The less-obvious problem is that we are calling `notifyDataSetChanged()` when the action mode is dismissed, to force a full repaint of the `RecyclerView` contents. While this works, it is overkill, as probably only a subset of the visible items are checked. Ideally, we would only update the specific positions that were checked and now, with the action mode finished, are unchecked. We could find the affected `RowController` instances, using `findViewHolderByPosition()` on `RecyclerView`, as we did in the single-choice list sample. But, really, updating the checked state is just another manifestation of the same problem that capitalizing or removing words causes: we need to ensure that the `RecyclerView` depicts the current model state, ideally with minimum work.

So, let's see how this is accomplished, by looking at the RecyclerView/ActionModeList2 sample project. As the name suggests, this is a clone of the `ActionModeList` shown in the preceding section. This time, we will fully implement `onActionItemClicked()` and allow our model data to be mutable.

Updating Existing Contents

With `AdapterView` and `Adapter` classes based on `BaseAdapter`, the only way we had to tell the `AdapterView` about model data changes was `notifyDataSetChanged()`. This would trigger a rebuild of the entire `AdapterView`, which is slow and expensive.

While `RecyclerView.Adapter` has its own `notifyDataSetChanged()`, that is really for total reloads of the model data, such as having gotten a fresh `Cursor` from a database and not knowing exactly what the changes are. If you are driving the changes yourself from the UI — and particularly if your model data is something like an `ArrayList` of model objects – you can use methods on `RecyclerView.Adapter` that are more fine-grained than is `notifyDataSetChanged()`.

If an item was updated in place — such as a word now being capitalized – you can use `notifyItemChanged()` on `RecyclerView.Adapter` to point out the specific position that changed. Alternatives include:

- `notifyItemMoved()`, to indicate that an item is still in the model data but now is in a new position
- `notifyItemRangeChanged()`, to indicate a range of positions that were modified, instead of having to repeatedly call `notifyItemChanged()`

`ActionModeList2` uses `notifyItemChanged()` when the user capitalizes words, to get those items repainted, if needed. It may not be needed immediately, if one or more of those items are not presently visible within the `RecyclerView`.

However, so far, our model data has been a static `String` array, and now we need a mutable model. So, we take the same approach as the `ListView` action mode samples use, converting our model to be an `ArrayList` that happens to be populated by a static `String` array.

The `items` data member of `MainActivity` is now an `ArrayList` of `String`, with the static `String` array being converted into `ORIGINAL_ITEMS`:

```
  private static final String[] ORIGINAL_ITEMS={"lorem", "ipsum", "dolor",
          "sit", "amet",
          "consectetuer", "adipiscing", "elit", "morbi", "vel",
          "ligula", "vitae", "arcu", "aliquet", "mollis",
          "etiam", "vel", "erat", "placerat", "ante",
          "porttitor", "sodales", "pellentesque", "augue", "purus"};
  private ArrayList<String> items;
```

Places that used to refer to `items` now use a private `getItems()` method, which lazy-instantiates the list if needed:

```
  private ArrayList<String> getItems() {
    if (items==null) {
      items=new ArrayList<String>();

      for (String s : ORIGINAL_ITEMS) {
        items.add(s);
      }
    }

    return(items);
  }
```

We also need to ensure that we hold onto the items across configuration changes, since those items could be changed by the user. So, our `onSaveInstanceState()` and `onRestoreInstanceState()` methods on `MainActivity` now handle that chore, in addition to their original behavior of having the `ChoiceCapableAdapter` persist checked states:

```
  @Override
  public void onSaveInstanceState(Bundle state) {
    adapter.onSaveInstanceState(state);
    state.putStringArrayList(STATE_ITEMS, items);
  }

  @Override
  public void onRestoreInstanceState(Bundle state) {
    adapter.onRestoreInstanceState(state);
    items=state.getStringArrayList(STATE_ITEMS);
  }
```

(here, `STATE_ITEMS` is a static data member, serving as the constant key for the `Bundle` entry)

In order to be able to capitalize or remove the checked words from the list, we need to know which ones are checked. Rather than expose that data directly, `ChoiceMode` now has a `visitChecks()` method, where we can supply a `Visitor` to be invoked for every checked position:

```
package com.commonsware.android.recyclerview.actionmodelist2;

import android.os.Bundle;

public interface ChoiceMode {
  void setChecked(int position, boolean isChecked);
  boolean isChecked(int position);
  void onSaveInstanceState(Bundle state);
  void onRestoreInstanceState(Bundle state);
  int getCheckedCount();
  void clearChecks();
  void visitChecks(Visitor v);

  public interface Visitor {
    void onCheckedPosition(int position);
  }
}
```

`MultiChoiceMode` implements `visitChecks()` by iterating over a *copy* of the `checkStates` `ParcelableSparseBooleanArray`. That way, if the visitor modifies `checkStates` (e.g., unchecks a position), our loop is unaffected.

```
  @Override
  public void visitChecks(Visitor v) {
    SparseBooleanArray copy=checkStates.clone();

    for (int i=0;i<copy.size();i++) {
      v.onCheckedPosition(copy.keyAt(i));
    }
  }
```

`visitChecks()` is also exposed by `ChoiceCapableAdapter`, as are all the other methods on `ChoiceMode`.

Now, `IconicAdapter` can capitalize the words, by using `visitChecks()`:

```
        case R.id.cap:
          visitChecks(new ChoiceMode.Visitor() {
            @Override
            public void onCheckedPosition(int position) {
              String word=getItems().get(position);

              word=word.toUpperCase(Locale.ENGLISH);
              getItems().set(position, word);
              notifyItemChanged(position);
            }
          });
          break;
```

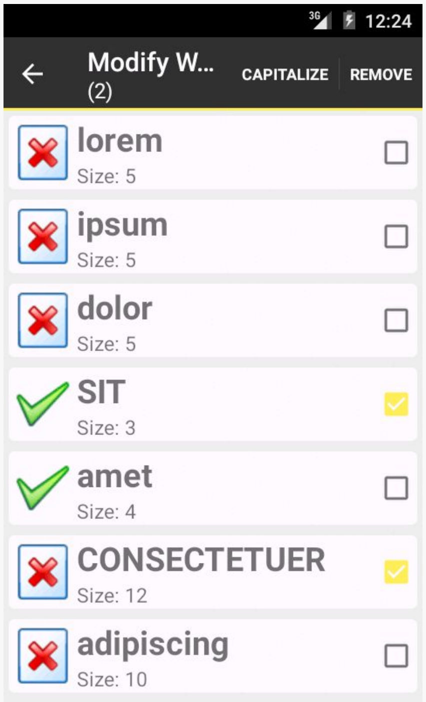
Here, for each checked item, we capitalize the word, replace the original word with its capitalized equivalent, and call `notifyItemChanged()` to let the `RecyclerView` know that this position had its model data changed and therefore should be repainted, if needed.

We also use `visitChecks()` now in `onDestroyActionMode()`, to avoid the `notifyDataSetChanged()` call:

```
  @Override
  public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
      activeMode=null;
      visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
          onChecked(position, false);
          notifyItemChanged(position);
        }
      });
    }
  }
```

Each item that was checked is unchecked, and we use `notifyItemChanged()` to ensure that the item is repainted if needed.

Now, checking some items and choosing "CAPITALIZE" from the action mode will capitalize those words:



lorem

Figure 445: ActionModeList2 RecyclerView Demo, with Capitalized Words

Adding and Removing Items

There are also methods on `RecyclerView.Adapter` to specifically call out when you are adding or removing items from the adapter. Not only does this cause the

RecyclerView to update itself, but it will animate the changes, if the relevant position(s) are visible.

Specifically, you can call:

- notifyItemInserted(), to indicate that a new item was inserted at a specified position, with everything else moving one position later in the roster
- notifyItemRangeInserted(), to insert several items in a block
- notifyItemRemoved(), to indicate a position that had an item removed from the roster, with later items moving up to take over earlier positions
- notifyItemRangeRemoved(), to remove several items in a block

The ActionModeList2 sample uses notifyItemRemoved() as part of its handling of the remove action mode item:

```
        case R.id.remove:
          final ArrayList<Integer> positions=new ArrayList<Integer>();

          visitChecks(new ChoiceMode.Visitor() {
            @Override
            public void onCheckedPosition(int position) {
              positions.add(position);
            }
          });

          Collections.sort(positions, Collections.reverseOrder());

          for (int position : positions) {
            getItems().remove(position);
            notifyItemRemoved(position);
          }

          clearChecks();
          activeMode.finish();
          break;
```

Because items slide up to take over vacated positions, when removing items, it is important to remove the lowest items first and work your way up the roster. That is why this code:

- Aggregates the list of positions that are checked
- Sorts the checked items in reverse order
- Iterates over the checked items, removing each from the ArrayList and calling notifyItemRemoved() to inform the adapter that the old item at this position is now gone

- Clears all of the checks from the ChoiceMode (as all checked items are now removed) and finishes the action mode (as there are no more checked items)

The result is that when the user removes items, they rapidly fade out, then later items in the list slide up to occupy the now-vacated space. If you would prefer to use other animations, you can do so, by creating your own subclass of RecyclerView.ItemAnimator and attaching it to the RecyclerView with setItemAnimator().

The Order of Things

Version 22+ of recyclerview-v7 offers SortedList. On the surface, the class appears to be a regular List that offers sorting. However, it also has a callback interface designed to be tied into RecyclerView, so that changes made to the SortedList can be reflected in the RecyclerView itself, complete with animations, optional batched processing, and so on.

This is illustrated in the RecyclerView/SortedList sample project. Along the way, we will also see how to use RecyclerView in a fragment and how to populate RecyclerView from the background thread.

The Gradle Change

This project requires version 22 or higher of recyclerview-v7, as the original v21 release of recyclerview-v7 did not have SortedList. So, the Gradle build file requests something appropriate:

```
dependencies {
    compile 'com.android.support:recyclerview-v7:22.1.1'
    compile 'com.android.support:cardview-v7:22.1.1'
}
```

Note that it pulls in the same version of cardview-v7. In general, it is best to try to keep Android Support package libraries in sync, at least in terms of major versions. Similarly, it is best to have the compileSdkVersion match the major library version, as the library may be conditionally using APIs made available in that version of Android. Hence, the project also has compileSdkVersion (and buildTools) set to pull from v22:

```
    compileSdkVersion 22
    buildToolsVersion "22.0.1"
```

The RecyclerViewFragment

Prior samples in this chapter used a RecyclerViewActivity for basic RecyclerView setup. However, in this sample, we want to use a retained fragment for managing the AsyncTask, which suggests putting the RecyclerView in a fragment, rather than having it be managed directly by the activity.

So, this project has a reworking of RecyclerViewActivity into RecyclerViewFragment:

```
package com.commonsware.android.recyclerview.sorted;

import android.app.Fragment;
import android.os.Bundle;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup container,
                           Bundle savedInstanceState) {
    RecyclerView rv=new RecyclerView(getActivity());

    rv.setHasFixedSize(true);

    return(rv);
  }

  public void setAdapter(RecyclerView.Adapter adapter) {
    getRecyclerView().setAdapter(adapter);
  }

  public RecyclerView.Adapter getAdapter() {
    return(getRecyclerView().getAdapter());
  }

  public void setLayoutManager(RecyclerView.LayoutManager mgr) {
    getRecyclerView().setLayoutManager(mgr);
  }

  public RecyclerView getRecyclerView() {
    return((RecyclerView)getView());
  }
}
```

Basically, what had been in onCreate() mostly moves into onCreateView(), where we set up the RecyclerView. The rest of the core API is unchanged.

The project has SortedFragment, which extends RecyclerViewFragment and handles loading of the data — we will examine more of it later in this chapter.

The revised `MainActivity` then just loads up `SortedFragment` via a `FragmentTransaction`:

```
package com.commonsware.android.recyclerview.sorted;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new SortedFragment()).commit();
    }
  }
}
```

The SortedFragment

Most of `SortedFragment` is reminiscent of the original `AsyncTask` demo from the chapter on threads, mashed up with one of the `CardView`/`RecyclerView` samples from earlier in this chapter. However, the `SortedList` gets weaved throughout.

The SortedList

The `model` in the original `AsyncTask` demo was a simple `ArrayList`. Now it is a `SortedList`, initialized in `onCreate()` of the `SortedFragment`:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    model=new SortedList<String>(String.class, sortCallback);

    task=new AddStringTask();
    task.execute();
  }
```

The `SortedList` constructor takes two parameters:

- the Java class object for the models inside the list (in this case, `String.class`)

- a SortedList.Callback object that will be invoked when the model changes based on List APIs (e.g., add(), insert(), remove())

There is an optional third parameter for the capacity, unused in this sample.

We will take a peek at the SortedList.Callback implementation, named sortCallback, shortly.

The IconicAdapter

The IconicAdapter from earlier RecyclerView samples worked directly off of the static array of String values. Now, we want it to work off of the model SortedList. Hence, onBindViewHolder() and getItemCount() need to be modified to refer to appropriate methods on the model:

```
class IconicAdapter extends RecyclerView.Adapter<RowController> {
  @Override
  public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
    return(new RowController(getActivity().getLayoutInflater()
                              .inflate(R.layout.row, parent, false)));
  }

  @Override
  public void onBindViewHolder(RowController holder, int position) {
    holder.bindModel(model.get(position));
  }

  @Override
  public int getItemCount() {
    return(model.size());
  }
}
```

Also note that when we create the adapter in onViewCreated(), that we hold onto it in an adapter data member of the fragment:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  setLayoutManager(new LinearLayoutManager(getActivity()));
  adapter=new IconicAdapter();
  setAdapter(adapter);
}
```

The SortedList.Callback

The job of the `SortedList.Callback` is to serve as the bridge between the `SortedList` and the `RecyclerView.Adapter`.

`SortedList`, as the name suggests, sorts its contents. That means that any change to the `SortedList` contents can have different impacts on the `RecyclerView`. For example, while an `add()` to an `ArrayList` would just add a new row to the end of the `RecyclerView`, an `add()` on `SortedList` might need to insert a row in the middle of the `RecyclerView`, to maintain the sorted order.

Hence, your `SortedList.Callback` is responsible for two things:

- Helping with the sorting itself, by comparing elements
- Passing information about how the sorting is done out to the `RecyclerView.Adapter`, so the appropriate moves can be made there, complete with animations

With that in mind, here is the `sortedCB` implementation of `SortedList.Callback`:

```
private SortedList.Callback<String> sortCallback=new SortedList.Callback<String>() {
  @Override
  public int compare(String o1, String o2) {
    return o1.compareTo(o2);
  }

  @Override
  public boolean areContentsTheSame(String oldItem, String newItem) {
    return(areItemsTheSame(oldItem, newItem));
  }

  @Override
  public boolean areItemsTheSame(String oldItem, String newItem) {
    return(compare(oldItem, newItem)==0);
  }

  @Override
  public void onInserted(int position, int count) {
    adapter.notifyItemRangeInserted(position, count);
  }

  @Override
  public void onRemoved(int position, int count) {
    adapter.notifyItemRangeRemoved(position, count);
  }

  @Override
  public void onMoved(int fromPosition, int toPosition) {
    adapter.notifyItemMoved(fromPosition, toPosition);
  }
```

```
    @Override
    public void onChanged(int position, int count) {
      adapter.notifyItemRangeChanged(position, count);
    }
  };
```

The first method is your standard sort of `compare()` comparison method, as you might implement on a `Comparator`. It should return zero if the two model objects are the same from a sorting standpoint, a negative number if the first parameter sorts before the second parameter, or a positive number if the first parameter sorts after the second parameter.

Then there are two similarly-named methods that serve as more-or-less replacements for the `equals()` that you might have on a `Comparator`: `areContentsTheSame()` and `areItemsTheSame()`.

`areItemsTheSame()` should return `true` if the two passed-in values represent the same actual logical item. In the case of `SortedFragment`, that is simply whether or not the strings are equal. But, with a more complex data model, you might be comparing primary keys or some other form of immutable identifier.

`areContentsTheSame()` should return `true` if the visual representation of the items look the same, as this will be used to optimize the changes made to the `RecyclerView`.

For example, suppose a shopping cart fragment wanted to use `SortedList`. Further suppose that if you added three boxes of laundry detergent to the cart, rather than having one row in the list with "Quantity: 3", you were representing them as three rows in the `RecyclerView`. In this case:

- `compare()` returns a value to indicate the sorting rules of those shopping cart items, perhaps based on the title of the item
- `areItemsTheSame()` might return `false` for any combination of these three items, as they are logically distinct rows within the `RecyclerView`
- `areContentsTheSame()` might return `true` for any combination of these three items, as while they are three separate line items, each is visually identical in terms of what the `RecyclerView` rows look like

In many cases, `areContentsTheSame()` can simply invoke `areItemsTheSame()`, under the premise that different items *probably* have different visual representations. That is what is done in this sample, where `areItemsTheSame()` in turn uses `compare()` to see whether or not the items are the same.

Finally, there are four on...() methods that are simply forwarded along to their RecyclerView.Adapter counterparts, so changes to the SortedList make the corresponding changes to the RecyclerView contents.

Note that there is a SortedListAdapterCallback that takes a RecyclerView.Adapter as a constructor parameter and handles the on...() methods for you. However, since we want to retain the SortedList across configuration changes, and since SortedList does not allow us to change the SortedList.Callback object, we cannot readily switch the SortedList to the new fragment and new adapter after a configuration change.

The AsyncTask

The AddStringTask is the same as with the original AsyncTask sample, except that now it adds the words to the SortedList, which (via its Callback) will update the RecyclerView:

```
private class AddStringTask extends AsyncTask<Void, String, Void> {
  @Override
  protected Void doInBackground(Void... unused) {
    for (String item : items) {
      if (isCancelled())
        break;

      publishProgress(item);
      SystemClock.sleep(400);
    }

    return(null);
  }

  @Override
  protected void onProgressUpdate(String... item) {
    if (!isCancelled()) {
      model.add(item[0]);
    }
  }

  @Override
  protected void onPostExecute(Void unused) {
    Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
        .show();

    task=null;
  }
}
```

The Results

If you run this sample, you will see the words be added to the list, every 400ms. However, in the original `ListView`-based sample, new rows were appended to the end, and so you would not see new rows appear after the `ListView` space was filled. In this sample, the Latin words are sorted by `SortedList`, and you will see them animate into position at the appropriate spots as they are added. In the end, you get the same look as in earlier `CardView`-based `RecyclerView` implementations, except that the words are sorted:

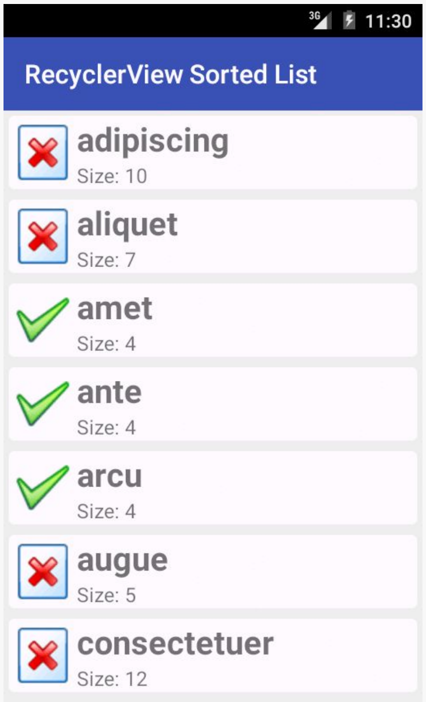

Figure 446: SortedList RecyclerView Demo

Other Bits of Goodness

To quote the infamous American infomercial line: "But wait! There's more!"

In addition to `LinearLayoutManager` and `GridLayoutManager`, there is `StaggeredGridLayoutManager`. With a vertically-scrolling `GridLayoutManager`, rows are all a consistent height, but the cell widths might vary. With a vertically-scrolling `StaggeredGridLayoutManager`, the columns are all the same width, but the cell heights might vary.

All three of the standard layout managers support horizontal operation as well, through a `boolean` on a constructor. In these cases, the content will scroll horizontally, rather than vertically. This eliminates the need for third-party horizontal `ListView` implementations and the like.

And, of course, you can implement your own `RecyclerView.LayoutManager`, eschewing any of the built-in ones.

The March of the Libraries

By this point in time, you may be wailing in anguish and rending your garments over how much is involved in getting `RecyclerView` going.

(pro tip: do not rend your garments in public, to avoid running afoul of indecency laws)

There is little doubt that `RecyclerView` is the epitome of "some assembly required". However, other developers have come to the forefront with libraries that can help fill in these gaps without you having to roll all the code yourself.

Note that the author has not tried many of these libraries, and listing them here neither is an endorsement of these libraries nor a knock on any libraries not listed here.

DynamicRecyclerView

The DynamicRecyclerView library offers:

- Drag and drop reordering of items, via a simple custom `OnItemTouchListener` implementation
- An implementation of the horizontal "swipe-to-dismiss" UI pattern, also via a custom `OnItemTouchListener` implementation
- An implementation of choice modes, akin to those shown in this chapter
- An implementation of click-style events, by handling them as touch events using yet another custom `OnItemTouchListener` implementation

Advanced RecyclerView

The Advanced RecyclerView library offers its own drag-and-drop and swipe-to-dismiss implementations. Rather than using `OnItemTouchListener` implementations, you implement certain interfaces on your RecyclerView.Adapter and RecyclerView.ViewHolder classes to support drag-and-drop and/or swipe-to-dismiss, plus work with "manager" classes to tie the support together.

It also supports an expandable item, where clicking on the item expands or collapses a set of views vertically beneath the item, offering an approach for using RecyclerView to replace ExpandableListView. And, it has a few item decorators, including a basic divider implementation.

SuperRecyclerView

The SuperRecyclerView library has its own swipe-to-dismiss implementation. It also supports the "swipe layout" pattern, where a horizontal swipe gesture slides out the main view and uncovers a set of contextual operations on the item.

It also offers:

- scrollbars (which are not enabled on RecyclerView)
- progress bars and/or empty views to handle the asynchronous loading of data
- an "endless" or "infinite scrolling" implementation, where when the user scrolls to the bottom of the data, you get a chance to go load more data
- sticky headers, where as the user scrolls, the top-most header remains pinned to the top of the RecyclerView, until replaced by a new header that scrolls to the top

However, this library requires that you inherit from a custom RecyclerView subclass.

FlexibleDivider

The FlexibleDivider library does just one thing: provides dividers. However, it offers *deep* support for dividers, where you can easily control all sorts of aspects, from color and width to margins and path effects (e.g., dashed lines versus solid lines).

The RecyclerView/FlexDividerList sample project is a clone of the ManualDividerList sample from earlier in the chapter, where the dividers are now provided by the FlexibleDivider library, which is loaded via the build.gradle file:

```
repositories {
    jcenter()
}
```

```
dependencies {
    compile 'com.android.support:recyclerview-v7:22.2.0'
    compile 'com.yqritc:recyclerview-flexibledivider:1.0.1'
}
```

Then, we use the library's `HorizontalDividerItemDecoration` to set up our dividers:

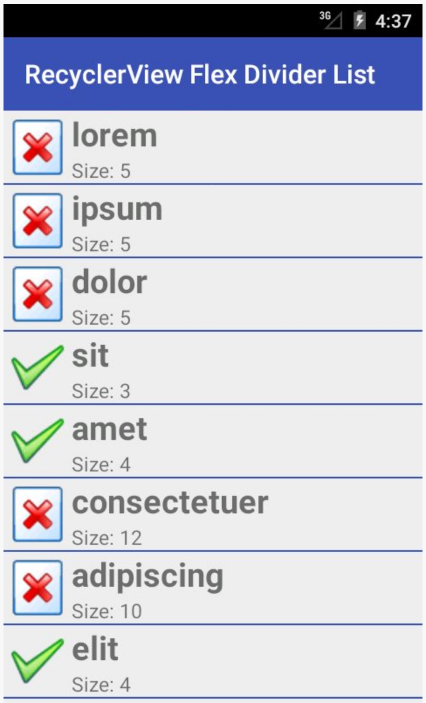
```
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);

    setLayoutManager(new LinearLayoutManager(this));

    RecyclerView.ItemDecoration decor=
        new HorizontalDividerItemDecoration.Builder(this)
          .color(getResources().getColor(R.color.primary))
          .build();

    getRecyclerView().addItemDecoration(decor);
    setAdapter(new IconicAdapter());
  }
```

The results are a solid blue divider:



lorem
Size: 5

ipsum
Size: 5

Figure 447: FlexDividerList RecyclerView Demo

Of course, through the library, you can change a lot more about the divider than just its color, through its builder-style API.

Implementing a Navigation Drawer

Each year brings a new design pattern in Android that takes the development community by storm. In 2011, it was the action bar. In 2012, it was `ViewPager`. In 2013, it was the navigation drawer.

This chapter covers that navigation drawer pattern: what it is, where you use it, and how you implement it, using a `DrawerLayout` class supplied by the Android Support package.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, one section ties into the chapter on action modes.

What is a Navigation Drawer?

Complex apps often require complex navigation, to get to all of the different areas of the app. And, in many cases, that navigation is tied to nouns, reflecting different types of content, more so than verbs, reflecting operations to be performed against a particular piece of content. Verbs are actions, and can usually go in the action bar as action bar items (e.g., toolbar-style buttons). Nouns *could* be put in the action bar as well as items, though having a mixed bunch of nouns and verbs makes the action bar item roster inconsistent.

Back before the action bar, the “go-to” design pattern for navigation was the so-called “dashboard”:

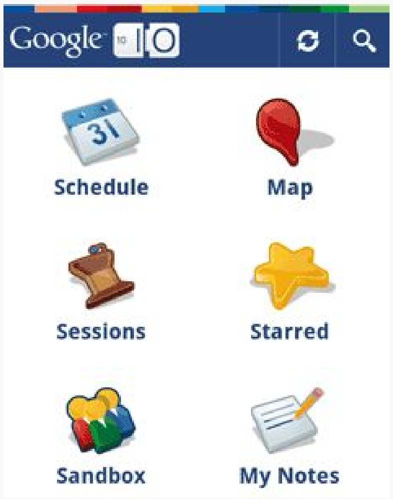

Figure 448: Google IO 2010 Conference App, with Dashboard

But this took up the whole screen and was therefore only available as the "home" activity of an app.

The navigation drawer, or "sliding menu", pattern has the same sort of content navigation options available in a drawer that slides out from the side of the screen:

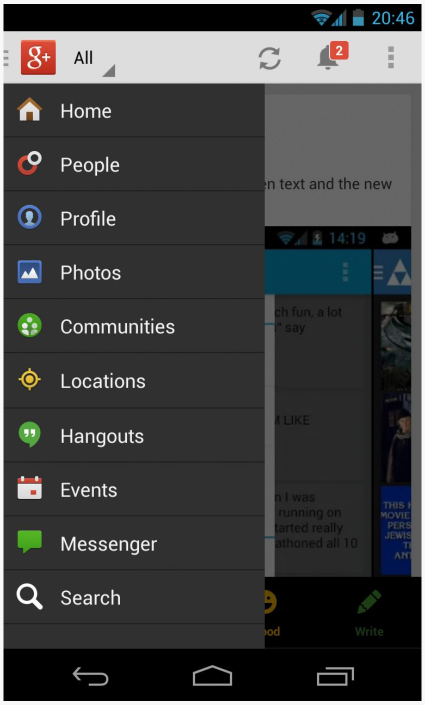

Figure 449: Google+, with Open Navigation Drawer

The drawer can be accessed from many, if not all, activities in the app, to allow the user to get wherever they need to from wherever they happen to be.

A Simple Navigation Drawer

The good news is that Google released an implementation of the navigation drawer pattern, called `DrawerLayout`, in the Android Support package (`support-v4` and `support-v13`).

The bad news is that it still takes a bit of work to get this integrated with your app.

This section will review the [`NavDrawer/Simple`] sample project, that shows a fairly simplistic integration of a `DrawerLayout` into an activity.

The Activity Layout

The root element of your activity layout, for an activity using `DrawerLayout`, is `DrawerLayout` itself:

```
<android.support.v4.widget.DrawerLayout xmlns:android="http://schemas.android.com/apk/
res/android"
  android:id="@+id/drawer_layout"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/content"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>

  <ListView
    android:id="@+id/drawer"
    android:layout_width="240dp"
    android:layout_height="match_parent"
    android:layout_gravity="start"
    android:background="#111"
    android:choiceMode="singleChoice"
    android:divider="@android:color/transparent"
    android:dividerHeight="0dp"/>

</android.support.v4.widget.DrawerLayout>
```

`DrawerLayout` itself is rather unremarkable in the layout resource: you size and position it, usually to fill the screen. It needs to have precisely two child elements:

1. The first child represents the "real" activity content
2. The second child represents the contents of the drawer that can be opened and closed

If you are adapting an existing activity to use the `DrawerLayout`, that first child could well be an `<include>` element pointing to your existing activity layout resource, so that you can leave it undisturbed and just point your activity to start with this new `DrawerLayout` resource.

There are a couple of attributes in the children that are important for proper `DrawerLayout` operation:

- The second child — often a `ListView` — needs to have its `android:layout_gravity` set to indicate what side of the screen the drawer will slide out from. Typically this will be `left` (or `start` if you are on API Level 17+ and are taking advantage of the RTL layout support).
- The second child also specifies its `android:layout_width` to indicate the size of the drawer when opened. This should *not* be the full width of the screen, and the Android design guidelines suggest a width between 240dp and 320dp.

The ActionBarDrawerToggle

The `onCreate()` method of `MainActivity` is responsible for setting up the drawer, as well as the activity's main content:

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
      showLorem();
    }

    ListView drawer=(ListView)findViewById(R.id.drawer);

    drawer.setAdapter(new ArrayAdapter<String>(
                                                 this,
                                                 R.layout.drawer_row,

getResources().getStringArray(R.array.drawer_rows)));
    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
                                  R.drawable.ic_drawer,
                                  R.string.drawer_open,
                                  R.string.drawer_close);
    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);
  }
```

In terms of the content, if the `FrameLayout` placed in the layout resource is empty, we call `showLorem()` to lazy-create a `LoremFragment` (a `ListFragment` with 25 Latin words) and run a `FragmentTransaction` to display it:

```
  private void showLorem() {
    if (lorem == null) {
      lorem=new LoremFragment();
    }

    if (!lorem.isVisible()) {
      getFragmentManager().beginTransaction()
                          .replace(R.id.content, lorem).commit();
    }
  }
```

`onCreate()` then retrieves the `ListView`, sets the contents of the list to be a `<string-array>` resource named `drawer_rows`, and sets up the activity itself to respond to clicks on the list.

onCreate() then sets up an ActionBarDrawerToggle. This allows the app icon on the left of the action bar to open and close the navigation drawer. The ActionBarDrawerToggle constructor takes five parameters:

- The Activity as a Context
- The DrawerLayout widget to be managed by this toggle
- The icon to superimpose on the app icon to indicate that there is a toggle
- String resources for the open and close operations, for accessibility

The sample app uses icons from Google's discontinued "Action Bar Icon Pack" for the third parameter. In addition, the Android Asset Studio offers a way for you to customize the navigation drawer indicator artwork for other themes.

In addition to creating the toggle instance, we need to:

- Associate it with the DrawerLayout, by calling setDrawerListener() on it
- Enable the app icon via setHomeButtonEnabled() and enable it for "up" navigation via setDisplayHomeAsUpEnabled()
- Forward the onPostCreate(), onConfigurationChanged(), and onOptionsItemSelected() activity callback methods on to the toggle:

```
@Override
protected void onPostCreate(Bundle savedInstanceState) {
  super.onPostCreate(savedInstanceState);

  toggle.syncState();
}

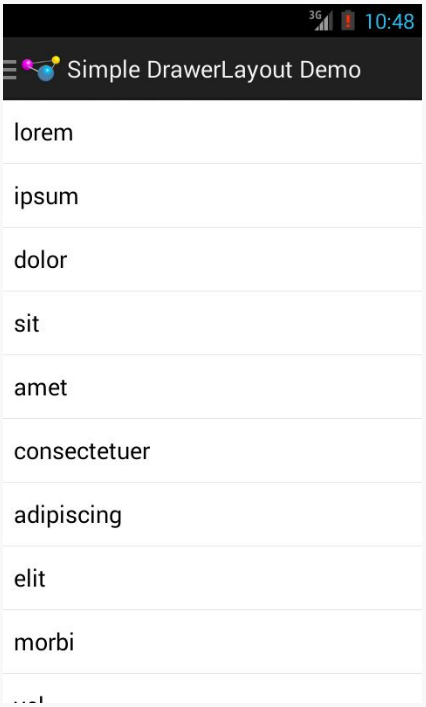
@Override
public void onConfigurationChanged(Configuration newConfig) {
  super.onConfigurationChanged(newConfig);

  toggle.onConfigurationChanged(newConfig);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
  if (toggle.onOptionsItemSelected(item)) {
    return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

Without any additional work, launching the app will show the "mini hamburger" navigation drawer icon in the action bar:



lorem
ipsum
dolor
sit
amet
consectetuer
adipiscing
elit
morbi

Figure 450: Nav Drawer Sample App, Showing the Mini Hamburger

Tapping the app icon will open the drawer:

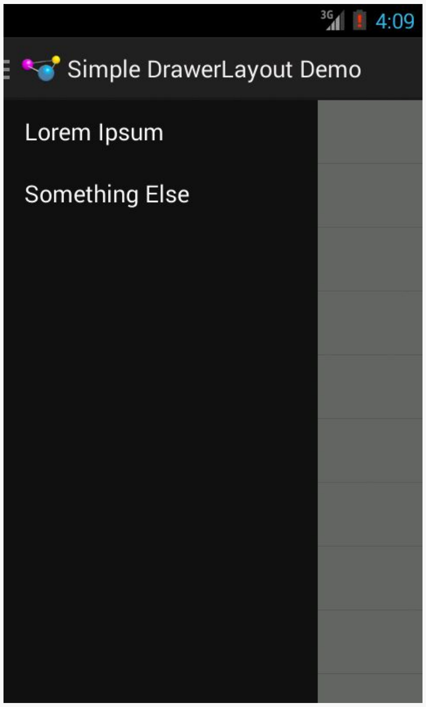


Figure 451: Nav Drawer Sample App, with Drawer Open

The drawer slides over the content, rather than pushing the content away, which is why we do not see the words peeking out on the right side of the screen.

Tapping the app icon again will close the drawer.

The user can also open the drawer via gestures. A bezel swipe from the left side will open the drawer, and swiping the open drawer right to left will close it. In addition, tapping and holding on the left edge of the content will cause the drawer to “peek” open by a handful of pixels, to hint to the user that there may be something that they can access by swiping from the left.

NOTE: This implementation of `ActionBarDrawerToggle` is officially deprecated as of the `21.0.0` version of the Android Support library. However, it is still necessary, at this time, for using `DrawerLayout` with the native action bar.

The Actions on Navigation Clicks

Of course, a navigation drawer is useless unless we do something when the user interacts with it, clicking on list rows in this case.

Our list is very simple, with just two elements. The app simply toggles between two fragments based upon the list item click:

```
@Override
public void onItemClick(AdapterView<?> listView, View row,
                        int position, long id) {
  if (position == 0) {
    showLorem();
  }
  else {
    showContent();
  }

  drawerLayout.closeDrawers();
}
```

We also close the drawer, using `closeDrawers()`, as otherwise the `DrawerLayout` is unaware that the user chose something and that we should return to the content.

Alternative Row Layouts

The rows in the sample app's `ListView` were fairly conventional. Rows in a nav drawer should be fairly simple, as you are merely trying to lead the users to pieces of content, not present content itself.

That being said, the navigation options can have a bit more to them than what the sample app showed. The [Android design guidelines] will steer you in the direction of how best to style:

- Rows with leading icons
- Rows with trailing badges (e.g., unread message counts)
- Expandable sections (e.g., less-important items but still worth having in the drawer)
- Dividers, to help organize groups of related rows

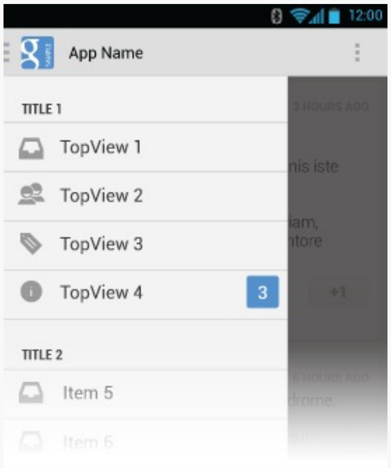

Figure 452: Sample Navigation Drawer Rows with Icons and Badges

You will see other apps experiment with other capabilities. For example, Gmail used to use `RadioButton` widgets for the accounts:

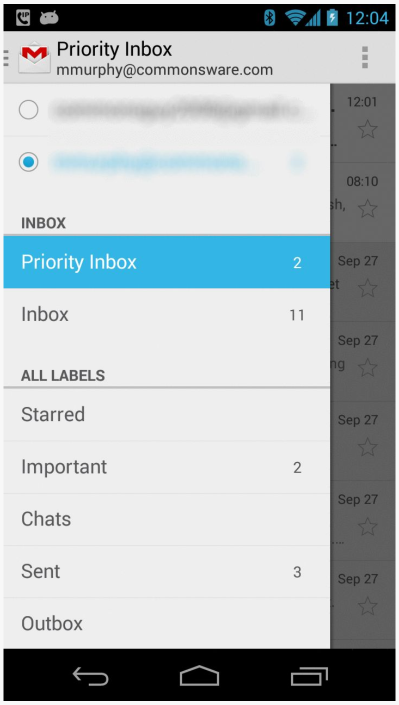

Figure 453: Gmail Navigation Drawer, with RadioButtons, Dividers, and Badges (Sans Backgrounds)

That being said, the closer you can stick with the official design guidelines, the better off you will tend to be, in terms of meeting user expectations and not encountering rendering or click event oddities with `DrawerLayout`.

Additional Considerations

Beyond putting the right things into the navigation drawer, there are some other things that you will need to take into account, particularly as your navigation drawer interacts with the rest of the activity and overall application.

Highlighting the Current Location

If the user opens the navigation drawer, and they are already at one of the navigation destinations shown in the drawer, that destination should show up with the `activated` state, to indicate to the user that she is already there. Conversely, if the user has drilled down into some part of your application that does *not* have a corresponding entry in the navigation drawer, the navigation drawer should show no activated entry.

One way to handle this is to keep the `ListView` updated as the user navigates (whether through the navigation drawer or by other means), selecting and de-selecting items as needed.

The row layout used in the original sample, culled from [Google's `DrawerLayout` sample code](), already has the `activated` background:

```
<android.support.v4.widget.DrawerLayout xmlns:android="http://schemas.android.com/apk/
res/android"
  android:id="@+id/drawer_layout"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/content"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>

  <ListView
    android:id="@+id/drawer"
    android:layout_width="240dp"
    android:layout_height="match_parent"
    android:layout_gravity="start"
    android:background="#111"
    android:choiceMode="singleChoice"
    android:divider="@android:color/transparent"
    android:dividerHeight="0dp"/>
```

```
</android.support.v4.widget.DrawerLayout>
```

However, we were not using it in that sample, so the drawer ListView did not give the user any indication that they had already navigated to a navigable destination. But, we have the NavDrawer/Activated sample project, a clone of the original sample, that adds this activation capability, and demonstrates the headaches it causes.

First, as part of our onCreate() work in MainActivity, we need to configure the ListView to work in single-choice mode (the ListView engine behind the activated state), along with the rest of the ListView setup:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.activity_main);

  drawer=(ListView)findViewById(R.id.drawer);
  drawer.setChoiceMode(ListView.CHOICE_MODE_SINGLE);

  String[] rows=getResources().getStringArray(R.array.drawer_rows);

  drawer.setAdapter(new ArrayAdapter<String>(this,
                                             R.layout.drawer_row,
                                             rows));
  drawer.setOnItemClickListener(this);

  drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
  toggle=
      new ActionBarDrawerToggle(this, drawerLayout,
                                R.drawable.ic_drawer,
                                R.string.drawer_open,
                                R.string.drawer_close);
  drawerLayout.setDrawerListener(toggle);
  getActionBar().setDisplayHomeAsUpEnabled(true);
  getActionBar().setHomeButtonEnabled(true);

  getFragmentManager().addOnBackStackChangedListener(this);

  if (getFragmentManager().findFragmentById(R.id.content) == null) {
    showLorem();
  }
}
```

Our showLorem() method now will post() a Runnable, named onNavChange, after it calls commit() on its FragmentTransaction:

```
private void showLorem() {
  if (lorem == null) {
    lorem=new LoremFragment();
  }
```

```
    if (!lorem.isVisible()) {
      getFragmentManager().popBackStack();
      getFragmentManager().beginTransaction()
                          .replace(R.id.content, lorem).commit();
      drawer.post(onNavChange);
    }
  }
```

That magic `onNavChange` `Runnable` simply sees what fragment is presently visible and updates the checked item in the nav drawer's `ListView` to match:

```
  private Runnable onNavChange=new Runnable() {
    @Override
    public void run() {
      if (lorem != null && lorem.isVisible()) {
        drawer.setItemChecked(0, true);
      }
      else if (content != null && content.isVisible()) {
        drawer.setItemChecked(1, true);
      }
      else {
        int toClear=drawer.getCheckedItemPosition();

        if (toClear >= 0) {
          drawer.setItemChecked(toClear, false);
        }
      }
    }
  };
```

By using `post()`, we schedule the `Runnable` to be executed after the fragment change has occurred. Ideally, we would somehow more explicitly attach the `Runnable` to the `FragmentTransaction`, but that does not appear to be an option.

Since we call `showLorem()` in `onCreate()`, this causes our navigation drawer to show that we are in `LoremFragment` when the activity first starts up:

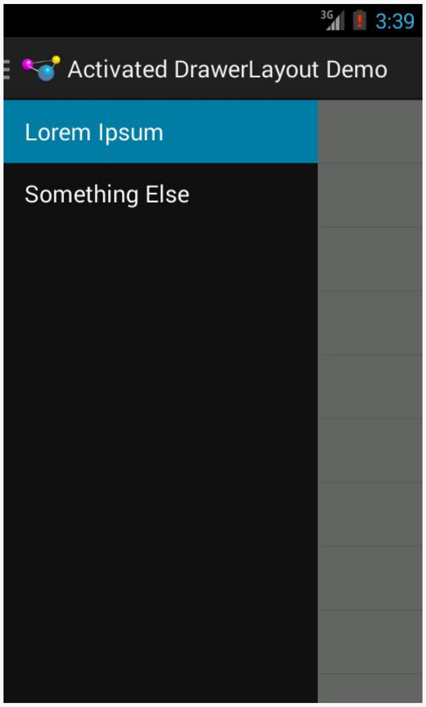

Figure 454: Activated Navigation Drawer Demo, As Initially Launched

The natural behavior of a single-choice `ListView` will check the row that we tap upon, and so when the user taps on an entry in the navigation drawer, it automatically becomes activated. This means we do not have to do our own work for that.

If *everything* in your app is represented by an entry in the navigation drawer, your work is done. However, most likely, there are parts of your app that do not directly map to entries in the navigation drawer… and that is where things get a wee bit complex.

To demonstrate this, we need a bit more to our UI. So, we make `LoremFragment` use the contract pattern, seen elsewhere in the book. We override `onListItemClick()` to call a `wordClicked()` method on the contract, to let the hosting activity know about that UI operation:

```
package com.commonsware.android.drawer.activated;

import android.os.Bundle;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.ListView;
```

```
public class LoremFragment extends ContractListFragment<LoremFragment.Contract> {
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };

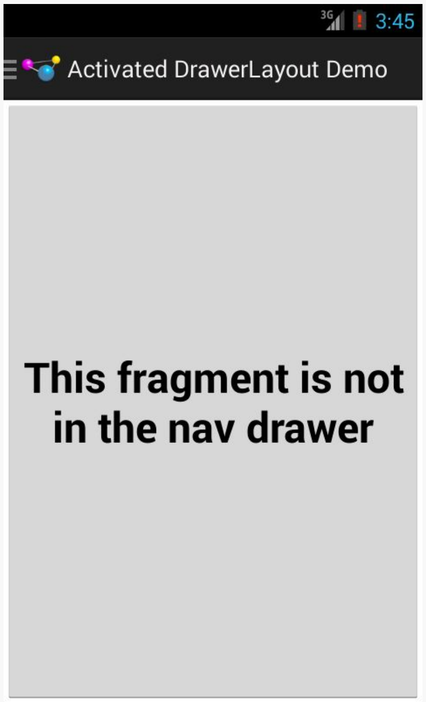
  @Override
  public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    setListAdapter(new ArrayAdapter<String>(
                                        getActivity(),
                                        android.R.layout.simple_list_item_1,
                                        items));
  }

  @Override
  public void onListItemClick(ListView l, View v, int position, long id) {
    getContract().wordClicked();
  }

  interface Contract {
    void wordClicked();
  }
}
```

We also create a `StuffFragment` that displays a simple message:



This fragment is not in the nav drawer

Figure 455: Activated Navigation Drawer Demo, Showing StuffFragment

The idea is that clicking on a word in the LoremFragment should bring up the StuffFragment, as if this were a master/detail implementation.

The implementation of wordClicked() in MainActivity does indeed show a StuffFragment (while also adding it to the back stack), but it also needs to make the drawer ListView have no checked items, reflecting the fact that the UI state does not reflect one of the navigation destinations:

```
@Override
public void wordClicked() {
  if (stuff == null) {
    stuff=new StuffFragment();
  }

  getFragmentManager().beginTransaction()
                      .replace(R.id.content, stuff)
                      .addToBackStack(null).commit();
  drawer.post(onNavChange);
}
```

Note that we also post() the onNavChange Runnable here as well.

The result is that when we do tap on a word in the list, the StuffFragment appears, but the navigation drawer shows no activated row:

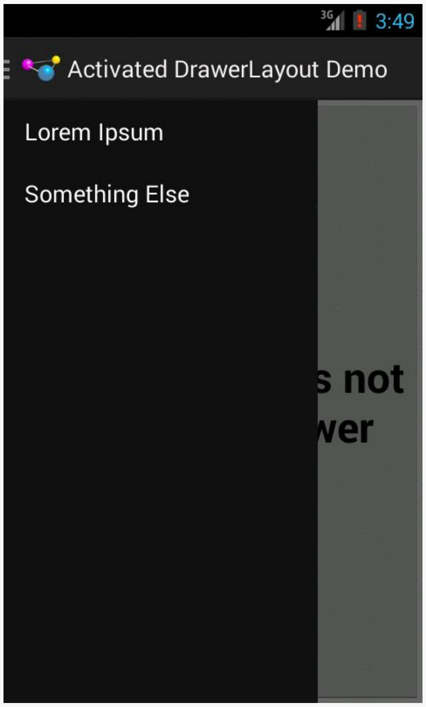


Figure 456: Activated Navigation Drawer Demo, Showing StuffFragment and Navigation Drawer

However, since we manually cleared the checked state, we now need to re-check a row if the user navigates back to one of the other fragments. There are two ways the user could return to one of those other fragments: via the navigation drawer, or via the BACK button (popping our transaction off the back stack).

If they navigate to one of the other fragments via the navigation drawer, the appropriate row will be activated automatically by the user's click event. However, we need to consider what to do about that transaction hanging around the back stack from before. One option is to remove it, so the other fragments behave as they do normally, where BACK exits the activity. That is a matter of calling `popBackStack()` on the `FragmentManager` as part of showing one of the fragments, such as the `showContent()` method that shows the `ContentFragment`:

```
private void showContent() {
  if (content == null) {
    content=new ContentFragment();
  }

  if (!content.isVisible()) {
    getFragmentManager().popBackStack();
    getFragmentManager().beginTransaction()
                        .replace(R.id.content, content).commit();
```

```
      drawer.post(onNavChange);
    }
  }
```

If the user presses the BACK button, having the earlier fragment reappear happens automatically. However, we need to fix up the navigation drawer to show the proper row as being activated. To do that, we implement `OnBackStackChangedListener` on `MainActivity` and call `addOnBackStackChangedListener()` on the `FragmentManager` in the `onCreate()` initialization work. That way, `onBackStackChanged()` will be called when there is a change in the state of the back stack. Then, it is merely a matter of calling `post()` for `onNavChanged` again, to update the nav drawer:

```
  @Override
  public void onBackStackChanged() {
    drawer.post(onNavChange);
  }
```

Hiding Context-Specific Action Bar Items

Another Google design guideline that makes sense, but adds complexity, is to only show action bar items that pertain to the entire application while the navigation drawer is visible. So, for example, a "Help" action bar item should remain visible, to allow users to switch over to that. But an "Edit" action bar item, to edit something in the main activity, should be hidden while the navigation drawer is visible.

The navigation drawer is effectively an application-level construct, even if we wind up implementing it on a per-activity basis due to the way Android user interfaces are constructed. Hence, the action bar items with the drawer open should pertain to the same scope that the drawer itself does: the application, not a particular activity or fragment inside of it.

Also, on phone-sized screens, the user may not be able to see much of the underlying UI, as the drawer itself will occlude most of it. They may not remember exactly what was showing, and therefore may forget what that "Delete" action bar item would actually delete. Hiding such a context-specific item, while the drawer is open, is safer.

The converse, of course, is that when the drawer closes, you will need to show once again the items that you hid when the drawer opened.

`DrawerLayout` supports a `DrawerListener`, an instance of which you can attach to the drawer itself, to be notified of when the drawer opens and closes, so you can adjust your action bar items to match.

Interacting with an Action Mode

You may be using your own custom action modes (a.k.a., contextual action bars), such as allowing the user to perform operations on multiple selections in a `ListView`.

Since the navigation drawer is tied to the application as a whole, not necessarily just the current activity or the selections in it, Google's recommendation is for you to temporarily dismiss the action mode when the navigation drawer is opened. This will allow the action bar to show items of relevance to the app, not to the selection. If the user navigates elsewhere using the navigation drawer, you would leave the action mode dismissed. If the user slides the navigation drawer closed, though, you could re-enable the action mode, tied back into the multiple selections the user has already made.

Advertising Your Drawer

Users who have spent some time with Android will have a decent shot at recognizing that tapping the action bar item adorned with the nav drawer artwork will open a drawer. However, not all users will necessarily make that connection, particularly users relatively new to Android.

As noted earlier in this chapter, `DrawerLayout` implements the "peek" pattern, where a long-tap on the edge of the screen will cause the drawer to open just a bit, to hint that there is something that can be opened with a swipe gesture. This is nice and subtle, but perhaps too subtle, as users are not necessarily likely to tap-and-hold on the screen edge just to see if something interesting happens.

Another possibility is to have the drawer open automatically, either the first time that your app is launched, or every time your app is launched until you detect that the user has manually opened the drawer (e.g., by adding a `DrawerListener` and watching for `onDrawerSlide()` and `onDrawerOpened()` events not triggered by you). On the plus side, this puts the drawer "front and center", so the user cannot miss it. Once the user taps in your activity (inside or outside of the drawer), the drawer will close with the animated slide to the edge. The hope is that the user will either eventually realize that they can bezel-swipe to get that drawer open, or they will learn about the action bar option (where you have it). This works if the drawer is fairly useful, relative to what the activity would be displaying by default. If, however, the drawer pales in comparison to the main activity view, forcing the drawer open may reduce, not improve, usability.

What Should Not Be in the Drawer

Your navigation drawer should only provide access to the major areas of content in your app. If you do not have many “major areas of content in your app”, reconsider having a navigation drawer, and use something else (e.g., `ViewPager` with a tabbed indicator) to get to what content you have.

Also, there are certain things that should not go into a navigation drawer:

- Actions (verbs) generally do not belong in the navigation drawer. “Edit”, “Save”, and so forth belong as action bar items, or perhaps as part of an action mode, not in the navigation drawer.
- Content itself does not belong in the navigation drawer. Bits of metadata, in the form of badges and similar sorts of indicators, are fine, to hint to the user about the content that is available in that area of your app. But the navigation drawer is not meant to be the “master” in the master/detail pattern, nor is it some sort of “sidebar” of additional content that you just want to have hidden away.
- Low-priority areas of your app, particularly those that are traditionally in the action bar, should not be in the navigation drawer. “Help” and “About” are classic examples. “Settings” is another, though the line starts to get a bit fuzzy (while “Settings” might be something traditional for the action bar, “Accounts” is not). The overflow menu of an action bar is a fine place to have those sorts of areas be available to the user without cluttering up the primary action bar or the navigation drawer.

Independent Implementations

The navigation drawer pattern did not begin with the introduction of `DrawerLayout`. There have been many independent implementations of such a “sliding menu” that pre-dated `DrawerLayout` and the Android design guidelines for navigation drawers. Examples include:

- Jeremy Feinstein’s SlidingMenu
- 6Wunderkinder’s Sliding Layer
- David Scott’s RibbonMenu

Just bear in mind that these implementations do not necessarily adhere to everything in the design guidelines, requiring you to perhaps make modifications or simply ignore those guidelines as needed.

The Android Design Support Library

In 2014, to much fanfare, Google released their first edition of the Material Design guidelines.

What was missing was an actual implementation of most of these guidelines.

Beyond the obvious question of "how do you know that it will work well if you have not tried it?", it put Android developers in the unenviable position of being pressured to make their apps "look more material" without having anything really to do that.

In the months that followed Google I|O 2014, various developers took this implementation gap as a challenge and created their own implementations of many bits of Material Design. Much of this was released in the form of open source components, easily added to an app via dependencies added to a project's `build.gradle` file (at least, for Android Studio developers and other Gradle users).

In 2015, to a bit less fanfare, Google released the Android Design Support Library. The vision is that this would be the official implementation of many Material Design core components, like floating action buttons (FABs), snackbars, and the like.

This chapter explores some components from the Android Design Support Library. This chapter also explores some independent implementations of the same components, particularly ones that seem to be superior to what Google is offering at present.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on the action bar. You also should read the chapter on the `appcompat-v7` action bar backport.

Note that the examples in this chapter are clones of a couple from the core chapters. This chapter's prose was written assuming that you were familiar with those samples, so you may need to go back and review them as needed.

One of the book samples makes use of the animator framework.

GUIs and the Support Package

Many developers think that the libraries in the Android Support Package are purely backports. They then get confused when they realize that certain classes, like `ViewPager`, are not part of the core Android framework for any API level and exist only in the Android Support Package.

In truth, a lot of what is in the Android Support Package consists of backports: fragments, the action bar, `NotificationCompat`, and so on. However, the Android Support Package really consists of code that Google wants to make available to developers that can be used right away, even on older devices.

Many pieces of the Android Support Package are GUI-related, yet are not backports:

- `support-v4` and `support-v13` have the aforementioned `ViewPager`
- `cardview-v7` has `CardView`
- `recyclerview-v7` has `RecyclerView`
- `leanback-v17` has classes for "the ten-foot UI" approach used for Android apps appearing on televisions, such as via Android TV boxes

Now, we can add the Android Design Support Library to that list. Right now, this library is focused on Material Design components, and that is likely to remain its near-term focus. It remains to be seen if other GUI components, not specifically tied to Material Design, wind up in the Android Design Support Library, in `support-v4`/`support-v13`, or in other libraries.

Adding the Library… and What Comes With It

On the surface, Android Studio users can simply add `com.android.support:design:...` (for some version number for `...`, such as `22.2.1`) as a dependency:

```
compile 'com.android.support:design:22.2.1'
```

However, this library has a transitive dependency that pulls in `appcompat-v7`. Most pieces of the Android Design Support Library do indeed seem to require that you use `appcompat-v7`, using `Theme.AppCompat`, `AppCompatActivity`, and friends. This is true even if you planned on using `Theme.Material` itself, with a `minSdkVersion` of 21 or higher.

This is one of the major benefits of the third-party implementations that will be explored in this chapter: they work without requiring `appcompat-v7`.

Some Notes About Icons

Google occasionally publishes icon libraries. Their current incarnation of this is their "material icons library", which contains lots of icons for lots of nouns and verbs, already pre-scaled for Android into various densities. Moreover, these icons were created with Google's Material Design aesthetic in mind. Some of the sample apps in this chapter will use some of these icons.

However, given that Google has a tendency to delete things, it would behoove you to keep a copy of this library on your development machine, rather than download icons one at a time from the Web.

Snackbars: Sweeter than Toasts

The `Toast` has been in Android since the beginning. It allows you to pop up a message to show the user, one that does not interfere with the rest of your activity layout. And, it is fairly easy to use.

However, some people get burned by `Toast`:

- A `Toast` is modeless, so you cannot get user input via a `Toast`

- Because a Toast is modeless, it is time-limited, and therefore the user might never see your message, because the user is not glancing at the screen during the short window your Toast is visible
- A Toast is a separate window from the window that is displaying your activity, so your Toast will remain visible even if the user navigates to some other activity, which can be annoying at times

The Material Design guidelines instead call for the use of a "snackbar", and the Design Support Library offers a Snackbar implementation of this UI pattern. In contrast to a Toast:

- A Snackbar is part of your activity's UI, and so it can collect input from the user, while it is around, usually in the form of some sort of "action"
- A Snackbar can be time-limited (for information notices) or durable (for errors or getting user input)
- While a Snackbar is part of your activity (and will go away when the user leaves your activity), you do not have to declare it in your layout files

With that in mind, let's take a look at some use cases for a Snackbar and how they can be implemented.

Alerts

The quintessential reason to use a Toast was to display a simple message to the user. You can use a Snackbar in the same role, with most of the same code.

Snackbar has a static make() method, mirroring the makeText() method on Toast. make() takes three parameters, only slightly different from those on makeText():

1. A View in the activity that wishes to show the Toast
2. The message, in the form of a CharSequence (e.g., a String) or a string resource ID
3. The duration of the Snackbar, which is either Snackbar.LENGTH_SHORT, Snackbar.LENGTH_LONG, or possibly something else (the documentation is inconsistent on this point)

As with makeText() on Toast, simply calling make() on Snackbar creates a Snackbar object for you, but does not display anything. You need to call show() on the Snackbar instance to get it to appear.

The DesignSupport/Snackbar sample project is a clone of the `Threads/AsyncDemo` sample from earlier in the book. The app shows a list of 25 Latin words, progressively added to the list via an `AsyncTask`. When the list is fully populated, the original sample would display a `Toast`, from `onPostExecute()` of the `AsyncTask`.

The revised sample substitutes a `Snackbar`:

```
    @Override
    protected void onPostExecute(Void unused) {
      Snackbar.make(getListView(), R.string.done,
          Snackbar.LENGTH_LONG).show();

      task=null;
    }
```

On phone-sized screens, the `Snackbar` will be centered along the bottom:

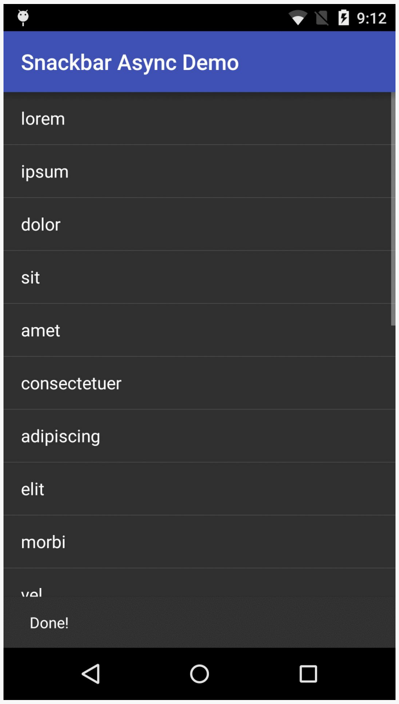

Figure 457: Official Snackbar, on a Nexus 5

On tablet-sized screens, the `Snackbar` will appear at the bottom but off to the side:

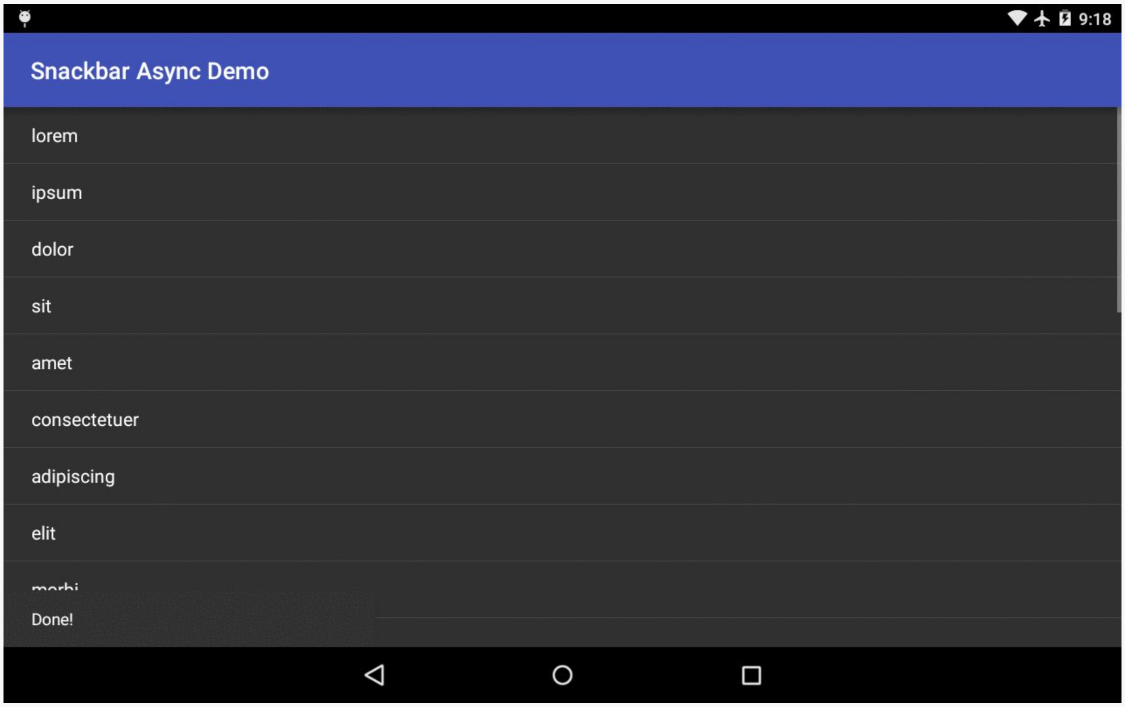

Figure 458: Official Snackbar, on a Nexus 7

Unfortunately, there does not seem to be much support for styling the look of the Snackbar. To do this manually, you can obtain the actual `View` for the `Snackbar` via `getView()`. While you should make few assumptions about what this `View` actually is, you should be able to call setters on that `View` to change things like background colors.

Also note that the user can get rid of a `Snackbar` via a swipe gesture, in addition to allowing the `Snackbar` to time out on its own. This is not possible with `Toast`, as a `Toast` is modeless.

Action Bars. No, Not Those Action Bars.

We can expand upon the user interaction with a `Snackbar` by adding an action to it. To do this, just call `setAction()` on the `Snackbar` after creating it, passing in the display string for the action (what the user will see on the `Snackbar`) and a `View.OnClickListener` that will get control when the user taps on that action. The look and feel of the action is up to the `Snackbar` implementation.

The DesignSupport/SnackbarAction sample project is a clone of the previous sample, adding one of these actions. Specifically, once the list is loaded, we want a

"Restart" action to clear the list and load it again. Perhaps the user found loading the list to be exciting and wishes to see it happen all over again.

To that end, we should pull out the work of loading our list into a `loadModel()` method that can be used from multiple places:

```
private void loadModel() {
  task=new AddStringTask();
  task.execute();
}
```

The `onCreate()` method now delegates to `loadModel()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  setRetainInstance(true);

  adapter=
      new ArrayAdapter<String>(getActivity(),
          android.R.layout.simple_list_item_1,
          model);

  loadModel();
}
```

And, more importantly for this section, we also call `loadModel()` from the `View.OnClickListener` of the action that we add to our `Snackbar`:

```
  @Override
  protected void onPostExecute(Void unused) {
    Snackbar munchie=Snackbar.make(getListView(), R.string.done,
        Snackbar.LENGTH_LONG);

    munchie.setAction(R.string.snackbar_action_restart,
      new View.OnClickListener() {
        @Override
        public void onClick(View view) {
          adapter.clear();
          loadModel();
        }
      });

    munchie.show();

    task=null;
  }
```

The action will appear on the `Snackbar` itself, both on phones:

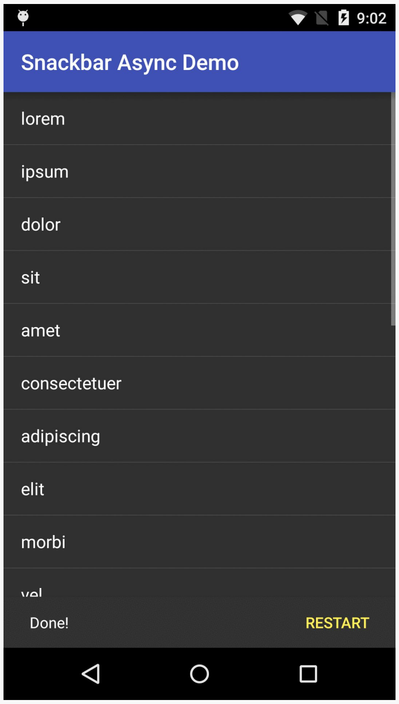

Figure 459: Official Snackbar, with an Action, on a Nexus 5

…and on tablets:

Done!

Figure 460: Official Snackbar, with an Action, on Nexus 7

Tapping the action triggers the listener, which in our case clears the list and starts the load all over again.

Third-Party Snackbars

At the present time, there does not appear to be a currently-maintained independent implementation of the snackbar UI pattern.

Absolutely FABulous

Perhaps no single element of the Material Design aesthetic has gotten more attention than has the floating action button, or FAB. These are round buttons, usually floating towards the bottom of the screen over top of the main UI:

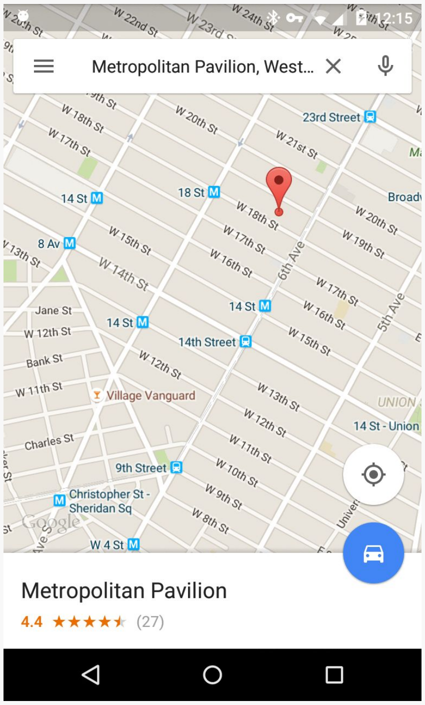

Figure 461: Google Maps, with a Pair of FABs, on a Nexus 4

The job of the FAB is to provide rapid access to the primary action that users might take on that particular screen. Typically, in a master/detail sort of UI, the FAB will allow creating a new item for the collection:

- A voice recording app showing a list of previous recordings might have a FAB to make a new recording
- A blood pressure monitoring app showing a list of previous readings might have a FAB to take a new reading
- A to-do list app showing the current tasks might have a FAB to add a new task

However, the FAB does not have to be an "add" operation. The only real limitation is that it should be a screen-level operation, not affecting only some selected item on that screen. So, for example, in the video recording app example, you would not use a FAB to play back one of the existing videos… at least on a screen listing those videos. If tapping a video in that list brings up some sort of detail screen, *that* screen could possibly have a FAB to play back the video.

The Design Support library has a rudimentary FAB implementation, and there are third-party alternatives that either add power or solve other FAB-related problems.

FAB Mechanics

In many respects, setting up a FAB is not that different from setting up any other widget: put it in your layout, positioned where you want it, then access it in Java code to set up listeners. In particular, Google's FAB implementation supports a `View.OnClickListener` much like a regular `Button`.

The DesignSupport/FAB sample project is a clone of the first `Snackbar` sample from earlier in this chapter. The second `Snackbar` sample added a "restart" action to the `Snackbar`. In this sample, we instead have a "restart" action on a FAB.

Before, we did not need a layout resource for the `AsyncDemoFragment`, as it was an ordinary `ListFragment` and therefore would supply a `ListView` automatically. However, this time, we want to have a FAB as well, so we need our own layout file:

```xml
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
    />

  <android.support.design.widget.FloatingActionButton
    android:id="@+id/refresh"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:src="@drawable/ic_refresh_black_24dp"
    android:layout_marginRight="@dimen/fab_margin"
    android:layout_marginBottom="@dimen/fab_margin"
    android:layout_alignParentBottom="true"
    android:layout_alignParentRight="true"/>

</RelativeLayout>
```

Here, the FAB (a.k.a., `android.support.design.widget.FloatingActionButton`) is later in a `RelativeLayout` than is the `ListView`, so the FAB will have higher elevation and will appear to float over the `ListView`. The `android:src` attribute points to a drawable resource, much like how that attribute works on an `ImageButton`. In this case, it points to an icon from Google's material icons collection.

However, the interesting bit is the pair of margin attributes (`android:layout_marginRight` and `android:layout_marginBottom`). They point to a fab_margin dimension resource, one with some specific values required due to bugs (or curious implementation choices) in Google's FAB implementation.

By default, the fab_margin in res/values/dimens.xml is used, which has a dimension of 0dp:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">0dp</dimen>
</resources>
```

You might think that this would cause the FAB to be slammed up against the side and bottom of the RelativeLayout. However, the FAB has built-in margins… on older devices.

But, for whatever reason, on API Level 21+, that automatic margin vanishes. So, we have another definition of fab_margin, in res/values-v21/dimens.xml, setting it to 16dp:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">16dp</dimen>
</resources>
```

Furthermore, Google's Material Design docs state that there should be 24dp margin on tablets, not 16dp. So, we have a *third* definition of fab_margin, in res/values-sw720dp-v21, to set the margin to 24dp:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="fab_margin">24dp</dimen>
</resources>
```

It is possible that a full implementation of this would need a fourth fab_margin value, for Android 4.x tablets, where fab_margin would be set to something that gives a 24dp margin but takes into account the automatic margin that the FAB seems to have prior to API Level 21. This sample eschews this, going with the automatic margin on all tablets, regardless of API level.

The Java code is fairly straightforward, retrieving the FAB in onViewCreated() and hooking up a View.OnClickListener to the FAB, where that listener is the `AsyncDemoFragment itself:

```
  @Override
  public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);
    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);

    FloatingActionButton fab=(FloatingActionButton)v.findViewById(R.id.refresh);

    fab.setOnClickListener(this);
  }
```

In `onClick()`, if the `AsyncTask` is still running, we `cancel()` it. Then, we clear the list and kick off a fresh task via the same sort of `loadModel()` method as seen in the second `Snackbar` example:

```
  @Override
  public void onClick(View view) {
    if (task!=null) {
      task.cancel(false);
    }

    adapter.clear();
    loadModel();
  }

  void loadModel() {
    task=new AddStringTask();
    task.execute();
  }
```

This gives us our FAB on Android 4.x devices:

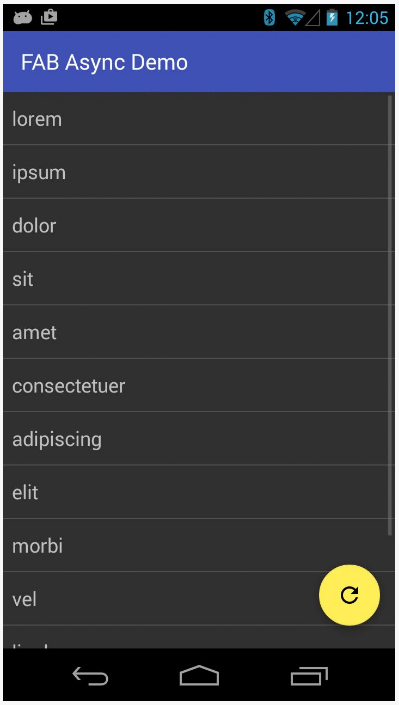

Figure 462: Official FAB, on a Galaxy Nexus

…on Android 5.x phones:

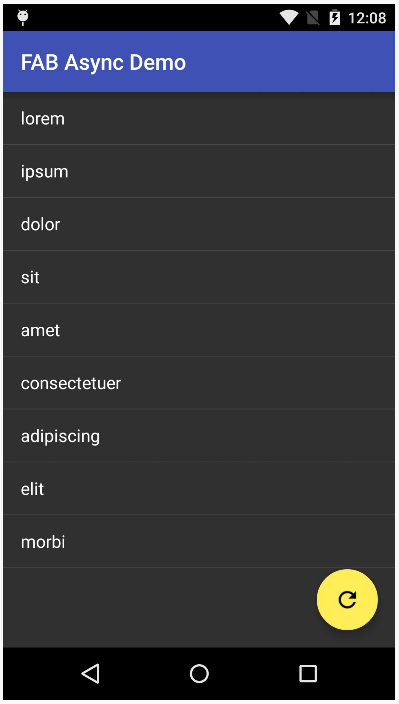

Figure 463: Official FAB, on a Nexus 5

…and on Android 5.x tablets:

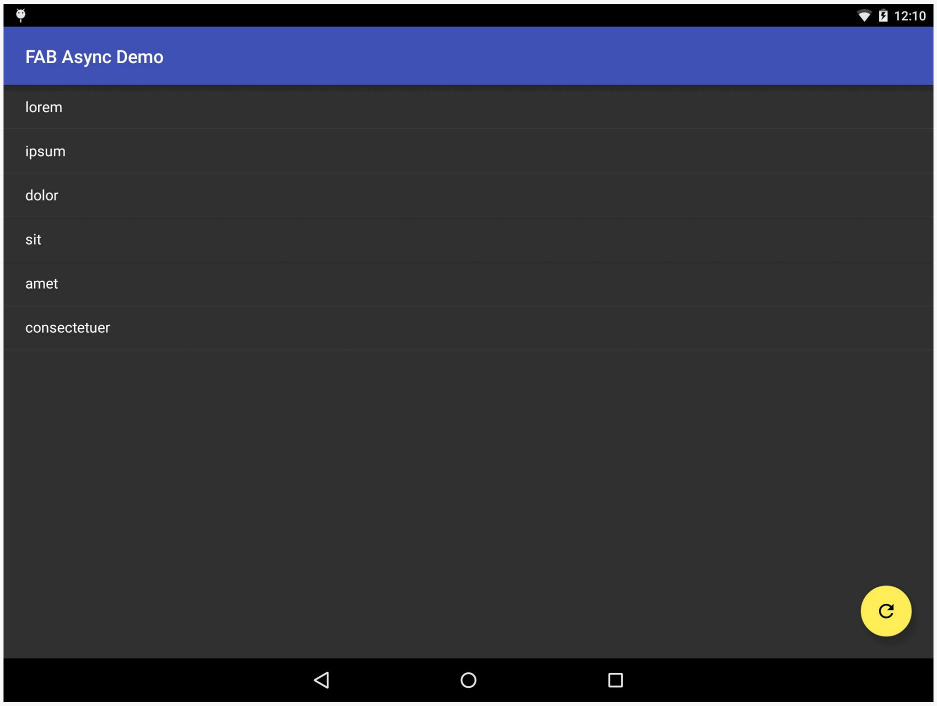

Figure 464: Official FAB, on a Nexus 9

Coordinating with Snackbars

However, what the above screenshots do *not* illustrate is what happens when our `Snackbar` appears:

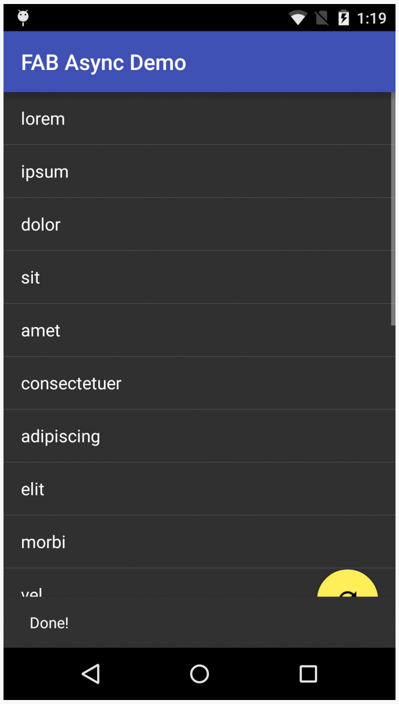

Figure 465: Official FAB, on a Nexus 5, Conflicting with the Snackbar

The fact that the `Snackbar` overlaps the FAB should not be much of a surprise. After all, the `Snackbar` overlaps the `ListView` as well. A `Toast` would also overlap the list and FAB. Hence, to some extent, the fact that there is this lack of coordination between the `Snackbar` and the FAB seems to be fairly normal.

That being said, the Design Support library has a container designed for coordinating between different children as those children animate and scroll. This container — `CoordinatorLayout` — is a subclass of `FrameLayout`, meaning other than Z-axis ordering (elevation) and gravity, it has no other notable layout rules. It merely exists to perform this sort of coordination.

As it turns out, `CoordinatorLayout` has special awareness of `Snackbar` and the FAB, so simply using `CoordinatorLayout` will cause the FAB to slide upwards to make room for the `Snackbar`.

The DesignSupport/CoordinatedFAB sample project is a clone of the previous FAB example, except that we switch from a `RelativeLayout` root container to a `CoordinatorLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout
```

```
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
    />

  <android.support.design.widget.FloatingActionButton
    android:id="@+id/refresh"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="bottom|right"
    android:layout_marginBottom="@dimen/fab_margin"
    android:layout_marginRight="@dimen/fab_margin"
    android:src="@drawable/ic_refresh_black_24dp"/>

</android.support.design.widget.CoordinatorLayout>
```

Since CoordinatorLayout is based on FrameLayout, not RelativeLayout, we have to adjust the layout rules on the FAB to match, using android:layout_gravity to position the FAB towards the bottom right corner.

With no other changes, we now get coordinated movements of the FAB and the Snackbar as the Snackbar appears and disappears:

Third-Party FABs… and FAMs

The Design Support implementation of a FAB works, and it works nicely "out of the box" with `CoordinatorLayout`. However, it implements only a subset of the Material Design FAB capabilities, let alone related structures like the floating action menu (FAM).

As a result, there are many FAB projects listed on the Android Arsenal, offering other implementations of a FAB. The author of this book uses the Clans FAB implementation, in part because it offers support for the FAM pattern as well:

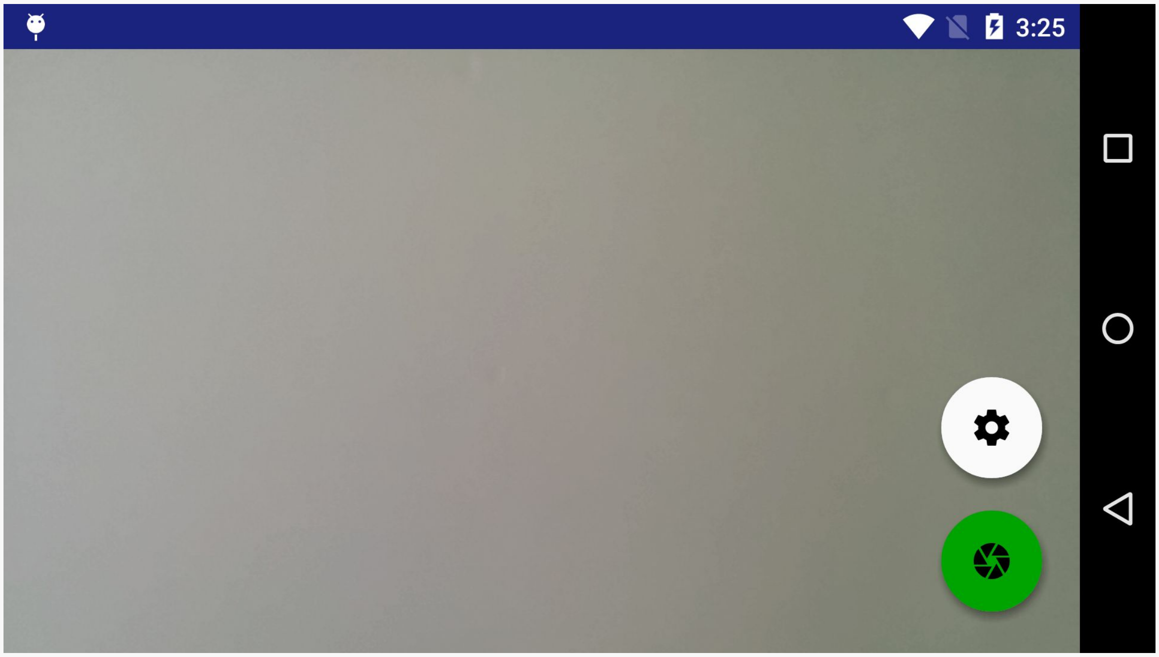

Figure 467: CWAC-Cam2 CameraActivity, Showing Clans FAB and FAM

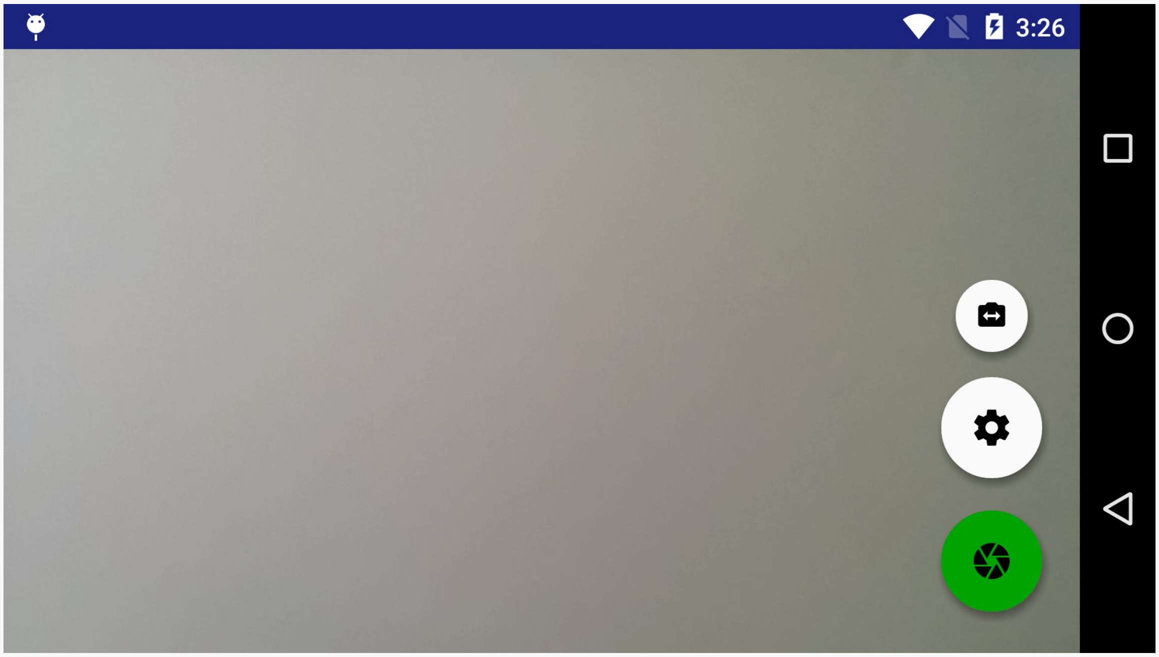

Figure 468: CWAC-Cam2 CameraActivity, Showing Clans FAB and FAM, with FAM Open

The DesignSupport/FABClans sample project is a clone of the original FAB sample shown above, where the Clans FAB implementation is used, along with a FAM.

The layout now switches to show the FAB, the FAM, and a smaller FAB that appears when the FAM is opened:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:fab="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
    />

  <com.github.clans.fab.FloatingActionButton
    android:id="@+id/refresh"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:src="@drawable/ic_refresh_black_24dp"
    android:layout_marginBottom="@dimen/fab_margin"
    android:layout_marginRight="@dimen/fab_margin"
    android:layout_alignParentBottom="true"
    android:layout_alignParentRight="true"/>

  <com.github.clans.fab.FloatingActionMenu
    android:id="@+id/settings"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_above="@id/refresh"
    android:layout_alignRight="@id/refresh"
    android:layout_marginBottom="@dimen/fam_bottom_margin"
    fab:menu_colorNormal="@color/fam"
    fab:menu_colorPressed="@color/fam_pressed"
    fab:menu_icon="@drawable/ic_action_settings">

    <com.github.clans.fab.FloatingActionButton
      android:id="@+id/settings_item"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:src="@drawable/ic_switch_camera"
      fab:fab_colorNormal="@color/fam"
      fab:fab_colorPressed="@color/fam_pressed"
      fab:fab_size="mini"/>

  </com.github.clans.fab.FloatingActionMenu>

</RelativeLayout>
```

In terms of the primary FAB, the element is largely the same, other than changing the class to be com.github.clans.fab.FloatingActionButton.

Below that in the layout XML is a com.github.clans.fab.FloatingActionMenu. This is a FAB that knows how to show and hide a menu of secondary FABs when clicked. In this case, we set it to appear above the FAB with 4dp of margin between them. In addition, we set the colors for the normal and pressed states, pointing to a pair of color resources:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="primary">#3f51b5</color>
  <color name="primary_dark">#1a237e</color>
  <color name="accent">#ffee58</color>
  <color name="fam">#fafafa</color>
  <color name="fam_pressed">#f1f1f1</color>
</resources>
```

Also, for whatever reason, the icon for the FAM is not handled via the android:src attribute used for the FAB, but instead via a fab:menu_icon attribute.

The children of the FAM are supposed to be FABs that will appear and disappear as the FAM is clicked on. For this, we use fab:fab_size="mini" for the smaller FAB, in addition to tailoring the color.

In onViewCreated(), we get our hands on the main FAB and set up the View.OnClickListener, just as we did with the Design Support edition of the FAB. However, we also retrieve the FAM and call a changeMenuIconAnimation() method:

```
  @Override
  public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
    setListAdapter(adapter);

    FloatingActionButton fab=(FloatingActionButton)v.findViewById(R.id.refresh);

    fab.setOnClickListener(this);

    changeMenuIconAnimation((FloatingActionMenu)v.findViewById(R.id.settings));
  }
```

The recommended visual effect when tapping on a FAM is not only to show the menu, but also to change the icon to a close icon, to indicate that tapping the FAM again will close the menu. Unfortunately, the Clans FAM implementation does not do this automatically. The changeMenuIconAnimation() method sets it up, using a combination of the Android SDK animator framework and hooks provided by the FAM for the `AnimatorSet` to be invoked when the user toggles the FAM between open and closed:

```
// based on https://goo.gl/3IUM8K

private void changeMenuIconAnimation(final FloatingActionMenu menu) {
  AnimatorSet set=new AnimatorSet();
  final ImageView v=menu.getMenuIconView();
  ObjectAnimator scaleOutX=ObjectAnimator.ofFloat(v, "scaleX", 1.0f, 0.2f);
  ObjectAnimator scaleOutY=ObjectAnimator.ofFloat(v, "scaleY", 1.0f, 0.2f);
  ObjectAnimator scaleInX=ObjectAnimator.ofFloat(v, "scaleX", 0.2f, 1.0f);
  ObjectAnimator scaleInY=ObjectAnimator.ofFloat(v, "scaleY", 0.2f, 1.0f);

  scaleOutX.setDuration(50);
  scaleOutY.setDuration(50);

  scaleInX.setDuration(150);
  scaleInY.setDuration(150);
  scaleInX.addListener(new AnimatorListenerAdapter() {
    @Override
    public void onAnimationStart(Animator animation) {
      v.setImageResource(menu.isOpened()
          ? R.drawable.ic_action_settings
          : R.drawable.ic_close);
    }
  });

  set.play(scaleOutX).with(scaleOutY);
  set.play(scaleInX).with(scaleInY).after(scaleOutX);
  set.setInterpolator(new OvershootInterpolator(2));
  menu.setIconToggleAnimatorSet(set);
}
```

Here, we:

- Create an `AnimatorSet`
- Create four `ObjectAnimator` instances, for scaling the size of something on both axes, for both scaling out (shrinking) and scaling in (growing)
- Configure the durations of each of those scale animator instances
- Add a listener to one animator to toggle the drawable used for the icon when the animation begins
- Configure the animator set to scale the old drawable out, then switch to the new icon and scale that drawable in, with an `OvershootInterpolator` for a bit of a "bounce" effect
- Tell the FAM to use that `AnimatorSet` each time the user taps the FAM

In principle, we should also be setting up a `View.OnClickListener` on the mini FAB that is inside the menu, as usually the point behind having a FAM is to respond to taps on those menu items. This is skipped in this sample in the interests of simplicity.

The resulting UI shows the FAB and the FAM, much like those from the CWAC-Cam2 library shown earlier in this section:

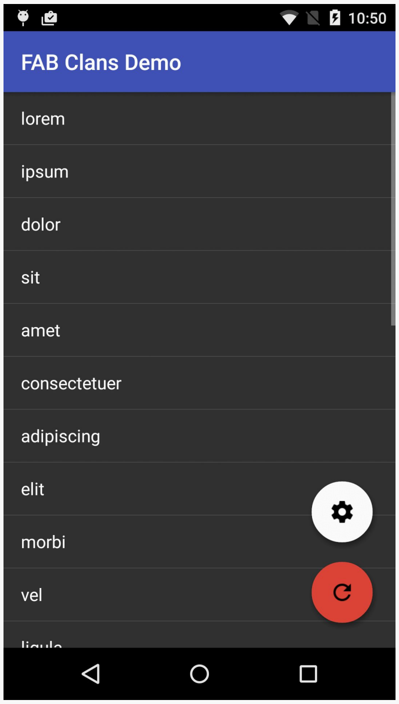

Figure 469: FABClans Sample, Showing Clans FAB and FAM

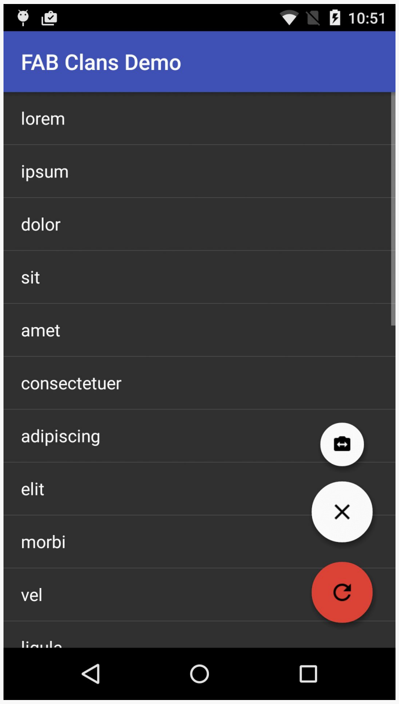

Figure 470: FABClans Sample, Showing Clans FAB and FAM, with FAM Open

Third-Party FAB Add-Ons

In addition to complete FAB and FAM implementations, developers have been publishing libraries that add on other Material Design features to existing FAB implementations, such as:

- Wrapping a progress bar around a FAB, perhaps to show the progress of some work triggered by a previous click on the FAB
- Using a "material sheet" or a "floating action toolbar" as an alternative to the FAM pattern

As usual, the Android Arsenal has a category devoted to FABs that is worth checking out.

Material Tabs with TabLayout

Android has had a myriad of tab implementations over the years:

- `TabHost` and `TabWidget`

- FragmentTabHost and TabWidget
- the now-deprecated action bar tabs
- PagerTabStrip, used in conjunction with a ViewPager

The Design Support library adds yet another tab implementation: TabLayout. Specifically, this implementation's claim to fame is a faithful implementation of a subset of Google's Material Design guidelines for how tabs should look and behave.

TabLayout can be used with or without a ViewPager. If you elect to skip the ViewPager, TabLayout works in a form reminiscent of action bar tabs, where it is responsible for the tab UI and you are responsible for updating the rest of your UI based upon the chosen tab (e.g., commit a FragmentTransaction). If you elect to use a ViewPager, TabLayout can lightly integrate with the ViewPager, so navigating by one means (e.g., swiping the pager) updates the other UI (e.g., changing the selected tab).

From a layout standpoint, you use TabLayout much like you would use TabWidget: put it where the tabs should go. Since Material Design wants the tabs on top, that means that typically you would put TabLayout inside a vertical LinearLayout, with the actual tabbed content beneath the TabLayout.

This is illustrated in the DesignSupport/TabLayout sample project. It is based on the original ViewPager samples, showing a set of editors in pages, this time using a TabLayout as the tab implementation (as opposed to PagerTabStrip or the TabPagerIndicator from the ViewPagerIndicator library).

The layout loaded by the activity has a setup much as described above: a vertical LinearLayout wrapped around a TabLayout and our ViewPager:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              android:layout_width="match_parent"
              android:layout_height="match_parent"
              android:orientation="vertical">

  <android.support.design.widget.TabLayout
    android:id="@+id/tabs"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>
</LinearLayout>
```

TabLayout can have its tabs operate in one of two modes: fixed and scrollable. With fixed tabs, all tabs will be on the screen at all times, where they divide the available horizontal space between them. This works fine for just a few tabs. But for lots of tabs, each tab becomes very small, making it unlikely that the user can read the tab caption. Scrollable tabs each take up as much room as their caption requires, and if the roster of tabs becomes too wide for the screen, the user can swipe the tabs.

The sample app demonstrates both of these approaches, using a checkable action bar item to toggle between three editors with fixed tabs or ten editors with scrollable tabs. The default state is to be in fixed-tab mode:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android"
      xmlns:app="http://schemas.android.com/apk/res-auto">
  <item
    android:id="@+id/fixed"
    android:title="@string/menu_fixed"
    android:checkable="true"
    android:checked="true"
    app:showAsAction="never"/>
</menu>
```

The entire app was switched over to use AppCompatActivity and the fragment backport, as that is what the Design Support library requires. Beyond that, the EditorFragment is pretty much unchanged from the original implementations, just showing a large EditText widget with a hint based on the page number.

Our PagerAdapter — SamplePagerAdapter — has one change beyond the switch to the fragment backport. To accommodate switching between fixed and scrollable tabs, rather than hard-coding the number of pages, the adapter offers a setPageCount() method to stipulate the number of pages. The page count defaults to 3.

```
package com.commonsware.android.tablayout;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
  private final Context ctxt;
  private int pageCount=3;

  public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);

    this.ctxt=ctxt;
  }
  @Override
  public int getCount() {
    return(pageCount);
  }

  @Override
  public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
  }

  @Override
  public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
  }

  void setPageCount(int pageCount) {
    this.pageCount=pageCount;
  }
}
```

In `MainActivity`, in `onCreate()`, we set up the `ViewPager` and the `TabLayout`:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    adapter=new SampleAdapter(this, getSupportFragmentManager());
    pager.setAdapter(adapter);

    tabs=(TabLayout)findViewById(R.id.tabs);
    tabs.setupWithViewPager(pager);
    tabs.setTabMode(TabLayout.MODE_FIXED);
  }
```

The bulk of the `TabLayout` setup work is handled with one call to `setupWithViewPager()`. This:

- Creates one tab for every page, based on whatever the `PagerAdapter` in the `ViewPager` is reporting at the time of this call
- Sets up the appropriate listeners, so that taps on a tab switches pages in the `ViewPager`, and swipes between pages update the selected tab

We also call `setTabMode(TabLayout.MODE_FIXED)`, as we are going with fixed tabs at the outset.

This gives us our three tabs:

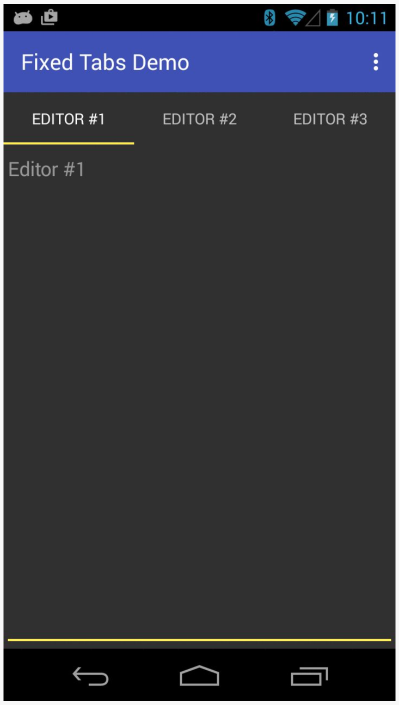

Figure 471: TabLayout Sample, As Initially Launched, Showing Three Fixed Tabs

But we also have that menu resource, to allow the user to switch between fixed and scrollable tabs. We `inflate()` that resource in `onCreateOptionsMenu()` as usual, and we handle the checked state change in `onOptionsItemSelected()`:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
  getMenuInflater().inflate(R.menu.actions, menu);

  return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
  if (item.getItemId()==R.id.fixed) {
    item.setChecked(!item.isChecked());

    if (item.isChecked()) {
      adapter.setPageCount(3);
      tabs.setTabMode(TabLayout.MODE_FIXED);
    }
    else {
      adapter.setPageCount(10);
      tabs.setTabMode(TabLayout.MODE_SCROLLABLE);
    }

    adapter.notifyDataSetChanged();
    tabs.setTabsFromPagerAdapter(adapter);
```

```
      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

If the user taps on our checkable overflow item, we invert the item's checked state (which, unfortunately, does not happen automatically). Then, we call `setPageCount()` on the `SampleAdapter` and `setTabMode()` on the `TabLayout` based on the now-current checked state, to either have three fixed tabs or ten scrollable tabs.

Changing the page count of the `SampleAdapter` requires calling `notifyDataSetChanged()` to alert the `ViewPager` that the data set changed and it needs to repaint. Unfortunately, while `TabLayout` could also find out about this change and repaint, Google elected not to implement this. To re-sync the `TabLayout` with the current roster of tabs in the `ViewPager`, you need to call `setTabsFromPagerAdapter()`. This, like `setupWithViewPager()`, sets the tab roster based on what the `PagerAdapter` reports. However, `setTabsFromPagerAdapter()` does not affect the listeners, which were already set up and do not need to be changed here.

Clicking on the "Fixed" checkable overflow item, and thereby unchecking it from its initial checked state, gives us ten scrollable tabs:

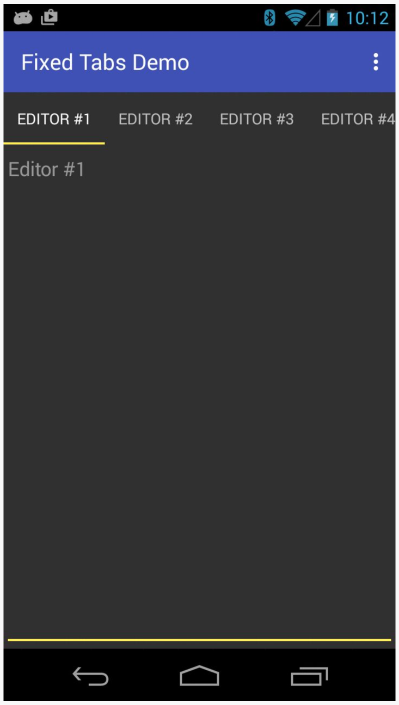

Figure 472: TabLayout Sample, Showing Scrollable Tabs

Note that while this particular sample app shows `TabLayout` working with a `ViewPager`, a `ViewPager` is not required to be able to use `TabLayout`. You can simply have the `TabLayout` plus your own system for whatever the tabs switch in your UI. Then, you can use methods like `addTab()` and `setOnTabSelectedListener()` to set up tabs and find out when the user taps on them, so you can adjust your UI to match the selected tab. That being said, many users may come to expect that they can horizontally swipe to move between pages of content, and so definitely consider using a `ViewPager` if practical.

Third-Party Material Tabs

There are other implementations of Material Design-inspired tabs, including ones that do not have the `appcompat-v7` requirement.

One that seems to work fairly well is Karim Frenn's `MaterialTabs`. Not only can it work with native fragments and the native action bar, but it also adds features that `TabLayout` lacks, like:

- Continuous synchronization with the `ViewPager` (though there is a bug related to that, which we will examine shortly)

- More customization options, including custom fonts or even custom views for the tabs

On the other hand, MaterialTabs is limited to working with a ViewPager. It does not presently offer an API for adding tabs manually and responding to tab selection.

The DesignSupport/TabLayoutPizza sample project is so named because Mr. Frenn's GitHub account is named pizza. This project is a clone of the TabLayout sample, but it substitutes in MaterialTabs as the tab implementation.

In the app/ module's build.gradle file, we replace the com.android.support:design dependency with one for MaterialTabs and one for com.android.support:support-v13. The latter is so we can use native fragments for our pages in the ViewPager; MaterialTabs itself depends upon support-v4.

```
apply plugin: 'com.android.application'

dependencies {
    compile 'io.karim:materialtabs:2.0.2'
    compile 'com.android.support:support-v13:22.2.1'
}

android {
    compileSdkVersion 22
    buildToolsVersion "22.0.1"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 18
    }
}
```

EditorFragment and SampleAdapter are unchanged from the previous sample, except that they now use native fragments rather than the fragments backport.

The layout for MainActivity (main.xml) now has a io.karim.MaterialTabs widget instead of a TabLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              xmlns:app="http://schemas.android.com/apk/res-auto"
              android:layout_width="match_parent"
              android:layout_height="match_parent"
              android:orientation="vertical">

  <io.karim.MaterialTabs
    android:id="@+id/tabs"
    android:layout_width="match_parent"
    android:layout_height="48dp"
    app:mtIndicatorColor="@color/accent"
    app:mtSameWeightTabs="true"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>
</LinearLayout>
```

`MaterialTabs` has a lot of custom attributes that you can set. Here, we use two:

1. `app:mtIndicatorColor` provides the color to use for the bar that indicates the selected tab.
2. `app:mtSameWeightTabs` says that if all tabs can fit on the screen, give them all the same weight, to provide the same sort of look as we get with the fixed mode with `TabLayout`. Note that `MaterialTabs` does not require manually switching modes, as it automatically switches into a scrollable mode when the number of tabs exceeds the available space.

Setting up `MaterialTabs` is then just a matter of calling `setViewPager()` on the `MaterialTabs` object to connect the tabs to the pager:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SampleAdapter(this, getFragmentManager());
    pager.setAdapter(adapter);

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);
  }
```

Since `MaterialTabs` *does* pay attention to when the `PagerAdapter` is called with `notifyDataSetChanged()`, ideally switching between “fixed” and “scrollable” would just be a matter of setting the number of pages (via `setPageCount()`) and calling `notifyDataSetChanged()`. Unfortunately, `MaterialTabs` 2.0.2 has a bug when you reduce the number of pages, and the workaround gets a bit tricky:

```
  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.fixed) {
      item.setChecked(!item.isChecked());

      if (item.isChecked()) {
        if (pager.getCurrentItem()>2) {
          pager.setCurrentItem(2);
        }
        pager.postDelayed(new Runnable() {
          @Override
          public void run() {
            adapter.setPageCount(3);
            adapter.notifyDataSetChanged();
          }
        }, 100);
      }
      else {
        adapter.setPageCount(10);
        adapter.notifyDataSetChanged();
      }

      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

TabLayout, when you call setTabsFromViewPager(), always resets your current tab to the first tab. This sucks, as the user loses her place when we add pages (or remove pages but the selected tab still exists), but at least it is reliable.

MaterialTabs, on the other hand, crashes if the selected tab no longer exists due to a reduction in page count. To work around this, we have to manually set the current tab to a safe tab by calling setCurrentItem() on the ViewPager, before we try changing the page count. Worse, we have to postpone the actual page count change until after setCurrentItem() affects the ViewPager and the MaterialTabs objects. Hopefully, in the future, the postDelayed() call will no longer be needed here.

Visually, the results are pretty much the same as you get with TabLayout, just with the native action bar and fragments:

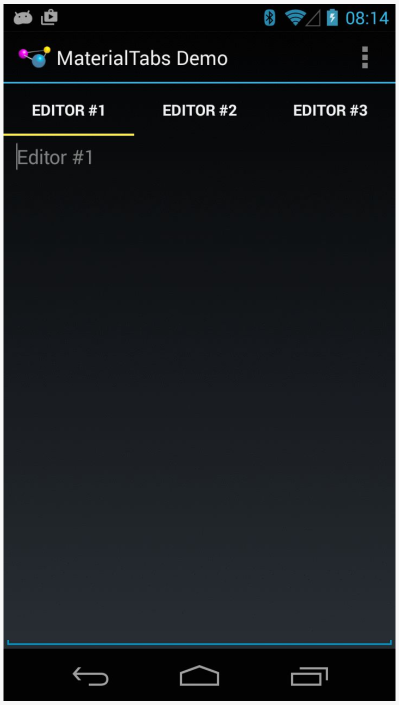

Figure 473: TabLayoutPizza Sample, As Initially Launched, Showing Three Tabs

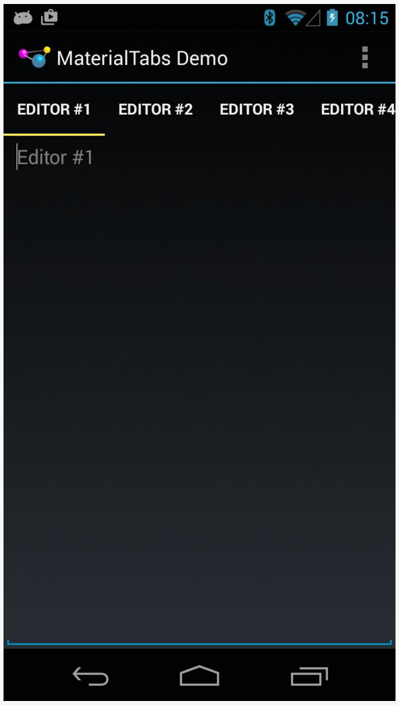

Figure 474: TabLayoutPizza Sample, As Initially Launched, Showing Ten Tabs

Floating Labels

The EditText widget supports the android:hint attribute. The hint is shown in the EditText when the EditText is otherwise empty. However, if the EditText has actual text in it (whether typed by the user, loaded from a database, or whatever), the hint is not shown. This saves screen space compared to having a TextView label always visible; the hint itself serves as the label.

However, the hint-as-label pattern has a major drawback: the hint is not visible if there is text in the EditText. In the long term, as the user learns your UI, this is not a big problem. However, particularly early on, the user might look at a filled-in field and wonder what that field is for. This is even more likely in cases where the user is not the one who typed the text into the field in the first place, such as editing a database entry pulled from a server, where somebody (or something) else had created the entry in the first place.

The "floating label" pattern starts with a hint in the field. However, when the field is used, the hint animates out of the field itself and "floats" above the field in a shrunken form. This way, the label is always visible. However, in its smaller floating state, it takes up less screen space, yet while the field is otherwise empty, we can take advantage of that space to offer a "full-size" label instead.

The Design Support library offers TextInputLayout as a way of implementing the floating label pattern. This is not a subclass of EditText, but rather a ViewGroup that is wrapped around the EditText. This is convenient, insofar as it allows developers to use other EditText subclasses and still get the floating-label behavior.

TextInputLayout also supports an error state, where we can optionally show an error message below the EditText, such as an indication of an invalid bit of data entry.

Using TextInputLayout

The DesignSupport/FloatingLabel sample project is a clone of an earlier sample where we allowed the user to enter in a URL and then, upon a button click, would parse the URL into a Uri, wrap that in an ACTION_VIEW Intent, then try to start an activity for that Intent.

The original sample's layout looks like:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <EditText
    android:id="@+id/url"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:hint="@string/url"
    android:inputType="textUri"/>

  <Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me"/>

</LinearLayout>
```

In this revised sample, the original `EditText` is augmented with a `TextInputLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              android:layout_width="match_parent"
              android:layout_height="match_parent"
              android:orientation="vertical">

  <Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me">

    <requestFocus/>
  </Button>

  <android.support.design.widget.TextInputLayout
    android:id="@+id/til"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <EditText
      android:id="@+id/url"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:hint="@string/url"
      android:inputType="textUri"/>
  </android.support.design.widget.TextInputLayout>

</LinearLayout>
```

You will notice that there are a few changes here:

- The EditText is wrapped by an android.support.design.widget.TextInputLayout container that provides the actual floating label itself
- The Button is moved ahead of the EditText, in terms of the top-down organization of our vertical LinearLayout
- The Button has a <requestFocus/> child element, indicating to Android that this widget should get the focus first

Those latter two changes are due to one major limitation with TextInputLayout: the hint moves out of the EditText into the floating position when *either* there is text in the EditText *or* the EditText gains the focus. Strangely, simply putting the Button before the EditText is insufficient, as is simply adding <requestFocus/> on the Button. Both have to be implemented to cause the TextInputLayout to show the hint in its default location at the outset.

The Java code is also augmented a bit from the original sample, to take advantage of the error-reporting feature of TextInputLayout:

```
package com.commonsware.android.design.til;

import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.support.design.widget.TextInputLayout;
import android.support.v7.app.AppCompatActivity;
import android.util.Patterns;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends AppCompatActivity {
  private TextInputLayout til;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);

    til=(TextInputLayout)findViewById(R.id.til);
    til.setErrorEnabled(true);
  }

  public void showMe(View v) {
    EditText urlField=(EditText)findViewById(R.id.url);
    String url=urlField.getText().toString();

    if (Patterns.WEB_URL.matcher(url).matches()) {
      startActivity(new Intent(Intent.ACTION_VIEW, Uri.parse(url)));
    }
    else {
      til.setError(getString(R.string.til_error));
    }
  }
}
```

The `Patterns` class in Android contains a series of stock regular expressions. One, `WEB_URL`, is designed to see if the URL that was entered looks like a Web URL. When the user taps the button, if the pattern matches what the user entered in the field, we go ahead and try to start the activity. If not, we show an error.

To show the error, we need to do two things:

1. Up front, we call `setErrorEnabled()`, to tell `TextInputLayout` to reserve some space for an error message
2. At the point where we want to show the error, we call `setError()` on the `TextInputLayout`

When we run the app, the `TextInputLayout` leaves the hint in the `EditText` itself, as the `EditText` is empty and does not have the focus:

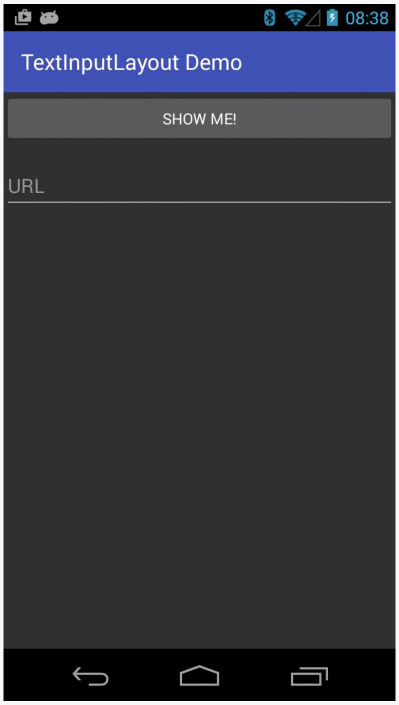

Figure 475: FloatingLabel Sample, As Initially Launched

Once the user taps on the field, though, the hint “floats” above the `EditText`:

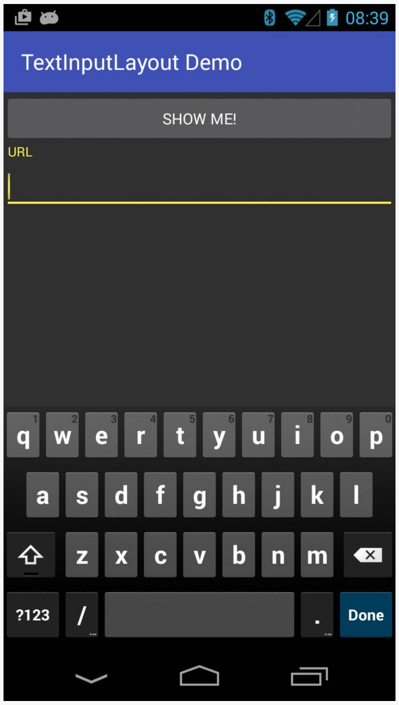

Figure 476: FloatingLabel Sample, After Focus Change

And, if the user tries entering an invalid URL, the error message appears when the user taps the button to try to visit the invalid URL:

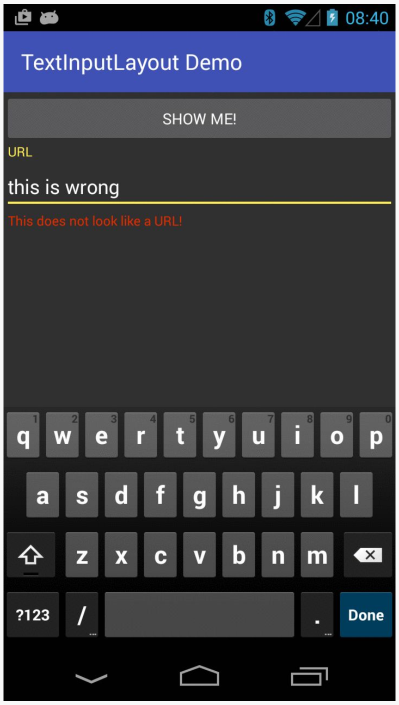

Figure 477: FloatingLabel Sample, After Erroneous Data Entry

Third-Party Floating Labels

As with the rest of the Design Support library, `TextInputLayout` requires `appcompat-v7`. There are other implementations of the floating label pattern that do not require `appcompat-v7`, or perhaps offer additional features that you may want.

`FloatLabeledEditText` is one such implementation. It lacks the error message capability of `TextInputLayout`. However:

- It only floats the hint when there is text in the `EditText` widget, not when the `EditText` gets the focus, and
- It does not require `appcompat-v7`

The DesignSupport/FloatingLabelNative sample project is a clone of the previous sample, where the `TextInputLayout` is replaced by a `FloatLabeledEditText`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
              android:layout_width="match_parent"
              android:layout_height="match_parent"
              android:orientation="vertical">
```

```
  <com.wrapp.floatlabelededittext.FloatLabeledEditText
    android:id="@+id/til"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <EditText
      android:id="@+id/url"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:hint="@string/url"
      android:inputType="textUri"/>
  </com.wrapp.floatlabelededittext.FloatLabeledEditText>

  <Button
    android:id="@+id/browse"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:onClick="showMe"
    android:text="@string/show_me"/>

</LinearLayout>
```

As with `TextInputLayout`, `FloatLabeledEditText` is a decorating container around a regular `EditText`. Here, since the hint is left alone when the `EditText` gets focus, we have it back in its original position at the top of the form.

Visually, it is fairly similar to `TextInputLayout`, albeit with the native action bar:

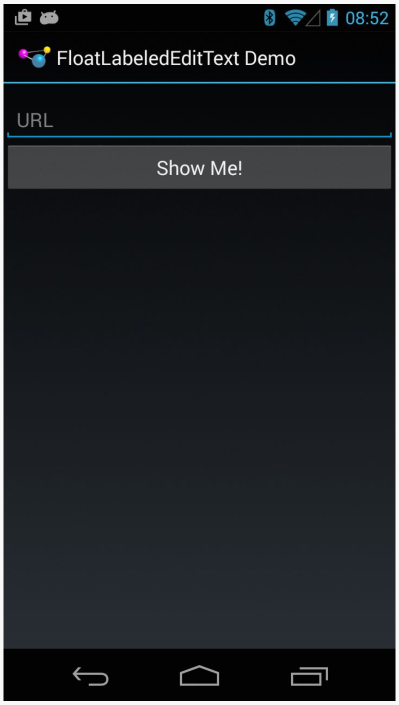

Figure 478: FloatingLabelNative Sample, As Initially Launched

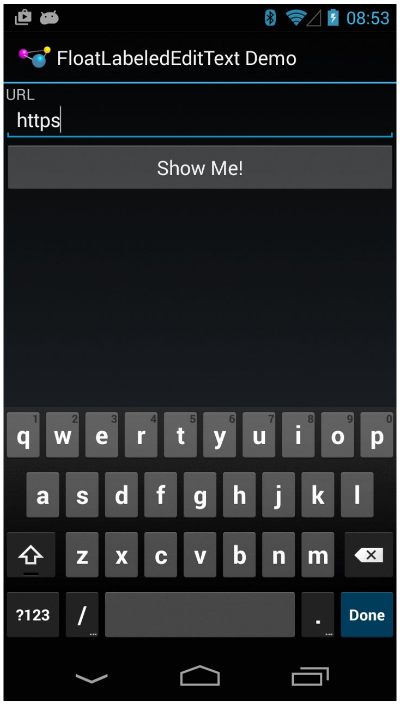


Advanced Uses of WebView

Android uses the WebKit browser engine as the foundation for both its Browser application and the `WebView` embeddable browsing widget. The Browser application, of course, is something Android users can interact with directly; the `WebView` widget is something you can integrate into your own applications for places where an HTML interface might be useful.

Earlier in this book, we saw a simple integration of a `WebView` into an Android activity, with the activity dictating what the browsing widget displayed and how it responded to links.

Here, we will expand on this theme, and show how to more tightly integrate the Java environment of an Android application with the JavaScript environment of WebKit.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one covering `WebView`. Some of the samples use `LocationManager` for obtaining a GPS fix.

Friends with Benefits

When you integrate a `WebView` into your activity, you can control what Web pages are displayed, whether they are from a local provider or come from over the Internet, what should happen when a link is clicked, and so forth. And between `WebView`, `WebViewClient`, and `WebSettings`, you can control a fair bit about how the embedded browser behaves. Yet, by default, the browser itself is just a browser, capable of showing Web pages and interacting with Web sites, but otherwise gaining nothing from being hosted by an Android application.

Except for one thing: `addJavascriptInterface()`.

The `addJavascriptInterface()` method on `WebView` allows you to inject a Java object into the `WebView`, exposing its methods, so they can be called by JavaScript loaded by the Web content in the `WebView` itself.

Now you have the power to provide access to a wide range of Android features and capabilities to your `WebView`-hosted content. If you can access it from your activity, and if you can wrap it in something convenient for use by JavaScript, your Web pages can access it as well.

For example, HTML5 offers geolocation, whereby the Web page can find out where the device resides, by browser-supplied means. We can do much of the same thing ourselves via `addJavascriptInterface()`.

In the [WebKit/GeoWeb1]() project, you will find a fairly simple layout (`main.xml`):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <WebView android:id="@+id/webkit"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
  />
</LinearLayout>
```

All this does is host a full-screen `WebView` widget.

Next, take a look at the `GeoWebOne` activity class:

```
package com.commonsware.android.geoweb;

import android.annotation.SuppressLint;
import android.app.Activity;
import android.content.Context;
import android.location.Location;
import android.location.LocationListener;
import android.location.LocationManager;
import android.os.Bundle;
import android.webkit.JavascriptInterface;
import android.webkit.WebView;
import org.json.JSONException;
import org.json.JSONObject;
```

```
public class GeoWebOne extends Activity {
  private static String PROVIDER=LocationManager.GPS_PROVIDER;
  private WebView browser;
  private LocationManager myLocationManager=null;

  @SuppressLint("SetJavaScriptEnabled")
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);

    setContentView(R.layout.main);
    browser=(WebView)findViewById(R.id.webkit);

    myLocationManager=(LocationManager)getSystemService(Context.LOCATION_SERVICE);

    browser.getSettings().setJavaScriptEnabled(true);
    browser.addJavascriptInterface(new Locater(), "locater");
    browser.loadUrl("file:///android_asset/geoweb1.html");
  }

  @Override
  public void onResume() {
    super.onResume();
    myLocationManager.requestLocationUpdates(PROVIDER, 10000,
                                              100.0f,
                                              onLocation);
  }

  @Override
  public void onPause() {
    super.onPause();
    myLocationManager.removeUpdates(onLocation);
  }

  LocationListener onLocation=new LocationListener() {
    public void onLocationChanged(Location location) {
      // ignore...for now
    }

    public void onProviderDisabled(String provider) {
      // required for interface, not used
    }

    public void onProviderEnabled(String provider) {
      // required for interface, not used
    }

    public void onStatusChanged(String provider, int status,
                                  Bundle extras) {
      // required for interface, not used
    }
  };

  public class Locater {
    @JavascriptInterface
    public String getLocation() throws JSONException {
      Location loc=myLocationManager.getLastKnownLocation(PROVIDER);
      if (loc==null) {
        return(null);
      }

      JSONObject json=new JSONObject();

      json.put("lat", loc.getLatitude());
      json.put("lon", loc.getLongitude());

      return(json.toString());
    }
  }
}
```

This looks a bit like some of the WebView examples from earlier in this book. However, it adds three key bits of code:

- It sets up the LocationManager to provide updates when the device position changes, routing those updates to a do-nothing LocationListener callback object
- It has a Locater inner class that provides a convenient API for accessing the current location, in the form of latitude and longitude values encoded in JSON
- It uses addJavascriptInterface() to expose a Locater instance under the name locater to the Web content loaded in the WebView

The Locater API uses JSON to return both a latitude and a longitude at the same time. We are limited to using data types that are in common between JavaScript and Java, so we cannot pass back the Location object we get from the LocationManager. Hence, we convert the key Location data into a simple JSON structure that the JavaScript on the Web page can parse.

Note that the getLocation() method on Locater has the @JavascriptInterface annotation. This is required of apps with android:targetSdkVersion set to 17 or higher, though it is a good idea to start using it anyway. With such an android:targetSdkVersion, in an app running on an Android 4.2 or higher device, *only* public methods with the @JavascriptInterface annotation will be accessible by JavaScript code. On earlier devices, or with an earlier android:targetSdkVersion, *all* public methods on the Locater object would be accessible by JavaScript, including those inherited from superclasses like Object. Note that your build target (i.e., compileSdkVersion in Android Studio) will need to be Android 4.2 or higher in order to reference the @JavascriptInterface annotation.

Also note that onCreate() has the @SuppressLint("SetJavaScriptEnabled") annotation. This overrides a Lint warning about the use of setJavaScriptEnabled(true), where Lint wants to make sure that you understand the risks of allowing arbitrary JavaScript to execute inside your app. In this case, the JavaScript is code that we wrote, and so we can ensure that it is safe and sane.

Later in this chapter, we will cover security issues with WebView and put those annotations into context.

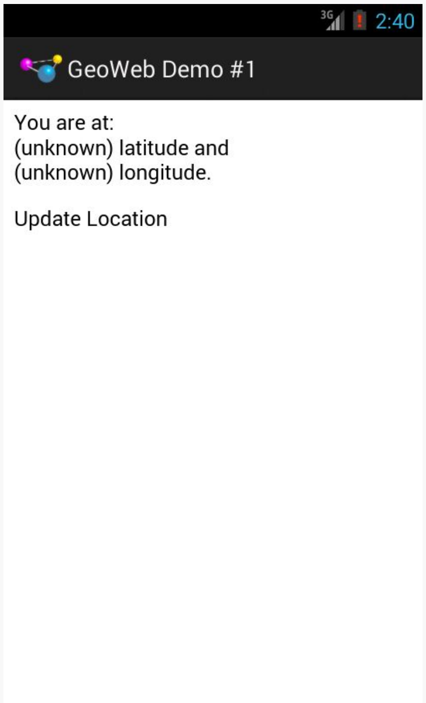
The Web page itself is referenced in the source code as file:///android_asset/geoweb1.html, so the GeoWeb1 project has a corresponding assets/ directory containing geoweb1.html:

```
<html>
<head>
<title>Android GeoWebOne Demo</title>
<script language="javascript">
  function whereami() {
    var location=JSON.parse(locater.getLocation());

    document.getElementById("lat").innerHTML=location.lat;
    document.getElementById("lon").innerHTML=location.lon;
  }
</script>
</head>
<body>
<p>
You are at: <br/> <span id="lat">(unknown)</span> latitude and <br/>
<span id="lon">(unknown)</span> longitude.
</p>
<p><a onClick="whereami()">Update Location</a></p>
</body>
</html>
```

When you click the “Update Location” link, the page calls a whereami() JavaScript function, which in turn uses the locater object to update the latitude and longitude, initially shown as “(unknown)” on the page.

