new apply() method on SharedPreferences.Editor, which works asynchronously.

If you need to support older versions of Android, or you really want the boolean return value from commit(), consider doing the commit() call in an AsyncTask or background thread.

And, of course, to support both of these, you will need to employ tricks like conditional class loading. You can see that used for saving SharedPreferences in the CPU-Java/PrefsPersist sample project. The activity reads in a preference, puts the current value on the screen, then updates the preference with the help of an AbstractPrefsPersistStrategy class and its persist() method:

```
package com.commonsware.android.tuning.prefs;

import android.app.Activity;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.widget.TextView;

public class PrefsPersistActivity extends Activity {
  private static final String KEY="counter";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    SharedPreferences prefs=
      PreferenceManager.getDefaultSharedPreferences(this);
    int counter=prefs.getInt(KEY, 0);

    ((TextView)findViewById(R.id.value)).setText(String.valueOf(counter));

    AbstractPrefsPersistStrategy.persist(prefs.edit().putInt(KEY, counter+1));
  }
}
```

AbstractPrefsPersistStrategy is an abstract base class that will hold a strategy implementation, depending on Android version. On pre-Honeycomb builds, it uses an implementation that forks a background thread to perform the commit():

```
package com.commonsware.android.tuning.prefs;

import android.content.SharedPreferences;
import android.os.Build;

abstract public class AbstractPrefsPersistStrategy {
  abstract void persistAsync(SharedPreferences.Editor editor);

  private static final AbstractPrefsPersistStrategy INSTANCE=initImpl();

  public static void persist(SharedPreferences.Editor editor) {
    INSTANCE.persistAsync(editor);
  }

  private static AbstractPrefsPersistStrategy initImpl() {
    int sdk=new Integer(Build.VERSION.SDK).intValue();

    if (sdk<Build.VERSION_CODES.HONEYCOMB) {
      return(new CommitAsyncStrategy());
    }

    return(new ApplyStrategy());
  }

  static class CommitAsyncStrategy extends AbstractPrefsPersistStrategy {
    @Override
    void persistAsync(final SharedPreferences.Editor editor) {
      (new Thread() {
        @Override
        public void run() {
          editor.commit();
        }
      }).start();
    }
  }
}
```

On Honeycomb and higher, it uses a separate strategy class that uses the new apply() method:

```
package com.commonsware.android.tuning.prefs;

import android.content.SharedPreferences.Editor;

public class ApplyStrategy extends AbstractPrefsPersistStrategy {

  @Override
  void persistAsync(Editor editor) {
    editor.apply();
  }
}
```

By separating the Honeycomb-specific code out into a separate class, we can avoid loading it on older devices and encountering the dreaded `VerifyError`.

Whether using the built-in `apply()` method is worth dealing with multiple strategies, versus simply calling `commit()` on a background thread, is up to you.

Improve Throughput and Responsiveness

Being efficient and doing work on the proper thread may still not be enough. It could be that your work is not consuming excessive CPU time, but is taking too long in "wall clock time" (e.g., the user sits waiting too long at a `ProgressDialog`). Or, it could be that your work, while efficient and in the background, is causing difficulty for foreground operations.

The following sections outline some common problems and solutions in this area.

Minimize Disk Writes

Earlier in this book, we emphasized moving disk writes off to background threads.

Even better is to get rid of some of the disk writes entirely.

A big culprit here comes in the form of database operations. By default, each `insert()`, `update()`, or `delete()`, or any `execSQL()` invocation that modifies data, will occur in its own transaction. Each transaction involves a set of disk writes. Many times, this is not a problem. But, if you are doing a lot of these – such as importing records from a CSV file — hundreds or thousands of transactions will mean thousands of individual disk writes, and that can take some time. You may wish to wrap those operations in your own transaction, using methods like `beginTransaction()`, simply to reduce the number of transactions and, therefore, disk writes.

If you are doing your own disk I/O beyond databases, you may encounter similar sorts of issues. Overall, it is better to do a few larger writes than lots of little ones.

Set Thread Priority

Threads you fork, by default, run at a default priority: `THREAD_PRIORITY_DEFAULT` as defined on the `Process` class. This is a lower priority than the main application thread (`THREAD_PRIORITY_DISPLAY`).

Threads you use via AsyncTask run at a lower priority (THREAD_PRIORITY_BACKGROUND). If you fork your own threads, then, you might wish to consider moving them to a lower priority as well, to affect how much time they get compared to the main application thread. You can do this via setThreadPriority() on the Process class.

The lowest possible priority, THREAD_PRIORITY_LOWEST, is described as “only for those who really, really don’t want to run if anything else is happening”. You might use this for “idle-time processing”, but bear in mind that the thread will be paused a lot to allow other threads to run.

Lower-priority threads will help ensure that your background work does not affect your foreground UI. Processes themselves are put in a lower-priority class as they move to the background (e.g., you have no activities visible), which further reduces the amount of CPU time you will be using at any given moment.

Also, note that IntentService uses a thread at default (*not* background) priority — you may wish to drop the priority of this thread to something that will be lower than your main application thread, to minimize how much CPU time the IntentService steals from your UI.

Do the Work Some Other Time

Just because you could do the work now does not mean you should do the work now. Perhaps a better answer is to do the work later, or do part of the work now and part of the work later.

For example, suppose that you have your own database of points of interest for your custom map application. Periodically, you publish a new database on your Web site, which your Android app should download. Odds are decent that the user is not in desperate need for this new database right away. In fact, the CPU time and disk I/O time to download and save the database might incrementally interfere with the foreground application, despite your best efforts.

In this case, not only should you check for and download the database when the user is unlikely to be using the device (e.g., before dawn), but you should check whether the screen is on via isScreenOn() on PowerManager, and delay the work to sometime when the screen is off. For example, you could have AlarmManager set up to have your code check for updates every 24 hours at 4am. If, at 4am, the screen is on, your code could skip the download and wait until tomorrow, or skip the download and add a one-shot alarm to wake you up in 30 minutes, in hopes that the user will no longer be using the device.

At the same time, you may wish to consider having a “refresh” menu choice somewhere, for when the user specifically wants you to go get the update (if available) *now*, for whatever reason.

Finding and Eliminating Jank

A user interface is considered "janky" if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Finding and eliminating the causes of janky behavior ("jank") is part science, part art, and part throwing darts at a dartboard.

This chapter will outline some techniques for identifying and removing jank from a user interface. The steps shown here originated in a blog post by Google's Romain Guy, with a few additional twists and turns due to the different nature of the particular case being studied. Mr. Guy's blog post is essential reading for all advanced Android developers, and the author is deeply indebted to Mr. Guy for his work in this area.

Prerequisites

The only hard prerequisite for this chapter is having read the core chapters and the chapter on finding CPU bottlenecks.

That being said, having read the chapter on animators would help understand portions of this chapter a bit better.

The Case: ThreePaneDemoBC

In the chapter on animators, we examined an implementation of the Gmail-style three-pane layout with animated transitions (a.k.a., "The Three-Fragment Problem"). The implementation shown there originated with a Stack Overflow question with the solution presented in this book offered as an answer.

A commenter on that answer pointed out that he detected some stutter, even on decent hardware.

This chapter reviews the steps that were taken to determine if we really are doing things incorrectly, what specifically we are doing wrong, and what can be done to fix it.

Are We Janky?

In the eyes of this book's author, the three-pane implementation presented in the chapter on animators was perfectly reasonable on good hardware.

There are two lessons to take from this:

1. It is better to come up with an objective definition for "jank" and test to see if your code meets that definition at various points
2. The author of this book is very tolerant of janky user interfaces

The results shown in the chapter on CPU measurement for the `gfxinfo` and `systrace` tools comes from the three-pane demo code. The `gfxinfo` and the `systrace` results both point to the three-pane demo spending too much time doing work and therefore dropping some number of frames. This lines up with the visual report, and indicates that we have some work to do to try to improve matters.

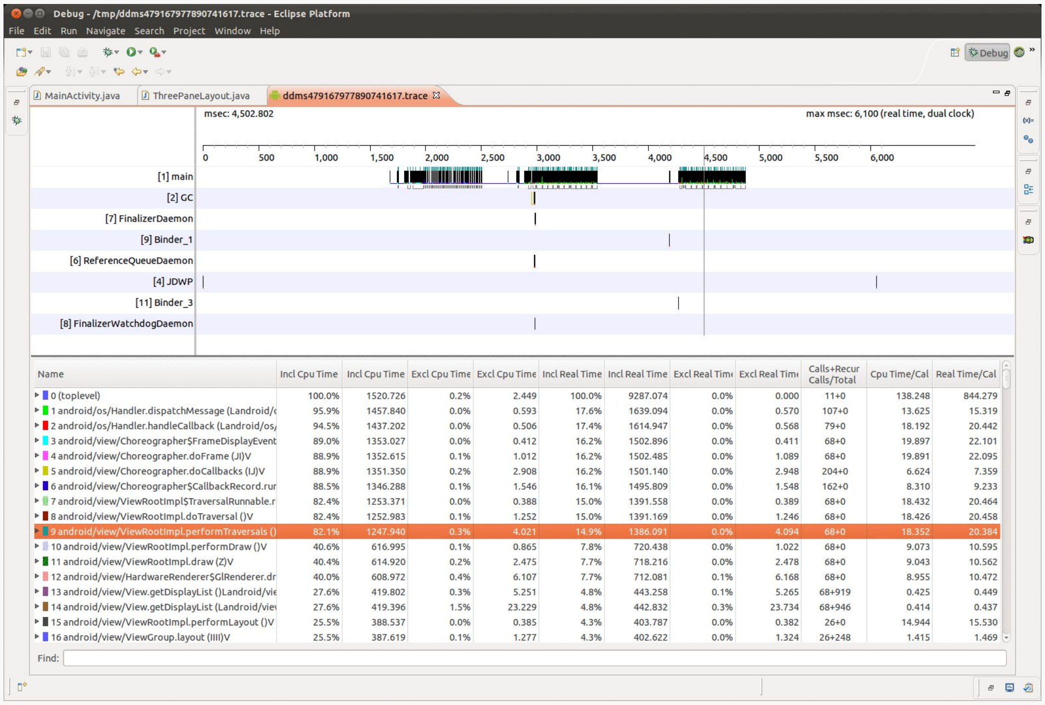
Finding the Source of the Jank

Just because we know that we are janky does not mean that we have any idea what to do about it. We need to conduct some further analysis to determine where, exactly, our jank is coming from.

Traceview

One thing that we can do to help further refine the source of our trouble is to use Traceview. As outlined in the section on Traceview, Traceview reports how many calls were made of various methods in our code (and in the framework code) and how much time was spent there.

Here are some of the results from a Traceview run on the three-pane demo on a Nexus 7:



Name	Incl Cpu Time	Incl Cpu Time	Excl Cpu Time	Excl Cpu Time	Incl Real Time	Incl Real Time	Excl Real Time	Excl Real Time	Calls+Recur Calls/Total	Cpu Time/Call	Real Time/Call

Figure 834: Traceview of Three-Pane Demo

We see that 88.9% of our CPU time is spent in `doFrame()` on `Choreographer` and the calls triggered from it. `doFrame()` is a private method which, as the name suggests, performs the drawing, processing, and executing of a single frame's worth of rendering. More importantly, we see that `doFrame()` was called 68 times during our test run, meaning that our UI changed 68 times during the ~3 seconds of activity during our trace.

Further down the table, we see that `layout()` on `ViewGroup` was called 26 times directly (and 248 more times via recursion), contributing about 25% of the time consumed by `doFrame()`. Since `layout()` is called on less than half of the `doFrame()` calls, the time consumed by `layout()` makes up a fairly significant portion of the `doFrame()` time during those 26 frames.

More importantly, `layout()` is something that *we* trigger. It implies that we have made some change to our UI content that requires a layout pass of some `ViewGroup`.

Having a layout pass on occasion is perfectly normal, particularly in response to user input. A `layout()` might be triggered by the user tapping on a row in one of our `ListViews`, for example. But we are not doing 26 user input events in our test — all we are doing is tapping one time each on a pair of `ListView` rows, then pressing the

BACK button. This implies that something else in our code is causing `layout()` to be needed.

Unfortunately, at this point, Traceview does not help much, because the calls to `layout()` are asynchronous with respect to our own code, so it will not be all that obvious where the extra calls are coming from. This is where we need some expert help, as we will see later in this chapter.

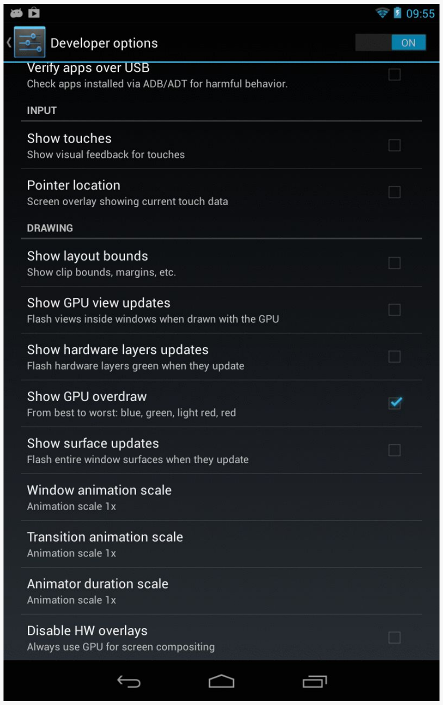
Overdraw

Another common source of jank is overdraw. Overdraw refers to the act of painting the same pixel several times, due to overlapping components. For example:

- The activity window itself has a background
- You have a container that fills the activity's content, such as a `ListView`, which has a background
- You have children in that container with backgrounds (row), who have their own children with backgrounds and, eventually, content (widgets like `ImageView` and `TextView`)

Places where there is overlap, the OS might set the color of a pixel several times per frame, wasting time.

The easiest way to track down overdraw is to use the "Show GPU overdraw" option in the Developer Options portion of the Settings app:



Verify apps over USB ☐
Check apps installed via ADB/ADT for harmful behavior.

INPUT

Show touches ☐
Show visual feedback for touches

Pointer location ☐
Screen overlay showing current touch data

DRAWING

Show layout bounds ☐
Show clip bounds, margins, etc.

Show GPU view updates ☐
Flash views inside windows when drawn with the GPU

Show hardware layers updates ☐
Flash hardware layers green when they update

Show GPU overdraw ☑
From best to worst: blue, green, light red, red

Show surface updates ☐
Flash entire window surfaces when they update

Window animation scale
Animation scale 1x

Transition animation scale
Animation scale 1x

Animator duration scale
Animation scale 1x

Disable HW overlays ☐
Always use GPU for screen compositing

Figure 835: Nexus 7 Developer Options, with "Show GPU overdraw"

This option is only available on Android 4.2 and higher.

When you enable this option, then restart your app's process (if it was already running), Android will shade pixels that are overdrawn:

- Blue for pixels that are drawn twice
- Green for pixels that are drawn three times
- Pink for pixels that are drawn four times
- Red for pixels that are drawn five or more times

In short: pink and red are bad. Green and blue are OK, though if you have large patches of either shade, you might consider trying to see if there's a way to get rid of the overdraw.

Of course, the fact that these are shades applied to existing pixel colors may make it a bit difficult to tell exactly where the overdraw is occurring. For example, a red portion of your UI might be red from overdraw… or it might be red because you made it red. Temporarily changing your color scheme to something else (e.g., yellow) will help distinguish what is overdraw and what is just the natural UI coloration.

If you enable this option on a Nexus 7 and run the three-pane demo, you will see very little blue or green (beyond the normal blue of the activated state of our `ListView` rows), and virtually no red:

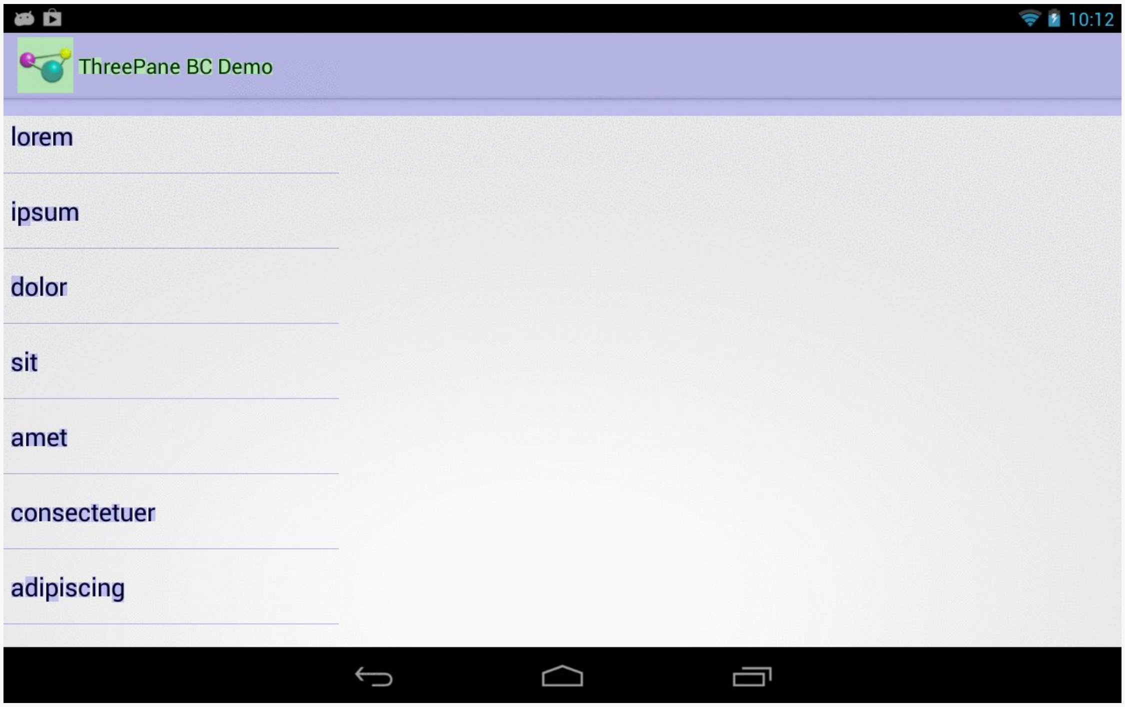


Figure 836: Three-Pane Demo, As Initially Launched, Showing Overdraw

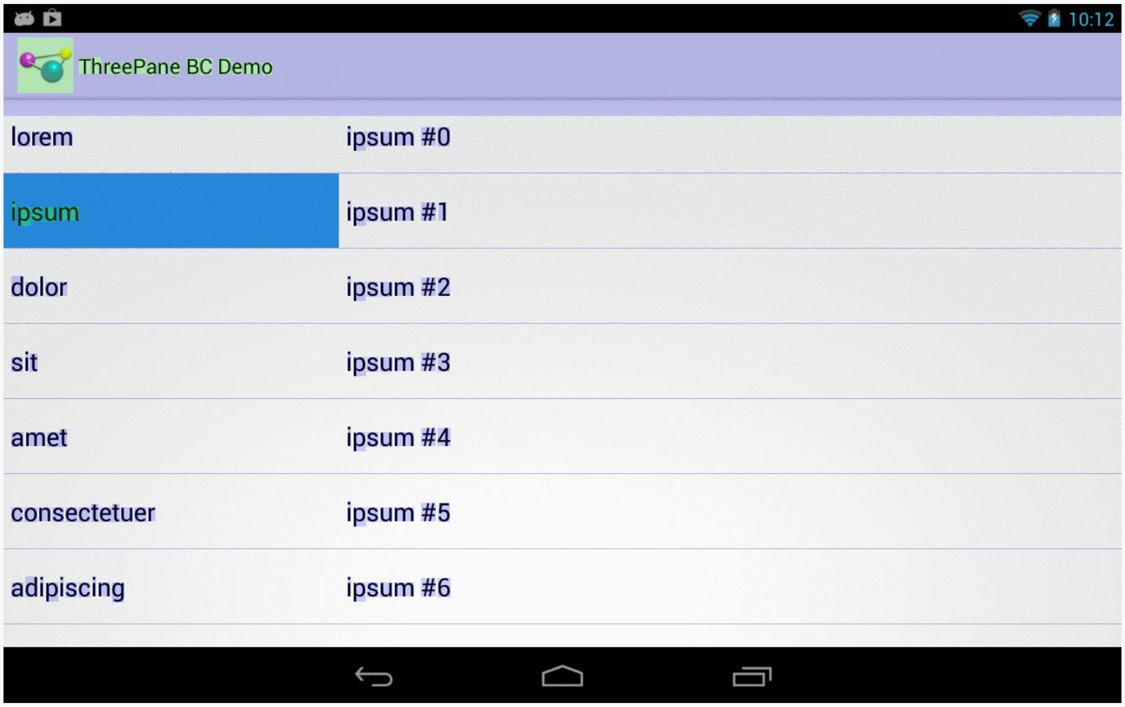

Figure 837: Three-Pane Demo, Left and Middle Panes, Showing Overdraw

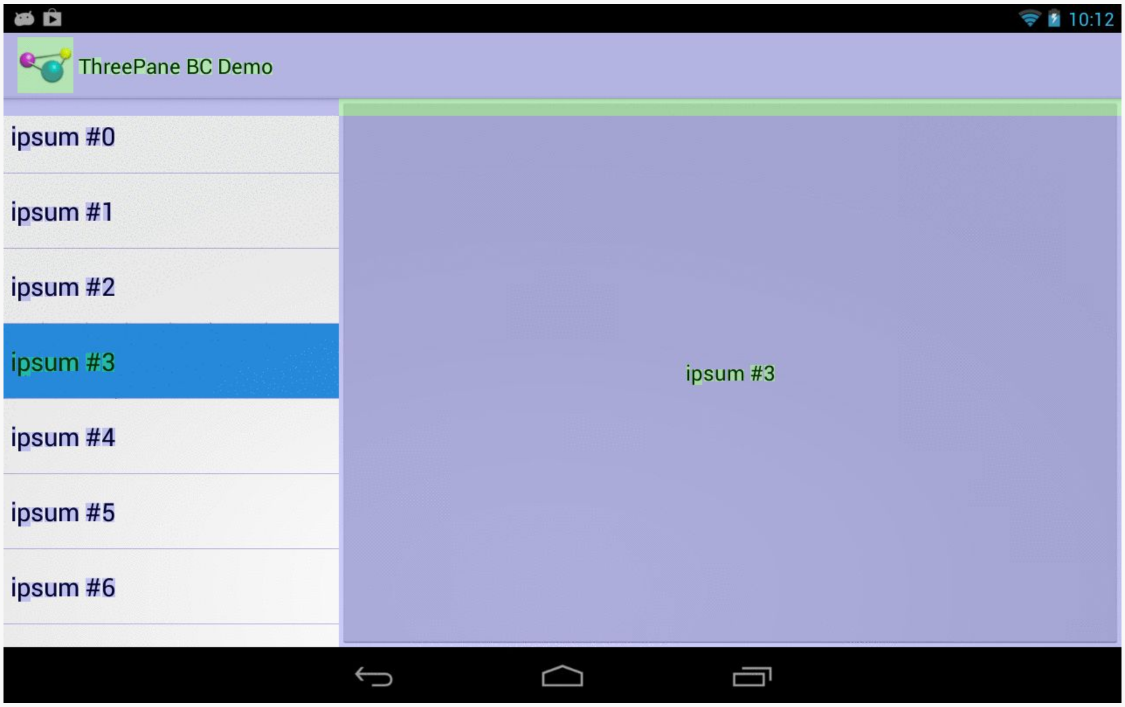

Figure 838: Three-Pane Demo, Middle and Right Panes, Showing Overdraw

sit	ipsum #3
amet	ipsum #4
consectetuer	ipsum #5
adipiscing	ipsum #6

Figure 839: Three-Pane Demo, Left and Middle Panes Via BACK, Showing Overdraw

On the other hand, bringing up the Contacts app on the same Nexus 7 shows significantly more overdraw:

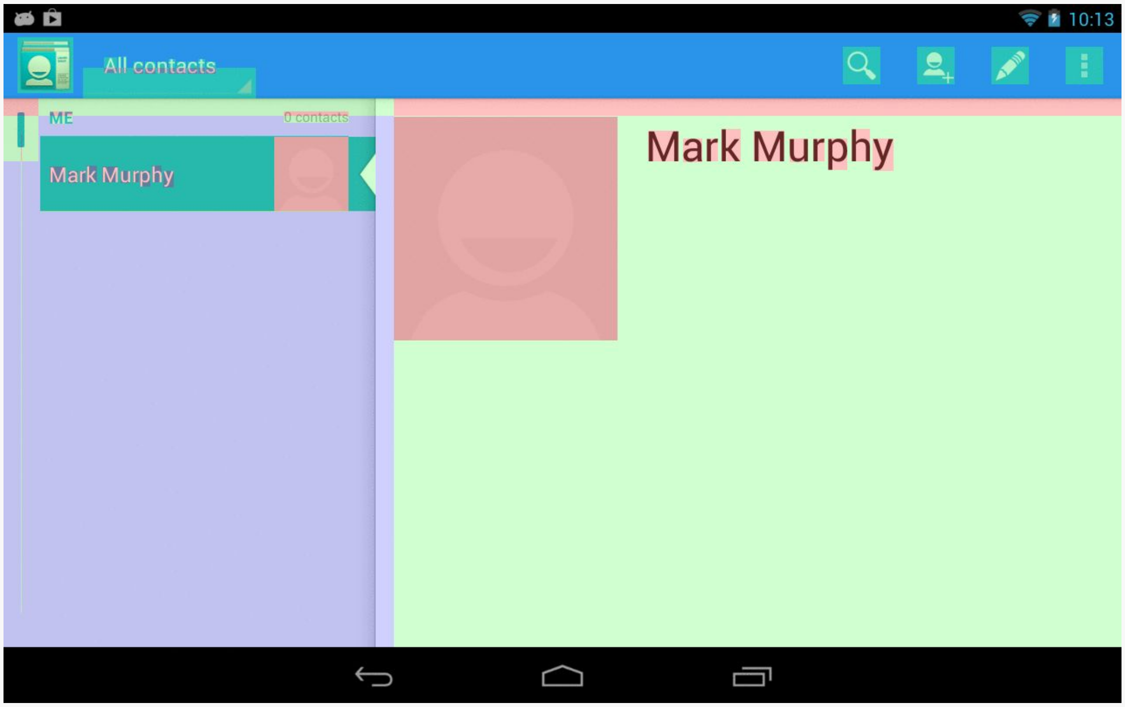

Figure 840: Contacts App, Showing Overdraw

The good news is that our app is not suffering performance problems due to overdraw.

The bad news is that the Contacts app is.

The good news is that if you are reading this, you are probably not responsible for maintaining the Contacts app.

The Contacts app's major problems come from the contact photos, or placeholders as seen here. Either the `ImageView` has a background, or the `ImageView` fills some container with a background. For example, the `ImageView` might be in some container with a background to provide a bevel effect around the image. Making the portion of the background that is behind the `ImageView` be transparent will eliminate the overdraw.

Note: some GPU architectures can automatically fix overdraw in select places, while others cannot. Notably, the Tegra 3 cannot. Hence, the Tegra 3 is a good test platform for using this overdraw-detection feature of Android.

Extraneous Views

Another related source of jank is having too many extraneous views. Each widget and container contributes to the cost of drawing the overall UI, so having extraneous views adds overhead.

Perhaps the most common scenario for extraneous views is the single-child container. If a container will only ever hold one child, perhaps you can get rid of that container. Not only will this speed up execution at runtime, but it can help avoid running out of stack space.

One likely way to find these extraneous views is to bring up your user interface in Hierarchy View on an emulator (or possibly on a device by using `ViewServer`). In particular, single-child containers are fairly obvious — look for bubbles that have just one child bubble on the right.

There are two such cases in the UI for our three-pane demo, though neither are our fault.

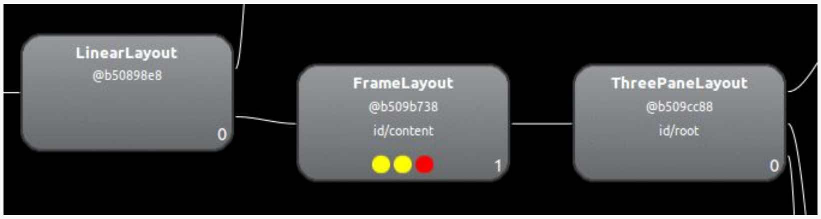

Figure 841: Single-Child FrameLayout in Three-Pane Demo, from Hierarchy View

Here, we have a `FrameLayout` holding onto just one child, our `ThreePaneLayout` custom view. We set up `ThreePaneLayout` as being our activity's content view. The "content view" of an activity is poured into a `FrameLayout`, supplied by the Android framework — that is the `FrameLayout` seen in Hierarchy View. We have no good way to get rid of this `FrameLayout`. Fortunately, `FrameLayout` is a very cheap container, in terms of runtime execution speed.

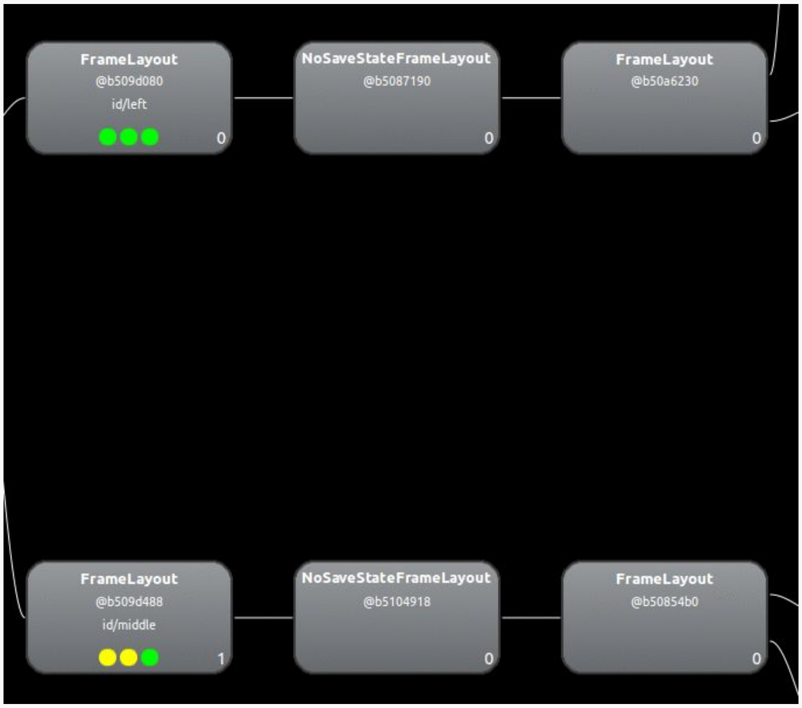

Figure 842: More Single-Child Containers in Three-Pane Demo, from Hierarchy View

Here, we see that our left and middle `FrameLayout` containers, for our left and middle panes, each contain one child, a `NoSaveStateFrameLayout`, which in turn each hold one child, a `FrameLayout`. These containers are added by `ListFragment`, not directly by our code. A `ListFragment` is surprisingly complex, adding several widgets and containers beyond the `ListView` itself:

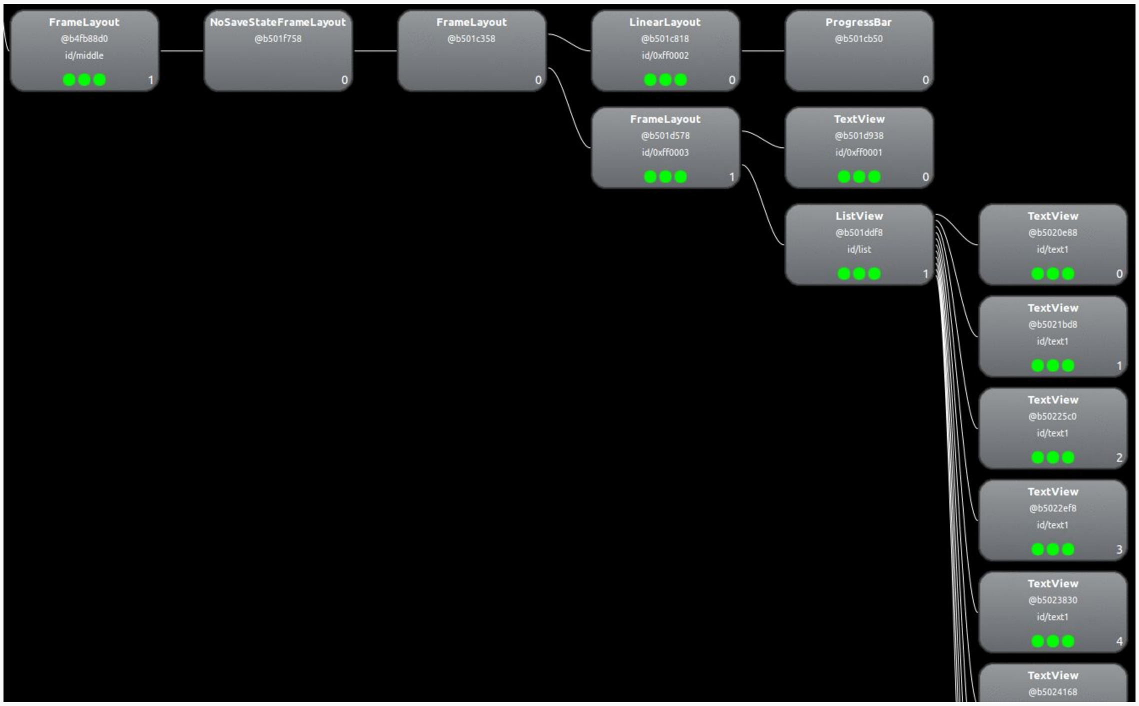

Figure 843: Contents of a ListFragment, from Hierarchy View

Short of writing our own fragment for holding a `ListView`, there is nothing we can do about these extraneous views.

Conclusion: Too Many layout() Calls?

Given that overdraw does not seem to be a problem and that we have few extraneous views under our control, it would seem that perhaps we should return our attention to the extra `layout()` calls. While trying to get rid of the `ListFragment` extraneous views would make those `layout()` calls incrementally cheaper, we will get more value by getting rid of the unnecessary calls in the first place, if indeed they are unnecessary.

Where Things Went Wrong

Of course, it doesn't hurt to call in an expert, to try to confirm exactly what is going on.

Chet Haase — Google engineer on Android, celebrated book author, and part-time comedian – chimed in with an answer to a Stack Overflow question about this threepane animation, asked by the person who commented about the dropped frames on the original Stack Overflow question.

The key statement from his answer was:

> Sliding things around is fine (translationX/Y), fading things in/out is good (alpha), but actually laying things out on every frame? Just say no.

Specifically, he is referring to our use of `ObjectAnimator` to change the width of the middle pane as we show and hide the right pane. Each time we change the width of the middle pane, we trigger a `layout()` call, to reposition the child widgets within that pane as needed. Our animations are adding ~20 `layout()` calls, introducing overhead that is pushing us over the per-frame limit on the Nexus 7.

Removing the Jank

To remove the jank, we need to remove the `ObjectAnimator` changing the width of the middle pane on the fly. You can see the results of this in the `Jank/ThreePaneBC` sample app.

Now, our `showLeft()` and `hideLeft()` methods immediately change the width of the middle pane, rather than arranging its animation:

```
public void hideLeft() {
  if (leftWidth == -1) {
    leftWidth=left.getWidth();
    middleWidthNormal=middle.getWidth();
    resetWidget(left, leftWidth);
    resetWidget(middle, middleWidthNormal);
    resetWidget(right, middleWidthNormal);
    requestLayout();
  }

  translateWidgets(-1 * leftWidth, left, middle, right);
  setMiddleWidth(leftWidth);
}

public void showLeft() {
  translateWidgets(leftWidth, left, middle, right);
  setMiddleWidth(middleWidthNormal);
}

private void setMiddleWidth(int value) {
  middle.getLayoutParams().width=value;
  requestLayout();
}
```

This does not provide nearly as good of a UI as the original. However, the revised solution does reduce the jank, as seen in this `gfxinfo` output:

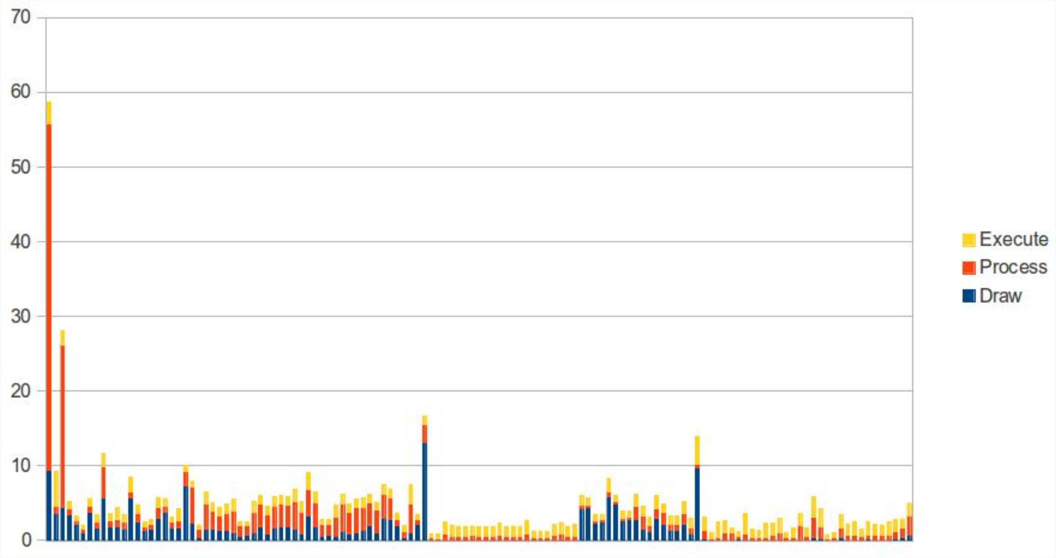

Figure 844: gfxinfo Output of Revised ThreePaneDemoBC

There are probably ways to improve upon the revised jank-free implementation. Lacking that, it is up to you to decide if the amount of jank found in the original implementation is worth the improved animation or not.

Issues with Bandwidth

As anyone who owned an Apple Newton or Palm V PDA back in the 1990's knows, handheld devices have been around for quite some time. For a very long time, they were a niche product, associated with geeks, nerds, and the occasional business executive.

Internet access changed all of that.

Blackberry for enterprise messaging — an outgrowth of its original two-way paging approach — blazed part of the trail, but the concept "crossed the chasm" to ordinary people with the advent of the iPhone, Android devices, and similar equipment.

Therefore, it is not terribly surprising when Android developers want to add Internet capabilities to their apps. To the contrary, it is almost unusual when you encounter an app that does *not* want to use the Internet for something or another.

However, mobile Internet access inherits all of the classic problems of Internet access (e.g., "server not found") and adds new and exciting challenges, all of which can leave a developer with an app that has performance issues.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

You’re Using Too Much of the Slow Stuff

To paraphrase America’s Founding Fathers, “all Internet connections are not created equal”.

One form of inequality is speed. Different classes of connection have different theoretical upper bounds. WiMAX and other 4G connections are theoretically faster than 3G connections, which are theoretically faster than 2G or EDGE connections. WiFi is theoretically ridiculously fast though it is typically limited by the ISP connection, and ISP connections can run the gamut from really fast to merely good.

However, “theoretical” bounds tend to run afoul of reality. There are plenty of places where high-speed mobile data connections are non-existent, despite what the carriers’ coverage maps claim. 2G mobile data works, but is not especially speedy. This layers on top of the typical Internet congestion issues, along with typically transitory problems (e.g., trying to get connectivity while attending a technology conference keynote presentation).

Beyond that, there are financial issues. While WiFi is usually unmetered (no incremental cost per MB/GB), many mobile data connections are metered. Those mobile data connections that are not metered in theory – advertised as “unlimited” — have usage caps that, once exceeded, impose costs or impose speed limits.

Hence, what runs quickly in the lab may run much more slowly in users’ hands.

If you followed the instructions in previous chapters on CPU bottlenecks, the limited bandwidth will not cause your UI to become “janky”, in that it will be responsive to touches and taps. However, poor connectivity will mean that you are simply slow to respond to user requests. For example, clicking the “check for new email” menu button has no immediate effect. If you feel that you need a splash screen or progress indicator to tell the user that “we are really checking for new email, honest”, then you know that your Internet access is slower than is ideal.

Obviously, some of this is unavoidable. However, the objective of the chapters in this part of the book is to give you an idea of ways to reduce your bandwidth consumption, making those delays be that much less annoying for your users.

You're Using Too Much of the Expensive Stuff

Mobile data tends to come with more strings attached than does WiFi.

In the US, it used to be that mobile data connections included unlimited usage. Now, at best, a mobile data plan has "unlimited" usage for a curious definition of the term "unlimited". More and more carriers are moving towards a hard cap — go above the cap, and you either cannot use more bandwidth, have your speeds curtailed, or pay significantly for additional bandwidth.

Outside of the US, the "pay significantly for bandwidth" approach is fairly typical. So-called "metered" data plans simply charge you such-and-so per MB or GB of bandwidth.

And, to top it off, roaming almost always is a metered plan. So, a US resident traveling overseas, even with a SIM and phone that supports international usage, would pay a ridiculous sum for bandwidth. Stories of phone bills in the tens of thousands of dollars abound, where people simply used their phone as they normally would when they were outside of their home network.

Hence, if you use a fair bit of bandwidth, it would be really nice if you offered users means to consume less of it when they are on mobile data compared to WiFi (which is typically unmetered). You could elect to poll your server less frequently, for example, giving the users the ability to specify separate polling periods depending on which type of connection they have.

And, of course, there are other "costs" for using bandwidth besides direct monetary costs. For example, downloading data over a slower mobile data connection may consume more power than downloading the same data over WiFi — while the WiFi radio might consume additional power, the time difference might account for more power consumption, if the CPU could be powered down for the rest of that time.

These chapters will show you how you can react to changes in connectivity and approaches for how to use that information to reduce costs for the user.

You're Using Too Much of Somebody Else's Stuff

It is easy for developers to think that they alone are using a user's device. Alas, this is infrequently the case, particularly when it comes to background Internet access.

While your application is busily downloading stuff, some other application might be busily downloading stuff. In principle, this should not be an issue, as multiple applications can access the Internet simultaneously. However, bandwidth can become an issue. If you are in the background, and the other application is in the foreground, the user might notice that bandwidth is an issue. For example, users might be unhappy if your downloads are impeding their ability to watch streaming video, or play their favorite Android-based MMORPG, or whatever.

A polite Android application will test to see whether the foreground application is heavily using the Internet and will curtail its own Internet use while that is going on. This chapter will help you learn how to make that determination and how to respond.

You're Using Too Much… And There Is None

Not only might location dictate how much bandwidth you have, but whether you have any bandwidth at all.

While some people think that the entire planet has connectivity, reality once again dictates otherwise. Major metropolitan areas have connectivity. Outlying areas are much more hit-or-miss. Voice is sometimes a challenge, let alone data. And it only *seems* as though there is a Starbucks every 100 meters in the US, which might actually provide blanket WiFi coverage.

Then, of course, there are planes (many still do not offer in-flight WiFi at this time), international travel without an international-capable phone plan, and so on.

Some Android applications have the potential to still offer near-complete functionality despite this, with a bit of user assistance. For example, Google Maps for Android has an offline caching feature, which will download data for a 10-mile radius from a given point, for use while the device is otherwise offline.

Here, the issue becomes less one of bandwidth (other than detecting that you have no connection) and more one of caching and storage. The space-related issues that these techniques can raise will be covered elsewhere in this book.

Focus On: TrafficStats

To be able to have more intelligent code — code that can adapt to Internet activity on the device — Android offers the `TrafficStats` class. This class really is a gateway to a block of native code that reports on traffic usage for the entire device and per-application, for both received and transmitted data. This chapter will examine how you can access `TrafficStats` and interpret its data.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

TrafficStats Basics

The `TrafficStats` class is not designed to be instantiated — you will not be invoking a constructor by calling `new TrafficStats()` or something like that. Rather, `TrafficStats` is merely a collection of static methods, mapped to native code, that provide access to point-in-time traffic values. No special permissions are needed to use any of these methods. Most of the methods were added in API Level 8 and therefore should be callable on most Android devices in use today.

Device Statistics

If you are interested in overall traffic, you will probably care most about the `getTotalRxBytes()` and `getTotalTxBytes()` on `TrafficStats`. These methods return received and transmitted traffic, respectively, measured in bytes.

You also have:

1. `getTotalRxPackets()` and `getTotalTxPackets()`, if for your case measuring IP packets is a better measure than bytes
2. `getMobileRxBytes()` and `getMobileTxBytes()`, which return the traffic going over mobile data (also included in the total)
3. `getMobileRxPackets()` and `getMobileTxPackets()`, which are the packet counts for the mobile data connection

Per-Application Statistics

Technically, `TrafficStats` does not provide per-application traffic statistics. Rather, it provides per-UID traffic statistics. In most cases, the UID (user ID) of an application is unique, and therefore per-UID statistics map to per-application statistics. However, it is possible for multiple applications to share a single UID (e.g., via the `android:sharedUserId` manifest attribute) — in this case, `TrafficStats` would appear to provide traffic data for all applications sharing that UID.

There are per-UID equivalents of the first four methods listed in the previous section, replacing “Total” with “Uid”. So, to find out overall traffic for an application, you could use `getUidRxBytes()` and `getUidTxBytes()`. However, these are the only two UID-specific methods that were implemented in API Level 8. Equivalents of the others (e.g., `getUidRxPackets()`) were added in API Level 12. API Level 12 also added some TCP-specific methods (e.g., `getUidTcpTxBytes()`). Note, though, that the mobile-only method are only available at the device level; there are no UID-specific versions of those methods.

Interpreting the Results

You will get one of two types of return value from these methods.

In theory, you will get the value the method calls for (e.g., number of bytes, number of packets). The documentation does not state the time period for that value, so while it is possible that it is really “number of bytes since the device was booted”, we do not know that for certain. Hence, `TrafficStats` results should be used for comparison purposes, either comparing the same value over time or comparing multiple values at the same time. For example, to measure bandwidth consumption, you will need to record the `TrafficStats` values at one point in time, then again later — the difference between them represents the consumed bandwidth during that period of time.

In practice, while the "total" methods seem reliable, the per-UID methods may return `-1`. Three possible meanings are:

1. The device is old and is not set up to measure per-UID values
2. There has been no traffic of that type on that UID since boot, or
3. You do not have permission to know the traffic of that type on that UID

Hence, the per-UID values are a bit "hit or miss", which you will need to take into account.

Example: TrafficMonitor

To illustrate the use of `TrafficStats` methods and analysis, let us walk through the code associated with the `Bandwidth/TrafficMonitor` sample application. This is a simple activity that records a snapshot of the current traffic levels on startup, then again whenever you tap a button. On-screen, it will display the current value, previous value, and difference ("delta") between them. In LogCat, it will dump the same information on a per-UID basis.

TrafficRecord

It would have been nice if `TrafficStats` were indeed an object that you would instantiate, that captured the traffic values at that moment in time. Alas, that is not how it was written, so we need to do that ourselves. In the `TrafficMonitor` project, this job is delegated to a `TrafficRecord` class:

```
package com.commonsware.android.tuning.traffic;

import android.net.TrafficStats;

class TrafficRecord {
  long tx=0;
  long rx=0;
  String tag=null;

  TrafficRecord() {
    tx=TrafficStats.getTotalTxBytes();
    rx=TrafficStats.getTotalRxBytes();
  }

  TrafficRecord(int uid, String tag) {
    tx=TrafficStats.getUidTxBytes(uid);
    rx=TrafficStats.getUidRxBytes(uid);
    this.tag=tag;
  }
}
```

There are two separate constructors, one for the total case and one for the per-UID case. The total case just logs `getTotalRxBytes()` and `getTotalTxBytes()`, while the per-UID case uses `getUidRxBytes()` and `getUidTxBytes()`. The per-UID case also stores a "tag", which is simply a `String` identifying the UID for this record — as you will see, `TrafficMonitor` uses this for a package name.

TrafficSnapshot

An individual `TrafficRecord`, though, is insufficient to completely capture the traffic figures at a moment in time. We need a collection of `TrafficRecord` objects, one for the device ("total") and one per running UID. The work to collect all of that is handled by a `TrafficSnapshot` class:

```
package com.commonsware.android.tuning.traffic;

import java.util.HashMap;
import android.content.Context;
import android.content.pm.ApplicationInfo;

class TrafficSnapshot {
  TrafficRecord device=null;
  HashMap<Integer, TrafficRecord> apps=
    new HashMap<Integer, TrafficRecord>();

  TrafficSnapshot(Context ctxt) {
    device=new TrafficRecord();

    HashMap<Integer, String> appNames=new HashMap<Integer, String>();

    for (ApplicationInfo app :
          ctxt.getPackageManager().getInstalledApplications(0)) {
      appNames.put(app.uid, app.packageName);
    }

    for (Integer uid : appNames.keySet()) {
      apps.put(uid, new TrafficRecord(uid, appNames.get(uid)));
    }
  }
}
```

The constructor uses `PackageManager` to iterate over all installed applications and builds up a `HashMap`, mapping the UID to a `TrafficRecord` for that UID, tagged with the application package name (e.g., `com.commonsware.android.tuning.traffic`). It also creates one `TrafficRecord` for the device as a whole.

TrafficMonitorActivity

`TrafficMonitorActivity` is what creates and uses `TrafficSnapshot` objects. This is a fairly conventional activity with a TableLayout-based UI:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/table"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <Button
    android:onClick="takeSnapshot"
    android:text="Take Snapshot"/>

  <TableRow>

    <TextView
      android:layout_column="1"
      android:layout_gravity="right"
      android:text="@string/received"
      android:textSize="20sp"/>

    <TextView
      android:layout_gravity="right"
      android:text="@string/sent"
      android:textSize="20sp"/>
  </TableRow>

  <TableRow>

    <TextView
      android:layout_marginRight="@dimen/margin_right"
      android:gravity="right"
      android:text="@string/latest"
      android:textSize="20sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/latest_rx"
      android:layout_marginRight="@dimen/margin_right"
      android:gravity="right"
      android:textSize="20sp"/>

    <TextView
      android:id="@+id/latest_tx"
      android:gravity="right"
      android:textSize="20sp"/>
  </TableRow>

  <TableRow>

    <TextView
      android:layout_marginRight="@dimen/margin_right"
      android:gravity="right"
      android:text="@string/previous"
      android:textSize="20sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/previous_rx"
      android:layout_marginRight="@dimen/margin_right"
      android:gravity="right"
      android:textSize="20sp"/>

    <TextView
      android:id="@+id/previous_tx"
      android:gravity="right"
      android:textSize="20sp"/>
  </TableRow>

  <TableRow>

    <TextView
      android:layout_marginRight="@dimen/margin_right"
      android:gravity="right"
      android:text="@string/delta"
      android:textSize="20sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/delta_rx"
      android:layout_marginRight="@dimen/margin_right"
      android:gravity="right"
      android:textSize="20sp"/>

    <TextView
      android:id="@+id/delta_tx"
      android:gravity="right"
      android:textSize="20sp"/>
  </TableRow>

</TableLayout>
```

The activity implementation consists of three methods. There is your typical `onCreate()` implementation, where we initialize the UI, get our hands on the `TextView` widgets for output, and take the initial snapshot:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    latest_rx=(TextView)findViewById(R.id.latest_rx);
    latest_tx=(TextView)findViewById(R.id.latest_tx);
    previous_rx=(TextView)findViewById(R.id.previous_rx);
    previous_tx=(TextView)findViewById(R.id.previous_tx);
    delta_rx=(TextView)findViewById(R.id.delta_rx);
    delta_tx=(TextView)findViewById(R.id.delta_tx);

    takeSnapshot(null);
  }
```

The takeSnapshot() method creates a new TrafficSnapshot (held in a latest data member) after moving the last TrafficSnapshot to a previous data member. It then updates the TextView widgets for the latest data and, if the previous data member is not null, also for the previous snapshot and the difference between them. This alone is sufficient to update the UI, but we also want to log per-UID data to LogCat:

```
public void takeSnapshot(View v) {
  previous=latest;
  latest=new TrafficSnapshot(this);

  latest_rx.setText(String.valueOf(latest.device.rx));
  latest_tx.setText(String.valueOf(latest.device.tx));

  if (previous!=null) {
    previous_rx.setText(String.valueOf(previous.device.rx));
    previous_tx.setText(String.valueOf(previous.device.tx));

    delta_rx.setText(String.valueOf(latest.device.rx-previous.device.rx));
    delta_tx.setText(String.valueOf(latest.device.tx-previous.device.tx));
  }

  ArrayList<String> log=new ArrayList<String>();
  HashSet<Integer> intersection=new HashSet<Integer>(latest.apps.keySet());

  if (previous!=null) {
    intersection.retainAll(previous.apps.keySet());
  }

  for (Integer uid : intersection) {
    TrafficRecord latest_rec=latest.apps.get(uid);
    TrafficRecord previous_rec=
          (previous==null ? null : previous.apps.get(uid));

    emitLog(latest_rec.tag, latest_rec, previous_rec, log);
  }

  Collections.sort(log);

  for (String row : log) {
    Log.d("TrafficMonitor", row);
  }
}
```

One possible problem with the snapshot system is that the process list may change between snapshots. One simple way to address this is to only log to LogCat data where the application's UID exists in both the previous and latest snapshots. Hence, takeSnapshot() uses a HashSet and retainAll() to determine which UIDs exist in both snapshots. For each of those, we call an emitLog() method to record the data to an ArrayList, which is then sorted and dumped to LogCat.

The emitLog() method builds up a line with the package name and bandwidth consumption information, assuming that there is bandwidth to report (i.e., we have a value other than -1):

```
private void emitLog(CharSequence name, TrafficRecord latest_rec,
                      TrafficRecord previous_rec,
                      ArrayList<String> rows) {
  if (latest_rec.rx>-1 || latest_rec.tx>-1) {
    StringBuilder buf=new StringBuilder(name);

    buf.append("=");
    buf.append(String.valueOf(latest_rec.rx));
    buf.append(" received");

    if (previous_rec!=null) {
      buf.append(" (delta=");
      buf.append(String.valueOf(latest_rec.rx-previous_rec.rx));
      buf.append(")");
    }

    buf.append(", ");
    buf.append(String.valueOf(latest_rec.tx));
    buf.append(" sent");

    if (previous_rec!=null) {
      buf.append(" (delta=");
      buf.append(String.valueOf(latest_rec.tx-previous_rec.tx));
      buf.append(")");
    }

    rows.add(buf.toString());
  }
}
```

Since the lines created by emitLog() start with the package name, and since we are sorting those before dumping them to LogCat, they appear in LogCat in sorted order by package name.

Using TrafficMonitor

Running the activity gives you the initial received and sent counts (in bytes):

	Received	Sent
Latest	254326126	126645374
Previous		
Delta		

Figure 845: The TrafficMonitor sample application, as initially launched

Tapping Take Snapshot grabs a second snapshot and compares the two:

	Received	Sent
Latest	254328236	126647372
Previous	254326126	126645374
Delta	2110	1998

Figure 846: The TrafficMonitor sample application, after Take Snapshot was clicked

Also, LogCat will show how much was used by various apps:

```

```

Other Ways to Employ TrafficStats

Of course, there are more ways you could use `TrafficStats` than simply having an activity to report them on a button click. `TrafficMonitor` is merely a demonstration of using the class and providing a lightweight way to get value out of that data. Depending upon your application's operations, though, you may wish to consider using `TrafficStats` in other ways, in your production code or in your test suites.

In Production

If your app is a bandwidth monitor, the need to use `TrafficStats` is obvious. However, even if your app does something else, you may wish to use `TrafficStats` to understand what is going on in terms of Internet access within your app or on the device as a whole.

For example, you might want to consider bandwidth consumption to be a metric worthy of including in the rest of the "analytics" you generate from your app. If you are using services like Flurry to monitor which activities get used and so on, you might consider also logging the amount of bandwidth your application consumes. This not only gives you much more "real world" data than you will be able to collect on your own, but it may give you ideas of how users are using your application beyond what the rest of your metrics are reporting.

Another possibility would be to include your app's bandwidth consumption in error logs reported via libraries like ACRA. Just as device particulars can help identify certain bug report patterns, perhaps certain crashes of your app only occur when users are using a lot of bandwidth in your app, or using a lot of bandwidth elsewhere and perhaps choking your own app's Internet access.

The chapter on bandwidth mitigation strategies will also cover a number of uses of `TrafficStats` for real-time adjustment of your application logic.

During Testing

You might consider adding `TrafficStats`-based bandwidth logging for your application in your test suites. While individual tests may or may not give you useful data, you may be able to draw trendlines over time to see if you are consuming more or less bandwidth than you used to. Take care to factor in that you may have changed the tests, in addition to changing the code that is being tested.

From a JUnit-based unit test suite, measuring bandwidth consumption is not especially hard. You can bake it into the `setUp()` and `tearDown()` methods of your test cases, either via inheritance or composition, and log the output to a file or LogCat.

From an external test engine, like monkeyrunner or NativeDriver, recording bandwidth usage is more tricky, because your test code is not running on the device or emulator. You may have to include a `BroadcastReceiver` in your production code that will log bandwidth usage and trigger that code via the `am broadcast` shell command.

Measuring Bandwidth Consumption

The first step towards addressing bandwidth concerns is to get a better picture of how much bandwidth you are actually consuming, when, and under what conditions. Only then will you be able to determine where your efforts need to be applied and whether those efforts are actually giving you positive results. This chapter will examine a handful of ways you can determine how much bandwidth you are really using in your application.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

On-Device Measurement

Many times, you are best served by measuring your bandwidth consumption right on the device itself:

1. This is your only option for gathering bandwidth metrics from copies of your app in end users' hands, unless they invite you to their home or office and have you sniff on their personal network, which seems unlikely
2. This is your only option for gathering bandwidth metrics when you are using mobile data plans (e.g., 3G) instead of WiFi, since you probably do not control the wireless telecommunications infrastructure in your area
3. This is your simplest option for tying bandwidth metrics to events within your app or occurring on the device

4. This is your only option for using bandwidth metrics to adjust your application behavior in real time, in addition to using the metrics to learn how best to adjust your code in future updates to the app

Hence, in addition to perhaps other off-device techniques, you really should consider one of the on-device approaches outlined in the following sections.

Yourself, via TrafficStats

The preceding chapter outlined how to use the `TrafficStats` class to collect metrics on the bandwidth consumed by applications (including yours) and for the device as a whole. This gives you the most flexibility, because you can write your own code to collect whatever portion of this data you need. It can address all of the bullets shown above, for example.

It is not perfect, though:

1. It requires you to write your own code, adding yet more work to your plate
2. Per-UID traffic data may or may not be available, depending upon the device

Data Usage Screen in Settings

For more casual use, the Settings app in most Android devices offers a “Data Usage” screen that shows how much bandwidth has been consumed over a period of time:

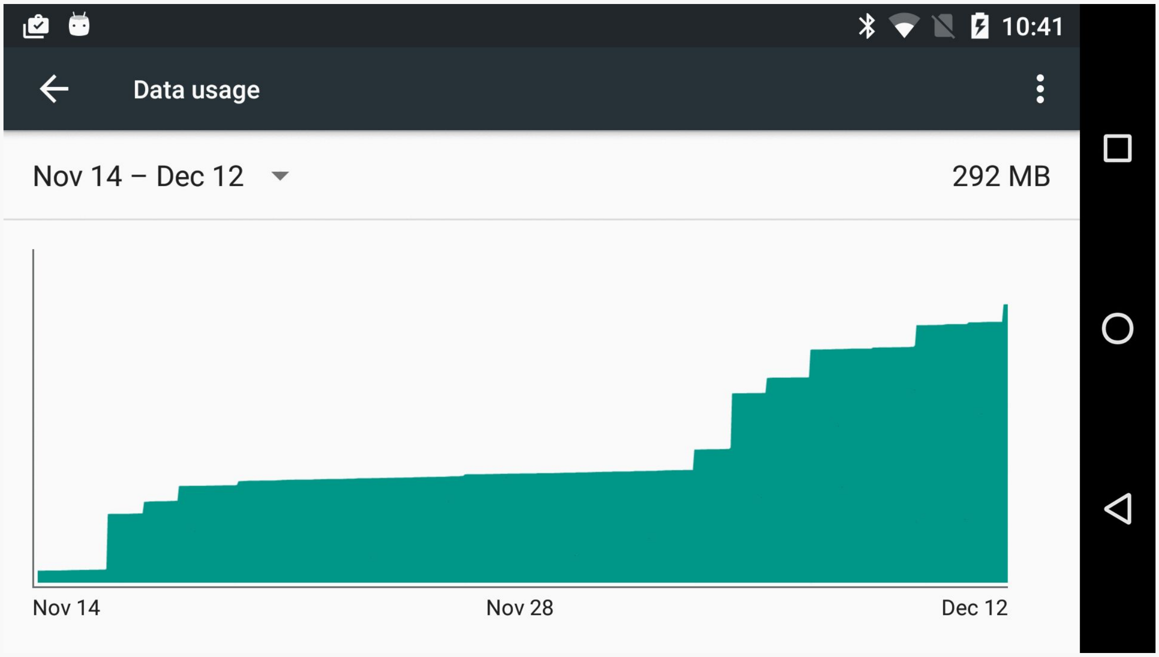

Figure 847: Settings, App, Data Usage Screen, Data Usage Graph

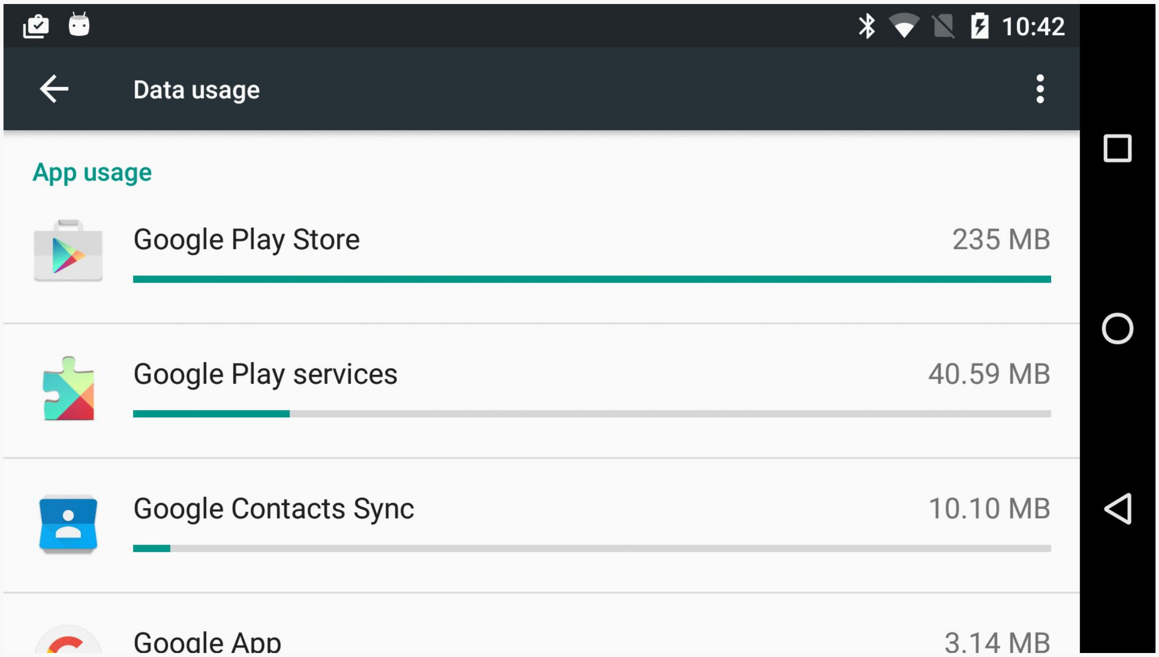
Scrolling further down will give you details of what apps were involved in that data usage:

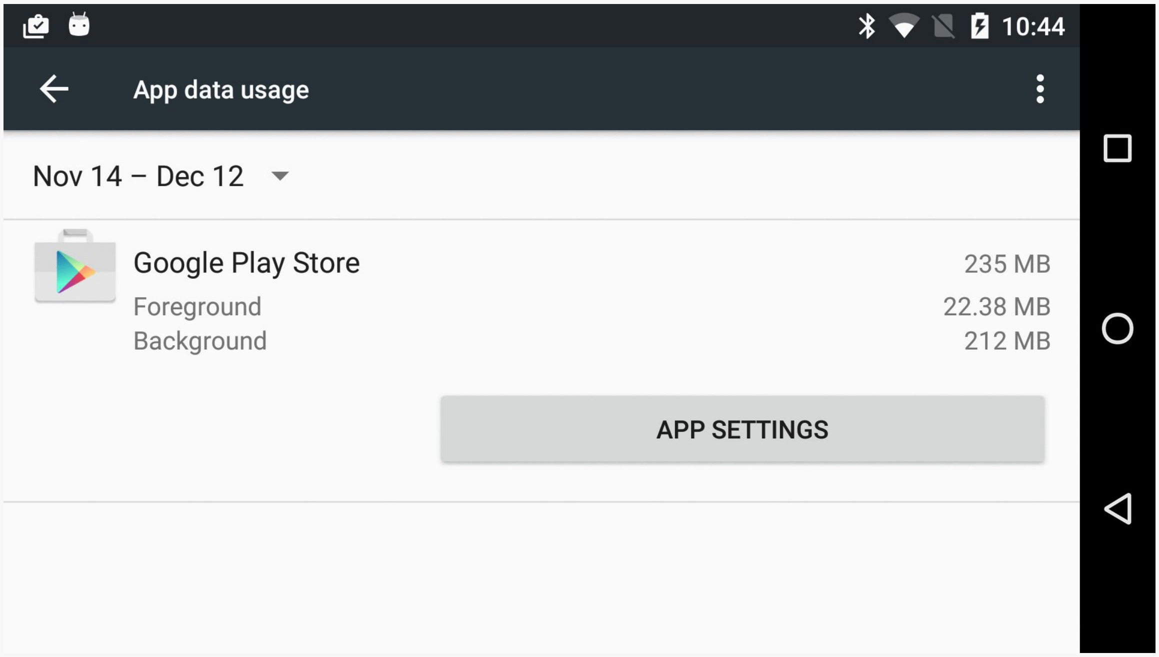


App usage

Google Play Store	235 MB
Google Play services	40.59 MB
Google Contacts Sync	10.10 MB
Google App	3.14 MB

Figure 848: Settings, App, Data Usage Screen, Data Usage "Blame List"

Tapping on any one of those list items will give you a bit more detail, specifically how much of that bandwidth was consumed while the app was in the foreground or the background:



Google Play Store 235 MB
Foreground 22.38 MB
Background 212 MB

Figure 849: Settings, App, Data Usage Screen, Data Usage App Details

Off-Device Measurement

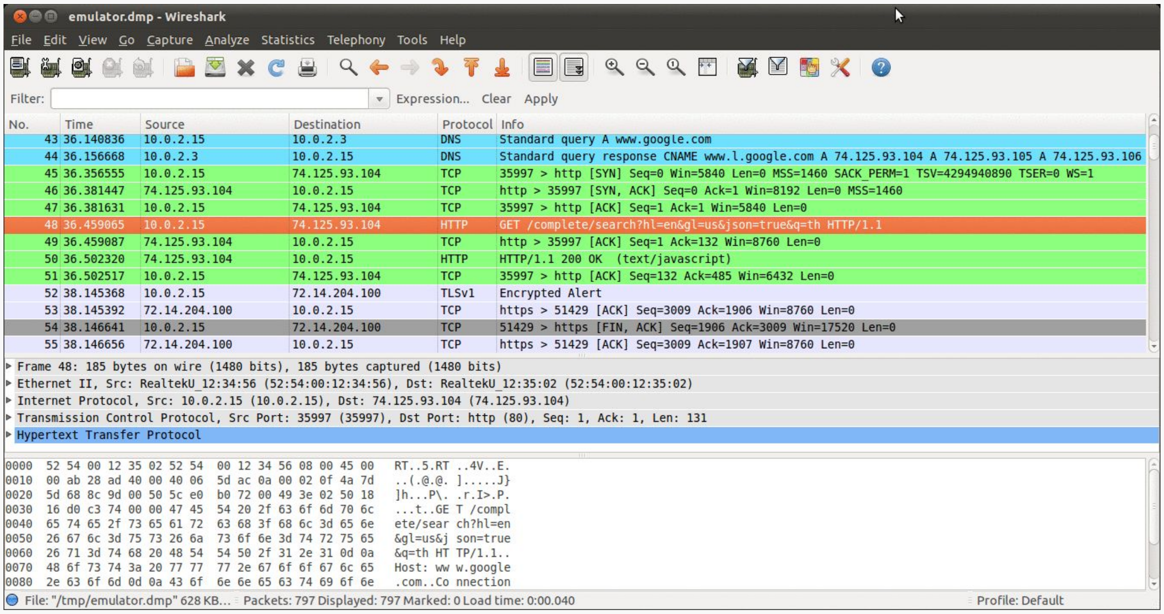
The biggest limitation of `TrafficStats` is that it only gives you gross metrics: numbers of bytes, packets, and so on. Sometimes, that is not enough to help you understand why those bytes, packets, and so on are actually being sent or received. Sometimes, it would be nice to understand the traffic in more detail, from the ports and IP addresses to perhaps the actual data being transmitted. For obvious security reasons, this is not something an ordinary Android SDK application can do. However, there are techniques for accomplishing this, mostly for use over WiFi in your own home or office network. Some of these are outlined in the following sections.

Wireshark

Wireshark, formerly known as Ethereal, is perhaps the world's leading open source network traffic analyzer and packet inspector. Using it, you can learn in great detail what is going on with your local network. And, Android provides additional options for you to leverage Wireshark to make sense of application behavior. Wireshark is available for Linux, OS X, and Windows.

There is a lightly-documented `-tcpdump` switch available on the Android emulator. If you launch the emulator from the command line with that switch (plus `-avd` to identify the AVD file you want to use), all network access is dumped to your specified log file. You can then load that data into Wireshark for analysis, via File|Open from the main menu.

For example, here is a screenshot of Wireshark examining data from such an emulator dump file, in which the emulator was used to conduct a Google search:



emulator.dmp - Wireshark

Figure 850: Wireshark examining captured emulator packets

This screenshot shows an HTTP request in the highlighted line in the list, with the hex and ASCII contents of the request shown in the bottom pane.

In terms of using Wireshark to monitor traffic from actual hardware, that is indubitably possible. However, WiFi packet collection is a tricky process with Wireshark, being very dependent upon operating system and possibly even the WiFi adapter chipset. You also get much lower-level information, making it a bit more challenging to figure out what is going on. Attempting to cover all of this is well beyond the scope of this book and the author's Wireshark expertise.

Networking Hardware

Sophisticated firewalls sometimes have packet tracing/sniffing capability. In this case, “sophisticated” does not necessarily mean “expensive”, as open source router/firewall distributions, like OpenWrt, can be used for this sort of work. In this case, the router captures the packets and, in many cases, routes them to Wireshark for analysis. Some might offer on-board analysis (e.g., Web interface to packet capture logs).

This is particularly useful on a Windows wireless network. Wireshark has limits, imposed by Windows, that cause some problems when trying to capture WiFi packets. By offloading the packet capture to networking hardware, those limits can be bypassed.

Android Studio Network Monitor

`TrafficStats` is great for measuring gross bandwidth consumption over some period of time. However, it requires coding, logging, and your own analysis mechanism.

In Android Studio, tabs inside the Android Monitor tool allow you to examine the real-time behavior of your app with respect to various system resources, such as bandwidth consumption. These tabs appear alongside the “logcat” tab, in a tab strip towards the top of the Android Monitor tool frame.

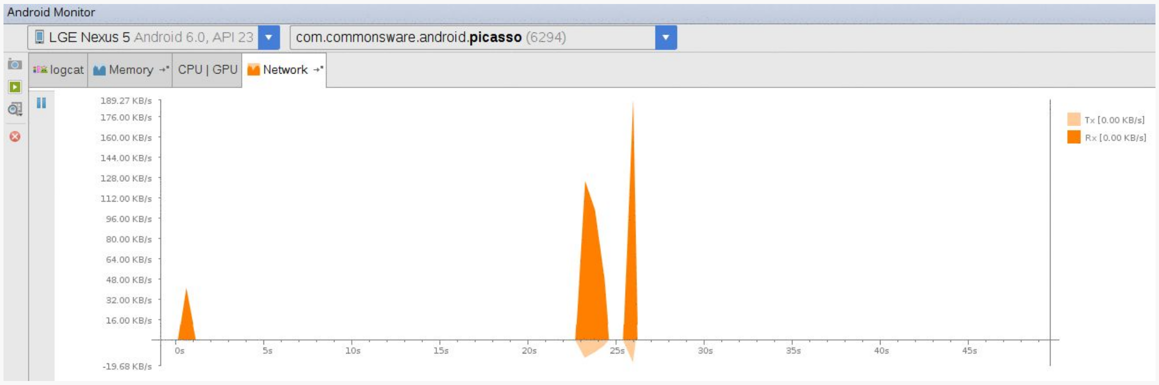

Figure 851: Android Studio, Android Monitor, Network Tab

This graph comes from a Picasso demo application from earlier in the book, which retrieves the latest 25 `android` questions on Stack Overflow and shows them in a `ListView`, along with the avatar for the person asking the question. The graph shows the initial load of data from the Stack Exchange JSON API, followed ~20 seconds later by some scrolling in the app, forcing Picasso to go load more avatars.

Values above the horizontal axis represent downloads ("Rx", meaning received packets). Values below the horizontal axis represent uploads ("Tx", meaning transmitted packets).

As this responds in near-real-time to things you do in your app, you can see if the graph shows network accesses at unexpected times, or more bandwidth consumed than you might expect. For example, once all the avatars were loaded, no more bandwidth should be consumed by the Picasso sample app, assuming all the avatars could fit in Picasso's memory cache.

Being Smarter About Bandwidth

Given that you are collecting metrics about bandwidth consumption, you can now start to determine ways to reduce that consumption. You may be able to permanently reduce that consumption (at least on a per-operation basis). You may be able to shunt that consumption to times or networks that the user prefers. This chapter reviews a variety of means of accomplishing these ends.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the chapter on Internet access.

Bandwidth Savings

The best way to reduce bandwidth consumption is to consume less bandwidth.

(in other breaking news, water is wet)

In recent years, developers have been able to be relatively profligate in their use of bandwidth, pretty much assuming everyone has an unlimited high-speed Internet connection to their desktop or notebook and the desktop or Web apps in use on them. However, those of us who lived through the early days of the Internet remember far too well the challenges that dial-up modem accounts would present to users (and perhaps ourselves). Even today, as Web apps try to “scale to the Moon and back”, bandwidth savings becomes important not so much for the end user, but for the Web app host, so its own bandwidth is not swamped as its user base grows.

Fortunately, widespread development problems tend to bring rise to a variety of solutions — a variant on the "many eyes make bugs shallow" collaborative development phenomenon. Hence, there are any number of tried-and-true techniques for reducing bandwidth consumption that have had use in Web apps and elsewhere. Many of these are valid for native Android apps as well, and a few of them are profiled in the following sections.

Classic HTTP Solutions

Trying to get lots of data to fit on a narrow pipe — whether that pipe is on the user's end or the provider's end — has long been a struggle in Web development. Fortunately, there are a number of ways you can leverage HTTP intelligently to reduce your bandwidth consumption.

GZip Encoding

By default, HTTP requests and response are uncompressed. However, you can enable GZip encoding and thereby request that the server compress its response, which is then decompressed on the client. This trades off CPU for bandwidth savings and therefore needs to be done judiciously.

Enabling GZip compression is a two-step process:

- Adding the `Accept-Encoding: gzip` header to the HTTP request
- Determine if the response was compressed and, if so, decompressing it

Bear in mind that the Web server may or may not honor your GZip request, for whatever reason (e.g., response is too small to make it worthwhile).

If-Modified-Since / If-None-Match

Of course, avoiding a download offers near-100% compression. If you are caching data, you can take advantage of HTTP headers to try to skip downloads that are the same content as what you already have, specifically `If-Modified-Since` and `If-None-Match`.

An HTTP response can contain either a `Last-Modified` header or an `ETag` header. The former will contain a timestamp and the latter will contain some opaque value. You can store this information with the cached copy of the data (e.g., in a database table). Later on, when you want to ensure you have the latest version of that file, your HTTP GET request can include an `If-Modified-Since` header (with the cached Last-Modified value) or an `If-None-Match` header (with the cached `ETag` value). In either case, the server should return either a `304` response, indicating that your cached copy is up to date, or a `200` response with the updated data. As a result, you avoid the download entirely (other than HTTP headers) when you do not need the updated data.

Binary Payloads

While XML and JSON are relatively easy for humans to read, that very characteristic means they tend to be bloated in terms of bandwidth consumption. There are a variety of tools, such as Google's Protocol Buffers and Apache's Thrift, that allow you to create and parse binary data structures in a cross-platform fashion. These might allow you to transfer the same data that you would in XML or JSON in less space. As a side benefit, parsing the binary responses is likely to be faster than parsing XML or JSON. Both of these tools involve the creation of an IDL-type file to describe the data structure, then offer code generators to create Java classes (or equivalents for other languages) that can read and write such structures, converting them into platform-neutral on-the-wire byte arrays as needed.

Minification

If you are loading JavaScript or CSS into a `WebView`, you should consider standard tricks for compressing those scripts, collectively referred to as "minification". These techniques eliminate all unnecessary whitespace and such from the files, rename variables to be short, and otherwise create a syntactically-identical script that takes up a fraction of the space. There are services like box.js that can even aggregate several scripts into one file and minify them, to further reduce HTTP overhead.

Keep-Alive Semantics

A chunk of the overhead involved in HTTP operations is simply establishing the socket connection with the Web server. Advertising that you want the socket to be kept alive, in anticipation of upcoming follow-on requests, can reduce this overhead.

Using higher-level HTTP clients, like OkHttp, helps here, because usually they handle all the details of keeping the socket open.

With SSL, though, keep-alive was not an option, until Google released the SPDY specification. SPDY in turn formed the basis of HTTP/2, the new standard for Web communications (replacing the venerable HTTP/1.1). OkHttp supports SPDY and HTTP/2.

Push versus Poll

Another way to consume less bandwidth is to only make the requests when it is needed. For example, if you are writing an email client, the way to use the least bandwidth is to download new messages only when they exist, rather than frequently polling for messages.

Off the cuff, this may seem counter-intuitive. After all, how can we know whether or not there are any messages if we are not polling for them?

The answer is to use a low-bandwidth push mechanism. The quintessential example of this is GCM, the Google Cloud Messaging system, available for Android 2.2 and newer. This service from Google allows your application to subscribe to push notifications sent out by your server. Those notifications are delivered asynchronously to the device by way of Google's own servers, using a long-lived socket connection. All you do is register a `BroadcastReceiver` to receive the notifications and do something with them.

For example, Remember the Milk — a task management Web site and set of mobile apps — uses GCM to alert the device of task changes you make through the Web site. Rather than the Remember the Milk app having to constantly poll to see if tasks were added, changed, or deleted, the app simply waits for GCM events.

You could create your own push mechanism, perhaps using a WebSocket or MQTT. The downside is that you will need a service in memory all of the time to manage the socket and thread that monitors it. If you only need this while your service is in memory for other reasons, that is fine. However, keeping a service in memory 24x7 has its own set of issues, not the least of which is that users will tend to smack it down using a "task killer" or the Manage Services screen in the Settings app. Doze mode on Android 6.0+ will also cause problems with this approach.

Thumbnails and Tiles

A general rule of thumb is: don't download it until you really need it.

Sometimes, you do not know if you really need a particular item until something happens in the UI. Take a `ListView` displaying thumbnails of album covers for a music app. Assuming the album covers are not stored locally, you will need to download them for display. However, which covers you need varies based upon scrolling. Downloading a high-resolution album cover that might get tossed in a matter of milliseconds (after an expensive rescale to fit a thumbnail-sized space) is a waste of bandwidth.

In this case, either the album covers are something you control on the server side, or they are not. If they are, you can have the server prepare thumbnails of the covers, stored at a spot that the app can know about (e.g., `.../cover.jpg` it is `.../thumbnail.jpg`). The app can then download thumbnails on the fly and only grab the full-resolution cover if needed (e.g., user clicks on the album to bring up a detail screen). If you do not control the album covers, this option might still be available to you if you can run your own server for the purposes of generating such thumbnails.