If you run the application, initially, the page is pretty boring:

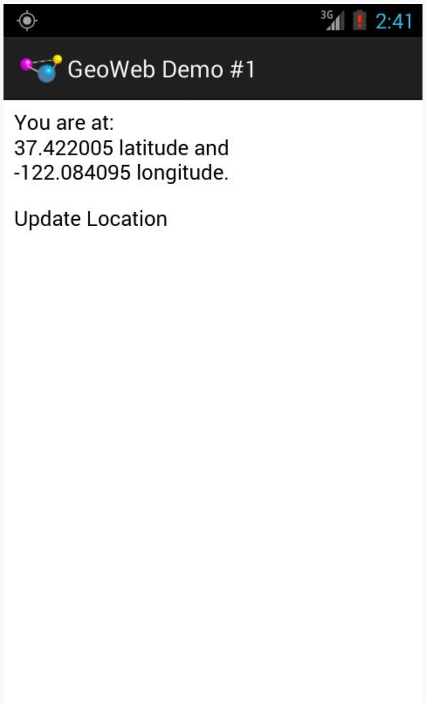


You are at:
(unknown) latitude and
(unknown) longitude.

Update Location

Figure 479: The GeoWebOne sample application, as initially launched

However, if you wait a bit for a GPS fix, and click the “Update Location” link… the page is still pretty boring, but it at least knows where you are:



You are at:
37.422005 latitude and
-122.084095 longitude.

Update Location

Figure 480: The GeoWebOne sample application, after clicking the Update Location link

Turnabout is Fair Play

Now that we have seen how JavaScript can call into Java, it would be nice if Java could somehow call out to JavaScript. In our example, it would be helpful if we could expose automatic location updates to the Web page, so it could proactively update the position as the user moves, rather than wait for a click on the "Update Location" link.

Well, as luck would have it, we can do that too. This is a good thing, otherwise, this would be a really weak section of the book.

What is unusual is how you call out to JavaScript. One might imagine there would be an `evaluateJavaScript()` counterpart to `addJavascriptInterface()`, where you could supply some JavaScript source and have it executed within the context of the currently-loaded Web page.

Actually, there *is* such a method on Android 4.4. However, earlier versions of Android lacked that method. Instead, on older versions of Android, given your snippet of JavaScript source to execute, you call `loadUrl()` on your `WebView`, as if you were going to load a Web page, but you put `javascript:` in front of your code and use that as the "address" to load.

If you have ever created a "bookmarklet" for a desktop Web browser, you will recognize this technique as being the Android analogue – the `javascript:` prefix tells the browser to treat the rest of the address as JavaScript source, injected into the currently-viewed Web page.

So, armed with this capability, let us modify the previous example to continuously update our position on the Web page.

The layout for the WebKit/GeoWeb2 sample project is the same as before. The Java source for our activity changes a bit:

```
package com.commonsware.android.geoweb2;

import android.annotation.SuppressLint;
import android.annotation.TargetApi;
import android.app.Activity;
import android.content.Context;
import android.location.Location;
import android.location.LocationListener;
import android.location.LocationManager;
import android.os.Build;
import android.os.Bundle;
import android.webkit.JavascriptInterface;
import android.webkit.WebView;
import org.json.JSONException;
import org.json.JSONObject;

public class GeoWebTwo extends Activity {
  private static String PROVIDER="gps";
  private WebView browser;
  private LocationManager myLocationManager=null;

  @SuppressLint("SetJavaScriptEnabled")
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);
    browser=(WebView)findViewById(R.id.webkit);

    myLocationManager=
        (LocationManager)getSystemService(Context.LOCATION_SERVICE);

    browser.getSettings().setJavaScriptEnabled(true);
    browser.addJavascriptInterface(new Locater(), "locater");
    browser.loadUrl("file:///android_asset/geoweb2.html");
  }

  @Override
  public void onResume() {
    super.onResume();
    myLocationManager.requestLocationUpdates(PROVIDER, 0, 0, onLocation);
  }

  @Override
  public void onPause() {
    super.onPause();
    myLocationManager.removeUpdates(onLocation);
  }

  LocationListener onLocation=new LocationListener() {
    @TargetApi(Build.VERSION_CODES.KITKAT)
    public void onLocationChanged(Location location) {
      StringBuilder buf=new StringBuilder("whereami(");

      buf.append(String.valueOf(location.getLatitude()));
      buf.append(",");
      buf.append(String.valueOf(location.getLongitude()));
      buf.append(")");

      if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        browser.evaluateJavascript(buf.toString(), null);
      }
      else {
        browser.loadUrl("javascript:" + buf.toString());
      }
    }

    public void onProviderDisabled(String provider) {
      // required for interface, not used
    }

    public void onProviderEnabled(String provider) {
      // required for interface, not used
    }

    public void onStatusChanged(String provider, int status,
                                  Bundle extras) {
      // required for interface, not used
    }
  };

  public class Locater {
    @JavascriptInterface
    public String getLocation() throws JSONException {
      Location loc=myLocationManager.getLastKnownLocation(PROVIDER);

      if (loc == null) {
        return(null);
      }

      JSONObject json=new JSONObject();

      json.put("lat", loc.getLatitude());
      json.put("lon", loc.getLongitude());

      return(json.toString());
    }
  }
}
```

Before, the `onLocationChanged()` method of our `LocationListener` callback did nothing. Now, it builds up a call to a `whereami()` JavaScript function, providing the latitude and longitude as parameters to that call. So, for example, if our location were 40 degrees latitude and –75 degrees longitude, the call would be `whereami(40,-75)`.

What happens then depends upon the version of Android the device is running.

- For devices running Android 4.4+, it calls `evaluateJavascript()`. This takes the JavaScript source code, plus an optional callback, and executes it in the context of the currently-loaded Web page.
- For devices running older versions of Android, it puts `javascript:` in front of the Javascript source and calls `loadUrl()` on the `WebView`. This is the same syntax used for "bookmarklets" in desktop Web browsers.

The result is that a `whereami()` function in the Web page gets called with the new location.

That Web page, of course, also needed a slight revision, to accommodate the option of having the position be passed in:

```
<html>
<head>
<title>Android GeoWebTwo Demo</title>
<script language="javascript">
  function whereami(lat, lon) {
    document.getElementById("lat").innerHTML=lat;
    document.getElementById("lon").innerHTML=lon;
  }

  function pull() {
    var location=JSON.parse(locater.getLocation());

    whereami(location.lat, location.lon);
  }
</script>
</head>
<body>
<p>
You are at: <br/> <span id="lat">(unknown)</span> latitude and <br/>
<span id="lon">(unknown)</span> longitude.
</p>
<p><a onClick="pull()">Update Location</a></p>
</body>
</html>
```

The basics are the same, and we can even keep our "Update Location" link, albeit with a slightly different onClick attribute.

If you build, install, and run this revised sample on a GPS-equipped Android device, the page will initially display with "(unknown)" for the current position. After a fix is ready, though, the page will automatically update to reflect your actual position. And, as before, you can always click "Update Location" if you wish.

Navigating the Waters

There is no navigation toolbar with the WebView widget. This allows you to use it in places where such a toolbar would be pointless and a waste of screen real estate. That being said, if you want to offer navigational capabilities, you can, but you have to supply the UI. WebView offers ways to perform garden-variety browser navigation, including:

- reload() to refresh the currently-viewed Web page
- goBack() to go back one step in the browser history, and canGoBack() to determine if there is any history to go back to
- goForward() to go forward one step in the browser history, and canGoForward() to determine if there is any history to go forward to
- goBackOrForward() to go backwards or forwards in the browser history, where negative numbers represent a count of steps to go backwards, and positive numbers represent how many steps to go forwards
- canGoBackOrForward() to see if the browser can go backwards or forwards the stated number of steps (following the same positive/negative convention as goBackOrForward())
- clearCache() to clear the browser resource cache and clearHistory() to clear the browsing history

Settings, Preferences, and Options (Oh, My!)

With your favorite desktop Web browser, you have some sort of "settings" or "preferences" or "options" window. Between that and the toolbar controls, you can tweak and twiddle the behavior of your browser, from preferred fonts to the behavior of JavaScript.

Similarly, you can adjust the settings of your WebView widget as you see fit, via the WebSettings instance returned from calling the widget's getSettings() method.

There are lots of options on `WebSettings` to play with. Most appear fairly esoteric (e.g., `setFantasyFontFamily()`). However, here are some that you may find more useful:

- Control the font sizing via `setDefaultFontSize()` (to use a point size) or `setTextSize()` (to use constants indicating relative sizes like LARGER and SMALLEST)
- Control Web site rendering via `setUserAgent()`, so you can supply your own user agent string to make the Web server think you are a desktop browser, another mobile device (e.g., iPhone), or whatever. The settings you change are not persistent, so you should store them somewhere (such as via the Android preferences engine) if you are allowing your users to determine the settings, versus hard-wiring the settings in your application.

Security and Your WebView

More so than normal widgets, `WebView` opens up potential security issues, just as a Web browser could. If all you are doing is displaying your own content, the risks are minimal. If, on the other hand, you are displaying content from third parties, it is possible that their content is malicious in a way that can compromise your app's security, to your users' detriment.

Rogue JavaScript Risks

If you call `setJavaScriptEnabled(true)` on your `WebSettings`, you are allowing JavaScript code to be loaded and executed by `WebView`. In many cases, this is essential to get your content to render properly (e.g., the JavaScript is issuing AJAX calls). However, if you did not write the scripts, you do not know what they might be doing. If there are flaws in `WebView` — such as those discussed in the next sections — then your users may be at risk.

Even in the absence of such bugs, JavaScript can always:

- Consume so much CPU that it represents an attempt at a denial-of-service attack on the user's device
- Access anything the user enters into the Web page
- Access anything *you* enter into the Web page, using approaches as `javascript:` URLs or `evaluateJavaScript()`

The addJavascriptInterface() Bugs

Another way that rogue JavaScript can attack users is if you use `addJavascriptInterface()` to allow JavaScript code to call out to a Java object that you supply.

As was noted earlier in this chapter, when `addJavascriptInterface()` was introduced, there is this `@JavascriptInterface` annotation that we should apply to the methods we want JavaScript to be able to call on the object we supply via `addJavascriptInterface()`. This is because of a bug in the `addJavascriptInterface()` implementation, whereby on 4.1 and below *any* method on the Java object could be called by JavaScript. This includes methods like `getClass()`… which in turn would allow JavaScript to use `Class.forName()` to get at arbitrary stuff. This was used by various bits of malware.

Hence, using `addJavascriptInterface()` on Android 4.1 and below is rather risky, if you are loading arbitrary third-party JavaScript. If you have the means of examining that JavaScript (e.g., you are loading the scripts yourself), you might perform some simple scans of it to see if they appear to be doing anything unfortunate with your Java object that you injected into JavaScript via `addJavascriptInterface()`.

Worse, Android sometimes also injects its *own* objects, without our requesting them.

In particular, this security bug points out that, through Android 4.3, if users have enabled an accessibility service, Android automatically injects objects into `WebView`, using `addJavascriptInterface()`, named `accessibility` and `accessibilityTraversal`. So, even if you do not inject any objects yourself via `addJavascriptInterface()`, your `WebView` may be at risk. The security researchers who uncovered this attack vector suggest using `removeJavascriptInterface()` to specifically get rid of those objects.

The Same-Origin Policy Bug

Due to a bizarre bug in the parsing of URLs, it is possible for JavaScript code to violate the “same-origin policy” of a `WebView` on Android 4.3 and earlier.

Quoting Wikipedia from September 2014:

> the same-origin policy is an important concept in the web application security model. The policy permits scripts running on pages originating

> from the same site — a combination of scheme, hostname, and port number — to access each other's DOM with no specific restrictions, but prevents access to DOM on different sites… This mechanism bears a particular significance for modern web applications that extensively depend on HTTP cookies to maintain authenticated user sessions, as servers act based on the HTTP cookie information to reveal sensitive information or take state-changing actions. A strict separation between content provided by unrelated sites must be maintained on the client side to prevent the loss of data confidentiality or integrity.

All modern Web browsers implement the same-origin policy (SOP)… but there can be bugs. A security researcher disclosed that the original AOSP Browser application failed to implement the SOP properly, when a `javascript:` URL has a null byte before the `j` in `javascript`. And while the report was focused on the AOSP Browser app, the problem really lies with `WebView`.

To see this in action, load `https://commonsware.com/misc/sop-demo.html` in the AOSP Browser app on Android 4.3 or lower. This Web page consists of:

```
<html>
<head>
<title>WebView SOP Test</title>
</head>
<body>
<h1>WebView SOP Test</h1>
<iframe name="test" src="http://developer.android.com"></iframe>
<input type=button value="test"
onclick="window.open('\u0000javascript:alert(document.domain)','test')">
</body>
</html>
```

It is derived from a similar example found in the blog post outlining the security flaw.

In an SOP-compliant browser, clicking the button will have no effect. In the AOSP Browser app, clicking the button shows the domain name of the document in the `iframe`. And, loading this HTML into a `WebView` has the same effect.

Part of the `WebView` overhaul in Android 4.4 — replacing the original implementation with a new one backed by Chromium — had the effect of fixing this bug, whether intentionally or inadvertently.

There is no obvious mitigation approach for this bug, insofar as for the attack shown above, none of the callbacks on `WebViewClient` or `WebChromeClient` seem to allow us to intercept this URL before its JavaScript is executed. If you are loading HTML yourself from a third party, you might consider scanning that HTML for obvious signs of the attack (e.g., regular expression check for `\u0000javascript`), but that will be limited at best. Beyond that, try to limit the content in a `WebView` to be from only one origin, so that there is nothing for attackers to obtain via this bug.

Also note that the security researcher who found this bug has also found another SOP violation, suggesting that mitigation strategies may be impractical.

The Input Method Framework

We think of Android devices as having “soft keyboards”. The official term for this is that Android devices offer one or more “input method editors” (or “input methods” for short). These input methods allow for text entry on a touchscreen, avoiding the need for a physical keyboard. Note, though, that “text entry” does not necessarily imply an on-screen keyboard equivalent — for example, the old PalmOS Graffiti text entry system is available as an app on the Play Store.

While it is possible to create custom input method editors — as the authors of Graffiti Pro did — this chapter is focused more on how ordinary app developers are affected by input methods, and how an app can help steer the behavior of the input method to benefit the user.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the section covering the `EditText` widget.

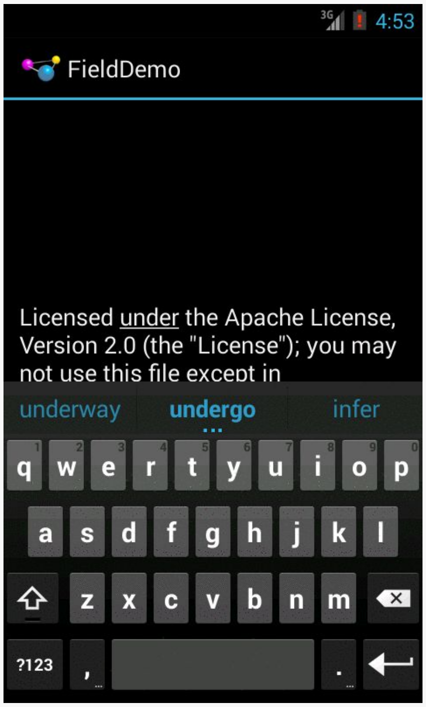
Keyboards, Hard and Soft

Some Android devices have a hardware keyboard that is visible some of the time (when it is slid out). A few Android devices have a hardware keyboard that is always visible (so-called “bar” or “slab” phones). Most Android devices, though, have no hardware keyboard at all.

The IMF handles all of these scenarios. In short, if there is no hardware keyboard, an input method editor (IME) will be available to the user when they tap on an enabled `EditText`.

This requires no code changes to your application… if the default functionality of the IME is what you want. Fortunately, Android is fairly smart about guessing what you want, so it may be you can just test with the IME but otherwise make no specific code changes.

Of course, the keyboard may not quite behave how you would like. For example, in the `Basic/Field` sample project, the `FieldDemo` activity has the IME overlaying the multiple-line `EditText`:



Licensed under the Apache License, Version 2.0 (the "License"); you may not use this file except in

Figure 481: The input method editor, as seen in the FieldDemo sample application

It would be nice to have more control over how this appears, and for other behavior of the IME. Fortunately, the framework as a whole gives you many options for this, as is described over the bulk of this chapter.

Tailored To Your Needs

Android 1.1 and earlier offered many attributes on `EditText` widgets to control their style of input, such as `android:password` to indicate a field should be for password entry (shrouding the password keystrokes from prying eyes). Starting in Android 1.5, with the IMF, many of these have been combined into a single `android:inputType` attribute.

The `android:inputType` attribute takes a class plus modifiers, in a pipe-delimited list (where `|` is the pipe character). The class generally describes what the user is allowed to input, and this determines the basic set of keys available on the soft keyboard. The available classes are:

1. `text` (the default)
2. `number`
3. `phone`
4. `datetime`
5. `date`
6. `time`

Many of these classes offer one or more modifiers, to further refine what the user will be entering. To help explain those, take a look at the `res/layout/main.xml` file from the `InputMethod/IMEDemo1` project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:stretchColumns="1"
  >
  <TableRow>
    <TextView
      android:text="No special rules:"
    />
    <EditText
    />
  </TableRow>
  <TableRow>
    <TextView
      android:text="Email address:"
    />
    <EditText
      android:inputType="text|textEmailAddress"
    />
  </TableRow>
  <TableRow>
    <TextView
      android:text="Signed decimal number:"
    />
    <EditText
      android:inputType="number|numberSigned|numberDecimal"
    />
  </TableRow>
  <TableRow>
    <TextView
      android:text="Date:"
    />
    <EditText
      android:inputType="date"
    />
  </TableRow>
  <TableRow>
    <TextView
      android:text="Multi-line text:"
    />
    <EditText
      android:inputType="text|textMultiLine|textAutoCorrect"
      android:minLines="3"
      android:gravity="top"
    />
  </TableRow>
</TableLayout>
```

Here, you will see a `TableLayout` containing five rows, each demonstrating a slightly different flavor of `EditText`:

- One has no attributes at all on the `EditText`, meaning you get a plain text entry field
- One has `android:inputType = "text|textEmailAddress"`, meaning it is text entry, but specifically seeks an email address
- One allows for signed decimal numeric input, via `android:inputType = "number|numberSigned|numberDecimal"`
- One is set up to allow for data entry of a date (`android:inputType = "date"`)
- The last allows for multi-line input with auto-correction of probable spelling errors (`android:inputType = "text|textMultiLine|textAutoCorrect"`)

The class and modifiers tailor the keyboard. So, a plain text entry field results in a plain soft keyboard:

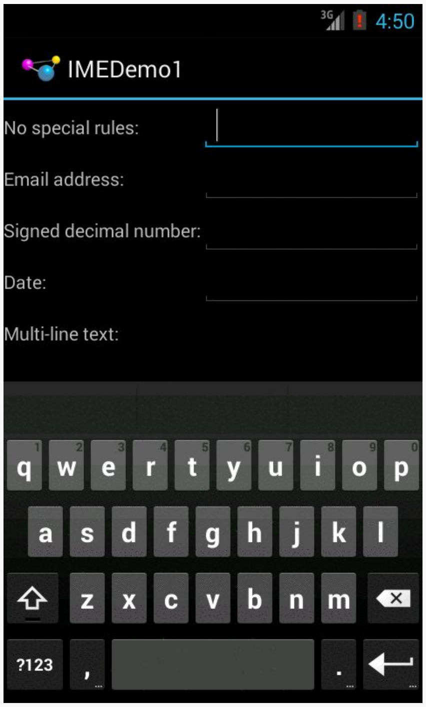


Figure 482: A standard input method editor (a.k.a., soft keyboard)

An email address field might put the `@` symbol on the soft keyboard, perhaps at the cost of a smaller spacebar, depending on the keyboard implementation:

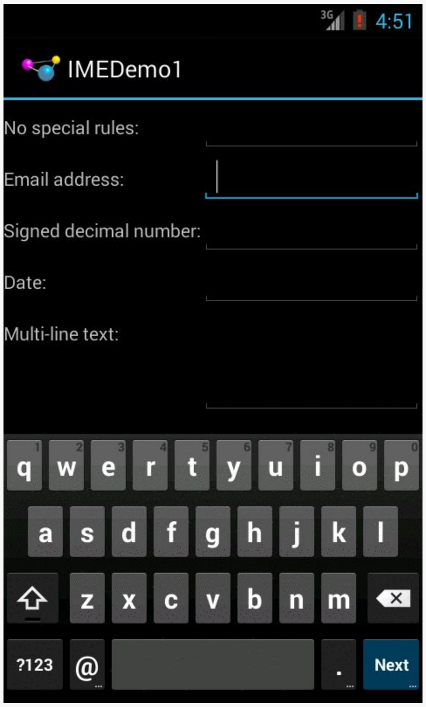

Figure 483: The input method editor for email addresses

Note, though, that this behavior is specific to the input method editor. Some editors might put an @ sign on the primary keyboard for an email field. Some might put a ".com" button on the primary keyboard. Some might not react at all. It is up to the implementation of the input method editor — all you can do is supply the hint.

Numbers and dates restrict the keys to numeric keys, plus a set of symbols that may or may not be valid on a given field:

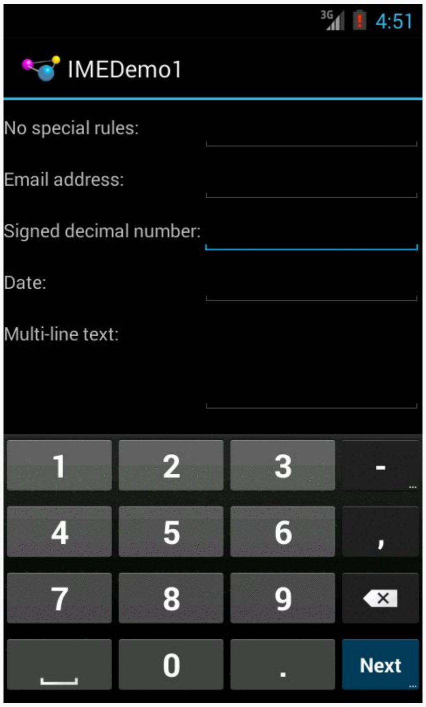

Figure 484: The input method editor for signed decimal numbers

And so on.

By choosing the appropriate `android:inputType`, you can give the user a soft keyboard that best suits what it is they should be entering.

Tell Android Where It Can Go

You may have noticed a subtle difference between the first and second input method editors, beyond the addition of the `@` key. If you look in the lower-right corner of the soft keyboard, the second field's editor has a "Next" button, while the first field's editor has a newline button.

This points out two things:

- `EditText` widgets are multi-line by default if you do not specify `android:inputType`
- You can control what goes on with that lower-right-hand button, called the action key

By default, on an `EditText` where you have specified `android:inputType`, the action key will be "Next", moving you to the next `EditText` in sequence, or "Done", if you are on the last `EditText` on the screen. You can manually stipulate what the action key will be labeled via the `android:imeOptions` attribute. For example, in the `res/layout/main.xml` from the InputMethod/IMEDemo2 sample project, you will see an augmented version of the previous example, where two input fields specify what their action key should look like:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
>
  <TableLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
    >
    <TableRow>
      <TextView
        android:text="No special rules:"
      />
      <EditText
      />
    </TableRow>
    <TableRow>
      <TextView
        android:text="Email address:"
      />
      <EditText
        android:inputType="text|textEmailAddress"
        android:imeOptions="actionSend"
      />
    </TableRow>
    <TableRow>
      <TextView
        android:text="Signed decimal number:"
      />
      <EditText
        android:inputType="number|numberSigned|numberDecimal"
        android:imeOptions="actionDone"
      />
    </TableRow>
    <TableRow>
      <TextView
        android:text="Date:"
      />
      <EditText
        android:inputType="date"
      />
    </TableRow>
    <TableRow>
      <TextView
        android:text="Multi-line text:"
      />
      <EditText
        android:inputType="text|textMultiLine|textAutoCorrect"
        android:minLines="3"
        android:gravity="top"
      />
    </TableRow>
  </TableLayout>
</ScrollView>
```

Here, we attach a “Send” action to the action key for the email address (`android:imeOptions = "actionSend"`), and the “Done” action on the middle field (`android:imeOptions = "actionDone"`).

By default, “Next” will move the focus to the next `EditText` and “Done” will close up the input method editor. However, for those, or for any other ones like “Send”, you can use `setOnEditorActionListener()` on `EditText` (technically, on the `TextView` superclass) to get control when the action key is clicked or the user presses the `<Enter>` key. You are provided with a flag indicating the desired action (e.g., `IME_ACTION_SEND`), and you can then do something to handle that request (e.g., send an email to the supplied email address).

If you need more control over the action button, you can set:

- `android:imeActionId`, which provides a custom value for the `actionId` that is passed to `onEditorAction()` of your `OnEditorActionListener`
- `android:imeActionLabel`, where you provide your own caption for the button (bearing in mind that your desired caption may or may not fit)

Fitting In

You will notice that the `IMEDemo2` layout shown above has another difference from its `IMEDemo1` predecessor: the use of a `ScrollView` container wrapping the `TableLayout`. This ties into another level of control you have over the input method editors: what happens to your activity’s own layout when the input method editor appears?

There are three possibilities, depending on circumstances:

1. Android can “pan” your activity, effectively sliding the whole layout up to accommodate the input method editor, or overlaying your layout, depending on whether the `EditText` being edited is at the top or bottom. This has the effect of hiding some portion of your UI.
2. Android can resize your activity, effectively causing it to shrink to a smaller screen dimension, allowing the input method editor to sit below the activity

itself. This is great when the layout can readily be shrunk (e.g., it is dominated by a list or multi-line input field that does not need the whole screen to be functional).

3. In landscape mode, Android may display the input method editor full-screen, obscuring your entire activity. This allows for a bigger keyboard and generally easier data entry.

Android controls the full-screen option purely on its own. And, by default, Android will choose between pan and resize modes depending on what your layout looks like. If you want to specifically choose between pan and resize, you can do so via an `android:windowSoftInputMode` attribute on the `<activity>` element in your `AndroidManifest.xml` file. For example, here is the manifest from `IMEDemo2`:

```xml
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.imf.two"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".IMEDemo2"
      android:label="@string/app_name"
      android:windowSoftInputMode="adjustResize">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Because we specified resize, Android will shrink our layout to accommodate the input method editor. With the `ScrollView` in place, this means the scrollbar will appear as needed when the user is scrolling:

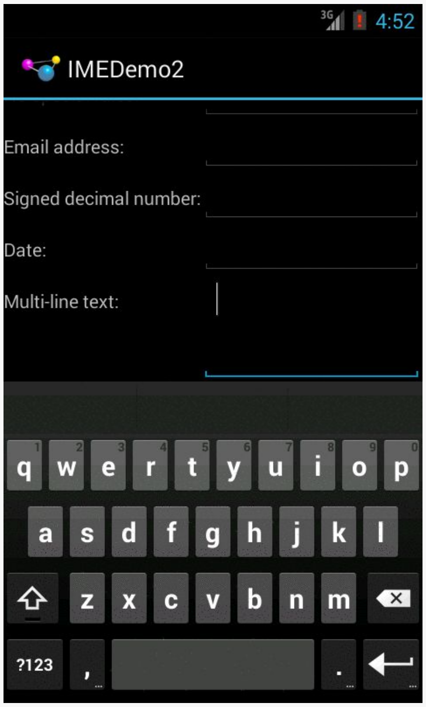

Figure 485: The shrunken, scrollable layout

Jane, Stop This Crazy Thing!

Sometimes, you need the input method editor to just go away. For example, if you make the action button be "Search", the user tapping that button will not automatically hide the editor.

To hide the editor, you will need to make a call to the `InputMethodManager`, a system service that controls these input method editors:

```
InputMethodManager
mgr=(InputMethodManager)getSystemService(INPUT_METHOD_SERVICE);

mgr.hideSoftInputFromWindow(fld.getWindowToken(), 0);
```

(where `fld` is the `EditText` whose input method editor you want to hide)

Fonts

Inevitably, you'll get the question "hey, can we change this font?" when doing application development. The answer depends on what fonts come with the platform, whether you can add other fonts, and how to apply them to the widget or whatever needs the font change.

Android is no different. It comes with some fonts plus a means for adding new fonts. Though, as with any new environment, there are a few idiosyncrasies to deal with.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on files.

Love The One You're With

Android natively knows three fonts, by the shorthand names of "sans", "serif", and "monospace". For Android 1.x, 2.x, and 3.x, these fonts are actually the Droid series of fonts, created for the Open Handset Alliance by Ascender. A new font set, Roboto, is used in Android 4.x and beyond, though the look of the font changed somewhat in Android 5.0.

For those fonts, you can just reference them in your layout XML, if you choose, such as the following layout from the `Fonts/FontSampler` sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
```

```
android:stretchColumns="1">
<TableRow>
  <TextView
    android:text="sans:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/sans"
    android:text="Hello, world!"
    android:typeface="sans"
    android:textSize="20sp"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="serif:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/serif"
    android:text="Hello, world!"
    android:typeface="serif"
    android:textSize="20sp"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="monospace:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/monospace"
    android:text="Hello, world!"
    android:typeface="monospace"
    android:textSize="20sp"
  />
</TableRow>
<TableRow>
  <TextView
    android:text="Custom:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
    android:id="@+id/custom"
    android:text="Hello, world!"
    android:textSize="20sp"
  />
</TableRow>
<TableRow android:id="@+id/filerow">
  <TextView
    android:text="Custom from File:"
    android:layout_marginRight="4dip"
    android:textSize="20sp"
  />
  <TextView
```

```
      android:id="@+id/file"
      android:text="Hello, world!"
      android:textSize="20sp"
    />
  </TableRow>
</TableLayout>
```

This layout builds a table showing short samples of five fonts. Notice how the first three have the `android:typeface` attribute, whose value is one of the three built-in font faces (e.g., “sans”).

The three built-in fonts are very nice. However, it may be that a designer, or a manager, or a customer wants a different font than one of those three. Or perhaps you want to use a font for specialized purposes, such as a “dingbats” font instead of a series of PNG graphics.

The easiest way to accomplish this is to package the desired font(s) with your application. To do this, simply create an `assets/` folder in the project root, and put your TrueType (TTF) fonts in the assets. You might, for example, create `assets/fonts/` and put your TTF files in there. Note that Android has some support for OpenType (OTF) fonts, as well.

Then, you need to tell your widgets to use that font. Unfortunately, you can no longer use layout XML for this, since the XML does not know about any fonts you may have tucked away as an application asset. Instead, you need to make the change in Java code:

```
package com.commonsware.android.fonts;

import android.app.Activity;
import android.graphics.Typeface;
import android.os.Bundle;
import android.os.Environment;
import android.view.View;
import android.widget.TextView;
import java.io.File;

public class FontSampler extends Activity {
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);

    TextView tv=(TextView)findViewById(R.id.custom);
    Typeface face=Typeface.createFromAsset(getAssets(),
                                          "fonts/HandmadeTypewriter.ttf");

    tv.setTypeface(face);

    File font=new File(Environment.getExternalStorageDirectory(),
                       "MgOpenCosmeticaBold.ttf");

    if (font.exists()) {
      tv=(TextView)findViewById(R.id.file);
      face=Typeface.createFromFile(font);

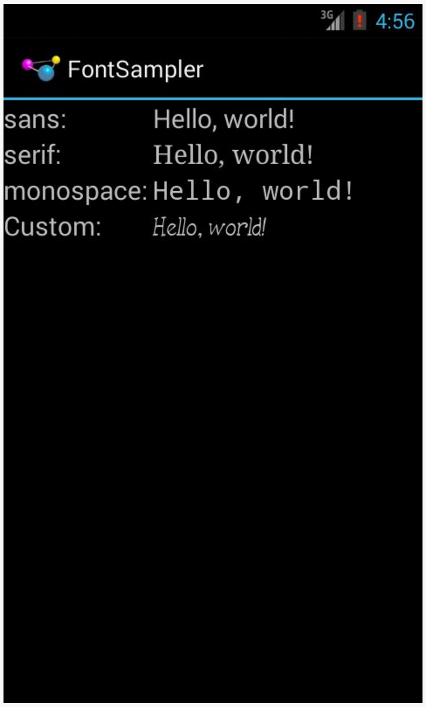
      tv.setTypeface(face);
    }
    else {
      findViewById(R.id.filerow).setVisibility(View.GONE);
    }
  }
}
```

Here we grab the TextView for our "custom" sample, then create a Typeface object via the static createFromAsset() builder method. This takes the application's AssetManager (from getAssets()) and a path within your assets/ directory to the font you want.

Then, it is just a matter of telling the TextView to setTypeface(), providing the Typeface you just created. In this case, we are using the Handmade Typewriter font.

You can also load a font out of a local file and use it. The benefit is that you can customize your fonts after your application has been distributed. On the other hand, you have to somehow arrange to get the font onto the device. But just as you can get a Typeface via createFromAsset(), you can get a Typeface via createFromFile(). In our FontSampler, we look in the root of "external storage" (typically the SD card) for the MgOpenCosmeticaBold TrueType font file, and if it is found, we use it for the fifth row of the table. Otherwise, we hide that row.

The results?



```
sans:       Hello, world!
serif:      Hello, world!
monospace:  Hello, world!
Custom:     Hello, world!
```

Figure 486: The FontSampler application

Note that Android does not seem to like all TrueType fonts. When Android dislikes a custom font, rather than raise an `Exception`, it seems to substitute Droid Sans ("sans") quietly. So, if you try to use a different font and it does not seem to be working, it may be that the font in question is incompatible with Android, for whatever reason.

Yeah, But Do We Really Have To Do This in Java?

One common complaint with font handling in Android is that you have to apply a custom font on a per-widget basis in Java code.

This gets old quickly.

It is not too bad with just a single `TextView`. But for a whole activity, or a whole application, changing all of the relevant `TextView` widgets (and descendents, like `Button`) gets to be a bit tedious.

While there are "traverse the widget hierarchy and fix up the fonts" code snippets available, you are probably better served using a third-party library, like Christoper

Jenkins' Calligraphy, which lets you define custom fonts in layout XML files or style resources.

Here a Glyph, There a Glyph

TrueType fonts can be rather pudgy, particularly if they support an extensive subset of the available Unicode characters. The Handmade Typewriter font used above runs over 70KB; the DejaVu free fonts can run upwards of 500KB apiece. Even compressed, these add bulk to your application, so be careful not to go overboard with custom fonts, lest your application take up too much room on your users' phones.

Conversely, bear in mind that fonts may not have all of the glyphs that you need. As an example, let us talk about the ellipsis.

Android's `TextView` class has the built-in ability to "ellipsize" text, truncating it and adding an ellipsis if the text is longer than the available space. You can use this via the `android:ellipsize` attribute, for example. This works fairly well, at least for single-line text.

The ellipsis that Android uses is not three periods. Rather it uses an actual ellipsis character, where the three dots are contained in a single glyph. Hence, any font that you use in a `TextView` where you also use the "ellipsizing" feature will need the ellipsis glyph.

Beyond that, though, Android pads out the string that gets rendered on-screen, such that the length (in characters) is the same before and after "ellipsizing". To make this work, Android replaces one character with the ellipsis, and replaces all other removed characters with the Unicode character 'ZERO WIDTH NO-BREAK SPACE' (`U+FEFF`). This means the "extra" characters after the ellipsis do not take up any visible space on screen, yet they can be part of the string.

However, this means any custom fonts you use for `TextView` widgets that you use with `android:ellipsize` must also support this special Unicode character. Not all fonts do, and you will get artifacts in the on-screen representation of your shortened strings if your font lacks this character (e.g., rogue X's appear at the end of the line).

And, of course, Android's international deployment means your font must handle any language your users might be looking to enter, perhaps through a language-specific input method editor.

Hence, while using custom fonts in Android is very possible, there are many potential problems, and so you must weigh carefully the benefits of the custom fonts versus their potential costs.

Rich Text

Plain text is so, well, plain.

Fortunately, Android has fairly extensive support for formatted text, before you need to break out something as heavy-weight as WebView. However, some of this rich text support has been shrouded in mystery, particularly how you would allow users to edit formatted text.

This chapter will explain how the rich text support in Android works and how you can take advantage of it, with particular emphasis on some open source projects to help you do just that.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on basic widgets and the input method framework.

The Span Concept

You may have noticed that many methods in Android accept or return a CharSequence. The CharSequence interface is little used in traditional Java, if for no other reason than there are relatively few implementations of it outside of String. However, in Android, CharSequence becomes much more important, because of a sub-interface named Spanned.

Spanned defines sequences of characters (CharSequence) that contain *inline markup rules*. These rules — mostly instances of CharacterStyle and ParagraphStyle subclasses – indicate whether the “spanned” portion of the characters should be rendered in an alternate font, or be turned into a hyperlink, or have other effects applied to them.

Methods that take a `CharSequence` as a parameter, therefore, can work equally well with `String` objects as well as objects that implement `Spanned`.

Implementations

The base interface for rich-text `CharSequence` objects is `Spanned`. This is used for any `CharSequence` that has inline markup rules, and it defines methods for retrieving markup rules applied to portions of the underlying text.

The primary concrete implementation of `Spanned` is `SpannedString`. `SpannedString`, like `String`, is immutable — you cannot change either the text or the formatting of a `SpannedString`.

There is also the `Spannable` sub-interface of `Spanned`. `Spannable` is used for any `CharSequence` with inline markup rules that can be modified, and it defines the methods for modifying the formatting. There is a corresponding `SpannableString` implementation.

Finally, there is a related `Editable` interface, which is for a `CharSequence` that can have its *text* modified in-place. `SpannableStringBuilder` implements both `Editable` and `Spannable`, for modifying text and formatting at the same time.

TextView and Spanned

One of the most important uses of `Spanned` objects is with `TextView`. `TextView` is capable of rendering a `Spanned`, complete with all of the specified formatting. So, if you have a `Spanned` that indicates that the third word should be rendered in italics, `TextView` will faithfully italicize that word.

`TextView`, of course, is an ancestor of many other widgets, from `EditText` to `Button` to `CheckBox`. Each of those, therefore, can use and render `Spannable` objects. The fact that `EditText` has the ability to render `Spanned` objects — and even allow them to be edited — is key for allowing users to enter rich text themselves as part of your UI.

Available Spans

As noted above, the markup rules come in the form of instances of base classes known as CharacterStyle and ParagraphStyle. Despite those names, most of the SDK-supplied subclasses of CharacterStyle and ParagraphStyle end in Span (not Style), and so you will likely see references to these as "spans" as often as "styles". That also helps minimize confusion between character styles and style resources.

There are well over a dozen supplied CharacterStyle subclasses, including:

1. ForegroundColorSpan and BackgroundColorSpan for coloring text
2. StyleSpan, TextAppearanceSpan, TypefaceSpan, UnderlineSpan, and StrikethroughSpan for affecting the true "style" of text
3. AbsoluteSizeSpan, RelativeSizeSpan, SuperscriptSpan, and SubscriptSpan for affecting the size (and, in some cases, vertical position) of the text

And so on. Similarly, ParagraphStyle has subclasses like BulletSpan for bulleted lists.

You can implement your own custom subclasses of CharacterStyle and ParagraphStyle, though the book does not cover this subject at this time.

Loading Rich Text

Spanned objects do not appear by magic. Plenty of things in Java will give you ordinary strings, from XML and JSON parsers to loading data out of a database to simply hard-coding string constants. However, there are only a few ways that you as a developer will get a Spanned complete with formatting, and that includes you creating such a Spanned yourself by hand.

String Resource

The primary way most developers get a Spanned object into their application is via a string resource. String resources support inline markup in the form of HTML tags. Bold (<b>), italics (<i>), and underline (<u>) are officially supported, such as:

```
<string name="welcome">Welcome to <b>Android</b>!</string>
```

When you retrieve the string resource via `getText()`, you get back a `CharSequence` that represents a `Spanned` object with the markup rules in place.

HTML

The next-most common way to get a `Spanned` object is to use `Html.fromHtml()`. This parses an HTML string and returns a `Spanned` object, with all recognized tags converted into corresponding spans. You might use this for text loaded from a database, retrieved from a Web service call, extracted from an RSS feed, etc.

Unfortunately, the list of tags that `fromHtml()` understands is undocumented. Based upon the source code to `fromHtml()`, the following seem safe:

- `<a href="...">`
- `<b>`
- `<big>`
- `<blockquote>`
- `<br>`
- `<cite>`
- `<dfn>`
- `<div align="...">`
- `<em>`
- `<font size="..." color="..." face="...">`
- `<h1>`
- `<h2>`
- `<h3>`
- `<h4>`
- `<h5>`
- `<h6>`
- `<i>`
- `<img src="...">`
- `<p>`
- `<small>`
- `<strong>`
- `<sub>`
- `<sup>`
- `<tt>`
- `<u>`

However, do bear in mind that these are undocumented and therefore are subject to change. Also note that `fromHtml()` is perhaps slower than you might think, particularly for longer strings.

You might also wind up using some other support code to get your HTML. For example, some data sources might publish text formatted as Markdown — Stack Overflow, GitHub, etc. use this extensively. Markdown can be converted to HTML, through any number of available Java libraries or via CWAC-AndDown, which wraps the native hoedown Markdown-to-HTML converter for maximum speed. CWAC-AndDown will be explored in a bit more detail in the chapter on the NDK.

From EditText

The reason why so much sample code calls `getText()` followed by `toString()` on an `EditText` widget is because `EditText` is going to return an `Editable` object from `getText()`, not a simple string. That's because, in theory, `EditText` could be returning something with formatting applied. The call to `toString()` simply strips out any potential formatting as part of giving you back a `String`.

However, you could elect to use the `Editable` object (presumably a `SpannableStringBuilder`) if you wanted, such as for pouring the entered text into a `TextView`, complete with any formatting that might have wound up on the entered text.

Actually getting formatting applied to the contents of an `EditText` is covered later in this chapter.

Manually

You are welcome to create a `SpannableString` via its constructor, supplying the text that you wish to display, then calling various methods on `SpannableString` to format it. We will see an example of this later in this chapter.

Or, you are welcome to create a `SpannableStringBuilder` via its constructor. In some respects, `SpannableStringBuilder` works like the classic `StringBuilder` — you call `append()` to add more text. However, `SpannableStringBuilder` also offers `delete()`, `insert()`, and `replace()` methods to modify portions of the existing content. It also supports the same methods that `SpannableString` does, via the `Spannable` interface, for applying formatting rules to portions of text.

Editing Rich Text

If the `Spannable` you wound up with is a `SpannedString`, it is what it is — you cannot change it. If, however, you have a `SpannableString`, that can be modified by you, or by the user. Of course, allowing the user to modify a `Spannable` gets a wee bit tricky, and is why the `RichEditText` project was born.

RichEditText

If you load a `Spannable` into an `EditText`, the formatting will not only be displayed, but it will be part of the editing experience. For example, if the phrase "**the fox jumped**" is in bold, and the user adds in more words to make it "**the quick brown fox jumped**", the additional words will also be in boldface. That is because the user is modifying text in the middle of a defined span, and so therefore the adjusted text is rendered according to that span.

The biggest problem is that `EditText` alone has no mechanism to allow users to *change* formatting. Perhaps someday it will have options for that. In the meantime, though, `RichEditText` is designed to fill that gap.

`RichEditText` is a CWAC project that offers a reasonably convenient API for applying, toggling, or removing effects applied to the current selected text. You have your choice of creating your own UI for this (e.g., implementing a toolbar) or enabling an extension to the `EditText` action modes to allow the users to format the text.

More information on using `RichEditText` can be found on the project site, and a future version of this chapter will go into details not only of its use, but also its construction, once the project has matured a little more.

Manually

`Spannable` offers two methods for modifying its formatting: `setSpan()` to apply formatting, and `removeSpan()` to get rid of an existing span. And, since `Spannable` extends `Spanned`, a `Spannable` also has `getSpans()`, to return existing spans of a current type within a certain range of characters in the text. These methods, along with others on `Spanned`, allow you to get and set whatever formatting you wish to apply on a `Spannable` object, such as a `SpannableString`.

For example, let's take a look at the RichText/Search sample project. Here, we are going to load some text into a TextView, then allow the user to enter a search string in an EditText, and we will use the Spannable methods to highlight the search string occurrences inside the text in the TextView.

Our layout is simply an EditText atop a TextView (wrapped in a ScrollView):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <EditText
    android:id="@+id/search"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:singleLine="true">

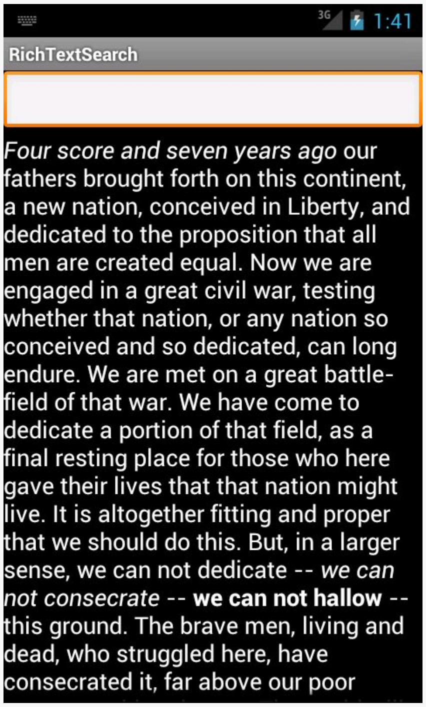
    <requestFocus/>
  </EditText>

  <ScrollView
    android:id="@+id/scroll"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
      android:id="@+id/prose"
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
      android:text="@string/address"
      android:textAppearance="?android:attr/textAppearanceMedium"/>
  </ScrollView>

</LinearLayout>
```

We pre-fill the TextView with a string resource (@string/address), which in this project is the text of Lincoln's Gettysburg Address, with a bit of inline markup (e.g., "Four score and seven years ago" italicized). So, when we fire up the project at the outset, we see the formatted prose from the string resource:



Four score and seven years ago our fathers brought forth on this continent, a new nation, conceived in Liberty, and dedicated to the proposition that all men are created equal. Now we are engaged in a great civil war, testing whether that nation, or any nation so conceived and so dedicated, can long endure. We are met on a great battle-field of that war. We have come to dedicate a portion of that field, as a final resting place for those who here gave their lives that that nation might live. It is altogether fitting and proper that we should do this. But, in a larger sense, we can not dedicate -- *we can not consecrate* -- **we can not hallow** -- this ground. The brave men, living and dead, who struggled here, have consecrated it, far above our poor

Figure 487: The RichTextSearch sample, as initially launched

In `onCreate()` of our activity, we find the `EditText` widget and designate the activity itself as being an `OnEditorActionListener` for the `EditText`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  search=(EditText)findViewById(R.id.search);
  search.setOnEditorActionListener(this);
}
```

That means when the user presses `<Enter>`, we will get control in an `onEditorAction()` method. There, we pass the search text to a private `searchFor()` method, plus ensure that the input method editor is hidden (if one was used to fill in the search text):

```
@Override
public boolean onEditorAction(TextView v, int actionId, KeyEvent event) {
  if (event == null || event.getAction() == KeyEvent.ACTION_UP) {
    searchFor(search.getText().toString());

    InputMethodManager imm=
        (InputMethodManager)getSystemService(INPUT_METHOD_SERVICE);
    imm.hideSoftInputFromWindow(v.getWindowToken(), 0);
  }

  return(true);
}
```

The `searchFor()` method is where the formatting is applied to our search text:

```
private void searchFor(String text) {
  TextView prose=(TextView)findViewById(R.id.prose);
  Spannable raw=new SpannableString(prose.getText());
  BackgroundColorSpan[] spans=raw.getSpans(0,
                                           raw.length(),
                                           BackgroundColorSpan.class);

  for (BackgroundColorSpan span : spans) {
    raw.removeSpan(span);
  }

  int index=TextUtils.indexOf(raw, text);

  while (index >= 0) {
    raw.setSpan(new BackgroundColorSpan(0xFF8B008B), index, index
        + text.length(), Spanned.SPAN_EXCLUSIVE_EXCLUSIVE);
    index=TextUtils.indexOf(raw, text, index + text.length());
  }

  prose.setText(raw);
}
```

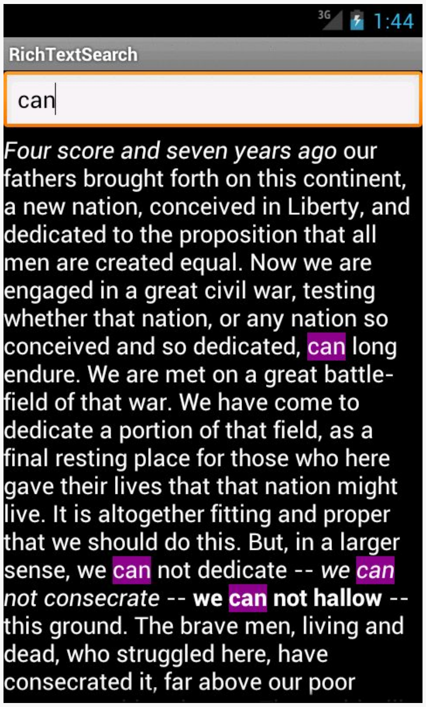
First, we get a `Spannable` object out of the `TextView`. While an `EditText` returns an `Editable` from `getText()`, `getText()` on a `TextView` returns a `CharSequence`. In particular, the first time we execute `searchFor()`, `getText()` will return a `SpannedString`, as that is what a string resource turns into. However, that is not modifiable, so we convert it into a `SpannableString` so we can apply formatting to it. An optimization would be to see if `getText()` returns something implementing `Spannable` and then just using it directly.

We want to highlight the search terms using a `BackgroundColorSpan`. However, that means we first need to get rid of any existing `BackgroundColorSpan` objects applied to the prose from a previous search — otherwise, we would keep highlighting more and more of the prose. So, we use `getSpans()` to find all `BackgroundColorSpan` objects anywhere in the prose (from index 0 through the length of the text). For each that we find, we call `removeSpan()` to get rid of it from our `Spannable`.

Then, we use `indexOf()` on `TextUtils` to find the first occurrence of whatever the user typed into the `EditText`. If we find it, we create a new `BackgroundColorSpan` and apply it to the matching portion of the prose using `setSpan()`. The last parameter to `setSpan()` is a flag, indicating what should happen if text is inserted at either the starting or ending point. In our case, the text itself is remaining constant, so the flag does not matter much – here, we use `SPAN_EXCLUSIVE_EXCLUSIVE`, which would mean that the span would not cover any text inserted at the starting or ending point of the span.

We then continue using `indexOf()` to find any remaining occurrences of the search text. Once we are done modifying our `Spannable`, we put it into the `TextView` via `setText()`.

The result is that all matching substrings are highlighted in a purple/magenta shade:



Four score and seven years ago our fathers brought forth on this continent, a new nation, conceived in Liberty, and dedicated to the proposition that all men are created equal. Now we are engaged in a great civil war, testing whether that nation, or any nation so conceived and so dedicated, can long endure. We are met on a great battle-field of that war. We have come to dedicate a portion of that field, as a final resting place for those who here gave their lives that that nation might live. It is altogether fitting and proper that we should do this. But, in a larger sense, we can not dedicate -- *we can not consecrate* -- **we can not hallow** -- this ground. The brave men, living and dead, who struggled here, have consecrated it, far above our poor

Figure 488: The RichTextSearch sample, after searching on "can"

Saving Rich Text

`SpannableString` and `SpannedString` are not `Serializable`. There is no built-in way to persist them directly.

However, `Html.toHtml()` will convert a `Spanned` object into corresponding HTML, for all `CharacterStyle` and `ParagraphStyle` objects that can be readily converted into HTML. You can then persist the resulting HTML any place you would persist a String (e.g., database column).

In principle, you could create other similar conversion code, such as something to take a Spanned and return the corresponding Markdown source.

The author of this book has a CWAC-RichTextUtils library. That library contains code to convert a Spanned object into XHTML and back again, with an eye towards providing more robust support for persisting Spanned objects.

Manipulating Rich Text

The TextUtils class has many utility methods that manipulate a CharSequence, to allow you to do things that you might ordinarily have done just with methods on String. These utility methods will work with any CharSequence, including SpannedString and SpannableString.

Some are specifically aimed at Spanned objects, such as copySpansFrom() (to apply formatting from one CharSequence onto another). Some are clones of String equivalents, such as split(), join(), and substring(). Yet others are designed for developers using the Canvas 2D drawing API, such as ellipsize() and commaEllipsize() for intelligently truncating messages.

Animators

Users like things that move. Or fade, spin, or otherwise offer a dynamic experience.

Much of the time, such animations are handled for us by the framework. We do not have to worry about sliding rows in a `ListView` when the user scrolls, or as the user pans around a `ViewPager`, and so forth.

However, sometimes, we will need to add our own animations, where we want effects that either are not provided by the framework innately or are simply different (e.g., want something to slide off the bottom of the screen, rather than off the left edge).

Android had an animation framework back in the beginning, one that is still available for you today. However, Android 3.0 introduced a new *animator* framework that is going to be Android's primary focus for animated effects going forward. Many, but not all, of the animator framework capabilities are available to us as developers via a backport.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on custom views, to be able to make sense of one of the samples.

ViewPropertyAnimator

Let's say that you want to fade out a widget, instead of simply setting its visibility to `INVISIBLE` or `GONE`.

For a widget whose name is v, on API Level 11 or higher, that is as simple as:

```
v.animate().alpha(0);
```

Here, “alpha” refers to the “alpha channel”. An alpha of 1 is normal opacity, while an alpha of 0 is completely transparent, with values in between representing various levels of translucence.

That may seem rather simple. The good news is, it *really* is that easy. Of course, there is a lot more you can do here, and you might have to worry about supporting older Android versions, and we need to think about things other than fading widgets in and out, and so forth.

First, though, let’s consider what is really going on when we call `animate()` on a widget on API Level 11+.

Native Implementation

The call to `animate()` returns an instance of `ViewPropertyAnimator`. This object allows us to build up a description of an animation to be performed, such as calling `alpha()` to change the alpha channel value. `ViewPropertyAnimator` uses a so-called [fluent interface](), much like the various builder classes (e.g., `Notification.Builder`) — calling a method on a `ViewPropertyAnimator()` usually returns the `ViewPropertyAnimator` itself. This allows you to build up an animation via a chained series of method calls, starting with that call to `animate()` on the widget.

You will note that we do not end the chain of method calls with something like a `start()` method. `ViewPropertyAnimator` will automatically arrange to start the animation once we return control of the main application thread back to the framework. Hence, we do not have to explicitly start the animation.

You will also notice that we did not indicate any particulars about how the animation should be accomplished, beyond stating the ending alpha channel value of `0`. `ViewPropertyAnimator` will use some standard defaults for the animation, such as a default duration, to determine how quickly Android changes the alpha value from its starting point to `0`. Most of those particulars can be overridden from their defaults via additional methods called on our `ViewPropertyAnimator`, such as `setDuration()` to provide a duration in milliseconds.

There are four standard animations that `ViewPropertyAnimator` can perform:

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget's rotation, around any of the three axes
4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

We will see an example of changing a widget's position, using the `translationXBy()` method, later in this chapter.

You are welcome to use more than one animation effect simultaneously, such as using both `alpha()` and `translationXBy()` to slide a widget horizontally and have it fade in or out.

There are other aspects of the animation that you can control. By default, the animation happens linearly — if we are sliding 500 pixels in 500ms, the widget will move evenly at 1 pixel/ms. However, you can specify a different "interpolator" to override that default linear behavior (e.g., start slow and accelerate as the animation proceeds). You can attach a listener object to find out about when the animation starts and ends. And, you can specify `withLayer()` to indicate that Android should try to more aggressively use hardware acceleration for an animation, a concept that we will get into in greater detail later in this chapter.

To see this in action, take a look at the `Animation/AnimatorFade` sample app.

The app consists of a single activity (`MainActivity`). It uses a layout that is dominated by a single `TextView` widget, whose ID is `fadee`:

```xml
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <TextView
    android:id="@+id/fadee"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerHorizontal="true"
    android:layout_centerVertical="true"
    android:text="@string/fading_out"
    android:textAppearance="?android:attr/textAppearanceLarge"
    tools:context=".MainActivity"/>

</RelativeLayout>
```

In onCreate(), we load up the layout and get our hands on the fadee widget:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.activity_main);

  fadee=(TextView)findViewById(R.id.fadee);
}
```

MainActivity itself implements Runnable, and our run() method will perform some animated effects:

```
@Override
public void run() {
  if (fadingOut) {
    fadee.animate().alpha(0).setDuration(PERIOD);
    fadee.setText(R.string.fading_out);
  }
  else {
    fadee.animate().alpha(1).setDuration(PERIOD);
    fadee.setText(R.string.coming_back);
  }

  fadingOut=!fadingOut;

  fadee.postDelayed(this, PERIOD);
}
```

Specifically, we use ViewPropertyAnimator to fade out the TextView over a certain period (fadee.animate().alpha(0).setDuration(PERIOD);) and set its caption to a value indicating that we are fading out. If we are to be fading back in, we perform the opposite animation and set the caption to a different value. We then flip the fadingOut boolean for the next pass and use postDelayed() to reschedule ourselves to run after the period has elapsed.

To complete the process, we run() our code initially in onResume() and cancel the postDelayed() loop in onPause():

```
@Override
public void onResume() {
  super.onResume();

  run();
}

@Override
public void onPause() {
  fadee.removeCallbacks(this);

  super.onPause();
}
```

The result is that the TextView smoothly fades out and in, alternating captions as it goes.

However, it would be really unpleasant if all this animator goodness worked only on API Level 11+. Fortunately for us, somebody wrote a backport.

Backport Via NineOldAndroids

Jake Wharton, author of ActionBarSherlock, ViewPagerIndicator, and other libraries, also wrote NineOldAndroids. This is, in effect, a backport of ViewPropertyAnimator and its underpinnings. There are some slight changes in how you use it, because NineOldAndroids is simply a library. It cannot add methods to existing classes (like adding animate() to View), nor can it add capabilities that the underlying firmware simply lacks. But, it may cover many of your animator needs, even if the name is somewhat inexplicable, and it works going all the way back to API Level 1, ensuring that it will cover any Android release that you care about.

As with ActionBarSherlock, NineOldAndroids is an Android library project.

Eclipse users will need to download that project (look in the library/ directory of the ZIP archive) and import the project. Android Studio users can add a compile statement to their dependencies closure in build.gradle to pull in com.nineoldandroids:library:... (for some version indicated by ...).

Since NineOldAndroids cannot add animate() to View, the recommended approach is to use a somewhat obscure feature of Java: imported static methods. An import static statement, referencing a particular static method of a class, makes that method available as if it were a static method on the class that you are writing, or as some sort of global function. NineOldAndroids has an animate() method that you can import this way, so instead of v.animate(), you use animate(v) to accomplish the same end. Everything else is the same, except perhaps some imports, to reference NineOldAndroids instead of the native classes.

You can see this in the Animation/AnimatorFadeBC sample app.

In addition to having the NineOldAndroids JAR in libs/, the only difference between this edition and the previous sample is in how the animation is set up. Instead of lines like:

```
fadee.animate().alpha(0).setDuration(PERIOD);
```

we have:

```
animate(fadee).alpha(0).setDuration(PERIOD);
```

This takes advantage of our static import:

```
import static com.nineoldandroids.view.ViewPropertyAnimator.animate;
```

If the static import makes you queasy, you are welcome to simply import the `com.nineoldandroids.view.ViewPropertyAnimator` class, rather than the static method, and call the `animate()` method on `ViewPropertyAnimator`:

```
ViewPropertyAnimator.animate(fadee).alpha(0).setDuration(PERIOD);
```

The Foundation: Value and Object Animators

`ViewPropertyAnimator` itself is a layer atop of a more primitive set of animators, known as value and object animators.

A `ValueAnimator` handles the core logic of transitioning some value, from an old to a new value, over a period of time. `ValueAnimator` offers replaceable “interpolators”, which will determine how the values change from start to finish over the animation period (e.g., start slowly, accelerate, then end slowly). `ValueAnimator` also handles the concept of a “repeat mode”, to indicate if the animation should simply happen once, a fixed number of times, or should infinitely repeat (and, in the latter cases, whether it does so always transitioning from start to finish or if it reverses direction on alternate passes, going from finish back to start).

What `ValueAnimator` does *not* do is actually change anything. It is merely computing the different values based on time. You can call `getAnimatedValue()` to find out the value at any point in time, or you can call `addUpdateListener()` to register a listener object that will be notified of each change in the value, so that change can be applied somewhere.

Hence, what tends to be a bit more popular is `ObjectAnimator`, a subclass of `ValueAnimator` that automatically applies the new values. `ObjectAnimator` does this by calling a setter method on some object, where you supply the object and the “property name” used to derive the getter and setter method names. For example, if you request a property name of `foo`, `ObjectAnimator` will try to call `getFoo()` and `setFoo()` methods on your supplied object.

As with ViewPropertyAnimator, ValueAnimator and ObjectAnimator are implemented natively in API Level 11 and are available via the NineOldAndroids backport as well.

To see what ObjectAnimator looks like in practice, let us examine the Animation/ObjectAnimator sample app.

Once again, our activity's layout is pretty much just a centered TextView, here named word:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <TextView
    android:id="@+id/word"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerHorizontal="true"
    android:layout_centerVertical="true"
    android:textAppearance="?android:attr/textAppearanceLarge"
    tools:context=".MainActivity"/>

</RelativeLayout>
```

The objective of our activity is to iterate through 25 words, showing one at a time in the TextView:

```
package com.commonsware.android.animator.obj;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;
import com.nineoldandroids.animation.ObjectAnimator;
import com.nineoldandroids.animation.ValueAnimator;

public class MainActivity extends Activity {
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };
  private TextView word=null;
  int position=0;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    word=(TextView)findViewById(R.id.word);
    ValueAnimator positionAnim = ObjectAnimator.ofInt(this, "wordPosition", 0, 24);
    positionAnim.setDuration(12500);
    positionAnim.setRepeatCount(ValueAnimator.INFINITE);
    positionAnim.setRepeatMode(ValueAnimator.RESTART);
    positionAnim.start();
  }

  public void setWordPosition(int position) {
    this.position=position;
    word.setText(items[position]);
  }

  public int getWordPosition() {
    return(position);
  }
}
```

To accomplish this, we use NineOldAndroids version of `ObjectAnimator`, saying that we wish to "animate" the `wordPosition` property of the activity itself, from 0 to 24. We configure the animation to run for 12.5 seconds (i.e., 500ms per word) and to repeat indefinitely by restarting the animation from the beginning on each pass. We then call `start()` to kick off the animation.

For this to work, though, we need `getWordPosition()` and `setWordPosition()` accessor methods for the theoretical `wordPosition` property. In our case, the "word position" is simply an integer data member of the activity, which we return in `getWordPosition()` and update in `setWordPosition()`. However, we also update the `TextView` in `setWordPosition()`, to display the word at that position.

The net effect is that words appear in our `TextView`, changing on average every 500ms.

Animating Custom Types

In the previous section, we animated an `int` property of an `Activity`. That works, because Android knows how to compute `int` values between the start and end position, through simple math.

But, what if we wanted to animate something that is not a simple number? For example, what if we want to animate a `Color`, or a `LatLng` from Maps V2, or a `TastyTreat` class of our own design?

So long as *we* can perform the calculations, we can animate a type of anything we want, using `TypeEvaluator` and `ofObject()` on `ObjectAnimator`.

A TypeEvaluator is a simple interface, containing a single method that we need to override: evaluate(). However, TypeEvaluator uses generics, and so our implementation will actually be of some concrete class (e.g., a TypeEvaluator of TastyTreat). Our job in evaluate() is to return a value of our designated type (e.g., TastyTreat) given three inputs:

1. The initial value for our animation range, in the form of our designated type
2. The end value for our animation range, in the form of our designated type
3. The fraction along that range that represents how much we have moved from the initial value to the end value

Note that the fraction is not limited to being between 0 and 1, as certain interpolators (e.g., an overshoot interpolator) might result in a fraction being negative (e.g., we overshot past the initial value) or greater than one (e.g., we overshot past the end value).

For example, to have a TypeEvaluator of Color, we might have evaluate() generate a new Color instance based upon applying the fraction to the initial and end red, green, blue, and alpha channels.

To use a TypeEvaluator, instead of ofInt(), ofFloat(), or similar simple factory methods on ObjectAnimator, we use ofObject(). ofObject() takes the object to be animated, the property to be animated, the TypeEvaluator to assist in the actual animation, and the final value of the animation (or, optionally, a series of waypoints to be animated along).

A flavor of ofObject() that takes the property name — akin to the wordPosition ofInt() used in the previous section — has been around since API Level 11. API Level 14 added an ofObject() method that takes a Property value instead of the name of the property. This version has the added benefit of type-safety, as it can ensure that your object to be animated, TypeEvaluator, and final position are all of the same type.

You can see an example of using TypeEvaluator this way in the chapter on Maps V2, as we animate the movement of a map marker from a starting point to an ending point.

Hardware Acceleration

Animated effects operate much more smoothly with hardware acceleration. There are two facets to employing hardware acceleration for animations: enabling it overall and directing its use for the animations themselves.

Hardware acceleration is enabled overall on Android devices running Android 4.0 or higher (API Level 14). On Android 3.x, hardware acceleration is available but is disabled by default — use `android:hardwareAccelerated="true"` in your `<application>` or `<activity>` element in the manifest to enable it on those versions. Hardware acceleration for 2D graphics operations like widget animations is not available on older versions of Android.

While this will provide some benefit across the board, you may also wish to consider rendering animated widgets or containers in an off-screen buffer, or "hardware layer", that then gets applied to the screen via the GPU. In particular, the GPU can apply certain animated transformations to a hardware layer without forcing software to redraw the widgets or containers (e.g., what happens when you `invalidate()` them). As it turns out, these GPU-enhanced transformations match the ones supported by `ViewPropertyAnimator`:

1. Changes in alpha channel values, for fading widgets in and out
2. Changes in widget position, by altering the X and Y values of the upper-left corner of the widget, from wherever on the screen it used to be to some new value
3. Changes in the widget's rotation, around any of the three axes
4. Changes in the widget's size, where Android can scale the widget by some percentage to expand or shrink it

By having the widget be rendered in a hardware layer, these `ViewPropertyAnimator` operations are significantly more efficient than before.

However, since hardware layers take up video memory, generally you do not want to keep a widget or container in a hardware layer indefinitely. Instead, the recommended approach is to have the widget or container be rendered in a hardware layer only while the animation is ongoing, by calling `setLayerType()` for `LAYER_TYPE_HARDWARE` before the animation begins, then calling `setLayerType()` for `LAYER_TYPE_NONE` (i.e., return to default behavior) when the animation completes. Or, for `ViewPropertyAnimator` on API Level 16 and higher, use `withLayer()` in the fluent interface to have it apply the hardware layer automatically just for the animation duration.

We will see examples of using hardware acceleration this way in the next section.

The Three-Fragment Problem

The original tablet implementation of Gmail organized its landscape main activity into two panes, one on the left taking up ~30% of the screen, and one on the right taking up the remainder:

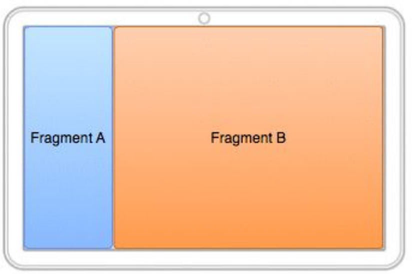


Figure 489: Gmail Fragments (image courtesy of Google and AOSP)

Gmail had a very specific navigation mode in its main activity when viewed in landscape on a tablet, where upon some UI event (e.g., tapping on something in the right-hand area):

- The original left-hand fragment (Fragment A) slid off the screen to the left
- The original right-hand fragment (Fragment B) slid to the left edge of the screen and shrunk to take up the spot vacated by Fragment A
- Another fragment (Fragment C) slid in from the right side of the screen and expanded to take up the spot vacated by Fragment B

And a BACK button press reversed this operation.

This is a bit tricky to set up, leading to the author of this book posting a question on Stack Overflow to get input. Here, we will examine one of the results of that discussion, based in large part on the implementation of the AOSP Email app, which has a similar navigation flow. The other answers on that question may have merit in other scenarios as well.

You can see one approach for implementing the three-pane solution in the `Animation/ThreePane` sample app.

The ThreePaneLayout

The logic to handle the animated effects is encapsulated in a `ThreePaneLayout` class. It is designed to be used in a layout XML resource where you supply the contents of the three panes, sizing the first two as you want, with the third "pane" having zero width at the outset:

```
<com.commonsware.android.anim.threepane.ThreePaneLayout
xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/root"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <FrameLayout
    android:id="@+id/left"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="3"/>

  <FrameLayout
    android:id="@+id/middle"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="7"/>

  <Button
    android:layout_width="0dp"
    android:layout_height="match_parent"/>

</com.commonsware.android.anim.threepane.ThreePaneLayout>
```

`ThreePaneLayout` itself is a subclass of `LinearLayout`, set up to always be horizontal, regardless of what might be set in the layout XML resource.

```
  public ThreePaneLayout(Context context, AttributeSet attrs) {
    super(context, attrs);
    initSelf();
  }

  void initSelf() {
    setOrientation(HORIZONTAL);
  }
```

When the layout finishes inflating, we grab the three panes (defined as the first three children of the container) and stash them in data members named `left`, `middle`, and `right`, with matching getter methods:

```
  @Override
  public void onFinishInflate() {
    super.onFinishInflate();
    left=getChildAt(0);
    middle=getChildAt(1);
    right=getChildAt(2);
  }

  public View getLeftView() {
    return(left);
  }

  public View getMiddleView() {
    return(middle);
  }

  public View getRightView() {
    return(right);
  }
```

The major operational API, from the standpoint of an activity using `ThreePaneLayout`, is `hideLeft()` and `showLeft()`. `hideLeft()` will switch from showing the `left` and `middle` widgets in their original size and position to showing the `middle` and `right` widgets wherever `left` and `middle` had been originally. `showLeft()` reverses the operation.

The problem is that, initially, we do not know where the widgets are or how big they are, as that should be able to be set from the layout XML resource and are not known until the `ThreePaneLayout` is actually applied to the screen. Hence, we lazy-retrieve those values in `hideLeft()`, plus remove any weights that had been originally defined, setting the actual pixel widths on the widgets instead:

```
  public void hideLeft() {
    if (leftWidth == -1) {
      leftWidth=left.getWidth();
      middleWidthNormal=middle.getWidth();
      resetWidget(left, leftWidth);
      resetWidget(middle, middleWidthNormal);
      resetWidget(right, middleWidthNormal);
      requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", middleWidthNormal,
                         leftWidth).setDuration(ANIM_DURATION).start();
  }
```

The work to change the weights into widths is handled in `resetWidget()`:

```
  private void resetWidget(View v, int width) {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)v.getLayoutParams();

    p.width=width;
    p.weight=0;
  }
```

After the lazy-initialization and widget cleanup, we perform the two animations. `translateWidgets()` will slide each of our three widgets to the left by the width of the `left` widget, using a `ViewPropertyAnimator` and a hardware layer:

```
  private void translateWidgets(int deltaX, View... views) {
    for (final View v : views) {
      v.setLayerType(View.LAYER_TYPE_HARDWARE, null);

      v.animate().translationXBy(deltaX).setDuration(ANIM_DURATION)
       .setListener(new AnimatorListenerAdapter() {
         @Override
         public void onAnimationEnd(Animator animation) {
           v.setLayerType(View.LAYER_TYPE_NONE, null);
         }
       });
    }
  }
```

The resize animation — to set the `middle` size to be what `left` had been – is handled via an `ObjectAnimator`, for a theoretical property of `middleWidth` on `ThreePaneLayout`. That is backed by a `setMiddleWidth()` method that adjusts the `width` property of the `middle` widget's `LayoutParams` and triggers a redraw:

```
  @SuppressWarnings("unused")
  private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
  }
```

The `showLeft()` method simply performs those two animations in reverse:

```
  public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);

    ObjectAnimator.ofInt(this, "middleWidth", leftWidth,
                         middleWidthNormal).setDuration(ANIM_DURATION)
                  .start();
  }
```

Using the ThreePaneLayout

The sample app uses one activity (`MainActivity`) and one fragment (`SimpleListFragment`) to set up and use the `ThreePaneLayout`. The objective is a UI that roughly mirrors that of the AOSP Email app: a list on the left, a list in the middle (whose contents are based on the item chosen in the left list), and something else on the right (whose contents are based on the item chosen in the middle list).

SimpleListFragment is used for both lists. Its newInstance() factory method is handed the list of strings to display. SimpleListFragment just loads those into its ListView, also setting up CHOICE_MODE_SINGLE for use with the activated style, and routing all clicks on the list to the MainActivity that hosts the fragment:

```
package com.commonsware.android.anim.threepane;

import android.app.ListFragment;
import android.os.Bundle;
import android.view.View;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import java.util.ArrayList;
import java.util.Arrays;

public class SimpleListFragment extends ListFragment {
  private static final String KEY_CONTENTS="contents";

  public static SimpleListFragment newInstance(String[] contents) {
    return(newInstance(new ArrayList<String>(Arrays.asList(contents))));
  }

  public static SimpleListFragment newInstance(ArrayList<String> contents) {
    SimpleListFragment result=new SimpleListFragment();
    Bundle args=new Bundle();

    args.putStringArrayList(KEY_CONTENTS, contents);
    result.setArguments(args);

    return(result);
  }

  @Override
  public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    setContents(getArguments().getStringArrayList(KEY_CONTENTS));
  }

  @Override
  public void onListItemClick(ListView l, View v, int position, long id) {
    ((MainActivity)getActivity()).onListItemClick(this, position);
  }

  void setContents(ArrayList<String> contents) {
    setListAdapter(new ArrayAdapter<String>(
                                            getActivity(),
                                            R.layout.simple_list_item_1,
                                            contents));
  }
}
```

MainActivity populates the left FrameLayout with a SimpleListFragment in onCreate(), if the fragment does not already exist (e.g., from a configuration change). When an item in the left list is clicked, MainActivity populates the middle FrameLayout. When an item in the middle list is clicked, it sets the caption of the right Button and uses hideLeft() to animate that Button onto the screen, hiding the left list. If the user presses BACK, and our left list is not showing, MainActivity calls showLeft() to reverse the animation:

```
package com.commonsware.android.anim.threepane;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;
import java.util.ArrayList;

public class MainActivity extends Activity {
  private static final String KEY_MIDDLE_CONTENTS="middleContents";
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };
  private boolean isLeftShowing=true;
  private SimpleListFragment middleFragment=null;
  private ArrayList<String> middleContents=null;
  private ThreePaneLayout root=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    root=(ThreePaneLayout)findViewById(R.id.root);

    if (getFragmentManager().findFragmentById(R.id.left) == null) {
      getFragmentManager().beginTransaction()
                          .add(R.id.left,
                               SimpleListFragment.newInstance(items))
                          .commit();
    }

    middleFragment=
        (SimpleListFragment)getFragmentManager().findFragmentById(R.id.middle);
  }

  @Override
  public void onBackPressed() {
    if (!isLeftShowing) {
      root.showLeft();
      isLeftShowing=true;
    }
    else {
      super.onBackPressed();
    }
  }
  @Override
  protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putStringArrayList(KEY_MIDDLE_CONTENTS, middleContents);
  }

  @Override
  protected void onRestoreInstanceState(Bundle inState) {
    middleContents=inState.getStringArrayList(KEY_MIDDLE_CONTENTS);
  }

  void onListItemClick(SimpleListFragment fragment, int position) {
    if (fragment == middleFragment) {
      ((Button)root.getRightView()).setText(middleContents.get(position));

      if (isLeftShowing) {
        root.hideLeft();
        isLeftShowing=false;
      }
    }
    else {
      middleContents=new ArrayList<String>();

      for (int i=0; i < 20; i++) {
        middleContents.add(items[position] + " #" + i);
      }

      if (getFragmentManager().findFragmentById(R.id.middle) == null) {
        middleFragment=SimpleListFragment.newInstance(middleContents);
        getFragmentManager().beginTransaction()
                            .add(R.id.middle, middleFragment).commit();
      }
      else {
        middleFragment.setContents(middleContents);
      }
    }
  }
}
```

The Results

If you run this app on a landscape tablet running API Level 11 or higher, you start off with a single list of words on the left:

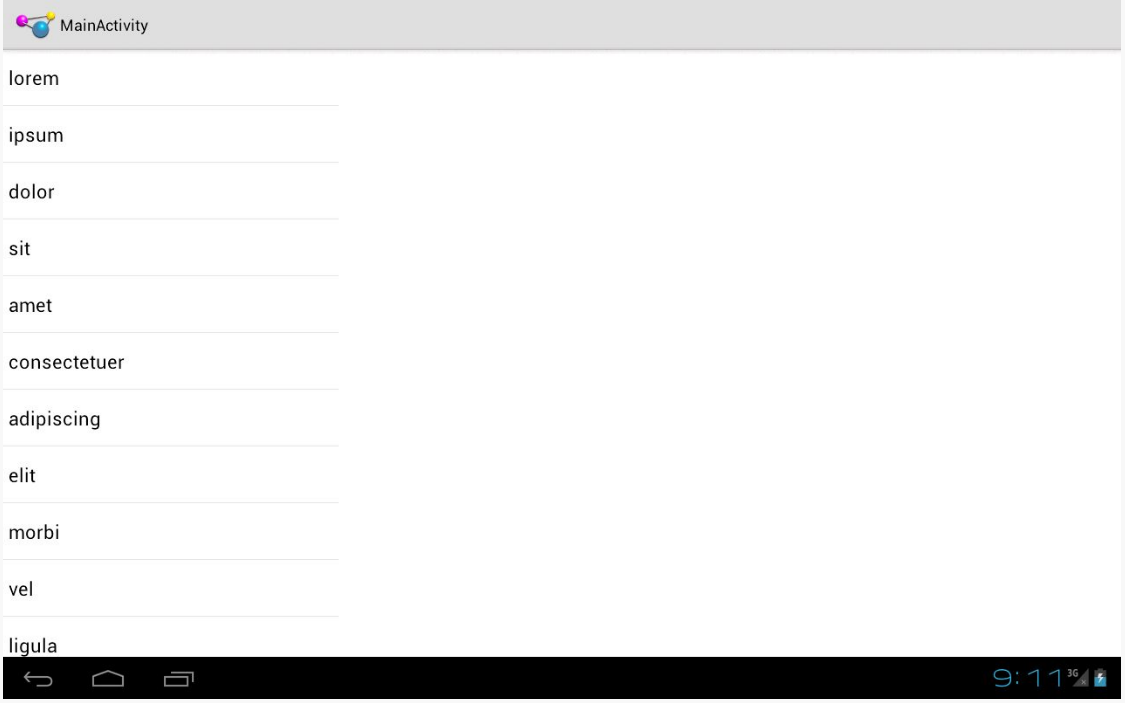

Figure 490: ThreePane, As Initially Launched

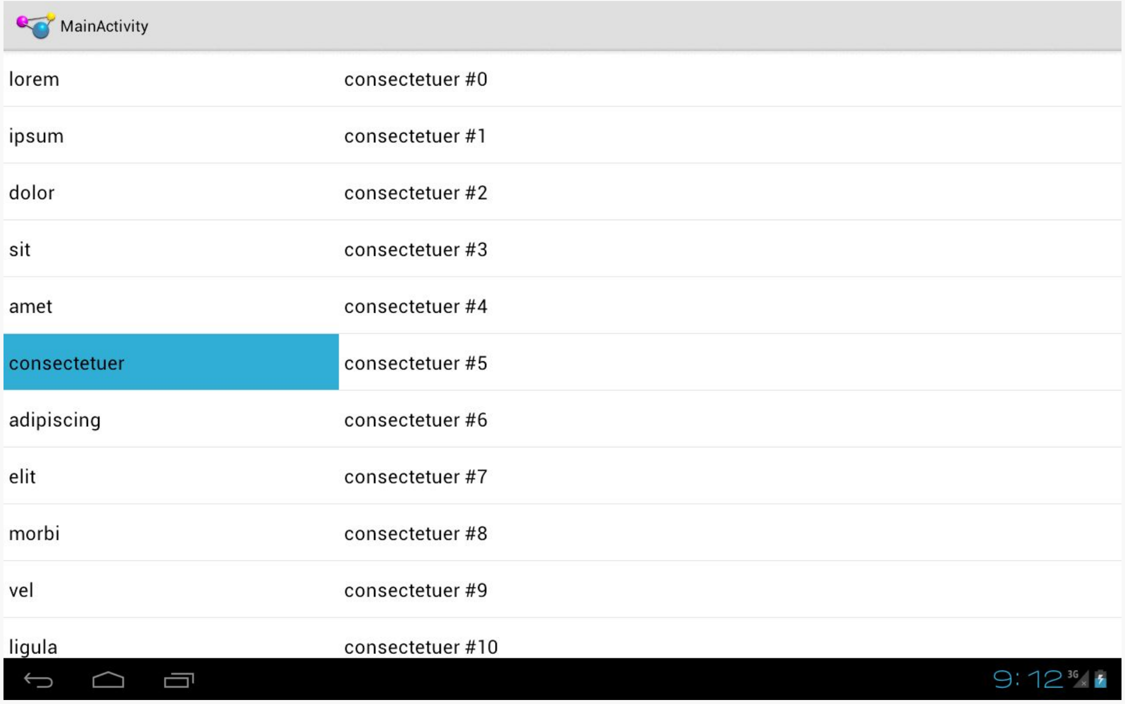
Clicking on a word brings up a second list, taking up the rest of the screen, with numbered entries based upon the clicked-upon word:

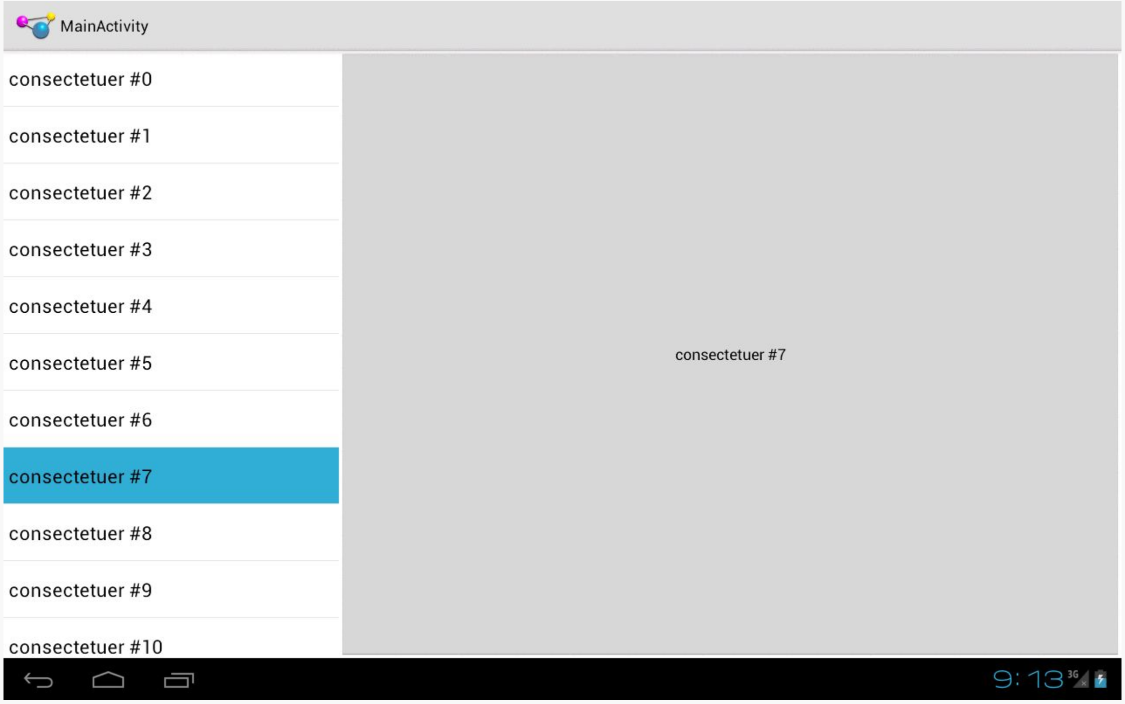


MainActivity

lorem	consectetuer #0
ipsum	consectetuer #1
dolor	consectetuer #2
sit	consectetuer #3
amet	consectetuer #4
consectetuer	consectetuer #5
adipiscing	consectetuer #6
elit	consectetuer #7
morbi	consectetuer #8
vel	consectetuer #9
ligula	consectetuer #10

Figure 491: ThreePane, After Clicking a Word

Clicking on an entry in the second list starts the animation, sliding the first list off to the left, sliding the second list into the space vacated by the first list, and sliding in a “detail view” into the right portion of the screen:



MainActivity

consectetuer #0

consectetuer #1

consectetuer #2

consectetuer #3

consectetuer #4

consectetuer #5

consectetuer #6

consectetuer #7

consectetuer #8

consectetuer #9

consectetuer #10

consectetuer #7

Figure 492: ThreePane, After Clicking a Numbered Word

Pressing BACK once will reverse the animation, restoring you to the two-list perspective.

The Backport

The `ThreePane` sample described above uses the native API Level 11 version of the animator framework and the native implementation of fragments. However, the same approach can work using the Android Support package's version of fragments and NineOldAndroids. You can see this in the [`Animation/ThreePaneBC`] sample app.

Besides changing the import statements and adding the NineOldAndroids JAR file, the only other changes of substance were:

- Using `ViewPropertyAnimator.animate(v)` instead of `v.animate()` in `translateWidgets()`
- Conditionally setting the hardware acceleration layers via `setLayerType()` in `translateWidgets()` based upon API level, as that method was only added in API Level 11

The smoothness of animations, though, will vary by hardware capabilities. For example, on a first-generation Kindle Fire, running Android 2.3, the backport works but is not especially smooth, while the animations are very smooth on more modern hardware where hardware acceleration can be applied.

The Problems

As we will see in the chapter on "jank", there is some stutter in the rendering of this app. Fixing it requires removing the animated change in the width of the middle pane, which in turn makes the animation itself look worse. More details on the analysis can be found in the "jank" chapter.

Legacy Animations

Before ViewPropertyAnimator and the rest of the animator framework were added in API Level 11, we had the original Animation base class and specialized animations based upon it, like TranslateAnimation for movement and AlphaAnimation for fades. On the whole, you will want to try to use the animator framework where possible, as the new system is more powerful and efficient than the legacy Animation approach. However, particularly for apps where the NineOldAndroids backport is insufficient, you may wish to use the legacy framework.

After an overview of the role of the animation framework, we go in-depth to animate the movement of a widget across the screen. We then look at alpha animations, for fading widgets in and out. We then see how you can get control during the lifecycle of an animation, how to control the acceleration of animations, and how to group animations together for parallel execution. Finally, we see how the same framework can now be used to control the animation for the switching of activities.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on basic resources and basic widgets. Also, you should read the chapter on custom views.

It's Not Just For Toons Anymore

Android has a package of classes (android.view.animation) dedicated to animating the movement and behavior of widgets.

They center around an `Animation` base class that describes what is to be done. Built-in animations exist to move a widget (`TranslateAnimation`), change the transparency of a widget (`AlphaAnimation`), revolve a widget (`RotateAnimation`), and resize a widget (`ScaleAnimation`). There is even a way to aggregate animations together into a composite `Animation` called an `AnimationSet`. Later sections in this chapter will examine the use of several of these animations.

Given that you have an animation, to apply it, you have two main options:

1. You may be using a container that supports animating its contents, such as a `ViewFlipper` or `TextSwitcher`. These are typically subclasses of `ViewAnimator` and let you define the "in" and "out" animations to apply. For example, with a `ViewFlipper`, you can specify how it flips between `Views` in terms of what animation is used to animate "out" the currently-visible `View` and what animation is used to animate "in" the replacement `View`.
2. You can simply tell any `View` to `startAnimation()`, given the `Animation` to apply to itself. This is the technique we will be seeing used in the examples in this chapter.

A Quirky Translation

Animation takes some getting used to. Frequently, it takes a fair bit of experimentation to get it all working as you wish. This is particularly true of `TranslateAnimation`, as not everything about it is intuitive, even to authors of Android books.

Mechanics of Translation

The simple constructor for `TranslateAnimation` takes four parameters describing how the widget should move: the before and after X offsets from the current position, and the before and after Y offsets from the current position. The Android documentation refers to these as `fromXDelta`, `toXDelta`, `fromYDelta`, and `toYDelta`.

In Android's pixel-space, an `(X,Y)` coordinate of `(0,0)` represents the upper-left corner of the screen. Hence, if `toXDelta` is greater than `fromXDelta`, the widget will move to the right, if `toYDelta` is greater than `fromYDelta`, the widget will move down, and so on.

Imagining a Sliding Panel

Some Android applications employ a sliding panel, one that is off-screen most of the time but can be called up by the user (e.g., via a menu) when desired. When anchored at the bottom of the screen, you get a container that slides up from the bottom and slides down and out when being removed.

One way to implement such a panel is to have a container (e.g., a `LinearLayout`) whose contents are absent (`INVISIBLE`) when the panel is closed and is present (`VISIBLE`) when the drawer is open. If we simply toggled `setVisibility()` using the aforementioned values, though, the panel would wink open and closed immediately, without any sort of animation. So, instead, we want to:

1. Make the panel visible and animate it up from the bottom of the screen when we open the panel
2. Animate it down to the bottom of the screen and make the panel invisible when we close the panel

The Aftermath

This brings up a key point with respect to `TranslateAnimation`: the animation temporarily moves the widget, but if you want the widget to stay where it is when the animation is over, you have to handle that yourself. Otherwise, the widget will snap back to its original position when the animation completes.

In the case of the panel opening, we handle that via the transition from `INVISIBLE` to `VISIBLE`. Technically speaking, the panel is always "open", in that we are not, in the end, changing its position. But when the body of the panel is `INVISIBLE`, it takes up no space on the screen; when we make it `VISIBLE`, it takes up whatever space it is supposed to.

Later in this chapter, we will cover how to use animation listeners to accomplish this end for closing the panel.

Introducing SlidingPanel

With all that said, turn your attention to the [`Animation/SlidingPanel`] sample project and, in particular, the `SlidingPanel` class.

This class implements a layout that works as a panel, anchored to the bottom of the screen. A `toggle()` method can be called by the activity to hide or show the panel. The panel itself is a `LinearLayout`, so you can put whatever contents you want in there.

We use two flavors of `TranslateAnimation`, one for opening the panel and one for closing it.

Here is the opening animation:

```
    anim=new TranslateAnimation(0.0f, 0.0f,
                                getHeight(),
                                0.0f);
```

Our `fromXDelta` and `toXDelta` are both `0`, since we are not shifting the panel's position along the horizontal axis. Our `fromYDelta` is the panel's height according to its layout parameters (representing how big we want the panel to be), because we want the panel to start the animation at the bottom of the screen; our `toYDelta` is `0` because we want the panel to be at its "natural" open position at the end of the animation.

Conversely, here is the closing animation:

```
    anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,
                                getHeight());
```

It has the same basic structure, except the Y values are reversed, since we want the panel to start open and animate to a closed position.

The result is a container that can be closed:

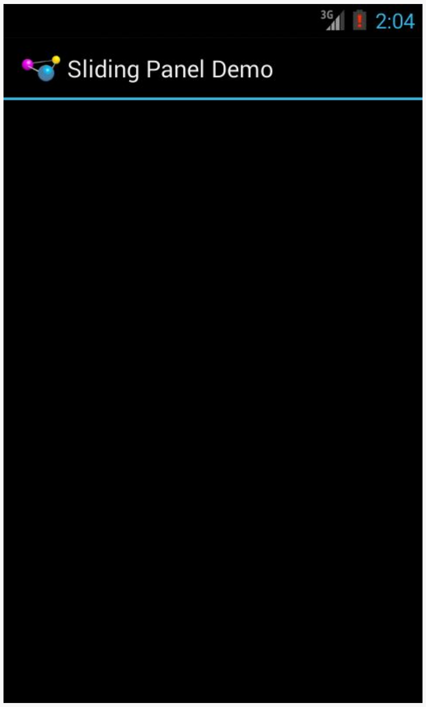


Figure 493: The SlidingPanel sample application, with the panel closed

… or open, in this case toggled via a menu choice in the `SlidingPanelDemo` activity:

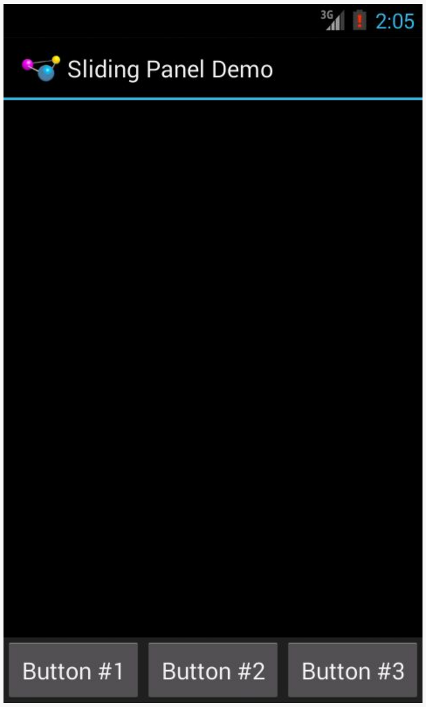

Figure 494: The SlidingPanel sample application, with the panel open

Using the Animation

When setting up an animation, you also need to indicate how long the animation should take. This is done by calling `setDuration()` on the animation, providing the desired length of time in milliseconds.

When we are ready with the animation, we simply call `startAnimation()` on the `SlidingPanel` itself, causing it to move as specified by the `TranslateAnimation` instance.

Fading To Black. Or Some Other Color.

`AlphaAnimation` allows you to fade a widget in or out by making it less or more transparent. The greater the transparency, the more the widget appears to be "fading".

Alpha Numbers

You may be used to alpha channels, when used in #AARRGGBB color notation, or perhaps when working with alpha-capable image formats like PNG.

Similarly, AlphaAnimation allows you to change the alpha channel for an entire widget, from fully-solid to fully-transparent.

In Android, a float value of 1.0 indicates a fully-solid widget, while a value of 0.0 indicates a fully-transparent widget. Values in between, of course, represent various amounts of transparency.

Hence, it is common for an AlphaAnimation to either start at 1.0 and smoothly change the alpha to 0.0 (a fade) or vice versa.

Animations in XML

With TranslateAnimation, we showed how to construct the animation in Java source code. One can also create animation resources, which define the animations using XML. This is similar to the process for defining layouts, albeit much simpler.

For example, there is a second animation project, Animation/SlidingPanelEx, which demonstrates a panel that fades out as it is closed. In there, you will find a res/anim/ directory, which is where animation resources should reside. In there, you will find fade.xml:

```
<?xml version="1.0" encoding="utf-8"?>
<alpha xmlns:android="http://schemas.android.com/apk/res/android"
  android:fromAlpha="1.0"
  android:toAlpha="0.0" />
```

The name of the root element indicates the type of animation (in this case, alpha for an AlphaAnimation). The attributes specify the characteristics of the animation, in this case a fade from 1.0 to 0.0 on the alpha channel.

This XML is the same as calling new AlphaAnimation(1.0f,0.0f) in Java.

Using XML Animations

To make use of XML-defined animations, you need to inflate them, much as you might inflate a View or Menu resource. This is accomplished by using the loadAnimation() static method on the AnimationUtils class, seen here in our SlidingPanel constructor:

```
public SlidingPanel(final Context ctxt, AttributeSet attrs) {
  super(ctxt, attrs);

  TypedArray a=ctxt.obtainStyledAttributes(attrs,
                                          R.styleable.SlidingPanel,
                                          0, 0);

  speed=a.getInt(R.styleable.SlidingPanel_speed, 300);

  a.recycle();

  fadeOut=AnimationUtils.loadAnimation(ctxt, R.anim.fade);
}
```

Here, we are loading our fade animation, given a Context. This is being put into an Animation variable, so we neither know nor care that this particular XML that we are loading defines an AlphaAnimation instead of, say, a RotateAnimation.

When It's All Said And Done

Sometimes, you need to take action when an animation completes.

For example, when we close the panel, we want to use a TranslationAnimation to slide it down from the open position to closed… then *keep* it closed. With the system used in SlidingPanel, keeping the panel closed is a matter of calling setVisibility() on the contents with INVISIBLE.

However, you cannot do that when the animation begins; otherwise, the panel is gone by the time you try to animate its motion.

Instead, you need to arrange to have it become invisible when the animation ends. To do that, you use an animation listener.

An animation listener is simply an instance of the AnimationListener interface, provided to an animation via setAnimationListener(). The listener will be invoked when the animation starts, ends, or repeats (the latter courtesy of CycleInterpolator, discussed later in this chapter). You can put logic in the onAnimationEnd() callback in the listener to take action when the animation finishes.

For example, here is the AnimationListener for SlidingPanel:

```
Animation.AnimationListener collapseListener=new Animation.AnimationListener() {
  public void onAnimationEnd(Animation animation) {
    setVisibility(View.INVISIBLE);
  }

  public void onAnimationRepeat(Animation animation) {
    // not needed
  }

  public void onAnimationStart(Animation animation) {
    // not needed
  }
};
```

All we do is set our content's visibility to be `INVISIBLE`, thereby closing the panel.

Loose Fill

You will see attributes, available on `Animation`, named `android:fillEnabled` and `android:fillAfter`. Reading those, you may think that you can dispense with the `AnimationListener` and just use those to arrange to have your widget wind up being "permanently" in the state represented by the end of the animation. All you would have to do is set each of those to true in your animation XML (or the equivalent in Java), and you would be set.

At least for `TranslateAnimation`, you would be mistaken.

It actually will look like it works — the animated widgets will be drawn in their new location. However, if those widgets are clickable, they will not be clicked in their new location, but rather in their old one. This, of course, is not terribly useful.

Hence, even though it is annoying, you will want to use the `AnimationListener` techniques described in this chapter.

Hit The Accelerator

In addition to the `Animation` classes themselves, Android also provides a set of `Interpolator` classes. These provide instructions for how an animation is supposed to behave during its operating period.

For example, the `AccelerateInterpolator` indicates that, during the duration of an animation, the rate of change of the animation should begin slowly and accelerate until the end. When applied to a `TranslateAnimation`, for example, the sliding movement will start out slowly and pick up speed until the movement is complete.

There are several implementations of the Interpolator interface besides AccelerateInterpolator, including:

1. AccelerateDecelerateInterpolator, which starts slowly, picks up speed in the middle, and slows down again at the end
2. DecelerateInterpolator, which starts quickly and slows down towards the end
3. LinearInterpolator, the default, which indicates the animation should proceed smoothly from start to finish
4. CycleInterpolator, which repeats an animation for a number of cycles, following the AccelerateDecelerateInterpolator pattern (slow, then fast, then slow)

To apply an interpolator to an animation, simply call setInterpolator() on the animation with the Interpolator instance, such as the following line from SlidingPanel:

```
    anim.setInterpolator(new AccelerateInterpolator(1.0f));
```

You can also specify one of the stock interpolators via the android:interpolator attribute in your animation XML file.

Animate. Set. Match.

For the Animation/SlidingPanelEx project, though, we want the panel to slide open, but also fade when it slides closed. This implies two animations working at the same time (a fade and a slide). Android supports this via the AnimationSet class.

An AnimationSet is itself an Animation implementation. Following the composite design pattern, it simply cascades the major Animation events to each of the animations in the set.

To create a set, just create an AnimationSet instance, add the animations, and configure the set. For example, here is the logic from the SlidingPanel implementation in Animation/SlidingPanelEx:

```
  public void toggle() {
    TranslateAnimation anim=null;
    AnimationSet set=new AnimationSet(true);

    isOpen=!isOpen;

    if (isOpen) {
      setVisibility(View.VISIBLE);
      anim=new TranslateAnimation(0.0f, 0.0f,
                                  getHeight(),
                                  0.0f);
    }
    else {
      anim=new TranslateAnimation(0.0f, 0.0f, 0.0f,
                                  getHeight());
      anim.setAnimationListener(collapseListener);
      set.addAnimation(fadeOut);
    }

    set.addAnimation(anim);
    set.setDuration(speed);
    set.setInterpolator(new AccelerateInterpolator(1.0f));
    startAnimation(set);
  }
```

If the panel is to be opened, we make the contents visible (so we can animate the motion upwards), and create a `TranslateAnimation` for the upward movement. If the panel is to be closed, we create a `TranslateAnimation` for the downward movement, but also add a pre-defined `AlphaAnimation` (`fadeOut`) to an `AnimationSet`. In either case, we add the `TranslateAnimation` to the set, give the set a duration and interpolator, and run the animation.

Active Animations

Starting with Android 1.5, users could indicate if they wanted to have inter-activity animations: a slide-in/slide-out effect as they switched from activity to activity. However, at that time, they could merely toggle this setting on or off, and applications had no control over these animations whatsoever.

Starting in Android 2.0, though, developers have a bit more control. Specifically:

1. Developers can call `overridePendingTransition()` on an `Activity`, typically after calling `startActivity()` to launch another activity or `finish()` to close up the current activity. The `overridePendingTransition()` indicates an in/out animation pair that should be applied as control passes from this activity to the next one, whether that one is being started (`startActivity()`) or is the one previous on the stack (`finish()`).
2. Developers can start an activity via an `Intent` containing the `FLAG_ACTIVITY_NO_ANIMATION` flag. As the name suggests, this flag requests that animations on the transitions involving this activity be suppressed.

These are prioritized as follows:

- Any call to `overridePendingTransition()` is always taken into account
- Lacking that, `FLAG_ACTIVITY_NO_ANIMATION` will be taken into account
- In the normal case, where neither of the two are used, whatever the user's preference, via the Settings application, is applied

Custom Drawables

Many times, our artwork can simply be some PNG or JPEG files, perhaps with different variations in different resource directories by density.

Sometimes, though, we need something more.

In addition to supporting standard PNG and JPEG files, Android has a number of custom drawable resource formats — mostly written in XML — that handle specific scenarios.

For example, you may wish to customize "the background" of a `Button`, but a `Button` really has several different background images for different circumstances (normal, pressed, focused, disabled, etc.). Android has a certain type of drawable resource that aggregates other drawable resources, indicating which of those other resources should be used in different circumstances (e.g., for a normal button use X, for a disabled button use Y).

In this chapter, we will explore these non-traditional types of "drawables" and how you can use them within your apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on basic resources and basic widgets.

Having read the chapters on animators and legacy animations would be useful.

Where Do These Things Go?

All of the drawables described in this chapter, unless otherwise noted, are density-independent. The best spot for them is in a `res/drawable-nodpi/` directory, indicating to Android that these resources should not be adjusted based upon density. However, since Android has no way to adjust them based upon density anyway, you are welcome to put these drawables in `res/drawable/` as well. `res/drawable/` is really a synonym for `res/drawable-mdpi/`, and so you should be careful when using it for bitmaps (PNG, JPEG, etc.), but for density-independent drawables, `res/drawable/` is safe.

ColorDrawable

The simplest XML drawable format, by far, is for `ColorDrawable`. Not surprisingly, this defines a `Drawable` that is a solid color.

So, you can have a `res/drawable/thing.xml` file, containing something like this:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="#80FF00FF"/>
```

From there, you can use `@drawable/thing` or `R.drawable.thing` in the same places that you would use any other drawable resource.

Note that a `ColorDrawable` is different than a color resource. A color resource (e.g., `res/values/colors.xml`) specifies a color. A `ColorDrawable` resource defines a `Drawable` of a color. A `ColorDrawable` resource is welcome to reference a color defined by a color resource, though:

```
<color xmlns:android="http://schemas.android.com/apk/res/android"
    android:color="@color/primary_dark"/>
```

AnimationDrawable

The original way of doing animation on the Web was via the animated GIF. An individual GIF file could contain many frames, and the browser would switch between those frames to display a basic animated effect. This was used by Web designers for things both good (animated progress “spinners”) and bad (“hit the monkey” ad banners).

Android, on the whole, does not support animated GIF files, certainly not as regular images for use with widgets like `ImageView`.

However, there are times where having this sort of frame-by-frame animation would be useful. For example, in another chapter, we will look at `ProgressBar`, which is Android's primary way of demonstrating progress of background work. You may wish to customize the "spinning wheel" image that Android uses by default, to match your app's color scheme, or to spin your company logo, or whatever. On the Web, particularly on older browsers, you might use an animated GIF for that — on Android, that is not an option.

An `AnimationDrawable`, though, *is* an option.

`AnimationDrawable` has the net effect of an animated GIF:

- You define a series of images that serve as the frames of the animation
- You define how long each of those images should be on the screen
- You define whether the animation should loop back to the beginning after it reaches the end or not

However, rather than encoding all of this in an animated GIF, you instead encode this information in an XML file, stored as a drawable resource.

XML-encoded drawable resources are typically stored in a drawable directory that does *not* contain density information, such as `res/drawable/`. That is because the XML-encoded drawable resources are density-invariant: they behave the same regardless of density. Those, like the `AnimationDrawable`, that refer to other images might well refer to other images that are stored in density-dependent resource directories, but the XML-encoded drawable itself is independent of density.

An `AnimationDrawable` is defined as in XML with a root `<animation-list>` element, containing a series of `<item>` elements for each frame:

```xml
<animation-list xmlns:android="http://schemas.android.com/apk/res/android"
    android:oneshot="true">
    <item android:drawable="@drawable/frame1" android:duration="250" />
    <item android:drawable="@drawable/frame2" android:duration="250" />
    <item android:drawable="@drawable/frame3" android:duration="250" />
    <item android:drawable="@drawable/frame4" android:duration="250" />
</animation-list>
```

The root <animation-list> element can have an android:oneshot attribute, indicating whether the animation should repeat after displaying the last frame (false) or stop (true).

The <item> elements have android:drawable attributes pointing to the individual images for the individual frames. Usually these frames are PNG or JPEG files, but you refer to them as drawable resources, using @drawable syntax, so Android can find the right image based upon the density (or other characteristics) of the current device. The <item> elements also need an android:duration attribute, specifying the time in milliseconds that this frame should be on the screen. While the above example has all durations the same, that is not required.

For example, the Android OS uses AnimationDrawable resources in a few places. One is for the download icon used in a Notification for use with DownloadManager and similar situations. That drawable resource – stat_sys_download.xml — looks like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/status_icon_background.xml
**
** Copyright 2008, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:oneshot="false">
    <item android:drawable="@drawable/stat_sys_download_anim0" android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim1" android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim2" android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim3" android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim4" android:duration="200" />
    <item android:drawable="@drawable/stat_sys_download_anim5" android:duration="200" />
</animation-list>
```

Here, we have a repeating animation (android:oneshot="false"), consisting of six frames, each on the screen for 200 milliseconds.

By specifying an AnimationDrawable in your Notification for its icon, you too can have this sort of animated effect. Of course, the animation is "fire and forget": other than by removing or replacing the Notification, you cannot affect the animation in any other way.

Animated GIF Conversion

It may be that you have an animated GIF that you would like to use as the basis for your AnimationDrawable. If you have passing familiarity with Ruby, the author of this book has published a Ruby script, named gif2animdraw, that automates the conversion.

To use gif2animdraw, in addition to the script itself and a Ruby interpreter, you will need the RMagick, slop, and builder gems. Note that RMagick, in turn, will require ImageMagick libraries and therefore is a bit more complicated to install than is your ordinary gem.

On Linux environments, you can also chmod the script to run it directly; otherwise, you would run it via the ruby command.

The script takes four command-line switches:

- -i should point to the GIF file to be converted
- -o should point to the root output directory, which typically would be a project's res/ directory
- -d should have, as a value, one of the Android density bucket names (e.g., hdpi); this will be used as the density for the frames of the GIF
- Optionally, include --oneshot to indicate that this should be a one-shot animation, not a repeating one

The results will be:

- A drawable/ directory underneath your supplied root, containing a file with the same name as the GIF file, but with a .xml extension, representing the AnimationDrawable itself
- A drawable-XXXX/ directory, where XXXX is your stated density, containing each frame of the animated GIF, as a PNG file, with a sequentially numbered filename based on the GIF's filename

Animated GIF Libraries

There are also a handful of third-party libraries that can load a GIF into an `ImageView` or make a GIF available as some form of `Drawable` to be applied elsewhere.

StateListDrawable

Another XML-defined drawable resource, the `StateListDrawable`, is key if you want to have different images when widgets are in different states.

As outlined in the introduction to this chapter, what makes a `Button` visually be a `Button` is its background. To handle different looks for the `Button` background for different states (normal, pressed, disabled, etc.), the standard `Button` background is a `StateListDrawable`, one that looks something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

     Licensed under the Apache License, Version 2.0 (the "License");
     you may not use this file except in compliance with the License.
     You may obtain a copy of the License at

          http://www.apache.org/licenses/LICENSE-2.0

     Unless required by applicable law or agreed to in writing, software
     distributed under the License is distributed on an "AS IS" BASIS,
     WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
     See the License for the specific language governing permissions and
     limitations under the License.
-->

<selector xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:state_window_focused="false" android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
    <item android:state_window_focused="false" android:state_enabled="false"
        android:drawable="@drawable/btn_default_normal_disable" />
    <item android:state_pressed="true"
        android:drawable="@drawable/btn_default_pressed" />
    <item android:state_focused="true" android:state_enabled="true"
        android:drawable="@drawable/btn_default_selected" />
    <item android:state_enabled="true"
        android:drawable="@drawable/btn_default_normal" />
    <item android:state_focused="true"
        android:drawable="@drawable/btn_default_normal_disable_focused" />
    <item
         android:drawable="@drawable/btn_default_normal_disable" />
</selector>
```

The XML has a <selector> root element, indicating this is a StateListDrawable. The <item> elements inside the root describe what Drawable resource should be used if the StateListDrawable is being used in some state. For example, if the "window" (think activity or dialog) does not have the focus (android:state_window_focused="false") and the Button is enabled (android:state_enabled="true"), then we use the @drawable/btn_default_normal Drawable resource. That resource, as it turns out, is a nine-patch PNG file, described later in this chapter.

Android applies each rule in turn, top-down, to find the Drawable to use for a given state of the StateListDrawable. The last rule has no android:state_* attributes, meaning it is the overall default image to use if none of the other rules match.

So, if you want to change the background of a Button, you need to:

- Copy the above resource, found in your Android SDK as res/drawable/btn_default.xml inside any of the platforms/ directories, into your project
- Copy each of the Button state nine-patch images into your project
- Modify whichever of those nine-patch images you want, to affect the visual change you seek
- If need be, tweak the states and images defined in the StateListDrawable XML you copied
- Reference the local StateListDrawable as the background for your Button

The backgrounds of most widgets that have backgrounds by default will use a StateListDrawable. Searching a platform version's res/drawable/ directory for XML files containing <selector> elements comes up with a rather long list.

ColorStateList

A ColorStateList is analogous to a StateListDrawable, in that it defines states and identifies what should be used for a given state. Whereas StateListDrawable ties states to drawables, ColorStateList ties states to colors. This allows you to, say, change the color of some text based upon whether that text is drawn in a widget that is being pressed, or has the focus, or is disabled. If you tailor the background of a text-based widget using a StateListDrawable, you may well wind up tailoring the foreground text using a ColorStateList.

While this chapter mentions ColorStateList, technically a ColorStateList is not a Drawable. You do not use it in methods that take drawables or in widget XML attributes that take drawables. Rather, there are other methods and other attributes that take a `ColorStateList`, such as `android:textColor`.

Similarly, while you can define a `ColorStateList` in XML, you do not do so in a `res/drawable/` resource directory, but rather a `res/color/` resource directory. Beyond that, though, a `ColorStateList` XML resource looks a lot like a `StateListDrawable` XML resource, such as this definition of `@android:color/primary_text_dark` from Android 4.4:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

     Licensed under the Apache License, Version 2.0 (the "License");
     you may not use this file except in compliance with the License.
     You may obtain a copy of the License at

          http://www.apache.org/licenses/LICENSE-2.0

     Unless required by applicable law or agreed to in writing, software
     distributed under the License is distributed on an "AS IS" BASIS,
     WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
     See the License for the specific language governing permissions and
     limitations under the License.
-->

<selector xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:state_enabled="false" android:color="@android:color/
bright_foreground_dark_disabled"/>
    <item android:state_window_focused="false" android:color="@android:color/
bright_foreground_dark"/>
    <item android:state_pressed="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
    <item android:state_selected="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
    <item android:state_activated="true" android:color="@android:color/
bright_foreground_dark_inverse"/>
    <item android:color="@android:color/bright_foreground_dark"/> <!-- not selected -->
</selector>
```

Based upon the state, the `ColorStateList` pulls in a separate resource to define the actual color. Those colors, in turn, are defined via `<color>` elements in `res/values/colors.xml` as color resources, or are pulled in from system-defined colors (`@android:color/...` syntax):

```
    <color name="background_dark">#ff000000</color>
    <color name="background_light">#ffffffff</color>
    <color name="bright_foreground_dark">@android:color/background_light</color>
    <color name="bright_foreground_light">@android:color/background_dark</color>
    <color name="bright_foreground_dark_disabled">#80ffffff</color>
    <color name="bright_foreground_light_disabled">#80000000</color>
    <color name="bright_foreground_dark_inverse">@android:color/
bright_foreground_light</color>
```

```
    <color name="bright_foreground_light_inverse">@android:color/
bright_foreground_dark</color>
```

LayerDrawable

A `LayerDrawable` basically stacks a bunch of other drawables on top of each other. Later drawables are drawn on top of earlier drawables, much as later children of a `RelativeLayout` are drawn on top of earlier children.

Typically, you will create a `LayerDrawable` via a `<layer-list>` XML drawable resource.

For example, a `ToggleButton` widget has a `LayerDrawable` as its background:

```
?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

     Licensed under the Apache License, Version 2.0 (the "License");
     you may not use this file except in compliance with the License.
     You may obtain a copy of the License at

          http://www.apache.org/licenses/LICENSE-2.0

     Unless required by applicable law or agreed to in writing, software
     distributed under the License is distributed on an "AS IS" BASIS,
     WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
     See the License for the specific language governing permissions and
     limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@+android:id/background" android:drawable="@android:drawable/
btn_default_small" />
    <item android:id="@+android:id/toggle" android:drawable="@android:drawable/
btn_toggle" />
</layer-list>
```

This `LayerDrawable` draws two images on top of each other. One is a standard small button background (`@android:drawable/btn_default_small`). The other is the actual face of the toggle itself — a `StateListDrawable` that uses different images for checked and unchecked states.

In the `<layer-list>`, you can have several `<item>` elements. Each `<item>` element usually will need an `android:drawable` attribute, pointing to the drawable that should be drawn. Optionally, you can assign ID values to the items via `android:id` attributes, much like you would do for widgets in a layout XML resource. Later on, you can call `findDrawableByLayerId()` on the `LayerDrawable` to retrieve an individual `Drawable` representing the layer, given its `android:id` value.

There are also `android:left`, `android:right`, `android:top`, and `android:bottom` attributes, which you can use to provide dimension values to offset an image within the layered set. For example, you could use `android:left` to inset one of the layers by a certain number of pixels (or `dp` or whatever).

By default, the layers in the `LayerDrawable` are scaled to fit the size of whatever `View` is holding them (e.g., the size of the `ToggleButton` using the `LayerDrawable` as a background). To prevent this, you can skip the `android:drawable` attribute, and instead nest a `<bitmap>` element inside the `<item>`, where you can provide an `android:gravity` attribute to control how the image should be handled relative to its containing `View`. We will get more into nested `<bitmap>` elements later in this chapter.

TransitionDrawable

A `TransitionDrawable` is a `LayerDrawable` with one added feature: for a two-layer drawable, it can smoothly transition from showing one layer to another on top.

For example, you may have noticed that when you tap-and-hold on a row in a `ListView` that the selector highlight has an animated effect, slowly shifting colors from the color used for a simple click to one signifying that you have long-clicked the row. Android accomplishes this via a `TransitionDrawable`, set up as a `<transition>` XML drawable resource:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2008 The Android Open Source Project

     Licensed under the Apache License, Version 2.0 (the "License");
     you may not use this file except in compliance with the License.
     You may obtain a copy of the License at

<transition xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:drawable="@android:drawable/list_selector_background_pressed"  />
    <item android:drawable="@android:drawable/list_selector_background_longpress"  />
</transition>
```

The TransitionDrawable object has a startTransition() method that you can use, that will have Android smoothly switch from the first drawable to the second. You specify the duration of the transition as a number of milliseconds passed to startTransition(). There are also options to reverse the transition, set up more of a cross-fade effect, and the like.

LevelListDrawable

A LevelListDrawable is similar in some respects to a StateListDrawable, insofar as one specific item from the "list drawable" will be displayed based upon certain conditions. In the case of StateListDrawable, the conditions are based upon the state of the widget using the drawable (e.g., checked, pressed, disabled). In the case of LevelListDrawable, it is merely an integer level.

For example, the status or system bar of your average Android device has an icon indicating the battery charge level. That is actually implemented as a LevelListDrawable, via an XML resource containing a root <level-list> element:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/* //device/apps/common/res/drawable/stat_sys_battery.xml
**
** Copyright 2007, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->

<level-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:maxLevel="4" android:drawable="@android:drawable/stat_sys_battery_0"
/>
    <item android:maxLevel="15" android:drawable="@android:drawable/
stat_sys_battery_15" />
    <item android:maxLevel="35" android:drawable="@android:drawable/
stat_sys_battery_28" />
    <item android:maxLevel="49" android:drawable="@android:drawable/
stat_sys_battery_43" />
    <item android:maxLevel="60" android:drawable="@android:drawable/
stat_sys_battery_57" />
    <item android:maxLevel="75" android:drawable="@android:drawable/
```

```
stat_sys_battery_71" />
    <item android:maxLevel="90" android:drawable="@android:drawable/
stat_sys_battery_85" />
    <item android:maxLevel="100" android:drawable="@android:drawable/
stat_sys_battery_100" />
</level-list>
```

This `LevelListDrawable` has eight items, whose `android:drawable` attributes point to specific other drawable resources (in this case, standard PNG files with different implementations for different densities). Each `<item>` has an `android:maxLevel` value. When someone calls `setLevel()` on the `Drawable` or `setImageLevel()` on the `ImageView`, Android will choose the item with the lowest `maxLevel` that meets or exceeds the requested level, and show that. In the case of the battery icon, when the battery level changes, the status bar picks up that change and calls `setImageLevel()` with the battery charge percentage (expressed as an integer from 0-100) — that, in turn, triggers the right PNG file to be displayed.

Another use of `LevelListDrawable` is with a `RemoteViews`, such as for an app widget. The `setImageLevel()` method is "remotable", despite not being directly part of the `RemoteViews` API. Hence, given that you use a `LevelListDrawable` in your app widget's layout, you should be able to use `setInt()` with a method name of `"setImageLevel"` to have the app widget update to display the proper image.

ScaleDrawable and ClipDrawable

A `ScaleDrawable` does pretty much what its name suggests: it scales another drawable. A `ClipDrawable` does pretty much what *its* name suggests: it clips another drawable.

How they do this, and how you control it, requires a bit more explanation.

Like `LevelListDrawable`, `ScaleDrawable` and `ClipDrawable` leverage the `setLevel()` method on `Drawable` (or the `setImageLevel()` method on `ImageView`). Whereas `LevelListDrawable` uses this to choose an individual image out of a set of possible images, `ScaleDrawable` and `ClipDrawable` use the level to control how much an image should be scaled or clipped. For this, they support a range of levels from 0 to 10000.

Scaling

For a level of 0, `ScaleDrawable` will not draw anything. For a level from 1 to 10000, `ScaleDrawable` will scale an image from a configurable minimum size to the bounds of the `View` to which the drawable is applied.

The amount of scaling is determined by `android:scaleHeight` and `android:scaleWidth` attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<scale xmlns:android="http://schemas.android.com/apk/res/android"
  android:drawable="@android:drawable/btn_default"
  android:scaleGravity="left|top"
  android:scaleHeight="50%"
  android:scaleWidth="50%"/>
```

The above `ScaleDrawable` (denoted by the `<scale>` root element) says that we should scale both height and width of the underlying drawable to 50% of the available space for the drawable, when the level is at its maximum (10000).

Note that you do not have to scale along both dimensions. If, for example, you kept `android:scaleWidth` but deleted `android:scaleHeight`, `setImageLevel()` would control the scaled width of the underlying image (provided via `android:drawable`) but not the height.

The `android:scaleGravity` attribute indicates where the scaled image should reside within the available space (the 10000 level, determined by the bounds of the `View` to which the drawable is applied). The value shown above, `center`, keeps the image centered within the available space, and shrinks or expands it around the center. A value of `left|top` would keep the image in the upper-left corner of the space, having the visual effect of moving the lower-right corner based upon the supplied level.

Clipping

Scaling proportionally reduces the height and/or width of an image. Clipping, on the other hand, chops off part of the height or width of the image.

```
<clip xmlns:android="http://schemas.android.com/apk/res/android"
  android:clipOrientation="horizontal"
  android:drawable="@drawable/btn_default_normal"
  android:gravity="left"/>
```

In this sample `ClipDrawable` (indicated by the `<clip>` root element), we are going to allow the level to chop off part of the image indicated by the `android:drawable` attribute. Our `android:clipOrientation`, set to `horizontal`, means we are going to chop off part of the width (`vertical` would have us chop off part of the height). The amount that is going to be chopped off is the level you supply (e.g., `setImageLevel()`) divided by 10000. Hence, a level of 5000 will chop off 0.5 (a.k.a., 50%) of the image.

Where in the image the clipping occurs is determined by the `android:gravity` attribute. An `android:clipOrientation` of `horizontal` and an `android:gravity` of `left`, as in the sample drawable above, means that the left side of the image is retained, and the image will be clipped on the right. Specifying `right` instead of `left` would reverse that, clipping the image from the right, while `center` would clip equally from both sides. There are other gravity values as well, such as `top` and `bottom` values to be used with a `vertical` orientation.

Seeing It In Action

To see these effects, take a look at the `Drawable/ScaleClip` sample project. This is derived from an earlier example showing how to use `ViewPager` with `PagerTabStrip`. In that example, we had 10 tabs, each being a large `EditText` widget. In this example, we have 2 tabs, "Scale" and "Clip", both using the same layout:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ImageView
    android:id="@+id/image"
    android:layout_width="150dp"
    android:layout_height="150dp"
    android:layout_centerHorizontal="true"
    android:layout_marginTop="20dp"
    android:scaleType="fitXY"/>

  <SeekBar
    android:id="@+id/level"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:layout_marginBottom="20dp"
    android:layout_marginLeft="20dp"
    android:layout_marginRight="20dp"
    android:max="10000"
    android:progress="10000"/>

</RelativeLayout>
```

This is simply a `150dp` square `ImageView` towards the top of the screen and a `SeekBar` towards the bottom of the screen. The `SeekBar` will be used to control the level applied to a ScaleDrawable and ClipDrawable, which is why we have android:max set to 10000. We also have our "progress" (original SeekBar value) set to 10000, so the bar's thumb will be fully slid over to the right at the outset.