You can see a similar effect with the map tiles in Google Maps. When zooming out, the existing map tiles are scaled down, with placeholders (the gridlines) for the remaining spots, until the tiles for those spots are downloaded. When zooming in, the existing map tiles are scaled up with a slight blurring effect, to give the user some immediate feedback while the full set of more-detailed tiles is downloaded. And, if the user pans, you once again get placeholders while the tiles for the newly uncovered areas are downloaded. In this fashion, Google Maps is able to minimize bandwidth consumption by giving users partial results immediately and back-filling in the final results only when needed. This same sort of approach may be useful with your own imagery.

Bandwidth Shaping

Sometimes, you have no ability to reduce the bandwidth itself. Perhaps you do not control both ends of the communications pipeline. Perhaps the data you are trying to exchange is already compressed (e.g., downloading an MP4 video). Perhaps some of the techniques in the preceding section were unavailable to you (e.g., cannot route data through third-party servers like Google's for GCM).

There still may be ways for you to help your users, by shaping your bandwidth use. Rather than just blindly doing whatever you want whenever you want, you learn what the *user* wants and what *other applications* want and tailor your bandwidth use on the fly to match those needs. The following sections outline some ways of achieving this.

Driven by Preferences

If you are consuming enough bandwidth that this chapter is relevant to you, you probably are consuming enough bandwidth that you should be asking the user how best to consume that bandwidth. After all, they are the one paying the price — in time as well as money – for that consumption.

The following sections present some possible strategies for preference-based bandwidth shaping.

Budgets

One strategy is for the user to give you a budget (e.g., 20MB/day) and for you to stick within that budget.

Collecting the budget is fairly easy — just use `SharedPreferences`. Either use a `ListPreference` with likely budget value or an `EditTextPreference` and a bit of validation for a free-form budget amount.

Next, you will need to have some idea how much bandwidth any given network operation will consume. For some things, this might be an estimate based on your experiments as a developer, or perhaps it is based on historical averages for this user and type of operation. For example, a "podcatcher" (feed reader designed to download podcast episodes) should have some idea how big a given RSS or Atom feed download should be. In some cases, it might be worthwhile to get a better estimate — for example, the podcatcher might use an HTTP `HEAD` request to determine the size of the MP3 or OGG file before deciding whether to download it.

Then, you need to be keeping track of your budget. This could be a simple flat file with the initial `TrafficStats` bandwidth values for your process. Re-initialize that file on the first network operation of the day (or whatever period you chose for your budget). Before doing another network operation, compare the current `TrafficStats` values with the initial ones and see how close you are to the budget. If the new network operation will exceed the budget, skip the operation, perhaps putting it in a work queue to perform in the next budget. You might even hold a reserve for certain types of operations. For example, the podcatcher might ensure there is at least 10% of the budget available for downloading the feeds, even if it means putting a podcast on the queue for download tomorrow. That way, you can present to the user the latest podcast information, with icons indicating which are downloaded and which are queued for download — the user might be able to then request to override the budget and download something on demand.

For devices that lack per-UID `TrafficStats` support, you will have to "fake it" a bit. Use your own calculations of how much bandwidth each operation consumes and track that information, even if you wind up missing out on some bytes here or there.

Connectivity

If the user might not care how much bandwidth you consume, so long as it is unmetered bandwidth, you might include a `CheckBoxPreference` to indicate if large network operations should be limited to WiFi and avoid mobile data.

You could then use `ConnectivityManager` and `getActiveNetworkInfo()` to see what connection you have before performing a network operation. If it is a background operation (e.g., the podcatcher checking for new podcasts every hour), if the network is not the desired one, you can skip the operation or put it on a work queue for re-trying later. If it is a foreground operation (e.g., the user clicked a "refresh" menu choice), you could pop up a confirmation `AlertDialog` to warn the user that they are on mobile data — perhaps this time they are interested in doing the operation anyway.

Another approach for handling the background operations is to register a `BroadcastReceiver` for the `CONNECTIVITY_ACTION` broadcast (defined on `ConnectivityManager`). If the connectivity switches to mobile data, cancel your outstanding `AlarmManager` alarms; if connectivity switches to WiFi, re-enable those alarms.

Of course, you should also consider monitoring the background data setting — the global Settings checkbox indicating whether background network operations are allowed. On `ConnectivityManager`, `getBackgroundDataSetting()` tells you the state of this checkbox, and `ACTION_BACKGROUND_DATA_SETTING_CHANGED` allows you to set up a `BroadcastReceiver` to watch for changes in its state.

Windows

If your user is less concerned about the bandwidth or the network, but does care about the time of day (e.g., does not want your application consuming significant bandwidth when they might be getting a VOIP call), you could offer preferences for that as well. Cook up a `TimePreference` and use that to collect start and stop times for the high-bandwidth window. Then, set up alarms with `AlarmManager` for those points in time. The alarm for the start time of the window sets up a third alarm with your regular polling interval. The alarm for the stop time of the window cancels the polling interval alarm.

Driven by Other Usage

If your network I/O is part of a foreground application, one presumes that you are the most important thing in the user's life right now. Or, at least, the most important thing on the user's phone right now. Hence, what other applications might want to do with the Internet connection is not a major concern.

If, however, your network I/O is part of a background operation, it might be nice to try to avoid doing things that might upset the user. If the user is watching streaming video or is on a VOIP call or otherwise is aware of bandwidth changes, the bandwidth you use might impact the user in ways that the user will not appreciate very much. This is unlikely to be a big problem for small operations (e.g., downloading a 1KB JSON file), but larger operations (e.g., downloading a 5MB podcast) might be more noticeable.

You can use `TrafficStats` to help here. Before doing the actual network I/O, grab the current traffic data, wait a couple of seconds, and compare the latest to the previous values. If little to no bandwidth was consumed during that period, assume it is safe and go ahead and do your work. If, however, a bunch of bandwidth was consumed, you might want to consider:

1. Skipping this polling cycle and trying again later, or
2. Adding a one-off alarm using set() on `AlarmManager` to give you control again in a minute, with the current traffic data packaged as an extra on the `Intent`, so you can make a decision after a bigger sample size of bandwidth consumption, or
3. Adding an entry in a persistent work queue, so you know later on to try again if bandwidth contention has improved

You could try to get more sophisticated, by using `ActivityManager` and the per-UID values from `TrafficStats` to see if it is a foreground application that is the one consuming the bandwidth. It is unclear how reliable this will be, both in determining who is consuming the bandwidth (again, per-UID traffic is not available on many devices) and in avoid user angst. It may be simpler just to assume the worst and side-step your I/O until the other apps have quieted down.

Avoiding Metered Connections

Android 4.1 added `isActiveNetworkMetered()` as a method on `ConnectivityManager`. In principle, this will return `true` if Android thinks that the current data connection may involve bandwidth charges. You can examine this value and steer your bandwidth consumption accordingly.

Android 5.0 added `JobScheduler`, as an alternative to `AlarmManager` for arranging periodic work. One feature of `JobScheduler` is that you can indicate that certain jobs require Internet access, in which case Android will not bother giving you control unless such access is available. A further refinement is that you can state that a job requires an unmetered Internet connection, so you avoid doing bandwidth-hogging work on an expensive connection.

Issues with Application Heap

RAM. Developers nowadays are used to having lots of it, and a virtual machine capable of using as much of it as exists (and more, given swap files and page files).

"Graybeards" — like the author of this book — distinctly remember a time when we had 16KB of RAM and were happy for it. Such graybeards would also appreciate it if you would get off their respective lawns.

Android comes somewhere in the middle. We have orders of magnitude more RAM than, say, the TRS-80 Model III. We do not have as much RAM as does the modern notebook, let alone a Web server. As such, it is easy to run out of RAM if you do not take sufficient care.

There are two facets of memory issues with Android:

- What are the problems we encounter inside our own app, in terms of our application heap?
- What problems can we encounter with system RAM overall, and how can we resolve them?

This part of the book examines memory-related issues, with this chapter focusing on the application heap. Another chapter will deal with system RAM issues. These are not to be confused with any memory-related issues inherent to graybeards.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the chapter on Android's process model.

You Are in a Heap of Trouble

When we think of “memory” and Java-style programming, the primary form of memory is the heap. The heap holds all of our Java objects – from an `Activity` to a widget to a `String`.

Traditional Java applications have an initial heap size determined by the virtual machine, possibly configured via command-line options when the program was run. Traditional Java applications can also request additional memory from the OS, up to some maximum, also configurable.

Android applications have the same basic structure, with very limited configurability and much lower maximums than you might expect.

The original Android devices had a heap limit of 16MB. As screens increase in resolution, the heap limit tends to rise, but only to a point. 32MB to 64MB of heap space is fairly typical, but less-expensive devices, such as Android One models, will tend towards the lower end of that range.

This heap limit can be problematic. For example, each widget or layout manager instance takes around 1KB of heap space. This is why `AdapterView` provides the hooks for view recycling — we cannot have a `ListView` with literally thousands of row views without potentially running out of heap.

API Level 11+ supports applications requesting a “large heap”. This is for applications that specifically need tons of RAM, such as an image editor to be used on a tablet. This is not for applications that run out of heap due to leaks or sloppy programming. Bear in mind that users will feel effects from large-heap applications, in that their other applications will be kicked out of memory more quickly, possibly irritating them. Also, garbage collection on large-heap applications runs more slowly, consuming more CPU time. To enable the large heap, add `android:largeHeap="true"` to the `<application>` element of your manifest. Finally, bear in mind that your “large heap” may not be any bigger than your regular heap would have been, as the “large heap” size is determined by the device manufacturer and takes into account things like available system RAM.

Determining Your Heap Size At Runtime

To get a sense for how much heap you will be able to potentially grow to, you can call `getMemoryClass()` on an `ActivityManager`. This will return your per-process heap limit in megabytes.

If you requested `android:largeHeap="true"` in the manifest, use `getLargeMemoryClass()` on `ActivityManager` to learn how large your "large heap" actually is. Note that it is entirely possible that the "large heap" is not all that large, or potentially is no bigger than the standard heap, depending upon how much RAM is physically present on the device.

Fragments of Memory

The Dalvik garbage collector is a non-compacting implementation, which makes `OutOfMemoryError` messages somewhat more likely than you would find on traditional Java environments.

Here, "non-compacting" means that Dalvik does not try to move objects around in physical memory to "compact" the use of physical memory, leaving a large contiguous block of free physical memory for future allocations.

For example, suppose that we allocate three 1K byte arrays, named A, B, and C. As it turns out, they were allocated using adjacent portions of physical memory, so that the last byte of A immediately precedes the first byte of B, and so on. Hence, we consumed 3K of available heap space to create these three 1K blocks.

If we release all references to A and B, they can be garbage-collected. Dalvik, like Java, will see that A and B are adjacent and will free up their physical memory, such that the memory is available as one contiguous 2K block for future allocations.

If, however, released all references to A and C instead of A and B, Dalvik would be unable to make their blocks be contiguous, and so our heap would have two free 1K blocks, in addition to whatever other free memory that the heap already had.

Hence, allocating memory not only ties up that memory while it is in use, but it may *fragment* the memory even when it is released, such that our formerly pristine heap is now comprised of lots of little free blocks of space, separated from other such blocks by in-use objects. When we try to make a large allocation, such as setting up a byte array for a large image, it may be that while we have enough *total* heap available for the request, there is no single block that would meet our request, and so we get an `OutOfMemoryError`.

One technique to help address this is to pre-allocate any large buffers that you know you need, up front when your process starts up, such as via a custom `Application` subclass. Then, use an "object pool" approach to obtain, use, and reuse these pre-allocated buffers, rather than having them be garbage-collected and have to be re-allocated later.

ART — the runtime engine used on Android 5.0+ — has a compacting garbage collector. However, it only compacts the heap when the app is in the background. So long as your application is in the foreground, ART behaves like Dalvik does, and your heap will continue to fragment.

Getting a Trim

It would be nice if we knew when a good time would be to cut back on our heap usage. For example, if we are caching a lot of data in our process, to save on future disk I/O, we could free up those caches at some point to help minimize our heap usage.

Fortunately, Android has some hooks for doing just that.

onTrimMemory() Callbacks

Starting in API Level 14, your activities, services, content providers, and custom `Application` classes all offer an `onTrimMemory()` method that you can override. This will be called from time to time to let you know about changes in the state of your app that might indicate it is time to free up some caches or otherwise cut back on memory consumption.

`onTrimMemory()` is passed a "level", indicating how serious the memory crunch is. At the present time, there are seven such levels, but others may be added in future versions of Android. However, these levels are in priority order, and the documentation indicates that Google will ensure that future levels are slotted into the order as appropriate. Hence, you can watch for levels of a certain severity *or higher* and take appropriate action at those points in time.

The seven levels are all defined as constants on the ComponentCallbacks2 interface that defines onTrimMemory(). Four were defined in API Level 14, while the remaining three were defined in API Level 16. They are (in order of increasing severity):

- TRIM_MEMORY_RUNNING_MODERATE (added in API Level 16)
- TRIM_MEMORY_RUNNING_LOW (added in API Level 16)
- TRIM_MEMORY_RUNNING_CRITICAL (added in API Level 16)
- TRIM_MEMORY_UI_HIDDEN (added in API Level 14)
- TRIM_MEMORY_BACKGROUND (added in API Level 14)
- TRIM_MEMORY_MODERATE (added in API Level 14)
- TRIM_MEMORY_COMPLETE (added in API Level 14)

In particular, TRIM_MEMORY_BACKGROUND (or higher) indicates that your process is now on the list of processes to terminate to free up memory, and so the more memory you can free up, the less likely it is that your process will be terminated. Also, at TRIM_MEMORY_UI_HIDDEN or higher, your UI is no longer visible to the user, and so this is a fine time to free up UI-related memory that is safe to release, such as perhaps widget hierarchies that you would be rebuilding in onResume() later on anyway.

Note that while the focus tends to be on activities implementing onTrimMemory() to clean up UI-related resources, you are welcome to implement onTrimMemory() in services, content providers, and any custom Application subclass, so that you can free up memory that those may be managing as caches.

In the chapter on system RAM, we will get into why freeing up memory may help keep your process around, as we discuss the relationship between your application heap and available system RAM.

Warning: Contains Graphic Images

However, the most likely culprit for OutOfMemoryError messages are bitmaps. Bitmaps take up a remarkable amount of heap space. Developers often look at the size of a JPEG file and think that “oh, well, that’s only a handful of KB”, without taking into account:

1. the fact that most image formats, like JPEG and PNG, are compressed, and Android needs the uncompressed image to know what to draw
2. the fact that each pixel may take up several bytes (2 bytes per pixel for RGB_565, 3 bytes per pixel for RGB_888)

3. what matters is the resolution of the bitmap in its original form, as much (if not more) than the size in which it will be rendered – an 800x480 image displayed in an 80x48 ImageView still consumes 800x480 worth of pixel data
4. there are an awful lot of pixels in an image — 800 times 480 is 384,000

Android can make some optimizations, such as only loading in one copy of a Drawable resource no matter how many times you render it. However, in general, each bitmap you load takes a decent sized chunk of your heap, and too many bitmaps means not enough heap. It is not unheard of for an application to have more than half of its heap space tied up in various bitmap images.

Compounding this problem is that bitmap memory, before Android 3.0, was difficult to measure. In the actual Dalvik heap, a Bitmap would need ~80 bytes or so, regardless of image size. The actual pixel data was held in "native heap", the space that a C/C++ program would obtain via calls to malloc(). While this space was still subtracted from the available heap space, many diagnostic programs — such as MAT, to be examined in the next chapter — will not know about it. Android 3.0 moved the pixel data into the Dalvik heap, which will improve our ability to find and deal with memory leaks or overuse of bitmaps.

Bitmap Caching

Many Android libraries, like Picasso, offer bitmap caching. Using an existing caching implementation is a lot easier than is rolling your own.

However:

- Make sure that the library is intelligently sizing the cache based upon possible heap space, such as via getMemoryClass() as is noted earlier in this answer.
- Where possible, tie your cache to onTrimMemory() so that you can flush that cache when appropriate.
- Be careful about using *multiple* libraries, each of which might implement its own cache, that you do not wind up caching too much overall. Each library tends to think that it is The One True Cache for your app and will be oblivious to any other caches — bitmap or otherwise — that you may have in your app. Ideally, the library will have a way for you to set the maximum cache size.

Bitmap Sizing

Sometimes, you do not need a full-size image. For example, if you are showing thumbnails of images in a ListView, but only expect to show the full-size image for a few (e.g., rows that the user clicks upon), it is wasteful to load the full-size image for everything in the list.

BitmapFactory.Options offers inSampleSize, which tells the framework to sample the image as it is loaded, to result in a smaller image. inSampleSize of 2 will result in an image that is half the width and half the height; inSampleSize of 4 will result in an image that is a quarter the width and a quarter the height; etc. Note that inSampleSize is limited to powers of 2 and will round as needed.

If you know ahead of time the size of the image, you can calculate an appropriate inSampleSize to use. Otherwise, for local content, you can use BitmapFactory twice:

- Once with a BitmapFactory.Options set with inJustDecodeBounds set to true, which will merely tell you how big the image is via outHeight and outWidth on the BitmapFactory.Options itself
- Once with a BitmapFactory.Options set with inSampleSize set to your desired value and inJustDecodeBounds set to false, to really load the image, but downsampled to consume less memory

This approach does not work well for images being downloaded directly from the Internet, as you do not want to download the image twice, once just to figure out how big it is. Instead, download the image *without* using BitmapFactory to a local file, then use BitmapFactory to load in the image. If you are electing to use a two-level cache (memory plus disk), you might download the image to the disk cache, for example.

For example, let's look at the Bitmaps/InSampleSize sample project, which demonstrates the memory impact (and visual impact) of loading bitmaps at varying sample sizes.

In the assets/ directory, we have a ~70KB JPEG file of a flower (courtesy of the Wikimedia Project) and a ~50KB PNG of the CommonsWare logo. Both images are 672 pixels square, which makes them relatively large images. These are in assets to ensure that Android will not attempt any sort of density-based conversion of the images, if they were to be in a drawable resource directory.

The MainActivity of the project simply loads up a ViewPager and attaches it to a SampleAdapter:

```
package com.commonsware.android.bitmap.iss;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    pager.setAdapter(buildAdapter());
  }

  private PagerAdapter buildAdapter() {
    return(new SampleAdapter(this, getFragmentManager()));
  }
}
```

SampleAdapter, in turn, populates the ViewPager with four instances of a BitmaFragment, where we supply the newInstance() factory method of BitmapFragment with a value of 1, 2, 4, or 8 (1 << position), indicating the inSampleSize value we want to use for that fragment instance:

```
package com.commonsware.android.bitmap.iss;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
  Context ctxt=null;

  public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);
    this.ctxt=ctxt;
  }

  @Override
  public int getCount() {
    return(4);
  }

  @Override
  public Fragment getItem(int position) {
    return(BitmapFragment.newInstance(1 << position));
  }
  @Override
  public String getPageTitle(int position) {
    return(BitmapFragment.getTitle(ctxt, 1 << position));
  }
}
```

`BitmapFragment` then:

- Inflates a layout consisting of four `ImageView` widgets, two at `672dp` square for the "natural" size (scaling only for density), and two at `128dp` square to illustrate how the images appear when constrained to a smaller space:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
      android:id="@+id/byte_count"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="center_horizontal"
      android:layout_marginBottom="16dp"
      android:textSize="20sp"
      android:textStyle="bold"/>

    <ImageView
      android:id="@+id/flower_large"
      android:layout_width="672dp"
      android:layout_height="672dp"
      android:layout_gravity="center_horizontal"
      android:layout_marginBottom="16dp"
      android:contentDescription="@string/flower_large"
      android:scaleType="fitCenter"/>

    <ImageView
      android:id="@+id/logo_large"
      android:layout_width="672dp"
      android:layout_height="672dp"
      android:layout_gravity="center_horizontal"
      android:layout_marginBottom="16dp"
      android:contentDescription="@string/logo_large"
      android:scaleType="fitCenter"/>

    <ImageView
      android:id="@+id/flower_small"
      android:layout_width="128dp"
      android:layout_height="128dp"
      android:layout_gravity="center_horizontal"
      android:layout_marginBottom="16dp"
      android:contentDescription="@string/flower_small"
      android:scaleType="fitCenter"/>

    <ImageView
      android:id="@+id/logo_small"
      android:layout_width="128dp"
      android:layout_height="128dp"
      android:layout_gravity="center_horizontal"
      android:contentDescription="@string/logo_small"
      android:scaleType="fitCenter"/>
  </LinearLayout>

</ScrollView>
```

- Uses a private `load()` method to load the images at the desired `inSampleSize` using a `BitmapFactory.Options` object
- Pours the images each into two `ImageView` widgets, one large and one small
- Updates some `TextView` widgets in the fragment to show how much memory those images are consuming

```
package com.commonsware.android.bitmap.iss;

import android.annotation.TargetApi;
import android.app.Fragment;
import android.content.Context;
import android.content.res.AssetManager;
import android.graphics.Bitmap;
import android.graphics.BitmapFactory;
import android.os.Build;
import android.os.Bundle;
import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.TextView;
import java.io.IOException;

public class BitmapFragment extends Fragment {
  private static final String KEY_SAMPLE_SIZE="inSampleSize";
  private AssetManager assets=null;

  static BitmapFragment newInstance(int inSampleSize) {
    BitmapFragment frag=new BitmapFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_SAMPLE_SIZE, inSampleSize);
    frag.setArguments(args);

    return(frag);
  }

  static String getTitle(Context ctxt, int inSampleSize) {
    return(String.format(ctxt.getString(R.string.title), inSampleSize));
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.sample, container, false);
    int inSampleSize=getArguments().getInt(KEY_SAMPLE_SIZE, 1);

    try {
      Bitmap flower=
          load("Tibouchina_urvilleana_flower_ja.jpg", inSampleSize);
      Bitmap logo=load("square.png", inSampleSize);

      ImageView iv=(ImageView)result.findViewById(R.id.flower_large);

      iv.setImageBitmap(flower);
      iv=(ImageView)result.findViewById(R.id.flower_small);
      iv.setImageBitmap(flower);
      iv=(ImageView)result.findViewById(R.id.logo_large);
      iv.setImageBitmap(logo);
      iv=(ImageView)result.findViewById(R.id.logo_small);
      iv.setImageBitmap(logo);

      TextView tv=(TextView)result.findViewById(R.id.byte_count);

      tv.setText(String.valueOf(byteCount(flower)));
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception loading bitmap", e);
    }

    return(result);
  }

  private Bitmap load(String path, int inSampleSize) throws IOException {
    BitmapFactory.Options opts=new BitmapFactory.Options();

    opts.inSampleSize=inSampleSize;

    return(BitmapFactory.decodeStream(assets().open(path), null, opts));
  }

  private AssetManager assets() {
    if (assets == null) {
      assets=getActivity().getResources().getAssets();
    }

    return(assets);
  }

  @TargetApi(Build.VERSION_CODES.KITKAT)
  private int byteCount(Bitmap b) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
      return(b.getAllocationByteCount());
    }

    return(b.getByteCount());
  }
}
```

If you run this on a device, you will see the images at the various sample sizes, one sample size per page of the `ViewPager`. While the quality of the loaded images decreases as `inSampleSize` increases, the smaller `ImageView` widgets are still usable for the flower JPEG, though the line-art PNG suffers.

NOTE: The following screenshots will themselves be modified as part of the publishing process of the book and are here only for illustration purposes. You will want to run the demo and see the results first-hand.

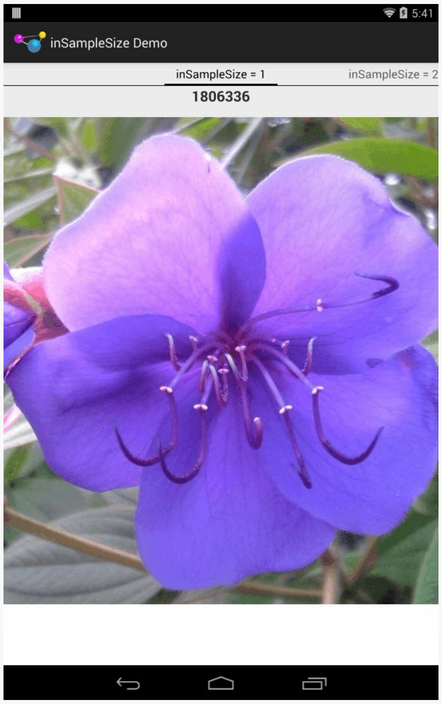

Figure 852: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 1, Flower JPEG, Full Size

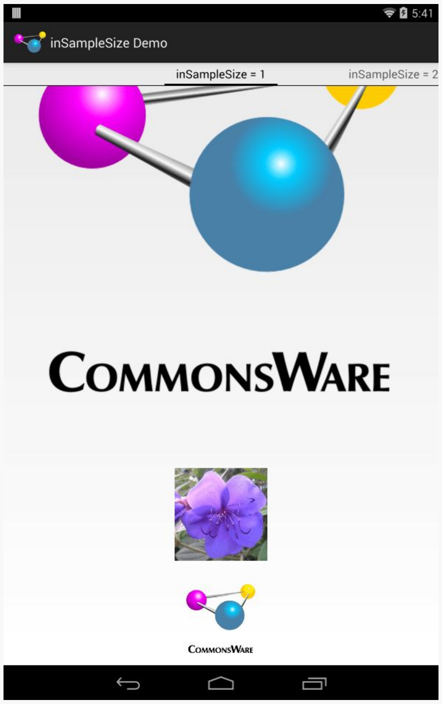

Figure 853: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 1, CW Logo PNG (Full Size) and Smaller Sizes

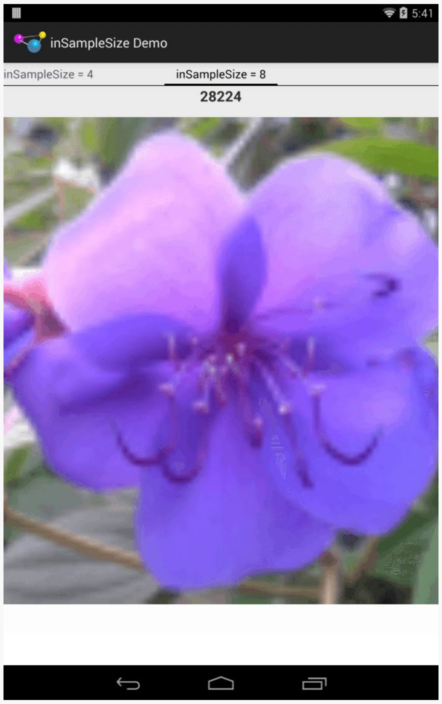

28224

Figure 854: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 8, Flower JPEG, Full Size

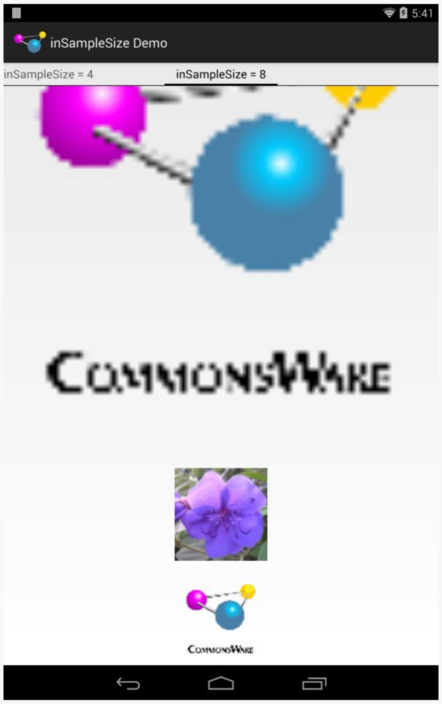

Figure 855: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 8, CW Logo PNG (Full Size) and Smaller Sizes

The key, though, is the reduced memory footprint. The images loaded without sampling (`inSampleSize` of `1`) take up 1,806,336 bytes of heap space (672 x 672 x 4 bytes per pixel). The `inSampleSize` of `8`, by contrast, take up 28,244 bytes of heap space, less than 2% of the original.

You should consider experimenting with `inSampleSize` and determine an appropriate sampling level for the types of images you will receive (photos work better than line art) and the sizes you intend to use them in.

Bitmap Color Space

`BitmapFactory` will load images as `ARGB_8888` by default. That means that each pixel takes up four bytes, one each for the red, green, and blue color channels, plus a byte for the alpha channel (transparency).

However, particularly for thumbnails of photographs, where transparency probably does not exist and the image is small when viewed by the user, four bytes per pixel may be overkill.

Instead, you can set `inPreferredConfig` of the `BitmapFactory.Options` to `RGB_565`, which uses only two bytes (five bits for red, six bits for green, five bits for blue, and no transparency). This will cut your memory consumption for the bitmap in half, with no loss of resolution (as you get with `inSampleSize`).

Bitmap Reuse

If you will be doing a lot of work with bitmaps, particularly bitmaps of the same size, an object pool can be of tremendous help to minimize heap fragmentation. You can reuse the same `Bitmap` over and over again, by supplying it via `inBitmap` in the `BitmapFactory.Options` object. If the `Bitmap` is compatible with what you are looking to decode, it will be reused, rather than have a new `Bitmap` (backed by a new hunk of heap space) be created.

Here, “compatible” means:

- The image is the same bit depth configuration (`ARGB_8888` versus `RGB_565`)
- For API Level 18 and below, the resolution is identical; for API Level 19+, the `inBitmap` resolution is the same as or higher than the bitmap to be loaded

Releasing SQLite Memory

SQLite maintains a “page cache” of loaded pages from your database files. Curiously, it does so on a static basis, not on a per-`SQLiteDatabase` basis. Hence, even after you have closed your databases, you might still be consuming more memory than you need to, due to this cache.

From `onTrimMemory()`, you can call the static `releaseMemory()` method on SQLite, to try to free up some of this memory. This should not cause any database errors, but it may slow down the next few database accesses, as the necessary pages may no longer be cached and may have to be loaded again from disk.

Finding Memory Leaks

Android Studio's heap analyzer is your #1 tool for identifying memory leaks and the culprits behind running out of heap space. Particularly when used with Android 3.0+ versions of Android, the heap analyzer can tell you:

1. Who are the major sources of memory consumption, both directly (e.g., bitmaps) or indirectly (e.g., leaked activities holding onto lots of widgets)
2. What is keeping objects in memory unexpectedly, defying standard garbage collection — the way that you leak memory in a managed runtime environment like Dalvik or ART

Android Studio's heap analyzer builds on the earlier Memory Analysis Tool (MAT), used by Java developers, and by Android developers prior to Android Studio.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the chapter on Android's process model. Reading the introductory chapter to this trail might be nice.

Android Studio Realtime Monitor

The first question is: when do we bother looking for leaks? Complex apps are complex, and so we might spend a lot of time looking for leaks that either do not exist or do not matter much.

In Android Studio, tabs inside the Android Monitor tool allow you to examine the real-time behavior of your app with respect to various system resources, such as heap space in your app. These tabs appear alongside the "logcat" tab, in a tab strip towards the top of the Android Monitor tool frame.

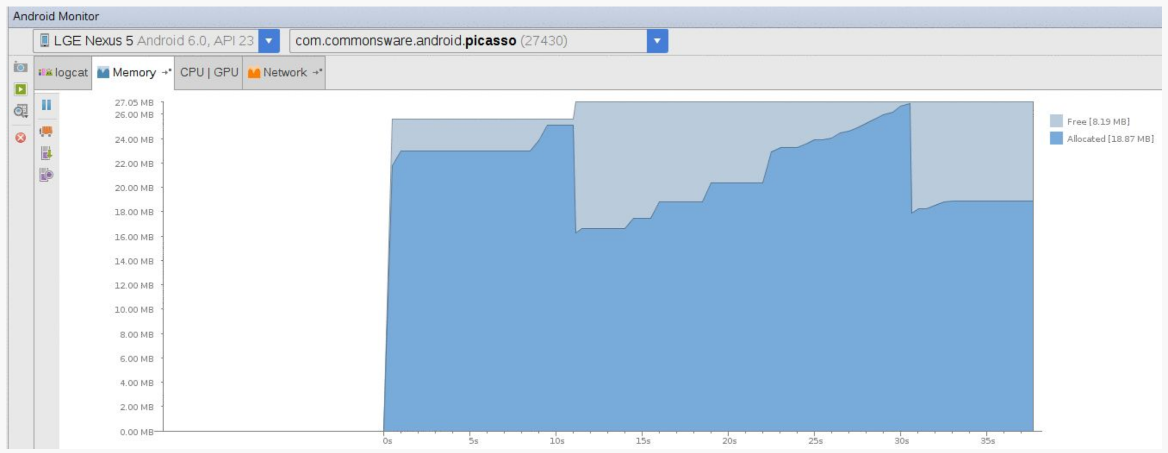

Figure 856: Android Studio, Android Monitor, Memory Tab

The darker blue shows how much heap space we have allocated, including outstanding garbage. The light blue shows how much free space is in the heap. The overall height indicates the size of our heap.

When you see the dark blue line drop, that means the system performed a garbage collection. Our heap size stayed the same, but memory moved from the allocated state to the free state.

When you see the light blue line rise, that means the system got more memory from the OS and increased the size of our heap. This can continue to the point of reaching the heap limit for the app (`getMemoryClass()` on `ActivityManager`).

On Android 5.0+ devices, the light blue line can also fall… while your app is no longer in the foreground:

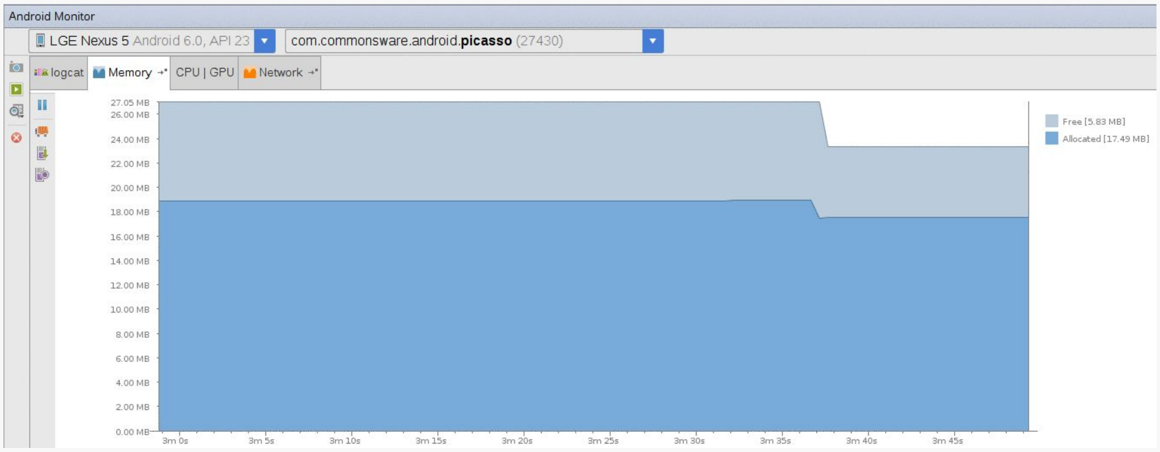

Figure 857: Android Studio, Android Monitor, Memory Tab, Showing Shrunken Heap

Here, the app was moved to the background. A little while after that occurs, ART will do a more aggressive garbage collection run, including moving objects in heap space to coalesce free blocks. If this frees up some of the allocated pages from the OS, ART can then free those pages, returning the memory to the OS and reducing our app's overall memory footprint.

You can also perform a manual garbage collection run by tapping the "garbage truck" icon in the toolbar in the memory tab (second down from the top, below the "pause" icon):

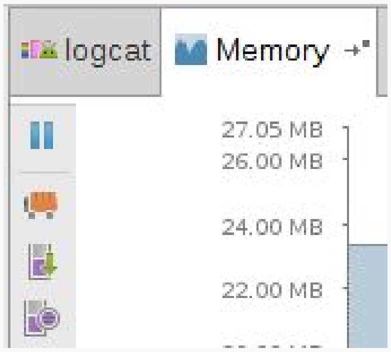

Figure 858: Android Studio, Android Monitor, Memory Tab, Toolbar

Anything in dark blue that survives a full garbage collection (whether manual or ART-induced) represents objects that cannot be garbage collected. If, over time, the level represented by that dark blue area keeps climbing, that suggests a possible memory leak.

Note, though, that the Y axis will automatically rescale, as the overall heap size climbs. That affects everything currently visible in the graph, but that is only ~45 seconds of history. Pay attention to the numbers shown in the legend (in the screenshots, on the right) in addition to the apparent level based upon the graph itself.

If we have a leak, though, while the memory tab will suggest that we have a problem (ever-growing amount of allocated objects after a garbage collection), it will not tell us exactly what is going wrong. For that, we need to analyze our app's heap.

Getting Heap Dumps

The first step to analyzing what is in your heap is to actually get your hands on what is in your heap. This is referred to as creating a "heap dump" — what amounts to a log file containing all your objects and who points to what.

In Android Studio

In the Android Monitor tool in Android Studio, when you have selected a process in the list, a "Dump Java Heap" toolbar button will be enabled in the Memory tab:

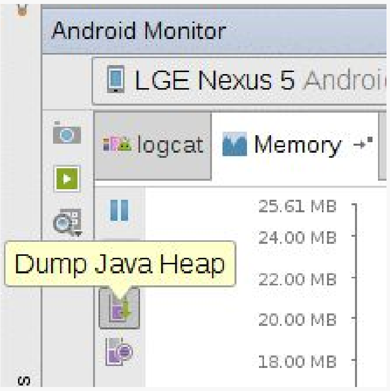

Figure 859: "Dump Java Heap" Toolbar Button in Android Studio

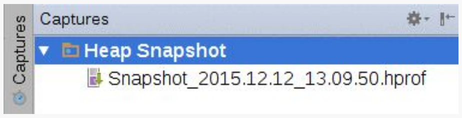
Tapping that, and waiting a few moments, will show the results of the heap dump in a new tab. These results are also saved in your project and are available from the Captures tool later on:



Captures
Heap Snapshot
Snapshot_2015.12.12_13.09.50.hprof

Figure 860: Android Studio, Heap Snapshot in Captures Tool

The actual heap dump data itself — known as an HPROF file – is stored in a `captures/` directory off of your project root. If you wish to use a different tool for analyzing the heap dump, such as MAT, you may be able to use that HPROF file. Note, though, that HPROF files are rather large.

From Code

Another possibility is to trigger the heap dump yourself from code. The `dumpHprofData()` static method on the `Debug` class (in the `android.os` package) will write out a heap dump to the file you indicate. Since these files can be big, and since you will need to transfer them off the device or emulator, it will be best to specify a path to a file on external storage, which means that your project will need the `WRITE_EXTERNAL_STORAGE` permission.

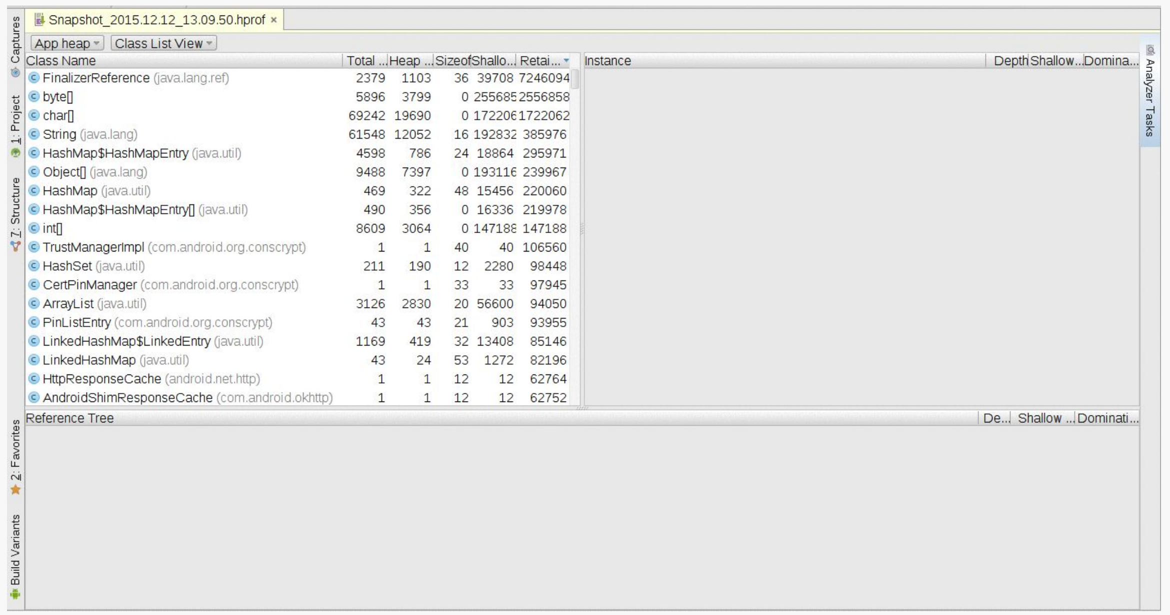
To view the results in Android Studio, you will need to transfer the file to your development machine from wherever you saved it on the device or emulator to your development machine.

Analyzing Heap Dumps in Android Studio

Having a heap dump is nice, but we need tools to determine exactly what is in there and what that means for our app. Fortunately, Android Studio nowadays has an integrated HPROF file tool to let us poke around with the contents of our heap and figure out where we are going wrong.

Navigating the Tab

The tab that you get from viewing a heap dump is… a little difficult to understand at the outset:



Class Name	Total ...	Heap ...	Sizeof	Shallo...	Retai...
FinalizerReference (java.lang.ref)	2379	1103	36	39708	7246094
byte[]	5896	3799	0	255685	2556858
char[]	69242	19690	0	172206	1722062
String (java.lang)	61548	12052	16	192832	385976
HashMap$HashMapEntry (java.util)	4598	786	24	18864	295971
Object[] (java.lang)	9488	7397	0	193116	239967
HashMap (java.util)	469	322	48	15456	220060
HashMap$HashMapEntry[] (java.util)	490	356	0	16336	219978
int[]	8609	3064	0	147188	147188
TrustManagerImpl (com.android.org.conscrypt)	1	1	40	40	106560
HashSet (java.util)	211	190	12	2280	98448
CertPinManager (com.android.org.conscrypt)	1	1	33	33	97945
ArrayList (java.util)	3126	2830	20	56600	94050
PinListEntry (com.android.org.conscrypt)	43	43	21	903	93955
LinkedHashMap$LinkedEntry (java.util)	1169	419	32	13408	85146
LinkedHashMap (java.util)	43	24	53	1272	82196
HttpResponseCache (android.net.http)	1	1	12	12	62764
AndroidShimResponseCache (com.android.okhttp)	1	1	12	12	62752

Figure 861: Android Studio, Heap Snapshot Tab

Let's break this down into component parts.

Class List

The table that comes filled in with data is a list of classes and primitive arrays, sorted by "retained size". This indicates how much memory those objects, and everything that they point to, consume.

The other columns of particular interest here are:

- Shallow Size: how much memory these instances consume in their own primitives, not including any other objects that they point to
- Total Count: the number of instances of this class found in your app's heap

(the difference between "Total Count" and "Heap Count" is undocumented, unfortunately)

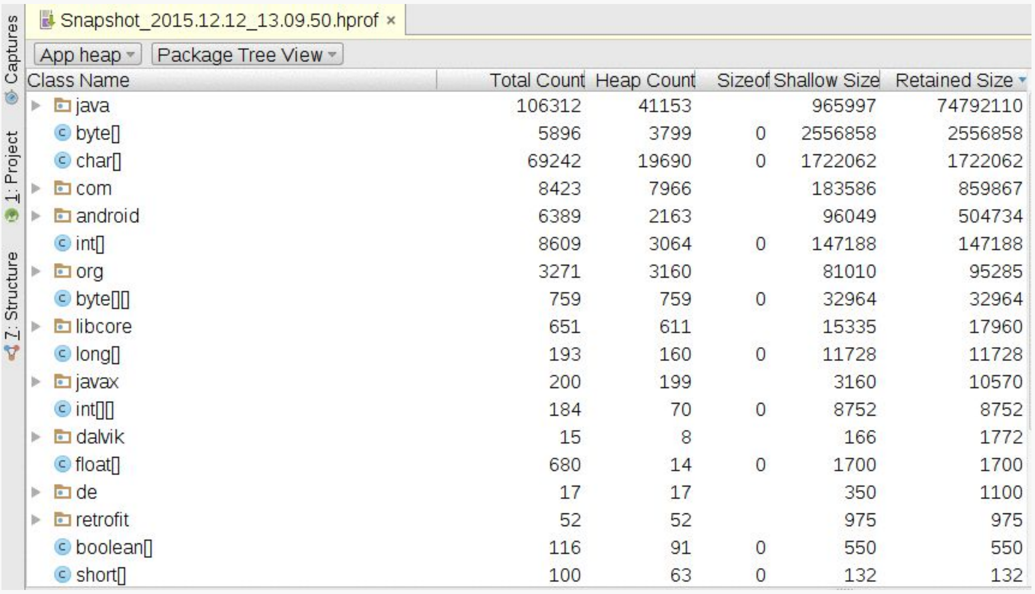
Heap Selector

The drop-down above the table that defaults to "App heap" will have other options on Android 5.0+ devices. Specifically, you can switch between the regular heap, the undocumented "image heap", and the equally-undocumented "zygote heap". The zygote is a core OS process, started when the device boots; all Android SDK apps are forked off of the zygote. Given that and other announced ART tidbits suggests that:

- the “image heap” may be the large object space, mostly set aside for bitmaps
- the “zygote heap” may be the objects in the heap that were instantiated by the zygote and its initialization of the Android framework classes, as opposed to your code

Package Tree View

The drop-down above the table that defaults to “Class List View” can be toggled to “Package Tree View”, which turns the table into a tree-table, for navigation by Java package name, with primitive arrays interspersed alphabetically:



Class Name	Total Count	Heap Count	Sizeof	Shallow Size	Retained Size

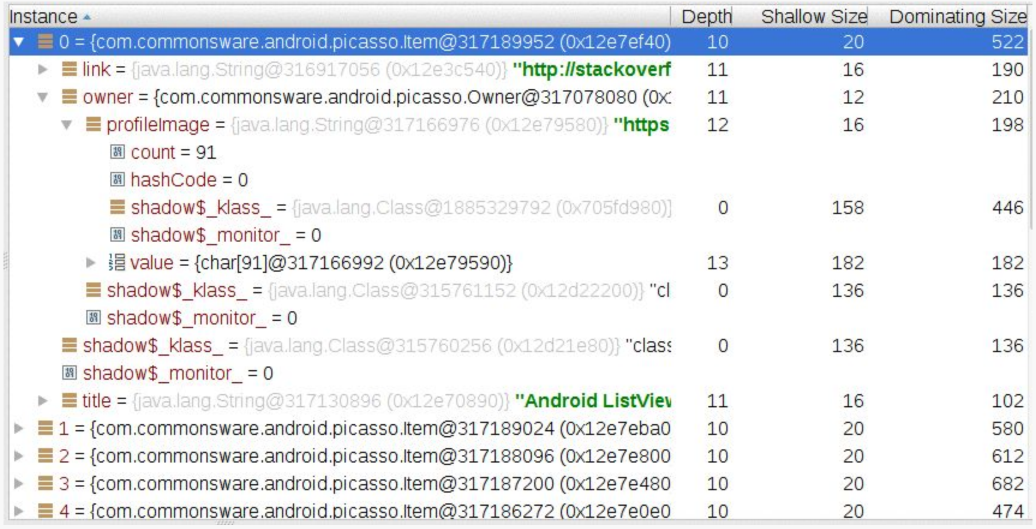
Figure 864: Heap Snapshot Tab, Instance List

The “shallow size” refers to the number of bytes consumed directly by that particular instance, such as by primitive fields. The “dominating size” roughly equates to “how much memory can this object be blamed for”. In other words, if that object could be garbage-collected, how much would we recover, not only from the “shallow size” but from other objects uniquely referenced by this object?

The “depth” refers to how many hops away from a garbage collection root (“GC root”) this object is.

This table initially appears as a simple table. In reality, though, it is a tree table. You can expand nodes in the tree to drill down into all the objects referenced by a particular instance:



Instance	Depth	Shallow Size	Dominating Size
0 = {com.commonsware.android.picasso.Item@317189952 (0x12e7ef40)	10	20	522
link = {java.lang.String@316917056 (0x12e3c540)} "http://stackoverf	11	16	190

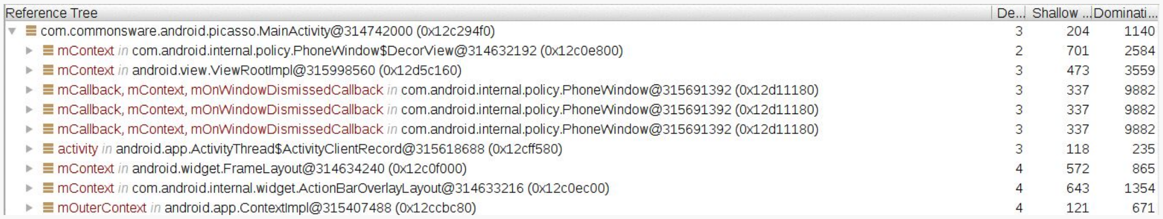
Figure 865: Heap Snapshot Tab, Instance Tree

Reference Tree

If you highlight an instance in the instance list — or if there is only one instance of the class — the Reference Tree view will be populated. This lists the instance you chose, and drills down into the objects that *reference* this instance. So, if the tree in the instance table shows you what Object X holds onto, the reference tree shows you what holds onto Object X:



Reference Tree	De...	Shallow ...	Dominati...
com.commonsware.android.picasso.MainActivity@314742000 (0x12c294f0)	3	204	1140
mContext in com.android.internal.policy.PhoneWindow$DecorView@314632192 (0x12c0e800)	2	701	2584
mContext in android.view.ViewRootImpl@315998560 (0x12d5c160)	3	473	3559
mCallback, mContext, mOnWindowDismissedCallback in com.android.internal.policy.PhoneWindow@315691392 (0x12d11180)	3	337	9882
mCallback, mContext, mOnWindowDismissedCallback in com.android.internal.policy.PhoneWindow@315691392 (0x12d11180)	3	337	9882

Figure 866: Heap Snapshot Tab, Reference Tree

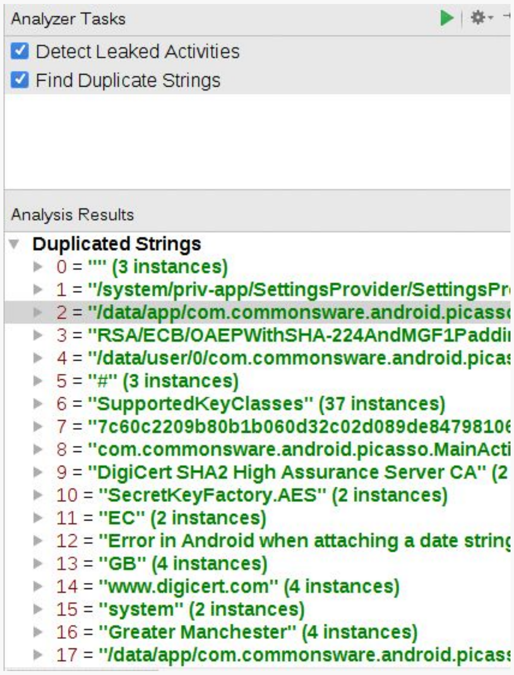
You can further expand the tree to see who references some of those references, and so on.

Identifying Leak Candidates

All of that is just great, but you still need to determine if you have a memory leak and, if so, where is it coming from.

Analyzer Tasks

Google recognizes that finding memory leaks is troublesome. The heap snapshot tab has an "Analyzer Tasks" view — by default docked on the right — to try to automate certain checks:



Analyzer Tasks

☑ Detect Leaked Activities
☑ Find Duplicate Strings

Analysis Results

```
▼ Duplicated Strings
   ▶ 0 = "" (3 instances)
   ▶ 1 = "/system/priv-app/SettingsProvider/SettingsPr
   ▶ 2 = "/data/app/com.commonsware.android.picass
   ▶ 3 = "RSA/ECB/OAEPWithSHA-224AndMGF1Paddi
   ▶ 4 = "/data/user/0/com.commonsware.android.pica
   ▶ 5 = "#" (3 instances)
   ▶ 6 = "SupportedKeyClasses" (37 instances)
   ▶ 7 = "7c60c2209b80b1b060d32c02d089de8479810
   ▶ 8 = "com.commonsware.android.picasso.MainActi
   ▶ 9 = "DigiCert SHA2 High Assurance Server CA" (2
   ▶ 10 = "SecretKeyFactory.AES" (2 instances)
   ▶ 11 = "EC" (2 instances)
   ▶ 12 = "Error in Android when attaching a date strin
   ▶ 13 = "GB" (4 instances)
   ▶ 14 = "www.digicert.com" (4 instances)
   ▶ 15 = "system" (2 instances)
   ▶ 16 = "Greater Manchester" (4 instances)
   ▶ 17 = "/data/app/com.commonsware.android.picas
```

Figure 867: Heap Snapshot Tab, Analyzer Tasks

Clicking the run button in the analyzer tasks toolbar will perform the automated checks.

The two checks that are automated today are finding leaked activities (i.e., activities that have been destroyed but cannot yet be garbage-collected) and duplicate strings. However, most of the duplicate strings are from the framework and zygote, not your code. So, while you may wish to skim through the list of duplicate strings to see if there are any that you recognize, in general they will not be all that useful.

We will see leaked activities more later in this chapter.

By Eyeball

Since the automated checks only catch so many things, you may have to find leak candidates the old-fashioned way: by eyeball. Basically, you rummage through the class list or package tree, looking for classes that either:

- you would not expect to be there (e.g., all instances should have been garbage-collected)
- you would not expect to be so numerous
- you would not expect to retain so much heap space

Bear in mind that the act of generating a heap dump only logs objects that are reachable from other objects, or themselves are considered "garbage collection roots" (a.k.a., "GC roots"). Any objects that are actual garbage, but perhaps have not yet been collected by the garbage collector, do not appear in the dump. Hence, if you see it in the heap snapshot tab, the objects are "real", not uncollected garbage.

Conversely, just because you find an object in the heap does not mean that it is truly "leaked". For example:

- Activities that have not been destroyed are not leaked, strictly speaking, though you may wish to consider whether changes to your app's navigation can allow you to reuse existing activity instances better.
- Objects that are part of a cache, such as Picasso's memory caching of downloaded images, are intentionally "leaked". You may use what you see in the heap snapshot tab to elect to reduce the size of those caches, or perhaps better consolidate multiple disparate caches, where possible.
- Objects in use by a running thread are not leaked… unless the thread itself is effectively leaked (i.e., exists, and refers to objects, but you do not know why that thread is still outstanding).

Common Leak Scenarios

With all that in mind, let's look at three common scenarios of leaking objects, to see what those leaks look like when we do a heap dump and analyze that dump in Android Studio.

The Static Widget

The `Leaks/StaticWidget` sample project does something naughty:

```
package com.commonsware.android.button;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;

public class ButtonDemoActivity extends Activity {
  private static Button pleaseDoNotDoThis;

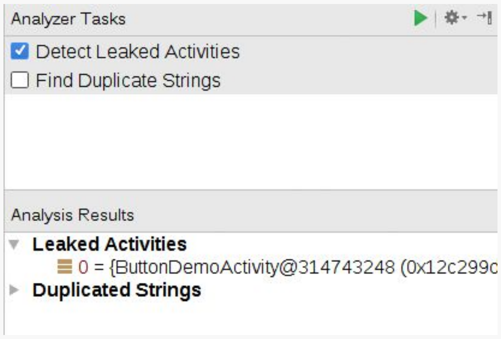
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pleaseDoNotDoThis=(Button)findViewById(R.id.button1);
  }
}
```

We take a widget (specifically a `Button`) and put it in a static data member, and never replace it with null.

As a result, even if the user presses BACK to get out of the activity, the static data member holds onto `Button`, which itself has a reference back to our `Activity`.

Because we are leaking an activity, the analyzer tasks can automatically find this leak for us:



Analyzer Tasks

☑ Detect Leaked Activities

☐ Find Duplicate Strings

Analysis Results

▾ **Leaked Activities**

  0 = {ButtonDemoActivity@314743248 (0x12c299c

▸ **Duplicated Strings**

Figure 868: Heap Snapshot Tab, Analyzer Tasks, Showing Leak

Tapping on that `ButtonDemoActivity` entry in the analyzer tasks brings it up in the instance table and reference tree:

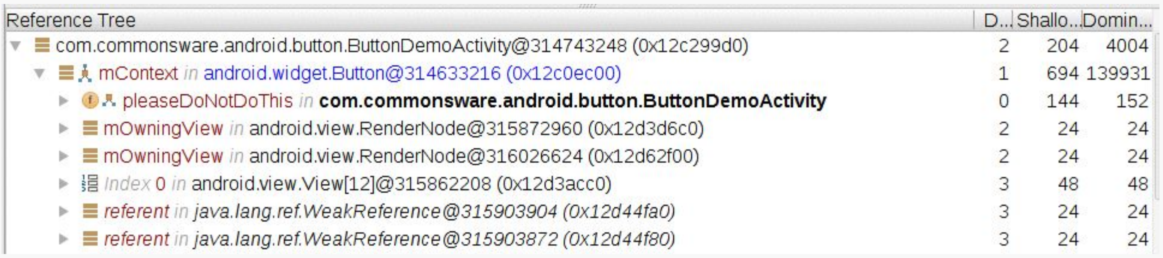
Figure 869: Heap Snapshot Tab, Showing Leak

The reference tree is sorted in descending order by depth. Hence, usually, the source of your leak will appear fairly early on in the tree. In our case, it happens to be the first entry:



Reference Tree	D...	Shallo...	Domin...
com.commonsware.android.button.ButtonDemoActivity@314743248 (0x12c299d0)	2	204	4004
mContext in android.widget.Button@314633216 (0x12c0ec00)	1	694	139931

mOwningView in android.view.RenderNode@316026624 (0x12d62f00)	2	24	24
Index 0 in android.view.View[12]@315862208 (0x12d3acc0)	3	48	48
referent in java.lang.ref.WeakReference@315903904 (0x12d44fa0)	3	24	24
referent in java.lang.ref.WeakReference@315903872 (0x12d44f80)	3	24	24

Figure 870: Heap Snapshot Tab, Showing Leak and Path to a GC Root

The leaked object (`ButtonDemoActivity`) is referenced by an `mContext` field in a static `pleaseDoNotDoThis` field in `ButtonDemoActivity` itself. The latter item has a depth of 0, so we know that it is a GC root. The hope is that you will recognize some of the items shown here (e.g., field names like `pleaseDoNotDoThis`) and can see how those items affect the ability for Android to garbage collect the leaked object.

Thread References

The Leaks/LeakedThread sample project does something else naughty:

```
package com.commonsware.android.leak.thread;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;

public class LeakedThreadActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    new Thread() {
      public void run() {
        while(true) {
          SystemClock.sleep(100);
        }
      }
    }.start();
  }
}
```

Here, we kick off a `Thread` from `onCreate()` of our activity and have it enter a pseudo-polling loop, sleeping for 100ms per pass through the loop.

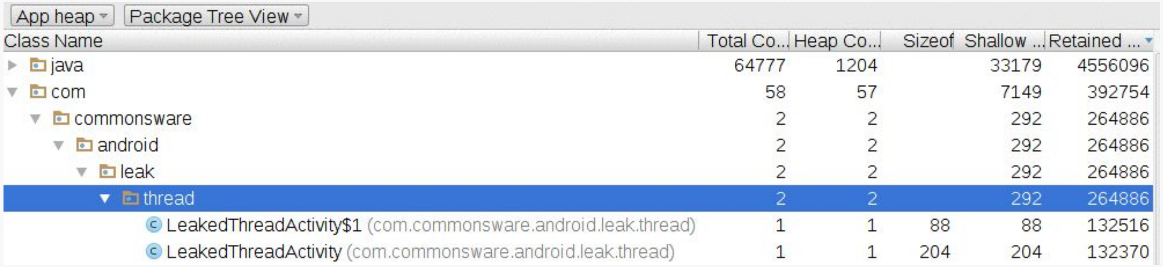
This is naughty for all sorts of reasons:

- Fast polling loops like this are bad for the battery
- We start a thread and never stop it
- We are using an anonymous inner class for our `Thread`

The latter two flaws combine to cause a memory leak.

Once again, the analyzer tasks pick up on this leaked activity. However, not all leaks will necessarily show up in the analyzer tasks, in part because not all leaks are leaked activities. What if we were leaking something else?

One way to find leaks is to go through the package tree view, find your Java packages for your code, and see what objects from those packages are outstanding:

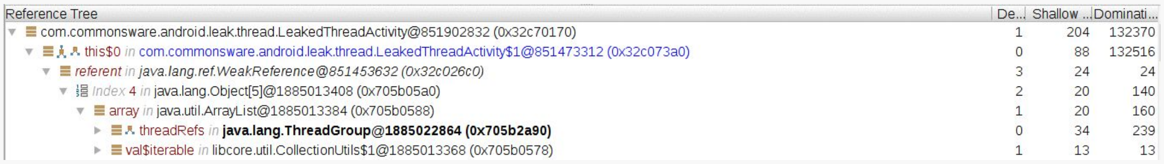


Class Name	Total Co...	Heap Co...	Sizeof	Shallow ...	Retained ...
java	64777	1204		33179	4556096
com	58	57		7149	392754
commonsware	2	2		292	264886
android	2	2		292	264886
leak	2	2		292	264886
thread	2	2		292	264886
LeakedThreadActivity$1 (com.commonsware.android.leak.thread)	1	1	88	88	132516
LeakedThreadActivity (com.commonsware.android.leak.thread)	1	1	204	204	132370

Figure 871: Heap Snapshot Tab, Showing Classes In App Package

Here, we see that we have leaked two objects. One is `LeakedThreadActivity`. The other is an anonymous inner class of `LeakedThreadActivity` (assigned the name `LeakedThreadActivity$1` by the Java compiler).

Clicking on the activity and expanding the first child in the reference tree once again discloses the leak:



Reference Tree	De...	Shallow ...	Dominati...
com.commonsware.android.leak.thread.LeakedThreadActivity@851902832 (0x32c70170)	1	204	132370
this$0 in com.commonsware.android.leak.thread.LeakedThreadActivity$1@851473312 (0x32c073a0)	0	88	132516
referent in java.lang.ref.WeakReference@851453632 (0x32c026c0)	3	24	24
Index 4 in java.lang.Object[5]@1885013408 (0x705b05a0)	2	20	140
array in java.util.ArrayList@1885013384 (0x705b0588)	1	20	160
threadRefs in **java.lang.ThreadGroup@1885022864 (0x705b2a90)**	0	34	239
val$iterable in libcore.util.CollectionUtils$1@1885013368 (0x705b0578)	1	13	13

Figure 872: Heap Snapshot Tab, Showing Another Leak and Its Path to a GC Root

Our zero-depth entry is `threadRefs`, which is basically the collection of all Java `Thread` objects that are still alive in this process. One of those is our anonymous inner class (`LeakedThreadActivity$1`), which holds onto the activity instance.

To avoid this sort of leak:

- Do not have everlasting threads — whatever component creates a thread needs to stop the thread when the component is being destroyed
- Do not use anonymous inner classes when creating threads, as an anonymous inner class has an implicit reference back to the outer class instance that created it (in this case, our activity), and that outer class instance cannot be garbage-collected until the thread terminates

Issues with System RAM

Your application heap is your little corner of the system RAM on the device that you focus on in your Java development. However, there are other things that you might do that consume system RAM, such as use the NDK to add C/C++ code to your app. How much system RAM you consume overall will have an impact on user acceptance of your app, as the more RAM you use, the more frequently the user's other apps are terminated to make room for you. And, as a result, the more system RAM you use, the more likely it is that *your* process will be terminated when you are not in the foreground, to free up RAM for other apps. Hence, while system RAM is not something you necessarily think about as often as you do your application heap, it *is* something that you should pay attention to, at least a little bit.

This chapter will explain a bit more about the relationship between your app and system RAM, how you can measure how much system RAM your app is consuming, and how you can reduce that consumption.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the chapter on Android's process model. Reading the chapter on issues with the application heap is also a good idea.

Can't We All Just Get Along?

Alas, we have not invented the device with infinite RAM, nor the application that takes zero memory. In fact, our devices have fairly limited RAM (e.g., 1GB), and our apps therefore fight over that memory. That includes both apps that the user runs explicitly (e.g., via the home screen launcher) and apps that run based upon external factors (e.g., the app that receives a GCM push event and uses that trigger to update some data).

The good news is that the user tends to be a bit oblivious to all of the comings and goings of apps. Android keeps process around while it can and terminates them as needed to free up system RAM for other processes, without the user's explicit involvement. Of course, power users might try to employ "task managers" and the like to be more involved in decision-making, but that's something they opted into, not something that was forced upon them, the way that older mobile operating systems like Windows Mobile required.

However, there is a fundamental assumption in Android that apps play fair. The per-process heap limits — and the fact that apps do not necessarily have to use all the way up to those limits — means that a given Android device can power many processes at once. That starts to break down when apps do various things to consume an excessive amount of system RAM, more than what the per-process heap limit would normally constrain them to. Hence, it is a good idea to keep tabs on how much you use of system RAM, so that you can be a "good citizen" and not cause the user undue angst or force them to employ task managers to try to keep you in line.

Contributors to System RAM Consumption

There are many factors that contribute towards your system RAM consumption, including:

- Your heap usage, up to the per-process heap limit, for each process that you are running
- Your native libraries (`.so` files) from the NDK
- The system RAM allocated by that native code, which does not count against your per-process heap usage

In addition, the reporting tools usually allocate a portion of shared RAM to your app. Your app's process is forked from the `zygote` process, which contains the Dalvik runtime environment, framework JAR (for all those `android.*` classes), and related libraries. Your app shares that memory with all other processes forked from the `zygote`. However, to reflect the fact that there is this overhead, your app's share of it (roughly calculated as the amount of shared RAM divided by the number of processes) tends to get added to your memory consumption totals.

Measuring System RAM Consumption: Tools

Figuring out how much RAM your application is using is not easy. Or, as Dianne Hackborn put it:

> Note that memory usage on modern operating systems like Linux is an extremely complicated and difficult to understand area. In fact the chances of you actually correctly interpreting whatever numbers you get is extremely low. (Pretty much every time I look at memory usage numbers with other engineers, there is always a long discussion about what they actually mean that only results in a vague conclusion.)

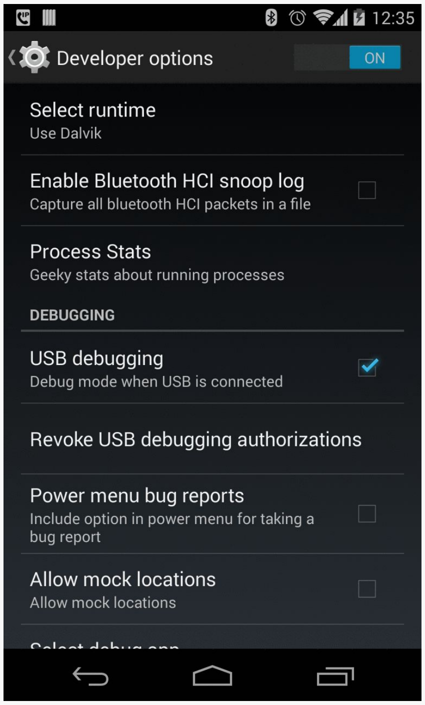
Fortunately, particularly in Android 4.4, a fair bit of work has gone into trying to help us determine how much our apps impact system RAM.

Process Stats in Settings

On Android 4.4, in Settings > Developer Options, you will find:

> Process Stats: Geeky stats about running processes

(here, “geeky” is presumably used as a term of endearment)



Select runtime
Use Dalvik

Enable Bluetooth HCI snoop log ☐
Capture all bluetooth HCI packets in a file

Process Stats
Geeky stats about running processes

DEBUGGING

USB debugging ☑
Debug mode when USB is connected

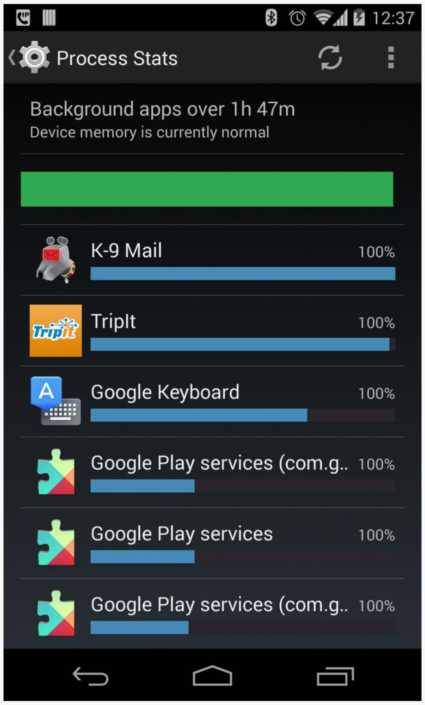
Revoke USB debugging authorizations

Power menu bug reports ☐
Include option in power menu for taking a bug report

Allow mock locations ☐
Allow mock locations

Figure 873: Developer Options in Android 4.4, Showing "Process Stats"

Tapping on that entry brings up a screen that describes the current state of the system, with respect to RAM:



Background apps over 1h 47m
Device memory is currently normal

K-9 Mail	100%
TripIt	100%
Google Keyboard	100%
Google Play services (com.g..	100%
Google Play services	100%
Google Play services (com.g..	100%

Figure 874: Process Stats in Android 4.4

While it may look simple, this screen, and its child screens, are remarkably complex, particularly once you start playing around with various options from the action bar overflow.

The Summary

At the top, you will see:

- How much history is being reported in this screen (“1h 47m”)
- What the current status of the system is with respect to RAM (“currently normal”)
- What the status of the system has been over that range of time, as illustrated by the bar, where green is “normal”

The bar is not so much a timeline as a stacked bar chart, where the mix of red and yellow indicates the amount of time the device was in a low-memory state, contrasted with the green “normal” state.

Usually, your device should be “normal” with a mostly-green or completely-green bar.

The Roster

The list beneath the summary shows some running processes. What is included in this list depends on what mode Process Stats in running in. The summary indicates that our mode is “Background apps”. There are three major categories for apps:

1. Foreground, which includes whatever app is truly in the visible foreground, plus any apps that have a foreground service
2. Background, which is pretty much everything else with a service
3. Cached, which are all apps that still have running processes but do not have a service

By default, Process Stats will show background processes.

Each row in the list shows details for a specific process:

- the application label for the app that owns the process (e.g., “K-9 Mail”)
- the percentage of time, for the time period Process Stats is reporting, that this process was running (e.g., “100%”)
- the “relative computed memory load” of that process, as is indicated by the blue bar, with longer blue bars indicating greater load

The list is sorted in order of “relative computed memory load”.

Many background apps will have a running percentage of 100%, indicating that they have an always-running service. Those with a percentage less than 100% indicate an app that had a service running at the point in time of the Process Stats snapshot that you are examining, but did not necessarily have a service running for the entire timeframe (e.g., periodic `IntentService` doing background work)

Refresh and Duration

There is a “refresh” icon in the action bar that will update the current view to reflect changes since you last opened or refreshed the screen.

How long the timeframe is depends a bit upon device operation and also on the “Duration” entry in the overflow menu:

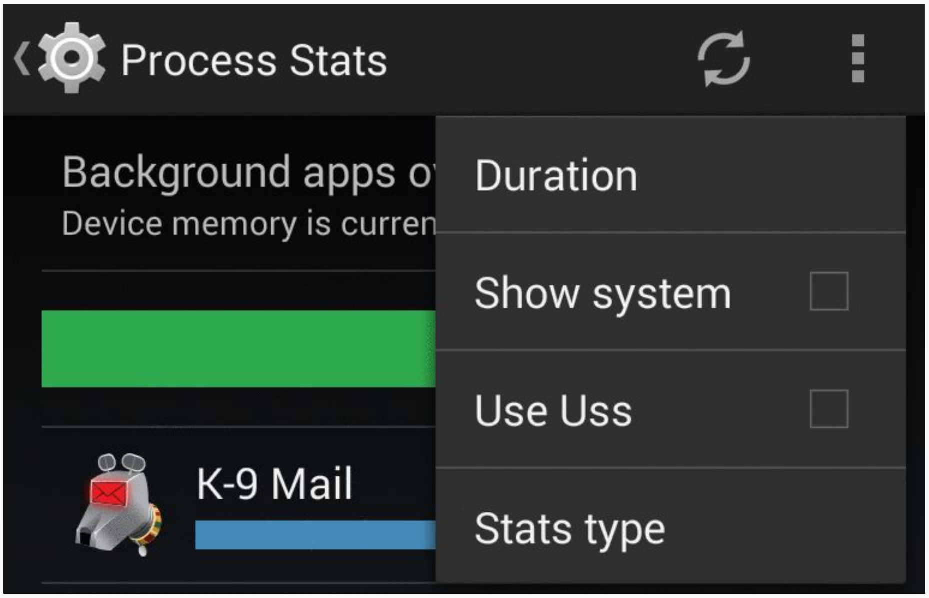


Figure 875: Process Stats Overflow in Android 4.4

Tapping that gives you a roster of available timeframes:

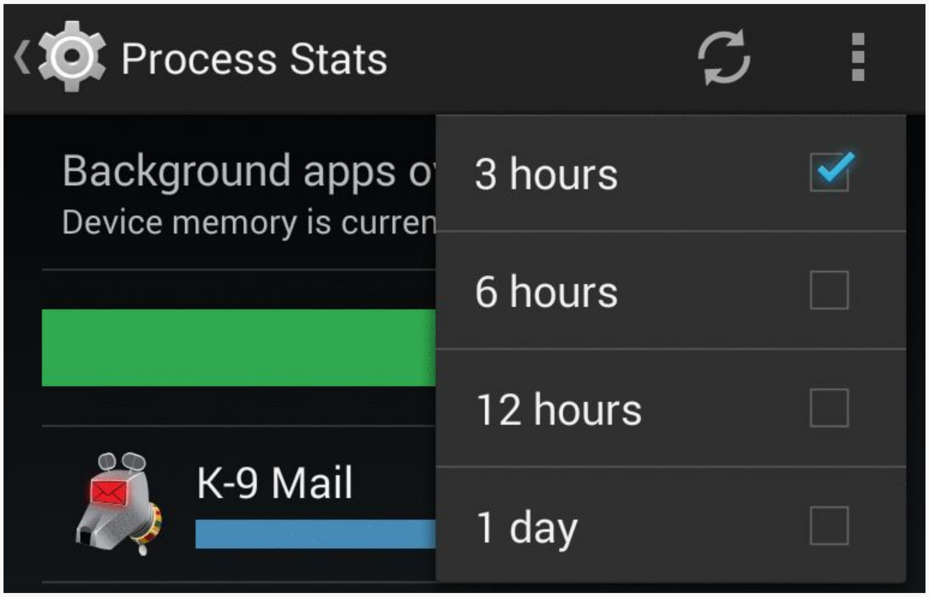

Figure 876: Process Stats Duration Options in Android 4.4

Even though these items render with checkboxes, they function as radio buttons, so whatever you tap on becomes the new duration. Upon making a change, the summary area will reflect the newly-chosen duration. Note that this choice is not persistent, as exiting Process Stats via the BACK button and re-entering it returns you to a three-hour duration.

Controlling What is Shown

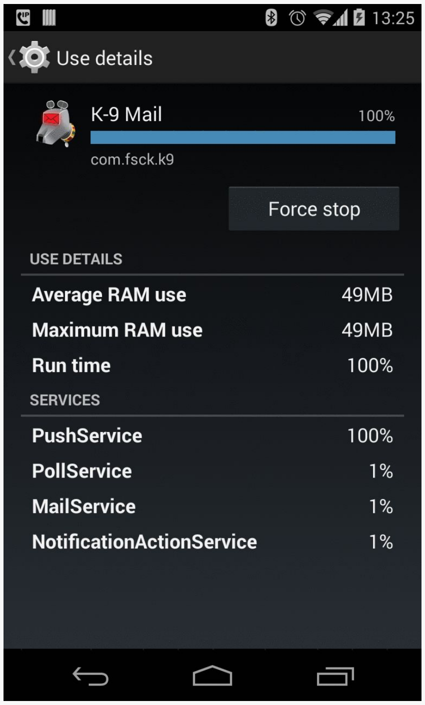
If your application is not showing up in the background roster, it may be classified as "foreground" (e.g., if you have a foreground service) or "cached" (if not). The "Stats type" overflow option will let you toggle between these categories, to see what processes are reported in each.

Note that an app can appear in more than one roster, since the roster is by *process*. For example, at the time of this writing, Evernote appears in the author's Nexus 4 both in "foreground" and in "cached", for separate processes.

As with the duration, the choice of category is not persistent, and you will be returned to the background process roster if you exit Process Stats via the BACK button and later return to it.

Drilling Down Into an App

Tapping on an item in the list will bring up details about that particular app and process:



13:25

Use details

K-9 Mail 100%

com.fsck.k9

Force stop

USE DETAILS

Average RAM use	49MB
Maximum RAM use	49MB
Run time	100%

SERVICES

PushService	100%
PollService	1%
MailService	1%
NotificationActionService	1%

Figure 877: Process Stats Details for K-9 Mail

The "Average RAM use" value shows how much system RAM is attributed to your app. This will include:

- All system RAM used uniquely by your app (e.g., your heap)
- A portion of system RAM shared by your app and others (e.g., the Dalvik runtime)

This is known as "Proportional Set Size" or "PSS" in Linux, and is a common way of coming up with a simple number for the amount of RAM that a particular process is responsible for.

The blue bar is based on this average RAM use (or PSS) value, multiplied by the percentage of the time that the process was running.

The "Maximum RAM use" value is the highest PSS associated with your process during the period under examination.

Also listed are the services of your app and the percentage of time that they were in a running state. Everlasting services will show up as 100%, while transient services (e.g., `IntentService`) will show up with a much smaller percentage.

How You Want Your App to Appear

Ideally:

- Your app spends most of its time in the “cached” process list, not the “background” or “foreground” list
- Your app has a low percentage of time spent running
- Your app has a low “relative computed memory load” and, ideally, a low “Average RAM use” value

The better you are in these areas, the more likely it is that you are not seriously impacting system RAM.

procstats

The data that powers the Process Stats screen in Settings is also available as human-readable text output, using the `adb shell dumpsys procstats` command, against your Android 4.4 device or emulator.

Running that command will give you three blocks of information:

- Process memory usage, aggregated over the last 24 hours
- Process memory usage, aggregated over the last 3 hours
- A snapshot of the current memory usage, at the time you ran the command

This can be a long report, even for just one of those blocks. For example, here is the last-3-hours block, run on the author’s personal Nexus 4:

```
AGGREGATED OVER LAST 3 HOURS:
  * com.android.bluetooth / 1002:
           TOTAL: 100% (7.8MB-7.8MB-7.8MB/7.0MB-7.0MB-7.0MB over 2)

```

Unfortunately, it is rather cryptic and rather long.

There are various command-line switches you can add to help manage the output. Use the `-h` switch to see the full roster. Some notable options:

- `-csv` switches the output to be in CSV format, for importing into a spreadsheet or running through an analysis tool, with other switches (e.g., `-csv-proc`) to control what is included in the CSV output
- `--current` will only report the current snapshot
- `--hours NNN` will only report the aggregate over the stated number of hours
- `--full-details` provides a somewhat more documented report, at the cost of greatly increasing its verbosity

Also, including a package name (e.g., `com.commonsware.android.sample`) at the end of the command line will constrain the output to solely that package, which is useful if you are only looking to examine your own app's data.

The numbers in parentheses (e.g., `(4.7MB-4.7MB-4.7MB/3.8MB-3.8MB-3.8MB over 2)`) report:

- the minimum proportional set size (PSS) seen
- the average PSS seen
- the maximum PSS seen
- the minimum unique set size (USS) seen, where this is the amount of memory consumed by your app that is *not* shared with other processes (i.e., it is how much memory that would be freed if your process were terminated)
- the average USS seen
- the maximum USS seen
- the number of samples taken of the memory during the timeframe being analyzed

The listing also shows the percentage of time your process was in various states (e.g., cached vs. service vs. "important foreground")

meminfo

Older devices that do not support `procrank` can support `meminfo`, accessed via **`adb shell dumpsys meminfo`**. Run as-is, it will generate a report of all processes and their PSS, plus the same roster broken down into various process categories (e.g., foreground, cached), and other summary data. The report for the same Nexus 4 that generated the `procrank` shown earlier in this chapter is:

```
Applications Memory Usage (kB):
Uptime: 95955008 Realtime: 788076654

```

This can show you:

- How much memory is being consumed by your Dalvik bytecode (`.dex mmap`), native libraries used directly by you or by framework components (`.so mmap`), etc.
- How many objects of various types are in the Dalvik heap, such as views and activities
- How much memory is used by SQLite for its page cache and related process-level buffers, plus which databases you have open that are contributing to memory consumption

Note that the combination of the `Private Dirty` and `Private Clean` columns is roughly analogous to the USS reported by `procstats`, in that it represents the amount of memory private to your process and that would be released should your process be terminated.

Measuring System RAM Consumption: Runtime

Some of the same information that the aforementioned reports contain is available at runtime via `ActivityManager` and other framework classes.

getMemoryInfo()

`getMemoryInfo()` on `ActivityManager` will fill in a supplied `ActivityManager.MemoryInfo` object. This will report to you:

- The total memory on the device (`totalMem`)
- The "available memory" (whose definition is a bit unclear) (`availMem`)
- What level of "available memory" is considered "low" and should trigger Android to start terminating processes beyond those that are cached, such as ones with running services (`threshold`)
- Whether we are presently in such a low-memory state (`lowMemory`)

getMyMemoryState()

`ActivityManager` also has a `getMyMemoryState()` method, on API Level 16+, that will populate an `ActivityManager.RunningAppProcessInfo` object with information about your process. While not everything in this object will be filled in, you will be able to get:

- The last trim level reported to your activities and `Application` via `onTrimMemory()` (`lastTrimLevel`)
- What importance level the OS considers your process to be in (`importance`), such as `IMPORTANCE_FOREGROUND` and `IMPORTANCE_EMPTY`
- For processes in the `IMPORTANCE_BACKGROUND` category — meaning the process has outstanding activities but is not in the foreground and has no service — the relative standing of the process compared to other background processes from a least-recently-used standpoint (`lru`), where lower numbers mean more recent usage

getProcessMemoryInfo()

The getProcessMemoryInfo() method on ActivityManager returns an array of Debug.MemoryInfo objects corresponding to the array of int process IDs (pids) that you pass in. The Debug.MemoryInfo objects report how much memory those identified processes are consuming. Of particular note, getTotalPss() returns the PSS for that process.

To get the Debug.MemoryInfo for your own process, you can use getMemoryInfo() on the Debug class, rather than find your own process ID and use getProcessMemoryInfo(). Or, on API Level 14+, you can simply call getPss() on Debug directly to find out your PSS.

Learn To Let Go (Of Your Heap)

Part of the reason for worrying a bit about your system RAM consumption is simply to “play nice” with the other apps that the user wants to use. However, since part of Android’s decision-making about what processes to terminate tie into how much RAM those processes take up, the lower your system RAM footprint, the more likely it is that you can hang around for a while.

Part of reducing your system RAM consumption involves cleaning up your heap.

The reason the framework calls callback methods like onTrimMemory() is to help you reduce your heap usage to avoid OutOfMemoryError exceptions. However, allowing objects to be garbage-collected not only gives you more heap space, but it *also may reduce your system RAM footprint*.

To limit your system RAM usage, your process is not allocated all of its possible heap when the process is started up. Instead, the heap starts small and expands as you allocate more and more memory. However, the reverse is also true: if you release memory, the heap can shrink, returning RAM to the system. Android expands the heap on a “paged” basis, allocate more system RAM to add more pages to the heap. If, as a result of garbage collection, Dalvik sees that there are too many totally empty pages, Dalvik can free up those pages, returning them to the OS for use by other processes.

As noted in the chapter on the application heap, Dalvik’s garbage collector is non-compacting, meaning that it does not move objects around to try to clean up pages or otherwise coalesce free memory blocks. Hence, a fragmented heap not only limits how well you can allocate new memory, but it also inhibits Dalvik’s ability to reduce your system RAM usage.

Issues with Battery Life

Most Android devices are powered by batteries — Android TV is the biggest class of device that is not. Batteries are wonderful gizmos with one major problem: they are *always* running out of power.

Hence, users are very sensitive to battery consumption. Their ability to use their phones as actual *phones*, let alone for Android apps, depends on having enough battery power. The more apps drain the battery, the more frequently the user has to find a way to recharge the phone, and the more frequently the user fails and their phone shuts down.

The catch is that you may not notice the battery issues in your day-to-day development. The Android emulator's emulated battery does not drain based on you running your app. Your devices are often connected to your development machine via USB for testing and debugging, meaning they are perpetually being charged. Unless you are a regular user of your own app, you might not notice any increased power drain.

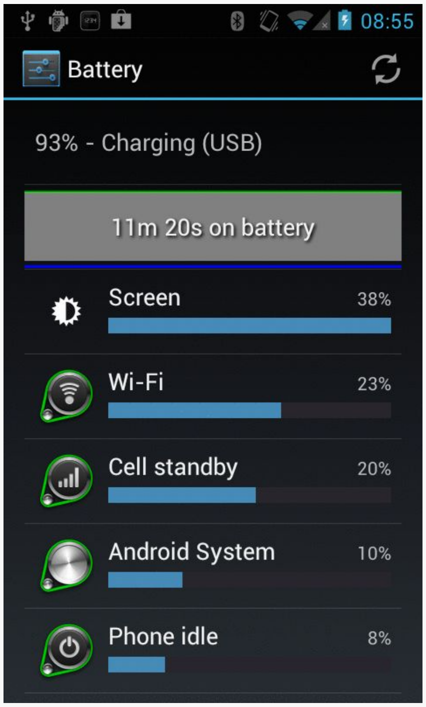
This part of the book is focused on helping you understand what is draining power and what you can do to be kinder and gentler on your users' batteries.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

You’re Getting Blamed

Users, for better or worse, have limited ability to determine what is responsible for draining the battery of their phone. Their #1 tool for this is the “Power Usage Summary” screen in the Settings app, sometimes referred to as the “battery blame screen”.



Battery

93% - Charging (USB)

11m 20s on battery

Screen 38%

Wi-Fi 23%

Cell standby 20%

Android System 10%

Phone idle 8%

Figure 878: Battery Screen from Settings App

This lists both device features (e.g., the display) and applications. Android incrementally improves the accuracy of this screen with each passing release, trying to make sure the user understands what specifically is consuming the power.

If your application starts appearing on this screen, and the user does not feel that it is justified, the user is likely to become irritated with you.

Now, your appearance on this list might be perfectly reasonable. If you have written a video player app, and the user has just watched a few hours’ worth of video, it is very likely that you will appear on this list and will be justified in your battery consumption.

However, anything that you can do to not appear on this screen, or appear lower in the list, will help with user acceptance of your app.

This part of the book will show you how to measure your power usage and ways of trying to use less of it.

Not All Batteries Are Created Equal

Roughly speaking, battery capacity is proportional to screen size. Larger screens mean physically larger devices, and since the rest of the components (e.g., CPU) tend to be the same size, a larger device offers more room for a larger battery. This is good, as the screen is one of the major power draws on a device, and bigger screens draw more power.

Conversely, the battery on a “wearable” — whether eyewear like Google Glass, a smartwatch, or other form factors — tends to be much smaller than average, just because the wearables are physically smaller. A wearable is likely to have a battery with less than a third of the capacity of a phone, which in turn may have a battery with less than a third of the capacity of a large tablet.

Hence, depending upon where your app will be running, the amount of battery available in total will vary widely. What might be considered acceptable battery consumption on a tablet would be considered excessive on a wearable.

Stretching Out the Last mWh

Sometimes, what the user wants your app to do in one case is not what the user wants your app to do in other cases. Serious power-draining might be reserved for when the device is plugged in, or when the device has at least such-and-so power remaining. The user may value the last milliwatt-hours (mWh) more than others and want your application to use less power in those circumstances.

Hence, if your application polls the Internet, you might offer a feature to poll less frequently, or perhaps not at all, when power is low. If your application uses GPS to find a location (e.g., automatic “check-ins” to social networks like Foursquare), you might offer to skip such actions when the battery is low. You might want to signal to the user when the battery gets low during playback of a video, or during the game they are in. And so on.

ISSUES WITH BATTERY LIFE

This part of the book will help you identify when the battery is low and strategies for making use of that information.

Power Measurement Options

As with any situation where you are trying to reduce your use of some system resource, you need to be able to accurately measure how much you are using that resource. Otherwise, you will have no idea whether your attempts to reduce usage are helping. It is possible that what you think will consume less of the resource actually consumes *more*, because of unanticipated side-effects. And, if nothing else, if the change makes your code more complicated and does not help much with resource consumption, you may be better served sticking with the original, simpler implementation.

So, when it comes to power usage, it helps to know how much power you are consuming, to determine if your attempts to use less power actually do help.

Unfortunately, compared to things like RAM and bandwidth, power measurement is a significant challenge. You really need to have hardware specifically instrumented to report power consumption for pieces of that hardware (CPU versus screen versus GPS versus mobile data radio versus …). Even if you cannot get power usage per component, just having accurate power consumption overall is not something you can necessarily get from any Android device. Alas, getting that level of power usage knowledge can be troublesome in its own right, for a variety of reasons.

This chapter will explore a few ways of measuring power usage, along with the pros and cons of that approach.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

batterystats and the Battery Historian

Android 5.0 brought us "Project Volta", an initiative to reduce the amount of power consumed by apps, the framework classes, and the OS itself.

Part of what we got from Project Volta is `batterystats`, a dump of data pertaining to power consumption. Since that data dump can be large and inscrutable, we also have the Battery Historian, a tool that can convert key `batterystats` output into a timeline of events.

However, none of this is especially well-documented at this time, and so the usefulness of these utilities is limited at present. The following sections provide some basic guidance for trying to use these tools.

Running a Test

First, since `batterystats` is obtained via **`adb shell dumpsys`**, you will want **`adb`** to be in your `PATH`, by adding your SDK installation's `platform-tools/` directory to your `PATH` environment variable.

Then, in a terminal, run:

```
adb shell dumpsys batterystats --enable full-wake-history
adb shell dumpsys batterystats --reset
```

This will ensure that `batterystats` captures all relevant information about `WakeLock` behavior, and it resets all of the logs.

At this point, run your tests. Ideally, you would do so in a fairly power-neutral environment, such as not using a USB cable for an `adb` connection (as that charges the device).

When your test scenario is complete, run **`adb shell dumpsys batterystats`**, redirecting the output to some file:

```
adb shell dumpsys batterystats > /tmp/bs.txt
```

You can optionally supply your `applicationId` as part of the `batterystats` command, which will restrict the output to events pertaining to your app. However, some events that are from other processes, like the Play Services Framework, may be of interest to you. You will need to experiment to determine which mode (full or filtered for your app) will work best for you.

Interpreting the Text Output

Depending on how long your test runs, the information included in the `batterystats` output can be anywhere from tens of KB to tens of MB in size. The output will also vary by Android OS release.

Battery History

The file will lead off with the "Battery History" section:

```
Battery History (13% used, 35KB used of 256KB, 68 strings using 4232):
          0 (9) RESET:TIME: 2014-10-25-19-54-07

   +6s968ms (2) 100 -wake_lock_in=1027:"NfcService:mRoutingWakeLock"
.
.
.
```

This contains information about how much the battery was drained during the test run, along with a detailed roster of the power-related events that occurred during the test run. The timestamps on those roster entries are relative to the first entry in the roster. Beyond that, there is little explanation of what the roster entries mean.

Per-PID Stats

Next, there will be a short stanza labeled “Per-PID Stats” and, possibly, “Discharge step durations”:

```
Per-PID Stats:
  PID 0 wake time: +134ms
  PID 536 wake time: +1m35s993ms
  PID 0 wake time: +10s842ms
  PID 881 wake time: +301ms
  PID 536 wake time: +70ms
  PID 989 wake time: +23s167ms
  PID 1136 wake time: +2s974ms
  PID 1193 wake time: +230ms
  PID 0 wake time: +1s123ms
  PID 617 wake time: +187ms
  PID 536 wake time: +18ms
  PID 536 wake time: +13ms
  PID 627 wake time: +586ms
  PID 536 wake time: +184ms
  PID 3690 wake time: +9m42s965ms

Discharge step durations:
  #0: +4h8m36s976ms to 97 (screen-off, power-save-off)
  #1: +3h7m47s132ms to 98 (screen-off, power-save-off)
```

If you determine your process’ PID, you will see how long the process’ “wake time” was. The precise definition of “wake time” is undocumented.

Daily Stats

Next may be a section entitled “Daily stats”:

```
Daily stats:
  Current start time: 2015-12-12-05-27-33
  Next min deadline: 2015-12-13-01-00-00
  Next max deadline: 2015-12-13-03-00-00
    Package changes:
      Update com.google.android.dialer vers=20312
      Update com.google.android.apps.cloudprint vers=113
      Update com.android.chrome vers=252608301
      Update com.google.android.marvin.talkback vers=40400003
      Update com.google.android.contacts vers=10307
      Update com.commonsware.empublite vers=1
      Update com.commonsware.android.picasso vers=1
  Daily from 2015-12-11-05-55-34 to 2015-12-12-05-27-33:
    Discharge step durations:
      #0: +4h49m4s38ms to 93 (screen-off, power-save-off, device-idle-on)
      #1: +3h53m22s969ms to 94 (screen-off, power-save-off)
      #2: +5h8m4s10ms to 95 (screen-off, power-save-off, device-idle-on)
      #3: +3h33m53s102ms to 96 (screen-off, power-save-off, device-idle-on)
        Discharge total time: 18d 3h 10m 2s 900ms  (from 4 steps)
        Discharge screen off time: 18d 3h 10m 2s 900ms  (from 4 steps)
        Discharge screen off device idle time: 18d 18h 33m 58s 300ms  (from 3 steps)
    Package changes:
      Update com.commonsware.empublite vers=1
  Daily from 2015-12-10-04-55-48 to 2015-12-11-05-55-34:
    Discharge step durations:
      #0: +5h1m15s618ms to 98 (screen-off, power-save-off, device-idle-on)
      #1: +42m34s7ms to 98 (screen-off, power-save-off, device-idle-off)
        Discharge total time: 11d 22h 31m 21s 200ms  (from 2 steps)
        Discharge screen off time: 11d 22h 31m 21s 200ms  (from 2 steps)
        Discharge screen off device idle time: 20d 22h 6m 1s 800ms  (from 1 steps)
    Package changes:
      Update com.commonsware.ct3 vers=1
      Update com.commonsware.ct3 vers=1
      Update com.commonsware.ct3 vers=1
      Update com.commonsware.ct3 vers=1
      Update com.commonsware.ct3 vers=1
      Update com.commonsware.ct3 vers=1
      Update com.commonsware.android.fsendermnc vers=1
...
```

This indicates, for various time slices, what apps were updated and what the "discharge step durations" are (which is undocumented).

"Statistics since last charge" Summary

Next up will be a "Statistics since last charge" header, with a few summary blocks of data:

```
Statistics since last charge:
  System starts: 0, currently on battery: false
  Time on battery: 11h 30m 29s 177ms (99.9%) realtime, 16m 13s 306ms (2.3%) uptime
  Time on battery screen off: 11h 30m 7s 940ms (99.9%) realtime, 15m 52s 69ms (2.3%)
uptime
  Total run time: 11h 30m 55s 300ms realtime, 16m 39s 430ms uptime
  Start clock time: 2014-10-25-19-54-07
  Screen on: 21s 237ms (0.1%) 2x, Interactive: 20s 191ms (0.0%)
  Screen brightnesses:
    dark 21s 237ms (100.0%)
  Total partial wakelock time: 10m 22s 877ms
  Mobile total received: 0B, sent: 0B (packets received 0, sent 0)
  Phone signal levels:
    none 11h 30m 29s 177ms (100.0%) 0x
  Signal scanning time: 9s 0ms
  Radio types:
    none 11h 30m 29s 177ms (100.0%) 0x
  Mobile radio active time: 0ms (0.0%) 0x
  Wi-Fi total received: 0B, sent: 0B (packets received 0, sent 0)
  Wifi on: 11h 30m 29s 177ms (100.0%), Wifi running: 11h 30m 29s 177ms (100.0%)
  Wifi states: (no activity)
  Wifi supplicant states:
    group-handshake 16ms (0.0%) 12x
    completed 11h 30m 29s 161ms (100.0%) 12x
  Wifi signal levels:
    level(4) 11h 30m 29s 177ms (100.0%) 1x
  Bluetooth on: 0ms (0.0%)
  Bluetooth states: (no activity)

  Device battery use since last full charge
    Amount discharged (lower bound): 2
    Amount discharged (upper bound): 3
    Amount discharged while screen on: 0
    Amount discharged while screen off: 3

  Estimated power use (mAh):
    Capacity: 3448, Computed drain: 107, actual drain: 69.0-103
    Idle: 40.3
    Wifi: 36.4
    Uid u0a58: 14.8
    Uid 0: 12.8
    Uid 1000: 1.75
    Uid u0a20: 0.521
    Uid u0a7: 0.389
    Screen: 0.375
    Uid 1013: 0.0775
    Uid 1001: 0.0219
    Uid u0a42: 0.0168
    Uid u0a12: 0.0138
    Uid 1027: 0.0110
    Uid u0a5: 0.00866
    Uid u0a33: 0.00253
    Uid u0a16: 0.000867
    Uid u0a3: 0.000815
    Uid u0a29: 0.000523
    Uid u0a2: 0.000474
    Over-counted: 4.04
```

The first block has useful data about how much various radios were on, how much data they transmitted, how long the screen was on, how long the device had an outstanding partial `WakeLock`, etc.

Also, the “Estimated power use (mAh)” block is basically the data that underlies the “battery blame screen” in Settings. You will see how many milliamp-hours (mAh) were attributed to your process.

WakeLock Summary

Next up may a summary of `WakeLock` events:

```
All kernel wake locks:
Kernel Wake lock PowerManagerService.WakeLocks: 10m 23s 46ms (717 times) realtime
Kernel Wake lock qcom_rx_wakelock: 9m 9s 836ms (1537 times) realtime
Kernel Wake lock alarm_rtc: 55s 327ms (717 times) realtime
Kernel Wake lock sns_async_ev_wakelock: 16s 525ms (9 times) realtime
Kernel Wake lock power-supply: 15s 730ms (1448 times) realtime
Kernel Wake lock event0-536: 11s 822ms (1484 times) realtime
Kernel Wake lock event2-536: 10s 686ms (1509 times) realtime
Kernel Wake lock event4-536: 10s 234ms (1509 times) realtime
Kernel Wake lock alarm: 7s 972ms (1239 times) realtime
Kernel Wake lock wlan: 1s 608ms (2 times) realtime
Kernel Wake lock PowerManagerService.Display: 611ms (2 times) realtime
Kernel Wake lock main: 608ms (0 times) realtime
Kernel Wake lock KeyEvents: 136ms (1548 times) realtime
Kernel Wake lock mmc0_detect: 38ms (1507 times) realtime
Kernel Wake lock deleted_wake_locks: 28ms (170 times) realtime
Kernel Wake lock event5-536: 20ms (2 times) realtime

All partial wake locks:
Wake lock u0a58 wake:com.commonsware.android.job/.DemoScheduledService: 9m 0s 153ms
(671 times) realtime
Wake lock 1000 *alarm*: 44s 114ms (683 times) realtime
Wake lock u0a7 Checkin Service: 16s 572ms (4 times) realtime
Wake lock 1000 NetworkStats: 7s 347ms (338 times) realtime
Wake lock 1013 AudioMix: 5s 833ms (2 times) realtime
Wake lock 1000 DHCP: 4s 953ms (12 times) realtime
Wake lock u0a7 *net_scheduler*: 1s 504ms (82 times) realtime
Wake lock u0a7 Event Log Service: 1s 98ms (18 times) realtime
Wake lock u0a42 DownloadManager: 322ms (1 times) realtime
Wake lock u0a7 Config Service fetch: 235ms (1 times) realtime
Wake lock u0a7 Icing: 197ms (5 times) realtime
Wake lock u0a7 Event Log Handoff: 143ms (18 times) realtime
Wake lock u0a58 *alarm*: 120ms (24 times) realtime
Wake lock u0a7 GCM_CONN: 61ms (36 times) realtime
Wake lock u0a7 GmsDownloadService: 47ms (1 times) realtime
Wake lock u0a7 *alarm*: 42ms (10 times) realtime
Wake lock u0a7 Wakeful StateMachine: GeofencerStateMachine: 35ms (8 times) realtime
Wake lock 1000 SyncManagerHandleSyncAlarm: 34ms (6 times) realtime
Wake lock u0a7 GCM_HB_ALARM: 34ms (36 times) realtime
Wake lock u0a7 Checkin Handoff: 12ms (4 times) realtime
Wake lock 1000 SyncLoopWakeLock: 8ms (4 times) realtime
Wake lock u0a33 *alarm*: 7ms (4 times) realtime
Wake lock u0a42 *alarm*: 4ms (3 times) realtime
Wake lock u0a7 GCoreFlp: 2ms (5 times) realtime
```

If you do not have a separate section for these, they may be interleaved in the "Statistics since last charge:" data.

Your code will tend to show up in the "All partial wake locks" section, showing how many `WakeLocks` you acquired and for how long overall.

And, if you show up here, you can definitely find out your app's PID — for example, `u0a58` is associated with the `com.commonsware.android.job` package.

Per PID Summary

Next up may be summaries of information per process; otherwise, this information is interleaved in the "Statistics since last charge:" section. Your process will show up somewhere in the list:

```
.
.
```

```
.
u0a58:
  Wake lock wake:com.commonsware.android.job/.DemoScheduledService: 9m 0s 153ms partial
(671 times) realtime
  Wake lock *alarm*: 120ms partial (24 times) realtime
  TOTAL wake: 9m 0s 273ms partial realtime
  Foreground activities: 7s 817ms realtime (1 times)
  Foreground for: 12s 959ms
  Active for: 3h 58m 47s 853ms
  Running for: 11h 30m 29s 177ms
  Proc com.commonsware.android.job:
    CPU: 1m 4s 370ms usr + 21s 140ms krn ; 400ms fg
  Proc *wakelock*:
    CPU: 43s 690ms usr + 1m 19s 590ms krn ; 0ms fg
  Apk com.commonsware.android.job:
    672 wakeup alarms
    Service com.commonsware.android.job.DemoScheduledService:
      Created for: 11m 14s 174ms uptime
      Starts: 647, launches: 647
.
.
.
```

As usual, the exact definitions of the information here is largely undocumented.

Installing the Battery Historian

While `batterystats` is part of the Android 5.0+ runtime environment, and tools like `adb` are part of the Android SDK, the Battery Historian is neither. Instead, it is a separate project that you have to download to your development machine from its GitHub project.

The original implementation of the Battery Historian was a Python script. This is still available as the `historian.py` file in that GitHub repository, until such time as Google elects to delete it.

Battery Historian 2.0 is now a server written in the Go programming language. This requires a fair bit more work to set up, as you need to:

- install a Go compiler
- download Go dependencies manually
- modify your `PATH` environment variable, plus add new environment variables
- deal with the intrinsic hassles and risks of running an unnecessary server

This chapter focuses on the original Python script.

Running the Battery Historian

Once you have downloaded that Python script, and assuming that you have a Python interpreter installed, you can run the script, supplying it with the output of your `batterystats` run, and redirecting the script's output to an HTML file:

```
python historian.py /tmp/bs.txt > /tmp/bs-report.html
```

Interpreting the Historian Output

You can then load that HTML into a Web browser (Chrome-flavored ones are probably a good choice, given that it is Google-generated HTML). This will give you a timeline across the horizontal axis, with event categories culled from the "Battery History" section of the `batterystats` output on the vertical axis:

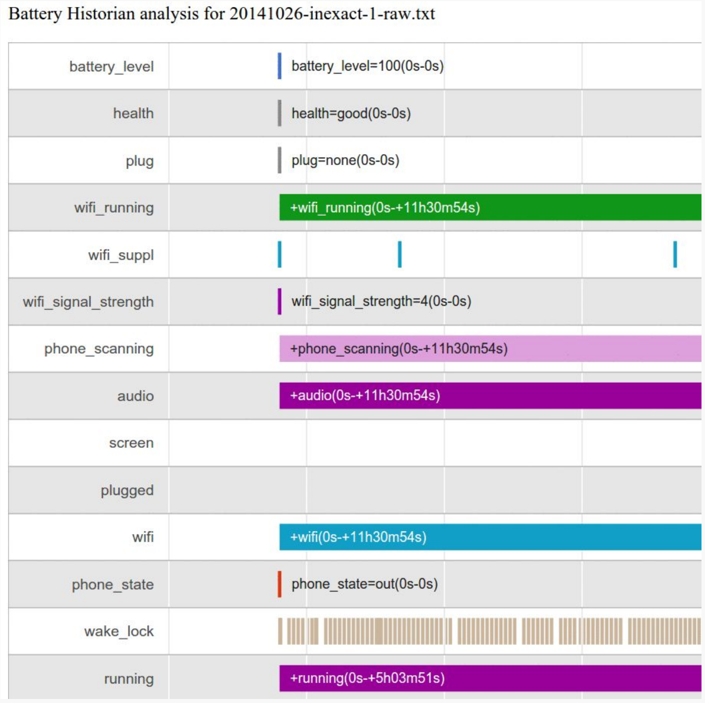

Figure 879: Battery Historian Timeline, Partial View

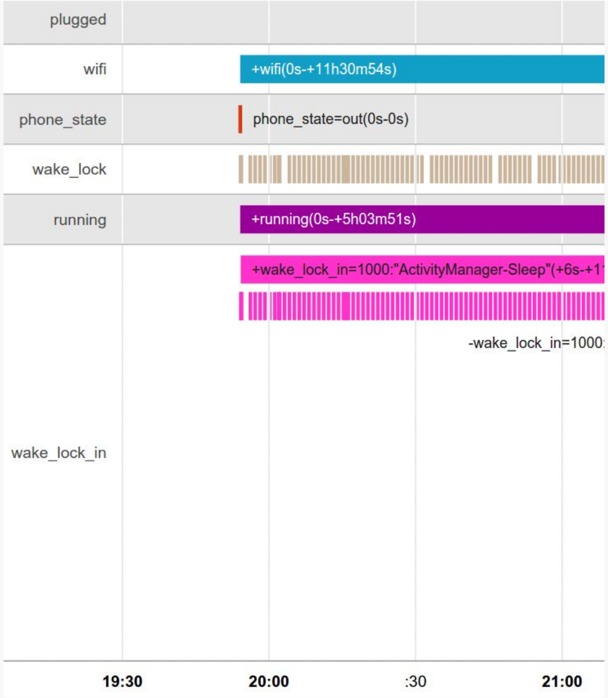

Figure 880: Battery Historian Timeline, Additional

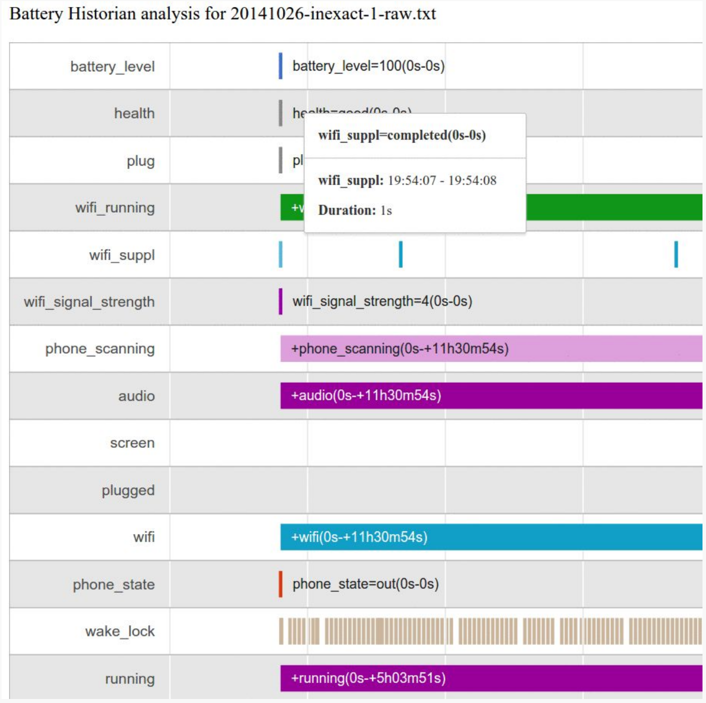
The length of the bar shows the approximate duration of the event, though really short events have a *de minimus* length to give you something to see. Hovering your mouse over one of the bars brings up a pop-up with more details about that event:



Battery Historian analysis for 20141026-inexact-1-raw.txt

wifi_suppl=completed(0s-0s)

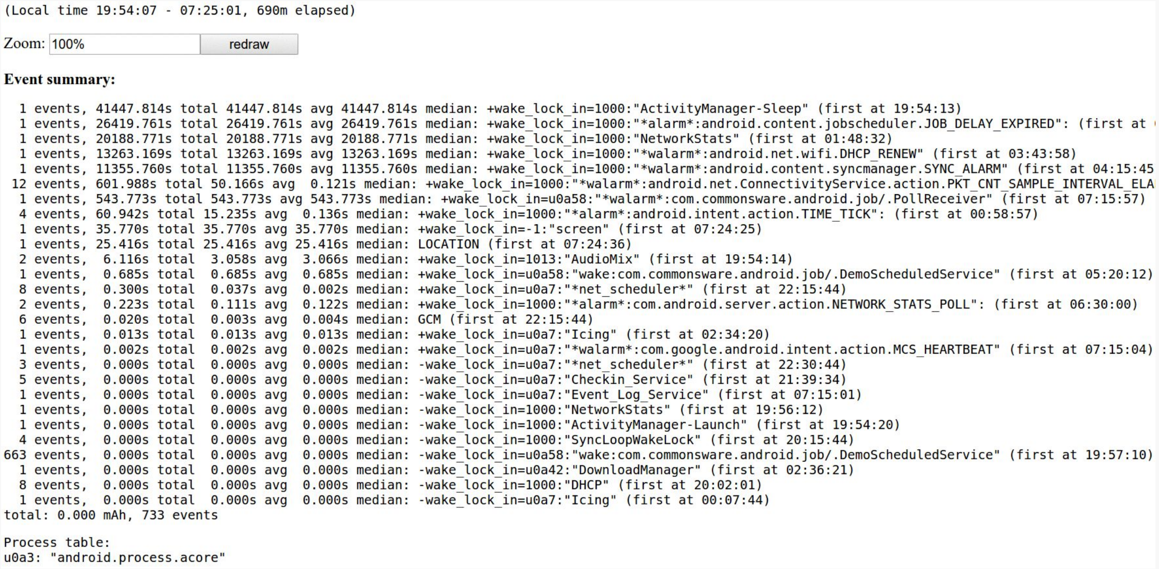
wifi_suppl: 19:54:07 - 19:54:08

Duration: 1s

Figure 881: Battery Historian Timeline, Partial View, with Pop-Up

If the bar is really long, you may need to scroll your browser horizontally to see the pop-up, as the rendering of the pop-up location does not seem to pay attention to the browser viewport very well.

Below the main chart is a "Zoom" field that you can use to change the scale of the horizontal axis, along with an "Event summary":



```
(Local time 19:54:07 - 07:25:01, 690m elapsed)
```

Event summary:

```
  1 events, 41447.814s total 41447.814s avg 41447.814s median: +wake_lock_in=1000:"ActivityManager-Sleep" (first at 19:54:13)

Again, this is largely undocumented.

The Qualcomm Tool (That Must Not Be Named)

Qualcomm makes the chipsets that drive a substantial percentage of Android devices. Qualcomm also offers a number of things to further help Android developers, such as open source libraries like AllJoyn (P2P communications).

Qualcomm makes a tool that can help you measure power consumption. There are two versions of this tool:

1. The best version is designed to run on [the Qualcomm MDP series of reference hardware](), and takes advantage of specific capabilities of that hardware to provide excellent power consumption data
2. Another version can be used with other Android devices powered by Qualcomm chipsets, providing information about power usage, though not quite as much as you get from the first version

Alas, this book does not cover this tool.

The current versions of this tool have a license agreement containing crudely-implemented non-disclosure terms:

> You shall not to disclose or permit the disclosure of the Materials in any form or any information relating to the Materials (including without limitation the results of use or testing) to any third party without QTI's prior written permission… You further acknowledge and agree that if QTI, in its sole discretion, chooses to provide any form of support or information relating to the Materials, such support and information shall be deemed confidential and proprietary to QTI and shall be protected in accordance with this Section 4.

In this case, "Materials" refers to the two versions of the tool, plus accompanying documentation, and QTI is Qualcomm Technologies.

The non-disclosure terms do not come with the normal "you can talk about anything that has been already publicly disclosed" caveats. Hence, even the Qualcomm public Web site regarding this tool falls under the "any form of support or information".

Regardless, you may be interested in visiting Qualcomm's developer support site in hopes that you can find this unnamed tool.

PowerTutor

Perhaps the best-known third-party power analyzer is PowerTutor. PowerTutor is the outcome of a research project from the University of Michigan, with a bit of assistance from Google. In principle, PowerTutor is capable of letting you know power consumption on a device, much along the lines of what Trepn can record on a Qualcomm MDP. In practice, PowerTutor is significantly less powerful and sophisticated.

PowerTutor was created with the HTC Dream (T-Mobile G1), HTC Magic (T-Mobile G2), and Nexus One in mind. Its power output values will be as accurate as they could make it for those devices. If you run PowerTutor on other hardware, the results will be less accurate.

You can obtain PowerTutor from the Play Store, or from the PowerTutor Web site, or you can compile it from source.

PowerTutor is not tied to testing a particular application. As such, you can simply run PowerTutor whenever you want from its launcher icon, then press "Start Power Profiler" in the main activity:

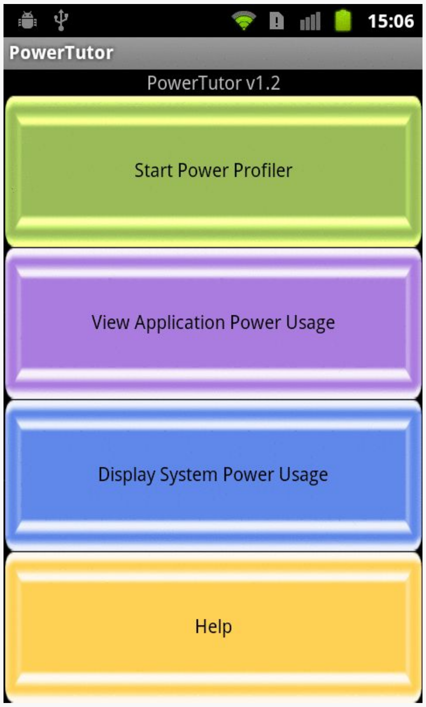

Figure 883: The PowerTutor main activity

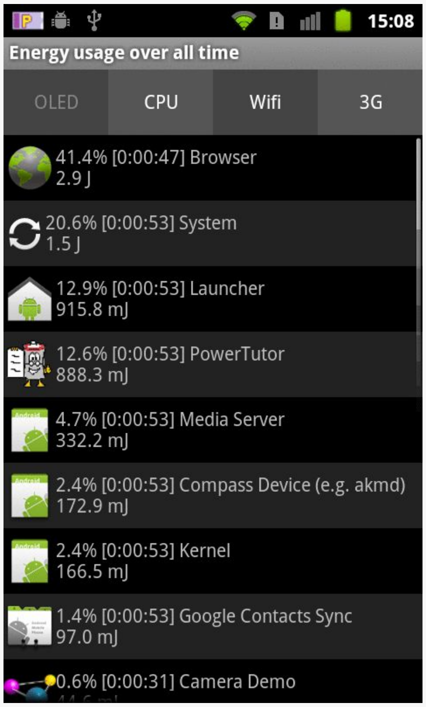
At this point, you can start playing with your application, or running your unit test suite, or whatever. When you want to get an idea of how much power you have been consuming, you can switch back to the PowerTutor activity and choose "View Application Power Usage". This brings up a list of processes and toggle buttons to show various power consumption values for each:



Energy usage over all time

41.4% [0:00:47] Browser
2.9 J

20.6% [0:00:53] System
1.5 J

12.9% [0:00:53] Launcher
915.8 mJ

12.6% [0:00:53] PowerTutor
888.3 mJ

4.7% [0:00:53] Media Server
332.2 mJ

2.4% [0:00:53] Compass Device (e.g. akmd)
172.9 mJ

2.4% [0:00:53] Kernel
166.5 mJ

1.4% [0:00:53] Google Contacts Sync
97.0 mJ

0.6% [0:00:31] Camera Demo

Figure 884: The PowerTutor application roster

Tapping the list entry brings up a graph for that particular process, though since this information is only available while PowerTutor is recording new data, the graph is usually empty unless you have logic running in the background:

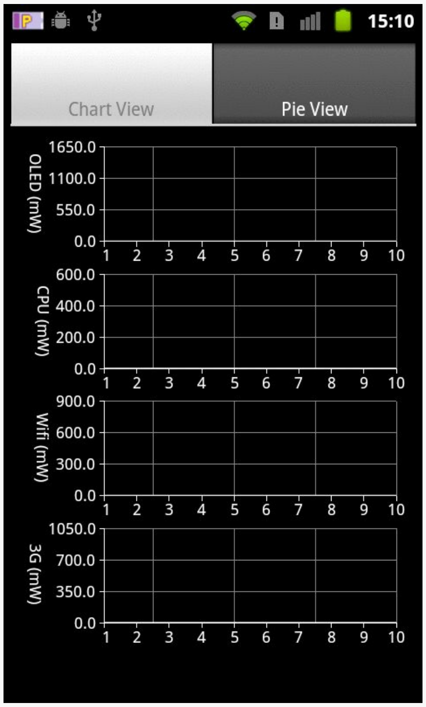


Figure 885: The PowerTutor live charts for a single process current power consumption

You can also bring up a chart showing what portion of your power consumption came from various sources for the whole device, such as a pie chart of current consumption:

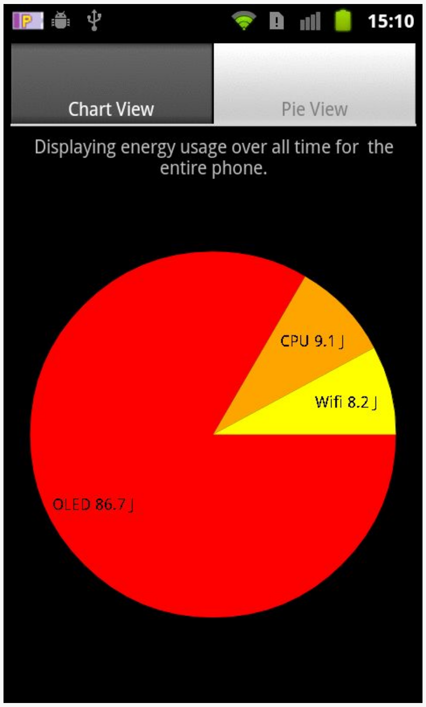

Figure 886: The PowerTutor pie chart for current overall power consumption

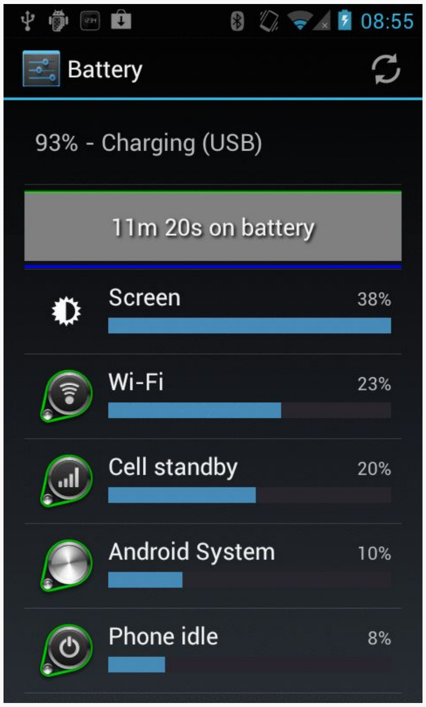
Given that the source code is available, one might augment PowerTutor to:

1. Saving results, both as data files for offline analysis (akin to Trepn's CSV files) or for viewing charts and tables on the device when data is not being actively collected
2. Allowing one to record application states, akin to Trepn, to better correlate application functionality to saved power results

Battery Screen in Settings Application

Of course, what developers tend to focus on most with power is the battery consumption screen in the Settings application, as shown in a previous chapter:



Battery

93% - Charging (USB)

11m 20s on battery

Screen 38%

Wi-Fi 23%

Cell standby 20%

Android System 10%

Phone idle 8%

Figure 887: Battery Screen from Settings App

After all, this is what users will tend to focus on — anything showing up in here is a source of blame for whatever power woes the user believes she is experiencing. Conversely, if your application does not show up in this screen during normal operation, then there is no compelling reason for you to do further analysis, as users will tend to be oblivious to your actual power consumption.

If you do show up in the list, tapping on your entry can give you some more details of what power you consumed and why:

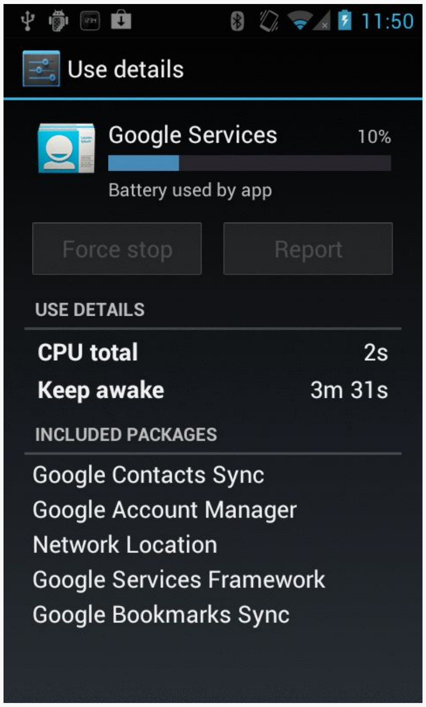


Figure 888: Battery Details Screen from Settings App

However, the information contained in here is mostly guesswork, using a more refined version of the same approach that PowerTutor uses. Ordinary Android hardware simply lacks enough fine-grained power measurement instrumentation to do an accurate job of apportioning power usage among different processes. So, the details of how long you kept the CPU powered on may be accurate, but the percentage of battery consumption associated with your app is just an estimate.

BatteryInfo Dump

Yet another possibility on older Android devices is to use the `adb shell dumpsys batteryinfo` command from your command prompt or terminal on your development workstation. This will emit a fair amount of data that probably means something to somebody, such as general device information:

```
Battery History:

(... and lots more...)
```

and per-process information (here, showing power used by PowerTutor itself):

```
#10058:
    Wake lock window: 5s 71ms window (1 times) realtime
    Proc edu.umich.PowerTutor:
      CPU: 11s 750ms usr + 4s 530ms krn
      1 proc starts
    Apk edu.umich.PowerTutor:
      Service edu.umich.PowerTutor.service.UMLoggerService:
        Created for: 4m 4s 750ms  uptime
        Starts: 1, launches: 1
```

In principle, one might create tools that use this output — or perhaps steal a peek at the data used by the Settings application – to create something a bit more developer-friendly.

Sources of Power Drain

If you can measure power drain well yourself, that is the best way for you to determine precisely where your power consumption is going. Alas, for various reasons, you may not be able to get good power consumption data.

Which means you may have to guess.

We know the general sorts of things that consume power in a device, such as the screen and the CPU. We know that if we use these things less, we will use less power. Eventually, though, we have an app that does nothing, and while this may result in optimal power usage, we are still likely to get poor reviews, because *the app does nothing*.

What we need is some rough idea of how bad certain things are, so we can weigh our use of those system components appropriately.

This chapter will try to give you some "rule of thumb" heuristics of how to estimate power usage of various system components, plus some general recommendations of how to use less of that particular component without necessarily eliminating useful functionality from your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Also note that:

- mA = milliamps, where the ampere (or "amp") is the SI unit of current

- mAH = milliamp-hours, which is how battery capacities are measured (e.g., 2000mAH can power a 200mA draw for 10 hours)

Screen

Screen size and battery size generally trend together. Tablets have bigger batteries and bigger screens than do phones, which in turn are bigger in both areas than are wearables.

A rough rule of thumb is to expect to consume ~10% of the device's battery for every hour you keep the screen on. Or, to look at it another way, on a phone-sized screen, expect a power draw of ~100-200mA, depending on variations in screen size and display technology (e.g., AMOLED).

Normally, the user is in control over how long your app is in the foreground and therefore is "to blame" for the screen being on. There are a couple of cases where you can make the screen be more of a problem.

The first is if you `acquire()` a `WakeLock` (other than a `PARTIAL_WAKE_LOCK`)… and forget to ever `release()` it. Since the `WakeLock` will keep the screen on, the screen will stay on, even if your app is in the background, until such time as your process is terminated or the device shuts down due to low battery.

In fact, such `WakeLock` types have been deprecated, with the last of them being flagged as deprecated in API Level 17. The recommended alternative is to use `android:keepScreenOn` or `setKeepScreenOn()` on some `View`. This will keep the screen on, so long as the activity hosting that `View` is in the foreground. That way, just moving to the background releases the underlying `WakeLock`, allowing the device to return to sleep.

However, in some cases, even that may be insufficient. Suppose that the user is in your activity, and they get distracted, putting down their device for an extended period. Unless you somehow detect the inactivity, and manually turn off the keep-screen-on mode, the screen will stay on indefinitely, until the power is drained. Hence, if you have a decent way of determining if the user is still using your activity, consider using that as a way to determine when the device is inactive (e.g., a `postDelayed()` that gets canceled and rescheduled when the user does something, so if the `postDelayed()` `Runnable` gets invoked, you know the user has done nothing for the delay period). Then, if you know the device is inactive, call `setKeepScreenOn(false)` to return the screen to its normal operating mode.

The academic paper “How is Energy Consumed in Smartphone Display Applications?” has a more extended analysis of screen power draw.

Disk I/O

Disk I/O gets more efficient with bigger operations.

You can see this in something like SQLite, where wrapping a bunch of `INSERT` statements into a single transaction can have substantial benefits in terms of how long the I/O takes.

Not surprisingly, this has a similar impact on power consumption:

- Writing 1GB of data 1,000 bytes at a time is about twice as expensive as is writing it 10,000,000 bytes at a time
- Writing 1GB of data 100 bytes at a time is about five times as expensive as is writing it 1,000 bytes at a time

Hence, you want to try to batch up your disk I/O, where possible, to do fewer, bigger operations, rather than lots of little ones. This includes:

- Batching database I/O in a transaction, as noted above
- Caching data that you intend to log to disk in memory and only writing when your in-memory buffer reaches a certain size or age (though beware the dangers of your process being terminated before you get a chance to write the data)
- Consider using larger buffer sizes with `BufferedInputStream` and `BufferedOutputStream`, if you can afford the heap space, though the 8KB defaults are not that bad

As a rough model, consider disk I/O to draw ~200mA. The smaller the I/O operations, the more time it takes you to accomplish the work, and hence the less efficient those operations are.

While disk I/O is relatively expensive while it is occurring, most apps are not continuously reading or writing, and therefore the total impact to the battery will not be that bad. Apps that *do* continuously use the disk — such as music or video players — will

WiFi and Mobile Data

Internet access via WiFi and mobile data networks is another area that you, the developer, tend to control. Some apps require continuous Internet access and only while in the foreground, like a streaming media player. But many more apps wind up doing Internet access periodically in the background, looking for new information on some server somewhere. Unfortunately, these are the sorts of "vampire" apps that can drain the battery without users necessarily being aware of it. Individually, these apps might not even appear all that bad, but when a device has dozens of them, the combined impact results in poor battery life.

Moreover, we also have the problem of dealing with multiple ways of getting to the Internet. Simple solutions will leave us totally oblivious to the differences in downloading via WiFi versus mobile data, at the potential cost in battery consumption. Slightly less-simple solutions optimize for mobile data, to try to minimize power drain in that model. More-elaborate solutions detect what sort of connection we have (using `ConnectivityManager`) and choose among different strategies as connectivity changes.

Here are some things you can do to try to help manage your Internet power consumption.

Use Less

The simplest, rough-cut way to consume less power for Internet access is to do less Internet access in the first place. The less time you spend downloading (or uploading) data, the less power you tend to draw while doing so. In a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

And, of course, consuming less bandwidth can have other benefits, particularly for people on metered mobile data plans.

There are chapters elsewhere in the book that cover ways to deal with bandwidth consumption for bandwidth's sake.

Use What You Already Downloaded

For data that is likely to be unchanging, use a disk cache, so you can avoid downloading the same content again. Such a cache can be used at two levels:

1. Simply by having the file in the cache can be a signal to your app that you already have the data and can avoid any sort of request to fetch it again.
2. For HTTP, by recording some additional details (`If-Modified-Since` and `ETag` headers), you can make a request to the server to download the content again, where the server can tell you if you already have the current copy of the content (via a `304` response code).

Many of the Internet libraries discussed earlier in this book offer disk caching as part of their services.

Use In Batches

As noted earlier in this section, in a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

Unfortunately, that approximation is pretty coarse.

We as developers tend to think of Internet access as being like a faucet with two states: on and off. In reality, wireless radios tend to have three states: full power, low power, and standby mode. Opening a socket will bring the radio to full power. An idle radio (no packets transferred) will drop to low power after a while, and eventually back to standby mode. Not surprisingly, the power draw for full power is substantially more than low power, which in turn is more than standby.

However, this model introduces some problems:

- There is some latency to move from standby or low power to full power. This slows down data transfer while the radio "warms up".
- The idle time needed to transition to a lower power state is substantial, with values in the 5-15 second range well within reason. This means that making a request has lingering power cost even *after* our request has completed.

The net is that you want to bring the radio to full power as few times as possible (to minimize the percentage of time we are slowly dropping back to standby and consuming power while we do). And, while we are at full power, we want to do all necessary — or perhaps possibly necessary — data transfers, to avoid having to go back to full power again any time soon.

In other words, you want to batch your network I/O. This is reminiscent of the recommendations to batch disk I/O from earlier in this chapter.

So, for example, if you are going to upload data to a server, use that same pulse of work to download anything that needs downloading, rather than having separate schedules for uploads and downloads. Doing more in a batch and having fewer batches will reduce the cost of the power state changes.

Use When the Server Wants You To

One common pattern for Internet access is to poll a server. This is fairly easy to code, using something like `AlarmManager` to get control every so often.

However, this approach resembles children in the back seat of a car, frequently pestering their parents with "Are we there yet?".

Just as the parents will tell the children "We will get there when we get there, and we will tell you when we get there", you can take a similar approach, using Google Cloud Messaging (GCM). Rather than poll the server periodically, have the server contact your app on the device when there is data ready to be downloaded. This works well in cases where polls are likely to result in "yes, we have no data" responses — the pushes can be far less frequent than the polls would be. This can also reduce load on your servers, for not having to respond to poll requests across all your users.

Note, though, that the battery benefits are from using GCM itself. From the standpoint of an app, GCM is "always on", and the power consumed by GCM is attributed to Android itself, not to the app. Hence, pushes are almost "free" from the standpoint of power cost. This will *not* be the case if you "roll your own" push system (MQTT, WebSockets, etc.). In this case, you are attempting to keep a long-lived socket yourself, *in addition* to the one maintained by GCM. Clearly, there are ways to do this that minimize the power consumption of the long-lived socket connection, but that is not easy to accomplish. Hence, you need to weigh the costs of depending upon the Play Services SDK and routing your communications through Google's servers with the costs of trying to do your own separate push mechanism in a battery-friendly fashion.

Use When Android Wants You To

If server push through GCM is impractical (e.g., you do not control the server), you can reduce your power use for Internet access by batching *across apps*, in addition to batching within your app.

What Google wants you to use for synchronizing data with a server is the `SyncManager`. This is an overly-complicated framework that, among other things, gives you control to sync to the server at the same time that other apps needing to sync get control. That way, we can "warm up" the wireless radio once and handle several apps' worth of data transfers at once. `SyncManager` will be covered in this book eventually.

Part of the reason why Android moved to make alarms with `AlarmManager` more "inexact" in API Level 19+ is for this same sort of batching. While `AlarmManager` certainly can be used for a variety of purposes, a lot of apps use it for Internet data transfer. Allowing Android to control when those alarms occur allows Android to try to coalesce them, and perhaps even time them to happen when `SyncManager`-led transfers occur, with the objective of minimizing the number of times we bring the wireless radio out of standby mode.

Use Additional Reading

The Android developer documentation has a series of "training" pages on minimizing power consumption for data transfers. This expands upon Reto Meier's Google I|O presentations that touch upon this topic.

GPS

In light testing, GPS seems to draw ~35mA. Additional power will be consumed for using those results, though, and so the net effect on the battery will be somewhat higher, depending upon what your app does when it gets a GPS fix.

That figure is corroborated by the academic paper "An Analysis of Power Consumption in a Smartphone", though that paper tested rather old devices (HTC Dream and Nexus One).

Again, different devices will have different components, and some devices' GPS modules may be more or less efficient.

Hence, GPS itself is a power drain, but not a massive one… if what you are doing with the GPS fixes itself is efficient. Keeping the GPS on for several hours will certainly take a chunk out of the battery charge, but if you are doing lots of work (e.g., navigation app) in response to those fixes, several hours may be more than the battery can handle.

If you can get by with the dependency on the Play Services SDK, using `LocationClient` can help here, particularly in cases where the user may not be moving much, as Google's fused location provider uses the accelerometer to help determine how much they need to use GPS versus other possible means of determining location.

Camera

The camera will consume power while it is actively receiving input, whether that is for the preview frames or for taking full-resolution pictures or video. Of course, it will also consume additional power when recording images to disk, whether those be still photos or continuous video.

A rough guide is that a camera preview will draw ~200mA *plus* the power for screen, CPU, etc. That could easily total over 350mA, even if you are not doing much. Normally, though, the camera preview is on for short periods of time, and only under user control.

A corresponding value for recording video, including the disk I/O and camera preview, would be ~600mA (plus the screen). That is the sort of thing you only want to do in short bursts, as a couple of hours of video recording can really take a bite out of battery. However, once again, normally the user is the one controlling when video is recorded.

Additional Sources

The above sources of power drain are comparatively easy to model and provide a heuristic for determining your possible power usage.

However, there are plenty of other things that can drain the battery, for which this chapter does not provide such a heuristic. In many cases, the usage patterns of the system component will vary so widely that a simple heuristic is unrealistic. In some cases, the power drain from components from different manufacturers will be very different. In some cases, the author of this book simply lacks sufficient expertise with the technology to provide much help (e.g., Bluetooth).

The sections that follow will try to provide some help, though.

CPU/GPU

Perhaps the biggest source of power drain beyond the components listed above will be the processors: the CPU and the GPU. These draw a fair bit of power, which is why processor manufacturers go to great lengths to try to adapt to varying conditions, turning off cores or switching clock speeds, to try to minimize the power drain.

Usually, so long as we are in the foreground, any CPU/GPU usage impact on power will be considered “normal” by the user. Of course, trying to boost performance here can benefit the user, not only in terms of possibly reduced power consumption, but less lag or other forms of sluggishness. Hence, trying to optimize processor utilization is worthwhile.

However, the bigger complaints from the user will come from power drain while your app is in the background. The biggest source of those complaints will come from your use of `WakeLocks`, preventing the device from going into a low-power sleep state.

There are some apps available on the Play Store that reportedly can give you some idea of how long you may be holding a `WakeLock`, however they generally require root, particularly for Android 4.4+.

Sensors

Sensors, more so than many other device components, seem to get sourced from a wide range of manufacturers. They also seem to be tied into the devices differently from device to device. For example, some devices allow sensors to continue collecting data while the device is otherwise in a sleep mode, while many do not.

As such, it is difficult to give much guidance in terms of power drain tied to your use of sensors.

That being said, here are a few notes that may help:

1. Generally speaking, the more you use a sensor, the more likely it is that it will reflect in power drain. However, only some of that power drain will be from the sensor hardware itself. Your application code processing sensor events will bear much of the blame. Reducing the periods of time when you are registered for sensor events, using longer delays between events, and

sensor event batching are ways that you can reduce the power drain associated with the sensors and your associated code.

2. Conversely, in some environments, use of a particular sensor may be “free”, insofar as the device uses the sensor itself on a continuous basis. For example, the accelerometer and/or gyroscope is used by devices to detect orientation changes. Hence, those sensors must be powered on regularly, and therefore you cannot be “blamed” for the fact that the sensors are drawing power. Your use of the sensor data may contribute to power drain, of course.

Audio Input and Output

Playing audio through the earpiece, speaker, wired headset, or Bluetooth, will consume some amount of power. The amount will vary by how long you are playing the audio and how the audio is played (e.g., Bluetooth may require more power than on-device audio output). However, in both cases, usually the user has control over the audio, particularly if it is to be playing for a lengthy period of time (e.g., music player), and so the power drain associated with audio playback is less likely to be considered to be a problem, as users will get annoyed with *uncontrolled* power drain, more so than power drain that they can manage themselves.

Recording audio via the on-board microphone or Bluetooth should also consume some incremental power. In cases where the user is in control over when recording is happening, the power drain is unlikely to cause the user much distress.

Where both playback and recording of audio may cause a perceived power problem is in places where the user has less control. For example, an alarm clock app should have some sort of timeout to stop playing the ringtone (or whatever) after some period, if the user fails to respond to the alarm. After all, it is possible that the user is not where the device is and is not in position to stop the alarm. In this case, the power drain will be from several components, audio playback being just one, but it is the uncontrolled nature of the power drain that can get you in trouble.

Addressing Application Size Issues

Sometimes, our apps are just too big, where "too big" can be defined as:

- Bigger than the 100MB limit imposed by the Play Store
- Bigger than some other limit imposed by some other distribution channel
- Big enough that we worry about bandwidth costs, particularly for users on metered data plans
- Big enough that we hit some internal Dalvik limitations

This chapter will review various techniques for trying to keep the size of your app down to a reasonable level.

Prerequisites

This chapter assumes that you have read the core chapters of the book.

Java Code, and the 64K Method Limit

In ordinary Java development, there are few limits as to how big your applications can get. You tend to run into physical limitations, such as available system RAM, before you run into any limitations of the programming language or runtime environment.

And, normally, in Android applications, you do not worry about how many classes or methods you have. However, "normally" is not "always", and there is a specific scenario that complex apps need to worry about.

What Is It?

Quoting Andy Fadden, Android platform engineer:

> The issue is not with the Dalvik runtime nor the DEX file format, but with the current set of Dalvik instructions.
>
> You can reference a very large number of methods in a DEX file, but you can only invoke the first 65536, because that's all the room you have in the method invocation instruction.
>
> I'd like to point out that the limitation is on the number of methods referenced, not the number of methods defined. If your DEX file has only a few methods, but together they call 70,000 different externally-defined methods, you're going to exceed the limit.
>
> [An externally-defined method is] a method defined in a separate DEX file. For most apps this would just be framework and core library / uses-library stuff.

Specifically, you will crash at compile time, with an error message akin to:

```
Unable to execute dex: method ID not in [0, 0xffff]: 65536
Conversion to Dalvik format failed: Unable to execute dex: method ID not
in [0, 0xffff]: 65536
```

64K Seems Like a Lot of Typing…

Well, it is, and it isn't.

First, it is not merely your own methods. You can reach the 64K method limit without implementing 64K methods in your application yourself. You can:

- Call lots of methods defined by the framework
- Absorb lots of methods from libraries, particularly larger libraries that offer many more features than your app uses

This still tends to mean that simpler apps are unlikely to run into this limit, while more complex apps might.

Jake Wharton has published a shell script that can provide you with a count of referenced methods.

Mitigation Tactics

If you are relatively close to the 64K method limit, you may be able to tweak your project to get back under the limit without having to significantly rework your project.

Use Granular Libraries

Some libraries, like Google Play Services, come in two forms: a "kitchen sink" and more granular libraries for individual features. If your need for the library can be met by the granular libraries, use them, and you can remove your dependency on the "kitchen sink".

In the case of Google Play Services, try *not* to depend upon the `com.google.android.gms:play-services` artifact. Instead, try to depend upon one of the more granular artifacts, such as `com.google.android.gms:play-services-maps` for Maps V2. For services, like Google Cloud Messaging, that have no specific granular artifact, depend instead upon `com.google.android.gms:play-services-base` — while still large, this is far smaller than is `com.google.android.gms:play-services`.

Use Better Libraries

One common culprit of hitting the 64K method limit comes from libraries, as their methods count along with yours. Hence, choosing different libraries can perhaps reduce your method count.

One specific case of this comes from the code generated by Google's Protocol Buffers. If you are using Protocol Buffers heavily, your generated classes may each be defining hundreds of unused methods. Switching to an alternative implementation can reduce this significantly. Some such implementations include:

- micro-protobuf
- Square's Wire

Use ProGuard

If your debug builds are failing due to the 64K method limit, try a release build. If that works, the reason is ProGuard and its ability to strip out code that is deemed to be unreachable.

In this case, you can "buy yourself some time" by arranging to build your app in debug mode with ProGuard, but without ProGuard's normal code obfuscation work (e.g., `-dontoptimize -dontobfuscate` switches in the ProGuard configuration). [Quoting Eric Lafortune](), ProGuard's lead developer:

> If you apply ProGuard with shrinking enabled but optimization and obfuscation disabled (-dontoptimize -dontobfuscate), the code will already be more compact, and you can still use a debugger. The source files, class names, method names, line numbers, etc remain unchanged and any breakpoints in removed unreachable code are irrelevant.

However, this is not possible with standard Eclipse builds and is difficult to arrange with Ant. With Gradle-based builds, it should be possible to set this up using `minifyEnabled true` and a custom ProGuard configuration file:

```
android {
    buildTypes {
        debug {
            minifyEnabled true
            proguardFile 'proguard-no-obfuscate.txt'
        }
    }
}
```

(where `proguard-no-obfuscate.txt` contains the `-dontoptimize -dontobfuscate` switches)

Mitigation Strategies

If the aforementioned tactics are insufficient — or if they help somewhat, but you are still near the limit with a lot of development yet to be done — you may need to pursue some more strategic ways of resolving your application size.

Don't Go Overboard

One source of method explosion comes from too much adherence to server-side Java coding styles.

For example, if you find yourself defining hundreds of interfaces and/or abstract classes, with `Factory` classes (and perhaps `FactoryFactory` classes), you are more likely to hit the 64K method limit due to all those separate definitions. Consider whether the flexibility that you believe that you obtain from this coding style is worth the risk.

Smaller Apps, Loosely Connected

It may be that you are simply creating an app that is entirely too complicated for the Android environment. Android's `Intent` system is designed to enable apps to inter-operate, and so you may need to consider splitting your app into pieces, such as:

- A suite of related apps
- A host app and plugin apps that enable additional functionality
- An app and an affiliated Web app, where certain functionality is handled by the Web app in a standard browser

Splitting Into Separate DEX Files

It is also possible — though rather risky — to split your app into multiple DEX files. The basic technique is outlined by Google in an Android Developers Blog post.

In Google's formulation, the secondary DEX file is packaged as an application asset and is unpacked into internal storage on first run of your app. This keeps all of your code in your one APK file for distribution.

The risk comes in if you decide to *not* ship the secondary DEX file with the APK, but rather obtain it by other means, such as downloading it from your own Web site. If somebody hacks your Web site, or employs a man-in-the-middle attack when users try downloading the DEX file, your DEX could be replaced by one that contains malware or otherwise harms the user. If you elect to distribute the secondary DEX files yourself by this sort of means, *please* consider the security ramifications and take appropriate steps to ensure that the DEX you download is the unmodified DEX file.

Native Code

Native code, implemented as NDK-compiled libraries, represent another source of app bloat. This will occur regardless of whether the NDK code is yours or if you are using a third-party library that supplies those binaries (e.g., SQLCipher for Android).

Native code is not intrinsically large. However, in some cases, native code is a port from some other environment (or environments) and may contain a lot of stuff that your app does not need. Worse, ProGuard will not strip out unused native code, as its algorithms only work with Java-style bytecode. Hence, it is not out of the question for apps to devote several MB just to the Linux `.so` files that make up the NDK-compiled libraries.

Fortunately, there are some workarounds.

Mitigation via Per-CPU APKs

Some distribution channels, like the Play Store, support publishing multiple versions of an APK, with different versions for different CPU architectures. Hence, you could have one APK with x86 binaries and one APK with ARM binaries, as opposed to having one "fat binary" with both.

While setting this up using the classic build tools would be a major pain, Gradle for Android makes this fairly straight-forward, using product flavors for the CPU architectures:

```
productFlavors {
    x86 {
        ndk {
            abiFilter "x86"
        }
    }
    arm {
        ndk {
            abiFilter "armeabi-v7a"
        }
    }
    mips {
        ndk {
            abiFilter "mips"
        }
    }
}
```

Using product flavors this way will give you separate commands for compiling each of the CPU architectures (e.g., `gradle assembleArmRelease`).

More details about using the NDK with Gradle can be found elsewhere in the book.

Mitigation via libhoudini

As is noted in the chapter on the NDK, `libhoudini` is proprietary Intel code that allows ARM-compiled NDK binaries to run on x86 CPUs, using the same sort of opcode translation that is used by the Android emulator. Many, though not all, x86-powered Android devices have `libhoudini`. Those that do could run your app even if you only ship ARM NDK binaries and not x86 ones. This gives you the same sort of space savings as you would get by publishing separate ARM vs. x86 APKs (per the previous section), without having to manage multiple APKs yourself. The cost is speed, as the translation layer adds significant overhead, much as you see with the Android emulator running ARM emulator images instead of x86 ones.

Mitigation via Ignoring Non-ARM

Of course, what a lot of developers do is simply only worry about ARM.

While Google does not publish percentages of CPU architectures the way they do Android OS versions, it is safe to say that, as of early 2014, ~1% of Android devices are powered by non-ARM CPUs. That percentage may climb, particularly as Intel pushes more x86 chipsets. But the *vast* majority of Android devices are powered by ARM. So, even if some of those x86 environments lack `libhoudini` (e.g., the manufacturer did not license `libhoudini` from Intel), they are so few in number that developers are prone to ignore x86.

Ironically, what drives x86 for developers is the development environment itself, not the production environment. The x86 emulator is nicely responsive, compared to a similarly-configured ARM emulator image. Many developers eschew the ARM emulator entirely, with it being too slow. Hence, developers may be interested in having x86 binaries in the APK to allow the app to run on the x86 emulator (which lacks `libhoudini`). In this case, it may be worthwhile to have a dedicated release build process that strips out the x86 binaries, if the space that those binaries take up is more than you can afford.

Images

Bitmap images are notorious for taking up lots of heap space. However, they can also swell the size of your APK. While the bitmap PNG or JPEG files will be compressed on disk, if you have enough of them, they can still consume many MB of space in the APK, particularly since the APK cannot compress them further.

Mitigation via Resource Aliases

You may have multiple copies of the same image.

The example cited in the Android documentation is where you want to have locale-specific drawable images. For example, perhaps you want to show a flag, and you use language resource sets to try to map the right flag to the right language. However, some flags are going to be used in multiple languages, such as the Canadian flag being needed for `en-rCA` and `fr-rCA`. By default, you would place your flag icon in each of those resource sets, duplicating your results. This gets worse if you have a few versions of the same flag icon for different densities.

However, you can elect to use a resource aliases to handle this differently.

Suppose that your code refers to a `flag` drawable resource (e.g., `@drawable/flag` or `R.drawable.flag`). For many languages, you would have a unique flag in the appropriate resource set. For cases where the same flag is used in multiple situations:

1. Put the flag in a resource set that is not tied to locale (e.g., `res/drawable-hdpi/` instead of `res/drawable-en-rCA-hdpi/`), for as many densities as you choose, but under a different name (e.g., `flag_canada.png` instead of `flag.png`)
2. Create a small XML file, `flag.xml`, in each of the locale-specific directories (e.g., `res/drawable-en-rCA/` and `res/drawable-fr-rCA/`), pointing to your `flag_canada` drawable:

```xml
<?xml version="1.0" encoding="utf-8"?>
<bitmap
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/flag_canada" />
```

When you reference `R.drawable.flag` on an `en-rCA` or `fr-rCA` device, Android will read in the XML resource, then turn around and retrieve the `flag_canada` drawable, and use that. Since the two XML files are likely to be smaller than the sum total of the duplicate copies, you save disk space.

Mitigation via pngquant

In practice, the above technique is just not that commonly used, because it addresses a fairly narrow scenario. A more general-purpose solution is to try to tweak the images to be visually nearly identical, yet take up less disk space.

There are a variety of tools for this, mostly aimed at Web development, where smaller image file sizes means faster-loading Web pages.

One such tool is pngquant. Given a PNG file as input, it generates a smaller PNG file as output, one with an optimized color palette, using mathematical techniques to choose colors that will maintain as much of the original look as possible. Many of the images in this book were optimized using pngquant, at a substantial savings in disk size, without materially sacrificing image quality.

APK Expansion Files

The ultimate solution to disk space concerns, for distribution through the Play Store, is to get stuff out of your app entirely and distribute that stuff by other means. The Play Store offers APK expansion files with this in mind. You can publish one or two expansion files, each containing up to 2GB of files. While these will not be treated as resources or assets, you do have access to the file contents at runtime. Game developers will use these for sound effects, additional artwork, and so on. The biggest limitation is that these files may not be supported by all distribution channels.

Trail: Scripting Languages

The Role of Scripting Languages

A scripting language, for the purpose of this book, has two characteristics:

1. It is interpreted from source and so does not require any sort of compilation step
2. It cannot (presently) be used to create a full-fledged Android application without at least some form of custom Java-based stub, and probably much more than that

In this part of the book, we will look at scripting languages on Android and what you can accomplish with them, despite any limitations inherent in their collective definition.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

All Grown Up

Interpreted languages have been a part of the programming landscape for decades. The language most associated with the desktop computer revolution — BASIC — was originally an interpreted language. However, the advent of MS-DOS and the IBM PC (and clones) led developers in the direction of C for "serious programming", for reasons of speed. While interpreted languages continued to evolve, they tended to be described as "scripting" languages, used to glue other applications together. Perl, Python, and the like were not considered "serious" contenders for application development.

The follow-on revolution, for the Internet, changed all of that. Most interactive Web sites were written as CGI scripts using these "toy" languages, Perl first and foremost. Even in environments where Perl was unpopular, such as Windows, Web applications were still written using scripting languages, such as VBScript in Active Server Pages (ASP). While some firms developed Web applications using C/C++, scripting languages ruled the roost. That remains to this day, where you are far more likely to find people writing Web applications in PHP or Ruby than you will find them writing in C or C++. The most likely compiled language for Web development — Java — is still technically an interpreted language, albeit not usually considered a scripting language.

Nowadays, writing major components of an application using a scripting language is not terribly surprising. While this is still most common with Web applications, you can find scripting languages used in the browser (JavaScript), games (Lua), virtual worlds (LSL), and so on. Even though these languages execute more slowly than their C/C++ counterparts, they offer much greater flexibility, and faster CPUs make the performance of scripts less critical.

Following the Script

Scripting languages are not built into Android, beyond the JavaScript interpreter in the WebKit Web browser. Despite this, there is quite a bit of interest in scripting on Android, and the biggest reasons for this come down to experience and comfort level.

Your Expertise

Perhaps you have spent your entire career writing Python scripts, or you cut your teeth on Perl CGI programs, or you have gotten seriously into Ruby development.

Maybe you used Java in previous jobs and hate it with the fiery passion of a thousand suns.

Regardless of the cause, your expertise may lie outside the traditional Android realm of Java-based development. Perhaps you would never touch Android if you had to write in Java, or maybe you feel you would just be significantly more productive in some other language. How much that productivity gain is real versus "in your head" is immaterial — if you want to develop in some other language, you owe it to yourself to try.

Your Users' Expertise

Maybe you are looking to create a program where not only you can write scripts, but so can your users. This might be a utility, or a game, or rulesets for email management, or whatever.

In that case, you need:

1. Something interpreted, so you can execute what the user types in
2. Something embeddable, so your larger application (typically written in Java, of course) is capable of executing those scripts
3. Something your users will be comfortable using for scripting

The last criterion is perhaps the toughest, as non-developers typically have limited experience in writing scripts in any language, let alone one that runs on Android. Perhaps the most popular such language is Basic, in the form of VBA and VBScript on Windows… but there are no interpreters for those languages for Android at this time.

Crowd-Developing

Perhaps your users will not only be entering scripts for their own benefit, but for others' benefit as well.

Many platforms have been improved by power users and amateur developers alike. Browser users gain from those writing GreaseMonkey scripts. Bloggers benefit from those writing WordPress themes. And so on.

To facilitate this sort of work, not only do you need an interpreted, embeddable, user-familiar scripting environment, but you need some means for users to publish their scripts and download the scripts of others. Fortunately, with Android having near-continuous connectivity, your challenge will lie more on organizing and hosting the scripts, more so than getting them on and off of devices.

Going Off-Script

Scripting languages on Android have their fair share of issues. It is safe to say that while Android does not prohibit the use of scripting languages, its architecture does not exactly go out of its way to make them easy to use, either.

Security

For a scripting language to do much that is interesting, it is going to need some amount of privileges. A script cannot access the Internet unless its process has that right. A script cannot modify the user's contacts unless its process has that right. And so on.

For scripts you write, so long as those scripts cannot be modified readily by malware authors, security is whatever you define it to be. If your script-based application needs Internet access, so be it.

For scripts your users write, things get a bit more challenging, since permissions cannot be modified on the fly by applications. Many interpreters will tend to request (or otherwise have access to) permissions that are broader than any individual user might need, because those permissions are needed by somebody. However, the risk is still minimal to the user, so long as they are careful with the scripts they write.

For scripts your users might download, written by others, security becomes a big problem. If the interpreter has a wide range of permissions, downloaded scripts can easily host malware that exploits those permissions for nefarious ends. An interpreter with both Internet access and the right to read the user's contacts means that any script the user might download and run could copy the user's contact data and send it to spammers or identity thieves.

Performance

Java, as interpreted by the Dalvik virtual machine, is reasonably fast, particularly on Android 2.2 and newer versions. C/C++, through the NDK, is far faster.

Scripting languages are a mixed bag.

Some scripting languages for Android have interpreters that are implemented in C code. Those interpreters' performance is partly a function of how well they were written and ported over to the chipsets Android runs on. However, if those interpreters expose Android APIs to the language, that can add considerable overhead. For example, the Scripting Layer for Android (SL4A) makes Android APIs available to scripting languages via a tiny built-in Java Web server and a Web service API. While convenient for language integration, converting simple Java calls into Web service calls slows things down quite a bit.

Some scripting languages have interpreters that themselves are written in Java and run on the virtual machine. Those are likely to perform worse on an Android device than when they are run on a desktop or server, simply because of the performance differences between the standard Java VMs and the Dalvik VM. However, they will have quicker access to the Java class libraries that make up much of Android than will C-based interpreters.

Cross-Platform Compatibility

Most of the scripting languages for Android are ports from versions that run across multiple platforms. This is one of their big benefits – that is where you and your users may have gained experience with those languages. However, just as, say, Perl and Python run a bit differently on Windows than on Linux or OS X, there will be some differences in how those languages run on Android. The Android operating system is not a traditional Linux environment, and so file paths, environment variables, available pre-installed programs, and the like will not be the same. Some of those may, in turn, impact how the scripting languages operate. You may need to make some modification to any existing scripts for those languages that you attempt to run on Android.

Maturity… On Android

Some scripting languages that have been ported to Android are rather old, like Perl and Python. Others are old and somewhat abandoned for traditional development, like BeanShell. Yet others are fairly new to the programming scene altogether, like JRuby.

However, none of them have a long track record on Android, simply because Android itself has not been around very long. This has several implications:

1. There is more likely to be bugs in newer ports of a language than older ports
2. Fewer people will have experience in supporting these languages on Android (compared to supporting them on Linux, for example)
3. The number of production applications built using these languages on Android is minuscule compared to their use on more traditional environments

The Scripting Layer for Android

When it comes to scripting languages on Android, the first stop should always be the Scripting Layer for Android (SL4A). Led by Damon Kohler, this project is rather popular, both among hardcore Android developers and those people looking to automate a bit more of their Android experience.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

The Role of SL4A

What started as an experiment to get Python and Lua going on Android, back in late 2008, turned into a more serious endeavor in June 2009, when the Android Scripting Environment (now called the Scripting Layer for Android, or SL4A) was announced on the Google Open Source blog and the Google Code site for it was established. Since then, SL4A has been a magnet for people interested in getting their favorite language working on Android or advancing its support.

On-Device Development

Historically, the primary role of SL4A was as a tool to allow people to put together scripts, often written on the device itself, to take care of various chores. This appealed to developers who were looking for something lightweight compared to the Android SDK and Java. For those used to tinkering with scripts on other mobile Linux platforms (e.g., the Nokia N800 running Maemo), SL4A promised a similar sort of capability.

Over time, SL4A's scope in this area has grown, including preliminary support for SL4A scripts packaged as APK files, much like an Android application written in Java or any of the alternative frameworks described in this book.

Getting Started with SL4A

SL4A is a bit more difficult to install than is the average Android application, due to the various interpreters it uses and their respective sizes. That being said, none of the steps involved with getting SL4A set up are terribly difficult, and most are just part of the application itself.

Installing SL4A

At the time of this writing, SL4A is not distributed via the Android Market. Instead, you can download it to your device off of the SL4A Web site. Perhaps the easiest way to do that is to scan the QR code on the SL4A home page using Barcode Scanner or a similar utility.

Installing Interpreters

When you first install SL4A, the only available scripting language is for shell scripts, as that is built into Android itself. If you want to work with other interpreters, you will need to download those. That is why the base SL4A download is so small (~200KB) — most of the smarts are separate downloads, largely due to size.