The fragments that we will use for the tabs both inherit from a common abstract FragmentBase class:

```
package com.commonsware.android.scaleclip;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.SeekBar;

abstract public class FragmentBase extends Fragment implements
    SeekBar.OnSeekBarChangeListener {
  abstract void setImageBackground(ImageView image);

  private ImageView image=null;

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    setRetainInstance(true);

    View result=inflater.inflate(R.layout.scaleclip, container, false);
    SeekBar bar=((SeekBar)result.findViewById(R.id.level));

    bar.setOnSeekBarChangeListener(this);
    image=(ImageView)result.findViewById(R.id.image);
    setImageBackground(image);
    image.setImageLevel(bar.getProgress());

    return(result);
  }

  @Override
  public void onProgressChanged(SeekBar seekBar, int progress,
                                boolean fromUser) {
    image.setImageLevel(progress);
  }

  @Override
  public void onStartTrackingTouch(SeekBar seekBar) {
    // no-op
  }

  @Override
  public void onStopTrackingTouch(SeekBar seekBar) {
    // no-op
  }
}
```

In `onCreateView()`, we inflate the above layout file, hook up the fragment itself to be the listener for `SeekBar` change events, call the subclass' `setImageBackground()` method to populate the `ImageView` with an image, and set the `ImageView`'s level to be the initial value of the `SeekBar`. When the `SeekBar` value changes, our `onProgressChanged()` method will adjust the level.

The concrete subclasses — `ScaleFragment` and `ClipFragment` — simply populate the `ImageView` with the `ScaleDrawable` and `ClipDrawable` resources shown earlier in this section:

```
package com.commonsware.android.scaleclip;

import android.widget.ImageView;

public class ScaleFragment extends FragmentBase {
  @Override
  void setImageBackground(ImageView image) {
    image.setImageResource(R.drawable.scale);
  }
}
```

```
package com.commonsware.android.scaleclip;

import android.widget.ImageView;

public class ClipFragment extends FragmentBase {
  @Override
  void setImageBackground(ImageView image) {
    image.setImageResource(R.drawable.clip);
  }
}
```

Those two drawables based their scaling and clipping on `res/drawable-xdpi/btn_default_normal.9.png`. This is a slightly-modified copy of the default button background, and is a nine-patch PNG file. We will discuss nine-patch PNG files later in this chapter — suffice it to say for now that it is a PNG file with rules about how it should be stretched.

Our scale tab starts off showing the full image:

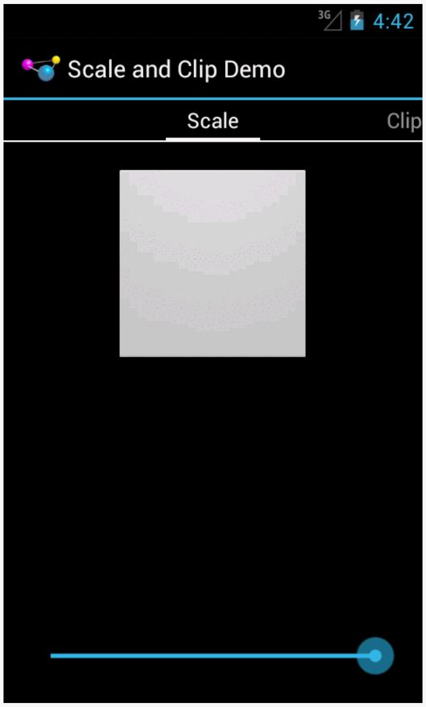

Figure 495: ScaleDrawable, Level of 10000

As we start sliding the `SeekBar` thumb to the left, the image shrinks progressively:

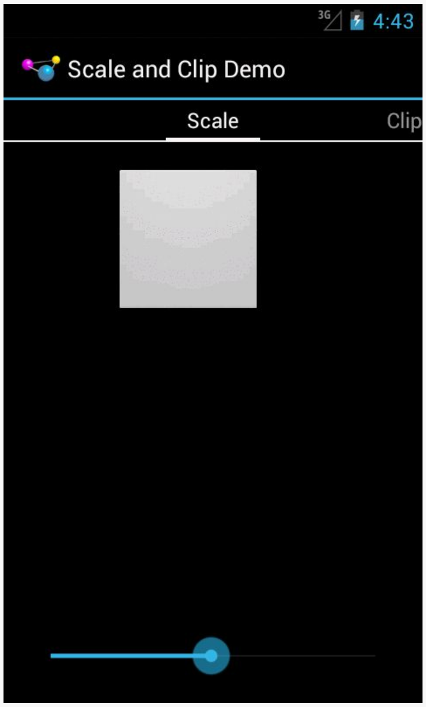

Figure 496: ScaleDrawable, Level of Approximately 5000

It eventually tends towards the 50% level specified in our `android:scaleHeight` and `android:scaleWidth` values:

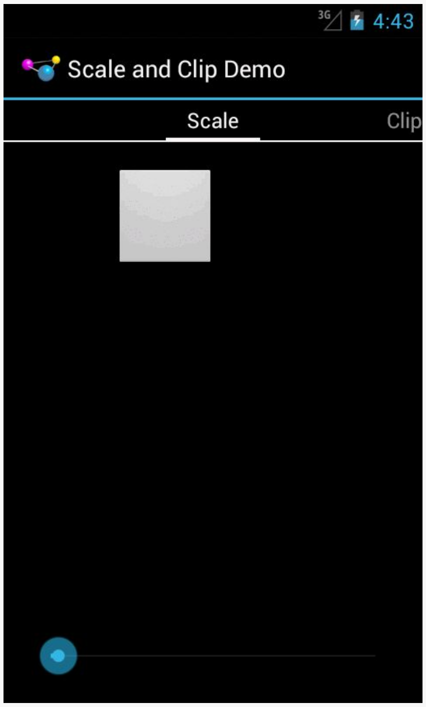

Figure 497: ScaleDrawable, Level of Approximately 100

Sliding it all the way to the left, though, causes the image to vanish.

The `ClipDrawable` starts off looking much like the `ScaleDrawable`:

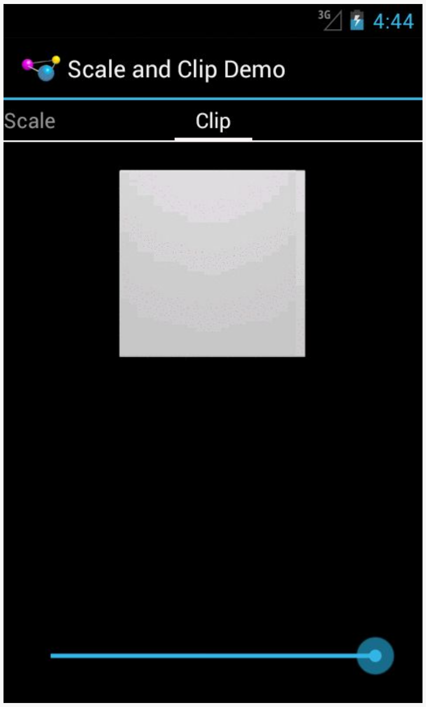

Figure 498: ClipDrawable, Level of 10000

As we slide the `SeekBar` to the left, the right side of the image gets clipped:

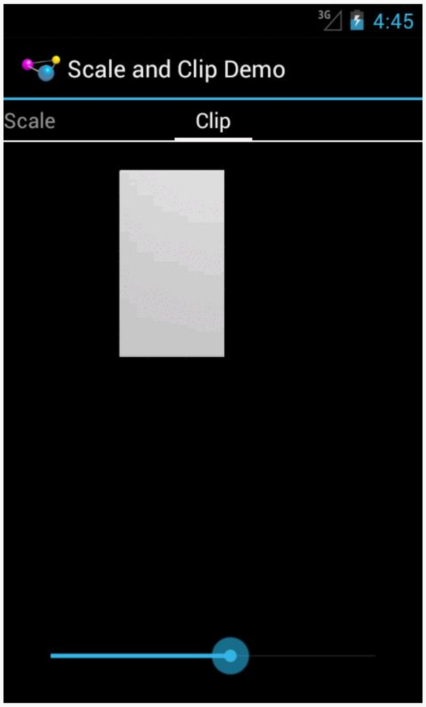

Figure 499: ClipDrawable, Level of Approximately 5000

InsetDrawable

An `InsetDrawable` allows you to apply insets on any side (or all sides) of some other drawable resource. The use case cited in the documentation is "This is used when a View needs a background that is smaller than the View's actual bounds". However, at the present time, nothing in the Android open source code uses this particular type of resource, or even the Java class.

In principle, though, you could have an XML drawable resource that looked like this:

```xml
<?xml version="1.0" encoding="utf-8"?>
<inset xmlns:android="http://schemas.android.com/apk/res/android"
    android:drawable="@drawable/something_or_another"
    android:insetLeft="20dp"
    android:insetTop="10dp" />
```

When used as the background for some `View`, for example, Android would pull in the `something_or_another` resource and effectively add `20dp` of left margin and `10dp` of top margin on the background when calculating its size and drawing it on the screen.

Vectors

Android 5.0 added native support for a `VectorDrawable`, which uses the SVG path specification to represent vector art. However, unless your `minSdkVersion` was 21 or higher, vector drawable resources were not that useful, as there was no good way to support the same artwork on older devices. You could somehow arrange to have PNGs for the same artwork, but then, why bother with the vector artwork in the first place?

Nowadays, vector drawable resources are more practical. Not only do more devices run Android 5.0+, but we have better tool support. Android Studio offers a Vector Asset wizard that helps you add vector drawable resources to your project, and the build system will automatically generate PNG files at various densities to be used on older devices.

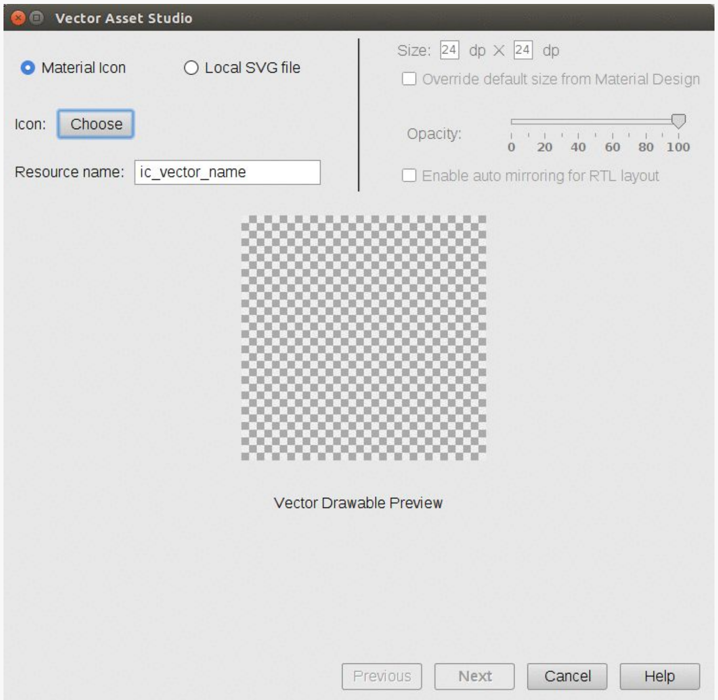
Getting the Artwork

You have two major sources of vector drawable artwork: XML files already in the vector drawable XML format, or SVG files that you wish to convert to vector drawable XML format. Since writing the vector drawable XML by hand will be difficult at best, most vector drawable XML will start from an SVG file. Whether you do the conversion, or whether somebody else did the conversion for you, is the major difference.

For SVG that you wish to try to convert to vector drawable XML, the simpler the SVG is, the more likely it is that you will have success. In particular, SVG features like gradients and patterns are not supported. The apparent vision is for vector drawable artwork to be used mostly for things like action bar icons, where things like gradients and patterns are not necessary.

Android Studio Vector Asset Wizard

The primary way most developers will get vector drawable XML into their projects is via the Android Studio Vector Asset wizard. You can bring this up by right-clicking over the `res/` directory of your desired sourceset, and choosing New > Vector Asset from the context menu:



Vector Asset Studio

● Material Icon ○ Local SVG file

Icon: Choose

Resource name: ic_vector_name

Size: 24 dp × 24 dp

□ Override default size from Material Design

Opacity: 0 20 40 60 80 100

□ Enable auto mirroring for RTL layout

Figure 500: Android Studio Vector Asset Wizard

You need to select either a material icon (via the "Choose" button), or a local SVG file (by toggling that radio button, then selecting the path to the image file). The "material icon" option gives you pre-fabricated vector drawable resources, culled from Google's offical roster of Material Design icons:

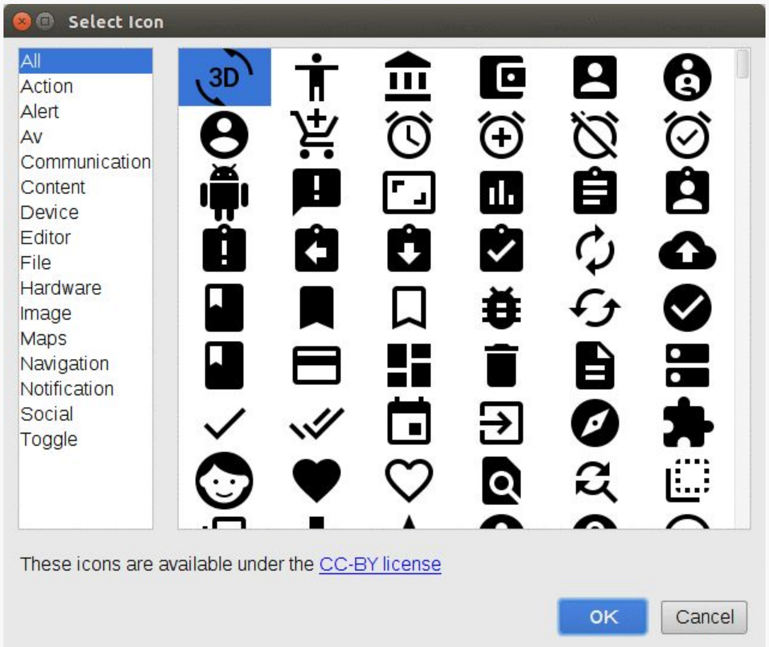


Figure 501: Android Studio Vector Asset Wizard, Material Icon Selector

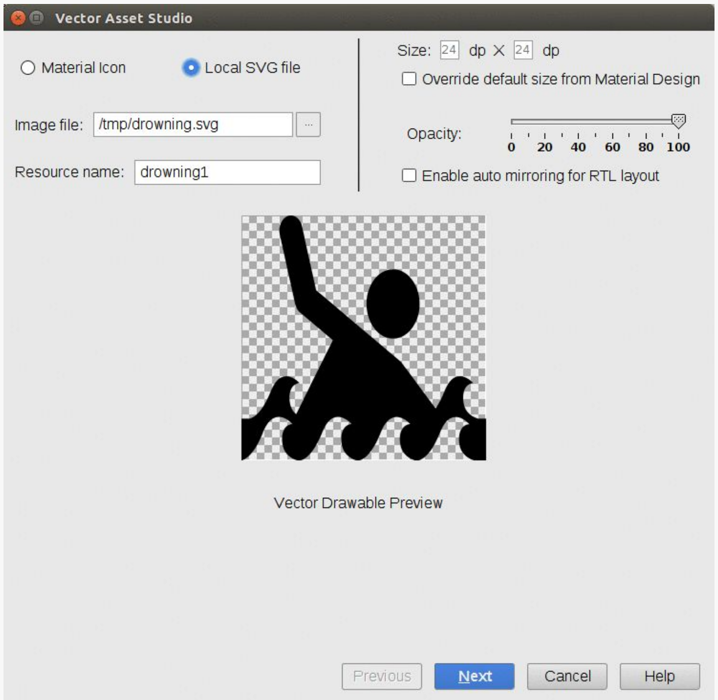
Whatever you load in will show up in the preview area in the center of the dialog:



○ Material Icon ● Local SVG file

Image file: /tmp/drowning.svg

Resource name: drowning1

Size: 24 dp × 24 dp

□ Override default size from Material Design

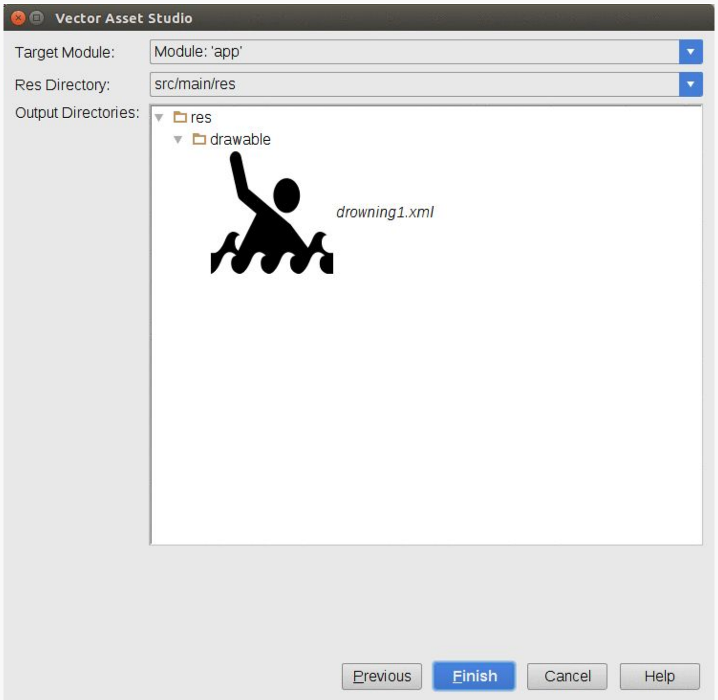
□ Enable auto mirroring for RTL layout

Figure 502: Android Studio Vector Asset Wizard, Showing Imported SVG

By default, the Vector Asset wizard is trying to make action bar icon-sized images, 24dp square. You can override this by checking the "Override default size from Material Design" checkbox and specifying your own size. The opacity slider allows you to indicate whether non-transparent pixels should be translucent (value from 0-99) or solid (100). If the image contains text or otherwise needs to be inverted for RTL languages, there is a checkbox to enable auto-mirroring support for that.

Also note that you can define the resource name, below where you chose the icon or SVG file. When importing an SVG file, by default, the resource name will be the same as the base name of the SVG file… even if this is an invalid resource name. Be sure to modify this to some unique, valid resource name before proceeding in the wizard.

Clicking the "Next" button brings up a confirmation screen, where you can also change the module and sourceset if you perhaps brought up the wizard in the wrong spot:



Vector Asset Studio

Target Module: Module: 'app'

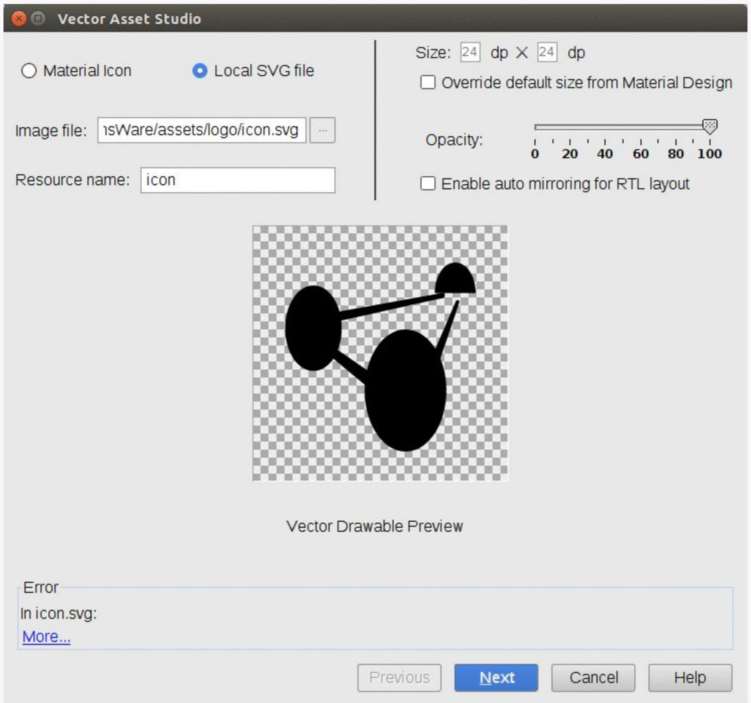
Res Directory: src/main/res

Output Directories:

Figure 503: Android Studio Vector Asset Wizard, Confirmation Screen

Clicking Finish will import the resource and add it to `res/drawable/` in your project. When you build your project, if your `minSdkVersion` is below 21, the Android Plugin for Gradle will generate PNG files to be used for those older devices. Note that these generated PNG files show up in your `build/` tree, not as part of your project source code.

The preview shown in the wizard should give you an indication if your SVG is being imported properly:



Vector Asset Studio

○ Material Icon ● Local SVG file

Image file: ısWare/assets/logo/icon.svg

Resource name: icon

Size: 24 dp × 24 dp

☐ Override default size from Material Design

Opacity:

☐ Enable auto mirroring for RTL layout

Vector Drawable Preview

Error

In icon.svg:

More...

Figure 504: Android Studio Vector Asset Wizard, Showing Failed SVG Import

However, even if the preview turned out OK, be sure to test your app, both on Android 5.0+ and (if relevant) Android 4.4-and-older devices, to ensure that your artwork looks the way you want it to.

Other Tools

Juraj Novák maintains a separate Android SVG to vector drawable XML converter as a Web page. If you are running into problems with the Vector Asset wizard's import support, you might consider trying this site. It may give you better vector drawables directly, and it definitely gives you more indications about *why* your SVG may not convert properly.

Using the Artwork

You use vector drawable resources the same way that you use any other drawable resource. Under the covers, the Java class that handles rendering the artwork is `VectorDrawable`… on Android 5.0+. Older devices will wind up using the PNG bitmaps generated by the build process.

VectorDrawable Backports

There is no official backport of `VectorDrawable` available in the Android Support set of libraries. There had been signs that Google was going to release a `VectorDrawableCompat`, but that code has since been removed from the official AOSP Git repositories.

There are at least three independent backports, though, that you can try if you want to use the vector artwork directly on the older devices, rather than use PNGs generated from that vector artwork:

- https://github.com/wnafee/vector-compat
- https://github.com/a-student/BetterVectorDrawable
- https://github.com/telly/MrVector

The last one was marked as deprecated, as the author expected Google to release their own backport. It is unclear if that project will resume.

ShapeDrawable

`ShapeDrawable` is the original approach to implementing limited vector art on Android. It gives you what amounts to a very tiny subset of SVG, for creating simple vector art shapes.

The root element of a `ShapeDrawable` resource is `<shape>`, which may have child elements, along with attributes, to configure what gets rendered on the screen when the drawable is applied.

This section will review the elements and attributes available to you, with sample drawables (and screenshots) culled from the [`Drawable/Shape`]() sample project.

This is a “sampler” project, designed to depict a number of `ShapeDrawables`. To accomplish this, we will use action bar tabs. Our activity (`MainActivity`) has a pair of static `int` arrays, one pointing at string resources to use for tab captions, the other pointing at corresponding drawable resources:

```
package com.commonsware.android.shape;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.widget.ImageView;

public class MainActivity extends Activity implements TabListener {
  private static final int TABS[]= { R.string.solid, R.string.gradient,
      R.string.border, R.string.rounded, R.string.ring,
      R.string.layered };
  private static final int DRAWABLES[]= { R.drawable.rectangle,
      R.drawable.gradient, R.drawable.border, R.drawable.rounded,
      R.drawable.ring, R.drawable.layered };
  private ImageView image=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    image=(ImageView)findViewById(R.id.image);

    ActionBar bar=getActionBar();
    bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

    for (int i=0; i < TABS.length; i++) {
      bar.addTab(bar.newTab().setText(getString(TABS[i]))
                    .setTabListener(this));
    }
  }

  @Override
  public void onTabSelected(Tab tab, FragmentTransaction ft) {
    image.setImageResource(DRAWABLES[tab.getPosition()]);
  }

  @Override
  public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
  }

  @Override
  public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
  }
}
```

In `onCreate()`, we toggle the `ActionBar` into tab-navigation mode, then iterate over the arrays and add one tab per element.

Our layout is an `ImageView`, named `image`, centered on the screen, taking up 80% of the horizontal space, plus has `20dp` of top and bottom margin:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/LinearLayout1"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="horizontal"
  android:gravity="center"
  android:weightSum="10">

    <ImageView
      android:id="@+id/image"
      android:src="@drawable/rectangle"
      android:layout_width="0dp"
      android:layout_height="match_parent"
      android:layout_marginTop="20dp"
      android:layout_marginBottom="20dp"
      android:layout_gravity="center"
      android:layout_weight="8"/>

</LinearLayout>
```

In our activity's `onTabSelected()` — implemented because the activity is the `TabListener` for our tabs — we get the position of our tab and fill in the appropriate drawable into the `ImageView`.

Given that, let's take a look at how to construct a `ShapeDrawable`, along with some sample drawables.

<shape>

Your root element, not surprisingly, is `<shape>`.

The primary thing that you will define on the `<shape>` element is the redundantly-named `android:shape` attribute, to define what sort of shape you want:

- `line` (a shape with no interior)
- `oval` (also for ellipses)
- `rectangle` (including rounded rectangles)
- `ring` (for partially-filled circles)

There are some other attributes available on `<shape>` for a `ring`, which we will examine later in this chapter.

<solid>

Your shape will usually require some sort of fill, to say what color goes in the shape. There are two types of fills: solid and gradient.

For a solid fill, add a `<solid>` child element to the `<shape>`, with an `android:color` attribute indicating what color to use. As with most places in Android, this can either be a literal color or a reference to a color resource.

So, for example, we can specify a solid red rectangle as:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
  android:shape="rectangle">
  <solid android:color="#FFAA0000"/>
</shape>
```

This gives us the following visual result:

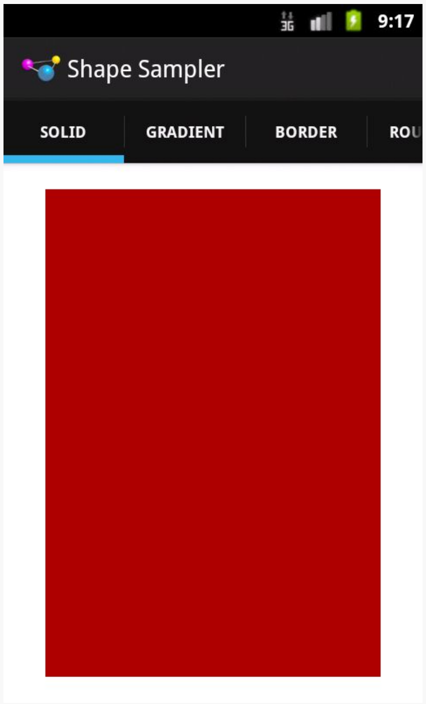


Figure 505: ShapeDrawable, Solid Red Rectangle

<gradient>

Your alternative fill is a gradient. The nice thing about gradients with `ShapeDrawable` is that they are generated at runtime from the specifications in the `ShapeDrawable`, and therefore will be smooth. Gradients that appear in PNG files and the like, if stretched, will tend to have a banding effect.

Gradient fills are defined via a `<gradient>` child element of the `<shape>` element.

The simplest way to set up a gradient is to use three attributes:

- `android:startColor` and `android:endColor`, to specify the starting and ending colors of the gradient, respectively, and
- `android:angle`, to specify what direction the gradient "flows" in

The angle must be a multiple of 45 degrees. 0 degrees is left-to-right, 90 degrees is bottom-to-top, 180 degrees is right-to-left, and 270 degrees is top-to-bottom.

So, for example, we could change our rectangle to have a gradient fill, from red to blue, with red at the top, via:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
  android:shape="rectangle">

  <gradient
    android:angle="270"
    android:endColor="#FF0000FF"
    android:startColor="#FFFF0000"/>

</shape>
```

That gives us:

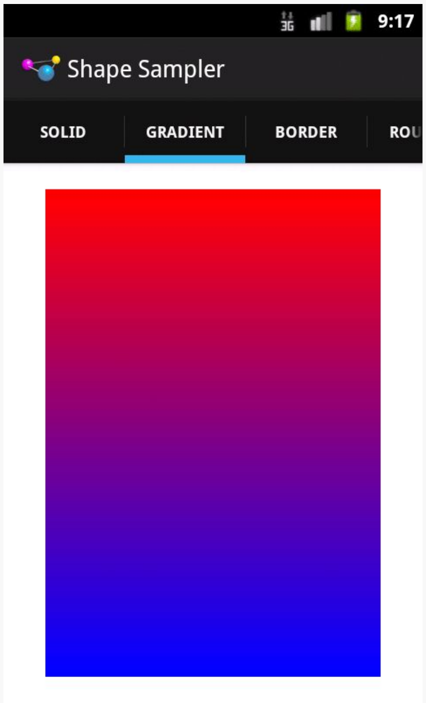

Figure 506: ShapeDrawable, Gradient Fill Rectangle

We will examine some other gradient options in the section on rings, later in this chapter.

<stroke>

If you want a separate color for a border around your shape, you can use the `<stroke>` element, as a child of the `<shape>` element, to configure one.

There are four attributes that you can declare. The two that you will probably always use are `android:color` (to indicate the color of the border) and `android:width` (to indicate the thickness of the border). By default, using just those two will give you a solid line around the edge of your shape.

If you would prefer a dashed border, you can add in `android:dashWidth` (to indicate how long each dash segment should be) and `android:dashGap` (to indicate how long the gaps between dash segments should be).

So, for example, we can add a dashed border to our gradient rectangle via a suitable `<stroke>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
  android:shape="rectangle">

  <gradient
    android:angle="270"
    android:endColor="#FF0000FF"
    android:startColor="#FFFF0000"/>

  <stroke
    android:width="2dp"
    android:dashGap="4dp"
    android:dashWidth="20dp"
    android:color="#FF000000"/>

</shape>
```

This gives us:

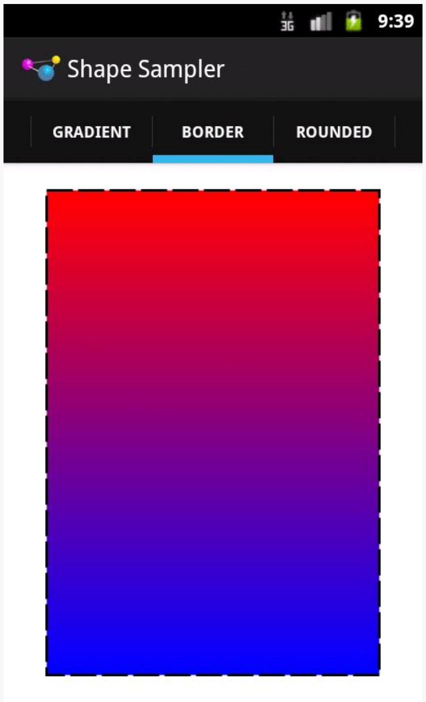

Figure 507: ShapeDrawable, Gradient Fill Rectangle with Dashed Border

<corners>

If we are implementing a `rectangle` shape, but we really want it to be a rounded rectangle, we can add a `<corners>` element as a child of the `<shape>` element. You can specify the radius to apply to the corners, either for all corners (e.g., `android:radius`), or for individual corners (e.g., `android:topLeftRadius`). Here, "radius" basically means the size of the circle that should implement the corner, where a radius of `0dp` would indicate the default square corner.

So, if we wanted to add rounded corners to our gradient-filled, dash-outlined rectangle, we could use this:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
  android:shape="rectangle">

  <gradient
    android:angle="270"
    android:endColor="#FF0000FF"
    android:startColor="#FFFF0000"/>

  <stroke
    android:dashGap="4dp"
    android:dashWidth="20dp"
    android:width="2dp"
    android:color="#FF000000"/>

  <corners android:radius="8dp"/>

</shape>
```

This gives us the following:

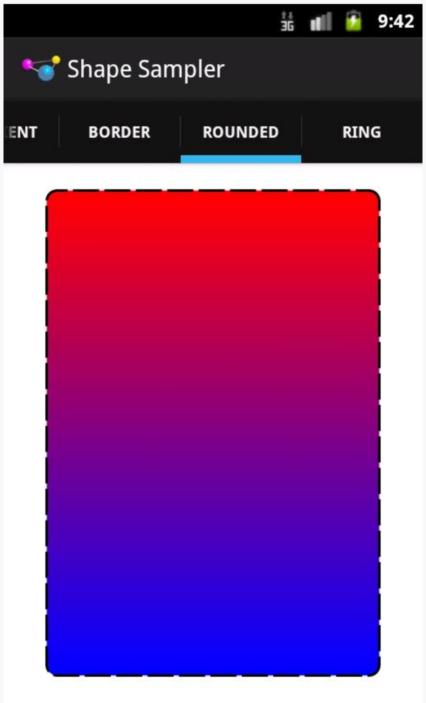

Figure 508: ShapeDrawable, Gradient Fill Rounded Rectangle with Dashed Border

<padding> and <size>

There are also `<padding>` and `<size>` elements that you can add, that specify padding to put on the various sizes and the overall size of the drawable. More often than not, you would actually handle this on the `ImageView` or other widget that is using your drawable, but if you would prefer to define those things in the drawable itself, you are welcome to do so.

Put a Ring On It

Rings are a bit more complicated, in large part because they are not completely filled. With a ring, the "fill" is filling what goes in the ring itself, not the "hole" in the center of the ring. This means that we need to teach Android more about how that "hole" is supposed to be set up.

To do that, we need to provide two pieces of information:

1. How big the inner radius should be, where by "inner radius" Android means "the radius of the hole"
2. How thick the ring should be

The ring will then be drawn based upon that inner radius and thickness.

You might wonder, "well, where does the size of the actual drawable come into play?" After all, if we specify an inner radius of 20dp and a thickness of 10dp, that would give us an outer radius of 30dp, for a total width of 60dp… regardless of how big the actual drawable is.

And that is completely correct.

However, for both the inner radius and the thickness, you have two choices of how to specify their values:

1. As actual sizes (dimensions or references to dimension resources)
2. As ratios to the overall drawable width (defined by <size> or the widget that is using the drawable)

This gives us four total attributes to choose from, to be placed on the <shape> element for ring drawables:

1. android:innerRadius
2. android:innerRadiusRatio
3. android:thickness
4. android:thicknessRatio

Therefore, if you want the ring's size to be based on the size of the drawable, you would use innerRadiusRatio, thicknessRatio, or both.

The other thing about rings is that they are round. Hence, a default linear gradient fill — going from one side of the drawable to another – may not be what you really want. You can control the type of gradient fill to use via the android:type attribute on the <gradient> element. There are three possible values:

1. linear (the default behavior)
2. radial, where the gradient starts from the center (or another point that you define) and changes color from that center to the edges
3. sweep, where the gradient revolves clockwise in a circle, starting from whatever android:angle you specify (or 0, meaning "east", as the default)

So, for example, take a look at the following ShapeDrawable:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
```

```
  android:innerRadiusRatio="3"
  android:shape="ring"
  android:thickness="15dp"
  android:useLevel="false">

  <gradient
    android:centerColor="#4c737373"
    android:endColor="#ff9933CC"
    android:startColor="#4c737373"
    android:type="sweep"/>

</shape>
```

Here, we:

- Declare that our shape is a `ring`
- Indicate that the distance between the inner radius and the outer radius of the ring should be `15dp`
- Indicate that there is a 3:1 ratio between the width of the image and the radius of the "hole" in the ring
- Indicate that the fill should be a gradient that sweeps clockwise from the default angle of 0
- Indicate that the first half of the gradient (start to center) should remain a constant color
- Indicate that the second half of the gradient (center to end) should change color from gray to purple

We also have `android:useLevel="false"` in the `<shape>` element. For unknown reasons, this is required for rings but not for other types of shapes.

This gives us:

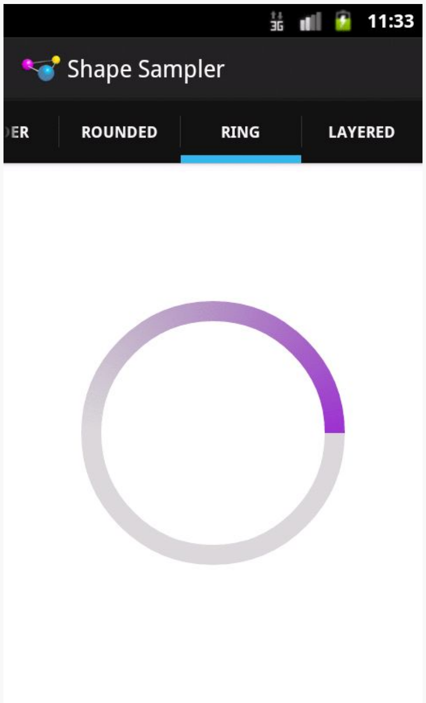

Figure 509: ShapeDrawable, Ring with Gradient Fill

VectorDrawable

Android 5.0 introduced `VectorDrawable`, an expansion upon the `ShapeDrawable` concept that supports SVG-style path structures for drawing arbitrary lines, shapes, etc. Android 5.0 also has `AnimatedVectorDrawable`, which animates transitions of a `VectorDrawable`. If you have seen an Android 5.0+ device "morph" the nav drawer icon (the "hamburger") into a leftward-facing arrow and back again, that is an `AnimatedVectorDrawable`.

While Google has not shipped a backport of this, [the MrVector library]() offers one. There are also sites, like [svg2android](), that can help you convert an SVG file into a `VectorDrawable` resource.

BitmapDrawable

Having an XML drawable format named `BitmapDrawable` may seem like a contradiction in terms. However, `BitmapDrawable` is not an XML representation of a bitmap, but rather an XML representation of operations to perform on an actual bitmap.

The big thing that `BitmapDrawable` offers is `android:tileMode`, which turns a single bitmap into a repeating bitmap. The bitmap is tiled, horizontally and vertically, using a tiling mode that you specify.

This is demonstrated in the [`Drawable/TileMode`]() sample project.

Our activity's layout is just a `LinearLayout`, set to fill the screen:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/widget"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="horizontal">

</LinearLayout>
```

Our activity populates action bar tabs, where it applies a particular background image to the `LinearLayout` (known as `R.id.widget`) based on the selected tab:

```
package com.commonsware.android.tilemode;

import android.app.ActionBar;
import android.app.ActionBar.Tab;
import android.app.ActionBar.TabListener;
import android.app.Activity;
import android.app.FragmentTransaction;
import android.os.Bundle;
import android.view.View;

public class MainActivity extends Activity implements TabListener {
  private static final int TABS[]= { R.string._default, R.string.clamp,
      R.string.repeat, R.string.mirror };
  private static final int DRAWABLES[]= { R.drawable._default,
      R.drawable.clamp, R.drawable.repeat, R.drawable.mirror };
  private View widget=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    widget=findViewById(R.id.widget);

    ActionBar bar=getActionBar();
    bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

    for (int i=0; i < TABS.length; i++) {
      bar.addTab(bar.newTab().setText(getString(TABS[i]))
                    .setTabListener(this));
    }
  }

  @Override
  public void onTabSelected(Tab tab, FragmentTransaction ft) {
    widget.setBackgroundResource(DRAWABLES[tab.getPosition()]);
  }

  @Override
  public void onTabUnselected(Tab tab, FragmentTransaction ft) {
    // no-op
  }

  @Override
  public void onTabReselected(Tab tab, FragmentTransaction ft) {
    // no-op
  }
}
```

The `res/drawable/_default.xml` resource, used on the first tab, is an unadorned `BitmapDrawable` resource, where our `<bitmap>` element simply has an `android:src` attribute pointing to a bitmap to be used for this `BitmapDrawable`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"/>
```

Since we have not specified a tile mode, the image is stretched to fill the size of our `LinearLayout` when serving as its background:

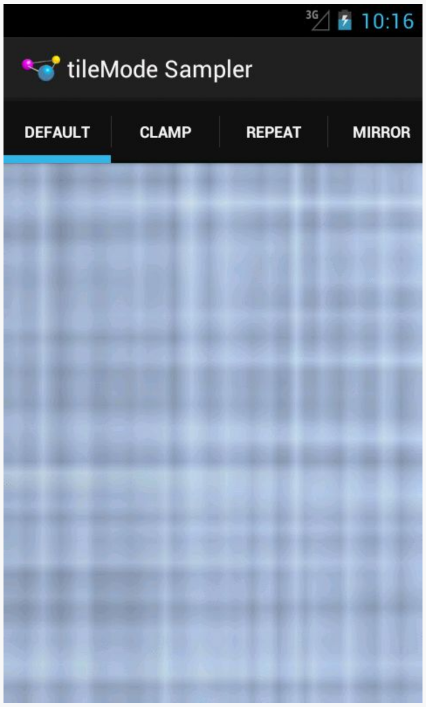

Figure 510: BitmapDrawable, Without android:tileMode

The `res/drawable/clamp.xml` resource, used on the second tab, adds `android:tileMode="clamp"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="clamp"/>
```

This causes the right-most column of pixels and the bottom-most column of pixels to be repeated to fill the available space:

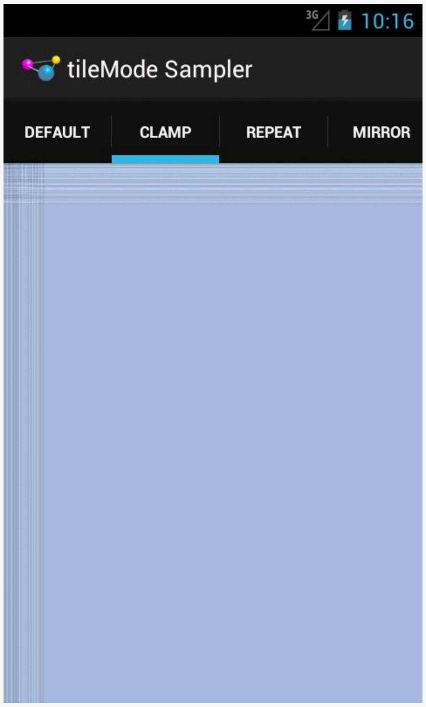

Figure 511: BitmapDrawable, Clamped

Zooming in on the upper-left portion of our `LinearLayout` demonstrates this:

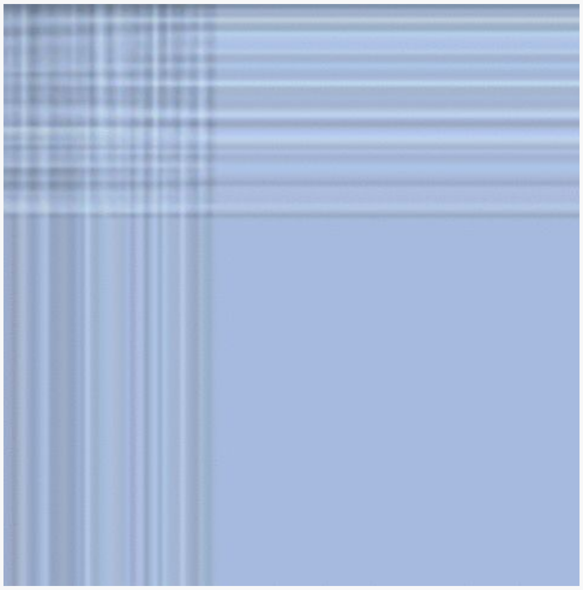

Figure 512: Portion of BitmapDrawable, Clamped

The `res/drawable/repeat.xml` resource, used on the third tab, employs `android:tileMode="repeat"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="repeat"/>
```

Here, the image is simply repeated *in toto* to fill the available space, rather than only its lower-right edges:

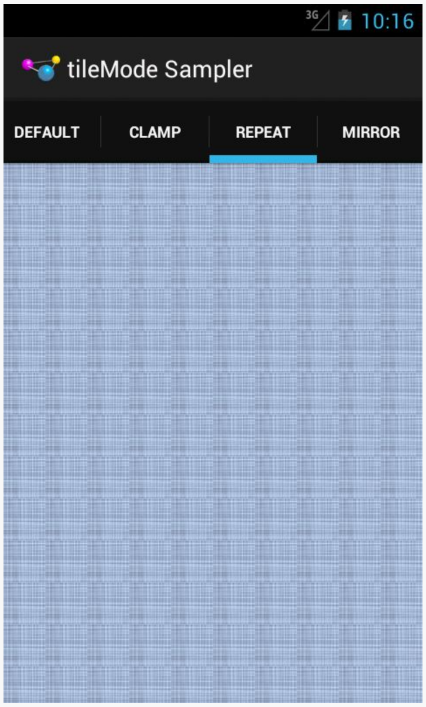

Figure 513: BitmapDrawable, Repeated

Zooming in on an arbitrary chunk of the `LinearLayout` shows this effect:

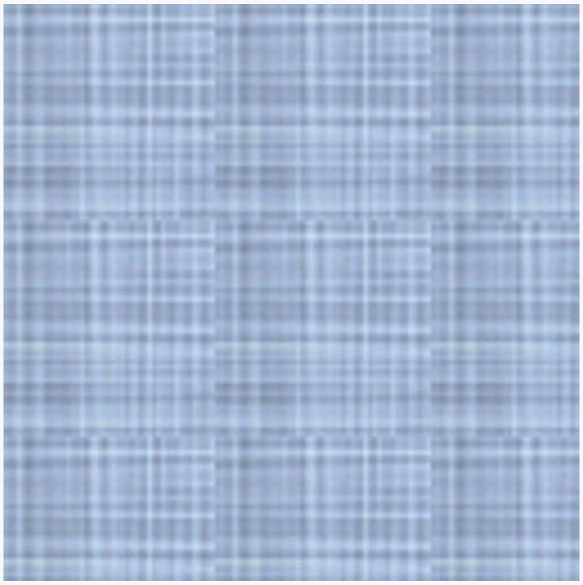

Figure 514: Portion of BitmapDrawable, Repeated

The `res/drawable/mirror.xml` resource, used on the fourth tab, uses `android:tileMode="mirror"`:

```
<bitmap xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/hatch"
  android:tileMode="mirror"/>
```

Here, the image is repeated, but alternately mirrored along the repeating axis. So, it is flipped horizontally for each repeat along the horizontal axis, and it is flipped vertically for each repeat along the vertical axis:

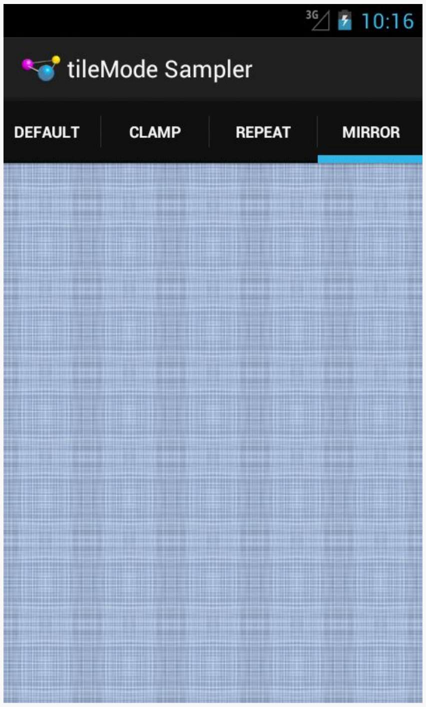

Figure 515: BitmapDrawable, Mirrored

Zooming in on an arbitrary chunk of the `LinearLayout` shows this effect:

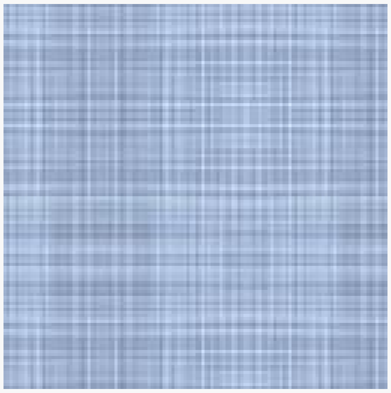

Figure 516: Portion of BitmapDrawable, Mirrored

Composite Drawables

Let’s say that we wanted to have a pair of `ShapeDrawable` images, one superimposed on another. Since a single `ShapeDrawable` defines only one shape, we would need something else to assist with stacking the images.

One possibility would be to use a `LayerDrawable`, creating three total resources:

1. The first `ShapeDrawable`, in its own resource file
2. The second `ShapeDrawable`, in its own resource file
3. The `LayerDrawable`, holding references to the two `ShapeDrawable` resources

And this will certainly work. But you have an alternative: put all of it into a single drawable resource.

An `android:drawable` attribute in an `<item>` element can be replaced by child elements representing another drawable structure. Hence, rather than having a `LayerDrawable` with two `<item>` elements pointing to other drawable resources, we could have those same `<item>` elements *contain* the other drawable XML structures, and thereby cut our number of files from 3 to 1.

For example, we could have something like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

  <item>
    <shape android:shape="rectangle">
      <gradient
        android:angle="270"
        android:endColor="#FF0000FF"
        android:startColor="#FFFF0000"/>

      <stroke
        android:dashGap="4dp"
        android:dashWidth="20dp"
        android:width="2dp"
        android:color="#FF000000"/>

      <corners android:radius="8dp"/>
    </shape>
  </item>
  <item>
    <shape
      android:innerRadiusRatio="3"
      android:shape="ring"
      android:thickness="15dp"
      android:useLevel="false">
      <gradient
        android:endColor="#FFFFFFFF"
        android:startColor="#ff000000"
        android:type="sweep"/>
    </shape>
  </item>

</layer-list>
```

This is a `LayerDrawable`, layering two `ShapeDrawable` structures. The first `ShapeDrawable` is our dash-bordered, gradient-filled, rounded rectangle from before. The second `ShapeDrawable` is a `ring` with a simple gradient sweep fill, from black to white.

This gives us:

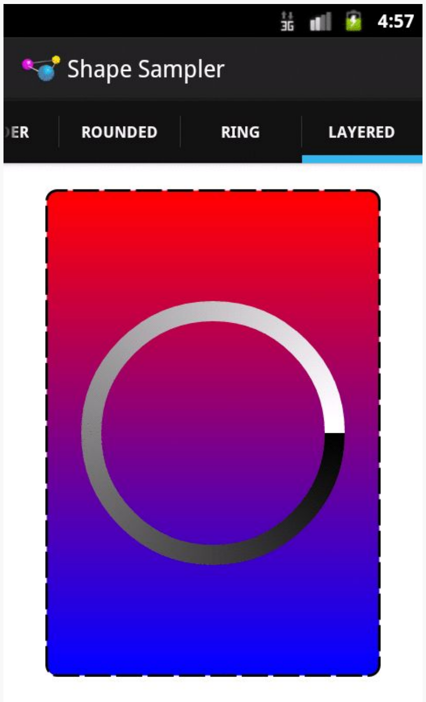

Figure 517: Composite Drawable

Hence, any of the drawable XML structures other than `ShapeDrawable` can, in their `<item>` elements, hold any drawable XML structure, instead of pointing to another separate resource.

Android uses this trick as well. For example, the stock `ProgressBar` image is based off of a `LayerDrawable` wrapped around three `ShapeDrawable` structures:

```
<?xml version="1.0" encoding="utf-8"?>

-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

    <item android:id="@android:id/background">
```

```
        <shape>
            <corners android:radius="5dip" />
            <gradient
                    android:startColor="#ff9d9e9d"
                    android:centerColor="#ff5a5d5a"
                    android:centerY="0.75"
                    android:endColor="#ff747674"
                    android:angle="270"
            />
        </shape>
    </item>

    <item android:id="@android:id/secondaryProgress">
        <clip>
            <shape>
                <corners android:radius="5dip" />
                <gradient
                        android:startColor="#80ffd300"
                        android:centerColor="#80ffb600"
                        android:centerY="0.75"
                        android:endColor="#a0ffcb00"
                        android:angle="270"
                />
            </shape>
        </clip>
    </item>

    <item android:id="@android:id/progress">
        <clip>
            <shape>
                <corners android:radius="5dip" />
                <gradient
                        android:startColor="#ffffd300"
                        android:centerColor="#ffffb600"
                        android:centerY="0.75"
                        android:endColor="#ffffcb00"
                        android:angle="270"
                />
            </shape>
        </clip>
    </item>

</layer-list>
```

We will get into how this works with a `ProgressBar` in a separate chapter.

A Stitch In Time Saves Nine

Most of the types of non-traditional drawable resources you can create in Android are described in XML… but not all.

As you read through the Android documentation, you no doubt ran into references to “nine-patch” or “9-patch” and wondered what Android had to do with quilting.

Rest assured, you will not need to take up needlework to be an effective Android developer.

If, however, you are looking to create backgrounds for resizable widgets, like a `Button`, you may wish to work with nine-patch images.

As the Android documentation states, a nine-patch is "a PNG image in which you define stretchable sections that Android will resize to fit the object at display time to accommodate variable sized sections, such as text strings". By using a specially-created PNG file, Android can avoid trying to use vector-based formats (e.g., `ShapeDrawable`) and their associated overhead when trying to create a background at runtime. Yet, at the same time, Android can still resize the background to handle whatever you want to put inside of it, such as the text of a `Button`.

In this section, we will cover some of the basics of nine-patch graphics, including how to customize and apply them to your own Android layouts.

Note that nine-patch PNG files, while they provide stretching rules, are still somewhat dependent upon density. You may wish to have different versions of your nine-patch PNG files for different densities, and therefore these images should be put in density-specific resource directories (e.g., `res/drawable-hdpi/`).

The Name and the Border

Nine-patch graphics are PNG files whose names end in `.9.png`. This means they can be edited using normal graphics tools, but Android knows to apply nine-patch rules to their use.

What makes a nine-patch graphic different than an ordinary PNG is a one-pixel-wide border surrounding the image. When drawn, Android will remove that border, showing only the stretched rendition of what lies inside the border. The border is used as a control channel, providing instructions to Android for how to deal with stretching the image to fit its contents.

Padding and the Box

Along the right and bottom sides, you can draw one-pixel-wide black lines to indicate the "padding box". Android will stretch the image such that the contents of the widget will fit inside that padding box.

For example, suppose we are using a nine-patch as the background of a `Button`. When you set the text to appear in the button (e.g., "Hello, world!"), Android will compute the size of that text, in terms of width and height in pixels. Then, it will stretch the nine-patch image such that the text will reside inside the padding box. What lies outside the padding box forms the border of the button, typically a rounded rectangle of some form.

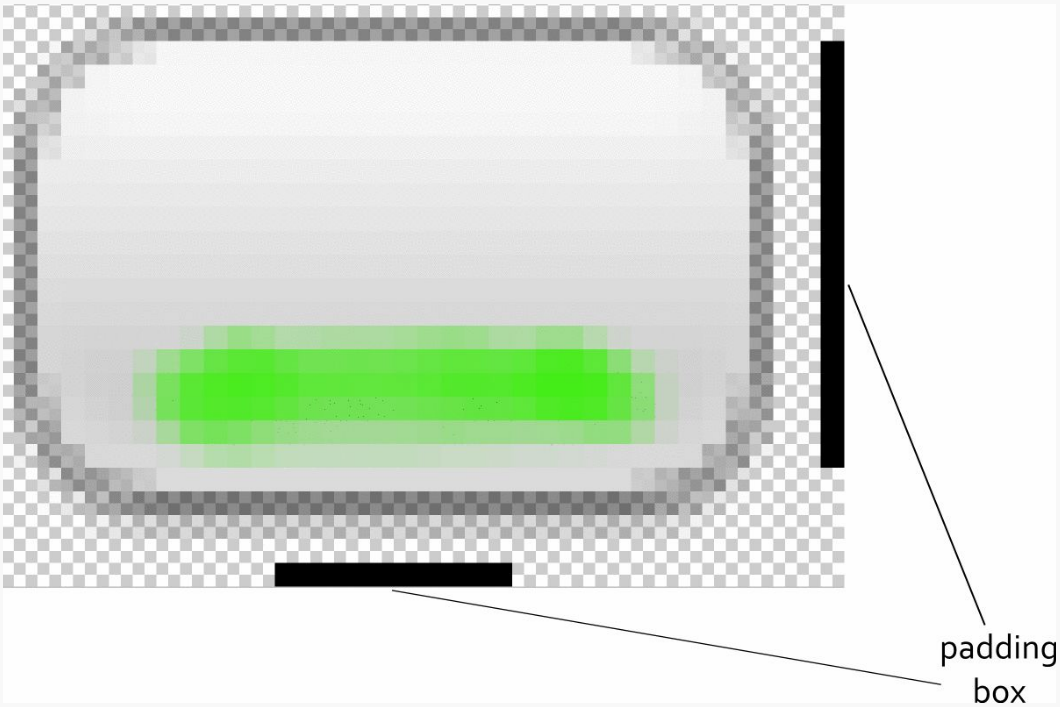

Figure 518: The padding box, as shown by a set of control lines to the right and bottom of the stretchable image

Stretch Zones

To tell Android where on the image to actually do the stretching, draw one-pixel-wide black lines on the top and left sides of the image. Android will scale the graphic only in those areas — areas outside the stretch zones are not stretched.

Perhaps the most common pattern is the center-stretch, where the middle portions of the image on both axes are considered stretchable, but the edges are not:

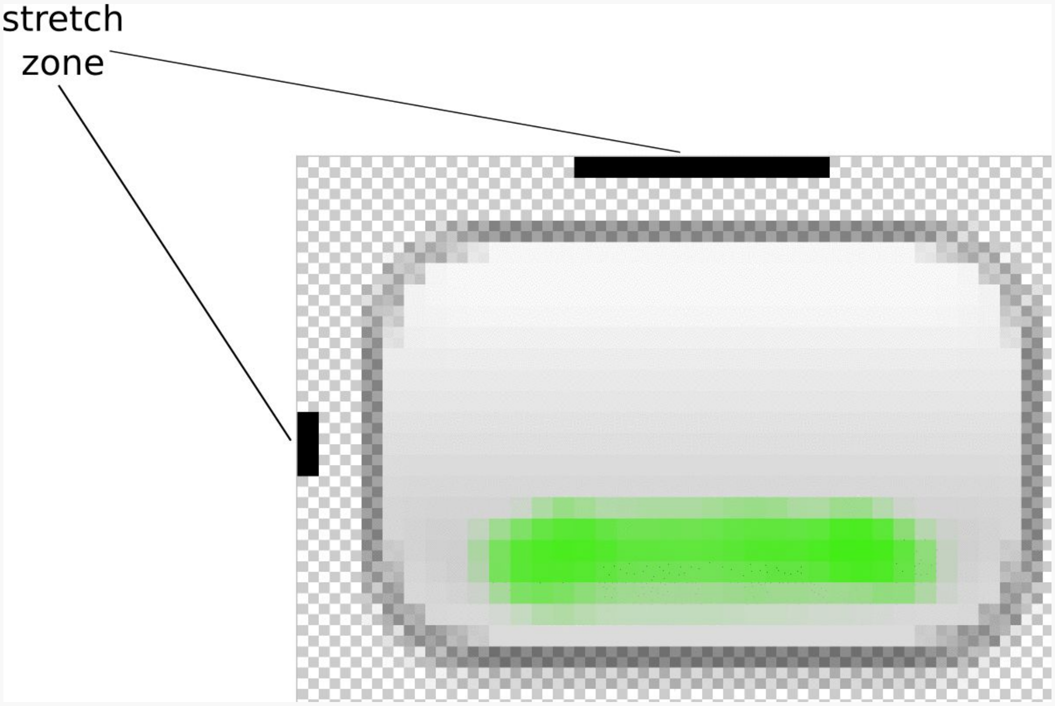

Figure 519: The stretch zones, as shown by a set of control lines to the left and top of the stretchable image

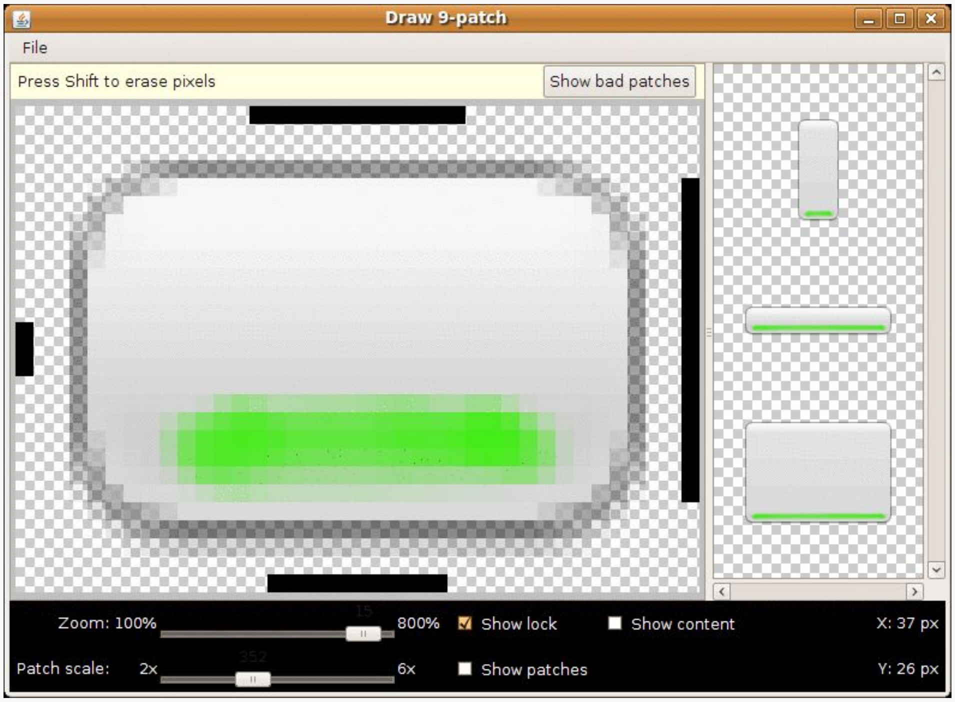
Here, the stretch zones will be stretched just enough for the contents to fit in the padding box. The edges of the graphic are left unstretched.

Some additional rules to bear in mind:

1. If you have multiple discrete stretch zones along an axis (e.g., two zones separated by whitespace), Android will stretch both of them but keep them in their current proportions. So, if the first zone is twice as wide as the second zone in the original graphic, the first zone will be twice as wide as the second zone in the stretched graphic.
2. If you leave out the control lines for the padding box, it is assumed that the padding box and the stretch zones are one and the same.

Tooling

To experiment with nine-patch images, you may wish to use the `draw9patch` program, found in the `tools/` directory of your SDK installation:



Zoom: 100% 800% ☑ Show lock □ Show content X: 37 px

Patch scale: 2x 6x □ Show patches Y: 26 px

Figure 520: The draw9patch tool

Neither Android Studio nor Eclipse, at the present time, have a built-in version of `draw9patch`, so IDE users will need to run the standalone copy from their SDK installation.

While a regular graphics editor would allow you to draw any color on any pixel, `draw9patch` limits you to drawing or erasing pixels in the control area. If you attempt to draw inside the main image area itself, you will be blocked.

On the right, you will see samples of the image in various stretched sizes, so you can see the impact as you change the stretchable zones and padding box.

While this is convenient for working with the nine-patch nature of the image, you will still need some other graphics editor to create or modify the body of the image itself. For example, the image shown above, from the `Drawable/NinePatch` project, is a modified version of a nine-patch graphic from the SDK's `ApiDemos`, where the GIMP was used to add the neon green stripe across the bottom portion of the image.

Using Nine-Patch Images

Nine-patch images are most commonly used as backgrounds, as illustrated by the following layout from the Drawable/NinePatch sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TableLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:stretchColumns="1"
  >
    <TableRow
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
    >
      <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:text="Horizontal:"
      />
      <SeekBar android:id="@+id/horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
      />
    </TableRow>
    <TableRow
      android:layout_width="match_parent"
      android:layout_height="wrap_content"
    >
      <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:text="Vertical:"
      />
      <SeekBar android:id="@+id/vertical"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
      />
    </TableRow>
  </TableLayout>
  <LinearLayout
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/resize"
      android:layout_width="96px"
      android:layout_height="96px"
      android:text="Hi!"
      android:textSize="10sp"
      android:background="@drawable/button"
    />
  </LinearLayout>
</LinearLayout>
```

Here, we have two SeekBar widgets, labeled for the horizontal and vertical axes, plus a Button set up with our nine-patch graphic as its background (android:background = "@drawable/button").

The NinePatchDemo activity then uses the two SeekBar widgets to let the user control how large the button should be drawn on-screen, starting from an initial size of 64px square:

```
package com.commonsware.android.ninepatch;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.LinearLayout;
import android.widget.SeekBar;

public class NinePatchDemo extends Activity {
  SeekBar horizontal=null;
  SeekBar vertical=null;
  View thingToResize=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    thingToResize=findViewById(R.id.resize);

    horizontal=(SeekBar)findViewById(R.id.horizontal);
    vertical=(SeekBar)findViewById(R.id.vertical);

    horizontal.setMax(144); // 240 less 96 starting size
    vertical.setMax(144);  // keep it square @ max

    horizontal.setOnSeekBarChangeListener(h);
    vertical.setOnSeekBarChangeListener(v);
  }

  SeekBar.OnSeekBarChangeListener h=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
                                  int progress,
                                  boolean fromTouch) {
      ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
      ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(64+progress,
                                                                   old.height);

      thingToResize.setLayoutParams(current);
    }
    public void onStartTrackingTouch(SeekBar seekBar) {
      // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
      // unused
    }
  };

  SeekBar.OnSeekBarChangeListener v=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar,
                                  int progress,
                                  boolean fromTouch) {
      ViewGroup.LayoutParams old=thingToResize.getLayoutParams();
      ViewGroup.LayoutParams current=new LinearLayout.LayoutParams(old.width,
                                                                    64+progress);

      thingToResize.setLayoutParams(current);
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
      // unused
    }

    public void onStopTrackingTouch(SeekBar seekBar) {
      // unused
    }
  };
}
```

The result is an application that can be used much like the right pane of `draw9patch`, to see how the nine-patch graphic looks on an actual device or emulator in various sizes:

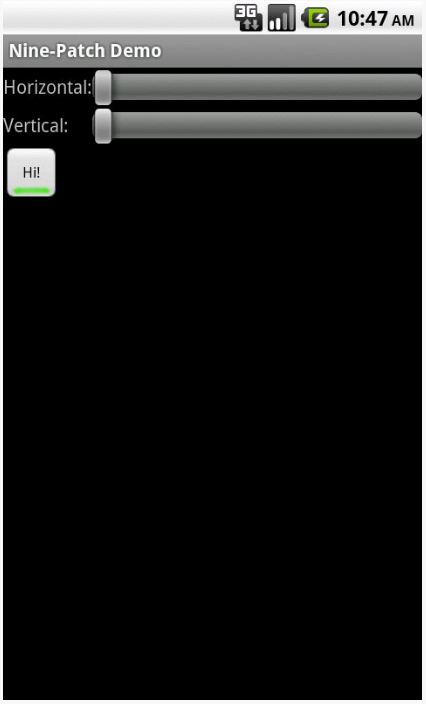


Figure 521: The NinePatch sample project, in its initial state

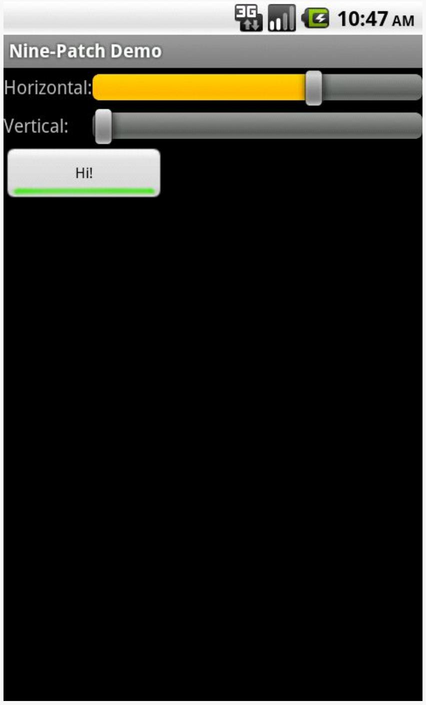

Figure 522: The NinePatch sample project, after making it bigger horizontally

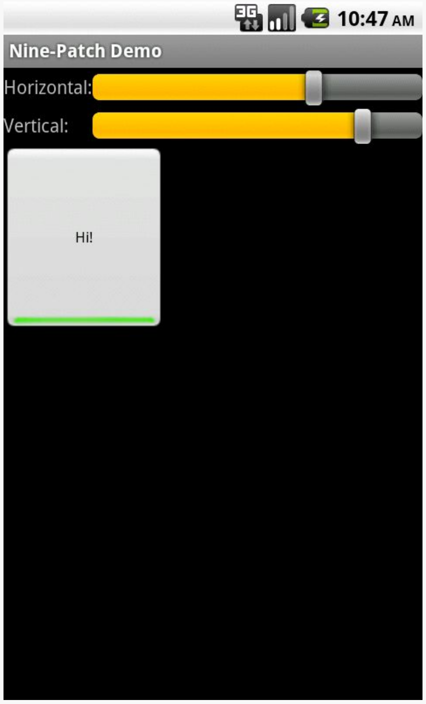

Figure 523: The NinePatch sample application, after making it bigger in both dimensions

Mapping with Maps V2

One of Google's most popular services — after search, of course – is Google Maps, where you can find everything from the nearest pizza parlor to directions from New York City to San Francisco (only 2,905 miles!) to street views and satellite imagery.

Android has had mapping capability from the beginning, with an API available to us as developers to bake maps into our apps. However, as we will see shortly, that original API was getting a bit stale.

In December 2012, Google released a long-awaited update to the mapping capabilities available to Android app developers. The original mapping solution, now known as the Maps V1, worked but had serious limitations. The new mapping solution, known as Maps V2, offers greater power and greater ease of handling common situations, though it too has its rough edges.

Prerequisites

Understanding this chapter requires that you have read the core chapters, along with the chapter on drawables. Also, one of the samples involves location tracking, and another of the samples involves the use of the animator framework.

One section involves the use of Picasso, covered in the chapter on Internet access.

This chapter also makes the occasional reference back to Maps V1 for comparisons, mostly for the benefit of developers already familiar with Maps V1 and looking to migrate to Maps V2. However, prior experience with Maps V1 is not necessary to understand this chapter.

A Brief History of Mapping on Android

Back in the dawn of Android, we were given the Maps SDK add-on. This would allow us to load a firmware-hosted mapping library into our applications, then embed maps into our activities, by means of a `MapView` widget.

And it worked.

More importantly, from the standpoint of users, the results from our apps were visually indistinguishable from the built-in Maps application available on devices that had the Maps SDK add-on.

This was the case through most of 2009. Eventually, though, the Google Maps team wanted to update the Maps application… but, for whatever reason, the decision was made to *not* update the Maps SDK add-on as well. At this point, the Google Maps team effectively forked the Maps SDK add-on, causing the Maps application to diverge from what other Android app developers could deliver. Over time, this feature gap became quite pronounced.

The release of Android 3.0 in early 2011 compounded the problems. Now, we needed to consider using fragments to help manage our code and deliver solutions to all screen sizes. Alas, while we could add maps to our fragments, we could only do so on API Level 11 or higher — the fragments backport from the Android Support package did not work with the Maps SDK add-on.

The release of Maps V2 helped all of this significantly. Now we have proper map support for native and backported versions of the fragment framework. We also have a look and feel that is closer to what the Maps application itself supports. While we still cannot reach feature parity with the Maps application, our SDK apps can at least look like they belong on the same device as the Maps application.

More importantly, as of the time of this writing, Maps V1 is no longer an option for new developers. Those who already have Maps V1 API keys can use Maps V1, but no new Maps V1 API keys are being offered. That leaves you with either using Maps V2 or some alternative mapping solution.

Where You Can Use Maps V2

Many devices will be able to use Maps V2… but not all. Notably:

- Devices need to support OpenGL ES 2.0+, to handle the new vector-based tiles that Maps V2 uses. Over 99% of Android devices in use today that support the Play Store (or its "Android Market" predecessor) also support OpenGL ES 2.0+.
- Devices will need an update to the Google Services Framework that accompanies the Play Store. Devices that do not have the Play Store — either because they are forever stuck on the old Android Market or, like the Kindle Fire, never had Play Store support in the first place — will be unable to use Maps V2.

Later in this chapter, we will look at other mapping libraries that you could use instead of either of Google's mapping solutions.

Licensing Terms for Maps V2

As with the original Maps SDK add-on, to use Maps V2, you must agree to a terms of service agreement to be authorized to embed Google Maps within your application. If you intend to use Maps V2, you should review these terms closely, as they place many restrictions on developers. The most notorious of these is that you cannot use Maps V2 to create an application that offers "real time navigation or route guidance, including but not limited to turn-by-turn route guidance that is synchronized to the position of a user's sensor-enabled device."

If you find these terms to be an issue for your application, you may need to consider alternative mapping solutions.

What You Need to Start

If you wish to use Maps V2 in one or more of your Android applications, this section will outline what you need to get started.

Your Signing Key Fingerprint(s)

As with the legacy Maps SDK add-on, you will need fingerprints of your app signing keys, to tie your apps to your Google account and the API keys you will be generating. However, unlike the legacy Maps SDK add-on, the fingerprints you will be using will be created using the SHA-1 hash algorithm, rather than MD5.

First, you will need to know where the keystore is for your signing key. For a production keystore that you created yourself for your production apps, you should know where it is located already. For the debug keystore, used by default during development, the location is dependent upon operating system:

- OS X and Linux: `~/.android/debug.keystore`
- Windows XP: `C:\Documents and Settings\$USER\.android\debug.keystore`
- Windows Vista and Windows 7: `C:\Users\$USER\.android\debug.keystore`

(where `$USER` is your Windows user name)

You will then need to run the `keytool` command, to dump information related to this keystore. The `keytool` command is in your Java SDK, not the Android SDK. You will need to run this from a command line (e.g., Command Prompt in Windows). The specific command to run is:

```
keytool -list -v -keystore ... -alias androiddebugkey -storepass android -keypass
android
```

where the `...` is replaced by the path to your debug keystore, enclosed in quotation marks if the path contains spaces. For your production keystore, you would supply your own alias and passwords.

This should emit output akin to:

```
Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate[1]:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
   MD5:  98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
   SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
   Signature algorithm name: SHA1withRSA
   Version: 3
```

You will need to make note of the `SHA1` entry (see third line from the bottom of the above sample).

Your Google Account

To sign up for an API key, you need a Google account. Ideally, this account would be the same one you intend to use for submitting apps to the Play Store (if, indeed, you intend to do so).

Your API Key

Given that you are logged into the aforementioned Google account, you can visit the Google Cloud Console to request access to the Maps V2 API. They have a tendency to keep changing this set of pages, but these instructions were good as of late February 2014:

- Create a project via the "Create project" option, if you have not done so already for something else (e.g., GCM)
- Open your project, then select "APIs & auth" from the left navigation bar, and in there select "APIs"
- Sift through the various APIs until you find "Google Maps Android API v2", then toggle that on
- Agree to the Terms of Service that appears when you try to toggle on Maps V2 access
- Click "Credentials" in the left navigation bar
- Click the "CREATE NEW KEY" button
- In the popup dialog, choose "Android key"
- In the fields that appear once you chose "Android key", fill in your app's package name and your SHA1 fingerprint, then click the "Create" button

This will give you an "API key" that you will need for your application.

If you wish to have more than one app use Maps V2, you can click "Edit allowed Android applications" for a key, to return to the dialog where you can paste in another SHA1 fingerprint and package name, separated by a semicolon. Or, if you prefer, you can create new keys for each application.

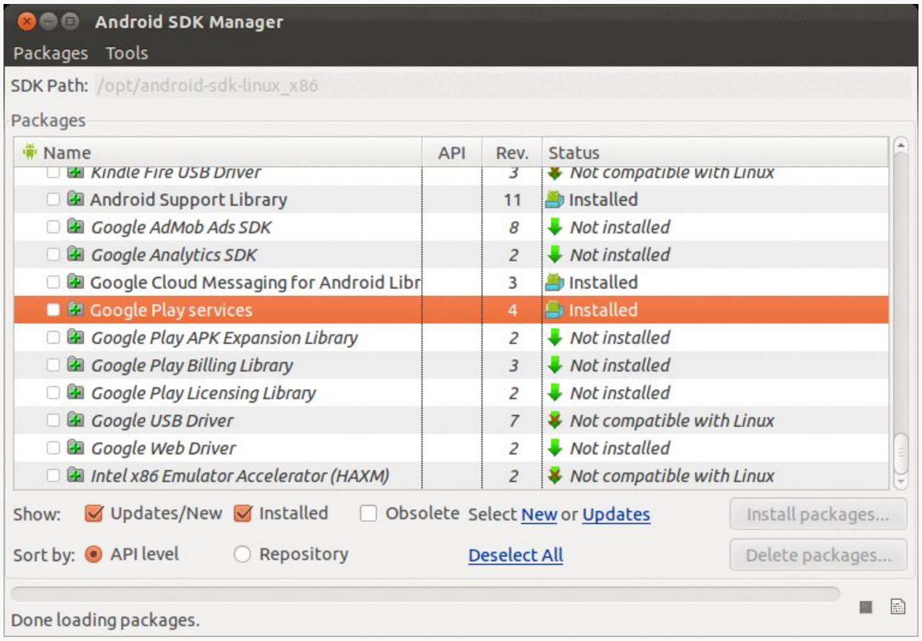
For apps that are in (or going to) production, you will need to supply both the debug and production SHA1 fingerprints with your package name. By doing this on the same key, you will use the same API key string for both debug and production builds, which simplifies things a fair bit over the separate API keys you would have used with the legacy Maps SDK add-on.

Also note that a single API key seems to only support a few fingerprint/package pairs. If you try adding a new pair, and the form ignores you, you will need to set up a separate API key for additional pairs.

The Play Services Library

You also need to set up the Google Play Services library for use with your app.

First, you will need to download the "Google Play services" package in your SDK Manager (see highlighted line):



SDK Path: /opt/android-sdk-linux_x86

Name	API	Rev.	Status
☐ Kindle Fire USB Driver		3	Not compatible with Linux
☐ Android Support Library		11	Installed
☐ Google AdMob Ads SDK		8	Not installed
☐ Google Analytics SDK		2	Not installed
☐ Google Cloud Messaging for Android Libr		3	Installed
☐ Google Play services		4	Installed
☐ Google Play APK Expansion Library		2	Not installed
☐ Google Play Billing Library		3	Not installed
☐ Google Play Licensing Library		2	Not installed
☐ Google USB Driver		7	Not compatible with Linux
☐ Google Web Driver		2	Not installed
☐ Intel x86 Emulator Accelerator (HAXM)		2	Not compatible with Linux

Show: ☑ Updates/New ☑ Installed ☐ Obsolete

Sort by: ● API level ○ Repository

Done loading packages.

Figure 524: Android SDK Manager, Showing "Google Play services"

Android Studio users will also want to download the "Google Repository", also in the same "Extras" area of the SDK Manager.

From there, things vary based on IDE.

Android Studio

Given that you have downloaded the above items, all you need to do is add a dependency on `com.google.android.gms:play-services-maps` for some likely version (e.g., com.google.android.gms:play-services-maps:6.5.87) to your dependencies closure.

Eclipse

You will need to add the Play Services Android library project to your workspace. You can do this via the "Import Existing Android Code into Workspace" wizard, pointing Eclipse to the extras/google/google_play_services/libproject/google-play-services_lib/ directory inside of your Android SDK (or to a copy of it that you make elsewhere, if you prefer).

When you create a project that is to use Maps V2, you will need to add a reference to that library project, via the Eclipse project properties dialog.

Play Services and ProGuard

Note that the Play Services documentation requests that you add the following stanza to your proguard-project.txt file for use by your production builds:

```
-keep class * extends java.util.ListResourceBundle {
    protected Object[][] getContents();
}

-keep public class com.google.android.gms.common.internal.safeparcel.SafeParcelable {
    public static final *** NULL;
}

-keepnames @com.google.android.gms.common.annotation.KeepName class *
-keepclassmembernames class * {
    @com.google.android.gms.common.annotation.KeepName *;
}

-keepnames class * implements android.os.Parcelable {
    public static final ** CREATOR;
}
```

The Book Samples… And You!

If you wish to try to run the book samples outlined in this chapter, you will need to make a few fixes to them for your own environment:

- Replace the Maps V2 API key in the manifest with your own
- Replace the reference to the Play Services Android library project with your own (Eclipse users only)

- Change the build target (i.e., compileSdkVersion in Android Studio) to an Android SDK that you have downloaded (or download the Android SDK used by the project)

Setting Up a Basic Map

With that preparation work completed, now you can start working on projects that use the Maps V2 API. In this section, we will review the MapsV2/Basic sample project, which simply brings up a Maps V2 map of the world.

The Dependency

While Eclipse users have to struggle through getting the Play Services SDK library project attached to their app project, Android Studio users can just have an entry in their top-level dependencies closure to pull in the Play Services SDK artifact:

```
dependencies {
    compile 'com.google.android.gms:play-services-maps:8.1.0'
}
```

The Project Setup and the Manifest

This project uses Maps V2, and so it has a reference to that library project.

Our manifest file is fairly traditional, though there are a number of elements in it that are required by Maps V2:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.android.mapsv2.basic"
          xmlns:android="http://schemas.android.com/apk/res/android"
          android:versionCode="1"
          android:versionName="1.0">

  <uses-permission
    android:name="android.permission.WRITE_EXTERNAL_STORAGE"
    android:maxSdkVersion="22"/>

  <uses-feature
    android:glEsVersion="0x00020000"
    android:required="false"/>

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
```

```
      android:name="MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <meta-data
      android:name="com.google.android.maps.v2.API_KEY"
      android:value="AIzaSyC4iyT46cBOOIdKGcy5EmAxK5uCOQX2Oy8"/>

    <meta-data
      android:name="com.google.android.gms.version"
      android:value="@integer/google_play_services_version"/>

    <activity android:name="LegalNoticesActivity">
    </activity>
  </application>

</manifest>
```

Specifically:

- We need the `WRITE_EXTERNAL_STORAGE` permissions, but only on Android 5.1 and below, so we can use `android:maxSdkVersion="22"` to only request that permission on older devices
- We need a `<meta-data>` element, with a name of `com.google.android.maps.v2.API_KEY`, whose value is the API key we got from the Google APIs Console for use with this particular package name.
- We can have a second `<meta-data>` element, with a name of `com.google.android.gms.version`, with a value of the `@integer/google_play_services_version` (an integer resource supplied by the Play Services SDK library project). Starting with version 8.1.0 of the Maps V2 library, this element is not essential, as it will be added automatically to our manifest via the manifest merger process. However, code written for older versions of Maps V2 than 8.1.0 will need the element, and there is no particular harm in having it.

We also should include a `<uses-feature>` element for OpenGL ES 2.0. If your app absolutely must be able to run Maps V2, have `android:required="true"` (or drop the `android:required` attribute entirely, as `true` is the default), which will force devices to have OpenGL ES 2.0 to run your app. If your app will gracefully degrade for devices incapable of running Maps V2, use `android:required="false"`, as is shown in the sample.

Beyond those items, everything else in this project is based on what the app needs, more so than what Maps V2 needs. Note, though, that the Play Services SDK library project will add additional items to our manifest, notably requests for a few other permissions, like INTERNET. Also note that we used to need to define and use a custom permission, based upon our app's package name and ending in MAPS_RECEIVE. This is not required as of Play Services 3.1.59 and the "rev 8" release of the Play Services SDK.

The Play Services Detection

In the fullness of time, all devices that are capable of using Maps V2 will already have the on-device portion of this logic, known as the "Google Play services" app.

However, it is entirely possible, in the short term, that you will encounter devices that are capable of using Maps V2 (e.g., they have OpenGL ES 2.0 or higher), but do not have the "Google Play services" app from the Play Store, and therefore you cannot actually *use* Maps V2 in your app.

This is a departure from the Maps V1 approach, where either the device shipped with maps capability, or it did not, and nothing (legally) could be done to change that state.

To determine whether or not the Maps V2 API is available to you, the best option is to call the isGooglePlayServicesAvailable() static method on the GooglePlayServicesUtil utility class supplied by the Play Services library. This will return an int, with a value of ConnectionResult.SUCCESS if Maps V2 can be used right away.

Actually assisting the user to get Maps V2 set up all the way is conceivable but is also bug-riddled and annoying. The MapsV2/Basic sample app has an AbstractMapActivity base class that is designed to hide most of this annoyance from you. If you wish to know the details of how this works, we will cover it later in this chapter.

The Fragment and Activity

Our main activity — MainActivity — extends from the aforementioned AbstractMapActivity and simply overrides onCreate(), as most activities do:

```
package com.commonsware.android.mapsv2.basic;

import android.os.Bundle;
```

```
public class MainActivity extends AbstractMapActivity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
      setContentView(R.layout.activity_main);
    }
  }
}
```

We call `setContentView()` to load up the `activity_main` layout resource:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/map"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  class="com.google.android.gms.maps.MapFragment"/>
```

That resource, in turn, has a `<fragment>` element pointing to a `com.google.android.gms.maps.MapFragment` class supplied by the Play Services library. This is a fragment that knows how to display a Maps V2 map. There is a corresponding `com.google.android.gms.maps.SupportMapFragment` class for use with the fragments backport from the Android Support library.

You will notice, though, that we only call `setContentView()` if a `readyToGo()` method returns `true`. The `readyToGo()` method is supplied by the `AbstractMapActivity` class and returns `true` if we are safe to go ahead and use Maps V2, `false` otherwise. In the `false` case, `AbstractMapActivity` will be taking care of trying to get Maps V2 going, and we need do nothing further.

The License

According to the terms of use for Maps V2, you must show Maps V2 license information in your app's UI, in some likely spot. Apps that show their own license terms, or have an "about" activity (or dialog) could display them there. Otherwise, you will need to have a dedicated spot for the Maps V2 license.

To obtain the license text, you can call `getOpenSourceSoftwareLicenseInfo()` on the `GooglePlayServicesUtil` utility class. This text can then be popped into a `TextView` somewhere in your app. `AbstractMapActivity` adds an action bar overflow item to display the license, which in turn invokes a `LegalNoticesActivity`, which simply displays the license text in a `TextView`. We will examine this in more detail later in this chapter.

The Result

When you run the app, assuming that Maps V2 is ready for use, you will get a basic map showing a good-sized chunk of the planet:

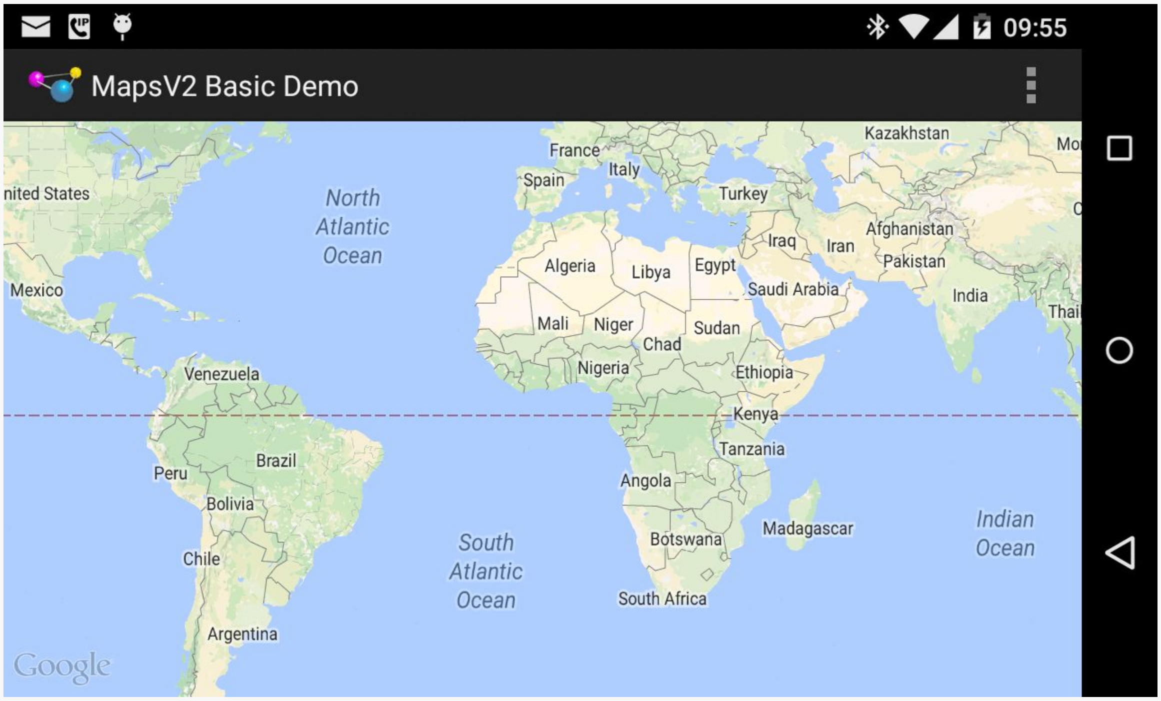


Figure 525: Maps V2 Map, as Initially Viewed

If you choose the "Legal Notices" action bar item, the view shifts to show a bunch of license terms:

Figure 526: Maps V2 License Terms

If your Maps V2 API key is incorrect, or you do not have this app's package name set up for that key in the Google APIs Console, you will get an "Authorization failure" error message in LogCat, and you will get a blank map, akin to the behavior seen in Maps V1 when you had an invalid `android:apiKey` attribute on the `MapView`.

Playing with the Map

Showing a map of a good-sized chunk of the planet is nice, and it is entirely possible that is precisely what you wanted to show the user. If, on the other hand, you wanted to show the user something else — another location, a closer look, etc. — you will need to further configure your map, via a `GoogleMap` object.

To see how this is done, take a look at the MapsV2/NooYawk sample application. This is a clone of `MapsV2/Basic` that adds in logic to center and zoom the map over a portion of New York City.

The `onCreate()` method of the revised `MapActivity` is now a bit more involved:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  if (readyToGo()) {
    setContentView(R.layout.activity_main);

    MapFragment mapFrag=
        (MapFragment)getFragmentManager().findFragmentById(R.id.map);

    if (savedInstanceState == null) {
      mapFrag.getMapAsync(this);
    }
  }
}
```

After calling `setContentView()`, we can retrieve our `MapFragment` via `findFragmentById()`, no different than any other static fragment.

Then, if `savedInstanceState` is `null` — meaning that the activity is not being recreated, but instead is being created from scratch — we call `getMapAsync()` on the `MapFragment`. This triggers some asynchronous work to set up a `GoogleMap` object. `getMapAsync()` takes an implementation of `OnMapReadyCallback` as a parameter. In this case, `OnMapReadyCallback` is implemented on the activity itself.

That `GoogleMap` object will then be delivered to us in `onMapReady()`. Most of our work in configuring the map will be accomplished by calling methods on this `GoogleMap` object:

```
@Override
public void onMapReady(GoogleMap map) {
  CameraUpdate center=
      CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
          -73.98180484771729));
  CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

  map.moveCamera(center);
  map.animateCamera(zoom);
}
```

To change where the map is centered, we can create a `CameraUpdate` object from the `CameraUpdateFactory` ("camera" in this case referring to the position of the user's virtual eyes with respect to the surface of the Earth). The `newLatLng()` factory method on `CameraUpdateFactory` will give us a `CameraUpdate` object that can re-center the map over a supplied latitude and longitude. Those coordinates are encapsulated in a `LatLng` object and are maintained as decimal degrees as Java `float` or `double` values (as opposed to the Maps V1 `GeoPoint`, which used integer microdegrees).

To change the zoom level of the map, we need another `CameraUpdate` object, this time from the `zoomTo()` factory method on `CameraUpdateFactory`. As with Maps V1, the zoom levels start at 1 and zoom in by powers of two. As you will see, a value of 15 gives you a nice block-level view of a city like New York City.

To actually apply these changes to the map, we have two methods on `GoogleMap`:

1. `moveCamera()` will perform a "smash cut" and immediately change the map based upon the supplied `CameraUpdate`
2. `animateCamera()` will smoothly animate the map from its original state to the new state supplied by the `CameraUpdate`

In our case, we immediately shift to the proper position, but then zoom in from the default zoom level to 15, giving us a map centered over Columbus Circle, in the southwest corner of Central Park in Manhattan:

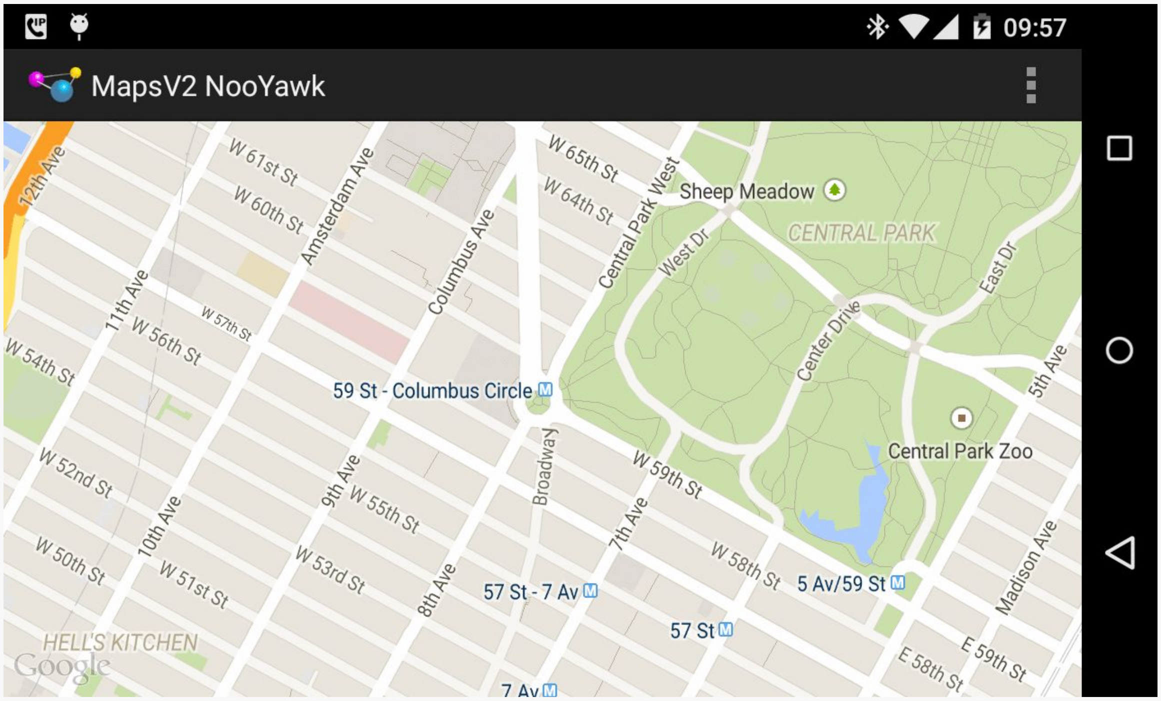

Figure 527: Maps V2 Centered Over Columbus Circle, New York City

Note that you might want to do both actions simultaneously, rather than have one be animated and one not as in this sample. In that case, you can manually create a `CameraPosition` object that describes the desired center, zoom, etc., then use the newCameraPosition() method on CameraUpdateFactory to get a CameraUpdate instance that will apply all of those changes.

Map Tiles

The map, by default, shows the normal tile set. setMapType() on the GoogleMap allows you to switch to satellite, hybrid (satellite view plus place labels), or terrain tile sets.

Placing Simple Markers

For markers — push-pins and the like — you simply hand markers to the GoogleMap for display, as is illustrated in the MapsV2/Markers sample application. This is a clone of MapsV2/NooYawk, with four markers for four landmarks within Manhattan.

Our onCreate() method on MainActivity now always invokes getMapAsync(), not just when the activity is first created. However, we still check savedInstanceState and set a new needsInit boolean data member to true if savedInstanceState is null:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  if (readyToGo()) {
    setContentView(R.layout.activity_main);

    MapFragment mapFrag=
        (MapFragment)getFragmentManager().findFragmentById(R.id.map);

    if (savedInstanceState == null) {
      needsInit=true;
    }

    mapFrag.getMapAsync(this);
  }
}
```

Our onMapReady() method performs the camera adjustments if needsInit is true. It also has four additional statements – calls to a private addMarker() method to define the four landmarks:

```
@Override
public void onMapReady(GoogleMap map) {
  if (needsInit) {
    CameraUpdate center=
        CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                                                 -73.98180484771729));
    CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

    map.moveCamera(center);
    map.animateCamera(zoom);
  }

  addMarker(map, 40.748963847316034, -73.96807193756104,
            R.string.un, R.string.united_nations);
  addMarker(map, 40.76866299974387, -73.98268461227417,
      R.string.lincoln_center,
      R.string.lincoln_center_snippet);
  addMarker(map, 40.765136435316755, -73.97989511489868,
      R.string.carnegie_hall, R.string.practice_x3);
  addMarker(map, 40.70686417491799, -74.01572942733765,
      R.string.downtown_club, R.string.heisman_trophy);
}
```

The `addMarker()` method on our `MainActivity` adds markers by creating a `MarkerOptions` object and passing it to the `addMarker()` on `GoogleMap`. `MarkerOptions` offers a so-called "fluent" interface, with a series of methods to affect one aspect of the `MarkerOptions`, each of which returns the `MarkerOptions` object itself. That way, configuring a `MarkerOptions` is a chained series of method calls:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
  map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                   .title(getString(title))
                                   .snippet(getString(snippet)));
}
```

Here, we:

- Set the `position()` of the marker, in the form of another `LatLng` object
- Set the `title()` and `snippet()` of the marker to be a pair of strings loaded from string resources

We will see other methods available on `MarkerOptions` in upcoming sections of this chapter.

`addMarker()` on `GoogleMap` returns an actual `Marker` object, which we could hold onto to change certain aspects of it later on (e.g., its title). In the case of this sample, we ignore this.

Now, you may be wondering why we set up the markers on every `onMapReady()` invocation, not just in the `needsInit` block. That is because while a `MapFragment` retains its camera information (center, zoom, etc.) on a configuration change, it does *not* retain its markers. Hence, we need to re-establish the markers in all calls to `onCreate()`, not just the very first one.

With no other changes, we get a version of the map that shows markers at our designated locations:

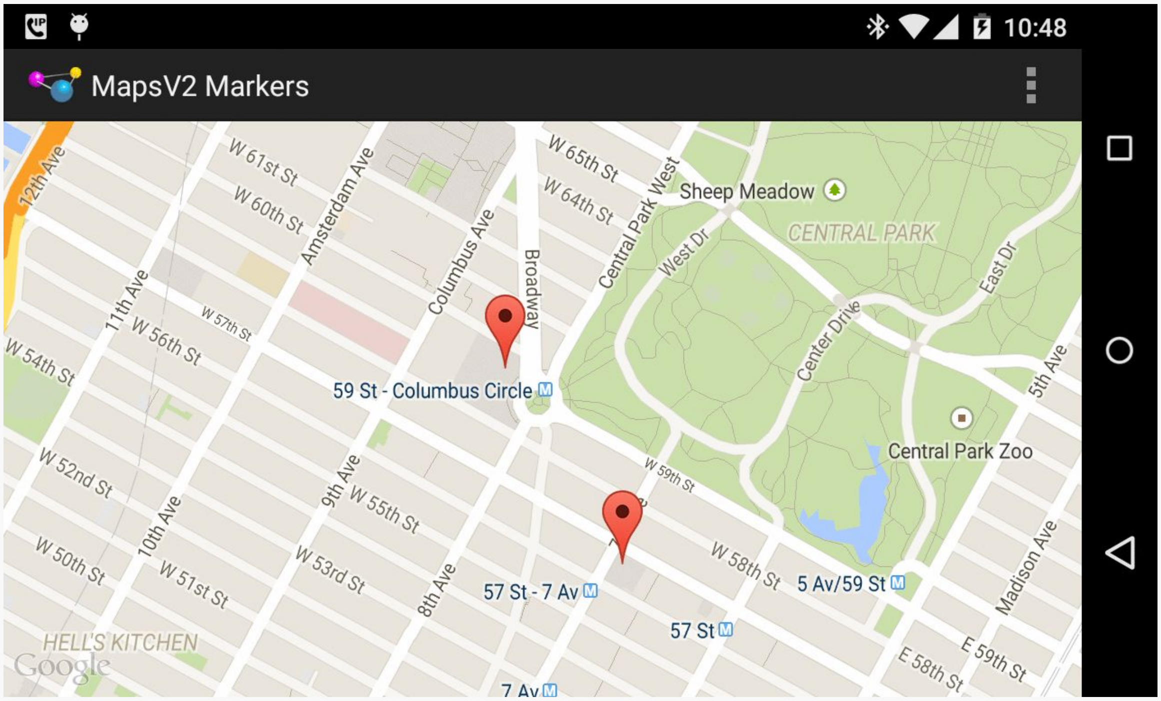

Figure 528: Maps V2 with Two Markers

Initially, we only see two markers, as the other two are outside the current center position and zoom level of the map. If the user changes the center or zoom, markers will come and go as needed:

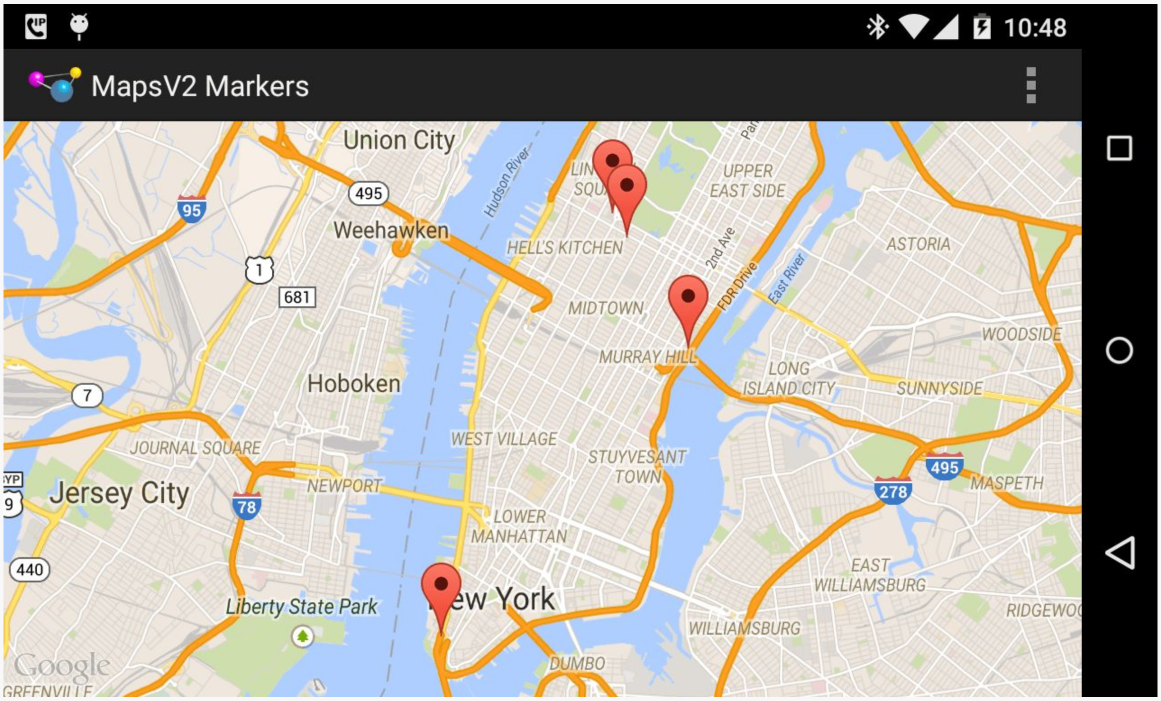

Figure 529: Maps V2 with All Four Markers

We do not need to worry about managing the markers ourselves, so long as the `GoogleMap` performance is adequate. It is likely that dumping 10,000 markers into a `GoogleMap` will still result in sluggish responses, though, so you may need to add and remove markers yourself based upon what portion of the world the user happens to be examining in the map at the moment.

Seeing All the Markers

When you add markers to a map, there is no guarantee that the markers will be visible given the map's current center position and zoom level. In fact, it is entirely possible that you add a bunch of markers and *none* are visible, so the user may not realize that the markers were added.

There is a way that you can center and zoom the map to show some set of markers, based on their positions. You get to choose the markers: all of them, the four nearest markers, etc.

We can see how this works in the MapsV2/Bounds sample application. This is a clone of MapsV2/Markers from the previous section, with reworked code to show all four markers when the map is first displayed.

The key to making this work is a LatLngBounds object. This represents a bounding box that contains all LatLng locations handed to the LatLngBounds. To build up a LatLngBounds, you can use the LatLngBounds.Builder class. So, our revised MainActivity has a LatLngBounds.Builder private data member:

```
private LatLngBounds.Builder builder=new LatLngBounds.Builder();
```

Our revised addMarker() method adds the LatLng values from our markers as they are added to the map:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
  Marker marker=
      map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                       .title(getString(title))
                                       .snippet(getString(snippet)));

  builder.include(marker.getPosition());
}
```

Finally, the revised onMapReady() moves the CameraUpdateFactory work until after all four of the addMarker() calls and changes it a bit:

```
@Override
public void onMapReady(final GoogleMap map) {
  addMarker(map, 40.748963847316034, -73.96807193756104,
            R.string.un, R.string.united_nations);
  addMarker(map, 40.76866299974387, -73.98268461227417,
            R.string.lincoln_center,
            R.string.lincoln_center_snippet);
  addMarker(map, 40.765136435316755, -73.97989511489868,
            R.string.carnegie_hall, R.string.practice_x3);
  addMarker(map, 40.70686417491799, -74.01572942733765,
            R.string.downtown_club, R.string.heisman_trophy);

  if (needsInit) {
    findViewById(android.R.id.content).post(new Runnable() {
      @Override
      public void run() {
        CameraUpdate allTheThings=
            CameraUpdateFactory.newLatLngBounds(builder.build(), 32);

        map.moveCamera(allTheThings);
      }
    });
  }
}
```

Specifically, we:

- Ask the `LatLngBounds.Builder` to `build()` the `LatLngBounds`
- Pass that to the `newLatLngBounds()` method on `CameraUpdateFactory`, along with an inset value in pixels (all `LatLng` locations will be that many pixels in from the edges, or more)
- Use `moveCamera()` to center and zoom the map based upon the resulting `CameraUpdate`

All of this is done in a `Runnable` which we `post()` to a `View` (here, the `FrameLayout` of our activity supplied by Android as `android.R.id.content`). `GoogleMap` cannot ensure that all of our markers are visible until it knows how big the map is, and that is not known until the map is rendered to the screen. `post()` will add our work to the end of the main application thread's work queue. The `Runnable` will not be run until after the map is on the screen, at which time the `CameraUpdate` can work.

Flattening and Rotating Markers

Markers, by default, appear to be "push pins" pressed into the surface of the map. This is not necessarily obvious with the default top-down perspective of the map camera. But, if you use a two-finger vertical swiping gesture, you can change the camera tilt, and that will illustrate the "push pin" effect a bit better:

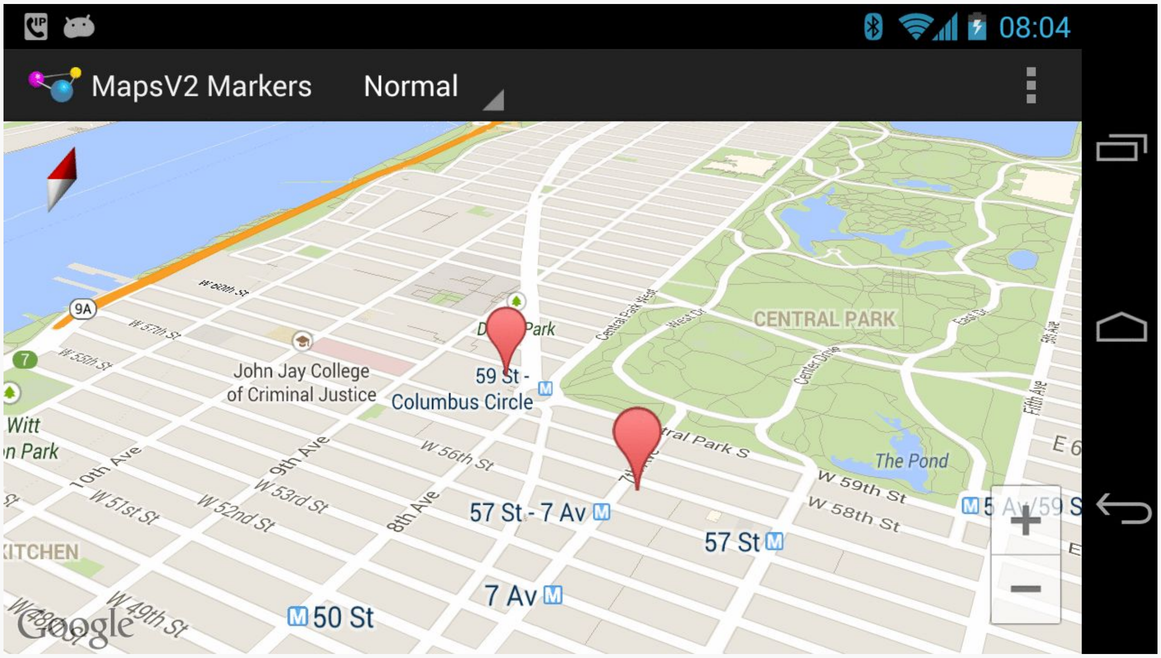

Figure 530: Maps V2 with Markers, Viewed on a Tilt

However, you have options for flat markers and rotated markers.

A flat marker is one that is flat on the map. In other words, rather than theoretically rising out of the Z axis of the map, the marker is kept on the X-Y plane:

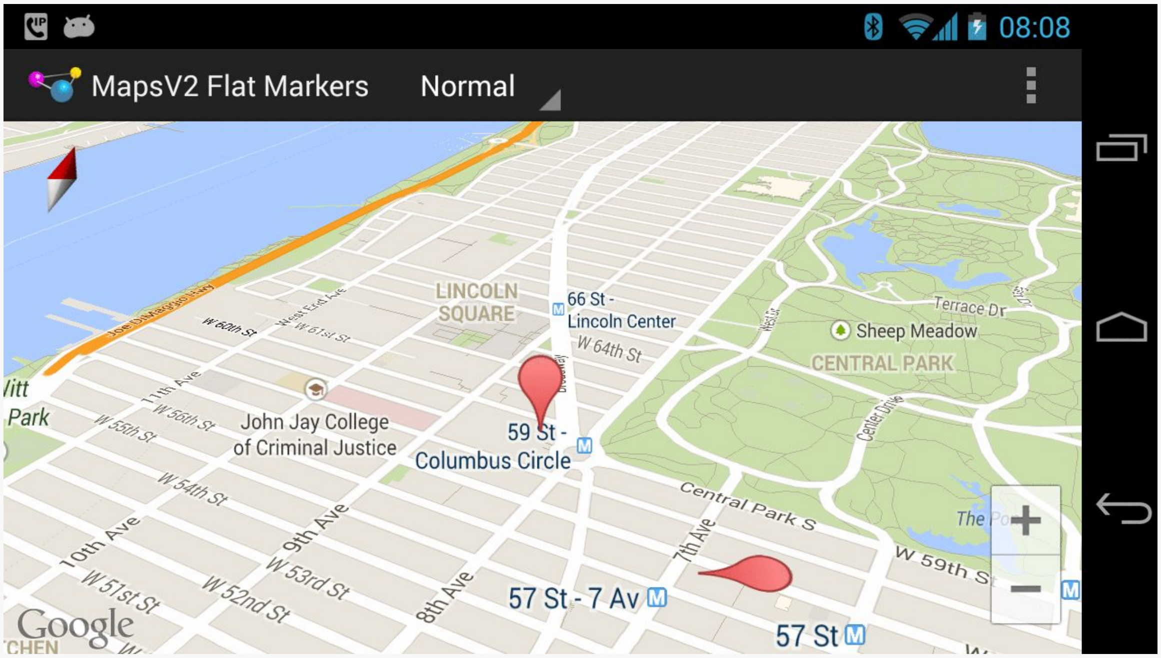

Figure 531: Maps V2 with Markers, One Normal, One Flat

It is also possible to rotate a marker. The flat marker in the previous screenshot is rotated 90 degrees from its normal "bulb on the north side" orientation. The following screenshot shows another flat marker, rotated 270 degrees from normal:

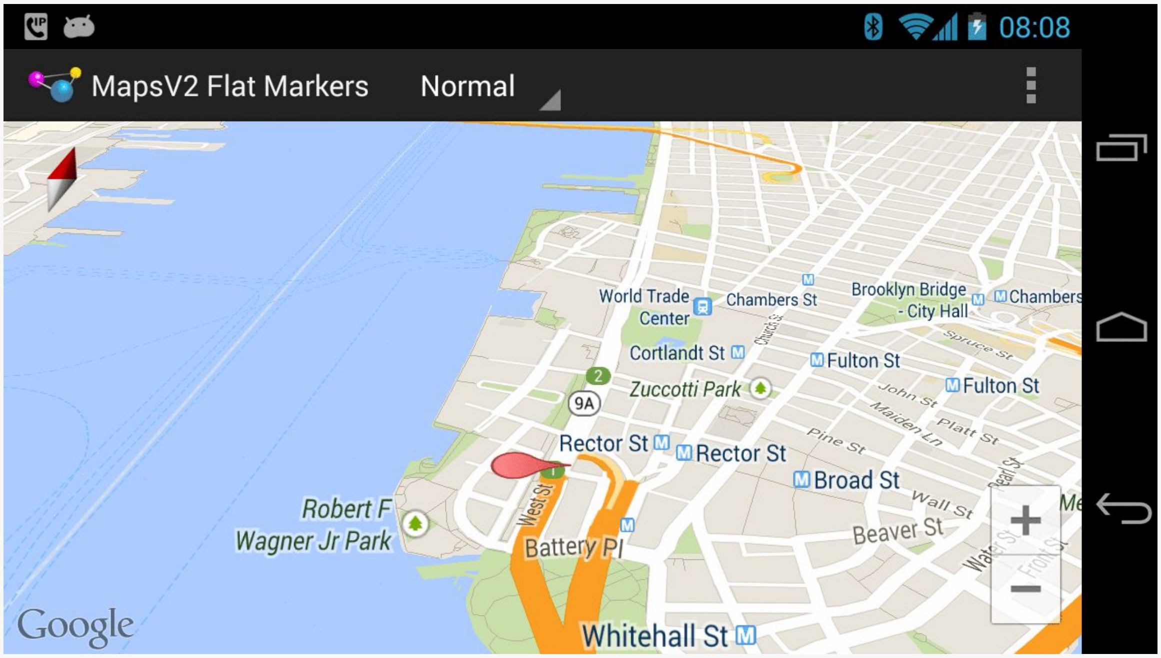

Figure 532: Maps V2 with Markers, Flat and Rotated

These features can be handy for providing pointers in a particular direction, such as indicating not only the location to make a turn, but what direction to turn at that location.

These capabilities are courtesy of `flat()` and `rotation()` methods on `MarkerOptions`, plus corresponding getters and setters on `Marker` itself. To see how this works, let's examine the [`MapsV2/FlatMarkers`]() sample application. This is a clone of `MapsV2/Markers`, with markers applied using different values for `flat()` and `rotation()`.

Specifically, our own `addMarker()` helper method now takes and applies a `boolean` parameter for `flat` (`true` means it is flat, `false` means normal behavior), as well as a `float` parameter for `rotation` (a value between `0` and `360` for the rotation off the default in degrees):

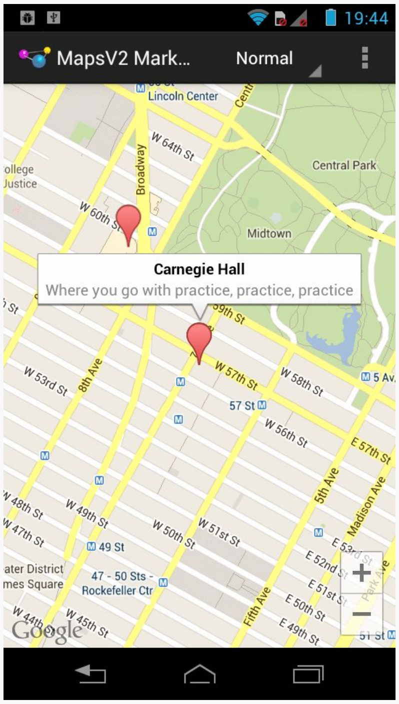
```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet, boolean flat,
                       float rotation) {
  map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                   .title(getString(title))
                                   .snippet(getString(snippet))
                                   .flat(flat).rotation(rotation));
}
```

When we call `addMarker()`, we supply corresponding values:

```
    addMarker(map, 40.748963847316034, -73.96807193756104,
              R.string.un, R.string.united_nations, false, 180);
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center,
              R.string.lincoln_center_snippet, false, 0);
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.carnegie_hall, R.string.practice_x3, true, 90);
    addMarker(map, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy, true,
              270);
```

Sprucing Up Your "Info Windows"

If the user taps on one of the markers from the preceding sample, Android will automatically display a popup, known as an "info window":



Carnegie Hall

Where you go with practice, practice, practice

Figure 533: Maps V2 with Default Info Window

You can tailor that "info window" if desired, either replacing just the interior portion (leaving the bounding border with its caret intact) or replacing the entire window. However, in the interests of memory conservation, you do not hand new `View` widgets to the MarkerOptions object. Instead, you can provide an adapter that will be called when info windows (or their contents) are required.