To add interpreters, launch SL4A from the launcher, then choose View > Interpreters from the option menu. You will be presented with the (presently short) list of installed interpreters:

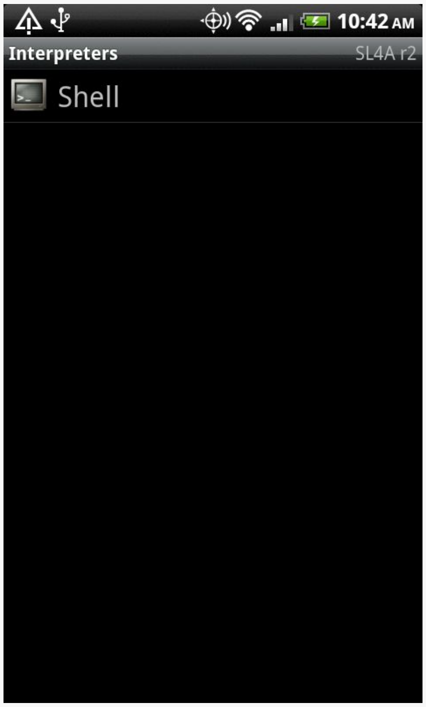

Figure 889: The initial list of installed SL4A interpreters

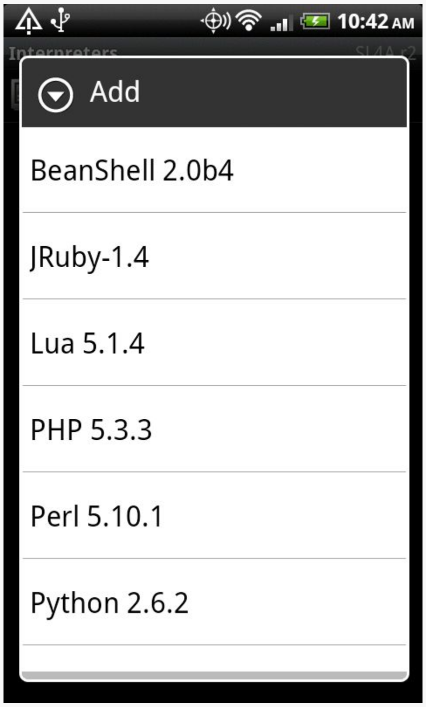
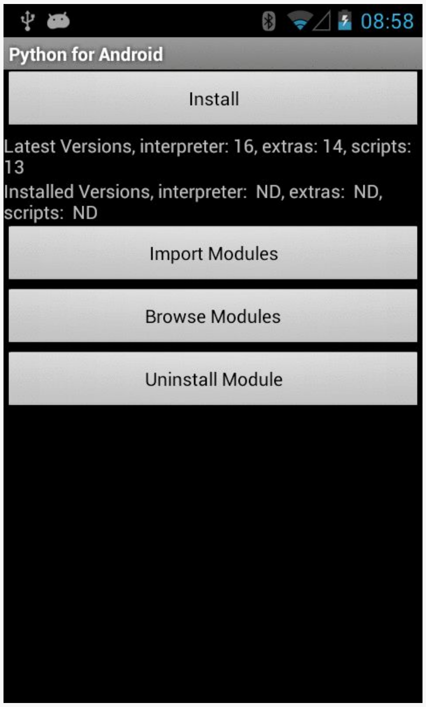
Then, to install additional interpreters, choose Add from the option menu. You will be given a roster of SL4A-compatible interpreters to choose from:



BeanShell 2.0b4
JRuby-1.4
Lua 5.1.4
PHP 5.3.3
Perl 5.10.1
Python 2.6.2

Figure 890: The list of available SL4A interpreters

Click on one of the interpreters, and this will trigger the download of an APK file for that specific interpreter. Slide down the notification drawer and click on that APK file to continue the installation process. When the APK itself is installed, open up that interpreter (e.g., click the "Open" button when the install is done). That will bring up an activity to let you download the rest of the interpreter binaries:



08:58

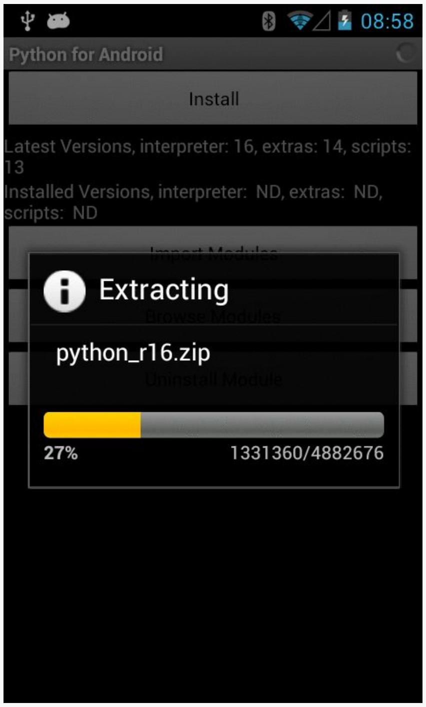
Python for Android

Latest Versions, interpreter: 16, extras: 14, scripts: 13

Installed Versions, interpreter: ND, extras: ND, scripts: ND

Figure 891: Downloading the Python SL4A interpreter, continued

Click the Install button, and SL4A will download and install the interpreter's component parts:



Latest Versions, interpreter: 16, extras: 14, scripts: 13

Installed Versions, interpreter: ND, extras: ND, scripts: ND

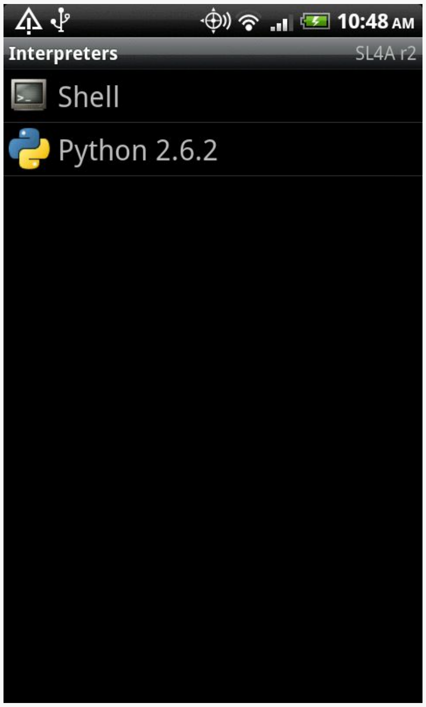
Extracting

python_r16.zip

27% 1331360/4882676

Figure 892: Downloading the Python SL4A interpreter

This may take one or several downloads, depending on the interpreter. When done, and after a few progress dialogs' worth of unpacking, the interpreter will appear in the list of interpreters:



10:48 AM

Interpreters SL4A r2

Shell

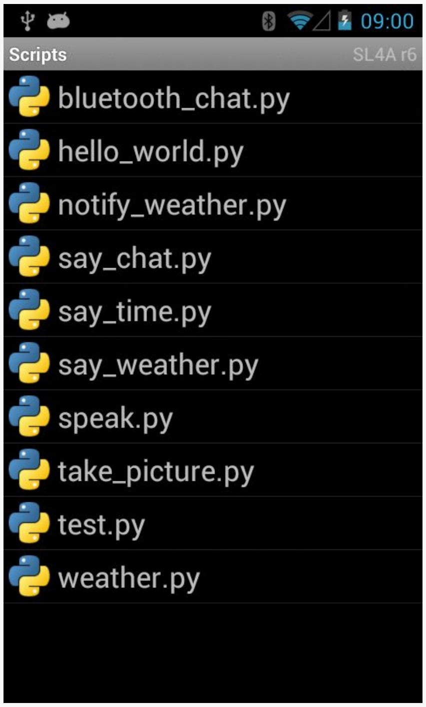
Python 2.6.2

Figure 893: The updated list of installed SL4A interpreters

Note that the interpreters will be installed on your device's "external storage" (typically some flavor of SD card), due to their size. You will find an `SL4A/` directory on that card with the interpreters and scripts.

Running Supplied Scripts

Back on the Scripts activity (e.g., what you see when you launch SL4A from the launcher), you will be presented with a list of the available scripts. Initially, these will be ones that shipped with the interpreters, as examples for how to write SL4A scripts in that language:



Scripts SL4A r6

bluetooth_chat.py
hello_world.py
notify_weather.py
say_chat.py
say_time.py
say_weather.py
speak.py
take_picture.py
test.py
weather.py

Figure 894: The list of SL4A scripts

Tapping on any of these scripts will bring up a “quick actions” balloon:

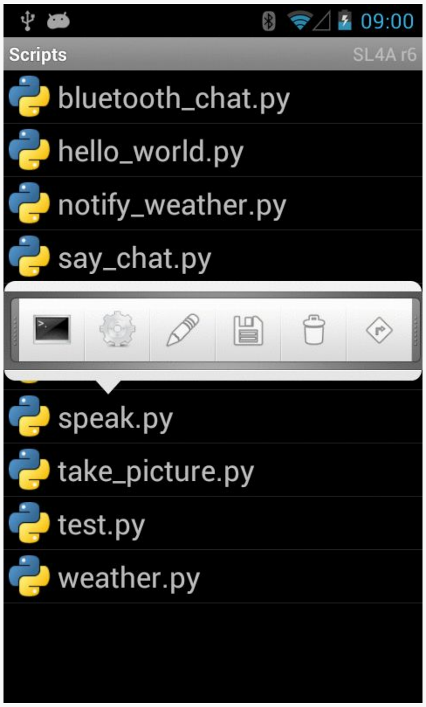


Figure 895: Quick actions for the speak.py script

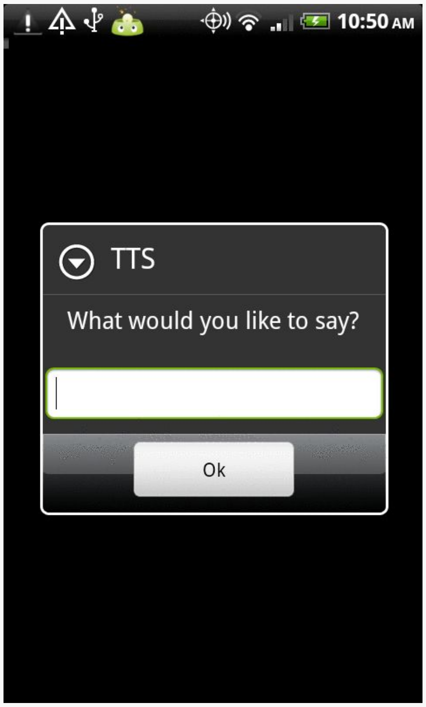
Click the little shell icon to run it, showing its terminal output along the way:



TTS

What would you like to say?

Figure 896: The visual results of running the speak.py SL4A script

Writing SL4A Scripts

While the scripts supplied with the interpreters are… entertaining, they only scratch the surface of what an SL4A script can accomplish. Of course, to go beyond what is there, you will need to start writing some scripts.

Editing Options

Since scripts are stored on your SD card (or whatever the "external storage" is for your device), you can create scripts using some other computer — one with fancy things like "mice" and "ergonomic keyboards" — and transfer it over via USB, like you would transfer over an MP3 file. This eases typing, but it will make for an awkward development cycle, since your computer and the Android device cannot both have access to the SD card simultaneously. The mount/unmount process may get a bit annoying. On the other hand, this is a great way to transfer over a script you obtained from somebody else.

Another option is to edit your scripts on the device. SL4A has a built in script editor designed for this purpose. Of course, the screen may be a bit small and the keyboard may be a bit… soft, but this is a great answer for small scripts.

To add a new script, from the Scripts activity, choose Add from the option menu. This will bring up a roster of available scripting languages and other items (e.g., add a folder):

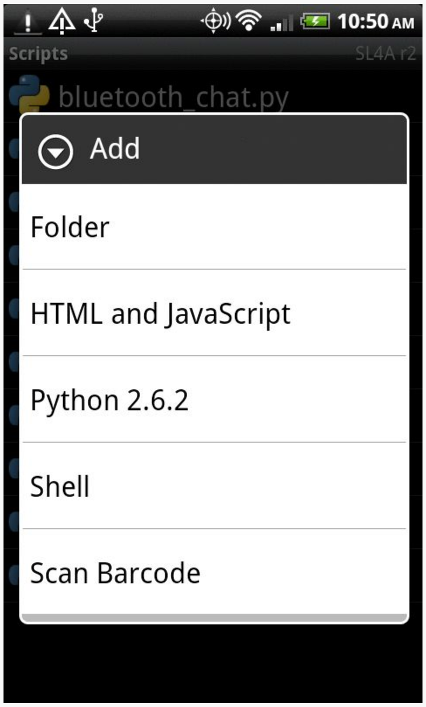


Figure 897: The add-script language selection dialog

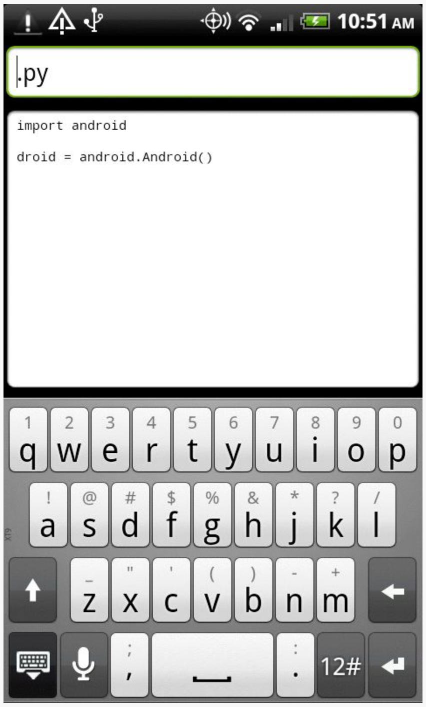
(the “Scan Barcode” option gives you an easy route to install a third-party script, one encoded in a QR code)

Tap the language you want, and you will be taken into the script editor:



```
import android

droid = android.Android()
```

Figure 898: The script editor

The field at the top is for the script name, and the large text area at the bottom is for the script itself. A file extension and boilerplate code will be supplied for you automatically.

In fact, that boilerplate code is rather important, as you will see momentarily.

To edit an existing script, long-tap on the script in the list and choose Edit from the context menu.

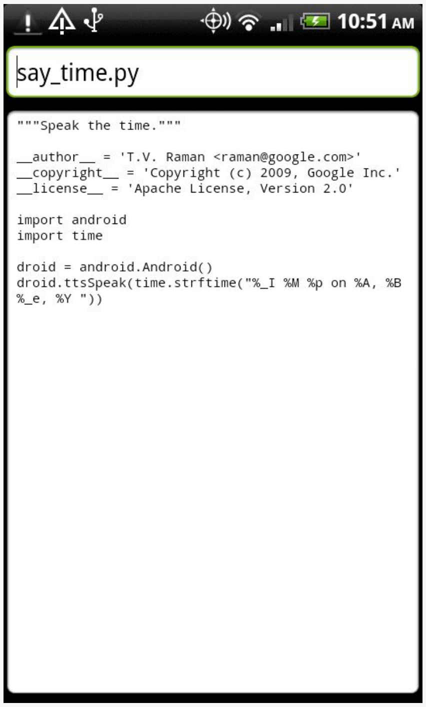
To save your changes to a new or existing script, choose the Save option from the script editor option menu. You can also "Save and Run" to test the script immediately.

Calling Into Android

In the real world, Perl knows nothing about Android. Neither does Python, BeanShell, or most of the other scripting languages available for SL4A. This would be rather limiting, as most of what you would want a script to do will have to deal with the device to some level: collect input, get a location, say some text using speech synthesis, dial the phone, etc.

Fortunately, SL4A has a solution, one of those “so crazy, it just might work” sorts of solutions: SL4A has a built-in RPC server. While implementing a server on a smartphone is not something one ordinarily does, it provides an ingenious bridge from the scripting language to the device itself.

Each scripting language is given a local object proxy that works with the RPC server. For example, here is a Python script that speaks the current time:



```
"""Speak the time."""

__author__ = 'T.V. Raman <raman@google.com>'
__copyright__ = 'Copyright (c) 2009, Google Inc.'
__license__ = 'Apache License, Version 2.0'

import android
import time

droid = android.Android()
droid.ttsSpeak(time.strftime("%_I %M %p on %A, %B
%_e, %Y "))
```

Figure 899: The script editor, showing the say_time.py script

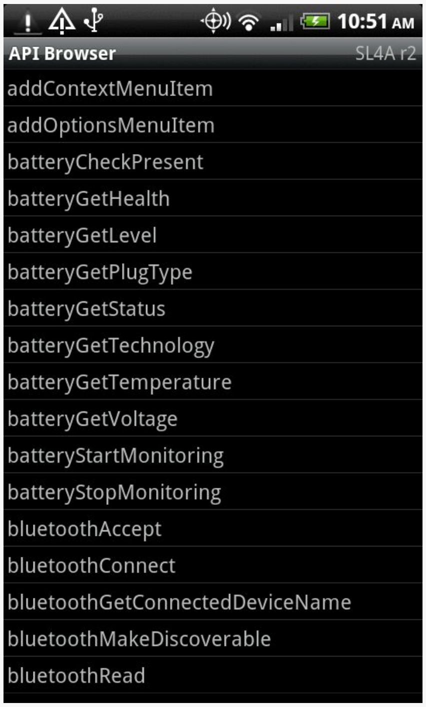
The `import android` and `droid=android.Android()` statements establish a connection between the Python interpreter and the SL4A RPC server. From that point, the `droid` object is available for use to access Android capabilities — in this case, speaking a message.

Python does not strictly realize that it is accessing local functionality. It simply makes RPC calls, ones that just so happen to be fulfilled on the device rather than via some remote RPC server accessed over the Internet.

Browsing the API

Therefore, SL4A effectively exposes an API to each of its scripting languages, via this RPC bridge. While the API is not huge, it accomplishes a lot and is ever-growing.

If you are editing scripts on the device, you can browse the API by choosing the API Browser option menu from the script editor. This brings up a list of available methods on your RPC proxy (e.g., `droid`) that you can call:



addContextMenuItem
addOptionsMenuItem
batteryCheckPresent
batteryGetHealth
batteryGetLevel
batteryGetPlugType
batteryGetStatus
batteryGetTechnology
batteryGetTemperature
batteryGetVoltage
batteryStartMonitoring
batteryStopMonitoring
bluetoothAccept
bluetoothConnect
bluetoothGetConnectedDeviceName
bluetoothMakeDiscoverable
bluetoothRead

Figure 900: The script editor's API browser

Tapping on any item in the list will "unfold" it to provide more details, such as the parameter list. Long-tapping on an item brings up a context menu where you can:

1. insert a template call to the method into your script at the cursor position
2. "prompt" you for the parameter values for the method, then insert the completed method call into your script

It is also possible to browse the API in a regular Web browser, if you are developing scripts off-device.

Running SL4A Scripts

Scripts are only useful if you run them, of course. We have seen two options for running scripts: tapping on them in the scripts list, or choosing “Save & Run” from the script editor. Those are not your only options, however.

Background

If you long-tap on a script in the script list, you will see a context menu option to “Start in Background”. As the name suggests, this kicks off the script in the background. Rather than seeing the terminal window for the script, the script just runs. A notification will appear in the status bar, with the SL4A icon, indicating that the RPC server is in operation and that script(s) may be running.

Shortcuts

Rather than have to open up SL4A every time, you can set up shortcuts on your home screen to run individual scripts.

Android 1.x/2.x

Just long-tap on the home screen background and choose Shortcuts from the context menu, then Scripts from the available shortcuts. This brings up the scripts list, but this time, when you choose a script, you are presented with a quick actions balloon for how to start it: in a terminal or in the background:

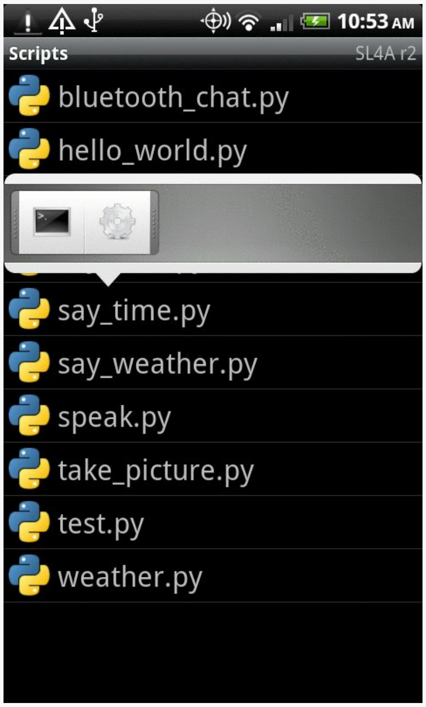


Figure 901: Configuring an SL4A shortcut

Choose one, and at this point, a shortcut, with the interpreter's icon and the name of the script, will appear on your home screen. Tapping it runs the script.

Android 3.0+

Go to where you install home screen widgets (e.g., "Widgets" tab in launcher), and you should see a "Scripts" entry:

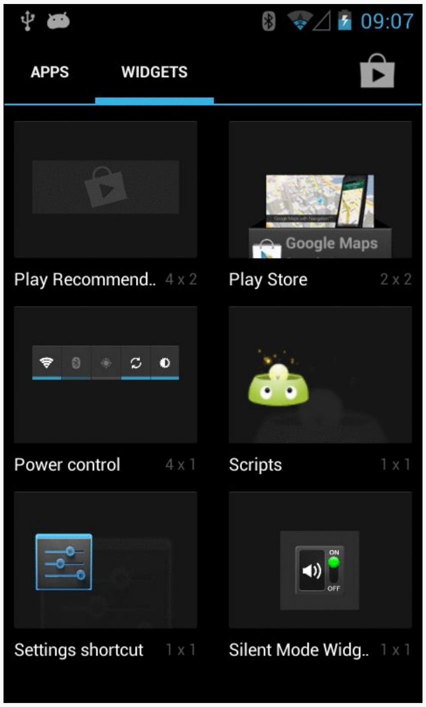

Figure 902: SL4A Shortcuts Option on Nexus S, Android 4.1

Add that to your home screen, the same as you would any other app widget (e.g., long press, then drag to the desired spot). That, in turn, will bring up the list of available scripts. Tapping on a script, as with Android 1.x/2.x, brings up a quick actions balloon for how to start it: in a terminal or in the background (see screenshot in previous section). This will then set up your shortcut on your home screen, so tapping it will launch your chosen script.

Other Alternatives

Users of Locale — an application designed to trigger events at certain times or when you get to certain locations — can trigger SL4A scripts in addition to invoking standard built-in tools.

In addition, there is preliminary support in SL4A for packaging scripts as APK files for wider distribution.

Potential Issues

As the SL4A Web site indicates, SL4A is “alpha-quality”. It is not without warts. How much those warts are an issue for you, in terms of crafting and running utility scripts, is up to you.

Security… From Scripts

SL4A itself holds a long list of Android permissions, including:

1. The ability to read your contact data
2. The ability to call phone numbers and place SMS messages
3. Access to your location
4. Access to your received SMS/MMS messages
5. Bluetooth access
6. Internet access
7. The ability to write to the SD card
8. The ability to record audio and take pictures
9. The ability to keep your device awake
10. The ability to retrieve the list of running applications and restart other applications
11. And so on

Hence, its scripts — via the RPC-based API — can perform all of those actions. For example, a script you download from a third party could read all your contacts and send that information to a spammer. Hence, you should only run scripts that you trust, since SL4A effectively “wires open” many aspects of Android’s standard security protections.

Security… From Other Apps

Originally, the on-device Web service supplying the RPC-based API was wide open. Any program that could find the port could connect to that Web service and invoke operations. That would not necessarily be all that bad… except that the Web service runs in its own process with its own permissions, and it may have permissions that other applications lack (e.g., right to access the Internet or to read contacts). Given that, malware could use SL4A to do things that it, by itself, could not do, allowing it to sneak onto more devices.

SL4A now uses a token-based authentication mechanism for using the Web service, to help close this loophole. In principle, only SL4A scripts should be able to use the RPC server.

JVM Scripting Languages

The Java virtual machine (JVM) is a remarkably flexible engine. While it was originally developed purely for Java, it has spawned its own family of languages, just as Microsoft's CIL supports multiple languages for the Windows platform. Some languages targeting the JVM as a runtime will work on Android, since the regular Java VM and Android's Dalvik VM are so similar.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Some of the sample code demonstrates JUnit test cases, so reading the chapter on unit testing may be useful.

Languages on Languages

Except for the handful of early language interpreters and compilers hand-constructed in machine code, every programming language is built atop earlier ones. C and C++ are built atop assembly language. Many other languages, such as Java itself, are built atop C/C++.

Hence, it should not come as much of a surprise that an environment as popular as Java has spawned another generation of languages whose implementations are in Java.

There are a few flavors of these languages. Some, like Scala and Clojure, are compiled languages whose compilers created JVM bytecodes, no different than would a Java compiler. These do not strictly qualify as a "scripting language", however, since they typically compile their source code to bytecode ahead of time.

Some Java-based scripting languages use fairly simple interpreters. These interpreters convert scripting code into parsed representations (frequently so-called "abstract syntax trees", or ASTs), then execute the scripts from their parsed forms. Most scripting languages at least start here, and some, like BeanShell, stick with this implementation.

Other scripting languages try to bridge the gap between a purely interpreted language and a compiled one like Scala or Clojure. These languages turn the parsed scripting code into JVM bytecode, effectively implementing their own just-in-time compiler (JIT). Since many Java runtimes themselves have a JIT to turn bytecode into machine code ("opcode"), languages with their own JIT can significantly outperform their purely-interpreted counterparts. JRuby and Rhino are two languages that have taken this approach.

A Brief History of JVM Scripting

Back in the beginning, the only way to write for the JVM was in Java itself. However, since writing language interpreters is a common pastime, it did not take long for people to start implementing interpreters in Java. These had their niche audiences, but there was only modest interest in the early days — interpreters made Java applets too large to download, for example.

Things got a bit more interesting in 1999, when IBM released the Bean Scripting Framework (BSF). This offered a uniform API for scripting engines, meaning that a hosting Java application could write to the BSF API, then plug in arbitrary interpreters at runtime. It was even possible, with a bit of extra work, to allow new interpreters to be downloaded and used on demand, rather than having to be pre-installed with the application. BSF also standardized how to inject Java objects into the scripting engines themselves, for access by the scripts. This allowed scripts to work with the host application's objects, such as allowing scripts to manipulate the contents of the jEdit text editor.

This spurred interest in scripting. In addition to some IBM languages (e.g., NetREXX) supporting BSF natively, other languages, like BeanShell, created BSF adapters to allow their languages to participate in the BSF space. On the consumer side, various Web frameworks started supporting BSF scripting for dynamic Web content generation, and so forth.

Interest was high enough that Apache took over stewardship of BSF in 2003. Shortly thereafter, Sun and others started work on JSR-223, which added the `javax.script` framework to Java 6. The `javax.script` framework advanced the BSF concept and standardized it as part of Java itself.

At this point, most JVM scripting languages that are currently maintained support `javax.script` integration, and may also support integration with the older BSF API as well.

Android does not include `javax.script` as part of its subset of the Java SE class library from the Apache Harmony project. This certainly does not preclude integrating scripting languages into Android applications, but it does raise the degree of difficulty a bit.

Limitations

Of course, JVM scripting languages do not necessarily work on Android without issue. There may be some work to get a JVM language going on Android, above and beyond the challenges for scripting languages in general on Android.

Android SDK Limits

Android is not Java SE, or Java ME, or even Java EE. While Android has many standard Java classes, it does not have a class library that matches any traditional pattern. As such, languages built assuming Java SE, for example, may have some dependency issues.

For languages where you have access to the source code, removing these dependencies may be relatively straightforward, particularly if they are ancillary to the operation of the language itself. For example, the language may come with miniature Swing IDEs, support for scripted servlets, or other capabilities that are not particularly relevant on Android and can be excised from the source code.

Wrong Bytecode

Android runs Dalvik bytecode, not Java bytecode. The conversion from Java bytecode to Dalvik bytecode happens at compile time. However, the conversion tool is rather finicky — it wants bytecode from Sun/Oracle's Java 1.5 or 1.6, nothing else. This can cause some problems:

1. You may encounter a JAR that is old enough to have been compiled with Java 1.4.2

2. You may encounter JARs compiled using other compilers, such as the GNU Compiler for Java (GCJ), common on Linux distributions
3. Java 7 has bytecode differences from Java 6; users of Java 7 need to compile their Java classes to Java 6 bytecode
4. Languages that have their own JIT compilers will have problems, because their JIT compilers will be generating Java bytecodes, not Dalvik bytecodes, meaning that the JIT facility needs to be rewritten or disabled

Again, if you have the source code, recompiling on an Android-friendly Java compiler should be a simple process.

Age

The heyday of some JVM languages is in the past. As such, you may find that support for some languages will be limited, simply because few people are still interested in them. Finding people interested in those languages on Android — the cross-section of two niches – may be even more of a problem.

SL4A and JVM Languages

SL4A supports three JVM languages today:

1. BeanShell
2. JRuby
3. Rhino (JavaScript)

You can use those within your SL4A environment no different than you can any other scripting language (e.g., Perl, Python, PHP). Hence, if what you are looking for is to create your own personal scripts, or writing small applications, SL4A saves you a lot of hassle. If there is a JVM scripting language you like but is not supported by SL4A, adding support for new interpreters within SL4A is fairly straightforward, though the APIs may change as SL4A is undergoing a fairly frequent set of revisions.

Embedding JVM Languages

While SL4A will drive end users towards writing their own scripts or miniature applications using JVM languages, another use of these languages is for embedding in a full Android application. Scripting may accelerate development, if the developers are more comfortable with the scripted language than with Java. Also, if the scripts are able to be modified or expanded by users, an ecosystem may emerge for user-contributed scripts.

Architecture for Embedding

Embedding a scripting language is not something to be undertaken lightly, even on a desktop or server application. Mobile devices running Android will have similar issues.

Asynchronous

One potential problem is that a script may take too long to execute. Android's architecture assume that work triggered by buttons, menus, and the like will either happen very quickly or will be done on background threads. Particularly for user-generated scripts, the script execution time is unknowable in advance — it might be a few milliseconds, or it might be several seconds. Hence, any implementation of a scripting extension for an Android application needs to consider executing all scripts in a background thread. This, of course, raises its own challenges for reflecting those scripts' results on-screen, since GUI updates cannot be done on a background thread.

Security

Scripts in Android inherit the security restrictions of the process that runs the script. If an application has the right to access the Internet, so will any scripts run in that application's process. If an application has the right to read the user's contacts, so will any scripts run in that application's process. And so on. If the scripts in question are created by the application's authors, this is not a big deal — the rest of the application has those same permissions, after all. But, if the application supports user-authored scripts, it raises the potential of malware hijacking the application to do things that the malware itself would otherwise lack the rights to do.

Inside the InterpreterService

One way to solve both of those problems is to isolate the scripting language in a self-contained low-permission APK — "sandboxing" the interpreter so the scripts it executes are less able to cause harm. This APK could also arrange to have the interpreter execute its scripts on a background thread. An even better implementation would allow the embedding application to decide whether or not the “sandbox” is important — applications with a controlled source of scripts may not need the extra security or the implementation headaches it causes.

With that in mind, let us take a look at the JVM/InterpreterService sample project, one possible implementation of the strategy described above.

The Interpreter Interface

The InterpreterService can support an arbitrary number of interpreters, via a common interface. This interface provides a simplified API for having an interpreter execute a script and return a result:

```
package com.commonsware.abj.interp;

import android.os.Bundle;

public interface I_Interpreter {
  Bundle executeScript(Bundle input);
}
```

As you can see, it is *very* simplified, offering just a single executeScript() method. That method accepts a Bundle (a key-value store akin to a Java HashMap) as a parameter — that Bundle will need to contain the script and any other objects needed to execute the script.

The interpreter will return another Bundle from executeScript(), containing whatever data it wants the script’s requester to have access to.

For example, here is the implementation of EchoInterpreter, which just returns the same Bundle that was passed in:

```
package com.commonsware.abj.interp;

import android.os.Bundle;

public class EchoInterpreter implements I_Interpreter {
  public Bundle executeScript(Bundle input) {
    return(input);
  }
}
```

A somewhat more elaborate sample is the SQLiteInterpreter:

```
package com.commonsware.abj.interp;

import android.database.Cursor;
import android.database.sqlite.SQLiteDatabase;
import android.os.Bundle;

public class SQLiteInterpreter implements I_Interpreter {
  public Bundle executeScript(Bundle input) {
    Bundle result=new Bundle(input);
    String script=input.getString(InterpreterService.SCRIPT);

    if (script!=null) {
      SQLiteDatabase db=SQLiteDatabase.create(null);
      Cursor c=db.rawQuery(script, null);

      c.moveToFirst();

      for (int i=0;i<c.getColumnCount();i++) {
        result.putString(c.getColumnName(i), c.getString(i));
      }

      c.close();
      db.close();
    }

    return(result);
  }
}
```

This class accepts a script, in the form of a SQLite database query. It extracts the script from the Bundle, using a pre-defined key (InterpreterService.SCRIPT). Assuming there is such a script, it creates an empty in-memory database and executes the SQLite query against that database.

The results come back in the form of a Cursor — itself a key-value store. SQLiteInterpreter takes those results and pours them into a Bundle to be returned.

The Bundle being returned starts from a copy of the input Bundle, so the script requester can embed in the input Bundle any identifiers it needs to determine how to handle the results from executing this script.

SQLiteInterpreter is not terribly flexible, but you can use it for simple numeric and string calculations, such as the following script:

```
SELECT 1+2 AS result, 'foo' AS other_result, 3*8 AS third_result;
```

This would return a Bundle containing a key of result with a value of 3, a key of other_result with a value of foo, and a key of third_result with a value of 24.

Of course, it would be nice to support more compelling interpreters, and we will examine a pair of those later in this chapter.

Loading Interpreters and Executing Scripts

Of course, having a nice clean interface to the interpreters does nothing in terms of actually executing them on a background thread, let alone sandboxing them. The `InterpreterService` class itself handles that.

`InterpreterService` is an `IntentService`, which automatically routes incoming `Intent` objects (from calls to `startService()`) to a background thread via a call to `onHandleIntent()`. `IntentService` will queue up `Intent` objects if needed, and `IntentService` even automatically shuts down if there is no more work to be done.

Here is the implementation of `onHandleIntent()` from `InterpreterService`:

```
@Override
protected void onHandleIntent(Intent intent) {
  String action=intent.getAction();
  I_Interpreter interpreter=interpreters.get(action);

  if (interpreter==null) {
    try {
      interpreter=(I_Interpreter)Class.forName(action).newInstance();
      interpreters.put(action, interpreter);
    }
    catch (Throwable t) {
      Log.e("InterpreterService", "Error creating interpreter", t);
    }
  }

  if (interpreter==null) {
    failure(intent, "Could not create interpreter: "+intent.getAction());
  }
  else {
    try {
      success(intent, interpreter.executeScript(intent.getBundleExtra(BUNDLE)));
    }
    catch (Throwable t) {
      Log.e("InterpreterService", "Error executing script", t);

      try {
        failure(intent, t);
      }
      catch (Throwable t2) {
        Log.e("InterpreterService",
              "Error returning exception to client",
              t2);
      }
    }
  }
}
```

We keep a cache of interpreters, since initializing their engines may take some time. That cache is keyed by the interpreter's class name, and that key comes in to the service by way of the action on the Intent that was used to start the service. In other words, the script requester tells us, by way of the Intent used in startService(), which interpreter to use.

Those interpreters are created using reflection. This way, InterpreterService has no compile-time knowledge of any given interpreter class. Interpreters can come and go, but InterpreterService remains the same.

Assuming an interpreter was found (either cached or newly created), we have it execute the script, with the input Bundle coming from an "extra" on the Intent. Methods named success() and failure() are then responsible for getting the results to the script requester… as will be seen in the next section.

Delivering Results

Script requesters can get the results of the script back — in the form of the interpreter's output Bundle — in one of two ways.

One option is a private broadcast Intent. This is a broadcast Intent where the broadcast is limited to be delivered only to a specific package, not to any potential broadcast receiver on the device.

The other option is to supply a PendingIntent that will be sent with the results. This could be used by an Activity and createPendingIntent() to have control routed to its onActivityResult() method. Or, an arbitrary PendingIntent could be created, to start another activity, for example.

The implementations of success() and failure() in InterpreterService simply build up an Intent containing the results to be delivered:

```
private void success(Intent intent, Bundle result) {
  Intent data=new Intent();

  data.putExtras(result);
  data.putExtra(RESULT_CODE, SUCCESS);

  send(intent, data);
}

private void failure(Intent intent, String message) {
  Intent data=new Intent();

  data.putExtra(ERROR, message);
  data.putExtra(RESULT_CODE, FAILURE);

  send(intent, data);
}

private void failure(Intent intent, Throwable t) {
  Intent data=new Intent();

  data.putExtra(ERROR, t.getMessage());
  data.putExtra(TRACE, getStackTrace(t));
  data.putExtra(RESULT_CODE, FAILURE);

  send(intent, data);
}
```

These, in turn, delegate the actual sending logic to a `send()` method that delivers the result `Intent` via a private broadcast or a `PendingIntent`, as indicated by the script requester:

```
private void send(Intent intent, Intent data) {
  String broadcast=intent.getStringExtra(BROADCAST_ACTION);

  if (broadcast==null) {
    PendingIntent pi=(PendingIntent)intent.getParcelableExtra(PENDING_RESULT);

    if (pi!=null) {
      try {
        pi.send(this, Activity.RESULT_OK, data);
      }
      catch (PendingIntent.CanceledException e) {
        // no-op -- client must be gone
      }
    }
  }
  else {
    data.setPackage(intent.getStringExtra(BROADCAST_PACKAGE));
    data.setAction(broadcast);

    sendBroadcast(data);
  }
}
```

Packaging the InterpreterService

There are three steps for integrating `InterpreterService` into an application.

First, you need to decide what APK the `InterpreterService` goes in – the main one for the application (no sandbox) or a separate low-permission one (sandbox).

Second, you need to decide what interpreters you wish to support, writing `I_Interpreter` implementations and getting the interpreters' JARs into the project's `libs/` directory.

Third, you need to add the source code for InterpreterService along with a suitable <service> entry in AndroidManifest.xml. This entry will need to support <intent-filter> elements for each scripting language you are supporting, such as:

```
    <service
      android:name=".InterpreterService"
      android:exported="false">
      <intent-filter>
        <action android:name="com.commonsware.abj.interp.EchoInterpreter"/>
      </intent-filter>
      <intent-filter>
        <action android:name="com.commonsware.abj.interp.SQLiteInterpreter"/>
      </intent-filter>
      <intent-filter>
        <action android:name="com.commonsware.abj.interp.BshInterpreter"/>
      </intent-filter>
      <intent-filter>
        <action android:name="com.commonsware.abj.interp.RhinoInterpreter"/>
      </intent-filter>
    </service>
```

From there, it is a matter of adding in appropriate startService() calls to your application wherever you want to execute a script, and processing the results you get back.

Using the InterpreterService

To use the InterpreterService, you need to first determine which I_Interpreter engine you are using, as that forms the action for the Intent to be used with the InterpreterService. Create an Intent with that action, then add in an InterpreterService.BUNDLE extra for the script and other data to be supplied to the interpreter. Also, you can add an InterpreterService.BROADCAST_ACTION, to be used by InterpreterService to send results back to you via a broadcast Intent. Finally, call startService() on the Intent, and the results will be delivered to you asynchronously.

For example, here is a test method from the EchoInterpreterTests test case:

```
package com.commonsware.abj.interp;

import android.os.Bundle;

public class EchoInterpreterTests extends InterpreterTestCase {
  protected String getInterpreterName() {
    return("com.commonsware.abj.interp.EchoInterpreter");
  }

  public void testNoInput() {
    Bundle results=execServiceTest(new Bundle());
    assertNotNull(results);
    assert (results.size() == 0);
  }

  public void testWithSomeInputJustForGrins() {
    Bundle input=new Bundle();

    input.putString("this", "is a value");

    Bundle results=execServiceTest(input);

    assertNotNull(results);
    assertEquals(results.getString("this"), "is a value");
  }
}
```

The echo "interpreter" simply echoes the input `Bundle` into the output. The `execServiceTest()` method is inherited from the `InterpreterTestCase` base class:

```
  protected Bundle execServiceTest(Bundle input) {
    Intent i=new Intent(getInterpreterName());

    i.putExtra(InterpreterService.BUNDLE, input);
    i.putExtra(InterpreterService.BROADCAST_ACTION, ACTION);

    getContext().startService(i);

    try {
      latch.await(5000, TimeUnit.MILLISECONDS);
    }
    catch (InterruptedException e) {
      // just keep rollin'
    }

    return(results);
  }
```

The `execServiceTest()` method uses a `CountDownLatch` to wait on the interpreter to do its work before proceeding (or 5000 milliseconds, whichever comes first). The broadcast `Intent` containing the results, registered to watch for `com.commonsware.abj.interp.InterpreterTestCase` broadcasts, stuffs the output `Bundle` in a results data member and drops the latch, allowing the main test thread to continue.

BeanShell on Android

What if Java itself were a scripting language? What if you could just execute a snippet of Java code, outside of any class or method? What if you could still import classes, call static methods on classes, create new objects, as well?

That was what BeanShell offered, back in its heyday. And, since BeanShell does not use sophisticated tricks with its interpreter – like JIT compilation of scripting code — BeanShell is fairly easy to integrate into Android.

What is BeanShell?

BeanShell is Java on Java.

With BeanShell, you can write scripts in loose Java syntax. Here, “loose” means:

1. In addition to writing classes, you can execute Java statements outside of classes, in a classic imperative or scripting style
2. Data types are optional for variables
3. Not every language feature is supported, particularly things like annotations that did not arrive until Java 1.5
4. Etc.

BeanShell was originally developed in the late 1990’s by Pat Niemeyer. It enjoyed a fair amount of success, even being considered as a standard interpreter to ship with Java (JSR-274). However, shortly thereafter, BeanShell lost momentum, and it is no longer being actively maintained. That being said, it works quite nicely on Android… once a few minor packaging issues are taken care of.

Getting BeanShell Working on Android

BeanShell has two main problems when it comes to Android:

- The publicly-downloadable JAR was compiled for Java 1.4.2, and Android requires Java 5 or newer
- The source code includes various things, like a Swing-based GUI and a servlet, that have no real place in an Android app and require classes that Android lacks

Fortunately, with BeanShell being open source, it is easy enough to overcome these challenges. You could download the source into an Android library project, then remove the classes that are not necessary (e.g., the servlet), and use that library project in your main application. Or, you could use an Android project for creating a JAR file that was compiled against the Android class library, so you are certain everything is supported.

However, the easiest answer is to use SL4A's BeanShell JAR, since they have solved those problems already. The JAR can be found in the SL4A source code repository, though you will probably need to check out the project using Mercurial, since JARs cannot readily be downloaded from the Google Code Web site.

Integrating BeanShell

The BeanShell engine is found in the `bsh.Interpreter` class. Wrapping one of these in an `I_Interpreter` interface, for use with `InterpreterService`, is fairly simple:

```
package com.commonsware.abj.interp;

import android.os.Bundle;
import bsh.Interpreter;

public class BshInterpreter implements I_Interpreter {
  public Bundle executeScript(Bundle input) {
    Interpreter i=new Interpreter();
    Bundle output=new Bundle(input);
    String script=input.getString(InterpreterService.SCRIPT);

    if (script != null) {
      try {
        i.set(InterpreterService.BUNDLE, input);
        i.set(InterpreterService.RESULT, output);

        Object eval_result=i.eval(script);

        output.putString("result", eval_result.toString());
      }
      catch (Throwable t) {
        output.putString("error", t.getMessage());
      }
    }

    return(output);
  }
}
```

BeanShell interpreters are fairly inexpensive objects, so we create a fresh `Interpreter` for each script, so one script cannot somehow access results from prior scripts. After setting up the output `Bundle` and extracting the script from the input `Bundle`, we inject both `Bundle` objects into BeanShell itself, where they can be accessed like global variables, named `_bundle` and `_result`.

At this point, we evaluate the script, using the `eval()` method on the `Interpreter` object. If all goes well, we convert the object returned by the script into a `String` and tuck it into the output `Bundle`, alongside anything else the script may have put into the Bundle. If there is a problem, such as a syntax error in the script, we put the error message into the output Bundle.

So long as the InterpreterService has an <intent-filter> for the com.commonsware.abj.interp.BshInterpreter action, and so long as we have a BeanShell JAR in the project's libs/ directory, InterpreterService is now capable of executing BeanShell scripts as needed.

With our inherited execServiceTest() method handling invoking the InterpreterService and waiting for responses, we can "simply" put our script as the InterpreterService.SCRIPT value in the input Bundle, and see what we get out. The first test script returns a simple value; the second test script directly calls methods on the output Bundle to return its results.

Rhino on Android

JavaScript arrived on the language scene hot on the heels of Java itself. The name was chosen for marketing purposes more so than for any technical reason. Java and JavaScript had little to do with one another, other than both adding interactivity to Web browsers. And while Java has largely faded from mainstream browser usage, JavaScript has become more and more of a force on the browser, and even now on Web servers.

And, along the way, the Mozilla project put JavaScript on Java and gave us Rhino.

What is Rhino?

If BeanShell is Java in Java, Rhino is JavaScript in Java.

As part of Netscape's failed "Javagator" attempt to create a Web browser in Java, they created a JavaScript interpreter for Java, code-named Rhino after the cover of O'Reilly Media's JavaScript: The Definitive Guide. Eventually, Rhino was made available to the Mozilla Foundation, which has continued maintaining it. At the present time, Rhino implements JavaScript 1.7, so it does not support the latest and greatest JavaScript capabilities, but it is still fairly full-featured.

Interest in Rhino has ticked upwards, courtesy of interest in using JavaScript in places other than Web browsers, such as server-side frameworks. And, of course, it works nicely with Android.

Getting Rhino Working on Android

Similar to BeanShell, Rhino has a few minor source-level incompatibilities with Android. However, these can be readily pruned out, leaving you with a still-functional JavaScript interpreter. However, once again, it is easiest to use SL4A's Rhino JAR, since all that work is done for you.

Integrating Rhino

Putting an `I_Interpreter` facade on Rhino is incrementally more difficult than it is for BeanShell, but not by that much:

```
package com.commonsware.abj.interp;

import android.os.Bundle;
import org.mozilla.javascript.*;

public class RhinoInterpreter implements I_Interpreter {
  public Bundle executeScript(Bundle input) {
    String script=input.getString(InterpreterService.SCRIPT);
    Bundle output=new Bundle(input);

    if (script != null) {
      Context ctxt=Context.enter();

      try {
        ctxt.setOptimizationLevel(-1);

        Scriptable scope=ctxt.initStandardObjects();
        Object jsBundle=Context.javaToJS(input, scope);
        ScriptableObject.putProperty(scope, InterpreterService.BUNDLE,
                                     jsBundle);

        jsBundle=Context.javaToJS(output, scope);
        ScriptableObject.putProperty(scope, InterpreterService.RESULT,
                                     jsBundle);
        String result=
            Context.toString(ctxt.evaluateString(scope, script,
                                                 "<script>", 1, null));

        output.putString("result", result);
      }
      finally {
        Context.exit();
      }
    }

    return(output);
  }
}
```

As with BshInterpreter, RhinoInterpreter sets up the output Bundle and extracts the script from the input Bundle. Assuming there is a script, RhinoInterpreter then sets up a Rhino Context object, which is roughly analogous to the BeanShell Interpreter object. One key difference is that you need to clean up the Context, by calling a static exit() method on the Context class, whereas with a BeanShell Interpreter, you just let garbage collection deal with it.

Rhino has a JIT compiler, one that unfortunately will not work with Android, since it generates Java bytecode, not Dalvik bytecode. However, Rhino lets you turn that off, by calling setOptimizationLevel() on the Context object with a value of -1 (meaning, in effect, disable all optimizations).

After that, we:

1. Create a language scope for our script and inject standard JavaScript global objects into that scope
2. Wrap our two Bundle objects with JavaScript proxies via calls to javaToJS(), then injecting those objects into the scope as

_bundle and _result via putProperty() calls

1. Execute the script via a call to evaluateString() on the Context object, converting the resulting object into a String and pouring it into the output Bundle

If our InterpreterService has an <intent-filter> for the com.commonsware.abj.interp.RhinoInterpreter action, and so long as we have a Rhino JAR in the project's libs/ directory, InterpreterService can now invoke JavaScript.

Other JVM Scripting Languages

As mentioned previously, there are many languages that, themselves, are implemented in Java and can be ported to Android, with varying degrees of difficulty. Many of these languages are fairly esoteric. Some, like JRuby, have evolved to the point where they transcend a simple "scripting language" on Android.

However, there are two other languages worth mentioning, as they are fairly well-known in Java circles: Groovy and Jython.

Groovy

Groovy is perhaps the most popular Java-based language that does not have its roots in some other previous language (Java, JavaScript, Python, etc.). Designed in some respects to be a "better Java than Java", Groovy gives you access to Java classes while allowing you to write scripts with dynamic typing, closures, and so forth. Groovy has an extensive community, complete with a fair number of Groovy-specific libraries and frameworks, plus some books on the market.

At the time of this writing, it does not appear that Groovy has been successfully ported to work on Android, though.

Jython

Jython is an implementation of a Python language interpreter in Java. It has been around for quite some time, and gives you Python syntax with access to standard Java classes where needed. While the Jython community is not as well-organized as that of Groovy, there are plenty of books covering the use of Jython.

Jython's momentum has flagged a bit in recent months, in part due to Sun's waning interest in the technology and the departure of Sun employees from the project. One attempt to get Jython working with Android has been shut down, with people steered towards SL4A. It is unclear if others will make subsequent attempts.

Trail: Alternatives for App Development

The Role of Alternative Environments

You might think that Android is all about Java. The official Android Software Development Kit (SDK) is for Java development, the build tools are for Java development, the discussion groups and blog posts and, yes, most books are for Java development. Heck, most of this book is about Java.

However (and with apologies to William Goldman), it just so happens that Android is only mostly Java. There's a big difference between mostly Java and all Java. Mostly Java is slightly not Java.

So, while Android's "sweet spot" will remain Java-based applications for the near term, you can still create applications using other technologies. This part of the book will take a peek at some of those alternatives.

This chapter starts with an examination of the pros and cons of Android's Java-centric strategy. It then enumerates some reasons why you might want to use something else for your Android applications. The downsides of alternative Android application environments – lack of support and technical challenges – are also discussed.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

In the Beginning, There Was Java…

The core Android team made a fairly reasonable choice of language when they chose Java. It is a very popular language, and in the mobile community it had a clear predecessor in Java Micro Edition (J2ME). Lacking direct access to memory addresses (so-called "pointers"), a Java-based application will be less prone to developer errors leading to buffer overruns, resulting in possible hacks. And there is a fairly robust ecosystem around Java, in terms of educational materials, existing code bases, integrated development environments (IDEs), and so on.

However, while you can program Android in the Java language, an Android device does not run a Java application. Instead, your Java code is converted into something that runs on the "Dalvik virtual machine". This is akin to the technology used for regular Java applications, but Dalvik is specifically tuned for Android's environment. Moreover, it limits the dependency of Android on Java itself to a handful of programming tools, important as Java's stewardship moves from Sun to Oracle to wherever.

That Dalvik virtual machine is also capable of running code from other programming languages, a feature that makes possible much of what this book covers.

… And It Was OK

No mobile development environment is perfect, and so the combination of Java and Android has its issues.

Java uses garbage collection to save people from having to keep track of all of their memory allocations. That works for the most part, and it is generally a boon to developer productivity. However, it is not a cure-all for every memory and resource allocation problem. You can still have what amounts to "memory leaks" in Java, even if the precise mechanics of those leaks differ from the classic leaks you get in C, C++, etc.

Most importantly, though, not everybody likes Java. It could be because they lack experience with it, or perhaps they have experience with it and did not enjoy that experience. Certainly, Java is slowly being considered as a language for big enterprise systems and, therefore, is not necessarily "cool". Advocates of different languages will have their own pet peeves with Java as well (e.g., to a Ruby developer, Java is really verbose).

So, while Java was not a bad choice for Android, it was not perfect, either.

Bucking the Trend

However, just because Java is the dominant way to build apps for Android, that does not mean it is the only way, and for you, it may not even be the best way.

Perhaps Java is not in your existing skill set. You might be a Web developer, more comfortable with HTML, CSS, and JavaScript. There are frameworks to help you with that. Or, maybe you cut your teeth on server-side scripting languages like Perl or Python — there are ways to sling that code on Android as well. Or perhaps you already have a bunch of code in C/C++, such as game physics algorithms, that would be painful to rewrite in Java — you should be able to reuse that code too.

Even if you would be willing to learn Java, it may be that your inexperience with Java and the Android APIs will just slow you down. You might be able to get something built much more quickly with another framework, even if you wind up replacing it with a Java-based implementation in the future. Rapid development and prototyping is frequently important, to get early feedback with minimal investment in time.

And, of course, you might just find Java programming to be irritating. You would not be the first, nor the last, to have that sentiment. Particularly if you are getting into Android as a hobby, rather than as part of your “day job”, having fun will be important to you, and you might not find Java to be much fun.

Support, Structure

However, “friendly” and “fully supported” are two different things.

Some alternatives to Java-based development are officially supported by the core Android team, such as C/C++ development via the Native Development Kit (NDK) and Web-style development via HTML5.

Some alternatives to Java-based development are supported by companies. Adobe supports AIR, Nitobi supports PhoneGap, Rhomobile supports Rhodes, and so on. Other alternatives are supported by standards bodies, like the World Wide Web Consortium (W3C) supporting HTML5. Still others are just tiny projects with only the backing of a couple of developers.

You will need to make the decision for yourself which of these levels of support will meet your requirements. For many things, support is not much of an issue, but there will always be cases where support becomes paramount (e.g., enterprise application development).

Caveat Developer

Of course, going outside the traditional Java environment for Android development has its issues, beyond just how much support might be available.

Some may be less efficient, in terms of processor time, memory, or battery life, than will development in Java. C/C++, on the whole, is probably better than Java, but HTML5 may be worse, for example. Depending on what you are writing and how heavily it will be used will determine how critical that inefficiency will be.

Some may not be available on all devices. Right now, Flash is the best example of this — some devices offer some amount of Flash support, while other devices have no Flash at all. Similarly, HTML5 support was only added to Android in Android 2.0, so devices running older versions of Android do not have HTML5 as a built-in option.

Every layer between you and officially supported environments makes it that much more difficult for you to ensure compatibility with new versions of Android, when they arise. For example, if you create an application using PhoneGap, and a new Android version becomes available, there may be incompatibilities that only the PhoneGap team can address. While they will probably address those quickly — and they may provide some measure of insulation to you from those incompatibilities — the response time is outside of your control. In some cases, that is not a problem, but in other cases, that might be bad for your project.

Hence, just because you are developing outside of Java does not mean everything is perfect. You simply have to trade off between these problems and the ones Java-based development might cause you. Where the balance lies is up to each individual developer or firm.

HTML5

Prior to the current wave of interest in mobile applications, the technology *du jour* was Web applications. A lot of attention was paid to AJAX, Ruby on Rails, and other techniques and technologies that made Web applications climb close to the experience of a desktop application, and sometimes superior.

The explosion of Web applications eventually drove the next round of enhancements to Web standards, collectively called HTML5. Android 2.0 added the first round of support for these HTML5 enhancements. Notably, Android supports offline applications and Web storage, meaning that HTML5 becomes a relevant technique for creating Android applications, without dealing with Java.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the chapter on `WebView` would be a good idea, as would reading the introduction to this trail.

Offline Applications

The linchpin for using HTML5 for offline applications — on Android or elsewhere — is the ability for those applications to be used when there is no connectivity, either due to problems on the client side (e.g., on an airplane sans WiFi) or on the server side (e.g., Web server maintenance).

What Does It Mean?

Historically, Web applications have had this annoying tendency to require Web servers. This led to all sorts of workarounds for offline use, up to and including shipping a Web server and deploying it to the desktop.

HTML5 solves this problem by allowing Web pages to specify their own caching rules. A Web app can publish a "cache manifest", describing which resources:

1. Can be safely cached, such that if the Web server is unavailable, the browser will just use the cached copy
2. Cannot be safely cached, such that if the Web server is unavailable, the browser should fail like it normally does
3. Have a "fallback" resource, such that if the Web server is unavailable, the cached fallback resource should be used instead

For mobile devices, this means that a fully HTML5-capable browser should be able to load all its assets up front and keep them cached. If the user loses connectivity, the application will still run. In this respect, the Web app behaves almost identically to a regular app.

How Do You Use It?

For this chapter, we will use the Checklist "mini app" created by Alex Gibson. While the most up-to-date version of this app can be found on Mr. Gibson's Web site, this chapter will review the copy found in `HTML5/Checklist`. This copy is also hosted online on the CommonsWare site, or via a shortened URL: `http://bit.ly/cw-html5`.

About the Sample App

Checklist is, as the name suggests, a simple checklist application. When you first launch it, the list will be empty:

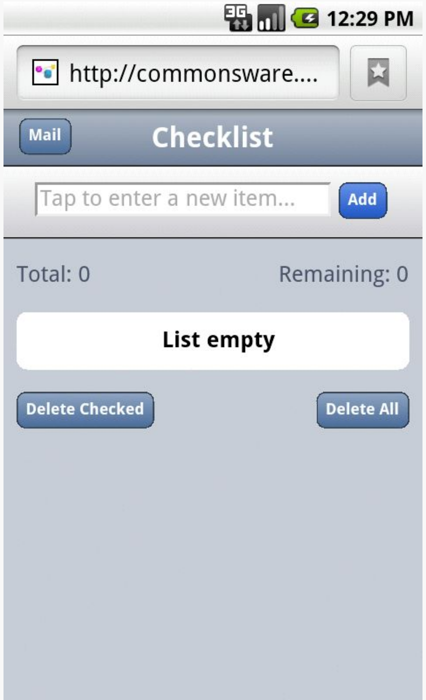

Figure 903: The Checklist, as initially launched

You can enter some text in the top field and click the Add button to add it to the list:

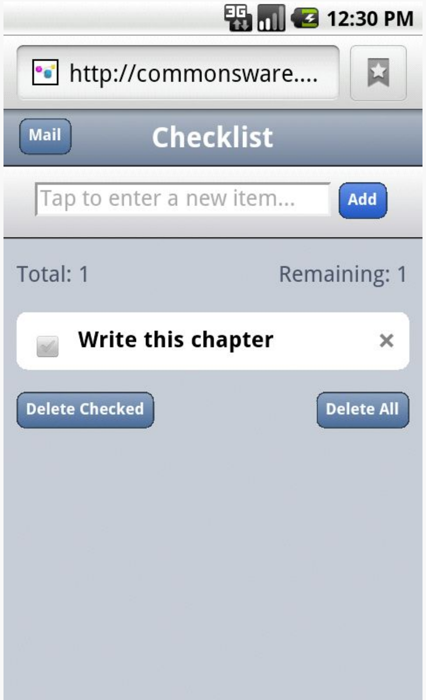

Figure 904: The Checklist, with one item added

You can “check off” individual items, which are then displayed in strike-through:

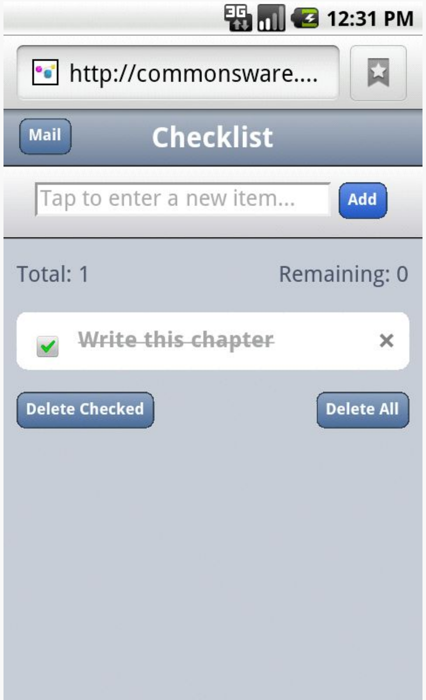

Figure 905: The Checklist, with one item marked as completed

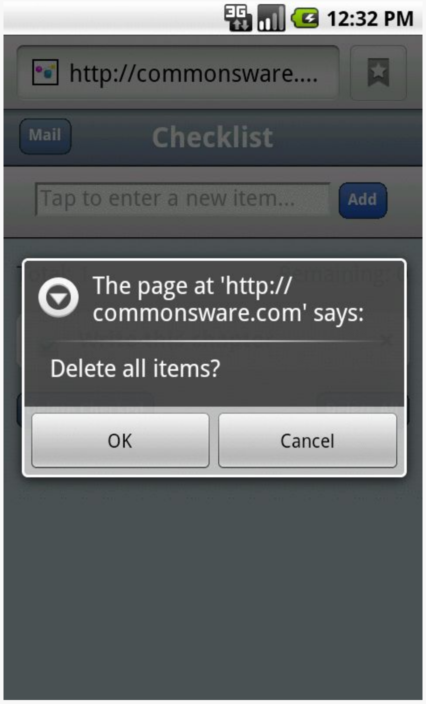
You can also delete the checked entries (via the Delete Checked button) or all entries (via the Delete All button), which will pop up a confirmation dialog before proceeding:



The page at 'http://commonsware.com' says:

Delete all items?

Figure 906: The Checklist's delete confirmation dialog

"Installing" Checklist on Your Phone

To access Checklist on your Android device, visit one of the URLs above for the hosted edition using the Browser application — the shortened one may be easiest to enter into the browser on the device. You can then add a bookmark for it (More > Add bookmark from the browser's options menu) to come back to it later.

You can even set up a shortcut for the bookmark on your home screen, if you so choose — just long-tap on the background, choose Bookmark, then choose the Checklist bookmark you set up before.

Examining the HTML

All of that is accomplished using just a handful of lines of HTML:

```
<!DOCTYPE html>
<html lang="en" manifest="checklist.manifest">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Checklist</title>
<meta name="viewport"
```

```
  content="width=device-width; initial-scale=1.0; maximum-scale=1.0; user-scalable=0;"
/>
<meta name="apple-mobile-web-app-capable" content="yes" />
<meta name="apple-mobile-web-app-status-bar-style" />
<link rel="apple-touch-startup-image" href="splashscreen.png" />
<link rel="stylesheet" href="styles.css" />
<link rel="apple-touch-icon-precomposed"
      href="apple-touch-icon-precomposed.png" />
</head>
<body>
<section>
    <header>
      <button type="button" id="sendmail">Mail</button>
      <h1>Checklist</h1>
    </header>
    <article>
       <form id="inputarea" onsubmit="addNewItem()">
          <input type="text" name="name" id="name" maxlength="75"
                  autocorrect placeholder="Tap to enter a new item&hellip;" />
          <button type="button" id="add">Add</button>
        </form>
        <ul id="maillist">
        <li class="empty"><a href="" id="maillink">Mail remaining items</a></li>
      </ul>
        <p id="totals"><span id="tally1">Total: <span id="total">0</span></span>
        <span id="tally2">Remaining: <span id="remaining">0</span></span></p>
      <ul id="checklist">
        <li class="empty">Loading&hellip;</li>
      </ul>
    </article>
    <fieldset>
      <button type="button" id="deletechecked">Delete Checked</button>
      <button type="button" id="deleteall">Delete All</button>
    </fieldset>
</section>
<script src="main.js"></script>
</body>
</html>
```

For the purposes of offline applications, though, the key is the `manifest` attribute of our `html` element. Here, we specify the relative path to a manifest file, indicating what the rules are for caching various portions of this application offline.

Examining the Manifest

So, since the manifest is where all the fun is, here is what Checklist's manifest looks like:

```
CACHE MANIFEST
#version 54
styles.css
main.js
splashscreen.png
```

The HTML5 manifest format is extremely simple. It starts with a CACHE MANIFEST line, followed by a list of files (technically, relative URLs) that should be cached. It also supports comments, which are lines beginning with #.

The manifest can also have a NETWORK: line, followed by relative URLs that should never be cached. Similarly, the manifest can have a FALLBACK: line, followed by pairs of relative URLs: the URL to try to fetch off the network, followed by the URL of a cached resource to use if the network is not available.

In principle, the manifest should request caching for everything that the application needs to run, though the page that requested the caching (index.html in this case) is also cached.

Web Storage

Caching the HTML5 application's assets for offline use is all well and good, but that will be rather limiting on its own. In an offline situation, the application would not be able to use AJAX techniques to interact with a Web service. So, if the application is going to be able to store information, it will need to do so on the browser itself.

Google Gears and related tools pioneered this concept and blazed the trail for what is now variously called "Web Storage" or "DOM Storage" for HTML5 applications. An HTML5 app can store data persistently on the client, within client-imposed limits. That, in conjunction with offline asset caching, means an HTML5 application can deliver far more value when it lacks an Internet connection, or for data that just does not make sense to store "in the cloud".

Note that, technically, Web Storage is not part of HTML5, but is a related specification. However, it tends to get "lumped in with" HTML5 in common conversation.

What Does It Mean?

On a Web Storage-enabled browser, your JavaScript code will have access to a localStorage object, representing your application's data. More accurately, each "origin" (i.e., domain) will have a distinct localStorage object on the browser.

The localStorage object is an "associative array", meaning you can work with it either via numerical indexes or string-based keys at your discretion. Values typically are strings. You can:

1. Find out how many entries are in the array via `length()`
2. Get and set items by key via `getItem()` and `setItem()`
3. Get the key for a numerical index via `key()`
4. Remove individual entries via `removeItem()` or remove all items via `clear()`

This means you do not have the full richness of a SQL database, like you might have with SQLite in a native Android application. But, for many applications, this should suffice.

How Do You Use It?

Checklist stores the list items as keys in the associative array, with a value of `0` for a regular item and `1` for a deleted item. Here, we see the code for putting a new item into the checklist:

```
try {
  localStorage.setItem(strippedString, data);
}
catch (e) {
  if (e == QUOTA_EXCEEDED_ERR) {
    alert('Quota exceeded!');
  }
}
```

Here is the code where those items are pulled back out of storage and put into an array for sorting and, later, display as DOM elements on the Web page itself:

```
/*get all items from localStorage and push them one by one into an
array.*/
for (i = 0; i <= listlength; i++) {

  var item = localStorage.key(i);
  myArray.push(item);
}

/*sort the array into alphabetical order.*/
myArray.sort();
```

When the user checks the checkmark next to an item, the storage is updated to toggle the checked setting persistently:

```
/*toggle the check flag.*/
if (target.previousSibling.checked) {
  data = 0;
}
else {
  data = 1;
}
/*save item in localStorage.*/
```

```
try {
  localStorage.setItem(name, data);
} catch (e) {

  if (e == QUOTA_EXCEEDED_ERR) {
    alert('Quota exceeded!');
  }
}
```

Checklist also has code to delete items from storage, either all those marked as checked:

```
/*remove every item from localStorage that has the data flag checked.*/
while (i <= localStorage.length-1) {

  var key = localStorage.key(i);
  if (localStorage.getItem(key) === '1') {
    localStorage.removeItem(key);
  }
  else { i++; }
}
```

… or all items:

```
/*deletes all items in the list.*/
deleteAll: function() {

  /*ask for user confirmation.*/
  var answer = confirm("Delete all items?");

  /*if yes.*/
  if (answer) {

    /*remove all items from localStorage.*/
    localStorage.clear();
    /*update view.*/
       checklistApp.getAllItems();
   }
   /*clear up.*/
   delete checklistApp.deleteAll;
},
```

Web SQL Database

Android's built-in browser also supports a "Web SQL Database" option, one where you can use SQLite-style databases from JavaScript. This adds a lot more power than basic Web Storage, albeit at a complexity cost. It is also not part of an active standard — the WHATWG team working on this standard has set it aside for the time being.

You might consider evaluating Lawnchair, which is a JavaScript API that allows you to store arbitrary JSON-encoded objects. It will use whatever storage options are available, and therefore will help you deal with cross-platform variety. In particular, it supports the Google Gears facility found in some older versions of Android.

Going To Production

Creating a little test application requires nothing magical. Presumably, though, you are interested in others using your application – perhaps many others. Classic Java-based Android applications have to deal with testing, having the application digitally signed for production, distribution through various channels (such as the Android Market), and updates to the application by one means or another. Those issues do not all magically vanish because HTML5 is used as the application environment. However, HTML5 does change things significantly from what Java developers have to do.

Testing

Since HTML5 works in other browsers, testing your business logic could easily take advantage of any number of HTML and JavaScript testing tools, from Selenium to QUnit to Jasmine.

For testing on Android proper — to ensure there are no issues related to Android's browser implementation — you can use Selenium's Android Driver or Remote Control modes.

Signing and Distribution

Unlike native Android applications, you do not need to worry about signing your HTML5 applications.

The downside of this is that there is no support for distribution of HTML5 applications through the Play Store, which today only supports native Android apps. Users will have to find your application by one means or another, visit it in the browser, bookmark the page, and possibly create a home screen shortcut to that bookmark.

Updates

Unlike native Android applications, which by default must be updated manually, HTML5 applications will be transparently updated the next time they run the app while connected to the Internet. The offline caching protocol will check the Web server for new editions of files before falling back to the cached copies. Hence, there is nothing more for you to do other than publish the latest Web app assets.

Issues You May Encounter

Unfortunately, nothing is perfect. While HTML5 may make many things easier, it is not a panacea for all Android development problems.

This section covers some potential areas of concern you will want to consider as you move forward with HTML5 applications for Android.

Android Device Versions

Not all Android devices support HTML5 — only those running Android 2.x or higher. Ideally, therefore, you do a bit of "user-agent sniffing" on your Web server and redirect older Android users to some other page explaining the limitations in their device.

Here is the user-agent string for a Nexus One device running Android 2.1:

```
Mozilla/5.0 (Linux; U; Android 2.1-update1; en-us; Nexus One
Build/ERE27) AppleWebKit/530.17 (KHTML, like Gecko) Version/4.0 Mobile
Safari/530.17
```

As you can see, it is formatted like a typical modern user-agent string, meaning it is quite a mess. It does indicate it is running `Android 2.1-update1`.

Eventually, somebody will create a database of user-agent strings for different device models, and from there we can derive appropriate regular expressions or similar algorithms to determine whether a given device can support HTML5 applications.

Screen Sizes and Densities

HTML5 applications can be run on a wide range of screen sizes, from QVGA Android devices to 1080p LCDs and beyond. Similarly, screen densities may vary quite a bit, so while a 48x48 pixel image on a smartphone may be an appropriate size, it may be too big for a 1080p television, let alone a 24" LCD desktop monitor.

Other than increasing the possible options on the low end of screen sizes, none of this is unique to Android. You will need to determine how best to design your HTML and CSS to work on a range of sizes and densities, even if Android were not part of the picture.

Limited Platform Integration

HTML5, while offering more platform integration than ever before, does not come close to covering everything an Android application might want to be able to do. For example, an ordinary HTML5 application cannot:

1. Launch another application
2. Work with the contacts database
3. Raise a notification
4. Do work truly in the background (though "Web workers" may alleviate this somewhat someday)
5. Interact with Bluetooth devices
6. Record audio or video
7. Use the standard Android preference system
8. Use speech recognition or text-to-speech
9. And so on

Many applications will not need these capabilities, of course. And, one can expect that other application environments, like PhoneGap, will evolve into "HTML5 Plus" for Android. That way, you could create a stock application that works across all devices and an enhanced Android application that leverages greater platform integration, at the cost of some additional amount of programming.

Performance and Battery

There has been a nagging concern for some time that HTML-based user interfaces are inefficient compared to native Android UIs, in terms of processor time, memory, and battery. For example, one of the stated reasons for avoiding BONDI-style Web widgets for the Android home screen is performance.

Certainly, it is possible to design HTML5 applications that will suck down the battery. For example, if you have a hunk of JavaScript code running every second indefinitely, that is going to consume a fair amount of processor time. However, outside of that, it seems unlikely that an ordinary application would be used so heavily as to materially impact battery life. Certainly, more testing will need to be done in this area.

Also, an HTML5 application may be a bit slower to start up than are other applications, if the Browser has not been used in a while, or if the network connection is there but has minimal bandwidth to your server.

Look and Feel

HTML5 applications can certainly look very slick and professional – after all, they are built with Web technologies, and Web apps can look very slick and professional.

However, HTML5 applications will not necessarily look like standard Android applications, at least not initially. Some enterprising developers will, no doubt, create some reusable CSS, JavaScript, and images that will, for example, mirror an Android native `Spinner` widget (a type of drop-down control). Similarly, HTML5 applications will tend to lack options menus, notifications, or other UI features that a native Android application may well use.

This is not necessarily bad. Considering the difficulty in creating a very slick-looking Android application, HTML5 applications may tend to look better than their Android counterparts. After all, there are many more people skilled in creating slick Web apps than are skilled in creating slick Android apps.

However, some users may complain about the look-and-feel disparity, just because it is different.

Distribution

HTML5 applications can be trivially added to a user's device — browse, bookmark, and add a shortcut to the home screen.

However, HTML5 applications will not show up in the Play Store, so users trained to look at the Market for available applications will not find HTML5 applications, even ones that may be better than their native counterparts.

It is conceivable that, someday, the Play Store will support HTML5 applications. It is also conceivable that, someday, Android users will tend to find their apps by means other than searching the Android Market, and will be able to get their HTML5 apps that way. However, until one of those becomes true, HTML5 applications may be less “discoverable” than their native equivalents.

HTML5: The Baseline

HTML5 is likely to become rather popular for conventional application development. It gives Web developers a route to the desktop. It may be the only option for Google’s Chrome OS. And, with ever-improving support on popular mobile devices — Android among them — developers will certainly be enticed by another round of “write once, run anywhere” promises.

It is fairly likely that, over time, HTML5 will be the #2 option for Android application development, after the conventional Java application written to the Android SDK. That will make HTML5 the baseline for comparing alternative Android development options — not only will those options be compared to using the SDK, they will be compared to using HTML5.

PhoneGap

PhoneGap is perhaps the original alternative application framework for Android, arriving on the scene in early 2009. PhoneGap is open source, backed by Adobe, who in 2011 acquired Nitobi, the firm founded by PhoneGap's creators.

Prerequisites

Understanding this chapter requires that you have read the chapter on `WebView` and the chapter on HTML5.

What Is PhoneGap?

As the PhoneGap About page puts it:

> Mobile development is a mess. Building applications for each device — iOS, Android, Windows Phone and more — requires different frameworks and languages. One day, the big players in mobile may decide to work together and unify third-party app development processes. Until then, PhoneGap will use standards-based web technologies to bridge web applications and mobile devices. Plus, because PhoneGap apps are standards compliant, they're future-proofed to work with browsers as they evolve.

PhoneGap, today, focuses on bridging the gap between Web technologies and native mobile development, with access to more features than HTML5 applications have.

What Do You Write In?

A PhoneGap application is made up of HTML, CSS, and JavaScript, no different than a mobile Web site or HTML5 application, except that the Web assets are packaged with the application, rather than downloaded on the fly.

A pre-installed PhoneGap application, therefore, can contain comparatively large assets, such as complex JavaScript libraries, that might be too slow to download over slower EDGE connections. However, PhoneGap will still be limited by the speed of mobile devices and how quickly WebKit can load and process those assets.

Also, development for WebKit-for-mobile has its differences over development for WebKit-for-desktops, particularly with respect to touch versus mouse events. Most actively-developed Web development frameworks either have built-in mobile support or have a related mobile-centric framework.

What Features Do You Get?

As with an HTML5 application, you get the basic capabilities of a Web browser, including AJAX support. Beyond that, PhoneGap adds a number of JavaScript APIs to allow you to get at the underlying features of the Android platform. At the time of this writing, that includes:

1. Accelerometer access, for detecting movement of the device
2. Audio recording
3. Camera access, for taking still pictures
4. Database access, both to databases of your creation (SQLite) or others built into Android (e.g., contacts)
5. File system access, such as to the SD card or other external storage
6. Geolocation, for determining where the device is
7. Vibration, for shaking the phone (e.g., force-feedback)

Since some of these are part of the HTML5 specification (e.g., geolocation), you have your choice of APIs. Also, this list changes over time, so you may have access to more than what is described here.

What Do Apps Look Like?

They will look like Web pages, more so than native Android apps. You can use CSS and images to mimic the Android look and feel to some extent, but only for those sorts of widgets that are readily able to be created in both Android and HTML. For example, the Android `Spinner` widget — which resembles a drop-down list — may be difficult to mimic in HTML.

Here is a screenshot of a PhoneGap example application:

How Does Distribution Work?

Distributing a PhoneGap application is pretty much identical to distributing any other standard Android application. After testing, you will create a standard APK file with the Android build tools, from an Android project generated for you by PhoneGap. This project will contain the Java, XML, and other necessary bits to wrap around your HTML, CSS, and JavaScript to make up your application. Then, you digitally sign the application and upload it to the Play Store or any other distribution mechanism you wish to use.

What About Other Platforms?

PhoneGap is not just for Android. You can create PhoneGap applications for iOS, Blackberry, some flavors of Symbian, and more. In theory, at least, you can create one application using HTML, CSS, JavaScript, and the PhoneGap JavaScript APIs, and have it run across many devices.

There are a couple of limitations that will hamper your progress to that goal:

- The Web browsing component used by PhoneGap across all those platforms is not identical. Even multiple platforms using WebKit will have different WebKit releases, based upon what was available when WebKit was integrated into a given device's firmware. Hence, you will want to test and ensure your CSS, in particular, works as you would expect on as many devices as possible.
- Not all PhoneGap JavaScript APIs are available on all devices as yet, due to a variety of factors (e.g., not exposed in the platform's native APIs, lack of engineering time to hoist the capability into the PhoneGap APIs). There is a table on the PhoneGap site that will keep you apprised of what works and what does not across the devices. You will want to restrict your feature use to match your desired platforms, or restrict your platforms to match your desired features.

How Is It Licensed?

PhoneGap is available under the Apache Software License 2.0. In 2011, Nitobi contributed PhoneGap to the Apache Software Foundation (ASF) for independent management, just prior to being acquired by Adobe. This has now turned into Apache Cordova.

Using PhoneGap

Now, let's look at more of the mechanics for using PhoneGap.

PhoneGap's installation and usage, as of the time of this writing, normally requires an expert in Java-based Android development. You need to install a whole bunch of tools, edit configuration files by hand, and so forth. If you want to do all of that, documentation is available on the PhoneGap site.

If you are reading this chapter, there's a decent chance that you would rather skip all of that. Hence, for many, the best answer is the PhoneGap/Build service.

Installation

The PhoneGap Web site will allow you to download the latest PhoneGap tools as a ZIP archive. You can unpack those wherever it makes sense for your development machine and platform.

For Android development, that is all of the PhoneGap-specific installation you will need. However, you will need the Android SDK and related tools (e.g., Eclipse, if you wish to use Eclipse) for setting up the project.

Creating and Installing Your Project

A PhoneGap Android project is, at its core, a regular Android project, which you can create following the instructions outlined earlier in this book. To convert the standard generated "Hello, World" application into a PhoneGap project, you need to do the following:

- From the `Android/` directory of wherever you unZIPped the PhoneGap ZIP file, copy the PhoneGap JAR file to the `libs/` directory of your project. If you are using Eclipse, you will also need to add it to your build path.
- Create an `assets/www/` directory in your project. Then, copy over the PhoneGap JS file from the `Android/` directory of wherever you unZIPped the PhoneGap ZIP file.
- Adjust the standard "Hello, World" activity to inherit from `DroidGap` instead of `Activity`. This will require you to import `com.phonegap.DroidGap`.
- In your activity's `onCreate()` method, replace `setContentView()` with `super.loadUrl("file:///android_asset/www/index.html");`
- In your manifest, add all of the permissions that PhoneGap requests, listed later in this chapter.
- Also in your manifest, add a suitable `<supports-screens>` element based upon what screen sizes you are willing to test and support.
- Also in your manifest, add `android:configChanges="orientation|keyboardHidden"` to your `<activity>` element, as `DroidGap` handles orientation-related configuration changes

At this point, you can create an `assets/www/index.html` file in your project and start creating your PhoneGap application using HTML, CSS, and JavaScript. You will need to have a reference to the PhoneGap JavaScript file (e.g., `<script type="text/javascript" charset="utf-8"`

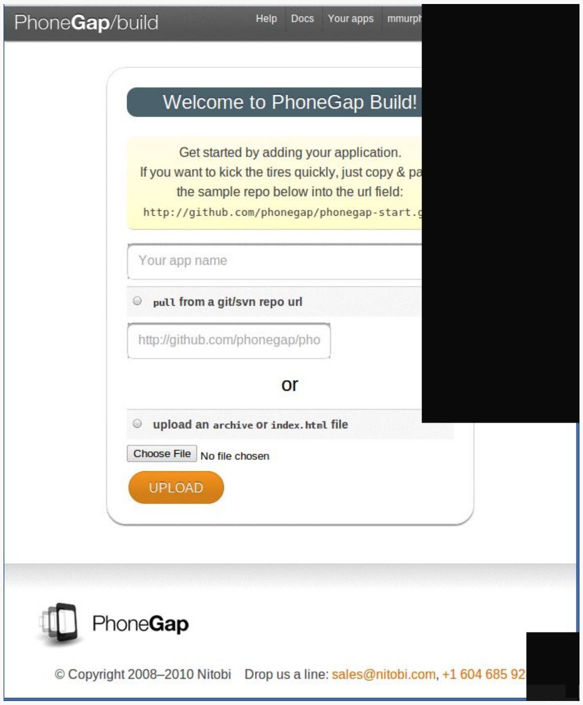
`src="phonegap.0.9.4.js" />`). When you want to test the application, you can build and install it like any other Android application (e.g., `ant clean debug install` if you are using the command line build process).

For somebody experienced in Android SDK development, setting this up is not a big challenge.

PhoneGap/Build

PhoneGap/Build is a Tools-as-a-Service (TaaS) hosted approach to creating PhoneGap projects. This way, all of the Android build process is handled for you by PhoneGap-supplied servers. You just focus on creating your HTML, CSS, and JavaScript as you see fit.

When you log into PhoneGap/Build, you are first prompted to create your initial project, by supplying a name and the Web assets to go into the app:



[redacted]

Welcome to PhoneGap Build!

Get started by adding your application.
If you want to kick the tires quickly, just copy & pa
the sample repo below into the url field:
http://github.com/phonegap/phonegap-start.g

Your app name

○ pull from a git/svn repo url

http://github.com/phonegap/pho

or

○ upload an archive or index.html file

Choose File No file chosen

UPLOAD

[redacted]

Figure 908: Creating your first project in PhoneGap/Build

You will be able to add new projects later on via a New App button, which gives you the same set of options.