To see how this works, we can examine the MapsV2/Popups sample application. This is a clone of MapsV2/Markers, where we are using our own layout file for the contents of the info windows, from the popup.xml layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:padding="2dip"
    android:src="@drawable/ic_launcher"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
      android:id="@+id/title"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="25sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/snippet"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="15sp"/>
  </LinearLayout>

</LinearLayout>
```

Here, we will show the title and snippet in our own chosen font size and weight, plus show the launcher icon on the left.

To use this layout, we must create an InfoWindowAdapter implementation — in the case of this sample project, that is found in the PopupAdapter class:

```
package com.commonsware.android.mapsv2.popups;

import android.annotation.SuppressLint;
import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
  private View popup=null;
  private LayoutInflater inflater=null;

  PopupAdapter(LayoutInflater inflater) {
    this.inflater=inflater;
  }

  @Override
  public View getInfoWindow(Marker marker) {
    return(null);
  }

  @SuppressLint("InflateParams")
  @Override
  public View getInfoContents(Marker marker) {
    if (popup == null) {
      popup=inflater.inflate(R.layout.popup, null);
    }

    TextView tv=(TextView)popup.findViewById(R.id.title);

    tv.setText(marker.getTitle());
    tv=(TextView)popup.findViewById(R.id.snippet);
    tv.setText(marker.getSnippet());

    return(popup);
  }
}
```

When an info window is to be displayed, Android will first call `getInfoWindow()` on our `InfoWindowAdapter`, passing in the `Marker` whose info window is needed. If we return a `View` here, that will be used for the entire info window. If, instead, we return `null`, Android will call `getInfoContents()`, passing in the same `Marker` object. If we return a `View` here, Android will use that as the "body" of the info window, with Android supplying the border. If we return `null`, the default info window is displayed. This way, we can conditionally do any of the three possibilities (replace the window, replace the contents, or accept the default).

In our case, `getInfoContents()` will inflate the `popup.xml` layout and populate the two `TextView` widgets with the title and snippet from the `Marker`. However, we cache the inflated layout and reuse it on the second and subsequent calls to `getInfoContents()`. Despite the "adapter" name conjuring up visions of `ListAdapter` and having multiple outstanding views, `InfoWindowAdapter` will only ever use one `View` at a time. Hence, rather than inflate our layout each time we need to show the info window, we can safely reuse the previously-used `View`.

Then, we just need to tell the GoogleMap to use our InfoWindowAdapter, via a call to setInfoWindowAdapter(), such as this statement from onMapReady() of our new edition of MainActivity:

```
    map.setInfoWindowAdapter(new PopupAdapter(getLayoutInflater()));
```

Now, when the user taps on a marker, they will get our customized info window:

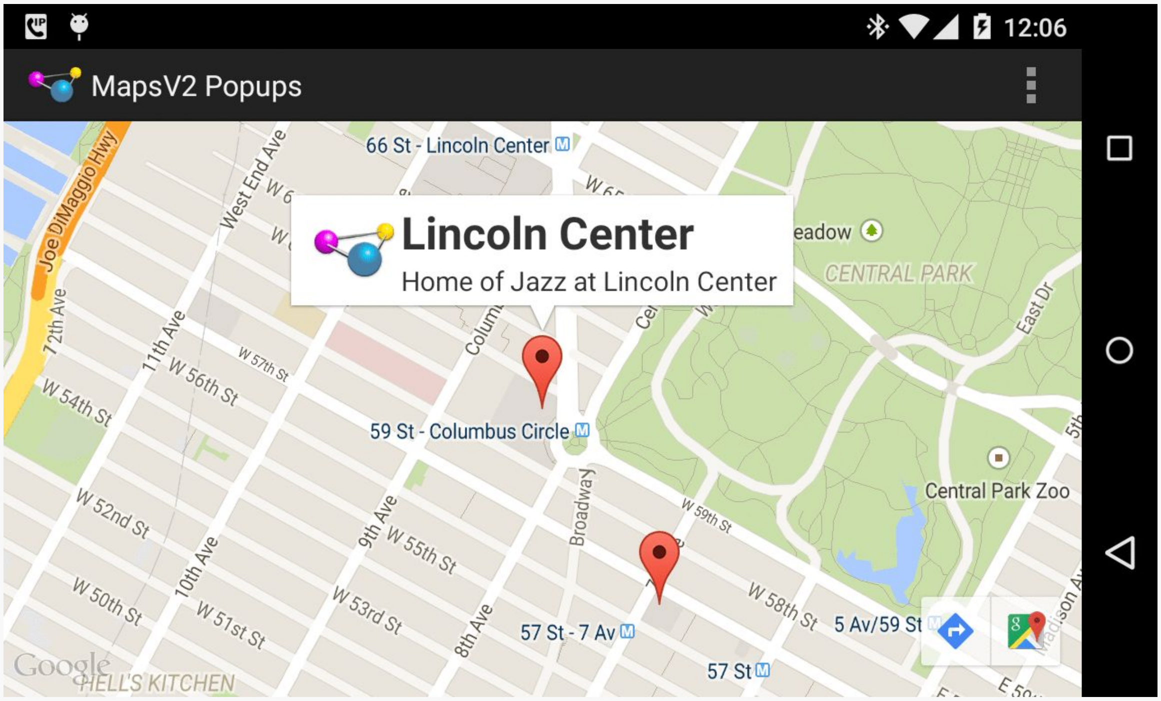


Figure 534: Maps V2 with Customized Info Window

We can also call setOnInfoWindowClickListener() on our GoogleMap, passing in an implementation of the OnInfoWindowClickListener interface, to find out when the user taps on the info window. In the case of MainActivity, we set up the activity itself to implement that interface and be the listener:

```
    map.setOnInfoWindowClickListener(this);
```

This requires us to implement an onInfoWindowClick() method, where we are passed the Marker representing the tapped-upon info window:

```
  @Override
  public void onInfoWindowClick(Marker marker) {
    Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();
  }
```

Here, we just display a `Toast` with the title of the `Marker` when the user taps an info window:

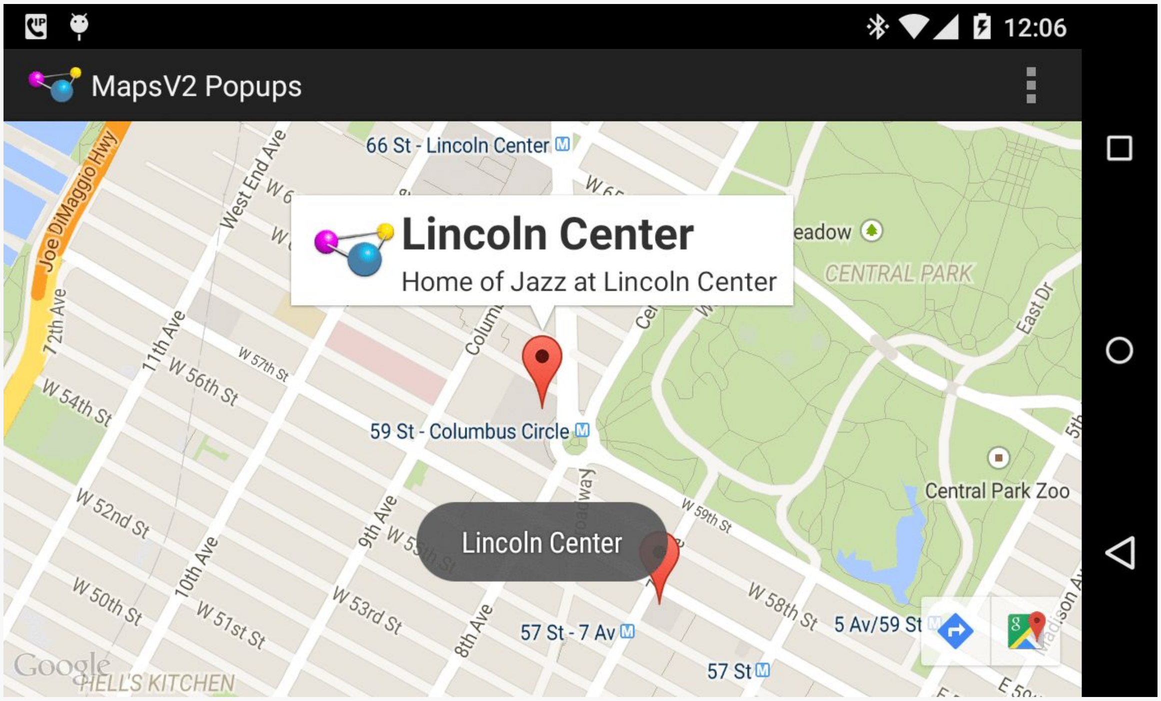

Figure 535: Maps V2 with Toast Triggered by Tap on Info Window

Note that, according to the documentation, you can only find out about taps on the entire info window. Indeed, if you try setting up click listeners on the widgets in your custom layout, you will find that they are not called. This is because the `View` you return for the info window is converted into a `Bitmap`, which is then displayed. Presumably, this is to steer developers in the direction of making larger tap targets, rather than expecting users to tap tiny elements within an info window. On the other hand, if your design calls for a large info window containing several navigation options, you will need to either re-think your design or avoid the info window system. We will see how to find out about taps on markers more directly later in this chapter.

Images and Your Info Window

The `Bitmap` approach that Maps V2 uses for the info window introduces an additional challenge: updating the info window itself. Normally, we would just update the individual widgets in the info window, the way we might update widgets in an already-visible row in a `ListView`. However, that is not an option here, as our widgets are discarded almost immediately.

One particular occurrence of this problem comes when you want to show an image in the info window. If the image is a resource, or is already in memory, showing it is not a big problem, as you can just populate your `ImageView` in your info window with it. However, if the image is a file (or, worse, needs to be downloaded), you want to load the image asynchronously. However, if you kick off some background thread, like an `AsyncTask`, to retrieve the image, you will return from your `InfoWindowAdapter` method long before the task is complete. Your info window will show whatever placeholder image you used; the image you loaded will never be seen, even if you update your original `ImageView`.

There are two solutions to this problem.

The best solution, by far, is to have the images before you need them, wherever possible. For example, if you are showing a map with 25 markers, for which you need 25 thumbnail images, start downloading those images while you are showing the map. With luck, at the point in time when the user taps on a marker to show the info window, you will have your image already.

However, this approach will not work well if:

- You need a ridiculous number of images, or
- You need images, but they need to be downloaded full-sized and turned into thumbnails locally, as that might consume quite a bit of bandwidth, or
- Your last name is Murphy, and therefore the user taps on an info window before you have had a chance to prepare its image

The workaround is to make note of the `Marker` the user tapped upon to open its info window, then call `showInfoWindow()` on that `Marker` to cause the info window to be redisplayed once you have your image, triggering calls to your `InfoWindowAdapter`. There, you can see that your image cache includes the image that you need, and you can apply it to the info window.

The problem *here* is that it is possible that the user tapped on another marker, after the first one, while you were busily fetching and loading the image. Hence, rather than blindly calling `showInfoWindow()` on the `Marker`, you should call `isInfoWindowShown()` first, and only call `showInfoWindow()` to force the refresh if `isInfoWindowShown()` returns `true`. Otherwise, some other marker's info window is shown. The user is not expecting this earlier info window to somehow magically reappear.

All of this is a pain. It can be made a bit less of a pain by use of an image fetching-and-caching library like Picasso. We can see how this can be applied by looking at the MapsV2/ImagePopups sample application. This is a clone of MapsV2/Popups, with some additions to handle lazy-populating an info window based upon a downloaded image.

First, since we are going to be generating some thumbnails based on downloaded imagery, it helps to establish a fixed-size ImageView for our icon. So, this project has a pair of dimension resources, for the image height and width:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <dimen name="icon_width">96dp</dimen>
    <dimen name="icon_height">64dp</dimen>

</resources>
```

Those are then used in a revised version of the popup layout resource:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="@dimen/icon_width"
    android:layout_height="@dimen/icon_height"
    android:padding="2dip"
    android:src="@drawable/ic_launcher"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:orientation="vertical">

    <TextView
      android:id="@+id/title"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="25sp"
      android:textStyle="bold"/>

    <TextView
      android:id="@+id/snippet"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:textSize="15sp"/>
  </LinearLayout>

</LinearLayout>
```

We need some way of keeping track of what images should be used for each marker. This is somewhat annoying to implement, as we cannot subclass `Marker`, since it is marked as `final` and cannot be extended. However, we can use `getId()` on a `Marker` to obtain a unique ID, and we can use that as the key to additional model data. We will examine variations on this technique later in this chapter. For now, this sample gets away with a simple `HashMap`, mapping the string ID of a `Marker` to a `Uri` representing an image to be shown for that `Marker`'s info window:

```
  private HashMap<String, Uri> images=new HashMap<String, Uri>();
```

Our private `addMarker()` method now takes a `String` name of an image, and it adds a `Uri` pointing to that image to the `HashMap`, keyed by the ID of the generated `Marker`:

```
  private void addMarker(GoogleMap map, double lat, double lon,
                         int title, int snippet, String image) {
    Marker marker=
        map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                         .title(getString(title))
                                         .snippet(getString(snippet)));

    if (image != null) {
      images.put(marker.getId(),
                 Uri.parse("http://misc.commonsware.com/mapsv2/"
                     + image));
    }
  }
```

For three of our markers, we pass in actual filenames; for a fourth, `null` is used, indicating that there is no suitable image for use:

```
    addMarker(map, 40.748963847316034, -73.96807193756104,
              R.string.un, R.string.united_nations, "UN_HQ.jpg");
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center,
              R.string.lincoln_center_snippet,
              "Avery_Fisher_Hall.jpg");
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.carnegie_hall, R.string.practice_x3,
              "Carnegie_Hall.jpg");
    addMarker(map, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy, null);
```

Note that the three images being used in this chapter come from Wikipedia. One is public domain, the others are licensed under the Creative Commons Attribution 1.0 license. Those two are a picture of Avery Fisher Hall, part of the Lincoln Center for the Performing Arts (courtesy of Geographer) and the other is a picture of the United Nations building (courtesy of WorldIslandInfo).

The `PopupAdapter` needs access to these images. It will also need access to a `Context`, for use with Picasso. So, `PopupAdapter` now has data members for these, which are passed into a revised version of its constructor by `MainActivity`. That constructor not only holds onto the new objects, but it retrieves the values of the dimension resources for our images, converted by Android into pixels for the screen density of the device that we are running on:

```
PopupAdapter(Context ctxt, LayoutInflater inflater,
             HashMap<String, Uri> images) {
  this.ctxt=ctxt;
  this.inflater=inflater;
  this.images=images;

  iconWidth=
      ctxt.getResources().getDimensionPixelSize(R.dimen.icon_width);
  iconHeight=
      ctxt.getResources().getDimensionPixelSize(R.dimen.icon_height);
}
```

The revised `getInfoContents()` method is significantly more complicated than was its predecessor:

```
@SuppressLint("InflateParams")
@Override
public View getInfoContents(Marker marker) {
  if (popup == null) {
    popup=inflater.inflate(R.layout.popup, null);
  }

  if (lastMarker == null
      || !lastMarker.getId().equals(marker.getId())) {
    lastMarker=marker;

    TextView tv=(TextView)popup.findViewById(R.id.title);

    tv.setText(marker.getTitle());
    tv=(TextView)popup.findViewById(R.id.snippet);
    tv.setText(marker.getSnippet());

    Uri image=images.get(marker.getId());
    ImageView icon=(ImageView)popup.findViewById(R.id.icon);

    if (image == null) {
      icon.setVisibility(View.GONE);
    }
    else {
      Picasso.with(ctxt).load(image).resize(iconWidth, iconHeight)
             .centerCrop().noFade()
             .placeholder(R.drawable.placeholder)
             .into(icon, new MarkerCallback(marker));
    }
  }

  return(popup);
}
```

We track the last `Marker` that we have processed in a `lastMarker` data member. Initially, of course, that will be `null`. If it is, or if the `Marker` passed into `getInfoContents()` is a different one (based on the `getId()` value), then we populate the popup `View`. This includes fetching the `Uri` from the `HashMap` of `Uri` values (given the `Marker` ID). If there is no `Uri`, `getInfoContents()` marks the `ImageView` as `GONE`, so it will not take up space in the popup. If, however, there *is* an image `Uri`, `getInfoContents()` asks Picasso to "do its thing":

- Load the image from the `Uri`
- Resize the image to be the desired dimensions for the `ImageView`, center-cropping to keep the right aspect ratio
- Skip the fade-in animation that is normally applied when Picasso populates an `ImageView` (as the Maps V2 `Bitmap` is generated before the animation completes, resulting in a washed-out image)
- Use a particular `placeholder` drawable resource while the image is loading
- Populate the `ImageView` with the results, specifying a `MarkerCallback` to be notified of the results

`MarkerCallback`, as an implementation of Picasso's `Callback` interface, needs `onError()` and `onSuccess()` methods. `onError()` just dumps a message to LogCat, while `onSuccess()` refreshes the info window, via a call to `showInfoWindow()` on the `Marker`, if that info window is still showing:

```
  static class MarkerCallback implements Callback {
    Marker marker=null;

    MarkerCallback(Marker marker) {
      this.marker=marker;
    }

    @Override
    public void onError() {
      Log.e(getClass().getSimpleName(), "Error loading thumbnail!");
    }

    @Override
    public void onSuccess() {
      if (marker != null && marker.isInfoWindowShown()) {
        marker.showInfoWindow();
      }
    }
  }
```

If you run this sample app, you will see the popup with a placeholder image at first, quickly being replaced by the thumbnail supplied by Picasso:

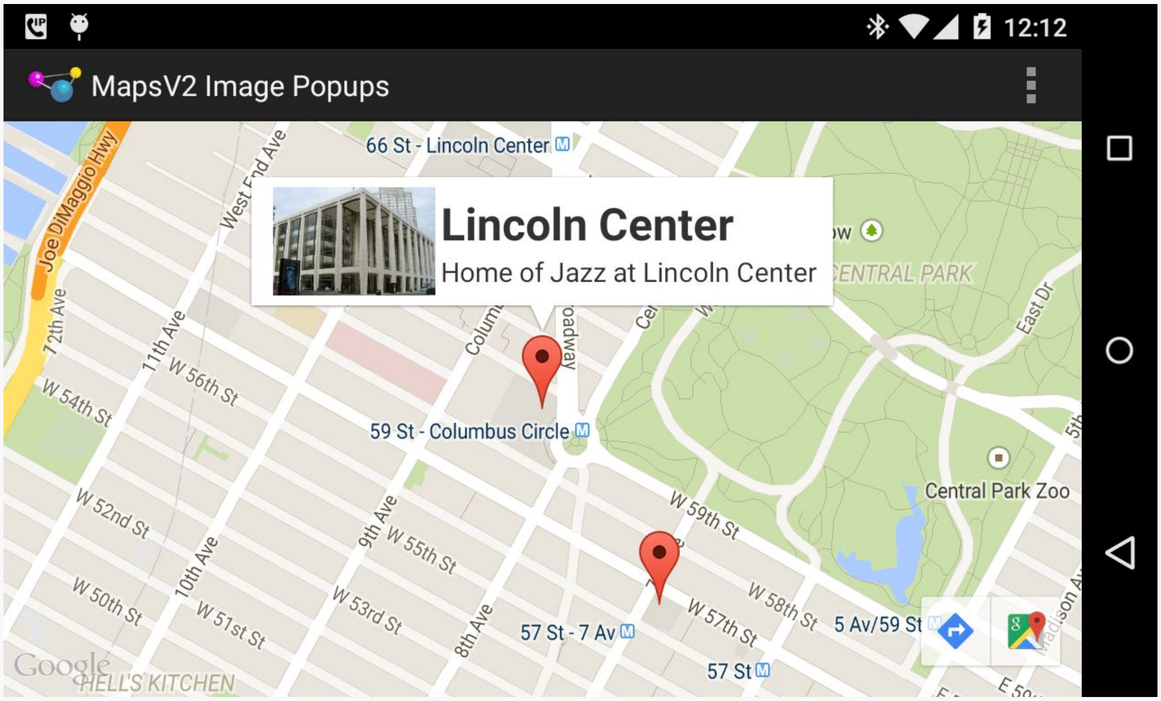

Figure 536: Maps V2 with Popup and Thumbnail

Setting the Marker Icon

Maps V2 includes a stock marker icon that looks a lot like the standard Google Maps marker. You have three major choices for what to use for your own markers:

1. Stick with the stock icon, which is the default behavior
2. Change the stock icon to a different hue
3. Replace the stock icon with your own from an asset, resource, file, or in-memory `Bitmap`

To indicate that you want a different icon than the stock one, use the `icon()` method on the `MarkerOptions` fluent interface. This takes a `BitmapDescriptor`, which you get from one of a series of static methods on the `BitmapDescriptorFactory` class.

For example, you might have a revised version of the `addMarker()` method of `MainActivity` that took a hue — a value from 0 to 360 representing different colors along a color wheel. 0 represents red, 120 represents green, and 240 represents blue, with different shades in between. There is a series of `HUE_` constants defined on `BitmapDescriptorFactory`, plus a `defaultMarker()` method that takes a hue as a parameter and returns a `BitmapDescriptor` that will use the stock icon, colored to the specified hue:

```
private void addMarker(GoogleMap map, double lat, double lon,
                        int title, int snippet, int hue) {
  map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                   .title(getString(title))
                                   .snippet(getString(snippet))
                                   .icon(BitmapDescriptorFactory.defaultMarker(hue)));
}
```

This could then be used to give you different colors per marker, or by category of marker, etc.:

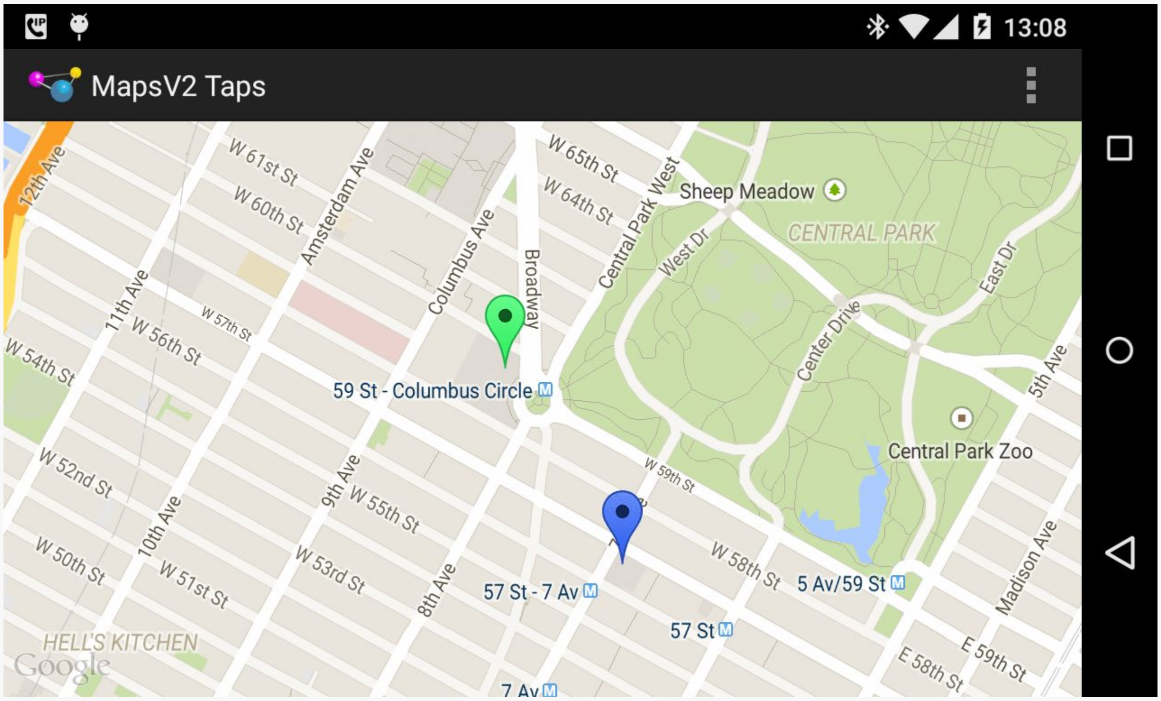

Figure 537: Maps V2 with Alternate Marker Hues

Note that you can modify the icon at runtime via the `setIcon()` method on the `Marker` returned by `addMarker()` method on `GoogleMap`.

However, you cannot draw the marker directly yourself, the way you might have with Maps V1. What you *can* do is draw to a `Bitmap`-backed `Canvas` object, then use the resulting `Bitmap` with `BitmapFactoryDescriptor` and its `fromBitmap()` factory method.

Responding to Taps

Perhaps we would like to find out when a user taps on one of our markers, instead of displaying an info window. Maybe we want to have some other UI response to that tap in our app.

To do that, simply create an implementation of the `OnMarkerClickListener` interface and attach it to the `GoogleMap` via `setOnMarkerClickListener()`. You will then be called with `onMarkerClick()` when the user taps on a marker, and you are passed the `Marker` object in question. If you return `true`, you are indicating that you are handling the event; returning `false` means that default handling (the info window) should be done.

You can see this, plus the multi-colored markers, in the [MapsV2/Taps] sample application. This takes `MapsV2/Popups` and adds a `Toast` when the user taps a marker, in addition to displaying the info window:

```
@Override
public boolean onMarkerClick(Marker marker) {
  Toast.makeText(this, marker.getTitle(), Toast.LENGTH_LONG).show();

  return(false);
}
```

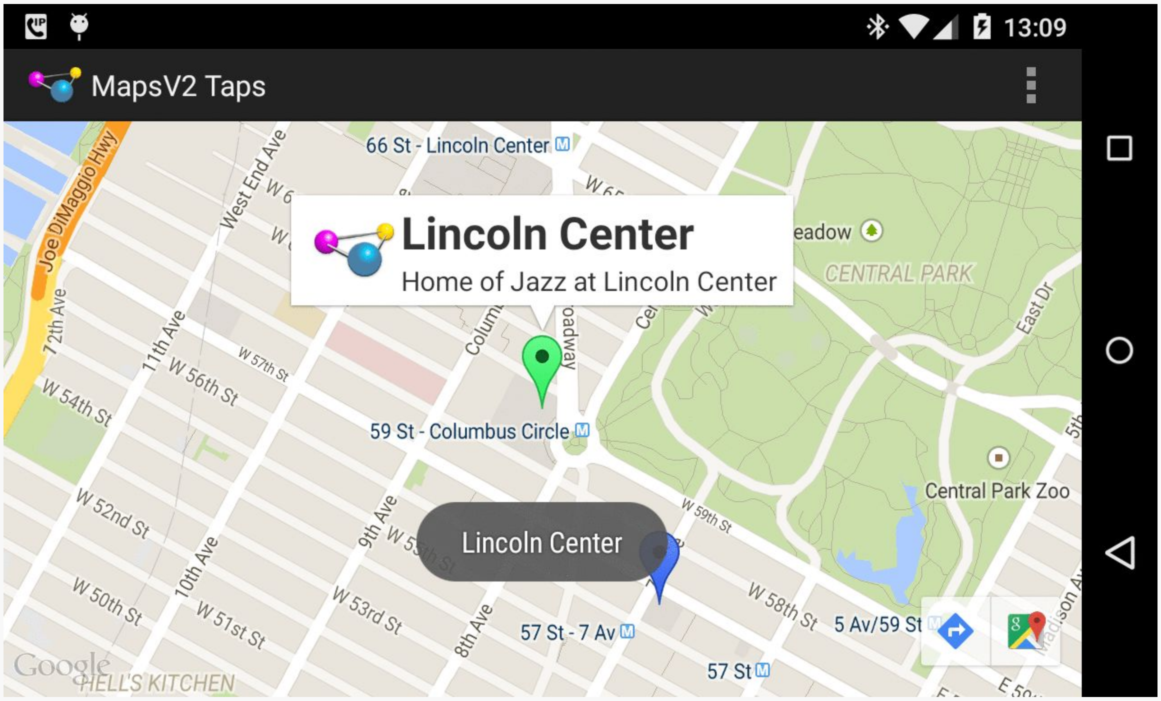

Figure 538: Maps V2 with Toast and Info Window

Our call to `setOnMarkerClickListener()` is up in the `onMapReady()` method of `MainActivity`:

```
    map.setOnMarkerClickListener(this);
```

Dragging Markers

By default, markers are not draggable. But, if you call `draggable(true)` on your `MarkerOptions` when creating the marker — or call `setDraggable(true)` on the `Marker` later on — Android will automatically support drag-and-drop. The user can tap-and-hold on the marker to enable drag mode, then slide the marker around the map.

Note that at the present time, this functionality is a little odd. When you tap-and-hold the marker, with drag mode enabled, the marker initially jumps away from its original position. The user can reposition the marker to any desired location, and the marker will seem to "drop" where the user requests. Why the marker makes the sudden shift at the outset, using the default marker settings, is unclear.

Of course, your code may need to know about drag-and-drop events, such as to update your own data model to reflect the newly-chosen location. You can register an `OnMarkerDragListener` that will be notified of the start of the drag, where the marker slides during the drag, and where the marker is dropped at the end of the drag.

You can see all of this in the [MapsV2/Drag] sample application, which is a clone of `MapsV2/Popup` with drag-and-drop enabled.

To enable drag-and-drop, we just chain `draggable(true)` onto the series of calls on our `MarkerOptions` when creating the markers:

```
private void addMarker(GoogleMap map, double lat, double lon,
                       int title, int snippet) {
  map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                   .title(getString(title))
                                   .snippet(getString(snippet))
                                   .draggable(true));
}
```

We also register `MainActivity` as being the drag listener, up in `onMapReady()`:

```
  map.setOnMarkerDragListener(this);
```

That requires `MainActivity` to implement `OnMarkerDragListener`, which in turn requires three methods to be defined: `onMarkerDragStart()`, `onMarkerDrag()`, and `onMarkerDragEnd()`:

```
@Override
public void onMarkerDragStart(Marker marker) {
  LatLng position=marker.getPosition();

  Log.d(getClass().getSimpleName(), String.format("Drag from %f:%f",
                                                  position.latitude,
                                                  position.longitude));
}

@Override
public void onMarkerDrag(Marker marker) {
  LatLng position=marker.getPosition();

  Log.d(getClass().getSimpleName(),
        String.format("Dragging to %f:%f", position.latitude,
                      position.longitude));
}

@Override
public void onMarkerDragEnd(Marker marker) {
  LatLng position=marker.getPosition();

  Log.d(getClass().getSimpleName(), String.format("Dragged to %f:%f",
      position.latitude,
      position.longitude));
}
```

Here, we just dump the information about the new marker position in LogCat.

So, if you run this app and drag-and-drop a marker, you will see output in LogCat akin to:

```
12-19 13:10:36.442: D/MainActivity(22510): Drag from 40.770876:-73.982499
12-19 13:10:36.892: D/MainActivity(22510): Dragging to 40.770876:-73.981593
12-19 13:10:36.912: D/MainActivity(22510): Dragging to 40.770795:-73.981352
12-19 13:10:36.932: D/MainActivity(22510): Dragging to 40.770754:-73.981141
.
.
.
12-19 13:10:38.292: D/MainActivity(22510): Dragging to 40.769596:-73.983615
12-19 13:10:38.372: D/MainActivity(22510): Dragged to 40.769596:-73.983615
```

The actual list of events was much longer, as `onMarkerDrag()` is called a *lot*, so the `...` in the LogCat entries above reflect another 50 or so lines for a drag-and-drop that took a couple of seconds.

Also, up in `onCreate()`, we retain our `MapFragment` across configuration changes via `setRetainInstance(true)`:

```
      mapFrag.setRetainInstance(true);
```

Retaining the fragment instance causes the fragment to keep our markers in their moved positions, rather than resetting them to their original positions.

The "Final" Limitations

In Maps V2, not only do you not create `Marker` objects directly yourself, but `Marker` is marked as `final` and cannot be extended. Hence, you cannot use a `Marker` directly to hold model data.

However, `Marker` does have `getId()`, an immutable identifier for the `Marker`. We can use that as a key for a `HashMap` that allows us to get at additional model data associated with the `Marker`.

You can see this approach in the `MapsV2/Models` sample application, which is a clone of `MapsV2/Popup` where we use the ID in just this fashion.

Our simplified model is merely the data we poured into our Marker objects in the original MapsV2/Popup project:

```
package com.commonsware.android.mapsv2.model;

import android.content.Context;

public class Model {
  String title;
  String snippet;
  double lat;
  double lon;

  Model(Context ctxt, double lat, double lon, int title,
        int snippet) {
    this.title=ctxt.getString(title);
    this.snippet=ctxt.getString(snippet);
    this.lat=lat;
    this.lon=lon;
  }

  String getTitle() {
    return(title);
  }

  String getSnippet() {
    return(snippet);
  }

  double getLatitude() {
    return(lat);
  }

  double getLongitude() {
    return(lon);
  }
}
```

Our activity holds onto a HashMap of these Model objects, with the map keyed by the Marker ID (a String):

```
  private HashMap<String, Model> models=new HashMap<String, Model>();
```

Of course, a real application would have a much more elaborate setup than this.

We then arrange to populate our map with Marker objects created from our Model objects, moving the add-the-markers-to-the-map logic to an addMarkers() method:

```
  private void addMarkers(GoogleMap map) {
    Model model=
        new Model(this, 40.748963847316034, -73.96807193756104,
                  R.string.un, R.string.united_nations);

    models.put(addMarkerForModel(map, model).getId(), model);
    model=
        new Model(this, 40.76866299974387, -73.98268461227417,
                  R.string.lincoln_center,
                  R.string.lincoln_center_snippet);
    models.put(addMarkerForModel(map, model).getId(), model);

    model=
        new Model(this, 40.765136435316755, -73.97989511489868,
                  R.string.carnegie_hall, R.string.practice_x3);
    models.put(addMarkerForModel(map, model).getId(), model);

    model=
        new Model(this, 40.70686417491799, -74.01572942733765,
                  R.string.downtown_club, R.string.heisman_trophy);
    models.put(addMarkerForModel(map, model).getId(), model);
  }

  private Marker addMarkerForModel(GoogleMap map, Model model) {
    LatLng position=
        new LatLng(model.getLatitude(), model.getLongitude());

    return(map.addMarker(new MarkerOptions().position(position)
                                            .title(model.getTitle())
                                            .snippet(model.getSnippet())));

  }
```

Notice that `addMarkerForModel()` returns the `Marker`, and we use `getId()` on that `Marker` as the key when adding a `Model` to the `HashMap`.

Our `PopupAdapter` gets the data for the info window from the `Model` (though, in truth, in this case, it could have gotten the data from the `Marker` itself, since we did not add more information to the info window):

```
package com.commonsware.android.mapsv2.model;

import android.view.LayoutInflater;
import android.view.View;
import android.widget.TextView;
import java.util.HashMap;
import com.google.android.gms.maps.GoogleMap.InfoWindowAdapter;
import com.google.android.gms.maps.model.Marker;

class PopupAdapter implements InfoWindowAdapter {
  LayoutInflater inflater=null;
  HashMap<String, Model> models=null;

  PopupAdapter(LayoutInflater inflater, HashMap<String, Model> models) {
    this.inflater=inflater;
    this.models=models;
  }

  @Override
  public View getInfoWindow(Marker marker) {
    return(null);
  }

  @Override
  public View getInfoContents(Marker marker) {
    View popup=inflater.inflate(R.layout.popup, null);

    TextView tv=(TextView)popup.findViewById(R.id.title);

    tv.setText(models.get(marker.getId()).getTitle());
    tv=(TextView)popup.findViewById(R.id.snippet);
    tv.setText(models.get(marker.getId()).getSnippet());

    return(popup);
  }
}
```

Visually, this is indistinguishable from the original `MapsV2/Popups` project. Of course, a real app would have more complex models, perhaps containing more discrete information for a more complex info window.

A Bit More About IPC

IPC is not only a problem in terms of disappearing `Marker` objects.

If you run a Maps V2 app under Traceview, to see what methods get called and how much time everything takes, you will see that many, many operations with `GoogleMap` do little in your process, but instead make synchronous calls to a Play Services process to do the real work:

Figure 539: Traceview Results for Maps V2 Map Creation

The preceding trace came from just the `onCreate()` method of the `MapsV2/Models` sample from the preceding section. Over 30% of the time to run `onCreate()` is tied up in IPC calls. And, unfortunately, you are not allowed to do much manipulation of a `GoogleMap` from a background thread (e.g., `moveCamera()`).

The moral of this story is to avoid manipulating your `GoogleMap` in time-sensitive portions of your code.

(the author would once again like to thank Cyril Mottier for pointing out this limitation in Maps V2)

Finding the User

Many times, the user is looking at a map to figure out where they are. Perhaps they are lost. Perhaps their spouse or significant other thinks that they are lost. Perhaps they think that they were teleported somewhere (e.g., a North African desert) after turning a "frozen wheel" in an icy cavern beneath an island, and therefore are *really* lost. Stranger things have happened.

(well, OK, perhaps not)

Regardless, it is often useful to help point out to the user their current location. That is a matter of adding a suitable location permission (e.g., `ACCESS_FINE_LOCATION`) and calling `setMyLocationEnabled(true)` on your `GoogleMap`. This activates a layer that will highlight their location, with the user having an option of having the "camera" (i.e., their perspective on the map) reposition itself to their location and move as they move. This latter capability is activated by a small icon in the upper right of the map.

You can see this in operation in the [`MapsV2/MyLocation`]() sample application, which is a clone of `MapsV2/Popup` with standard location tracking enabled.

All we do is call two additional methods on our `GoogleMap` in `onCreate()`:

- `setMyLocationEnabled()`, indicating that we want the "my location" layer added and automatic tracking to be enabled, and
- `setOnMyLocationChangeListener()`, indicating that we *also* want to be notified about changes in the user position

```
    map.setMyLocationEnabled(true);
    map.setOnMyLocationChangeListener(this);
```

That latter method also requires our activity to implement the `OnMyLocationChangeListener` interface, which in turn requires us to implement the `onMyLocationChange()` method, which will be called when Maps V2 gets a new location fix:

```
  @Override
  public void onMyLocationChange(Location lastKnownLocation) {
    Log.d(getClass().getSimpleName(),
        String.format("%f:%f", lastKnownLocation.getLatitude(),
            lastKnownLocation.getLongitude()));
  }
```

Here, we simply log the location to LogCat.

This is nice and easy, giving us our my-location overlay and arrow indicating the user's location and orientation:

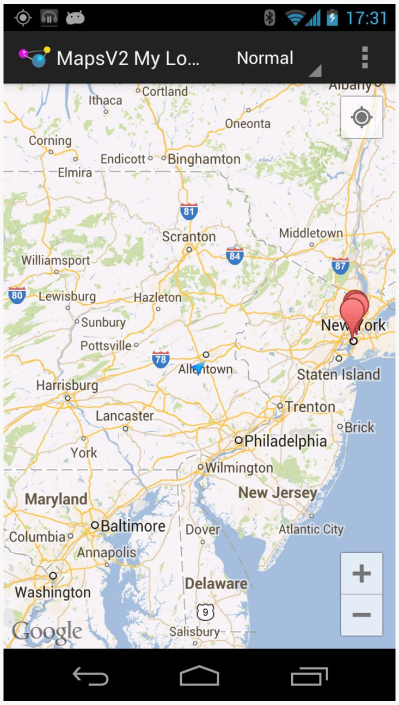

Figure 540: Maps V2, Showing the User's Location

However, there are three problems here. First, `setOnMyLocationChangeListener()` is now deprecated, as Google would prefer that you directly request the locations through [the `LocationClient` available from Play Services](#).

Second, there does not appear to be a way to *force* camera tracking of the user's position — you are reliant upon the user tapping that icon. You also have no control over the nature of the location provider that is used.

However, there is a workaround for this, proposed in [a Stack Overflow answer](#) – provide your own location data and update the camera yourself, by means of `setLocationSource()`. `setLocationSource()` lets *you* push locations to the `GoogleMap`, making other adjustments (e.g., camera position) along the way.

To see how this works, take a peek at the [`MapsV2/Location`](#) sample application, which is a clone of `MapsV2/Popup` with custom location tracking enabled.

Along with adding `ACCESS_FINE_LOCATION` to the manifest, this sample project adds some lines to the `onMapReady()` implementation of `MainActivity` to configure the `GoogleMap`:

```
    locMgr=(LocationManager)getSystemService(LOCATION_SERVICE);
    crit.setAccuracy(Criteria.ACCURACY_FINE);
    locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);

    map.setLocationSource(this);
    map.setMyLocationEnabled(true);
    map.getUiSettings().setMyLocationButtonEnabled(false);
```

The first three lines get access to a LocationManager, indicate that a Criteria object (initialized as a data member) should require fine accuracy, and request location updates. These come from the location tracking subsystem in Android.

The next two lines register our activity as being the source of location data and turns on location tracking in the GoogleMap, so the user's position will be marked on the map.

The last line disables the user's control over whether the camera position tracks their movement, since we want that to always be on in this case.

In onResume() and onPause() of MainActivity, we enable and disable getting location updates, as is typical of an activity needing location data. However, we also tell the GoogleMap that we are going to supply it with location data, rather than it having to obtain location data itself:

```
  @Override
  public void onResume() {
    super.onResume();

    if (locMgr!=null) {
      locMgr.requestLocationUpdates(0L, 0.0f, crit, this, null);
    }

    if (map!=null) {
      map.setLocationSource(this);
    }
  }

  @Override
  public void onPause() {
    map.setLocationSource(null);
    locMgr.removeUpdates(this);

    super.onPause();
  }
```

Note that we are blindly assuming that we will get location data. A production-grade app would put in better smarts to confirm that we will actually learn our location via this Criteria (e.g., the user does not have all location providers disabled).

Also note that because the map initialization is now happening on a background thread, `onResume()` might be called before `onMapReady()`, and so `onResume()` has to check to see if we already have a `LocationManager` and `GoogleMap` before proceeding.

The call to `setLocationSource()` — both in `onMapReady()` and `onResume()` – tells `GoogleMap` that our `MainActivity` itself is to be the source of location data. This requires `MainActivity` to implement the `LocationSource` interface, requiring us to implement `activate()` and `deactivate()` methods:

```
@Override
public void activate(OnLocationChangedListener listener) {
  this.mapLocationListener=listener;
}

@Override
public void deactivate() {
  this.mapLocationListener=null;
}
```

`activate()` provides us with an `OnLocationChangedListener`, from `GoogleMap`, to which we need to pass location data as we get it. `deactivate()` indicates that we should no longer attempt to contact that listener. In addition to holding onto that listener (or removing our reference to it when deactivated), we also take this opportunity to request and remove location updates.

The `onLocationChanged()` method — where we get our location fixes from `LocationManager` via the `LocationListener` interface — must pass the location along to the `GoogleMap`-supplied `OnLocationChangedListener`, if we have such a listener available:

```
@Override
public void onLocationChanged(Location location) {
  if (mapLocationListener != null) {
    mapLocationListener.onLocationChanged(location);

    LatLng latlng=
        new LatLng(location.getLatitude(), location.getLongitude());
    CameraUpdate cu=CameraUpdateFactory.newLatLng(latlng);

    map.animateCamera(cu);
  }
}
```

Here, we also create a `CameraUpdate` representing the new location and animate that update, to have the map slide over to the new location, centering the camera on the user's updated position.

The net effect of all of this is that the map continuously re-centers itself to show the user's position, which `GoogleMap` is highlighting on the map for us.

Dealing with Runtime Permissions

The previous section claimed three problems with the `MyLocation` sample, yet only explained two of them. That is because the third problem is shared by the `Location` sample as well: the apps are oblivious to Android 6.0's runtime permissions system.

Both samples have a `targetSdkVersion` of 22. They will install just fine on an Android 6.0 device, triggering the classic "accept all permissions at install time" dialog if installed by any means other than development tools. However, this also means that the apps will not know if the user goes into Settings and revokes the app's access to location data. Besides, *eventually* something will force your hand to have a `targetSdkVersion` of 23 or higher, and that will require you to adopt the new runtime permission system, whether you like it or not.

The `MapsV2/MyLocationMNC` sample application is nearly identical to the `MyLocation` sample, except that it has a `targetSdkVersion` of 23 and it makes limited use of the runtime permission system.

`onCreate()` of `MainActivity` now looks radically different:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  if (savedInstanceState==null) {
    needsInit=true;
  }
  else {
    isInPermission=
      savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
  }

  onCreateForRealz(canGetLocation());
}
```

Most of the original business logic from `onCreate()` has been moved into `onCreateForRealz()`. That method takes a `boolean` parameter, indicating whether or not we have permission to access the user's location. Here, we get that from a `canGetLocation()` method that, in turn, uses `ContextCompat.checkSelfPermission()` to see if we hold `ACCESS_FINE_LOCATION`:

```
private boolean canGetLocation() {
  return(ContextCompat.checkSelfPermission(this,
    Manifest.permission.ACCESS_FINE_LOCATION)==
    PackageManager.PERMISSION_GRANTED);
}
```

If we can work with locations, `onCreateForRealz()` will do what `onCreate()` used to do: call `readyToGo()` and, if we are ready to go, bring up the map:

```
private void onCreateForRealz(boolean canGetLocation) {
  if (canGetLocation) {
    if (readyToGo()) {
      setContentView(R.layout.activity_main);

      MapFragment mapFrag=
        (MapFragment)getFragmentManager().findFragmentById(
          R.id.map);

      mapFrag.getMapAsync(this);
    }
  }
  else if (!isInPermission) {
    isInPermission=true;

    ActivityCompat.requestPermissions(this,
      new String[] {Manifest.permission.ACCESS_FINE_LOCATION},
      REQUEST_PERMS);
  }
}
```

If we do not have access to the user's location, this particular sample app is not that interesting, so we will ask the user for permission, via a call to `ActivityCompat.requestPermissions()`. This will eventually trigger a call to `onRequestPermissionsResult()`:

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                       String[] permissions,
                                       int[] grantResults) {
  isInPermission=false;

  if (requestCode==REQUEST_PERMS) {
    if (canGetLocation()) {
      onCreateForRealz(true);
    }
    else {
      finish(); // denied permission, so we're done
    }
  }
}
```

Here, if we can now get the location, we go ahead and run through `onCreateForRealz()` again, to initialize the map. If, however, the user denied us the right to access the location, we `finish()` and exit the activity outright. One could argue that a better approach would be to show the map and simply not call `setMyLocationEnabled(true)` or `setOnMyLocationChangeListener()`. That would be another approach to dealing with the missing permission, and it is probably the better option if your primary goal was to just show a map.

Throughout this code, you have seen references to an `isInPermission` field. This tracks whether or not we are in the middle of requesting a permission:

- It is initialized to `false` in the activity
- It is set to `true` just before calling `requestPermissions()`
- It is set back to `false` in `onRequestPermissionsResult()`
- It is saved across configuration changes via `onSaveInstanceState()` and is retrieved from that state in `onCreate()`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
  super.onSaveInstanceState(outState);

  outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
}
```

(where `STATE_IN_PERMISSION` is a `static final String` to use as a key for the `Bundle` value)

This allows us to check whether or not we are in the middle of requesting permissions already in `onCreateForRealz()` and avoid popping up the permission-request dialog twice if the user rotates the screen while the first dialog is up, then denies the permission.

Also note that we are not taking any steps here to leverage `ActivityCompat.showShowPermissionRequestRationale()`, in case the user denied the permission on some previous run of our app, but then ran the app again. You could do something for that here, such as pop up a dialog and call `requestPermissions()` afterwards.

Drawing Lines and Areas

If you wanted to draw on a map in the Maps V1 framework, you created an `Overlay` and drew upon it. This forced you to handle low-level drawing work yourself, as you were handed a `Canvas` object and had to handle all the lines, fills, and so forth yourself.

Maps V2 offers a different approach. Free-form drawing is still conceivable, though it appears to have to be handled in the form of tile overlays instead of map overlays. However, for the simpler cases of drawing lines and areas, Maps V2 has built-in polyline, polygon, and circle support. You tell the `GoogleMap` what needs to be drawn, and it handles drawing it, both initially and as the map is zoomed or panned. A polyline is a line connecting a series of points; a polygon is a region defined by a series of corners. A circle, from the standpoint of Maps V2, is defined by a center coordinate and a radius.

We can see polylines and polygons on a `GoogleMap` in the [`MapsV2/Poly`]() sample application, which is a clone of `MapsV2/Popup` with two additions:

- A polyline connecting the locations of our four markers
- A polygon enclosing the area of Manhattan known as the Garment District (bounded by 34th Street, 42nd Street, Fifth Avenue, and Ninth Avenue)

To draw those, we simply add a few lines to `onMapReady()` of `MainActivity`:

```
    PolylineOptions line=
        new PolylineOptions().add(new LatLng(40.70686417491799,
                                             -74.01572942733765),
                                  new LatLng(40.76866299974387,
                                             -73.98268461227417),
                                  new LatLng(40.765136435316755,
                                             -73.97989511489868),
                                  new LatLng(40.748963847316034,
                                             -73.96807193756104))
                             .width(5).color(Color.RED);

    map.addPolyline(line);

    PolygonOptions area=
        new PolygonOptions().add(new LatLng(40.748429, -73.984573),
                                 new LatLng(40.753393, -73.996311),
                                 new LatLng(40.758393, -73.992705),
                                 new LatLng(40.753484, -73.980882))
                            .strokeColor(Color.BLUE);

    map.addPolygon(area);
```

The API for adding polylines and polygons is reminiscent of the API for adding markers: define an `...Options` object with the characteristics of the item to be drawn, then call an `add...()` method on `GoogleMap` to add the item.

So, to add a polyline, we create a `PolylineOptions` object. Using its fluent interface, we `add()` a series of `LatLng` objects, representing the points to be connected by the line. We also specify the line width in *pixels* via `width()` and the color of the line via color(). If we had several lines that might overlap, we could specify the zIndex(), where higher indexes indicate lines to be drawn over the top of lines with lower indexes. We add the polyline to the map by passing our PolylineOptions to addPolyline() on GoogleMap.

This gives us a line connecting the four markers, with GoogleMap handling the details of where the line should be drawn on the screen given the current map center and zoom levels:

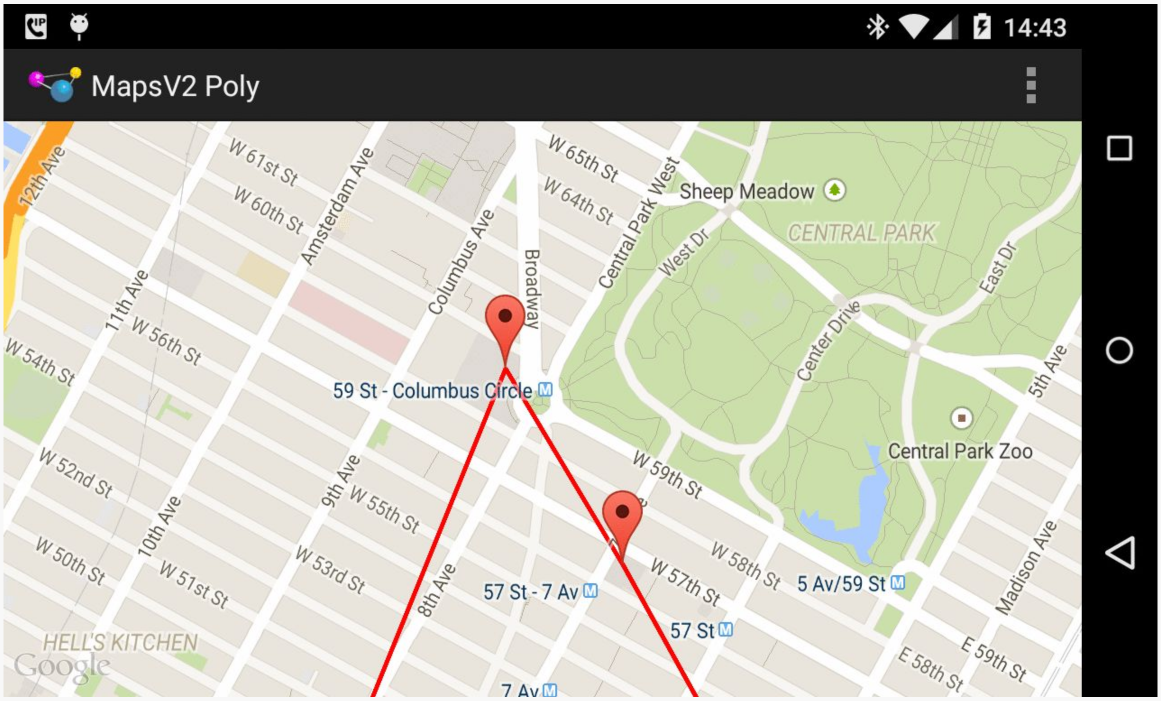

Figure 541: Maps V2 with Polyline

Note that the polyline is drawn using a flat Mercator projection by default. For most maps, that is perfectly fine. If your map will be showing countries and continents, rather than city blocks, you might want to call geodesic(true) on the PolylineOptions, to have the line drawn on a geodesic curve, reflecting the spherical nature of the Earth (dissenting opinions on that notwithstanding).

Similarly, we create a PolygonOptions object, configure it, and pass it to addPolygon for our Garment District box. The add() method on PolygonOptions will take the corners of our polygon, automatically enclosing that region. We also specify the strokeColor(). We could have specified a fillColor() (default is transparent), strokeWidth() (default is 10 pixels), zIndex(), and geodesic().

If we run the app and pan the map down to the south a bit, we see our polygon:

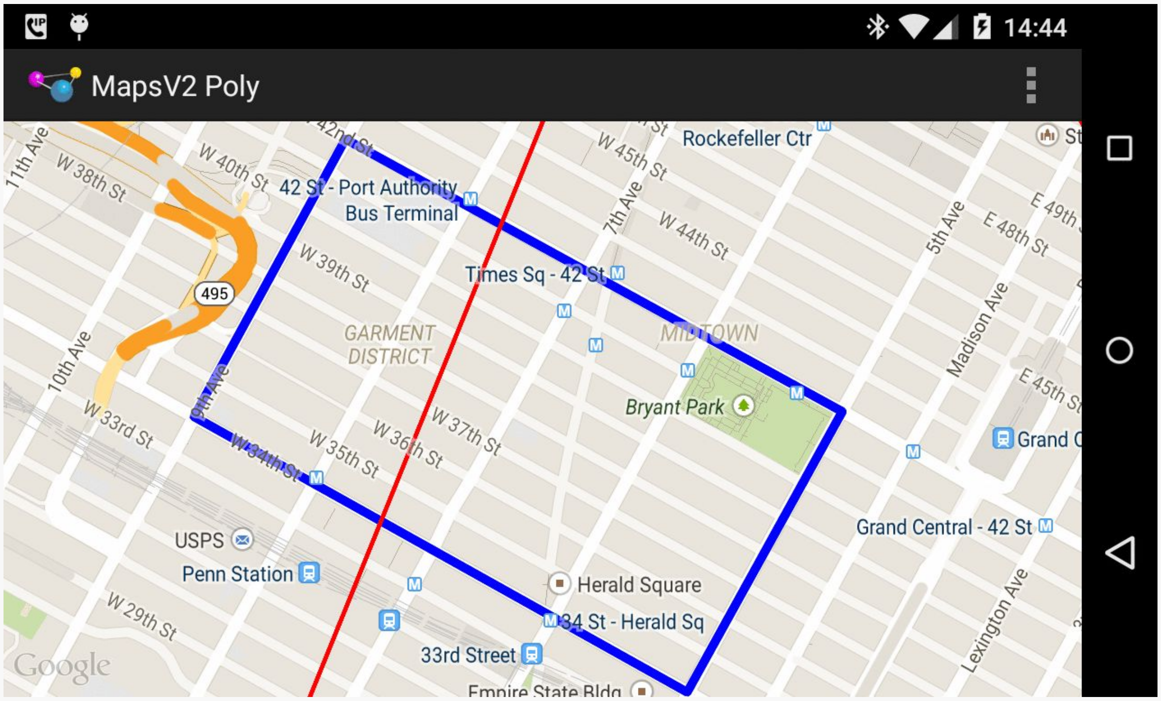

Figure 542: Maps V2 with Polyline and Polygon

As with the polyline, Android automatically handles drawing what is needed based on map center and zoom levels.

Note that, as with markers, we need to re-add the polylines and polygons after a configuration change, as the `GoogleMap` does not retain that information.

Gestures and Controls

By default, standard gestures and controls are enabled on your map:

- The user can change zoom level either by + and - buttons or via “pinch-to-zoom” gestures
- The user can change the center of the map via simple swipe gestures
- The user can change the camera tilt via two-finger vertical swipes, so instead of a traditional top-down perspective, the user can see things on an angle

- The user can change the orientation of the map via a two-finger rotating swipe, to change the typical "north is to the top of the map" to some other orientation

You can obtain a `UiSettings` object from your `GoogleMap` via `getUiSettings()` to disable these features, if desired:

- `setRotateGesturesEnabled()`
- `setScrollGesturesEnabled()` (for panning the map)
- `setTiltGesturesEnabled()`
- `setZoomControlsEnabled()` (for the + and - buttons)
- `setZoomGesturesEnabled()` (for pinch-to-zoom)

There is also `setAllGesturesEnabled()` to toggle on or off all gesture-based map control. This is roughly analogous to the `android:clickable` attribute on the Maps V1 edition of `MapView`.

There is also `setCompassEnabled()`, to indicate if a compass should be shown if the user changes the map orientation via a rotate gesture.

Tracking Camera Changes

If you have gestures enabled, the user can change the perspective of the map, referred to as changing the camera position. You may need to know about these changes, to perform various operations in your app based upon what is presently visible on the screen. To find out when the camera position changes, you can call `setOnCameraChangeListener()` on the `GoogleMap`, supplying an implementation of `OnCameraChangeListener`, which will be called with `onCameraChange()` as the user pans, zooms, or tilts the map.

To see how this works, we can take a quick peek at the [`MapsV2/Camera`]() sample application, which is a clone of `MapsV2/Popup` with camera position tracking enabled.

Late in `onMapReady()` of `MainActivity`, we call `setOnCameraChangeListener()` on our `GoogleMap`, supplying `MainActivity` itself as the listener:

```
    map.setOnCameraChangeListener(this);
```

This requires `MainActivity` to implement `OnCameraChangeListener` and supply an implementation of `onCameraChange()`:

```
@Override
public void onCameraChange(CameraPosition position) {
  Log.d(getClass().getSimpleName(),
        String.format("lat: %f, lon: %f, zoom: %f, tilt: %f",
                      position.target.latitude,
                      position.target.longitude, position.zoom,
                      position.tilt));
}
```

Here, we just log a message to LogCat on each camera position change, logging:

- the latitude and longitude of the map center, obtained from the `target` `LatLng` data member of the `CameraPosition` object supplied to `onCameraChange()`,
- the zoom level of the map, from the `zoom` data member of `CameraPosition`, and
- the tilt of the map, in degrees, from the `tilt` data member of `CameraPosition`

As a result, if you run this app and play around with the various gestures, you get a series of LogCat messages with the results:

```
12-26 15:36:39.456: D/MainActivity(31419): lat: 40.763727, lon: -73.983163, zoom:
15.000000, tilt: 0.000000
12-26 15:36:39.536: D/MainActivity(31419): lat: 40.763797, lon: -73.983118, zoom:
15.000000, tilt: 0.000000

15.875862, tilt: 59.296875
```

Maps in Fragments and Pagers

One key limitation of Maps V1 was that you could only have one MapView instance per *process*. Presumably, the proprietary code at the heart of the Maps SDK add-on used static data members for some state management, ones that would get messed up if there were two or more MapView widgets in active use.

Fortunately, Maps V2 gets rid of this restriction. You are welcome to have multiple MapFragment objects if that makes sense. Maps are relatively memory-intensive, so you should not be planning on having dozens or hundreds of them in use at a time, but you can have more than one.

To showcase this, the MapsV2/Pager sample application hosts 10 MapFragment instances as pages in a ViewPager. The bulk of the application is a clone of one of the ViewPager samples from the chapter on ViewPager.

Having maps in a ViewPager presents a bit of a problem, in terms of interpreting horizontal swipe events. Normally, ViewPager handles those itself. However, that would mean that the user cannot pan the map horizontally, which makes using the map somewhat challenging. In this sample, we will augment the ViewPager with logic to allow horizontal swiping on the maps and on the tab strip.

Our activity inflates a layout that contains our ViewPager along with a PagerTabStrip:

```
<?xml version="1.0" encoding="utf-8"?>
<com.commonsware.android.mapsv2.pager.MapAwarePager
xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/pager"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <android.support.v4.view.PagerTabStrip
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="top"/>

</com.commonsware.android.mapsv2.pager.MapAwarePager>
```

However, you will note that this is not ViewPager, but rather MapAwarePager, a custom subclass of ViewPager that we will examine shortly.

MainActivity then populates the MapAwarePager with an instance of a MapPageAdapter:

```
package com.commonsware.android.mapsv2.pager;

import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends AbstractMapActivity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (readyToGo()) {
      setContentView(R.layout.activity_main);

      ViewPager pager=(ViewPager)findViewById(R.id.pager);

      pager.setAdapter(buildAdapter());
    }
  }

  private PagerAdapter buildAdapter() {
    return(new MapPageAdapter(this, getFragmentManager()));
  }
}
```

MapPageAdapter is a FragmentStatePagerAdapter, not a FragmentPagerAdapter. This means that as the user swipes through our ViewPager, the adapter has the right to discard old fragments when it creates new ones. This helps reduce the overall memory footprint of our activity.

```
package com.commonsware.android.mapsv2.pager;

import android.content.Context;
import android.app.Fragment;
import android.app.FragmentManager;
import android.support.v13.app.FragmentStatePagerAdapter;

public class MapPageAdapter extends FragmentStatePagerAdapter {
  Context ctxt=null;

  public MapPageAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);
    this.ctxt=ctxt;
  }

  @Override
  public int getCount() {
    return(10);
  }

  @Override
  public Fragment getItem(int position) {
    return(new PageMapFragment());
  }

  @Override
  public String getPageTitle(int position) {
    return(ctxt.getString(R.string.map_page_title) + String.valueOf(position + 1));
  }
}
```

`MapPageAdapter` declares that there should be ten pages (in `getCount()`) and returns an instance of `PageMapFragment` for each page. `PageMapFragment` is a subclass of `MapFragment`, and so is responsible for displaying our map:

```
package com.commonsware.android.mapsv2.pager;

import android.os.Bundle;
import com.google.android.gms.maps.CameraUpdate;
import com.google.android.gms.maps.CameraUpdateFactory;
import com.google.android.gms.maps.GoogleMap;
import com.google.android.gms.maps.MapFragment;
import com.google.android.gms.maps.OnMapReadyCallback;
import com.google.android.gms.maps.model.LatLng;
import com.google.android.gms.maps.model.MarkerOptions;

public class PageMapFragment extends MapFragment implements
    OnMapReadyCallback {
  private boolean needsInit=false;

  @Override
  public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    if (savedInstanceState == null) {
      needsInit=true;
    }

    getMapAsync(this);
  }

  @Override
  public void onMapReady(final GoogleMap map) {
    if (needsInit) {
      CameraUpdate center=
          CameraUpdateFactory.newLatLng(new LatLng(40.76793169992044,
                                                   -73.98180484771729));
      CameraUpdate zoom=CameraUpdateFactory.zoomTo(15);

      map.moveCamera(center);
      map.animateCamera(zoom);
    }

    addMarker(map, 40.748963847316034, -73.96807193756104, R.string.un,
              R.string.united_nations);
    addMarker(map, 40.76866299974387, -73.98268461227417,
              R.string.lincoln_center, R.string.lincoln_center_snippet);
    addMarker(map, 40.765136435316755, -73.97989511489868,
              R.string.carnegie_hall, R.string.practice_x3);
    addMarker(map, 40.70686417491799, -74.01572942733765,
              R.string.downtown_club, R.string.heisman_trophy);
  }

  private void addMarker(GoogleMap map, double lat, double lon,
                         int title, int snippet) {
    map.addMarker(new MarkerOptions().position(new LatLng(lat, lon))
                                     .title(getString(title))
                                     .snippet(getString(snippet)));
  }
}
```

If we simply wanted to display an unconfigured map, we could just have `MapPageAdapter` create and return instances of `MapFragment` directly. If we want to configure our map, though, we need to get control when the `GoogleMap` object is ready for use. One way to do that is to extend `MapFragment` and override `onActivityCreated()` and call `getMapAsync()` there to begin the whole get-the-`GoogleMap`-loaded process. In `onMapReady()`, we can then go ahead and configure the map much as we have done in previous examples, just from within the fragment itself rather than from the hosting activity.

`MapAwarePager` overrides one key method of `ViewPager`: `canScroll()`:

```
package com.commonsware.android.mapsv2.pager;

import android.content.Context;
import android.support.v4.view.PagerTabStrip;
import android.support.v4.view.ViewPager;
import android.util.AttributeSet;
import android.view.SurfaceView;
import android.view.View;

public class MapAwarePager extends ViewPager {
  public MapAwarePager(Context context, AttributeSet attrs) {
    super(context, attrs);
  }

  @Override
  protected boolean canScroll(View v, boolean checkV, int dx, int x,
                              int y) {
    if (v instanceof SurfaceView || v instanceof PagerTabStrip) {
      return(true);
    }

    return(super.canScroll(v, checkV, dx, x, y));
  }
}
```

`canScroll()` should return `true` if the `View` (and specifically the supplied X and Y coordinates within that `View`) can be scrolled horizontally, `false` otherwise. In our case, we want to say that the map and the tab strip are each scrollable horizontally. As it turns out, the passed-in `View` for our `MapFragment` will be the map if it is a subclass of `SurfaceView` (determined by trial and error on the author's part, with hopes for a more authoritative solution in a future edition of the Maps V2 API). So, if the passed-in `View` is either a `SurfaceView` or a `PagerTabStrip`, we return `true`, otherwise we default to normal logic.

The result is a series of independent maps, one per page:

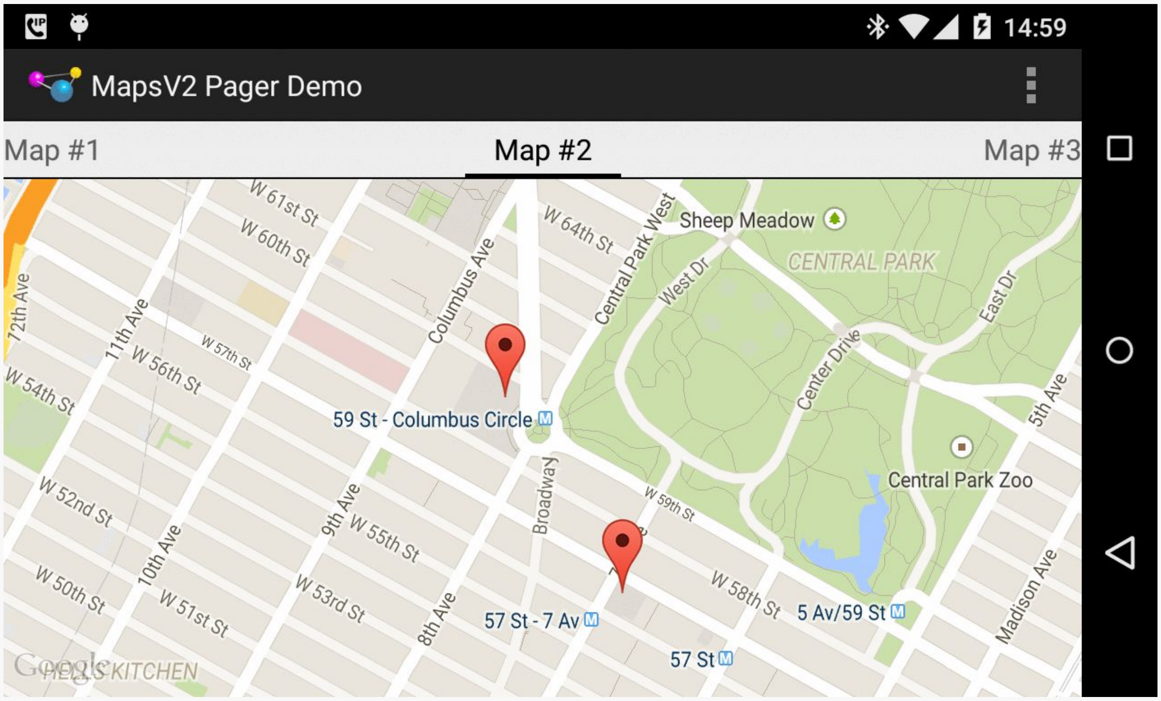

Figure 543: Multiple Maps V2 Maps in a ViewPager

Each map is independent: if the user pans or zooms one map, that has no impact on any of the other pages. Panning the maps horizontally works; to move between pages, use the tab strip.

Animating Marker Movement

Markers, by default, are static, unless you make them be draggable, and then only the user can drag them.

However, you are welcome to update the position of a Marker at any point, by calling setPosition() and supplying a new LatLng. The Marker then will jump to that position.

But what if you want to animate the movement of a Marker from its current position to a new one? Maps V2 does not offer anything “out of the box” for implementing this, but Google demonstrated approaches for this in a “DevBytes” video and related bit of code in a GitHub Gist. This section will cover the technique appropriate for API Level 14+, including a full working sample (the Gist shows code but not its usage).

Problem #1: Animating a LatLng

The position of a Marker is a LatLng, as we have seen previously. LatLng is not a simple number, and so the animator framework needs our assistance to animate them. Specifically, we need a TypeEvaluator for LatLng, with our evaluate() method taking the initial and end positions and computing another LatLng representing the fraction position between those other positions. This concept was introduced back in the chapter on the animator framework.

A simple approach to computing the fractional LatLng would be to apply the fraction to the latitude and the longitude as Java double values:

```
LatLng interpolate(float fraction, LatLng initial, LatLng end) {
  double lat = (end.latitude - initial.latitude) * fraction + initial.latitude;
  double lng = (end.longitude - initial.longitude) * fraction + initial.longitude;

  return(new LatLng(lat, lng));
}
```

That would work reasonably well for fairly close points, such as animating a marker within a city. However, animating markers across longer distances means that we have to take into account some geographic realities that a simple calculation will miss.

Problem #2: The Earth Is Not Flat (Really!)

One bit of reality is that the Earth is round. The above calculation assumes that the Earth is flat. Calculating “great circle” positions requires a fair bit of spherical trigonometry, known to cause loss of hair in software developers.

Hence, ideally, we will use somebody’s existing debugged algorithm for that.

Problem #3: 180 Equals –180, At Least For Longitude

The other problem is that longitudes wrap around, as 180 degrees longitude is equivalent to –180 degrees longitude, and longitudinal values are considered to be between 180 and –180. In cases where we would not cross 180 degrees longitude, this is not an issue. However, a simple calculation might miss this and wind up having our animation "take the long way" (e.g., animating from –175 degrees longitude to 175 degrees longitude by going 350 degrees around the Earth, rather than just 10 degrees and crossing the International Date Line).

Introducing Some Googly Assistance

Google themselves have released a utility library for Maps V2. It offers polyline and polygon decoding, primarily for interoperability with other location-related Google services like the Google Directions API. The `SphericalUtil` class handles all of the nasty math for computing distances along the surface of the Earth and related calculations. It also offers `BubbleIconFactory`, which makes it easy to create marker icons that look a bit like info windows (complete with border and caret) wrapping around a bit of text or an icon.

In our case, we can use `SphericalUtil` to handle Problem #2 and Problem #3, interpolating the location between two `LatLng` values, taking the curvature of the Earth and longitude idiosyncrasies into account.

Seeing This in Action

The `MapsV2/Animator` sample project is a modified version of the `MapsV2/Markers` project, adding in the notion of animating a marker from its original position (Lincoln Center) to a new position (Penn Station) within Manhattan.

Since we want to use the Google map utility library, we need to add it as a dependency.

- Android Studio users can simply add `compile 'com.google.maps.android:android-maps-utils:0.3.4'` (or a higher version) to the `dependencies` closure.
- Eclipse users will need to download and add it to the project by one means or another. Note, though, that this library project depends upon the Play Services SDK. Hence, you will need to update the project's configuration to have it reference your development environment's copy of the Play Services

SDK. Then, when you attach the library project to your project, you can remove your own reference to the Play Services SDK, as you will get that through the utility library.

We need to know where our starting and ending position for the animation will be, in terms of LatLng objects. Since those have no dependencies upon a Context or anything, we can simply declare them as static final values:

```
private static final LatLng PENN_STATION=new LatLng(40.749972,
                                                    -73.992319);
private static final LatLng LINCOLN_CENTER=
    new LatLng(40.76866299974387, -73.98268461227417);
```

We will also need the actual Marker object created when we add our starting position (LINCOLN_CENTER) to the map. So far, we have ignored the Marker returned by addMarker() on GoogleMap, but now we need that. So, our own addMarker() method now returns this value:

```
private Marker addMarker(GoogleMap map, double lat, double lon,
                         int title, int snippet) {
  return(map.addMarker(new MarkerOptions().position(new LatLng(lat,
                                                               lon))
                                          .title(getString(title))
                                          .snippet(getString(snippet))));
}
```

We also now have a markerToAnimate data member of the activity, for our Marker, which we populate from our modified addMarker() method:

```
  addMarker(map, 40.748963847316034, -73.96807193756104,
            R.string.un, R.string.united_nations);
  markerToAnimate=
      addMarker(map, LINCOLN_CENTER.latitude,
                LINCOLN_CENTER.longitude, R.string.lincoln_center,
                R.string.lincoln_center_snippet);
  addMarker(map, 40.765136435316755, -73.97989511489868,
            R.string.carnegie_hall, R.string.practice_x3);
  addMarker(map, 40.70686417491799, -74.01572942733765,
            R.string.downtown_club, R.string.heisman_trophy);
```

To make the sample work repeatedly, it would be nice to support bi-directional animation, starting with animating from Lincoln Center to Penn Station, then reversing the animation to go back to Lincoln Center. That means that we need to know, for any particular animation, where the end position should be. So, we track a LatLng for the next end position, surprisingly named nextAnimationEnd, initializing it to be PENN_STATION (since we are starting at the outset at LINCOLN_CENTER):

```
private LatLng nextAnimationEnd=PENN_STATION;
```

Next, we need to give the user a means of actually requesting the animation to run. To do that, we define a new menu XML resource for an `animate` menu item (using the `directions` icon for lack of a better handy icon):

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/animate"
    android:icon="@android:drawable/ic_menu_directions"
    android:showAsAction="ifRoom"
    android:title="@string/animate"/>

</menu>
```

We then load that menu resource in an overridden `onCreateOptionsMenu()` and direct the click event to an `animateMarker()` method in `onOptionsItemSelected()`:

```
  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.animate, menu);

    return(super.onCreateOptionsMenu(menu));
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.animate) {
      animateMarker();

      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

In `animateMarker()`, we need to do two things:

1. Actually run the animation
2. Ensure that the camera position is such that the animation will actually be visible, as it is pointless to animate a marker between two points if the currently-viewed portion of the map does not show those points

To handle the camera position, we need to use `moveCamera()` with a `CameraUpdate` from `CameraUpdateFactory`, as we used to set the initial camera position and zoom level. To handle the case where we want one or more points to be visible, we can use the `newLatLngBounds()` method on `CameraUpdateFactory`. This takes a `LatLngBounds` describing the area that needs to be visible, plus a padding amount in pixels for where that area should be inset within the map.

Of course, this implies that we have a LatLngBounds.

Since LatLngBounds also does not depend upon a Context or much of anything, we can define one of those as a static final data member, using a LatLngBounds.Builder instance:

```
private static final LatLngBounds bounds=
    new LatLngBounds.Builder().include(LINCOLN_CENTER)
                              .include(PENN_STATION).build();
```

A LatLngBounds.Builder takes one or more LatLng objects — passed in via include() – then constructs a LatLngBounds that encompasses all of those points via build().

Our animateMarker() method then starts off by using moveCamera() to reset the camera to show that defined region:

```
private void animateMarker() {
  map.moveCamera(CameraUpdateFactory.newLatLngBounds(bounds, 48));

  Property<Marker, LatLng> property=
      Property.of(Marker.class, LatLng.class, "position");
  ObjectAnimator animator=
      ObjectAnimator.ofObject(markerToAnimate, property,
                              new LatLngEvaluator(), nextAnimationEnd);
  animator.setDuration(2000);
  animator.start();

  if (nextAnimationEnd == LINCOLN_CENTER) {
    nextAnimationEnd=PENN_STATION;
  }
  else {
    nextAnimationEnd=LINCOLN_CENTER;
  }
}
```

Then, we need to set up the animation. To do this, we will use the object animator framework, specifically an ObjectAnimator. We know the Marker that we want to animate (markerToAnimate) and we know where we want to animate it to (nextAnimationEnd). What we need is to indicate the property to animate on this object, plus provide help to actually animate a LatLng.

To specify the property, we could just pass in the name of the property ("position"). However, in animateMarker(), we set up a Property object via the static of() factory method. This makes our use of ofObject() more type-safe, as Property will help enforce that we are animating a Marker using LatLng values.

To animate LatLng values, we need a TypeEvaluator for LatLng, here defined as a static inner class named LatLngEvaluator:

```
private static class LatLngEvaluator implements TypeEvaluator<LatLng> {
  @Override
  public LatLng evaluate(float fraction, LatLng startValue,
                         LatLng endValue) {
    return(SphericalUtil.interpolate(startValue, endValue, fraction));
  }
}
```

Our evaluate() method turns around and calls the static interpolate() method on SphericalUtil, supplied by Google's map utility library. interpolate() handles all the nasty spherical trigonometry and stuff, so we do not have to.

We then set the duration of the animation to be two seconds, and start the animation.

Finally, to reverse the animation for the next request, animateMarker() resets the value of nextAnimationEnd to be PENN_STATION or LINCOLN_CENTER, wherever we will animate to next.

This version of the app starts off as do all the others, except for the new action bar item:

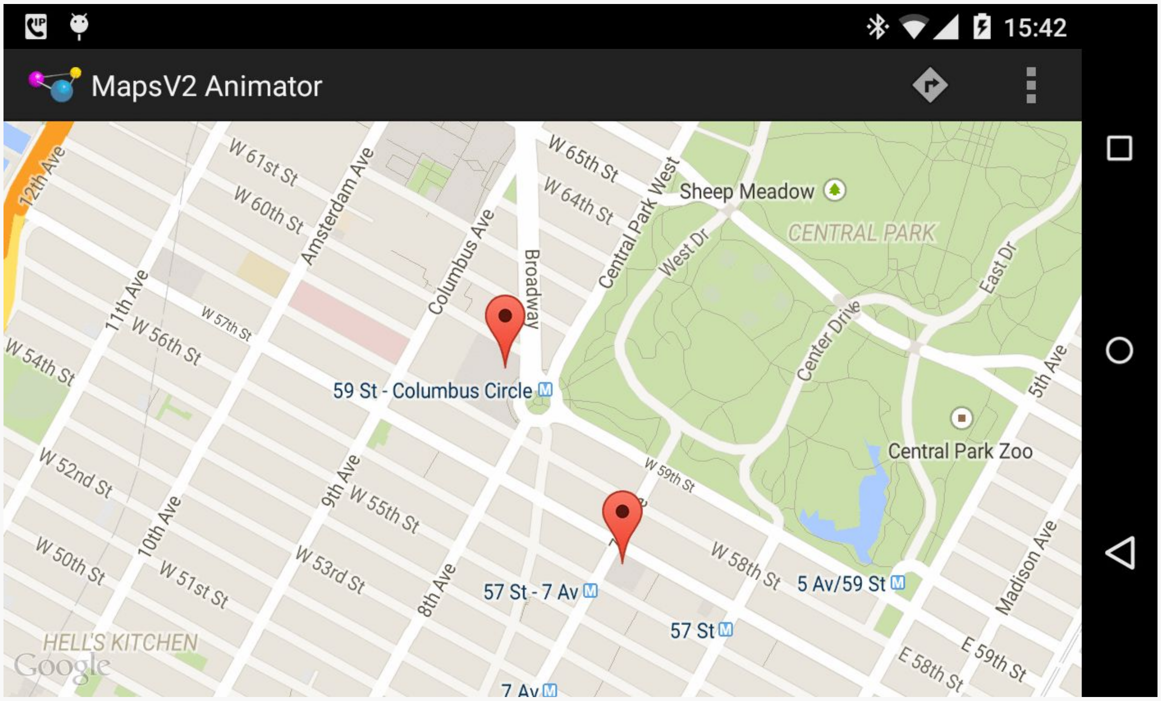

Figure 544: Maps V2 Animator Demo, As Initially Launched

Tapping that action bar item (“directions” icon) will reset the camera position and start animating the marker:

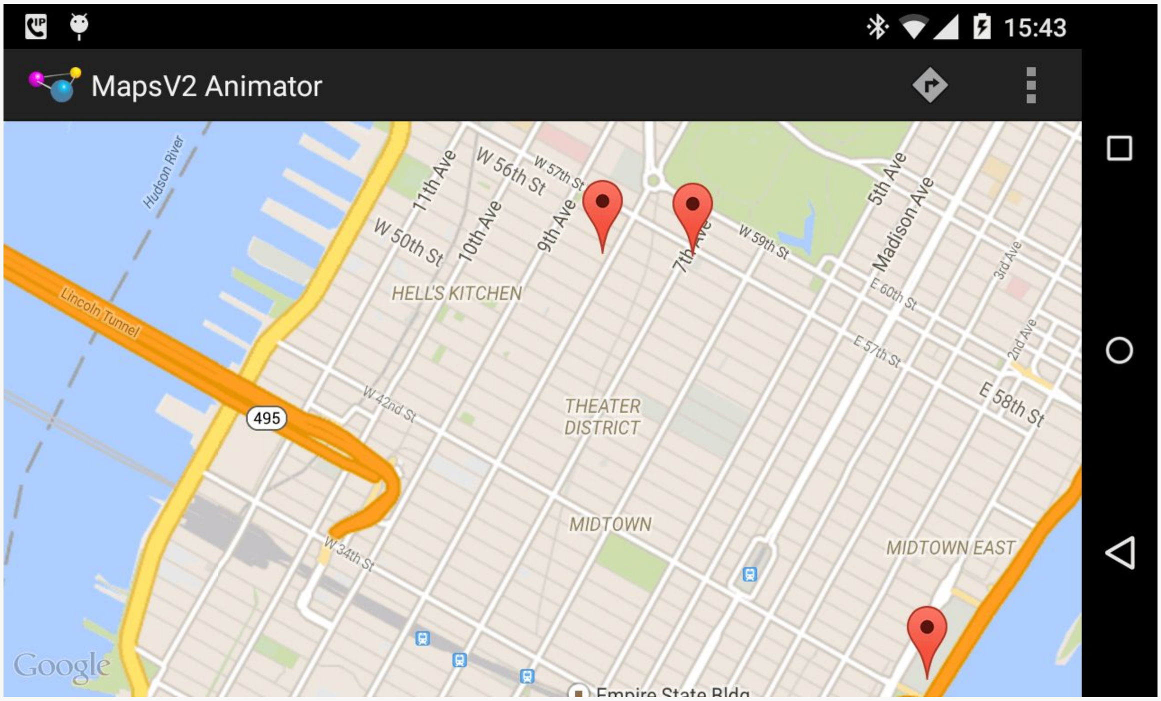

Figure 545: Maps V2 Animator Demo, Partially Through an Animation

Two seconds later, the marker will reach its destination, presumably to board a train:

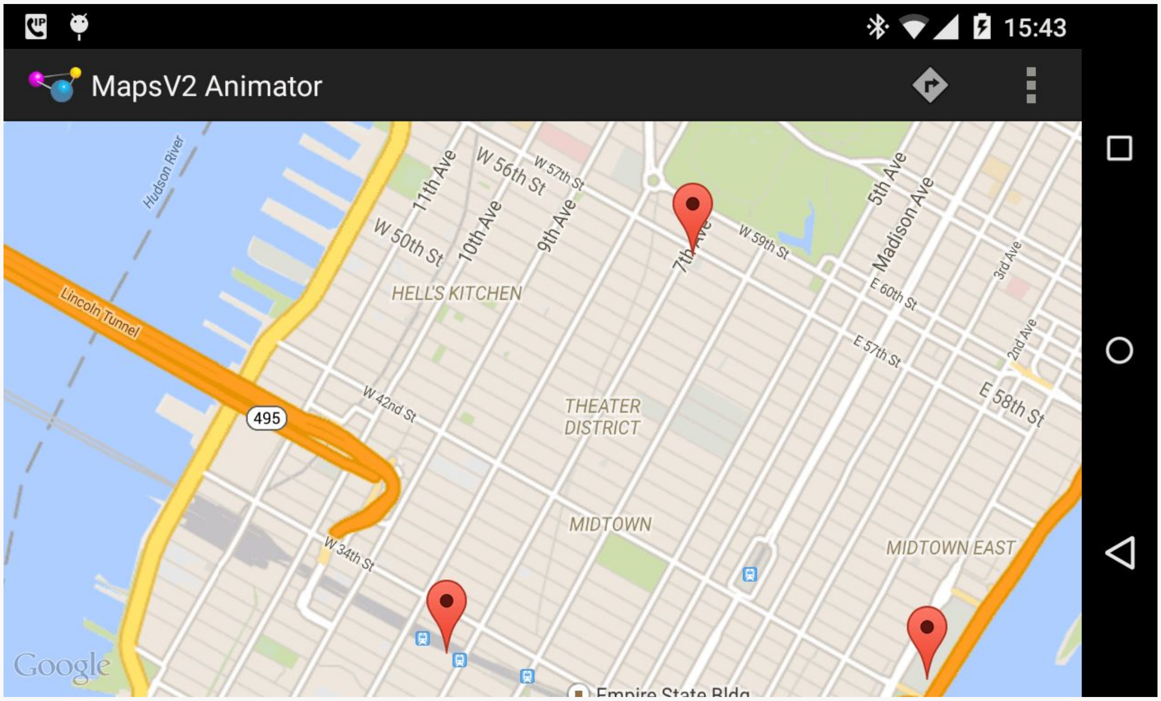

Figure 546: Maps V2 Animator Demo, with Marker Animated to Penn Station

Honoring Traffic Rules, Like "Drive Only On Streets"

You will notice that our animation ignores other aspects of reality, such as buildings that might be in the way. Sometimes, that is appropriate, such as animating the movement of:

- a bird
- a plane
- a costumed superhero with independent flight capability

Sometimes, though, we need to take into account those obstacles, such as animating the movement of:

- a pedestrian
- a car
- a costumed superhero "flying" by means of swinging between buildings using dynamically-generated cables of either natural or synthetic origin

However, to do this implies that we know where the obstacles are. Or, more accurately, we would need to animate the marker along known good waypoints, such as streets.

The animation would not be especially difficult, as `ofObject()` can take a series of waypoints. However, we would need to find those waypoints, and there is nothing in Maps V2 itself that supplies this data.

Maps, of the Indoor Variety

The good news is that Maps V2 supports Google's indoor maps, for those venues for which Google has indoor map data.

The bad news is that for some reason, only one map at a time supports indoor maps. The default will be that the first map you create will support indoor maps, and others will not.

To see if a given map offers indoor map capability, you can call `isIndoorEnabled()` on `GoogleMap`. To toggle this capability, call `setIndoorEnabled()`.

Taking a Snapshot of a Map

Once a map is drawn, you can take a snapshot of it, converting the viewed map into a `Bitmap` object. This is designed to take an image of the map and use it in places where a `MapFragment`, or even a `MapView`, cannot go, such as:

- Things tied to a `RemoteViews`, such as a custom `Notification`
- Thumbnails of maps, for an app that allows users to manipulate several maps at once

The `GoogleMap` object has two flavors of a `snapshot()` method. Both take a `SnapshotReadyCallback` object. You will need to supply an instance of something implementing the `SnapshotReadyCallback` interface, overriding `onSnapshotReady()`, where you will receive your `Bitmap`.

One flavor of `snapshot()` takes just the `SnapshotReadyCallback`; the other also takes a `Bitmap` of the proper dimensions, such as a previous snapshot `Bitmap` that you want to recycle. Using the latter `snapshot()` is recommended where possible, so you do not need to allocate new `Bitmap` objects on each `snapshot()` call.

Note that `snapshot()` will only work once the map is actually rendered. So, for example, calling `snapshot()` from `onCreate()` of your activity will fail, because the map has not been rendered yet. `snapshot()` is designed to be called based upon user input, either to manually capture a snapshot or based on navigation (e.g., tapping on a `ListView` item triggers saving a snapshot of the current map as a thumbnail before changing the map contents).

Also, the documentation for `snapshot()` contains the following:

> **Note**: Images of the map must not be transmitted to your servers, or otherwise used outside of the application. If you need to send a map to another application or user, send data that allows them to reconstruct the map for the new user instead of a snapshot.

As this statement may be tied to the terms and conditions of your use of Maps V2, you should talk with qualified legal counsel before:

- Saving a snapshot to external storage
- Sharing a snapshot via `ACTION_SEND`
- Sending a snapshot to your server

or similar operations.

MapFragment vs. MapView

So far, all the examples shown in this chapter use `MapFragment`. In most cases, this is the right thing to use.

However, there may be places where you really want to use a `View`, rather than a `Fragment`, for your maps.

The good news is that Maps V2 does have a `MapView`. `MapFragment` usually handles creating and managing the `MapView` for you, but you can, if you wish, eschew `MapFragment` and manage the `MapView` yourself.

The biggest limitation is that you need to forward the lifecycle methods from your activity or fragment on to the `MapView`, calling `onCreate()`, `onResume()`, `onPause()`, `onDestroy()`, and `onSaveInstanceState()` on the `MapView`. Normally, `MapFragment` would do that for you, saving you the trouble.

Also note that while MapView is a ViewGroup, you are not allowed to add child widgets to it.

About That AbstractMapActivity Class…

Early on, we hand-waved our way past the AbstractMapActivity that all of our MainActivity classes inherit from, and we skirted past the readyToGo() method that we were calling. Also, you may have noticed that our app has an action bar overflow item, that we do not seem to be creating in MainActivity.

Now, it is time to dive into what is going on in our AbstractMapActivity implementations.

Getting Maps V2 Ready to Go

The readyToGo() method in AbstractMapActivity is designed to help us determine if Maps V2 is "ready to go" and, if not, to help the user perhaps fix their device such that Maps V2 will work in the future:

```
protected boolean readyToGo() {
  GoogleApiAvailability checker=
    GoogleApiAvailability.getInstance();

  int status=checker.isGooglePlayServicesAvailable(this);

  if (status == ConnectionResult.SUCCESS) {
    if (getVersionFromPackageManager(this)>=2) {
      return(true);
    }
    else {
      Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
      finish();
    }
  }
  else if (checker.isUserResolvableError(status)) {
    ErrorDialogFragment.newInstance(status)
                       .show(getFragmentManager(),
                             TAG_ERROR_DIALOG_FRAGMENT);
  }
  else {
    Toast.makeText(this, R.string.no_maps, Toast.LENGTH_LONG).show();
    finish();
  }

  return(false);
}
```

Determining the availability of Maps V2 — or anything in the Play Services SDK — is handled through an instance of `GoogleApiAvailability`. You get a singleton instance of this class via its `static getInstance()` method.

First, we call `isGooglePlayServicesAvailable()` method the `GoogleApiAvailability` instance. This will return an integer indicating whether Maps V2 is available for our use or not.

If the return value is `ConnectionResult.SUCCESS` — meaning Maps V2 is indeed available to us – we check to see if OpenGL ES is version 2.0 or higher, as we did not require that in the manifest. There are a few ways in Android to check the OpenGL ES version. This sample uses some code from the Compatibility Test Suite (CTS), examining `PackageManager` to determine the major level:

```
  // following from
  // https://android.googlesource.com/platform/cts/+/master/tests/tests/graphics/src/
android/opengl/cts/OpenGlEsVersionTest.java

  /*

   */

  private static int getVersionFromPackageManager(Context context) {
    PackageManager packageManager=context.getPackageManager();
    FeatureInfo[] featureInfos=
        packageManager.getSystemAvailableFeatures();
    if (featureInfos != null && featureInfos.length > 0) {
      for (FeatureInfo featureInfo : featureInfos) {
        // Null feature name means this feature is the open
        // gl es version feature.
        if (featureInfo.name == null) {
          if (featureInfo.reqGlEsVersion != FeatureInfo.GL_ES_VERSION_UNDEFINED) {
            return getMajorVersion(featureInfo.reqGlEsVersion);
          }
          else {
            return 1; // Lack of property means OpenGL ES
                      // version 1
          }
        }
      }
    }
    return 1;
  }

  /** @see FeatureInfo#getGlEsVersion() */
  private static int getMajorVersion(int glEsVersion) {
    return((glEsVersion & 0xffff0000) >> 16);
  }
```

If the major version is 2 or higher, we return `true` from `readyToGo()`, so `MainActivity` knows to continue on setting up the map. If the major version is 1, we display a `Toast` — a production-grade app would do something else to let the user know of the problem, most likely.

But, what if `isGooglePlayServicesAvailable()` returns something else?

There are two major possibilities here:

1. The error is something that the user might be able to rectify, such as by downloading the Google Play Services app from the Play Store
2. The error is something that the user cannot recover from

We can distinguish these two cases by calling `isUserResolvableError()` on the `GoogleApiAvailability` instance, passing in the value we received from `isGooglePlayServicesAvailable()`. This will return `true` if the user might be able to fix the problem, `false` otherwise.

In the `false` case, the user is just out of luck, so we display a `Toast` to alert them of this fact, then `finish()` the activity and return `false`, so `MainActivity` skips over the rest of its work.

In the `true` case, we can display something to the user to prompt them to fix the problem. One way to do that is to use a dialog obtained from Google code, by calling the static `getErrorDialog()` method on a `GoogleApiAvailability` instance. In our case, we wrap that in a `DialogFragment` named `ErrorDialogFragment`, implemented as a static inner class of `AbstractMapActivity`:

```
  public static class ErrorDialogFragment extends DialogFragment {
    static final String ARG_ERROR_CODE="errorCode";

    static ErrorDialogFragment newInstance(int errorCode) {
      Bundle args=new Bundle();
      ErrorDialogFragment result=new ErrorDialogFragment();

      args.putInt(ARG_ERROR_CODE, errorCode);
      result.setArguments(args);
      return(result);
    }

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
      Bundle args=getArguments();
      GoogleApiAvailability checker=
        GoogleApiAvailability.getInstance();

      return(checker.getErrorDialog(getActivity(),
        args.getInt(ARG_ERROR_CODE), 0));
    }

    @Override
    public void onDismiss(DialogInterface dlg) {
      if (getActivity()!=null) {
        getActivity().finish();
      }
    }
  }
```

While the code and comments around `getErrorDialog()` suggest that there is some way for us to find out if the user performed actions that fix the problem, this code does not seem to work well in practice. After all, downloading Google Play Services is asynchronous, so even if the user returns to our app, it is entirely likely that Maps V2 is still unavailable. As a result, when the user is done with the dialog, we `finish()` the activity, forcing the user to start it again if and when they are done downloading Google Play Services.

Testing this code requires an older device, one in which the "Google Play services" app can be uninstalled… if it can be installed at all.

As it turns out, not all Android devices support the Play Store, or the Google Play Services by extension. Notably, if the device lacks the Play Store, `isUserRecoverableError()` returns `true`, even though the user cannot recover from this situation (except perhaps via a firmware update).

(An earlier problem where `getErrorDialog()` could return `null` even for cases where the error is supposedly user-recoverable has been fixed)

Handling the License Terms

`AbstractMapActivity` has implementations of `onCreateOptionsMenu()` and `onOptionsItemSelected()` that will add a "Legal Notices" item to the overflow menu and bring up `LegalNoticesActivity` when that menu item is tapped:

```
package com.commonsware.android.mapsv2.basic;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;
import com.google.android.gms.common.GooglePlayServicesUtil;

public class LegalNoticesActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.legal);

    TextView legal=(TextView)findViewById(R.id.legal);

    legal.setText(GooglePlayServicesUtil.getOpenSourceSoftwareLicenseInfo(this));
  }
}
```

`LegalNoticesActivity` simply has a `TextView` inside of a `ScrollView` and fills in the `TextView` with the results of calling `getOpenSourceSoftwareLicenseInfo()` on `GooglePlayServicesUtil`. This method returns the legalese that you need to display to the users from somewhere in your app.

Helper Libraries for Maps V2

Many developers have been busy writing libraries that help in the development of Maps V2 applications, beyond Google's own utility library mentioned in the section on animating markers.

Perhaps the most expansive of these is the Android Maps Extensions library. The big thing that this library offers is marker clustering, where as the user zooms out, individual markers are replaced by a marker representing a cluster, so you avoid flooding a small area with too many individual markers:

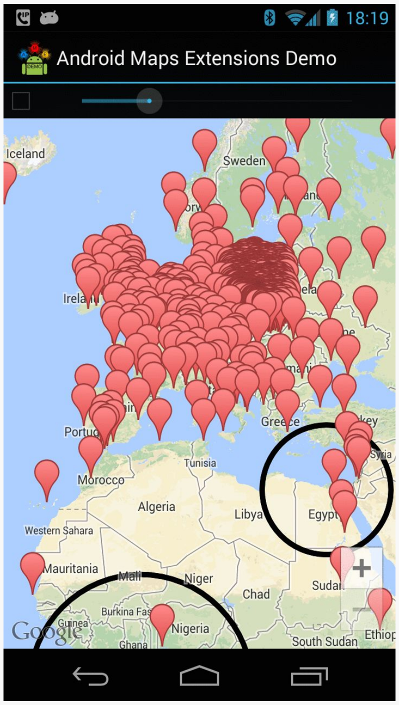

Figure 547: Map with Many Markers (from Android Maps Extensions demo app)

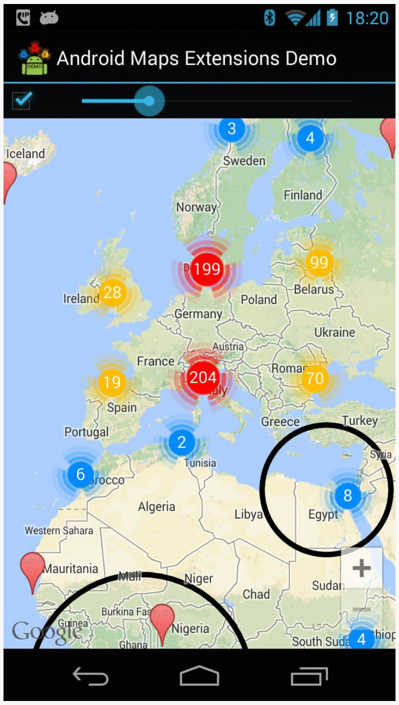

Figure 548: Same Map with Cluster Markers (from Android Maps Extensions demo app)

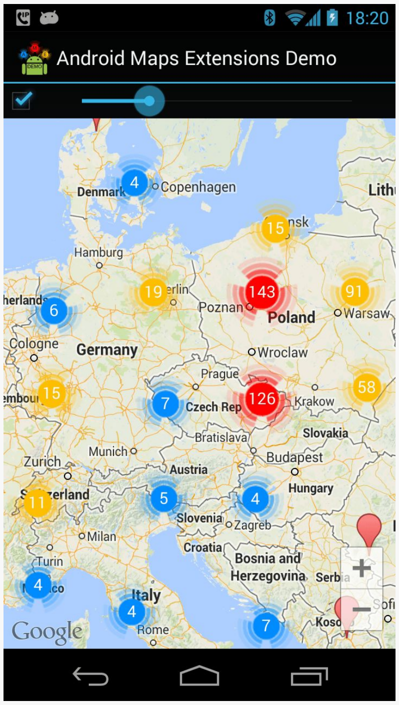

Figure 549: Same Map with Zoomed In Cluster Markers (from Android Maps Extensions demo app)

This library wraps the Maps V2 classes, allowing the library to offer extensions to the standard Maps V2 API, including:

- Associating your own data with `Marker`, `Polygon`, `Polyline`, and other classes, to tie them back to your models
- Getters to retrieve previously-defined markers, etc.
- Etc.

Another library offering marker clustering is clusterkraf, from Two Toasters.

The clusterkraf library can optionally integrate with Cyril Mottier's Polaris2 library. His original Polaris library aimed to provide more features to Maps V1; Polaris2 fills a similar role for Maps V2. At this time, Polaris2 is a smaller library, simply because Maps V2 handles much of what Polaris provided. Polaris2, like Android Maps Extensions, wraps the Maps V2 API with its own classes, in lieu of subclassing (since most Maps V2 classes are marked `final`). Of note, Polaris2 offers `reset()` methods on many of the `...Options` classes (e.g., `MarkerOptions`), and offers constants for the minimum and maximum valid latitude and longitude.

Problems with Maps V2 at Runtime

Portions of the logic that powers your Maps V2 `MapFragment` are supplied by the Google Play Services app. As a result, many operations with Maps V2, such as manipulating markers, require IPC calls between your app and Google Play Services. If those IPC calls are synchronous, they will add a bit of overhead to your app — enough that you will want to avoid them in time-critical pieces of code, tight loops, and the like.

Problems with Maps V2 Deployment

Of course, the key question is: should you be using Maps V2 at all?

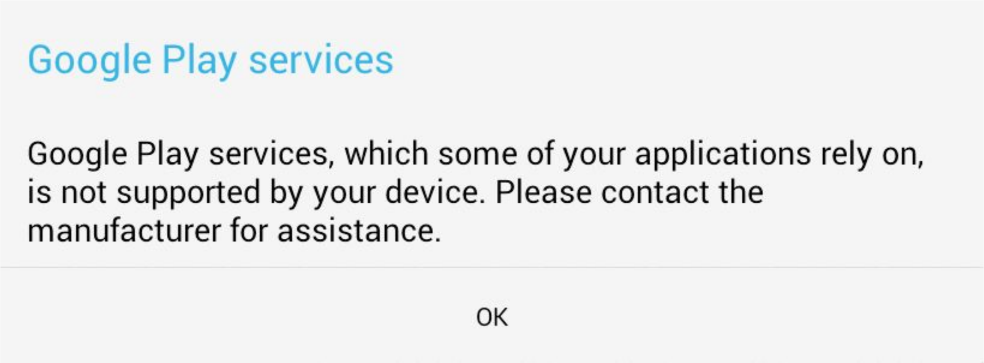
Google thinks so, as they have turned off access to new API keys for Maps V1. That makes ongoing development of Maps V1 solutions a bit risky, as you cannot create new API keys for new signing keys, such as if you need to replace your debug keystore.

However, Maps V2 has some deployment limitations at this time. While 99.8+% of Android devices that have the Play Store have the requisite OpenGL ES 2.0+, some devices that have a suitable OpenGL ES version may not have the Play Store or otherwise be unable to get Google Play Services, required for using Maps V2. The `isGooglePlayServicesAvailable()` approach advocated by Google can help determine this at runtime, though this approach used to have some bugs, and it still cannot always help you recover from this problem.

And, as the next section illustrates, not every Android device supports Maps V2, because not every device supports Google Play Services.

What Non-Compliant Devices Show

If your app tries to bring up Maps V2 on a device that cannot possibly have the Play Services Framework — such as a Kindle Fire — the user will see an error dialog:



Google Play services

Google Play services, which some of your applications rely on, is not supported by your device. Please contact the manufacturer for assistance.

Figure 550: Maps V2 Error on Kindle Fire

For those devices, you will need to consider some alternative source of maps.

Mapping Alternatives

Beyond using Maps V2 or Maps V1, you may need to consider other mapping alternatives. The Google mapping APIs are only available on Android devices that have the Maps SDK add-on (Maps V1) or Google Play Services (Maps V2). Not all devices have those. And, the limitations of Maps V2 deployment and the deprecation of Maps V1 may convince you that relying upon Google for maps is not safe at the present time.

The most common native replacement for Google's mapping is OpenStreetMap, which to some extent is "the Wikipedia of maps". OSMDroid is a library that provides a Maps V1-ish API for embedding OpenStreetMap-based maps into your application.

Another solution is to integrate Web-based Google maps into your app, the same way that you might embed them into your Web site. An activity hosting a `WebView` can display a Web-based Google Map, for example.

Certain devices may have access to other native mapping solutions. For example, Amazon has published their own maps API for use with the Kindle Fire.

News and Getting Help

The Maps V2 team maintains a set of release notes for when they ship updates to the Maps V2 support in the Play Services library project.

The official support point for Maps V2 for Android is Stack Overflow. Questions tagged with both `android` and `google-maps` should show up on Google's radar.

Crafting Your Own Views

One of the classic forms of code reuse is the GUI widget. Since the advent of Microsoft Windows — and, to some extent, even earlier – developers have been creating their own widgets to extend an existing widget set. These range from 16-bit Windows "custom controls" to 32-bit Windows OCX components to the innumerable widgets available for Java Swing and SWT, and beyond. Android lets you craft your own widgets as well, such as extending an existing widget with a new UI or new behaviors.

Note that the material in this chapter is focused on creating custom `View` classes for use within a single Android project. If your goal is to truly create reusable custom widgets, you will also need to learn how to package them so they can be reused — that is covered in a later chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Pick Your Poison

You have five major options for creating a custom `View` class.

First, your "custom `View` class" might really only be custom `Drawable` resources. Many widgets can adopt a radically different look and feel just with replacement graphics. For example, you might think that these toggle buttons from the Android 2.1 Google Maps application are some fancy custom widget:

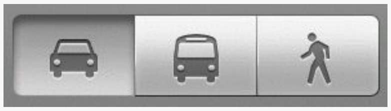


Figure 551: Google Maps navigation toggle buttons

In reality, those are just radio buttons with replacement images.

Second, your custom `View` class might be a simple subclass of an existing widget, where you override some behaviors or otherwise inject your own logic. Unfortunately, most of the built-in Android widgets are not really designed for this sort of simple subclassing, so you may be disappointed in how well this particular technique works.

Third, your custom `View` class might be a composite widget — akin to an activity's contents, complete with layout and such, but encapsulated in its own class. This allows you to create something more elaborate than you will just by tweaking resources. We will see this later in the chapter with `ColorMixer`.

Fourth, you might want to implement your own layout manager, if your GUI rules do not fit well with `RelativeLayout`, `TableLayout`, or other built-in containers. For example, you might want to create a layout manager that more closely mirrors the "box model" approach taken by XUL and Flex, or you might want to create one that mirrors Swing's `FlowLayout` (laying widgets out horizontally until there is no more room on the current row, then start a new row).

Finally, you might want to do something totally different, where you need to draw the widget yourself. For example, the `ColorMixer` widget uses `SeekBar` widgets to control the mix of red, blue, and green. But, you might create a `ColorWheel` widget that draws a spectrum gradient, detects touch events, and lets the user pick a color that way.

Some of these techniques are fairly simple; others are fairly complex. All share some common traits, such as widget-defined attributes, that we will see throughout the remainder of this chapter.

Colors, Mixed How You Like Them

The classic way for a user to pick a color in a GUI is to use a color wheel like this one:

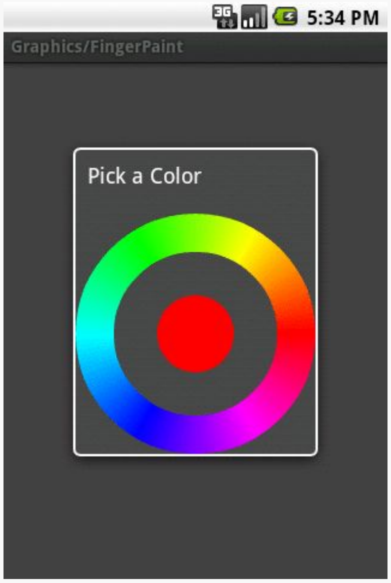

Figure 552: A color wheel from the API samples

There is even code to make one in the API samples.

However, a color wheel like that is difficult to manipulate on a touch screen, particularly a capacitive touchscreen designed for finger input. Fingers are great for gross touch events and lousy for selecting a particular color pixel.

Another approach is to use a mixer, with sliders to control the red, green, and blue values:

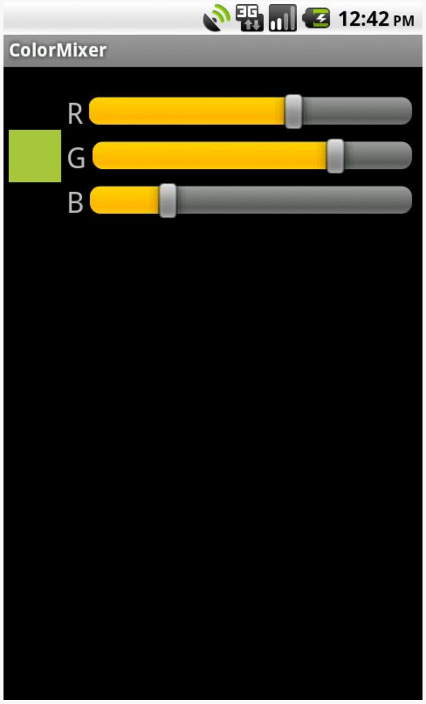

Figure 553: The ColorMixer widget, inside an activity

That is the custom widget you will see in this section, based on the code in the [`Views/ColorMixer`] sample project.

The Layout

`ColorMixer` is a composite widget, meaning that its contents are created from other widgets and containers. Hence, we can use a layout file to describe what the widget should look like.

The layout to be used for the widget is not that much: three `SeekBar` widgets (to control the colors), three `TextView` widgets (to label the colors), and one plain `View` (the "swatch" on the left that shows what the currently selected color is). Here is the file, found in `res/layout/mixer.xml` in the `Views/ColorMixer` project:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <View android:id="@+id/swatch"
    android:layout_width="40dip"
    android:layout_height="40dip"
    android:layout_alignParentLeft="true"
    android:layout_centerVertical="true"
    android:layout_marginLeft="4dip"
  />
  <TextView android:id="@+id/redLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/swatch"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:text="@string/red"
    android:textSize="24sp"
  />
  <SeekBar android:id="@+id/red"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/redLabel"
    android:layout_toRightOf="@id/redLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
  <TextView android:id="@+id/greenLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/redLabel"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:layout_marginTop="4dip"
    android:text="@string/green"
    android:textSize="24sp"
  />
  <SeekBar android:id="@+id/green"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/greenLabel"
    android:layout_toRightOf="@id/greenLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
  <TextView android:id="@+id/blueLabel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/greenLabel"
    android:layout_toRightOf="@id/swatch"
    android:layout_marginLeft="4dip"
    android:layout_marginTop="4dip"
    android:text="@string/blue"
    android:textSize="24sp"
  />
  <SeekBar android:id="@+id/blue"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/blueLabel"
    android:layout_toRightOf="@id/blueLabel"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="8dip"
  />
</merge>
```

One thing that is a bit interesting about this layout, though, is the root element: <merge>. A <merge> layout is a bag of widgets that can be poured into some other container. The layout rules on the children of `<merge>` are then used in conjunction with whatever container they are added to. As we will see shortly, `ColorMixer` itself inherits from `RelativeLayout`, and the children of the `<merge>` element will become children of `ColorMixer` in Java. Basically, the `<merge>` element is only there because XML files need a single root — otherwise, the `<merge>` element itself is ignored in the layout.

The Attributes

Widgets usually have attributes that you can set in the XML file, such as the `android:src` attribute you can specify on an `ImageButton` widget. You can create your own custom attributes that can be used in your custom widget, by creating a `res/values/attrs.xml` file containing `declare-styleable` resources to specify them.

For example, here is the attributes file for `ColorMixer`:

```xml
<resources>
  <declare-styleable name="ColorMixer">
    <attr name="initialColor" format="color" />
  </declare-styleable>
</resources>
```

The `declare-styleable` element describes what attributes are available on the widget class specified in the name attribute — in our case, `ColorMixer`. Inside `declare-styleable` you can have one or more `attr` elements, each indicating the `name` of an attribute (e.g., `initialColor`) and what data `format` the attribute has (e.g., `color`). The data type will help with compile-time validation and in getting any supplied values for this attribute parsed into the appropriate type at runtime.

Here, we indicate there is only one attribute: `initialColor`, which will hold the initial color we want the mixer set to when it first appears.

There are many possible values for the `format` attribute in an `attr` element, including:

1. `boolean`
2. `color`
3. `dimension`
4. `float`
5. `fraction`
6. `integer`

7. reference (which means a reference to another resource, such as a Drawable)
8. string

You can even support multiple formats for an attribute, by separating the values with a pipe (e.g., reference|color).

The Class

Our ColorMixer class, a subclass of RelativeLayout, will take those attributes and provide the actual custom widget implementation, for use in activities.

Constructor Flavors

A View has three possible constructors:

1. One takes just a Context, which usually will be an Activity
2. One takes a Context and an AttributeSet, the latter of which represents the attributes supplied via layout XML
3. One takes a Context, an AttributeSet, and the default style to apply to the attributes

If you are expecting to use your custom widget in layout XML files, you will need to implement the second constructor and chain to the superclass. If you want to use styles with your custom widget when declared in layout XML files, you will need to implement the third constructor and chain to the superclass. If you want developers to create instances of your View class in Java code directly, you probably should implement the first constructor and, again, chain to the superclass.

In the case of ColorMixer, all three constructors are implemented, eventually routing to the three-parameter edition, which initializes our widget. Below, you will see the first two of those constructors, with the third coming up in the next section:

```
public ColorMixer(Context context) {
  this(context, null);
}

public ColorMixer(Context context, AttributeSet attrs) {
  this(context, attrs, 0);
}
```

Using the Attributes

The ColorMixer has a starting color — after all, the SeekBar widgets and swatch View have to show something. Developers can, if they wish, set that color via a setColor() method:

```
public void setColor(int color) {
  red.setProgress(Color.red(color));
  green.setProgress(Color.green(color));
  blue.setProgress(Color.blue(color));
  swatch.setBackgroundColor(color);
}
```

If, however, we want developers to be able to use layout XML, we need to get the value of initialColor out of the supplied AttributeSet. In ColorMixer, this is handled in the three-parameter constructor:

```
public ColorMixer(Context context, AttributeSet attrs, int defStyle) {
  super(context, attrs, defStyle);

  ((Activity)getContext())
      .getLayoutInflater()
      .inflate(R.layout.mixer, this, true);

  swatch=findViewById(R.id.swatch);

  red=(SeekBar)findViewById(R.id.red);
  red.setMax(0xFF);
  red.setOnSeekBarChangeListener(onMix);

  green=(SeekBar)findViewById(R.id.green);
  green.setMax(0xFF);
  green.setOnSeekBarChangeListener(onMix);

  blue=(SeekBar)findViewById(R.id.blue);
  blue.setMax(0xFF);
  blue.setOnSeekBarChangeListener(onMix);

  if (attrs!=null) {
    TypedArray a=getContext()
                .obtainStyledAttributes(attrs,
                                         R.styleable.ColorMixer,
                                         0, 0);

    setColor(a.getInt(R.styleable.ColorMixer_initialColor,
                      0xFFA4C639));
    a.recycle();
  }
}
```

There are three steps for getting attribute values:

- Get a TypedArray conversion of the AttributeSet by calling obtainStyledAttributes() on our Context, supplying it the AttributeSet and the ID of our styleable resource (in this case, R.styleable.ColorMixer, since we set the name of the declare-styleable element to be ColorMixer)
- Use the TypedArray to access specific attributes of interest, by calling an appropriate getter (e.g., getInt()) with the ID of the specific attribute to fetch (R.styleable.ColorMixer_initialColor)
- Recycle the TypedArray when done, via a call to recycle(), to make the object available to Android for use with other widgets via an object pool (versus creating new instances every time)

Note that the name of any given attribute, from the standpoint of TypedArray, is the name of the styleable resource (R.styleable.ColorMixer) concatenated with an underscore and the name of the attribute itself (_initialColor).

In ColorMixer, we get the attribute and pass it to setColor(). Since getInt() on AttributeSet takes a default value, we supply some stock color that will be used if the developer declined to supply an initialColor attribute.

Also note that our ColorMixer constructor inflates the widget's layout. In particular, it supplies true as the third parameter to inflate(), meaning that the contents of the layout should be added as children to the ColorMixer itself. When the layout is inflated, the <merge> element is ignored, and the <merge> element's children are added as children to the ColorMixer.

Saving the State

Similar to activities, a custom View overrides onSaveInstanceState() and onRestoreInstanceState() to persist data as needed, such as to handle a screen orientation change. The biggest difference is that rather than receive a Bundle as a parameter, onSaveInstanceState() must return a Parcelable with its state… including whatever state comes from the parent View.

The simplest way to do that is to return a Bundle, in which we have filled in our state (the chosen color) and the parent class' state (whatever that may be).

So, for example, here are implementations of onSaveInstanceState() and onRestoreInstanceState() from ColorMixer:

```
@Override
public Parcelable onSaveInstanceState() {
  Bundle state=new Bundle();
```

```
    state.putParcelable(SUPERSTATE, super.onSaveInstanceState());
    state.putInt(COLOR, getColor());

    return(state);
  }

  @Override
  public void onRestoreInstanceState(Parcelable ss) {
    Bundle state=(Bundle)ss;

    super.onRestoreInstanceState(state.getParcelable(SUPERSTATE));

    setColor(state.getInt(COLOR));
  }
```

The Rest of the Functionality

`ColorMixer` defines a callback interface, named `OnColorChangedListener`:

```
  public interface OnColorChangedListener {
    public void onColorChange(int argb);
  }
```

`ColorMixer` also provides getters and setters for an `OnColorChangedListener` object:

```
  public OnColorChangedListener getOnColorChangedListener() {
    return(listener);
  }

  public void setOnColorChangedListener(OnColorChangedListener listener) {
    this.listener=listener;
  }
```

The rest of the logic is mostly tied up in the `SeekBar` handler, which will adjust the swatch based on the new color and invoke the `OnColorChangedListener` object, if there is one:

```
  private SeekBar.OnSeekBarChangeListener onMix=new SeekBar.OnSeekBarChangeListener() {
    public void onProgressChanged(SeekBar seekBar, int progress,
                                  boolean fromUser) {
      int color=getColor();

      swatch.setBackgroundColor(color);

      if (listener!=null) {
        listener.onColorChange(color);
      }
    }

    public void onStartTrackingTouch(SeekBar seekBar) {
      // unused
    }
    public void onStopTrackingTouch(SeekBar seekBar) {
      // unused
    }
  };
```

Seeing It In Use

The project contains a sample activity, ColorMixerDemo, that shows the use of the ColorMixer widget.

The layout for that activity, shown below, can be found in res/layout/main.xml of the Views/ColorMixer project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:mixer="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="vertical"
>
  <TextView android:id="@+id/color"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
  />
  <com.commonsware.android.colormixer.ColorMixer
    android:id="@+id/mixer"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    mixer:initialColor="#FFA4C639"
  />
</LinearLayout>
```

Notice that the root LinearLayout element defines two namespaces, the standard android namespace, and a separate one named mixer. The mixer namespace is given a URL of http://schemas.android.com/apk/res-auto, which indicates to the Android build system to match up mixer attributes with their respective widgets that are supplied via Android library projects.

Our ColorMixer widget is in the layout, with a fully-qualified class name (com.commonsware.android.colormixer.ColorMixer), since ColorMixer is not in the android.widget package. Notice that we can treat our custom widget like any other, giving it a width and height and so on.

The one attribute of our ColorMixer widget that is unusual is mixer:initialColor. initialColor, you may recall, was the name of the attribute we declared in res/values/attrs.xml and retrieve in Java code, to represent the color to start with. The mixer namespace is needed to identify where Android should be pulling the rules for what sort of values an `initialColor` attribute can hold. Since our `<attr>` element indicated that the `format` of `initialColor` was `color`, Android will expect to see a color value here, rather than a string or dimension.

The `ColorMixerDemo` activity is not very elaborate:

```
package com.commonsware.android.colormixer;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class ColorMixerDemo extends Activity {
  private TextView color=null;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);

    color=(TextView)findViewById(R.id.color);

    ColorMixer mixer=(ColorMixer)findViewById(R.id.mixer);

    mixer.setOnColorChangedListener(onColorChange);
  }

  private ColorMixer.OnColorChangedListener onColorChange=
    new ColorMixer.OnColorChangedListener() {
    public void onColorChange(int argb) {
      color.setText(Integer.toHexString(argb));
    }
  };
}
```

It gets access to both the `ColorMixer` and the `TextView` in the main layout, then registers an `OnColorChangedListener` with the `ColorMixer`. That listener, in turn, puts the value of the color in the `TextView`, so the user can see the hex value of the color along with the shade itself in the swatch.

ReverseChronometer: Simply a Custom Subclass

Sometimes, what you want to achieve only requires a basic subclass of an existing widget (or container), into which you can pour your business logic.

For example, Android has a `Chronometer` widget, which is used for denoting elapsed time of some operation. It works well, but it only counts up from zero. It cannot be used to display a countdown instead.

But, we can roll a ReverseChronometer that does, simply by subclassing TextView, as seen in the Views/ReverseChronometer sample project:

```
package com.commonsware.android.revchron;

import android.content.Context;
import android.graphics.Color;
import android.os.SystemClock;
import android.util.AttributeSet;
import android.widget.TextView;

public class ReverseChronometer extends TextView implements Runnable {
  long startTime=0L;
  long overallDuration=0L;
  long warningDuration=0L;

  public ReverseChronometer(Context context, AttributeSet attrs) {
    super(context, attrs);

    reset();
  }

  @Override
  public void run() {
    long elapsedSeconds=
        (SystemClock.elapsedRealtime() - startTime) / 1000;

    if (elapsedSeconds < overallDuration) {
      long remainingSeconds=overallDuration - elapsedSeconds;
      long minutes=remainingSeconds / 60;
      long seconds=remainingSeconds - (60 * minutes);

      setText(String.format("%d:%02d", minutes, seconds));

      if (warningDuration > 0 && remainingSeconds < warningDuration) {
        setTextColor(0xFFFF6600); // orange
      }
      else {
        setTextColor(Color.BLACK);
      }

      postDelayed(this, 1000);
    }
    else {
      setText("0:00");
      setTextColor(Color.RED);
    }
  }

  public void reset() {
    startTime=SystemClock.elapsedRealtime();
    setText("--:--");
    setTextColor(Color.BLACK);
  }

  public void stop() {
    removeCallbacks(this);
  }
  public void setOverallDuration(long overallDuration) {
    this.overallDuration=overallDuration;
  }

  public void setWarningDuration(long warningDuration) {
    this.warningDuration=warningDuration;
  }
}
```

ReverseChronometer is designed to show minutes and seconds remaining from some initial time. In the constructor, by means to a call to a reset() method, we set the text of the TextView to show a generic starting point ("-:–"), set its color to black, and note the current time (SystemClock.elapsedRealtime()) in a startTime data member.

ReverseChronometer also tracks two durations in seconds, with corresponding setter methods:

- overallDuration is how long the countdown should run from beginning to end
- warningDuration is how far from the end we should change the color of the TextView from black to orange, to hint to the viewer that time is running out

ReverseChronometer implements Runnable, and when its run() method is called, it determines how many seconds have elapsed since that startTime value. Depending on the amount of seconds remaining, we either:

- Just update the text to show the minutes and seconds remaining
- Update the text and set the color to black or orange
- Set the text to "0:00" (time has run out) and set the text color to red

In either of the first two cases, we also call postDelayed() to schedule ourselves to run again in a second, where we can update the TextView contents once more. That continues until somebody calls stop().