Your choices for the assets are to upload a ZIP file containing all of them, or to specify the URL to a public GitHub repository that PhoneGap/Build can pull from. The latter tends to be more convenient, if you are used to using Git for version control, and if your project is open source (and therefore has a public repository).

Once you click the Upload button, the PhoneGap/Build server will immediately start building your application for Android, plus Blackberry, Symbian, and WebOS:

	ANDROID	WEBOS	SYMBIAN	BLACKBERRY

Figure 911: Your project's settings in PhoneGap/Build

All in all, if you do not otherwise need the Android SDK and related tools on your development machine, PhoneGap/Build certainly simplifies the PhoneGap building process.

PhoneGap/Build is free for open source (public) projects, but there are fees associated with private use beyond a single app.

PhoneGap and the Checklist Sample

The beauty of PhoneGap is that it wraps around HTML, CSS, and JavaScript. In other words, you do not have to do much of anything PhoneGap-specific to be able to take advantage of PhoneGap delivering to you an APK suitable for installation on an Android device. That being said, PhoneGap does expose more stuff to you than you can get from the standards, if you need them and are willing to use proprietary PhoneGap APIs for them.

Sticking to the Standards

Given an existing HTML5 application, all you need to do to make it be an installable APK is wrap it in PhoneGap.

For example, to convert the HTML5 version of Checklist into an APK file, you need to:

- Follow the steps to create an empty PhoneGap project outlined earlier in this chapter
- Copy the HTML, CSS, JavaScript, and images from the HTML5 project into the `assets/www/` directory of the PhoneGap project (note that you do not need things unique to HTML5, such as the cache manifest)
- Make sure that your HTML entry point filename matches the path you used with the `loadUrl()` call in your activity (e.g., `index.html`)
- Add a reference to the PhoneGap JavaScript file from your HTML
- Build and install the project

Here is the `DroidGap` activity for our app, from the `PhoneGap/Checklist` project:

```
package com.commonsware.pg.checklist;

import android.app.Activity;
import android.os.Bundle;
import com.phonegap.DroidGap;

public class Checklist extends DroidGap {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    super.loadUrl("file:///android_asset/www/index.html");
  }
}
```

Here is the manifest, with all of the PhoneGap-requested settings added:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
          android:versionName="1.0"
          package="com.commonsware.pg.checklist"
          xmlns:android="http://schemas.android.com/apk/res/android">

  <application android:icon="@drawable/cw"
               android:label="@string/app_name">
    <activity android:configChanges="orientation|keyboardHidden"
              android:label="@string/app_name"
              android:name="Checklist">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />
        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
  <supports-screens android:anyDensity="true"
                    android:largeScreens="true"
                    android:normalScreens="true"
                    android:resizeable="true"
                    android:smallScreens="true" />
  <uses-permission android:name="android.permission.CAMERA" />
  <uses-permission android:name="android.permission.VIBRATE" />
  <uses-permission android:name="android.permission.ACCESS_COARSE_LOCATION" />
  <uses-permission android:name="android.permission.ACCESS_FINE_LOCATION" />
  <uses-permission android:name="android.permission.ACCESS_LOCATION_EXTRA_COMMANDS" />
  <uses-permission android:name="android.permission.READ_PHONE_STATE" />
  <uses-permission android:name="android.permission.INTERNET" />
  <uses-permission android:name="android.permission.RECEIVE_SMS" />
  <uses-permission android:name="android.permission.RECORD_AUDIO" />
  <uses-permission android:name="android.permission.MODIFY_AUDIO_SETTINGS" />
  <uses-permission android:name="android.permission.READ_CONTACTS" />
  <uses-permission android:name="android.permission.WRITE_CONTACTS" />
  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
  <uses-permission android:name="android.permission.ACCESS_NETWORK_STATE" />
</manifest>
```

And here is the HTML — almost identical to the HTML5 original, removing some HTML5 offline stuff (e.g., iOS icons) and adding in the reference to PhoneGap's JavaScript file:

```
<!DOCTYPE html>
<html lang="en" manifest="checklist.manifest">
<head>
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
    <title>Checklist</title>
    <meta name="viewport"
      content="width=device-width; initial-scale=1.0; maximum-scale=1.0;
user-scalable=0;" />
    <link rel="stylesheet" href="styles.css" />
    <script type="text/javascript" charset="utf-8" src="phonegap.0.9.4.js"></script>
</head>
<body>
    <section>
        <header>
          <button type="button" id="sendmail">Mail</button>
          <h1>Checklist</h1>
        </header>
        <article>
          <form id="inputarea" onsubmit="addNewItem()">
              <input type="text" name="name" id="name" maxlength="75"
                     autocorrect placeholder="Tap to enter a new item&hellip;" />
              <button type="button" id="add">Add</button>
            </form>
            <ul id="maillist">
            <li class="empty"><a href="" id="maillink">Mail remaining items</a></li>
          </ul>
            <p id="totals"><span id="tally1">Total: <span id="total">0</span></span>
            <span id="tally2">Remaining: <span id="remaining">0</span></span></p>
          <ul id="checklist">
            <li class="empty">Loading&hellip;</li>
          </ul>
        </article>
        <fieldset>
          <button type="button" id="deletechecked">Delete Checked</button>
          <button type="button" id="deleteall">Delete All</button>
        </fieldset>
    </section>
    <script src="main.js"></script>
</body>
</html>
```

For many applications, this is all you will need — you are simply looking at PhoneGap to give you something you can distribute on the Play Store, on the iOS App Store, and so on.

Adding PhoneGap APIs

If you want to take advantage of more device capabilities, you can augment your HTML5 application to use PhoneGap-specific APIs. These run the gamut from telling you the device's model to letting you get compass readings. Hence, their complexity will vary. For the purposes of this chapter, we will look at some of the simpler ones.

Set up Device-Ready Event Handler

For various reasons, PhoneGap will not be ready to respond to all of its APIs right away when your page is loaded. Instead, there is a `deviceready` event that you will need to watch for in order to know when it is safe to use PhoneGap-specific JavaScript globals. The typical recipe is:

- Add an `onload` attribute to your `<body>` tag, referencing a global JavaScript function (e.g., `onLoad()`)
- In `onLoad()`, use `addEventListener()` to register another global JavaScript function (e.g., `onDeviceReady()`) for the `deviceready` event
- In `onDeviceReady()`, start using the PhoneGap APIs

Use What PhoneGap Gives You

PhoneGap makes a number of methods available to you through a series of virtual JavaScript objects. Here, "virtual" means that you cannot check to see if the objects exist, but you can call methods and read properties on them. So, for example, there is a `device` object that has a handful of useful properties, such as `phonegap` to return the PhoneGap version and version to return the OS version. These virtual objects are ready for use in or after the deviceready event.

For example, here is a JavaScript file (props.js from the PhoneGap/ChecklistEx project) that implements an onLoad() function (to register for deviceready) and an onDeviceReady() function (to use the device object's properties):

```
// PhoneGap's APIs are not immediately ready, so set up an
// event handler to find out when they are ready

function onLoad() {
  document.addEventListener("deviceready", onDeviceReady, false);
}

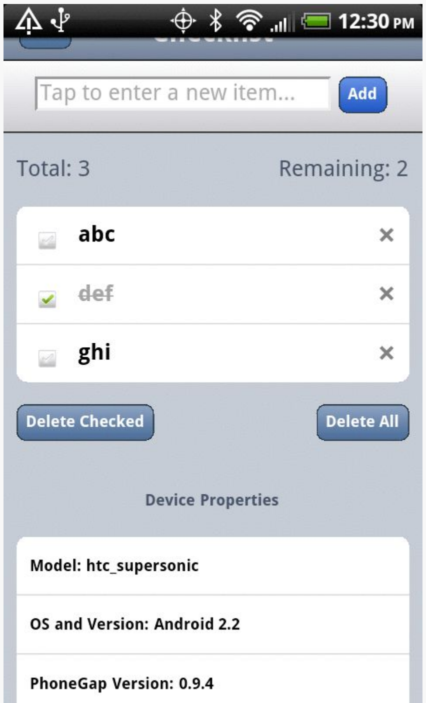
// Now PhoneGap's APIs are ready

function onDeviceReady() {
  var element=document.getElementById('props');

  element.innerHTML='<li>Model: '+device.name+'</li>' +
                    '<li>OS and Version: '+device.platform +' '+device.version+'</li>' +
                    '<li>PhoneGap Version: '+device.phonegap+'</li>';
}
```

The onDeviceReady() function needs a list element with an id of props.

The resulting app looks like:



Total: 3 Remaining: 2

□ abc

☑ ~~def~~

□ ghi

Device Properties

Model: htc_supersonic

OS and Version: Android 2.2

PhoneGap Version: 0.9.4

Figure 912: The PhoneGap Checklist application with device properties

Obviously, reading a handful of properties is far simpler than, say, taking a picture with the device's camera. However, the difference in complexity is mostly in what PhoneGap's virtual JavaScript objects give you and how you can use them, more so than anything peculiar to Android.

Issues You May Encounter

PhoneGap is a fine choice for creating cross-platform applications. However, it is not without its issues. Some of these issues may be resolved in time; some may be endemic to the nature of PhoneGap.

Security

Android applications use a permission system to request access to certain system features, such as making Internet requests or reading the user's contacts. Applications must request these permissions at install time, so the user can elect to abandon the installation if the requested permissions seem suspect.

A general rule of thumb is that you should request as few permissions as possible, and make sure that you can justify why you are requesting the remaining permissions.

PhoneGap, for a new project, requests quite a few permissions:

1. `CAMERA`
2. `VIBRATE`
3. `ACCESS_COARSE_LOCATION`
4. `ACCESS_FINE_LOCATION`
5. `ACCESS_LOCATION_EXTRA_COMMANDS`
6. `READ_PHONE_STATE`
7. `INTERNET`
8. `RECEIVE_SMS`
9. `RECORD_AUDIO`
10. `MODIFY_AUDIO_SETTINGS`
11. `READ_CONTACTS`
12. `WRITE_CONTACTS`
13. `WRITE_EXTERNAL_STORAGE`
14. `ACCESS_NETWORK_STATE`

Leaving this roster intact will give you an application that can use every API PhoneGap makes available to your JavaScript… and an application that will scare away many users. After all, it is unlikely that your application will be able to use, let alone justify, all of these permissions.

It is certainly possible for you to trim down this list, by modifying the `AndroidManifest.xml` file in the root of your PhoneGap project. However, you will then need to thoroughly test your application to make sure you did not get rid of a permission that you actually need. Also, it may be unclear to you which permissions you can safely remove.

Eventually, the PhoneGap project may have tools to help guide you in the choice of permissions, perhaps by statically analyzing your JavaScript code to see which PhoneGap APIs you are using. In the meantime, though, getting the proper set of permissions will involve a lot of trial and error.

Screen Sizes and Densities

Normal Web applications primarily focus on screen resolution and window sizes as their primary variables. However, mobile Web applications will not have to worry about window sizes, as browsers and apps typically run full-screen. Mobile Web applications will need to deal with physical size and density, though — issues that are “off the radar” for traditional Web development.

Netbooks can have screens that are 10” or smaller. Desktops can have screens that are 24” or larger. On the surface, therefore, physical screen size would seem to be something Web developers would need to address. However, generally, screen resolution (in pixels) tracks well with physical size in the netbook/notebook/desktop realm. That is because screen density is fairly consistent across their LCDs, and that density is fairly low.

Smartphones, on the other hand, have several different densities, causing the connection between resolution and size to be broken. Some low-end phones, particularly with small (e.g., 3”) LCDs, have densities on par with nice monitors. Mid-range phones have twice the density (240dpi versus 120dpi). Apple’s iPhone 4 has even higher density, and there are some Android devices with similar densities. Hence, an 800x480 resolution could be on a screen ranging anywhere from 4” to 7”, for example. Tablets add even more possible sizes to the mix.

This is compounded by the problems caused by touchscreens. A mouse can get pixel-level precision in its clicks. Fingers are much less precise. Hence, you tend to need to make your buttons and such that much bigger on a touchscreen, so it can be “finger-friendly”.

This causes some problems with scaling of assets, particularly images. What might be “finger-friendly” on a low-density 3” device might be entirely too small for a high-density 4” device.

Native Android applications have built-in logic for dealing with this issue, in the form of multiple sets of “resources” (e.g., images) that can be swapped in based upon device characteristics. Eventually, PhoneGap and similar tools will need to provide relevant advice for their users for how to create applications that can similarly adapt to circumstances.

Look and Feel

A Web app never quite looks like a native one. This is not necessarily a bad thing. However, some users may find it disconcerting, particularly since they will not understand why their newly-installed app (made with PhoneGap, for example) would necessarily look substantially different than any other similar app they may already have.

As HTML5 applications become more prominent on Android, this issue should decline in importance. However, it is something to keep in mind for the next year or two.

For More Information

At the moment, the best information on PhoneGap can be found on the PhoneGap site, including their API documentation.

Other Alternative Environments

The alternative application environments described in the preceding chapters are but the tip of the iceberg. Here, we will take a look at a few other alternative application environments, from the growing flood of such technologies.

Note that this area changes rapidly, and so the material in this chapter may be somewhat out of date relative to the progress each of these technologies has made.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading the introduction to this trail might not be a bad idea.

Rhodes

Spiritually, Rhodes is similar to PhoneGap, in that you develop an Android application whose user interface is defined via HTML, CSS, and JavaScript. The difference is that Rhodes bakes in a full Ruby environment, with a Rails-esque framework. Your Ruby code generates HTML and such to be "served" to an activity via a `WebView` widget, much like a server-side Ruby Web app would generate HTML to be served to a standalone Web browser.

Similar to PhoneGap, you can either build the project on your development machine or use their hosted build process. The latter is recommended, partly because the requirements for local builds are higher than those for PhoneGap — notably, Rhodes requires the Native Development Kit (NDK) for building and linking the Ruby interpreter to your application.

Rhodes winds up creating larger applications than does PhoneGap, due to the overhead of the Ruby interpreter (~1.5MB). However, if you are used to server-side Web development, Rhodes may be easier for you to pick up than would PhoneGap.

Flash, Flex, and AIR

Adobe has been hard at work extending their Flash, Flex, and AIR technologies to the mobile space. You can use Flex (the "Hero" edition) and Flash Builder (the "Burrito" edition… raising the question of whether the "hero" is hungry) to create Android APK files that can be distributed on the Play Store and deployed to Android devices. Those devices will need to have the AIR runtime installed — this is free, but a large download, and it only works on Android 2.2+ devices. The same projects can be repackaged for iOS and Blackberry OS 10 devices, and possibly future devices down the road.

AIR does not have quite as tight of integration to the platform as does PhoneGap (e.g., no access to the device's contacts), though one imagines that this is an area on which Adobe will devote more resources over time. And, Adobe is a large firm, with a large ecosystem behind it and many existing Flash, Flex, and AIR developer resources to tap into.

Note, though, that Adobe is officially discontinuing the Flash plug-in for Android after the Android 4.0 (Ice Cream Sandwich) release, which casts some doubt as to their long-term plans in the Flash/AIR space on mobile.

JRuby and Ruboto

One of the most popular languages designed to run on the JVM — besides Java itself — is JRuby. JRuby was quickly ported to run on Android, but with some optimizations disabled, since JRuby is really running on the Dalvik virtual machine that underlies the Android environment, not a classic Java VM.

However, JRuby alone cannot create Android applications. As a scripting language, there is no way for it to define an activity or other component — those need to be registered in the application's manifest as regular Java class files.

This is where Ruboto comes in.

Ruboto is a framework for a generic JRuby/Android application. It provides skeletal activities via a code generator and allows JRuby scripts to define handlers for all of the lifecycle methods (e.g., `onCreate()`), plus define user interfaces using JRuby code, etc. The result can be packaged up as an APK file using supplied Rake script. The results can be uploaded to the Play Store or distributed however else you desire.

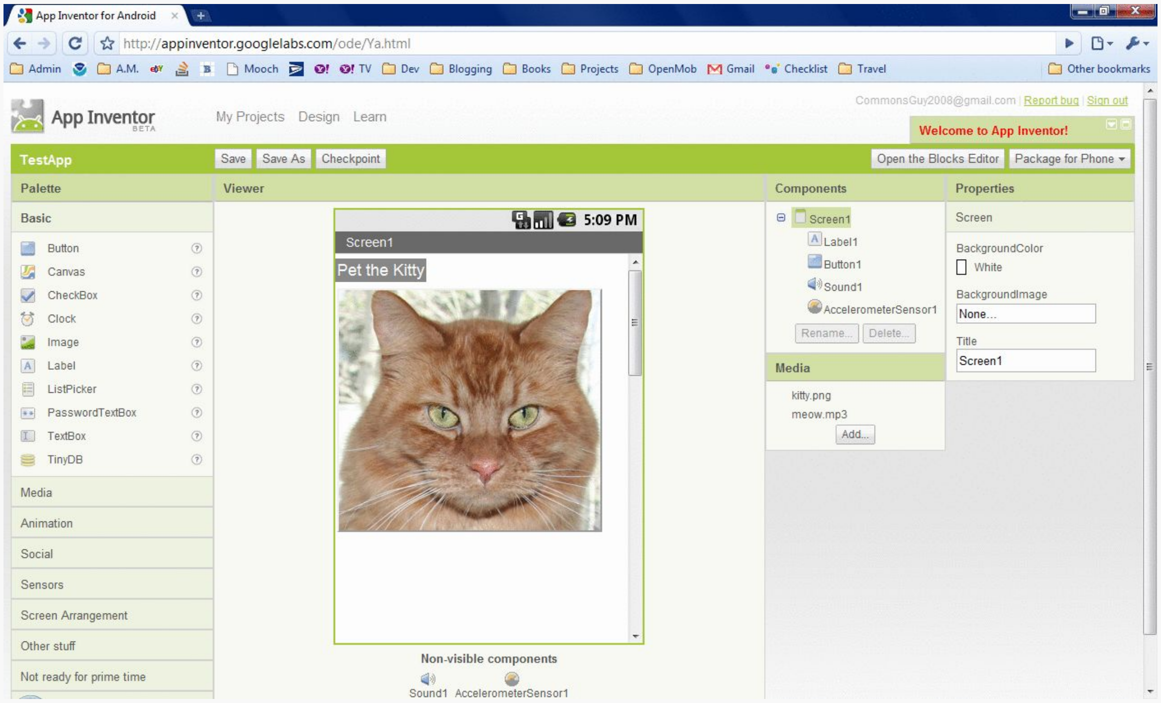
App Inventor

App Inventor is an Android application development tool originally made available by Google, but outside of the normal Android developer site. App Inventor was originally developed for use in education, but they have been inviting others into their closed beta.

App Inventor is theoretically a Web-based development tool. Here, "theoretically" means that, in practice, users have to do a fair amount of work outside of the browser to get everything set up:

1. Have Java installed and functioning in the browser, capable of running Java Web Start (.jnlp) applications
2. Download and install a large (~55MB) client-side set of tools
3. Have a phone and have it configured to work with App Inventor and the Android SDK

Once set up, App Inventor gives you a drag-and-drop GUI editor:



BackgroundColor
□ White
BackgroundImage
None...
Title
Screen1

Figure 913: The App Inventor "Designer" view

… and a "blocks" editor, where you attach behaviors to events (e.g., button clicks) by snapping together various "blocks" representing events, methods, and properties:

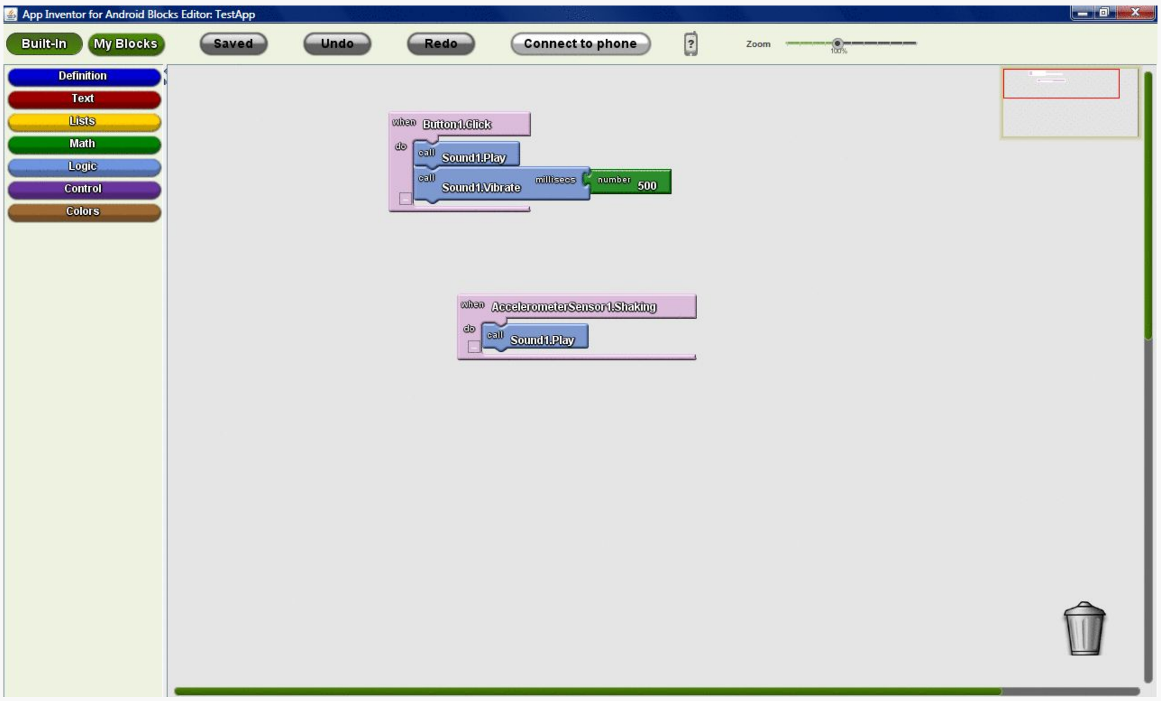


Figure 914: The App Inventor "Blocks" view

While working in the GUI editor, you see what you are building live on an attached phone and can be tested in real time. Later, when you are ready, you can package the application into a standard APK file.

However, App Inventor is not really set up for production application use today:

1. You cannot distribute App Inventor apps on the Play Store
2. It has more components aimed at "sizzle" (e.g., Twitter integration) and fewer delivering capabilities that a typical modern app might need (e.g., relational databases, lists)
3. Only one developer at a time can work on a project

In 2011, Google discontinued direct support for App Inventor, electing to transfer the project to MIT's Media Lab for ongoing development.

Titanium Mobile

Titanium Mobile's claim to fame is using JavaScript to completely define the user interface, eschewing HTML entirely. Rather, their JavaScript library — in addition to providing access to databases and platform capabilities — also lets you declare user interface widgets. Its layout capabilities, for positioning said widgets, leaves a bit to be desired.

As of the time of this writing, Appcelerator — the creators of Titanium Mobile — does not offer a cloud-based set of tools. Their Titanium tool has a very slick-looking UI, but it still requires the Java SDK and Android SDK in order to be able to build Android applications, making the setup a bit daunting for some.

As of the time of this writing, Titanium Mobile supports development for Android and iOS, with Blackberry support in a private beta.

Other JVM Compiled Languages

If your issue is less with regular Android development, but you just do not like Java, any language that can generate compatible JVM bytecode should work with Android. You would have to modify the build chain for that other language to do the rest of the Android build process (e.g., generate `R.java` from the resources, create the APK file in the end).

Scala and Clojure are two such languages, for which their respective communities have put together instructions for using their languages for Android development.

Crash Reporting Using ACRA

When you wrote your app, you intended for it to work.

Alas, the road to a very warm place is paved with good intentions.

Hence, it is fairly likely that your app will crash in the hands of your users. In order to be able to fix the underlying problems, you need to learn about the crashes and the state of the app at the time of the crash.

There are any number of solutions to this problem. This chapter will outline a few of them and focus on one open source solution: Application Crash Reports for Android, better known as ACRA.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Having read the chapter on notifications is also a good idea, though not absolutely essential.

What Happens When Things Go “Boom”?

In development, when your app crashes, you get a little dialog box indicating that the app crashed, and you get your Java stack trace in LogCat.

In production, little of that does you any good. In particular, you have no way of seeing LogCat from end user devices. Instead, you need to have some means of capturing that stack trace, along with perhaps additional data, and collect it somewhere.

App distribution channels may offer this as part of their feature set. The Play Store, in particular, offers its own crash reporting, where crashes "in the field" get reported to you by means of your Developer Console on the Web. However:

- You might not be distributing through the Play Store at all, let alone exclusively, and so the Play Store reporting does not help you for all your users
- The Play Store's approach makes reporting the crash optional, as the user can elect to not send a report, meaning that you don't find out about every crash
- You have no control over what data is and is not collected, both for ensuring that you have enough information to have a shot at fixing the bug and for minimizing extraneous data that might have privacy implications
- Google gets a copy of the crash data, which you may or may not find to be appropriate

Various other services, from Crashlytics to Crittercism, offer their own crash reporting as part of a larger suite of features. However, once again, you may not have control over what data is collected, and you certainly have no control over who all gets the data.

For the privacy-minded app developer, you want something along these lines, but where you can control to a fine degree of detail what gets collected and where the data is sent solely to you, not to some third party.

And that's where ACRA comes in.

Introducing ACRA

ACRA has been around since 2010, originally on Google Code, and now on GitHub. It comes in the form of a library that you add to your app, with code that will get control when an unhandled exception occurs inside your app. There, ACRA *carefully* will collect information about the crash (e.g., the stack trace) and the environment (e.g., what version of Android the app was running on). ACRA can then deliver that information to you by any number of means, plus optionally provide feedback to the user about the crash itself.

Since you control what ACRA collects and you control where ACRA sends the data, you can minimize how much information gets into the hands of third parties. The cost is in convenience, as either you have to:

- Fuss with managing your own server for receiving the crashes, or
- Use a third-party service for that server, reducing some of the privacy, or
- Use options that are clunky for everyone involved, such as the user sending emails containing crash reports

Where ACRA Reports Crashes

In the beginning, ACRA logged crashes to a Google Docs spreadsheet. Eventually, Google grumbled about this, and so that option is now deprecated.

That limitation notwithstanding, ACRA supports a range of possible ways for crash reports to get from the user's device to your eyes, so that you can try to fix whatever problems ail your app.

An Existing Crash Logging Service

Some crash logging services allow you to use ACRA in your code, rather than rely upon some proprietary library. You simply configure ACRA to send the data to their servers, which then notify you about crashes and give you dashboards and such to visualize how much your app is crashing.

[HockeyApp]*(http://support.hockeyapp.net/kb/client-integration-android/how-to-use-acra-with-hockeyapp) and Splunk Mint are two such services.

The advantage here is convenience coupled with control over the client side. However, you are still sharing crash details with third parties, potentially raising privacy or security issues.

Acralyzer

The official ACRA reporting server is Acralyzer. This, along with its `acra-storage` companion, are CouchApps, powered by Apache CouchDB. You upload the Acralyzer and `acra-storage` CouchApps into your own CouchDB instance, then configure ACRA in your app to talk to those apps.

Acralyzer and `acra-storage` are open source, as is CouchDB. You can either host a CouchDB instance on your own server or use various CouchDB hosting providers.

This solution offers the best blend of analysis features and user privacy and security. However, it does require you to learn enough about CouchDB to be able to set up and maintain an instance.

Email

The easiest solution to set up is the most awkward for everything else: have the user send you an email. In this model, ACRA prepares a report, then uses `ACTION_SENDTO` to lead the user to an email app to send the report to an email address that you configure in your app. The user can then just send the prepared email from their email client (e.g., Gmail), and the report shows up in the inbox for this email address.

You do not need to set up some sort of server, let alone maintain it. Your app does not even need the `INTERNET` permission.

However:

- The user might not send the email, choosing instead to abandon the mail client
- The user might not use their device for email, and therefore have no good means of getting you the report
- While you get the raw crash data, you do not get any of the nifty charts and such that you can get from a full-fledged crash reporting server

A Host for Testing

The protocol used by ACRA to communicate with a Web server is blissfully simple. Handling ACRA crash reports yourself does not require that much server-side code, in case you wanted to integrate this capability into the rest of your REST-style Web services.

For example, this trivial Ruby script implements an ACRA-compatible endpoint:

```
require 'fileutils'
require 'sinatra'
require 'json'

LOG_ROOT='/tmp/ACRAfier'

put '/reports/:id' do
  acra=JSON.parse(request.body.read)
  FileUtils.mkdir_p(LOG_ROOT) if !File.exist?(LOG_ROOT)
  f=File.join(LOG_ROOT, params[:id]+'.json')
  File.open(f, 'w') {|io| io.write(JSON.pretty_generate(acra))}
end
```

As we will see later in this chapter, you can configure ACRA to use a simple HTTP PUT request to submit a crash report to the server. This Ruby script implements a small REST-style Web service using Sinatra, where crash reports are pushed to a /reports/.../ URL, where ... is an ACRA-generated unique ID for the report. This script just logs the JSON that we get from ACRA to a file in a designated directory. With a few more lines of code, you could have it generate a human-readable report and email it to you, along with the JSON as an email attachment. Or, you could do whatever you want.

This Ruby script can be found as stub_server.rb in the book's GitHub repo If you have Ruby installed, just install the sinatra and json gems, then run ruby stub_server.rb to fire up the server.

In practice, you would need a bit more smarts on a publicly-visible Web service, to help prevent people from maliciously flooding your crash reporting server with bogus data. However, the minimal requirements for ACRA are very straightforward and could be implemented in any reasonable server-side Web framework.

ACRA Integration Basics

Given that you have identified how you want to receive the crash reports, the next step is to add ACRA to your project and configure it to send crash reports to your chosen location.

The ACRA/Simple sample project demonstrates a fairly simple ACRA integration.

Adding the Dependency

ACRA is distributed through standard Maven-style artifact repositories and should be automatically picked up when you add the appropriate compile directive to your dependencies:

```
dependencies {
    compile 'ch.acra:acra:4.6.2'
}
```

Note that this project is using ACRA 4.6.2, due to an outstanding issue with ACRA 4.7.0.

Build Types, Product Flavors, and ACRA

It is very likely that you will want to have different ACRA configurations based upon build types and/or product flavors:

- Have the `debug` build not use ACRA, but have the `jenkins` build by your CI server use ACRA to collect crashes and integrate them into the test results, and have the `release` build use your production ACRA server
- Skip ACRA for your Play Store distribution (because you decide you would rather just use the Play Store's crash reporting), but use ACRA for your `amazon` product flavor (the version of your app that you distribute through the Amazon AppStore for Android)
- And so on

`buildConfigField` is a great way to manage this. Use your `build.gradle` file to establish values for some constants, then use them in the ACRA configuration code in Java later on.

The sample app defines two such fields for `BuildConfig`:

- `ACRA_INSTALL`, a `boolean` that will be `true` if we should use ACRA, `false` otherwise
- `ACRA_URL`, a `String` that will point to the server to which we wish to push the ACRA-collected crash data

The sample app defines the same values for both fields in both build types (`debug` and `release`), simply because you are probably playing around with the sample in a `debug` build:

```
    buildTypes {
        debug {
            buildConfigField "String", "ACRA_URL", '"http://10.0.2.2:4567/reports"'
            buildConfigField "boolean", "ACRA_INSTALL", 'true'
        }

        release {
            buildConfigField "String", "ACRA_URL", '"http://10.0.2.2:4567/reports"'
            buildConfigField "boolean", "ACRA_INSTALL", 'true'
        }
    }
```

The URL used for `ACRA_URL` points to 10.0.2.2, the IP address on an Android emulator that refers back to the `localhost` of your developer machine. In particular, this URL is set up for the server Ruby script mentioned previously in this chapter. If you wish to use a different server, not only will you need to consider changing this URL, but you will need to make some other adjustments to the Java code, in all likelihood, as will be seen in the next couple of sections.

Creating a Custom Application

ACRA needs some one-time initialization, and it is set up to do that by means of a custom `Application` subclass. Most likely, you do not already have one of these, though some libraries will require you to create one, perhaps inheriting from some library-supplied `Application` subclass.

Regardless, you will need a subclass of `Application` in your project, and you will need to have the `android:name` attribute of your `<application>` element in the manifest point to that `Application` subclass:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonsware.android.button"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.INTERNET"/>

  <uses-sdk
    android:minSdkVersion="21"
    android:targetSdkVersion="21"/>

  <application
    android:name=".ACRAApplication"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".ButtonDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <activity
      android:name="org.acra.CrashReportDialog"
      android:excludeFromRecents="true"
      android:finishOnTaskLaunch="true"
      android:launchMode="singleInstance"
      android:process=":error_report"
      android:theme="@style/AppTheme.Dialog"/>
  </application>

</manifest>
```

Here, android:name points to an ACRAApplication class that we will examine shortly.

Also note that the manifest has a <uses-permission> element, asking for the INTERNET permission. Unless you use ACRA's built-in support for sending crash reports via the user's email app, you will need the INTERNET permission for getting crash reports to some server.

We will cover what that org.acra.CrashReportDialog <activity> is a bit later in this chapter. For the moment, ignore it.

Implementing the Application

The Application subclass that you create needs two items to configure ACRA:

1. A @ReportsCrashes annotation, providing the actual ACRA configuration itself
2. A call to ACRA.init() from onCreate(), to initialize the ACRA crash-detection subsystem and have it use the annotation to configure what to do when crashes occur

```
package com.commonsware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.annotation.ReportsCrashes;

@ReportsCrashes(
  formUri=BuildConfig.ACRA_URL,
  httpMethod=org.acra.sender.HttpSender.Method.PUT,
  reportType=org.acra.sender.HttpSender.Type.JSON
)
public class ACRAApplication extends Application {
  @Override
  public void onCreate() {
    super.onCreate();

    if (BuildConfig.ACRA_INSTALL) {
      ACRA.init(this);
    }
  }
}
```

@ReportsCrashes has many knobs to turn and switches to flip as part of configuring how ACRA should behave. We will look at a number of them in this chapter. This simple sample configures ACRA to:

- format the crash data as JSON (`reportType=org.acra.sender.HttpSender.Type.JSON`)
- send it to the server indicated by the `BuildConfig.ACRA_URL` value we configured in Gradle (`formUri=BuildConfig.ACRA_URL`)
- use an HTTP `PUT` operation to hand that JSON over to that server (`httpMethod=org.acra.sender.HttpSender.Method.PUT`)

These values work great with the Ruby script profiled earlier in this chapter. If you use some other server, you may need to change this configuration to match what that server wants.

Note that the `ACRA.init()` call is inside a check of the `BuildConfig.ACRA_INSTALL` `boolean` that we set up in the Gradle build files. If a particular build type or product flavor sets `ACRA_INSTALL` to `false`, ACRA will not be enabled. For simpler projects, rather than defining your own `ACRA_INSTALL`-style flag, you could just use `!BuildConfig.DEBUG`, to only configure ACRA on `release` builds. While there is nothing stopping you from using ACRA in development, you may find that it interferes somewhat with how you are used to debugging your crashes.

Reporting Crashes

Good news! You're done!

ACRA does not require you to litter your code with magic `try`/`catch` blocks to catch and report exceptions. After all, some Android exceptions – even those triggered from bugs in your code — are raised by Android framework code and your code appears nowhere in the stack trace.

Instead, ACRA takes advantage of `Thread` and its `setDefaultUncaughtExceptionHandler()` method, to get control when any unhandled exception occurs. All those crashes that normally would shut down a component or the whole app now go to ACRA and can be reported to your designated server.

Occasionally, you may wish to add some crashes that you *are* handling yourself to ACRA. For example, there may be some edge or corner cases that you are explicitly handling but are uncertain if they ever would happen. You could arrange to pass the `Exception` over to ACRA, which it will treat the same as any other crash that it intercepts.

To do this, call `getErrorReporter()` on the `ACRA` class, and call either `handleException()` or `handleSilentException()` on the error reporter. The difference is that `handleSilentException()` always reports the error silently, while `handleException()` will process this exception like any other, possibly alerting the user to the crash, as will be seen in the next section.

What the User Sees

The `Simple` sample app has ACRA configured, but this does us little good if we do not crash. So, the UI for the activity has a `Button`, and tapping that button will trigger a `RuntimeException`:

```
package com.commonsware.android.button;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;

public class ButtonDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void earthShatteringKaboom(View v) {
    throw new RuntimeException(getString(R.string.msg_kaboom));
  }
}
```

…whose message is tied to a string resource:

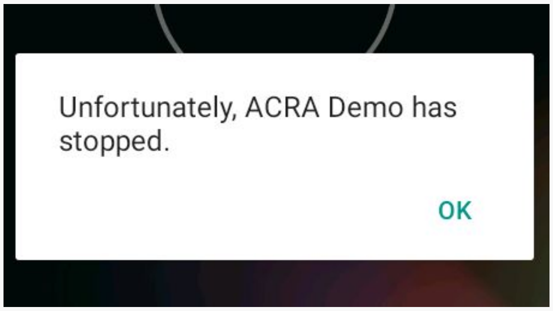
```
  <string name="msg_kaboom">Where699ebf8084c40133721d14feb5bc72a7#39;s the kaboom?
There was supposed to be an Earth-shattering kaboom!</string>
```

(with apologies to a certain Martian)

When you click the `Button`, ACRA will send a crash report to your designated server. What the *user* perceives, though, varies based upon configuration.

Default: “Silent”

If you do not specify otherwise in your ACRA configuration, the default behavior will be “silent”. In this case, “silent” means “the user is not told that a report is being sent via ACRA”. Instead, the user sees the traditional Android crash dialog, for whatever version of Android the app is running on:



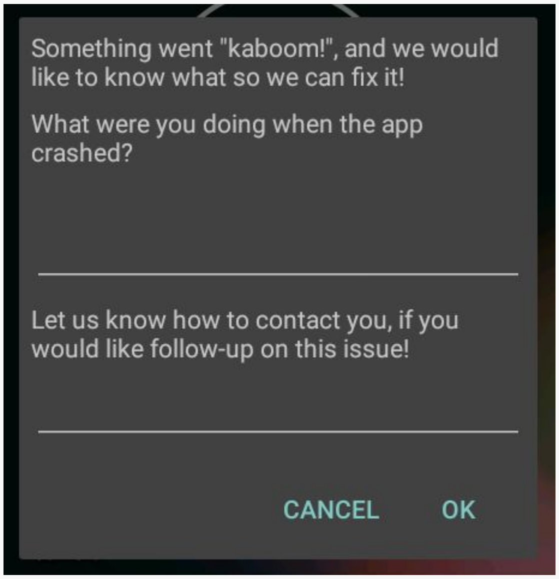
Unfortunately, ACRA Demo has stopped.

Figure 915: ACRA-Reported Crash, Silent Mode

However, there are several options that you can use instead of "silent" mode, if you so choose. One — showing a `Toast` — is not an especially good idea, as the user might not be looking at the screen right then and might not see the message.

Dialog

Another option is the "dialog" approach, where the user is shown a dialog-themed activity, indicating what happened and allowing the user to provide some additional information.



Something went "kaboom!", and we would like to know what so we can fix it!

What were you doing when the app crashed?

Let us know how to contact you, if you would like follow-up on this issue!

Figure 916: ACRA-Reported Crash, Dialog Mode

On the plus side, this is more transparent to the user, and the user can provide a bit more detail that might be useful to you. However, the user can also cancel out of the dialog, in which case you do not receive a crash report at all.

To set this up, you need to add a few more options to your ACRA configuration. You can see this in ACRADialogApplication in the sample project, which is a clone of ACRAApplication, set up for dialog-style reporting:

```
package com.commonsware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.ReportingInteractionMode;
import org.acra.annotation.ReportsCrashes;

@ReportsCrashes(
  formUri=BuildConfig.ACRA_URL,
  mode = ReportingInteractionMode.DIALOG,
  resToastText = R.string.msg_acra_toast,
  resDialogText = R.string.msg_acra_dialog,
  resDialogCommentPrompt = R.string.msg_acra_comment_prompt,
  resDialogEmailPrompt = R.string.msg_acra_email_prompt,
  httpMethod=org.acra.sender.HttpSender.Method.PUT,
  reportType=org.acra.sender.HttpSender.Type.JSON
)
public class ACRADialogApplication extends Application {
  @Override
  public void onCreate() {
    super.onCreate();

    if (BuildConfig.ACRA_INSTALL) {
      ACRA.init(this);
    }
  }
}
```

What turns on dialog mode is the mode = ReportingInteractionMode.DIALOG entry in the @ReportsCrashes annotation. This requires one additional entry, resDialogText, pointing to a string resource that is the message to display towards the top of the dialog.

You have a number of other optional settings to use to further customize the dialog. ACRADialogApplication demonstrates:

- resToastText, a string resource that will be shown in a Toast after the crash occurs and before the dialog appears. It takes ACRA a few seconds to collect the data for the crash report, and ACRA does not display the dialog until that data is collected. The Toast lets the user know that something is going on during this window of time.

- resDialogCommentPrompt, a string resource which, if included in @ReportsCrashes, enables a large EditText widget where the user can type in some comments about what they were doing at the time of the crash. The string resource serves as a label for this EditText.
- resDialogEmailPrompt, a string resource which, if included in @ReportsCrashes, enables an EditText widget where the user can type in an email address or other means of contacting the user. This value is saved in an ACRA-specific SharedPreferences value, and so it may already be filled in for the user, if the user had supplied a value previously. This, along with the comments, is included in the crash report for your use. The string resource serves as a label for this EditText.

You can also configure an icon for the dialog (resDialogIcon), a title to go across the top of the dialog (resDialogText), and the text for a Toast to be shown when the user taps OK (resDialogIkToast).

Of course, your android:name attribute of your <application> element in the manifest will need to point to this Application subclass. If you wish to try the dialog in the sample app, you will need to modify the sample app's manifest to point to ACRADialogApplication instead of ACRAApplication.

Beyond this, you will need to have the org.acra.CrashReportDialog <activity> element in your manifest, as mentioned above:

```
    <activity
      android:name="org.acra.CrashReportDialog"
      android:excludeFromRecents="true"
      android:finishOnTaskLaunch="true"
      android:launchMode="singleInstance"
      android:process=":error_report"
      android:theme="@style/AppTheme.Dialog"/>
```

Most of this is boilerplate (and, ideally, would come from manifest merger from ACRA, though that is not an option for some reason). The big thing that you need to do is set up dialog themes that the CrashReportDialog activity will use. This sample app only runs on API Level 21+ (as it depends upon Theme.Material for the main UI), so we only need to provide one theme definition, here called AppTheme.Dialog:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>

  <style
    name="AppTheme.Dialog"
    parent="@android:style/Theme.DeviceDefault.Dialog"/>
</resources>
```

Here, we follow ACRA's advice and have `AppTheme.Dialog` inherit from `Theme.DeviceDefault.Dialog`. `DeviceDefault` is a theme based on the core theme for the Android OS version (`Material` for Android 5.0+), but one that can be tailored by device manufacturers and custom ROM developers. By extending `Theme.DeviceDefault.Dialog`, we are saying that we want our dialog to be styled like other system dialogs.

`Theme.DeviceDefault.Dialog` should be a fine base theme for API Level 11+. If you are supporting older Android devices than that, for those older API levels, use `Theme.Dialog` instead.

Notification

While the dialog mode is great, it is unsuitable for crashes that may occur in the background. You do not want to pop a dialog box up unexpectedly, as users may not appreciate the interruption.

The default "silent" mode, for crashes originating in the background, will not show a dialog. This is far more suitable for background work, but it does not let the user know that a crash occurred.

The `Notification` mode serves as middle ground. When a crash occurs in the background, ACRA raises a `Notification`. Tapping on that `Notification`, in turn, brings up the same dialog that the dialog mode uses.

To use this, switch your `mode` to `ReportingInteractionMode.NOTIFICATION` in the `@ReportsCrashes` annotation. Then, in addition to all the dialog configuration, add three more string resource references:

- `resNotifTickerText`, shown as the "ticker text" of the `Notification` on Android 4.4 and below
- `resNotifTitle`, shown as the title of the `Notification` in its tile in the notification tray
- `resNotifText`, shown as the text of the `Notification` in its tile in the notification tray

Optionally, you can also set `resNotifIcon` to a particular drawable resource to use for the icon for the `Notification`.

The sample app has an `ACRANotificationApplication` that demonstrates this:

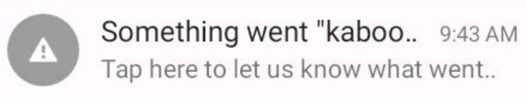
```
package com.commonsware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.ReportingInteractionMode;
import org.acra.annotation.ReportsCrashes;

@ReportsCrashes(
  formUri=BuildConfig.ACRA_URL,
  mode = ReportingInteractionMode.NOTIFICATION,
  resToastText = R.string.msg_acra_toast,
  resDialogText = R.string.msg_acra_dialog,
  resDialogCommentPrompt = R.string.msg_acra_comment_prompt,
  resDialogEmailPrompt = R.string.msg_acra_email_prompt,
  resNotifTickerText = R.string.msg_acra_notify_ticker,
  resNotifTitle = R.string.msg_acra_notify_title,
  resNotifText = R.string.msg_acra_notify_text,
  httpMethod=org.acra.sender.HttpSender.Method.PUT,
  reportType=org.acra.sender.HttpSender.Type.JSON
)
public class ACRANotificationApplication extends Application {
  @Override
  public void onCreate() {
    super.onCreate();

    if (BuildConfig.ACRA_INSTALL) {
      ACRA.init(this);
    }
  }
}
```

If you switch the `android:name` of the `<application>` manifest element over to point to `ACRANotificationApplication`, crashing the app will bring up the `Notification`:



Something went "kaboo.. 9:43 AM
Tap here to let us know what went..

Figure 917: ACRA-Reported Crash, Notification Mode

(pro tip: use short strings)

Limitations

The big limitation is that you get exactly one reporting mode for your app, for automatically-collected crashes. This means that your choice of reporting mode will be dictated by whether or not you are doing work in the background, while you do not have a UI in the foreground (e.g., a `Service`):

- If you are not doing background work, use the dialog or silent modes
- If you are doing background work, use the notification or silent modes

What You See

The sample app asks ACRA to send the crash data over in a JSON structure. That JSON contains all sorts of information by default, including `USER_COMMENT` and `USER_EMAIL` properties if you chose the dialog or notification modes.

Here is what we get from a crash of the sample app, using the dialog notification mode:

```
{
  "REPORT_ID": "7583e142-024d-4596-ba83-1a2cb6ae266d",
  "APP_VERSION_CODE": 1,

(note: some property values were truncated with . . ., as they were much too long to try to display in a book)

Your server can parse this and use it to take appropriate action.

Note that the Java stack trace (STACK_TRACE property) is formatted with embedded Java-style/C-style control characters (\n for newlines, \t for tabs). Your server can convert that into plain text with appropriate formatting.

Customizing Where Reports Go

The sample app uses one particular approach for sending crash-reports off-device: use an HTTP PUT operation, applied to a server configured in @ReportsCrashes.

That is not your only option.

HTTP

httpMethod=org.acra.sender.HttpSender.Method.PUT in @ReportsCrashes is what steers ACRA to use an HTTP PUT request to submit the crash report. Without this, by default, it will use an HTTP POST request.

However, with POST, it treats the URL (in the formUri property) a bit differently:

- For a PUT, the UUID of the crash report is appended to the URL (`http://localhost:10.0.2.2/reports/f4a411b0-7a5a-0133-dd79-14feb5bc72a7)
- For a POST, the URL is used directly without modification (http://localhost:10.0.2.2/reports), where the UUID only appears as the REPORT_ID value in the crash report

reportType=org.acra.sender.HttpSender.Type.JSON in @ReportsCrashes is what tells ACRA to generate a JSON document and submit that as a crash report. If you are using PUT, you probably want JSON. However, the default (no reportType) is a classic Web form encoded string, which would be a more natural choice for POST requests, as your server probably already has logic to convert a Web form into more convenient variables in your desired Web app framework and language.

If your server requires HTTP Basic authentication, formUriBasicAuthLogin and formUriBasicAuthPassword are available as @ReportsCrashes properties. Those are of somewhat limited utility, as anyone who can see the whole URL probably can see those HTTP headers without much additional work, and they have to be hard-coded into your app.

Email

Replacing formUri and the other HTTP @ReportsCrashes properties with mailTo (mailTo=omgomgomg@foo.com) will cause ACRA to not attempt to deliver the crash report directly. Instead, it will use ACTION_SENDTO with a mailto Uri, pointing at your requested email address, to try to bring up an email client. If the user does not have a configured email client, or if the user chooses not to send the email, you do not get the crash report.

DIY

If none of the stock ACRA delivery options works for you, you are welcome to add your own. You can create an implementation of the ReportSender interface, complete with a send() method that will be called to actually send the crash report. As part of initializing ACRA in your Application subclass' onCreate() method, you can create an instance of your ReportSender and register it via ACRA.getErrorReporter().setReportSender().

It is up to you to then get the crash report somewhere useful to you, by one means or another.

Adding Additional Data

As demonstrated in the preceding section, ACRA throws a lot of data into the crash report. However, you can add more than that, if you wish, to either better diagnose problems or to provide more individualized assistance.

Adding Stock Data to Emails

With any of the HTTP options, the crash report contains, by default, a lot of information. For email, though, rather than have an attachment with the full report, ACRA only sends along a few bits of data, such as the stack trace.

The customReportContent property on @ReportsCrashes allows you to tailor this, expanding it to include other report fields. There is a ReportField class that defines a series of constants that you use to indicate what should be in the report.

LogCat and Other Logs

ACRA uses some undocumented and unsupported means of collecting LogCat data and including it in the crash report. However, for most Android devices (those running Android 4.1+), this will only contain log lines from your app's process, due to some Android changes, for privacy reasons.

If you have elected to do your own logging elsewhere, you can teach ACRA to incorporate its logs into the crash report:

- Add ReportField.APPLICATION_LOG to the list of report fields in the customReportContent property on @ReportsCrashes
- Add an applicationLogFile property on @ReportsCrashes to indicate where the log file is
- Optionally add an applicationLogFileLines property on @ReportsCrashes to indicate how many lines from the log file to include in the crash report (where it defaults to 100)

Note, though, that it is unclear how you express the path to the log file (for applicationLogFile), as the actual filesystem path may vary by device and user.

Device Identifier

If your app has the READ_PHONE_STATE permission, ACRA will try to include a telephony hardware identifier (e.g., IMEI for GSM phones) in the crash report. However:

- This has privacy implications, and so ACRA has a way to allow the user to control whether this value is included, as will be covered later in this chapter.
- READ_PHONE_STATE is a dangerous permission, requiring you to request that permission at runtime on Android 6.0+ devices, if your targetSdkVersion is 23 or higher. You will not be in position to request this permission at the time of the crash, and so you will need to ask for it at some other point (e.g., on first run of your app).

If your objective is merely to correlate crash reports coming from the same installation of your app, consider storing a UUID in SharedPreferences (initialized on first run), as that will be included in your crash report, as is covered in the next section.

Additional SharedPreferences

If you use PreferenceManager.getDefaultSharedPreferences(), everything inside of there is included in your ACRA crash report.

If you use other SharedPreferences files (e.g., via getSharedPreferences()), and you want those SharedPreferences included in the crash report, add an additionalSharedPreferences property to @ReportsCrashes, supplying a list of the preferences filenames:

```
additionalSharedPreferences={"game_stats"}
```

Here, game_stats is the SharedPreferences filename, passed in as the first parameter to getSharedPreferences().

Your Own Data

ACRA also maintains a process-level LinkedHashMap that you can add to, where its contents are included in the crash report. Simply call ACRA.getErrorReporter().putCustomData(), supplying the key and value as String objects.

Because this is a LinkedHashMap, calling putCustomData() for some key will replace any past value for that key. The use of LinkedHashMap means that the data will be saved (and reported) in alphabetical order. Hence, you are welcome to generate unique keys if you want, perhaps based on SystemClock.uptimeMillis(), to use this custom data as an ersatz log.

However, since all of this data is kept in heap space, you will need to be judicious about its use. You are better served using actual file-based logs (whether LogCat or your own) for true logging, reserving this “custom data” for transient state or values that are non-changing.

Note that there is also removeCustomData(), which removes a value from the LinkedHashMap, given its key. In addition, getCustomData() returns the current value given its key, in case you wish to use this LinkedHashMap as the master copy of some data, in addition to having that data included in the crash report.

Removing Data

Conversely, you may wish to remove data from the ACRA crash reports. One key reason would be privacy, if there are specific things that you see showing up in the ACRA data that you think users might not like being disclosed. Another reason would be bandwidth, as there is little point in transferring data to be discarded over the Internet, adding load to your servers and perhaps costing your users money on their metered data connections.

Report Fields

As mentioned earlier in this chapter, the customReportContent property on @ReportsCrashes can be used to add fields to email-based crash reports, which normally only include a small subset of the actual available data.

Conversely, for HTTP-based crash reports — where customReportContent defaults to "everything" — customReportContent can be used to restrict what is included in the report.

SharedPreference Values

If there are specific SharedPreferences values that you would like to be excluded from crash reports, for privacy or security reasons, you can do that via an excludeMatchingSharedPreferencesKeys property on @ReportsCrashes. For example, if you use SharedPreferences to store some limited-life authorization token from a server, it is probably best to exclude that from the crash report.

excludeMatchingSharedPreferencesKeys takes a list of regular expression patterns, following the regular expression syntax used by Java's Pattern class. If you do not use any Pattern-specific control characters, the default is basically a plain string match.

So, for example, if you have a serverToken SharedPreferences value that you would like to exclude, use:

```
excludeMatchingSharedPreferencesKeys={"serverToken"}
```

in your @ReportsCrashes annotation.

End-User Configuration

ACRA monitors certain default SharedPreferences values and configures its behavior based upon them. By exposing those preferences in your own PreferenceFragment or PreferenceActivity, you can allow the user to control ACRA's behavior.

The following table outlines the options:

Preference Key	Role	Data Type	Preference Type
acra.disable	Enable or disable ACRA reporting outright	boolean	CheckBoxPreference
acra.syslog.enable	Include LogCat data in crash reports	boolean	CheckBoxPreference
acra.deviceid.enable	Include device ID (e.g., IMEI) in crash reports	boolean	CheckBoxPreference
acra.user.email	Email address to include in reports	String	EditTextPreference
acra.alwaysaccept	If true, reports are always sent, even for dialog or notification modes	boolean	CheckBoxPreference

Note that acra.disable has an acra.enable counterpart. Only use one of these. A value of true for acra.disable is equivalent to false for acra.enable.

Trail: Miscellaneous Topics

In-App Diagnostics

Android has many tools to help you make sense of what is going on in your app, from complex tools like Traceview to simpler things like LogCat. Plus, if you are using an IDE, you have access to a debugger, which can let you step through code, inspect data members and other variables, and so on.

However, they all have one element in common: they are general-purpose tools. They know nothing specifically about your app, just Android apps in general. As a result, there may be information that *you* can gather that would be of immense benefit for debugging and diagnostic purposes, but that the general-purpose tools cannot collect for you.

More importantly, you need some way to see any diagnostic data that you collect. Logging stuff to LogCat can sometimes work, but then you have to worry about accidentally shipping that logging code in production, which would be less than ideal. And there are many cases where LogCat itself will not be a great visualization of the information.

What would be better is if we could add our own diagnostic tools to our app, for use while debugging, while excluding them from our release builds. And it would be great if we could add in these tools without changing much, if anything, of our production code to reference them. This chapter will explore how to implement such tools.

Prerequisites

In addition to the core chapters, it would be a good idea if you had read:

- the chapter on Gradle and the new project structure, to understand more about the debug sourceset
- the chapter on manifest merging, to understand how the debug sourceset can contribute to the overall app's manifest

Also, one of the techniques bears some resemblance to the tapjacking attack, though fortunately without the privacy and security ramifications.

One of the sample apps is based on a `RecyclerView` sample app, and so you may wish to skim the `RecyclerView` material to ensure that you understand enough about what is going on with the sample.

One of the sample apps uses an embedded Web server, based on concepts and a module covered in another chapter.

The Diagnostic Activity

Having a "back door" to get at diagnostic information about a program is a time-honored technique. Alas, far too many of those back doors wind up in production code, and too many of those wind up resulting in privacy or security flaws. Yet, the approach is still used to this day.

From a GUI standpoint, these back doors usually required some sort of special key sequence to initiate (e.g., press Ctrl-Shift-Z three times in less than a second). The objective was to make them easy enough to get to but not something that would routinely get in the way. And, for those back doors that wound up shipping, eventually word would get out about the magic key sequence, leading to all sorts of trouble.

In Android, we can dispense with the magic key sequence (which is good, since we often are not using keyboards). An app can have as many launcher icons as it needs, so we just need a launcher icon to get into some custom diagnostic activity that we want. However, now we *really* do not want to ship this code in production, as the diagnostic activity is no longer hidden, but rather is in plain view in the user's home screen launcher.

Fortunately, the advent of sourcesets with Gradle for Android, plus a reasonably robust manifest merger process, makes setting up this sort of tool fairly easy, yet keeps it out of the production code. Most of the work will be in actually writing the activity to report on whatever it is that you wanted reported on.

The Diagnostics/Activity. sample project will illustrate this process.

This app is a clone of a previous sample that retrieves Stack Overflow questions in the android tag via Square's Retrofit library. It also uses Square's Picasso library to load in the avatars of the people asking the questions. Picasso has an API for getting at statistics about the images that were downloaded: how many, how big, how many were already cached, and so on. The revised sample shown in this section will create a diagnostic activity that reports this information, as an illustration of having such an activity supply statistics that may be useful in tuning, debugging, etc.

The Sourceset

This project has two sourcesets, main and debug. main is where the production code lies; debug is where the diagnostic activity resides. The debug sourceset is tied to the debug build type, so only when doing a debug build will our debug code be included in the app. Since your production signing key is (hopefully) only being used by your release build type, this helps ensure that the diagnostic code does not ship with your production app.

The Manifest

Both sourcesets have manifests. For debug builds, the debug sourceset's manifest will be merged with the main sourceset's manifest to create the combined result.

The objective is to have the debug sourceset's manifest have the minimum elements and attributes required to have it successfully add what it needs to the app. The more stuff in a sourceset's manifest, the more likely it is that the stuff will conflict with similar stuff from main or other manifests and cause build problems.

Here, the debug manifest simply declares a new <activity>:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android">

  <application>
    <activity
      android:name="com.commonsware.android.debug.util.PicassoDiagnosticActivity"
      android:label="@string/picasso_diagnostics"

android:taskAffinity="com.commonsware.android.debug.activity.PicassoDiagnosticActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Note that the class name for the PicassoDiagnosticActivity is fully-qualified (com.commonsware.android.debug.util.PicassoDiagnosticActivity). For the purposes of this particular diagnostic, the activity does not have to be in the same package as the rest of the app. In fact, this activity could be in a library that could be referenced by many apps, if desired.

Also note the taskAffinity for the <activity> is set to its fully-qualified class name. This helps ensure that this activity will reside in a different task than does our main UI, so that the diagnostics activity does not artificially alter BACK button processing and the like from the regular task.

Since the main sourceset will not contain this particular <activity> element, there are no collisions, and the manifest merger will turn out clean.

The Activity

The activity itself is rather boring.

It loads in a layout resource containing a TableLayout that will contain our Picasso diagnostic report:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <TableLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="8dp"
    android:shrinkColumns="1"
    android:stretchColumns="1">

    <TableRow>

      <TextView
        android:id="@+id/last_updated"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Last Updated"/>

      <TextView
```

```
        android:id="@+id/last_updated_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/avg_download_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Download Size"/>

      <TextView
        android:id="@+id/avg_download_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/avg_orig_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Original Bitmap Size"/>

      <TextView
        android:id="@+id/avg_orig_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/avg_xform_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Transformed Bitmap Size"/>

      <TextView
        android:id="@+id/avg_xform_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/cache_hits"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Cache Hits"/>

      <TextView
        android:id="@+id/cache_hits_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/cache_misses"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Cache Misses"/>

      <TextView
        android:id="@+id/cache_misses_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/download_count"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Download Count"/>

      <TextView
        android:id="@+id/download_count_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/max_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Max Size"/>

      <TextView
        android:id="@+id/max_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>
    <TableRow>

      <TextView
        android:id="@+id/orig_bitmap_count"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Original Bitmap Count"/>

      <TextView
        android:id="@+id/orig_bitmap_count_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Size"/>

      <TextView
        android:id="@+id/size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/total_dl_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Total Download Size"/>

      <TextView
        android:id="@+id/total_dl_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/total_orig_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Total Original Size"/>

      <TextView
        android:id="@+id/total_orig_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/total_xform_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Total Transformed Size"/>

      <TextView
        android:id="@+id/total_xform_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>

    <TableRow>

      <TextView
        android:id="@+id/xform_count"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Transformed Count"/>

      <TextView
        android:id="@+id/xform_count_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
    </TableRow>
  </TableLayout>
</ScrollView>
```

That layout, in turn, references some custom styles, to avoid having to repeat the configuration of each of the `TextView` widgets quite so much:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="TableText">
    <item name="android:textSize">12sp</item>
    <item name="android:layout_margin">8dp</item>
  </style>

  <style name="TableText.Title">
    <item name="android:textStyle">bold</item>
  </style>

  <style name="TableText.Value">
    <item name="android:typeface">monospace</item>
  </style>
</resources>
```

The activity loads the layout, gets a `StatsSnapshot` from Picasso containing a snapshot of the results of using Picasso, and pours the data into the various `TextView` widgets:

```
package com.commonsware.android.debug.util;

import android.app.Activity;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.widget.TextView;
import com.commonsware.android.debug.activity.R;
import com.squareup.picasso.Picasso;
import com.squareup.picasso.StatsSnapshot;

public class PicassoDiagnosticActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    StatsSnapshot ss=Picasso.with(this).getSnapshot();

    TextView tv=(TextView)findViewById(R.id.last_updated_value);

    tv.setText(DateUtils.formatDateTime(this, ss.timeStamp,
                                        DateUtils.FORMAT_SHOW_TIME));

    tv=(TextView)findViewById(R.id.avg_download_size_value);
    tv.setText(Long.toString(ss.averageDownloadSize));

    tv=(TextView)findViewById(R.id.avg_orig_size_value);
    tv.setText(Long.toString(ss.averageOriginalBitmapSize));

    tv=(TextView)findViewById(R.id.avg_xform_size_value);
    tv.setText(Long.toString(ss.averageTransformedBitmapSize));

    tv=(TextView)findViewById(R.id.cache_hits_value);
    tv.setText(Long.toString(ss.cacheHits));

    tv=(TextView)findViewById(R.id.cache_misses_value);
    tv.setText(Long.toString(ss.cacheMisses));

    tv=(TextView)findViewById(R.id.download_count_value);
    tv.setText(Long.toString(ss.downloadCount));

    tv=(TextView)findViewById(R.id.max_size_value);
    tv.setText(Long.toString(ss.maxSize));

    tv=(TextView)findViewById(R.id.orig_bitmap_count_value);
    tv.setText(Long.toString(ss.originalBitmapCount));

    tv=(TextView)findViewById(R.id.size_value);
    tv.setText(Long.toString(ss.size));

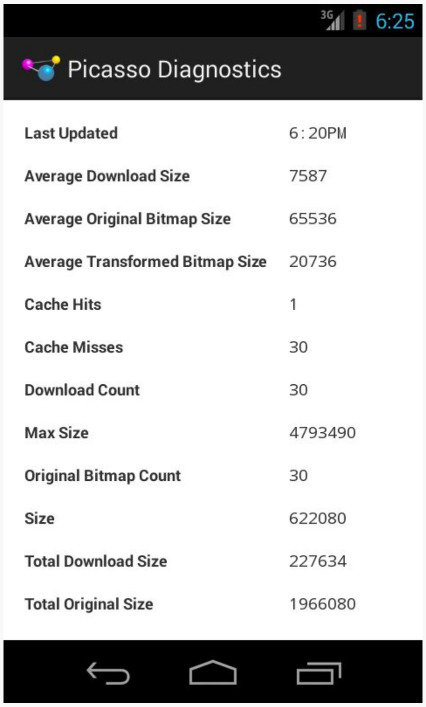
    tv=(TextView)findViewById(R.id.total_dl_size_value);
    tv.setText(Long.toString(ss.totalDownloadSize));
    tv=(TextView)findViewById(R.id.total_orig_size_value);
    tv.setText(Long.toString(ss.totalOriginalBitmapSize));

    tv=(TextView)findViewById(R.id.total_xform_size_value);
    tv.setText(Long.toString(ss.totalTransformedBitmapSize));

    tv=(TextView)findViewById(R.id.xform_count_value);
    tv.setText(Long.toString(ss.transformedBitmapCount));
  }
}
```

The Results

If you install the app on a device or emulator from a `debug` build, you will get two launcher icons. The one labeled "Picasso Diagnostics" will be the `PicassoDiagnosticsActivity`. If you bring up that activity after having run the main activity, you will see some information about the images that Picasso loaded:



Last Updated	6:20PM
Average Download Size	7587
Average Original Bitmap Size	65536
Average Transformed Bitmap Size	20736
Cache Hits	1
Cache Misses	30
Download Count	30
Max Size	4793490
Original Bitmap Count	30
Size	622080
Total Download Size	227634
Total Original Size	1966080

Figure 918: Picasso Diagnostic Activity

A `release` build, on the other hand, does not include the extra activity, its resources, or its manifest entry, since those are all in the `debug` sourceset.

Also, nothing from this affected our `main` sourceset contents. We did not have to add things to the manifest, or adjust our Java code, or anything of the sort.

The Limitations

While this sample is fairly trivial, these sorts of diagnostic activities can be as elaborate as is needed. In some cases, as with this sample, the results are reusable — so long as the app has Picasso, this code can add in the diagnostic activity.

However, this is only good for post-mortem sorts of diagnostics, where you do something in the "real" app, then head over to the diagnostic activity to see what it has to report. In many cases, this is perfectly reasonable. In other cases, the act of switching to the diagnostic activity might affect the diagnostics, if those diagnostics are dependent upon things like activity lifecycle methods. You also cannot learn anything in real time, seeing both the app and the diagnostics simultaneously (or nearly so).

However, there are other options that can improve in these areas, for situations that need such improvement.

The Diagnostic Web App

If switching the content of our device's screen impedes our ability to use the diagnostic information, is there a way we could get another screen involved?

One likely screen would be your development machine (desktop, notebook, etc.). After all, you can get that with LogCat messages. However, LogCat messages are limited in terms of formatting and rendering control. What would be interesting is if we could get information from our app to the development machine, in real time, other than via LogCat.

For example, we could have a Web app embedded in our Android app, to allow us to serve up Web pages to our development machine.

The What, Now?

We are used to having Web apps, but usually running on Web servers, whether shared hosts or cloud providers (e.g., Amazon's AWS) or that Web server box you have tucked in the corner of the office.

There is nothing stopping you from embedding a Web server in an Android app. After all, Android has access to Java's `ServerSocket`, just as Java EE servers do. It is merely a matter of having some HTTP server stack that is small enough to be embeddable but reasonably robust for whatever the targeted use is. In our case, the "targeted use" is being able to provide us with diagnostic data, which means we are not aiming for lots of simultaneous users, terabyte-scale data stores, or any of the typical things that you see "serious" Web developers have to deal with.

On the other hand, most "serious" Web developers do not have to worry about their Web servers hooking up to the WiFi in a coffee shop, either.

The Security Ramifications

Having any sort of open port on an Android device is a scary proposition from a security standpoint. At minimum, anyone on the same WiFi LAN segment can access that port. Some mobile carriers assign public IP addresses to devices on their networks, and in those cases, *anyone* can access that port.

In our case, we will only be using this Web server for debug builds, which limits the harm that can be caused. Now the only people who might be attacked are… ourselves.

When using this technique, you will also want to ensure that you have adequate controls to be able to stop the server, so it is only open and accepting requests when you want it to.

The Sample App

The `Diagnostics/WebServer`. sample project is based off of of the previous project, where we are trying to get diagnostic information about Picasso's operation and image cache. But, whereas the preceding project used a dedicated activity, this app will surface this information via an embedded Web server.

Once again, we will use the `debug` sourceset to minimize the amount of code changes needed to the `main` sourceset code and so we can feel confident that our Web server will not sneak into our production app somehow.

However, while Android has support for activities built in, it does not have a Web server built in, nor much in the way of a modern template engine for generating dynamic Web content. For those, we will turn to third parties.

The chapter on embedding a Web server covers the custom Web server implementation that we will be extending. If you have not read that chapter yet, probably you should do so before continuing. This section will not make much sense otherwise.

Adding the Library Module

This sample relies upon the reusable Web server module outlined in the chapter on embedding a Web server in your Android app.

This sample references the reusable Web server module directly, rather than via an AAR artifact, by hacking the relative path into `settings.gradle` for the project:

```
include ':app', ':webserver'

project(':webserver').projectDir=new File('../../WebServer/Reusable/webserver')
```

The `app` module, in turn, has some changes in its `build.gradle` file as well.

First, we have a dependency on the `:webserver` module added to `settings.gradle`. And, for whatever reason, Gradle and Android Studio are happier if we duplicate the `support-v13` dependency, which is already being pulled in via the dependency on `:webserver`:

```
dependencies {
    compile 'com.squareup.picasso:picasso:2.5.2'
    compile 'com.squareup.retrofit:retrofit:1.9.0'
    debugCompile project(':webserver')
    debugCompile 'com.android.support:support-v13:23.0.0'
}
```

Also, Android's build tools will want to compress HTML and JavaScript assets, even though that will interfere with our serving them. Hence, in the `android` closure, we have an `aaptOptions` closure that specifically requests to not compress those assets:

```
    aaptOptions {
        noCompress 'html', 'js'
    }
```

The Web Content

This app will use Handlebars.java as a template engine, since that is part of our resuable Web server module. It would help to have some actual templates. In our case, we really only need one, one that will show the Picasso diagnostic output. So, the sample app has a 1995-era Web page (sans `<blink>` tag, though) that has a simple table showing those Picasso values:

```
<html>
<head><title>Picasso Diagnostics</title></head>
<body>
<h1>Picasso Diagnostics</h1>
<table>
<tr><th style="text-align:right;
padding-right:16px;">Timestamp</th><td>{{timeStamp}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Average Download
Size</th><td>{{averageDownloadSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Average Original Bitmap
Size</th><td>{{averageOriginalBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Average Transformed Bitmap
Size</th><td>{{averageTransformedBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Cache
Hits</th><td>{{cacheHits}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Cache
Misses</th><td>{{cacheMisses}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Download
Count</th><td>{{downloadCount}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Max
Size</th><td>{{maxSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Original Bitmap
Count</th><td>{{originalBitmapCount}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Size</th><td>{{size}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Total Download
Size</th><td>{{totalDownloadSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Total Original Bitmap
Size</th><td>{{totalOriginalBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Total Transformed Bitmap
Size</th><td>{{totalTransformedBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Transformed Bitmap
Count</th><td>{{transformedBitmapCount}}</td></tr>
</table>
<hr/>
<a href="/stop">Stop Service</a>
</body>
</html>
```

The values themselves are represented as mustache-style value references (e.g., `{{cacheHits}}`). Those will be replaced at runtime by actual values pulled from Picasso and supplied to Handlebars.java.

This template resides in `assets/` of the `debug` sourceset. That means that the template will not ship with the production app.

PicassoDiagnosticService

`PicassoDiagnosticService` is a subclass of the reusable `WebServerService` that will publish our Picasso diagnostic information to Web browsers.

Many of the methods in `PicassoDiagnosticService` are there to satisfy `WebServerService` and its `abstract` methods. So, our `getPort()`, getMaxIdleTimeSeconds(), and getMaxSequentialInvalidRequests() methods are fairly rote:

```
@Override
protected int getPort() {
  return(4999);
}

@Override
protected int getMaxIdleTimeSeconds() {
  return(120);
}

@Override
protected int getMaxSequentialInvalidRequests() {
  return(10);
}
```

Similarly, buildForegroundNotification() just sets up our Notification with a pointer back to PicassoDiagnosticActivity, the activity that we will use to start and stop the server:

```
@Override
protected void buildForegroundNotification(NotificationCompat.Builder b) {
  Intent iActivity=new Intent(this, PicassoDiagnosticActivity.class);
  PendingIntent piActivity=PendingIntent.getActivity(this, 0,
    iActivity, 0);

  b.setContentTitle(getString(R.string.app_name))
    .setContentIntent(piActivity)
    .setSmallIcon(R.drawable.ic_launcher)
    .setTicker(getString(R.string.app_name));
}
```

In addition to stopping the server from PicassoDiagnosticActivity, it might be nice to be able to stop it from a link in the Web page being served up. So, that page has a link to a stop relative path, and we set up that route in configureRoutes():

```
@Override
protected boolean configureRoutes(AsyncHttpServer server) {
  server.get("/stop", new StopRequestCallback());

  return(true);
}
```

Returning true tells WebServerService to handle standard serve-content-from-assets logic itself, which we will be using for serving up a Web page based on the Handlebars template.

`StopRequestCallback` is a fairly trivial `HttpServerRequestCallback` implementation, just sending back some stub content and calling `stopSelf()` to stop the service (and, thereby, tear down the Web server):

```
  private class StopRequestCallback implements HttpServerRequestCallback {
    @Override
    public void onRequest(AsyncHttpServerRequest request, AsyncHttpServerResponse
response) {
      response.send("Goodbye, cruel world!");
      stopSelf();
    }
  }
```

Most of the business logic for this server lies in `getContextForPath()`. This will be called on our service whenever one of our Handlebars templates is requested, so we can provide the Handlebars `Context` (not to be confused with an Android `Context`). The `Context` is used to fill in all of the macros used in the template.

In our case, most of the macros are pulling from the Picasso `StatsSnapshot`, so we need to make sure that our `Context` has it. However, it would be nice to include the timestamp of when the snapshot was taken, formatted in a more conventional format than "milliseconds since the Unix epoch". While `StatsSnapshot` has the timestamp, we need to do the formatting.

So, `getPathForContext()` gets the `StatsSnapshot` and the formatted timestamp and combines them into a suitable `Context`:

```
  @Override
  protected Context getContextForPath(String relpath) {
    if ("picasso.hbs".equals(relpath)) {
      StatsSnapshot ss=Picasso
        .with(PicassoDiagnosticService.this)
        .getSnapshot();
      String formattedTime=DateUtils.formatDateTime(PicassoDiagnosticService.this,
        ss.timeStamp,
        DateUtils.FORMAT_SHOW_TIME);

      return(Context
        .newBuilder(ss)
        .combine("formattedTime", formattedTime)
        .resolver(FieldValueResolver.INSTANCE)
        .build());
    }

    throw new IllegalStateException("Did not recognize "+relpath);
  }
```

Here, we are saying that the core data comes from the `StatsSnapshot` (`newBuilder(ss)`), where macros are interpreted as fields on the object (resolver(FieldValueResolver.INSTANCE)). But, if anyone asks for formattedTime, we supply that separately (combine("formattedTime", formattedTime)).

Note that our manifest has our service, including the action string used by the reusable library to be able to stop our service from the foreground Notification:

```
    <service
      android:name="PicassoDiagnosticService"
      android:exported="false">
      <intent-filter>
        <action android:name="com.commonsware.android.webserver.WEB_SERVER_SERVICE"/>
      </intent-filter>
    </service>
```

The Launcher Activity

We need to arrange to start the PicassoDiagnosticService at some point.

One possibility would be to add code to the main app that checked to see if we were running a debug build and would start the service then. On the plus side, it would mean that the service would be running all the time, without additional work on the part of the developer. However:

- The service itself will affect the behavior of the app, particularly if we have no other services, such as by keeping the process around longer than normal, and this might affect our testing
- This approach would require modifying the main sourceset to be aware of the debug code, which is not ideal

Instead, we use a clone of the activity used in the other sample apps in the chapter on the embedded Web server:

```
package com.commonsware.android.debug.webserver;

import android.app.ListActivity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import com.commonsware.android.webserver.WebServerService;
import java.util.ArrayList;
import de.greenrobot.event.EventBus;

public class PicassoDiagnosticActivity extends ListActivity {
```

```
private MenuItem record, stop;

@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
}

@Override
protected void onResume() {
  super.onResume();

  EventBus.getDefault().registerSticky(this);
}

@Override
protected void onPause() {
  EventBus.getDefault().unregister(this);

  super.onPause();
}

@Override
public boolean onCreateOptionsMenu(Menu menu) {
  getMenuInflater().inflate(R.menu.actions, menu);

  record=menu.findItem(R.id.record);
  stop=menu.findItem(R.id.stop);

  WebServerService.ServerStartedEvent event=
    EventBus.getDefault().getStickyEvent(WebServerService.ServerStartedEvent.class);

  if (event!=null) {
    onEventMainThread(event);
  }

  return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
  Intent i=new Intent(this, PicassoDiagnosticService.class);

  if (item.getItemId()==R.id.record) {
    startService(i);
  }
  else {
    stopService(i);
  }

  return super.onOptionsItemSelected(item);
}

@Override
protected void onListItemClick(ListView l, View v, int position, long id) {
  startActivity(new Intent(Intent.ACTION_VIEW,
    Uri.parse(getListAdapter().getItem(position).toString())));
}

public void onEventMainThread(WebServerService.ServerStartedEvent event) {
    if (record!=null) {
      record.setVisible(false);
      stop.setVisible(true);

      ArrayList<String> diagUrls=new ArrayList<String>();

      for (String url : event.getUrls()) {
        diagUrls.add(url+"picasso.hbs");
      }

      setListAdapter(new ArrayAdapter<String>(this,
        android.R.layout.simple_list_item_1, diagUrls));
    }
  }

  public void onEventMainThread(WebServerService.ServerStoppedEvent event) {
    if (record!=null) {
      record.setVisible(true);
      stop.setVisible(false);
      setListAdapter(null);
    }
  }
}
```

Beyond updating class names to refer to our classes instead of ones from the other samples, the only change of significance comes in setting up the URLs for the `ListView`. Here, we append the `picasso.hbs` portion onto the base URL, so tapping the `ListView` row will bring up the desired Web page containing our report.

The Diagnostic Overlay

Sometimes, the information that we want needs to be presented to the developer in real time, while the user is looking at the UI of the app.

Take `StrictMode`, for example.

`penaltyDeath()` can be used to totally crash the app when, say, the app detects network I/O on the main application thread. However, this is rather harsh, particularly since Google ships all sorts of code in the framework that does improper things on the main application thread.

`penaltyLog()` is great, in that it gives us the stack trace of where the problem is but does not outright crash the app. However, we might not notice the stack traces, if we are not paying close attention to LogCat.

So, one popular combination is `penaltyFlashScreen()` combined with `penaltyLog()`. `penaltyFlashScreen()` will flash a red border around the edges of the screen, as a hint that "hey, something was detected – please check LogCat for details!" In the absence of this, or some other visual penalty, like penaltyDialog(), the developer might not learn what StrictMode is trying to tell her.

Another example is gfxinfo. As is noted in the chapter on jank, gfxinfo can give you some information about how long it takes for frames to be rendered, so you know when you are dropping frames. One option for this is via an overlay that appears on top of the main UI, so you can see in real time a bar chart of frame times, so you can see what user actions can trigger jank.

You can employ the same sorts of techniques yourself, to put an overlay on the screen, whether temporarily (e.g., the StrictMode penaltyFlashScreen() option) or more durably (e.g., the gfxinfo bar chart). The Diagnostics/Overlay. sample project will demonstrate the former, alerting you of slowdowns in the rendering of your items in a RecyclerView.

The Gradle Setup

For the purposes of demonstration, we need a sample app that can actually perform poorly, so we detect slowdowns and alert the developer via the screen overlay. At the same time, we need a sample app that does *not* perform poorly, so we can determine if the overlay works properly in both cases.

This sample project toggles between the two modes via a custom BE_STUPID field added to the BuildConfig class, based upon build type:

```
    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 22
    }

    buildTypes {
        debug {
            buildConfigField "boolean", "BE_STUPID", "true"
```

Admittedly, we could have skipped this and used the BUILD_TYPE field on BuildConfig. That will hold whatever the name of the build type was that built the APK that we installed, so it will be debug or release in this project. However, in case you wanted to have different rules for when the app should be stupid or not, we pull it out into a separate BuildConfig field. For example, you might elect to add two product flavors, so switching between true and false for BE_STUPID is based on product flavor instead of build type.