As with any custom View, we can reference this in a layout XML resource, fully-qualifying the class name used as the name of our XML element for the widget. And, since we inherit from TextView, we can set any of the attributes that we want on that TextView, in terms of styling the text, positioning it within a parent container, etc.:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  tools:context=".MainActivity">

  <com.commonsware.android.revchron.ReverseChronometer
    android:id="@+id/chrono"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerInParent="true"
    android:textSize="50sp"
    android:textStyle="bold"/>

</RelativeLayout>
```

All our activity needs to do is set the durations, then call `run()` and `stop()` at appropriate times, such as when the activity is resumed and paused:

```
package com.commonsware.android.revchron;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
  private ReverseChronometer chrono=null;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    chrono=(ReverseChronometer)findViewById(R.id.chrono);
    chrono.setOverallDuration(90);
    chrono.setWarningDuration(10);
  }

  @Override
  public void onResume() {
    super.onResume();

    chrono.run();
  }

  @Override
  public void onPause() {
    chrono.stop();

    super.onPause();
  }
}
```

The result is much as you would expect: a countdown of the time remaining:

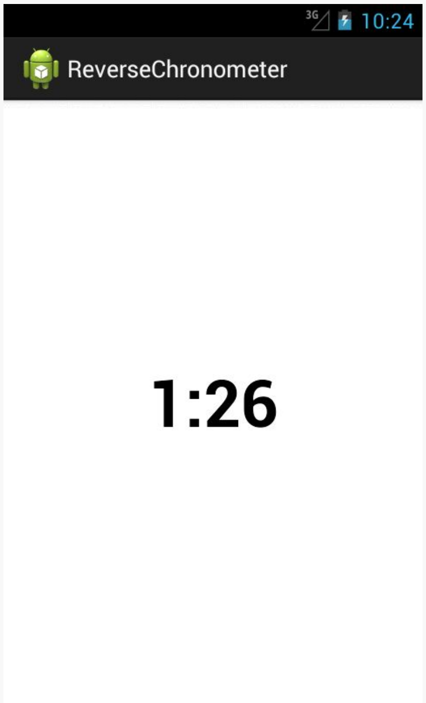

Figure 554: ReverseChronometer, Early in Countdown

…changing to orange when we are within the warning duration:

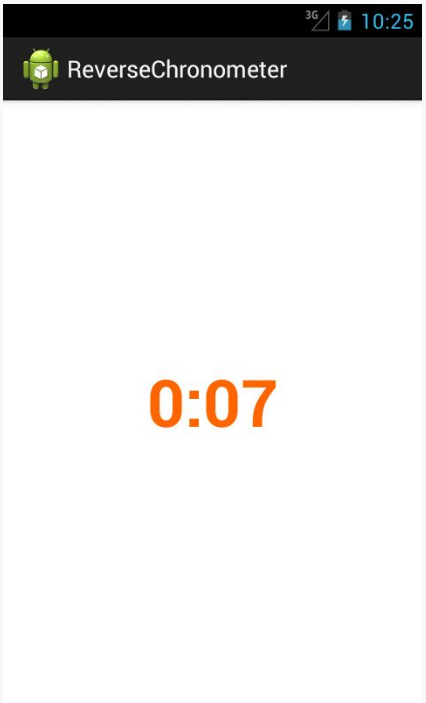

Figure 555: ReverseChronometer, Late in Countdown

…and changing to red when time has run out:

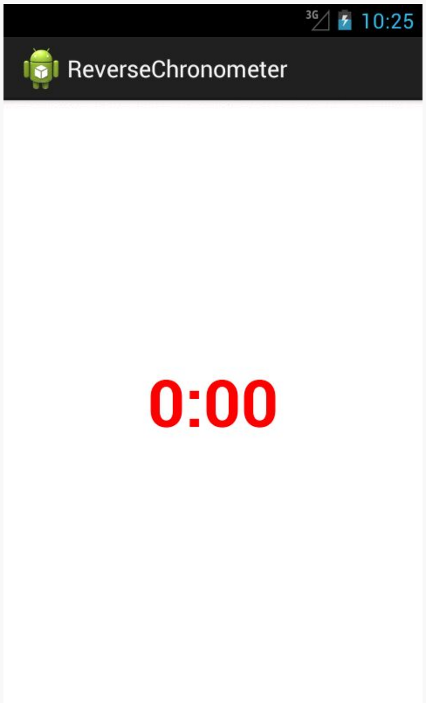

Figure 556: ReverseChronometer, With Complete Time Elapsed

Of course, much more could be done with this widget, if you chose:

- Support other constructors, beyond the two-argument constructor needed for layout inflation
- Support setting durations and colors via custom XML attributes
- Adding listeners for warning and expired events, so other things can be done at those points in time (e.g., play a sound, vibrate the device)

AspectLockedFrameLayout: A Custom Container

You can also craft your own custom container classes, whether inheriting straight from `ViewGroup` to implement your own set of layout rules, or by extending an existing `ViewGroup` to merely augment its functionality.

For example, there may be cases where you want to control the aspect ratio of some set of widgets. This is important when working with preview frames off of the `Camera` to prevent distortion, for example.

AspectLockedFrameLayout, therefore, is a custom extension of FrameLayout that ensures that its contents are kept within a particular aspect ratio, reducing the height or width of the contents to keep that aspect ratio.

AspectLockedFrameLayout is published as part of the CWAC-Layouts project, with its own GitHub repo. As with many of the CWAC projects, the reusable code is distributed as a JAR and as an Android library project, with a demo/ sub-project illustrating the use of some of the library's contents.

AspectLockedFrameLayout holds onto two data members:

- A double (aspectRatio) that represents a specific aspect ratio to maintain, initialized to 0.0
- A View (aspectRatioSource) that represents some other widget whose aspect ratio should be matched, initialized to null

AspectLockedFrameLayout has corresponding setters for each:

```
public void setAspectRatioSource(View v) {
  this.aspectRatioSource=new ViewAspectRatioSource(v);
}

public void setAspectRatioSource(AspectRatioSource aspectRatioSource) {
  this.aspectRatioSource=aspectRatioSource;
}

// from com.android.camera.PreviewFrameLayout, with slight
// modifications

public void setAspectRatio(double aspectRatio) {
  if (aspectRatio <= 0.0) {
    throw new IllegalArgumentException(
                                       "aspect ratio must be positive");
  }

  if (this.aspectRatio != aspectRatio) {
    this.aspectRatio=aspectRatio;
    requestLayout();
  }
}
```

The "business logic" of maintaining the aspect ratio comes in onMeasure(). onMeasure() is called on a ViewGroup when it is time for it to determine its actual size, based upon things like the requested height and width and the sizes of its children. In our case onMeasure() needs to be tweaked to maintain the aspect ratio, assuming that we have an aspect ratio to work with:

```
  @Override
  protected void onMeasure(int widthSpec, int heightSpec) {
    double localRatio=aspectRatio;

    if (localRatio == 0.0 && aspectRatioSource != null
        && aspectRatioSource.getHeight() > 0) {
      localRatio=
          (double)aspectRatioSource.getWidth()
              / (double)aspectRatioSource.getHeight();
    }

    if (localRatio == 0.0) {
      super.onMeasure(widthSpec, heightSpec);
    }
    else {
      int lockedWidth=MeasureSpec.getSize(widthSpec);
      int lockedHeight=MeasureSpec.getSize(heightSpec);

      if (lockedWidth == 0 && lockedHeight == 0) {
        throw new IllegalArgumentException(
                                           "Both width and height cannot be zero --
watch out for scrollable containers");
      }

      // Get the padding of the border background.
      int hPadding=getPaddingLeft() + getPaddingRight();
      int vPadding=getPaddingTop() + getPaddingBottom();

      // Resize the preview frame with correct aspect ratio.
      lockedWidth-=hPadding;
      lockedHeight-=vPadding;

      if (lockedHeight > 0 && (lockedWidth > lockedHeight * localRatio)) {
        lockedWidth=(int)(lockedHeight * localRatio + .5);
      }
      else {
        lockedHeight=(int)(lockedWidth / localRatio + .5);
      }

      // Add the padding of the border.
      lockedWidth+=hPadding;
      lockedHeight+=vPadding;

      // Ask children to follow the new preview dimension.
      super.onMeasure(MeasureSpec.makeMeasureSpec(lockedWidth,
                                                  MeasureSpec.EXACTLY),
                      MeasureSpec.makeMeasureSpec(lockedHeight,
                                                  MeasureSpec.EXACTLY));
    }
  }
```

We start by determining what actually is the desired aspect ratio, held onto in a `localRatio` local variable. That will be `aspectRatio` if we do not have an `aspectRatioSource` that already knows its size, otherwise we will calculate the aspect ratio from the source. And, if `localRatio` turns out to be `0.0`, indicating that we do not have an aspect ratio to maintain, we just chain to the superclass, so AspectLockedFrameLayout will behave just like a normal FrameLayout.

If we *do* have an aspect ratio to maintain, we start by determining our requested height and width. onMeasure() is passed a pair of "specs" that provides details about our requested size, and we can get the height and width from those by means of the MeasureSpec helper class. We remove any horizontal padding — padding is considered to be "outside" the locked area and therefore is ignored in aspect ratio calculations. We then adjust the height or the width, as needed, to maintain the aspect ratio. We add back in the padding, then chain to the superclass with revised height and width "specs" via MeasureSpec.

Note that much of this logic was derived from com.android.camera.PreviewFrameLayout from the AOSP Camera application, which is used to maintain the aspect ratio of the SurfaceView used to display preview frames.

To use an AspectLockedFrameLayout, just add it to your layout XML file, with an appropriate child widget/container representing the material that needs to maintain a particular aspect ratio. Since the AspectLockedFrameLayout is overriding its natural size, you can use android:layout_gravity to control its positioning within some parent widget, such as centering it:

```
<FrameLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <com.commonsware.cwac.layouts.AspectLockedFrameLayout
        android:id="@+id/source"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_gravity="center">

        <!-- children go here -->
    </com.commonsware.cwac.layouts.AspectLockedFrameLayout>
</FrameLayout>
```

Mirror and MirroringFrameLayout: Draw It Yourself

Another scenario where aspect ratios matter is when you are presenting information on an external display via Presentation, as is covered elsewhere in this book. Ideally, you fill the external display. And normally this will happen for you automatically, as your Presentation content view should fill the available screen space… assuming that the content has the right aspect ratio, or can be suitably stretched.

One scenario where this might be a problem is if you want *the same material* shown on both the main display and on the external display. For example, suppose that you are using `Presentation` to deliver… well… a presentation. The external display is probably some form of video projector, and you will want your slides or other materials shown there. However, it is useful for you to be able to see those same slides and such on the tablet, as typically the projector screen is behind, or to the side of, the presenter. If the presenter has to keep turning around to confirm what is shown on "the big screen", it can detract from the presentation.

Moreover, you might not only want to *show* the same material, but have it stem *from the same source*, on the tablet, for interactivity reasons. Suppose that you want to display a Web page. You might just pop up a `WebView` in the `Presentation`. But… how do you scroll? The `Presentation` offers no touch interface — projector screens do not magically respond to pinch-to-zoom just because we happen to be projecting something onto them from an Android tablet.

In this case, ideally we would like to *mirror* something. Have the actual widgets shown on the tablet, which can then respond to touch events and the like. At the same time, capture what is shown on the tablet and reproduce it, verbatim, on the `Presentation` for the audience to see. Now everybody can see the same material, and the presenter can manipulate that material.

But now aspect ratios come into play. We want to fill the `Presentation` display space, without black bars or stretching or whatever. That only works if our source material — the widgets and containers to be mirrored — have the same aspect ratio as the `Presentation`'s `Display` itself.

With that in mind, the CWAC Layouts project also contains two classes to solve this problem:

- `MirroringFrameLayout` is an `AspectLockedFrameLayout` that also can mirror its content to…
- `Mirror`, a `View` that takes a `Bitmap` representing the `MirroringFrameLayout` contents and displays it

Technically, `MirroringFrameLayout` works with a `MirrorSink`, an interface that can receive updates to the content to be mirrored when that content changes. `Mirror` implements `MirrorSink`, and you could have other classes implement `MirrorSink` as well if that made sense for your app. The sections that follow focus on MirroringFrameLayout working with a Mirror, as that is the most likely scenario.

MirroringFrameLayout

MirroringFrameLayout extends AspectLockedFrameLayout, so that we can lock the aspect ratio of the to-be-mirrored contents to match the aspect ratio of the Mirror. The Mirror is designed to be projected by the Presentation, and so if the Mirror fills the Presentation's Display, we want our MirroringFrameLayout to match the aspect ratio so the entire Display can indeed be filled.

Of course, a ViewGroup like FrameLayout normally just has its children draw to the screen. In our case, we need to capture what is drawn ourselves, to supply to the Mirror as needed. This is a bit tricky.

```
package com.commonsware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.ViewTreeObserver.OnPreDrawListener;

          bmp.recycle();
        }

        bmp=Bitmap.createBitmap(w, h, Bitmap.Config.ARGB_8888);
        bmpBackedCanvas=new Canvas(bmp);
      }
    }
  }
}
```

Our one-argument constructor uses `this()` to chain to the two-argument constructor. The two-argument constructor calls `setWillNotDraw(false)` indicating to Android that we want this `ViewGroup` to participate in the drawing process like a regular `View` — normally, certain steps in the drawing process are skipped as being irrelevant to `View` classes that do not draw anything themselves.

We have a `setMirror()` method, where the activity or fragment can supply the `MirrorSink` that is connected to this `MirroringFrameLayout`. In addition to holding onto the `MirrorSink` in a `mirror` data member, we call `setAspectRatioSource()`, inherited from `AspectLockedFrameLayout`, so our contents will match the aspect ratio from that source.

`MirroringFrameLayout` overrides `onAttachedToWindow()` and `onDetatchedFromWindow()`. As one might guess, these callbacks are called when views are attached and detached from some window. Usually, that window represents an activity, though it could represent a `Dialog` or a `Presentation`.

In those callbacks, we connect with the `ViewTreeObserver` of the `MirroringFrameLayout`. A `ViewTreeObserver` is a way to find out about events of a view tree, rooted at some `ViewGroup`. In our case, we want to find out when children are going to be drawn (`addOnPreDrawListener()`) and when they are scrolled (`addOnScrollChangedListener()`).

We override `onSizeChanged()`. This is called on any `View` when its size may have changed, either because it is being sized initially when the UI is being set up, or because something else nearby changed size (e.g., its parent) and therefore the size of the `View` itself may now be different. In our case, we use `onSizeChanged()` to set up a `Bitmap` object, sized to match our size, and a `Canvas` object that wraps around that `Bitmap` object. As you will see, we will use this `Canvas` to capture what is being drawn on the screen, for later use by the `Mirror`.

We also override `draw()`. This is, in effect, the “entry point” into the logic that causes a `View` to render itself on the screen, by drawing to a supplied `Canvas` object. Most `View` classes do not override `draw()`, as the real rendering is done in an `onDraw()`

method, as we will see with Mirror later in this chapter. However, in our case, we have to override draw() for one simple reason: we do not want to draw to the Canvas supplied by Android to the draw() method. We want to draw to our own Canvas, backed by that Bitmap.

To that end, if we have a MirrorSink, we:

- Make sure the Bitmap starts off blank by calling eraseColor()
- Chain to the superclass, replacing the Canvas given to us in draw() by our own Bitmap-backed Canvas
- Calculate a Rect object with our size and position, using getDrawingRect()
- Use that Rect and the Bitmap to render the Bitmap to the "real" Canvas supplied to us in draw()
- Call update() on the MirrorSink, to give it the new Bitmap

By rendering our contents to the Bitmap-backed Canvas, instead of the normal one, we capture a copy of the output, in the form of the Bitmap. Since the Bitmap has the same size as the "real" Canvas (courtesy of our onSizeChanged() work), when we draw the Bitmap onto the Canvas, we effectively "color in" the same pixels in the same spots as if we had skipped all of this and left the normal draw() logic alone. But, since we still hold onto our Bitmap, we can use those same pixels elsewhere… such as in our Mirror.

The problem with relying on draw() is that it is not always called when there are changes to widgets within the MirroringFrameLayout. In particular, WebView often does not trigger draw() on the MirroringFrameLayout. That's where the pre-draw and scroll-changed events from the ViewTreeObserver come into play: they give us more indication that we need to update our Bitmap.

The onPreDraw() method is called when a child of this MirroringFrameLayout is about to be drawn. If we have our MirrorSink, we then either call requestLayout() (if we have no bitmap yet) or invalidate() (if we do), to trigger Android to go through the draw process for the MirroringFrameLayout too, allowing us to update our Bitmap.

The onScrollChanged() method is called when a child of this MirroringFrameLayout has been scrolled. This delegates to onPreDraw(), to run through the same logic to force an update to the Bitmap.

Mirror

`Mirror` extends the base `View` class, and so it is the most "raw" of all the custom widgets and containers shown so far in this chapter. It has an `update()` method, used to connect the `MirroringFrameLayout` from which the `Mirror` can obtain what it is supposed to display:

```
package com.commonsware.cwac.layouts;

import android.content.Context;
import android.graphics.Bitmap;
import android.graphics.Canvas;
import android.graphics.Rect;
import android.util.AttributeSet;
import android.view.View;

public class Mirror extends View implements MirrorSink {
  private Rect rect=new Rect();
  private Bitmap bmp=null;

  public Mirror(Context context) {
    super(context);
  }

  public Mirror(Context context, AttributeSet attrs) {
    super(context, attrs);
  }

  public Mirror(Context context, AttributeSet attrs, int defStyle) {
    super(context, attrs, defStyle);
  }

  @Override
  public void update(Bitmap bmp) {
    this.bmp=bmp;
    invalidate();
  }

  @Override
  protected void onDraw(Canvas canvas) {
    super.onDraw(canvas);

    if (bmp != null) {
      getDrawingRect(rect);

      calcCenter(rect.width(), rect.height(), bmp.getWidth(),
                 bmp.getHeight(), rect);
      canvas.drawBitmap(bmp, null, rect, null);
    }
  }

  // based upon http://stackoverflow.com/a/14679729/115145

  static void calcCenter(int vw, int vh, int iw, int ih, Rect out) {
    double scale=
        Math.min((double)vw / (double)iw, (double)vh / (double)ih);
    int h=(int)(scale * ih);
    int w=(int)(scale * iw);
    int x=((vw - w) >> 1);
    int y=((vh - h) >> 1);

    out.set(x, y, x + w, y + h);
  }
}
```

The bulk of the "business logic" lies in `onDraw()`, plus a helper `calcCenter()` static method.

`onDraw()` is called on a `View` when it is time for that widget to actually draw its visual representation onto the supplied `Canvas`. Different widgets will use different drawing primitive methods offered by `Canvas`, to draw lines and text and whatnot. In our case, we:

- Calculate a `Rect` object with our size and position, using `getDrawingRect()`
- Get the `Bitmap` object from the `MirroringFrameLayout`, via a call to `getLastBitmap()` (which simply returns the `Bitmap` that the `MirroringFrameLayout` is using)
- Call `calcCenter` to adjust our `Rect` to take into account the fact that our size may be different than the size of the actual `Bitmap`
- Call `drawBitmap()` on our `Canvas`, to render the `Bitmap` into the location specified by the `Rect`, where `drawBitmap()` will automatically down-sample or up-sample the image as needed to fill the necessary space

Usage and Results

Normally, you would use the `Mirror` in a layout for a `Presentation` and the `MirroringFrameLayout` in an activity that controls the `Presentation`. However, it is possible to use both in the same layout file, for light testing. However, please do not put the `Mirror` inside of the `MirroringFrameLayout`, as this is likely to cause a rupture in the space-time continuum, and you really do not want to be responsible for that.

So, in the `SimpleMirrorActivity` from the `demo/` sub-project, we use a layout that has both `Mirror` and `MirroringFrameLayout`, with the latter set to mirror a `WebView`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
  tools:context=".SimpleMirrorActivity">

  <FrameLayout
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1">

    <com.commonsware.cwac.layouts.MirroringFrameLayout
      android:id="@+id/source"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:layout_gravity="center">

      <EditText
        android:id="@+id/editor"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:gravity="left|top"
        android:inputType="textMultiLine"/>
    </com.commonsware.cwac.layouts.MirroringFrameLayout>
  </FrameLayout>

  <View
    android:layout_width="match_parent"
    android:layout_height="4dip"
    android:background="#FF000000"/>

  <com.commonsware.cwac.layouts.Mirror
    android:id="@+id/target"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="2"/>

</LinearLayout>
```

In this case, we set the background of the `FrameLayout` holding our `MirroringFrameLayout` to green, to show how the `MirroringFrameLayout` size is changed to maintain our aspect ratio.

(or, perhaps we just like green)

Besides configuring the to-be-mirrored widgets, all you need to do is call `setMirror()` on the `MirroringFrameLayout` to enable the mirroring logic:

```
package com.commonsware.cwac.layouts.demo;

import android.app.Activity;
import android.os.Bundle;
import com.commonsware.cwac.layouts.Mirror;
import com.commonsware.cwac.layouts.MirroringFrameLayout;

public class SimpleMirrorActivity extends Activity {
  MirroringFrameLayout source=null;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.simple_mirror);

    source=(MirroringFrameLayout)findViewById(R.id.source);
    Mirror target=(Mirror)findViewById(R.id.target);

    source.setMirror(target);
  }
}
```

Figure 558: MirroringFrameLayout and Mirror, Showing Scrolled Contents

Limitations

`MirroringFrameLayout` only works for materials drawn in the Java layer, that therefore can be drawn to the `Bitmap`-backed `Canvas`. Content *not* drawn in the Java layer will not work with `MirroringFrameLayout`, notably anything involving a `SurfaceView`. This not only includes your own `SurfaceView` widgets, but anything else that depends upon `SurfaceView`, such as `VideoView` or the Maps V2 `MapView` and `MapFragment`.

Also, the re-sampling done by `Mirror` is not especially sophisticated and will cause jagged effects, particularly when up-sampling. Ideally, the `MirroredFrameLayout` will be the same size or larger than the `Mirror`. This may not always be possible, particularly with a `Mirror` shown on a 1080p external display, but the closer you can get will improve the output.

Advanced Preferences

We saw SharedPreferences and PreferenceFragment earlier in the book. However, we can have more elaborate preference collection options if we wish, such as a full master-detail implementation like the Settings app sports. There are also many other common attributes on the preference XML elements that we might consider taking advantage of, such as allowing us to automatically enable and disable preferences based upon whether some other preference is checked or unchecked.

In this chapter, we will explore some of these additional capabilities in the world of Android preferences.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on SharedPreferences.

Introducing PreferenceActivity

If you have a fairly simple set of preferences to collect from the user, using a single PreferenceFragment should be sufficient.

On the far other end of the spectrum, Android's Settings app collects a massive amount of preference values from the user. These are spread across a series of groups of preferences, known as preference headers.

While your app may not need to collect as many preferences as does the Settings app, you may need more than what could be collected easily in a single PreferenceFragment. In that case, you can consider adopting the same structure of headers-and-fragments that the Settings app uses, by means of a `PreferenceActivity`.

To see this in action, take a look at the [`Prefs/FragmentsBC`]() sample project. It is very similar to the original `SharedPreferences` demo app from [before](). However, this one arranges to collect a fifth preference value, in a separate `PreferenceFragment`, and uses `PreferenceActivity` to allow access to both `PreferenceFragment` UI structures.

Defining Your Preference Headers

In the master-detail approach offered by `PreferenceActivity`, the "master" list is a collection of preference headers. Typically, you would define these in another XML resource. In the sample project, that is found in `res/xml/preference_headers.xml`:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">

  <header
    android:fragment="com.commonsware.android.preffragsbc.EditPreferences$First"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
  </header>
  <header
    android:fragment="com.commonsware.android.preffragsbc.EditPreferences$Second"
    android:summary="@string/header2summary"
    android:title="@string/header2title">
  </header>

</preference-headers>
```

Here, your root element is `<preference-headers>`, containing a series of `<header>` elements. Each `<header>` contains at least three attributes:

1. `android:fragment`, which identifies the Java class implementing the `PreferenceFragment` to use for this header, as is described in the next section
2. `android:title`, which is a few words identifying this header to the user

Once again, you may wish to also include `android:summary`, which is a short sentence explaining what the user will find inside of this header.

You can, if you wish, include one or more `<extra>` child elements inside the `<header>` element. These values will be put into the "arguments" `Bundle` that the associated `PreferenceFragment` can retrieve via `getArguments()`.

Creating Your PreferenceActivity

`EditPreferences` — which in the original sample app was a regular `Activity` — is now a `PreferenceActivity`. It contains little more than the two fragments referenced in the above preference header XML:

```
package com.commonsware.android.preffragsbc;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import android.preference.PreferenceFragment;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
  @Override
  public void onBuildHeaders(List<Header> target) {
    loadHeadersFromResource(R.xml.preference_headers, target);
  }

  @Override
  protected boolean isValidFragment(String fragmentName) {
    if (First.class.getName().equals(fragmentName)
        || Second.class.getName().equals(fragmentName)) {
      return(true);
    }

    return(false);
  }

  public static class First extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
      super.onCreate(savedInstanceState);

      addPreferencesFromResource(R.xml.preferences);
    }
  }

  public static class Second extends PreferenceFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
      super.onCreate(savedInstanceState);

      addPreferencesFromResource(R.xml.preferences2);
    }
  }
}
```

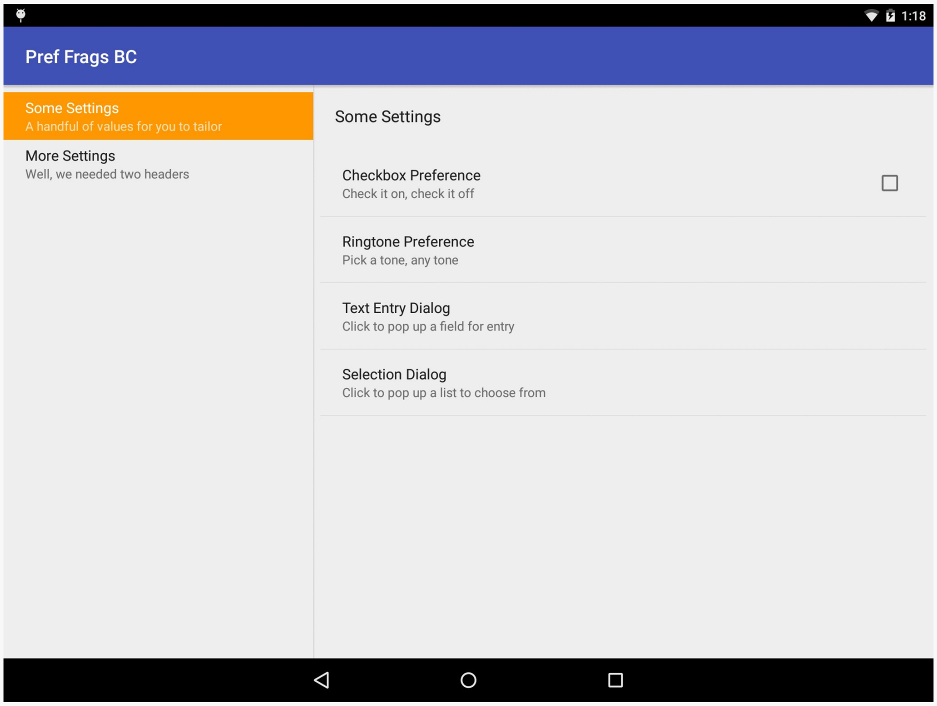
`onBuildHeaders()` is where we supply the preference headers, via a call to `loadHeadersFromResource()`.

We also need to have an `isValidFragment()` method, that will return `true` if the supplied fragment name is one we should be showing in this `PreferenceActivity`, `false` otherwise. This will only be called on Android 4.4+. However, we need to set up the project build target (e.g., `compileSdkVersion` in Android Studio, Project > Preferences > Android in Eclipse) to API Level 19 or higher. Failing to have this method will cause your app to crash on Android 4.4+ devices, when the user tries to bring up one of your `PreferenceFragments`.

Each `PreferenceFragment` is then responsible for calling `addPreferencesFromResource()` to populate its contents. In this case, we now have two such resources: `res/xml/preferences.xml` (the original, used by `First`) and `res/xml/preferences2.xml` (used by `Second`).

The Results

On a wide enough screen — like that of a Nexus 9 in landscape — we get a master-detail presentation:



Some Settings
A handful of values for you to tailor

More Settings
Well, we needed two headers

Some Settings

Checkbox Preference
Check it on, check it off ☐

Ringtone Preference
Pick a tone, any tone

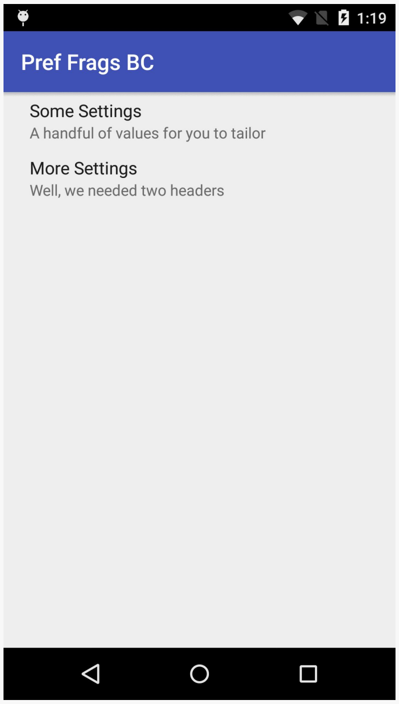
Text Entry Dialog
Click to pop up a field for entry

Selection Dialog
Click to pop up a list to choose from

Figure 559: PreferenceActivity UI, on a Landscape Nexus 9

Here, we see the first preference fragment already pre-selected, showing its settings. Tapping on the second header will show the other preferences.

On a smaller screen, the master-detail approach means that we see a list of headers first:



1:19

Pref Frags BC

Some Settings
A handful of values for you to tailor

More Settings
Well, we needed two headers

Figure 560: PreferenceActivity UI, on a Portrait Nexus 5

Tapping the headers give us access to the individual fragments.

Intents for Headers or Preferences

If you have the need to collect some preferences that are beyond what the standard preferences can handle, you have some choices.

One is to create a custom `Preference`. Extending `DialogPreference` to create your own `Preference` implementation is not especially hard. However, it does constrain you to something that can fit in a dialog.

Another option is to specify an `<intent>` element as a child of a `<header>` element. When the user taps on this header, your specified `Intent` is used with `startActivity()`, giving you a gateway to your own activity for collecting things that are beyond what the preference UI can handle. For example, you could have the following `<header>`:

```
<header android:icon="@drawable/something"
        android:title="Fancy Stuff"
        android:summary="Click here to transcend your
plane of existence">
  <intent android:action="com.commonsware.android.MY_CUSTOM_ACTION" />
</header>
```

Then, so long as you have an activity with an `<intent-filter>` specifying your desired action (`com.commonsware.android.MY_CUSTOM_ACTION`), that activity will get control when the user taps on the associated header.

Conditional Headers

The two-tier, headers-and-preferences approach is fine and helps to organize large rosters of preferences. However, it does tend to steer developers in the direction of displaying headers *all of the time*. For many apps, that is rather pointless, because there are too few preferences to collect to warrant having more than one header.

One alternative approach is to use the headers on larger devices, but skip them on smaller devices. That way, the user does not have to tap past a single-item `ListFragment` just to get to the actual preferences to adjust.

This is a wee bit tricky to implement. However, you have two options for how to accomplish it.

(The author would like to thank Richard Le Mesurier, whose question on this topic spurred the development of this section and its samples)

Option #1: Do Not Define the Headers

The basic plan in the first approach is to have smarts in `onBuildHeaders()` to handle this. `onBuildHeaders()` is the callback that Android invokes on our `PreferenceActivity` to let us define the headers to use in the master-detail pattern. If we want to have headers, we would supply them here; if we want to skip the headers, we would instead fall back to the classic (and, admittedly, deprecated) `addPreferencesFromResource()` method to load up some preference XML.

There is an `isMultiPane()` method on `PreferenceActivity`, starting with API Level 11, that will tell you if the activity will render with two fragments (master+detail) or not. In principle, this would be ideal to use. Unfortunately, it does not seem to be designed to be called from `onBuildHeaders()`. Similarly, `addPreferencesFromResource()` does not seem to be callable from onBuildHeaders(). Both are due to timing: onBuildHeaders() is called in the middle of the PreferenceActivity onCreate() processing.

So, we have to do some fancy footwork.

By examining the source code to PreferenceActivity, you will see that the logic that drives the single-pane vs. dual-pane UI decision boils down to:

```
onIsHidingHeaders() || !onIsMultiPane()
```

If that expression returns true, we are in single-pane mode; otherwise, we are in dual-pane mode. onIsHidingHeaders() will normally return false, while onIsMultiPane() will return either true or false based upon screen size.

So, we can leverage this information in a PreferenceActivity to conditionally load our headers, as seen in the EditPreferences class in the Prefs/SingleHeader sample project:

```
package com.commonsware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
  private boolean needResource=false;

  @SuppressWarnings("deprecation")
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (needResource) {
      addPreferencesFromResource(R.xml.preferences);
    }
  }

  @Override
  public void onBuildHeaders(List<Header> target) {
    if (onIsHidingHeaders() || !onIsMultiPane()) {
      needResource=true;
    }
    else {
      loadHeadersFromResource(R.xml.preference_headers, target);
    }
  }

  @Override
  protected boolean isValidFragment(String fragmentName) {
    return(StockPreferenceFragment.class.getName().equals(fragmentName));
  }
}
```

Here, if we are in dual-pane mode, onBuildHeaders() populates the headers as normal. If, though, we are in single-pane mode, we skip that step and make note that we need to do some more work in onCreate().

Then, in onCreate(), if we did not load our headers we use the classic addPreferencesFromResource() method.

The net result is that on Android 3.0+ tablets, we get the dual-pane, master-detail look with our one header, but on smaller devices (regardless of version), we roll straight to the preferences themselves.

Note that this sample application uses a single PreferenceFragment implementation, named StockPreferenceFragment:

```
package com.commonsware.android.pref1header;

import android.os.Bundle;
import android.preference.PreferenceFragment;

public class StockPreferenceFragment extends PreferenceFragment {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    int res=
        getActivity().getResources()
                     .getIdentifier(getArguments().getString("resource"),
                                    "xml",
                                    getActivity().getPackageName());

    addPreferencesFromResource(res);
  }
}
```

StockPreferenceFragment does what it is supposed to: call addPreferencesFromResource() in onCreate() with the resource ID of the preferences to load. However, rather than hard-coding a resource ID, as we normally would, we look it up at runtime.

The <extra> elements in our preference header XML supply the name of the preference XML to be loaded:

```
<preference-headers xmlns:android="http://schemas.android.com/apk/res/android">

  <header
    android:fragment="com.commonsware.android.pref1header.StockPreferenceFragment"
    android:summary="@string/header1summary"
    android:title="@string/header1title">
    <extra
```

```
      android:name="resource"
      android:value="preferences"/>
  </header>

</preference-headers>
```

We get that name via the arguments Bundle (getArguments().getString("resource")).

To look up a resource ID at runtime, we can use the Resources object, available from our activity via a call to getResources(). Resources has a method, getIdentifier(), that will return a resource ID given three pieces of information:

1. The base name of the resource (in our case, the value retrieved from the <extra> element)
2. The type of the resource (e.g., "xml")
3. The package holding the resource (in our case, our own package, retrieved from our activity via getPackageName())

Note that getIdentifier() uses reflection to find this value, and so there is some overhead in the process. Do not use getIdentifier() in a long loop – cache the value instead.

The net is that StockPreferenceFragment loads the preference XML described in the <extra> element, so we do not need to create separate PreferenceFragment implementations per preference header.

Option #2: Go Directly to the Fragment

The advantage of the above approach is that it works with Android's own logic of whether to display the master-detail fragments or just one at a time. However, that logic — the fact that onIsHidingHeaders() || !onIsMultiPane() determines the look of the activity — is not documented, and therefore may change in future Android releases.

Another option is to launch your PreferenceActivity in such a way that tells Android to skip showing the headers. This approach is better documented and therefore perhaps more stable. This can also be used in cases where you do want headers sometimes, but at other times you want to route the user to a specific PreferenceFragment. The downside is that this technique only works on API Level 11+.

To see how this works, take a look at the Prefs/SingleHeader2 sample project.

Our EditPreferences class is the same implementation as in the original sample for this chapter, except that we only load up the single XML resource's worth of preferences:

```
package com.commonsware.android.pref1header;

import android.preference.PreferenceActivity;
import java.util.List;

public class EditPreferences extends PreferenceActivity {
  @Override
  public void onBuildHeaders(List<Header> target) {
    loadHeadersFromResource(R.xml.preference_headers, target);
  }

  @Override
  protected boolean isValidFragment(String fragmentName) {
    return(StockPreferenceFragment.class.getName().equals(fragmentName));
  }
}
```

However, there is a change in our main activity (FragmentsDemo). Before, when the user chose the "Settings" action bar overflow item, we would just call startActivity() to bring up EditPreferences. Now, we delegate that work to an editPrefs() method on FragmentsDemo, which will have the smarts to control *how* we bring up the EditPreferences activity:

```
  private void editPrefs() {
    Intent i=new Intent(this, EditPreferences.class);

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT,
               StockPreferenceFragment.class.getName());

    Bundle b=new Bundle();

    b.putString("resource", "preferences");

    i.putExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT_ARGUMENTS, b);

    startActivity(i);
  }
```

Here, we will add two extras to our Intent:

- EXTRA_SHOW_FRAGMENT, set to the fully-qualified class name of the PreferenceFragment to be displayed, here obtained by calling getName() on the Class object for StockPreferenceFragment

- `EXTRA_SHOW_FRAGMENT_ARGUMENTS`, set to a `Bundle` containing the same values that would ordinarily be loaded from the `<extra>` elements in the preference header XML resource (in our case, the name of the preference XML resource to load)

Those extras will be automatically handled by `PreferenceActivity` (on API Level 11+) and will have the effect of directly taking the user to our one-and-only fragment, bypassing the headers.

Dependent Preferences

In the Settings app, or in other apps that appear to be using `PreferenceFragment`-based UIs, you may have noticed that there are times when preferences are disabled. They become enabled when you check a `CheckBoxPreference` or toggle on a `SwitchPreference`.

That is handled via the `android:dependency` attribute on the to-be-disabled preferences. The value of `android:dependency` is the key of a `TwoStatePreference` subclass, such as a `CheckBoxPreference` or a `SwitchPreference`. The enabled/disabled state of the preference with the `android:dependency` attribute depends on the checked state of the named dependency.

For example, the `Prefs/Dependency` sample project is a clone of the original `SharedPreferences` demo app with one slight change: all the preferences other than `checkbox` are now dependent upon `checkbox`:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">

  <CheckBoxPreference
    android:key="checkbox"
    android:summary="@string/pref1summary"
    android:title="@string/pref1title"/>

  <RingtonePreference
    android:dependency="checkbox"
    android:key="ringtone"
    android:showDefault="true"
    android:showSilent="true"
    android:summary="@string/pref2summary"
    android:title="@string/pref2title"/>

  <EditTextPreference
    android:dependency="checkbox"
    android:dialogTitle="@string/dialogtitle"
    android:key="text"
    android:summary="@string/pref3summary"
    android:title="@string/pref3title"/>
  <ListPreference
    android:dependency="checkbox"
    android:dialogTitle="@string/listdialogtitle"
    android:entries="@array/cities"
    android:entryValues="@array/airport_codes"
    android:key="list"
    android:summary="@string/pref4summary"
    android:title="@string/pref4title"/>

</PreferenceScreen>
```

When you run the project, the dependent preferences are disabled while the checkbox is unchecked:

Nested Screens

Perhaps you have more preferences than you want to collect on a single screen, but you do not feel that a master-detail presentation is the right structure. Or, perhaps you have *lots* of preferences to collect, and even collecting preferences into groups by header is insufficient.

Another possibility is to nest preference screens. One screen holds another. On the outer preference screen, the user has a "preference" entry that simply displays the nested screen, as opposed to directly collecting any preferences.

A `<PreferenceScreen>` element in your preference XML can hold another `<PreferenceScreen>` element. That inner `<PreferenceScreen>` can come in one of two forms:

1. Inside the inner `<PreferenceScreen>` you have more preference XML elements. This means there is only one `PreferenceFragment` for the whole structure (outer `<PreferenceScreen>`, including the inner

<PreferenceScreen>). However, visually, the user will “drill down” from the outer screen into the inner one by tapping on an entry.

2. The inner <PreferenceScreen> has an android:fragment attribute, just like a preference header might. This points to a Fragment — typically a PreferenceFragment — that will be responsible for the “inner” content. This is a bit more complex to set up, as it requires a couple of fragments. However, it gives you greater flexibility. Plus, it is fairly easy to then switch from using preference headers and the master-detail approach to using nested preference screens, or back again, as you are simply reusing the same PreferenceFragment implementations in either case.

The Prefs/NestedScreens sample project takes the master-detail approach shown earlier in this chapter and switches it to having a top-level screen and a nested screen. This is accomplished by adding a <PreferenceScreen> element to res/xml/preferences.xml, pointing to our Second PreferenceFragment:

```
  <PreferenceScreen
    android:fragment="com.commonsware.android.preffragsbc.EditPreferences$Second"
    android:key="unused"
    android:title="@string/nested_title"/>
```

Here, the android:title (and optional android:summary) will be shown on the *outer* screen, as an entry that the user can tap on to get to this inner screen. While in this sample, we are not using android:key, in principle you could use this to get at the PreferenceScreen itself to manipulate it at runtime (e.g., disable it).

For this style of <PreferenceScreen> to work, the preference XML must be used by a PreferenceFragment in a PreferenceActivity — you cannot use it with a regular Activity. However, just because you use PreferenceActivity does not mean that you have to opt into the master-detail structure. We can use the same onCreate(), show-the-PreferenceFragment approach that we use with a regular Activity.

However, there is one big catch: when the user taps on the entry that will launch the inner screen, the Android framework will start *another instance* of our PreferenceActivity. It will give us the same EXTRA_SHOW_FRAGMENT value as we saw earlier in this chapter. However, PreferenceActivity will automatically show that fragment; we do not need to show it ourselves.

But, this means that our onCreate() needs to distinguish between the “show the outer screen ourselves” case and the “show the inner screen automatically” case, which we can do by seeing if EXTRA_SHOW_FRAGMENT exists:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  if (getIntent().getStringExtra(PreferenceActivity.EXTRA_SHOW_FRAGMENT)==null) {
    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
      getFragmentManager().beginTransaction()
          .add(android.R.id.content,
              new First()).commit();
    }
  }
}
```

The result is that we see the outer screen first, containing our entry for the inner screen:

Listening to Preference Changes

Sometimes, you may need to take steps when the user interacts with a preference in your `PreferenceFragment`-based UI.

A common scenario for this comes with the summary. In some cases, is it handy to have the summary reflect the current value of the preference. While some preferences naturally show their value inline (e.g., a `CheckBoxPreference`), those that extend from `DialogPreference` only show their value when the user taps on the preference to display the dialog. Putting something in the summary that reflects the value can save the user a click.

However, by default, the summary is static, populated by the `android:summary` attribute in your preference XML. If you want it to reflect the current preference value, you not only need to be able to set the summary in Java, but to be able to respond when the user changes the value, so you can update the summary again.

The `Prefs/CustomSubtitle` sample project demonstrates how this works. This is yet another clone of the original `SharedPreferences` demo app. This time, the preference XML is unchanged from the original. However, we have a slightly more elaborate PreferenceFragment implementation:

```
public static class Prefs extends PreferenceFragment
    implements Preference.OnPreferenceChangeListener {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    addPreferencesFromResource(R.xml.preferences);

    Preference pref=findPreference("text");

    updateSummary(pref,
        pref.getSharedPreferences().getString(pref.getKey(), null));
    pref.setOnPreferenceChangeListener(this);
  }

  @Override
  public boolean onPreferenceChange(Preference pref, Object newValue) {
    updateSummary(pref, newValue.toString());

    return(true);
  }

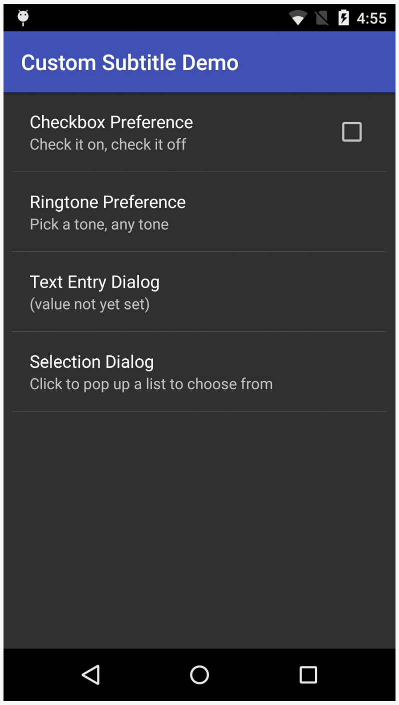
  private void updateSummary(Preference pref, String value) {
    if (value==null || value.length()==0) {
      pref.setSummary(R.string.msg_missing_text);
    }
    else {
      pref.setSummary(value);
    }
  }
}
```

In onCreate(), after addPreferencesFromResource(), we call findPreference() to retrieve the Preference object that manages the snippet of UI for a particular preference. The flow here mimics that of setContentView() and findViewById(): first you inflate the resource, then you find the Java object corresponding to some XML element out of that resource. findPreference() takes the key of the preference that you are looking for; in this case, we are looking for the EditTextPreference, whose key is text.

We then call a private updateSummary() method, which takes the Preference and the current value of that preference and updates the summary. To get the current value, onCreate() can ask the Preference for its backing SharedPreferences (via getSharedPreferences()), then retrieve the value using standard getters (e.g., getString()). updateSummary() then shows the string representation of the current value, or a canned message if there does not appear to be a current value.

We also register the fragment itself as being the `OnPreferenceChangeListener`, and register the fragment with the preference via `setOnPreferenceChangeListener()`. This means that when the user manipulates this preference, we will be called with `onPreferenceChange()`. This is done *before the `SharedPreferences` are updated*. Our options are either to return `true` and have the normal persistence process continue, or return `false` and manage persistence ourselves (e.g., perform some conversion on the raw value before storing it). In our case, we are just using this to call `updateSummary()` again.

If you install the app and run it, you will not have an existing value for the preference, and so the summary shows a stock message:



4:55

Defaults, and Defaults

When you use `SharedPreferences` to retrieve a value, you can usually provide a default value along with the key for the value that you want. If there is no preference value for that key, you get the default that you supplied.

A preference in preference XML also has an `android:defaultValue` attribute. This is, roughly speaking, the preference UI counterpart to that second parameter to the `SharedPreferences` getters. If the user interacts with the preference, the `android:defaultValue` value will be presented to the user if there was no preference value stored for that key in the underlying `SharedPreferences`.

To synchronize these, you can call `setDefaultValues()` on the `PreferenceManager` class. Given the resource ID of some preference XML, `PreferenceManager` will find all `android:defaultValue` attributes and then persist those default values to the `SharedPreferences` under their respective keys.

Listening to Preference Value Changes

Sometimes, you will have components that need to know when preference values are changed elsewhere in your app. For example, you may have a `Service` that is using information from `SharedPreferences`, and the `Service` may need to know when those values change.

One approach, used in all the sample apps, is simply to re-read the preference values as needed, rather than caching them in data members or something. After the first time `SharedPreferences` are accessed, the `SharedPreferences` themselves are held in heap space, and so accessing them can be fairly cheap. So, the sample apps' launcher activities just re-read the preference values in `onResume()` and update the UI that way.

If, however, that is inappropriate, inconvenient, or otherwise not what you want to do, you can call `registerOnSharedPreferenceChangeListener()` on a `SharedPreferences` object, supplying an instance of an implementation of the `OnSharedPreferenceChangeListener` interface. That object will be called with `onSharedPreferenceChanged()` every time a preference value changes. You are given the key to the changed value, so you can implement a filter to only pay attention to keys that matter to you. When one of those keys is reported to have changed, you can ask the `SharedPreferences` for the new value.

Custom Dialogs and Preferences

Android ships with a number of dialog classes for specific circumstances, like `DatePickerDialog` and `ProgressDialog`. Similarly, Android comes with a smattering of `Preference` classes for your `PreferenceActivity`, to accept text or selections from lists and so on.

However, there is plenty of room for improvement in both areas. As such, you may find the need to create your own custom dialog or preference class. This chapter will show you how that is done.

We start off by looking at creating a custom `AlertDialog`, not by using `AlertDialog.Builder`, but via a custom subclass. Then, we show how to create your own dialog-style `Preference`, where tapping on the preference pops up a dialog to allow the user to customize the preference value.

Prerequisites

Understanding this chapter requires that you have read the chapter on dialogs, along with the chapter on the preference system. Also, the samples here use the custom `ColorMixer View` described in another chapter.

Your Dialog, Chocolate-Covered

For your own application, the simplest way to create a custom `AlertDialog` is to use `AlertDialog.Builder`, as described in a previous chapter. You do not need to create any special subclass — just call methods on the `Builder`, then `show()` the resulting dialog.

However, if you want to create a reusable AlertDialog, this may become problematic. For example, where would this code to create the custom AlertDialog reside?

So, in some cases, you may wish to extend AlertDialog and supply the dialog's contents that way, which is how TimePickerDialog and others are implemented. Unfortunately, this technique is not well documented. This section will illustrate how to create such an AlertDialog subclass, as determined by looking at how the core Android team did it for their own dialogs.

The sample code is ColorMixerDialog, a dialog wrapping around the ColorMixer widget shown in a previous chapter. The implementation of ColorMixerDialog can be found in the CWAC-ColorMixer GitHub repository, as it is part of the CommonsWare Android Components.

Using this dialog works much like using DatePickerDialog or TimePickerDialog. You create an instance of ColorMixerDialog, supplying the initial color to show and a listener object to be notified of color changes. Then, call show() on the dialog. If the user makes a change and accepts the dialog, your listener will be informed.

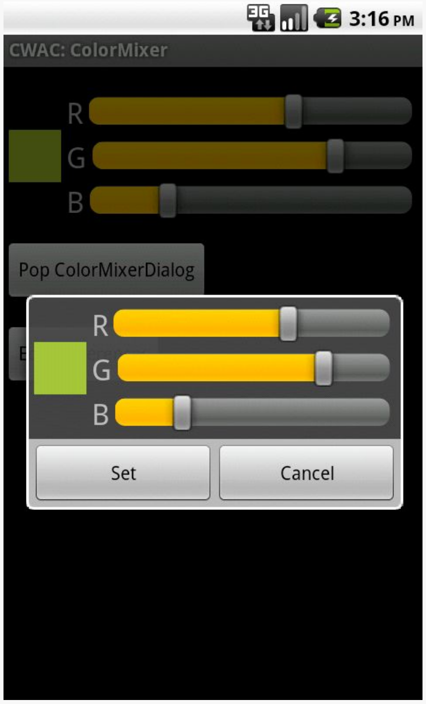

Figure 567: The ColorMixerDialog

Basic AlertDialog Setup

The `ColorMixerDialog` class is not especially long, since all of the actual color mixing is handled by the `ColorMixer` widget:

```
package com.commonsware.cwac.colormixer;

import android.app.AlertDialog;
import android.content.Context;
import android.content.DialogInterface;
import android.os.Bundle;

public class ColorMixerDialog extends AlertDialog
  implements DialogInterface.OnClickListener {
  static private final String COLOR="c";
  private ColorMixer mixer=null;
  private int initialColor;
  private ColorMixer.OnColorChangedListener onSet=null;

  public ColorMixerDialog(Context ctxt,
                          int initialColor,
                          ColorMixer.OnColorChangedListener onSet) {
    super(ctxt);

    this.initialColor=initialColor;
    this.onSet=onSet;

    mixer=new ColorMixer(ctxt);
    mixer.setColor(initialColor);

    setView(mixer);
    setButton(ctxt.getText(R.string.cwac_colormixer_set),
              this);
    setButton2(ctxt.getText(R.string.cwac_colormixer_cancel),
               (DialogInterface.OnClickListener)null);
  }

  @Override
  public void onClick(DialogInterface dialog, int which) {
    if (initialColor!=mixer.getColor()) {
      onSet.onColorChange(mixer.getColor());
    }
  }

  @Override
  public Bundle onSaveInstanceState() {
    Bundle state=super.onSaveInstanceState();

    state.putInt(COLOR, mixer.getColor());

    return(state);
  }

  @Override
  public void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);
    mixer.setColor(state.getInt(COLOR));
  }
}
```

We extend the AlertDialog class and implement a constructor of our own design. In this case, we take in three parameters:

1. A Context (typically an Activity), needed for the superclass
2. The initial color to use for the dialog, such as if the user is editing a color they chose before
3. A ColorMixer.OnColorChangedListener object, just like ColorMixer uses, to notify the dialog creator when the color is changed

We then create a ColorMixer and call setView() to make that be the main content of the dialog. We also call setButton() and setButton2() to specify a "Set" and "Cancel" button for the dialog. The latter just dismisses the dialog, so we need no event handler. The former we route back to the ColorMixerDialog itself, which implements the DialogInterface.OnClickListener interface.

Handling Color Changes

When the user clicks the "Set" button, we want to notify the application about the color change…if the color actually changed. This is akin to DatePickerDialog and TimePickerDialog only notifying you of date or times if the user clicks Set and actually changed the values.

The ColorMixerDialog tracks the initial color via the initialColor data member. In the onClick() method — required by DialogInterface.OnClickListener — we see if the mixer has a different color than the initialColor, and if so, we call the supplied ColorMixer.OnColorChangedListener callback object:

```
  @Override
  public void onClick(DialogInterface dialog, int which) {
    if (initialColor!=mixer.getColor()) {
      onSet.onColorChange(mixer.getColor());
    }
  }
```

State Management

Dialogs use onSaveInstanceState() and onRestoreInstanceState(), just like activities do. That way, if the screen is rotated, or if the hosting activity is being evicted from RAM when it is not in the foreground, the dialog can save its state, then get it back later as needed.

The biggest difference with `onSaveInstanceState()` for a dialog is that the `Bundle` of state data is not passed into the method. Rather, you get the `Bundle` by chaining to the superclass, then adding your data to the `Bundle` it returned, before returning it yourself:

```
@Override
public Bundle onSaveInstanceState() {
  Bundle state=super.onSaveInstanceState();

  state.putInt(COLOR, mixer.getColor());

  return(state);
}
```

The `onRestoreInstanceState()` pattern is much closer to the implementation you would find in an `Activity`, where the `Bundle` with the state data to restore is passed in as a parameter:

```
@Override
public void onRestoreInstanceState(Bundle state) {
  super.onRestoreInstanceState(state);

  mixer.setColor(state.getInt(COLOR));
}
```

Preferring Your Own Preferences, Preferably

The Android Settings application, built using the `Preference` system, has lots of custom `Preference` classes. You too can create your own `Preference` classes, to collect things like dates, numbers, or colors. Once again, though, the process of creating such classes is not well documented. This section reviews one recipe for making a `Preference` — specifically, a subclass of `DialogPreference` – based on the implementation of other `Preference` classes in Android.

The result is `ColorPreference`, a `Preference` that uses the `ColorMixer` widget. As with the `ColorMixerDialog` from the previous section, the `ColorPreference` is from the CommonsWare Android Components, and its source code can be found in the CWAC-ColorMixer GitHub repository.

One might think that `ColorPreference`, as a subclass of `DialogPreference`, might use `ColorMixerDialog`. However, that is not the way it works, as you will see.

The Constructor

A Preference is much like a [custom View](), in that there are a variety of constructors, some taking an `AttributeSet` (for the preference properties), and some taking a default style. In the case of `ColorPreference`, we need to get the string resources to use for the names of the buttons in the dialog box, providing them to `DialogPreference` via `setPositiveButtonText()` and `setNegativeButtonText()`.

Here, we just implement the standard two-parameter constructor, since that is the one that is used when this preference is inflated from a preference XML file:

```
public ColorPreference(Context ctxt, AttributeSet attrs) {
  super(ctxt, attrs);

  setPositiveButtonText(ctxt.getText(R.string.cwac_colormixer_set));
  setNegativeButtonText(ctxt.getText(R.string.cwac_colormixer_cancel));
}
```

Creating the View

The `DialogPreference` class handles the pop-up dialog that appears when the preference is clicked upon by the user. Subclasses get to provide the `View` that goes inside the dialog. This is handled a bit reminiscent of a `CursorAdapter`, in that there are two separate methods to be overridden:

- `onCreateDialogView()` works like `newView()` of `CursorAdapter`, returning a `View` that should go in the dialog
- `onBindDialogView()` works like `bindView()` of `CursorAdapter`, where the custom `Preference` is supposed to configure the `View` for the current preference value

In the case of `ColorPreference`, we use a `ColorMixer` for the `View`:

```
@Override
protected View onCreateDialogView() {
  mixer=new ColorMixer(getContext());

  return(mixer);
}
```

Then, in `onBindDialogView()`, we set the mixer's color to be `lastColor`, a private data member:

```
@Override
protected void onBindDialogView(View v) {
  super.onBindDialogView(v);

  mixer.setColor(lastColor);
}
```

We will see later in this section where `lastColor` comes from – for the moment, take it on faith that it holds the user's chosen color, or a default value.

Dealing with Preference Values

Of course, the whole point behind a `Preference` is to allow the user to set some value that the application will then use later on. Dealing with values is a bit tricky with `DialogPreference`, but not too bad.

Getting the Default Value

The preference XML format has an `android:defaultValue` attribute, which holds the default value to be used by the preference. Of course, the actual data type of the value will differ widely — an `EditTextPreference` might expect a `String`, while `ColorPreference` needs a color value.

Hence, you need to implement `onGetDefaultValue()`. This is passed a `TypedArray` — similar to how a custom `View` uses a `TypedArray` for getting at its custom attributes in an XML layout file. It is also passed an index number into the array representing `android:defaultValue`. The custom `Preference` needs to return an `Object` representing its interpretation of the default value.

In the case of `ColorPreference`, we simply get an integer out of the `TypedArray`, representing the color value, with an overall default value of `0xFFA4C639` (a.k.a., Android green):

```
  @Override
  protected Object onGetDefaultValue(TypedArray a, int index) {
    return(a.getInt(index, 0xFFA4C639));
  }
```

Setting the Initial Value

When the user clicks on the preference, the `DialogPreference` supplies the last-known preference value to its subclass, or the default value if this preference has not been set by the user to date.

The way this works is that the custom `Preference` needs to override `onSetInitialValue()`. This is passed in a boolean flag (`restoreValue`) indicating whether or not the user set the value of the preference before. It is also passed the `Object` returned by `onGetDefaultValue()`. Typically, a custom `Preference` will look at the flag and choose to either use the default value or load the already-set preference value.

To get the existing value, `Preference` defines a set of type-specific getter methods — `getPersistedInt()`, `getPersistedString()`, etc. So, `ColorPreference` uses `getPersistedInt()` to get the saved color value:

```
@Override
protected void onSetInitialValue(boolean restoreValue, Object defaultValue) {
  lastColor=(restoreValue ? getPersistedInt(lastColor) : (Integer)defaultValue);
}
```

Here, `onSetInitialValue()` stores that value in `lastColor` — which then winds up being used by `onBindDialogView()` to tell the `ColorMixer` what color to show.

Closing the Dialog

When the user closes the dialog, it is time to persist the chosen color from the `ColorMixer`. This is handled by the `onDialogClosed()` callback method on your custom `Preference`:

```
@Override
protected void onDialogClosed(boolean positiveResult) {
  super.onDialogClosed(positiveResult);

  if (positiveResult) {
    if (callChangeListener(mixer.getColor())) {
      lastColor=mixer.getColor();
      persistInt(lastColor);
    }
  }
}
```

The passed-in boolean indicates if the user accepted or dismissed the dialog, so you can elect to skip saving anything if the user dismissed the dialog. The other `DialogPreference` implementations also call `callChangeListener()`, which is somewhat ill-documented. Assuming both the flag and `callChangeListener()` are true, the `Preference` should save its value to the persistent store via `persistInt()`, `persistString()`, or kin.

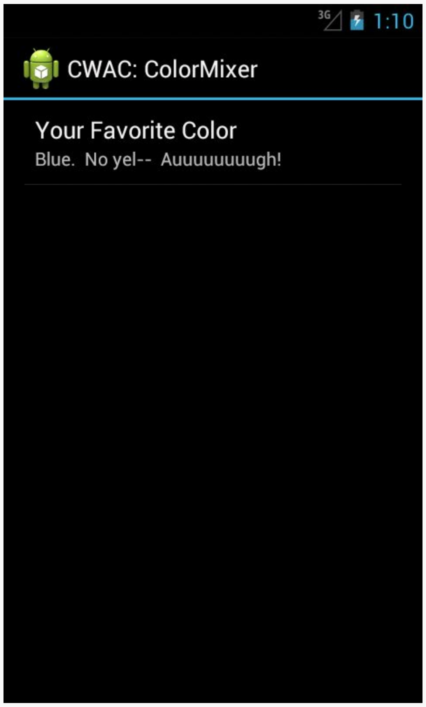
Using the Preference

Given all of that, using the custom `Preference` class in an application is almost anti-climactic. You simply add it to your preference XML, with a fully-qualified class name:

```
<PreferenceScreen
  xmlns:android="http://schemas.android.com/apk/res/android">
  <com.commonsware.cwac.colormixer.ColorPreference
    android:key="favoriteColor"
    android:defaultValue="0xFFA4C639"
    android:title="Your Favorite Color"
    android:summary="Blue.  No yel--  Auuuuuuuugh!" />
</PreferenceScreen>
```

At this point, it behaves no differently than does any other `Preference` type. Since `ColorPreference` stores the value as an integer, your code would use `getInt()` on the `SharedPreferences` to retrieve the value when needed.

The user sees an ordinary preference entry in the `PreferenceActivity`:



Your Favorite Color
Blue. No yel-- Auuuuuuuugh!

Figure 568: A PreferenceActivity, showing the ColorPreference

When tapped, it brings up the mixer:

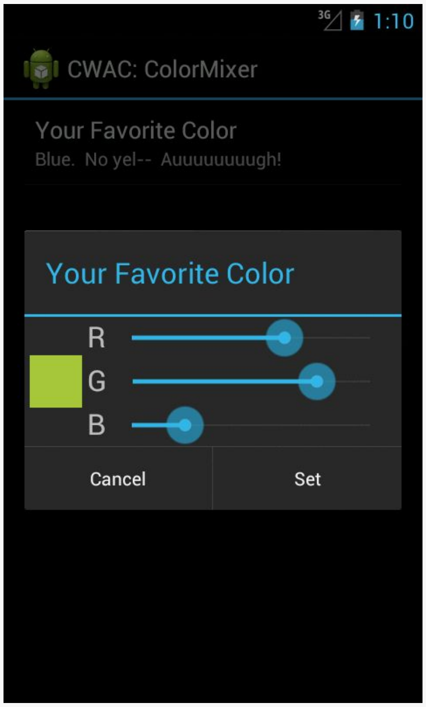


Figure 569: The ColorMixer in a custom DialogPreference

Choosing a color and clicking “Set” persists the color value as a preference.

Progress Indicators

Sometimes, we make the user wait. And wait. And wait some more.

Often, in these cases, it is useful to let the user know that something they requested is something that we are diligently working on. To do this, we can use some form of progress indicator. We saw basic use of a `ProgressBar` in the tutorials earlier in this book — now is the time to take a much closer look at `ProgressBar` and other means of displaying progress.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapters on dialogs, custom drawables, and animators is also a good idea.

Progress Bars

The classic way to tell the user that we are doing something for them is to use a `ProgressBar` widget, much as we briefly displayed one in the EmPubLite sample app in the tutorials.

However, a `ProgressBar` is much more than a simple spinning image. We can use it to display either indeterminate progress ("we will be done… sometime") or specific progress ("we are 34% complete"). We can use it either as a circle or as a classic horizontal bar, the latter typically used for specific progress. And, for specific progress, we can actually show two tiers of progress, known as "primary" and "secondary" (e.g., primary for the progress in copying a directory's worth of files, secondary for the progress on a specific file).

In this section, we will take a look at these different ways of using `ProgressBar`.

Circular vs. Horizontal

As the name suggests, a `ProgressBar` denotes progress. As the name does not suggest, a `ProgressBar` is not a bar, by default — it is a circle. Hence, the following element from an XML layout resource:

```
<ProgressBar
  android:id="@+id/progressCI"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:layout_gravity="center_horizontal"
  android:layout_marginBottom="20dp"
  android:layout_marginTop="20dp"/>
```

gives us:

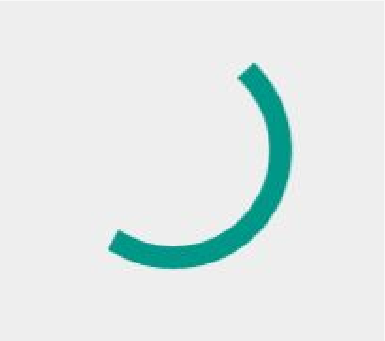

Figure 570: Android 5.1 ProgressBar, Default Style

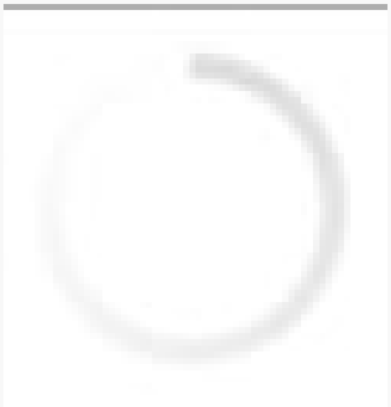

Figure 571: Android 4.0 ProgressBar, Default Style

However, referencing `style="?android:attr/progressBarStyleHorizontal"` in the element:

```
<ProgressBar
  android:id="@+id/progressHI"
  style="?android:attr/progressBarStyleHorizontal"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:layout_marginBottom="20dp"
  android:indeterminate="true"/>
```

gives us a horizontal bar:

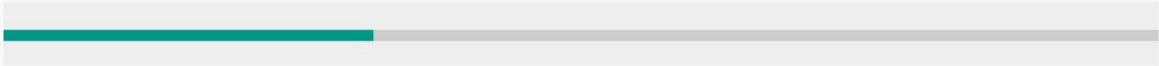

Figure 572: Android 5.1 ProgressBar, Horizontal Style

Figure 573: Android 4.0 ProgressBar, Horizontal Style

Note that the look-and-feel of these widgets have changed over the years. On Android 1.x and 2.x, they will look like this:

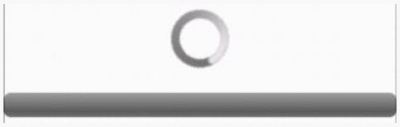

Figure 574: Android 2.3.3 ProgressBar, Both Styles

Specific vs. Indeterminate

Typically, you use the circular `ProgressBar` style for indeterminate progress, where the circle simply spins in place to let the user know that work is proceeding and the device (or activity) has not frozen. The horizontal `ProgressBar` style is used to illustrate specific amounts of progress, from 0 to a value you choose.

However, while those patterns are typical, the choice of whether to use indeterminate or some specific amount of progress is independent of the style of the widget.

The `android:indeterminate` attribute controls whether the `ProgressBar` will render an indeterminate look or a specific look. For the latter, calls to `setMax()` (or the android:max attribute) will set the upper end of the progress range (the default is 100), and setProgress() or incrementProgressBy() will set how much progress along that range is illustrated.

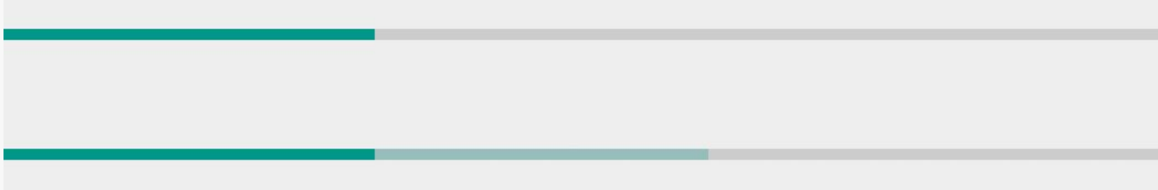

Figure 575: Android 5.1 ProgressBar, Horizontal Style, Indeterminate and Specific

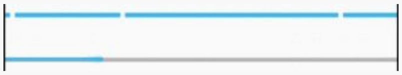

Figure 576: Android 4.0 ProgressBar, Horizontal Style, Indeterminate and Specific

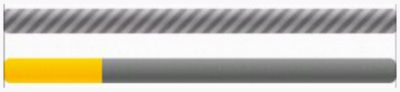

Figure 577: Android 2.3.3 ProgressBar, Horizontal Style, Indeterminate and Specific

Primary vs. Secondary

For specific progress, you actually have two independent amounts of progress. setProgress(), incrementProgressBy(), and android:progress control the primary progress, while setSecondaryProgress(), incrementSecondaryProgressBy(), and android:secondaryProgress control the secondary progress. Here, "primary progress" refers to the progress along an entire piece of work (e.g., copying a folder's worth of files), while "secondary progress" refers the progress along a discrete chunk of the overall work (e.g., copying an individual file).

A ProgressBar will render these with different colors, though primary trumps secondary, and so the secondary progress will only be visible when its value exceeds that of the primary progress:

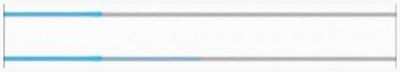

Figure 578: Android 4.0 ProgressBar, Horizontal Style, Primary-Only and Primary-Plus-Secondary

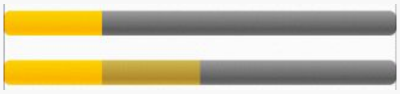

Figure 579: Android 2.3.3 ProgressBar, Horizontal Style, Primary-Only and Primary-Plus-Secondary

ProgressBar and Threads

Normally, you cannot update the UI of a widget from a background thread.

`ProgressBar` is an exception. You *can* safely call `setProgress()` and `incrementProgressBy()` from a background thread to update the primary progress, and you can safely call `setSecondaryProgress()` and `incrementSecondaryProgressBy()` from a background thread to update the secondary progress.

To see this in action, take a look at the [`Progress/BarSampler`] sample project.

This project has a single activity (`MainActivity`), whose layout (`activity_main.xml`) contains four `ProgressBar` widgets, two indeterminate and two for specific progress:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ProgressBar
    android:id="@+id/progressCI"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_horizontal"
    android:layout_marginBottom="20dp"
    android:layout_marginTop="20dp"/>

  <ProgressBar
    android:id="@+id/progressHI"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="true"/>

  <ProgressBar
    android:id="@+id/progressHS"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginBottom="20dp"
    android:indeterminate="false"
    android:max="100"/>

  <ProgressBar
    android:id="@+id/progressHS2"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:max="100"/>

</LinearLayout>
```

The activity gets access to the latter two `ProgressBar` widgets and sets up a `ScheduledThreadPoolExecutor` to get control every second in a background thread, which calls our `run()` method. The `run()` method will increment both `ProgressBar` widgets primary progress by 2 each time, and the secondary progress by 10 (dropping back to the starting point when the secondary progress reaches the maximum of 100). When the primary progress gets to 100, we cancel our scheduled work in the `ScheduledThreadPoolExecutor`:

```
package com.commonsware.android.progress;

import android.app.Activity;
import android.os.Bundle;
import android.widget.ProgressBar;
import java.util.concurrent.ScheduledThreadPoolExecutor;
import java.util.concurrent.TimeUnit;

public class MainActivity extends Activity implements Runnable {
  private static final int PERIOD_SECONDS=1;
  private ScheduledThreadPoolExecutor executor=
      new ScheduledThreadPoolExecutor(1);
  private ProgressBar primary=null;
  private ProgressBar secondary=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    primary=(ProgressBar)findViewById(R.id.progressHS);
    secondary=(ProgressBar)findViewById(R.id.progressHS2);

    executor.setExecuteExistingDelayedTasksAfterShutdownPolicy(false);
    executor.scheduleAtFixedRate(this, 0, PERIOD_SECONDS,
                                 TimeUnit.SECONDS);
  }

  @Override
  public void onDestroy() {
    executor.shutdown();

    super.onDestroy();
  }
  @Override
  public void run() {
    if (primary.getProgress() < 100) {
      primary.incrementProgressBy(2);
      secondary.incrementProgressBy(2);

      if (secondary.getSecondaryProgress() == 100) {
        secondary.setSecondaryProgress(10);
      }
      else {
        secondary.incrementSecondaryProgressBy(10);
      }
    }
    else {
      executor.remove(this);
    }
  }
}
```

The net effect is that you see the progress march across the screen, with the secondary progress going through five passes for the primary progress' single pass through the 0-100 range.

Tailoring Progress Bars

The stock ProgressBar look and feel is decent, if perhaps not spectacular. Often times, the stock look is sufficient for your needs. If you wish to have greater control over the look of your ProgressBar, the following sections will demonstrate some possibilities.

Changing the Progress Colors

The ProgressBar uses different colors for primary and secondary specific progress. By default, those colors are defined by the theme you are using, and the stock themes have firmware-defined colors (e.g., yellows for Android 1.x and 2.x, blues for Android 3.x and higher).

However, you can change the colors by using a LayerListDrawable and associating it with a ProgressBar by means of the android:progressDrawable attribute.

The ProgressBar background image needs to be a LayerListDrawable with three specific layers:

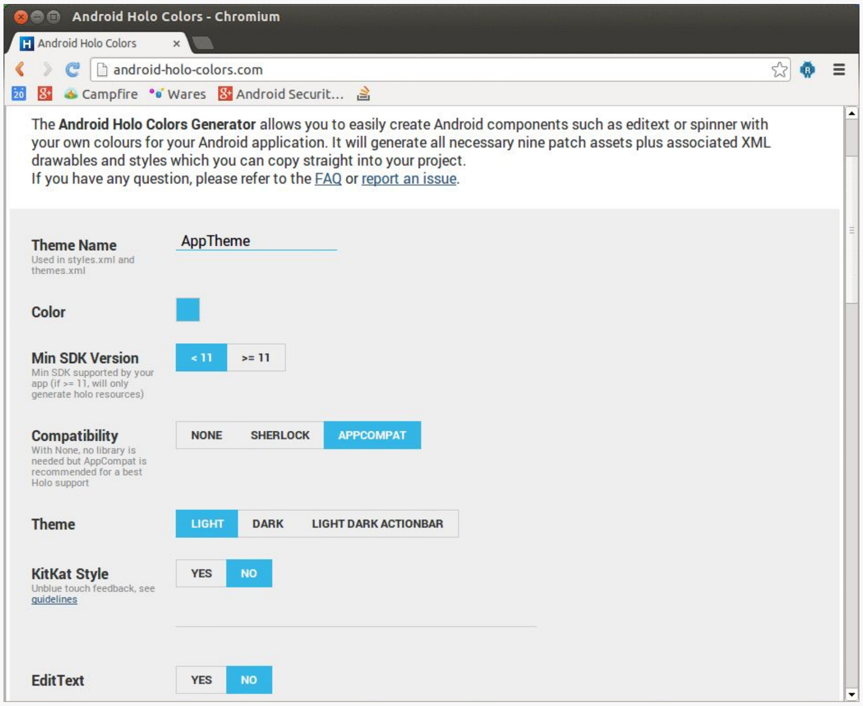
- android:id="@android:id/background" for the background color of the bar
- android:id="@android:id/progress" for the primary progress
- android:id="@android:id/secondaryProgress" for the secondary progress

Whether those layers are defined as ShapeDrawable structures, or as nine-patch PNG files is up to you, but they will need the ability to stretch to fit however big your bar winds up being.

To see what this means, let's take a look at the Progress/Styled sample project. This is a near-clone of the Progress/BarSampler project from earlier, using custom backgrounds for the bars. Here, we will look at the horizontal ProgressBar widgets — in the next section, we will look at how to change the background of a circular indefinite ProgressBar.

For the first horizontal ProgressBar (progressHS), for Android 4.x, we will use a custom style created by the Android Holo Colors Generator, a Web site set up to help us create custom versions of the holographic widget theme.

When you visit this site in Google Chrome (note: other browsers are not supported at this time), you can fill in a name for your theme (e.g., "AppTheme"), the color scheme to use for the theme, and the foundation theme to use (light or dark):



The **Android Holo Colors Generator** allows you to easily create Android components such as editext or spinner with your own colours for your Android application. It will generate all necessary nine patch assets plus associated XML drawables and styles which you can copy straight into your project.
If you have any question, please refer to the FAQ or report an issue.

Theme Name: AppTheme
Used in styles.xml and themes.xml

Color: 🟦

Min SDK Version: [✓ < 11] >= 11
Min SDK supported by your app (if >= 11, will only generate holo resources)

Compatibility: NONE SHERLOCK [✓ APPCOMPAT]
With None, no library is needed but AppCompat is recommended for a best Holo support

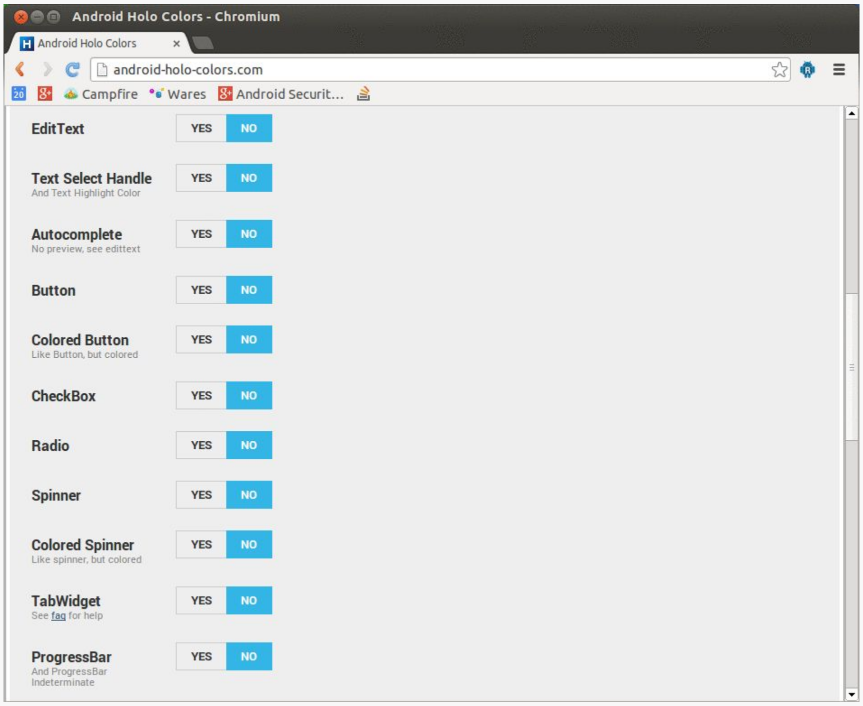
Theme: [✓ LIGHT] DARK LIGHT DARK ACTIONBAR

KitKat Style: YES [✓ NO]
Unblue touch feedback, see guidelines

EditText: YES [✓ NO]

Figure 580: Android Holo Colors Generator, Basic Info

You can then toggle on and off which widgets you intend to use, so the generator will create custom styles for them:



EditText YES [✓ NO]

Text Select Handle
And Text Highlight Color
YES [✓ NO]

Autocomplete
No preview, see edittext
YES [✓ NO]

Button YES [✓ NO]

Colored Button
Like Button, but colored
YES [✓ NO]

CheckBox YES [✓ NO]

Radio YES [✓ NO]

Spinner YES [✓ NO]

Colored Spinner
Like spinner, but colored
YES [✓ NO]

TabWidget
See faq for help
YES [✓ NO]

ProgressBar
And ProgressBar Indeterminate
YES [✓ NO]

Figure 581: Android Holo Colors Generator, Widget Selection

Then, the generator will create a ZIP file that you can download that contains the generated resources for your custom styles.

The `Progress/Styled` project contains the files generated by the generator, replacing the original style resources. Note that the generator does not create a `.DarkActionBar` version of the style resource, so the `values-v14` resource directory in the project has one hand-crafted based upon a regular generated style resource.

On Android 5.0+, we will use a theme with the same name, but where we are using tints in the theme to affect the colors of the progress indicators.

Our manifest points to our `AppTheme` as being how we wish to style widgets in this application:

```xml
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.progress"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="8"
    android:targetSdkVersion="15"/>
  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".MainActivity"
      android:label="@string/title_activity_main">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

That theme, defined in `apptheme_themes.xml`, points to style resources for horizontal `ProgressBar` widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated (in part) with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

  <style name="AppTheme" parent="android:Theme.Holo.Light.DarkActionBar">

    <item name="android:progressBarStyleHorizontal">@style/ProgressBarAppTheme</item>

  </style>

</resources>
```

The `ProgressBarAppTheme` style resource is defined in a separate `apptheme_styles.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>

<!-- Generated with http://android-holo-colors.com -->
<resources xmlns:android="http://schemas.android.com/apk/res/android">

  <style name="ProgressBarAppTheme"
parent="android:Widget.Holo.Light.ProgressBar.Horizontal">
      <item name="android:progressDrawable">@drawable/
progress_horizontal_holo_light</item>
      <item name="android:indeterminateDrawable">@drawable/
progress_indeterminate_horizontal_holo_light</item>
  </style>

</resources>
```

Here, we say that we want the `android:progressDrawable` property to be a `progress_horizontal_holo_light` drawable resource. We also set the android:indeterminateDrawable property — used for indeterminate bars — to a progress_indeterminate_horizontal_holo_light drawable resource.

Those are defined as XML-based drawables, in the res/drawable/ directory in the project. The progress_horizontal_holo_light resource is defined as:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2010 The Android Open Source Project

     limitations under the License.
-->

<layer-list xmlns:android="http://schemas.android.com/apk/res/android">

    <item android:id="@android:id/background"
          android:drawable="@drawable/progress_bg_holo_light" />

    <item android:id="@android:id/secondaryProgress">
        <scale android:scaleWidth="100%"
               android:drawable="@drawable/progress_secondary_holo" />
    </item>

    <item android:id="@android:id/progress">
        <scale android:scaleWidth="100%"
               android:drawable="@drawable/progress_primary_holo" />
    </item>

</layer-list>
```

The generator creates our LayerListDrawable resource with our three layers, each pointing to a nine-patch PNG file (with different versions for different densities) that contains our desired custom color. The progress and secondaryProgress layers use ScaleDrawable definitions to ensure that the images are measured against the complete width of the background layer, which in turn will be sized according to the size of the ProgressBar itself.

We will take a look at the progress_indeterminate_horizontal_holo_light drawable resource in the next section.

Note that you could skip the custom theme and style if you wished, and simply add the `android:progressDrawable` attribute to the `ProgressBar` widget definition in its layout XML resource.

Regardless, the result is that our progress bars have the desired purple color scheme:

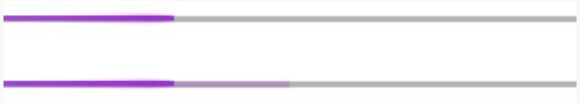

Figure 582: Custom ProgressBar Style, Primary and Secondary

Also, you can have your `LayerListDrawable` use `ShapeDrawable` layers, to avoid creating nine-patch PNG files, if you prefer, using a resource like this:

```
<?xml version="1.0" encoding="utf-8"?>
<layer-list xmlns:android="http://schemas.android.com/apk/res/android">
    <item android:id="@android:id/background">
        <shape>
            <stroke android:width="1dip" android:color="#FF333333" />
            <gradient
                    android:startColor="#FF9C9E9C"
                    android:centerColor="#FF5A5D5A"
                    android:centerY="0.71"
                    android:endColor="#FF6B716B"
                    android:angle="270"
            />
        </shape>
    </item>
    <item android:id="@android:id/secondaryProgress">
        <clip>
            <shape>
            <stroke android:width="1dip" android:color="#FF333333" />
                <gradient
                        android:startColor="#4cffffff"
                        android:centerColor="#4cE7E7E7"
                        android:centerY="0.71"
                        android:endColor="#4cFFFBFF"
                        android:angle="270"
                />
            </shape>
        </clip>
    </item>
    <item android:id="@android:id/progress">
        <clip>
            <shape>
                <stroke android:width="1dip" android:color="#FF333333" />
                <gradient
                        android:startColor="#FFFFFFFF"
                        android:centerColor="#FFE7E7E7"
                        android:centerY="0.71"
                        android:endColor="#FFFFFBFF"
                        android:angle="270"
                />
            </shape>
        </clip>
    </item>
</layer-list>
```

On Android 5.0+, we have it much easier, as `ProgressBar` automatically adopts the accent tint. So we go with a much simpler theme definition:

```
<resources>

  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>

</resources>
```

This references colors from a separate `colors.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="primary">#3f51b5</color>
  <color name="primary_dark">#1a237e</color>
  <color name="accent">#ffee58</color>
</resources>
```

The result are yellow-tinted progress bars:

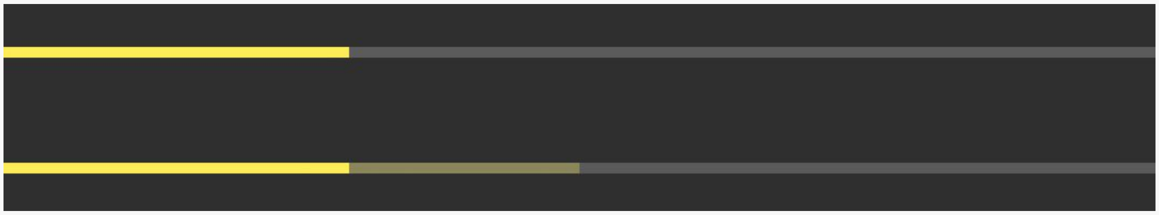

Figure 583: Material ProgressBar Style, Primary and Secondary

Changing the Indeterminate Animation

Similarly, for indefinite progress “bars”, changing the progress drawable will let you change the way they look. However, in this case, the drawable also needs to implement the animation itself. You can accomplish this either by using an [`AnimationDrawable`]() or by using some other type of drawable wrapped in an animation, such as [a `ShapeDrawable` wrapped in a `<rotate>` animation]().

For example, the Android 4.x custom theme created by the Android Holo Colors Generator assigns the following drawable resource to `android:indeterminateDrawable` in the theme:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
/*
** Copyright 2011, The Android Open Source Project
**
** Licensed under the Apache License, Version 2.0 (the "License");
** you may not use this file except in compliance with the License.
** You may obtain a copy of the License at
**
**     http://www.apache.org/licenses/LICENSE-2.0
**
** Unless required by applicable law or agreed to in writing, software
** distributed under the License is distributed on an "AS IS" BASIS,
** WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
** See the License for the specific language governing permissions and
** limitations under the License.
*/
-->
<animation-list
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:oneshot="false">
    <item android:drawable="@drawable/progressbar_indeterminate_holo1"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo2"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo3"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo4"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo5"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo6"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo7"
android:duration="50" />
    <item android:drawable="@drawable/progressbar_indeterminate_holo8"
android:duration="50" />
</animation-list>
```

Hence, every horizontal indeterminate `ProgressBar` will use that `AnimationDrawable`. The individual images in the animation are PNG files, with different versions for different densities.

Circular `ProgressBar` widgets also need a custom progress drawable, though obviously the image will need to be circular, not a bar. You can certainly use an `AnimationDrawable` for this, or you can use a `ShapeDrawable`, such as the `res/drawable/progress_circular.xml` resource shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rotate xmlns:android="http://schemas.android.com/apk/res/android"
  android:fromDegrees="0"
  android:pivotX="50%"
  android:pivotY="50%"
  android:toDegrees="360">

  <shape
    android:innerRadiusRatio="3"
    android:shape="ring"
    android:thicknessRatio="8"
    android:useLevel="false">
    <gradient
      android:centerColor="#4c737373"
      android:centerY="0.50"
      android:endColor="#ff9933CC"
      android:startColor="#4c737373"
      android:type="sweep"
      android:useLevel="false"/>
  </shape>

</rotate>
```

Here, we have a ring ShapeDrawable, with a certain thickness and radius, filled with a gradient. Half of the fill is actually a solid color (#4c737373), as the start and center colors are the same. The other half is a sweep gradient from the starting color to the same purple shade that is used by the other bar styles. This ring is then wrapped in a rotate animation. This yields a simple gradient-filled ring, that rotates smoothly to indicate progress:

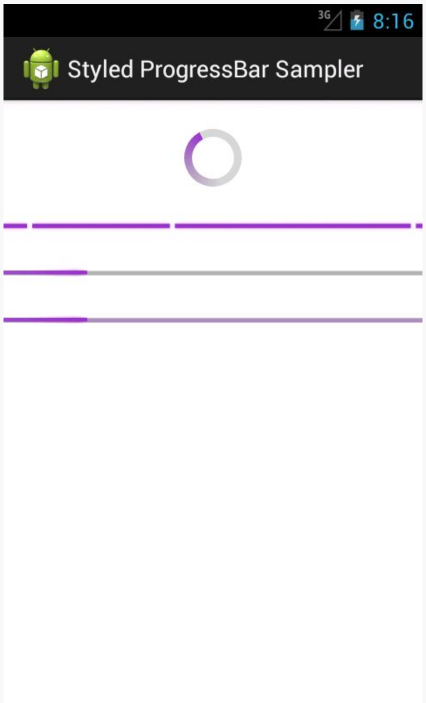

Figure 584: Custom ProgressBar Styles, Including Circular Indefinite

Note that the Android Holo Colors Generator does not generate circular indefinite `ProgressBar` resources as of the time of this writing.

Once again, Android 5.0+ can leverage `Theme.Material` and get rid of all the extra clutter. Just having an accent color defined will have your indefinite progress bars adopt that same color:

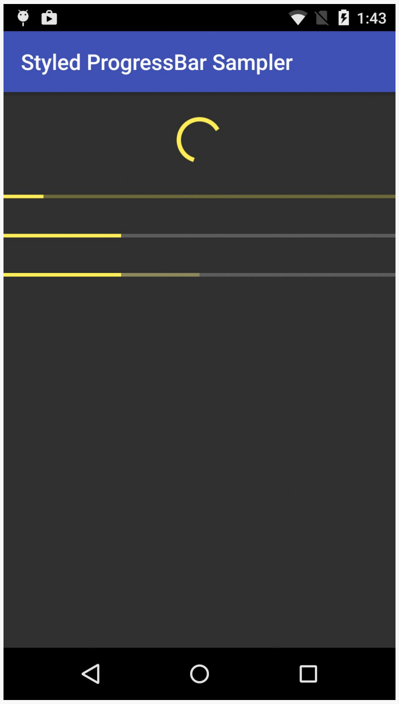

Figure 585: Material ProgressBar Styles, Including Circular Indefinite

Progress Dialogs

One use of a `ProgressBar` is to have it wrapped in a `ProgressDialog`. Like all dialogs, `ProgressDialog` is modal, preventing the user from interacting with an underlying activity while the dialog is displayed. From a UI design standpoint, a `ProgressDialog` is an easy way to temporarily show progress without having to find a spot for a `ProgressBar` widget somewhere in the UI. Also, since usually there are things in the activity that are dependent upon the work being done in the background, having the dialog in place prevents anyone from trying to use things that are not yet ready.

However, modal dialogs are not a great design approach, as they aggressively limit the user's options. `ProgressDialog` is perhaps the worst in this regard, as the user can do nothing except wait. While *part* of your app may not yet be ready, other parts surely are, such as reading the documentation, or adjusting settings, or clicking on your ad banners. Hence, using *anything* else other than `ProgressDialog`, while perhaps a bit more work, will be an improvement in the usability of your app.

That being said, let us see how to set up a ProgressDialog. The [Progress/Dialog] sample project is a near-clone of the [Dialogs/DialogFragment] sample project from [the chapter on dialogs]. The only difference is the onCreateDialog() method of our DialogFragment, where we directly create a ProgressDialog instead of using an AlertDialog.Builder to create an AlertDialog as before:

```
@Override
public Dialog onCreateDialog(Bundle savedInstanceState) {
  ProgressDialog dlg=new ProgressDialog(getActivity());

  dlg.setMessage(getActivity().getString(R.string.dlg_title));
  dlg.setIndeterminate(true);
  dlg.setProgressStyle(ProgressDialog.STYLE_SPINNER);

  return(dlg);
}
```

We create the ProgressDialog via its constructor, set the message explaining what we are waiting for via setMessage(), indicate that the ProgressBar should be an indeterminate one via setIndeterminate(), and indicate that we want a circular "spinner" ProgressBar rather than a horizontal one by calling setProgressStyle(ProgressDialog.STYLE_SPINNER). There are a variety of other things you could configure on the ProgressDialog if desired, and ProgressDialog inherits from AlertDialog, so some things you could configure on an AlertDialog will also be available on the ProgressDialog.

The result is a dialog that you may have seen from other apps in Android:

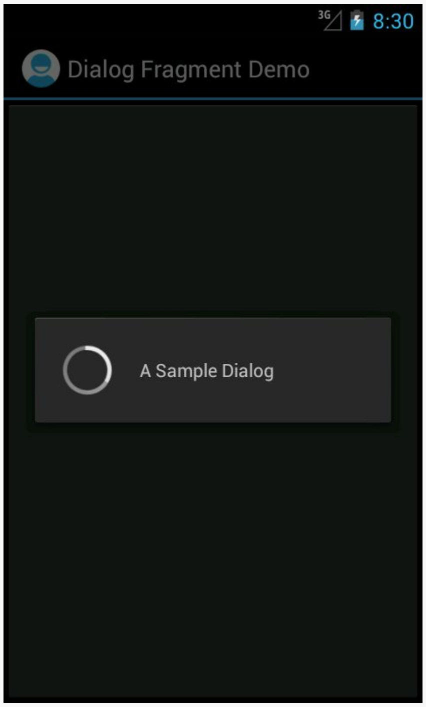

Figure 586: ProgressDialog

Title Bar and Action Bar Progress Indicators

Another place to let users know that you are doing something on their behalf is to put a progress indicator in the title bar or action bar of your activity. This avoids your having to put an indeterminate `ProgressBar` somewhere in your activity's UI. It is also very simple to set up, as we can see in the Progress/TitleBar sample project.

```java
package com.commonsware.android.titleprog;

import android.app.Activity;
import android.os.Bundle;
import android.view.Window;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);
    setProgressBarIndeterminateVisibility(true);
  }
}
```

Up front, as the first thing that you do in your `onCreate()` call, you need to call:

```
getWindow().requestFeature(Window.FEATURE_INDETERMINATE_PROGRESS);
```

This tells Android to reserve space in your title bar or action bar for an indeterminate progress indicator, though the indicator does not appear at this point.

Later on, when you want the indicator to actually appear, call `setProgressBarIndeterminateVisibility(true)` on your activity, and later call `setProgressBarIndeterminateVisibility(false)` to make the indicator go away.

This particular application has `android:targetSdkVersion` set to `11` or higher, but it is not using an action bar backport like ActionBarSherlock. Hence, when you run it on an older Android environment, you get a classic title bar with the progress indicator on the right:

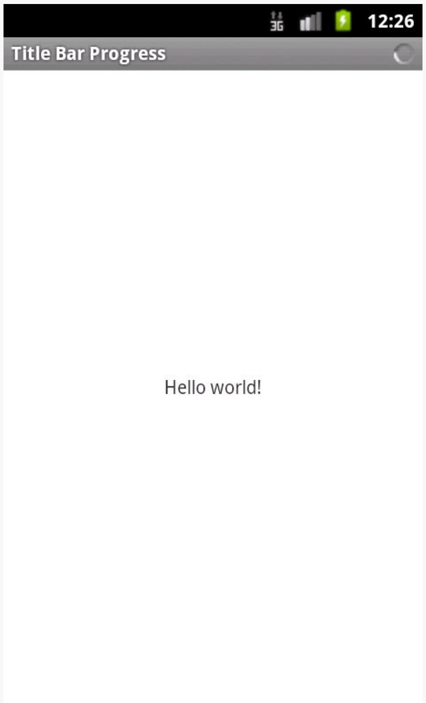

Figure 587: Progress Indicator in Title Bar

When you have an action bar, you get the same basic effect, albeit with a larger indicator to match the larger bar:

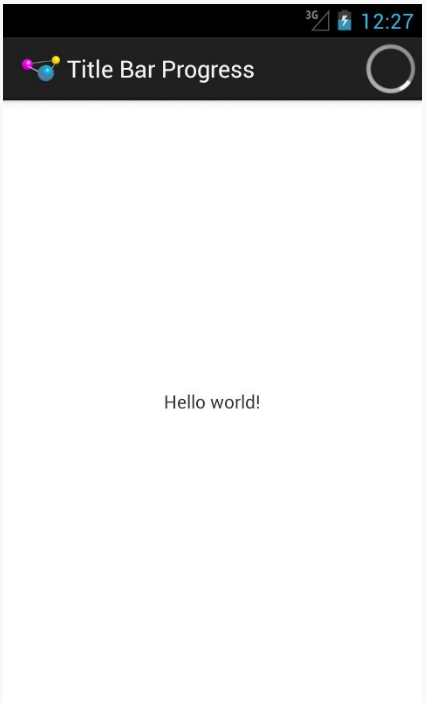

Figure 588: Progress Indicator in Action Bar

Note that this approach is not supported by `Theme.Material` or the `appcompat-v7` action bar backport, which makes it far less commonly used today.

Direct Progress Indication

Sometimes, the best way to let the user know about updates is to simply update the data in place. Rather than have some separate indicator, let the core UI itself convey the work being done.

We saw this in the chapter on threads, where we populated a `ListView` in "real time" as we loaded in data into its adapter. Other variations on this theme include:

- Updating a page count `TextView` to show the number of downloaded pages, while the user is reading earlier pages, perhaps with some sort of style (e.g., italics) or color coding (e.g., red) to indicate data that is being loaded.
- Simply disabling the buttons, action bar items, and other ways that the user could navigate to a point in your app where you need the data that is being loaded in the background. The key here is to make sure that users understand *why* those items are disabled, and sometimes that is not obvious.

Hence, while this step may be necessary, it is often tied in with progress indicators in the title bar or action bar or other means of indicating to the user the *reason* they cannot perform certain operations.

More Fun with Pagers

In earlier chapters, we saw basic uses of `ViewPager`, along with ways to show multiple pages at a time on larger screens. However, there are other ways to apply `ViewPager` and integrate it into the rest of your application, some of which we will examine in this chapter.

Prerequisites

This chapter assumes that you have read the core chapters, particularly the one showing how to use `ViewPager`.

Hosting ViewPager in a Fragment

Classically, the primary restriction on `ViewPager` was that you could not both have `ViewPager` be in a fragment *and* have `ViewPager` host fragments as its pages. You could do one or the other, but not both simultaneously.

As noted in a previous chapter, Android 4.2 supports nested fragments natively, and the latest Android Support package backport also supports nested fragments. With those, you can have `ViewPager` be in a fragment and host fragments as its pages. However, it requires a minor modification to the way we set up a `PagerAdapter`, as is illustrated in the `ViewPager/Nested` sample project. This is the same project as `ViewPager/Indicator`, with the twist that the pages are fragments and the `ViewPager` is inside a fragment.

Our activity now implements the standard add-the-fragment-if-it-does-not-exist pattern that we have seen previously:

```
package com.commonsware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;

public class ViewPagerIndicatorActivity extends FragmentActivity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
      getSupportFragmentManager().beginTransaction()
                                 .add(android.R.id.content,
                                      new PagerFragment()).commit();
    }
  }
}
```

This loads a PagerFragment, which contains most of the logic from our original activity:

```
package com.commonsware.android.pagernested;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PagerFragment extends Fragment {
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.pager, container, false);
    ViewPager pager=(ViewPager)result.findViewById(R.id.pager);

    pager.setAdapter(buildAdapter());

    return(result);
  }

  private PagerAdapter buildAdapter() {
    return(new SampleAdapter(getActivity(), getChildFragmentManager()));
  }
}
```

The biggest difference is that our call to the constructor of SampleAdapter no longer uses getSupportFragmentManager(). Instead, it uses getChildFragmentManager(). This allows SampleAdapter to use fragments hosted by PagerFragment, rather than ones hosted by the activity as a whole.

No other code changes are required, and from the user's standpoint, there is no visible difference.

Pages and the Action Bar

Fragments that are pages inside a ViewPager can participate in the action bar, supplying items to appear as toolbar buttons, in the overflow menu, etc. This is not significantly different than how any fragment participates in the action bar:

- Call setHasOptionsMenu() early in the fragment lifecycle (e.g., onCreateView()) to state that the fragment wishes to contribute to the action bar contents
- Override onCreateOptionsMenu() and onOptionsItemSelected(), much as you would with an activity

ViewPager and FragmentManager will manage the contents of the action bar, based upon the currently-visible page. That page's contributions will appear in the action bar, then will be removed when the user switches to some other page.

To see this in action, take a look at the ViewPager/ActionBar sample project. This is the same as the ViewPager/Indicator project from before, except:

- In onCreateView(), for even-numbered page positions (0, 2, etc.), we call setHasOptionsMenu(true):

```
@Override
public View onCreateView(LayoutInflater inflater,
                         ViewGroup container,
                         Bundle savedInstanceState) {
  View result=inflater.inflate(R.layout.editor, container, false);
  EditText editor=(EditText)result.findViewById(R.id.editor);

  position=getArguments().getInt(KEY_POSITION, -1);
  editor.setHint(getTitle(getActivity(), position));

  if ((position % 2)==0) {
    setHasOptionsMenu(true);
  }

  return(result);
}
```

- In onCreateOptionsMenu(), we inflate a res/menu/actions.xml menu resource:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
  inflater.inflate(R.menu.actions, menu);

  super.onCreateOptionsMenu(menu, inflater);
}
```

Normally, we would also implement `onOptionsItemSelected()`, to find out when the action bar item was tapped, though this is skipped in this sample.

The result is that when we have an even-numbered page position — equating to an odd-numbered title and hint — we have items in the action bar:

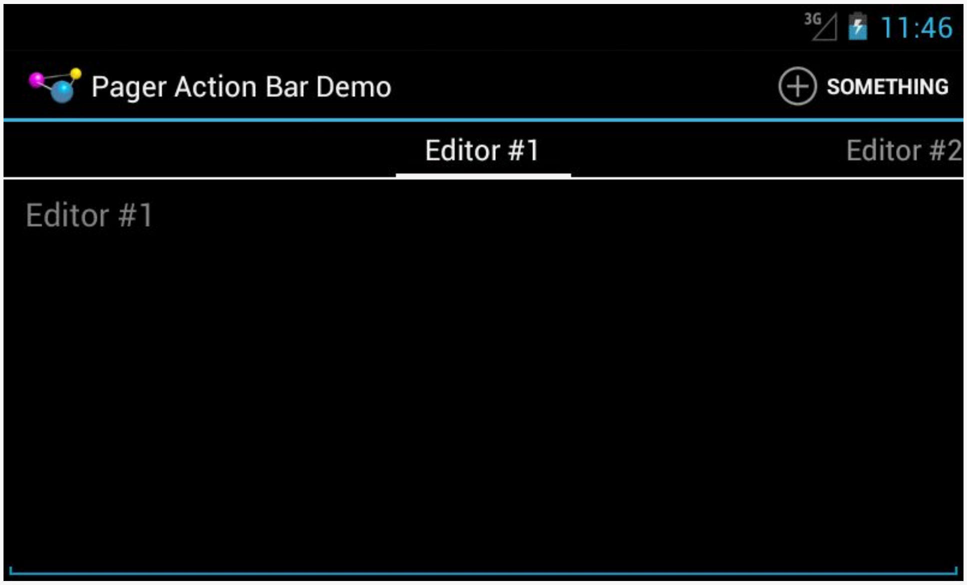

Figure 589: A ViewPager, PagerTabStrip, and Action Bar Item on Android 4.1

…but as soon as we swipe to an odd-numbered page position — equating to an even-numbered title and hint — our action bar item is removed, as that fragment did not call `setHasOptionsMenu(true)`:

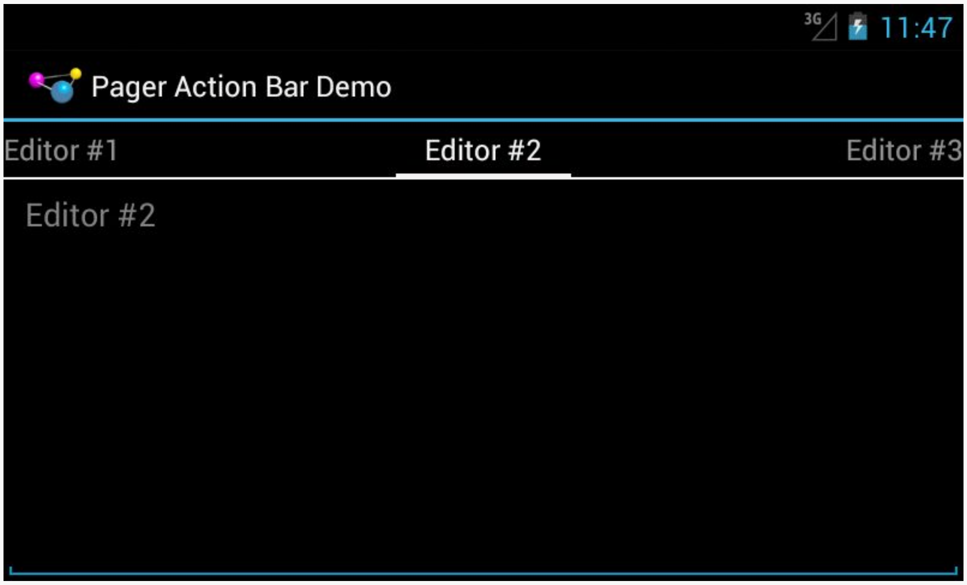

Figure 590: A ViewPager and PagerTabStrip, Sans Action Bar Item on Android 4.1

ViewPagers and Scrollable Contents

There are other things in Android that can be scrolled horizontally, besides a `ViewPager`:

- `HorizontalScrollView`
- `WebView`, for content that is wider than the width of the screen
- the deprecated `Gallery` widget
- maps from many mapping engines, such as Google Maps
- various third-party widgets

The challenge then comes in terms of dealing with horizontal swipe events. The ideal situation is for you to be able to swipe horizontally on the material inside the page, until you hit some edge (e.g., end of the `HorizontalScrollView`), then have swipe events move you to the adjacent page.

You can assist `ViewPager` in handling this scenario by subclassing it and overriding the `canScroll()` method. This will be called on a horizontal swipe, and it is up to you to indicate if the contents can be scrolled (returning `true`) or not (returning `false`). If the built-in logic is insufficient, tailoring `canScroll()` to your particular needs can help.

We will see an example of this later in the book, when we put some maps into a `ViewPager`.

Using ViewPagerIndicator

In addition to using `PagerTitleStrip` or `PagerTabStrip` to indicate context for the user, there are a plethora of other UI alternatives. Embodiments of many such patterns can be found in the ViewPagerIndicator library (VPI).

ViewPagerIndicator offers a variety of different indicator styles:

- A set of circles, colored lines, or your own icons to indicate different pages
- Another approach for implementing tabs, more readily customized for your needs (e.g., replacing the bar indicating the selected tab with an arrowhead)

ViewPagerIndicator is open source, released under the Apache Software License 2.0.

Downloading VPI

ViewPagerIndicator is distributed as an Android library project. On the ViewPagerIndicator home page you will find buttons to download a ZIP or a TGZ containing the library and sample code.

Android Studio users are a bit out of luck, in that there is no official AAR for this library. An unofficial AAR is available that you can use if you wish, using the following configuration of your top-level `repositories` and `dependencies` closures:

```
repositories {
    maven {
            url "http://dl.bintray.com/populov/maven"
    }
}

dependencies {
    compile 'com.viewpagerindicator:library:2.4.1@aar'
    compile 'com.android.support:support-v13:19.1.0'
}
```

The above example also shows loading in `support-v13`, as that (or `support-v4`) is needed for `ViewPager` itself.

If you are using Eclipse, you will need to import the project into your workspace, via File > Import, then choosing Android > Existing Android Code Into Workspace from the import wizard. Then you will need to attach the library to your main project, via Project > Properties > Android. This process is covered in greater detail in the chapter on library projects.

Replacing PagerTabStrip with TabPageIndicator

Earlier in the book, we looked at PagerTabStrip. The differences between using PagerTabStrip and one of the ViewPagerIndicator (VPI) classes, like TabPageIndicator, are fairly minor. The ViewPager/VPI sample project is a straight conversion of the PagerTabStrip sample to use TabPageIndicator.

First, your layout file will need to reference the VPI class instead of PagerTabStrip. The VPI indicators do not go as children of ViewPager; instead, you position them wherever makes sense using ordinary containers and layout rules. So, for example, you could have a classic vertical LinearLayout for stacking a TabPageIndicator atop the ViewPager:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <com.viewpagerindicator.TabPageIndicator
    android:id="@+id/titles"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>

</LinearLayout>
```

You also have to wire the indicator to the ViewPager, something that happens for you automatically when you use PagerTabStrip. This simply involves passing the ViewPager to the indicator via a setViewPager() method:

```
package com.commonsware.android.pager3;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
import com.viewpagerindicator.TabPageIndicator;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);
    TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

    pager.setAdapter(buildAdapter());
    tabs.setViewPager(pager);
  }

  private PagerAdapter buildAdapter() {
    return(new SampleAdapter(this, getFragmentManager()));
  }
}
```

For this sample, those are the only two required changes. However, if you were using an `OnPageChangeListener` with your `ViewPager`, you now need to attach it to the *indicator*, rather than the pager, so you find out about page changes triggered by the indicator. This is accomplished by calling `setOnPageChangeListener()` on your indicator object.

Styling the Indicator

It is also reasonably likely that you will want to style the indicator to meet your needs. In the case of the `TabPageIndicator`, you can control things like the font used for the tab title (size, color, style, etc.), the amount of padding to have to the left and right of the title to form the overall "tab", etc.

To do this, you will need to set up a custom theme for your project, if you do not already have one. That would involve creating a `style` resource, inheriting from whatever stock theme you want (e.g., `@android:style/Theme.Holo.Light.DarkActionBar`), and referencing your custom theme in your manifest:

```
  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>
```

In addition to any other theme customizations you want to make, you will need to have an `item`, named based upon the indicator class that you are using, that will point to a style resource to use for styling instances of that indicator class. In the case of `TabPageIndicator`, the name is `vpiTabPageIndicatorStyle`:

```
<style name="AppTheme" parent="@android:style/Theme.Holo.Light.DarkActionBar">
  <item name="vpiTabPageIndicatorStyle">@style/TabStyle</item>
</style>
```

Of course, you need to declare another `style` resource, using the name you supplied to the `vpiTabPageIndicatorStyle` `item`, where you tailor the look and feel of your indicator:

```
<style name="TabStyle" parent="Widget.TabPageIndicator">
  <item name="android:textColor">#FF33AA33</item>
  <item name="android:textSize">14sp</item>
  <item name="android:textStyle">italic</item>
  <item name="android:paddingLeft">16dp</item>
  <item name="android:paddingRight">16dp</item>
  <item name="android:fadingEdge">horizontal</item>
  <item name="android:fadingEdgeLength">8dp</item>
</style>
```

The easiest way to see what some of the options are is to look at the sample code for ViewPagerIndicator and the various custom styles that it defines.

With the custom style as defined above — specifying green italicized tab titles – we get tabs that look like these:

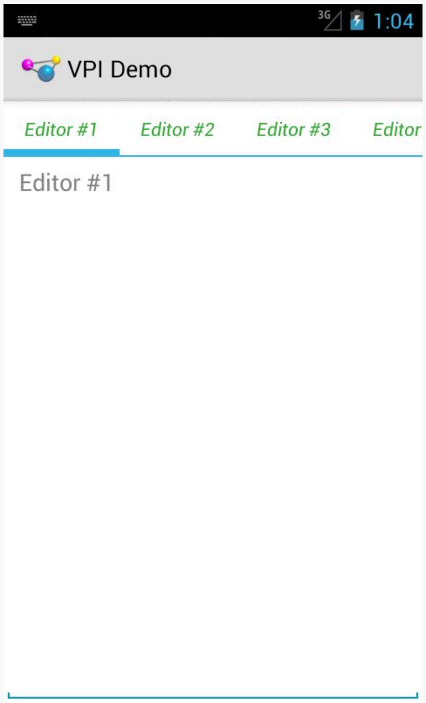

Figure 591: ViewPager with Customized TabPagerIndicator

Columns for Large, Pages for Small

In some cases, you can take better advantage of larger screens by using `ViewPager` more judiciously. In [a previous chapter](), we explored having `ViewPager` itself display more than one page at a time. A variation on that same theme is to only use a `ViewPager` on screen sizes where you lack sufficient room for everything, and to put those same pages on the screen at the same time when you have room for all of them.

For example, a Twitter client for Android could use the columns-or-pages support for displaying various streams of tweets: your timeline, your @ mentions, hashtags you follow, etc. Each stream is represented by a typical `ListView`, with one row per tweet. On a phone, since screen space is at a premium, those `ListView` widgets are set up in a `ViewPager`, with one list per page. Users can swipe between the lists, or use tabs to navigate the available lists. However, tablets offer more room, so the app could show three `ListView` widgets side-by-side in landscape mode, so you can take in three sets of content without further interaction with the screen.

The ViewPager/Columns1 sample project will demonstrate how you can accomplish the same basic approach in your own app… with some limitations. This is a clone of the ViewPagerIndicator sample from the previous section.

The Layouts

Our main activity layout — cunningly named `main` — has a `ViewPager`-based definition in `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <com.viewpagerindicator.TabPageIndicator
    android:id="@+id/titles"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>

</LinearLayout>
```

However, in `res/layout-large/`, for 5-inch devices on up, we have a horizontal `LinearLayout` with three `FrameLayout` containers, each representing an equal-sized slot for one of our “pages”:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:baselineAligned="false"
  android:orientation="horizontal">

  <FrameLayout
    android:id="@+id/editor1"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

  <FrameLayout
    android:id="@+id/editor2"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

  <FrameLayout
    android:id="@+id/editor3"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_weight="1"/>

</LinearLayout>
```

Android will automatically inflate the proper layout when we call `setContentView(R.layout.main)`.

The Activity

However, while Android handles the inflation for us, we obviously need to populate the contents a bit differently. In this sample, though, we are relying upon the fact that screen size will not change on the fly. Hence, an instance of our application will either show a `ViewPager` *or* show the horizontal `LinearLayout`, and not have to switch between those at runtime.

Our `SampleAdapter`, therefore, can remain unchanged, except for reducing the page count to 3:

```
package com.commonsware.android.pagercolumns;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
  Context ctxt=null;

  public SampleAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);
    this.ctxt=ctxt;
  }

  @Override
  public int getCount() {
    return(3);
  }

  @Override
  public Fragment getItem(int position) {
    return(EditorFragment.newInstance(position));
  }

  @Override
  public String getPageTitle(int position) {
    return(EditorFragment.getTitle(ctxt, position));
  }
}
```

Our `MainActivity` will still use the `SampleAdapter`, and if we have a `ViewPager`, it will use it the same way as before. However, if we do *not* have a `ViewPager`, we must be showing three panes of content side by side, in which case we just execute a `FragmentTransaction` to populate the three `FrameLayout` containers with the three items created by the `SampleAdapter`:

```
package com.commonsware.android.pagercolumns;

import android.app.Activity;
import android.os.Bundle;
import android.support.v13.app.FragmentPagerAdapter;
import android.support.v4.view.ViewPager;
import com.viewpagerindicator.TabPageIndicator;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    if (pager == null) {
      if (getFragmentManager().findFragmentById(R.id.editor1) == null) {
        FragmentPagerAdapter adapter=buildAdapter();

        getFragmentManager().beginTransaction()
                                 .add(R.id.editor1,
                                      adapter.getItem(0))
                                 .add(R.id.editor2,
                                      adapter.getItem(1))
                                 .add(R.id.editor3,
                                      adapter.getItem(2)).commit();
      }
    }
    else {
      TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

      pager.setAdapter(buildAdapter());
      tabs.setViewPager(pager);
    }
  }

  private FragmentPagerAdapter buildAdapter() {
    return(new SampleAdapter(this, getFragmentManager()));
  }
}
```

Of course, we skip the `FragmentTransaction` if the fragments already exist, such as due to a screen rotation configuration change.

The Results

On a phone, the `ViewPager`-based layout looks pretty much as it did before:

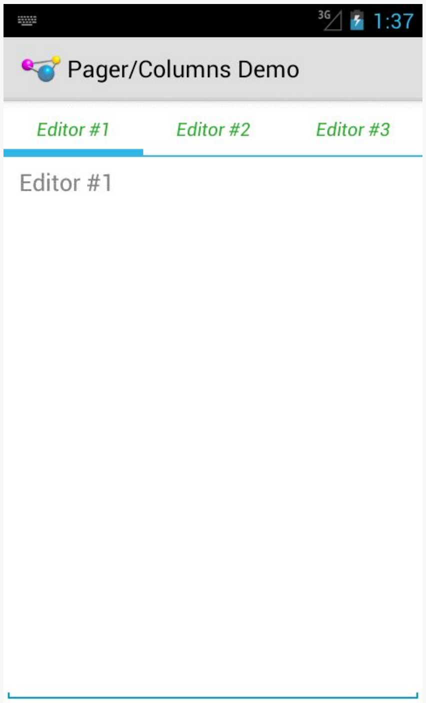

Figure 592: ViewPager with Customized TabPagerIndicator. Again.

However, on a tablet, we get our three editors side-by-side:

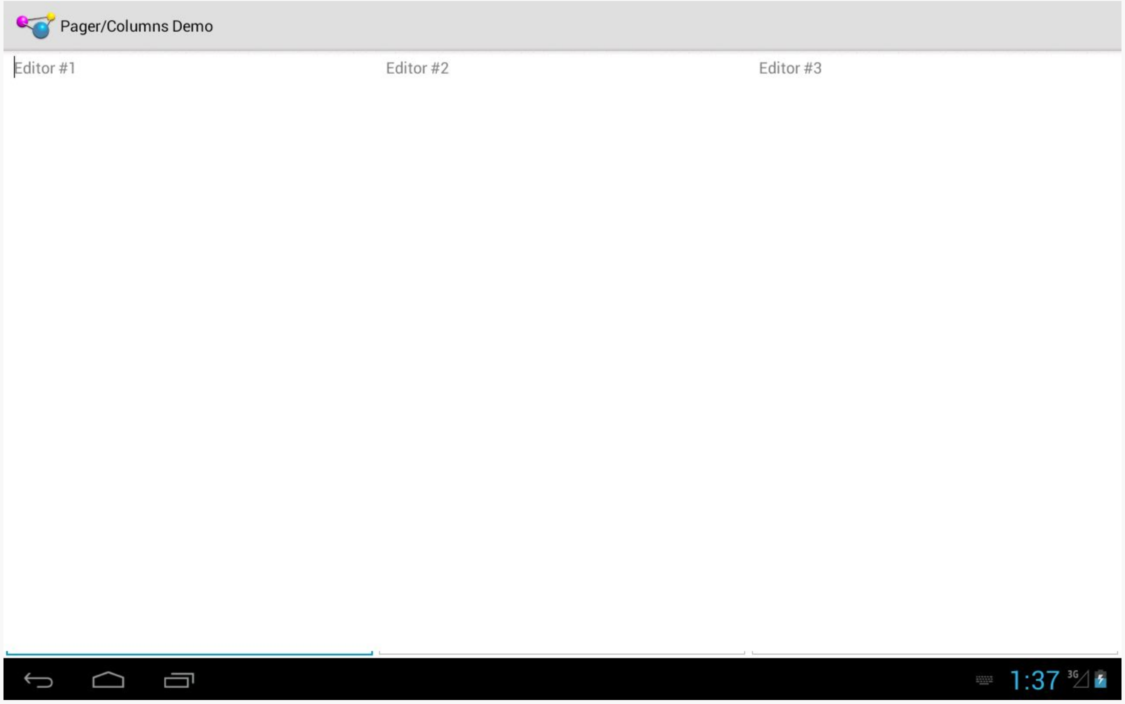

Figure 593: Same App, Large-Screen Layout with Side-By-Side Editors

The Limitations

The simplified large-screen layout does not contain any indicators above the three editors. This could be added by simple changes to the `res/layout-large/main.xml` layout resource, if desired.

The bigger limitation is that this only works if you want the same look in all configurations *except* screen size, and if the screen size never changes. However, it is eminently possible that you will want to have a different mix than that, such as using the three-column approach only on large-screen *landscape* layouts, using `ViewPager` everywhere else. In that case, our approach breaks down, as we will have different fragments inside the pager and outside the pager, meaning that we will lose our data on a configuration change. Addressing this issue is covered in the next two sections.

Introducing ArrayPagerAdapter

The flexibility of `ViewPager` is governed, to a large extent, by the implementation of its `PagerAdapter`. Inflexible `PagerAdapter` implementations lead to inflexible uses of `ViewPager`.

Notably, the two concrete `PagerAdapter` implementations shipped in the Android Support package — `FragmentPagerAdapter` and `FragmentStatePagerAdapter` — have their limitations when it comes to things like:

- Using fragments created by those adapters in other fashions, such as in the columns-or-pager scenario from the previous section
- Handling dynamically-changing contents, such as adding pages, removing pages, or reordering pages

The `ArrayPagerAdapter` is an attempt to provide a more flexible `PagerAdapter` implementation that still feels a lot like `FragmentPagerAdapter` in terms of its use of fragments. It also bears some resemblance to the `ArrayAdapter` used for `AdapterView` implementations like `ListView`, giving rise to its name.

`ArrayPagerAdapter` is part of the CWAC-Pager project and is available for use in any Android project compatible with the Apache License 2.0.

We will review the implementation of `ArrayPagerAdapter` later in this chapter. This section reviews how you can use `ArrayPagerAdapter` in your projects.

Adding the JAR

As the CWAC-Pager project does not need its own resources, it is packaged in the form of a simple JAR file.

Eclipse users can download the JAR and add to their projects by conventional means (e.g., putting it in the `libs/` directory). Android Studio users can use the `repositories` and `dependencies` closures outlined on the CWAC-Pager project home page:

```
repositories {
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}
```

```
dependencies {
    compile 'com.commonsware.cwac:pager:0.2.+'
}
```

Choosing the Package

There are two implementations of `ArrayPagerAdapter`. One, in the `com.commonsware.cwac.pager` package, is designed for use with native API Level 11 fragments. The other, in the `com.commonsware.cwac.pager.v4` package, is designed for use with the Android Support package's backport of fragments. You will need to choose the right `ArrayPagerAdapter` for the type of fragments that you are using.

However, other than choosing suitable versions of classes for `Fragment`, etc., there is no real public API difference between the two. Hence, the documentation that follows is suitable for either implementation of `ArrayPagerAdapter`, so long as you use the one that matches the source of your fragment implementation.

Note that only `ArrayPagerAdapter` lives in the `com.commonsware.cwac.pager.v4` package. The classes and interfaces that support `ArrayPagerAdapter`, like `PageDescriptor`, are implemented in `com.commonsware.cwac.pager` and used by both implementations of `ArrayPagerAdapter`.

Creating PageDescriptors

You might think that `ArrayPagerAdapter` would take an array of pages, much like `ArrayAdapter` takes an array of models.

That's not how it works.

Instead, `ArrayPagerAdapter` wants an `ArrayList` of `PageDescriptor` objects. `PageDescriptor` is an interface, requiring you to supply implementations of two methods:

- `getTitle()`, which will be the title used for this page, for things like `PagerTabStrip` and the ViewPagerIndicator family of indicators
- `getFragmentTag()`, which is a unique tag for this page's fragment

Also, `PageDescriptor` extends the `Parcelable` interface, and so any implementation of `PageDescriptor` must also implement the methods and `CREATOR` required by `Parcelable`.

You are welcome to create your own PageDescriptor if you wish. However, there is a built-in implementation, SimplePageDescriptor, which probably meets your needs. You just pass the tag and title into the SimplePageDescriptor constructor, and it handles everything else, including the Parcelable implementation.

Creating and Populating the Adapter

To work with ArrayPagerAdapter, you start by creating an ArrayList of PageDescriptor objects, one for each page that is to be in your pager.

Then, create a subclass of ArrayPagerAdapter. ArrayPagerAdapter uses Java generics, requiring you to declare the type of fragment the adapter is serving up to the ViewPager. So, for example, if you have a ViewPager that will have each page be an EditorFragment, you would declare your custom ArrayPagerAdapter to be:

```
static class SamplePagerAdapter extends ArrayPagerAdapter<EditorFragment>
```

If you will have pages come from a variety of fragments, just use the Fragment base class appropriate for your fragment source (e.g., android.app.Fragment).

Your custom ArrayPagerAdapter subclass will need to override (at minimum) one method: createFragment(). This method is responsible for instantiating fragments, as requested. You are passed the PageDescriptor for the fragment to be created — you simply create and return that fragment.

Hence, a custom ArrayPagerAdapter can be as simple as:

```
  static class SamplePagerAdapter extends
      ArrayPagerAdapter<EditorFragment> {
    public SamplePagerAdapter(FragmentManager fragmentManager,
                              ArrayList<PageDescriptor> descriptors) {
      super(fragmentManager, descriptors);
    }

    @Override
    protected EditorFragment createFragment(PageDescriptor desc) {
      return(EditorFragment.newInstance(desc.getTitle()));
    }
```

Then, you can create an instance of your custom ArrayPagerAdapter subclass as needed, supplying the constructor with a suitable FragmentManager and your ArrayList of PageDescriptor objects. Once attached to a ViewPager, ArrayPagerAdapter behaves much like a FragmentPagerAdapter by default.

There is another flavor of the ArrayPagerAdapter constructor, one that takes a RetentionStrategy as a parameter, as is described later in this chapter.

Modifying the Contents

ArrayPagerAdapter offers several methods to allow you to change the contents of the ViewPager:

- add() takes a PageDescriptor and adds a new page at the end of the current roster of pages
- insert() takes a PageDescriptor and an insertion point and inserts a new page before the current page at that insertion point
- remove() takes a position and removes the page at that position
- move() takes an old and new position and moves the page from the old position to the new position (effectively combining a remove() from the old position and an insert() of the same page into the new position

Other Useful Methods

getExistingFragment(), given a position, returns the existing fragment for that position in the ViewPager, if that fragment exists. Otherwise, it returns null.

getCurrentFragment() is like getExistingFragment(), but returns the fragment for the currently-viewed page in the ViewPager.

Columns for Large *Landscape*, Pages for the Rest

Earlier in this chapter, we saw how you could conditionally use a ViewPager in some circumstances, but not others, such as using a ViewPager on smaller screens and a set of columns for the "pages" on larger screens. The limitation noted at that time was that you were stuck with one pattern for the lifetime of the activity, meaning that in any configuration change, you had to stick with the ViewPager or the columns that you started with.

However, while the columnar approach for larger screens works well in landscape, you may find the columns to be too tall and too skinny in portrait. Hence, a better solution would be to use columns only on larger screens in landscape, and to use the ViewPager everywhere else.

This is annoyingly tricky to do, assuming that you want to use the same fragments in each case, so you can arrange to hold onto the contents of their widgets.

Jake Wharton — author of ViewPagerIndicator and a seemingly infinite number of other Android open source libraries — raised this issue in a Google+ post. He also posted a sample solution, but one that was limited to only two fragments. Quoting Mr. Wharton:

> Due the shenanigans performed by FragmentPagerAdapter we're forced to write a custom PagerAdapter which handles the instances our selves.

However, while two pages is reasonable, having some flexibility for a few more pages would be useful. So, let's see how we can accomplish the same aims, using `ArrayPagerAdapter`, in the `ViewPager/FlexColumns` sample project.

Fragments Inside and Outside the ViewPager

A fragment cannot be in two containers at once. The `ViewPager`, where we have one, is a different container than one of our columns, when we have one.

Hence, if the container is not changing during the operation of our activity — such as using a `ViewPager` in both portrait and landscape on smaller screens — we have no problem. But, if the container *is* changing — such as switching between columns and a `ViewPager` on larger screens — we need to take steps.

One option for those "steps", of course, is to simply run a separate set of fragments. One set serves as pages of the `ViewPager`; the other serves as the columns. However, then we have to do work to synchronize those on configuration changes, as from the *user's* perspective, the fact that we happen to render things in pages or columns should not cause the user to lose data they entered in one form when switching to the other.

If we want to use the same fragment instances, then we can use normal configuration-change logic, like `onSaveInstanceState()`, to ensure that we hold onto user-entered data during the change. However, we have to arrange to move the fragment from one container to another. This will involve running a `FragmentTransaction` to `remove()` the fragment from the old container and `add()` it to its new container.

Making this more complicated is that the PagerAdapter should be handling the add() part, when the fragment is being put into a page, as that is how fragment-based PagerAdapter implementations like FragmentPagerAdapter work.

Adding to the fun is a matter of timing. By default, a FragmentTransaction is committed asynchronously. Attempting to remove() a fragment and add() the same fragment in the same transaction will fail, because the add() will complain that the fragment is already in another container, because the remove() will not have happened. Even doing the remove() and add() in separate normal transactions will not help. Instead, we need to ensure that the remove() has completed processing first, before we try to add(). To help with this, FragmentManager has a executePendingTransactions() method we can call, to have it complete its own processing on committed FragmentTransactions synchronously. Committing the remove() transaction and calling executePendingTransactions() before committing the add() transaction works.

The Revised PagerAdapter

With all that in mind, let's look at how this revised sample behaves. The core functionality is the same as with the earlier pager-or-columns sample, but now we will only use the columns on -large screen devices in -land orientation, by simply renaming res/layout-large/ to res/layout-large-land/.

Our PagerAdapter is still called SamplePagerAdapter, but this time it is a ArrayPagerAdapter for our EditorFragment pages:

```
static class SamplePagerAdapter extends
    ArrayPagerAdapter<EditorFragment> {
  public SamplePagerAdapter(FragmentManager fragmentManager,
                            ArrayList<PageDescriptor> descriptors) {
    super(fragmentManager, descriptors);
  }

  @Override
  protected EditorFragment createFragment(PageDescriptor desc) {
    return(createFragment(desc.getTitle()));
  }

  EditorFragment createFragment(String title) {
    return(EditorFragment.newInstance(title));
  }
}
```

The Revised Activity

The onCreate() method of the earlier example would see if we had a ViewPager, then either populate the columns or populate the ViewPager from our PagerAdapter. The onCreate() method of the new example does the same basic thing, except that it delegates most of the work for actually filling in the columns to a private populateColumn() method:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  ViewPager pager=(ViewPager)findViewById(R.id.pager);

  if (pager == null) {
    if (getFragmentManager().findFragmentById(R.id.editor1) == null) {
      SamplePagerAdapter adapter=buildAdapter();
      FragmentTransaction ft=
          getFragmentManager().beginTransaction();

      populateColumn(getFragmentManager(), ft, adapter, 0,
                     R.id.editor1);
      populateColumn(getFragmentManager(), ft, adapter, 1,
                     R.id.editor2);
      populateColumn(getFragmentManager(), ft, adapter, 2,
                     R.id.editor3);
      ft.commit();
    }
  }
  else {
    SamplePagerAdapter adapter=buildAdapter();
    TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

    pager.setAdapter(adapter);
    tabs.setViewPager(pager);
  }
}
```

The buildAdapter() method changes a bit, to create our ArrayPagerAdapter subclass using an array of SimplePageDescriptor objects:

```
private SamplePagerAdapter buildAdapter() {
  ArrayList<PageDescriptor> pages=new ArrayList<PageDescriptor>();

  for (int i=0; i < 3; i++) {
    pages.add(new SimplePageDescriptor(buildTag(i), buildTitle(i)));
  }

  return(new SamplePagerAdapter(getFragmentManager(), pages));
}
```

buildAdapter(), in turn, uses buildTag() and buildTitle() methods to retrieve the tag and title to use given a position:

```
private String buildTag(int position) {
  return("editor" + String.valueOf(position));
}

private String buildTitle(int position) {
  return(String.format(getString(R.string.hint), position + 1));
}
```

Finally, our populateColumn() method handles the work to fill in one of our columns, if we are in column mode:

```
private void populateColumn(FragmentManager fm,
                            FragmentTransaction ft,
                            SamplePagerAdapter adapter, int position,
                            int slot) {
  EditorFragment f=adapter.getExistingFragment(position);

  if (f == null) {
    f=adapter.createFragment(buildTitle(position));
  }
  else {
    fm.beginTransaction().remove(f).commit();
    fm.executePendingTransactions();
  }

  ft.add(slot, f, buildTag(position));
}
```

First, we ask our ArrayPagerAdapter to retrieve for us the existing fragment, if any, for this given column/page, based on its position. This may return null, if this is the first time we have run our app, in which case we ask our ArrayPagerAdapter to create the fragment for us (using the same logic that it would when functioning inside of a ViewPager, via createFragment()).

Otherwise, getExistingFragment() should return an existing EditorFragment instance, one probably formerly managed by a ViewPager. So, we create, commit, and execute a FragmentTransaction to remove() this fragment from its existing container.

The net is that, in either case, we have an EditorFragment, set up for use in this column, that does not have a current container. To add it to our column, we simply call add() on the supplied FragmentTransaction, which is committed by our activity's onCreate() method. However, we use the three-parameter form of add(), which allows us not only to put the fragment into a container, but to assign it a tag as well. The tag is how ArrayPagerAdapter identifies the various fragments — by using the same tag, this fragment can be picked up by future instances of `ArrayPagerAdapter` in case of a configuration change.

You will notice that while we `remove()` the `EditorFragment` from the `ViewPager` and `add()` it to the column, we are not handling the reverse case, where we would `remove()` the fragment from the column and/or `add()` it to the `ViewPager`. That little bit of logic is supplied to us by `ArrayPagerAdapter`, as we will see when we examine the implementation of `ArrayPagerAdapter` later in this chapter.

The resulting activity works exactly the same as the previous one, except that we use the `ViewPager` in portrait mode on larger-screen devices. Rotating a large-screen device will show our fragments moving between pages and columns, with their contents (whatever you type into the `EditorFragment` instances) being maintained via the built-in `onSaveInstanceState()` support for `EditText` widgets.

Adding, Removing, and Moving Pages

`ArrayPagerAdapter` also supports modifying the roster of pages at runtime: adding, inserting, removing, and moving pages. For example, a Twitter client might:

- Allow users to add pages for new monitored hashtags or search results
- Allow users to reorder the pages, putting more frequently-used ones towards the "front", for easier access when the app starts from scratch
- Allow users to remove pages they do not use, such as ones they added earlier

To see how this works in practice, we can examine the demo project for the CWAC-Pager library. There are two versions of this demo, one for the "v4" fragments from the Android Support package, and one for native API Level 11 fragments. Here, we will take a look at the latter project.

Reviewing the Core Functionality

This project is yet another rendition of our bunch-of-`EditorFragment`-pages sample that we have been examining for various ways of using `ViewPager`. This one sets up 10 pages at the start. However, it also inflates a menu resource to add four actions to the action bar: add, split, remove, and swap:

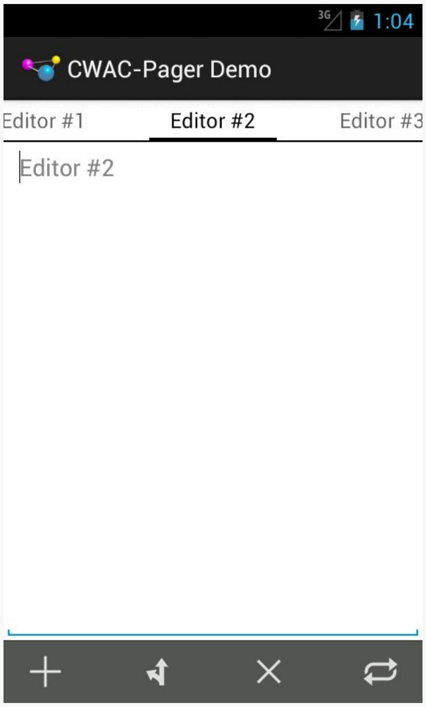

Figure 594: ArrayPagerAdapter Demo App, Showing First 3 Pages and Action Bar

`onOptionsItemSelected()` in our activity routes those four action items to three methods: `add()` (for add and split), `remove()`, and `swap()`.

Add and Split

Tapping the "add" action bar item will add a new page before the current one, with a title and hint based upon the number of existing pages (e.g., tapping "add" with 10 pages will add "Editor #11"):

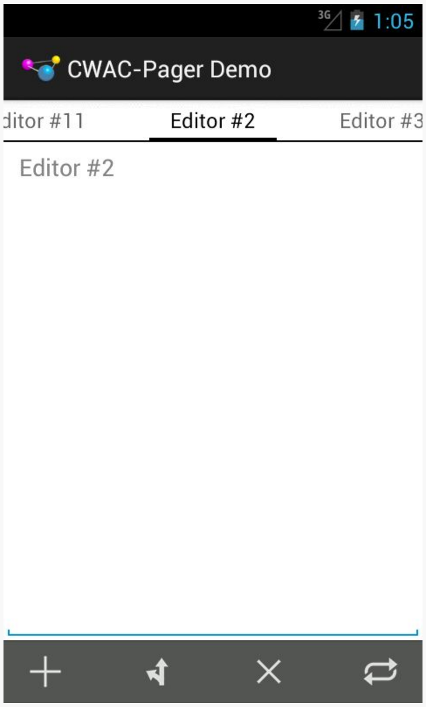

Figure 595: ArrayPagerAdapter Demo App, Showing Result of "Add" From Second Page

Tapping the "split" action bar item will add a new page after the currently-selected one.

Since both of these involve adding pages, this sample consolidates their work into a single `add()` method, taking a `boolean` parameter to indicate if we are inserting a page before the current one or after:

```
private void add(boolean before) {
  int current=pager.getCurrentItem();
  SimplePageDescriptor desc=
      new SimplePageDescriptor(buildTag(adapter.getCount()),
                               buildTitle(adapter.getCount()));

  if (before) {
    adapter.insert(desc, current);
  }
  else {
    if (current < adapter.getCount() - 1) {
      adapter.insert(desc, current + 1);
    }
    else {
      adapter.add(desc);
    }
    }
  }
```

We call getCurrentItem() on the ViewPager to determine what the position index is of the currently-selected page. From there, we set up our SimplePageDescriptor for the page that we will be adding, giving it a title based upon our hint string resource and a tag based upon the number of pages. We then call add() (if we are on the last page and the user clicked on "split") or insert() (for all other scenarios) to inject the new page. The ArrayPagerAdapter will be responsible for creating this page, just as it did for all previous pages.

Remove

Tapping "remove" will remove the currently-selected page, so long as we will still have at least one page remaining (just to keep the example simpler, so we do not have to worry about not having a "current page").

This is handled by the remove() method on our activity, which turns around and calls remove() on the ArrayPagerAdapter:

```
  private void remove() {
    if (adapter.getCount() > 1) {
      adapter.remove(pager.getCurrentItem());
    }
  }
```

Swap

Tapping "swap" will swap the positions of the current page and the one immediately after it. The exception is if you are on the last page, in which case we will swap the current page with the one immediately before it:

```
  private void swap() {
    int current=pager.getCurrentItem();

    if (current < adapter.getCount() - 1) {
      adapter.move(current, current + 1);
    }
    else {
      adapter.move(current, current - 1);
    }
  }
```

This is handled by the swap() method on our activity, which calls move() on the ArrayPagerAdapter. move() takes the position of the page to be moved and the position it should wind up in after the move, so we call move(current, current +

`1)` to swap the `current` page with the one after it or `move(current, current - 1)` to swap the `current` page with the one before it.

Inside ArrayPagerAdapter

`ArrayPagerAdapter` is a relatively large implementation of the `PagerAdapter` interface, and it helps to demonstrate some of the challenges faced when trying to create alternative fragment-based `PagerAdapter` implementations. Hence, this section will dive into portions of the innards of `ArrayPagerAdapter`, to explain how (and, sometimes, why) it does what it does.

Note that `ArrayPagerAdapter` will continue to expand over time, and so the copy in the master branch of the GitHub repo may be newer than the one profiled in this chapter. This chapter covers v0.2.2.

Also note that some of the code in `ArrayPagerAdapter` comes from `FragmentPagerAdapter` — as little of this code was altered as was practical, to help make it easier to integrate changes made to `FragmentPagerAdapter` over time.

Also, to simplify the discussion, this section will demonstrate the `ArrayPagerAdapter` set up for native API Level 11 fragments, in the `com.commonsware.cwac.pager` package.

PageDescriptor and PageEntry

`ArrayPagerAdapter` works with two representations of pages: `PageDescriptor` and `PageEntry`.

`PageDescriptor` is a simple interface, supplying the unique tag (`getFragmentTag()`) and indicator title (`getTitle()`) to use for a page:

```
package com.commonsware.cwac.pager;

import android.os.Parcelable;

public interface PageDescriptor extends Parcelable {
  String getFragmentTag();

  String getTitle();
}
```

Developers can use `SimplePageDescriptor` as an implementation of `PageDescriptor` in most cases. `SimplePageDescriptor` just holds onto those two strings, plus handles the implementation of the `Parcelable` interface:

```
package com.commonsware.cwac.pager;

import android.os.Parcel;
import android.os.Parcelable;

public class SimplePageDescriptor implements PageDescriptor {
  private String tag=null;
  private String title=null;

  public static final Parcelable.Creator<SimplePageDescriptor> CREATOR=
      new Parcelable.Creator<SimplePageDescriptor>() {
        public SimplePageDescriptor createFromParcel(Parcel in) {
          return new SimplePageDescriptor(in);
        }

        public SimplePageDescriptor[] newArray(int size) {
          return new SimplePageDescriptor[size];
        }
      };

  public SimplePageDescriptor(String tag, String title) {
    this.tag=tag;
    this.title=title;
  }

  private SimplePageDescriptor(Parcel in) {
    tag=in.readString();
    title=in.readString();
  }

  @Override
  public int describeContents() {
    return(0);
  }

  @Override
  public void writeToParcel(Parcel out, int flags) {
    out.writeString(tag);
    out.writeString(title);
  }

  public String getTitle() {
    return(title);
  }

  public String getFragmentTag() {
    return(tag);
  }
}
```

However, the actual data model held by `ArrayPagerAdapter` is not the `PageDescriptor`, but rather a `PageEntry`, that holds onto its corresponding `PageDescriptor` *plus* a `Fragment.SavedState` object:

```
private static class PageEntry implements Parcelable {
  private PageDescriptor descriptor=null;
  private Fragment.SavedState state=null;

  public static final Parcelable.Creator<PageEntry> CREATOR=
      new Parcelable.Creator<PageEntry>() {
        public PageEntry createFromParcel(Parcel in) {
          return new PageEntry(in);
        }

        public PageEntry[] newArray(int size) {
          return new PageEntry[size];
        }
      };

  PageEntry(PageDescriptor descriptor) {
    this.descriptor=descriptor;
  }

  PageEntry(Parcel in) {
    this.descriptor=in.readParcelable(getClass().getClassLoader());
    this.state=in.readParcelable(getClass().getClassLoader());
  }

  PageDescriptor getDescriptor() {
    return(descriptor);
  }

  @Override
  public int describeContents() {
    return(0);
  }

  @Override
  public void writeToParcel(Parcel out, int flags) {
    out.writeParcelable(descriptor, 0);
    out.writeParcelable(state, 0);
  }
}
```

`Fragment.SavedState` is a `Parceble` object we can request from a `Fragment` at any point, representing the saved state of that fragment, as obtained via `onSaveInstanceState()` and related code. At present, that `Fragment.SavedState` is unused, as will be explained in the next section.

RetentionStrategy

`ArrayPagerAdapter` also uses a `RetentionStrategy`, designed to abstract the logic for manipulating the fragments themselves as pages come and go within the

ViewPager. RetentionStrategy is an interface, with methods to attach() a fragment to be in the pager and to detach() the fragment from the pager:

```
public interface RetentionStrategy {
  void attach(Fragment fragment, FragmentTransaction currTransaction);

  void detach(Fragment fragment, FragmentTransaction currTransaction);
```

There is only one stock implementation of this strategy at this time, in the form of a static data member named KEEP. This strategy is designed to replicate the behavior of FragmentPagerAdapter, keeping all fragments around once created, and merely attach()-ing and detach()-ing them from the FragmentManager as dictated:

```
  }
}

public static final RetentionStrategy KEEP=new RetentionStrategy() {
  @TargetApi(Build.VERSION_CODES.HONEYCOMB_MR2)
  public void attach(Fragment fragment,
                     FragmentTransaction currTransaction) {
    currTransaction.attach(fragment);
  }

  @TargetApi(Build.VERSION_CODES.HONEYCOMB_MR2)
  public void detach(Fragment fragment,
                     FragmentTransaction currTransaction) {
```

A future implementation of ArrayPagerAdapter should include another strategy that behaves more like FragmentStatePagerAdapter, removing the fragments entirely and allowing them to be garbage collected, while using PageEntry to hold onto their Fragment.SavedState structures to repopulate them later on if the user swipes back to that page.

Class Declaration and Generics

ArrayPagerAdapter uses Java generics to allow developers to state what Fragment subclass the pages are. This is for use with convenience methods — getExistingFragment() and getCurrentFragment() — to help reduce the developer's need to downcast those Fragment instances to some subclass. If the pages in the ViewPager will all come from a single Fragment subclass, the developer would use that class as the T in the declaration; otherwise, the developer would just use Fragment:

```
abstract public class ArrayPagerAdapter<T extends Fragment> extends
```

Constructors

ArrayPagerAdapter offers two constructors. The simpler two-parameter constructor, taking the FragmentManager and the desired pages as an ArrayList of PageDescriptor objects, just chains to the three-parameter constructor. That third parameter is an instance of a RetentionStrategy, allowing reusers of ArrayPagerAdapter to try their own hand at implementing such a strategy. null — the default strategy from the standpoint of the constructors — is replaced with the default KEEP strategy, and the PageDescriptor objects are wrapped in PageEntry objects as the actual data model (an entries ArrayList):

```
public ArrayPagerAdapter(FragmentManager fragmentManager,
                         List<PageDescriptor> descriptors,
                         RetentionStrategy retentionStrategy) {
  this.fm=fragmentManager;
  this.entries=new ArrayList<PageEntry>();

  for (PageDescriptor desc : descriptors) {
    validatePageDescriptor(desc);

    entries.add(new PageEntry(desc));
  }

  this.retentionStrategy=retentionStrategy;

  if (this.retentionStrategy == null) {
    this.retentionStrategy=KEEP;
  }
```

Core PagerAdapter Methods

All PagerAdapter implementations have some core methods that they must handle. When you create a subclass of FragmentPagerAdapter and FragmentStatePagerAdapter, you only need to worry about getCount() and getPage(). However, if you are creating your own replacement for those fragment-based adapters, there are a few more standard PagerAdapter methods that you will need to override.

getCount()

getCount() is easy: all we need to do is return our desired number of pages. That is based on the number of PageDescriptor objects supplied to our adapter, which we wrapped into PageEntry objects and hold onto in entries:

```
@Override
public int getCount() {
  return(entries.size());
}
```

getPageTitle()

Similarly, `getPageTitle()` just needs to find the appropriate `PageDescriptor` and call `getTitle()` on it, to supply the title for a given page for use by an indicator like `PagerTabStrip`:

```
  @Override
  public String getPageTitle(int position) {
    return(entries.get(position).getDescriptor().getTitle());
  }
```

instantiateItem() and destroyItem()

The `instantiateItem()` method on `PagerAdapter` is responsible for setting up the user interface for a given page (indicated by `position`) and adding those widgets to a `ViewGroup` supplied as a parameter. It returns an `Object` that represents a “handle” to the page that `ViewPager` will return to the `PagerAdapter` in future calls, such as to `destroyItem()`.

A `Fragment`-based `PagerAdapter` can use the fragment itself as the “handle”, and the fragment’s `onCreateView()` as the means of obtaining the UI to pour into the `ViewGroup`.

Hence, the `ArrayPagerAdapter` implementation of `instantiateItem()` does the following:

- First, starts a `FragmentTransaction`, if there is not one already in progress
- Then, tries to find an existing `Fragment` for this `position`, using a `getExistingFragment()` helper method (described later in this chapter)
- If an existing fragment exists, `instantiateItem()` uses the `RetentionStrategy` to re-attach the UI
- If an existing fragment does not exist, `instantiateItem()` calls the abstract `createFragment()` method, to allow the subclass to return the actual `Fragment` object given the `PageDescriptor`, then `add()` that fragment to the UI
- If the fragment is not already the current page, make sure that its action bar contributions are hidden via `setMenuVisibility()` and `setUserVisibleHint()`
- Return the fragment itself as the “handle”

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
@Override
public Object instantiateItem(ViewGroup container, int position) {
  if (currTransaction == null) {
    currTransaction=fm.beginTransaction();
  }

  Fragment fragment=getExistingFragment(position);

  if (fragment != null) {
    retentionStrategy.attach(fragment, currTransaction);
  }
  else {
    fragment=createFragment(entries.get(position).getDescriptor());
    currTransaction.add(container.getId(), fragment,
                        getFragmentTag(position));
  }

  if (fragment != currPrimaryItem) {
    fragment.setMenuVisibility(false);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
      fragment.setUserVisibleHint(false);
    }
  }

  return(fragment);
}
```

Conversely, `destroyItem()` is responsible for cleaning up anything from a page that the `PagerAdapter` thinks is no longer needed. The `destroyItem()` method on `ArrayPagerAdapter` starts a transaction if there is none, then delegates the actual work to the `RetentionStrategy`:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void destroyItem(ViewGroup container, int position,
                        Object object) {
  if (currTransaction == null) {
    currTransaction=fm.beginTransaction();
  }

  retentionStrategy.detach((Fragment)object, currTransaction);
}
```

startUpdate() and finishUpdate()

The `startUpdate()` method will be called before any calls to `instantiateItem()` or `destroyItem()`, and so, if desired, we can do some initialization work there. In the case of `ArrayPagerAdapter`, all initialization is done lazily, and so `startUpdate()` is not needed. However, since `FragmentPagerAdapter` overrides `startUpdate()` with an empty implementation, we keep that for maximum fidelity with the stock implementation:

```
@Override
public void startUpdate(ViewGroup container) {
}
```

The `finishUpdate()` method will be called after any calls to `instantiateItem()` or `destroyItem()`, where we can do some cleanup work. `ArrayPagerAdapter` creates a `FragmentTransaction` as part of its work in `instantiateItem()` and `destroyItem()`, and so we need to commit that transaction in `finishUpdate()`. Once again, we reproduce the implementation from `FragmentPagerAdapter`, which uses `commitAllowingStateLoss()` (so we are not concerned with the timing of any state-saving being done at the activity level) and `executePendingTransactions()` (so all of the fragment work is done directly, rather than being posted to the end of the main application thread's work queue):

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@Override
public void finishUpdate(ViewGroup container) {
  if (currTransaction != null) {
    currTransaction.commitAllowingStateLoss();
    currTransaction=null;
    fm.executePendingTransactions();
  }
}
```

setPrimaryItem()

`ViewPager` will call `setPrimaryItem()` on the `PagerAdapter` when a new page is being brought into view, based on gestures or other calls on `ViewPager` itself (e.g., `setCurrentItem()`). Some `PagerAdapter` implementations will have nothing much to do here. Fragment-based `PagerAdapter` implementations, though, need to ensure that the right fragment's action bar items are shown. Hence, `ArrayPagerAdapter` removes the action bar items from the previously-current page and adds the action bar items of the newly-current page:

```
@TargetApi(Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1)
@SuppressWarnings("unchecked")
@Override
public void setPrimaryItem(ViewGroup container, int position,
                           Object object) {
  T fragment=(T)object;

  if (fragment != currPrimaryItem) {
    if (currPrimaryItem != null) {
      currPrimaryItem.setMenuVisibility(false);
```

```
        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
          currPrimaryItem.setUserVisibleHint(false);
        }
      }

      if (fragment != null) {
        fragment.setMenuVisibility(true);

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH_MR1) {
          fragment.setUserVisibleHint(true);
        }
      }

      currPrimaryItem=fragment;
    }
  }
```

isViewFromObject()

`isViewFromObject()` helps `ViewPager` keep track of the UI for pages and how it maps back to a page's "handle". In our case, since the "handle" is a `Fragment`, we need to see if the supplied `View` is the `View` from the supplied `Fragment`:

```
  @TargetApi(Build.VERSION_CODES.HONEYCOMB)
  @Override
  public boolean isViewFromObject(View view, Object object) {
    return ((Fragment)object).getView() == view;
  }
```

State Management

Our `PagerAdapter` is called with `saveState()` and `restoreState()` methods, to have us save the state of our data model and restore it, for configuration changes. `saveState()` returns a `Parcelable` which will form part of the state saved by the `ViewPager`, while `restoreState()` is handed back that `Parcelable` (or a copy).

The state of the *fragments* is handled by `FragmentManager`, no different than with any other fragments we might use in an activity. The mere fact that we happen to coordinate those fragments with a `PagerAdapter` does not change this. Hence, the "state" that we are dealing with in `saveState()` and `restoreState()` is solely the state of the `PagerAdapter` data model — in our case, the roster of pages.

To future-proof the implementation a bit, the state is represented as a `Bundle`, into which we can store other `Parcelable` objects. Since `Bundle` knows how to save an `ArrayList` of `Parcelable` objects, we can just call `putParcelableArrayList()` to save our `ArrayList` of `PageEntry` objects, restoring them in `restoreState()` via `getParcelableArrayList()`:

```
@Override
public Parcelable saveState() {
  Bundle state=new Bundle();

  state.putParcelableArrayList(KEY_DESCRIPTORS, entries);

  return(state);
}
```

Content Manipulation and Position Management

Perhaps the trickiest method on PagerAdapter that we have to worry about is innocuously named getItemPostion(). We are given the Object "handle" for a page, and we need to return the position of that page.

However, that's not really what is going on here.

getItemPosition() is used when we call notifyDataSetChanged() to indicate a structural change in our data model, such as an added or removed page. ViewPager is looking for getItemPosition() to tell us the *new* position of pages for this notifyDataSetChanged() call. So, as we manipulate our pages, we need to track what is going on with page positions, so getItemPosition() can return the correct data.

The actual value returned by getItemPosition() is either:

- The actual numerical position of the page, from 0 to getCount()-1, if the page moved to another position (where we return the new position)
- PagerAdapter.POSITION_UNCHANGED, if the page has not moved
- PagerAdapter.POSITION_NONE, if the page no longer exists (e.g., was removed)

ArrayPagerAdapter simply holds a HashMap (positionDelta), mapping our Fragment "handle" to the page to an Integer representing any change to the position of that page made by methods like add(). When getItemPosition() is called, we return the value for that page out of the HashMap, or POSITION_UNCHANGED if the page does not appear in the HashMap, indicating that the page has not been affected:

```
@Override
public int getItemPosition(Object o) {
  Integer result=positionDelta.get(o);

  if (result == null) {
    return(PagerAdapter.POSITION_UNCHANGED);
  }
```

```
    return(result);
  }
```

The add() method needs to add a new page to the data model, given the PageDescriptor. We clear() our positionDelta HashMap (as any previous changes should already have been picked up), add() a new PageEntry to our data model based on the supplied PageDescriptor, then call notifyDataSetChanged():

```
  public void add(PageDescriptor desc) {
    validatePageDescriptor(desc);

    positionDelta.clear();
    entries.add(new PageEntry(desc));
    notifyDataSetChanged();
  }
```

In this case, we did not need to add an entry to positionDelta, as ViewPager will use the natural position (based on where it appears in our data model) if we return POSITION_UNCHANGED.

The insert() method needs to do much the same thing, except rather than adding the new page to the end, we are adding it somewhere in the middle. This requires us to do everything we did in add(), plus add entries to the positionDelta map to indicate the new positions for every page that appears after the one being inserted:

```
  public void insert(PageDescriptor desc, int position) {
    validatePageDescriptor(desc);

    positionDelta.clear();

    for (int i=position; i < entries.size(); i++) {
      Fragment f=getExistingFragment(i);

      if (f != null) {
        positionDelta.put(f, i + 1);
      }
    }

    entries.add(position, new PageEntry(desc));
    notifyDataSetChanged();
  }
```

The remove() method needs to get rid of an existing page, given its position. Here, we are not given the “handle”, so we look it up via getExistingFragment(), then use that to put POSITION_NONE in the positionDelta map. We also update positionDelta to indicate the new positions for every page that appeared after the one being removed:

```
public void remove(int position) {
  positionDelta.clear();

  Fragment f=getExistingFragment(position);

  if (f != null) {
    positionDelta.put(f, PagerAdapter.POSITION_NONE);
  }

  for (int i=position + 1; i < entries.size(); i++) {
    f=getExistingFragment(i);

    if (f != null) {
      positionDelta.put(f, i - 1);
    }
  }

  entries.remove(position);
  notifyDataSetChanged();
}
```

Finally, a `move()` is simply treated as a `remove()` from the old position and an `insert()` of the same page into the new position:

```
public void move(int oldPosition, int newPosition) {
  if (oldPosition != newPosition) {
    PageDescriptor desc=entries.get(oldPosition).getDescriptor();

    remove(oldPosition);
    insert(desc, newPosition);
  }
}
```

Miscellany

One headache with `FragmentPagerAdapter` and `FragmentStatePagerAdapter` is that they like to manage the fragments themselves, making it annoying for you to get at those fragments independently later on. Some developers have resorted to holding onto fragments in their own array, which works, but then you run into problems when it comes to garbage collection with `FragmentStatePagerAdapter`.

`ArrayPagerAdapter` provides two convenience methods to address this:

- `getExistingFragment()` simply returns the fragment for a given `position`, by finding the tag for that fragment from the `PageDescription`, then looking up the fragment by that tag. This way, if the fragment does not exist due to garbage collection, we can return `null`
- `getCurrentFragment()` returns the `currPrimaryItem` value, indicating the page that we are presently on

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
@SuppressWarnings("unchecked")
public T getExistingFragment(int position) {
  return (T)(fm.findFragmentByTag(getFragmentTag(position)));
}

public T getCurrentFragment() {
  return(currPrimaryItem);
}
```

Both are set to return the generic type `T` that the developer uses when creating a subclass of `ArrayPagerAdapter`.

Focus Management and Accessibility

As developers, we are very used to creating apps that are designed to be navigated by touch, with users tapping on widgets and related windows to supply input.

However, not all Android devices have touchscreens, and not all Android users use touchscreens.

Internationalization (i18n) and localization (L10n) give you opportunities to expand your user base to audiences beyond your initial set, based on language. Similarly, you can expand your user base by offering support for non-touchscreen input and output. Long-term, the largest user base of these features may be those with televisions augmented by Android, whether via Android TV, OUYA consoles, or whatever. Short-term, the largest user base of these features may be those for whom touchscreens are rarely a great option, such as the blind. Supporting those with unusual requirements for input and output is called *accessibility* (a11y), and represents a powerful way for you to help your app distinguish itself from competitors.

In this chapter, we will first examine how to better handle focus management, and then segue into examining what else, beyond supporting keyboard-based input, can be done in the area of accessibility.

Prerequisites

Understanding this chapter requires that you have read the core chapters and are familiar with the concept of widgets having focus for user input.

Prepping for Testing

To test focus management, you will need an environment that supports "arrow key" navigation. Here, "arrow key" also includes things like D-pads or trackballs – basically, anything that navigates by key events instead of by touch events.

Examples include:

- The Android emulator, with the `DPad support` hardware property set to `yes`
- Phones that have actual D-pads, trackballs, arrow keys, or the like
- Television-based Android environments, such as Android TV or the OUYA console
- Devices that have dedicated keyboard accessories, such as the keyboard "slice" available for the ASUS Transfomer series of tablets
- A standard Android device accessed via a Bluetooth keyboard, gamepad, or similar sort of pointing device

Hence, even if the emulator will be insufficient for your needs, you should be able to set up a hardware test environment relatively inexpensively. Most modern Android devices support Bluetooth keyboards, and such keyboards frequently can be obtained at low relative cost.

For accessibility beyond merely focus control, you will certainly want to enable TalkBack, via the Accessibility area of the Settings app. This will cause Android to verbally announce what is on the screen, by means of its text-to-speech engine.

On Android 4.0 and higher devices, enabling Talkback will also optionally enable "Explore by Touch". This allows users to tap on items (e.g., icons in a `GridView`) to have them read aloud via TalkBack, with a double-tap to actually perform what ordinarily would require a single-tap without "Explore by Touch".

Controlling the Focus

Android tries its best to have intelligent focus management "out of the box", without developer involvement. Many times, what it offers is sufficient for your needs. Other times, though, the decisions Android makes are inappropriate:

- Trying to navigate in a certain direction (e.g., right) moves focus to a widget that is not logically what should have the focus

- Focus has other side effects, like showing the soft keyboard on an `EditText` widget, that is not desirable

Hence, if you feel that you need to take more control over how focus management is handled, you have many means of doing so, covered in this section.

Establishing Focus

In order for a widget to get the focus, it has to be focusable.

You might think that the above sentence was just a chance for the author to be witty. It was… a bit. But there are actually two types of "focusable" when it comes to Android apps:

- Is it focusable when somebody is using a pointing device or the keyboard?
- Is it focusable in touch mode?

There are three major patterns for the default state of a widget:

1. Some are initially focusable in both cases (e.g., `EditText`)
2. Some are focusable in non-touch mode but are not focusable in touch mode (e.g., `Button`)
3. Some are not focusable in either mode (e.g., `TextView`)

So, when a `Button` is not focusable in touch mode, that means that while the button will take the focus when the user navigates to it (e.g., via keys), the button will *not* take the focus when the user simply taps on it.

You can control the focus semantics of a given widget in four ways:

- You can use `android:focusable` and `android:focusableInTouchMode` in a layout
- You can use `setFocusable()` and `setFocusableInTouchMode()` in Java

We will see examples of these shortly.

Requesting (or Abandoning) Focus

By default, the focus will be granted to the first focusable widget in the activity, starting from the upper left. Often times, this is a fine solution.

If you want to have some other widget get the focus (assuming that the widget is focusable, per the section above), you have two choices:

1. Call `requestFocus()` on the widget in question
2. You can give the widget's layout element a child element, named `<requestFocus />`, to stipulate that this widget should be the one to get the focus

Note that this is a child element, not an attribute, as you might ordinarily expect.

For example, let's look at the Focus/Sampler sample project, which we will use to illustrate various focus-related topics.

Our main activity, creatively named `MainActivity`, loads a layout named `request_focus.xml`, and demonstrates the `<requestFocus />` element:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <Button
    android:id="@+id/button1"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/a_button"/>

  <EditText
    android:id="@+id/editText1"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:contentDescription="@string/first_field"
    android:hint="@string/str_1st_field"
    android:inputType="text"/>

  <EditText
    android:id="@+id/editText2"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:contentDescription="@string/second_field"
    android:hint="@string/str_2nd_field"
    android:inputType="text">

    <requestFocus/>
  </EditText>

</LinearLayout>
```

Here, we have three widgets in a horizontal `LinearLayout`: a `Button`, and two `EditText` widgets. The second `EditText` widget has the `<requestFocus />` child element, and so it gets the focus when we display our launcher activity:

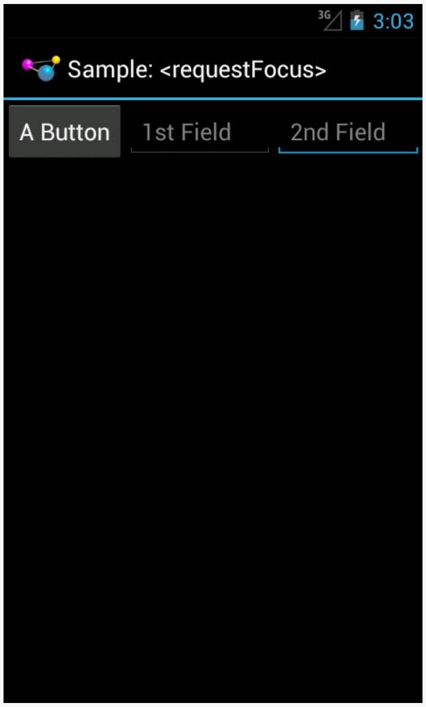

Figure 596: Focus Sampler, Showing Requested Focus

If we had skipped the `<requestFocus />` element, the focus would have wound up on the first `EditText`… assuming that we are working in touch mode. If the activity had been launched via the pointing device or keyboard, then the `Button` would have the focus, because the `Button` is focusable in non-touch mode by default.

Calling `requestFocus()` from Java code gets a bit trickier. There are a few flavors of the `requestFocus()` method on `View`, of which two will be the most popular:

- An ordinary zero-argument `requestFocus()`
- A one-argument `requestFocus()`, with the argument being the direction in which the focus should theoretically be coming from

You might look at the description of the second flavor and decide that the zero-argument `requestFocus()` looks a lot easier. And, sometimes it will work. However, sometimes it will not, as is the case with our second activity, `RequestFocusActivity`.

In this activity, our layout (`focusable_button`) is a bit different:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <EditText
    android:id="@+id/editText1"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:contentDescription="@string/first_field"
    android:hint="@string/str_1st_field"
    android:inputType="text"/>

  <EditText
    android:id="@+id/editText2"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:contentDescription="@string/second_field"
    android:hint="@string/str_2nd_field"
    android:inputType="text">
  </EditText>

  <Button
    android:id="@+id/button1"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:focusableInTouchMode="true"
    android:text="@string/a_button"/>

</LinearLayout>
```

Here, we put the `Button` last instead of first. We have no `<requestFocus />` element anywhere, which would put the default focus on the first `EditText` widget. And, our `Button` has `android:focusableInTouchMode="true"`, so it will be focusable regardless of whether we are in touch mode or not.

In `onCreate()` of our activity, we use the one-parameter version of `requestFocus()` to give the `Button` the focus:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.focusable_button);
    initActionBar();

    button=findViewById(R.id.button1);
    button.requestFocus(View.FOCUS_RIGHT);
    button.setOnClickListener(this);
  }
```

If there were only the one EditText before the Button, the zero-argument requestFocus() works. However, with a widget between the default focus and our Button, the zero-argument requestFocus() does not work, but using requestFocus(View.FOCUS_RIGHT) does. This tells Android that we want the focus, and it should be as if the user is moving to the right from where the focus currently lies.

All of our activities inherit from a BaseActivity that manages our action bar, with an overflow menu to get to the samples and the app icon to get to the original activity.

So, if you run the app and choose "Request Focus" from the overflow menu, you will see:

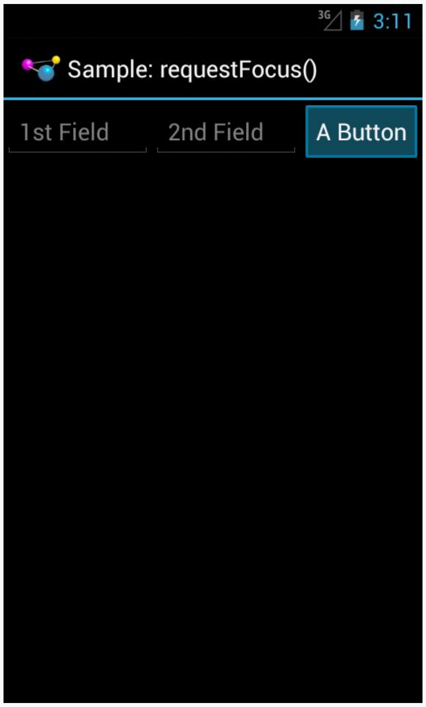

Figure 597: Focus Sampler, Showing Manually-Requested Focus

We also wire up the Button to the activity for click events, and in onClick(), we call clearFocus() to abandon the focus:

```
@Override
public void onClick(View v) {
  button.clearFocus();
}
```

What `clearFocus()` will do is return to the original default focus for this activity, in our case the first `EditText`:

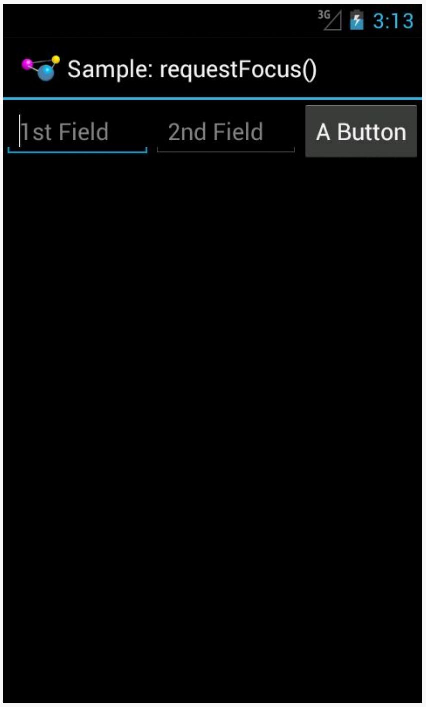

Figure 598: Focus Sampler, After Clearing the Focus

Focus Ordering

Beyond manually placing the focus on a widget (or manually clearing that focus), you can also override the focus order that Android determines automatically. While Android's decisions usually are OK, they may not be optimal.

A widget can use `android:nextFocus...` attributes in the layout file to indicate the widget that should get control on a focus change in the direction indicated by the `...` part. So, `android:nextFocusDown`, applied to Widget A, indicates which widget should receive the focus if, when the focus is on Widget A, the user "moves down" (e.g., presses a DOWN key, presses the down direction on a D-pad). The same logic holds true for the other three directions (`android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`).

For example, the `res/layout/table.xml` resource in the `FocusSampler` project is based on the `TableLayout` sample from early in this book, with a bit more focus control:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:stretchColumns="1">

  <TableRow>

    <TextView android:text="@string/url"/>

    <EditText
      android:id="@+id/entry"
      android:layout_span="3"
      android:inputType="text"
      android:nextFocusRight="@+id/ok"/>
  </TableRow>

  <TableRow>

    <Button
      android:id="@+id/cancel"
      android:layout_column="2"
      android:text="@string/cancel"/>

    <Button
      android:id="@+id/ok"
      android:text="@string/ok"/>
  </TableRow>

</TableLayout>
```

In the original `TableLayout` sample, by default, pressing either RIGHT or DOWN while the `EditText` has the focus will move the focus to the “Cancel” button. This certainly works. However, it does mean that there is no single-key means of moving from the `EditText` to the “OK” button, and it would be nice to offer that, so those using the pointing device or keyboard can quickly move to either button.

This is a matter of overriding the default focus-change behavior of the `EditText` widget. In our case, we use `android:nextFocusRight="@+id/ok"` to indicate that the “OK” button should get the focus if the user presses RIGHT from the `EditText`. This gives RIGHT and DOWN different behavior, to reach both buttons.

Scrolling and Focusing Do Not Mix

Let’s suppose that you have a UI design with a fixed bar of widgets at the top (e.g., action bar), a `ListView` dominating the activity, and a panel of widgets at the bottom (e.g., a `Toolbar`). This is a common UI pattern on iOS, though it is relatively uncommon on Android nowadays. You used to see it with the so-called “split action bar”, which is now officially deprecated as a pattern:

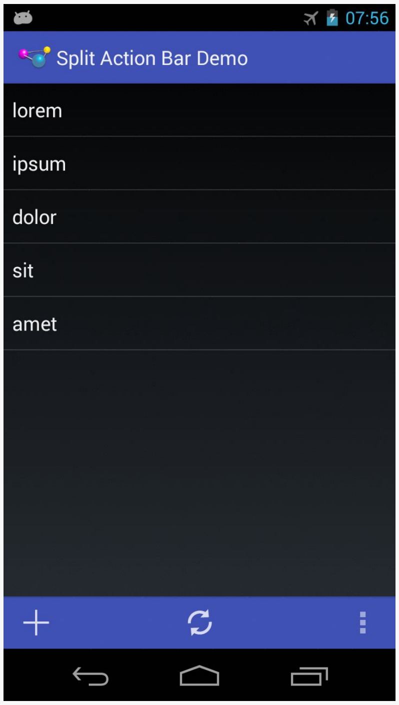

Figure 599: Split Action Bar

However, this UI pattern does not work well for those using pointing devices or keyboards for navigation. In order to get to the bottom panel of widgets, they will have to scroll through the entire list first, because scrolling trumps focus changes. So while this is easy to navigate via a touchscreen, it is a major problem to navigate for those not using a touchscreen.

Similarly, if the user has scrolled down the list, and now wishes to get to the action bar at the top, the user would have to scroll all the way to the top of the list first.

Workarounds include:

- Overriding focus control such that left and right navigation from the list moves you to the action bar or bottom `Toolbar` (e.g., left moves you to the action bar, right moves you to the `Toolbar`)
- In a television setup, having the "action bar" be vertical down the left, and the tools be vertical down the right, so you automatically get the left/right navigation to move between these "zones"
- Eliminating the `Toolbar` entirely, moving those items instead to the action bar, or perhaps an action mode (a.k.a., contextual action bar) if the items are only relevant if the user checks one or more items in the list

- Offer a hotkey, separate from navigation, that repositions the focus (e.g., CTRL-A to jump to the action bar), if you believe that users will read your documentation to discover this key combination

Accessibility and Focus

People suffering from impaired vision, including the blind, have had to rely heavily on proper keyboard navigation for their use of Android apps, at least prior to Android 4.0 and "Explore by Touch". These users need focus to be sensible, so that they can find their way through your app, with TalkBack supplying prompts for what has the focus. Having widgets that are unreachable in practice will eliminate features from your app for this audience, simply because they cannot get to them.

"Explore by Touch" provides accessibility assistance without reliance upon proper focus. However:

- "Explore by Touch" is new to Android 4.0, and a few visually-impaired users will be using older devices
- "Explore by Touch" is less reliable than keyboard-based navigation, insofar as users have to remember specific screen locations (and get to them without seeing those locations), rather than simply memorizing certain key combinations
- "Explore by Touch", by requiring additional taps (e.g., double-tap to tap a `Button`), may cause some challenges when the UI itself requires additional taps (e.g., a double-tap on a widget to perform an action — is this now a triple-tap in "Explore by Touch" mode?)
- "Explore by Touch" is mostly for the visually impaired, and does not help others that might benefit from key-based navigation (e.g., people with limited motor control)

So, even though "Explore by Touch" will help people use apps that cannot be navigated purely through key events, the better you can support keyboards, the better off your users will be.

Accessibility Beyond Focus

While getting focus management correct goes a long way towards making your application easier to use, it is not the only thing to consider for making your application truly accessible by all possible users. This section covers a number of other things that you should consider as part of your accessibility initiatives.

Content Descriptions

For TalkBack to work, it needs to have something useful to read aloud to the user. By default, for most widgets, all it can say is the type of widget that has the focus (e.g., "a checkbox"). That does not help the TalkBack-reliant user very much.

Please consider adding `android:contentDescription` attributes to most of your widgets, pointing to a string resource that briefly describes the widget (e.g., "the Enabled checkbox"). This will be used in place of the basic type of widget by TalkBack.

Classes that inherit from `TextView` will use the text caption of the widget by default, so your `Button` widgets may not need `android:contentDescription` if their captions will make sense to TalkBack users.

However, with an `EditText`, since the text will be what the user types in, the text is not indicative of the widget itself. Android will first use your `android:hint` value, if available, falling back to `android:contentDescription` if `android:hint` is not supplied.

Also, bear in mind that if the widget changes purpose, you need to change your `android:contentDescription` to match. For example, suppose you have a media player app with an `ImageButton` that you toggle between "play" and "pause" modes by changing its image. When you change the image, you also need to change the `android:contentDescription` as well, lest sighted users think the button will now "pause" while blind users think that the button will now "play".

Custom Widgets and Accessibility Events

The engine behind TalkBack is an accessibility service. Android ships with some, like TalkBack, and third parties can create other such services.

Stock Android widgets generate relevant accessibility events to feed data into these accessibility services. That is how `android:contentDescription` gets used, for example — on a focus change, stock Android widgets will announce the widget that just received the focus.

If you are creating custom widgets, you may need to raise your own accessibility events. This is particularly true for custom widgets that draw to the `Canvas` and process raw touch events (rather than custom widgets that merely aggregate existing widgets).

The Android developer documentation provides instructions for when and how to supply these sorts of events.

Announcing Events

Sometimes, your app will change something about its visual state in ways that do not get picked up very well by any traditional accessibility events. For example, you might use `GestureDetector` to handle some defined library of gestures and change state in your app. Those state changes may have visual impacts, but `GestureDetector` will not know what those are and therefore cannot supply any sort of accessibility event about them.

To help with this, API Level 16 added `announceForAccessibility()` as a method on `View`. Just pass it a string and that will be sent out as an "announcement" style of `AccessibilityEvent`. Your code leveraging `GestureDetector`, for example, could use this to explain the results of having applied the gesture.

Font Selection and Size

For users with limited vision, being able to change the font size is a big benefit. Android 4.0 finally allows this, via the Settings app, so users can choose between small, normal, large, and huge font sizes. Any place where text is rendered and is measured in `sp` will adapt.

The key, of course, is the `sp` part.

`sp` is perhaps the most confusing of the available dimension units in Android. `px` is obvious, and `dp` (or `dip`) is understandable once you recognize the impacts of screen density. Similarly, `in`, `mm`, and `pt` are fairly simple, at least once you remember that `pt` is 1/72nd of an inch.

If the user has the font scale set to "normal", `sp` equates to `dp`, so a dimension of `30sp` and `30dp` will be the same size. However, values in `dp` do not change based on font scale; values in `sp` will increase or decrease in physical size based upon the user's changes to the font scale.

We can see how this works in the `Accessibility/FontScale` sample project.

In our layout (`res/layout/activity_main.xml`), we have six pieces of text: two each (regular and bold) measured at `30px`, `30dp`, and `30sp`:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/LinearLayout1"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30px"
    android:textSize="30px"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30px"
    android:textSize="30px"
    android:textStyle="bold"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30dp"
    android:textSize="30dp"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30dp"
    android:textSize="30dp"
    android:textStyle="bold"
    tools:context=".MainActivity"/>

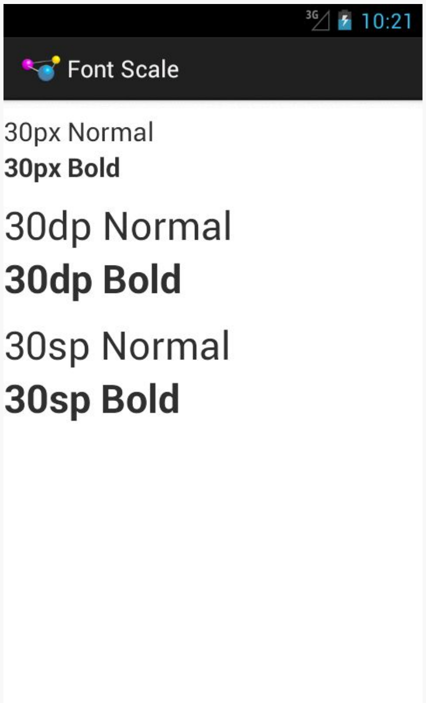
  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="10dp"
    android:text="@string/normal_30sp"
    android:textSize="30sp"
    tools:context=".MainActivity"/>

  <TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/bold_30sp"
    android:textSize="30sp"
    android:textStyle="bold"
    tools:context=".MainActivity"/>

</LinearLayout>
```

You will be able to see the differences between `30px` and `30dp` on any Android OS release, simply by running the app on devices with different densities. To see the changes between `30dp` and `30sp`, you will need to run the app on an Android 4.0+ device or emulator and change the font scale from the Settings app (typically in the Display section).

Here is what the text looks like with a normal font scale:



30px Normal

30px Bold

30dp Normal

30dp Bold

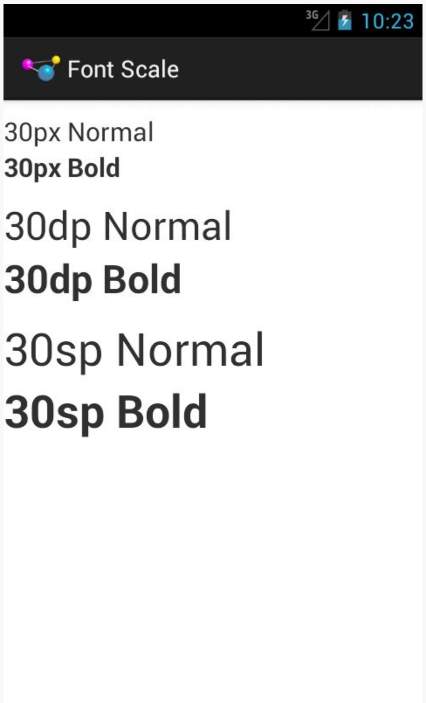
30sp Normal

30sp Bold

Figure 600: Fonts at Normal Scale

As you can see, `30dp` and `30sp` are equivalent.

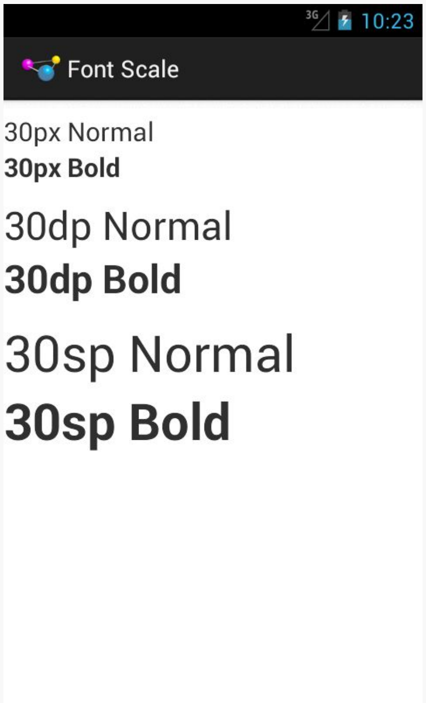
If we raise the font scale to "large", the `30sp` text grows to match:



30px Normal
30px Bold
30dp Normal
30dp Bold
30sp Normal
30sp Bold

Figure 601: Fonts at Large Scale

Moving to "huge" scale increases the `30sp` text size further:



10:23

Font Scale

30px Normal

30px Bold

30dp Normal

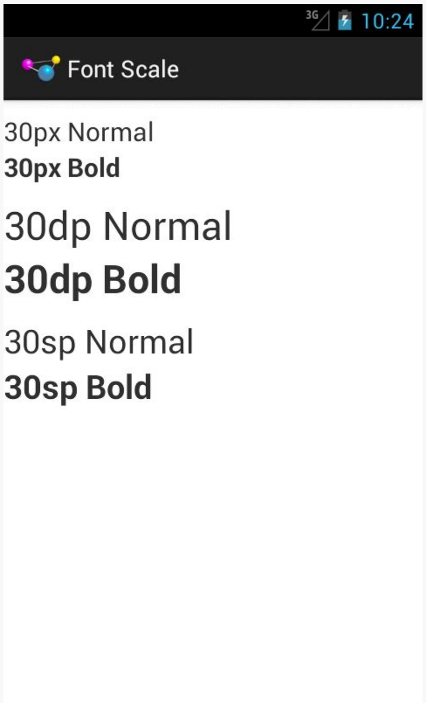
30dp Bold

30sp Normal

30sp Bold

Figure 602: Fonts at Huge Scale

In the other direction, some users may elect to drop their font size to "small", with a corresponding impact on the `30sp` text:



30px Normal

30px Bold

30dp Normal

30dp Bold

30sp Normal

30sp Bold

Figure 603: Fonts at Small Scale

As a developer, your initial reaction may be to run away from `sp`, because you do not control it. However, just as Web developers should deal with changing font scale in Web browsers, Android developers should deal with changing font scale in Android apps. Remember: the user is changing the font scale because the *user* feels that the revised scale is easier for them to use. Blocking such changes in your app, by avoiding `sp`, will not be met with love and adoration from your user base.

Also, bear in mind that changes to the font scale represent a configuration change. If your app is in memory at the time the user goes into Settings and changes the scale, if the user returns to your app, each activity that comes to the foreground will undergo the configuration change, just as if the user had rotated the screen or put the device into a car dock or something.

Widget Size

Users with ordinary sight already have trouble with tiny widgets, as they are difficult to tap upon.

Users trying to use the Explore by Touch facility added in Android 4.1 have it worse, as they cannot even see (or see well) the tiny target you are expecting them to tap upon. They need to be able to reliably find your widget based on its relative position on the screen, and their ability to do so will be tied, in part, on widget size.

The Android design guidelines recommend 7-10mm per side minimum sizes for tappable widgets. In particular, they recommend 48dp per side, which results in a size of about 9mm per side.

You also need to consider how closely packed your widgets are. The closer the tap targets lie, the more likely it is that all users — whether using Explore by Touch or not — will accidentally tap on the wrong thing. Google recommends 8dp or more of margin between widgets. Also note that the key is *margins*, as while increasing padding might visually separate the widgets, the padding is included as part of the widget from the standpoint of touch events. While padding may help users with ordinary sight, margins provide similar help while also being of better benefit to those using Explore by Touch.

Gestures and Taps

If you employ gestures, be careful when employing the same gesture in different spots for different roles, particularly within the same activity.

For example, you might use a horizontal swipe to the right to switch pages in a `ViewPager` in some places and remove items from a `ListView` in others. While there may be visual cues to help explain this to users with ordinary sight, it may be far less obvious what is going on for TalkBack users. This is even more true if you are somehow combining these things (e.g., the `ListView` in question is in a page of the `ViewPager`).

Also, be a bit careful as you “go outside the box” for tap events. You might decide that a double-tap, or a two-finger tap, has special meaning on some widgets. Make sure that this still works when users use Explore by Touch, considering that the first tap will be “consumed” by Explore by Touch to announce the widget being tapped upon.

Enhanced Keyboard Support

All else being equal, users seeking accessibility assistance will tend to use keyboards when available. For users with limited (or no) sight, tactile keyboards are simply easier to use than touchscreens. For users with limited motor control, external devices that interface as keyboards may allow them to use devices that otherwise they could not.

Of course, plenty of users will use keyboards outside of accessibility as well. For example, devices like the ASUS Transformer series form perfectly good “netbook”-style devices when paired with their keyboards.

Hence, consider adding hotkey support, to assist in the navigation of your app. Some hotkeys may be automatically handled (e.g., Ctrl-C for copy in an `EditText`). However, in other cases you may wish to add those yourself (e.g., Ctrl-C for “copy” with respect to a checklist and its selected rows, in addition to a “copy” action mode item).

API Level 11 adds `KeyEvent` support for methods like `isCtrlPressed()` to detect meta keys used in combination with regular keys.

Audio and Haptics

Of course, another way to make your app more accessible is to provide alternative modes of input and output, beyond the visual.

Audio is popular in this regard:

- Using tones or clicks to reinforce input choices
- Integrating your own text-to-speech to augment TalkBack
- Integrating speech recognition for simple commands

However, bear in mind that deaf users will be unable to hear your audio. You are better served using both auditory and visual output, not just one or the other.

In some cases, haptics can be helpful for input feedback, by using the `Vibrator` system service to power the vibration motor. While most users will be able to feel vibrations, the limitation here is whether the device is capable of vibrating:

- Some tablets lack a vibration motor
- Television-based Android environment may or may not have some sort of vibration output (e.g., remote controls probably will not, but game controllers might)
- Devices not held in one’s hand, such as those in a dock, will make haptics less noticeable

So, audio and vibration can help augment visual input and output, though they should not be considered complete replacements except in rare occurrences.

Color and Color Blindness

Approximately 8% of men (and 0.5% of women) in the world are colorblind, meaning that they cannot distinguish certain close colors:

> …It's not that colorblind people (in most cases) are incapable or perceiving "green," instead they merely distinguish fewer shades of green than you do. So where you see three similar shades of green, a colorblind user might only see one shade of green.

(from "Tips for Designing for Colorblind Users")

Hence, relying solely on colors to distinguish different items, particularly when required for user input, is not a wise move.

Make sure that there is something more to distinguish two pieces of your UI than purely a shift in color, such as:

- Labels or icons
- Textures (e.g., solid vs. striped)
- Borders (e.g., drop shadow)

Accessibility Beyond Impairment

Accessibility is often tied to impaired users: ones with limited (or no) sight, ones with limited (or no) hearing, ones with limited motor control, etc.

In reality, accessibility is for *situations* where users may have limitations. For example, a user who might not normally think of himself as "impaired" has limited sight, hearing, and motor control when those facilities are already in use, such as while driving.

Hence, offering features that help with accessibility can benefit *all* your users, not just ones you think of as "impaired". For example:

- Offer a UI mode with an eye towards use in low-visibility situations that can either be manually invoked (e.g., via a preference) or automatically invoked (e.g., via a car dock)
- Offer voice input (commands) and output (text-to-speech) — iOS's Siri is not just for the blind, after all

- Offer hotkeys, not only to help those requiring a keyboard as their primary mode of input (e.g., blind users minimizing touchscreen use), but to help those who opt into using it for input (e.g., using a keyboard with an Android tablet in lieu of a traditional notebook or netbook)

Miscellaneous UI Tricks

While well-written GUI frameworks are better organized than XKCD's take on home organization, there are always a handful of tidbits that do, indeed, get categorized as "miscellaneous".

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having an appreciation for XKCD is welcome, but optional.

Full-Screen and Lights-Out Modes

Full-screen mode, in Android parlance, means removing any system-supplied "bars" from the screen: title bar, action bar, status bar, system bar, navigation bar, etc. You might use this for games, video players, digital book readers, or other places where the time spent in an activity is great enough to warrant removing some of the normal accouterments to free up space for whatever the activity itself is doing.

Lights-out mode, in Android parlance, is where you take the system bar or navigation bar and dim the widgets inside of them, such that the bar is still usable, but is less visually distracting. This is a new concept added in Android 3.0 and has no direct analogue in Android 1.x or 2.x.

Android 1.x/2.x

To have an activity be in full-screen mode, you have two choices:

1. Having the activity use a theme of `Theme.NoTitleBar.Fullscreen` (or some custom theme that inherits from `Theme.NoTitleBar.Fullscreen`)
2. Execute the following statements in `onCreate()` of your activity *before* calling `setContentView()`:

```
requestWindowFeature(Window.FEATURE_NO_TITLE);
getWindow().setFlags(WindowManager.LayoutParams.FLAG_FULLSCREEN,
                     WindowManager.LayoutParams.FLAG_FULLSCREEN);
```

The first statement removes the title bar or action bar. The second statement indicates that you want the activity to run in full-screen mode, hiding the status bar.

Android 4.0+

Things got significantly more messy once we started adding in the system bar (and, later, the navigation bar as the replacement for the system bar). Since these bars provide the user access to HOME, BACK, etc., it is usually important for them to be available. Android's behavior, therefore, varies in how you ask for something to happen and what then happens, based upon whether the device is a phone or a tablet.

The `Activities/FullScreen` sample project tries to enumerate some of the possibilities. On an Android 4.0 device, we have three `RadioButtons`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <RadioGroup
    android:id="@+id/screenStyle"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <RadioButton
      android:id="@+id/normal"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:checked="true"
      android:text="@string/display_normal"/>

    <RadioButton
      android:id="@+id/lowProfile"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/display_low_profile"/>

    <RadioButton
      android:id="@+id/hideNav"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/display_hide_navigation"/>
  </RadioGroup>

  <Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>

</RelativeLayout>
```

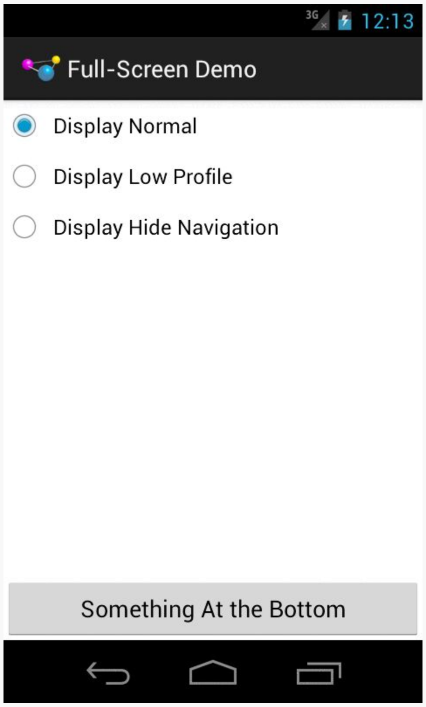


Figure 604: Sample UI, As Initially Launched on Android 4.0

…while on Android 4.1 or higher, we have another two possibilities:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <RadioGroup
    android:id="@+id/screenStyle"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <RadioButton
      android:id="@+id/normal"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:checked="true"
      android:text="@string/display_normal"/>

    <RadioButton
      android:id="@+id/lowProfile"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/display_low_profile"/>

    <RadioButton
      android:id="@+id/hideNav"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/display_hide_navigation"/>

    <RadioButton
      android:id="@+id/hideStatusBar"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/hide_status_bar"/>

    <RadioButton
      android:id="@+id/fullScreen"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:text="@string/display_full_screen"/>
  </RadioGroup>

  <Button
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:text="@string/something_at_the_bottom"/>

</RelativeLayout>
```

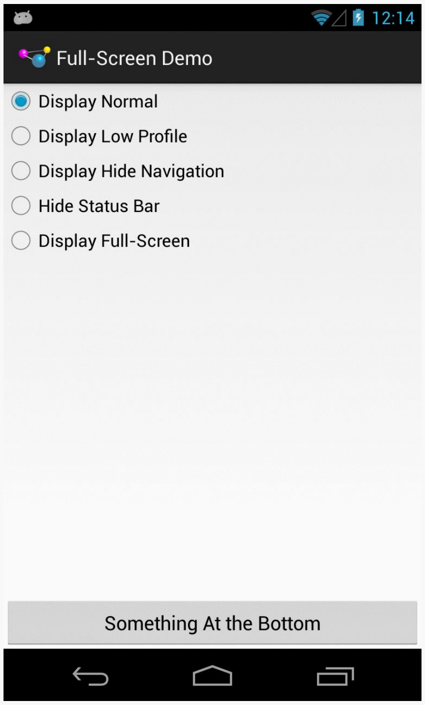

Figure 605: Sample UI, As Initially Launched on a Nexus 4/Android 4.2

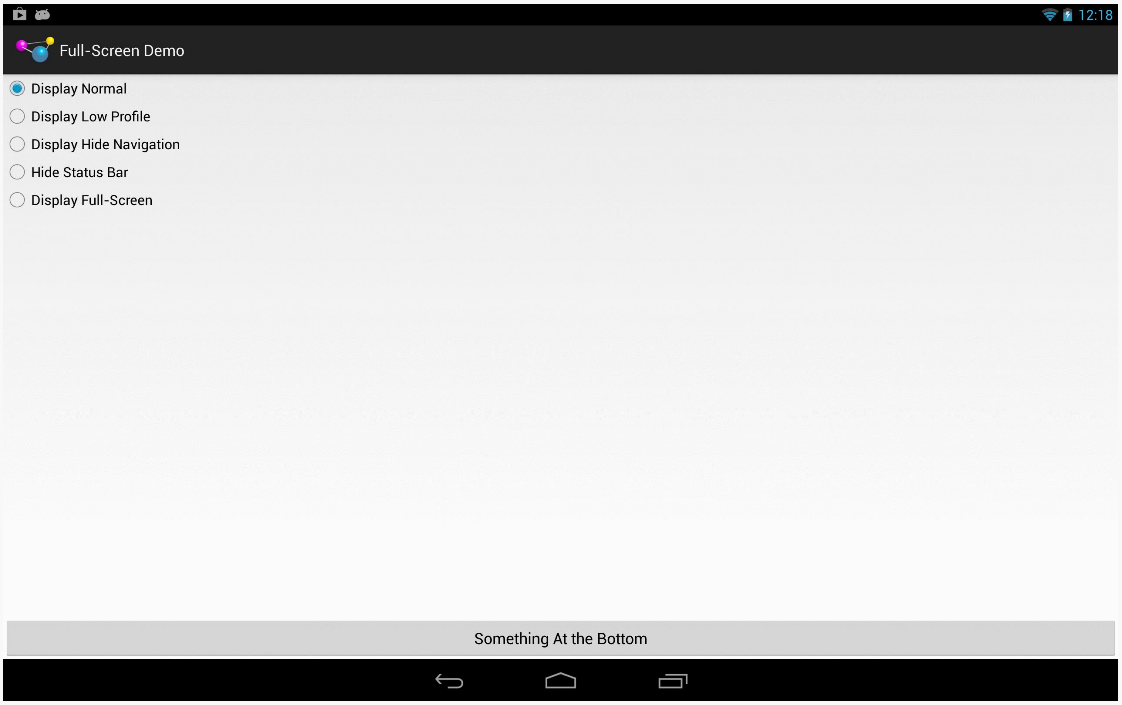
Controlling the full-screen and lights-out modes is managed via a call to `setSystemUiVisibility()`, a method on `View`. You pass in a value made up of an OR'd (`|`) set of flags indicating what you want the visibility to be, with the default being normal operation. Hence, in the screenshot above, you see a Nexus 4 in normal mode. Here is the same UI on a Nexus 10 in normal mode:



Full-Screen Demo

● Display Normal

○ Display Low Profile

○ Display Hide Navigation

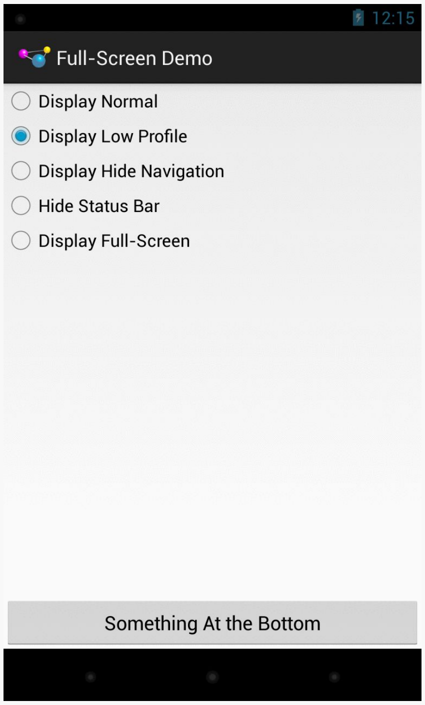
○ Hide Status Bar

○ Display Full-Screen

Something At the Bottom

Figure 606: Sample UI, As Initially Launched on a Nexus 10/Android 4.2

Lights-out, or low-profile mode, is achieved by calling `setSystemUiVisibility()` with the `View.SYSTEM_UI_FLAG_LOW_PROFILE` flag. This will dim the navigation or system bar, so the bar is there and the buttons are still active, but that they are less visually intrusive:



12:15

Full-Screen Demo

○ Display Normal

● Display Low Profile

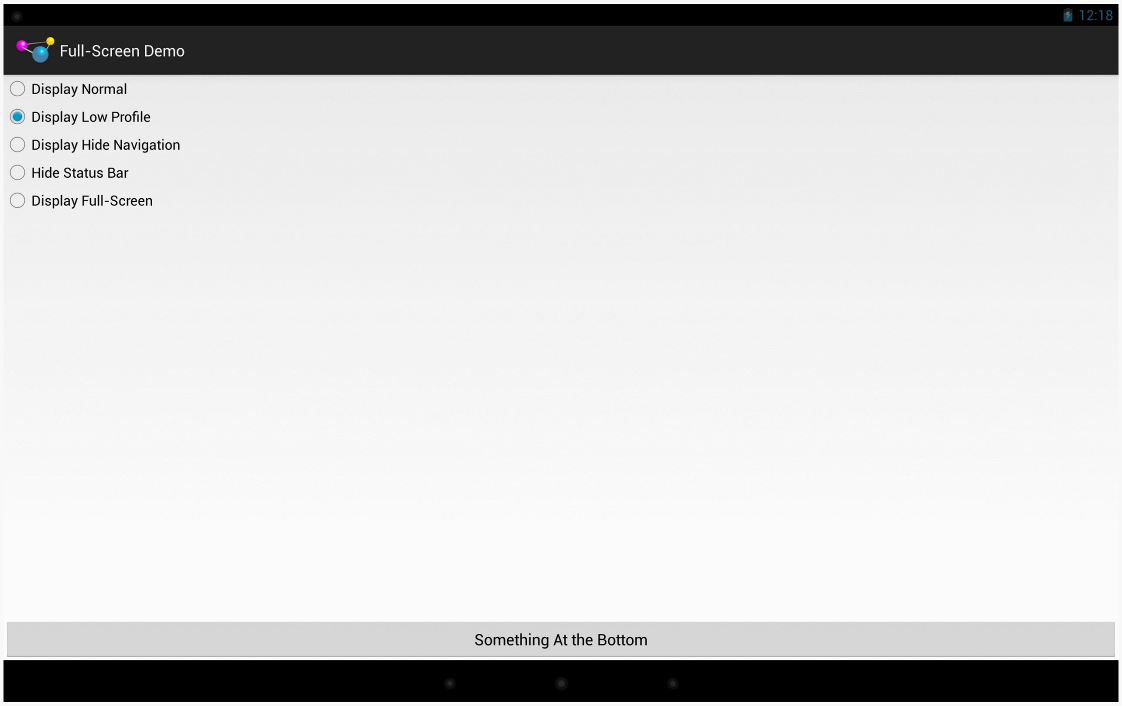
○ Display Hide Navigation

○ Hide Status Bar

○ Display Full-Screen

Something At the Bottom

Figure 607: Sample UI, Lights-Out Mode, Nexus 4/Android 4.2



12:18

Full-Screen Demo

○ Display Normal

● Display Low Profile

○ Display Hide Navigation

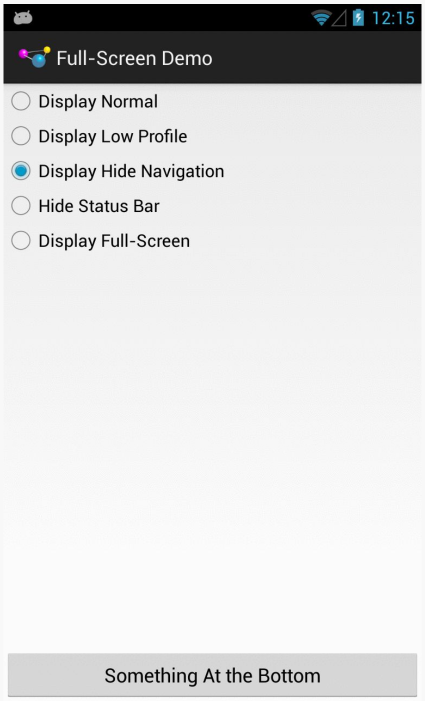
○ Hide Status Bar

○ Display Full-Screen

Something At the Bottom

Figure 608: Sample UI, Lights-Out Mode, Nexus 10/Android 4.2

You can temporarily hide the navigation bar (or system bar) by passing `View.SYSTEM_UI_FLAG_HIDE_NAVIGATION` to `setSystemUiVisibility()`. The bar will disappear, until the user touches the UI, in which case the bar reappears:



○ Display Normal
○ Display Low Profile
● Display Hide Navigation
○ Hide Status Bar
○ Display Full-Screen

Figure 609: Sample UI, Hidden-Navigation Mode, Nexus 4/Android 4.2

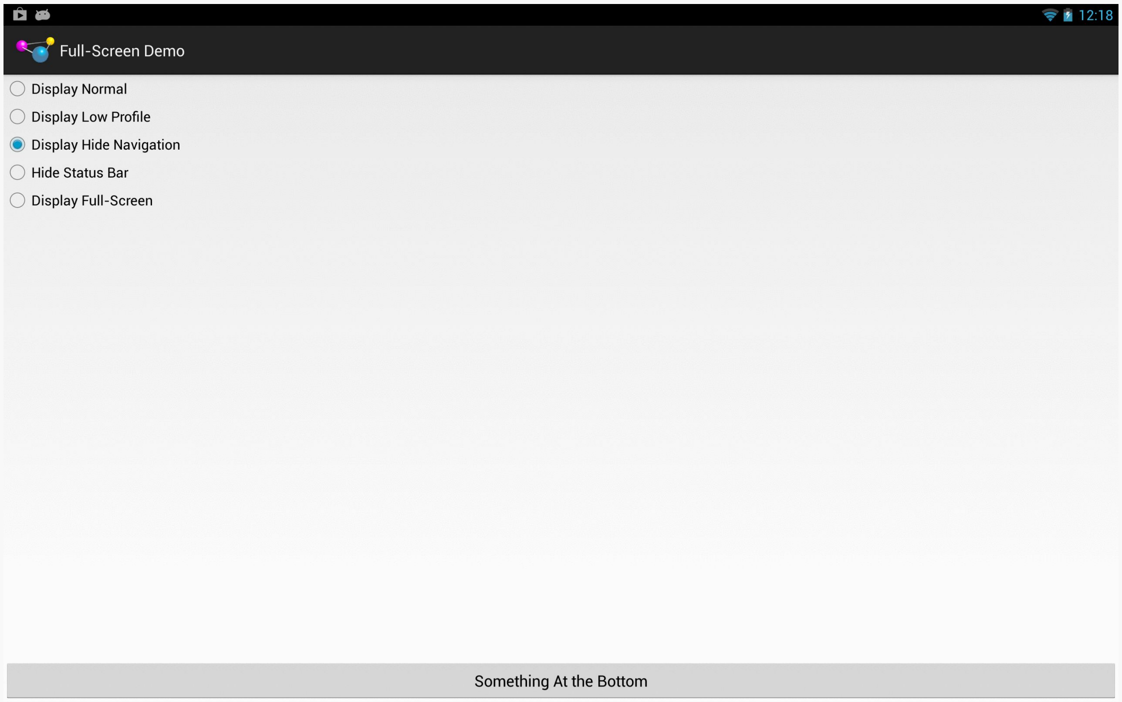


Figure 610: Sample UI, Hidden-Navigation Mode, Nexus 10/Android 4.2

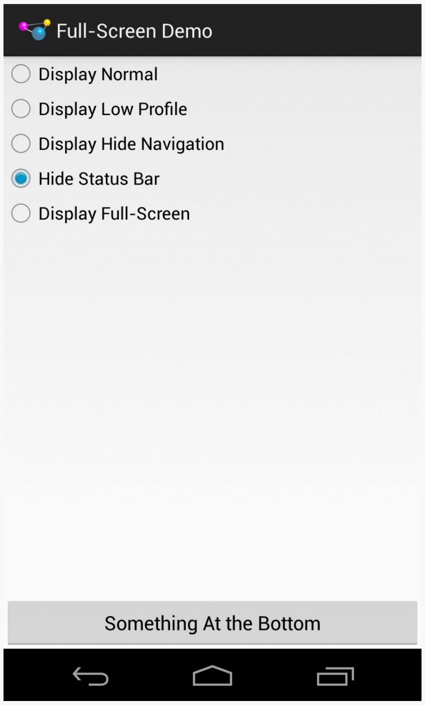
Similarly, you can hide the status bar by passing `View.SYSTEM_UI_FLAG_FULLSCREEN` to `setSystemUiVisibility()`. However, despite this flag's name, it does not affect the navigation or system bar:



Full-Screen Demo

○ Display Normal

○ Display Low Profile

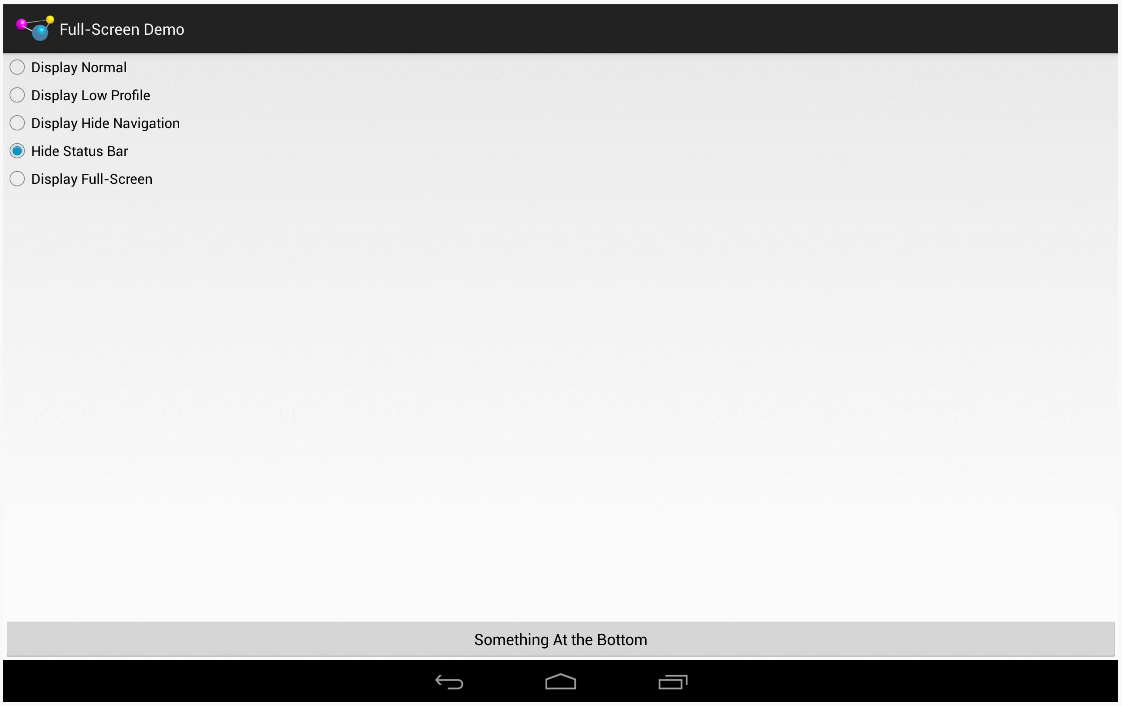
○ Display Hide Navigation

● Hide Status Bar

○ Display Full-Screen

Something At the Bottom

Figure 611: Sample UI, "Full-Screen" Mode, Nexus 4/Android 4.2



Full-Screen Demo

○ Display Normal

○ Display Low Profile

○ Display Hide Navigation

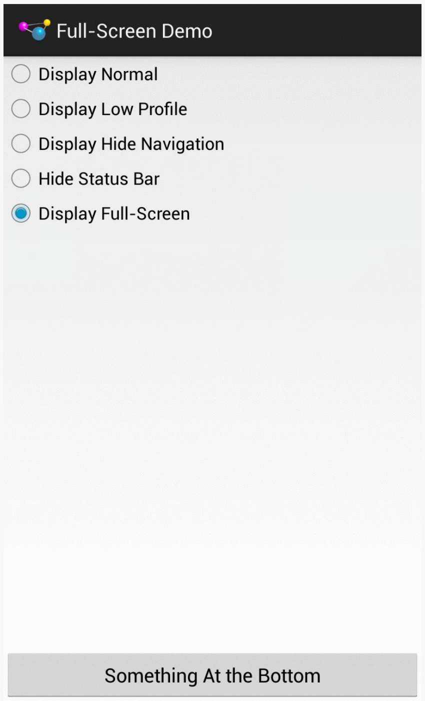
● Hide Status Bar

○ Display Full-Screen

Something At the Bottom

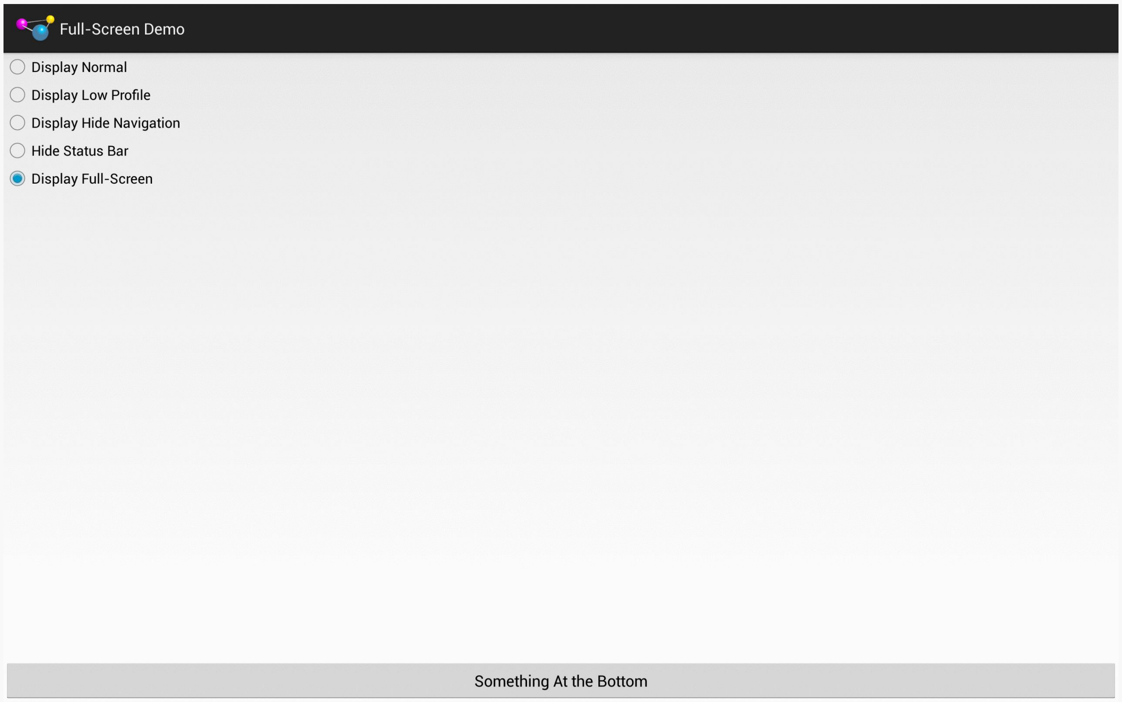
Figure 612: Sample UI, "Full-Screen" Mode, Nexus 10/Android 4.2

Hence, to hide both the status bar and the navigation or system bar, you need to pass both flags (`View.SYSTEM_UI_FLAG_FULLSCREEN | View.SYSTEM_UI_FLAG_HIDE_NAVIGATION`):



○ Display Normal
○ Display Low Profile
○ Display Hide Navigation
○ Hide Status Bar
● Display Full-Screen

Figure 613: Sample UI, True Full-Screen Mode, Nexus 4/Android 4.2



Full-Screen Demo

○ Display Normal
○ Display Low Profile
○ Display Hide Navigation
○ Hide Status Bar
● Display Full-Screen

Something At the Bottom

Figure 614: Sample UI, True Full-Screen Mode, Nexus 10/Android 4.2

Note that showing and hiding the `ActionBar` is also possible, via calls to `show()` and `hide()`, respectively.

Offering a Delayed Timeout

Android makes it easy for activities to keep the screen on while the activity is in the foreground, by means of `android:keepScreenOn` and `setKeepScreenOn()`.

However, these are very blunt instruments, and too many developers simply ask to keep the screen on constantly, even when that is not needed and can cause excessive battery drain. That is because it is very easy to *always* keeps the screen on.

Say, for example, you are playing a game. Keeping the screen on while the game is being played is probably a good thing, particularly if the game does not require constant interaction with the screen. However, if you press the in-game pause button, the game might keep the screen on while the game is paused. This might lead you to press pause, put down your tablet (expecting it to fall asleep in a normal period of time), and then have the tablet keep going and going and going… until the battery runs dead.

Whether you use `setKeepScreenOn()` or directly use a `WakeLock`, it is useful to think of three tiers of user interaction.

The first tier is when your app is doing its "one big thing": playing the game, playing the video, displaying the digital book, etc. If you expect that there will be periods of time when the user is actively engaged with your app, but is not interacting with the screen, keep the screen on.

The second tier is when your app is delivering something to the user that *probably* would get used without interaction in the short term, but not indefinitely. For example, a game might reasonably expect that 15 seconds could be too short to have the screen time out, but if the user has not done anything in 5-10 minutes, most likely they are not in front of the game. Similarly, a digital book reader should not try to keep the screen on for an hour without user interaction.

The third tier is when your app is doing anything other than the main content, where normal device behavior should resume. A video player might keep the screen on while the video is playing, but if the video ends, normal behavior should resume. After all, if the person who had been watching the video fell asleep, they will not be in position to press a power button.

The first and third tiers are fairly easy from a programming standpoint. Just `acquire()` and `release()` the `WakeLock`, or toggle `setKeepScreenOn()` between `true` and `false`.

The second tier — where you are willing to have a screen timeout, just not too quickly — requires you to add a bit more smarts to your app. A simple, low-overhead way of addressing this is to have a `postDelayed()` loop, to get a `Runnable` control every 5-10 seconds. Each time the user interacts with your app, update a `lastInteraction` timestamp. The `Runnable` compares `lastInteraction` with the current time, and if it exceeds some threshold, release the `WakeLock` or call `setKeepScreenOn(false)`. When the user interacts again, though, you will need to re-acquire the `WakeLock` or call `setKeepScreenOn(true)`. Basically, you have your *own* inactivity timing mechanism to control when you are inhibiting normal inactivity behavior or not.

To see the second tier in action, take a look at the [`MiscUI/DelayedTimeout`]() sample project.

The UI is a simple button. We want to keep the screen awake while the user is using the button, but let it fall asleep after a period of inactivity that *we* control. To accomplish this, we will use a `postDelayed()` loop, to get control every 15 seconds to see if there has been user activity:

```
package com.commonsware.android.timeout;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;

public class MainActivity extends Activity implements Runnable {
  private static int TIMEOUT_POLL_PERIOD=15000; // 15 seconds
  private static int TIMEOUT_PERIOD=300000; // 5 minutes
  private View content=null;
  private long lastActivity=SystemClock.uptimeMillis();

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    content=findViewById(android.R.id.content);
    content.setKeepScreenOn(true);
    run();
  }

  @Override
  public void onDestroy() {
    content.removeCallbacks(this);

    super.onDestroy();
  }

  @Override
  public void run() {
    if ((SystemClock.uptimeMillis() - lastActivity) > TIMEOUT_PERIOD) {
      content.setKeepScreenOn(false);
    }

    content.postDelayed(this, TIMEOUT_POLL_PERIOD);
  }

  public void onClick(View v) {
    lastActivity=SystemClock.uptimeMillis();
  }
}
```

In `onCreate()`, we call `setKeepScreenOn(true)` to keep the screen on, regardless of what the user's default timeout is. Then, we call the `run()` method from our `Runnable` interface (implemented on the activity itself). `run()` sees if 5 minutes has elapsed since the last bit of user activity (initially set to be the time the activity launches). If 5 minutes has elapsed, we revert to normal screen-timeout behavior with `setKeepScreenOn(false)`. We also schedule ourselves, as a `Runnable`, to get control again in 15 seconds, to see if 5 minutes has elapsed since the last-seen activity. Our button's `onClick()` method simply updates the last-seen timestamp, and `onDestroy()` cleans up our `postDelayed()` loop by calling `removeCallbacks()` to stop invoking our `Runnable`.

The net is that the device's screen will remain on for 5 minutes since the last time the user taps the button, even if the user's default screen timeout is set to shorter than 5 minutes. Yet, at the same time, we do not keep the screen on *forever*, causing unnecessary battery drain.

Note that to test this, you will probably need to unplug your USB cable after installing the app on the device (since many developers have it set up to keep the screen on while plugged in). Also, you will need to set your device's screen timeout to be under 5 minutes, if it is not set that way already.

This is a primitive implementation, missing lots of stuff that you would want in production code (e.g., it never calls `setKeepScreenOn(true)` if we flipped it to `false` but *then* tap the button). And the complexity of determining if the user interacted with the screen will be tied to the complexity of your UI.

That being said, by having a more intelligent use of `WakeLock` and `setKeepScreenOn()`, you can deliver value to the user while not accidentally causing excessive battery drain. Users do not always remember to press the power button, so you need to make sure that just because the user made a mistake, that you do not make it worse.

Event Bus Alternatives

Earlier in the book, we covered the concept of an event bus as a way of communicating between portions of our app, focusing on one event bus implementation: greenrobot's EventBus. Later, in the chapter on broadcast `Intent` objects, we briefly covered `LocalBroadcastManager`.

However, those are not the only event buses available for Android, and others may fit your needs better. In this chapter, we will explore these and other event bus implementations, to compare and contrast.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapters on basic event bus usage, broadcast `Intents`, `AlarmManager` and the scheduled service pattern, and `Notifications`.

A Brief Note About the Sample Apps

The sample apps in this chapter are generally designed to run forever.

It is unlikely that you really want them to run forever, though. Hence, please uninstall each sample after experimenting with it, particularly if you are testing on hardware, such as your personal phone. Your battery will appreciate it.

Standard Intents as Event Bus

You can think of the standard `Intent` and `<intent-filter>` system as a three-channel event bus:

- One channel is used for starting activities
- One channel is used for starting or binding to services
- One channel is used for more ad-hoc "broadcast" events

The component starting an activity does not need to communicate directly with code for that activity — in fact, often times this is impossible, as they are separate apps running in separate processes. Instead, the component starting an activity sends an event indicating the particular operation to be performed (e.g., view this URL), and Android and the user determine which of candidate consumers is the one to process that event.

However, broadcast `Intent` objects are a closer analogue to a real "event bus", in that an event produced by somebody can be consumed by zero, one, or several subscribed consumers, based upon the filtering provided by `<intent-filter>` elements in the manifest or `IntentFilter` objects for use with `registerReceiver()`.

In theory, you could use broadcast `Intent` objects as the backbone for a fairly flexible event bus within your app. In practice, this is not usually a good idea:

- Each broadcast involves inter-process communication (IPC), even if the event producer and consumer(s) are in the same process. This adds overhead.
- Because broadcasts are intrinsically IPC, you have to take security into account, to ensure only authorized producers can publish events that the consumers pick up.

However, if you specifically need a cross-process event bus, such as between a suite of related apps, using a broadcast `Intent` is a very likely choice.

LocalBroadcastManager as Event Bus

As was briefly noted earlier in the book, the Android Support package offers a `LocalBroadcastManager`. This is designed to offer an event bus with a feel very similar to classic broadcast `Intent` objects, but local to your process. Not only does this avoid IPC overhead, but it improves security, as other apps have no means of spying on your internal communications.

`LocalBroadcastManager` is supplied by both the `support-v4` and `support-v13` libraries. Generally speaking, if your `minSdkVersion` is less than 13, you probably should choose `support-v4`.

A Simple LocalBroadcastManager Sample

Let's see LocalBroadcastManager in action via the Intents/Local sample project.

Here, our LocalActivity sends a command to a NoticeService from onCreate():

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    notice=(TextView)findViewById(R.id.notice);
    startService(new Intent(this, NoticeService.class));
  }
```

The NoticeService simply delays five seconds, then sends a local broadcast using LocalBroadcastManager:

```
package com.commonsware.android.localcast;

import android.app.IntentService;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.LocalBroadcastManager;

public class NoticeService extends IntentService {
  public static final String BROADCAST=
      "com.commonsware.android.localcast.NoticeService.BROADCAST";
  private static Intent broadcast=new Intent(BROADCAST);

  public NoticeService() {
    super("NoticeService");
  }

  @Override
  protected void onHandleIntent(Intent intent) {
    SystemClock.sleep(5000);
    LocalBroadcastManager.getInstance(this).sendBroadcast(broadcast);
  }
}
```

Specifically, you get at your process' singleton instance of LocalBroadcastManager by calling getInstance() on the LocalBroadcastManager class.

Our LocalActivity registers for this local broadcast in onResume(), once again using getInstance() on LocalBroadcastManager:

```
  @Override
  public void onResume() {
    super.onResume();

    IntentFilter filter=new IntentFilter(NoticeService.BROADCAST);
    LocalBroadcastManager.getInstance(this).registerReceiver(onNotice,
                                                            filter);
  }
```

LocalActivity unregisters for this broadcast in onPause():

```
  @Override
  public void onPause() {
    super.onPause();

    LocalBroadcastManager.getInstance(this).unregisterReceiver(onNotice);
  }
```

The BroadcastReceiver simply updates a TextView with the current date and time:

```
  private BroadcastReceiver onNotice=new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
      notice.setText(new Date().toString());
    }
  };
```

If you start up this activity, you will see a "(waiting...)" bit of placeholder text for about five seconds, before having that be replaced by the current date and time.

The BroadcastReceiver, the IntentFilter, and the Intent being broadcast are the same as we would use with full broadcasts. It is merely how we are using them — via LocalBroadcastManager – that dictates they are local to our process versus the standard device-wide broadcasts.

A More Elaborate Sample

That sample is not terribly realistic, but it is simple.

A somewhat more realistic sample is the one using WakefulIntentService from earlier in the book. However, that app was also fairly unrealistic, at least in terms of its output, as LogCat is not very useful to users. A more typical approach for a background service like this is to notify a foreground Activity, if there is one, about work that was accomplished, and otherwise display a Notification. We described that pattern in the chapter on Notifications.

In the EventBus/LocalBroadcastManager sample project, we blend:

- Having a service wake up every so often to do some work
- Arranging to let the user know of background accomplishments via an Activity or a Notification

- Using LocalBroadcastManager to keep the communications in-process

The Activity

The EventDemoActivity that is our app's entry point is a bit similar to the one used in the WakefulIntentService demo, in that it calls scheduleAlarms() on PollReceiver to set up the AlarmManager schedule:

```
package com.commonsware.android.eventbus.lbm;

import android.app.Activity;
import android.os.Bundle;

public class EventDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager().beginTransaction()
                          .add(android.R.id.content,
                               new EventLogFragment()).commit();

      PollReceiver.scheduleAlarms(this);
    }
  }
}
```

However, we also put an EventLogFragment on the screen, if it is not already there, via a FragmentTransaction. This is where we will display events coming from the service, while our activity is in the foreground. We will examine EventLogFragment and how it participates in the event bus shortly.

The PollReceiver

PollReceiver is unchanged from its WakefulIntentService demo original edition. This BroadcastReceiver will be used both for getting control at boot time (to reschedule the alarms, wiped on the reboot) and for sending the work to the ScheduledService for processing:

```
package com.commonsware.android.eventbus.lbm;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonsware.cwac.wakeful.WakefulIntentService;
```

```
public class PollReceiver extends BroadcastReceiver {
  private static final int PERIOD=15000; // 15 seconds
  private static final int INITIAL_DELAY=1000; // 1 second

  @Override
  public void onReceive(Context ctxt, Intent i) {
    if (i.getAction() == null) {
      WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
    }
    else {
      scheduleAlarms(ctxt);
    }
  }

  static void scheduleAlarms(Context ctxt) {
    AlarmManager mgr=
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
                     SystemClock.elapsedRealtime() + INITIAL_DELAY,
                     PERIOD, pi);

  }
}
```

Note that on Android 5.1 and higher, despite the fact that we are asking for a 15-second polling period, the actual polling period will be one minute, as `AlarmManager` no longer supports sub-minute polling periods.

ScheduledService and Sending Events

Before, our `ScheduledService` just dumped a message to LogCat. This was crude but effective for what that demo required. Now, we want our service to let the UI layer know about some work that was accomplished, or to raise a `Notification`.

In this case, the “work” is generating a random number.

```
package com.commonsware.android.eventbus.lbm;

import android.app.Notification;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.support.v4.app.NotificationCompat;
import android.support.v4.content.LocalBroadcastManager;
import java.util.Calendar;
import java.util.Random;
import com.commonsware.cwac.wakeful.WakefulIntentService;

public class ScheduledService extends WakefulIntentService {
  private static int NOTIFY_ID=1337;
  private Random rng=new Random();

  public ScheduledService() {
    super("ScheduledService");
  }

  @Override
  protected void doWakefulWork(Intent intent) {
    Intent event=new Intent(EventLogFragment.ACTION_EVENT);
    long now=Calendar.getInstance().getTimeInMillis();
    int random=rng.nextInt();

    event.putExtra(EventLogFragment.EXTRA_RANDOM, random);
    event.putExtra(EventLogFragment.EXTRA_TIME, now);

    if (!LocalBroadcastManager.getInstance(this).sendBroadcast(event)) {
      NotificationCompat.Builder b=new NotificationCompat.Builder(this);
      Intent ui=new Intent(this, EventDemoActivity.class);

      b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
       .setContentTitle(getString(R.string.notif_title))
       .setContentText(Integer.toHexString(random))
       .setSmallIcon(android.R.drawable.stat_notify_more)
       .setTicker(getString(R.string.notif_title))
       .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

      NotificationManager mgr=
          (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

      mgr.notify(NOTIFY_ID, b.build());
    }
  }
}
```

LocalBroadcastManager, as we have seen, uses the same Intent and IntentFilter and BroadcastReceiver structures as are used with regular broadcasts, just via a singleton message bus (LocalBroadcastManager.getInstance()) instead of the framework's IPC engine. Hence, we need an Intent that represents the message, so we create one, using an action string published by the EventLogFragment. We also attach two extras to this Intent, using keys published by EventLogFragment: the random number, plus the time of this event.

We then call sendBroadcast() on the singleton LocalBroadcastManager. This returns a boolean value, true indicating that one or more locally-registered receivers were delivered the Intent, false otherwise. Hence, if sendBroadcast() returns true, we can assume that somebody in the UI layer picked up our message and is now responsible for displaying these results to the user.

Conversely, if sendBroadcast() returns false, we must assume that the UI layer did not receive the message, and so the service should inform the user directly, in this case via a Notification, showing the random number as the text in the notification drawer.

EventLogFragment and Receiving Events

EventLogFragment, therefore, is responsible for:

- Registering (and unregistering) to receive the broadcasts to be sent locally by the service
- Doing something with those events to inform the user about the all-important random numbers

In this case, we use a retained ListFragment with a ListView set into transcript mode, meaning that entries are added at the bottom, and older entries scroll off the top, like a chat transcript:

```
package com.commonsware.android.eventbus.lbm;

import android.annotation.SuppressLint;
import android.app.ListFragment;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.content.IntentFilter;
import android.os.Bundle;
import android.support.v4.content.LocalBroadcastManager;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.ArrayList;
import java.util.Date;
import java.util.Locale;

public class EventLogFragment extends ListFragment {
  static final String EXTRA_RANDOM="r";
  static final String EXTRA_TIME="t";
  static final String ACTION_EVENT="e";
  private EventLogAdapter adapter=null;

  @Override
  public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    setRetainInstance(true);
    getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);

    if (adapter == null) {
      adapter=new EventLogAdapter();
    }

    setListAdapter(adapter);
  }

  @Override
  public void onResume() {
    super.onResume();

    IntentFilter filter=new IntentFilter(ACTION_EVENT);

    LocalBroadcastManager.getInstance(getActivity())
                         .registerReceiver(onEvent, filter);
  }

  @Override
  public void onPause() {
    LocalBroadcastManager.getInstance(getActivity())
                         .unregisterReceiver(onEvent);

    super.onPause();
  }

  class EventLogAdapter extends ArrayAdapter<Intent> {
    DateFormat fmt=new SimpleDateFormat("HH:mm:ss", Locale.US);

    public EventLogAdapter() {
      super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<Intent>());
    }

    @SuppressLint("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
      TextView row=
          (TextView)super.getView(position, convertView, parent);
      Intent event=getItem(position);
      Date date=new Date(event.getLongExtra(EXTRA_TIME, 0));

      row.setText(String.format("%s = %x", fmt.format(date),
                                event.getIntExtra(EXTRA_RANDOM, -1)));

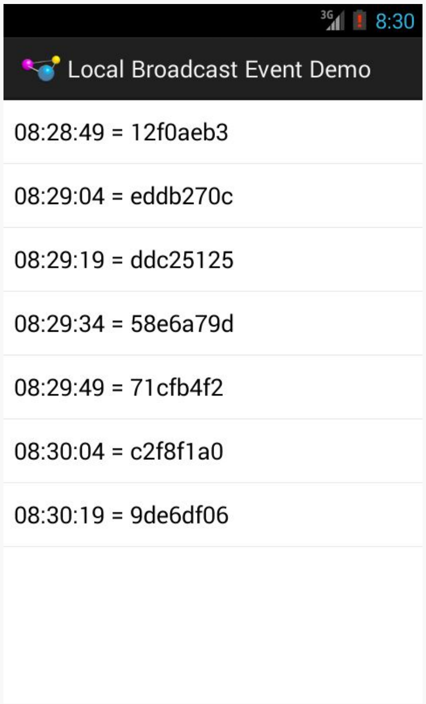
      return(row);
    }
  }

  private BroadcastReceiver onEvent=new BroadcastReceiver() {
    @Override
    public void onReceive(Context context, Intent intent) {
      adapter.add(intent);
    }
  };
}
```

The ListAdapter for the ListView is an EventLogAdapter, an ArrayAdapter for Intent objects, where in getView() we populate the list rows with the time and random value.

In `onResume()` and `onPause()`, we register for (and unregister from) the desired broadcast, pointing to an `onEvent` `BroadcastReceiver` that adds the incoming `Intent` to the `EventLogAdapter`. That, in turn, updates the `ListView`.

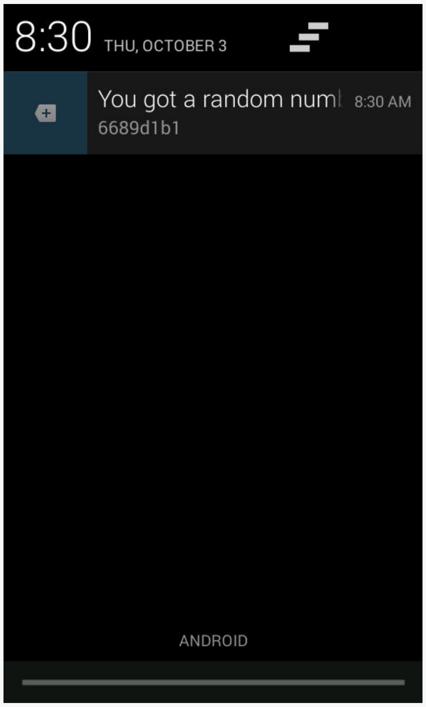
The result is that while the activity is in the foreground, the events will be displayed to the user directly:



```
08:28:49 = 12f0aeb3
08:29:04 = eddb270c
08:29:19 = ddc25125
08:29:34 = 58e6a79d
08:29:49 = 71cfb4f2
08:30:04 = c2f8f1a0
08:30:19 = 9de6df06
```

Figure 615: LocalBroadcastManager as Event Bus, Demo Activity

Whereas if events are processed while the activity is not in the foreground, a `Notification` will be shown with the last results:



You got a random num 8:30 AM
6689d1b1

Figure 616: LocalBroadcastManager as Event Bus, Demo Notification

Reference, Not Value

When you send a "real" broadcast Intent, your Intent is converted into a byte array (courtesy of the Parcelable interface) and transmitted to other processes. This occurs even if the recipient of the Intent is within your own process — that is what makes LocalBroadcastManager faster, as it avoids the inter-process communication.

However, since LocalBroadcastManager does not need to send your Intent between processes, that means it does not turn your Intent into a byte array. Instead, it just passes the Intent along to any registered BroadcastReceiver with a matching IntentFilter. In effect, while "real" broadcasts are pass-by-value, local broadcasts are pass-by-reference.

This can have subtle side effects.

For example, there are a few ways that you can put a collection into an Intent extra, such as putStringArrayListExtra(). This takes an ArrayList as a parameter. With a real broadcast, once you send the broadcast, it does not matter what happens to the original ArrayList — the rest of the system is working off of a copy. With a local broadcast, though, the Intent holds onto the ArrayList you supplied via the setter.

If you change that ArrayList elsewhere (e.g., clear it for reuse), the recipient of the Intent will see those changes.

Similarly, if you put a Parcelable object in an extra, the Intent holds onto the actual object while it is being broadcast locally, whereas a real broadcast would have resulted in a copy. If you change the object while the broadcast is in progress, the recipient of the broadcast will see those changes.

This can be a feature, not a bug, when used properly. But, regardless, it is a non-trivial difference, one that you will need to keep in mind.

Limitations of Local

While LocalBroadcastManager is certainly useful, it has some serious limitations.

The biggest is that it is purely local. While traditional broadcasts can either be internal (via setPackage()) or device-wide, LocalBroadcastManager only handles the local case. Hence, anything that might involve other processes, such as a PendingIntent, will not use LocalBroadcastManager. For example, you cannot register a receiver through LocalBroadcastManager, then use a getBroadcast() PendingIntent to try to reach that BroadcastReceiver. The PendingIntent will use the regular broadcast Intent mechanism, which the local-only receiver will not respond to.

Similarly, since a manifest-registered BroadcastReceiver is spawned via the operating system upon receipt of a matching true broadcast, you cannot use such receivers with LocalBroadcastManager. Only a BroadcastReceiver registered via registerReceiver() on the LocalBroadcastManager will use the LocalBroadcastManager. For example, you cannot implement the Activity-or-Notification pattern that we will see later in this book via LocalBroadcastManager.

Also, LocalBroadcastManager does not offer ordered or sticky broadcasts.

Square's Otto

LocalBroadcastManager has two major advantages:

1. It is part of the Android Support package, and therefore it is part of the officially-supported corner of the Android ecosystem

2. It works like traditional broadcasts, which will make it easier for some developers to "wrap their heads around" it

However, that same dependency on the Intent and IntentFilter structure adds bulk and limits flexibility. Hence, it is not surprising that there are alternative event buses to LocalBroadcastManager.

Java, outside of Android, has had a few event bus implementations. One of the more popular ones in recent years has been the event bus that is part of Google's Guava family of libraries. However, while a Java event bus perhaps can be used on Android, it may not be *optimal* for Android. Hence, a few projects have started with Guava's event bus implementation and have extended it to be a bit more Android-aware, or perhaps even Android-centric.

Square's Otto is one such event bus.

Basic Usage and Sample App

With LocalBroadcastManager, you work with a singleton instance, calling methods like registerReceiver() and sendBroadcast() upon it to subscribe to and raise events, respectively.

With Otto, you work with a singleton instance of a Bus, calling methods like register() and post() upon it to subscribe to and raise events, respectively.

Hence, at the core, Otto behaves much like LocalBroadcastManager. What differs is in the nature of the events and the subscribers.

With LocalBroadcastManager, events are Intent objects. With Otto, an event can be whatever data type you like. Hence, you can create your own ...Event classes, holding whatever bits of data, in whatever data types suit you — you are not restricted to things that can go in an Intent extra. However, as has been noted on occasion, "with great power comes great responsibility", and so you will need to ensure that you use this carefully and do not wind up creating some sort of memory leak as a result. For example, do not pass something from an Activity to a Service via a custom event, where the Service will hold onto that information for a long time, if that "something" holds a reference back to the Activity.

With LocalBroadcastManager, subscribers are BroadcastReceivers, who use an IntentFilter to identify which events they are interested in. With Otto, subscribers are any class you want. A special @Subscribe annotation is used to both indicate what sorts of events the subscriber is interested in (based on the parameter to the annotated method) and what method should be invoked when a matching event is raised (the annotated method itself). Hence, not only do you use custom event classes to allow you to carry along custom data, but you use them as a filtering mechanism, much like you would use custom action strings with LocalBroadcastManager.

To see how this works, take a look at the EventBus/Otto sample project, which is a clone of the EventBus/LocalBroadcastManager demo, but one where we substitute in Otto as a replacement for LocalBroadcastManager. Our activity and PollReceiver are unchanged: they did not directly interact with LocalBroadcastManager and do not need to interact with Otto. The changes are isolated in our ScheduledService and EventLogFragment.

ScheduledService and Sending Events

First, we need a singleton Otto Bus instance, that serves the same basic role as does the singleton LocalBroadcastManager retrieved by getInstance(). However, Otto does not offer a similar getInstance() method. It is up to you to create and manage your own singleton. This gives you greater flexibility, such as having multiple independent buses for disparate event channels. However, it does mean that you need to put a Bus somewhere.

Fortunately, Bus does not need a Context, and so we can initialize a singleton as a static data member somewhere. Here, the “somewhere” is on ScheduledService:

```
  static final Bus bus=new Bus(ThreadEnforcer.ANY);
```

The parameter to the Bus constructor is the threading rule to be enforced on this bus. If you attempt to use the Bus on a thread that is disallowed by the supplied ThreadEnforcer, you will get an IllegalStateException at runtime. ThreadEnforcer.MAIN ensures that you only use the Bus on Android’s main application thread. ThreadEnforcer.ANY allows the use of the Bus on any thread… though then you will need to do your own work to route control back to the main application thread, if needed.

Now, when it comes time for us to send a message, we can call post() on the Bus, supplying whatever sort of event object that we want:

```
  @Override
  protected void doWakefulWork(Intent intent) {
    bus.post(new RandomEvent(rng.nextInt()));
  }
```

Here, we are posting an instance of a `RandomEvent`:

```
package com.commonsware.android.eventbus.otto;

import java.util.Calendar;
import java.util.Date;

public class RandomEvent {
  Date when=Calendar.getInstance().getTime();
  int value;

  RandomEvent(int value) {
    this.value=value;
  }
}
```

EventLogFragment and Receiving Events

Over in our `EventLogFragment`, rather than register and unregister a `BroadcastReceiver` in `onResume()` and `onPause()`, we register and unregister the fragment itself with the singleton `Bus`:

```
  @Override
  public void onResume() {
    super.onResume();

    ScheduledService.bus.register(this);
  }

  @Override
  public void onPause() {
    ScheduledService.bus.unregister(this);

    super.onPause();
  }
```

Now, we can use the `@Subscribe` annotation to arrange to receive any event we want that is delivered via this `Bus`, based on event class. Since we want to receive `RandomEvent` messages, we merely need to have a `public void` method, taking a `RandomEvent` parameter, marked with the `@Subscribe` annotation, such as `onRandomEvent()`:

```
  @Subscribe
  public void onRandomEvent(final RandomEvent event) {
    if (getActivity() != null) {
      getActivity().runOnUiThread(new Runnable() {
        @Override
        public void run() {
          adapter.add(event);
        }
      });
    }
  }
```

Note that the method name can be anything we want, as it is the annotation, not the method name, that identifies this as being an event handling method.

In this method, we can do what we need to with our RandomEvent. In our case, EventLogAdapter has been modified to be an ArrayAdapter of RandomEvent, as opposed to being an ArrayAdapter of Intent as in the earlier sample. What we want to do is append the new RandomEvent to the end of the adapter.

However, while LocalBroadcastManager will only deliver events on the main application thread, Otto delivers events *on whatever thread they were sent upon*. In this case, we know that this will be a background thread, the one used by the IntentService. We cannot safely modify the EventLogAdapter on a background thread, as that will update the UI. So, we need to call add() on the adapter on the main application thread. Here, we use runOnUiThread() to pass a Runnable to the main application thread containing our add() call. However, it is possible that we do not have an activity right this moment, such as due to a configuration change. This demo simply drops those events; a production-grade app might wish to queue those within the fragment and apply them in some later lifecycle event (e.g., onAttach(), onActivityCreated()).

Handling the "Nobody's Home" Scenario

What is missing, though, is the logic we used in LocalBroadcastManager to determine if somebody received our message, where we raised a Notification if that is not the case.

The solution for this with Otto is to have ScheduledService listen for DeadEvent events. A DeadEvent is delivered on the bus when an attempt to deliver some other event failed with no subscribers. The DeadEvent has an event field that contains the original event that failed to be delivered. If we can get the DeadEvent, we know the RandomEvent was not handled at the UI layer, and we can raise the Notification.

To do this, not only do we need to register EventLogFragment with the Bus, but we also need to register ScheduledService itself, so it can listen for a DeadEvent:

```
  @Override
  public void onCreate() {
    super.onCreate();

    bus.register(this);
  }
```

```
  @Override
  public void onDestroy() {
    bus.unregister(this);

    super.onDestroy();
  }
```

Then, our Notification logic can be moved into some method that has the @Subscribe annotation and a DeadEvent parameter:

```
  @Subscribe
  public void onDeadEvent(DeadEvent braiiiiiiinz) {
    RandomEvent original=(RandomEvent)braiiiiiiinz.event;
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);
    Intent ui=new Intent(this, EventDemoActivity.class);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
     .setContentTitle(getString(R.string.notif_title))
     .setContentText(Integer.toHexString(original.value))
     .setSmallIcon(android.R.drawable.stat_notify_more)
     .setTicker(getString(R.string.notif_title))
     .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

    NotificationManager mgr=
        (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
  }
```

Event Producers

Standard broadcasts in Android can be broadcast in a "sticky" fashion. When an app registers for a sticky broadcast, not only does the app get any future matching broadcasts, but immediately it gets the last-broadcast Intent that matches.

LocalBroadcastManager does not offer a similar capability, and neither does Otto in the direct sense. However, Otto does have the concept of event producers, which can play a similar role.

You can annotate a method with @Produce, to indicate that it is an event producer. The method should take no parameters, but its return type should be one of your event classes (e.g., RandomEvent).

When an app calls `register()` on a `Bus`, Otto finds all of the `@Subscribe`-annotated methods and keeps track of them, for dispatching future events. However, in addition, Otto also checks to see if there is a matching event producer for the event type requested by the `@Subscribe` method. If there is a matching producer, the producer method is called, and that event is passed to the subscriber immediately, as part of the `register()` processing.

So, if we had a `@Produce` method in the sample app that returned a `RandomEvent`, the `onRandomEvent()` method would have been invoked immediately with the result of calling that `@Produce` method, in addition to being called with any future events raised by the app.

This is useful for cases where there may be interruptions in event processing. For example, in a configuration change, your activity and fragments are destroyed and recreated by default. But if you are posting events on a background thread, as we did in the sample, those events could occur while a configuration change is in process, and there may not be an available subscriber for the event right at that moment. The `@Produce` pattern would allow you to cache that result and give it to the new activity or fragment.

Revisiting greenrobot's EventBus

Of the three major in-process event bus implementations, greenrobot's EventBus is slightly less popular than `LocalBroadcastManager` and Otto. `LocalBroadcastManager` is part of the Android SDK (albeit in the Android Support package), and so it will gain popularity from that status alone. Square has a vast range of libraries and has a following simply from all the work they have done, plus the work of individual Square engineers (e.g., Jake Wharton, author of ActionBarSherlock, ViewPagerIndicator, and many others).

This is not to say that greenrobot's EventBus is weaker than the alternatives. In fact, it may be the most powerful of the three. Like Otto, greenrobot's EventBus has Guava's EventBus in its heritage. Unlike Otto, greenrobot eschewed annotations, opting instead for a convention-based system utilizing method name patterns, to avoid the overhead of runtime annotations on Android prior to 4.0.

The `EventBus/GreenRobot` sample project is a clone of the `EventBus/Otto` project, replacing Otto with greenrobot's EventBus, that we will examine in this section.

Basic Usage and Sample App

As both Otto and greenrobot's EventBus have Guava's EventBus as antecedents, the flow of using both is similar, just with differing details.

ScheduledService

`ScheduledService` has a very similar feel to its Otto equivalent:

```
package com.commonsware.android.eventbus.greenrobot;

import android.app.Notification;
import android.app.NotificationManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.support.v4.app.NotificationCompat;
import java.util.Random;
import com.commonsware.cwac.wakeful.WakefulIntentService;
import de.greenrobot.event.EventBus;
import de.greenrobot.event.NoSubscriberEvent;

public class ScheduledService extends WakefulIntentService {
  private static int NOTIFY_ID=1337;
  private Random rng=new Random();

  public ScheduledService() {
    super("ScheduledService");
  }

  @Override
  public void onCreate() {
    super.onCreate();

    EventBus.getDefault().register(this);
  }

  @Override
  protected void doWakefulWork(Intent intent) {
    EventBus.getDefault().post(new RandomEvent(rng.nextInt()));
  }

  @Override
  public void onDestroy() {
    EventBus.getDefault().unregister(this);

    super.onDestroy();
  }

  public void onEvent(NoSubscriberEvent event) {
    RandomEvent randomEvent=(RandomEvent)event.originalEvent;
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);
    Intent ui=new Intent(this, EventDemoActivity.class);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_SOUND)
```

```
      .setContentTitle(getString(R.string.notif_title))
      .setContentText(Integer.toHexString(randomEvent.value))
      .setSmallIcon(android.R.drawable.stat_notify_more)
      .setTicker(getString(R.string.notif_title))
      .setContentIntent(PendingIntent.getActivity(this, 0, ui, 0));

    NotificationManager mgr=
        (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
  }
}
```

There are only two significant differences.

First, we use `EventBus.getDefault()` to get the stock `EventBus` singleton, rather than create our own instance as we did with Otto. We *could* create our own instance, though, as opposed to `LocalBroadcastManager`, which seems to prefer its own singleton.

Second, instead of having an `onDeadEvent()` `@Subscribe` method, we register our own interest in EventBus events, by calling `register()` on the `EventBus` instance in `onCreate()`.

The service itself then has an `onEvent()` method for our `NoSubscriberEvent`, where it raises the `Notification`.

When using greenrobot's EventBus, rather than using annotations to denote event-handling methods, we use a naming scheme: `onEvent()` (or variations on that theme, as will be seen shortly). Since Java allows method overloading with different parameter lists, this works just fine — we can have N event-handling methods in a class, with N different event types as the parameter. The greenrobot code simply finds all of the event-handling methods by name, rather than by annotation. This does limit the flexibility in choosing method names, though.

The `NoSubscriberEvent` fills the same basic role as the `DeadEvent` in Otto – it is raised when somebody else raises an event that nobody subscribed to. In our case, as with Otto's `DeadEvent`, we are using `NoSubscriberEvent` to determine when the `RandomEvent` is not picked up by the `EventLogFragment`, so we can raise the `Notification`.

EventLogFragment

The modified EventLogFragment also uses EventBus.getDefault() to register and unregister from the default bus instance. It too has a renamed event-handling method, now called onEventMainThread():

```
public void onEventMainThread(final RandomEvent event) {
  adapter.add(event);
}
```

The default behavior of threading with greenrobot's EventBus is to deliver the event on the same thread that posted the event, much like Otto. The onEvent() method used in ScheduledService, for example, accepts the event on the posting thread. However, there are other variations of the onEvent() method name that you can use, to signify that you want to have the event delivered on some other thread. onEventMainThread() indicates that we want to have the event delivered to the method on the main application thread, which is why the EventLogFragment can safely update the UI.

Hence, while the fragment is in the foreground, it will handle the RandomEvent; otherwise, the service will.

Other Notable Capabilities

In addition to the threading features, greenrobot's EventBus has a few other noteworthy bells and whistles:

- register() and unregister() optionally take an event class (e.g., RandomEvent.class) as a second parameter, allowing you to register and unregister from specific events, in addition to the default behavior of registering for all events for which you have handlers.
- postSticky() and registerSticky() allow you to have sticky events, much like sticky broadcasts with the classic broadcast Intent system.
- Ordered event processing as an option, akin to ordered broadcasts.
- Whereas Otto matches events only on the concrete base event class itself, greenrobot's EventBus also allows you to register event handlers for event class superclasses. For example, you could have a common AppEvent base class, with subclasses for specific scenarios, and have some object register with an onEvent(AppEvent) method to find out about *all* of your events that inherit from AppEvent.

Tasks

One of the most confusing aspects of Android to deal with is the concept of tasks. Fortunately, the automatic management of tasks is *almost* enough to get by, without you having to do much customization. However, many apps will have needs to tailor how their app interacts with the task system, and understanding what is possible and how to do it is not easy. It is made even more complicated by changes to Android, from both engineering and design perspectives, over the years.

This chapter will attempt to untie the knot of knowledge surrounding Android's task system, explaining why things are the way they are. However, there will be a few places where the knot turns a bit Gordian, and we will have to settle for more about "how" and less about "why" the task system works as it does.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

One sample app makes heavy use of the `PackageManager` system service and refers in a few places to the `Launchalot` sample app profiled in that chapter.

First, Some Terminology

It will be useful to establish some common definitions of terms that you will encounter, both in this chapter and in other materials that describe the task system.

Task

So, what exactly *is* a "task"?

The Android developer documentation describes it as:

> A task is a collection of activities that users interact with when performing a certain job. The activities are arranged in a stack (the back stack), in the order in which each activity is opened.

In that sense, a task is reminiscent of a tab in a tabbed browser. As the user navigates, clicking links and submitting forms, the user advances into other Web pages. Those pages could be on the same site as they started or could be on different sites. The browser BACK button is supposed to reverse the navigation, allowing the user to return from whence they came.

Back Stack

The user perceives tasks mostly in the form of pressing the BACK button, using this to return to previous "screens" that they had been on previously.

Sometimes, BACK button processing is handled within a single activity, such as when you put a dynamic fragment onto the "back stack" via `addToBackStack()` on a `FragmentTransaction`. Or, the activity could override `onBackPressed()` and do special stuff in certain scenarios. Those are part of the user experience of pressing BACK. From the standpoint of the task system, though, internal consumption of the BACK button presses do not affect the task.

At the task level, the "back stack" refers to a chain of activities. This matches the behavior of Web sites, where while pressing the browser BACK button *might* trigger in-page behavior, usually it returns you to the previous page. Similarly, while pressing BACK on an Android device *might* trigger in-activity behavior, usually it triggers a call to `finish()` on the foreground activity and returns control to whatever had preceded it on the back stack.