Introducing RVAdapterWrapper

The wrapper pattern in Java can be fairly powerful, allowing you to extend Java objects without changing inheritance hierarchies. Rather, you wrap the object in a wrapper that implements the same interface (or inherits from the same base class). The wrapper can do some things on its own (the extended behavior) and delegate to the wrapped object for everything else. Plus, *subclasses* of the wrapper can basically override stock wrapper behavior and behavior the wrapped object.

Android has a few such wrapper classes, like `CursorWrapper` and `ContextWrapper`. The author of this book published an `AdapterWrapper`, for the `AdapterView` family of classes, as a tiny open source library. And this chapter has `RVAdapterWrapper`, which implements a wrapper for `RecyclerView.Adapter`:

```java
package com.commonsware.android.debug.videolist;

import android.support.v7.widget.RecyclerView;
import android.view.ViewGroup;

public class RVAdapterWrapper<T extends RecyclerView.ViewHolder> extends
RecyclerView.Adapter<T> {
  private final RecyclerView.Adapter<T> wrapped;

  public RVAdapterWrapper(RecyclerView.Adapter<T> wrapped) {
    super();

    this.wrapped=wrapped;
  }

  public RecyclerView.Adapter<T> getWrappedAdapter() {
    return(wrapped);
  }

  @Override
  public T onCreateViewHolder(final ViewGroup parent, final int viewType) {
   return(wrapped.onCreateViewHolder(parent, viewType));
  }

  @Override
  public void onBindViewHolder(final T holder, final int position) {
    wrapped.onBindViewHolder(holder, position);
  }

  @Override
  public long getItemId(int position) {
    return(wrapped.getItemId(position));
  }

  @Override
  public int getItemViewType(int position) {
    return(wrapped.getItemViewType(position));
  }
  @Override
  public void onAttachedToRecyclerView(RecyclerView recyclerView) {
    wrapped.onAttachedToRecyclerView(recyclerView);
  }

  @Override
  public void onDetachedFromRecyclerView(RecyclerView recyclerView) {
    wrapped.onDetachedFromRecyclerView(recyclerView);
  }

  @Override
  public void onViewAttachedToWindow(T holder) {
    wrapped.onViewAttachedToWindow(holder);
  }

  @Override
  public void onViewDetachedFromWindow(T holder) {
    wrapped.onViewDetachedFromWindow(holder);
  }

  @Override
  public void onViewRecycled(T holder) {
    wrapped.onViewRecycled(holder);
  }

  @Override
  public void registerAdapterDataObserver(RecyclerView.AdapterDataObserver observer) {
    wrapped.registerAdapterDataObserver(observer);
  }

  @Override
  public void setHasStableIds(boolean hasStableIds) {
    wrapped.setHasStableIds(hasStableIds);
  }

  @Override
  public void unregisterAdapterDataObserver(RecyclerView.AdapterDataObserver observer) {
    wrapped.unregisterAdapterDataObserver(observer);
  }

  @Override
  public int getItemCount() {
    return(wrapped.getItemCount());
  }
}
```

The constructor takes the `RecyclerViwe.Adapter` to be wrapped, and `RVAdapterWrapper` offers a `getWrappedAdapter()` to retrieve that object. Everything else is a simple implementation of the wrapper pattern, overriding all methods from `ReyclerView.Adapter` and delegating them to the wrapped adapter.

TimingWrapper (a.k.a., StrictMode for RecyclerView)

RVAdapterWrapper exists mostly to serve as a base class for TimingWrapper. TimingWrapper arranges to collect the time used by onCreateViewHolder() and onBindViewHolder(), so we can see if those times exceed some threshold and therefore is worthy of alerting the developer.

Its constructor takes the RecyclerView.Adapter to wrap, along with the Activity that is hosting this UI. In addition to chaining to the superclass and holding onto that Activity (as a data member named host), the constructor also retrieves a WindowManager system service:

```
  public TimingWrapper(RecyclerView.Adapter<T> wrapped, Activity host) {
    super(wrapped);

    this.host=host;
    wm=(WindowManager)host.getSystemService(Context.WINDOW_SERVICE);
  }
```

TimingWrapper overrides onCreateViewHolder() and onBindViewHolder(), tracking the amount of time that those calls take, and calling a private warn() method with the time for the call:

```
  public TimingWrapper(RecyclerView.Adapter<T> wrapped, Activity host) {
    super(wrapped);

    this.host=host;
    wm=(WindowManager)host.getSystemService(Context.WINDOW_SERVICE);
  }
```

Here, T is the RecyclerView.ViewHolder used by the wrapped adapter and declared by the specific use of the TimingAdapter:

```
public class TimingWrapper<T extends RecyclerView.ViewHolder> extends
RVAdapterWrapper<T> {
```

warn() sees if the amount of time the call took exceeds some threshold, set here to be 7ms. If it does, we first log a stack trace to LogCat, following the technique used by StrictMode itself of having a private LogStackTrace Exception that is just there to collect a stack trace:

```
  private void warn(long delta) {
    if (delta>7) {
      String msg=String.format("RVAdapterWrapper violation: ~duration= %d ms",
          delta);

      Log.e(TAG, msg, new LogStackTrace());
      if (v==null) {
        WindowManager.LayoutParams params=new WindowManager.LayoutParams(
            WindowManager.LayoutParams.MATCH_PARENT,
            WindowManager.LayoutParams.MATCH_PARENT,
            WindowManager.LayoutParams.TYPE_SYSTEM_OVERLAY,
            WindowManager.LayoutParams.FLAG_NOT_FOCUSABLE
                | WindowManager.LayoutParams.FLAG_NOT_TOUCHABLE,
            PixelFormat.TRANSLUCENT);

        v=new View(host);
        v.setBackgroundResource(R.drawable.border);
        wm.addView(v, params);

        v.postDelayed(new Runnable() {
          @Override
          public void run() {
            wm.removeView(v);
            v=null;
          }
        }, 500);
      }
    }
  }

  private static class LogStackTrace extends Exception {}
```

Then, if we are not presently showing an overlay (i.e., the `v` data member is not `null`), we:

- create a `WindowManager.LayoutParams` that will fill the screen, using `TYPE_SYSTEM_OVERLAY` as the type, and indicating that it has a translucent background
- create a simple `View` and give it a background defined as the `border` drawable resource
- use the `WindowManager` to show that view
- use `postDelayed()` to get control in 500ms and remove that view, also setting `v` back to `null`

`border` is defined in `res/drawable-nodpi/` as a `ShapeDrawable`, consisting of a transparent rectangle with a 16dp-wide green border:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
       android:shape="rectangle">
  <stroke android:color="#ff00ff00" android:width="@dimen/border_width"/>
</shape>
```

The net effect is that the border will flash a 16dp-wide green line around the edge of the screen for 500ms before being removed.

Note that to use the `TYPE_SYSTEM_OVERLAY`, we have to hold the `SYSTEM_ALERT_WINDOW` permission:

```
    android:icon="@drawable/ic_launcher"
```

We will get more into the ramifications of that permission on Android 6.0+ devices later in this chapter.

The RecyclerViewActivity

You will notice that the `RVAdapterWrapper` and `TimingWrapper` code is in the `main` sourceset. Hence, those classes will exist on `debug` and `release` builds. However, we only *use* them on some builds, courtesy of a tweaked `RecyclerViewActivity`. The revised activity has `getAdapter()` and `setAdapter()` implementations that work with an unwrapped adapter, but hold onto a wrapped adapter, on `DEBUG` builds:

```
package com.commonsware.android.debug.videolist;

import android.app.Activity;
import android.os.Build;
import android.provider.Settings;
import android.support.v7.widget.RecyclerView;

public class RecyclerViewActivity extends Activity {
  private RecyclerView rv=null;

  public void setAdapter(RecyclerView.Adapter adapter) {
    boolean canDrawOverlays=
        (Build.VERSION.SDK_INT<=Build.VERSION_CODES.LOLLIPOP_MR1);

    if (!canDrawOverlays) {
      canDrawOverlays=Settings.canDrawOverlays(this);
    }

    if (BuildConfig.DEBUG && canDrawOverlays) {
      adapter=new TimingWrapper(adapter, this);
    }

    getRecyclerView().setAdapter(adapter);
  }

  public RecyclerView.Adapter getAdapter() {
    RecyclerView.Adapter result=getRecyclerView().getAdapter();

    if (result instanceof RVAdapterWrapper) {
      result=((RVAdapterWrapper)result).getWrappedAdapter();
    }

    return(result);
  }

  public void setLayoutManager(RecyclerView.LayoutManager mgr) {
    getRecyclerView().setLayoutManager(mgr);
  }

  public RecyclerView getRecyclerView() {
    if (rv==null) {
      rv=new RecyclerView(this);
      setContentView(rv);
    }

    return(rv);
  }
}
```

One criterion for whether we will use the `TimingWrapper` is whether or not we are on a debug build. The other criteria take a bit more explanation, which we will get to later in this chapter.

Being Stupid

The overall sample app is a clone of a `RecyclerView` sample that loads videos from `MediaStore` and shows them in alphabetical order, along with thumbnails of the videos. This version of the sample is augmented with Advanced Be-Stupid Technology™, where `RowController` does the thumbnail retrieval on the main application thread when being stupid or uses Universal Image Loader when not:

```
  void bindModel(Cursor row) {
    title.setText(row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    int uriColumn=row.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
    int videoId=row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID));

    videoUri=row.getString(uriColumn);
    videoMimeType=row.getString(mimeTypeColumn);

    if (BuildConfig.BE_STUPID) {
      ContentResolver cr=thumbnail.getContext().getContentResolver();
      BitmapFactory.Options options=new BitmapFactory.Options();

      options.inSampleSize = 1;

      Bitmap thumb=MediaStore.Video.Thumbnails.getThumbnail(cr, videoId,
          MediaStore.Video.Thumbnails.MICRO_KIND, options);

      thumbnail.setImageBitmap(thumb);
    }
    else {
      Uri video=
          ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
              videoId);

      imageLoader.displayImage(video.toString(), thumbnail, opts);
    }
  }
```

The Results

The green border will flash if a call to `onCreateViewHolder()` or `onBindViewHolder()` takes more than 7ms. In theory, this should only occur if one of those methods does a non-trivial bit of work on the main application thread.

In practice, this seems to generate a fair number of false positives, presumably due to context-switching between threads on the available device cores. This effect will be exacerbated on the emulator, due to the fact that it emulates a single-core environment.

Areas for Improvement

Those results point at areas where this technique might be improved:

- Pass the timing value into the `TimingWrapper` constructor, rather than hard-coding it to 7ms
- Rather than worrying about individual calls exceeding a 7ms threshold, point out if a rolling average of recent calls exceeds the threshold, to perhaps smooth out the data a bit and avoid the false positives

What Changed in Android 6.0

Let's go back to the `setAdapter()` implementation, where we conditionally apply the `TimingAdapter`:

```
  public void setAdapter(RecyclerView.Adapter adapter) {
    boolean canDrawOverlays=
        (Build.VERSION.SDK_INT<=Build.VERSION_CODES.LOLLIPOP_MR1);

    if (!canDrawOverlays) {
      canDrawOverlays=Settings.canDrawOverlays(this);
    }

    if (BuildConfig.DEBUG && canDrawOverlays) {
      adapter=new TimingWrapper(adapter, this);
    }

    getRecyclerView().setAdapter(adapter);
  }
```

As noted earlier, we only use `TimingWrapper` on debug builds, not release builds.

We also only use TimingAdapter if one of two things is true:

- Either we are on some version of Android prior to 6.0, or
- We are allowed to draw overlays

Historically, the SYSTEM_ALERT_WINDOW permission was merely listed as dangerous. Users would be notified about it at install time, but otherwise it was just a standard permission.

Originally, few apps requested this permission. Over time, more and more apps started using this for things like Facebook's "chatheads" UI.

In Android 6.0, SYSTEM_ALERT_WINDOW was moved to be a signature-level permission. Ordinarily, the net effect of this change would be that apps could no longer hold the permission, unless they were signed by the signing key that signed the firmware. While that's possible for device manufacturers and custom ROM developers, ordinary Android SDK developers would be left out.

However, Android 6.0 provided another means to get the rights to use TYPE_SYSTEM_OVERLAY windows, through a double-opt-in mechanism. The user not only has to install the app, but has to go to a particular screen in the Settings app to agree to grant your app the right to draw over top of other apps.

The default way for a user to get to that screen is to go into Settings > App, then click the gear icon in the action bar of the Settings app:

Figure 919: Android 6.0 Settings App, Apps Screen, with Gear Icon

Tapping that brings up a “Configure apps” screen:

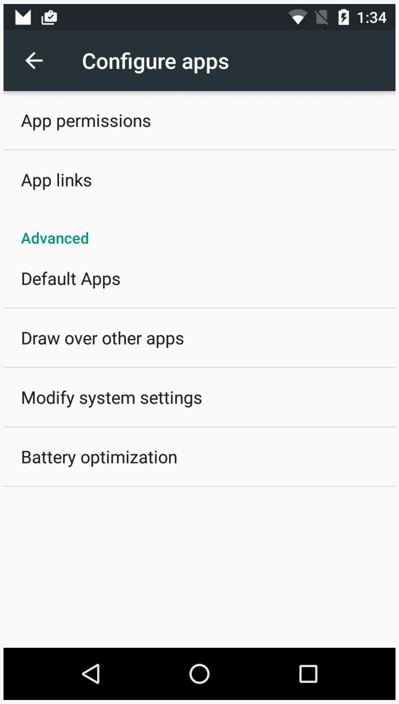

Figure 920: Android 6.0 Settings App, Configure Apps Screen

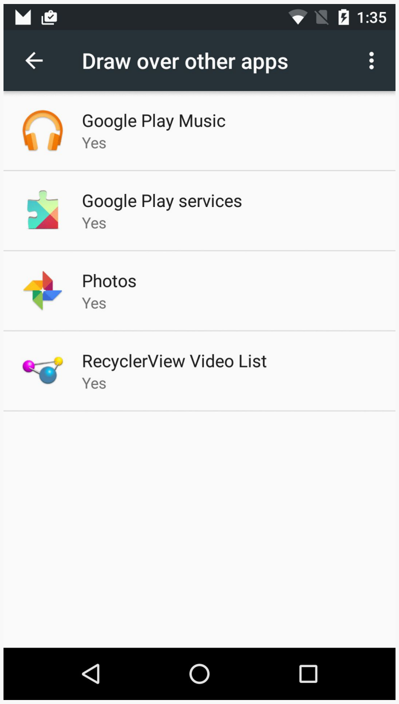
There, tapping the "Draw over other apps" entry brings up a list of all of the apps that have requested the `SYSTEM_ALERT_WINDOW` permission:



Google Play Music
Yes

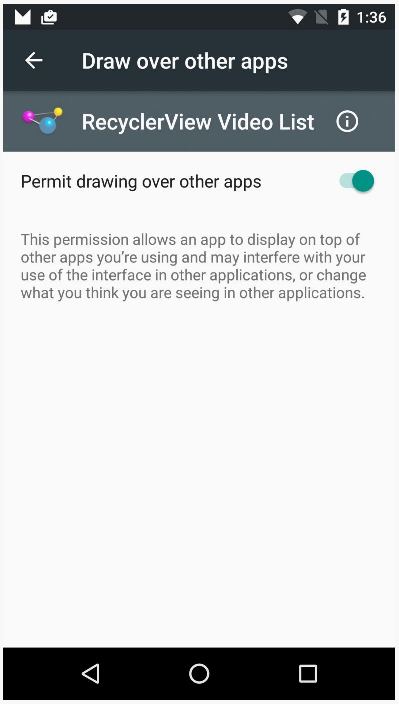
Google Play services
Yes

Photos
Yes

RecyclerView Video List
Yes

Figure 921: Android 6.0 Settings App, Draw Over Other Apps Screen

Tapping on any one of those allows the user to toggle on or off this access:



Permit drawing over other apps

This permission allows an app to display on top of other apps you're using and may interfere with your use of the interface in other applications, or change what you think you are seeing in other applications.

Figure 922: Android 6.0 Settings App, Configuring Overlay Permission

In code, you can find out if the user has enabled this access by calling `canDrawOverlays()` on the `Settings` class, as we did in `setAdapter()` above. However:

- This requires you to have a `compileSdkVersion` of 23 or higher
- You cannot call that method on pre-Android 6.0 devices

On Android 6.0+, if `canDrawOverlays()` returns `false`, you are welcome to lead the user over to the appropriate screen in Settings to try to convince them to allow you to draw over other apps. To do that:

- Create a `package: Uri` that points to your app
- Wrap that in an `ACTION_MANAGE_OVERLAY_PERMISSION Intent`
- Call `startActivity()` to bring up that screen

```
Intent i=new Intent(Settings.ACTION_MANAGE_OVERLAY_PERMISSION,
                    Uri.parse("package:" + getPackageName()));

startActivity(intent);
```

Note that apps with a targetSdkVersion of 22 or lower are “grandfathered” into having default access to draw over other apps, simply by having requested the SYSTEM_ALERT_WINDOW permission. However, the user can still go into the Settings app and revoke that capability, in which case attempting to draw over another app will result in a SecurityException

```

```

In many cases, there is no good way to recover from this SecurityException, in which case you really want to consider switching to compileSdkVersion of 23 or higher and calling canDrawOverlays() to detect this potential problem before it occurs.

Anti-Patterns

Much of this book has been focused on what you should do. In contrast, this chapter is focused on what you should *not* do.

All platforms have their anti-patterns: things that are technically possible but are not in the best interests of the users of that platform. Android is no exception. Some anti-patterns are simply annoying to users, while other anti-patterns can significantly infringe upon a user's use of their Android device, or even the user's freedom.

Much as the Hippocratic Oath directs doctors to "first, do no harm", Android application developers owe it to the users of their apps to avoid these anti-patterns to the greatest extent possible.

Prerequisites

This chapter assumes that you have read much of the book, particularly the core chapters.

Leak Threads… Or Things Attached to Threads

Leaking a thread means that you start a thread and never cause it to stop. For example, you might start a thread that runs in an infinite loop, doing some work and then sleeping for a while. The problem with infinite loops is that "infinite" is an awfully long time.

All threads should clean up, in a timely fashion, when the component (e.g., activity, service) that started the thread is destroyed — or, in the case of an activity, perhaps just moved into the background.

How you ensure that the thread gets cleaned up is up to you. For threads doing transactional work, such as literally running a database transaction, it may be fine to just let them run to completion and shut down of their own accord. For "infinite" loops, there should be some way to tell the thread that it is no longer needed, such as via an `AtomicBoolean` flag, or using something more structured than a plain timing loop, such as a `ScheduledExecutorService`.

Also, bear in mind that you are responsible for threads that are created, on your behalf, by other things that you do. The most common leak scenario here comes with listeners associated with system services, like `LocationManager` and `SensorManager`. If you register a `LocationListener` via `requestLocationUpdates()` and fail to unregister that listener, you will not only be leaking the listener, but the component associated with that listener, and every system resource tied to that listener, such as any background threads.

The Costs

Threads are intrinsically static in scope. Hence, any object they can reach, directly or indirectly, cannot be garbage-collected while the thread is still running. Hence, if an activity forks a thread, it might do so using an anonymous inner class:

```
new Thread() {
  public void run() {
    // do something
  }
}).start();
```

Instances of an inner class — anonymous or otherwise — have an implicit reference back to the object that created them. Hence, the `Thread` would hold onto the `Activity` that created the thread, which in turn would hold onto all of its widgets and so forth. None of that can be garbage-collected until after the thread terminates, even if the activity is destroyed.

The Counter-Arguments

I want the thread to keep running even after the activity is destroyed

In this case, the thread should be created and managed by a service, not simply leaked. Not only does this give you an opportunity to clean up the thread when needed, but it also alerts Android that you are still trying to do some work, so Android will not necessarily terminate your process very quickly.

However, be careful about assuming that you can have a thread — even one managed by a service — run forever, as you will see in the next couple of sections.

I do not know when the thread is no longer needed

Then you have a serious design problem.

A common variation on this theme is:

The thread is needed so long as I have an activity in the foreground

This is a bit tricky, as Android does not really expose the concept of *applications* being in the foreground, just activities.

The safest course of action is to have the thread be managed by a service, then keep track of whether or not you have an activity in the foreground. For example, in `onPause()` of each activity, use `postDelayed()` to return control to you after a short delay, and in `onResume()`, update a timestamp of your last return to the foreground (held in a static data member). When the `Runnable` for `postDelayed()` executes, check that timestamp — if it is too old, you know that none of your activities are in the foreground, and you can stop the service, having it stop your thread.

Use Large Heap Unnecessarily

Encountering an `OutOfMemoryError` certainly sucks. These are caused either by a memory leak or by trying to use more memory than is practical given the device. For example, loading up lots of bitmaps can easily chew up your available heap space.

To some, therefore, `android:largeHeap` seems to be the perfect solution.

Added in API Level 11, `android:largeHeap` tells Android to give you a much larger heap size than is normally given to a process. So, instead of having 32MB or 48MB or so of heap, you might have 256MB of heap.

The right solution, in most cases, is to fix the underlying memory problem, not to mask it by requesting an over-sized heap.

The Costs

To you, having hundreds of megabytes of extra heap may be a blessing. To the user, it may be a curse. That memory has to come from somewhere, and the "somewhere" is from other processes. Your app will force other apps' processes to be terminated far more quickly than normal, which may slow the user down when she tries to switch between your app and others. Your app may even materially harm the functionality of other apps, who have their processes terminated before they can finish their work, just to satisfy your memory craving.

Bear in mind that Android does not employ swap space (the Linux equivalent of a Windows pagefile). Hence, whereas Windows can allocate lots of memory and slows down as it goes, Android is far more limited, in accordance with its mobile roots.

Furthermore, in many cases, adding more heap space does not eliminate the problem, any more than spraying air freshener gets rid of the dead cat in your living room that is causing the odor. With a memory leak, for example, all the larger heap does is increase the time before you eventually run out of memory.

The Counter-Arguments

I really need to be able to manipulate large chunks of memory

There are certainly apps for which `android:largeHeap` is justified, such as complex data editors, such as image editors, video editors, etc.

Hence, in practice, the real anti-pattern is not using `android:largeHeap`, but rather in doing so for apps where the user would not feel that the resulting effects are justified. For example, neither a Twitter client, nor a banking app, should need a large heap, even if the developer is running into memory management issues.

Android makes it too hard to manage memory, so I need a large heap

There is no question that developing mobile applications is challenging, particularly when it comes to memory management. That is not unique to Android — embedded systems developers are used to writing apps where the heap size is better measured in KB instead of MB, for example.

Outside of bitmaps and massive data sets, though, it is a bit difficult to actually run out of memory. While a `TextView` may take up 1KB of heap space, it takes a *lot* of `TextView` widgets to chew through a 48MB heap.

The reason why bitmaps tend to trip up developers is that Android makes using them *too easy*. For example, it is simple to set a bitmap as a background of some container like a `LinearLayout`, where developers then blindly ignore the fact that if the bitmap is not *precisely* the size of the container, Android will need to scale the image, consuming more heap space.

Misuse the MENU Button

The MENU button on Android devices is designed to display either the options menu (on Android 1.x/2.x devices that are not using an action bar backport like ActionBarSherlock) or the action bar overflow menu.

The MENU button is *not* designed for any other purpose. Some developers have taken to using it for arbitrary aims, and that is a mistake.

The Costs

The MENU button does not exist on many Android devices. In particular, devices designed for Android 3.0 and higher do not *need* a MENU button. Some will have them, but most will not. Hence, anything that requires the MENU button will simply be unavailable on those devices.

And, as of Android 4.4, Google is putting increasing pressure on device manufacturers to dump the MENU button, making it less likely to appear in the future.

The Counter-Arguments

Well, if I keep `targetSdkVersion` below 11, I can have a soft MENU button

This is true, insofar as a menu affordance will be added to the system bar or navigation bar on devices that lack a dedicated MENU button.

Whether the *user* is expecting to use this button is another thing entirely.

As more and more users run Android 3.0+ devices, they will use more and more apps that have `android:targetSdkVersion` set to 11 or higher. The remaining handful of apps that do not will be "weird". In particular, they may not notice the menu affordance, as they are not looking for one, or they may not know what it does, as they are not used to needing it.

Moreover, eventually, other things will drive you to want an `android:targetSdkVersion` higher than 10, as the menu affordance is not the only feature driven by this value. The sooner you can remove your dependence on a menu affordance, the sooner you can upgrade your `android:targetSdkVersion` to solve other problems that you are encountering.

I think the action bar is ugly, a waste of space, or otherwise bad

That's nice. It does not mean that you need a menu affordance and a tie to a MENU button.

For example, well-written games will have a menu integrated into the game UI itself. This was often done even before Android 3.0, since the options menu UI would not look much like the game's UI, and the developer wanted a consistent look-and-feel.

So long as the user recognizes how to reach the menu (e.g., a three-dots or three-bars icon), the menu does not have to be driven by Android, but instead could be handled by your app directly. You can see this in the Google Navigation app, which avoids an action bar but still displays its own menu from its own on-screen menu affordance.

Interfere with Navigation

Some developers try to take over the device. They attempt to block the use of anything not related to their app: the HOME key, the recent tasks list, the notification drawer, etc.

Android treats such behavior as malware. Android is designed to keep control of the device in the hands of the user and tries very hard to prevent apps from stealing that control.

The Costs

While there are certain cases where blocking navigation outside the app may seem justified (see the counter-arguments, below), there is simply too much opportunity for malfeasance. Users tend to want to use their devices on their terms, not necessarily the terms of some random developer. Malware authors, in particular, love to learn about script-kiddie hacks that allow them to control a device, and by extension, control the users.

The Counter-Arguments

I am writing a lock screen

No, you are not. You are writing something that you *think* is a lock screen. Really what you are writing is something that weakens device security… if the app in question is designed to be downloaded and run on arbitrary devices.

Android devices can be rebooted into "safe mode". Much like the Windows boot option that bears the same name, "safe mode" only runs apps that are part of the system firmware, not any third-party apps.

So, let's assume that the user installs your "lock screen". Inevitably, part of the setup of a third-party "lock screen" is to disable any sort of security that is part of the native lock screen, so the user does not have to unlock things twice. Even though your lock screen may implement all sorts of security, all somebody else has to do is reboot the device in safe mode, and they now have complete access to the device, including the ability to uninstall your lock screen. By contrast, the native lock screen is in force even if the device reboots in safe mode.

I am writing a parental control app

Rebooting in safe mode is within the motor-control skills of your average three-year-old child. Hence, the primary limitation is whether or not the child knows *how* to reboot the device in safe mode, which they can learn from the Internet, friends, etc. And, if the device is really an adult's device, where the "lock screen" allows access to a subset of child-friendly apps, the real risk is not from the child rebooting the device in safe mode, but from the crook who steals the device rebooting in safe mode.

I am writing a lock screen designed to run on whole-disk-encrypted devices

While whole disk encryption — available on Android 4.0+ — does solve the issue of rebooting in safe mode, bear in mind that users then cannot disable the required password security on the native lock screen, as that is tied into the whole disk encryption process.

I am writing a kiosk app

Here, the term "kiosk app" refers to an app that represents the functionality of a single-purpose device. For example, a restaurant might want to distribute menus to customers in the form of a tablet app; the menu app would be the "kiosk app".

In this case, the owner of the device is the one trying to lock it down to be single-purpose. That is completely reasonable… except that it runs counter to the behavior of standard consumer builds of Android.

The right solution, in this case, is to create custom firmware for the single-purpose devices. This firmware can set up the kiosk app to be the home screen (thereby blunting the effectiveness of HOME, BACK, etc.), and modifications to the firmware can apply access controls to other aspects of the device (e.g., notifications). Unfortunately, there are few (if any) businesses set up to help create such single-purpose firmware for single-purpose devices.

Use android:sharedUserId

If you are creating more than one application, where those applications should be sharing data, you may be tempted to use `android:sharedUserId`. This attribute, applied to the root `<manifest>` element in your manifest, allows two or more apps to share a Linux user account. That will allow these apps full access to the other apps' files. The limitations are that you must use the same value for `sharedUserId` and that all such apps must be signed with the same signing key.

However, this is a fairly crude and somewhat risky approach to sharing information between apps. In most cases, you will be better served using any of the structured IPC options within Android, such as remote services and content providers.

The Costs

First, you must make the decision to use `android:sharedUserId` before you ever ship your app in production. Should you change the `sharedUserId` value — or switch from no value to a new value — when your change is installed, the new version of your app will have no rights to access the old version of your app's files. This is unlikely to turn out well.

Second, it will be up to you to maintain data integrity of these files in the face of simultaneous access from multiple apps. SQLite should handle this for you for your databases, as it is set up to use process-level locking — this is why SQLite can be used as the out-of-the-box database solution for Web frameworks like Rails.

However, any other sort of file, including `SharedPreferences`, will lack that coordination, unless you somehow arrange to do it yourself. And even the SQLite-level coordination has its limits, as one app has no way to know about another app's changes to the data, except by re-querying the database.

Third, using `android:sharedUserId` limits your flexibility. You cannot use it with third-party apps. You cannot readily sell one of your apps in your suite, as then it becomes a third-party app and can no longer be signed by the same signing key as are the rest of your apps. Basically, `sharedUserId` causes multiple separate APKs to behave, in some respects, as one larger APK.

The Counter-Arguments

I need to ensure only my apps can share the data, not others

Use a signature-level permission. This gives you the same level of security as does `android:sharedUserId` without most of the risks.

Writing IPC code is tedious

So is writing cross-process data integrity code.

Implement a "Quit" Button

Perhaps the most contentious question and answer on Stack Overflow's `android` tag is "Quitting an application - is that frowned upon?". This exchange is nearly three years old (as of the time of this writing), yet the answer receives both upvotes (and a few downvotes) with some regularity.

Other Android experts, such as Reto Meier, have weighed in on the issue and have offered similar recommendations – that is, do not have a "quit" or "exit" button in your app.

(here, "button" is shorthand for any command-style interface, and includes menu options, action bar items, and the like by extension)

The reason is simple: whatever your "quit" or "exit" button does *should be happening in other conditions as well*, and handling those other conditions should eliminate the need for the button.

If the app moves into the background *for any reason*, you need to treat the user and her device with respect. This means stopping background threads that are not needed, releasing system resources like the GPS radio (immediately or after a modest delay), and the like. The user should not need to "quit" your app to accomplish this, because your app will move to the background for other reasons, such as incoming phone calls, or the user pressing the HOME button.

The Costs

You might think "well, what's the harm in having the 'quit' button that, say, just calls `finish()`?"

First, rarely is it that simple. Calling `finish()` will return the user to the previous activity, and so for any multi-activity app, there will be scenarios where `finish()` is not really "quit". The only simple thing you can universally do is have "quit" bring up the home screen, in which case all you have done is waste screen real estate duplicating the HOME button functionality. Worse, the developer might say "oh, well, I will just terminate my process when they press 'quit'", and *that* anti-pattern is coming up next in this chapter.

Second, the user will start to think that they *need* to press "quit", or else bad things might happen. They will see an explicit "quit" option and start to wonder "well, gee, when am I supposed to press that, and what happens if I do not?" This, in turn, will lead to the user going out of their way to make sure to press your "quit" button, even if doing so does not actually change anything about the behavior of your app, courtesy of the placebo effect.

The Counter-Arguments

I need to let the user log out of the app, so I need a "quit" button

No, you need a "logout" button that clears your cached authentication credentials (e.g., sets a static data member to `null`), then brings up the login activity using `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to wipe out all other activities in your process. And, probably, you need to have some sort of inactivity-based "timeout" that also logs out the user (e.g., sets that static data member to `null`).

I am running stuff in the background, so I need a "quit" button

No, you need a "stop that background stuff" button, preferably with a shorter, more specific label. And, you need that to also be available from the `Notification` that you are using with your foreground service, where applicable.

Terminate Your Process

Closely related to the above anti-pattern is to forcibly stop your process, such as via `System.exit()`, `Runtime.exit()`, `Process#killProcess()`, and so forth. These are often used in concert with an in-app "quit" button, or sometimes for other reasons (e.g., could not figure out how to handle an exception gracefully).

The Costs

Simply put, Google has warned, repeatedly, that there may be side effects from terminating your own process, rather than having Android do proper cleanup first.

- "You should really think about not exiting the application. This is not how Android apps usually work." (Romain Guy)
- "To be clear: using System.exit() is strongly recommended against, and can cause some poor interactions with the system. Please don't design your app to need it." (Dianne Hackborn)
- "There is no reason or need to call [exit()]" (Dianne Hackborn)
- "Nobody has said anything about Process.kill() not doing anything. You want to kill your *own* process and cause the user to experience your *own* application having weird behavior at times due to it? Have at it. I just want to be clear that this is not what we recommend doing… and you are likely to cause bad behavior in your app at least at times due to it… There is no API to quit an application, because there is no such concept on Android, and trying to implement such a thing is going to result in fighting against how Android works." (Dianne Hackborn)

The Counter-Arguments

I am using a C library that is buggy, so I need to terminate my process

Fix the bugs in the library. For example, C libraries that rely too heavily on global variables may need to be adjusted to use session handles that get passed around.

Well, it is not my C library, but one from a third party, so I need to terminate my process

Find a library that is Android-compatible, then. It is likely that you will encounter other problems with this library, if it is not designed to work on Android (e.g., not set up to work properly on ARM CPUs).

There is a bug in Android for which I have found no workaround short of terminating my process

This is one of the few legitimate reasons for terminating a process, but it is so rare that it is difficult to find a citation of a place where such a bug (and workaround) exists.

I need to do *something* from my top-level exception handler!

Set relevant static data members to `null`, then start up your launcher activity, using `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to wipe out all other activities in your task. This should reset you to your original state, as if the user had launched the app.

Try to Hide from the User

Some developers view the user as the enemy. These developers try to insulate their app from the user, to make data inaccessible to the user, to make the app "unkillable" by the user, etc. In many cases, this is at the behest of some enterprise, wanting to exert control over the user's use of the app or even the device.

Android is a consumer operating system. It is designed to put power in the hands of whoever is holding the device and can authenticate themselves to the device (e.g., via a password on the lock screen). Enterprises and malware authors have much the same interests: they wish to take control away from the user and give the control to somebody else. Android defends against malware; enterprises get caught in the crossfire.

Inevitably, the right solution here will be an enterprise remix of Android, designed to be loaded on enterprise-supplied devices, that put the control in the hands of the enterprise.

The Costs

Simply put, you are wasting your time, which could be better spent on other pursuits.

With respect to data, if your app can access that data, by definition, a sufficiently talented user can get at the data:

- If you put it on internal storage, the user can root the device
- If you further encrypt the data, the user can find the encryption algorithm and key in your app, then decrypt the data
- If you try obfuscation or other techniques to mask the encryption algorithm and key, the user will use cracking tools to find this information anyway, or will transfer your app to a ROM mod that contains a modified version of the Android framework that can collect this information when you go to decrypt the data
- And so on

With respect to the process, the user can force-stop any installed app via the Settings app. And, even if you use script-kiddie tricks to try to prevent access to Settings, the user can nuke your app from orbit via the command line, using the full Android SDK or third-party tools.

The Counter-Arguments

I am creating an app for an enterprise, and we need to control the app

Then you further need to control the device, which leads to the "enterprise flavor of Android" solution mentioned earlier in this section.

I am creating a lock screen/parental control app/kiosk app

Please see the counter-arguments for "Interfering with Navigation" from earlier in this chapter.

Use Multiple Processes

Some Android professionals recommend the use of `android:process` to have components run in separate processes from the main one for an application. For example, you might have all of your activities in the main process but isolate a service in a separate process. Or, you might have some memory-intensive activity (e.g., an image editor) run in a separate process.

As with most of these anti-patterns, while the `android:process` feature is valid, it is rarely necessary. To some extent, developers get caught up in process isolation from its use on servers and forget that mobile devices typically have fewer resources — RAM and CPU — than do their server counterparts. Few of Google's apps use `android:process`; even complex apps like Gmail or the original Browser avoid it.

The Costs

Each process gets its own heap space, cutting into the heap available for other applications. As with the large-heap anti-pattern discussed above, this will tend to force other apps to be ejected from memory sooner than normal, with commensurate impacts on user experience.

Inter-process communication (IPC) is not cheap, compared with normal method invocation within a process. Hence, tightly-coupled processes will chew through more CPU than their single-process counterparts. While it is unlikely that you will see major performance implications (unless you are doing a preposterous amount of IPC), this will consume more battery than is otherwise warranted.

The Counter-Arguments

I am using a C library that is buggy, and you told me not to terminate my process

As noted earlier, fix the bugs in the library.

Hello? It is not my C library, but one from a third party!

Find a library that is Android-compatible, then.

I need more heap space

On Android 3.0 and higher, `android:largeHeap` is available, though its misuse is another anti-pattern, discussed above. However, prior to Android 3.0, `android:largeHeap` was not an option. One workaround used by some apps is to fork several processes, thereby getting several "small" heap allocations (e.g., 32MB) instead of just one.

In cases where `android:largeHeap` is indeed justified, using multiple processes as a workaround on older Android versions is justified as well. However, bear in mind that IPC overhead is non-trivial, so have a plan to dump the multiple processes and use `android:largeHeap` once you drop support for Android 1.x/2.x.

I want my UI not to freeze when doing background work

Use threads, not processes, for this.

Hog System Resources

Some of these anti-patterns, like the multiple-process one just now, are really concrete sub-types of a more general anti-pattern: assuming yours is the only app running on the device. While your app may be the only one running in the foreground (assuming that you actually *are* in the foreground), there are other apps in the background, and ones that soon will come to the foreground. You need to "play nice" and ensure that these other apps will have their fair share of system resources.

One example is open files on external storage. For some devices — but not all – there is a limit of 1,024 simultaneously open files. In principle, that should be plenty. However, if some app — maybe yours? — opens a whole bunch of files, it is possible that other apps trying to access external storage at that point will crash because the limit was hit.

The Counter-Arguments

Um, well, I'm just more important than those other developers

::facepalm::

Trail: Widget Catalog

Widget Catalog: AdapterViewFlipper

A regular ViewFlipper shows only one child widget or container at a time. So does an AdapterViewFlipper. The difference is where the children come from. With a regular ViewFlipper, you add children much like you would any other standard container class, such as defining the children in your layout XML resource. With AdapterViewFlipper, the children come from an Adapter.

While AdapterViewFlipper does not inherit from ViewFlipper (or vice versa, for that matter), their public API is largely the same:

- You can control which child is visible, either by index or via showNext()/showPrevious() methods to rotate between them.
- You can set up animated effects to control how a child leaves and the next one enters, such as applying a sliding effect.
- You can set up AdapterViewFlipper to automatically flip between children on a specified period.

There are two key advantages for AdapterViewFliper:

1. Since it uses an Adapter model, it can be more memory efficient for lots of children, through child view recycling
2. It is available for use in an app widget

However, AdapterViewFlipper is new to API Level 11 and is unavailable on older versions of Android. It is not included in the Android Support package backport.

Key Usage Tips

All of the usage tips from ViewFlipper are relevant for AdapterViewFlipper.

A Sample Usage

The sample project can be found in WidgetCatalog/AdapterViewFlipper.

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<AdapterViewFlipper xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/details"
  android:layout_width="match_parent"
  android:layout_height="match_parent"/>
```

Activity:

```
package com.commonsware.android.avflip;

import android.app.Activity;
import android.os.Bundle;
import android.widget.AdapterViewFlipper;
import android.widget.ArrayAdapter;

public class FlipperDemo2 extends Activity {
  static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
      "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
      "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
      "placerat", "ante", "porttitor", "sodales", "pellentesque",
      "augue", "purus" };
  AdapterViewFlipper flipper;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);

    flipper=(AdapterViewFlipper)findViewById(R.id.details);
    flipper.setAdapter(new ArrayAdapter<String>(this, R.layout.big_button, items));
    flipper.setFlipInterval(2000);
    flipper.startFlipping();
  }
}
```

Visual Representation

There is no visual representation of an `AdapterViewFlipper` itself, as it renders no pixels on its own. Rather, it simply shows the current child.

Widget Catalog: CalendarView

CalendarView, as you might have guessed, displays a calendar to the user, designed to allow the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Note that this is a small calendar – it is not designed to show details *within* a date, such as appointments and times.

This view is available standalone and also as an optional adjunct to the DatePicker widget.

This view was added in API Level 11 and therefore will not be available on older versions of Android, though a backport is available that works on Android 2.2 onwards.

Key Usage Tips

If you do nothing, the CalendarView will start with today's date, though you can call a setDate() method to pass in a Calendar object to use to change the initially-selected date. You can also call setOnDateChangeListener() to supply an OnDateChangeListener to learn when the user changes the date in the CalendarView.

CalendarView works well with Calendar and GregorianCalendar, in terms of setting and getting the year/month/day-of-month from the CalendarView (as supplied to the onSelectedDayChange() method of your OnDateChangeListener) and converting it into something you can use in your code.

A Sample Usage

The sample project can be found in WidgetCatalog/CalendarView.

Layout:

```
<CalendarView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/calendar"
  android:layout_width="match_parent"
  android:layout_height="match_parent"/>
```

Activity:

```
package com.commonsware.android.wc.calendar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CalendarView;
import android.widget.CalendarView.OnDateChangeListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class CalendarDemoActivity extends Activity implements
    OnDateChangeListener {
  CalendarView calendar=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    calendar=(CalendarView)findViewById(R.id.calendar);
    calendar.setOnDateChangeListener(this);
  }

  @Override
  public void onSelectedDayChange(CalendarView view, int year,
                                  int monthOfYear, int dayOfMonth) {
    Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

    Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
         .show();
  }
}
```

Visual Representation

This is what a `CalendarView` looks like in a few different Android versions and configurations, based upon the sample app shown above.

Widget Catalog: DatePicker

DatePicker, as the name might suggest, allows the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Key Usage Tips

If you do nothing, the DatePicker will start with today's date. However, if you want to set up an OnDateSetListener to find out when the date changes, you will need to call init() to do so, in which you also need to set the date.

DatePicker works well with Calendar and GregorianCalendar, in terms of setting and getting the year/month/day-of-month from the DatePicker and converting it into something you can use in your code.

API Level 11 introduced an optional CalendarView adjunct to the DatePicker, determined via setCalendarViewShown() or android:calendarViewShown. This works well on -normal screens in landscape and on -large/-xlarge screens. On -normal screens in portrait, the year portion of the picker may be chopped off to save room. Using the CalendarView option on -small screens is probably not a good idea.

However, on Android 5.0+, the CalendarView is *always* shown and cannot be removed, as the "picker" itself does not allow the user to pick a date. The user uses the CalendarView to pick a date, or taps on the year in the "picker" to choose a year. This means that DatePicker is not a particularly good widget to use, especially on smaller screens.

A Sample Usage

The sample project can be found in WidgetCatalog/DatePicker.

Layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
  android:gravity="center_horizontal">

  <DatePicker
    android:id="@+id/picker"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
    android:calendarViewShown="true"/>

  <CheckBox
    android:id="@+id/showCalendar"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:checked="true"
    android:text="@string/calendar"/>

</LinearLayout>
```

Activity:

```
package com.commonsware.android.wc.datepick;

import android.app.Activity;
import android.os.Build;
import android.os.Bundle;
import android.view.View;
import android.widget.CheckBox;
import android.widget.CompoundButton;
import android.widget.CompoundButton.OnCheckedChangeListener;
import android.widget.DatePicker;
import android.widget.DatePicker.OnDateChangedListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class DatePickerDemoActivity extends Activity implements
    OnCheckedChangeListener, OnDateChangedListener {
  DatePicker picker=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
    CheckBox cb=(CheckBox)findViewById(R.id.showCalendar);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.HONEYCOMB) {
      cb.setOnCheckedChangeListener(this);
    }
    else {
      cb.setVisibility(View.GONE);
    }

    GregorianCalendar now=new GregorianCalendar();

    picker=(DatePicker)findViewById(R.id.picker);
    picker.init(now.get(Calendar.YEAR), now.get(Calendar.MONTH),
                now.get(Calendar.DAY_OF_MONTH), this);
  }

  @Override
  public void onCheckedChanged(CompoundButton buttonView,
                               boolean isChecked) {
    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.HONEYCOMB) {
      picker.setCalendarViewShown(isChecked);
    }
  }

  @Override
  public void onDateChanged(DatePicker view, int year, int monthOfYear,
                            int dayOfMonth) {
    Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

    Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
         .show();
  }
}
```

The CheckBox is tied to the visibility of the CalendarView. Since this is only available on API Level 11 and higher, we simply remove the CheckBox on earlier versions of Android, so we do not have to worry about whether or not the CheckBox gets unchecked by the user.

Visual Representation

This is what a DatePicker looks like in a few different Android versions and configurations, based upon the sample app shown above.

Widget Catalog: ExpandableListView

Android does not have a "tree" widget, allowing users to navigate an arbitrary hierarchy of stuff. In large part, that is because such trees are difficult to navigate on small touchscreens with comparatively large fingers.

Android *does* have `ExpandableListView`, a subclass of `ListView` that supports a two-layer hierarchy: groups and children. Groups can be expanded to show their children or collapsed to hide them, and you can get control on various events for the groups or the children.

Key Usage Tips

Android offers an `ExpandableListActivity` as a counterpart to its `ListActivity`. However, it does not offer an `ExpandableListFragment`. This is not a major issue, as you can work with an `ExpandableListView` inside a regular `Fragment` yourself, just as you would for most other widgets not named `ListView`.

Rather than use a `ListAdapter` with `ExpandableListView`, you will use an `ExpandableListAdapter`, where you can control separate details for groups and children. These include:

- `SimpleExpandableListAdapter`, roughly analogous to `ArrayAdapter`, where your data resides in a `List` of `Map` objects for groups, and a `List` of a `List` of `Map` objects for the children
- `CursorTreeAdapter` and `SimpleCursorTreeAdapter`, roughly analogous to `CursorAdapter` and `SimpleCursorAdapter`, for mapping data in a `Cursor` to rows and columns

In many cases, though, the complexity of managing groups and children will steer you down the path of extending `BaseExpandableListAdapter` and handling all of the view construction yourself. There are many methods that you will need to implement:

- `getGroupCount()`, to return the number of groups
- `getGroup()` and `getGroupId()`, to return an `Object` and unique `int` ID for a group given its position
- `getGroupView()`, to return the `View` that should be used to render the group, perhaps using the built-in `android.R.layout.simple_expandable_list_item_1` that is set up for such groups and handles rendering the expanded and collapsed states
- `getChildrenCount()`, to return the number of children for a given group
- `getChild()` and `getChildId()`, to return an `Object` and unique `int` ID for a child given its position (and its group's position)
- `getChildView()`, to return the `View` that should be used to render the child, given its position and its group's position
- `isChildSelectable()`, to indicate if the user can select a given child, given its position and its group's position
- `hasStableIds()`, to indicate if the ID values you returned from `getGroupId()` and `getChildId()` will remain constant for the life of this adapter

There are four major events that you will be able to respond to with respect to the user's interaction with an `ExpandableListView`:

- Clicks on a child (`setOnChildClickListener()`)
- Clicks on a group (`setOnGroupClickListener()`)
- When groups expand (`setOnGroupExpandListener()`) or collapse (`setOnGroupCollapseListener()`)

If you use `setOnGroupClickListener()` to be notified about clicks on a group, be sure to return `false` from your implementation of the `onGroupClick()` method required by the `OnGroupClickListener` interface. If you return `true`, you consume the click event, which prevents `ExpandableListView` from using that event to expand or collapse the group.

A Sample Usage

The sample project can be found in [`WidgetCatalog/ExpandableListView`](WidgetCatalog/ExpandableListView).

Layout:

```
<ExpandableListView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/elv"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

</ExpandableListView>
```

JSON data:

```
{
  "Group A": ["Child A1", "Child A2", "Child A3"],
  "Group B": ["Child B1", "Child B2"],
  "Group C": ["Child C1"],
  "Group D": [],
  "Group E": ["Child E1", "Child E2", "Child E3"]
}
```

Activity:

```
package com.commonsware.android.wc.elv;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.ExpandableListAdapter;
import android.widget.ExpandableListView;
import android.widget.ExpandableListView.OnChildClickListener;
import android.widget.ExpandableListView.OnGroupClickListener;
import android.widget.ExpandableListView.OnGroupCollapseListener;
import android.widget.ExpandableListView.OnGroupExpandListener;
import android.widget.Toast;
import java.io.BufferedReader;
import java.io.InputStream;
import java.io.InputStreamReader;
import org.json.JSONObject;

public class MainActivity extends Activity implements
    OnChildClickListener, OnGroupClickListener, OnGroupExpandListener,
    OnGroupCollapseListener {
  private ExpandableListAdapter adapter=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    InputStream raw=getResources().openRawResource(R.raw.sample);
    BufferedReader in=new BufferedReader(new InputStreamReader(raw));
    String str;
    StringBuffer buf=new StringBuffer();

    try {
      while ((str=in.readLine()) != null) {
        buf.append(str);
        buf.append('\n');
      }

      in.close();

      JSONObject model=new JSONObject(buf.toString());

      ExpandableListView elv=(ExpandableListView)findViewById(R.id.elv);

      adapter=new JSONExpandableListAdapter(getLayoutInflater(), model);
      elv.setAdapter(adapter);

      elv.setOnChildClickListener(this);
      elv.setOnGroupClickListener(this);
      elv.setOnGroupExpandListener(this);
      elv.setOnGroupCollapseListener(this);
    }
    catch (Exception e) {
      Log.e(getClass().getName(), "Exception reading JSON", e);
    }
  }

  @Override
  public boolean onChildClick(ExpandableListView parent, View v,
                              int groupPosition, int childPosition,
                              long id) {
    Toast.makeText(this,
                   adapter.getChild(groupPosition, childPosition)
                          .toString(), Toast.LENGTH_SHORT).show();

    return(false);
  }

  @Override
  public boolean onGroupClick(ExpandableListView parent, View v,
                              int groupPosition, long id) {
    Toast.makeText(this, adapter.getGroup(groupPosition).toString(),
                   Toast.LENGTH_SHORT).show();

    return(false);
  }

  @Override
  public void onGroupExpand(int groupPosition) {
    Toast.makeText(this,
                   "Expanding: "
                       + adapter.getGroup(groupPosition).toString(),
                   Toast.LENGTH_SHORT).show();
  }

  @Override
  public void onGroupCollapse(int groupPosition) {
    Toast.makeText(this,
                   "Collapsing: "
                       + adapter.getGroup(groupPosition).toString(),
                   Toast.LENGTH_SHORT).show();
  }
}
```

This activity loads up a JSON file from a raw resource on the main application thread in `onCreate()`, which is not a good idea. It would be better to do that work in a background thread, perhaps an `AsyncTask` managed by a retained fragment. The implementation shown here is designed to keep the sample small, not to demonstrate the best way to load data from a raw resource.

Adapter:

```
package com.commonsware.android.wc.elv;

import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.BaseExpandableListAdapter;
import android.widget.TextView;
import java.util.Iterator;
import org.json.JSONArray;
import org.json.JSONException;
import org.json.JSONObject;

public class JSONExpandableListAdapter extends
    BaseExpandableListAdapter {
  LayoutInflater inflater=null;
  JSONObject model=null;

  JSONExpandableListAdapter(LayoutInflater inflater, JSONObject model) {
    this.inflater=inflater;
    this.model=model;
  }

  @Override
  public int getGroupCount() {
    return(model.length());
  }

  @Override
  public Object getGroup(int groupPosition) {
    @SuppressWarnings("rawtypes")
    Iterator i=model.keys();

    while (groupPosition > 0) {
      i.next();
      groupPosition--;
    }

    return(i.next());
  }

  @Override
  public long getGroupId(int groupPosition) {
    return(groupPosition);
  }

  @Override
  public View getGroupView(int groupPosition, boolean isExpanded,
                           View convertView, ViewGroup parent) {
    if (convertView == null) {
      convertView=
          inflater.inflate(android.R.layout.simple_expandable_list_item_1,
                           parent, false);
    }

    TextView tv=
        ((TextView)convertView.findViewById(android.R.id.text1));
    tv.setText(getGroup(groupPosition).toString());

    return(convertView);
  }

  @Override
  public int getChildrenCount(int groupPosition) {
    try {
      JSONArray children=getChildren(groupPosition);

      return(children.length());
    }
    catch (JSONException e) {
      // JSONArray is really annoying
      Log.e(getClass().getSimpleName(), "Exception getting children", e);
    }

    return(0);
  }

  @Override
  public Object getChild(int groupPosition, int childPosition) {
    try {
      JSONArray children=getChildren(groupPosition);

      return(children.get(childPosition));
    }
    catch (JSONException e) {
      // JSONArray is really annoying
      Log.e(getClass().getSimpleName(),
            "Exception getting item from JSON array", e);
    }

    return(null);
  }

  @Override
  public long getChildId(int groupPosition, int childPosition) {
    return(groupPosition * 1024 + childPosition);
  }

  @Override
  public View getChildView(int groupPosition, int childPosition,
                           boolean isLastChild, View convertView,
                           ViewGroup parent) {
    if (convertView == null) {
      convertView=
          inflater.inflate(android.R.layout.simple_list_item_1, parent,
                           false);
    }
```

```
    TextView tv=(TextView)convertView;
    tv.setText(getChild(groupPosition, childPosition).toString());

    return(convertView);
  }

  @Override
  public boolean isChildSelectable(int groupPosition, int childPosition) {
    return(true);
  }

  @Override
  public boolean hasStableIds() {
    return(true);
  }

  private JSONArray getChildren(int groupPosition) throws JSONException {
    String key=getGroup(groupPosition).toString();

    return(model.getJSONArray(key));
  }
}
```

This adapter wraps a `JSONObject` and assumes that the JSON structure is an object, keyed by strings, whose values are arrays of strings. The object returned by `getGroup()` is the key for that group's position; the object returned by `getChild()` is the string at that child's array index for it's group's array. Since the data structure is treated as immutable, and since there are no other better IDs in the data structure itself, the group ID is simply the group's position, and the child's ID is simply a mash-up of the group and child positions.

Visual Representation

This is what an `ExpandableListView` looks like in a few different Android versions and configurations, based upon the sample app shown above.

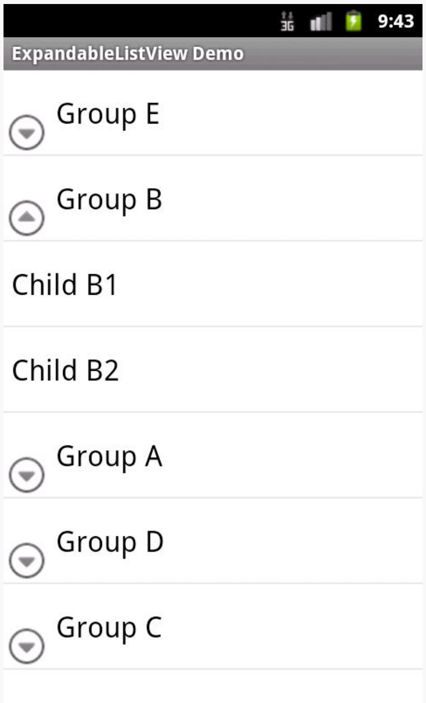

Figure 933: Android 2.3.3, Portrait

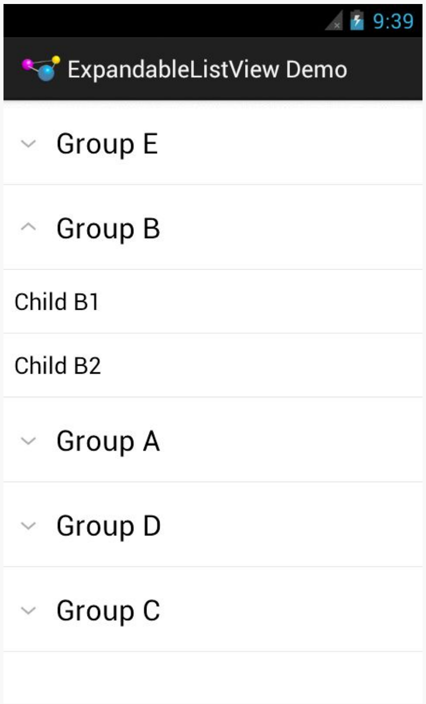

Figure 934: Android 4.0.3, Portrait

Note that while the data in the JSON file has the groups sorted alphabetically, because `JSONObject` effectively loads its data into a `HashMap`, the sorting gets lost in the data model, which is why the groups appear out of order.

Also note that the visual representation of the "collapsed" and "expanded" states is controlled by the `ExpandableListAdapter` and the view used for the groups. In this sample, we use `android.R.layout.simple_expandable_list_item_1` for the groups, which gives us the caret designation for expanded versus collapsed states in 4.0.3 and the lower-left arrowhead-in-circle icon for 2.3.3. You can create your own rows with your own indicators as you see fit.

Widget Catalog: SeekBar

SeekBar allows the user to choose a value along a continuous range by sliding a "thumb" along a horizontal line. In effect — and in practice, as it turns out – SeekBar is a user-modifiable ProgressBar.

Key Usage Tips

The value range of a SeekBar runs from 0 to a developer-set maximum value. As with ProgressBar, the default maximum is 100, but that can be changed via an android:max attribute or the setMax() method. The minimum value is always 0, so if you want a range starting elsewhere, just add your starting value to the actual value (obtained via getProgress()) to slide the range as desired.

You can find out about changes in the SeekBar value by attaching an OnSeekBarChangeListener implementation. The primary method on that interface is onProgressChanged(), where you are notified about changes in the progress value (second parameter) and whether that change was initiated directly by the user interacting with the widget (third parameter). The interface also has onStartTrackingTouch() and onStopTrackingTouch(), to indicate when the user is attempting to change the position of the thumb via the touchscreen, though these methods are less-commonly used.

A Sample Usage

The sample project can be found in WidgetCatalog/SeekBar.

Layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:gravity="center_vertical"
  tools:context=".MainActivity">

  <TextView
    android:id="@+id/value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="0"
    android:ems="2"
    android:gravity="right|center_vertical"
    android:layout_marginRight="10dp"
    android:textAppearance="@android:style/TextAppearance.Large"/>

  <SeekBar
    android:id="@+id/seek_bar"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:layout_marginRight="10dp"
    android:max="50"/>

</LinearLayout>
```

Activity:

```
package com.commonsware.android.wc.seekbar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.SeekBar;
import android.widget.SeekBar.OnSeekBarChangeListener;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnSeekBarChangeListener {
  TextView value=null;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    value=(TextView)findViewById(R.id.value);

    SeekBar seekBar=(SeekBar)findViewById(R.id.seek_bar);

    seekBar.setOnSeekBarChangeListener(this);
  }

  @Override
  public void onProgressChanged(SeekBar seekBar, int progress,
                                boolean fromUser) {
    value.setText(String.valueOf(progress));
  }
  @Override
  public void onStartTrackingTouch(SeekBar seekBar) {
    // no-op
  }

  @Override
  public void onStopTrackingTouch(SeekBar seekBar) {
    // no-op
  }
}
```

Widget Catalog: SlidingDrawer

Having some form of means of allowing the user to swipe to show more things is an important visual pattern. We saw this earlier in the book with the `ViewPager` container. And there are other modern techniques for doing this that you will see in apps like Google+.

`SlidingDrawer`, while implementing a variation on this pattern, is a bit out of date at present. Mostly, that's a question of its UI: tapping a drawer "handle" to open it is not what you tend to see nowadays. That being said, it works perfectly well, wrapping around a container to make it appear or disappear based on user input, complete with a sliding animation effect.

Note that `SlidingDrawer` was deprecated in API Level 17 (a.k.a., Android 4.2). This means that Google is steering you in other directions, including forking the AOSP code for `SlidingDrawer` and maintaining it yourself. The animator framework offers other ways of implementing sliding widgets that may be better suited for your UI, anyway.

Also note that `SlidingDrawer` is broken on Android 5.0, and so you *definitely* should be considering alternative widgets at this time.

Key Usage Tips

The `SlidingDrawer` itself is transparent, except for the button to trigger the slide and its accompanying horizontal bar. Hence, if you want the drawer contents to completely obscure what is outside of the drawer, you will need to use an appropriate background. Otherwise, the drawer contents and what lies outside the drawer will be alpha-blended based on their own translucency, as is seen in the screenshots later in this chapter.

The `SlidingDrawer` can be horizontal or vertical; it is vertical by default. However, it only slides one way (bottom-to-top for vertical, right-to-left for horizontal). There is no way to reverse the direction of the sliding effect.

You must supply `android:content` and `android:handle` attributes in `SlidingDrawer`, containing references to the widget that forms the content of the drawer and the drawer's handle, respectively. Typically, the drawer's handle is an `ImageView`. Note that you *must* supply a handle — you cannot skip either of these attributes.

A Sample Usage

The sample project can be found in [WidgetCatalog/SlidingDrawer]().

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <Button
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/drawer_closed"/>

  <SlidingDrawer
    android:id="@+id/drawer"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:content="@+id/content"
    android:handle="@+id/handle">

    <ImageView
      android:id="@id/handle"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:src="@drawable/tray_handle_normal"/>

    <Button
      android:id="@id/content"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:text="@string/drawer_msg"/>
  </SlidingDrawer>

</RelativeLayout>
```

Activity:

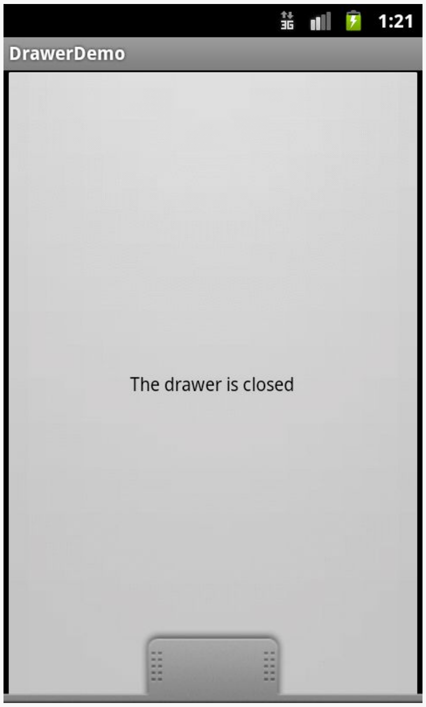
```
package com.commonsware.android.drawer;

import android.app.Activity;
import android.os.Bundle;

public class DrawerDemo extends Activity
{
    /** Called when the activity is first created. */
    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

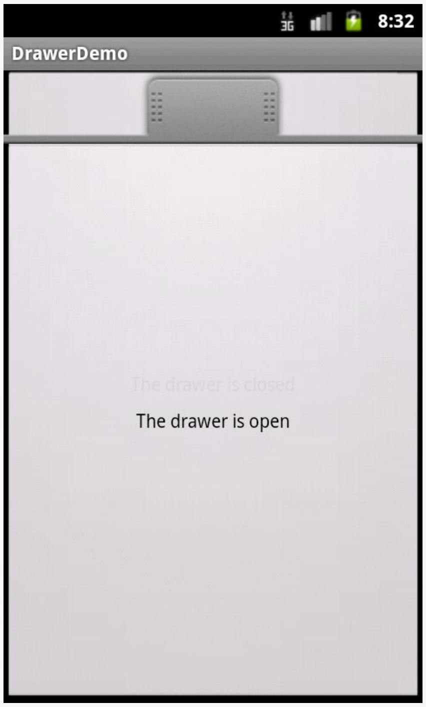
Visual Representation

This is what a `SlidingDrawer` looks like in a few different Android versions and configurations, based upon the sample app shown above.



The drawer is closed

Figure 938: Android 2.3.3, with Drawer Closed



The drawer is open

Widget Catalog: StackView

`StackView` is an `AdapterView`. Whereas `ListView` uses a horizontal scrolling list as its UI metaphor, `StackView` uses a stack of cards as its metaphor. Just as `ListView` shows a handful of rows, `StackView` shows a handful of cards. These cards can be swiped away via a swipe towards the southwest corner of the screen. The top card is fully visible; the edges of a few other cards can be seen but are otherwise obscured by cards "higher in the stack".

While certainly usable in activities and fragments, `StackView` was introduced in support of app widgets. App widgets like bookmarks, Google Books covers, and the like use `StackView` to show an item and allow users to navigate to the rest of the items by flipping these virtual cards.

Key Usage Tips

Generally speaking, working with `StackView` is not significantly different than is working with any other `AdapterView`. You create an `Adapter` defining the contents (in this case, defining the cards), you attach the `Adapter` to the `StackView`, and put the `StackView` somewhere on the screen.

As the cards overlap, however, transparency becomes an issue. If the top card is not completely opaque, you will see the card beneath it "peeking through" as its contents are blended in via the alpha channel. In some cases, this is a perfectly desirable outcome. However, if that is not what you want, make sure that the backgrounds of your overall container for the card's contents (e.g., a `RelativeLayout`) has an opaque background, such as a color with `FF` for the alpha value.

Also, since the objective is to have the children be visually stacked, the children cannot be the size of the `StackView` itself (e.g., the children cannot use `match_parent` for a dimension). `StackView` seems to work best with children that have explicit sizes (e.g., values in `dp`).

A Sample Usage

The sample project can be found in WidgetCatalog/StackView.

Activity Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<StackView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/details"
  android:layout_width="match_parent"
  android:layout_height="match_parent"/>
```

Item Layout:

```
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="200dp"
  android:layout_height="200dp"
  android:background="#FFFF0000"
  android:gravity="center"
  android:textAppearance="?android:attr/textAppearanceLarge"/>
```

Activity:

```
package com.commonsware.android.wc.stack;

import android.app.Activity;
import android.content.Context;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.StackView;

public class MainActivity extends Activity {
  static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
      "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
      "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
      "placerat", "ante", "porttitor", "sodales", "pellentesque",
      "augue", "purus" };
  StackView stack;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);
    stack=(StackView)findViewById(R.id.details);
    stack.setAdapter(new ItemAdapter(this, R.layout.item, items));
  }

  private static class ItemAdapter extends ArrayAdapter<String> {
    public ItemAdapter(Context context, int textViewResourceId,
                       String[] objects) {
      super(context, textViewResourceId, objects);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
      View result=super.getView(position, convertView, parent);

      result.setBackgroundColor(0xFF330000 + (position * 0x0A0A));

      return(result);
    }
  }
}
```

Visual Representation

This is what a `StackView` looks like in Android 4.0.3, based upon the sample app shown above:

Widget Catalog: TabHost and TabWidget

Before we had the action bar and ViewPager, we had TabHost and TabWidget as our means of displaying tabs. Nowadays, in most cases, using tabs in the action bar would be preferable, or perhaps using "swipey tabs" with ViewPager. However, there may be cases where the classic tabs are a better solution, or you may have inherited legacy code that still uses TabHost.

Deprecation Notes

Just as ListActivity helps one use a ListView, TabActivity helps one use a TabHost. However, TabActivity is marked as deprecated. That is largely because its parent class, ActivityGroup, is deprecated. While you can still use TabActivity, it is no longer recommended. It also is not necessary, as there are ways to use TabHost and TabWidget without using TabActivity, as will be demonstrated later in this chapter.

Key Usage Tips

There are a few widgets and containers you need to use in order to set up a tabbed portion of a view:

- TabHost is the overarching container for the tab buttons and tab contents
- TabWidget implements the row of tab buttons, which contain text labels and optionally contain icons
- FrameLayout is the container for the tab contents; each tab content is a child of the FrameLayout

You load contents into that `FrameLayout` in one of two ways:

1. You can define the contents simply as child widgets (or containers) of the `FrameLayout` in a layout XML file you are using for the whole tab setup
2. You can define the contents at runtime

Curiously, you do not define what goes in the tabs themselves, or how they tie to the content, in the layout XML file. Instead, you must do that in Java, by creating a series of `TabSpec` objects (obtained via `newTabSpec()` on `TabHost`), configuring them, then adding them in sequence to the `TabHost` via `addTab()`.

The two key methods on `TabSpec` are:

- `setContent()`, where you indicate what goes in the tab content for this tab, typically the `android:id` of the view you want shown when this tab is selected
- `setIndicator()`, where you provide the caption for the tab button and, in some flavors of this method, supply a `Drawable` to represent the icon for the tab

Note that tab "indicators" can actually be views in their own right, if you need more control than a simple label and optional icon.

Also note that you must call `setup()` on the `TabHost` before configuring any of these `TabSpec` objects. The call to `setup()` is not needed if you are using the `TabActivity` base class for your activity.

A Sample Usage

The sample project can be found in [WidgetCatalog/Tab]().

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<TabHost xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/tabhost"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <LinearLayout
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <TabWidget android:id="@android:id/tabs"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
    />
    <FrameLayout android:id="@android:id/tabcontent"
      android:layout_width="match_parent"
      android:layout_height="match_parent">
      <AnalogClock android:id="@+id/tab1"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
      />
      <Button android:id="@+id/tab2"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:text="A semi-random button"
      />
    </FrameLayout>
  </LinearLayout>
</TabHost>
```

Activity:

```
package com.commonsware.android.tabhost;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TabHost;

public class TabDemo extends Activity {
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);

    TabHost tabs=(TabHost)findViewById(R.id.tabhost);

    tabs.setup();

    TabHost.TabSpec spec=tabs.newTabSpec("tag1");

    spec.setContent(R.id.tab1);
    spec.setIndicator("Clock");
    tabs.addTab(spec);

    spec=tabs.newTabSpec("tag2");
    spec.setContent(R.id.tab2);
    spec.setIndicator("Button");
    tabs.addTab(spec);
  }
}
```

Note that ordinarily you would use icons with your tabs, and so the second parameter to `setIndicator()` would be a reference to a drawable resource. This particular sample skips the icons.

Visual Representation

This is what a `TabHost` and `TabWidget` look like in a few different Android versions and configurations, based upon the sample app shown above.

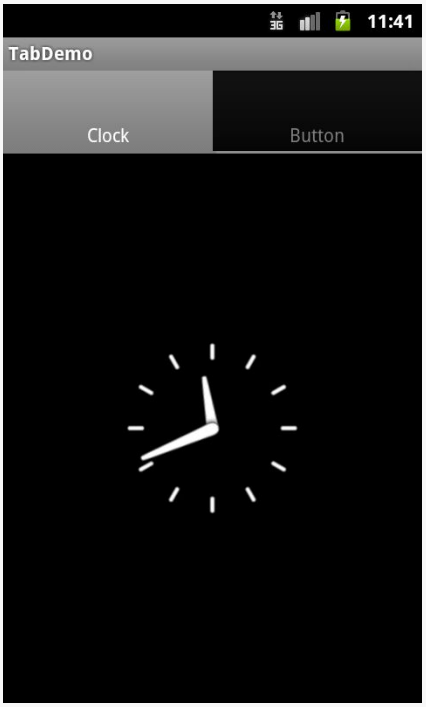

Figure 942: Android 2.3.3

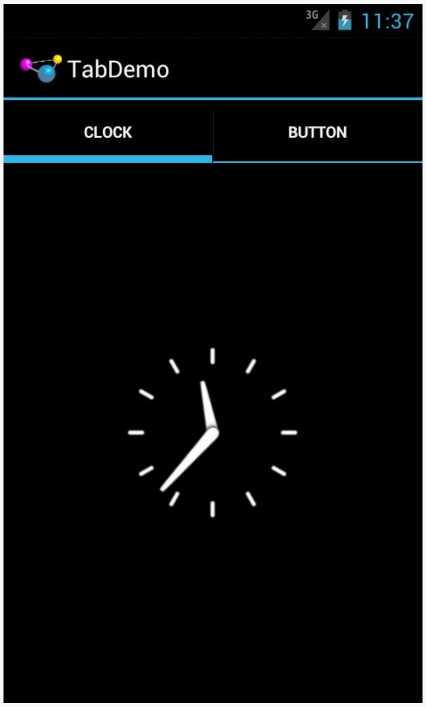

Figure 943: Android 4.0.3

Widget Catalog: TimePicker

Just as DatePicker allows the user to pick a date, TimePicker allows the user to pick a time. This widget is a bit simpler to use, insofar as you do not have the option of the integrated CalendarView as you do with DatePicker. In other respects, TimePicker follows the patterns established by DatePicker.

Note that TimePicker only supports hours and minutes, not seconds or finer granularity.

Key Usage Tips

With DatePicker, the act of supplying an OnDateSetListener also required you to supply the year/month/day to use as a starting point. TimePicker is more intelligently designed: setting the OnTimeSetListener is independent from adjusting the hour or minute.

As with DatePicker, TimePicker works well with Calendar and GregorianCalendar, in terms of setting and getting the hour/minute/second from the TimePicker and converting it into something you can use in your code.

There is a bug in Android 4.0/4.0.3 in which your OnTimeSetListener is not invoked when the user changes between AM and PM when viewing the TimePicker in 12-hour display mode.

A Sample Usage

The sample project can be found in WidgetCatalog/TimePicker.

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
  android:gravity="center_vertical">

  <TimePicker
    android:id="@+id/picker"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

</LinearLayout>
```

Activity:

```
package com.commonsware.android.wc.timepick;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TimePicker;
import android.widget.TimePicker.OnTimeChangedListener;
import android.widget.Toast;
import java.util.Calendar;

public class TimePickerDemoActivity extends Activity implements
    OnTimeChangedListener {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    TimePicker picker=(TimePicker)findViewById(R.id.picker);

    picker.setOnTimeChangedListener(this);
  }

  @Override
  public void onTimeChanged(TimePicker view, int hourOfDay, int minute) {
    Calendar then=Calendar.getInstance();

    then.set(Calendar.HOUR_OF_DAY, hourOfDay);
    then.set(Calendar.MINUTE, minute);
    then.set(Calendar.SECOND, 0);

    Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_SHORT)
         .show();
  }
}
```

Widget Catalog: ViewFlipper

A `ViewFlipper` behaves a bit like a `FrameLayout` that is set up such that only one child can be visible at a time. You can control which of those children is visible, either by index or via `showNext()`/`showPrevious()` methods to rotate between them.

You can also set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.

And, you can set up `ViewFlipper` to automatically flip between children on a specified period, without further developer involvement. This, coupled with the animation, can be used for news tickers, ad banner rotations, or the like where light animations (e.g., fade out and fade in) can be used positively.

Key Usage Tips

`ViewFlipper` can have as many children as needed (within memory constraints), though you will want at least two for it to be meaningful.

By default, the transition between children is an immediate "smash cut" — the old one vanishes and the new one appears instantaneously. You can call `setInAnimation()` and/or `setOutAnimation()` to supply [an `Animation` object or resource](#) to use for the transitions instead.

By default, the `ViewFlipper` will show its first child and stay there. You can manually flip children via `showNext()`, `showPrevious()`, and `setDisplayedChild()`, the latter of which taking a position index of which child to display. You can also have automatic flipping, by one of two means:

1. In your layout, `android:flipInterval` will set up the amount of time to display each child before moving to the next, and `android:autoStart` will indicate if the automated flipping should begin immediately or not
2. In Java, `setFlipInterval()` serves the same role as `android:flipInterval`, and you can control when flipping is enabled via `startFlipping()` and `stopFlipping()`

A Sample Usage

The sample project can be found in [WidgetCatalog/ViewFlipper]().

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
  <ViewFlipper android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
  </ViewFlipper>
</LinearLayout>
```

Activity:

```
package com.commonsware.android.flipper2;

import android.app.Activity;
import android.os.Bundle;
import android.view.ViewGroup;
import android.widget.Button;
import android.widget.ViewFlipper;

public class FlipperDemo2 extends Activity {
  static String[] items={"lorem", "ipsum", "dolor", "sit", "amet",
                          "consectetuer", "adipiscing", "elit",
                          "morbi", "vel", "ligula", "vitae",
                          "arcu", "aliquet", "mollis", "etiam",
                          "vel", "erat", "placerat", "ante",
                          "porttitor", "sodales", "pellentesque",
                          "augue", "purus"};
  ViewFlipper flipper;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);
    flipper=(ViewFlipper)findViewById(R.id.details);

    for (String item : items) {
      Button btn=new Button(this);

      btn.setText(item);

      flipper.addView(btn,
                      new ViewGroup.LayoutParams(
                              ViewGroup.LayoutParams.FILL_PARENT,
                              ViewGroup.LayoutParams.FILL_PARENT));
    }

    flipper.setFlipInterval(2000);
    flipper.startFlipping();
  }
}
```

Visual Representation

There is no visual representation of a `ViewFlipper` itself, as it renders no pixels on its own. Rather, it simply shows the current child.

Chrome and Chrome OS

Ever since Android and Chrome were moved under the same executive within Google, rumors abounded that Android and Chrome OS would merge in one form or fashion.

In 2015, Google started down that path, offering the ability for developers to start packaging Android apps to run on Chrome OS. This is currently in a beta state, though it is likely to reach a full production-level state sometime in 2015.

Right now, the official support is limited to Chrome OS. However, the tools used to package these apps also work on the Chrome desktop browser. It is likely that, at some point, not only will Google support Chrome OS in production for Android apps, but also allow them on the Chrome desktop browser.

While Chromebooks appear to be reasonably popular (a few million sold per year in 2013 and 2014), the bigger market is for users of the desktop Chrome browser. In 2013, Google claimed 750 million active users of Chrome. While that number probably includes some Android and Chrome OS users, it would appear that there are hundreds of millions of desktop users as well.

For developers distributing apps through public channels, reaching Chrome and Chrome OS users could substantially increase the size of their available markets. For developers creating apps for internal use, Chrome and Chrome OS offer the ability to "write once, run on all form factors", with Chrome and Chrome OS covering desktops, notebooks, and netbooks, to go along with Android's native phones, tablets, and TVs.

NOTE: the material covered in this chapter pertains to a beta release of this technology. The technology itself may change substantially prior to release, as may the tools used to get your Android apps onto Chrome/Chrome OS environments.

These changes may also evolve a lot more rapidly than will this chapter, so bear that in mind when reading the following material.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Welcome to the ARC

Here, "ARC" is not referring to Paul Graham's Lisp dialect, nor the American Red Cross, nor a fictional energy source for a superhero.

Instead, it is short for App Runtime for Chrome.

ARC is a Chrome extension, powered by Native Client (NaCl), that provides an Android runtime capable of running a **single app** (more or less). This is in contrast to Android itself, whether on hardware or SDK-style emulators, which can run several apps.

It is unclear whether ARC will remain a Chrome extension long-term, or whether it might be "baked" into Chrome and Chrome OS themselves at some future time.

Note that the process of creating your ARC app is *not* creating some sort of HTML5 UI. You cannot take the ARC app and run it in, say, Firefox.

The ARC Welder

Right now, the way that people wind up working with ARC is via the ARC Welder. This provides two things of importance:

1. The ARC extension itself, to be able to run…
2. …Chrome apps (extensions) created via the ARC Welder from an Android APK

For creating ARC apps, and for running them, right now you need the ARC Welder set up in your Chrome browser or your Chrome OS device. Long-term, it is likely that there will be some other means of getting the ARC extension for running ARC apps, and that the ARC Welder will be relegated to a developer tool for packaging up an ARC app.

To install ARC Welder on either Chrome OS or the Chrome desktop browser, visit the ARC Welder app on the Chrome Web Store. This will download ~114MB of material, in the form of a CRX file (Chrome extension). Note that it can be installed on Chromium as well, particularly for Linux developers who have opted for Chromium over Chrome.

At this point, ARC Welder should show up in the list of installed apps in your browser:

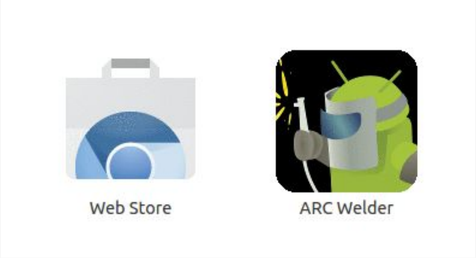

Figure 947: ARC Welder, As Seen in Chrome Desktop List of Apps

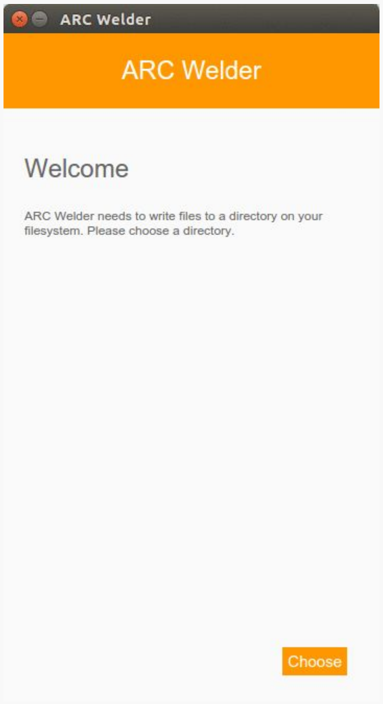
Launching it will prompt you to choose a directory for ARC Welder to use for its files. This is a combination working directory and standard location for output, so you probably do not want to use a temporary directory (e.g., `/tmp` on OS X or Linux).