Recent Tasks

In a tabbed Web browser, if we have several tabs open, we think of all of them as being "running". Frequently, we do not really even think about the concept, any more than we might think about the state of tabs in an IDE other than the one that we are working in right now. However, if you have ever had some browser tab all of a sudden start playing audio, such as from a reloaded page pulling in an audio-enabled ad banner, you are well aware that tabs are “running”, while you are also “running” to try to figure out what tab is playing the audio so you can get rid of it.

However, that is the behavior on a desktop Web browser. A desktop Web browser is not subject to heap size limitations the way Android apps are. And, historically, mobile devices had less system RAM than did their desktop and notebook counterparts, though that is rapidly changing.

In Android, therefore, developers are used to the notion that their processes may be terminated, while in the background, to free up memory for other processes. This is being done to allow for more apps to deliver more value in less system RAM.

However, from a multitasking standpoint, having apps just up and vanish is awkward. Hence, Android has the notion of “recent tasks”. These are tasks, with their corresponding back stacks, that the user has been in “recently”. How far back “recently” goes depends a bit on the version of Android – there could be as few as eight items. These “recent tasks” may or may not have a currently-running *process* associated with them. However, if the user chooses to return to one of those recent tasks, and there is no process for it, Android will seamlessly fork a fresh process, to be able to not only start up those apps, but return the user to where they were, in terms of UI contents (e.g., saved instance state `Bundle`) and in terms of back stack contents (e.g., where the user goes if the user now presses BACK).

Overview Screen

In a tabbed Web browser, you can navigate between different tabs in some browser-specific way. Some tabs may have the actual “tab” visible around the address bar. Some tabs might only be reachable via some sort of scrolling operation, or via a drop-down list, for people who have lots and lots of tabs open. Regardless, there is some UI means to pick the tab that you want to be viewing in the main browser area.

In Android, the “overview screen” is where the user can view the recent tasks and choose to return to one of them. Many people, including this author, refer to this as the “recent tasks list”, but apparently the official term is “overview screen”.

The way the overview screen has looked and worked has changed over the years.

Android 1.x/2.x

In the early days of Android, long-pressing the HOME button would bring up the overview screen, with up to eight recent tasks:

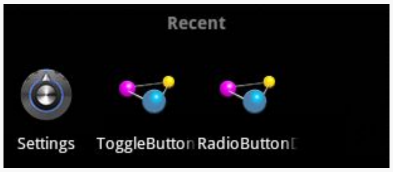


Figure 617: Overview Screen, from Android 2.3.3

And… that was pretty much it.

Android 3.x/4.x

The overall move to the holographic theme for Android brought with us a new icon, for a dedicated way to get to the overview screen:

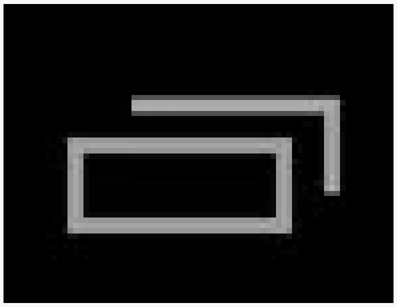

Figure 618: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 4.3

Devices that offered a navigation bar at the bottom would have this button. Devices that chose to have off-screen affordances for BACK and HOME might have a similar button for the overview screen. For those that neither had a navigation bar nor a dedicated off-screen button for the overview screen, long-pressing HOME would bring up the overview screen.

The overview screen could have more apps (15 or so) before old tasks would be dropped:

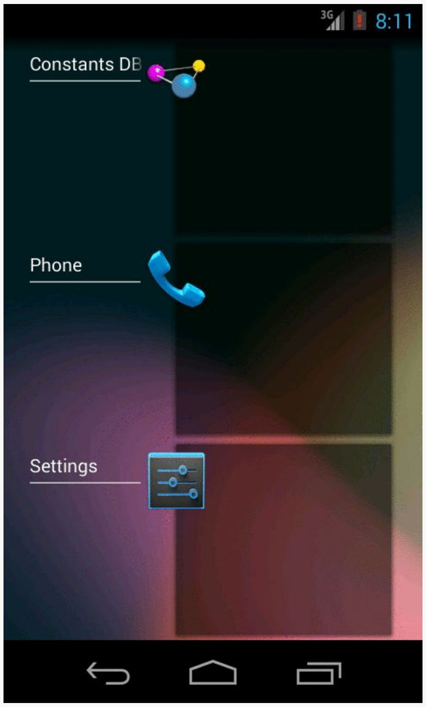

Figure 619: Overview Screen, from Android 4.3

The overview screen also added more improvements:

- Thumbnails of the top activity in each task's back stack, except for those activities that used `FLAG_SECURE` to block this, and except on some emulator images
- Swiping an entry off the list would remove that recent task

Android 5.x

Functionally, the Android 5.x overview screen functions much like its 4.x counterpart, with the ability to see previews of tasks and remove tasks from the screen.

However, there are some differences, starting with the navigation bar icon used to bring up the overview screen:

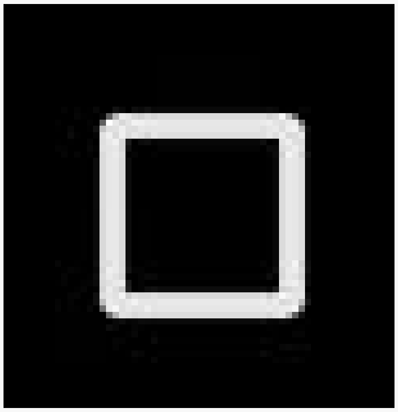

Figure 620: Overview Screen/Recent Tasks Navigation Bar Icon, from Android 5.0

Also, the previews are larger and stacked like cards, more so than being a classically vertically-scrolling list:

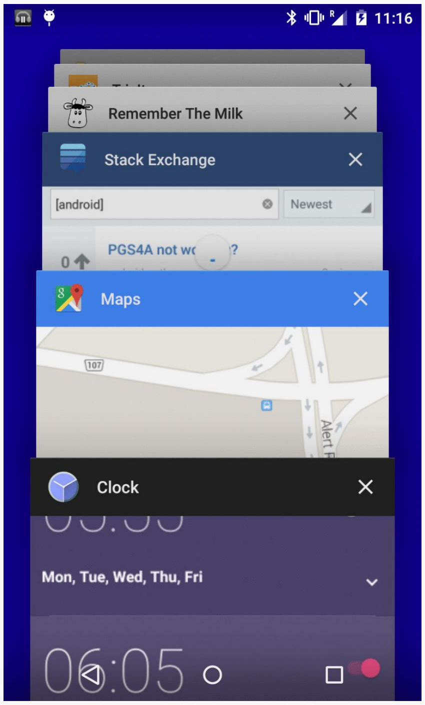

Figure 621: Overview Screen, from Android 5.0

More importantly:

- The roster of recent tasks will be restored after a reboot, and

- If there is a limit on how many entries can appear in the list, the author has not run into it yet

Running Tasks

A running task is a task that has running process(es) associated with it. Recent tasks may or may not be running.

And Now, a Bit About Task Killers

In October 2008, the first Android device was publicly released (the T-Mobile G1, a.k.a., HTC Dream).

Around December of 2008, the first task killers appeared on the Android Market (now the Play Store).

While the techniques used in 2008 to kill tasks were removed in later releases, some amount of task management behavior still exists in Android. Having a task killer is useful for understanding how tasks (and their killers) behave on Android. In particular, it is useful to have a way to emulate an app's process being terminated due to low memory conditions… which is exactly what modern task killers do.

So, in this section, we will explore the concept of task killers, including how to implement one, before using this tool to help us explore the overall Android task system.

What Do Task Killers Do?

Despite the name, task killers do not kill tasks.

Rather, task killers terminate background processes. This does not impact the task, insofar as it will still be in the recent tasks roster and will still show up on the overview screen. However, the process for the app associated with the task will shut down.

Task killers can only request to terminate background processes. If your app is in the foreground (i.e., has the foreground activity), you cannot be terminated by a task killer.

To terminate background processes, task killers need to hold the KILL_BACKGROUND_PROCESSES permission, via a <uses-permission> element in their manifests. That enables them to be able to call the killBackgroundProcesses() method on ActivityManager. Supplied an application ID, killBackgroundProcesses() will terminate any background process(es) associated with that application. Normally, there will only be one such process, but if the app in question is using the android:process attribute in the manifest to have multiple processes, then all the app's processes will be terminated.

This termination is done using the same internal mechanism that is used by the "out-of-memory killer", which is responsible for freeing up system RAM due to low memory conditions.

Killing vs. Force-Stopping

For ordinary users, there are a few options for terminating background processes. Using a task killer, or swiping the task off the overview screen on Android 4.0+, will terminate background processes. Both use killBackgroundProcesses() (or internal equivalents).

However, users can also go into the Settings app, find the app in the list of installed apps, and click a "Force Stop" button associated with that app. On the surface, this has a similar effect to the above techniques, as the background process is terminated. However, force-stopping the app also unschedules any AlarmManager or JobScheduler events for that app, plus moves the app back into the "stopped state", blocking manifest-registered broadcast receivers. Hence, force-stopping an app has a much larger impact than does merely using a task killer.

A few devices have manufacturer-supplied task managers (a.k.a., task killers), where stopping an app from those apps actually does a force stop behind the scenes, rather than killBackgroundProcesses(). This is not a good idea, as force-stopping an app has the aforementioned side effects. Fortunately, third-party task killers cannot force-stop apps, barring any security flaws in Android that might make this possible.

Why Use One?

Nowadays, normally, users do not need task killers. Occasionally one can be useful, to stop a background process for a poorly-written app (e.g., one that powers on GPS but fails to let go of GPS when the app moves to the background). On most modern Android devices, swiping the app off the overview screen usually suffices, and so task killers are not nearly as crucial as they were in Android 1.x/2.x, where there was no such built-in background process management solution.

For developers, the problem with swiping an app off the overview screen is that it not only terminates background processes, but it also removes the task entirely. This makes it difficult to see what the behavior is when apps' processes terminate for more conventional reasons (e.g., out-of-memory killer) and how tasks tie into that. While developers have the ability to stop processes through development tools (e.g., the process list in DDMS), that just terminates the process, and it may do so slightly differently than does the out-of-memory killer. Hence, having a task killer around can be useful for experimentation purposes.

And, since getting a task killer on an emulator can be challenging (since emulators do not have access to the Play Store), having the source code for a simple task killer is useful for developers. So, let's look at how to implement a task killer.

A Killer Sample

The `Tasks/Nukesalot` sample application implements the Nukesalot app. This is a reworked version of the Launchalot sample from elsewhere in the book. Launchalot lists the launchable activities and lets the user launch those activities by clicking on them in a `ListView`. Nukesalot lists the running applications and allows the user to kill those applications' background processes by clicking on them in a `ListView`.

Finding Killable Apps

First, we need to find apps that are eligible to be killed.

In `onCreate()` of the `MainActivity`, we get our hands on an `ActivityManager` system service. `ActivityManager` is not strictly tied to the UI construct known as activities, but rather to general "activity" of the user with respect to the device.

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.main);

  am=(ActivityManager)getSystemService(ACTIVITY_SERVICE);
}
```

In `onResume()`, we then call a private `buildAdapter()` method to create an instance of an `AppAdapter` for us:

```
@Override
public void onResume() {
  super.onResume();

  adapter=buildAdapter();
  setListAdapter(adapter);
}
```

We do this in `onResume()` so that when our activity returns to the foreground, it shows a fresh list of running apps. This activity lacks the ability to detect new running processes on the fly, something that could be addressed by a manual refresh option (e.g., action bar item). The implementation of this is left as an exercise for the reader.

`buildAdapter()` needs to find out the application ID (a.k.a., package name) of the running applications. It would be easier to list all applications, but there is little point in listing apps that cannot be killed simply because they are not running. The roster of application IDs of the running apps is a `HashSet` named `runningPackages`, initially empty:

```
private AppAdapter buildAdapter() {
  HashSet<String> runningPackages=new HashSet<String>();

  for (ActivityManager.RunningAppProcessInfo proc :
      am.getRunningAppProcesses()) {
    for (String pkg : proc.pkgList) {
      runningPackages.add(pkg);
    }
  }

  PackageManager pm=getPackageManager();
  List<ApplicationInfo> apps=new ArrayList<ApplicationInfo>();

  for (ApplicationInfo app : pm.getInstalledApplications(0)) {
    if (runningPackages.contains(app.packageName)) {
      apps.add(app);
    }
  }

  Collections.sort(apps,
      new ApplicationInfo.DisplayNameComparator(pm));

  return(new AppAdapter(pm, apps));
}
```

We then iterate over the running application processes, obtained via a call to `getRunningAppProcesses()` on the `ActivityManager`. In theory (though it is unclear how this works in practice), a running app process could hold code from multiple packages. We find out those packages via the `pkgList` in each

RunningAppProcessInfo object that we get back from getRunningAppProcesses(). We then iterate over the strings in pkgList and add each to runningPackages.

Next, in order to display icons and names for these apps, we really need ApplicationInfo objects for each app. Plus, it would be nice if these were in some logical order. So, we get a PackageManager, create an ArrayList of ApplicationInfo objects named apps, and iterate over all installed applications (via getInstalledApplications() on PackageManager). For each app, if its package name (via the packageName attribute on the ApplicationInfo) is in our runningPackages, we add the ApplicationInfo to the ArrayList. We then sort the ArrayList using an ApplicationInfo.DisplayNameComparator convenience class provided by the Android SDK, which will sort ApplicationInfo arrays based on the display name. We then wrap the ApplicationInfo list in an AppAdapter and return it.

Displaying Killable Apps

AppAdapter itself is an ArrayAdapter for ApplicationInfo objects, designed to render them in rows containing the app's icon and display name:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal"
  >
  <ImageView android:id="@+id/icon"
    android:layout_width="48dp"
    android:layout_height="48dp"
    android:layout_alignParentLeft="true"
    android:layout_margin="2dp"
    android:scaleType="fitCenter"
    android:layout_gravity="center_vertical"
  />
  <TextView
    android:id="@+id/label"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:textSize="24sp"
    android:layout_margin="2dp"
    android:layout_gravity="center_vertical"
  />
</LinearLayout>
```

AppAdapter steals a page from CursorAdapter and has getView() delegate to newView() and bindView() methods. newView() is called when there is no row to recycle, and it just inflates the row layout. bindView() uses PackageManager to populate the icon and display name widgets using `loadIcon()` and `loadLabel()` calls:

```
class AppAdapter extends ArrayAdapter<ApplicationInfo> {
  private PackageManager pm=null;

  AppAdapter(PackageManager pm, List<ApplicationInfo> apps) {
    super(Nukesalot.this, R.layout.row, apps);
    this.pm=pm;
  }

  @Override
  public View getView(int position, View convertView,
                      ViewGroup parent) {
    if (convertView==null) {
      convertView=newView(parent);
    }

    bindView(position, convertView);

    return(convertView);
  }

  private View newView(ViewGroup parent) {
    return(getLayoutInflater().inflate(R.layout.row, parent, false));
  }

  private void bindView(int position, View row) {
    TextView label=(TextView)row.findViewById(R.id.label);

    label.setText(getItem(position).loadLabel(pm));

    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    icon.setImageDrawable(getItem(position).loadIcon(pm));
  }
}
```

`loadIcon()` and `loadLabel()` are methods on `ApplicationInfo` that, given a `PackageManager`, can find the proper resources for those items and retrieve them from the foreign app's package.

The result is a `ListView` filled with running apps… including Nukesalot itself:

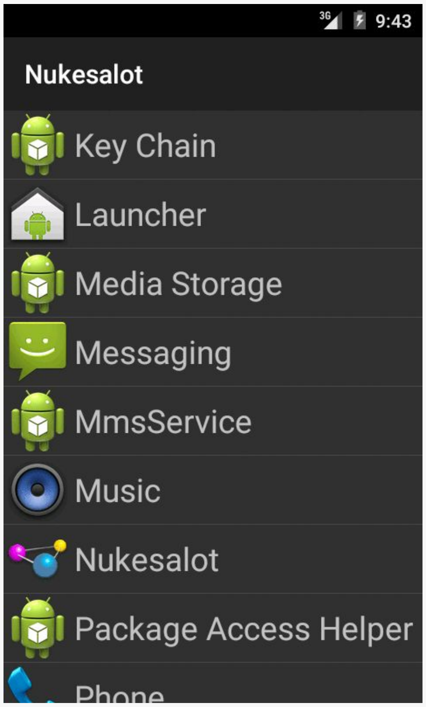

Figure 622: Nukesalot, on Android 5.0

That App Needed Killin'

The idea is that when the user taps on a row in the list, Nukesalot will go and terminate that app's process. So, in `onListItemClick()`, we determine the `ApplicationInfo` of the clicked-upon app, and call `killBackgroundProcesses()` on that app's package name. Then, we refresh the adapter, to show the updated roster of running apps:

```
@Override
protected void onListItemClick(ListView l, View v,
                               int position, long id) {
  ApplicationInfo app=adapter.getItem(position);

  am.killBackgroundProcesses(app.packageName);
  adapter=buildAdapter();
  setListAdapter(adapter);
}
```

`killBackgroundProcesses()` requires the `KILL_BACKGROUND_PROCESSES` permission, which we have in the manifest:

```
<uses-permission android:name="android.permission.KILL_BACKGROUND_PROCESSES"/>
```

If you tap on a row for some ordinary Android app, other than Nukesalot itself, that process will be terminated. However:

- Nukesalot cannot kill itself, as it is not a background process, but rather is the foreground process. In principle, we could detect this case, `finish()` the activity, and fork a background thread to call `killBackgroundProcesses()` after a short delay to ensure that our process is categorized as a background process. In practice, that seems like an awful lot of work for a book example.
- Some system processes (e.g., "Android System") simply cannot be killed using `killBackgroundProcesses()`.

More importantly, from the standpoint of this chapter, is that killing a background process using Nukesalot does not disturb the recent-tasks list. Our task still shows up there, even though we terminated the process for it, and that will be useful as we examine the behavior of Android's task system.

A Canary for the Task's Coal Mine

In order to see some of the effects of fussing with our tasks, we need an app where we can see when our saved instance state comes and goes. To that end, we have the [Tasks/TaskCanary]() sample application. It consists of a single activity, with a UI that is merely a full-screen `EditText`. In addition to the automatic saving of the `EditText` contents in the saved instance state `Bundle`, we also keep track of the time we first worked with that `Bundle`, in a data member named `creationTime`, backed by a `STATE_CREATION_TIME` entry in the `Bundle` itself:

```
package com.commonsware.android.task.canary;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.Settings;
import android.util.Log;
import android.view.Menu;
import android.view.MenuItem;

public class MainActivity extends Activity {
  private static final String STATE_CREATION_TIME="creationTime";
  private long creationTime=-1L;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.activity_main);
  }

  @Override
  protected void onRestoreInstanceState(Bundle savedInstanceState) {
    super.onRestoreInstanceState(savedInstanceState);

    dumpBundleToLog("restore", savedInstanceState);
    creationTime=savedInstanceState.getLong(STATE_CREATION_TIME, -1L);
  }

  @Override
  protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putLong(STATE_CREATION_TIME, getCreationTime());
    dumpBundleToLog("save", outState);
  }

  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.settings) {
      startActivity(new Intent(Settings.ACTION_DATE_SETTINGS));
    }
    else if (item.getItemId()==R.id.other) {
      startActivity(new Intent(this, OtherActivity.class));
    }

    return(super.onOptionsItemSelected(item));
  }

  private long getCreationTime() {
    if (creationTime==-1L) {
      creationTime=System.currentTimeMillis();
    }

    return(creationTime);
  }

  // inspired by http://stackoverflow.com/a/14948713/115145

  private void dumpBundleToLog(String msg, Bundle b) {
    Log.d(getClass().getSimpleName(),
        String.format("Task ID #%d", getTaskId()));

    for (String key: b.keySet()) {
      Log.d(getClass().getSimpleName(),
          String.format("(%s) %s: %s", msg, key, b.get(key)));
    }
  }
}
```

Each time we save and restore the instance state, we dump the `Bundle` to LogCat, so we can see what is in that `Bundle`. We wind up with lines like:

```
D/MainActivity: (save) android:viewHierarchyState: Bundle[...]
D/MainActivity: (save) creationTime: 1427032894794
D/MainActivity: (restore) android:viewHierarchyState: Bundle[...]
D/MainActivity: (restore) creationTime: 1427032894794
```

(where the `...` is a bit long to reproduce in the book and is not essential for the sample)

This way, both in the UI and in the logs, we can confirm that our state is being saved and restored as expected… or perhaps not as expected, in some cases.

You will notice that we have a pair of action bar items. One will bring up a screen from the Settings app, which we will use to see how this affects our task. The other one will bring up another activity from our app, which we will use to explore how to start a clean task.

The Default User Experience

With all that behind us, let's start talking about tasks, focusing first on what behavior the developer gets "out of the box", with no task-specific logic in the app. In other words, what is the default user experience for an ordinary Android app?

NOTE: if you wish to reproduce the results described here, you will want to have Nukesalot and the Task Canary installed on your device or emulator.

Starting from the Home Screen

Assume that we are "starting from scratch". For example, the user has installed your app (or bought a device with your app pre-installed) but has never run your app before. Or, perhaps the overview screen is cleared of all tasks.

If the user taps your home screen launcher icon, not only is a process forked to run your app, but a new task is created, and your app's task will appear in the overview screen.

(see! that wasn't so hard!)

To reproduce this behavior:

- Clear the overview screen of all tasks, by swiping them off the screen. Note that this may take some time on an Android 5.x device that is really being

used (versus just being some test device), as there may be a *lot* of tasks to clear.
- Run your app, from the home screen or IDE.

Resuming from the Overview Screen

Eventually, the user wanders away from your app. Then, later on, the user returns to your app, by finding the task associated with your app in the overview screen and tapping upon it.

In the end, you wind up in the same state as before: you have a process for your app, and your task is still in the overview screen. How we get there depends a bit on what happened with your process, in between when you had been in the foreground and when the user taps on your task in the overview screen.

If your app's process was still running, nothing much happens of note, other than you return to the foreground. From a state standpoint, your app would be called with `onSaveInstanceState()` when the user left your app, but you will not be called with `onRestoreInstanceState()`, because your activity was not destroyed yet. Note that this assumes that you did not undergo a configuration change (e.g., user originally was in your app in portrait, then returned to you from the overview screen while the device was in landscape). In the case of a configuration change, your activity would be destroyed and recreated by default, and you *would* be called with `onRestoreInstanceState()`, but that would be due to the configuration change more so than the use of the task and the overview screen.

To reproduce the above behavior, given that your device was in the state after the "Starting from the Home Screen" section above:

- Press HOME to move your app to the background, and notice the "(saved)" entries being reported to LogCat.
- Quickly press RECENTS (or, if you have no such option, long-press HOME) to bring up the overview, and tap on your task there.

However, it is entirely possible that while your task is around that your process is terminated to free up memory for other processes. If the user returns to your app via the overview screen, a fresh process will be forked for your app. This would trigger a call to `onRestoreInstanceState()`, because your old activity no longer exists, because its process no longer exists.

To reproduce the above behavior, given that your device was in the state after the "Starting from the Home Screen" section above:

- Press HOME to move your app to the background, and notice the "(saved)" entries being reported to LogCat.
- Run Nukesalot, find the Task Canary in the list of running apps, and tap upon that entry to terminate its process. You should see its process go away in the list of debuggable processes in DDMS. You could also experiment with just terminating the process directly from DDMS, but Nukesalot may be a bit closer to "natural" device behavior, in terms of how the process is terminated.
- Press RECENTS (or, if you have no such option, long-press HOME) to bring up the overview, and tap on your task there. Note your "(restored)" LogCat entries, which should include the same `creationTime` as you saved, even though it is now in the future.

Note that if you leave a task for an extended period of time — say, 30 minutes or so — the task may be "cleared" when you return to it. This means that you are taken back to whatever the "root" activity of the task is, where by "root" we mean the original activity put into the task.

Starting Another App

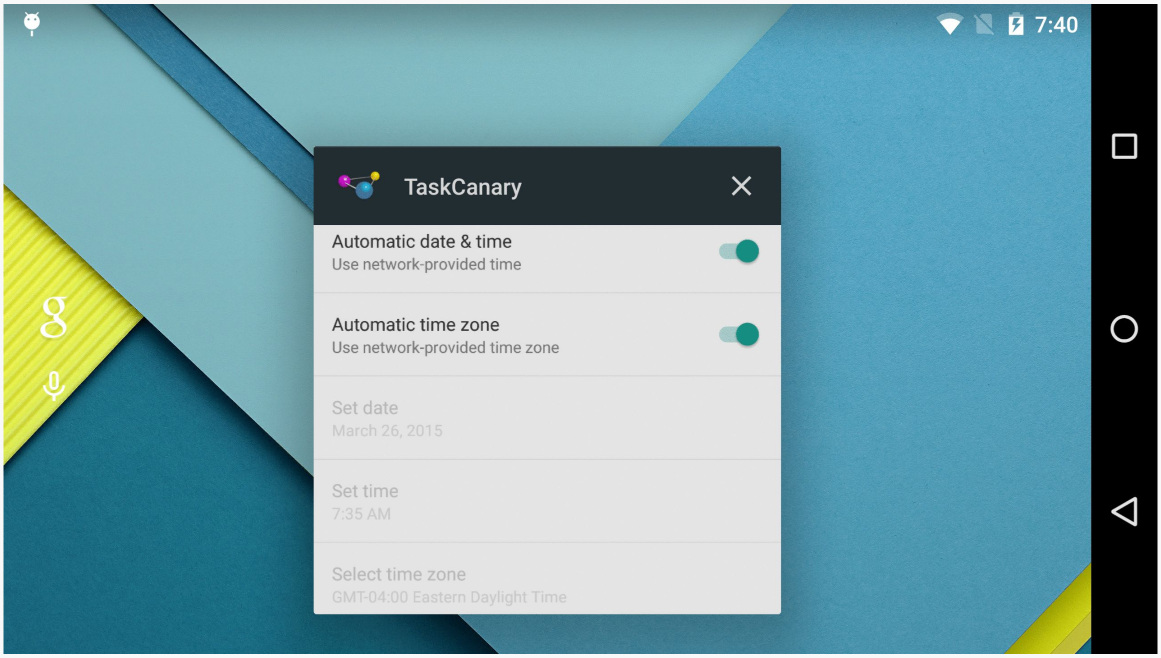
Some apps only start up other activities within the same app. However, many apps start up activities from other apps, either directly via `startActivity()` or indirectly (e.g., clicking in links in a `WebView`). For example, the Task Canary app has an item in the action bar overflow that, when clicked, brings up the Settings screen for adjusting date and time settings.

You might think that when the user taps on this overflow item, and Task Canary calls `startActivity()`, that a new task is created. After all, the Settings app is a completely separate app from the Task Canary app.

However, try this:

- Clear the overview screen
- Launch Task Canary
- Choose the Settings action bar overflow item to bring up the date-and-time Settings screen
- Press HOME to bring up the home screen
- Press RECENTS or otherwise bring up the overview screen

You will see one entry in the overview screen, for Task Canary, rather than two. Furthermore, particularly on Android 5.x devices, you will see the Settings screen as the top-most activity within the Task Canary task:



Automatic date & time
Use network-provided time

Automatic time zone
Use network-provided time zone

Set date
March 26, 2015

Set time
7:35 AM

Select time zone
GMT-04:00 Eastern Daylight Time

Figure 623: The Task Canary Task, on Android 5.1

However, suppose that instead of using `ACTION_DATE_SETTINGS` for the `Intent`, we used `ACTION_APN_SETTINGS` instead, to allow the user to view mobile access point names and such. You might think, given the above flow, that we would wind up with just one task, as we did with `ACTION_DATE_SETTINGS`. In reality, you will see two tasks, instead of just one:

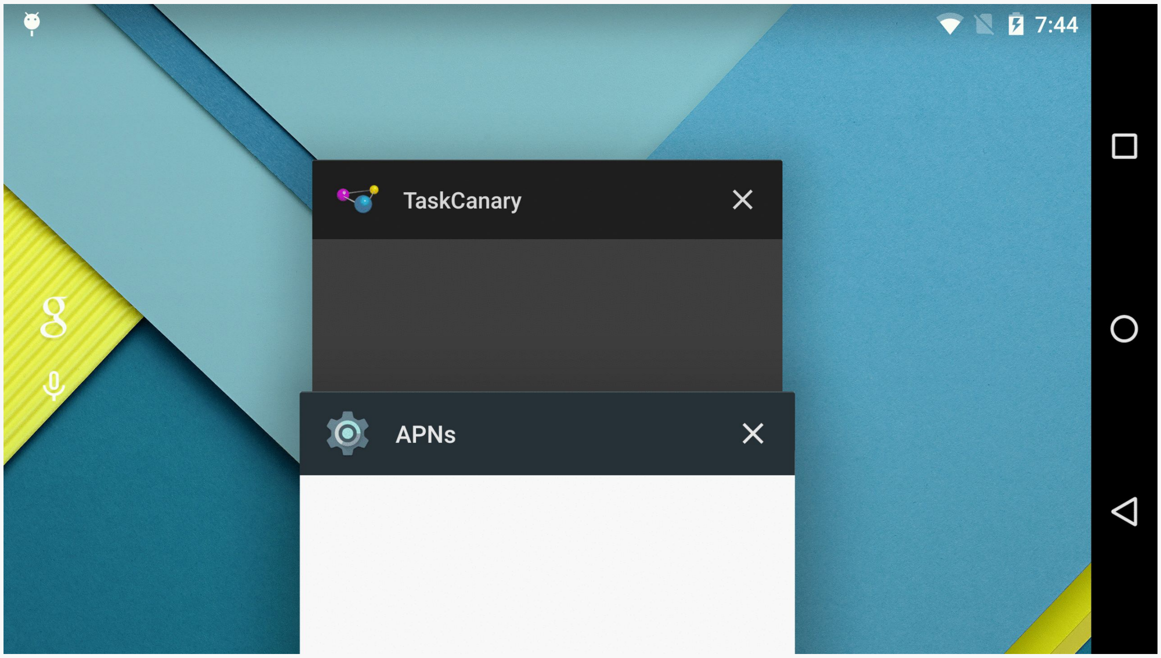


Figure 624: Two Tasks on Android 5.1

This is where things start to get a bit confusing.

Explaining the Default Behavior

With the user experience as background, let's now dive into what is really going on with these operations.

When Tasks are Created

A task is not created just because an activity is started. Otherwise, even individual apps would have lots of tasks, one per activity.

A task is not created just because a task from a different app is started. Otherwise, the two Settings scenarios above would have both resulted in a new task.

Instead, tasks are created when somebody *asks* for a task to be created. That "somebody" could be the author of the app calling `startActivity()` or the author of the activity being started.

There are three major approaches for indicating that a new task should be started: flags on the `Intent` used with `startActivity()`, task affinity values, and launch modes. We will get into launch modes [later in this chapter](), as the normally-used launch modes have no impact on tasks. Instead, we will focus on the other two approaches here.

Task-Management Intent Flags

If you want to start an activity, and ensure that the activity starts in a new task, add `Intent.FLAG_ACTIVITY_NEW_TASK` to the flags on the `Intent` being used with `startActivity()`:

```
startActivity(new Intent(SOME_ACTION_STRING)
                .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK))
```

What will happen, when you call `startActivity()` with `FLAG_ACTIVITY_NEW_TASK`, is that Android will see if there is a task that already has this activity in it. If there is, that task will be brought to the foreground, and the user will see whatever is on the top of that task's stack. Otherwise, if there is no task with this activity in it, Android will create a new task and associate a new instance of the activity with this task.

This is what home screen launchers do. When you tap on a home screen launcher icon, if there is a task that has a copy of your home screen activity in it, that task is brought back to the foreground. Otherwise, a new task is started.

If you *also* add `Intent.FLAG_ACTIVITY_MULTIPLE_TASK`, then Android skips the search for existing tasks and unconditionally launches the activity into a new task. This is generally not a good idea, as the user can wind up with many copies of this activity, not know which one is which, and perhaps have difficulty getting back to the right one.

Task Affinities

By default, if Android needs to create a new task as a result of `FLAG_ACTIVITY_NEW_TASK`, it just creates a task. And, if there is no such flag on the `Intent`, Android will put the activity into the task of whoever called `startActivity()`.

If, however, the activity has an `android:taskAffinity` attribute in its `<activity>` element in the manifest, then Android will specifically start this activity in a certain task, identified by the string value of the attribute. Other activities with the same task affinity will also go into this task.

The reason why the two Settings screens behave differently is that the ACTION_APN_SETTINGS activity has a certain task affinity value, while ACTION_DATE_SETTINGS does not. The task affinity of the ACTION_APN_SETTINGS activity is shared by many, though not all, activities within the Settings app. Those activities, when started, will always go into the task identified by the affinity. Hence, when we start ACTION_DATE_SETTINGS, it goes in *our* task (because that activity has no affinity and we did not include FLAG_ACTIVITY_NEW_TASK), but when we start the ACTION_APN_SETTINGS activity, it goes into a Settings-specific task.

Note that you can also have the android:taskAffinity value defined on the <application> element, to provide a default task affinity for all activities. The overall default is "", or no affinity.

When Tasks are Removed

On Android 3.0 and higher, the user can get rid of a task by swiping the task off of the overview screen.

Otherwise, prior to Android 5.0, a task would automatically go away after some amount of user activity, as there were only so many "slots" available for tasks.

On Android 5.0+, though, it is unclear if there is an upper bound to how many tasks can exist. Beyond that, tasks survive a reboot, as information about those tasks is persisted. We will get more into the ramifications of this, and how you can take advantage of it, later in this chapter.

When Tasks (and Processes) are Resumed

A task will be resumed and brought back to the foreground in several situations, including:

- the user manually requests it via the overview screen, by clicking on one of the recent tasks
- if FLAG_ACTIVITY_NEW_TASK is added (without FLAG_ACTIVITY_MULTIPLE_TASK) to the Intent used to start an activity, and there is a task containing the activity in question
- if the taskAffinity for the activity being started ties it to another task
- if the launch mode for the activity being started ties it to another task

However, just because the task exists does not mean that the process(es) exist for the activities in the task. As needed, Android will fork fresh processes, to be able to load in the app's code and start the necessary activities. Android will deliver to the newly-created activities the same `Intent` that was used to create the original incarnation of the activity (via `getIntent()`) and the saved instance state `Bundle`.

What Happens to Services

In theory, services are immune to task behavior. Tasks can come and go, and services are usually oblivious to this.

A service should be called with `onTaskStopped()` if a task associated with one or more of the app's activities is removed. The service might use that as a signal that it too should shut itself down.

There appears to be a quasi-documented `android:stopWithTask` attribute on the `<service>` element in the manifest. The default is `false`, but if you override it to be `true` on your `<service>`, then `onTaskStopped()` will not be called, and Android will simply destroy your service when the task is removed.

However, as of Android 4.4, there are many reports that services may be destroyed when a task is removed, even without `android:stopWithTask="true"`, though on a slight delay. Developers concerned about this should keep an eye on this issue and this issue, both for various hacky workarounds and for any signs that this is being permanently addressed.

What's Up with onDestroy()?

If the user swipes away the task using the overview screen, `onDestroy()` will be called on all outstanding activities.

If, however, you use Nukesalot to kill the background process, Android does *not* call `onDestroy()` on any outstanding activities. Since other task killers will use the same techniques as does Nukealot, this means that your `onDestroy()` methods will not be called when your process is terminated by those apps as well.

So, removing a *task* is a graceful exit, and Android calls `onDestroy()`, but an explicit termination of your process by another is a not-so-graceful exit, and Android skips `onDestroy()`.

As a result, as previously advised in this book and elsewhere, you cannot count on your onDestroy() methods being called, and you need to take this into account in terms of what sorts of code you put in them.

Basic Scenarios for Changing the Behavior

In many cases, the default behavior of tasks is just fine. However, there are many scenarios in which we may want to override the default behavior, routing activities to specific tasks, to have a better flow for the user.

Reusing an Activity

By default, each time you call startActivity(), a new instance of the activity is created. Depending upon the user flow, that may not be a bad approach. For example, it may be that the only logical path out of the started activity will be to press BACK and destroy it.

However, there will be plenty of cases where we will not want to keep creating new activity instances. For example, if you elect to have several activities reachable via a nav drawer, you do not want to create fresh instances of activities that the user has already visited via that drawer. Otherwise, they will keep piling up, continuing to consume heap space. Instead, it would be better to try to reuse an existing activity instance, if one is available, creating a fresh one only if needed.

The most flexible approach for accomplishing this involves using a flag on the Intent used to start the activity: Intent.FLAG_ACTIVITY_REORDER_TO_FRONT. This tells Android to bring an existing activity matching our Intent to the foreground, if one already exists in our task. If there is no such activity, then go ahead and create a new instance.

The Tasks/RoundRobin sample application demonstrates this. It consists of two activities (FirstActivity and SecondActivity), each of whose UI consists of one really big button. Clicking the button should start the other activity, so clicking the button in FirstActivity should start an instance of SecondActivity. But, we want to reuse activity instances where available, and confirm that indeed we *are* reusing those instances.

FirstActivity accomplishes that by adding FLAG_ACTIVITY_REORDER_TO_FRONT to the Intent used to start SecondActivity when the button is clicked:

```
package com.commonsware.android.tasks.roundrobin;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class FirstActivity extends Activity implements View.OnClickListener {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.first);
    findViewById(R.id.button).setOnClickListener(this);

    Log.d(getClass().getSimpleName(),
        String.format("onCreate for %x", hashCode()));
  }

  @Override
  protected void onResume() {
    super.onResume();

    Log.d(getClass().getSimpleName(),
          String.format("onResume for %x", hashCode()));
  }

  @Override
  protected void onDestroy() {
    Log.d(getClass().getSimpleName(),
        String.format("onDestroy for %x", hashCode()));

    super.onDestroy();
  }

  @Override
  public void onClick(View view) {
    startActivity(new Intent(this, SecondActivity.class)
                    .addFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT));
  }
}
```

`SecondActivity` has a nearly identical implementation, just routing back to `FirstActivity`.

If you run the app, the user's perspective is that clicking the button "ping-pongs" the user between the two activities. Looking at LogCat, you will see new instances created the first time the user visits an activity, courtesy of the `Log.d()` call in `onCreate()`. But, if the user returns to an existing instance via the button click, you will see that `onCreate()` is not called, and that the `hashCode()` reported in `onResume()` matches the `hashCode()` of the previously-created instance of this activity:

```
D/FirstActivity: onCreate for b31b9430
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onCreate for b31eb8a8
D/SecondActivity: onResume for b31eb8a8
D/FirstActivity: onResume for b31b9430
D/SecondActivity: onResume for b31eb8a8
```

If you use Nukesalot to terminate the process for RoundRobin, then return to RoundRobin (e.g., via the overview screen), you will see that Android has to create a new instance of whatever activity had been in the foreground, as the old instance went away when the old process did. An instance of the other activity will not be created until the user returns to it, such as via a click of the really big button. In other words, Android lazy-instantiates the activities in the task's back stack, only creating instances when it is absolutely required based upon user navigation.

Note that launch modes offer another way to control this behavior, having the activity being started indicate that its instance should always be reused. However, this is a specialty case, one that most apps will not require.

Forcing a Clean Task

Let's suppose that you have an app that requires in-app authentication, via some form of login screen. For example, your app's data is held in SQLCipher for Android, and so you need the user to supply a passphrase for the database.

In the beginning, when your app is launched from the home screen, your `LAUNCHER` activity appears. If that is your login screen, all is good. You collect the passphrase, create your singleton instance of the SQLCipher-enabled `SQLiteOpenHelper`, and you can access the database.

Eventually, the user presses HOME, and time passes. Android terminates your process to free up system RAM. The user then tries returning to your existing task, such as via the overview screen. Android creates a fresh process for you and takes you to the activity on the top of that task's back stack. But at this point, your singleton `SQLiteOpenHelper` is gone, and you need to collect a passphrase again.

You might think that this is purely a UI issue. Rather than collecting the passphrase in an activity, you collect it in a fragment, one that your `LAUNCHER` activity uses directly, and one that other activities can use via a `DialogFragment`. This way, you can arrange for every activity to be able to complete the re-initialization of your process and give you access to the encrypted database again.

Another approach would be to say that you want to wipe out this task and start over, routing the user back to the LAUNCHER activity for authentication.

There are two main approaches for implementing this: setting Intent flags or using android:clearTaskOnLaunch in the manifest.

Starting a Cleared Task Yourself

One way to do that is to have each activity check to see if a new task is needed (e.g., "is the SQLiteOpenHelper singleton null?"). When that situation is detected, you call startActivity() for your LAUNCHER activity, with two flags: FLAG_ACTIVITY_NEW_TASK and FLAG_ACTIVITY_CLEAR_TASK.

For example, the Tasks/Tasksalot sample application is a straight-up clone of Launchalot with only one change of substance: using FLAG_ACTIVITY_CLEAR_TASK instead of FLAG_ACTIVITY_RESET_TASK_IF_NEEDED:

```
@Override
protected void onListItemClick(ListView l, View v,
                               int position, long id) {
  ResolveInfo launchable=adapter.getItem(position);
  ActivityInfo activity=launchable.activityInfo;
  ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                       activity.name);
  Intent i=new Intent(Intent.ACTION_MAIN);

  i.addCategory(Intent.CATEGORY_LAUNCHER);
  i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
              Intent.FLAG_ACTIVITY_CLEAR_TASK);
  i.setComponent(name);

  startActivity(i);
}
```

To see this in action:

- Run the TaskCanary sample app and use the overflow to bring up OtherActivity
- Press HOME
- Run Tasksalot
- Click on the "Task Canary" entry in Tasksalot

At this point, you will see the TaskCanary sample app return to the screen. From the logs in LogCat, you will see it is the same task ID as before. Yet, you are seeing the FirstActivity. OtherActivity was removed from the task as part of FLAG_ACTIVITY_CLEAR_TASK processing.

This differs from what you see in a home screen, with FLAG_ACTIVITY_RESET_TASK_IF_NEEDED. If you run the same test, but rather than use Tasksalot, you tap on the "Task Canary" icon in the home screen launcher, the task will return to the foreground, but you will be taken to OtherActivity. FLAG_ACTIVITY_CLEAR_TASK *always* clears the task and makes the activity that you are starting up be the root of the newly-cleared task.

Always Starting a Cleared Task

Perhaps you *always* want to start with a cleared task, whenever the user returns to the task after having left it previously. In other words, you always want to start back at whatever your task's root activity is, which is typically your launcher activity.

To do this, simply have android:clearTaskOnLaunch="true" on that launcher activity. Then, for any task where that activity is the root, when the user returns to the task, any other activities in the task are reparented (if applicable) or dropped.

Note, though, that this does not mean that you get a new *process*. Hence, any singletons you had before may or may not still be there.

So, in the authentication scenario described above, using android:clearTaskOnLaunch="true" would take the user back to your initial activity, where you can perform the authentication. However, if you detect that the SQLiteOpenHelper still exists, and therefore you do not need the user to log in again, you could switch over to showing your initial content (e.g., run a FragmentTransaction).

This is far simpler than having the detect-the-null-singleton-on-each-activity approach. However, the downside is that the user loses context. If they were six activities deep into your app, and they get interrupted by a phone call, when they come back to your app, they are back at the beginning.

Launching an App Into a New Task

A home screen launcher app, when it invokes the user's selected activity, will use code something like this from the Launchalot sample:

```
@Override
protected void onListItemClick(ListView l, View v,
                               int position, long id) {
  ResolveInfo launchable=adapter.getItem(position);
  ActivityInfo activity=launchable.activityInfo;
```

```
    ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                         activity.name);
    Intent i=new Intent(Intent.ACTION_MAIN);

    i.addCategory(Intent.CATEGORY_LAUNCHER);
    i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
                Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
    i.setComponent(name);

    startActivity(i);
  }
```

Here, we:

- Create a `ComponentName` identifying the specific activity in the specific app to be started (in this case, based on the `ResolveInfo` that the user chose)
- Create an `Intent` for the `MAIN` action and the `LAUNCHER` category
- Set the `FLAG_ACTIVITY_NEW_TASK` and the `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` flags in the `Intent`
- Attach the `ComponentName` to the `Intent`, to convert it from an implicit `Intent` into an explicit `Intent`
- Start the activity using the `Intent`

`FLAG_ACTIVITY_NEW_TASK` indicates that we want the activity being started to be the root of a new task. If there is no outstanding task for this app, a new task will be created, a new activity instance will be created, and that activity will be the root of the task. Here, "root" means that if the user presses BACK and destroys the activity, the task itself is removed and the user returns to the home screen.

However, despite its name, `FLAG_ACTIVITY_NEW_TASK` does not necessarily create a new task. If there is an existing task for this app containing this activity, that task is brought back to the foreground and is left intact. The activity we request is not created, let alone brought to the foreground.

That is where `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` comes in. It ensures that the task that is brought to the foreground is showing the requested activity. This may involve reparenting activities as well.

Another possibility, instead of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, is `FLAG_ACTIVITY_MULTIPLE_TASK`. This *always* starts a fresh task, with a fresh instance of the requested activity in the root of that task. However, this now may mean that the user has multiple tasks for the same app, which may be confusing in some circumstances. However, this also lies at the core of Android 5.0's documents-as-tasks support and therefore may become more familiar to users over time.

The Invisible Activity

Several sample apps in this book use an "invisible activity", one with the theme set to `Theme.NoDisplay`. These are useful in cases where something outside your app needs an activity, but you do not really have a UI that you want to display. In the case of the book samples, having a `LAUNCHER` activity makes it much easier for readers like you to simply run the samples from the IDE.

However, those sample apps usually do not have any other activities. The invisible activity is just there to kick-start something else, such as `AlarmManager` events.

However, if you have a mix of invisible and regular activities in an app, your invisible activities still wind up potentially having a visible impact.

For example, suppose that we have an ordinary Android app, with regular activities. However, we want a home screen shortcut icon to allow the user to start something in the background, such as playing music. While an app widget would allow us to control what happens when the user taps on an icon in that app widget, a home screen shortcut icon *always* launches an activity. So, we make the start-the-music activity invisible via `Theme.NoDisplay`.

If the user taps on that shortcut, and none of our other activities are part of a task, things proceed as expected: the music starts and the user sees nothing (other than perhaps a `Toast` that we show to let the user know that we are responding to their request).

But, if one or more of our activities are in some task, launching the invisible activity *brings the task back to the foreground*. While our invisible activity is still invisible, the user now sees whatever other activity of ours they had last been in. It is possible that this is a feature, and not a bug, for some apps. But, in other cases, we might want the invisible activity to not have this effect.

The solution: task affinity.

Your ordinary activities can use the default task affinity, or have other task affinities as needs dictate. Your invisible activity, though, would have an `android:taskAffinity` value that is distinct from all others, to force it into its own task. That way, when the user taps on the shortcut, the invisible activity routes to its own task. That task will not yet exist, so the invisible activity causes the task to be created. When the invisible activity calls `finish()` to destroy itself after kicking off the background work, the task is now empty and is removed. Since this was a new task, no existing UI would be brought back to the foreground, and since the task is removed in the end, we are "reset" for the next time the user taps on the shortcut.

Reparenting Tasks

One of the more unusual features of Android's task system is the ability for activities to be "reparented", or moved from one task to another. On the surface, this feels a bit odd, as if a Web page on one browser tab might magically show up in a separate browser tab, just via navigation. And, in truth, it is a specialized use case, but one that could conceivably apply to your app.

Suppose that you were writing an SMS client. You have an activity that is your message composer, where the user can type in a text message to send to somebody. You export that activity, with `Intent` actions like `ACTION_SEND` and `ACTION_SENDTO`. A third-party app, using one of those `Intent` actions, starts up your message composer activity. In the absence of a `taskAffinity` to stipulate otherwise, by default, your message composer activity will be in the task of the third-party app.

Now, suppose that the user fails to actually send a message, such as by pressing HOME from the third-party app's task. Some time later, the user taps on your app's home screen launcher icon. At this point, there are two possibilities as to what happens:

1. You may decide that you want to have the already-running message composer activity appear, to remind the user that they were in the middle of composing a text message and failed to either send it or explicitly BACK out of the activity.
2. You may decide that you do not care, and you are willing to ignore that outstanding message composer activity instance.

The default is option #2. If, instead, you want to offer option #1, that is where task reparenting comes into play.

On your `<activity>` (or on `<application>` to set an app-wide default), you can have `android:allowTaskReparenting="true"`. This indicates to Android that the message composing activity, that is on some other app's task, can move to your app's task when that task is created.

The trigger for this "reparenting" is the task affinity. If you do not specify a task affinity for an activity, the default affinity is for a task rooted in one of your app's activities, typically the launcher activity. In some circumstances, when a task for your app is created, Android will search through other tasks to see if there is any activity, in another task, that has an affinity for your task and allows reparenting. If there is a match, that activity is brought into your task.

The "some circumstances" mentioned in the preceding paragraph is something using two `Intent` flags when calling `startActivity()`:

- `FLAG_ACTIVITY_NEW_TASK`, to create a new task if one is needed, and
- `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED`, to clear out the task if it already has contents *and* reparent any activities in other tasks to this one if appropriate

As it turns out, home screen launchers are supposed to use this pair of flags when they respond to the user tapping on a home screen launcher icon.

The `Tasks/ReparentDemo` sample Android Studio project contains a pair of applications as modules that demonstrate this effect, based on David Wasser's epic Stack Overflow answer.

One module, `app/`, contains an application with two activities, where the second activity (`ReparentableActivity`) has `android:allowTaskReparenting="true"`:

```
<manifest
  xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.tasks.reparent">

  <application
    android:allowBackup="true"
    android:label="@string/app_name"
    android:icon="@drawable/ic_launcher">
    <activity android:name=".MainActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>
        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <activity
      android:name=".ReparentableActivity"
      android:allowTaskReparenting="true">
      <intent-filter>
        <action android:name="com.commonsware.android.tasks.reparent.WHEEEEE"/>
        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

The two activities just display static messages, indicating which of those two activities you are seeing in the foreground. They also log process and task IDs to LogCat. MainActivity does that in onCreate():

```
package com.commonsware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
          String.format("Process ID %d, Task ID %d",
              android.os.Process.myPid(), getTaskId()));
  }
}
```

ReparentableActivity logs the same information in onResume():

```
package com.commonsware.android.tasks.reparent;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class ReparentableActivity extends Activity {
  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.reparent);
  }

  @Override
  public void onResume() {
    super.onResume();

    Log.d(getClass().getSimpleName(),
        String.format("Process ID %d, Task ID %d",
            android.os.Process.myPid(), getTaskId()));
  }
}
```

The other module, app2/, contains an application with one activity, whose UI consists of one really big button. Clicking that button triggers a launch() method that calls startActivity() on an Intent identifying the ReparentableActivity from the first app:

```
package com.commonsware.android.tasks.reparent.app2;
```

```
import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import android.view.View;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    Log.d(getApplicationInfo().loadLabel(getPackageManager()).toString(),
        String.format("Process ID %d, Task ID %d",
            android.os.Process.myPid(), getTaskId()));
  }

  public void launch(View v) {
    startActivity(new Intent("com.commonsware.android.tasks.reparent.WHEEEEE"));
  }
}
```

To see this behavior in action, install both apps. If you run them straight from your IDE, you will want to clear out all relevant tasks, either by swiping them off the recent-tasks list or by rebooting the device or emulator.

Then, start up the “Reparent Demo Aux” app (from the `app2/` module). Click the button, and you will see the `ReparentableActivity` appear. If you press HOME, bring up the recent-tasks list, and go back to this task, you will see the same `ReparentableActivity`. The task, however, is for “Reparent Demo Aux”.

Now, press HOME, then start up the “Reparent Demo” app (from the `app/` module). Rather than seeing the `MainActivity` from that app, you see the `ReparentableActivity` instance from before. The logs will illustrate that your process ID has not changed, but that the task ID for this activity *has* changed, from the task ID used by the `app2/` app to the task ID created for `app/`. The activity has been reparented.

The use of `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` may sound a lot like `FLAG_ACTIVITY_CLEAR_TASK`. The “if needed” part comes into play in two cases:

- If a new task is being created, the “reset” work is really the reparenting described above
- If an existing task is being brought back to the foreground, then get rid of resettable activities

Here, by “resettable activities”, we mean:

- Activities launched with the FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET flag
- Any activities that are higher on the back stack than other explicitly resettable activities

So, if our back stack consists of activities A-B-C-D, and C was started with FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET, and we start up one of these activities (say, A) with FLAG_ACTIVITY_RESET_TASK_IF_NEEDED, and this existing task is coming back to the foreground, C and D will be cleared from the task. The user ordinarily would be taken to activity D, but instead will be taken to activity B, because C is explicitly resettable and D is higher on the back stack.

The Self-Destructing Activity

Sometimes, you only want an activity around while it is in the foreground and the user can see it. Once the user leaves the app, you no longer want that activity to exist. For example, a bank app showing bank account details might want this behavior, so that highly-sensitive information like this does not hang around. Or, you might want this for certain activities that are memory-intensive, so they release their heap space and reduce the odds of an OutOfMemoryError.

You could attempt to manage this yourself, via timely calls to finish(), but catching all the cases when finish() is needed could get troublesome.

Instead, Android has a pair of options to have no-history activities: activities that automatically finish when the user leaves them:

- An activity can decide for itself that it should be removed upon a task switch via the android:noHistory attribute on the <activity> in the manifest
- You can decide ad-hoc to have activities exhibit this behavior by adding Intent.FLAG_ACTIVITY_NO_HISTORY on the Intent used to start those activities

You can see these in action in the Tasks/NoHistory sample application. This is a near-clone of a simple two-activity app that we saw back when we first learned about how to have multiple activities.

There are only two real differences in this version of the sample app.

First, the launcher activity (MainActivity) has android:noHistory="true" on its <activity> element:

```
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name"
      android:noHistory="true">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
```

Second, when that activity goes to start `OtherActivity`, it adds `FLAG_ACTIVITY_NO_HISTORY` to the `Intent` used with `startActivity()`:

```
  public void showOther(View v) {
    Intent other=new Intent(this, OtherActivity.class);

    other.putExtra(OtherActivity.EXTRA_MESSAGE,
                   getString(R.string.other));
    other.addFlags(Intent.FLAG_ACTIVITY_NO_HISTORY);

    startActivity(other);
  }
```

Both of these inherit from the original sample's `LifecycleLoggingActivity`, which just logs messages to LogCat on the major lifecycle methods. If you run the app, click the big button to go from `MainActivity` to `OtherActivity`, then switch to some other app (via the overview screen, via the home screen launcher, etc.), you will see that both activities are destroyed, even though we do not press BACK, call `finish()`, or do anything else ourselves to destroy them.

This has a key side-effect: you cannot combine no-history with `startActivityForResult()` especially well. If the activity that calls `startActivityForResult()` has no-history enabled (via the manifest attribute or the `Intent` flag), it will simply not be called with `onActivityResult()`.

A related attribute is `android:finishOnTaskLaunch`. If set to `true`, and if the user leaves the task and returns to it, the activity is destroyed. Whereas `android:noHistory` removes the activity when the user leaves the *activity*, `android:finishOnTaskLaunch` only removes the activity when the user leaves the task and returns to it.

The Hidden Task

Perhaps you have a use case where you want your entire task to be hidden from the overview screen.

To do that, you can indicate that the activity that is the root of the task (e.g., your launcher activity) is to be "excluded from recents". To do that, you can:

- Add `android:excludeFromRecents="true"` to the appropriate `<activity>` element in your manifest, or
- Add `Intent.FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS` to the `Intent` used to start up the activity and its task

Note that this only matters if the activity in question is the task root (i.e., the one that started the task). Having this setting on other activities higher in the back stack will have no effect on the visibility of the task.

Also, please note that this does not eliminate the task itself. It merely hides it from the overview screen. So, for example, suppose you were to:

- Add `android:excludeFromRecents="true"` to `MainActivity` in the `TaskCanary` sample
- Run the sample app
- Press HOME and note the task ID that shows up in LogCat
- Press RECENTS and note that the task does not show up there
- Return to the home screen, find `TaskCanary` in the launcher, and tap on the launcher icon
- Press HOME again and note the task ID that shows up in LogCat

You will see that those task IDs are the same. So, the task is there, and we can return to that task, but the task is merely suppressed from the listing shown in the overview screen.

Dealing with the Persistent Tasks

As noted previously in this chapter, on Android 5.0+, tasks live forever, insofar as they survive a reboot. That, coupled with a seemingly-infinite roster of recent tasks — compared with rather finite lists in earlier versions of Android — means that your app usually will be brought back from an existing task on Android 5.0+.

However, there are a few key differences.

The State of Your State

For normal process termination, in between device reboots, the Bundle that we get in onSaveInstanceState() is held onto in RAM by some core OS process. Of course, on a reboot, that process is terminated along with everything else. And a Bundle can hold onto objects that, while perhaps Parcelable, are not designed to be persisted.

The default behavior is that when your task is brought back to the foreground after a reboot, only the task's root activity is created, and that is the only activity in the task. This effectively mimics the behavior of pre-Android 5.0 versions of Android.

However, if you want to, you can control a bit more how your task behaves on a reboot.

Your <activity> element in the manifest can have a largely-undocumented android:persistableMode attribute. If you set this to persistAcrossReboots on the activity that serves as the root of your task (e.g., your launcher activity), then you will be able to override three additional methods on your Activity:

- onCreate()
- onSaveInstanceState()
- onRestoreInstanceState()

Right now, you may think that the author of this book is drunk, as we covered those methods already, far earlier in the book.

However, what API Level 21 adds, for persistAcrossReboots activities, are flavors of those methods that take two parameters: a Bundle (as normal) and a PersistableBundle. Values that you store in the latter parameter will be delivered to you when your activity is re-created as part of your task coming back to the foreground, even after a reboot.

Note that all of the above requires that you set your compileSdkVersion to 21 or higher.

PersistableBundle allows you to save int, long, double, and String values, along with arrays of each. On Android 5.1+, you can also save boolean and arrays of boolean values. Notably, you cannot put a Parcelable (or, strangely, a Serializable) in a PersistableBundle.

If your activity has persistAcrossReboots set — as does MainActivity in the Tasks/PersistentCanary sample application — you will be called both with the single-parameter and dual-parameter versions of those methods, in that order. Unless your app has a minSdkVersion of 21 or higher, you will probably wind up overriding both versions of each method, where you put stuff in the Bundle in the single-parameter method and you put stuff in the PersistableBundle in the dual-parameter method. Since versions of Android prior to 5.0 do not know about PersistableBundle or methods that take one, only the single-parameter versions of those methods will be called on those devices. If your minSdkVersion is 21 or higher, though, you could just override the dual-parameter versions of the methods and work with both Bundle and PersistableBundle as needed.

Where You Return To

Normally, if your task is in the overview screen, and the user returns to it, the user will be taken to whatever activity was at the top of the back stack.

However, if the device reboots, and the user returns to your task, what happens depends on that semi-documented persistableMode value:

- If the value for the root activity of the task is persistNever, the task is not persisted across reboots
- If the value for the root activity of the task is persistRootOnly, the task will be persisted, but only for that root activity; other activities higher on the back stack are discarded
- If the value for the root activity of the task is persistAcrossReboots, then not only is the task persisted for the root activity, but other activities on the back stack are also persisted if they too have persistAcrossReboots (and were not launched with the FLAG_CLEAR_TASK_WHEN_RESET flag)

So, in the case of PersistentCanary, even if you use the overflow to bring up the date-and-time Settings screen, since that activity has the default persistRootOnly value for persistableMode, only the MainActivity will be in the task after a reboot.

Documents As Tasks

Tasks used to be relatively app-centric. By and large, each app had its own task, and just one task.

Android 5.0 extended the task system to support the notion of "documents" as tasks. Now, an app may be in several tasks, with different tasks focused on different "documents" or other specific contexts.

The vision is that this would be used by:

- Web browsers, where different browser tabs would be represented as separate tasks
- Editors, where different editing sessions on different content could be represented as separate tasks
- And so on

The benefit to the user is a standard way to switch between these different contexts, by means of the overview screen. The risk is that the overview screen becomes unwieldy, choked with too many entries to sift through.

When You Should Do This

An app should open a new "document" based on some specific explicit "open" operation by the user. So, for example:

- If the user asks to open a new "tab" in a browser, that could start a new document
- If the user asks to open a new file into an editor, that *might* start a new document, if you feel that the user understands that there are N other documents out there already opened in this editor
- If the user launches one of your activities from outside of the home screen, such as by clicking on a link in a Web browser, that might start a new document, to keep that work separate from any past work that might be part of other active tasks

Conversely, an app should not open a new document based on pure navigation operations:

- Swiping to a new page in a `ViewPager` should not open a new document
- Choosing an item in a nav drawer should not open a new document
- Tapping on an action bar item on its own should not open a new document, though it might lead the user down a path to open a new document

Adding a Document

You have a few options for launching an activity as a new document, indicating that it should have a separate entry on the Android 5.0+ overview screen.

android:documentLaunchMode

If you always want this activity to form the basis of a new document, add `android:documentLaunchMode="always"` to the `<activity>` element of your manifest, and you are done. Every time you start up an instance, you will get a new document.

This can be seen in the Tasks/Docs sample application, which has an `EditorActivity` with the aforementioned attribute:

```
    <activity
      android:name=".EditorActivity"
      android:documentLaunchMode="always"
      android:maxRecents="3"
      android:autoRemoveFromRecents="true"/>
```

(we will cover those other new attributes shortly)

There are four possible values for `android:documentLaunchMode`:

- `always`, as noted, always starts a new document
- `intoExisting`, which looks for an existing document, where the root activity is the same class and the `Intent` is for the same `Uri`, and brings it back to the foreground, or starts a new document if a match cannot be found
- `never` prevents this activity from ever being launched as a new document
- `none`, which is the default, indicates that the activity will only be launched as a new document if `Intent` flags indicate that it should, as will be explained shortly

Since `intoExisting` depends upon `Uri` matches, you only want to use `intoExisting` if you are passing `Uri` values into the activity when starting it. Otherwise, use `always`.

FLAG_ACTIVITY_NEW_DOCUMENT

To conditionally launch an activity as a new document, have its `android:documentLaunchMode` set to `none` (or missing, since that is the default), and add Intent.FLAG_ACTIVITY_NEW_DOCUMENT to the Intent that is used to start up the activity that would represent a new document. This will have the behavior akin to intoExisting for android:documentLaunchMode, meaning that Android will search for a matching document and bring it back to the foreground if the match is available.

To replicate always functionality, add both Intent.FLAG_ACTIVITY_NEW_DOCUMENT and Intent.FLAG_ACTIVITY_MULTIPLE_TASK to the Intent.

Capping the Number of Documents

By default, you can launch as many documents as you want. However, unless you get rid of the document (as will be described below), or the user gets rid of the document (by swiping it off the overview screen), your roster of documents can keep piling up. Users may get frustrated if their overview screen is flooded by entries for your app.

You can employ an automatic least-recently-used (LRU) algorithm here by adding android:maxRecents to the <activity> that is the root of the task for the document. This indicates the maximum number of entries there should be in the overview screen for that activity, where Android will remove older tasks to make way for new ones if needed.

So, in the Docs sample, android:maxRecents="3" limits the number of EditorActivity tasks to 3; if the user tries opening more than this, older ones are quietly removed.

Note that the default value for android:maxRecents is 16. Also, there is a cap, ranging from 25 to 50, depending on device RAM — you will be unable to set it higher than this.

Removing and Retaining Documents

Android's default behavior is that the document will exist forever, or until the user swipes it off the overview screen.

It is rather unlikely that this is really the behavior that you or your users will want. Hence, you are going to want to take some steps to ensure that your documents will go away from the overview screen when they are no longer needed.

The simplest solution is to add `android:autoRemoveFromRecents="true"`. This indicates that once the root activity is finished (e.g., the user presses BACK), the document is removed. By default, pressing BACK does *not* remove the document, so you need to opt into this behavior.

However, that approach assumes that it is fairly easy for the user to get back to the task's root activity and press BACK. If you have a complex navigation of activities within the "document", it may not be easy for the user to trigger document removal this way.

You can also forcibly get rid of the document by calling `finishAndRemoveTask()` yourself on an activity in the task. For example, in a tabbed Web browser, if you have a "close tab" UI element (e.g., action bar item), that could call `finishAndRemoveTask()` to get rid of the "document".

Other Task-Related Activity Properties

There are other attributes that you can place on your `<activity>` element in the manifest that have impacts on how that activity participates with the task system.

launchMode

Occasionally, particular techniques become much too popular in Android development, courtesy of some blog posts or other resources touting them as "quick hacks" to address certain issues. The `android:launchMode` attribute is one of those. Most Android apps should have no need to change `launchMode` off of its default value of `standard`, or occasionally `singleTop`. Yet, because the Android task system is rather confusing, some developers latch onto other launch modes and use them in places where there are better, more fine-grained solutions.

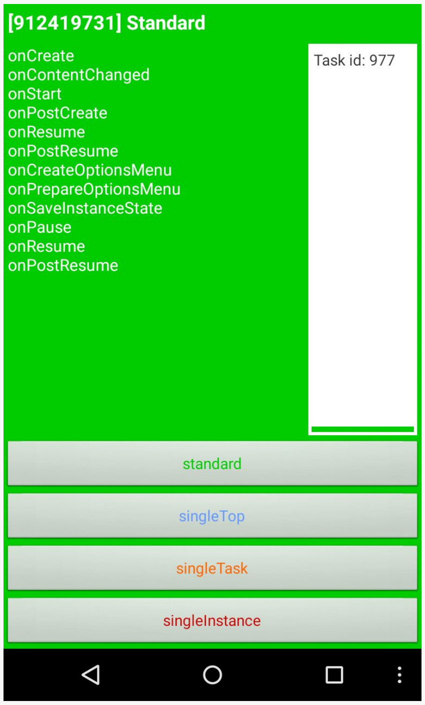
That being said, let's explore the launch modes, with the help from the fine people at Novoda. The Novoda developers released an app on the Play Store, and an accompanying GitHub repo that helps to illustrate the launch modes.

That app has four activities, one for each of the four launch modes:

- `standard`
- `singleTop`
- `singleTask`
- `singleInstance`

The launcher activity is the `standard` activity. Each activity has four buttons, to start up that activity via `startActivity()`, by default with no particular `Intent` flags (though there's a legacy options menu that allows you to play with those as well). The color-coded UI for each activity also shows a unique identifier of the activity, the task ID of the task that the activity is in, the lifecycle methods that were invoked on that instance, and a set of stacked bars designed to illustrate what should be on the back stack for that task (using some techniques of dubious reliability, but the sort of thing that should be OK for a demo app like this).

So, when we launch the app, we get a green UI for a `standard` activity:



[912419731] Standard

```
onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume
onCreateOptionsMenu
onPrepareOptionsMenu
onSaveInstanceState
onPause
onResume
onPostResume
```

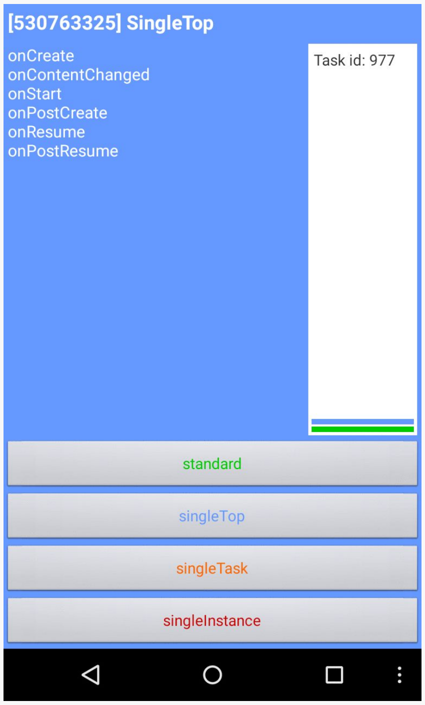
Task id: 977

Figure 625: Novoda Demo App, As Initially Launched

`singleTop`

Using `singleTop` for the `launchMode` has one effect: controlling whether a new instance of the activity is created. Normally, calling `startActivity()` will create a new instance of the activity, unless `Intent` flags dictate otherwise. With `singleTop`, if the activity being started is already at the top of its stack, that existing instance is simply called with `onNewIntent()`. Otherwise, `singleTop` behaves as does `standard`.

So, if we tap the button to launch a `singleTop` method in the Novoda demo app, from our earlier state, we get a blue `singleTop` activity:



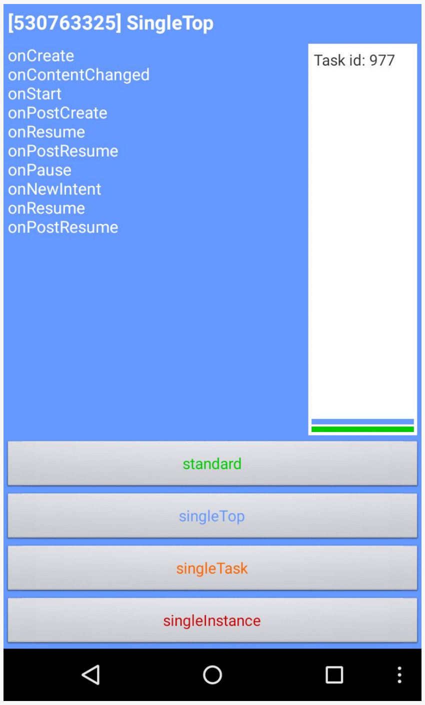
[530763325] SingleTop

onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume

Task id: 977

Figure 626: Novoda Demo App, After Starting singleTop Activity

That worked just like `standard`. But, if we tap the same button again, we do *not* get a new instance of the activity. However, the transcript of lifecycle methods shows that `onNewIntent()` was called:



[530763325] SingleTop

onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume
onPause
onNewIntent
onResume
onPostResume

Task id: 977

Figure 627: Novoda Demo App, After Starting singleTop Activity Again

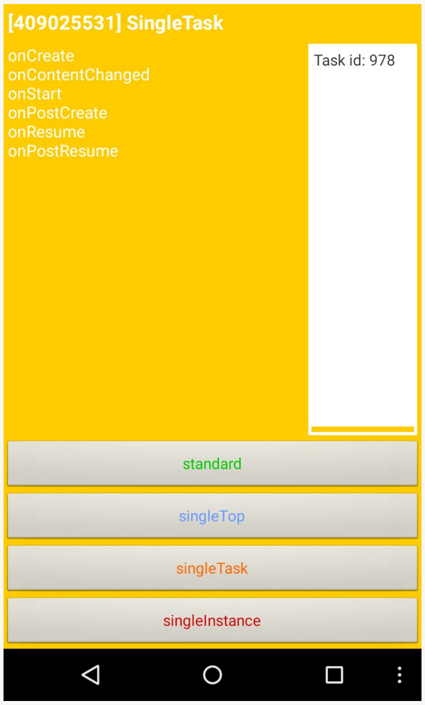
Note that you can get a similar result by including `Intent.FLAG_ACTIVITY_SINGLE_TOP` on a `startActivity()` call. Using `launchMode` says you *always* want single-top behavior; using `FLAG_ACTIVITY_SINGLE_TOP` says that *this time* you want single-top behavior.

Pressing BACK returns you to the original green `standard` activity, with the blue `singleTop` activity having been destroyed.

singleTask

A `launchMode` of `singleTask` says that this activity must *always* be the root activity of a task.

If the task does not have that activity, a new task is created. So, if we tap the button to launch the `singleTask` activity in the Novoda demo app, we get a new task (ID 978, compared to the previous 977), with an instance of the yellow `singleTask` activity as its root:



[409025531] SingleTask

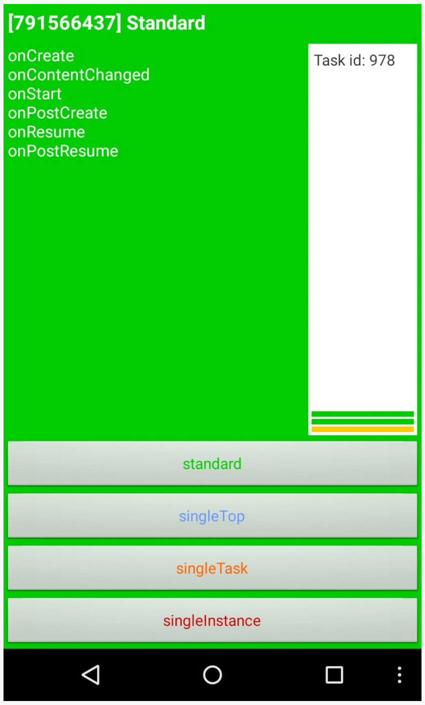
```
onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume
```

Task id: 978

Figure 628: Novoda Demo App, After Starting singleTask Activity

However, if the activity in question is already there as the root of the task, all other activities on the back stack are cleared, and we are taken to the `singleTask` activity again.

So, in the Novoda demo app, if after we start the `singleTask` activity, we tap the button to launch a `standard` activity or two:



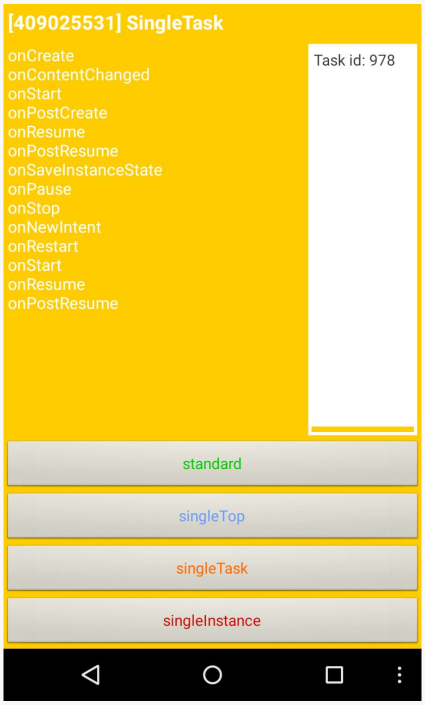
[791566437] Standard

onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume

Task id: 978

Figure 629: Novoda Demo App, Two standard Activities After singleTask Activity

…then tap the button to launch the `singleTask` activity, we get largely the same screen as before, just with a few more lifecycle methods logged:



[409025531] SingleTask

```
onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume
onSaveInstanceState
onPause
onStop
onNewIntent
onRestart
onStart
onResume
onPostResume
```

Task id: 978

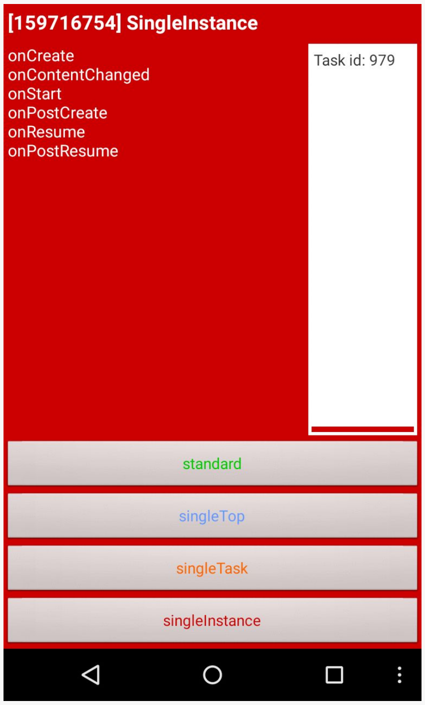
Figure 630: Novoda Demo App, After Starting singleTask Activity Again

It is the same task and the same instance, but with the other activities removed.

singleInstance

`singleInstance` works much like `singleTask`, except that the task will only ever hold this one activity. No other activities will be placed into the task.

So, tapping the button to start a `singleInstance` activity in the Novoda demo app brings up the red `singleInstance` UI:



[159716754] SingleInstance

```
onCreate
onContentChanged
onStart
onPostCreate
onResume
onPostResume
```

Task id: 979

Figure 631: Novoda Demo App, After Starting singleInstance Activity

Tapping the same button again just triggers `onNewIntent()` and other lifecycle methods on the same activity in the same task. If, however, you try tapping on the button for the `standard` activity, your activity will go to another task. Depending on when and how you try the Novoda demo app, this could be a prior task associated with our app (e.g., one you used for earlier `standard` tests), or it could be a new task (if you do not have any other ones). This is based on the `taskAffinity` of the activity being started.

In general, `singleTask` and `singleInstance` are for unusual use cases, and ordinary Android apps should have little reason to use them. Google specifically urges you *not* to use them:

> ...standard is the default mode and is appropriate for most types of activities. SingleTop is also a common and useful launch mode for many types of activities. The other modes — singleTask and singleInstance — are not appropriate for most applications, since they result in an interaction model that is likely to be unfamiliar to users and is very different from most other applications.

alwaysRetainTaskState

As noted earlier in the chapter, tasks may be cleared by Android if the user has not been in the task for some time (e.g., 30+ minutes). In these cases, the user is taken back to the root activity.

If, however, the root activity has `android:alwaysRetainTaskState="true"` in its manifest entry, then Android will not apply this timeout rule. So long as the task exists, its entire state will be retained and used when the user returns to the task. This is useful for tasks where there is a lot of state that the user might regret losing.

Other Task-Related Activity Methods

There are a handful of other task-related methods and such floating around the `Activity` class:

finishAffinity()

This calls `finish()` not only on the current activity, but on all activities immediately behind it on the back stack for this task that have the same `taskAffinity` as does the current activity. Much of the time, the activities on the stack will all share an affinity, and therefore this will frequently finish all activities in the task. If the task has a mixed set of affinities (e.g., a mix of explicitly-named affinities and other activities using the default affinity), this method would only wipe out those behind the current with a specific match.

This method is not commonly used.

finishAndRemoveTask()

This calls `finish()` on all activities in the task and removes the task outright.

For example, a "logout" operation might call `finishAndRemoveTask()` to flush the current task, then call `startActivity()` to launch the login activity. That login activity will wind up in a fresh task (since the current one will be removed), and the old activity instances will go away, so the user cannot somehow stumble into them when they are not yet logged in.

getTaskId()

Returns a unique integer that identifies the task the activity resides in.

This method is not commonly used.

isTaskRoot()

`isTaskRoot()` is a method on `Activity`. It will return `true` if this activity instance is at the root of a task, meaning that pressing BACK should remove the task and return the user to the home screen.

moveTaskToBack()

This method moves the current task to the background. What comes to the foreground is undocumented but generally seems to be the task for the home screen. Some apps use this to offer a "minimize" or "go to background" option within the app, though this is superfluous, as the task will move to the background naturally as the user navigates their device.

setTaskDescription()

For Android 5.0+, `setTaskDescription()` allows you to associate an `ActivityManager.TaskDescription` instance with your task. Here you can provide values that help drive what the task looks like on the overview screen. Specifically, you can provide the icon, title, and background color to use for the title bar over your thumbnail on the overview screen.

The Assist API ("Now On Tap")

Android 6.0 introduced the concept of the device "assistant". The assistant can be triggered by a long-press of the HOME button or via a spoken phrase (if the user has always-on keyphrase detection) enabled. An assistant is a special app that has access to the content of the foreground activity and other visible windows, much like an accessibility service does.

For the vast majority of users of Google Play ecosystem devices running Android 6.0 or higher, the "assistant" is known as Now On Tap. This is marketed as an extension of the Google Now UI, where Now On Tap will take the data from the foreground activity and use that to find other relevant things for the user to do based upon that data.

For example, suppose the user receives a text message, suggesting dinner at a particular restaurant. The restaurant is merely named — no URL — and so the text messaging client would just display the name of the restaurant as part of the message. If the user invokes Now On Tap, Google will take the contents of this message (and anything else on the screen), and presumably send it to Google's servers, sending back things like details about the restaurant (e.g., URL to Web site, Google's scanned reviews of the restaurant, link to Google Maps for driving directions). Google's search engine technology would scan the data from the app, recognize that the restaurant name appears to be something significant, and give Now On Tap details of what to offer the user.

As with many things from Google, Now On Tap is very compelling and very much a privacy problem. Now On Tap is automatically installed and enabled on Android 6.0 devices — users have to go through some work to disable it. Users and app developers have limited ability to control Now On Tap, in terms of what data it collects and what it does with that data. On the other hand, certain apps (for which there are no privacy considerations) might wish to provide *more* data to Now On

Tap, beyond what is visible in widgets, to help provide more context for Now On Tap to help users.

In this chapter, we will explore the Assist API, in terms of:

- what data gets collected
- how apps can add to that data
- how apps can block sensitive information from the assistant
- how to write your own assistant, as a Now On Tap replacement

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

What Data Gets Disclosed

Quite a bit of data is made available to Now On Tap or other assistants through the Assist API alone, as will be explored in this section.

Assistants are welcome to use other APIs as well, subject to standard Android permissions and such. So, for example, an app might not show the device's location, and therefore an assistant could not get the location from the Assist API, but the assistant could use `LocationManager` or the Play Services location API to find out the device's location.

There is also a risk of pre-installed assistants using undocumented means of getting at data beyond what the normal Android SDK would allow.

All that being said, assistants will get a lot of information about the currently-visible UI, just from what the Assist API provides.

Screenshot

Assistants can get a screenshot of the current screen contents — minus the status bar — when the user activated the assistant (e.g., long-pressed HOME). Developers can block this for select activities or other windows. Hence, an assistant cannot *assume* that it will get a screenshot, though frequently it will.

Presumably, the "vision" here is to use computer vision and other image recognition techniques on the screenshot to find things of interest. For example, the user might bring up Now On Tap for some activity that is showing a photo of a monument. The activity might not be showing any other details about the monument, such as its name. However, Google's servers might well recognize what monument it is and therefore give the user links to Wikipedia pages about the monument, a map of where the monument is located, etc.

View Structure

By far the largest dump of data that the assistant gets comes in the form of the view structure. This is represented by a tree of `AssistStructure.ViewNode` objects, one per widget or container within a window. These provide similar information as to what one gets from the accessibility APIs. For most assistants, the key data is the text or content description in the widget. In the case of text, this is available as a `CharSequence` and so may contain additional information (e.g., hyperlinks represented in `URLSpan` objects) beyond the words visible to the user.

Developers can restrict what widgets and containers are disclosed, but that is something developers have to do explicitly. In other words, making data available to assistants is something a developer has to opt out of, not opt into.

Other Data

In addition to the view structure and a largely-undocumented `Bundle`, the other piece of data supplied to the assistant is the `AssistContent`. Here is where an app can provide some additional context about the foreground activity.

Specifically, the app can provide:

- an `Intent` that represents the activity, replacing the `Intent` that was used to start the activity, if there is a better one for long-term use (e.g., the activity was started via a `Notification` action and you want to route the user through a different `Intent` for other scenarios)
- a `Uri` that points to some Web page of relevance for this activity
- a string of "structured data", designed to be populated by a snippet of JSON using the schema.org specification, to provide details of the book, song, video, or whatever happens to be in the activity at the moment
- another undocumented `Bundle`
- an undocumented `ClipData`

Assistants can use this directly (e.g., offer a link to the `Uri` supplied in this content) or indirectly (e.g., using the schema.org JSON to find places where the user can purchase related content).

Adding to the Data

You may wish to provide some additional information to Now On Tap or other assistants, such as the `Intent` or JSON described above. Or, you may just generally want to ensure that your app provides the maximum amount of information to these assistants, without necessarily trying to invent new data to provide.

There are a few options for accomplishing this.

Accessibility

The big one is to ensure that your app provides text or content descriptions for everything visible. This will not only help these assistants, but this will make your app far more accessible to those using TalkBack or other accessibility services.

Mostly, this is a matter of ensuring that your `ImageView` widgets and other non-textual widgets have a content description, whether set via `android:contentDescription` attributes or by `setContentDescription()` in Java. `TextView` and its subclasses automatically use their text as the content description; `EditText` will use the hint if there is no text in the field at the moment.

More advice regarding accessibility can be found in the chapter on accessibility and focus management.

Assist-Specific Data

Beyond that, you can contribute to the `AssistContent` (where the `Intent`, `Uri`, and JSON live) and other assist-related information for a given invocation of the assistant by the user.

You have a few options of where to place this logic: in one spot globally, on a per-activity basis, and, for custom views, on a per-view basis.

Globally

You can call `registerOnProvideAssistDataListener()` on the global `Application` object (retrieved by calling `getApplicationContext()` on some other `Context`, like your `Activity`). This takes an `OnProvideAssistDataListener` implementation, which in turn provides an `onProvideAssistData()` implementation, that will be called when the assistant is requested. You are passed the `Activity` of yours that is in the foreground, along with a `Bundle` that you can fill in.

However, the documentation only says that the `Bundle` will go into the `EXTRA_ASSIST_CONTEXT` extra on the `Intent` that invokes the assistant. What that `Bundle` is supposed to contain is undocumented.

Per-Activity

Your primary hooks for customizing the assist data come in the form of two callbacks on your `Activity` subclasses: `onProvideAssistData()` and `onProvideAssistContent()`.

`onProvideAssistData()` is given the same `Bundle` that is given to the `OnProvideAssistDataListener` on a global basis. However, it is unclear what goes in that `Bundle`, and the contents of that `Bundle` do not appear to make it to the assistant, at least through the documented Assist API.

`onProvideAssistContent()`, though, is more relevant.

The [`Assist/MoAssist`]() sample project is a clone of [a sample app demonstrating the use of tabs in Android](). The clone has its `compileSdkVersion` bumped to 23, and it overrides `onProvideAssistData()` and `onProvideAssistContent()`:

```
@Override
public void onProvideAssistData(Bundle data) {
  super.onProvideAssistData(data);

  data.putInt("random-value", new SecureRandom().nextInt());
}

@TargetApi(23)
@Override
public void onProvideAssistContent(AssistContent outContent) {
  super.onProvideAssistContent(outContent);

  outContent.setWebUri(Uri.parse("https://commonsware.com"));

  try {
    JSONObject json=new JSONObject()
      .put("@type", "Book")
      .put("author", "https://commonsware.com/mmurphy")
      .put("publisher", "CommonsWare, LLC")
      .put("name", "The Busy Coder's Guide to Android Development");

    outContent.setStructuredData(json.toString());
  }
  catch (JSONException e) {
    Log.e(getClass().getSimpleName(),
      "Um, what happened here?", e);
  }
}
```

The `onProvideAssistData()` simply puts a random number into the `Bundle`. That random number does not appear anywhere in the data collected by an assistant.

`onProvideAssistContent()` fills in two items in the `AssistContent`:

- a Web URL of relevance to the activity, in this case the home page of the book's publisher
- a bit of JSON, following the published schema.org `Book` structure, with metadata about this book

This information *is* supplied to assistants and can be used by them to do something useful, such as offer links for the user to click on to visit the sites.

Per-View

If you are implementing your own custom views, particularly those that render their own text using low-level `Canvas` APIs, you may wish to override `onProvideStructure()` and/or `onProvideVirtualStructure()`. These will be called on your widgets to provide the `AssistStructure.ViewNode` details to be passed to the assistant.

However, in all likelihood, you would want to instead work with the accessibility APIs to publish data to be used by accessibility services, such as the text that you are rendering. If you do that, the default implementations of `onProvideStructure()` and `onProvideVirtualStructure()` should suffice.

Removing from the Data

While some developers may embrace Now On Tap, others may specifically want to prevent Now On Tap or other assistants from "spying" on application data. You have a few options for controlling what is provided to assistants; however, all require work and some have side effects. For example, there is nothing in the manifest that you can specify to make your activities opt out of providing assist data.

FLAG_SECURE

The standard approach for making private activities *really* private is to use FLAG_SECURE:

```
public class FlagSecureTestActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    getWindow().setFlags(LayoutParams.FLAG_SECURE,
                         LayoutParams.FLAG_SECURE);

    setContentView(R.layout.main);
  }
}
```

Call setFlags() before setContentView(), in this case setting FLAG_SECURE.

The classic effect of FLAG_SECURE is to block screenshots, both user-initiated ones and system-initiated ones (e.g., the screenshots used in the overview/recent-tasks screen on Android 4.0+).

If the user triggers an assistant for a secure activity, the assistant will not get the full view structure (i.e., no widgets and no text) and will not get a screenshot.

Password Fields

An EditText that is set up as a password field will have its text blocked from the view structure. The widget will be listed, but its text will be null.

Presumably, this relies on the EditText using a PasswordTransformationMethod, as that is Android's typical approach for determining whether or not an EditText is deemed to be secure. If you have implemented your own TransformationMethod (e.g., with a different approach for shrouding the user input), either have it extend PasswordTransformationMethod or use other approaches to prevent this field's contents from being published to assistants.

NoAssistFrameLayout

The apparently-official way to block a widget or container from participating in the assist API is to create a subclass of it and override `dispatchProvideStructure()`. The stock implementation of this triggers the calls to `onProvideStructure()` and `onProvideVirtualStructure()`. Plus, for a `ViewGroup`, it will iterate over the children and call `dispatchProvideStructure()` on each of them.

If you are creating your own custom view, and you want it eliminated from the view structure, just override `dispatchProvideStructure()` and have it do nothing.

Or, you can create a container that is there solely to block the assist data collection. The `Assist/NoAssist` sample project does this, in the form of a `NoAssistFrameLayout`:

```
package com.commonsware.android.assist.no;

import android.annotation.TargetApi;
import android.content.Context;
import android.os.Build;
import android.util.AttributeSet;
import android.view.ViewStructure;
import android.widget.FrameLayout;

public class NoAssistFrameLayout extends FrameLayout {
  public NoAssistFrameLayout(Context context) {
    super(context);
  }

  public NoAssistFrameLayout(Context context,
                             AttributeSet attrs) {
    super(context, attrs);
  }

  public NoAssistFrameLayout(Context context,
                             AttributeSet attrs,
                             int defStyleAttr) {
    super(context, attrs, defStyleAttr);
  }

  @TargetApi(Build.VERSION_CODES.LOLLIPOP)
  public NoAssistFrameLayout(Context context,
                             AttributeSet attrs,
                             int defStyleAttr,
                             int defStyleRes) {
    super(context, attrs, defStyleAttr, defStyleRes);
  }

  @Override
  public void dispatchProvideStructure(ViewStructure structure) {
    // no, thanks
  }
}
```

EditorFragment — responsible for showing a large multi-line EditText for the user to type into — will conditionally use a NoAssistFrameLayout, specifically on the third tab (a ViewPager position of 2):

```
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    int position=getArguments().getInt(KEY_POSITION, -1);
    View result;

    if (position==2) {
      ViewGroup doctorNo=new NoAssistFrameLayout(getActivity());
      inflater.inflate(R.layout.editor, doctorNo);
      result=doctorNo;
    }
    else {
      result=inflater.inflate(R.layout.editor, container, false);
    }

    EditText editor=(EditText)result.findViewById(R.id.editor);

    editor.setHint(getTitle(getActivity(), position));

    if (position==1) {
      editor.
        setTransformationMethod(PasswordTransformationMethod.
          getInstance());
    }

    return(result);
  }
```

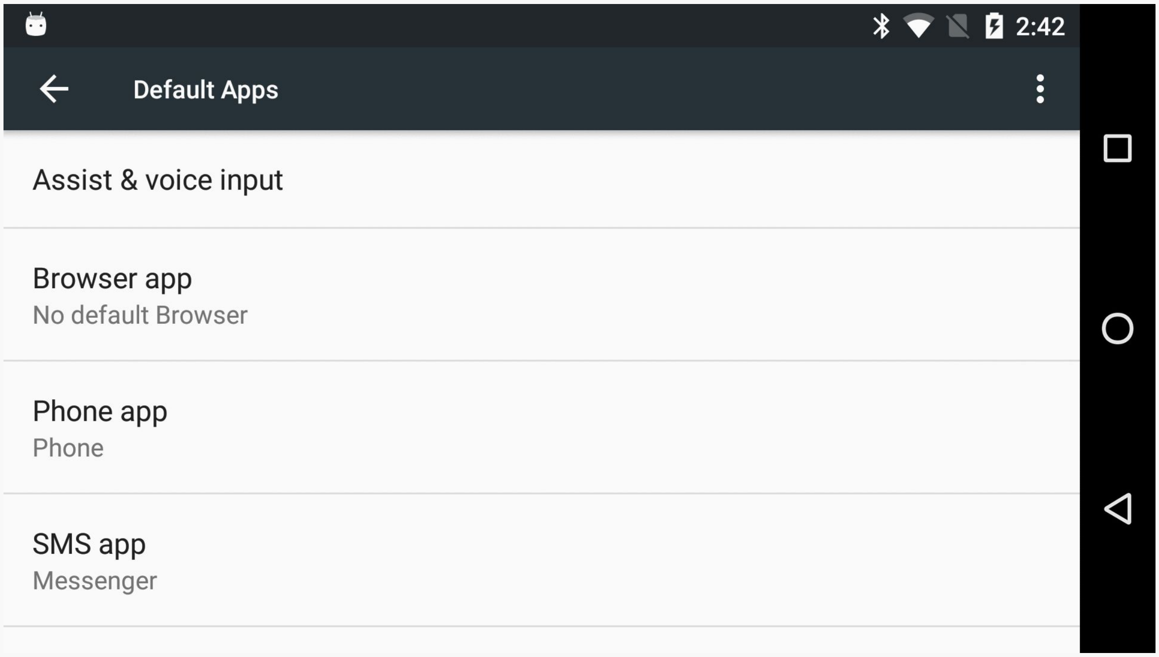
If we are on the third tab, we create a NoAssistFrameLayout and inflate our EditText into it. Otherwise, we inflate the layout normally.

Note that this sample also applies a PasswordTransformationMethod for the second page of the ViewPager (a position of 1), to illustrate the null text that will be recorded as a result.

Blocking Assist as a User

It is possible that your reaction to all of this is that you want to opt out of Now On Tap as a user. Or, perhaps you want to provide some instructions to your users on how to opt out of Now On Tap.

Go to Settings > Apps. There should be an option for advanced app configuration actions (on Nexus-series devices, this is a gear icon in the action bar). Tap that, then choose "Default Apps" to bring up categories of default apps for various actions:



Assist & voice input

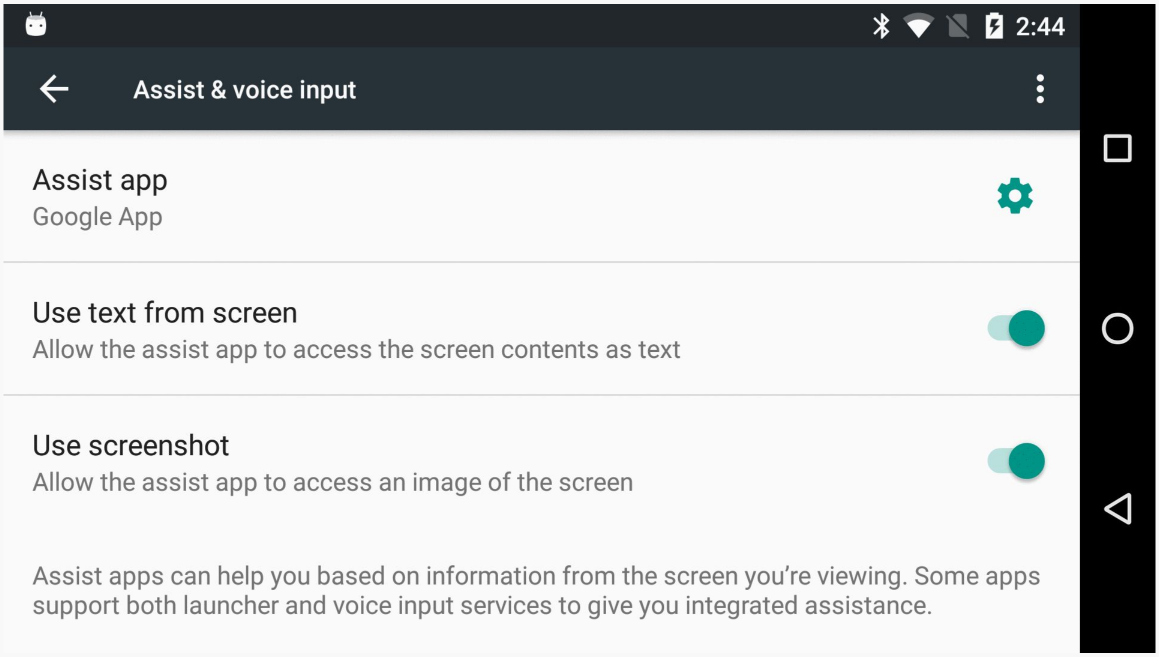
Browser app
No default Browser

Phone app
Phone

SMS app
Messenger

Figure 632: Android 6.0 Default Apps Screen in Settings

In there, tap on "Assist & voice input". By default, you should see "Google App" as the chosen option, which means that Now On Tap is active:



2:44

Assist & voice input

Assist app
Google App

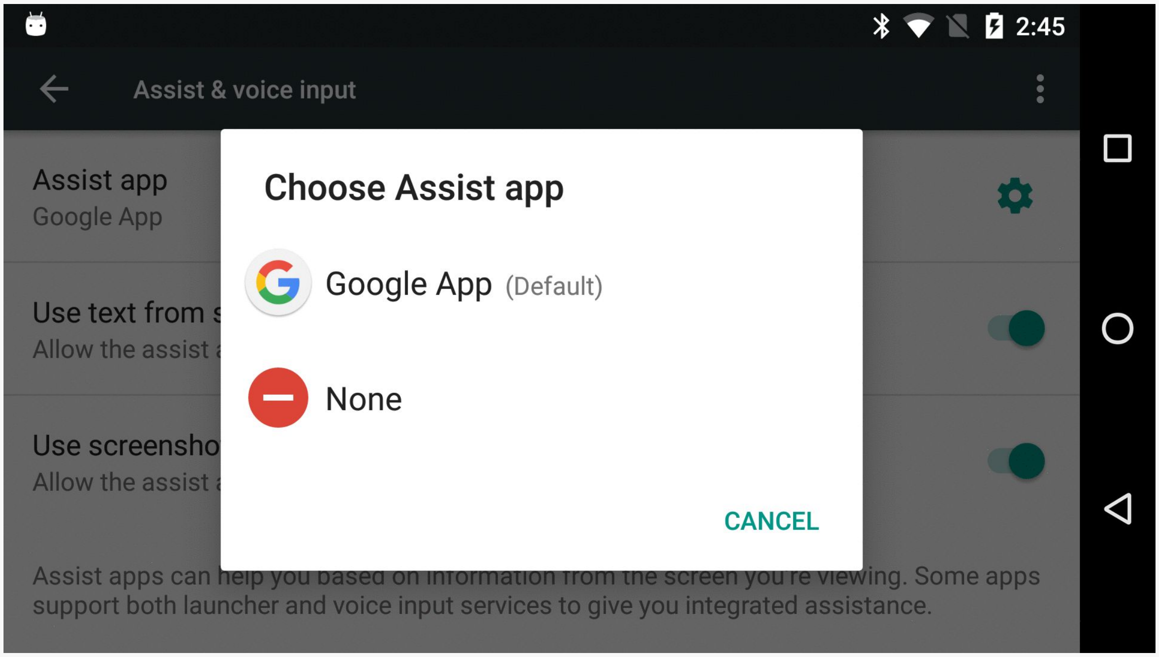
Use text from screen
Allow the assist app to access the screen contents as text

Use screenshot
Allow the assist app to access an image of the screen

Assist apps can help you based on information from the screen you're viewing. Some apps support both launcher and voice input services to give you integrated assistance.

Figure 633: Android 6.0 Assist & Voice Input Screen in Settings

Tapping on that entry will bring up a list of available options, including "None":



2:45

Choose Assist app

Google App (Default)

None

CANCEL

Figure 634: Android 6.0 Assist & Voice Input Options in Settings

Implementing Your Own Assistant

While Now On Tap is pre-installed and pre-activated, and while users can disable Now On Tap, another option for users is to activate some other assistant. Any app that implements the proper pieces of the Assist API will appear in the roster of available assistants for the user to choose from, as described in the previous section. The Assist/AssistLogger sample project represents one such app.

Primarily, this app is for diagnostic purposes, showing you exactly what your activity is "leaking" to assistants. It was essential in figuring out how the APIs shown in earlier examples in this chapter worked, for instance. However, it also serves as a demonstration of the minimum requirements to implement an assistant in general.

Creating an assistant is technically part of a larger bit of work on handling voice interactions in Android. However, if all you want is an assistant, you can ignore the voice-related bits.

A Stub VoiceInteractionService

Some of what is needed to set up an assistant is some boilerplate.

For example, the entry point for assistants and voice interactions is a custom subclass of VoiceInteractionService. If you only are concerned with implementing an assistant, your VoiceInteractionService can be empty:

```
package com.commonsware.android.assist.logger;

import android.service.voice.VoiceInteractionService;

public class AssistLoggerService extends VoiceInteractionService {
}
```

However, it needs to exist, and in particular it needs to have its <service> entry in your manifest:

```
    <service
      android:name=".AssistLoggerService"
      android:permission="android.permission.BIND_VOICE_INTERACTION">
      <meta-data
        android:name="android.voice_interaction"
        android:resource="@xml/assist_service"/>
      <intent-filter>
        <action android:name="android.service.voice.VoiceInteractionService"/>
      </intent-filter>
    </service>
```

The keys to the manifest entry are:

- It needs to have the `android:permission` attribute, limiting it clients that hold the `BIND_VOICE_INTERACTION` permission, which should limit clients to those that are part of the device firmware
- It needs to have the `<intent-filter>` advertising that it supports the `android.service.voice.VoiceInteractionService` action string
- It needs an `android.voice_interaction` `<meta-data>` element, pointing to an XML resource that further configures the voice interaction/assistant implementation

The sample project has that metadata in `res/xml/assist_service.xml`:

```
<voice-interaction-service
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:recognitionService="com.commonsware.android.assist.logger.AssistLoggerService"

android:sessionService="com.commonsware.android.assist.logger.AssistLoggerSessionService"
  android:supportsAssist="true"/>

<!--
  android:settingsActivity="com.android.test.voiceinteraction.SettingsActivity"
-->
```

There are three attributes required on the `<voice-interaction-service>` root element to enable an assistant:

- `android:recognitionService` points back to your `VoiceInteractionService` subclass
- `android:sessionService` points to a subclass of `VoiceInteractionSessionService` (we will examine the project's implementation shortly)
- `android:supportsAssist` should be `true`

If you want, you can also have an `android:settingsActivity` attribute, shown in this XML as a commented-out snippet at the end of the file. This can point to an activity in your app. If you have this, a gear icon will appear on the "Assist & voice input" Settings screen that, when tapped, will bring up this activity, to configure the behavior of your assistant. The sample app skips this.

A Trivial VoiceInteractionSessionService

The service pointed to by `android:sessionService` in the metadata needs to be a subclass of `VoiceInteractionSessionService`. The only method that you need to override is onNewSession(), where you can return an instance of a VoiceInteractionSession:

```
package com.commonsware.android.assist.logger;

import android.os.Bundle;
import android.service.voice.VoiceInteractionSession;
import android.service.voice.VoiceInteractionSessionService;

public class AssistLoggerSessionService extends
  VoiceInteractionSessionService {
  @Override
  public VoiceInteractionSession onNewSession(Bundle args) {
    return(new AssistLoggerSession(this));
  }
}
```

Here, we return an instance of AssistLoggerSession, which is where all of our real business logic resides for our assistant.

Note that this service also should use android:permission to limit clients to those that hold the android.permission.BIND_VOICE_INTERACTION permission:

```
    <service
      android:name=".AssistLoggerSessionService"
      android:permission="android.permission.BIND_VOICE_INTERACTION"/>
```

The VoiceInteractionSession

VoiceInteractionSession has a *lot* of methods that you can override, both for voice interactions and for assistant invocations. The sample app overrides the minimum required for an assistant, as its mission simply is to log all of the data received by our assistant to files on external storage, for diagnostic purposes.

NOTE: Running this sample app on hardware that is actually used with private data is stupid beyond words. Any app can then read the files on external storage and see what information is published by whatever apps are in the foreground at the times when you invoke the assistant. Please use this only on test environments.

Basic Setup

Akin to components, a VoiceInteractionSession has an onCreate() method, called as part of setting up the session. In there, AssistLoggerSession sets up an output directory for logging the results, assuming that external storage is available:

```
@Override
public void onCreate() {
  super.onCreate();

  if (Environment.MEDIA_MOUNTED
    .equals(Environment.getExternalStorageState())) {
    String logDirName=
      "assistlogger_"+
        new SimpleDateFormat("yyyyMMdd'-'HHmmss").format(new Date());

    logDir=
      new File(getContext().getExternalCacheDir(), logDirName);
    logDir.mkdirs();
  }
}
```

onHandleScreenshot()

If the user invokes your assistant, you will be called with `onHandleScreenshot()`. Usually, you will be passed a `Bitmap` that contains the screenshot. However, if the foreground activity is using `FLAG_SECURE`, the `Bitmap` that is passed to you will be `null`, so make sure you check it before doing anything with it.

The `AssistLoggerSession` forks a `ScreenshotThread` to save this screenshot in the background:

```
@Override
public void onHandleScreenshot(Bitmap screenshot) {
  super.onHandleScreenshot(screenshot);

  if (screenshot!=null) {
    new ScreenshotThread(logDir, screenshot).start();
  }
}
```

`ScreenshotThread`, in turn, just uses `compress()` on `Bitmap` to write the image out as a PNG to the directory that we are using for logging:

```
private static class ScreenshotThread extends Thread {
  private final File logDir;
  private final Bitmap screenshot;

  ScreenshotThread(File logDir, Bitmap screenshot) {
    this.logDir=logDir;
    this.screenshot=screenshot;
  }

  @Override
  public void run() {
    if (logDir!=null) {
      try {
        File f=new File(logDir, "screenshot.png");
```

```
          FileOutputStream fos=new FileOutputStream(f);

          screenshot.compress(Bitmap.CompressFormat.PNG, 100, fos);
          fos.flush();
          fos.getFD().sync();
          fos.close();
          Log.d(getClass().getSimpleName(),
            "screenshot written to: "+f.getAbsolutePath());
        }
        catch (IOException e) {
          Log.e(getClass().getSimpleName(),
            "Exception writing out screenshot", e);
        }
      }
      else {
        Log.d(getClass().getSimpleName(),
          String.format("onHandleScreenshot: %dx%d",
            screenshot.getWidth(), screenshot.getHeight()));
      }
    }
  }
```

onHandleAssist()

`onHandleAssist()` is your other main assistant callback. Here is where you get:

- a `Bundle` of undocumented stuff
- the `AssistStructure` outlining the contents of the windows, including the view hierarchy
- the `AssistContent` with the `Intent`, Web `Uri`, JSON, and so on

`AssistLoggerSession` kicks off an `AssistDumpThread` to record this data in the background:

```
  @Override
  public void onHandleAssist(Bundle data,
                             AssistStructure structure,
                             AssistContent content) {
    super.onHandleAssist(data, structure, content);

    new AssistDumpThread(logDir, data, structure, content).start();
  }
```

`AssistDumpThread` itself is a *long* class that generates a JSON file containing the information found in the parameters to `onHandleAssist()`:

```
package com.commonsware.android.assist.logger;

import android.app.assist.AssistContent;
import android.app.assist.AssistStructure;
import android.content.Intent;
import android.os.Bundle;
import android.util.Log;
import org.json.JSONArray;
import org.json.JSONException;
import org.json.JSONObject;
import java.io.File;
import java.io.FileOutputStream;
import java.io.OutputStreamWriter;
import java.io.PrintWriter;
import java.util.Set;

class AssistDumpThread extends Thread {
  private final File logDir;
  private final Bundle data;
  private final AssistStructure structure;
  private final AssistContent content;

  AssistDumpThread(File logDir, Bundle data,
                   AssistStructure structure,
                   AssistContent content) {
    this.logDir=logDir;
    this.data=data;
    this.structure=structure;
    this.content=content;
  }

  @Override
  public void run() {
    if (logDir!=null) {
      JSONObject json=new JSONObject();

      try {
        json.put("data", dumpBundle(data, new JSONObject()));
      }
      catch (JSONException e) {
        Log.e(getClass().getSimpleName(),
          "Exception saving data", e);
      }

      try {
        json.put("content", dumpContent(new JSONObject()));
      }
      catch (JSONException e) {
        Log.e(getClass().getSimpleName(),
          "Exception saving content", e);
      }

      try {
        json.put("structure", dumpStructure(new JSONObject()));
      }
      catch (JSONException e) {
        Log.e(getClass().getSimpleName(),
          "Exception saving structure", e);
      }

      File f=new File(logDir, "assist.json");

      try {
        FileOutputStream fos=new FileOutputStream(f);
        OutputStreamWriter osw=new OutputStreamWriter(fos);
        PrintWriter pw=new PrintWriter(osw);

        pw.print(json.toString(2));
        pw.flush();
        fos.getFD().sync();
        fos.close();
        Log.d(getClass().getSimpleName(),
          "assist data written to: "+f.getAbsolutePath());
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(),
          "Exception writing out assist data", e);
      }
    }
    else {
      Log.d(getClass().getSimpleName(), "onHandleAssist");
    }
  }

  JSONObject dumpBundle(Bundle b, JSONObject json)
    throws JSONException {

  }
}
```

Making a Real Assistant

AssistLogger is a faithful implementation of an assistant, but it does not really assist the user, except in seeing what sorts of information Google gets via Now On Tap.

If you wanted to make an actual assistant that is a true replacement for Now On Tap, you would also need to implement methods like:

- onCreateContentView(), where you can inflate a layout or otherwise assemble the basic UI to be shown to the user when your assistant is invoked
- onShow(), where you can populate that UI with the details for this particular assist request
- onHide(), called when your UI is no longer visible to the user

…and so on.

Determining the Active Assistant

If you elect to create your own assistant, you might be interested in knowing whether or not your app has been chosen as the user's assistant. Unfortunately, there is no documented and supported means of doing this.

So, here is the undocumented and unsupported approach that works on Android 6.0.

WARNING: this code may not work on all Android 6.0 devices, let alone on future versions of Android, as it relies a bit on internal implementation that could be changed by device manufacturers or custom ROM authors. Please use this *very carefully* and do not be shocked if it stops working.

Settings.Secure holds the details of the currently-chosen assistant. However, the key under which those details are stored is a hidden entry in Settings.Secure, and so it does not show up in the Android SDK. The key is "voice_interaction_service". The value is the ComponentName of the assistant, serialized (or "flattened") into a String. So, to get the ComponentName of the assistant, you can use:

```
String assistant=
  Settings.Secure.getString(getContentResolver(),
    "voice_interaction_service");
```

```
boolean areWeGood=false;

if (assistant!=null) {
  ComponentName cn=ComponentName.unflattenFromString(assistant);
}
```

cn will then hold the ComponentName.

Leading the User to Make an Assistant Change

If you implement your own assistant, and at the moment you are not the user's chosen assistant, you might have the need to lead the user over to the spot in the Settings app where they can change this. Once again, this is not explicitly documented.

However, for Android 6.0, Settings.ACTION_VOICE_INPUT_SETTINGS contains the action string that opens up the screen where the user can choose their assistant implementation. So, you could call:

```
startActivity(new Intent(Settings.ACTION_VOICE_INPUT_SETTINGS));
```

to lead the user to that screen, plus use a Toast or something to remind the user to tap on the "Assist app" entry to choose the assistant.

However:

- Since Settings.ACTION_VOICE_INPUT_SETTINGS is not guaranteed to be on all devices, please wrap the startActivity() call in an ActivityNotFoundException try/catch block and deal with the missing action accordingly
- There is no guarantee that Settings.ACTION_VOICE_INPUT_SETTINGS will lead the user to the correct screen on all Android 6.0+ devices, as the Settings app might be altered by the device manufacturer or custom ROM author ||| Trail: Home Screen Effects |||

Home Screen App Widgets

App widgets are live elements that the user can add to her home screen. Android ships with a variety of app widgets, such as a music player, and device manufacturers frequently add more. However, developers can add their own — in this chapter, we will see how this is done.

For the purposes of this book, “app widgets” will refer to these items that go on the home screen. Other uses of the term “widget” will be reserved for the UI widgets, subclasses of `View`, usually found in the `android.widget` Java package.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on:

- basic widgets
- broadcast `Intents`
- services

App Widgets and Security

Creating app widgets looks little like creating an activity. That is because the home screen is showing your app widget, whereas your own app shows your own activities. Having a third-party app (a home screen) show a UI from your app has some security ramifications.

Android’s security model is based heavily on Linux user, file, and process security. Each application is (normally) associated with a unique user ID. All of its files are owned by that user, and its process(es) run as that user. This prevents one application from modifying the files of another or otherwise injecting their own code into another running process. It would be dangerous for the home screen to run arbitrary code itself or somehow allow its UI to be directly manipulated by another process.

The app widget architecture, therefore, is set up to keep the home screen application independent from any code that puts app widgets on that home screen, so bugs in one cannot harm the other.

The Big Picture for a Small App Widget

The way Android pulls off this bit of security is through the use of `RemoteViews`.

The application component that supplies the UI for an app widget is not an `Activity`, but rather a `BroadcastReceiver` (often in tandem with a `Service`). The `BroadcastReceiver`, in turn, does not inflate a normal `View` hierarchy, like an `Activity` would, but instead inflates a layout into a `RemoteViews` object.

`RemoteViews` encapsulates a limited edition of normal widgets, in such a fashion that the `RemoteViews` can be "easily" transported across process boundaries. You configure the `RemoteViews` via your `BroadcastReceiver` and make those `RemoteViews` available to Android. Android in turn delivers the `RemoteViews` to the app widget host (usually the home screen), which renders them to the screen itself.

This architectural choice has many impacts:

- You do not have access to the full range of widgets and containers. You can use `FrameLayout`, `LinearLayout`, and `RelativeLayout` for containers, and `AnalogClock`, `Button`, `Chronometer`, `ImageButton`, `ImageView`, `ProgressBar`, and `TextView` for widgets. And, on API Level 11 and higher, you can use some `AdapterView`-based widgets, like `ListView`, as we will examine in the next chapter. And, as of API Level 16 (Android 4.1), you can use `GridLayout`… but not its backport on earlier devices.
- The only user input you can get is clicks of the `Button` and `ImageButton` widgets. In particular, there is no `EditText` for text input.
- Because the app widgets are rendered in another process, you cannot simply register an `OnClickListener` to get button clicks; rather, you tell `RemoteViews` a `PendingIntent` to invoke when a given button is clicked.

- You do not hold onto the RemoteViews and reuse them yourself. Rather, you create and send out a brand-new RemoteViews whenever you want to change the contents of the app widget. This, coupled with having to transport the RemoteViews across process boundaries, means that updating the app widget is expensive in terms of CPU time, memory, and battery life, when compared to equivalent UI updates of one of your own activities.
- Because the component handling the updates is a BroadcastReceiver, you have to be quick (lest you take too long and Android consider you to have timed out), you cannot use background threads, and your component itself is lost once the request has been completed. Hence, if your update might take a while, you will probably want to have the BroadcastReceiver start a Service and have the Service do the long-running task and eventual app widget update.

Crafting App Widgets

This will become somewhat easier to understand in the context of some sample code. In the AppWidget/PairOfDice project, you will find an app widget that displays a roll of a pair of dice. Clicking on the app widget re-rolls, in case you want a better result.

The Manifest

First, we need to register our BroadcastReceiver implementation in our AndroidManifest.xml file, along with a few extra features:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.appwidget.dice"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <uses-feature
    android:name="android.software.app_widgets"
    android:required="true"/>

  <application
```

```
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver
      android:name=".AppWidget"
      android:icon="@drawable/cw"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
      </intent-filter>

      <meta-data
        android:name="android.appwidget.provider"
        android:resource="@xml/widget_provider"/>
    </receiver>

    <activity
      android:name="PairOfDiceActivity"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Here, along with a do-nothing activity, we have a `<receiver>`. Of note:

1. Our `<receiver>` has `android:label` and `android:icon` attributes, which are not normally needed on `BroadcastReceiver` declarations. However, in this case, those are used for the entry that goes in the roster of available widgets to add to the home screen. Hence, you will probably want to supply values for both of those, and use appropriate resources in case you want translations for other languages.
2. Our `<receiver>` has an `<intent-filter>` for the `android.appwidget.action.APPWIDGET_UPDATE` action. This means we will get control whenever Android wants us to update the content of our app widget. There may be other actions we want to monitor — more on this in a later section.
3. Our `<receiver>` also has a `<meta-data>` element, indicating that its `android.appwidget.provider` details can be found in the `res/xml/widget_provider.xml` file. This metadata is described in greater detail shortly.

The uses-feature Element

If the central point of your application is to provide an app widget, you should strongly consider adding a `<uses-feature>` element to advertise this fact to markets like the Play Store:

```
<uses-feature android:name="android.software.app_widgets" android:required="true" />
```

In principle, having this element means that markets should block the installation of your app on devices where there is no app-widget-capable home screen or other known places for supporting app widgets.

If, however, your app has an app widget, but it is an adjunct to other forms of UI (typically a launcher activity), then you may wish to leave off this `<uses-feature>` element, or set it to `android:required="false"`.

The Metadata

Next, we need to define the app widget provider metadata. This has to reside at the location indicated in the manifest — in this case, in `res/xml/widget_provider.xml`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
  android:minWidth="144dip"
  android:minHeight="72dip"
  android:updatePeriodMillis="900000"
  android:initialLayout="@layout/widget"
/>
```

Here, we provide a few pieces of information:

1. The minimum width and height of the app widget (`android:minWidth` and `android:minHeight`). These are approximate — the app widget host (e.g., home screen) will tend to convert these values into “cells” based upon the overall layout of the UI where the app widgets will reside. However, they should be no smaller than the minimums cited here. Also, ideally, you use `dip` instead of `px` for the dimensions, so the number of cells will remain constant regardless of screen density.
2. The frequency in which Android should request an update of the widget’s contents (`android:updatePeriodMillis`). This is expressed in terms of milliseconds, so a value of `3600000` is a 60-minute update cycle. Note that the minimum value for this attribute is 30 minutes — values less than that will be “rounded up” to 30 minutes. Hence our 15-minute (`900000` millisecond) request will actually result in an update every 30 minutes.

3. The initial layout to use for the app widget, for the time between when the user requests the app widget and when `onUpdate()` of our `AppWidgetProvider` gets control.

Note that the calculations for determining the number of cells for an app widget varies. The `dip` dimension value for an N-cell dimension was (74 * N) - 2 (e.g., a 2x3 cell app widget would request a width of `146dip` and a height of `220dip`). The value as of API Level 14 (a.k.a., Ice Cream Sandwich) is now (70 * N) - 30 (e.g., a 2x3 cell app widget would request a width of `110dip` and a height of `180dip`). To have your app widgets maintain a consistent number of cells, you will need two versions of your app widget metadata XML, one in `res/xml-v14/` (with the API Level 14 calculation) and one in `res/xml/` (for prior versions of Android).

The Layout

Eventually, you are going to need a layout that describes what the app widget looks like. You need to stick to the widget and container classes noted above; otherwise, this layout works like any other layout in your project.

For example, here is the layout for the `PairOfDice` app widget:

```xml
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
  <ImageView android:id="@+id/left_die"
    android:layout_centerVertical="true"
    android:layout_alignParentLeft="true"
    android:src="@drawable/die_5"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginLeft="7dip"
  />
  <ImageView android:id="@+id/right_die"
    android:layout_centerVertical="true"
    android:layout_alignParentRight="true"
    android:src="@drawable/die_2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginRight="7dip"
  />
</RelativeLayout>
```

All we have is a pair of ImageView widgets (one for each die), inside of a RelativeLayout. The RelativeLayout has a background, specified as a nine-patch PNG file. This allows the RelativeLayout to have guaranteed contrast with whatever wallpaper is behind it, so the user can tell the actual app widget bounds.

The BroadcastReceiver

Next, we need a BroadcastReceiver that can get control when Android wants us to update our RemoteViews for our app widget. To simplify this, Android supplies an AppWidgetProvider class we can extend, instead of the normal BroadcastReceiver. This simply looks at the received Intent and calls out to an appropriate lifecycle method based on the requested action.

The one method that frequently needs to be implemented on the provider is onUpdate(). Other lifecycle methods may be of interest and are discussed later in this chapter.

For example, here is the implementation of the AppWidgetProvider for PairOfDice:

```
package com.commonsware.android.appwidget.dice;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class AppWidget extends AppWidgetProvider {
  private static final int[] IMAGES={R.drawable.die_1,R.drawable.die_2,
                                      R.drawable.die_3,R.drawable.die_4,
                                      R.drawable.die_5,R.drawable.die_6};

  @Override
  public void onUpdate(Context ctxt, AppWidgetManager mgr,
                        int[] appWidgetIds) {
    ComponentName me=new ComponentName(ctxt, AppWidget.class);

    mgr.updateAppWidget(me, buildUpdate(ctxt, appWidgetIds));
  }

  private RemoteViews buildUpdate(Context ctxt, int[] appWidgetIds) {
    RemoteViews updateViews=new RemoteViews(ctxt.getPackageName(),
                                            R.layout.widget);

    Intent i=new Intent(ctxt, AppWidget.class);

    i.setAction(AppWidgetManager.ACTION_APPWIDGET_UPDATE);
    i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_IDS, appWidgetIds);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0 , i,
                                                PendingIntent.FLAG_UPDATE_CURRENT);

    updateViews.setImageViewResource(R.id.left_die,
                                     IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.left_die, pi);
    updateViews.setImageViewResource(R.id.right_die,
                                     IMAGES[(int)(Math.random()*6)]);
    updateViews.setOnClickPendingIntent(R.id.right_die, pi);
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    return(updateViews);
  }
}
```

To update the RemoteViews for our app widget, we need to build those RemoteViews (delegated to a buildUpdate() helper method) and tell an AppWidgetManager to update the widget via updateAppWidget(). In this case, we use a version of updateAppWidget() that takes a ComponentName as the identifier of the widget to be updated. Note that this means that we will update all instances of this app widget presently in use — the concept of multiple app widget instances is covered in greater detail later in this chapter.

Working with RemoteViews is a bit like trying to tie your shoes while wearing mittens — it may be possible, but it is a bit clumsy. In this case, rather than using methods like findViewById() and then calling methods on individual widgets, we need to call methods on RemoteViews itself, providing the identifier of the widget we wish to modify. This is so our requests for changes can be serialized for transport to the home screen process. It does, however, mean that our view-updating code looks a fair bit different than it would if this were the main View of an activity or row of a ListView.

To create the RemoteViews, we use a constructor that takes our package name and the identifier of our layout. This gives us a RemoteViews that contains all of the widgets we declared in that layout, just as if we inflated the layout using a LayoutInflater. The difference, of course, is that we have a RemoteViews object, not a View, as the result.

We then use methods like:

1. setImageViewResource() to set the image for each of our ImageView widgets, in this case a randomly chosen die face (using graphics created from a set of SVG files from the OpenClipArt site)
2. setOnClickPendingIntent() to provide a PendingIntent that should get fired off when a die, or the overall app widget background, is clicked

We then supply that `RemoteViews` to the `AppWidgetManager`, which pushes the `RemoteViews` structure to the home screen, which renders our new app widget UI.

The Result

If you compile and install all of this, you will have a new app widget entry available. How you add app widgets to the home screen varies based upon Android version and the home screen implementation, and there are too many possibilities to try to list here.