Welcome

ARC Welder needs to write files to a directory on your filesystem. Please choose a directory.

Figure 948: ARC Welder, First-Launch Opening Screen

On Chrome OS, it is unclear where Google actually expects you to create this directory, though "Downloads" seems to work.

Once you have chosen this directory, you are ready to start converting apps for use with ARC.

Packaging Your Android App for Chrome

Now, you are in position to create the ARC app, assuming that you have an Android app that you want to try out.

ARC Welder

Given that you have installed ARC Welder on your Chrome browser or Chrome OS machine, run ARC Welder, to bring up the main ARC Welder UI:

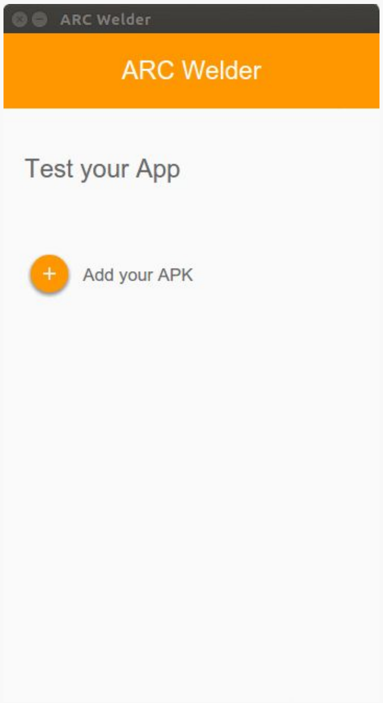


Figure 949: ARC Welder, Standard Opening Screen

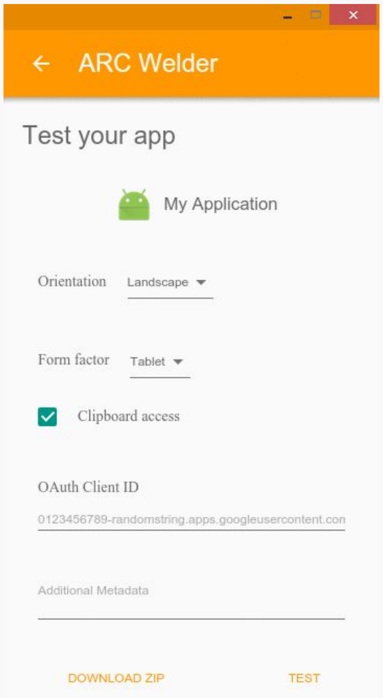
Click the round orange "plus" button to pick an APK off of your development machine. Note that APKs built by Eclipse will be under the `bin/` directory of your project, while APKs built by Android Studio will be under the `build/outputs/apk/` directory of the module (e.g., `app/`). Also note that this window does not seem to support drag-and-drop — you will need to use the file-open dialog that appears when clicking the "plus" button.

Once you have chosen an APK — and after a brief bit of processing – the ARC Welder UI will show you your app's icon and label, along with some UI choices for you to make:



Test your app

My Application

Orientation Landscape

Form factor Tablet

☑ Clipboard access

OAuth Client ID

0123456789-randomstring.apps.googleusercontent.con

Additional Metadata

Figure 950: ARC Welder, App Configuration Screen

The “Orientation” drop down lets you choose whether your default behavior is to have the launcher activity appear in landscape or portrait. However, as is noted later in this chapter, manifest settings will also play a role, particularly for other activities in your app.

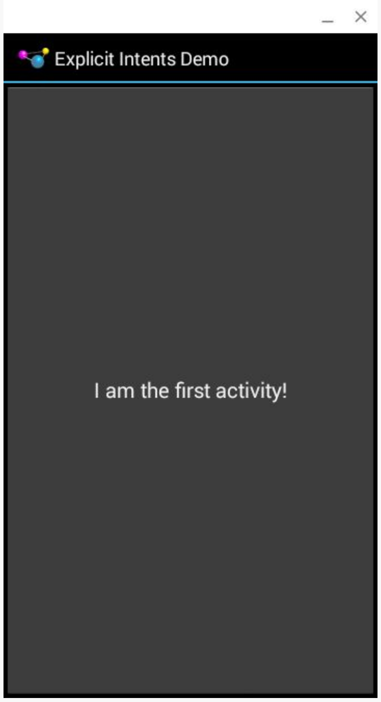
The “Form Factor” radio buttons indicate how big of a window should be allocated for your activity. Your choices are “Phone” (small), “Tablet” (medium), “Maximized” (large), and “Fullscreen”. The “Fullscreen” option did not work in light testing on Chrome on the desktop, though it works fine when using ARC Welder on Chrome OS.

You also have a checkbox for whether you need clipboard access, along with “OAuth Client ID” and “Additional Metadata” fields. Those latter bits of information are part of standard Chrome extension packaging and, while you are getting started with ARC, can be ignored.

Buttons at the bottom allow you to download a ZIP file that is the packaged ARC app and to actually run the app in ARC on your desktop. The back button in the app bar at the top will return you to the main ARC Welder screen.

Note that at the present time ARC Welder appears to only allow you to have one ARC app installed at a time, so if you choose “Launch App” to run your app, and you had done this previously, you will be prompted to have ARC Welder remove the previous app. This includes running the same app, after having changed it in ARC Welder (e.g., switching from landscape to portrait).

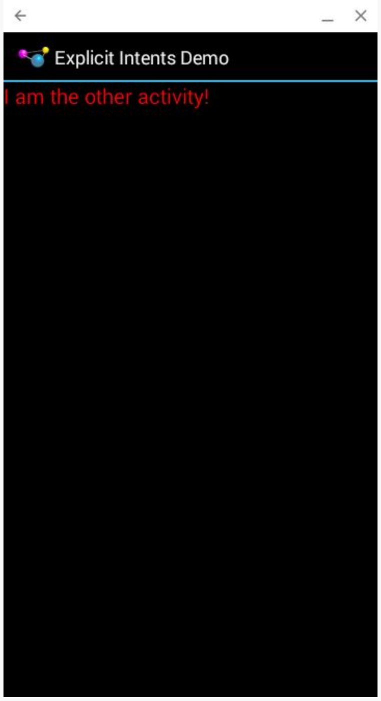
Running the app gives you a window that has your requested Android UI in it:



I am the first activity!

Figure 951: Explicit Intents Demo App, First Activity, in ARC

If you launch another activity of yours via `startActivity()`, a BACK button will appear in the title bar of the window:



I am the other activity!

Figure 952: Explicit Intents Demo App, Second Activity, in ARC

Tapping that returns you to the previous activity. Note that the `Esc` key will also return you to the previous activity, much as it does in the Android SDK emulator.

Clicking the "Download ZIP" button will pop up a file-save dialog, for you to choose where to save the ARC app. By default it is a file, named the same as the APK file but with a `.zip` extension, located in the directory that you designated for ARC Welder to use on your machine.

Ummm… What About the Command-Line? Or an IDE?

At the present time, the only official way to build an ARC app involves the use of the ARC Welder, which is a GUI.

That being said, the ZIP file that comprises your ARC app is *very* simple, and is mostly a static wrapper around your APK file. Some of the details collected in the ARC Welder UI, like your desired window size and orientation, are encoded into the `manifest.json` in the root of the ZIP file, as with any Chrome extension. Hence, it should not be long before somebody creates a Gradle plugin or other options for creating an ARC app from an APK that can be automated.

Distribution Options

Of course, creating an ARC app is pointless if nobody but you can run it. If you use ARC Welder to save the ZIP file, you have the options of distributing it to other Chrome users who have ARC Welder installed.

The official solution is to publish on the Chrome Web Store. This may be a reasonable option for developers used to distributing through the Play Store or similar public distribution channels.

For your own testing, Google recommends testing on Chrome OS and packaging your APK via ARC Welder on that Chrome OS device. While that is OK for developers, that has issues for distributing to testers, clients, etc.

For private distribution, the simplest solution at the moment is to use your ARC app as an “unpacked extension”. Here, “unpacked extension” means “unZIP the ZIP file into a directory”.

To do this:

1. UnZIP the ZIP file into an empty directory. For desktop Chrome users, that directory could be anywhere. If you want to transfer the app to a Chrome OS environment, you may wish to unZIP it onto some removable medium (USB thumb drive, SD card, etc.) that your Chrome OS device supports.
2. In Chrome (desktop or Chrome on Chrome OS), visit the `chrome://extensions/` local URL. That will bring up a page listing your installed extensions:

Figure 955: Chrome Extensions Screen, With ARC Installed

The pink warning box appears to be an artifact of how ARC apps are packaged today and do not seem to be indicative of an actual problem.

At this point, the app will be installed alongside your other apps and can be launched normally.

Hopefully, future editions of this chapter will demonstrate packaging an ARC app as a CRX file that can be more seamlessly distributed (e.g., to company employees).

Trying Your App

Now that you can get your ARC app running on Chrome OS and the Chrome desktop browser, you can start testing your app to see what behaves and what does not.

I Can Haz Logs?

Alas, it is likely that not everything is going to work, and you are going to encounter some amount of problems. For those, it would be useful to get at LogCat, much along the lines of how you diagnose problems in Android devices and emulators.

Unfortunately, the previous instructions for getting at LogCat no longer work as of Chrome OS 45, as Google has not bothered updating the ARC Welder documentation.

Your App on Chrome OS

The ARC environment runs a lot like an Android emulator, but it does not precisely line up with the emulators that you are used to, let alone Android devices. As such, your app may require some amount of adjustment to work well in ARC, much as it may require some amount of fine-tuning for use on a TV. Also, ARC presents its own roster of characteristics, just as phones and tablets will differ among themselves, and your app will need to accommodate all of this.

So, what does ARC look like, from your app's standpoint?

NOTE: Most of what is in this section is based upon some basic testing of ARC on Chrome OS 45, as expected behavior is mostly undocumented. This is also an area that is likely to change significantly over time, hopefully mostly improvements with few regressions.

Environment

At present, ARC is powered by API Level 19 (KitKat) on desktop Chrome and API Level 21 (Lollipop) on Chrome OS 45, and so should generally behave as an API Level 19 device.

We can tell this by logging `Build.VERSION.SDK_INT`, along with other values, as seen in the [Introspection/EnvDump] sample app. This has a single activity, designed to collect a bunch of device data and dump it to LogCat:

```
package com.commonsware.android.envdump;

import android.app.Activity;
import android.app.ActivityManager;
import android.content.pm.FeatureInfo;
import android.content.res.Configuration;
import android.os.Build;
import android.os.Bundle;
import android.util.DisplayMetrics;
import android.util.Log;

public class MainActivity extends Activity {
  private static final String TAG="EnvDump";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    logBuildValues();
    logSystemFeatures();
    logActivityManagerStuff();
    logDisplayMetrics();
    logConfiguration();
  }

  private void logBuildValues() {
    Log.d(TAG, "Build.VERSION.SDK_INT="+Build.VERSION.SDK_INT);

    Log.d(TAG, "Build.BRAND="+Build.BRAND);
    Log.d(TAG, "Build.DEVICE="+Build.DEVICE);
    Log.d(TAG, "Build.DISPLAY="+Build.DISPLAY);
    Log.d(TAG, "Build.HARDWARE="+Build.HARDWARE);
    Log.d(TAG, "Build.ID="+Build.ID);
    Log.d(TAG, "Build.MANUFACTURER="+Build.MANUFACTURER);
    Log.d(TAG, "Build.MODEL="+Build.MODEL);
    Log.d(TAG, "Build.PRODUCT="+Build.PRODUCT);
    Log.d(TAG, "Build.PRODUCT="+Build.PRODUCT);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
      StringBuilder buf=new StringBuilder();

      for (String abi : Build.SUPPORTED_ABIS) {
        if (buf.length() > 0) {
          buf.append(',');
        }

        buf.append(abi);
      }

      Log.d(TAG, "Build.SUPPORTED_APIS=" + buf);
    }
    else {
      Log.d(TAG, "Build.CPU_API="+Build.CPU_ABI);
      Log.d(TAG, "Build.CPU_API2="+Build.CPU_ABI2);
    }
  }

  private void logSystemFeatures() {
    for (FeatureInfo feature :
        getPackageManager().getSystemAvailableFeatures()) {
      Log.d(TAG, "System Feature: "+feature.name);
    }
  }
  private void logActivityManagerStuff() {
    ActivityManager mgr=(ActivityManager)getSystemService(ACTIVITY_SERVICE);

    Log.d(TAG, "heap limit="+mgr.getMemoryClass());
    Log.d(TAG, "large-heap limit="+mgr.getLargeMemoryClass());
  }

  private void logDisplayMetrics() {
    DisplayMetrics dm=new DisplayMetrics();

    getWindowManager().getDefaultDisplay().getMetrics(dm);

    Log.d(TAG, "DisplayMetrics.densityDpi="+dm.densityDpi);
    Log.d(TAG, "DisplayMetrics.xdpi="+dm.xdpi);
    Log.d(TAG, "DisplayMetrics.ydpi="+dm.ydpi);
    Log.d(TAG, "DisplayMetrics.scaledDensity="+dm.scaledDensity);
    Log.d(TAG, "DisplayMetrics.widthPixels="+dm.widthPixels);
    Log.d(TAG, "DisplayMetrics.heightPixels="+dm.heightPixels);
  }

  private void logConfiguration() {
    Configuration cfg=getResources().getConfiguration();

    Log.d(TAG, "Configuration.densityDpi="+cfg.densityDpi);
    Log.d(TAG, "Configuration.fontScale="+cfg.fontScale);
    Log.d(TAG, "Configuration.hardKeyboardHidden="+cfg.hardKeyboardHidden);
    Log.d(TAG, "Configuration.keyboard="+cfg.keyboard);
    Log.d(TAG, "Configuration.keyboardHidden="+cfg.keyboardHidden);
    Log.d(TAG, "Configuration.locale="+cfg.locale);
    Log.d(TAG, "Configuration.mcc="+cfg.mcc);
    Log.d(TAG, "Configuration.mnc="+cfg.mnc);

D/EnvDump (  204): Configuration.navigation=2
D/EnvDump (  204): Configuration.navigationHidden=1
D/EnvDump (  204): Configuration.orientation=1
D/EnvDump (  204): Configuration.screenHeightDp=615
D/EnvDump (  204): Configuration.screenWidthDp=360
D/EnvDump (  204): Configuration.touchscreen=1
```

Of note:

- The `Build` values clearly indicate that we are on ARC, but provide no details about the actual underlying hardware
- The CPU is reported as ARM, despite the fact that it is actually x86, because right now ARC treats all devices as ARM, as will be explored later in this chapter
- While the heap limit is generous (256MB), asking for a large heap will do you no good, as it is the same limit
- The screen density values, particularly `xdpi` and `ydpi` on `DisplayMetrics`, are wrong
- It does correctly report the existence of a hardware keyboard and a navigation device (in this case, referring to the arrow keys on the Chromebook's keyboard)

Trying the same `EnvDump` app on an Acer CB5-311 Chromebook (13" 1080p display, powered by ARM) gives us a nearly identical report:

```
D/EnvDump (  204): Build.VERSION.SDK_INT=19
D/EnvDump (  204): Build.BRAND=chromium
```

```
D/EnvDump (  204): Build.DEVICE=generic
D/EnvDump (  204): Build.DISPLAY=41.4410.244.23
D/EnvDump (  204): Build.HARDWARE=arc
D/EnvDump (  204): Build.ID=41.4410.244.23
D/EnvDump (  204): Build.MANUFACTURER=chromium
D/EnvDump (  204): Build.MODEL=App Runtime for Chrome
D/EnvDump (  204): Build.PRODUCT=arc
D/EnvDump (  204): Build.PRODUCT=arc
D/EnvDump (  204): Build.CPU_API=armeabi-v7a
D/EnvDump (  204): Build.CPU_API2=armeabi
D/EnvDump (  204): System Feature: android.hardware.faketouch
D/EnvDump (  204): System Feature: android.hardware.wifi
D/EnvDump (  204): System Feature: android.hardware.location.network
D/EnvDump (  204): System Feature: android.hardware.usb.accessory
D/EnvDump (  204): System Feature: android.hardware.camera.any
D/EnvDump (  204): System Feature: android.hardware.microphone
D/EnvDump (  204): System Feature: android.hardware.location
D/EnvDump (  204): System Feature: android.hardware.location.gps
D/EnvDump (  204): System Feature: android.hardware.screen.landscape
D/EnvDump (  204): System Feature: android.hardware.camera.front
D/EnvDump (  204): System Feature: android.hardware.screen.portrait
D/EnvDump (  204): System Feature: null
D/EnvDump (  204): heap limit=128
D/EnvDump (  204): large-heap limit=128
D/EnvDump (  204): DisplayMetrics.densityDpi=160
D/EnvDump (  204): DisplayMetrics.xdpi=160.0
D/EnvDump (  204): DisplayMetrics.ydpi=160.0
D/EnvDump (  204): DisplayMetrics.scaledDensity=1.0
D/EnvDump (  204): DisplayMetrics.widthPixels=360
D/EnvDump (  204): DisplayMetrics.heightPixels=640
D/EnvDump (  204): Configuration.densityDpi=160
D/EnvDump (  204): Configuration.fontScale=1.0
D/EnvDump (  204): Configuration.hardKeyboardHidden=1
D/EnvDump (  204): Configuration.keyboard=2
D/EnvDump (  204): Configuration.keyboardHidden=1
D/EnvDump (  204): Configuration.locale=en_US
D/EnvDump (  204): Configuration.mcc=0
D/EnvDump (  204): Configuration.mnc=0
D/EnvDump (  204): Configuration.navigation=2
D/EnvDump (  204): Configuration.navigationHidden=1
D/EnvDump (  204): Configuration.orientation=1
D/EnvDump (  204): Configuration.screenHeightDp=615
D/EnvDump (  204): Configuration.screenWidthDp=360
D/EnvDump (  204): Configuration.touchscreen=1
```

Curiously, despite the larger screen size, we have a lower heap limit (128MB). Otherwise, the report appears identical.

Running the same app on desktop Chrome gives us:

```
D/EnvDump (  204): Build.VERSION.SDK_INT=19
D/EnvDump (  204): Build.BRAND=chromium
D/EnvDump (  204): Build.DEVICE=generic
D/EnvDump (  204): Build.DISPLAY=41.4410.244.23
D/EnvDump (  204): Build.HARDWARE=arc
D/EnvDump (  204): Build.ID=41.4410.244.23
D/EnvDump (  204): Build.MANUFACTURER=chromium
```

```
D/EnvDump (  204): Build.MODEL=App Runtime for Chrome
D/EnvDump (  204): Build.PRODUCT=arc
D/EnvDump (  204): Build.PRODUCT=arc
D/EnvDump (  204): Build.CPU_API=armeabi-v7a
D/EnvDump (  204): Build.CPU_API2=armeabi
D/EnvDump (  204): System Feature: android.hardware.faketouch
D/EnvDump (  204): System Feature: android.hardware.wifi
D/EnvDump (  204): System Feature: android.hardware.location.network
D/EnvDump (  204): System Feature: android.hardware.usb.accessory
D/EnvDump (  204): System Feature: android.hardware.camera.any
D/EnvDump (  204): System Feature: android.hardware.microphone
D/EnvDump (  204): System Feature: android.hardware.location
D/EnvDump (  204): System Feature: android.hardware.location.gps
D/EnvDump (  204): System Feature: android.hardware.screen.landscape
D/EnvDump (  204): System Feature: android.hardware.camera.front
D/EnvDump (  204): System Feature: android.hardware.screen.portrait
D/EnvDump (  204): System Feature: null
D/EnvDump (  204): heap limit=256
D/EnvDump (  204): large-heap limit=256
D/EnvDump (  204): DisplayMetrics.densityDpi=160
D/EnvDump (  204): DisplayMetrics.xdpi=160.0
D/EnvDump (  204): DisplayMetrics.ydpi=160.0
D/EnvDump (  204): DisplayMetrics.scaledDensity=1.0
D/EnvDump (  204): DisplayMetrics.widthPixels=360
D/EnvDump (  204): DisplayMetrics.heightPixels=640
D/EnvDump (  204): Configuration.densityDpi=160
D/EnvDump (  204): Configuration.fontScale=1.0
D/EnvDump (  204): Configuration.hardKeyboardHidden=1
D/EnvDump (  204): Configuration.keyboard=2
D/EnvDump (  204): Configuration.keyboardHidden=1
D/EnvDump (  204): Configuration.locale=en_US
D/EnvDump (  204): Configuration.mcc=0
D/EnvDump (  204): Configuration.mnc=0
D/EnvDump (  204): Configuration.navigation=2
D/EnvDump (  204): Configuration.navigationHidden=1
D/EnvDump (  204): Configuration.orientation=1
D/EnvDump (  204): Configuration.screenHeightDp=615
D/EnvDump (  204): Configuration.screenWidthDp=360
D/EnvDump (  204): Configuration.touchscreen=1
```

Of note here, the `android.hardware.location.gps` feature is still reported, despite the fact that the notebook used for this test definitely does *not* have a GPS radio. Since there is no evidence that either of the Chromebooks have a GPS radio, this indicates that either ARC has a bug or it is faking location data in an effort to maximize compatibility with apps.

Lifecycle Events

The biggest issue — and what will be a show-stopper for many Android developers at the moment — is that the user can close the window for the app, and the foreground activity is not called with `onPause()`, let alone `onStop()`. The current behavior is as if the foreground process could be terminated due to low memory conditions, with no lifecycle methods called at all.

With luck, this will get fixed.

Outside of that, lifecycle methods of activities behave pretty much as normal. While `onPause()` and `onStop()` are not called when the app window is closed, they *will* be called in other standard scenarios, such as when the user presses the BACK button in the title bar of the app window.

What makes the bug more pernicious is that there *is* no BACK button for the root activity of your task (in this case, your `LAUNCHER` activity). The user will only ever leave the app by closing the app window.

Also, given that Chrome OS has a windowed UI, lifecycle events also tie into window usage. Your activity will be paused and stopped, with appropriate lifecycle method calls, if the user navigates to another Chrome OS window (e.g., Chrome itself). The lifecycle events will occur some seconds after the other window takes over the foreground, as if a screen timeout occurred. The same effect can be seen with desktop Chrome — your activity will be paused and stopped after a delay if the user switches to a new window.

Touchscreen and Keyboard Input

Most Chrome OS devices lack touchscreens. As such, ARC implements a "faketouch" environment, where touch events are triggered using a touchpad or mouse. This works, but it does have ramifications:

- Any gestures or other touch input requiring more than one pointer (e.g., pinch to zoom) will be unavailable
- As with the Android emulator, some widgets, like `ViewPager`, are just annoying to try to manipulate with a mouse

Clearly, ARC offers more touch options than does something like Android TV or Fire TV. That being said, you will want to skew your app towards simpler touch events, plus keyboard support. Key events work fine, including tab and arrow keys for built-in focus navigation. You may wish to adjust your app for more appropriate focus flow, though.

Size and Orientation

In ARC Welder, you choose a screen size and orientation as part of packaging your app. However, if you have one or more activities with `android:screenOrientation` attributes, those attributes will take precedence. The orientation that you provide to

ARC Welder serves as the default, for any activities that do not specify an orientation.

Presently, the user cannot affect anything about the window size. However, reports are that the Chrome 42 version of ARC will allow you to opt into having a resizable window for your app.

NDK

The good news is that NDK binaries can work. However, you may run into issues.

Curiously, even though many Chrome OS devices are powered by x86 CPUs, ARC does not presently use x86 NDK binaries. It always uses ARM binaries, transcoding instructions from ARM to x86 as needed. Since most Android developers start off supporting ARM binaries in the first place, your code will not have to change in all likelihood. However, NDK code may perform worse than expected on Chrome OS devices, simply due to the ARM->x86 conversion process. It seems probable that ARC will support native x86 NDK binaries in the future.

Also, not everything will necessarily work on ARC, even if it works on Android proper, due to the way ARC is compiled. One noteworthy example of this is SQLCipher for Android. Chrome's NaCl layer, that powers ARC, does not appear to support `O_CLOEXEC`, which SQLCipher requires, and as such SQLCipher will crash. Whether this gets fixed in a future version of ARC remains to be seen.

Storage

Internal and external storage both work fine on Chrome and Chrome OS. However, outside of debugging tools, you do not have any ability to work with the files themselves as a developer, much like how you are limited in accessing files that are part of an emulator image.

You do not have direct filesystem access to the host computer (e.g., the Chromebook). However, `ACTION_GET_CONTENT` will bring up a platform-specific option for choosing a file, such as a file-open dialog for desktop Chrome. What you get back is a `Uri` that can be used via `ContentResolver` to read in that content (and, possibly, modify the file — this has not been tested). In this fashion, you can get to removable storage as well, just not with local filesystem access.

Internet Access

On the whole, HTTP access “just works”, whether you are using `WebView` or `HttpUrlConnection`.

However, Chrome and Chrome OS are not supporting all socket options at this time, including `SO_KEEPALIVE`.

SSL also “just works”, subject to the same sorts of limitations that you see in normal Android development, such as what root certificates are available for validating the SSL certificate for a particular `https://` URL.

The author has not tested lower-level socket operations at this time.

System Capabilities

While Chrome OS devices may not have a GPS chip, ARC still claims to support GPS, in terms of available system features and in terms of what `LocationManager` offers. The locations provided by `LocationManager` are frighteningly good, based (presumably) on known locations of the WiFi hotspots or routers that you connect to.

ARC supports use of the `Camera` class, for direct access to the camera, on Chrome OS. It does not appear to do so with ARC on desktop Chrome. It also supports `ACTION_IMAGE_CAPTURE` for launching a stock camera UI for taking a picture. To support this, a limited edition of the AOSP Camera app appears to be part of ARC.

Audio playback APIs, like `MediaPlayer`, appear to work, though perhaps not for the full slate of standard Android codecs. The author has not tried video playback.

Some capabilities that might exist on the hardware underlying Chrome or Chrome OS will not be available to ARC apps at this time. This includes:

- Bluetooth
- NFC
- USB

Inter-App Links

Some `ACTION_VIEW` `Intent` structures will work. On a regular Android device, they would pull up some third-party app. On Chrome and Chrome OS, they will do whatever Chrome itself might do with that `Uri`. So, for example, an `http://` or `https://` `Uri` will open up a tab in a Web browser for that URL. Interestingly, at least for desktop Chrome on Linux, the URL is opened in the user's default browser, whether or not that browser is Chrome.

However, since the ARC Welder does not support multiple ARC apps at once, it is difficult to tell whether or not two open ARC apps might be able to communicate with each other. It is unlikely that this will be supported in general, as each app is in its own sandboxed copy of Android.

System Services and Stock Providers

In terms of core Android capabilities — system services and standard `ContentProviders` — the story is going to be mixed.

On the `ContentProvider` front, they will probably all "work", insofar as they should not crash. However, they just will not have any content. So, for example, querying `MediaStore` will turn up nothing.

The one major exception to that is `ContactsContract`, as ARC has an implementation that is backed by your Google contacts. However, that requires you to get an API key and set up your app the same way as you would for Google Play Services.

In terms of some notable system services:

- `ClipboardManager` works, if you enabled "Clipboard Access" in the ARC Welder when packaging the app
- `AlarmManager` works though is probably pointless, since your app will not be running in the background (the user will close the window and your process)
- `NotificationManager` works, but the notifications appear outside the app window as standard Chrome notifications
- `DevicePolicyManager` will not work, as there is no way for the user to make your app be an active device administrator, since there is no Settings app
- `DisplayManager` does not appear to detect an HDMI monitor plugged into a Chromebook, let alone allow presentations to be directed to it

Limited Google Play Services

There is limited support for Google Play Services in ARC. It adds a few wrinkles to what you are going to be used to.

First, only a subset of the Play Services SDK is supported in ARC. Right now, that includes:

- Google Cloud Messaging (GCM)
- MapsV2
- the fused location provider
- other APIs outside of the scope of this book, such as ads

Second, the version of Play Services inside the ARC environment may not be as up to date as is the one in conventional Android devices. There is no means for a user of an ARC app to be able to upgrade the Play Services edition themselves, other than by updating ARC itself if and when that is available. This may cause issues for you when trying to use the Play Services SDK, as through the version `<meta-data>` element, it wants to try to force devices to update. You may need to stick with an older version of the Play Services SDK, one that is compatible with ARC. This will be much easier for Android Studio users, who can find and reference an appropriate version number for the relevant Play Services SDK artifacts.

To use Play Services on ARC, your app must have an entry on the Chrome Web Store, so you can get an appropriate API key (referred to as the `crx_key`). In addition, your app may need to have a project in the Play Console, not as an Android app, but as a Chrome app, to get an API key specific to some API that you are using (e.g., GCM). The documentation provides more details about this.

Am I On an ARC?

It may be that some combination of the above issues means that your app needs to react differently when running as an ARC-packaged app rather than running as a native Android app.

The official advice, for detecting whether your app is running in ARC is:

> …look for `chromium` as the `android.os.Build.BRAND` and `android.os.Build.MANUFACTURER`

Apps Sans Role

Many different sorts of apps will have no real role in a Chrome/Chrome OS environment, such as:

- home screens and app-widget-only apps
- apps that primarily work in the background, as the user has to keep the ARC app's window open for the process to remain running
- task managers, like this book's own `Nukesalot` sample, as there are no other tasks of note in any given ARC app's process

Also, apps that go beyond the boundaries of the Android SDK, such as poking at various Linux elements inside of Android, will likely encounter problems as ARC apps in Chrome and Chrome OS.

Other Security Notes

Chrome and Chrome OS have their own security model that does not map precisely to Android's. As a result, ARC-packaged apps may have somewhat different security responses than would an equivalent native Android app.

A good example here is the `INTERNET` permission. As with an app on native Android, an ARC-packaged app lacking the `INTERNET` permission cannot use things like `HttpURLConnection` to access the Internet. However, in Android, attempts to use sockets without the `INTERNET` permission should result in a `SecurityException`. In ARC, the same operations just quietly fail.

Getting Help

At the present time, Google has delegated developer support to the `google-chrome-arc` tag on Stack Overflow, with no other obvious support option for inquiries that are off-topic for Stack Overflow.

Trail: Device Catalog

Device Catalog: Kindle Fire

The most aggressive firm in creating a Google-free Android ecosystem is Amazon. The most visible aspect of that work is Amazon's Kindle Fire series of devices. From 2011 through 2013, each year has brought forth a new generation of Kindle Fire models, each with newer versions of Android and more powerful hardware. However, none support the Play Store or other Google proprietary apps and technologies. As a result, Amazon has also been building their own replacements, which developers can elect to use if they need the capabilities but are targeting the Fire.

This chapter will outline what you should expect as you start working on apps for the Kindle Fire series of devices.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Introducing the Kindle Fire series

Once upon a time, there was the Kindle Fire. It was a 7" tablet, made by Amazon.

Nowadays, there is a series of devices in the Kindle Fire family:

- The original first-generation Kindle Fire
- The second-generation Kindle Fire, with an updated OS and slightly faster CPU
- The Kindle Fire HD 7", with a 720p display

- The Kindle Fire HD 8.9” with a 1080p display (available as a WiFi-only device or with mobile data capability)
- The Kindle Fire HDX 7”, with a 1920x1200 display and optional mobile data
- The Kindle Fire HDX 8.9”, with a 2560x1600 display and optional mobile data

This chapter will attempt to point out which of these devices certain statements pertain to. The phrase “the original Kindle Fire” refers to the first-generation Kindle Fire.

What Features and Configurations Does It Use?

Any time you are looking at a device that is known to be a significant departure from conventional Android devices, you need to consider what capabilities the device has and how that relates to your code and graphic assets. Android’s flexibility means that, in many cases, you can work within the limits of the SDK to craft something that will look well on unusual devices. However, you will need to understand what is and is not possible for the device in question, in this case the Kindle Fire.

However, there are now several devices in the Kindle Fire family, which makes this more complicated.

OS Version

Amazon has branded their variation of Android “FireOS”.

The first-generation Kindle Fire runs an Amazon-customized version of Android 2.3.3. The HD models run an Amazon-customized version of Android 4.0.3, while the HDX models run a FireOS based on Android 4.2.2.

Note that these devices will not show up in Google’s “Device Dashboard” pie chart, as Google can only count those devices that use the Play Store, which the Kindle Fire series lacks.

Screen Size and Density

The original Kindle Fire (first and second generation) uses `-large`, `-mdpi` resources. On the surface, this would not be terribly surprising, as the 7” display works out to around 169dpi, and 7” displays are definitely in the `-large` resource bucket.

However, bear in mind that Android 2.3 did not fully support tablets. The only Google-endorsed tablet that shipped with Android 2.x was the original Samsung Galaxy Tab, and that technically was a really large phone that, er, could not place phone calls.

As such, Android 2.3 did not consider a 1024x600 display to be `-large`. It considered such a display to be `-xlarge`. This was corrected in Android 3.1, in preparation for a new line of ~7" Honeycomb tablets.

In general, this should not pose an issue when testing your app on hardware. In practice, it will pose a problem for your emulator, as will be explained later in this chapter.

The Kindle Fire HD 7" and 8.9" are `-large`, though they are `-hdpi` in terms of screen density.

The Kindle Fire HDX 7" is `-large`, while the Kindle Fire HDX 8.9" is `-xlarge`. Both are `xhdpi` in terms of screen density.

Hardware Features

All of the Kindle Fire devices support:

1. An accelerometer, both for direct use and for detecting screen orientation changes
2. Multitouch, but only for two fingers (e.g., pinch-to-zoom)
3. WiFi
4. The USB accessory interface
5. A light/proximity sensor

The Kindle Fire HD devices add:

1. Front-facing camera
2. Network-based location (the Kindle Fire HD 8.9", with the mobile data option, also has GPS)
3. Bluetooth
4. Microphone

The Kindle Fire HDX devices add:

1. GPS

2. Compass

The Kindle Fire HDX 8.9" offers a rear-facing camera in addition to the front-facing camera.

None of the Kindle Fire series support telephony (voice or SMS).

If your application truly needs any of those missing capabilities, you are out of luck.

If your application could use some of those capabilities but can get by without them, be sure to add the appropriate `<uses-feature>` elements to your manifest with `android:required="false"` (e.g., `<uses-feature android:name="android.hardware.camera" android:required="false" />`). Otherwise, your app will not be available for the original Kindle Fire if Android thinks that you really do need the capability (e.g., you have requested the `CAMERA` permission).

What Is Really Different?

All of the devices profiled in this part of the book are clearly different than what you are used to from an Android development standpoint. Some things, like availability of Bluetooth, will fit within the Android SDK's framework for optional capabilities. Other things will represent where a device manufacturer has meandered farther from the Android device norm, in ways that may not be completely obvious to you, let alone your code.

The Menu Bar

As was noted previously in this chapter, the original version of the Kindle Fire runs Android 2.3, a version of Android not designed for tablets. Moreover, Android 2.3 was designed for devices that had dedicated off-screen options for HOME, BACK, and MENU buttons. However, Amazon apparently wanted to avoid such buttons, yet they lacked source code access to Honeycomb, where support for the system bar was added.

So, they faked it.

The Kindle Fire supports what Amazon refers to as the "menu bar". This is akin to the system bar found on tablets running Android 3.0+, insofar as:

1. It appears at the bottom of the screen
2. It contains the HOME, BACK, and MENU buttons, along with a search button

However, unlike the system bar:

1. The menu bar disappears when not in use, in some cases
2. There is still a status bar at the top containing signal strength, battery level, time, etc.

Here, for example, is an application running on the original Kindle Fire:

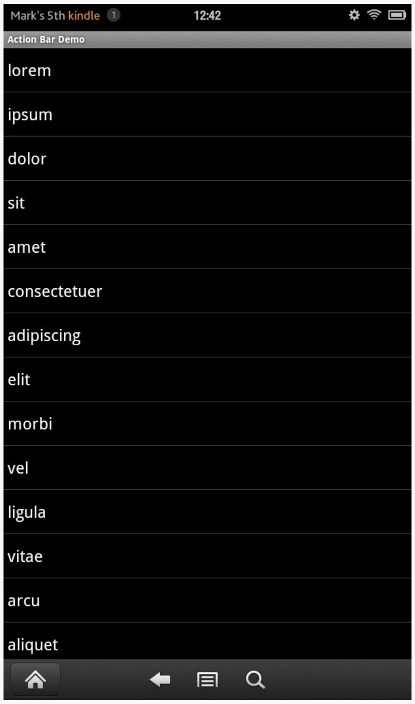

Figure 956: The original Kindle Fire, running a sample application, showing the menu bar

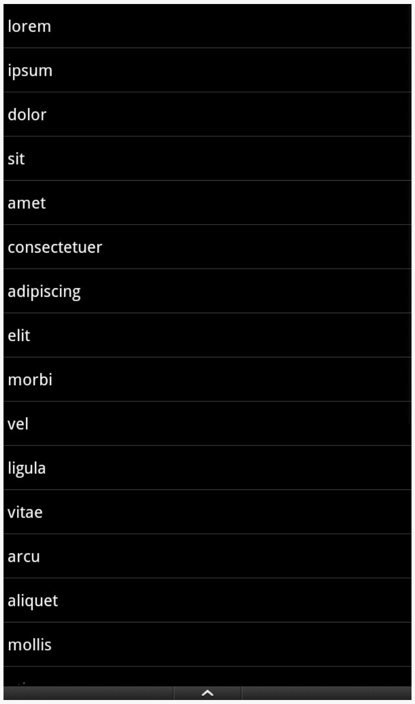
In this case, this is a normal activity, and the menu bar is always visible.

However, here is the same activity with `android:theme="@android:style/Theme.NoTitleBar.Fullscreen"` in the manifest:



lorem
ipsum
dolor
sit
amet
consectetuer
adipiscing
elit
morbi
vel
ligula
vitae
arcu
aliquet
mollis

Figure 957: The original Kindle Fire, running a sample application, with the menu bar collapsed

Hence, if you set your activity to be full-screen, the status bar at the top goes away, and the menu bar shrinks to a smaller bar. Tapping on that bar brings back the menu bar, but this time overlaying the bottom portion of your activity.

Nothing Googly

The Kindle Fire lacks Google Maps, both the app and the library used for things like `MapView`.

The Kindle Fire lacks the Play Store and anything that depends upon it, such as GCM.

The Kindle Fire lacks Gmail.

The Kindle Fire lacks anything from Google that is not part of the Android Open Source Project.

If your application depends on one or more of these, your app will not work well on a Kindle Fire without adjustments, though some have alternatives from Amazon that can be used.

Sideloading Limitations

If you enable the standard Android setting, you can install apps on the Kindle Fire from alternative sources, such as sideloading via USB. This is how the development tools deploy apps to a device when you are working on your app, and anyone can use this technique so long as they have the Android SDK (or at least enough to provide `adb` access).

However, there is one notable limitation of sideloading: icon quality.

When you submit your app for distribution through the Amazon AppStore, you will upload what they refer to as the "thumbnail" image. This is a 512x512 pixel rendition of your icon and is independent from any icons you may have put as resources in the APK file itself. When your app is installed from the Amazon AppStore, your thumbnail is downloaded as well and is used for the home screen carousel, among other things:

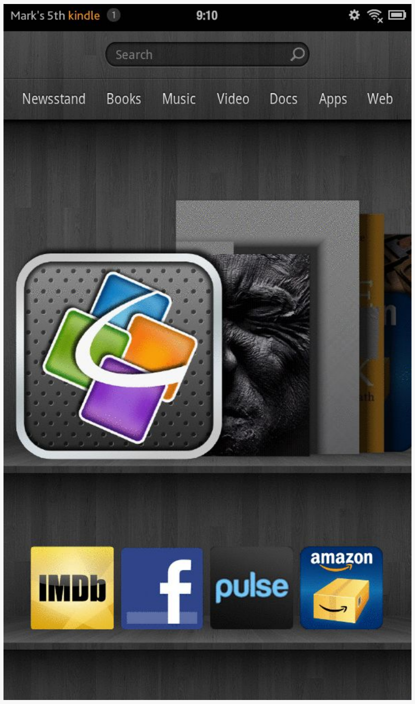


Figure 958: The original Kindle Fire home screen, with a high-resolution version of the QuickOffice icon

However, when you sideload an app, or install it off the Web, there is no “thumbnail”. The Kindle Fire will use your in-APK icon, no different than any other home screen. However, when it blows up your, say, 72x72 pixel icon to the large shelf in the carousel, it does not look very pretty:

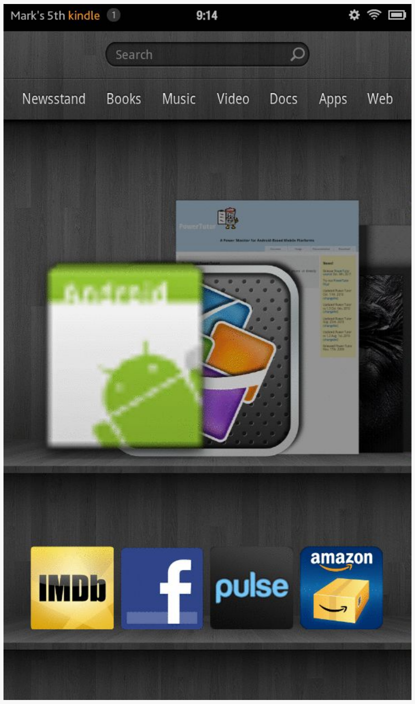

Figure 959: The original Kindle Fire home screen, with a not-so-high-resolution version of the stock Android launcher icon

Things are somewhat better on the HD series:

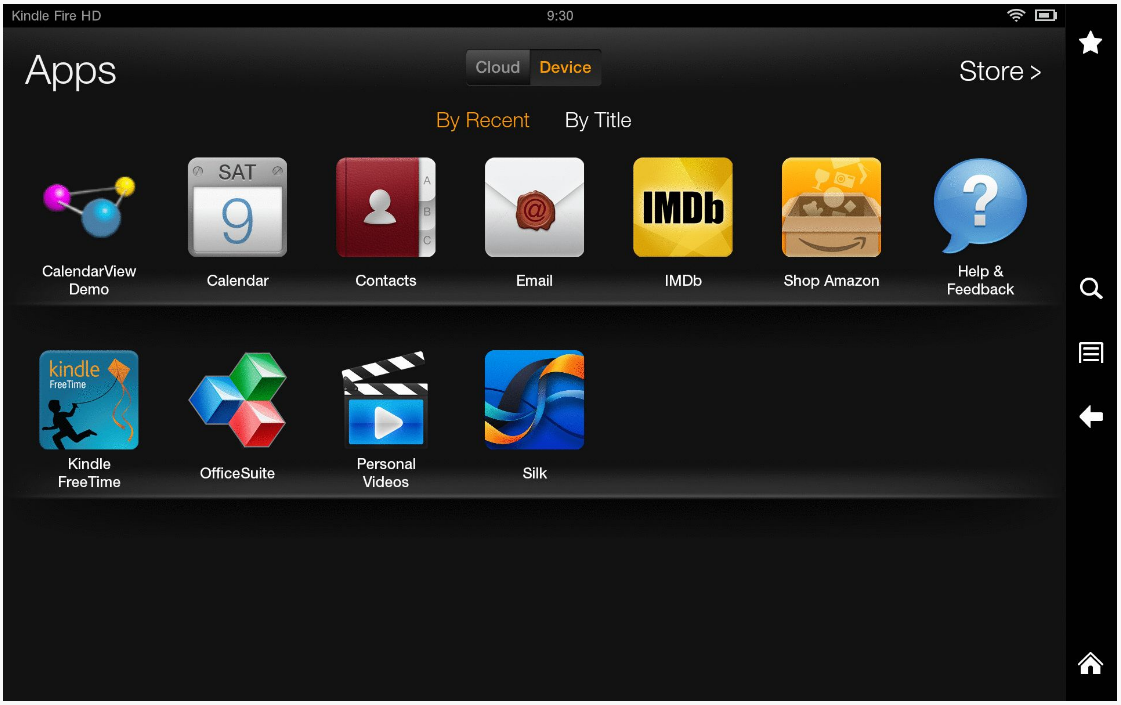

Figure 960: Kindle Fire HD, with CommonsWare App Icon

Getting Your Development Environment Established

Developing for the Kindle Fire series is best accomplished using an actual Kindle Fire device. For example, there is no good way to simulate the behavior of the Kindle Fire menu bar using the standard Android emulator. That being said, having an emulator that at least resembles the Kindle Fire will be useful for debugging purposes, since you can do more with an emulator (e.g., run Hierarchy View) than you can with production devices.

Emulator Configuration

Amazon does not distribute an emulator image for the Fire, meaning that developers have to fake it as best they could using a stock emulator. This is fairly limiting, as the Fire does not look much like a standard Android emulator.

Briefly, Amazon was distributing an SDK add-on with emulator images, but that SDK add-on no longer seems to offer such images.

Note that the emulators in portrait mode get a bit tall, in terms of pixels, so be sure to use the scaling option in the AVD Manager to scale down the emulator so that it will fit your development machine's monitor.

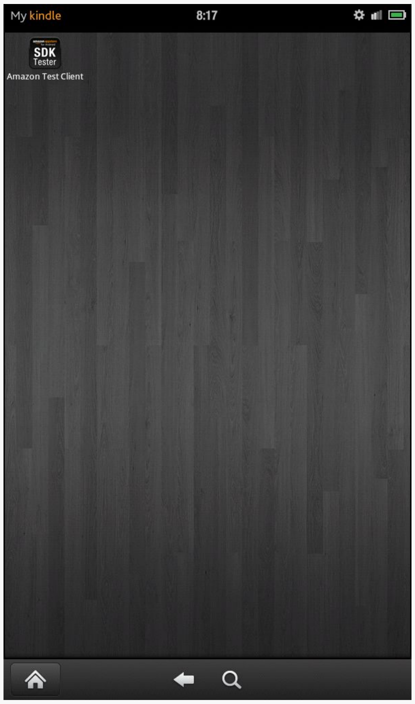

Figure 961: Kindle Fire Emulator

The official original Kindle Fire emulator image also overcomes a limitation in the standard Android emulator image.

As mentioned earlier in this chapter, Gingerbread did not support tablets. More importantly, it had a snippet of code that assumes that devices running with the Kindle Fire's resolution must be `-xlarge`. In reality, the Kindle Fire (and other 7" tablets) should use a `-large` configuration. However, the standard Android emulator will use `-xlarge`. However, the official Kindle Fire emulator will correctly report the emulator as `-large`, matching the device.

Developing on Hardware

The Kindle Fire is ready for use with your development tools, once you teach your development machine how to have `adb` connect to the fire.

Linux and OS X users simply need to run `android update adb`, after having installed the Kindle Fire SDK components, to have the ADB USB entries added to the `adb_usb.ini` file.

On Windows, you will need to do that too, after doing some other things to unpack a local copy of the device drivers. Details for this process can be found in the Kindle Fire developer documentation.

Note that the original Kindle Fire automatically switches into USB Mass Storage mode when you plug it into a PC using the USB cable. This means that apps on the Kindle Fire do not have access to external storage. You will need to unmount the Kindle from your development machine's OS and click the Disconnect button on the Kindle Fire's "You can now transfer files from your computer to Kindle" screen to be both connected via USB *and* allow apps access to external storage.

How Does Distribution Work?

Unlike the vast majority of Android devices, the Kindle Fire series lacks the Play Store. It is quite likely the most popular device ever shipped that does not include the Play Store, though it is far from the first. Hence, if you want your app to be available to Kindle Fire users, you will need to explore other ways of promoting and delivering the app.

Amazon AppStore

The primary way to reach Kindle Fire users is through the Amazon AppStore. This is Amazon's equivalent to the Play Store. And, unlike the Play Store, which is only available pre-installed on devices, any Android device can download an app client for the Amazon AppStore. That, coupled with Amazon's promotions like the "free app of the day", means that your app on the Amazon AppStore has reach beyond just the Kindle Fire series and future Amazon Android devices.

At a high level, publishing on the Amazon AppStore is not significantly different than publishing on the Play Store: you supply the APK and descriptive material to Amazon, and it gets listed. However, the devil, as they say, is in the details:

1. Your app will be reviewed by Amazon before publishing, and it may be rejected for the same sorts of reasons why apps are rejected from the iOS App Store, for anything from content concerns to poor programming practices

2. If you are trying to sell a paid app, Amazon holds final pricing decisions, and your prices on the Amazon AppStore cannot be higher than on other venues
3. Your app will be wrapped in Amazon-supplied code and re-signed by Amazon, so that if a non-Kindle Fire user uninstalls the Amazon AppStore client, your app will no longer run
4. And so on

This is not to say that distributing through the Amazon AppStore is intrinsically a bad idea. Because of some of these hurdles, plus the AppStore's much smaller user base, many developers are skipping it. This results in less competition and greater visibility for your app. However, you need to review all the Amazon AppStore developer rules and make decisions for yourself as to whether it makes sense for you and what you are trying to accomplish with the app.

In April 2013, Amazon also launched Coins, which is their replacement for Google's in-app purchasing model for the Play Store.

Alternatives

Because Amazon did not license the Play Store or other commercial components from Google, you cannot reach Kindle Fire users through the Market (except for those who install pirated versions of the Play Store client on their devices).

However, all other distribution vectors should work as they would on any other device. In addition to sideloading via USB, users can install apps off of the Web by visiting a URL in the device's browser (by default, Amazon Silk) and tapping on the link to the APK. This will trigger a download of the app — users can then tap on the `Notification` for the download to trigger an install. Similarly, one would imagine that other apps whose job is to download and install apps (e.g., enterprise app "markets") should work normally as well.

Note, though, that all off-AppStore installs will have rough icons, so you will want to supply your icons in all densities, in hopes that the Kindle Fire will choose a higher-quality rendition of the icon.

Amazon Equivalents of Google Services

Since Amazon does not license the Google proprietary apps, the Kindle Fire series lacks common things like Google Maps.

However, Amazon has their own equivalents for some of these:

- The Amazon Maps API allows you to embed maps on Kindle Fire devices like you would embed Google Maps on more traditional Android devices
- The Amazon Device Messaging API is roughly analogous to GCM for pushing messages to a Kindle Fire device
- The Amazon In-App Purchasing API allows your apps to tie into Amazon Payments and the like for collecting fees from users inside your app

Getting Help with the Kindle Fire

Amazon maintains a set of documentation related to Kindle Fire and Kindle Fire HDX development, along with a set of forums for asking Amazon-specific development questions regarding the Kindle Fire or their various SDKs.

Amazon is also reported to monitor the `kindle-fire` tag on Stack Overflow.

Device Catalog: BlackBerry

BlackBerry — formerly Research In Motion (BlackBerry) — is known around the world for their phones and messaging services. In 2011, they leapt into the tablet arena with the BlackBerry Playbook, and the 2.0 version of the Playbook OS supported running carefully repackaged Android applications.

While the Playbook itself had modest success, the ability to distribute Android applications to BlackBerry devices continues with their BlackBerry 10 platform, where they have several phones that can run Android apps. Many developers have enjoyed success distributing their app through BlackBerry World (the primary distribution channel for apps to BlackBerry products) and Amazon Appstore for Android (which BlackBerry licensed and distributes on their devices as well).

This chapter will describe a bit about what is involved in getting your Android app to BlackBerry devices.

I Thought BlackBerry Had Their Own OS?

They do.

However, current versions of that OS — this chapter was last updated when version 10.3 was the latest shipping version — contain an Android runtime environment. BlackBerry OS can run Android apps alongside apps written natively for BlackBerry OS or running on other runtimes (e.g., Adobe AIR). This gives developers a wide range of ways to get their app onto modern BlackBerry devices. However, it does mean that our apps may have somewhat less direct access to hardware, as there is another layer between us and that hardware.

What Else Is Different?

At its core, BlackBerry is a device manufacturer, no different than any other manufacturer that you may have dealt with previously. The biggest difference is BlackBerry's ability to run Android applications that you prepare for their devices.

That being said, the world of BlackBerry is a *bit* different than what you may be used to.

Hardware

BlackBerry makes phones with a variety of capabilities, much as do other manufacturers. You should be writing your apps to support a range of device characteristics, such as screen size and density. That will help you with BlackBerry support, just as it helps you with support for other manufacturers' devices.

Note, though, that BlackBerry has some history which will affect their device designs, and your apps by extension. Notably, BlackBerry has been renowned for their hardware keyboards. While not all BlackBerry devices today have such keyboards, it is likely that BlackBerry will ship keyboard-equipped devices for some time to come.

This has three impacts upon you as a developer:

1. Do not assume that the user is using a soft keyboard. Usually, this is not a problem from a programming standpoint, though you may wish to take it into account in documentation.
2. Do not assume that the user always uses the touchscreen to navigate. Some BlackBerry users may use the hardware keyboard for navigation. This is particularly true for users who gravitate towards hardware keyboards for accessibility reasons. Your app should support proper focus to allow it to be navigated without accessing the touchscreen, to the greatest extent possible.
3. BlackBerry keyboards often have not been "slider" keyboards (i.e., ones that might slide under the display when not in use). Rather, they are always available, below the screen. This will often result in somewhat smaller screen sizes, and odd aspect ratios, compared to what you are used to. There simply is not enough room for a large touchscreen *and* an always-available physical keyboard without having an excessively large device. The BlackBerry Q10, for example, has a 720x720 resolution screen, and most Android developers do not encounter square screen resolutions. You will need to take this into

account, but only in cases where such an aspect ratio might cause you problems (e.g., full-screen image backgrounds).

BlackBerry OS 10.3

Beyond the hardware, the BlackBerry OS — and the Android runtime environment that executes our Android apps — puts some limits on what we can do in our apps. Of note:

- BlackBerry OS 10.3's Android environment uses Android 4.3 (API Level 18), so apps that have an `android:minSdkVersion` higher than that will not be eligible to run on 10.2 devices.
- Some classes will be non-functional, particularly those related to telephony capabilities. You cannot use `SmsManager`, for example.
- Some types of apps will not work well, because the Android runtime runs alongside other non-Android apps on the hardware. Replacement home screen implementations, for example, are unlikely to work. Similarly, background apps that display a UI (e.g., Facebook "chatheads"-style popups) using `SYSTEM_ALERT_WINDOW` are unlikely to work.
- App widgets are not supported. So long as the app widget is a non-essential feature of your app, this should not be a problem — after all, the user does not *have* to use your app widget on any Android device. However, if the *sole purpose* of your app is to provide an app widget, such an app will not be useful on BlackBerry.
- Not all connectivity is surfaced in the Android runtime from the underlying hardware. For example, WiFiDirect and direct USB access are all unavailable.

Navigation

Like most Android tablets, BlackBerry devices offer little in the way of physical or off-screen navigation buttons. For example, there is no BACK button. However, a navigation bar will contain a BACK soft button for users. If your app takes over the full screen, this bar will not be there all the time, but a swipe down from the top of the screen should expose it.

Similarly, your menu will not be accessed via a MENU key, but rather via a downward swipe to expose the menu. This also means that any special MENU-button logic of yours may not work, if you are using the MENU button for things other than displaying the action bar overflow or other form of options menu.

Nothing Googly

As with other devices cited in this book, the BlackBerry series of devices lack support for Google's proprietary apps. For app developers, this means that you lack access to Google Play Services and the various APIs exposed by it, such as Maps V2 and Google Cloud Messaging.

BlackBerry does offer its replacement for GCM, in the form of the BlackBerry Push Service. However, for maps, they steer you towards using `geo:` Intent structure and `startActivity()`.

If you are dependent upon other APIs offered by Google Play Services (e.g., `LocationClient`), you will need to reconsider your use of those APIs if you wish to ship on devices that are outside the Google ecosystem.

Package Name Length

The BlackBerry Android runtime appears to only support package names of 29 characters or less. The build tools will fail if your package name is longer than 29 characters.

Note that this should only pertain to the "application ID" role of a package name, not the "hey, where does `R.java` get generated?" role of the package name. Hence, it should be possible to replace the application ID of your app via a Gradle for Android product flavor, to give yourself a shorter identifier while not breaking your source code references to resources.

What Are We Making?

This might seem like an odd question. After all, the point of this chapter is to make an Android application that can run on BlackBerry devices.

Up until early 2014, that meant you had one option: write a BAR.

A BAR (BlackBerry ARchive, presumably) is a repackaged version of an Android APK, designed to be distributed by BlackBerry and installed on BlackBerry devices. Most of the tooling supplied by BlackBerry surrounds this process of validating that an APK should abide by BlackBerry's requirements and converting that APK into a BAR.

Starting with BlackBerry OS 10.2.1, though, BlackBerry device users can download and install an APK directly. That APK still needs to work within the confines of the BlackBerry Android runtime and must avoid things that will not work there (e.g., replacement home screens). But the user is no longer reliant upon the developer going ahead and creating a BAR file.

So, what you are creating depends a bit on how you want to distribute the app:

- If you wish to distribute via BlackBerry world, you will need to repackage your APK as a BAR file
- If you wish to distribute through Amazon Appstore for Android, or if you wish to self-distribute, you can still ship an APK, though you may wish to use some of BlackBerry's tools to help ensure that your APK will be compatible

Getting Your Development Environment Established

By and large, developing an app to run on the BlackBerry OS Android runtime is the same as is developing an app to run on any other Android environment. You have your standard choices of IDEs and other development tools, the ability to use third-party libraries, and so forth.

Where things start to differ is in testing, where BlackBerry OS ships a Simulator that fills a role similar to that of the Android emulator. To use the Simulator, you will need to package your app into a BAR file, and BlackBerry provides tools to assist you in that process as well.

Checking and Repackaging Your App

There are two basic technical steps for preparing your app for distribution through the BlackBerry World market.

The first is to validate that your app does indeed stick to APIs that are supported by the BlackBerry Android runtime. This helps prevent apps from appearing on BlackBerry World that are guaranteed to fail.

The second is to convert the APK into a BAR file. BAR files are used for all of the BlackBerry OS runtimes, including ones like Adobe AIR. Your BAR will contain the same stuff that is in your APK, plus some additional metadata, in a format shared by all of the other runtimes, for interpretation and use by the BlackBerry OS. Again, if you are not planning on distributing through BlackBerry world, you will not need to worry about a BAR file.

Android Studio Plugin

BlackBerry is distributing an Android Studio plugin to help with preparing Android apps for BlackBerry. Note, though, that this is an *Android Studio* plugin, not a Gradle plugin. On the plus side, this gives you new BlackBerry-related options in the Android Studio UI. However, since Android Studio evolves frequently, there is a decent chance that the BlackBerry plugin will not work on some newer Android Studio builds, until BlackBerry catches up.

This plugin includes:

- an `adb` proxy that allows Android Studio to work with BlackBerry devices and running simulators
- a UI for obtaining a "device debug token", required to allow you to test your apps on BlackBerry devices
- package an APK as a BAR

Eclipse Plugin

BlackBerry publishes an Eclipse plugin that provides the same basic set of features as does its Android Studio counterpart.

Note, though, that the Eclipse plugin is available only for Windows and OS X, not Linux, at the present time (mid-2015).

Standalone GUIs

You also have the option for doing BlackBerry-related chores from standalone GUIs, independent of any IDE.

Basically, both IDE plugins simply provide menu options and toolbar buttons for launching the standalone GUIs from within the IDE. If you are not using either Android Studio or Eclipse, those GUIs are available independently that you can run like any other desktop development tool.

BlackBerry 10 Simulator

BlackBerry distributes VMWare images that embody a BlackBerry 10 Simulator. You can use these with VMWare Player (Windows and Linux) or VMWare Fusion (OS X), versions 3.1 or higher.

The Simulator fills a role similar to that of the standard Android emulator, allowing you to test your apps for BlackBerry OS without necessarily having a Blackberry OS 10 device, or for testing scenarios that are difficult to test with actual hardware.

In particular, the Simulator offers a wide range of simulated input and output, including:

- Simulated sensor input for the accelerometer and ambient light sensor
- Using a development machine's Bluetooth adapter for testing Bluetooth
- Simulated NFC tags

In addition, the Simulator supports some of the same types of simulated input that you see with the Android emulator, such as simulated GPS fixes and simulated incoming phone calls.

The VMWare image will have its own IP address, which you can obtain from the Simulator running in the image. You can then deploy your BAR to it using the `adb` proxy, which you can launch from your IDE or the standalone GUI.

Developing on Hardware

A BlackBerry OS 10 device can run either signed or unsigned BAR files. Unsigned BAR files, though, require a one-time upload of a "debug token", the creation of which requires the same credentials as you would use to sign the BAR in the first place.

How Does Distribution Work?

As with any environment where the Play Store is not available, developers have to determine how best to get their apps to the users of BlackBerry devices.

As with most non-Play Store ecosystems, there is the official solution… and then there are the other solutions.

BlackBerry World

BlackBerry's own "market" is BlackBerry World. This supports native BlackBerry apps, plus those for runtimes like the Android runtime. So long as your app is packaged as a BAR, it should be able to be released through BlackBerry World, much like how you distribute an APK through the Play Store.

BlackBerry World is a curated marketplace, meaning that BlackBerry staff will review your app submissions and may reject them if they violate requirements or other terms.

Beyond that, BlackBerry World has most of the standard capabilities that you would expect from an app market, such as paid apps, in-app purchases, multiple billing options (PayPal and carrier billing), control for distribution to various countries and mobile carriers, etc.

Amazon Appstore for Android

However, many Android developers will probably elect to distribute through Amazon Appstore for Android, now that it ships on new BlackBerry devices.

Partly, it is for improved reach: by distributing through Amazon's channel, you reach the Kindle Fire and Fire TV series of devices, plus any other Android devices that happen to have the Amazon Appstore for Android installed.

Partly, you can distribute in the form of an APK, rather than having to mess around with registering for BlackBerry World, creating BAR files, and the like.

Alternatives

Starting with BlackBerry OS 10.2.1, you can distribute APK files through your Web site or similar means, and BlackBerry users can download and install them. However, nothing is done to validate that the apps you download will work on BlackBerry OS's Android runtime, as they may use APIs that are not available.

Also note that the BlackBerry OS settings have an equivalent to the Android "allow apps from other sources" setting that must be enabled for such installation to occur.

As an example, you can install the F-Droid "market" app to download free and open source Android apps to a BlackBerry OS device. How many of the apps distributed through F-Droid will work on BlackBerry OS, besides F-Droid itself, is unknown.

Device Catalog: Wrist Wearables

A new growth area in mobile technology is the rise of the "wearable": a device designed to be worn on the body in one way or another.

Figure 962: NOTE: Clocks Are Not Normally Considered "Wearables" (image courtesy of Wikimedia Commons)

While large timepieces are not in the domain of what we think of as "wearables", the humble wristwatch has been converted into a new location for computing power. Major manufacturers, such as Samsung and SONY, have launched forays into wrist wearables, and Google has pushed forward with its Android Wear initiative.

In this chapter, we will cover some of the players in the wrist wearable space and what things you may need to think of as you look to start developing apps for such items.

Note that this chapter is focused on general design/implementation issues. Specific coverage of Android Wear, with respect to notifications, can be found in the chapter on advanced notifications.

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book.

Divvying Up the Wearables Space

For the purposes of this chapter, we will consider wearables along two axes:

- What OS does the wearable run?
- What OS can we use for developing apps for the wearable?

Devices vs. Accessories

For this chapter, a "device" is a wearable that runs a recognized mobile operating system. Mostly, right now, that is Android, for devices like the Android Wear watch series, the Omate TrueSmart, and the I'm Watch. In principle, in the future, other operating systems used on phones or tablets could make the jump to run directly on the wearable.

In contrast, an "accessory" is a wearable that runs… something else. Usually, this is some proprietary OS, one we do not work with directly. So, the Pebble smartwatch is an accessory, as the Pebble runs its own OS, not something like Android that is popularly used on phones and tablets.

App OS

In the case of devices, usually we will write apps for the OS of the device. Writing an app for the Omate TrueSmart is reminiscent of writing an app for a small-screen Android phone, for example. Writing apps for Android Wear are a bit different, in that Google has a specific way to package those as part of an app for a mobile device, but otherwise it is relatively similar.

In the case of accessories, the accessory maker may have provided SDKs to allow for apps to be created that run on a phone or tablet that the accessory is tethered to. Basically, the phone or tablet provides the "brains", while the accessory is simply a very tiny input/output terminal. Since this book is on Android application development, either an accessory supports apps that run on Android, or it does not (e.g., it only supports iOS at the moment).

NOTA (None Of The Above)

Some devices do not fit these buckets, for the simple reason that they do not support app development of any kind at present. For example, the first-generation Galaxy Gear from Samsung, and the Qualcomm Toq, are closed environments. In the case of the Toq, it is unclear if anyone has an SDK for it. In the case of the Galaxy Gear, Samsung appears to have a private SDK that they have made available to select partners, eschewing the broader Android development ecosystem for the time being.

Example Wrist Wearables

The following sections outline several wrist wearable devices. This is not meant to be an exhaustive list. Instead, it is here to give you a sense of what is available, both in terms of brands and opportunities for app developers.

Android Wear

Google announced the Android Wear initiative at Google I|O 2014, and the first devices soon followed. Some are square (e.g., Samsung Galaxy Gear), while others are round (e.g., Moto 360). All are wearable devices, as they run Android 4.4W, which is standard Android minus a few things, like `WebView`.

Fitbit

Fitbit is a wrist wearable, one with only a few LEDs for output, designed almost exclusively for collecting sensor input (e.g., pedometer). While the Fitbit site offers an API, it is not an API to the Fitbit wearable, but rather to a Fitbit Web service, for retrieving Fitbit results. As such, the Fitbit does not qualify as either a device or an accessory in terms of this chapter's model.

I'm Watch

The I'm Watch was one of the first wrist wearable devices, running Android. The I'm Watch runs Android 1.6, which works well in limited hardware, and with only 128MB of RAM and a ~400MHz CPU, the I'm Watch hardware is limited. From the standpoint of Android developers, Android 1.6 is "rather long in the tooth", as most developers have abandoned Android 1.x development, and many have even stopped worrying about Android 2.x.

The I'm Watch offers a 1.5", 240x240 pixel screen, 4GB of on-board storage, and a couple of sensors (accelerometer and magnetic field). Distribution of apps for the I'm Watch is handled through the manufacturer's own storefront, though developers can deploy apps through `adb`.

MetaWatch

MetaWatch was born out of a Kickstarter project. It is an accessory, running some tiny OS of its own, designed for "widgets" (MetaWatch apps) to be powered by a tethered device. Alas, momentum seems to have stalled on their app SDKs, and so there does not appear to be a well-supported way to create apps to run on Android devices that push content to the MetaWatch.

Omate TrueSmart

Another Kickstarter was for the Omate TrueSmart. This is a wearable device, powered by Android 4.2. Writing apps for the Omate TrueSmart closely resembles developing apps for a tiny Android phone.

The hardware specs are more in line with modern devices, when compared with the I'm Watch:

- Dual-core ARM 1.3GHz CPU
- 512MB or 1GB of system RAM
- 4-8GB of internal storage, plus microSD expansion
- 1.5" 240x240 touchscreen
- WiFi, mobile data, and Bluetooth

As of February 2014, the Omate TrueSmart has shipped to most of its Kickstarter backers and should be available for sale to others shortly.

Pebble

Of course, the Kickstarter that, um, kick-started the whole "Kickstart-a-wearable" phenomenon was the Pebble smartwatch. The Pebble is an accessory, where the on-board OS runs apps written in C that can optionally communicate with Android or iOS apps running on tethered devices.

Qualcomm Toq

Qualcomm, in late 2013, decided to get into the wearables game directly, via their Toq smartwatch. This is an accessory, designed to work in conjunction with an Android device. In February 2014, Qualcomm released an SDK to allow Android developers to create apps that can work with the Toq.

However, the license terms for this SDK contain clauses that should be discussed with qualified legal counsel, including:

- granting Qualcomm the right to modify and demonstrate your application to whoever it wants to;
- precluding the development of apps (or libraries) that employ a number of popular open source licenses;
- prohibiting distribution of an app without Qualcomm's prior written permission; and
- giving Qualcomm the right to tell you to uninstall your app, from any device, at any time, for any reason

Samsung Gear Series

One of the bigger brands to get into wrist wearables has been Samsung, with their Galaxy Gear device. The Galaxy Gear is a device, running Android. However, as of February 2014, there is no publicly-available SDK for writing apps for this device, nor any officially-supported means of installing third-party apps on the device. You can load apps on it via `adb`, though this is not supported and has substantial limitations (e.g., no Internet access).

In February 2014, Samsung announced the Gear 2 and Gear 2 Neo. These are devices, but running Tizen, not Android. Samsung released an SDK for these devices](http://developer.samsung.com/samsung-gear) in March 2014.

In February 2014, Samsung also announced the Gear Fit. This *does* have an SDK (as part of Samsung's overall mobile SDK package), and qualifies as an accessory.

SONY SmartWatch and SmartWatch 2

SONY is another major brand to get into wrist wearables. In fact, they were the first major brand to do so, debuting their SONY SmartWatch back in 2012. SONY then released the SmartWatch 2 in 2013. Both are accessories, where the apps for the SmartWatch actually run on a tethered Android device, with the SmartWatch serving as a display surface and input mechanism (via simple taps and gestures on the touchscreen).

That Theorized Apple Watch

Of course, the brand that everyone is waiting for to get into the wearables space is Apple. There have been rumors of an "iWatch" for quite some time, though with no actual device having been released as of February 2014.

WIMM One (RIP)

There used to be a firm called WIMM Labs, which made a wrist wearable device called the WIMM One. The device was much along the lines of the I'm Watch and Omate TrueSmart, falling roughly in between them in terms of Android OS version and hardware capability. Their approach was to be more of an OEM, though, looking to supply branded versions of the WIMM One to firms who might want a wearable but were not in that technology space, such as clothiers like Nike.

Google acquired WIMM Labs, at which time the WIMM One was pulled from the market. Some of the WIMM Labs capabilities perhaps moved into the Google Glass project, though it is certainly possible that Google could offer a "Nexus Watch" sometime in the future.

Strategic Considerations

Before leaping into extending your app to support wearables of any sort — ones worn on the wrist or otherwise — you really need to spend some time thinking about whether or not this is the best thing for you and your users.

Do We Bother?

While wearables are touted as “the next big thing”, there have been plenty of such “things” that have never gotten to be that big. This is not to suggest that wearables will go the way of tree-style Web site directories, but they may not become quite as popular as the phones and tablets they are meant to accompany.

While developing for wearables has a “cool factor”, the time you spend on wearables is time taken away from other things. For developers, you lose time that you might have spent on other features of your app. For independent developers, the time might come out of your time budgets for marketing or product research.

While a pure hobbyist might pursue wearables just because it is an interesting area to get into, many other developers need to weigh whether adding wearable support will be worth the time investment.

Which Types?

Developing apps for Android wearable devices, like the Omate TrueSmart and the I’m Watch, is comparatively straight-forward. Device limitations may cause you to spend some more development time, such as crafting a UI that works well on ~1.5" displays. And, depending on the device, you may have to use alternative APIs for some basic operations — the WIMM One, for example, did not have its own WiFi or mobile data, and so you had to wait until the WIMM One told you it was safe to try Internet operations, when the device was tethered to a phone that had its own connectivity. But, at the end of the day, it is still the same Android development that you have come to love (or at least tolerate, occasionally through gritted teeth).

Accessories, or devices running other mobile operating systems, require custom development. And, since there are no standards in this area yet, it usually requires per-device custom development. This may be a graceful extension of logic you already have, such as repurposing your app widget code to use for a watch. But the APIs for delivering content to, say, a SONY SmartWatch do not closely resemble app widget APIs, which will require some restructuring of your code, in addition to the SONY-specific work. How little or how much work this is will vary by app and, secondarily, by wearable.

Which Devices?

Once again, developing for Android wearable devices may be a small enough leap that you could consider them as a matter of course. This is especially true of "pure" enough devices that your business logic will just work, with only a watch-sized UI being needed. It may be that one pulse of work can get your app working on multiple Android wearables that share common capabilities (similar screen sizes, standard connectivity, etc.).

However, beyond that, you are going to need to consider whether developing for a specific wearable is worth the specific work. For example, many of these wearables use their own "market" or "store" for app distribution. Will listing your app in their market get you enough results to make the work worthwhile? Will the wearable maker offer any sorts of co-marketing opportunities, to help promote your app? Does their market offer things that you are used to from more traditional markets, like in-app purchases, that your app uses? Is your app so tightly tied to the Play Services Framework (e.g., Maps V2, GCM, `LocationClient`) that it simply cannot be distributed by any other means?

So, for example, the I'm Watch has their own store, and you will be limited by the capabilities of that store. SONY, on the other hand, expects apps for their SmartWatch line to be distributed however you want, particularly through the Play Store, which gives you more options.

Tactical Considerations

Given that, for strategic reasons or "just because", you have decided to go ahead and work on extending your app to wearables, there are a variety of things you are going to need to think about as you start in on that work. A lot of the details will vary by the specific wearable device or accessory you are trying to support, but some common themes will emerge. Some of those themes are discussed in this section.

The Postage Stamp User Interface

When writing apps to display to televisions — whether for a dedicated box like an OUYA game console or for an external display attached to a traditional touchscreen device — you think of the "10-foot user interface". Here, "10-foot" is not referring to the size of the television (usually), but the distance between the viewer's eyes and the television. Even though you may have a nice 1080p television, you sit so much farther back from it than you do a 1080p phone or tablet, that the UI needs to take this into account. Also, input options for a television tend to be different than on a phone or tablet, as televisions rarely are touchscreens.

Writing apps for wearables has a similar UI distinction, though in a much smaller dimension. Trying to determine how best to package your content to be accessible on a ~1.5" screen is tricky.

One approach is to consider your app widget, if you have one. An app widget on a phone or tablet often times takes up a watch-sized chunk of space on the home screen. Also, app widgets have constrained forms of user input (simple taps, scrolling or swiping only on select widgets like `ListView`), matching the constraints imposed by some wearable APIs and by the reality of large fingers and small touchscreens.

Your UI design for your app widget may be a fine starting point for your UI design for your wrist wearable. In some cases, the same UI will work, while in other cases, some tweaks may be required:

- You designed your app widget to be rectangular, rather than square, so a slight redesign will be needed to take best advantage of a (roughly) square smartwatch display
- You designed your app widget with `ListView` at its core, but the particular wearable you are targeting does not support `ListView`, so you have to revert to other UI structures
- You designed your app widget around a rich color screen, but the wearable that you are supporting offers a more limited color palette, due to its use of particular types of display technology (e.g., “e-ink”)
- And so on

Connectivity (Or Lack Thereof)

Some wearables have their own WiFi radios. Some have their own mobile data options, if they are outfitted with a suitable SIM card. If these are devices, writing an app for the device’s operating system should allow you to connect to the Internet more or less as you do with an app for a phone or tablet.

Some wearables have apps that run on the device, but the device lacks any native Internet connectivity. In that case, you may have access to some APIs that allow you to work with an app on a tethered phone or tablet, and be able to access the Internet that way.

Wearables where the app itself runs on the phone or tablet return you to regular connectivity options, as the wearable does not need independent Internet access.

In sum, how well you can get to the Internet is partly determined by the nature of the wearable, and partly determined by normal mobile development practices (e.g., are we connected to WiFi?).

Power (Or Lack Thereof)

The Omate TrueSmart is one of the larger wrist wearable devices. It has a 600mAH battery, a fraction of the size of batteries in most Android phones, let alone tablets.

On the one hand, a wearable will tend to draw less power, simply because the wearable manufacturer will have taken steps to minimize power drain. One example is turning off the LCD more aggressively than you might expect to see on a corresponding phone or tablet.

That being said, power drain is an issue on phones and tablets already; it will be that much worse in the world of wearables. In some cases, you have *two* batteries' worth of power to consider: the wearable's own battery, plus the battery of some phone or tablet (particularly in the case of an accessory, where the app runs on that phone or tablet).

Security (Or… Well, You Get the Picture)

Few, if any, wearable devices offer much in the way of on-board security, such as full-disk encryption, or even a PIN or password for access. That is because a wearable is designed for rapid access, and such security usually impedes such access. The assumption is that if the wearable falls into the wrong hands, that anything on the wearable is subject to inspection.

As such, you need to be a bit careful about what you use the wearable for. Most apps involving a wearable may have limited security requirements, but not all. Wearable devices, in particular, have the risk that they offer some amount of on-board storage that your on-device app can use, making it somewhat more likely that you might try actually storing something there… something that the user might want to keep secret.

Similarly, the communications between a wearable and a tethered phone or tablet may be insufficiently secure. For example, Bluetooth communications may be secure, or they may not, depending on hardware and circumstances.

This does not prohibit the creation of secure wearable apps, but it make it more difficult.

What About Android Wear?

Android Wear is an initiative by Google for wearable devices, with a particular emphasis on wrist wearables. This book will cover Android Wear in a future edition.

Device Catalog: Android TV

Google not only offers the Chromecast, but also offers Android TV as a way to get content "into the living room". Android TV devices — whether they be set-top boxes or are integrated into televisions directly — run Android apps directly, unlike Chromecast. Android TV, therefore, is a competitor to devices like Amazon's Fire TV.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on "ten-foot" user experiences is also a good idea.

Hey, Wait a Minute… I Thought the Name Was "Google TV"?

You can be forgiven for any confusion over the names.

Google TV was Google's initial attempt to get content onto televisions. Debuting in 2011, Google TV has some of the same characteristics as does Android TV:

- It ran Android apps directly (at the time, on Android 3.1)
- It could be a dedicated set-top box, integrated into other sorts of media players (e.g., Blu-Ray), or integrated into televisions

However, Google TV did not prove all that popular.

In 2014, Google announced that they were no longer supporting app development for Google TV, much to the consternation of the ~17 people still using Google TV devices.

That being said, designing an app for Android TV resembles designing an app for Google TV or for any other “ten-foot” user experience. Hence, design guidance that you may run across for Google TV may have some tips that are still relevant for Android TV and other TV-centric Android environments.

Some Android TV Hardware

Android TV debuted in 2014. However, as of the end of 2014, there were a total of two Android TV device models… both available from Google. While other manufacturers had announced plans regarding Android TV, none were available at the time of this writing.

ADT-1

When Google TV was announced, there was a similar lack of hardware. To help ensure that there were TV-capable apps at the time of a wider Google TV rollout, Google offered free developer devices to various firms and solo developers.

Google did the same thing with Android TV, where they offered a free ADT-1 device to qualified registrants. While deliveries of the ADT-1 were spread out over a few months, they generally arrived significantly in advance of production Android TV hardware.

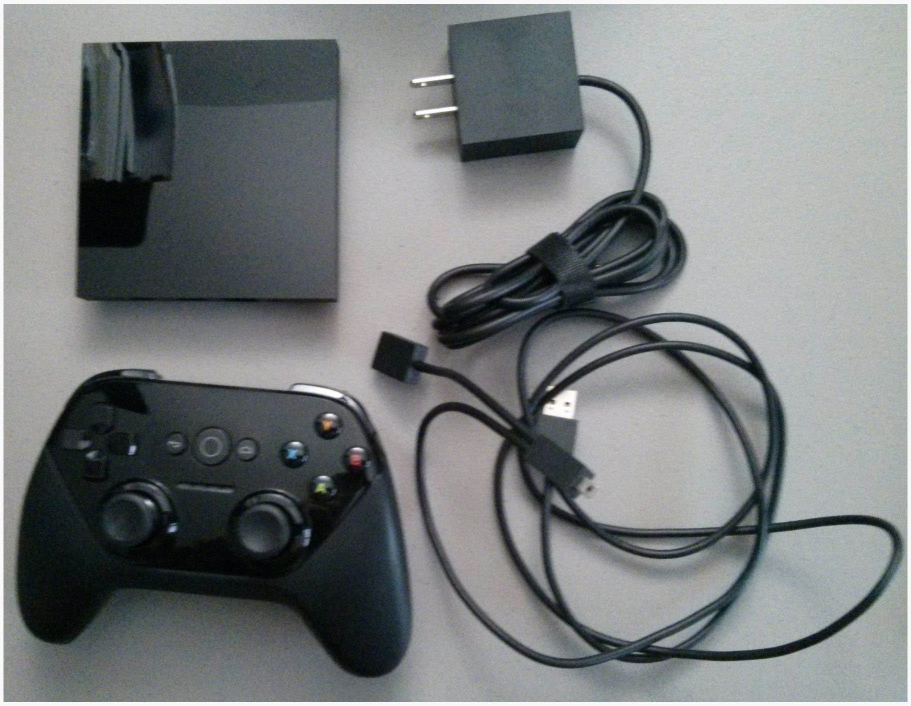

Figure 963: ADT-1 Developer Android TV Device

Nexus Player

The first production-grade Android TV device is Google's own Nexus Player. As with the ADT-1, the Nexus Player has an HDMI port for connecting to a TV (or projector, monitor, etc.). It also has its own remote control and power adapter.

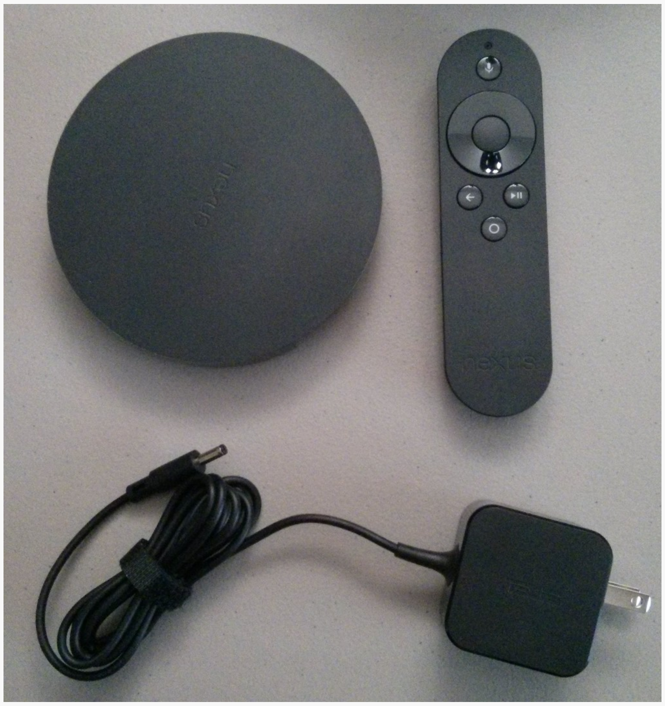

Figure 964: Nexus Player Android TV Device

Both the ADT-1 and the Nexus Player are presently running Android 5.0.

What Features and Configurations Does It Use?

Android has built into the SDK a fair bit of device flexibility. Most of this comes in the form of configurations (things that affect resources) and features (other stuff). If your application can handle a range of configurations and features, or can advertise that they need certain configurations or features, they can handle Android TV or arrange to not be available for Android TV on the Play Store.

Screen Size and Density

Android TV devices are always categorized as `xlarge` screen size.

Densities, however, are a bit more complicated.

Android TV is for use with HDTV, whether Android TV is integrated into the television or it comes as an external set-top box. There are two predominant HDTV resolutions, known as 720p (1280x720) and 1080p (1920x1080). A 1080p television will be categorized as an `xhdpi` density device. A 720p television will be categorized as a `tvdpi` device. `tvdpi` is for devices around 213dpi, in between `mdpi` and `hdpi`. In practice, you might elect to skip `tvdpi` for your drawable resources, allowing Android to resample your `mdpi`, `hdpi`, or `xhdpi` drawables as needed.

Input Devices

Android TV will not normally be navigated using a touchscreen. Instead, the normal form of input will be a D-pad remote. Developers will need to ensure that their apps are navigable this way.

Other Hardware

Android TV has no sensors, no camera, no microphone, and no telephony features. As such, any application requiring such features will not run on Android TV and will not even show up in the Play Store for such devices.

Bear in mind that some of these will be driven by permissions. If you ask for the `SEND_SMS` permission, Android will assume you need android.hardware.telephony unless you specifically state otherwise, via a `<uses-feature>` element for `android.hardware.telephony` with `android:required="false"`.

What Is Really Different?

Beyond the features and configurations, there are other things about Android TV that will depart from what you might expect for an Android environment, due to the nature of the TV set-top box platform and the Android implementation upon it.

Overscan

Since Android TV typically uses a television for its primary output, overscan can be an issue. Addressing overscan is covered as part of the chapter on the “10 foot UI”.

Ethernet

While Android TV devices will generally be connected to the Internet, it may not be via WiFi. Since Android TV devices generally are not portable, some will have Ethernet jacks, and hence some users will elect to wire in their Android TV as opposed to using WiFi.

The upshot is that you should not assume that WifiManager will necessarily give you useful results. Also, ConnectivityManager should report wired Ethernet as TYPE_ETHERNET, added in API Level 13, when you call methods like getActiveNetworkInfo().

Location

Generally speaking, Android TV devices will tend not to move, earthquakes and large dogs notwithstanding.

As such, Android TV devices do not have GPS receivers. Rather, location is determined in an approximate fashion via address-based lookups, using a postal code. Hence, asking Android for a GPS fix on a Android TV device will be ineffective.

However, since users of Android TV devices tend not to be moving much at the time, it is a bit more likely than normal that they will want information about some location other than where they are. If your app is exclusively tied to providing information about their current location, you may wish to consider how you could extend your app to help users get information about other places that they may be interested in.

Media Keys

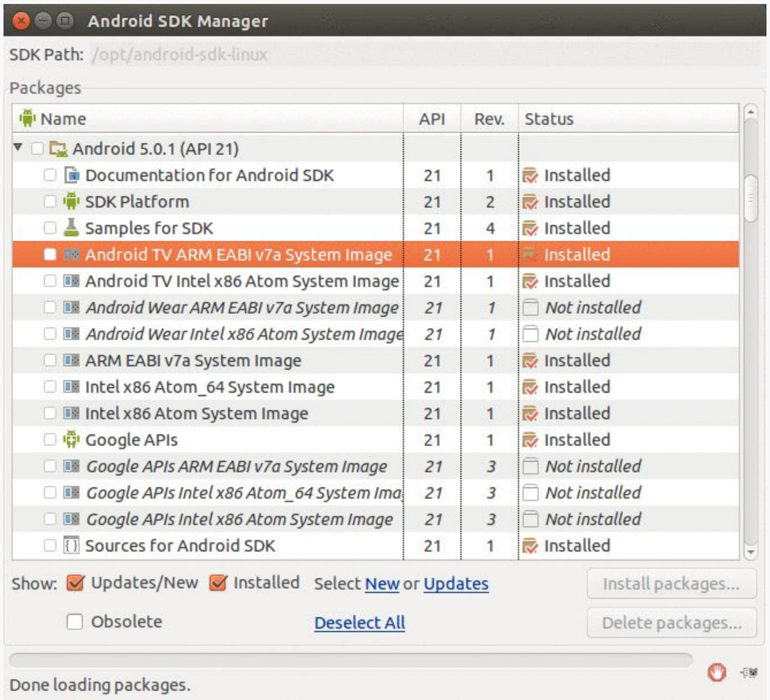
Android TV devices are usually manipulated by remote controls. Some of these remotes will have lots of buttons, such as media-specific buttons for play, pause, etc.

The KeyEvent class has had support for some media buttons since API Level 3, mostly for use with wired headsets. API Level 11 added a bunch more media buttons. Your Android TV application may wish to respond to these, via onKeyDown() in a View or Activity.

In particular, an Android TV application should not be using on-screen controls for play, pause, etc., as they take up screen space that probably could be put to better use. Rather, use layouts that offer such controls for touchscreen devices (e.g., phones and tablets) but rely on the media buttons for non-touchscreen devices.

Getting Your Development Environment Established

Android TV emulator images are available in the SDK Manager for Android 5.0 and above:



Android SDK Manager

SDK Path: /opt/android-sdk-linux

Packages

Connecting to Physical Devices

The ADT-1 and Nexus Player have micro-USB ports for debugging purposes. This, though, requires that your player and your development machine be within USB cable reach of one another. The author of this book uses a pico projector to be able to work with TV-native devices (Android TV, Fire TV, etc.) or external displays (HDMI, MHL, etc.).

To enable an Android TV for debugging, you will need to enable developer options, much like you do for a mobile device (click on the build number 7 times in the Setting's About screen). Then, in the "Developer Options" screen, you can go into Debugging and elect to enable "USB debugging".

How Does Distribution Work?

Your app probably falls in one of three buckets: you want it on Android TV (along with other devices), it *only* supports Android TV, or it will not work on Android TV. Whichever of those buckets best fits your device will determine the manifest settings you will want to ensure that the Play Store (and perhaps other third-party markets in the future) will honor your request.

Getting Your App on Android TV

The first criterion for getting your app visible to Android TV devices on the Play Store is to add a <uses-feature> element to your manifest, indicating that you do not require the android.hardware.touchscreen feature:

```
<uses-feature android:name="android.hardware.touchscreen" android:required="false"/>
```

By default, Android assumes that you need a touchscreen, and so without this clarification in your manifest, you will not appear in the Play Store.

Also, add similar <uses-feature> elements for any hardware that you might like to use where available but do not absolutely need, particularly hardware that Android TV may lack. The documentation outlines the features that Android TV devices will likely lack.

You need to have an activity that has an <intent-filter> for ACTION_MAIN and CATEGORY_LEANBACK_LAUNCHER. This will be your launcher activity on Android TV devices, instead of your ACTION_MAIN/CATEGORY_HOME activity. Of course, you are welcome to have one activity serving as the launcher for both types of devices, if you can come up with one with a solid presentation for both mobile devices and TVs.

In addition, do not have any activities with android:screenOrientation set to portrait, as Android TV devices always display in landscape

Supporting Only Android TV

If your app only supports Android TV, in addition to the above requirements, you should also add one more <uses-feature> element to your manifest:

```
<uses-feature android:name="android.hardware.type.television" android:required="true"/>
```

This will filter you out of the Market for all non-TV environments.

Avoiding Android TV

If your app specifically is untested on Android TV, you need to have something in the manifest that will keep you *off* Android TV devices' views of the Play Store. The easiest is to say that you need a touchscreen:

```
<uses-feature android:name="android.hardware.touchscreen" android:required="true"/>
```

Note that `true` is the default setting for this particular feature, though putting it in your manifest to remind you that you do require a touchscreen is a good idea.

Device Catalog: Amazon Fire TV and Fire TV Stick

Amazon has joined the TV set-top box fray with the Fire TV and, more recently, the Fire TV Stick. These devices are powered by FireOS, Amazon's variation of Android. And, as with other Amazon FireOS devices, like the Kindle Fire tablet series, you can write apps that run on Fire TV and the Fire TV Stick.

This chapter will review these devices from a developer's standpoint, to help you create apps for this platform. Note that the Fire TV line of devices have some elements in common with Amazon's Kindle Fire series of tablets, covered elsewhere in this book.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with the chapter on the Kindle Fire tablets. Reading the chapter on the ten-foot user interface is also recommended, either before or after this chapter.

Also, some sections will make reference to Android TV as a point of reference.

Introducing the Fire TV Devices

As of January 2015, there were two major flavors of Fire TV device: the original Fire TV, and the Fire TV Stick.

Fire TV

As with most Android-powered set-top boxes, the original Fire TV is small and is designed to connect with your television (or monitor, or projector, or whatever) via HDMI:

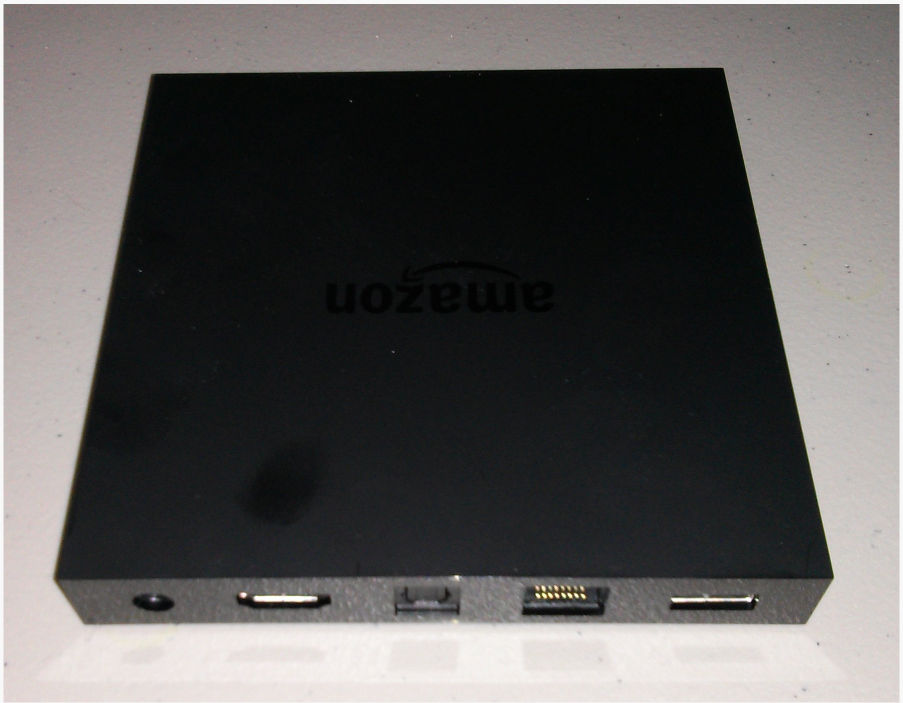

Figure 968: Fire TV

It comes with a small wireless remote designed for basic controls, akin to what you might find on other streaming boxes or similar entertainment devices:

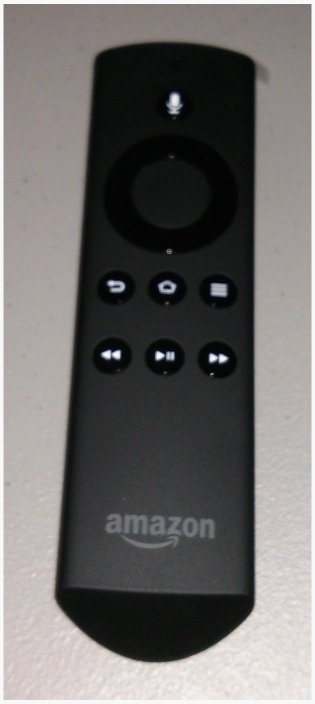

Figure 969: Fire TV Remote

Optionally, you can get a gaming controller that works with the Fire TV. While the regular controller is fine for navigating the Fire TV UI, the gaming controller will be more suitable for more serious game play:

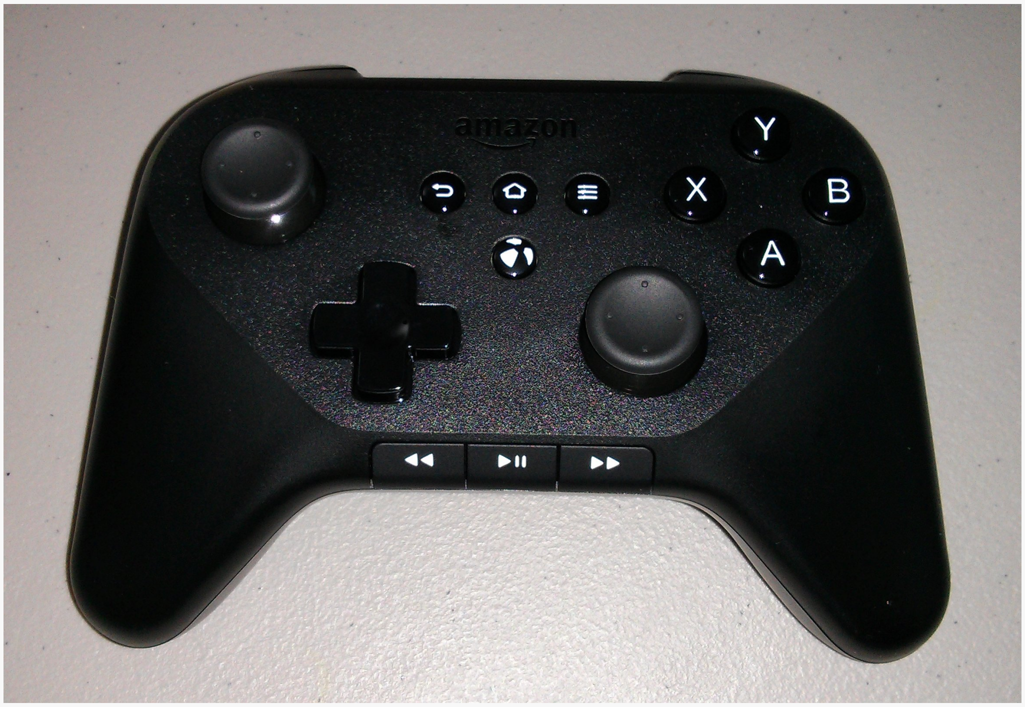

Figure 970: Fire TV Gaming Controller

While the Fire TV is powered by Android, the on-device UI is definitely targeting a set-top box environment. The home screen is dominated by media, coming from whatever supported streaming content providers you have set up with the Fire TV (e.g., Amazon Prime):

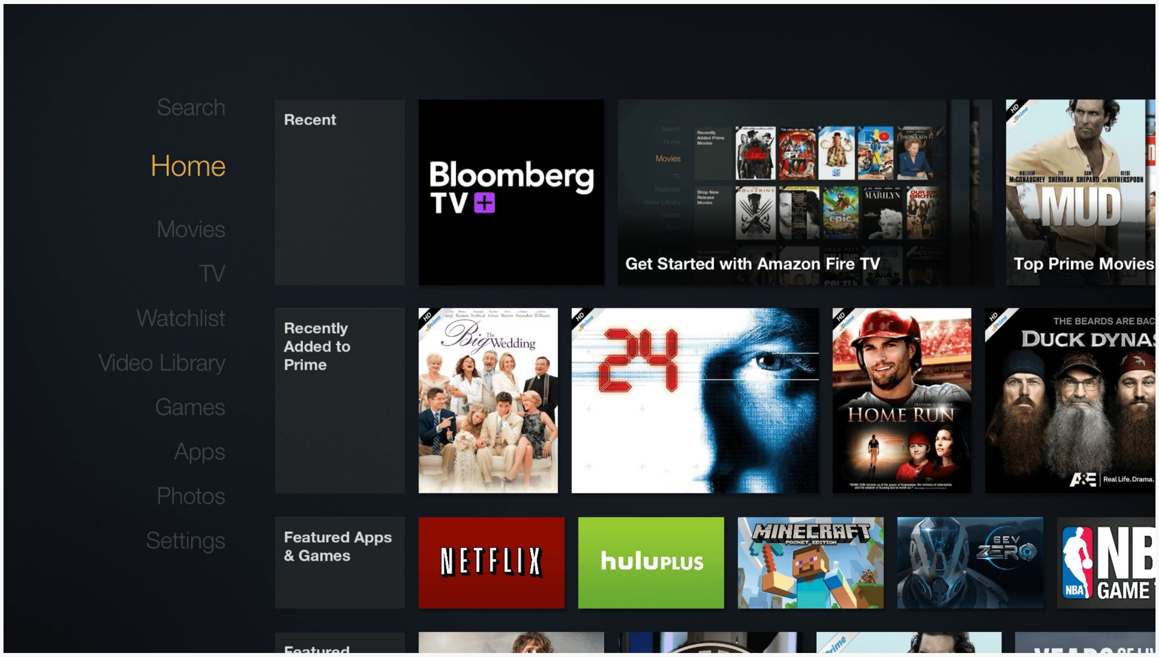

Figure 971: Fire TV Home Screen

The “Apps” section shows a mix of what is installed and what is available for you to download, with “cloud” icons indicating apps that are available but are not presently installed:

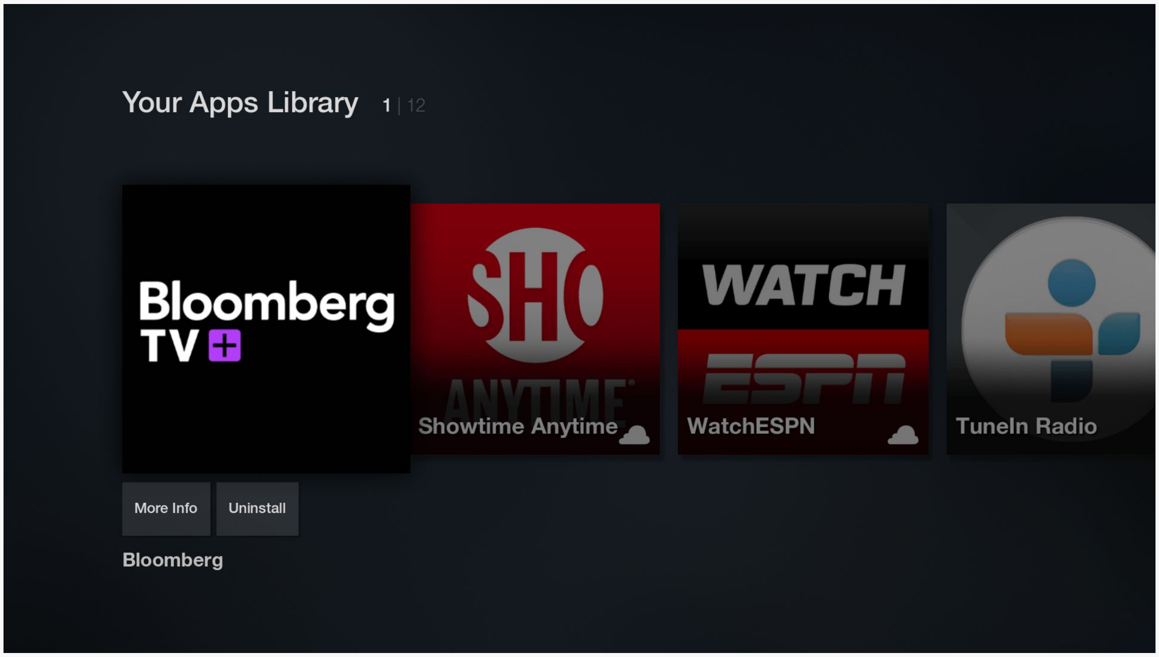

Figure 972: Fire TV "Your Apps Library"

FIre TV Stick

The Fire TV Stick is physically substantially smaller than is the Fire TV, designed to more closely resemble the Chromecast:

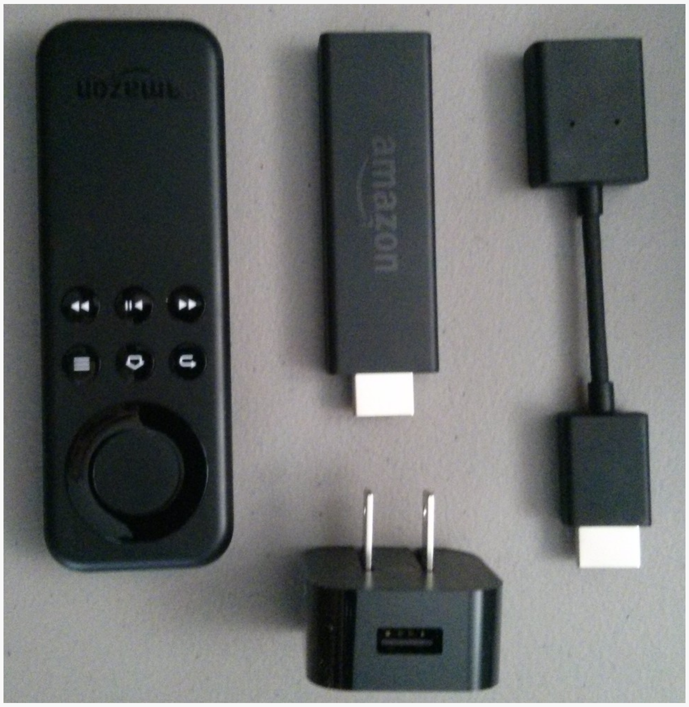

Figure 973: Fire TV Stick, with Remote, AC Adapter, and HDMI Extension Cable

The user experience of a Fire TV Stick, though, is largely the same as with a regular Fire TV. Both run the same FireOS environment, with the same sort of browsing metaphor.

The biggest difference is that the Fire TV Stick is less powerful (less RAM, weaker CPU and GPU). For conventional apps, this is unlikely to be a problem, as the Fire TV Stick is as powerful as many standard Android phones and tablets. Games, however, are more likely to stress the hardware.

From the user's standpoint, the Fire TV Stick's big selling point is its low price, about a third of what the Fire TV costs.

What Features and Configurations Do They Use?

The Fire TV device family behaves a bit like a "mashup" of other TV-centric devices (Android TV, OUYA, etc.) and the Kindle Fire series.

OS Version

At the present time, Fire TV devices are powered by a version of FireOS that corresponds to Android 4.2.2 (API Level 17). It is possible that Fire TV devices could be upgraded to a newer version of FireOS in the future, one based on a newer version of Android, but there are no guarantees.

Screen Size, Density, and Orientation

One area where the Fire TV series differs from pretty much anything that came before it comes with the behavior of the screen. As with other TV-centric devices like Android TV and the OUYA, the assumption is that the screen is locked to landscape. However, beyond that, Amazon has struck out on its own in terms of screen characteristics.

With Android TV, the screen size and density are based on the type of display that the Android TV box is plugged into.

With the Fire TV devices, your code deals with a rendering surface of 1920x1080 pixels, regardless of whether the device is plugged into a 1080p screen or something else (720p, 4K, etc.). The density is always treated as `-xhdpi`, giving you a resolution of 960dp by 540dp, and a `-large` screen size. The hardware will handle scaling the output down (or, in theory, up for 4K) as needed.

On the plus side, this simplifies app development, as you do not need to deal with different screen capabilities yourself. However, it remains to be seen how well the Fire TV will scale the output.

Also, note that Fire TV devices do not address overscan when they apply this scaling. Hence, you will want to keep your content away from the edges of the available space, only showing your background there, in case those edges are not visible on some televisions.

As with any TV-centric device, since the screen is locked to landscape, activities that are locked to portrait (e.g., `android:screenOrientation="portrait"` in the manifest for the activity) will behave oddly. If you are targeting devices like the Fire TV series, be sure to allow your activities to work in portrait *or* landscape, not just portrait.

Input Devices

As noted earlier, Fire TV devices ship with a simple remote control, designed for media management (play, pause, etc.) and basic D-pad navigation. Some users may also elect to pick up a Fire TV game controller or use other Bluetooth game controllers. Technical details for working with these input devices can be found later in this chapter.

Conversely, Fire TV devices do not have touchscreens. You cannot assume that the user can tap on random portions of the screen. Instead, you need to make sure that your app is completely reachable via a D-pad. This is described in greater detail in the chapter on the "ten-foot UI".

Hardware Features

As a set-top box, Fire TV devices lack a lot of hardware that you normally associate with phones and tablets, such as:

- GPS
- camera
- microphone
- sensors
- telephony

The microphone is actually a bit complicated. The Fire TV remote has a microphone and a button to activate it. The Fire TV Stick remote does not have a microphone. There is a Fire TV Remote app available on the Play Store and Amazon Appstore for Android that offers microphone input as well. However, all these microphones are just for Fire TV voice search. There is no means for developers to use these for arbitrary audio input, the way that a microphone on a phone or a tablet can.

What Is Really Different?

Some things are "really different" simply because the output screen is TV-sized, not phone-sized or tablet-sized. See the chapter on the "ten-foot UI" for more about this.

Some things are "really different" in the same way that they are "really different" for the Kindle Fire series, such as having nothing "Googly", like Google Maps or Google

Cloud Messaging. Note that the Amazon Maps API does not work on the Fire TV series, as those devices have no location services.

The biggest additional "really different" item is the limitation on where apps can come from, which is discussed later in this chapter as part of the overall app distribution options for Fire TV devices.

Note that Fire TV devices have their own way of representing notifications. A standard Android `Notification` will not appear anywhere on a Fire TV device. Instead, you will need to support the Fire TV series' own notifications API. While their API is modeled after Android's `Notification` and `NotificationManager`, they do have their own classes, and the results are more reminiscent of `Toasts` and `Dialogs`.

Also note that Fire TV devices do not display an Android action bar, representing those items in a pop-up menu triggered by the MENU button of the Fire TV remote control.

Casting and Fire TV

The success of Chromecast means that TV-connected Android devices will tend to be compared to Chromecast, particularly in terms of how apps on phones and tablets can work with the TV-connected device.

At the time of this writing, Amazon has not shipped anything for Fire TV that would enable apps using `MediaRouteActionProvider` and `RemotePlaybackClient` to work with Fire TV. In principle, Amazon or somebody else could implement a `MediaRouteProvider` and distribute that as an app that goes on ordinary Android phones and tablets, where that `MediaRouteProvider` enables media routes pointing to a connected Fire TV. The `MediaRouteProvider` would forward requests from the phone or tablet to the Fire TV, which would be displayed by some app on the Fire TV.

Amazon more formally supports the "Discovery and Launch" (DIAL) protocol with Fire TV. DIAL allows an app on a phone or tablet to launch apps on Fire TV. Unfortunately, documentation for this is lacking at the present time.

Also, the Fire TV series can serve as a Miracast endpoint. In Settings > Display & Sounds, you will find an option to "enable display mirroring". This turns on Miracast support, allowing mobile devices to mirror their screen content via the Fire TV to the connected television, projector, or monitor. This also works with Android's `Presentation` support, allowing you to direct separate content to the Fire TV's "mirror" than what you show on the device's own screen.

Getting Your Development Environment Established

Developing for the Fire TV series, as with developing for the Kindle Fire series, is best accomplished using an actual Fire TV or Fire TV Stick device. That being said, having an emulator that at least resembles a Fire TV device may be useful for debugging purposes.

Emulator Configuration

Amazon is distributing an SDK add-on that supplies an emulator image you can use, in theory, to emulate a Fire TV device.

To install it:

- Start the SDK Manager, such as via the toolbar button in Android Studio or Eclipse
- Choose Tools > Manage Add-on Sites from the SDK Manager main menu
- Click on the User Defined Sites tab, and click the New… button
- Fill in `https://s3.amazonaws.com/android-sdk-manager/redist/addon.xml` as the URL in the field in the "Add Add-on Site URL" dialog, then click OK (to close up that dialog), then click Close (to close up the Manage Add-on Sites dialog)
- Wait for the progress bar at the bottom of the SDK Manager to finish
- Install the Fire TV entry in API Level 17

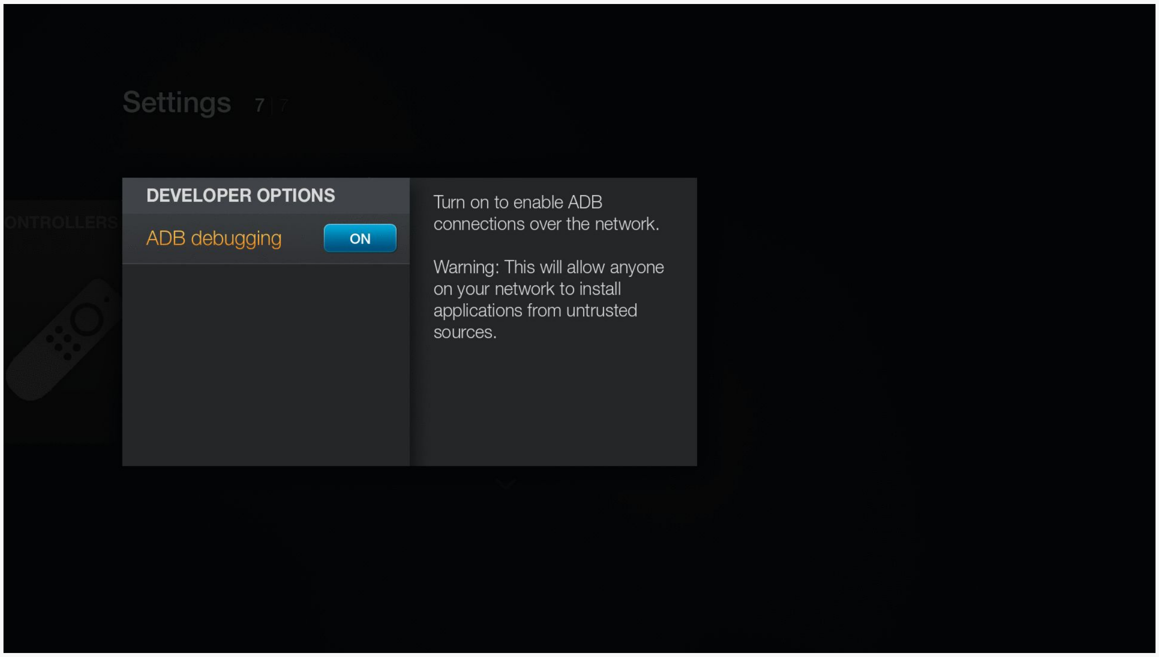
This will give you an "Amazon Fire TV SDK" option as an API level target when setting up an emulator image. However, you will also need to set up a device definition that emulates a suitable screen resolution (e.g., 1080p). And, the resulting emulator does not even vaguely resemble a Fire TV device in terms of the firmware and such.

In truth, at present, you will need to use Fire TV hardware to develop for Fire TV.

Developing on Hardware

The primary thing notably different about testing your app on a Fire TV device is that it does not use a micro USB cable for the `adb` connection, the way that you may be used to from testing with most Android hardware. It does not even use some sort of proprietary cable. Instead, `adb` runs over the network.

To set this up, you must first enable USB debugging, much like you do with other Android devices. On a Fire TV device, this is in Settings > System > Developer Options:



Settings 7 | 7

DEVELOPER OPTIONS

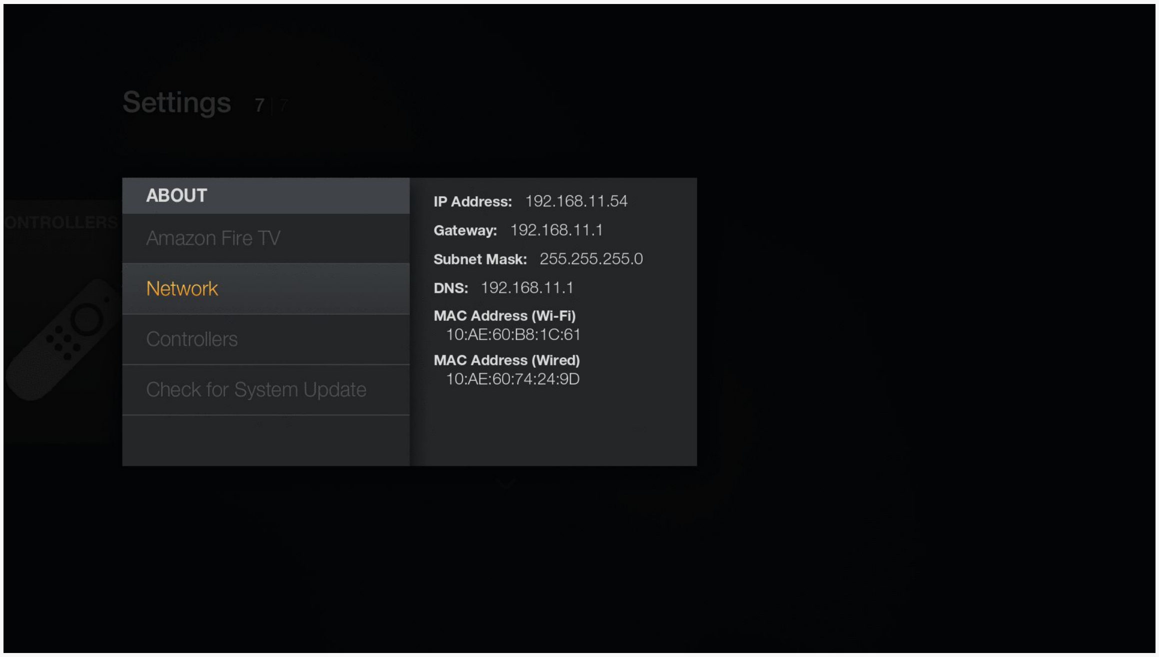
ADB debugging ON

Turn on to enable ADB connections over the network.

Warning: This will allow anyone on your network to install applications from untrusted sources.

Figure 974: Fire TV Developer Settings

You will then need the IP address of your Fire TV device. Most likely the easiest way for you to find that is via the Settings > System > About > Network screen:



IP Address: 192.168.11.54
Gateway: 192.168.11.1
Subnet Mask: 255.255.255.0
DNS: 192.168.11.1
MAC Address (Wi-Fi)
10:AE:60:B8:1C:61
MAC Address (Wired)
10:AE:60:74:24:9D

Figure 975: Fire TV Network Settings

You can then run `adb connect` (followed by the IP address) at a command prompt to make the connection. You may need to stop and restart `adb` before doing this, via `adb kill-server` and `adb start-server`.

At this point, if all is set up properly, `adb devices` will list the Fire TV device's IP address, and the Fire TV device will be accessible from your IDEs and other development tools.

Note that this `adb` setup will persist until `adb` is next restarted, even if the Fire TV device is powered down. You can use `adb disconnect` (followed by the IP address) to break the connection if you no longer need it.

Working with the Remote and Controller

Your Fire TV users will be interacting with their Fire TV using the supplied remote, the Fire TV gaming controller, or other controllers.

Wireless Remote

Mostly, the wireless remote offers buttons that you should be handling already, assuming you are implementing a ten-foot UI or are otherwise correctly handling focus management and accessibility. BACK and the D-pad buttons will work on the Fire TV much as you would expect.

The Fire TV device remote has a MENU button, which will bring up an old-style Android options menu. Your simple action bar items, particularly those in the overflow, will appear in this menu without issue. Most likely you will want to skip the action bar on your Fire TV apps, though, which means that action views, action providers, and the like will need to be replaced with alternatives.

The remote also offers play/pause, rewind, and fast-forward buttons that map to their corresponding Android `KeyEvent` types (e.g., `KEYCODE_MEDIA_PLAY_PAUSE`). You can watch for these events in `onKeyDown()` of your activity to be able to respond to them.

Note that you do not have the ability to intercept home or voice search button presses on the wireless remote. And, the Fire TV Stick's remote does not offer the voice search button.

Gaming Controller

The wireless remote's input options are purely buttons. The Fire TV series gaming controller, like most such controllers, are designed for more "analog" input, where the force you apply to a stick might trigger slightly different behavior in a game.

As such, the gaming controller support in Android and FireOS takes a two-tier approach, with primary and secondary ways of handling events. If your code consumes the primary event, the secondary event is not triggered. The idea is that fairly "vanilla" apps might pay attention to the secondary events, as they tend to be more in common with the events you might get from the wireless remote or non-Fire TV devices. But apps that are more game-centric might pay attention to the primary events instead.

For analog inputs — the left and right sticks and the D-pad — the primary event input is supplied as `MotionEvent` objects, which you can pick up in methods like `onGenericMotionEvent()` in a `View`. Secondary event input comes in the form of standard D-pad events. So, an ordinary app will automatically support the sticks and D-pad, simply by accepting D-pad input.

Some buttons also take the two-tier approach. The A button (bottom one in the button cluster on the upper-right side of the controller) can be picked up either as a `KEYCODE_BUTTON_A` `KeyEvent` (primary) or a `KEYCODE_DPAD_CENTER` `KeyEvent` (secondary). The B button (right one) maps to `KEYCODE_BUTTON_B` (primary) and `KEYCODE_BACK` (secondary).

Other buttons just fire simple `KeyEvents` (e.g., left shoulder is `KEYCODE_BUTTON_L1`), while the two triggers just use `MotionEvents` (`AXIS_BRAKE` on the left, `AXIS_GAS` on the right).

Amazon's Fire TV site has full details of the options and how to use them, plus a dedicated game controller API to help you manage multiple controllers and the like.

How Does Distribution Work?

Like the Kindle Fire, Fire TV devices lack the Play Store. If you want your app to be available to Fire TV device users, you will need to explore other ways of promoting and delivering the app.

The principal — and nearly exclusive — way to get apps onto a Fire TV device is by listing them in the Amazon AppStore for Android, much as you would do for Kindle Fire devices.

However, for ordinary users, that is the *only* option. Most Android devices — including the Kindle Fire series — allow the user to download apps from Web sites, if they have the appropriate option checked in Settings. The Fire TV lacks this setting, and therefore ordinary users cannot download an app to the Fire TV from third-party app stores.

"Sideloading" an app using **`adb`** works, though this is usually only viable for developers or serious power users. Such apps will not appear in the home screen launcher and must be launched instead via Settings > Applications.

Getting Help

Amazon maintains a set of documentation related to Fire TV device development, along with a set of forums for asking Amazon-specific development questions regarding the Fire TV device series or their various SDKs.

Trail: Appendices

Appendix A: CWAC Libraries

CommonsWare — the publisher of this book — has also published a series of open source libraries, collectively named the CommonsWare Android Components (CWAC). If you have read through the book, you will have seen many of these libraries.

This appendix lists all of the CWAC libraries. If the library is covered elsewhere in the book, the appendix links you to that coverage. Those that are not covered elsewhere will be described in this appendix, to accompany the online documentation found at the library's GitHub repository.

cwac-adapter

The cwac-adapter repository contains a small `AdapterWrapper` class that wraps a `ListAdapter`. The default implementation of all `AdapterWrapper` methods is to forward the request along to the wrapped `ListAdapter`. However, you can subclass `AdapterWrapper` to override that behavior.

cwac-cam2

The cwac-cam2 repository holds a CommonsWare library to assist with the use of the hardware cameras on Android devices. This library is covered extensively in the chapter on using the camera.

cwac-colormixer

The cwac-colormixer repository holds a custom ColorMixer View, along with wrappers for using that View as a dialog, activity, or preference for use with PreferenceScreen.

ColorMixerDialog and ColorPreference are covered in the chapter on custom dialogs. The ColorMixer widget is similar to the implementation found in the chapter on custom views.

This library also contains a ColorMixerActivity, which you can use via startActivityForResult() to obtain a color, rather than by integrating the widget, dialog, or preference.

cwac-layouts

The cwac-layouts repository contains a series of custom containers and related views.

The current contents of this library — AspectLockedFrameLayout, MirroringFrameLayout, and kin — are covered in the chapter on custom views.

cwac-merge

The cwac-merge repository contains MergeAdapter. It simply stitches together lots of smaller ListAdapters into one larger ListAdapter to put inside of a ListView or similar AdapterView. It also allows you to blend individual “row” Views with other ListAdapters.

One use of this is for section headers, using row Views for the headers and ListAdapters for the sections.

Another use is where you have multiple disparate data sources (e.g., queries across a few databases or ContentProviders), each with distinct row formatting, but you want to present them as one contiguous list.

cwac-pager

The cwac-pager repository includes code written in support of the `ViewPager` widget.

`ArrayPagerAdapter` is covered in the chapter on advanced uses of `ViewPager`.

cwac-presentation

The cwac-presentation repository contains code in support of the `Presentation` system, for sending alternative content to an external display, independent of the device's primary screen.

All of the classes in this repository are covered in the chapter on the `Presentation` system.

cwac-provider

The cwac-provider repository contains `StreamProvider`, a riff on Google's `FileProvider`, offering a "canned" implementation of a `ContentProvider` that can serve files from a variety of sources, such as assets and raw resources from your project.

This is discussed briefly in the chapter on `ContentProvider` implementations.

cwac-richedit

The cwac-richedit repository contains the `RichEditText` widget, a drop-in replacement for `EditText` that supports "rich text" (a.k.a., formatted text) editing, such as bold and italics. The use of this widget is covered in the chapter on Android's rich text handling.

cwac-sacklist

The cwac-sacklist repository contains `SackOfViewsAdapter`, which implements the `ListAdapter` interface for a collection of individual `Views` that serve as rows. This is used in support of the `MergeAdapter`, for example.

cwac-security

The cwac-security repository contains code to help app developers help their users defend against attacks. At the moment, this contains the `PermissionUtils` class, used to help determine if a custom permission was defined by another app before yours was installed. This is discussed in the chapter on advanced permission techniques.

cwac-strictmodeex

The cwac-strictmodeex repository contains classes that serve a similar role to Android's `StrictMode`, yelling at you for problematic code.

Specifically, this repository contains `StrictAdapter`, which measures the timing of methods like `getView()`, logging information about slow adapters that may result in sluggish `ListView` scrolling.

cwac-wakeful

The cwac-wakeful repository contains the `WakefulIntentService` and related support classes, for doing work and keeping the device awake while that work is going on. This is covered in the chapter on `AlarmManager`.

Appendix B: Android 6.0 Developer Preview

In May 2015, Google released the M Developer Preview. This was a "preview of coming attractions", representing what amounts to a beta release of the next version of Android. You will also see references to "MNC" for this preview, where MNC was short for "macademia nut cookie".

In late August 2015, Google upgraded that to a preview of Android 6.0, complete with an official API level (23), an official "tasty treat" (Marshmallow), and the official SDK. However, Android 6.0 will not be made available to ordinary people via over-the-air upgrades until later in 2015.

Android developers may wish to download and experiment with the preview release of Android 6.0, to understand what is changing and how those changes may affect their apps. Some changes are tiny. Some changes are… not so tiny.

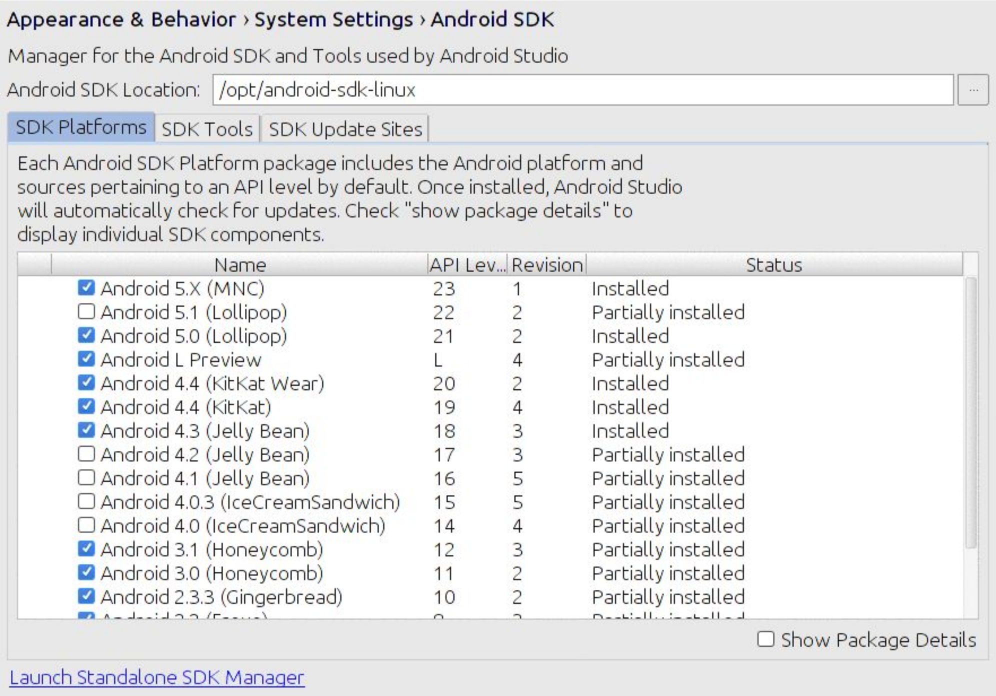
This appendix will outline a number of the changes in Android 6.0, with links to the places elsewhere in the book where these new concepts are covered. Note that this appendix will be removed from the book in Version 6.0, tentatively slated to be released in December, by which point in time Android 6.0 should be fully released.

Updating to Android 6.0

If you wish to start playing with the Android 6.0 SDK and preview, you will need to download some materials, tweak your project to use the new SDK, and then try it out on devices or emulators.

SDK Platform, Tools, and Documentation

Android Studio’s native SDK Manager may or may not show Android 6.0. Android Studio 1.3, in particular, does not:



Appearance & Behavior › System Settings › Android SDK

Manager for the Android SDK and Tools used by Android Studio

Android SDK Location: /opt/android-sdk-linux

SDK Platforms | SDK Tools | SDK Update Sites

Each Android SDK Platform package includes the Android platform and sources pertaining to an API level by default. Once installed, Android Studio will automatically check for updates. Check "show package details" to display individual SDK components.

Figure 977: Classic SDK Manager, Showing Android 6.0

From there, you can download whatever you want, such as the SDK Platform (to compile against new APIs), documentation, emulator images, and so forth.

Project Setup

If you wish to compile against the Android 6.0 SDK, change your `compileSdkVersion` to 23.

You may also wish to set your `targetSdkVersion` to 23, to indicate that you are opting into conditional behaviors added in API Level 23. That is particularly important if you want to adopt the new runtime permissions system.

In addition, you will need to update your Android Plugin for Gradle to use `1.3.0` (or something newer, if it exists):

```
buildscript {
    repositories {
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.3.0'
    }
}
```

This, in turn, may cause you to want to upgrade the Gradle that your project uses. In `gradle/wrapper/gradle-wrapper.properties`, adjust the version number in the `distributionUrl` to be 2.4 or newer:

```
distributionUrl=https\://services.gradle.org/distributions/gradle-2.4-all.zip
```

And, you want your `buildToolsVersion` to be `23.0.0` (or something newer, if it exists).

Emulator and Devices

You can download new emulator images for Android 6.0 from the SDK Manager and use them more or less like any other emulator images.

If you have a spare Nexus 5, Nexus 6, Nexus 9, or Nexus Player, you can also flash a copy of the Android 6.0 preview release onto hardware. To do this:

1. Download the appropriate image for your device and check the MD5 or SHA-1 checksums when the file is downloaded. Do not install an image where the checksums do not match.
2. Go into Settings > Developer Options on the existing device, see if there is an "OEM Fastboot" option, and enable it. This will be required for the Nexus 9, but not the Nexus 5 (Nexus 6 and Nexus Player were not tested).
3. Plug the device into your development machine and get USB debugging going, if you have not done so already for this device.
4. Run `adb reboot bootloader` from the command line. This requires the `platform-tools/` directory of your Android SDK installation to be in your `PATH`. This command reboots your device into the bootloader.
5. Run `fastboot oem unlock` from the command line, to unlock the bootloader.
6. Unpack the image archive that you downloaded in step #1, go into the directory that it creates, and run the `flash-all` shell script or batch file. This will run for a minute or so. **DO NOT UNPLUG YOUR DEVICE WHILE THIS IS GOING ON**. When completed, the device will reboot, and you will be greeted by the Android 6.0 setup wizard, as if you had bought the device with Android 6.0 installed.

Also, if you ever plan on taking this device out of the lab, you will want to relock the bootloader. To do this, you will need to set up USB debugging again, run `adb reboot bootloader` again, and run `fastboot oem lock` (as opposed to the `unlock` you ran previously). Note that this may factory reset your device, forcing you to set up the device yet again.

More details about flashing images onto the Nexus devices can be found in the documentation.

What's New in Android 6.0?

So, with all that behind us, what did we get in Android 6.0 that may be of interest to you?

ART Changes and Support Library Requirements

If you are using `appcompat-v7` and/or `recyclerview-v7`, you need to upgrade to Version 23 or higher of those libraries. There are changes to ART – the Android runtime used on Android 5.0+ — that apparently will break the older versions of these libraries.

Apache HttpClient Removal

Android baked in a copy of Apache's HttpClient library back in Android 1.0. In Android 5.1, they marked it as deprecated. And, in Android 6.0, they have all but removed it entirely from the Android SDK.

If you have been using HttpClient, you are strongly encouraged to switch to something else. Google suggests `HttpUrlConnection`, the classic Java HTTP API. There is also OkHttp and a variety of higher-level networking libraries (e.g., Retrofit for REST-style Web services).

If you really need to stick with the HttpClient API for now, consider using OkHttp and its HttpClient compatibility layer. Or, consider adding Apache's own Android port of HttpClient as a library and using it instead.

And, if you cannot do any of that, and you are using Gradle for Android for your builds (e.g., you are using Android Studio's default settings), you can add `useLibrary 'org.apache.http.legacy'` to the `android` closure to give you access to Android's stock HttpClient API:

```
android {
    useLibrary 'org.apache.http.legacy'
    // other settings go here
}
```

And if you cannot do any of that — such as you are using Eclipse – you are out of luck.

App Permissions

We have had permissions, principally in the form of `<uses-permission>` elements, since Android 1.0. Little has changed about their fundamental workings since that time. While we have gained new permissions, and occasionally started needing permissions for things that used to not be protected by them, the basic recipe for permissions remained the same:

1. Have the needed `<uses-permission>` elements in the manifest
2. Hope the user agrees to install your app, thereby giving you all of the requested permissions
3. ???
4. Profit!

However, Android 6.0 significantly alters the behavior of certain permissions. Not only will the user not be asked for them at install time (supposedly), but we will need to request them at runtime, and the user can say "no". This has a lot of ramifications for app design.

This is covered in great detail in the chapter on permissions and in a standalone tutorial demonstrating how to migrate an app to use the new runtime permission system.

Background Work

Android 6.0 has declared a war on background processing. In an effort to further improve battery life, `AlarmManager`, `JobScheduler`, and the like no longer behave as originally envisioned. You may ask to get control every 15 minutes, but how frequently you *actually* get control will vary based on environmental factors, such as whether the device is moving or is charging.

This is covered in detail in the chapter on `JobScheduler`.

"Adoption" of Removable Storage

In Android 6.0, users can "adopt" removable storage, such as a micro SD card, and have that effectively extend the amount of space available for internal storage. The old `android:installLocation` manifest attribute, generally unused on modern devices, becomes relevant again, as you can decide whether or not your app can be moved to removable storage.

This is covered in greater detail in the chapter on advanced manifest features.

App Links

Android 6.0 allows apps, in conjunction with developer-owned Web sites, to "claim" URLs. Activities can advertise that they should be the one to respond to such URLs. An `ACTION_VIEW` `Intent` on claimed URLs will launch the designated activities, bypassing the chooser.

This is covered in greater detail in the chapter on responding to URLs.

There were some noteworthy changes in Android 6.0 from the behavior in the M Developer Preview:

- The filename hosted on the server is now `assetlinks.json`, not `statements.json`.
- The URL pointing to `/.well-known/assetlinks.json` on your server needs to support the `https` protocol.
- *Every* Web URL supported by your app, for all activities and `<intent-filter>` structures has to work with app links, or none will. Even if you set `android:autoeVerify` to `true` for only one `<intent-filter>`, every `<activity>` and `<intent-filter>` will be tested. If you have multiple domains specified in those `<intent-filter>` structures, they *all* need to have `/.well-known/assetlinks.json` files, listing your app, available via HTTPS.

Direct Share

The classic means of "sharing" content between apps is via `ACTION_SEND`. You create an `ACTION_SEND` `Intent`, identifying the content to share, and use it with `startActivity()`. The decision of what the candidates are to share with is based solely on the MIME type of the content in question.

Sometimes, sharing of content with another app really means sharing that content with some other person, folder, or finer-grained context within the other app. ACTION_SEND, on its own, does not do anything for this. The user chooses the other app, then inside that app chooses the finer-grained context. While ACTION_SENDTO supports the sender indicating who to share the content with, that only works for select Uri schemes (mailto and smsto, mostly), and it requires that the sender have a suitable Uri to identify the recipient. As a result, few apps support ACTION_SENDTO.

Android M introduces "direct share targets". Now, the recipients of sharing operations can elect to serve up specific share targets, pointing not only to the app but to the finer-grained context within the app. The user will then see these targets listed in the "chooser" window, alongside other standard share targets.

This involves creating a subclass of ChooserTargetService and tying it via some <meta-data> to your activity supporting the ACTION_SEND <intent-filter>. That service will then be called with onGetChooserTargets(), where it is told what activity and <intent-filter> was matched, and the service can return a list of ChooserTarget objects. Those ChooserTarget objects each represent a single direct share target, where the ChooserTarget wraps up a dedicated caption, icon, and PendingIntent for each. Those may be presented to the user in the chooser; if the user chooses one, the PendingIntent is invoked.

The Intents/FauxSenderMNC sample project is a revised version of the FauxSender sample. FauxSender has an implementation of an ACTION_SEND activity, plus a LAUNCHER activity that just uses startActivity() to trigger an ACTION_SEND Intent. FauxSenderMNC augments the original sample with direct-share functionality.

The ChooserTargetService

The bulk of the business logic goes in your subclass of ChooserTargetService, here named CTService:

```
package com.commonsware.android.fsendermnc;

import android.app.PendingIntent;
import android.content.ComponentName;
import android.content.Intent;
import android.content.IntentFilter;
import android.graphics.drawable.Icon;
import android.os.Bundle;
import android.service.chooser.ChooserTarget;
import android.service.chooser.ChooserTargetService;
import java.util.ArrayList;
import java.util.List;
```

```
public class CTService extends ChooserTargetService {
  private String titleTemplate;

  @Override
  public void onCreate() {
    super.onCreate();

    titleTemplate=getString(R.string.title_template);
  }

  @Override
  public List<ChooserTarget> onGetChooserTargets(ComponentName sendTarget,
                                                 IntentFilter matchedFilter) {
    ArrayList<ChooserTarget> result=new ArrayList<ChooserTarget>();

    for (int i=1;i<=6;i++) {
      result.add(buildTarget(i));
    }

    return(result);
  }

  private ChooserTarget buildTarget(int targetId) {
    String title=String.format(titleTemplate, targetId);
    int iconId=getResources().getIdentifier("ic_share" + targetId,
        "drawable", getPackageName());
    Icon icon=Icon.createWithResource(this, iconId);
    float score=1.0f-((float)targetId/40);
    ComponentName cn=new ComponentName(this, FauxSender.class);
    Bundle extras=new Bundle();

    extras.putInt(FauxSender.EXTRA_TARGET_ID, targetId);

    return(new ChooserTarget(title, icon, score, cn, extras));
  }
}
```

You are welcome to override the `onCreate()` and `onDestroy()` lifecycle methods in your `ChooserTargetService` if you want, though it is not required. Here, we override `onCreate()` just to grab a string resource value that will be used as a template, stashing it in a data member.

The one method that you have to implement is `onGetChooserTargets()`. This will be called when direct-share is triggered, as directed by some manifest entries that we will examine in a bit. Your job is to return a `List` of `ChooserTarget` objects that represent specific ways to share the content into your app, such as sharing to particular contacts or folders or something.

Note that whatever you return from `onGetChooserTargets()` is included *along with your regular `ACTION_SEND` activity itself*. Hence, you only want to return `ChooserTarget` objects that improve the user flow beyond your base `ACTION_SEND` activity — you do not need to have a ChooserTarget that simply replicates what the user would get from the ACTION_SEND activity itself.

In this case, onGetChooserTargets() returns a six-element ArrayList of ChooserTarget objects, each built using a private buildTarget() method.

A ChooserTarget is a simple wrapper around five pieces of data:

- A String to use as a caption for your direct-share icon
- An Icon that represents the icon itself
- A float "score" that represents the relative importance of this direct-share target over any others that you return, where 1.0f means "the user is really going to like this one", 0.0f means "the user could conceivably want this, but probably not", and values in between 0 and 1 represent shades of gray in the realm of importance
- A ComponentName identifying either an activity in your app (the typical answer) or an exported activity in another app (rather unusual)
- A Bundle of extras to go into the Intent that the framework will create, using that ComponentName, to trigger the activity in question

Note that the ComponentName does *not* have to start the same activity that is your ACTION_SEND activity. In this sample, it happens to use the same activity. But that is not a requirement, and frequently you will use some other activity. For example, if your normal ACTION_SEND flow would first have the user choose a folder, then provide additional information about the shared item (e.g., confirm the title, add tags), if you create direct-share targets that specify particular folders, you would want to bypass the folder-selection step in your own UI. If the ACTION_SEND activity implements the folder-selection logic and forwarded the user along to some other activity to handle the rest, your ChooserTarget ComponentName objects might just drive straight to the second activity, skipping the folder-selection UI.

Also note that you may be creating several ChooserTarget objects, probably having each pointing to the same activity. You will need to ensure that the extras Bundle contains what you need to distinguish one request from the next. However, do not put custom Parcelable objects in this Bundle, as Android will attempt to un-parcel them as part of its work, and it will fail to do so since Android does not have your custom Parcelable class.

An Icon is a new construct in Android 6.0, serving as a wrapper around multiple possible image sources. You can create an Icon from a drawable resource (as the sample app does), from a Bitmap, from a byte array representing PNG or JPEG data, from a file path pointing to a PNG or JPEG file, or from a `Uri` to a `ContentProvider` pointing to an image.

The Manifest Entries

Your `ChooserTargetService` will have a typical `<service>` manifest entry, with two special bits:

- An `android:permission="android.permission.BIND_CHOOSER_TARGET_SERVICE"` attribute, to limit access to your service to the framework, rather than being spoofed by other clients, and
- An `<intent-filter>` for the `android.service.chooser.ChooserTargetService` action

```
    <service
      android:name=".CTService"
      android:permission="android.permission.BIND_CHOOSER_TARGET_SERVICE">
      <intent-filter>
        <action android:name="android.service.chooser.ChooserTargetService"/>
      </intent-filter>
    </service>
```

Your `ACTION_SEND` activity will have its normal `<activity>` element, with just one change: a `<meta-data>` element pointing to your `ChooserTargetService`:

```
    <activity
      android:name="FauxSender"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter android:label="@string/app_name">
        <action android:name="android.intent.action.SEND"/>

        <data android:mimeType="text/plain"/>

        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
      <meta-data
        android:name="android.service.chooser.chooser_target_service"
        android:value=".CTService"/>
    </activity>
```

It is possible that your app has multiple `ACTION_SEND` activities. In that case, each could have its own `ChooserTargetService`. However, you could elect to have all of your `ACTION_SEND` activities route to the same `ChooserTargetService` if you prefer. `onGetChooserTargets()` is passed two parameters to help identify where the direct-share request is coming from:

- the ComponentName of the ACTION_SEND activity that was tied to your service, and
- the IntentFilter that triggered that activity in the first place, so you can determine things like the MIME type of the to-be-shared content

Note that you are *not* given the content itself, in the form of the Intent that will eventually be delivered to your ACTION_SEND activity or to your direct-share target via its ComponentName. This is for privacy reasons; otherwise, an app could ask to share anything and be able to peek at anything the user tried sharing with any app.

The Results

The FauxSender activity — the one handling the ACTION_SEND Intent and the direct-share Intent — now looks for the EXTRA_TARGET_ID that the CTService put in its Intent and includes it in the Toast:

```
package com.commonsware.android.fsendermnc;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.widget.Toast;

public class FauxSender extends Activity {
  public static final String EXTRA_TARGET_ID="targetId";

  @Override
  public void onCreate(Bundle savedInstanceState) {
    String epilogue="";

    super.onCreate(savedInstanceState);

    int targetId=getIntent().getIntExtra(EXTRA_TARGET_ID, -1);

    if (targetId>0) {
      epilogue=" for target ID #"+targetId;
    }

    String msg=getIntent().getStringExtra(Intent.EXTRA_TEXT);

    if (TextUtils.isEmpty(msg)) {
      msg=getIntent().getStringExtra(Intent.EXTRA_SUBJECT);
    }

    if (TextUtils.isEmpty(msg)) {
      msg=getString(R.string.no_message_supplied);
    }

    Toast.makeText(this, msg+epilogue, Toast.LENGTH_LONG).show();

    finish();
  }
}
```

If you run the sample app from Android Studio, the launcher activity will trigger an `ACTION_SEND` of some text. That, in turn, will bring up the chooser panel… but on an Android 6.0 device, that panel will start off with our six direct-share targets:

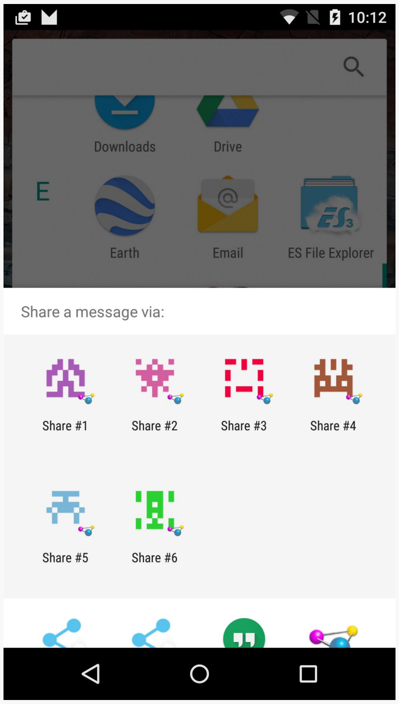

Figure 978: Chooser, Showing Direct-Share Targets

Expanding the panel shows that our original `ACTION_SEND` activity is also there, after the direct-share targets:

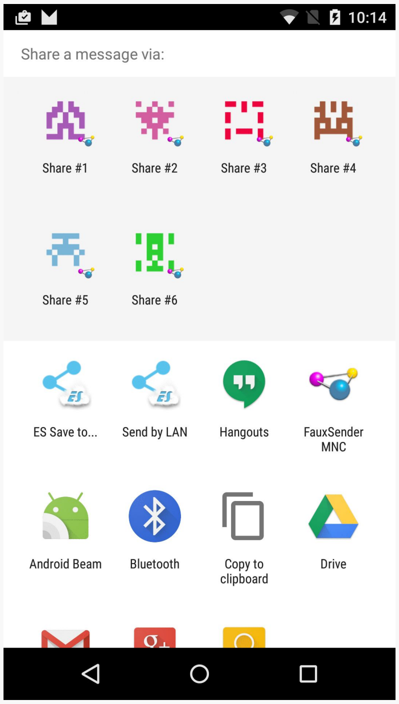

Figure 979: Chooser, Showing More Share Targets

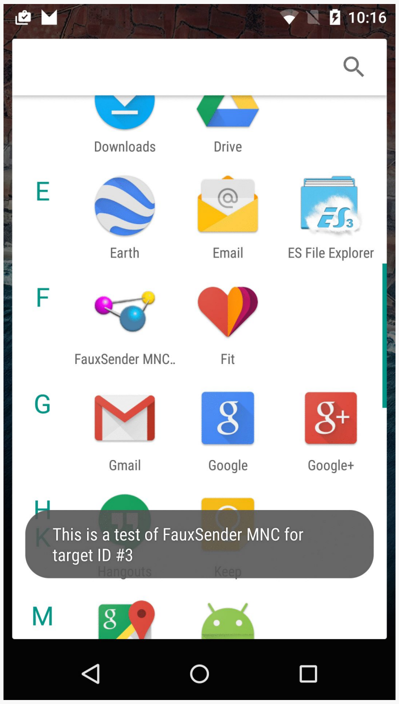
If the user taps on the regular `ACTION_SEND` activity icon, the sample works as it did originally, showing a `Toast` with the text supplied by the launcher activity. If, however, the user taps on one of the direct-share targets, the `Toast` also shows which target was chosen:



This is a test of FauxSender MNC for target ID #3

Figure 980: Toast from a Direct-Share Target

Now, our `Bundle` for the direct-share target did not include the shared text, because we did not have it. Instead, the regular `ACTION_SEND` extras are merged in with our own extras, so our activity gets all of the relevant extras.

But… I Got Nothin'!

If you do not have any direct-share targets for a particular request, returning an empty list is perfectly fine.

If you know in advance that you will not have any direct-share targets — for example, the user has not really worked with your app yet after installation — you can disable the service (`android:enabled="false"`). Even though the `<meta-data>` will point to the service, the framework seems to detect the disabled service and continues on unabated.

Even if you elect to leave the service enabled at the outset for Android 6.0, you should consider disabling the service for earlier versions of Android, since it is useless on those devices. You could do this using boolean resources:

- Have a `res/values/bools.xml` file with a `bool` resource (e.g., `offer_direct_share`) set to `false`
- Have a `res/values-v23/bools.xml` file redefining that resource to `true` (NOTE: this assumes that Android M will be API Level 23)
- Have `android:enabled="@bool/offer_direct_share" on your service, to have it be enabled only on Android 6.0 and higher

Best Practices

At the moment, it appears that Android 6.0 is limiting the number of share targets, only showing 8 of them. If you provide more than 8, Android will choose the ones with the highest score.

Since returning the list of direct-share targets should be involving IPC, there may be capacity limitations, for the number and size of the direct-share targets. Do not be surprised if you get a "FAILED BINDER TRANSACTION" exception if your roster of direct-share targets exceeds 1MB.

Hence, between those two limitations, you will want to constrain how many share targets you try returning from your `ChooserTargetService`.

As with other places in Android 5.0+ (e.g., large icons in notifications), your app's icon will be applied as a badge over the icons that you use for direct-share targets. Make sure that your app's icon will work both as a launcher icon and as a direct-share target badge.

Notification Changes

Historically, while we could supply a "large bitmap" (e.g., photo or avatar) to a `Notification` for use in the tile in the notification tray as a `Bitmap`, the "small icon" used for the status bar always had to be a resource in our app. This was aggravating for developers that wanted to tailor the small icon, such as a weather app showing the current temperature. Now, we can supply an `Icon` object, which can wrap a drawable resource, a `Uri` to a `ContentProvider`, a `byte` array of encoded bitmap data, a `Bitmap`, or a path to a local PNG or JPEG file. Any of those can be used for the small icon, offering greater flexibility. That being said, please do bear in mind that the small icon is small (i.e., tiny changes may not be noticeable) and that ideally it should adhere to the platform aesthetic for notification icons (i.e., do not use a photo).

The user can now disable our heads-up notifications, if the user finds them irritating. We can get an idea of what the user's chosen notification policies are via `getCurrentInterruptionFilter()` and `getNotificationPolicy()`, so we have some general sense of what the user is and is not expecting to see in terms of notifications.

And, at long last, we can find out all of our active notifications, via a `getActiveNotifications()` method. This will include any notification that is visible to the user (i.e., the user has not dismissed it and we have not gotten rid of it via `cancel()`).

Floating Action Mode and `ACTION_PROCESS_TEXT`

A new `Intent` action, `ACTION_PROCESS_TEXT`, was added in Android 6.0. Apps with activities that advertise support for this action will be integrated into text selection options, such as in an `EditText`, of other apps. Google's Translate app, for example, uses `ACTION_PROCESS_TEXT` to allow for users to translate any selectable text, just by highlighting it and choosing "TRANSLATE" from a floating action mode.

The chapter on miscellaneous integration techniques has a section on this new `Intent` action.

Assist API / "Now On Tap"

At Google I|O 2015, Google heavily touted "Now on Tap", a feature where Google Now can peek into a running app and provide contextual assistance. A post on ProgrammableWeb suggests that "Now on Tap" will be accomplishing this via "the view hierarchy", presumably meaning the accessibility APIs.

There is an "assist API" that an app can use to surface additional information that "Now on Tap" (or equivalent capabilities for non-Play devices) could use.

However, "Now on Tap" is not shipping as part of the Android 6.0 preview devices, and so we cannot readily test how all this works, or confirm that `FLAG_SECURE` will block this functionality.

Chrome Custom Tabs

Google announced that "Chrome custom tabs" will be available soon, serving as middle ground between using a `WebView` in your own app and launching a URL into a separate Web browser.

With a `WebView`, you have complete control over the overall user experience within your app. However, your `WebView` is decoupled from any other browser the user may be using on the device. Conversely, launching URLs into the user's chosen browser gives the user their normal browsing experience, but you have no control over the user experience, as the user is now in the browser app, not your app.

With Chrome custom tabs, while Chrome is handling the URL, it will allow you limited control over the action bar (color and custom actions). It also simplifies some things that you might otherwise have had to handle yourself, such as pre-fetching a Web page to be able to quickly switch to it. Basic integration is also fairly easy, coming in the form of extras on the same sort of `ACTION_VIEW Intent` that you might have used for launching the URL in a standalone browser.

At the same time, there are some concerns:

- The documentation states that there is a "Shared Cookie Jar and permissions model so users don't have to log in to sites they are already connected to, or re-grant permissions they have already granted", which would require significant testing to ensure that you are not leaking information into Chrome that might be somehow delivered to other sites (including Google).
- While it uses an `ACTION_VIEW Intent`, and so the user can choose to view the URL in a different browser, you will not get the custom integration in that case. This may be fine, but you will need to make sure that from a marketing and documentation standpoint you handle both the case where the user chooses Chrome (and you get the "custom tab") and the case where the user chooses something else.
- Since any app could handle the `ACTION_VIEW Intent`, you need to take into account that any information in the custom extras, like the `PendingIntent` to use for an custom action bar item, is stuff that you are willing for *arbitrary* apps to get their hands on. Do not assume that your communications will solely be with Chrome.

Also, at the moment, this is only available on the "dev" channel for Chrome, and therefore is not going to be available to the vast majority of Android users. It should ship in final form later in 2015.

Auto Backup for Apps

All Android apps are by default opted into "auto backup for apps", where your app data will be silently copied to Google's servers, available to be restored if the user buys another device.

This feature raises many issues, particularly since the data does not appear as though it will be encrypted with a user-supplied key.

Please consider opting out, at least initially, by having `android:allowBackup="false"` on the `<application>` element in your manifest, until you and your legal advisors can determine the scope of the risk to you and your users.

Encrypted Networks

One easy way to boost the security of your app is to use SSL when communicating to Web servers. However, it is easy to accidentally using `http` URLs instead of `https` counterparts by accident. Android M offers a couple of approaches for trying to detect those problems during testing.

Requiring Encryption

As John Kozyrakis points out, Android M supports an `usesCleartextTraffic` attribute on the `<application>` element in the manifest. If this is set to `false`, you are saying that your app not only should be using SSL for everything, but that you expressly want to crash the app in case you wind up *not* using SSL.

For example, the `Service/DownloaderMNC` sample project is a clone of the `Service/Downloader` sample, where we use an `IntentService` to download a file. The `DownloaderMNC` edition has the `usesCleartextTraffic` attribute, where the value is tied to a similarly-named `bool` resource:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.android.downloader"
          xmlns:android="http://schemas.android.com/apk/res/android"
          android:versionCode="1"
          android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="14"/>

  <uses-permission android:name="android.permission.INTERNET"/>
  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>

  <application
```

```
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar"
    android:usesCleartextTraffic="@bool/usesCleartextTraffic">
    <activity
      android:name="DownloaderDemo"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <service android:name="Downloader"/>
  </application>

</manifest>
```

That bool resource comes from product flavor definitions in build.gradle, set up via resValue directives:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.squareup.picasso:picasso:2.5.2'
    compile 'com.squareup.retrofit:retrofit:1.9.0'
    compile 'com.android.support:support-v13:22.2.0'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.0"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 18
        versionCode 1
        versionName "1.0"
    }

    productFlavors {
        https {
            resValue "bool", "usesCleartextTraffic", "false"
            buildConfigField "String", "DOWNLOAD_URL", '"https://commonsware.com/misc/
molecule.png"'
            buildConfigField "boolean", "APPLY_STRICT_MODE", "false"
        }

        httpValidated {
            resValue "bool", "usesCleartextTraffic", "false"
            buildConfigField "String", "DOWNLOAD_URL", '"http://commonsware.com/misc/
molecule.png"'
            buildConfigField "boolean", "APPLY_STRICT_MODE", "false"
        }
        http {
            resValue "bool", "usesCleartextTraffic", "true"
            buildConfigField "String", "DOWNLOAD_URL", '"http://commonsware.com/misc/
molecule.png"'
            buildConfigField "boolean", "APPLY_STRICT_MODE", "false"
        }

        httpRuntime {
            resValue "bool", "usesCleartextTraffic", "true"
            buildConfigField "String", "DOWNLOAD_URL", '"http://commonsware.com/misc/
molecule.png"'
            buildConfigField "boolean", "APPLY_STRICT_MODE", "true"
        }
    }
}
```

There are four product flavors, each controlling the `usesCleartextTraffic` resource and the `DOWNLOAD_URL` value for `BuildConfig`:

Product Flavor	usesCleartextTraffic	`DOWNLOAD_URL` Scheme
`https`	`false`	`https`
`httpValidated`	`false`	`http`
`http`	`true`	`http`
`httpRuntime`	`true`	`http`

(we will look at the `httpRuntime` one a bit more later in this chapter)

The `DOWNLOAD_URL` value is then used when crafting the `Intent` used as the command to the `IntentService`:

```
  @Override
  public void onClick(View v) {
    b.setEnabled(false);

    Intent i=new Intent(getActivity(), Downloader.class);

    i.setData(Uri.parse(BuildConfig.DOWNLOAD_URL));

    getActivity().startService(i);
  }
```

The Build Variants view in Android Studio will allow you to toggle between those four product flavors (mixed in with the two stock build types to create eight build variants). If you run either the `http` or `https` flavors, the sample app works, because the scheme matches the `usesCleartextTraffic` value. If, however, you run the `httpValidated` flavor, you will crash when you attempt to download the file, with a stack trace akin to:

```
06-19 08:03:46.325    6420-6478/com.commonsware.android.downloader E/
com.commonsware.android.downloader.Downloader: Exception in download
    java.net.UnknownServiceException: CLEARTEXT communication not supported: []
            at com.android.okhttp.Connection.connect(Connection.java:149)
            at com.android.okhttp.Connection.connectAndSetOwner(Connection.java:185)
            .
            .
            .
```

Here, `HttpUrlConnection` uses a variant of Square's OkHttp as its implementation, and it is failing the request because of the scheme mismatch with the `usesCleartextTraffic` value.

What is really going on "under the covers" is that this attribute sets a flag that HTTP client APIs can check, electing to fail a request if the flag says that SSL is required and the request's URL does not have the `https` scheme. Android's built-in HTTP clients should support this flag, but third-party HTTP stacks that manage their own socket connections may not. Also note that `WebView` does not honor `usesCleartextTraffic`.

Watching for Encryption

The downside of `usesCleartextTraffic` is that it is "all or nothing" and always terminates your process. That is wonderful in situations where SSL is crucial. It is less wonderful if your app crashes in production in situations where SSL would be a really good idea but is unavailable for whatever reason.

`StrictMode` now supports a way to be warned if your app performs unencrypted network operations, via a `detectCleartextNetwork()` method on `StrictMode.VmPolicy.Builder`. You can configure this, and suitable penalties, alongside the rest of your `StrictMode` setup. This can include doing different things for `debug` versus `release` builds, for example. So, in a `debug` build, you might choose `penaltyDeath()` to crash the process, while in a `release` build, you settle for `penaltyLog()` or something else less drastic.

That is where the fourth product flavor, `httpRuntime`, comes into play. If you choose that, we enable logging of cleartext requests without crashing the app, via some code in the `DownloaderDemo` activity:

```
    if (BuildConfig.APPLY_STRICT_MODE) {
      StrictMode.VmPolicy.Builder b=new StrictMode.VmPolicy.Builder();

      b.detectCleartextNetwork().penaltyLog();
      StrictMode.setVmPolicy(b.build());
    }
```

If you run the `httpRuntimeDebug` variant and click the button, the download will succeed, but you will get something like this in LogCat:

```
08-19 17:28:28.794    7117-7129/com.commonsware.android.downloader E/StrictMode:

            at android.os.Binder.execTransact(Binder.java:453)
```

If you are using a build server, you could set it up to watch for `StrictMode` LogCat messages coming from your app to find out about these accesses.

Fingerprint APIs

While various manufacturers have offered fingerprint sensors for a while, it took until Android 6.0 to have a standard API for working with them. You can request a fingerprint scan at any point, as a form of authentication. Also, you can trigger a standard device authentication at any point, to ensure that the actual user is the one manipulating your app, instead of having your own authentication scheme. However, bear in mind that the use of fingerprints for authentication may be impacted by laws in your jurisdiction. For example, there is a greater chance that US courts will force a defendant to decrypt his device via a fingerprint than via a password, courtesy of interpretations of the Fifth Amendment to the US Constitution.

Voice Actions and Voice Interactions

Google Now can already invoke your app in response to voice input. For example, if you implemented a Web browser, and you support `ACTION_VIEW` for `http`/`https` URLs, if the user asks Google Now to "open commonsware.com", this should work just as if the user had tapped on a link to commonsware.com in some random app, and your browser should be an available choice.

You can invent new voice actions and register them with Google, to help drive traffic to your app specifically.

And, through voice interactions, you can continue interacting with the user through speech, if you need more details in order to complete the requested action. This could be a simple confirmation or allowing the user to make a choice from some list of candidates. In other words, the interactions will be somewhat reminiscent of interactive voice response (IVR) systems used for routing calls and handling input in large phone systems.

Miscellaneous UI Changes

The `AnalogClock` widget has been deprecated. Developers can still use it, but Google is no longer maintaining it, and it's possible (though unlikely) that it will be removed from some future version of Android. With luck, somebody will create an open source `AnalogClock` replacement, or fork of the original `AnalogClock`, for those wishing to maintain this functionality in their apps.