No matter how you add the Pair of Dice, the app widget will appear on the home screen:

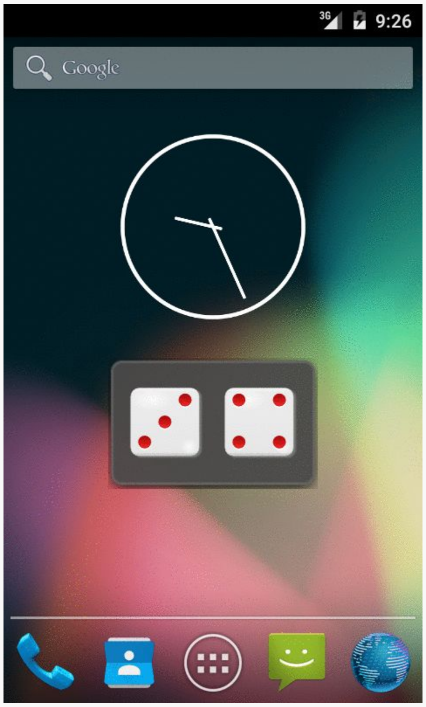

Figure 635: Pair of Dice, In Action

Another and Another

As indicated above, you can have multiple instances of the same app widget outstanding at any one time. For example, one might have multiple picture frames, or multiple "show-me-the-latest-RSS-entry" app widgets, one per feed. You will distinguish between these in your code via the identifier supplied in the relevant AppWidgetProvider callbacks (e.g., onUpdate()).

If you want to support separate app widget instances, you will need to store your state on a per-app-widget-identifier basis. You will also need to use an appropriate version of updateAppWidget() on AppWidgetManager when you update the app widgets, one that takes app widget identifiers as the first parameter, so you update the proper app widget instances.

Conversely, there is nothing requiring you to support multiple instances as independent entities. For example, if you add more than one PairOfDice app widget to your home screen, nothing blows up – they just show the same roll. That is because PairOfDice uses a version of updateAppWidget() that does not take any app widget IDs, and therefore updates all app widgets simultaneously.

App Widgets: Their Life and Times

There are three other lifecycle methods that AppWidgetProvider offers that you may be interested in:

1. onEnabled() will be called when the first widget instance is created for this particular widget provider, so if there is anything you need to do once for all supported widgets, you can implement that logic here
2. onDeleted() will be called when a widget instance is removed from the home screen, in case there is any data you need to clean up specific to that instance
3. onDisabled() will be called when the last widget instance for this provider is removed from the home screen, so you can clean up anything related to all such widgets

You will need to add appropriate action strings to your <intent-filter> for each of these events, such as ACTION_APPWIDGET_ENABLED to be notified about enabled events via onEnabled().

Controlling Your (App Widget's) Destiny

As PairOfDice illustrates, you are not limited to updating your app widget only based on the timetable specified in your metadata. That timetable is useful if you can get by with a fixed schedule. However, there are cases in which that will not work very well:

1. If you want the user to be able to configure the polling period (the metadata is baked into your APK and therefore cannot be modified at runtime)
2. If you want the app widget to be updated based on external factors, such as a change in location

The recipe shown in `PairOfDice` will let you use `AlarmManager` (described in another chapter) or proximity alerts or whatever to trigger updates. All you need to do is:

1. Arrange for something to broadcast an `Intent` that will be picked up by the `BroadcastReceiver` you are using for your app widget provider
2. Have the provider process that `Intent` directly or pass it along to a `Service` (such as an `IntentService`)

Also, note that the `updatePeriodMillis` setting not only tells the app widget to update every so often, it will even *wake up the phone* if it is asleep so the widget can perform its update. On the plus side, this means you can easily keep your widgets up to date regardless of the state of the device. On the minus side, this will tend to drain the battery, particularly if the period is too fast. If you want to avoid this wakeup behavior, set `updatePeriodMillis` to `0` and use `AlarmManager` to control the timing and behavior of your widget updates.

Note that if there are multiple instances of your app widget on the user's home screen, they will all update approximately simultaneously if you are using `updatePeriodMillis`. If you elect to set up your own update schedule, you can control which app widgets get updated when, if you choose.

One Size May Not Fit All

It may be that you want to offer multiple app widget sizes to your users. Some might only want a small app widget. Some might really like what you have to offer and want to give you more home screen space to work in.

Android 1.x/2.x

The good news: this is easy to do.

The bad news: it requires you, in effect, to have one app widget per size.

The size of an app widget is determined by the app widget metadata XML file. That XML file is tied to a `<receiver>` element in the manifest representing one app widget. Hence, to have multiple sizes, you need multiple metadata files and multiple `<receiver>` elements.

This also means your app widgets will show up multiple times in the app widget selection list, when the user goes to add an app widget to their home screen. Hence, supporting many sizes will become annoying to the user, if they perceive you are "spamming" the app widget list. Try to keep the number of app widget sizes to a reasonable number (say, one or two sizes).

Android 3.0+

As of API Level 11, it is possible to have a resizeable app widget. To do this, you can have an `android:resizeMode` attribute in your widget metadata, with a value of `horizontal`, `vertical`, or both (e.g., `horizontal|vertical`). When the user long-taps on an existing widget, they should see handles to allow the widget to be resized:

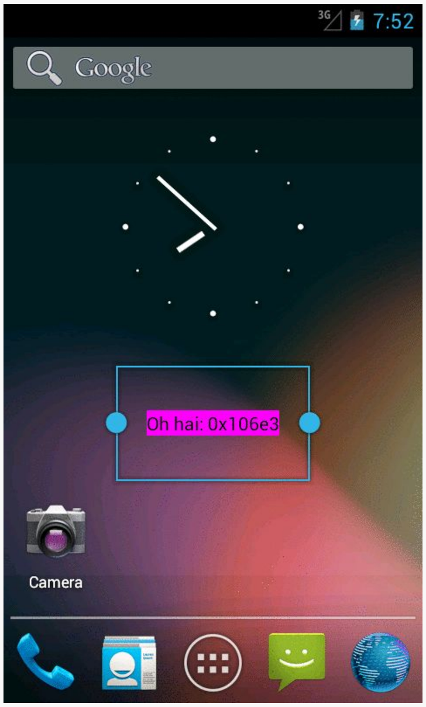

Figure 636: API Demos App Widget, Resizing

You can also have `android:minResizeWidth` and `android:minResizeHeight` attributes, measured in `dp`, that indicate the approximate smallest size that your app widget can support. These values will be interpreted in terms of "cells", as with the android:minWidth and android:minHeight attributes, and so the dp values you supply will not be used precisely.

However, for Android 3.x and 4.0 (API Level 11-15), your code would not be informed about being resized. You had to simply ensure that your layout would intelligently use any extra space automatically. Hence, resizing tended to be used primarily with adapter-driven app widgets, as will be discussed in the next chapter.

Starting with API Level 16, though, you can find out when the user resizes your app widget, so you can perhaps use a different layout for a different size, or otherwise adapt to the available space. Finding out about resize events takes a bit more work, as is illustrated in the AppWidget/Resize sample project.

This app widget project is similar to PairOfDice, described earlier in this chapter. However, our layout skips the dice, replacing them with a TextView widget in the RelativeLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/background"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:background="@drawable/widget_frame"
  android:orientation="horizontal">

  <TextView
    android:id="@+id/size"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerInParent="true"
    android:textAppearance="?android:attr/textAppearanceMedium">

  </TextView>

</RelativeLayout>
```

Our widget_provider.xml resource stipulates our desired android:resizeMode and minimum resize dimensions:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
  android:minWidth="180dip"
  android:minHeight="110dip"
  android:minResizeWidth="110dip"
  android:minResizeHeight="40dip"
  android:initialLayout="@layout/widget"
  android:resizeMode="horizontal|vertical"
/>
```

Finding out about app widget resizing is a different event than finding out about app widget updates. Hence, we need to add a new `<action>` element to the `<intent-filter>` of our `<receiver>` in the manifest, indicating that we want `APPWIDGET_OPTIONS_CHANGED` as well as `ACTION_UPDATE`:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name">
  <receiver
    android:name="AppWidget"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
      <action android:name="android.appwidget.action.APPWIDGET_OPTIONS_CHANGED"/>
    </intent-filter>
```

Then, our app widget implementation can override an `onAppWidgetOptionsChanged()` method:

```
@Override
public void onAppWidgetOptionsChanged(Context ctxt,
                                      AppWidgetManager mgr,
                                      int appWidgetId,
                                      Bundle newOptions) {
  RemoteViews updateViews=
      new RemoteViews(ctxt.getPackageName(), R.layout.widget);
  String msg=
      String.format(Locale.getDefault(),
                    "[%d-%d] x [%d-%d]",
                    newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH),
                    newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH),
                    newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT),
                    newOptions.getInt(AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT));

  updateViews.setTextViewText(R.id.size, msg);

  mgr.updateAppWidget(appWidgetId, updateViews);
}
```

You will notice that we skip `onUpdate()`. We will be called with `onAppWidgetOptionsChanged()` when the app widget is added and resized. Hence, in the case of this app widget, we can define what the app widget looks like from `onAppWidgetOptionsChanged()`, eschewing `onUpdate()`. That being said, more typical app widgets will wind up implementing both methods, especially if they are supporting lower API levels than 16, where `onAppWidgetOptionsChanged()` will not be called.

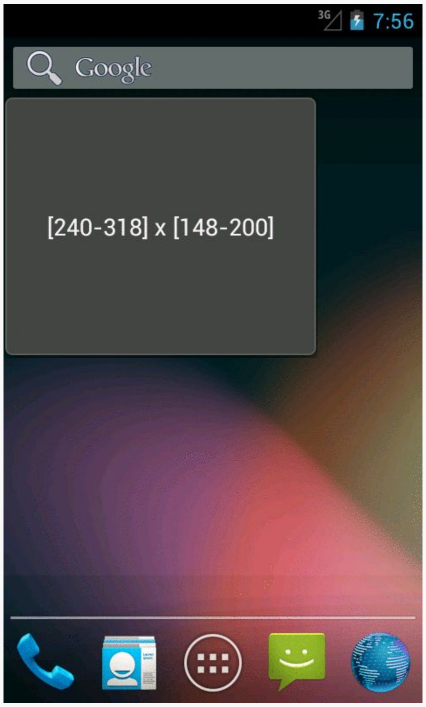
Also remember that your process may well be terminated in between calls to app widget lifecycle methods like `onUpdate()` and `onAppWidgetOptionsChanged()`. Hence, if there is data from one method that you want in the other, be sure to persist that data somewhere.

In the `AppWidget` implementation of `onAppWidgetOptionsChanged()`, we can find out about our new app widget size by means of the `Bundle` supplied to our method. What we *cannot* find out is our exact size. Rather, we are provided minimum and maximum dimensions of our app widget via four values in the `Bundle`:

- `AppWidgetManager.OPTION_APPWIDGET_MIN_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_WIDTH`
- `AppWidgetManager.OPTION_APPWIDGET_MIN_HEIGHT`
- `AppWidgetManager.OPTION_APPWIDGET_MAX_HEIGHT`

In our case, we grab these `int` values and pour them into a `String` template, using that to fill in the `TextView` of the app widget's contents.

When our app widget is initially launched, we show our initial size ranges:



[240-318] x [148-200]

Figure 637: Resize Widget, As Initially Added

When the user resizes our app widget, we show the new size ranges:

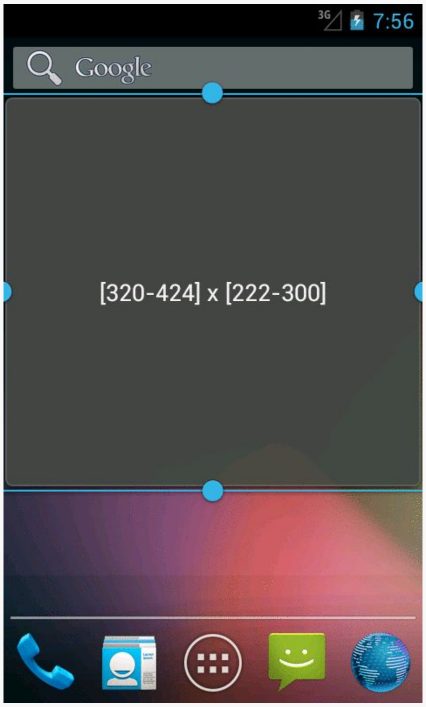


Figure 638: Resize Widget, During Resize Operation

However, not all home screen implementations will necessarily send the APPWIDGET_OPTIONS_CHANGED when an app widget is added to the home screen, only when the user resizes it later. For example, while the emulator's home screen for Android 4.1 broadcasts APPWIDGET_OPTIONS_CHANGED, it does not for 4.2 or 4.3. Hence, you may want to also examine the size information in onUpdate() as well, so that you react to the initial size as well as any future sizes. One way to do this is to simply iterate over the supplied app widget IDs and invoke your own onAppWidgetOptionsChanged() method:

```
// based on http://stackoverflow.com/a/18552461/115145

@Override
public void onUpdate(Context context,
                     AppWidgetManager appWidgetManager,
                     int[] appWidgetIds) {
  super.onUpdate(context, appWidgetManager, appWidgetIds);

  for (int appWidgetId : appWidgetIds) {
    Bundle options=appWidgetManager.getAppWidgetOptions(appWidgetId);

    onAppWidgetOptionsChanged(context, appWidgetManager, appWidgetId,
                              options);
  }
}
```

Lockscreen Widgets

Android's lockscreen (a.k.a., the keyguard) had long been unmodifiable by developers. This led to a number of developers creating so-called "replacement lockscreens", which generally reduce device security, as they can be readily bypassed. However, on Android 4.2 through 4.4, developers can create app widgets that the user can deploy to the lockscreen, helping to eliminate the need for "replacement lockscreens".

However, note that this capability was dropped with Android 5.0. As a result, this particular app widget feature may not be something that you want to worry about. That being said, it *is* available for those versions, and you are welcome to support it for those versions.

Declaring that an app widget supports being on the lockscreen instead of (or in addition to) the home screen is very easy. All you must do is add an `android:widgetCategory` attribute to your app widget metadata resource. That attribute should have a value of either `keyguard` (for the lockscreen), `home_screen`, or both (e.g., `keyguard|home_screen`), depending upon where you want the app widget to be eligible. By default, if this attribute is missing, Android assumes a default value of `home_screen`.

Users cannot resize the lockscreen widgets at this time. However, you still will want to specify an `android:resizeMode` attribute in your app widget metadata, as whether or not you include `vertical` resizing will affect the height of your app widget. Lockscreen widgets without `vertical` will have a fixed small height on tablets, while lockscreen widgets with `vertical` will fill the available height. Lockscreen widgets on phones will always be small (to fit above the PIN/password entry area), and lockscreen widgets on all devices will stretch to fill available space horizontally.

You can also specify a different starting layout to use when your app is added to the lockscreen, as opposed to being added to the home screen. To do this, just add an `android:initialKeyguardLayout` attribute to your app widget metadata, pointing to the lockscreen-specific layout to use.

To see this in action, take a look at the [`AppWidget/TwoOrThreeDice`]() sample project. This is a revised clone of the `PairOfDice` sample, allowing the dice to be added to the lockscreen, and showing three dice on the lockscreen instead of the two on the home screen.

Our app widget metadata now contains the lockscreen-related attributes: `android:widgetCategory` and `android:initialKeyguardLayout`:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
  android:minWidth="144dip"
  android:minHeight="72dip"
  android:updatePeriodMillis="900000"
  android:initialLayout="@layout/widget"
  android:initialKeyguardLayout="@layout/lockscreen"
  android:widgetCategory="keyguard|home_screen"
/>
```

Our `lockscreen` layout simply adds a third die, `middle_die`:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/background"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@drawable/widget_frame"
    >
  <ImageView android:id="@+id/left_die"
    android:layout_centerVertical="true"
    android:layout_alignParentLeft="true"
    android:src="@drawable/die_3"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginLeft="7dip"
  />
  <ImageView android:id="@+id/middle_die"
    android:layout_centerInParent="true"
    android:src="@drawable/die_2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginLeft="7dip"
    android:layout_marginRight="7dip"
  />
  <ImageView android:id="@+id/right_die"
    android:layout_centerVertical="true"
    android:layout_alignParentRight="true"
    android:src="@drawable/die_2"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_marginRight="7dip"
  />
</RelativeLayout>
```

However, by specifying a different layout for the lockscreen widget, we have a problem. We need to know, in our Java code, what layout to use for the `RemoteViews` and how many dice need to be updated. And, ideally, we would handle this in a backwards-compatible fashion, so our app widget will have its original functionality on older Android devices. Plus, supporting the lockscreen makes it that much more likely that the user will have more than one instance of our app widget (e.g., one on the lockscreen and one on the homescreen), so we should do a better job than PairOfDice did about handling multiple app widget instances.

To deal with the latter point, our new onUpdate() method iterates over each of the app widget IDs supplied to it and calls a private updateWidget() method for each, so we can better support multiple instances:

```
@Override
public void onUpdate(Context ctxt, AppWidgetManager mgr,
                     int[] appWidgetIds) {
  for (int appWidgetId : appWidgetIds) {
    updateWidget(ctxt, mgr, appWidgetId);
  }
}
```

The updateWidget() method is a bit more complicated than the PairOfDice equivalent code:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void updateWidget(Context ctxt, AppWidgetManager mgr,
                          int appWidgetId) {
  int layout=R.layout.widget;

  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
    int category=
        mgr.getAppWidgetOptions(appWidgetId)
           .getInt(AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY,
                   -1);

    layout=
        (category == AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD)
            ? R.layout.lockscreen : R.layout.widget;
  }

  RemoteViews updateViews=
      new RemoteViews(ctxt.getPackageName(), layout);
  Intent i=new Intent(ctxt, AppWidget.class);

  i.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);

  PendingIntent pi=
      PendingIntent.getBroadcast(ctxt, appWidgetId, i,
                                 PendingIntent.FLAG_UPDATE_CURRENT);

  updateViews.setImageViewResource(R.id.left_die,
                                   IMAGES[(int)(Math.random() * 6)]);
  updateViews.setOnClickPendingIntent(R.id.left_die, pi);
  updateViews.setImageViewResource(R.id.right_die,
                                   IMAGES[(int)(Math.random() * 6)]);
  updateViews.setOnClickPendingIntent(R.id.right_die, pi);
```

```
    updateViews.setOnClickPendingIntent(R.id.background, pi);

    if (layout == R.layout.lockscreen) {
      updateViews.setImageViewResource(R.id.middle_die,
                                       IMAGES[(int)(Math.random() * 6)]);
      updateViews.setOnClickPendingIntent(R.id.middle_die, pi);
    }

    mgr.updateAppWidget(appWidgetId, updateViews);
  }
```

First, we need to choose which layout we are working with. We assume that we are to use the original `R.layout.widget` resource by default. But, if we are on API Level 17 or higher, we can call `getAppWidgetOptions()` on the `AppWidgetManager`, to get the `Bundle` of options — the same options that we could be delivered in `onAppWidgetOptionsUpdate()` as described in the previous section. One value that will be in this `Bundle` is `AppWidgetManager.OPTION_APPWIDGET_HOST_CATEGORY`, which will be an `int` with a value of `AppWidgetProviderInfo.WIDGET_CATEGORY_KEYGUARD` if our app widget is on the lockscreen. In that case, we switch to using `R.layout.lockscreen`. In addition, we know then we need to update the `middle_die` when we are updating the other dice.

There is also a subtle change in our `getBroadcast()` call to `PendingIntent`: we pass in the app widget ID as the second parameter, whereas in `PairOfDice` we passed `0`. `PendingIntent` objects are cached in our process, and by default we will get the same `PendingIntent` when we call `getBroadcast()` for the same `Intent`. However, in our case, we may *want* two or more different `PendingIntent` objects for the same `Intent`, with differing extras (`EXTRA_APPWIDGET_ID`). Since extras are not considered when evaluating equivalence of `Intent` objects, just having different extras is insufficient to get different `PendingIntent` objects for those `Intent` objects. The second parameter to `getBroadcast()` (and `getActivity()` and `getService()`) on `PendingIntent` is a unique identifier, to differentiate between two otherwise equivalent `Intent` objects, forcing `PendingIntent` to give us distinct `PendingIntent` objects. This way, we can support two or more app widget instances, each having their own `PendingIntent` objects for their click events.

On an Android 4.2+ lockscreen, you should be able to swipe to one side (e.g., a bezel swipe from left to right), to expose an option to add an app widget:

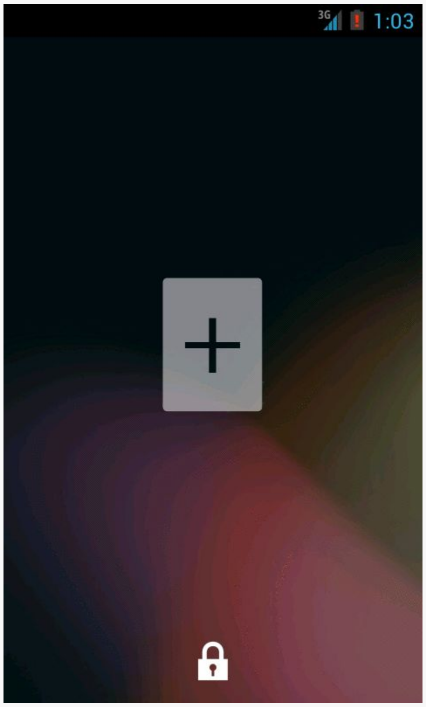

Figure 639: Lockscreen Add-A-Widget Panel, On a 4.2 Emulator

Tapping the “+” indicator (and, if needed, entering your device PIN or password), brings up an app widget chooser:

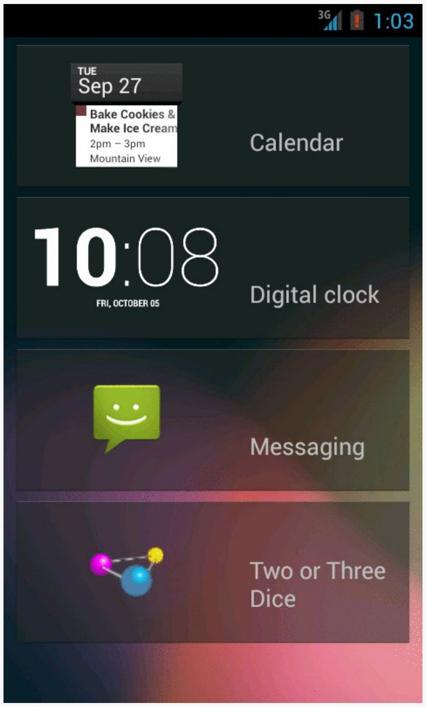

Figure 640: Lockscreen Widget Selection List, On a 4.2 Emulator

Choosing `TwoOrThreeDice` will then add the app widget to the lockscreen, with three dice, not two:

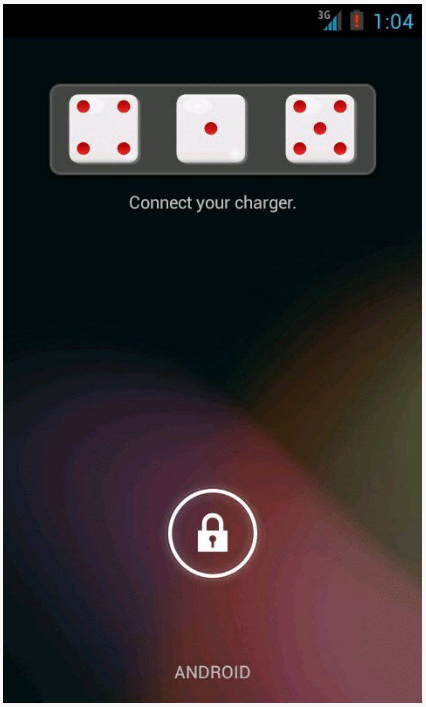

Figure 641: Lockscreen with TwoOrThreeDice, On a 4.2 Emulator

Preview Images

App widgets can have preview images attached. Preview images are drawable resources representing a preview of what the app widget might look like on the screen. On tablets, this will be used as part of an app widget gallery, replacing the simple context menu presentation you used to see on Android 1.x and 2.x phones:

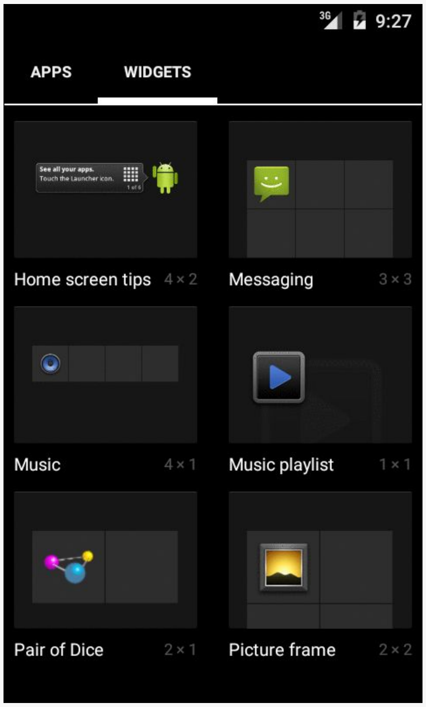

Figure 642: App Widget Gallery, on Android 5.0

To create the preview image itself, the Android 3.0+ emulator images contain a Widget Preview application that lets you run an app widget in its own container, outside of the home screen:

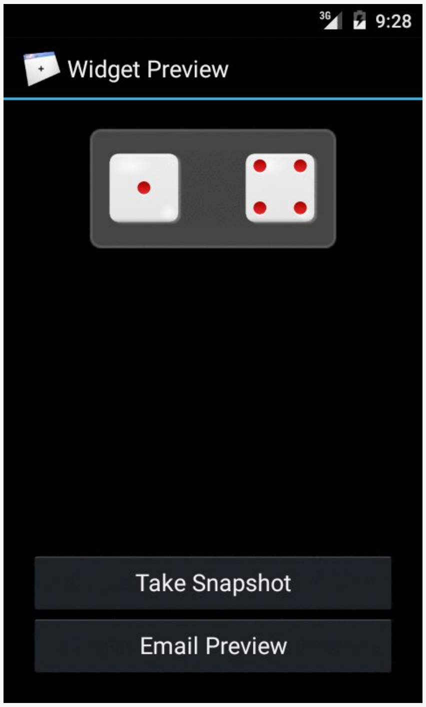

Figure 643: The Widget Preview application, showing a preview of the Analog Clock app widget

From here, you can take a snapshot and save it to external storage, copy it to your project's `res/drawable-nodpi/` directory (indicating that there is no intrinsic density assumed for this image), and reference it in your app widget metadata via an `android:previewImage` attribute. We will see an example of such an attribute in [the chapter on advanced app widgets](#).

Being a Good Host

In addition to creating your own app widgets, it is possible to host app widgets. This is mostly aimed for those creating alternative home screen applications, so they can take advantage of the same app widget framework and all the app widgets being built for it.

This is not very well documented, but it involves the `AppWidgetHost` and `AppWidgetHostView` classes. The latter is a `View` and so should be able to reside in an app widget host's UI like any other ordinary widget.

Adapter-Based App Widgets

API Level 11 introduced a few new capabilities for app widgets, to make them more interactive and more powerful than before. The documentation lags a bit, though, so determining how to use these features takes a bit of exploring. Fortunately for you, the author did some of that exploring on your behalf, to save you some trouble.

Prerequisites

Understanding this chapter requires that you have read the preceding chapter and all of its prerequisites.

AdapterViews for App Widgets

In addition to the classic widgets available for use in app widgets and `RemoteViews`, five more were added for API Level 11:

1. `GridView`
2. `ListView`
3. `StackView`
4. `ViewFlipper`
5. `AdapterViewFlipper`

Three of these (`GridView`, `ListView`, `ViewFlipper`) are widgets that existed in Android since the outset. `StackView` was added in API Level 11 to provide a “stack of cards” UI:

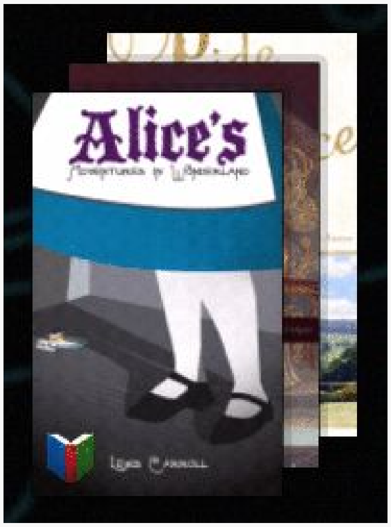

Figure 644: The Google Books app widget, showing a StackView

`AdapterViewFlipper` works like a `ViewFlipper`, allowing you to toggle between various children with only one visible at a time. However, whereas with `ViewFlipper` all children are fully-instantiated `View` objects held by the `ViewFlipper` parent, `AdapterViewFlipper` uses the `Adapter` model, so only a small number of actual `View` objects are held in memory, no matter how many potential children there are.

With the exception of `ViewFlipper`, the other four all require the use of an `Adapter`. This might seem odd, as there is no way to provide an `Adapter` to a `RemoteViews`. That is true, but API Level 11 added new ways for `Adapter`-like communication between the app widget host (e.g., home screen) and your application. We will take an in-depth look at that in an upcoming section.

Building Adapter-Based App Widgets

In an activity, if you put a `ListView` or `GridView` into your layout, you will also need to hand it an `Adapter`, providing the actual row or cell `View` objects that make up the contents of those selection widgets.

In an app widget, this becomes a bit more complicated. The host of the app widget does not have any `Adapter` class of yours. Hence, just as we have to send the contents of the app widget's UI via a `RemoteViews`, we will need to provide the rows or cells via `RemoteViews` as well. Android, starting with API Level 11, has a `RemoteViewsService` and `RemoteViewsFactory` that you can use for this purpose.

Let's take a look, in the form of the AppWidget/LoremWidget sample project, which will put a ListView of 25 Latin words into an app widget.

The AppWidgetProvider

At its core, our AppWidgetProvider (named WidgetProvider, in a stunning display of creativity) still needs to create and configure a RemoteViews object with the app widget UI, then use updateAppWidget() to push that RemoteViews to the host via the AppWidgetManager. However, for an app widget that involves an AdapterView, like ListView, there are two more key steps:

- You have to tell the RemoteViews the identity of a RemoteViewsService that will help fill the role that the Adapter would in an activity
- You have to provide the RemoteViews with a "template" PendingIntent to be used when the user taps on a row or cell in the AdapterView, to replace the onListItemClick() or similar method you might have used in an activity

For example, here is WidgetProvider for our Latin-word app widget:

```
package com.commonsware.android.appwidget.lorem;

import android.app.PendingIntent;
import android.appwidget.AppWidgetManager;
import android.appwidget.AppWidgetProvider;
import android.content.Context;
import android.content.Intent;
import android.net.Uri;
import android.widget.RemoteViews;

public class WidgetProvider extends AppWidgetProvider {
  public static String EXTRA_WORD=
    "com.commonsware.android.appwidget.lorem.WORD";

  @Override
  public void onUpdate(Context ctxt, AppWidgetManager appWidgetManager,
                       int[] appWidgetIds) {
    for (int i=0; i<appWidgetIds.length; i++) {
      Intent svcIntent=new Intent(ctxt, WidgetService.class);

      svcIntent.putExtra(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetIds[i]);
      svcIntent.setData(Uri.parse(svcIntent.toUri(Intent.URI_INTENT_SCHEME)));

      RemoteViews widget=new RemoteViews(ctxt.getPackageName(),
                                         R.layout.widget);

      widget.setRemoteAdapter(R.id.words, svcIntent);

      Intent clickIntent=new Intent(ctxt, LoremActivity.class);
      PendingIntent clickPI=PendingIntent
                              .getActivity(ctxt, 0,
                                           clickIntent,
                                            PendingIntent.FLAG_UPDATE_CURRENT);

      widget.setPendingIntentTemplate(R.id.words, clickPI);

      appWidgetManager.updateAppWidget(appWidgetIds[i], widget);
    }

    super.onUpdate(ctxt, appWidgetManager, appWidgetIds);
  }
}
```

The call to setRemoteAdapter() is where we point the RemoteViews to our RemoteViewsService for our AdapterView widget. The main rules for the Intent used to identify the RemoteViewsService are:

1. The service must be identified by its data (Uri), so even if you create the Intent via the Context-and-Class constructor, you will need to convert that into a Uri via toUri(Intent.URI_INTENT_SCHEME) and set that as the Uri for the Intent. Why? While your application has access to your RemoteViewsService Class object, the app widget host will not, and so we need something that will work across process boundaries. You could elect to add your own <intent-filter> to the RemoteViewsService and use an Intent based on that, but that would make your service more publicly visible than you might want.
2. Any extras that you package on the Intent — such as the app widget ID in this case — will be on the Intent that is delivered to the RemoteViewsService when it is invoked by the app widget host.

Note that there are two flavors of setRemoteAdapter(). An older deprecated one takes the app widget ID as the first parameter. The current one does not. The current one, though, is only available on API Level 14 and higher.

The call to setPendingIntentTemplate() is where we provide a PendingIntent that will be used as the template for all row or cell clicks. As we will see in a bit, the underlying Intent in the PendingIntent will have more data added to it by our RemoteViewsFactory.

In all other respects, our WidgetProvider is unremarkable compared to other app widgets. It will need to be registered in the manifest as a <receiver>, as with any other app widget.

The RemoteViewsService

Android supplies a RemoteViewsService class that you will need to extend, and this class is the one you must register with the RemoteViews for an AdapterView widget. For example, here is WidgetService (once again, a highly creative name) from the LoremWidget project:

```
package com.commonsware.android.appwidget.lorem;

import android.content.Intent;
import android.widget.RemoteViewsService;

public class WidgetService extends RemoteViewsService {
  @Override
  public RemoteViewsFactory onGetViewFactory(Intent intent) {
    return(new LoremViewsFactory(this.getApplicationContext(),
                                 intent));
  }
}
```

As you can see, this service is practically trivial. You have to override one method, onGetViewFactory(), which will return the RemoteViewsFactory to use for supplying rows or cells for the AdapterView. You are passed in an Intent, the one used in the setRemoteAdapter() call. Hence, if you have more than one AdapterView widget in your app widget, you could elect to have two RemoteViewsService implementations, or one that discriminates between the two widgets via something in the Intent (e.g., custom action string). In our case, we only have one AdapterView, so we create an instance of a LoremViewFactory and return it. Google has suggested using getApplicationContext() here to supply the Context object to RemoteViewsFactory, instead of using the Service as a Context, though it is unclear why this is.

Another thing different about the RemoteViewsService is how it is registered in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.appwidget.lorem"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="19"/>

  <uses-feature
    android:name="android.software.app_widgets"
    android:required="true"/>
  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="LoremActivity"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <receiver
      android:name="WidgetProvider"
      android:icon="@drawable/ic_launcher"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.appwidget.action.APPWIDGET_UPDATE"/>
      </intent-filter>

      <meta-data
        android:name="android.appwidget.provider"
        android:resource="@xml/widget_provider"/>
    </receiver>

    <service
      android:name="WidgetService"
      android:permission="android.permission.BIND_REMOTEVIEWS"/>
  </application>

</manifest>
```

Note the use of android:permission, specifying that whoever sends an Intent to WidgetService must hold the BIND_REMOTEVIEWS permission. This can only be held by the operating system. This is a security measure, so arbitrary applications cannot find out about your service and attempt to spoof being the OS and cause you to supply them with RemoteViews for the rows, as this might leak private data.

The RemoteViewsFactory

A RemoteViewsFactory interface implementation looks and feels a lot like an Adapter. In fact, one could imagine that the Android developer community might create CursorRemoteViewsFactory and ArrayRemoteViewsFactory and such to further simplify writing these classes.

For example, here is LoremViewsFactory, the one used by the LoremWidget project:

```
package com.commonsware.android.appwidget.lorem;
```

```
import android.appwidget.AppWidgetManager;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.widget.RemoteViews;
import android.widget.RemoteViewsService;

public class LoremViewsFactory implements
    RemoteViewsService.RemoteViewsFactory {
  private static final String[] items= { "lorem", "ipsum", "dolor",
      "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
      "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
      "vel", "erat", "placerat", "ante", "porttitor", "sodales",
      "pellentesque", "augue", "purus" };
  private Context ctxt=null;
  private int appWidgetId;

  public LoremViewsFactory(Context ctxt, Intent intent) {
    this.ctxt=ctxt;
    appWidgetId=
        intent.getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
                           AppWidgetManager.INVALID_APPWIDGET_ID);
  }

  @Override
  public void onCreate() {
    // no-op
  }

  @Override
  public void onDestroy() {
    // no-op
  }

  @Override
  public int getCount() {
    return(items.length);
  }

  @Override
  public RemoteViews getViewAt(int position) {
    RemoteViews row=
        new RemoteViews(ctxt.getPackageName(), R.layout.row);

    row.setTextViewText(android.R.id.text1, items[position]);

    Intent i=new Intent();
    Bundle extras=new Bundle();

    extras.putString(WidgetProvider.EXTRA_WORD, items[position]);
    extras.putInt(AppWidgetManager.EXTRA_APPWIDGET_ID, appWidgetId);
    i.putExtras(extras);
    row.setOnClickFillInIntent(android.R.id.text1, i);

    return(row);
  }

  @Override
  public RemoteViews getLoadingView() {
    return(null);
  }

  @Override
  public int getViewTypeCount() {
    return(1);
  }

  @Override
  public long getItemId(int position) {
    return(position);
  }

  @Override
  public boolean hasStableIds() {
    return(true);
  }

  @Override
  public void onDataSetChanged() {
    // no-op
  }
}
```

You need to implement a handful of methods that have the same roles in a `RemoteViewsFactory` as they do in an `Adapter`, including:

1. `getCount()`
2. `getViewTypeCount()`
3. `getItemId()`
4. `hasStableIds()`

In addition, you have `onCreate()` and `onDestroy()` methods that you must implement, even if they do nothing, to satisfy the interface.

You will need to implement `getLoadingView()`, which will return a `RemoteViews` to use as a placeholder while the app widget host is getting the real contents for the app widget. If you return `null`, Android will use a default placeholder.

The bulk of your work will go in `getViewAt()`. This serves the same role as `getView()` does for an `Adapter`, in that it returns the row or cell `View` for a given position in your data set. However:

1. You have to return a `RemoteViews`, instead of a `View`, just as you have to use `RemoteViews` for the main content of the app widget in your `AppWidgetProvider`
2. There is no recycling, so you do not get a `View` (or `RemoteViews`) back to somehow repopulate, meaning you will create a new `RemoteViews` every time

The impact of the latter is that you do not want to put large data sets into an app widget, as scrolling may get sluggish, just as you do not want to implement an Adapter without recycling unused View objects.

In LoremViewsFactory, the getViewAt() implementation creates a RemoteViews for a custom row layout, cribbed from one in the Android SDK:

```
<?xml version="1.0" encoding="utf-8"?>
<!-- Copyright (C) 2006 The Android Open Source Project

     Licensed under the Apache License, Version 2.0 (the "License");
     you may not use this file except in compliance with the License.
     You may obtain a copy of the License at

          http://www.apache.org/licenses/LICENSE-2.0

     Unless required by applicable law or agreed to in writing, software
     distributed under the License is distributed on an "AS IS" BASIS,
     WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
     See the License for the specific language governing permissions and
     limitations under the License.
-->

<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/text1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:textAppearance="?android:attr/textAppearanceLarge"
    android:gravity="center_vertical"
    android:paddingLeft="6dip"
    android:minHeight="?android:attr/listPreferredItemHeight"
/>
```

Then, getViewAt() pours in a word from the static String array of Latin words into that RemoteViews for the TextView inside it. It also creates an Intent and puts the Latin word in as an EXTRA_WORD extra, then provides that Intent to setOnClickFillInIntent(). In addition, it adds the app widget instance ID as an extra, reusing the framework's own AppWidgetManager.EXTRA_APPWIDGET_ID as the key. The contents of the "fill-in" Intent are merged into the "template" PendingIntent from setPendingIntentTemplate(), and the resulting PendingIntent is what is invoked when the user taps on an item in the AdapterView. The fully-configured RemoteViews is then returned.

The Rest of the Story

The app widget metadata needs no changes related to Adapter-based app widget contents. However, LoremWidget does add the android:previewImage attribute:

```
<appwidget-provider xmlns:android="http://schemas.android.com/apk/res/android"
  android:minWidth="146dip"
  android:minHeight="146dip"
  android:updatePeriodMillis="0"
  android:initialLayout="@layout/widget"
  android:autoAdvanceViewId="@+id/words"
  android:previewImage="@drawable/preview"
  android:resizeMode="vertical"
/>
```

This points to the `res/drawable-nodpi/preview.png` file that represents a "widgetshot" of the app widget in isolation, obtained from the Widget Preview application:

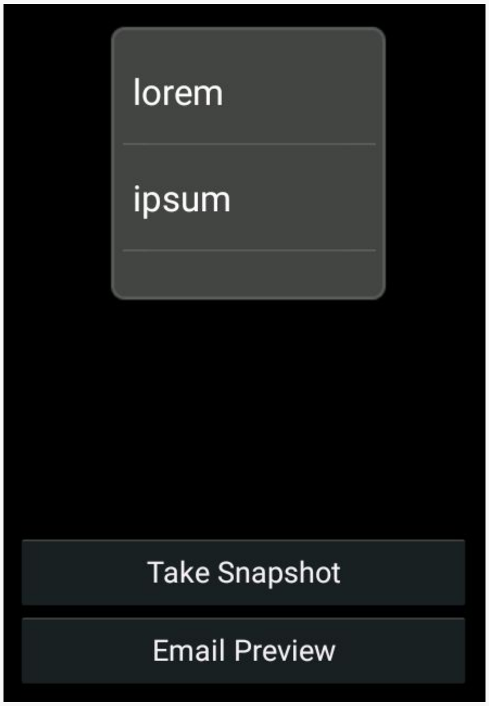

Figure 645: The preview of LoremWidget

Also, the metadata specifies `android:resizeMode="vertical"`. This attribute is new to Android 3.1, and allows the app widget to be resized by the user (in this case, only in the vertical direction, to show more rows). Older versions of Android will ignore this attribute, and the app widget will remain in your requested size. You can use `vertical`, `horizontal`, or both (via the pipe operator) as values for `android:resizeMode`.

When the user taps on an item in the list, our `PendingIntent` is set to bring up `LoremActivity`. This activity has `android:theme="@android:style/`

Theme.NoDisplay" set in the manifest, meaning that it will not have its own user interface. Rather, it will extract our EXTRA_WORD — and the app widget ID — out of the Intent used to launch the activity and displays it in a Toast before finishing:

```
package com.commonsware.android.appwidget.lorem;

import android.app.Activity;
import android.appwidget.AppWidgetManager;
import android.os.Bundle;
import android.widget.Toast;

public class LoremActivity extends Activity {
  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);

    String word=getIntent().getStringExtra(WidgetProvider.EXTRA_WORD);

    if (word == null) {
      word="We did not get a word!";
    }

    Toast.makeText(this,
                   String.format("#%d: %s",
getIntent().getIntExtra(AppWidgetManager.EXTRA_APPWIDGET_ID,
AppWidgetManager.INVALID_APPWIDGET_ID),
                                 word), Toast.LENGTH_LONG).show();

    finish();
  }
}
```

The Results

When you compile and install the application, nothing new shows up in the home screen launcher, because we have no activity defined to respond to ACTION_MAIN and CATEGORY_HOME. This would be unusual for an application distributed through the Play Store, as users often get confused if they install something and then do not know how to start it. However, for the purposes of this example, we should be fine, as readers of programming books never get confused about such things.

However, if you bring up the app widget gallery (e.g., long-tap on the home screen of an Android 6.0 device or emulator), you will see LoremWidget there, complete with preview image. You can drag it into one of the home screen panes and position it. When done, the app widget appears as expected:

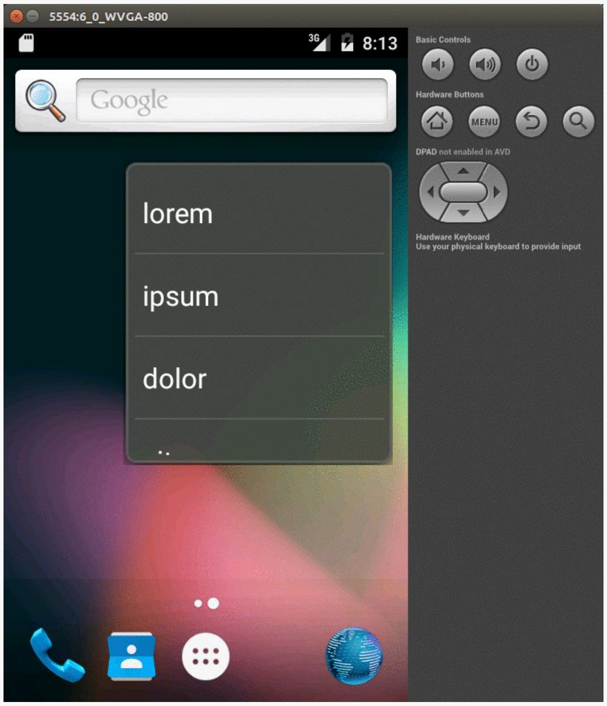

Figure 646: LoremWidget on Android Home Screen

The `ListView` is live and can be scrolled. Tapping an entry brings up the corresponding `Toast`.

If the user long-taps on the app widget, they will be able to reposition it. On Android 3.1 and beyond, when they lift their finger after the long-tap, the app widget will show resize handles on the sides designated by your `android:resizeMode` attribute:

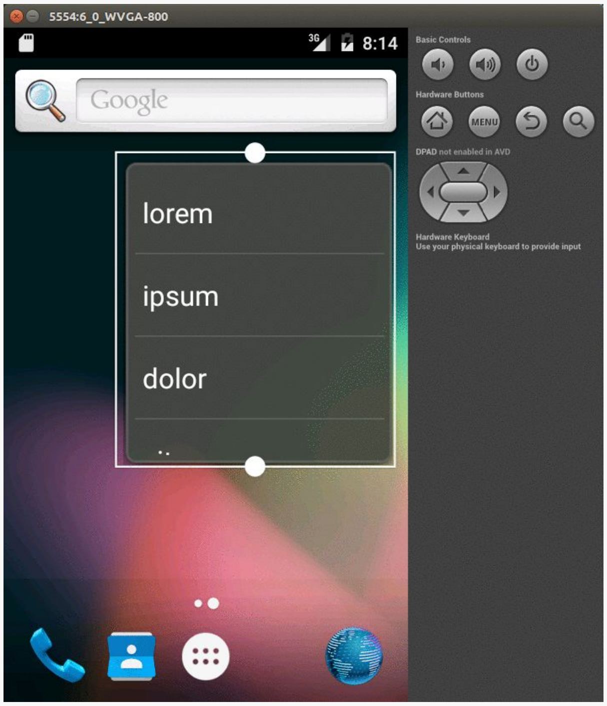

Figure 647: LoremWidget on Android Home Screen, with Resize Handles

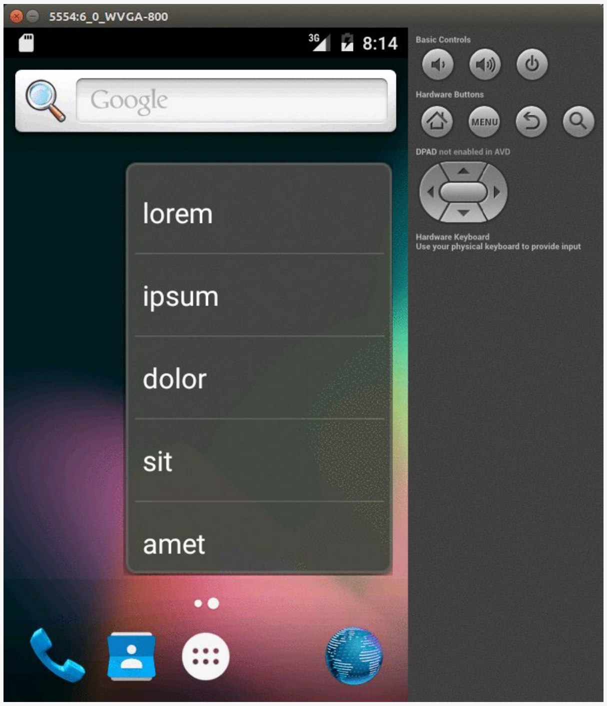
The user can then drag those handles to expand or shrink the app widget in the specified dimensions:



lorem

ipsum

dolor

sit

amet

Trail: Data Storage and Retrieval

Content Provider Theory

Android publishes data to you via an abstraction known as a “content provider”. Access to contacts and the call log, for example, are given to you via a set of content providers. In a few places, Android expects you to supply a content provider, such as for integrating your own search suggestions with the Android Quick Search Box. And, content providers are one way for you to supply data to third party applications, or to consume information from third party applications. As such, content providers have the potential to be something you would encounter frequently, even if in practice they do not seem used much.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on working with local databases.

Using a Content Provider

Any `Uri` in Android that begins with the `content://` scheme represents a resource served up by a content provider. Content providers offer data encapsulation using `Uri` instances as handles – you neither know nor care where the data represented by the `Uri` comes from, so long as it is available to you when needed. The data could be stored in a SQLite database, or in flat files, or retrieved off a device, or be stored on some far-off server accessed over the Internet.

Given a `Uri`, you may be able to perform basic CRUD (create, read, update, delete) operations using a content provider. `Uri` instances can represent either collections or individual pieces of content. Given a collection `Uri`, you may be able to create new pieces of content via insert operations. Given an instance `Uri`, you may be able to read data represented by the Uri, update that data, or delete the instance outright. Or, given a Uri, you may be able to open up a handle to what amounts to a file, that you can read and, possibly, write to.

These are all phrased as “may” because the content provider system is a facade. The actual implementation of a content provider dictates what you can and cannot do, and not all content providers will support all capabilities.

Pieces of a Uri

A Uri for a ContentProvider is made up of two to four components.

A provider Uri always has a content scheme. So, when represented as a string, you will see the Uri start with content://.

After the scheme, where in an http:// URL you would find a domain name or IP address, a provider Uri always has the authority string. This is unique on the device — only one provider will be tied to a given authority string.

What comes after the authority string is up to the provider. It is structured like the path segments of an http:// URL, but what those path segments mean is up to the provider implementation. The one approximate rule is that a Uri pointing to an individual piece of content — such as a row of a table or view in a database – frequently has the Uri end in a number, where the number indicates a unique identifier of that content.

Most of the Android APIs expect these to be Uri objects, though in common discussion, it is simpler to think of them as strings. The Uri.parse() static method creates a Uri out of the string representation.

Getting a Handle

So, where do these Uri instances come from?

Some Uri values are part of the framework. For example, ContactsContract.Contacts.CONTENT_URI is a Uri pointing at the collection of contacts.

You might also get Uri instances handed to you from other sources, such as getting Uri handles for contacts via activities responding to ACTION_PICK or ACTION_GET_CONTENT Intent objects.

You can also hard-wire literal `String` objects (e.g., `"content://contacts/people"`) and convert them into `Uri` instances via `Uri.parse()`. This is not an ideal solution, as the base `Uri` values could conceivably change over time. For example, while you *used* to access contacts via a `Uri` like `content://contacts/people`, that is no longer the case. `ContactsContract.Contacts.CONTENT_URI` is a different value and will give you better results.

The Database-Style API

Of the two flavors of API that a content provider may support, the database-style API is more prevalent. Using a `ContentResolver`, you can perform standard "CRUD" operations (create, read, update, delete) using what looks like a SQL interface.

Makin' Queries

Given a base `Uri`, you can run a query to return data out of the content provider related to that `Uri`. This has much of the feel of SQL: you specify the "columns" to return, the constraints to determine which "rows" to return, a sort order, etc. The difference is that this request is being made of a content provider, not directly of some database (e.g., SQLite).

You have two main options for running a query:

1. Use the `query()` method on `ContentResolver` from some sort of background thread
2. Use a `CursorLoader`, as is discussed in an upcoming chapter

The standard `query()` method on `ContentResolver` takes five parameters:

- The base `Uri` of the content provider to query, or the instance `Uri` of a specific object to query
- An array of properties (think "columns") from that content provider that you want returned by the query
- A constraint statement, functioning like a SQL `WHERE` clause
- An optional set of parameters to bind into the constraint clause, replacing any `?` that appear there
- An optional sort statement, functioning like a SQL `ORDER BY` clause

This method returns a `Cursor` object, which you can use to retrieve the data returned by the query.

This will hopefully make more sense given an example. This chapter shows some sample bits of code from the ContentProvider/ConstantsPlus sample project. This is the same basic application as was first shown back in the chapter on database access, but rewritten to pull the database logic into a content provider, which is then used by a retained ListFragment.

As before, in onViewCreated(), we kick off a LoadCursorTask if we do not already have our Cursor, such as via a configuration change:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  SimpleCursorAdapter adapter=
      new SimpleCursorAdapter(getActivity(), R.layout.row,
          current, new String[] {
          DatabaseHelper.TITLE,
          DatabaseHelper.VALUE },
          new int[] { R.id.title, R.id.value },
          0);

  setListAdapter(adapter);

  if (current==null) {
    task=new LoadCursorTask(getActivity()).execute();
  }
}
```

LoadCursorTask inherits from a BaseTask. BaseTask and its subclasses need a ContentResolver to be able to work with our ContentProvider. So, BaseTask takes a Context in its constructor and uses that to retrieve a ContentResolver:

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
  final ContentResolver resolver;

  BaseTask(Context ctxt) {
    super();

    resolver=ctxt.getContentResolver();
  }
```

In doInBackground(), LoadCursorTask calls a doQuery() method inherited from BaseTask, which in turn uses our ContentResolver to query our ContentProvider:

```
  protected Cursor doQuery() {
    Cursor result=resolver.query(Provider.Constants.CONTENT_URI,
        PROJECTION, null, null, null);

    result.getCount();
```

```
      return(result);
    }
```

In the call to query(), we provide:

1. The Uri for our provider (Provider.Constants.CONTENT_URI), in this case representing the collection of physical constants managed by the provider
2. A list of properties to retrieve
3. Three null values, indicating that we do not need a constraint clause (the Uri represents the instance we need), nor parameters for the constraint, nor a sort order (we should only get one entry back)

The biggest "magic" here is the list of properties. The lineup of what properties are possible for a given provider should be provided by the documentation (or source code) for the content provider itself. In this case, we define logical values on the Provider provider implementation class that represent the various properties (namely, the unique identifier, the display name or title, and the value of the constant), and we refer to them with our PROJECTION:

```
  private static final String[] PROJECTION=new String[] {
      Provider.Constants._ID, Provider.Constants.TITLE,
      Provider.Constants.VALUE };
```

Adapting to the Circumstances

Now that we have a Cursor via query(), we have access to the query results and can do whatever we want with them. You might, for example, manually extract data from the Cursor to populate widgets or other objects.

In our case, we are using the SimpleCursorAdapter, set up in onViewCreated(), to render our Cursor. This means that we need to take the Cursor that doQuery() generates and arrange to hand that to the SimpleCursorAdapter. The onPostExecute() method on BaseTask handles this:

```
    @Override
    public void onPostExecute(Cursor result) {
      ((CursorAdapter)getListAdapter()).changeCursor(result);
      current=result;
      task=null;
    }
```

Give and Take

Of course, content providers would be astonishingly weak if you couldn't add or remove data from them, and were instead limited to only update what is there. Fortunately, content providers offer these abilities as well.

To insert data into a content provider, you have two options available on the `ContentProvider` interface (available through `getContentResolver()` to your activity):

- Use `insert()` with a collection `Uri` and a `ContentValues` structure describing the initial set of data to put in the row
- Use `bulkInsert()` with a collection `Uri` and an array of `ContentValues` structures to populate several rows at once

The `insert()` method returns a `Uri` for you to use for future operations on that new object. The `bulkInsert()` method returns the number of created rows; you would need to do a query to get back at the data you just inserted.

For example, if the user chooses our "Add" overflow item, we pop up a dialog to collect a new constant:

```
private void add() {
  LayoutInflater inflater=getActivity().getLayoutInflater();
  View addView=inflater.inflate(R.layout.add_edit, null);
  AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

  builder.setTitle(R.string.add_title).setView(addView)
      .setPositiveButton(R.string.ok, this)
      .setNegativeButton(R.string.cancel, null).show();
}
```

Then, if the user taps the "OK" button in the dialog, our `onClick()` listener is called, where we collect the entered values from the user, pour them into a `ContentValues` structure, and pass that to an `InsertTask`:

```
@Override
public void onClick(DialogInterface dialog, int which) {
  ContentValues values=new ContentValues(2);
  AlertDialog dlg=(AlertDialog)dialog;
  EditText title=(EditText)dlg.findViewById(R.id.title);
  EditText value=(EditText)dlg.findViewById(R.id.value);

  values.put(DatabaseHelper.TITLE, title.getText().toString());
  values.put(DatabaseHelper.VALUE, value.getText().toString());
```

```
    task=new InsertTask(getActivity()).execute(values);
  }
```

InsertTask, in its doInBackground() method, calls insert() on a ContentResolver to insert this row:

```
    @Override
    protected Cursor doInBackground(ContentValues... values) {
      resolver.insert(Provider.Constants.CONTENT_URI, values[0]);

      return(doQuery());
    }
```

Notice that we also call doQuery() again. That is because our Cursor is now out of date, and we need to obtain a fresh Cursor with fresh results. And, as with LoadTask, InsertTask inherits from BaseTask, not only providing us with that doQuery() method but also the onPostExecute() method that puts the Cursor into the SimpleCursorAdapter.

To delete one or more rows from the content provider, use the delete() method on ContentResolver. This works akin to a SQL DELETE statement and takes three parameters:

- A Uri representing the collection (or instance) from which you wish to delete rows
- A constraint statement, functioning like a SQL WHERE clause, to determine which rows should be deleted
- An optional set of parameters to bind into the constraint clause, replacing any ? that appear there

The Streaming API

Sometimes, what you are trying to retrieve does not look like a set of rows and columns, but rather looks like a stream. For example, the MediaStore provider manages the index of all music, video, and image files available on external storage, and you can use MediaStore to open up a stream to read in the contents of one of those files. Here, working with the Uri and the provider is much like working with a URL and a Web server.

Some content providers, like MediaStore, support both the database-style and streaming APIs — you query to find media that matches your criteria, then can open some file that matches. Other content providers might only support the streaming API.

Working with the Stream

Given a Uri that represents some file managed by the content provider, you can use openInputStream() and openOutputStream() on a ContentResolver to access an InputStream or OutputStream, respectively. Note, though, that not all content providers may support both modes. For example, a content provider that serves files stored inside the application (e.g., assets in the APK file), you will not be able to get an OutputStream to modify the content.

Also note that openInputStream() and openOutputStream() work with both file:// and content:// Uri values — you do not need to manually inspect the Uri and handle files separately if you do not want to.

Retrieving Metadata

You can call getType() on a ContentResolver, supplying a Uri as a parameter. This will return the MIME type reported by the ContentProvider for the data at that Uri. For the streaming API, this will give you results reminiscent of a Web server — some specific MIME type if the provider knows it, otherwise probably some generic MIME type (e.g., application/octet-stream).

You can also call query() on the ContentResolver. Your projection (the list of columns to return) can include:

- OpenableColumns.SIZE, which will return the length of the file being streamed to you for that Uri, and
- OpenableColumns.DISPLAY_NAME, which should be some name for the file that the user might recognize

The DATA Anti-Pattern

However, the authors of MediaStore screwed up developer expectations, due to a legacy convention.

The legacy convention was that a content:// Uri might not be openable directly using something like openInputStream(). Instead, it pointed to a database row, retrievable via query(), and you would look in the DATA column for how to access the actual data. Some providers no doubt continue to use this pattern, as does MediaStore. The rules for what the DATA column would be were not well documented, but by convention they tended to be a path to a file. The problem is that this runs afoul of Google's current guidance, as there is no guarantee that other apps can access such a file.

Do not blindly assume that if you get a `content://` `Uri` that it is for the `DATA` pattern. Try to open a stream on the `Uri`, and if that fails, then see if the `DATA` pattern is in play. Or, if you `query()` to get the size and/or display name first, also request the `DATA` column, and if it exists and is not `null`, try that if opening the stream directly does not work.

Building Content Providers

Building a content provider is a very tedious task. There are many requirements of a content provider, in terms of methods to implement and public data members to supply. And, until you try using it, you have no great way of telling if you did any of it correctly (versus, say, building an activity and getting validation errors from the resource compiler).

That being said, building a content provider is of huge importance if your application wishes to make data available to other applications. If your application is keeping its data solely to itself, you may be able to avoid creating a content provider, just accessing the data directly from your activities. But, if you want your data to possibly be used by others — for example, you are building a feed reader and you want other programs to be able to access the feeds you are downloading and caching — then a content provider is right for you.

First, Some Dissection

The content `Uri` is the linchpin behind accessing data inside a content provider. When using a content provider, all you really need to know is the provider's base `Uri`; from there you can run queries as needed, or construct a `Uri` to a specific instance if you know the instance identifier.

When building a content provider, though, you need to know a bit more about the innards of the content `Uri`.

A content `Uri` has two to four pieces, depending on situation:

1. It always has a scheme (`content://`), indicating it is a content `Uri` instead of a `Uri` to a Web resource (`http://`).

2. It always has an authority, which is the first path segment after the scheme. The authority is a unique string identifying the content provider that handles the content associated with this `Uri`.
3. It may have a data type path, which is the list of path segments after the authority and before the instance identifier (if any). The data type path can be empty, if the content provider only handles one type of content. It can be a single path segment (`foo`) or a chain of path segments (`foo/bar/goo`) as needed to handle whatever data access scenarios the content provider requires.
4. It may have an instance identifier, which is an integer identifying a specific piece of content. A content `Uri` without an instance identifier refers to the collection of content represented by the authority (and, where provided, the data path).

For example, a content `Uri` could be as simple as `content://sekrits`, which would refer to the collection of content held by whatever content provider was tied to the `sekrits` authority (e.g., `SecretsProvider`). Or, it could be as complex as `content://sekrits/card/pin/17`, which would refer to a piece of content (identified as `17`) managed by the `sekrits` content provider that is of the data type `card/pin`.

Next, Some Typing

Next, you need to come up with some MIME types corresponding with the content your content provider will provide. There are three basic patterns.

For the streaming API, the MIME type that you will use should be the actual MIME type of the stream itself. Perhaps you already know the MIME type (e.g., you got it in an HTTP header when you downloaded the content from a Web server). Perhaps you will use `MimeTypeMap` to try to infer a MIME type based on a file extension. That is up to you, just as it is up to you to ensure that your Web server returns proper MIME types for streams that it serves up.

For the database-style API, even though the MIME type system is not really designed for this sort of thing, we still use MIME types. Each `Uri` will have an associated MIME type, indicating what is represented by that `Uri`. A `Uri` that points to a collection of content (e.g., a database table or view) will use one MIME type structure, while a `Uri` that points to an individual piece of content (e.g., a row in that database table or view) will use a different MIME type structure.

The collection MIME type should be of the form `vnd.X.cursor.dir/Y`, where `X` is the name of your firm, organization, or project, and `Y` is a dot-delimited type name. So, for example, you might use `vnd.tlagency.cursor.dir/sekrits.card.pin` as the MIME type for your collection of secrets.

The instance MIME type, for an individual piece of content, should be of the form `vnd.X.cursor.item/Y`, usually for the same values of `X` and `Y` as you used for the collection MIME type (though that is not strictly required).

Implementing the Database-Style API

Just as an activity and a receiver are both Java classes, so is a content provider. So, the big step in creating a content provider is crafting its Java class, with a base class of `ContentProvider`.

In your subclass of `ContentProvider`, you are responsible for implementing five methods that, when combined, perform the services that a content provider is supposed to offer to activities wishing to create, read, update, or delete content via the database-style API.

Implement onCreate()

As with an activity, the main entry point to a content provider is `onCreate()`. Here, you can do whatever initialization you want. In particular, here is where you should lazy-initialize your data store. For example, if you plan on storing your data in such-and-so directory on external storage, with an XML file serving as a "table of contents", you should check and see if that directory and XML file are there and, if not, create them so the rest of your content provider knows they are out there and available for use.

Similarly, if you have rewritten your content provider sufficiently to cause the data store to shift structure, you should check to see what structure you have now and adjust it if what you have is out of date.

Implement query()

As one might expect, the `query()` method is where your content provider gets details on a query some activity wants to perform. It is up to you to actually process said query.

The query method gets, as parameters:

1. A `Uri` representing the collection or instance being queried
2. A `String` array representing the list of properties that should be returned
3. A `String` representing what amounts to a SQL `WHERE` clause, constraining which instances should be considered for the query results
4. A `String` array representing values to “pour into” the `WHERE` clause, replacing any `?` found there
5. A `String` representing what amounts to a SQL `ORDER BY` clause

You are responsible for interpreting these parameters however they make sense and returning a `Cursor` that can be used to iterate over and access the data.

As you can imagine, these parameters are aimed towards people using a SQLite database for storage. You are welcome to ignore some of these parameters (e.g., you elect not to try to roll your own SQL `WHERE` clause parser), but you need to document that fact so activities only attempt to query you by instance `Uri` and not by using parameters that you elect to ignore.

Implement insert()

Your `insert()` method will receive a `Uri` representing the collection and a `ContentValues` structure with the initial data for the new instance. You are responsible for creating the new instance, filling in the supplied data, and returning a `Uri` to the new instance.

Implement update()

Your `update()` method gets the `Uri` of the instance or collection to change, a `ContentValues` structure with the new values to apply, a String for a SQL `WHERE` clause, and a `String` array with parameters to use to replace `?` found in the `WHERE` clause. Your responsibility is to identify the instance(s) to be modified (based on the `Uri` and `WHERE` clause), then replace those instances’ current property values with the ones supplied.

This will be annoying, unless you are using SQLite for storage. Then, you can pretty much pass all the parameters you received to the `update()` call to the database, though the `update()` call will vary slightly depending on whether you are updating one instance or several.

Implement delete()

As with `update()`, `delete()` receives a `Uri` representing the instance or collection to work with and a `WHERE` clause and parameters. If the activity is deleting a single instance, the `Uri` should represent that instance and the `WHERE` clause may be null. But, the activity might be requesting to delete an open-ended set of instances, using the `WHERE` clause to constrain which ones to delete.

As with `update()`, though, this is simple if you are using SQLite for database storage (sense a theme?). You can let it handle the idiosyncrasies of parsing and applying the `WHERE` clause — all you have to do is call `delete()` on the database.

Implement getType()

The last method you need to implement is `getType()`. This takes a `Uri` and returns the MIME type associated with that `Uri`. The `Uri` could be a collection or an instance `Uri`; you need to determine which was provided and return the corresponding MIME type.

Update the Manifest

The glue tying the content provider implementation to the rest of your application resides in your `AndroidManifest.xml` file. Simply add a `<provider>` element as a child of the `<application>` element, such as:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.constants"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="18"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <provider
      android:name=".Provider"
      android:authorities="com.commonsware.android.constants.Provider"
      android:exported="false"/>

    <activity
      android:name=".ConstantsBrowser"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

The `android:name` property is the name of the content provider class, with a leading dot to indicate it is in the stock namespace for this application's classes (just like you use with activities).

The `android:authorities` property should be a semicolon-delimited list of the authority values supported by the content provider. Recall, from earlier in this chapter, that each content `Uri` is made up of a scheme, authority, data type path, and instance identifier. Each authority from each `CONTENT_URI` value should be included in the `android:authorities` list. Now, when Android encounters a content `Uri`, it can sift through the providers registered through manifests to find a matching authority. That tells Android which application and class implements the content provider, and from there Android can bridge between the calling activity and the content provider being called.

Several other attributes relate to security:

- `android:exported` indicates whether third-party apps are able to initiate communications with your provider on their own
- `android:readPermission` and `android:writePermission` allow you to defend your provider with permissions; third-party apps have to have `<uses-permission>` elements for those permissions to be able to work with your provider
- `android:grantUriPermissions` indicates whether you are able to selectively "poke pinholes in the firewall" of your provider security, to say that for specific IPC operations (e.g., starting a third-party activity), that third party has limited access to your provider's content

These will be explored later in this book.

Add Notify-On-Change Support

A feature that your content provider can offer to its clients is notify-on-change support. This means that your content provider will let clients know if the data for a given content `Uri` changes.

For example, suppose you have created a content provider that retrieves RSS and Atom feeds from the Internet based on the user's feed subscriptions (via OPML, perhaps). The content provider offers read-only access to the contents of the feeds, with an eye towards several applications on the phone using those feeds versus everyone implementing their own feed poll-fetch-and-cache system. You have also implemented a service that will get updates to those feeds asynchronously, updating the underlying data store. Your content provider could alert applications using the feeds that such-and-so feed was updated, so applications using that specific feed can refresh and get the latest data.

On the content provider side, to do this, call `notifyChange()` on your `ContentResolver` instance (available in your content provider via `getContext().getContentResolver()`). This takes two parameters: the `Uri` of the piece of content that changed and the `ContentObserver` that initiated the change. In many cases, the latter will be `null`; a non-`null` value simply means that the observer that initiated the change will not be notified of its own changes.

On the content consumer side, an activity can call `registerContentObserver()` on its `ContentResolver` (via `getContentResolver()`). This ties a `ContentObserver` instance to a supplied `Uri` — the observer will be notified whenever `notifyChange()` is called for that specific `Uri`. When the consumer is done with the `Uri`, `unregisterContentObserver()` releases the connection.

Implementing the Streaming API

If you want to have a `ContentProvider` support streaming data via the streaming API, you will still need to set up the `<provider>` element, choose an authority, and create a subclass of `ContentProvider` as with the database-style API. From there, whether you are adding the streaming API to an existing provider or creating a new one, there is some additional work to be done.

Serving the Stream

If you want consumers of your `ContentProvider` to be able to call `openInputStream()` or `openOutputStream()` on a `Uri`, the most likely approach is to implement the `openFile()` method. The `openFile()` method returns a curious object called a `ParcelFileDescriptor`. Given that, the `ContentResolver` can obtain the `InputStream` or `OutputStream` that was requested. There are various static methods on `ParcelFileDescriptor` to create instances of it, such as an `open()` method that takes a `File` object as the first parameter. Note that this works for both files on external storage and files within your own project's app-local file storage (e.g., `getFilesDir()`).

`openFile()` also gets a `String` parameter that is the "mode" for opening the file. This can be converted into appropriate flags for use with `ParceFileDescriptor` and its `open()` method. Mostly, this is for determining whether we are opening the file for read or write operations.

Serving the Metadata

You should implement the `query()` method in your provider as well. If the `Uri` is pointing to one of your streams, you should create a one-row `MatrixCursor` and supply the `OpenableColumns` as the columns. `OpenableColumns` has two values: `DISPLAY_NAME` (for some human-readable name of the stream) and `SIZE` (the length of the stream in bytes). Based on the `projection` string array passed into `query()`, you can skip columns that the client is not requesting.

You also need to implement `getType()`. For the database-style API, you pretty much invent your own MIME types. For the streaming API, you should be returning MIME types for the `Uri` values that really represent the contents of that `Uri`. In other words, your `getType()` method should behave like you would expect a Web server to do with respect to the `Content-Type` header. If you know the MIME type for certain (e.g., you got it yourself in an HTTP or IMAP operation and saved it), use that. If you do not know the MIME type for certain, you can try the `MimeTypeMap` class, which knows how to map common file extensions to their MIME type counterparts. Worst-case, return `application/octet-stream`.

The Rest of the Requirements

You also have to implement the following `abstract` methods:

- `onCreate()`
- `insert()`
- `update()`
- `delete()`

If you are not supporting the database-style API, you are welcome to have `insert()`, `update()`, and `delete()` throw some `RuntimeException`, to indicate that those operations are not supported.

Issues with Content Providers

Content providers are not without their issues.

The biggest complaint seems to be the lack of an `onDestroy()` companion to the `onCreate()` method you can implement. Hence, if you open a database in `onCreate()`, you close it… never. Sometimes, you can alleviate this by initializing things on demand and releasing them immediately, such as opening a database as part of `insert()` and closing it within the same method. This does not always work, however — for example, you cannot close the database you query in `query()`, since the `Cursor` you return would become invalid. Holding onto an open `SQLiteDatabase` is not a problem, as all of your data changes are written to disk as part of committing transactions. So, many `ContentProvider` implementations settle for simply never closing the database.

The fact that `ContentProvider` is effectively a facade means that a consumer of a `ContentProvider` has no idea what to expect. It is up to documentation to explain what `Uri` values can be used, what columns can be returned, what query syntax is supported, and so on. And, the fact that it is a facade means that much of the richness of the SQLite interface is lost, such as `GROUP BY`. To top it off, the API supported by `ContentProvider` is rather limited — if what you want to share does not look like a database and does not look like a file, it may be difficult to force it into the `ContentProvider` API.

Another issue is the client's dependence upon the provider itself. If, for whatever reason, the provider's process is terminated while the client has an open `Cursor` on query results, the client's process is also terminated. It is unclear if the same effect occurs when the client has an open stream from a provider through the streaming API, though it seems likely. Now, in theory, the importance of the provider's process should be raised to the highest importance of any of its clients, though this behavior is not documented and may not occur in practice.

This behavior by Android is rather drastic, more drastic than what happens to HTTP clients when the Web server they are connected to crashes. There, the client winds up with some sort of exception and can move on. The moral of this story is: when working with a `ContentProvider`, it behooves you to use the data quickly, particularly if your app is in the background at the time.

Content Provider Implementation Patterns

The previous chapter focused on the concepts, classes, and methods behind content providers. This chapter more closely examines some implementations of content providers, organized into simple patterns.

Prerequisites

Understanding this chapter requires that you have read the preceding chapter, along with the chapter on permissions.

The Single-Table Database-Backed Content Provider

The simplest database-backed content provider is one that only attempts to expose a single table's worth of data to consumers. The `CallLog` content provider works this way, for example.

Step #1: Create a Provider Class

We start off with a custom subclass of `ContentProvider`, named, cunningly enough, Provider. Here we need the database-style API methods: `query()`, `insert()`, `update()`, `delete()`, and `getType()`.

onCreate()

Here is the `onCreate()` method for `Provider`, from the [`ContentProvider/ConstantsPlus`](ContentProvider/ConstantsPlus) sample application:

```
  @Override
  public boolean onCreate() {
    db=new DatabaseHelper(getContext());

    return((db == null) ? false : true);
  }
```

While that does not seem all that special, the “magic” is in the private `DatabaseHelper` object, a fairly conventional `SQLiteOpenHelper` implementation:

```
package com.commonsware.android.constants;

import android.content.ContentValues;
import android.content.Context;
import android.database.Cursor;
import android.database.sqlite.SQLiteOpenHelper;
import android.database.sqlite.SQLiteDatabase;
import android.hardware.SensorManager;

class DatabaseHelper extends SQLiteOpenHelper {
  private static final String DATABASE_NAME="constants.db";
  static final String TITLE="title";
  static final String VALUE="value";

  public DatabaseHelper(Context context) {
    super(context, DATABASE_NAME, null, 1);
  }

  @Override
  public void onCreate(SQLiteDatabase db) {
    Cursor c=db.rawQuery("SELECT name FROM sqlite_master WHERE type='table' AND
name='constants'", null);

    try {
      if (c.getCount()==0) {
        db.execSQL("CREATE TABLE constants (_id INTEGER PRIMARY KEY AUTOINCREMENT,
title TEXT, value REAL);");

        ContentValues cv=new ContentValues();

        cv.put(Provider.Constants.TITLE, "Gravity, Death Star I");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Earth");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_EARTH);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Jupiter");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_JUPITER);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Mars");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MARS);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Mercury");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MERCURY);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Moon");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_MOON);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Neptune");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_NEPTUNE);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Pluto");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_PLUTO);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Saturn");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SATURN);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Sun");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_SUN);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, The Island");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_THE_ISLAND);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Uranus");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_URANUS);
        db.insert("constants", Provider.Constants.TITLE, cv);

        cv.put(Provider.Constants.TITLE, "Gravity, Venus");
        cv.put(Provider.Constants.VALUE, SensorManager.GRAVITY_VENUS);
        db.insert("constants", Provider.Constants.TITLE, cv);
      }
    }
    finally {
      c.close();
    }
  }

  @Override
  public void onUpgrade(SQLiteDatabase db, int oldVersion, int newVersion) {
    android.util.Log.w("Constants", "Upgrading database, which will destroy all old
data");
    db.execSQL("DROP TABLE IF EXISTS constants");
    onCreate(db);
  }
}
```

Note that we are creating the DatabaseHelper in onCreate() and are never closing it. That is because there is no onDestroy() (or equivalent) method in a ContentProvider. While we might be tempted to open and close the database on every operation, that will not work, as we cannot close the database and still hand back a live Cursor from the database. Hence, we leave it open and assume that SQLite's transactional nature will ensure that our database is not corrupted when Android shuts down the ContentProvider.

query()

For SQLite-backed storage providers like this one, the query() method implementation should be largely boilerplate. Use a SQLiteQueryBuilder to convert the various parameters into a single SQL statement, then use query() on the builder to actually invoke the query and give you a Cursor back. The Cursor is what your query() method then returns.

For example, here is query() from Provider:

```
@Override
public Cursor query(Uri url, String[] projection, String selection,
                    String[] selectionArgs, String sort) {
  SQLiteQueryBuilder qb=new SQLiteQueryBuilder();

  qb.setTables(TABLE);

  String orderBy;

  if (TextUtils.isEmpty(sort)) {
    orderBy=Constants.DEFAULT_SORT_ORDER;
  }
  else {
    orderBy=sort;
  }

  Cursor c=
      qb.query(db.getReadableDatabase(), projection, selection,
               selectionArgs, null, null, orderBy);

  c.setNotificationUri(getContext().getContentResolver(), url);

  return(c);
}
```

We create a SQLiteQueryBuilder and pour the query details into the builder, notably the name of the table that we query against and the sort order (substituting in a default sort if the caller did not request one). When done, we use the query() method on the builder to get a Cursor for the results. We also tell the resulting Cursor what Uri was used to create it, for use with the content observer system.

insert()

Since this is a SQLite-backed content provider, once again, the implementation is mostly boilerplate: validate that all required values were supplied by the activity, merge your own notion of default values with the supplied data, and call `insert()` on the database to actually create the instance.

For example, here is `insert()` from `Provider`:

```
@Override
public Uri insert(Uri url, ContentValues initialValues) {
  long rowID=
      db.getWritableDatabase().insert(TABLE, Constants.TITLE,
                                      initialValues);

  if (rowID > 0) {
    Uri uri=
        ContentUris.withAppendedId(Provider.Constants.CONTENT_URI,
                                   rowID);
    getContext().getContentResolver().notifyChange(uri, null);

    return(uri);
  }

  throw new SQLException("Failed to insert row into " + url);
}
```

The pattern is the same as before: use the provider particulars plus the data to be inserted to actually do the insertion.

update()

Here is `update()` from `Provider`:

```
@Override
public int update(Uri url, ContentValues values, String where,
                  String[] whereArgs) {
  int count=
      db.getWritableDatabase()
        .update(TABLE, values, where, whereArgs);

  getContext().getContentResolver().notifyChange(url, null);

  return(count);
}
```

In this case, updates are always applied across the entire collection, though we could have a smarter implementation that supported updating a single instance via an instance `Uri`.

delete()

Similarly, here is `delete()` from `Provider`:

```
@Override
public int delete(Uri url, String where, String[] whereArgs) {
  int count=db.getWritableDatabase().delete(TABLE, where, whereArgs);

  getContext().getContentResolver().notifyChange(url, null);

  return(count);
}
```

This is almost a clone of the `update()` implementation described above.

getType()

The last method you need to implement is `getType()`. This takes a `Uri` and returns the MIME type associated with that `Uri`. The `Uri` could be a collection or an instance `Uri`; you need to determine which was provided and return the corresponding MIME type.

For example, here is `getType()` from `Provider`:

```
@Override
public String getType(Uri url) {
  if (isCollectionUri(url)) {
    return("vnd.commonsware.cursor.dir/constant");
  }

  return("vnd.commonsware.cursor.item/constant");
}
```

Step #2: Supply a Uri

You may wish to add a public static member… somewhere, containing the `Uri` for each collection your content provider supports, for use by your own application code. Typically, this is a public static final `Uri` put on the content provider class itself:

```
  public static final Uri CONTENT_URI=
      Uri.parse("content://com.commonsware.android.constants.Provider/constants");
```

You may wish to use the same namespace for the content `Uri` that you use for your Java classes, to reduce the chance of collision with others.

Bear in mind that if you intend for third parties to access your content provider, they will not have access to this public static data member, as your class is not in their project. Hence, you will need to publish the string representation of this `Uri` that they can hard-wire into their application.

Step #3: Declare the "Columns"

Remember those "columns" you referenced when you were using a content provider, in the previous chapter? Well, you may wish to publish public static values for those too for your own content provider.

Specifically, you may want a public static class implementing `BaseColumns` that contains your available column names, such as this example from `Provider`:

```
public static final class Constants implements BaseColumns {
  public static final Uri CONTENT_URI=
      Uri.parse("content://com.commonsware.android.constants.Provider/constants");
  public static final String DEFAULT_SORT_ORDER="title";
  public static final String TITLE="title";
  public static final String VALUE="value";
}
```

Since we are using SQLite as a data store, the values for the column name constants should be the corresponding column names in the table, so you can just pass the projection (array of columns) to SQLite on a `query()`, or pass the `ContentValues` on an `insert()` or `update()`.

Note that nothing in here stipulates the types of the properties. They could be strings, integers, or whatever. The biggest limitation is what a `Cursor` can provide access to via its property getters. The fact that there is nothing in code that enforces type safety means you should document the property types well, so people attempting to use your content provider know what they can expect.

Step #4: Update the Manifest

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.constants"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
```

```
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="18"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <provider
      android:name=".Provider"
      android:authorities="com.commonsware.android.constants.Provider"
      android:exported="false"/>

    <activity
      android:name=".ConstantsBrowser"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

The Local-File Content Provider

Implementing a content provider that supports serving up files based on `Uri` values is similar, and generally simpler, than creating a content provider for the database-style API. In this section, we will examine the `ContentProvider/Files` sample project. This project demonstrates a common use of the filesystem-style API: serving files from internal storage to third-party applications (who, by default, cannot read your internally-stored files).

Note that this sample project will only work on devices that have an application capable of viewing PDF files accessed via `content://` `Uri` values.

The FileProvider Class

Our `ContentProvider` is named `FileProvider`. However, most of the logic is contained in an `AbstractFileProvider` that will be used for a handful of sample apps in this chapter. We will look at both of those classes, focusing first on the `FileProvider`.

onCreate()

We have an `onCreate()` method. In many cases, this would not be needed for this sort of provider. After all, there is no database to open. In this case, we use `onCreate()` to copy the file(s) out of assets into the app-local file store. In principle, this would allow our application code to modify these files as the user uses the app (versus the unmodifiable editions in `assets/`).

```
  @Override
  public boolean onCreate() {
    File f=new File(getContext().getFilesDir(), "test.pdf");

    if (!f.exists()) {
      AssetManager assets=getContext().getResources().getAssets();

      try {
        copy(assets.open("test.pdf"), f);
      }
      catch (IOException e) {
        Log.e("FileProvider", "Exception copying from assets", e);

        return(false);
      }
    }

    return(true);
  }
```

This uses a static `copy()` method, inherited from `AbstractFileProvider`, that can copy an `InputStream` from an asset to a local `File`. We will take a peek at this later in this chapter.

openFile()

We need to implement `openFile()`, to return a `ParcelFileDescriptor` corresponding to the supplied `Uri`:

```
  @Override
  public ParcelFileDescriptor openFile(Uri uri, String mode)
                                                         throws
FileNotFoundException {
    File f=new File(getContext().getFilesDir(), uri.getPath());

    if (f.exists()) {
      return(ParcelFileDescriptor.open(f, parseMode(mode)));
    }

    throw new FileNotFoundException(uri.getPath());
  }
```

We are passed in a *nix-style string `mode`, which will be a value like `r` for read access, `wt` for write access (and truncate the file), etc. In API Level 19+, `ParcelFileDescriptor` has a convenience method for converting such modes into the equivalent `ParcelFileDescriptor` flag values. For older devices, you can simply use the `parseMode()` code that Google added:

```
// following is from ParcelFileDescriptor source code
// Copyright (C) 2006 The Android Open Source Project
// (even though this method was added much after 2006...)

private static int parseMode(String mode) {
  final int modeBits;
  if ("r".equals(mode)) {
    modeBits=ParcelFileDescriptor.MODE_READ_ONLY;
  }
  else if ("w".equals(mode) || "wt".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
  }
  else if ("wa".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_WRITE_ONLY
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_APPEND;
  }
  else if ("rw".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE;
  }
  else if ("rwt".equals(mode)) {
    modeBits=
        ParcelFileDescriptor.MODE_READ_WRITE
            | ParcelFileDescriptor.MODE_CREATE
            | ParcelFileDescriptor.MODE_TRUNCATE;
  }
  else {
    throw new IllegalArgumentException("Bad mode '" + mode + "'");
  }
  return modeBits;
}
```

Our `openFile()` method then uses `parseMode()` in the call to the static `open()` method on `ParcelFileDescriptor`, which opens the file (with the desired access mode) and gives us our `ParcelFileDescriptor` back that we can return. If the file is not found, we can throw a `FileNotFoundException` to indicate that.

getDataLength()

`AbstractFileProvider` gives us a callback — `getDataLength()` — where we can indicate how big a file is, given its `Uri`. That information will be made available to clients consuming this stream. The default will be to indicate that the file size is unknown… and that usually works. However, if it is easy for you to determine the file size, do so, and it will increase the compatibility of your app with possible consumers.

In this case, determining the size of a local file is easy:

```
protected long getDataLength(Uri uri) {
  File f=new File(getContext().getFilesDir(), uri.getPath());

  return(f.length());
}
```

The AbstractFileProvider Class

`AbstractFileProvider` is designed to handle a lot of common boilerplate for streaming providers like the one provided in this sample.

getType()

Just as our database-style `ContentProvider` needed to implement `getType()` to provide a MIME type given a `Uri`, so too do our streaming providers. The difference is that a streaming provider usually wants to use “real” MIME types, values that third-party apps are likely to recognize. For example, a PDF file should use a MIME type of `application/pdf`, as that is what PDF viewing apps will expect.

Android has some convenience code for determining a likely MIME type. You can use `MimeTypeMap` to convert a file extension to a MIME type, or you can use `guessContentTypeFromName()` on`URLConnection` to get a MIME type for a URL. Both use the same underlying database — the difference is mostly a matter of whether you have a bare file extension already or not. So, the default implementation of `getType()` in `AbstractFileProvider` uses `guessContentTypeFromName()`:

```
@Override
public String getType(Uri uri) {
  return(URLConnection.guessContentTypeFromName(uri.toString()));
}
```

If you know that *your* MIME type is unlikely to be recognized by Android (e.g., you invented your own), a subclass of AbstractFileProvider could handle those cases, chaining to the superclass for other Uri values.

insert(), update(), and delete()

ContentProvider itself is abstract, requiring us to implement a variety of methods to satisfy the compiler. Three of them — insert(), update(), and delete() — have no role in a pure-streaming ContentProvider, so AbstractFileProvider has stub implementations:

```
@Override
public Uri insert(Uri uri, ContentValues initialValues) {
  throw new RuntimeException("Operation not supported");
}

@Override
public int update(Uri uri, ContentValues values, String where,
                  String[] whereArgs) {
  throw new RuntimeException("Operation not supported");
}

@Override
public int delete(Uri uri, String where, String[] whereArgs) {
  throw new RuntimeException("Operation not supported");
}
```

A ContentProvider that supports *both* the database-style and streaming APIs will need real implementations of those methods for the database operations, perhaps throwing an Exception for requests to insert, update, or delete a Uri that represents a stream.

query() and getFileName()

We also need to implement query(). You can get by with having this be a stub similar to insert() and kin. However, for better compatibility, you should have a more robust query() implementation, as it will be used by ContentResolver to retrieve two pieces of metadata about a Uri:

- What is a valid filename to use to represent this Uri, should we need a human-readable name? After all, a ContentProvider Uri does not have to represent a human-readable path, and so the last segment of that Uri could be a cryptic string of hex digits or something, not a filename.
- What is the length of the data that should be delivered by the stream?

query() will be called with a projection that contains either OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE, or both. A streaming ContentProvider ideally supports returning a Cursor with this data. The AbstractFileProvider implementation of query() handles this for us:

```
abstract class AbstractFileProvider extends ContentProvider {
  private final static String[] OPENABLE_PROJECTION= {
      OpenableColumns.DISPLAY_NAME, OpenableColumns.SIZE };

  @Override
  public Cursor query(Uri uri, String[] projection, String selection,
                      String[] selectionArgs, String sortOrder) {
    if (projection == null) {
      projection=OPENABLE_PROJECTION;
    }

    final MatrixCursor cursor=new MatrixCursor(projection, 1);

    MatrixCursor.RowBuilder b=cursor.newRow();

    for (String col : projection) {
      if (OpenableColumns.DISPLAY_NAME.equals(col)) {
        b.add(getFileName(uri));
      }
      else if (OpenableColumns.SIZE.equals(col)) {
        b.add(getDataLength(uri));
      }
      else { // unknown, so just add null
        b.add(null);
      }
    }

    return(new LegacyCompatCursorWrapper(cursor));
  }
```

If the supplied projection is null, we assume that the caller wants the standard OpenableColumns; otherwise, we will use the supplied projection.

Our results will be packaged in a MatrixCursor. This amounts to a Cursor interface on a two-dimensional array, where you build up the rows in that array via a MatrixCursor.RowBuilder. In our case, there will only be one such row, for the relevant values for the file to be streamed in support of the requested Uri.

We iterate over the columns in the projection, calling out to getFileName() and getDataLength() methods for OpenableColumns.DISPLAY_NAME and OpenableColumns.SIZE respectively (and using null as the result for anything else). The default implementations of those methods return the last path segment of the Uri and AssetFileDescriptor.UNKNOWN_LENGTH, respectively:

```
  protected String getFileName(Uri uri) {
    return(uri.getLastPathSegment());
  }

  protected long getDataLength(Uri uri) {
    return(AssetFileDescriptor.UNKNOWN_LENGTH);
  }
```

Subclasses can override those as needed, as we saw with `getDataLength()` in the concrete `FileProvider` class.

However, `query()` does not return the `MatrixCursor` directly. Instead, it wraps it in a `LegacyCompatCursorWrapper`. This class comes from [the CWAC-Provider project](), from the author of this book. `LegacyCompatCursorWrapper` is designed to try to improve compatibility with clients that are expecting `query()` results to include a `_DATA` column, the way that `MediaStore` does. Poorly-written clients will crash if this column does not exist. `LegacyCompatCursorWrapper` wraps a `Cursor` and serves up an empty `_DATA` column for those clients that need one.

copy()

`AbstractFileProvider` also has a convenience `copy()` static method that copies an `InputStream` to a `File`, used from the `FileProvider` `onCreate()` method:

```
  static protected void copy(InputStream in, File dst)
                                                throws IOException {
    FileOutputStream out=new FileOutputStream(dst);
    byte[] buf=new byte[1024];
    int len;

    while ((len=in.read(buf)) >= 0) {
      out.write(buf, 0, len);
    }

    in.close();
    out.close();
  }
}
```

The Manifest

Finally, we need to add the provider to the `AndroidManifest.xml` file, by adding a `<provider>` element as a child of the `<application>` element, as with any other content provider:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.cp.files"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="9"
    android:targetSdkVersion="11"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="FilesCPDemo"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <provider
      android:name=".FileProvider"
      android:authorities="com.commonsware.android.cp.files"
      android:exported="true"/>
  </application>

</manifest>
```

Note, however, that we have `android:exported="true"` set in our `<provider>` element. This means that this content provider can be accessed from third-party apps or other external processes (e.g., the media framework for playing back videos).

Using this Provider

The activity is fairly trivial, simply creating an `ACTION_VIEW` `Intent` on our PDF file and starting up an activity for it, then finishing itself:

```
package com.commonsware.android.cp.files;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    startActivity(new Intent(Intent.ACTION_VIEW,
                              Uri.parse(FileProvider.CONTENT_URI
                                  + "test.pdf")));
    finish();
  }
}
```

Here, we use a CONTENT_URI published by FileProvider as the basis for identifying the file:

```
  public static final Uri CONTENT_URI=
      Uri.parse("content://com.commonsware.android.cp.files/");
```

The Protected Provider

The problem with the preceding example is that any app on the device, if it knows the right Uri to ask for, will be able to access the file. This may be desired, but often times it will not be. Instead, you may want to specifically indicate which apps, at specific points in time, can view the file.

Particularly if your objective is to start a third-party app to work with that file, setting up this sort of security is not that difficult. To see how that works, we will walk through the ContentProvider/GrantUriPermissions sample project. This is a clone of the ContentProvider/Files project with this extra security added on.

The way the defense works is by using Android's permission system. We will mark the ContentProvider as being not exported, then selectively grant that access to a specific Uri to the app that we want to view our file.

Step #1: Mark the Provider as Not Exported

Putting android:exported="false" on the <provider> element indicates that no app has the ability to make requests of your ContentProvider, except for specific cases where you authorize it:

```
    <provider
      android:name="FileProvider"
      android:authorities="com.commonsware.android.cp.files"
      android:exported="false"
      android:grantUriPermissions="false"
      tools:ignore="ExportedContentProvider">
      <grant-uri-permission android:path="/test.pdf"/>
    </provider>
```

With no other changes, if we tried to use the app, the third-party PDF viewer would crash when trying to read our PDF file from the `Uri`.

Step #2: Grant Access to the Uri

To allow third parties to get access only when we specify, we need to make a few more changes.

This `<provider>` element also has `android:grantUriPermissions="false"`. That is the default value for this attribute, shown here purely for illustration purposes. It also has a `<grant-uri-permissions>` child element, listing the local path (within the `ContentProvider`) to our PDF file.

The `<grant-uri-permissions>` element (or elements, plural) allow us to override the permission requirement for certain pieces of content, granting access to that content on a per-request basis. There are three possibilities:

1. If `android:grantUriPermissions` is `true`, then we will be able to grant access to any content within our provider
2. If `android:grantUriPermissions` is `false`, but we have `<grant-uri-permissions>` sub-elements, we can only grant access to the content identified by the `Uri` paths specified in those sub-elements
3. If `android:grantUriPermissions` is `false`, and we have no `<grant-uri-permissions>` sub-elements (the default case), we cannot grant access to any content within our provider

In this case, we specify that we will only grant access to `/test.pdf`. Since that is the only content in this provider, we could have the same net effect by setting `android:grantUriPermissions` to `true`.

Then, when we create an `Intent` used to interact with another component, we can include a flag indicating what permission we wish to grant:

```
package com.commonsware.android.cp.perms;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;

public class FilesCPDemo extends Activity {
  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    Intent i=new Intent(Intent.ACTION_VIEW, Uri.parse(FileProvider.CONTENT_URI +
"test.pdf"));

    i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);
    startActivity(i);
    finish();
  }
}
```

In this revised version of our activity, we add `FLAG_GRANT_READ_URI_PERMISSION` to the `Intent` used with `startActivity()`. This will grant the activity that responds to our `Intent` read access to the specific `Uri` in the `Intent`, overriding the exported status. That is why, when you run this app on a device, the PDF viewer will still be able to view the file.

There is also `FLAG_GRANT_WRITE_URI_PERMISSION` for granting write access, not needed here, as our provider only supports read access.

While this is most commonly used with `startActivity()` (e.g., allowing a mail program limited access to your attachments provider), this can also be used with `startService()`, `bindService()`, and the various flavors of sending broadcasts (e.g., `sendBroadcast()`).

The Stream Provider

Sometimes, we want a provider that looks like the local-file provider from the preceding section… but we do not have a file. Instead, we have data in some other form, such as a byte array, or a `String`, or an `InputStream`. Writing that material to a file may be problematic, or even counterproductive.

For example, imagine an app that stores data on the user's behalf in an encrypted fashion. One such file is a PDF, that the user would like to view. There are PDF viewers that can view files served via `content://` `Uri` values, as the previous section demonstrated… but that assumes an unencrypted file. While we could decrypt the file, writing the decrypted results to another file, and serve the decrypted data to the PDF viewer, now we have a persistent decrypted version of the data. That opens a window of time when the data might be accessed by people with nefarious intent, which is something we are trying to avoid by using the encrypted store in the first place. Rather, it would be nice if we could decrypt the data *on the fly* and give that decrypted result to the PDF viewer. Of course, there are security risks intrinsic to that too — after all, we do not know what the PDF viewer might do with the unencrypted data — but it is at least an improvement.

The good news is that Android does support streaming options for `openFile()`-style `ContentProvider` implementations. However, as one might expect, they are not the simplest things to implement.

In this section, we will examine the [`ContentProvider/Pipe`] sample project. This is a near clone of the `ContentProvider/Files` sample from the preceding section. However, rather than simply handing the file to Android to serve as content, we will stream it in ourselves. In principle, as part of this streaming, we could be decrypting it from an encrypted state. Since this sample shares much code with the previous sample, we will focus solely on the changes here.

Note that this sample was inspired by the sample found at https://github.com/nandeeshwar/Pfd-Create-Pipe.

The Pipes

Starting with API Level 9, it is possible to create a pipe between two processes, from the Android SDK, via `ParcelFileDescriptor`. In the previous section, we saw how `ParcelFileDescriptor` could be used to open a local file and make that available to other processes — the `createPipe()` method gives us a pipe.

The "pipe" returned by `createPipe()` is a two-element array of `ParcelFileDescriptor` objects. The first element in the array represents the "read" end of the pipe. In our case, that is the end that should be used by a PDF viewer to read in the file contents. The second element of the array represents the "write" end of the pipe, which we will use to supply the file's contents to the "read" end (and to the PDF viewer by extension).

The Revised openFile()

With that in mind, here is our revised `openFile()` method:

```
  @Override
  public ParcelFileDescriptor openFile(Uri uri, String mode)
                                                            throws
FileNotFoundException {
    ParcelFileDescriptor[] pipe=null;

    try {
      pipe=ParcelFileDescriptor.createPipe();
      AssetManager assets=getContext().getResources().getAssets();

      new TransferThread(assets.open(uri.getLastPathSegment()),
                       new AutoCloseOutputStream(pipe[1])).start();
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
      throw new FileNotFoundException("Could not open pipe for: "
          + uri.toString());
    }

    return(pipe[0]);
  }
```

We create our pipe via `createPipe()`, then get an `InputStream` on our PDF file stored as an asset — unlike the `ContentProvider/Files` sample, we do not need to copy the asset to a local file now. We then kick off a background thread, implemented in an inner class named `TransferThread`, to actually copy the data from the asset to the write end of the pipe.

Rather than supply `TransferThread` with a `ParcelFileDescriptor` for the write end of the pipe, we supply an `OutputStream`. Specifically, we pass in a `ParcelFileDescriptor.AutoCloseOutputStream`. This is an `OutputStream` that knows to close the `ParcelFileDescriptor` when we close the stream. Otherwise, it behaves like a fairly typical `OutputStream`.

The Transfer

`TransferThread` is a fairly conventional copy-data-from-stream-to-stream implementation:

```
  static class TransferThread extends Thread {
    InputStream in;
    OutputStream out;

    TransferThread(InputStream in, OutputStream out) {
      this.in=in;
      this.out=out;
    }

    @Override
    public void run() {
      byte[] buf=new byte[1024];
      int len;

      try {
        while ((len=in.read(buf)) >= 0) {
          out.write(buf, 0, len);
        }

        in.close();
        out.flush();
        out.close();
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(),
              "Exception transferring file", e);
        }
      }
    }
```

Here, we read in data in 1KB blocks from the InputStream (our asset) and write the data to our OutputStream (obtained from the ParcelFileDescriptor).

The Results

Our activity logic has not substantially changed. We still create an ACTION_VIEW Intent on the content:// Uri from our provider, pointing to our test.pdf asset. Any PDF viewer capable of handling content:// Uri values will use a ContentResolver to open an InputStream for our Uri. In the ContentProvider/Files sample, that InputStream would receive the contents of the file directly from Android. In this new sample, that InputStream is reading in bytes off of our pipe, until such time as it has read in all the streamed data and we have closed the OutputStream.

Not every possible consumer of a Uri will be able to work with our stream, though. For example, MediaPlayer expects to be able to move forwards and backwards within the stream, and while that works for file-backed ParcelFileDescriptors, it does not work for those representing a pipe. Hence, MediaPlayer will crash when trying to use a Uri to a pipe-based stream, which is certainly unfortunate.

The author would like to thank Reuben Scratton for his assistance in tracking down this MediaPlayer limitation.

FileProvider

The Android Support package now contains its own implementation of a FileProvider that greatly simplifies serving files from internal or external storage to another app.

Here, we will see Google's FileProvider in action via the ContentProvider/V4FileProvider sample project. This is a near clone of the ContentProvider/Pipe sample from the preceding section, just leveraging FileProvider to help us serve a file from internal storage.

The Rationale

The documentation for `FileProvider` states:

> Apps should generally avoid sending raw filesystem paths across process boundaries, since the receiving app may not have the same access as the sender. Instead, apps should send Uri backed by a provider like FileProvider.

This is not just an issue for passing files from internal storage to other apps. On Android 4.2+ tablets, it could even be an issue for external storage, as each user account gets its own portion of external storage. There may be scenarios in which your app (associated with one user) winds up needing to pass the contents of a file on external storage to another app (associated with another user). Regular filesystem paths will not work in this case, as one user account cannot directly access another user account's files, even on external storage.

The Sources of Files

Google's `FileProvider` offers automatic serving of files from three root points:

- `getFilesDir()` (i.e., the standard portion of internal storage for your app)
- `getCacheDir()` (i.e., internal storage, but files that the OS can purge if needed to free up disk space)
- `Environment.getExternalStorageDirectory()` (i.e., the root of external storage)

NOTE: there is a bug in the documentation for `FileProvider`, where the docs claim that `FileProvider` supports `getExternalFilesDir()`, not `Environment.getExternalStorageDirectory()`. The documentation is wrong; this chapter is based on the actual `FileProvider` implementation.

For each of these, you will be able to specify a specific subdirectory's worth of files that should be served, if you do not want the entire directory's contents published via `FileProvider`. You will also be able to specify an alias, which serves as the first path segment (after the authority in the `content://` `Uri`) — `FileProvider` maps that path segment to a specific location of files to serve.

The Manifest Entry

The information about what files to serve comes in the form of an XML resource file. You can name the file whatever you like, but its content needs to be a root <paths> element, with a series of children for the different directories you wish to serve. Those directories will be denoted via child elements with specific names:

- <files-path> for getFilesDir()
- <cache-path> for getCacheDir()
- <external-path> for Environment.getExternalStorageDirectory()

For example, our sample project has a res/xml/provider_paths.xml file with the following contents:

```
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
    <files-path name="stuff" />
</paths>
```

Here, we are saying that we want to serve the contents of getFilesDir(), using a virtual root path of stuff. With an authority of com.commonsware.android.cp.v4file, this means that a Uri of content://com.commonsware.android.cp.v4file/stuff/test.pdf would serve up a test.pdf file in the getFilesDir() directory.

The optional path attribute of the <files-path>, etc. elements indicates a particular subdirectory, relative to the element-specific root, that should be used as the source of files. So, for example, had the provider_paths.xml file looked like:

```
<?xml version="1.0" encoding="utf-8"?>
<paths xmlns:android="http://schemas.android.com/apk/res/android">
    <files-path name="stuff" path="help/" />
</paths>
```

…then content://com.commonsware.android.cp.v4file/stuff/test.pdf would map to help/test.pdf inside of getFilesDir().

You then point to this XML resource from a <meta-data> element in the <provider> element in the manifest, teaching FileProvider what to serve. For example, our <provider> element in this sample app is:

```
    <provider
      android:name="LegacyCompatFileProvider"
      android:authorities="com.commonsware.android.cp.v4file"
      android:exported="false"
      android:grantUriPermissions="true">
      <meta-data
        android:name="android.support.FILE_PROVIDER_PATHS"
        android:resource="@xml/provider_paths"/>
    </provider>
```

Here, our android:name points to a LegacyCompatFileProvider class that we will examine shortly. We still provide the android:authorities value, along with any permission rules that we want. Beyond that, we have a <meta-data> element, with an android:name of android.support.FILE_PROVIDER_PATHS, that points to our XML resource with the path information.

You will also notice that our android:exported attribute is set to false. As it turns out, FLAG_GRANT_READ_URI_PERMISSION trumps the exported status of a provider. If you pass a Uri to an activity using FLAG_GRANT_READ_URI_PERMISSION, the activity will be able to read the contents of that Uri, even if the provider itself is not exported.

The Legacy Compatibility

LegacyCompatFileProvider is a simple subclass of FileProvider, one that overrides query() and wraps its Cursor in a LegacyCompatCursorWrapper to try to improve compability with ill-behaved clients:

```
package com.commonsware.android.cp.v4file;

import android.database.Cursor;
import android.net.Uri;
import android.support.v4.content.FileProvider;
import com.commonsware.cwac.provider.LegacyCompatCursorWrapper;

public class LegacyCompatFileProvider extends FileProvider {
  @Override
  public Cursor query(Uri uri, String[] projection, String selection, String[]
selectionArgs, String sortOrder) {
    return(new LegacyCompatCursorWrapper(super.query(uri, projection, selection,
selectionArgs, sortOrder)));
  }
}
```

The Usage

At this point, the provider is ready for use, insofar as we can specify Uri values like content://com.commonsware.android.cp.v4file/stuff/test.pdf and get results. Of course, we actually need to have files in our internal storage, and we need to use such a Uri.

Hence, our activity combines the unpack-the-file-from-assets logic from our own providers in earlier samples, plus starts up a PDF viewer on our designated `test.pdf` file:

```
package com.commonsware.android.cp.v4file;

import android.app.Activity;
import android.content.Intent;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.support.v4.content.FileProvider;
import android.util.Log;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class FilesCPDemo extends Activity {
  private static final String AUTHORITY="com.commonsware.android.cp.v4file";

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);

    File f=new File(getFilesDir(), "test.pdf");

    if (!f.exists()) {
      AssetManager assets=getResources().getAssets();

      try {
        copy(assets.open("test.pdf"), f);
      }
      catch (IOException e) {
        Log.e("FileProvider", "Exception copying from assets", e);
      }
    }

    Intent i=
        new Intent(Intent.ACTION_VIEW,
                   FileProvider.getUriForFile(this, AUTHORITY, f));

    i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);
    startActivity(i);
    finish();
  }

  static private void copy(InputStream in, File dst) throws IOException {
    FileOutputStream out=new FileOutputStream(dst);
    byte[] buf=new byte[1024];
    int len;

    while ((len=in.read(buf)) > 0) {
      out.write(buf, 0, len);
    }

    in.close();
    out.close();
  }
}
```

FileProvider offers a handy getUriForFile() static helper method that will return a Uri for a given file, incorporating our specified content provider authority.

The result of running this activity is the same as the other file-serving provider samples from this chapter: a PDF viewer (if one is available) will display the test.pdf file.

StreamProvider

FileProvider is rather nice: you can serve up typical file-based content without having to roll your own implementation of ContentProvider and openFile(). However, it only supports a few sources of data: getFilesDir(), getCacheDir(), and Environment.getExternalStoragePublicDirectory().

The author of this book has written StreamProvider, a fork of FileProvider that adds support for serving content from assets, raw resources, getExternalFilesDir(), and getExternalCacheDir(). StreamProvider can be found in the CWAC-Provider project.

You can add this library to your Android Studio project much in the same way as you can other CWAC libraries: add the CWAC repository and request the dependency:

```
repositories {
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:provider:0.2.+'
}
```

Once you have added the CWAC-Provider dependency to your project, you use it much the same as you would use FileProvider:

- Define an XML metadata file with a <paths> root element, containing one or more elements describing what you want the provider to serve
- Add com.commonsware.cwac.provider.StreamProvider as a <provider> to your manifest, under your own android:authority, with a <meta-data> element (with a name of

com.commonsware.cwac.provider.STREAM_PROVIDER_PATHS), pointing to that XML metadata
- Use FLAG_GRANT_READ_URI_PERMISSION and FLAG_GRANT_WRITE_URI_PERMISSION in Intent objects you use to have third parties use the files the StreamProvider serves, to allow those apps selective, temporary access to the file

The XML metadata can have:

- <external-files-path> for serving files from getExternalFilesDir(null)
- <external-cache-path> for serving files from getExternalCacheDir()
- <raw-resource> for serving a particular raw resource, where the path is the name of the raw resource (without file extension)
- <asset> for serving files from assets/

These are in addition to the <files-path>, <external-path>, and <cache-path> supported by FileProvider.

Hence, StreamProvider is especially useful when you want to package some content — such as a PDF file for online help — that you want to serve from your app. Just drop the file in assets/ in your project, set up StreamProvider to serve up assets, and use an appropriate Intent with startActivity() to view that file.

Also, note that StreamProvider uses LegacyCompatCursorWrapper internally, so you do not have to blend that in as we did with some of the other samples in this chapter.

The Loader Framework

One perpetual problem in Android development is getting work to run outside the main application thread. Every millisecond we spend on the main application thread is a millisecond that our UI is frozen and unresponsive. Disk I/O, in particular, is a common source of such slowdowns, particularly since this is one place where the emulator typically out-performs actual devices. While disk operations rarely get to the level of causing an "application not responding" (ANR) dialog to appear, they can make a UI "janky".

Android 3.0 introduced a new framework to help deal with loading bulk data off of disk, called "loaders". The hope is that developers can use loaders to move database queries and similar operations into the background and off the main application thread. That being said, loaders themselves have issues, not the least of which is the fact that it is new to Android 3.0 and therefore presents some surmountable challenges for use in older Android devices.

This chapter will outline the programming pattern loaders are designed to solve, how to use loaders (both built-in and third-party ones) in your activities, and how to create your own loaders for scenarios not already covered.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- database access
- content provider theory
- content provider implementations

Cursors: Issues with Management

Android had the concept of "managed cursors" in Android 1.x/2.x. A managed Cursor was one that an Activity… well… manages. More specifically:

1. When the activity was stopped, the managed Cursor was deactivated, freeing up all of the memory associated with the result set, and thereby reducing the activity's heap footprint while it was not in the foreground
2. When the activity was restarted, the managed Cursor was requeried, to bring back the deactivated data, along the way incorporating any changes in that data that may have occurred while the activity was off-screen
3. When the activity was destroyed, the managed Cursor was closed.

This is a delightful set of functionality. Cursor objects obtained from a ContentProvider via managedQuery() were automatically managed; a Cursor from SQLiteDatabase could be managed by startManagingCursor().

The problem is that the requery() operation that was performed when the activity is restarted is executed on the main application thread. As has been noted elsewhere in the book, you *really* do not want to do disk I/O on the main application thread, as it freezes the UI and causes jank. This is particularly true for database I/O, where you may not know in advance exactly how much data you will get back or how long the query will take.

Introducing the Loader Framework

The Loader framework was designed to solve three issues with the old managed Cursor implementation:

- Arranging for a requery() (or the equivalent) to be performed on a background thread)
- Arranging for the original query that populated the data in the first place to also be performed on a background thread, which the managed Cursor solution did not address at all
- Supporting loading things other than a Cursor, in case you have data from other sources (e.g., XML files, JSON files, Web service calls) that might be able to take advantage of the same capabilities as you can get from a Cursor via the loaders

There are three major pieces to the Loader framework: LoaderManager, LoaderCallbacks, and the Loader itself.

LoaderManager

LoaderManager is your gateway to the Loader framework. You obtain one by calling getLoaderManager() (or getSupportLoaderManager(), as is described later in this chapter). Via the LoaderManager you can initialize a Loader, restart that Loader (e.g., if you have a different query to use for loading the data), etc.

LoaderCallbacks

Much of your interaction with the Loader, though, comes from your LoaderCallbacks object, such as your activity if that is where you elect to implement the LoaderCallbacks interface. Here, you will implement three "lifecycle" methods for consuming a Loader:

1. onCreateLoader() is called when your activity requests that a LoaderManager initialize a Loader. Here, you will create the instance of the Loader itself, teaching it whatever it needs to know to go load your data
2. onLoadFinished() is called when the Loader has actually loaded the data — you can take those results and pour them into your UI, such as calling swapCursor() on a CursorAdapter to supply the fresh Cursor's worth of data
3. onLoaderReset() is called when you should stop using the data supplied to you in the last onLoadFinished() call (e.g., the Cursor is going to be closed), so you can arrange to make that happen (e.g., call swapCursor(null) on a CursorAdapter)

When you implement the LoaderCallbacks interface, you will need to provide the data type of whatever it is that your Loader is loading (e.g., LoaderCallbacks<Cursor>). If you have several loaders returning different data types, you may wish to consider implementing LoaderCallbacks on multiple objects (e.g., instances of anonymous inner classes), so you can take advantage of the type safety offered by Java generics, rather than implementing LoaderCallbacks<Object> or something to that effect.

Loader

Then, of course, there is Loader itself.

Consumers of the Loader framework will use some concrete implementation of the abstract `Loader` class in their `LoaderCallbacks` `onCreateLoader()` method. API Level 11 introduced only one concrete implementation: `CursorLoader`, designed to perform queries on a `ContentProvider`, and described in a later section.

Honeycomb… Or Not

`Loader` and its related classes were introduced in Android 3.0 (API Level 11). If your application is only going to be deployed on such devices, you can use loaders "naturally" via the standard implementation.

If, however, you are interested in using loaders but also want to support pre-Honeycomb devices, the Android Support package offers its own implementation of `Loader` and the other classes. However, to use it, you will need to work within four constraints:

- You will need to add `support-v4` or `support-v13` as dependencies, from the Android Support package
- You will need to inherit from `FragmentActivity`, not the OS base `Activity` class or other refinements (e.g., `MapActivity`), or from other classes that inherit from `FragmentActivity` (e.g., `SherlockFragmentActivity`).
- You will need to import the `support.v4` versions of various classes (e.g., `android.support.v4.app.LoaderManager` instead of `android.app.LoaderManager`)
- You will need to get your `LoaderManager` by calling `getSupportLoaderManager()`, instead of `getLoaderManager()`, on your `FragmentActivity`

These limitations are the same ones that you will encounter when using fragments on older devices. Hence, while loaders and fragments are not really related, you may find yourself adopting both of them at the same time, as part of incorporating the Android Support package into your project.

Using CursorLoader

Let's start off by examining the simplest case: using a `CursorLoader` to asynchronously populate and update a `Cursor` retrieved from a `ContentProvider`. This is illustrated in the `Loaders/ConstantsLoader` sample project, which is the same show-the-list-of-gravity-constants sample application that we examined previously, updated to use the `Loader` framework. Note that this project does not use the Android Support package and therefore only supports API Level 11 and higher.

In `onCreate()`, rather than executing a `managedQuery()` to retrieve our constants, we ask our `LoaderManager` to initialize a loader, after setting up our `SimpleCursorAdapter` on a null `Cursor`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  adapter=new SimpleCursorAdapter(this,
                          R.layout.row, null,
                          new String[] {Provider.Constants.TITLE,
                                  Provider.Constants.VALUE},
                          new int[] {R.id.title, R.id.value});

  setListAdapter(adapter);
  registerForContextMenu(getListView());
  getLoaderManager().initLoader(0, null, this);
}
```

Using a `null Cursor` means we will have an empty list at the outset, a problem we will rectify shortly.

The `initLoader()` call on `LoaderManager` (retrieved via `getLoaderManager()`) takes three parameters:

- A locally-unique identifier for this loader
- An optional `Bundle` of data to supply to the loader
- A `LoaderCallbacks` implementation to use for the results from this loader (here set to be the activity itself, as it implements the `LoaderManager.LoaderCallbacks<Cursor>` interface)

The first time you call this for a given identifier, your `onCreateLoader()` method of the `LoaderCallbacks` will be called. Here, you need to initialize the `Loader` to use for this identifier. You are passed the identifier plus the `Bundle` (if any was supplied). In our case, we want to use a `CursorLoader`:

```
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
  return(new CursorLoader(this, Provider.Constants.CONTENT_URI,
                          PROJECTION, null, null, null));
}
```

`CursorLoader` takes a `Context` plus all of the parameters you would ordinarily use with `managedQuery()`, such as the content provider `Uri`. Hence, converting existing code to use `CursorLoader` means converting your `managedQuery()` call into an invocation of the CursorLoader constructor inside of your onCreateLoader() method.

At this point, the CursorLoader will query the content provider, but do so on a background thread, so the main application thread is not tied up. When the Cursor has been retrieved, it is supplied to your onLoadFinished() method of your LoaderCallbacks:

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
  adapter.swapCursor(cursor);
}
```

Here, we call the new swapCursor() available on CursorAdapter, to replace the original null Cursor with the newly-loaded Cursor.

Your onLoadFinished() method will also be called whenever the data represented by your Uri changes. That is because the CursorLoader is registering a ContentObserver, so it will find out about data changes and will automatically requery the Cursor and supply you with the updated data.

Eventually, onLoaderReset() will be called. You are passed a Cursor object that you were supplied previously in onLoadFinished(). You need to make sure that you are no longer using that Cursor at this point — in our case, we swap null back into our CursorAdapter:

```
public void onLoaderReset(Loader<Cursor> loader) {
  adapter.swapCursor(null);
}
```

And that's pretty much it, at least for using CursorLoader. Of course, you need a content provider to make this work, and creating a content provider involves a bit of work.

What Else Is Missing?

The Loader framework does an excellent job of handling queries in the background. What it does not do is help us with anything else that is supposed to be in the background, such as inserts, updates, deletes, or creating/upgrading the database. It is all too easy to put those on the main application thread and therefore possibly encounter issues. Moreover, since the thread(s) used by the Loader framework are an implementation detail, we cannot use those threads ourselves necessarily for the other CRUD operations.

Issues, Issues, Issues

Unfortunately, not all is rosy with the `Loader` framework.

There appears to be a bug in the Android Support package's implementation of the framework. If you use a `Loader` from a fragment that has `setRetainInstance()` set to `true`, you will not be able to use the `Loader` again after a configuration change, such as a screen rotation. This bug is not seen with the native API Level 11+ implementation of the framework.

Loaders Beyond Cursors

Loaders are not limited to loading something represented by a `Cursor`. You can load any sort of content that might take longer to load than you would want to spend on the main application thread. While the only concrete `Loader` implementation supplied by Android at this time loads a `Cursor` from a `ContentProvider`, you can create your own non-`Cursor` `Loader` implementation or employ one written by a third party.

What Happens When…?

Here are some other common development scenarios and how the `Loader` framework addresses them.

… the Data Behind the Loader Changes?

According to the `Loader` documentation, "They monitor the source of their data and deliver new results when the content changes".

The documentation is incorrect.

A `Loader` *can* "monitor the source of their data and deliver new results when the content changes". There is nothing in the framework that requires this behavior. Moreover, there are some cases where it is clearly a bad idea to do this — imagine a `Loader` loading data off of the Internet, needing to constantly poll some server to look for changes.

The documentation for a Loader implementation should tell you the rules. Android's built-in `CursorLoader` does deliver new results, by means of a behind-the-scenes ContentObserver. SQLiteCursorLoader does not deliver new results at this time. SharedPreferencesLoader hands you a SharedPreferences object, which intrinsically is aware of any changes, and so SharedPreferencesLoader does nothing special here.

… the Configuration Changes?

The managed Cursor system that the Loader framework replaces would automatically requery() any managed Cursor objects when an activity was restarted. This would update the Cursor in place with fresh data after a configuration change. Of course, it would do that on the main application thread, which was not ideal.

Your Loader objects are retained across the configuration change automatically. Barring bugs in a specific Loader implementation, your Loader should then hand the new activity instance the data that was retrieved on behalf of the old activity instance (e.g., the Cursor).

Hence, you do not have to do anything special for configuration changes.

… the Activity is Destroyed?

Another thing the managed Cursor system gave you was the automatic closing of your Cursor when the activity was destroyed. The Loader framework does this as well, by triggering a reset of the Loader, which obligates the Loader to release any loaded data.

… the Activity is Stopped?

The final major feature of the managed Cursor system was that it would deactivate() a managed Cursor when the activity was stopped. This would release all of the heap space held by that Cursor while it was not on the screen. Since the Cursor was refreshed as part of restarting the activity, this usually worked fairly well and would help minimize pressure on the heap.

Alas, this does not appear to be supported by the Loader framework. The Loader is reset when an activity is destroyed, not stopped. Hence, the Loader data will continue to tie up heap space even while the activity is not in the foreground.

For many activities, this should not pose a problem, as the heap space consumed by their `Cursor` objects is modest. If you have an activity with a massive `Cursor`, though, you may wish to consider what steps you can take on your own, outside of the `Loader` framework, to help with this.

The ContactsContract and CallLog Providers

One of the more popular stores of data on your average Android device is the contact list. Ever since Android 2.0, Android tracks contacts across multiple different "accounts", or sources of contacts. Some may come from your Google account, while others might come from Exchange or other services.

This chapter will walk you through some of the basics for accessing the contacts on the device. Along the way, we will revisit and expand upon our knowledge of using a `ContentProvider`.

First, we will review the contacts APIs, past and present. We will then demonstrate how you can connect to the contacts engine to let users pick and view contacts… all without your application needing to know much of how contacts work. We will then show how you can query the contacts provider to obtain contacts and some of their details, like email addresses and phone numbers. We wrap by showing how you can invoke a built-in activity to let the user add a new contact, possibly including some data supplied by your application.

In addition, we will take a peek at the `CallLog` provider, which, as the name suggests, gives you access to a log of calls made on the device.

Prerequisites

Understanding this chapter requires that you have read these chapters in addition to the core chapters:

- content provider theory

- content provider implementations
- the Loader framework

Introducing You to Your Contacts

Android makes contacts available to you via a complex ContentProvider framework, so you can access many facets of a contact's data — not just their name, but addresses, phone numbers, groups, etc. Working with the contacts ContentProvider set is simple… only if you have an established pattern to work with. Otherwise, it may prove somewhat daunting.

Organizational Structure

The contacts ContentProvider framework can be found as the set of ContactsContract classes and interfaces in the android.provider package. Unfortunately, there is a dizzying array of inner classes to ContactsContract.

Contacts can be broken down into two types: raw and aggregate. Raw contacts come from a sync provider or are hand-entered by a user. Aggregate contacts represent the sum of information about an individual culled from various raw contacts. For example, if your Exchange sync provider has a contact with an email address of jdoe@foo.com, and your Facebook sync provider has a contact with an email address of jdoe@foo.com, Android may recognize that those two raw contacts represent the same person and therefore combine those in the aggregate contact for the user. The classes relating to raw contacts usually have Raw somewhere in their name, and these normally would be used only by custom sync providers.

The ContactsContract.Contacts and ContactsContract.Data classes represent the "entry points" for the ContentProvider, allowing you to query and obtain information on a wide range of different pieces of information. What is retrievable from these can be found in the various ContactsContract.CommonDataKinds series of classes. We will see examples of these operations later in this chapter.

A Look Back at Android 1.6

Prior to Android 2.0, Android had no contact synchronization built in. As a result, all contacts were in one large pool, whether they were hand-entered by users or were added via third-party applications. The API used for this is the Contacts ContentProvider.

The Contacts ContentProvider still works, as it is merely deprecated in Android 2.0.1, not removed. In practice, it has one big limitation: it will only report contacts added directly to the device (as opposed to ones synchronized from Microsoft Exchange, Facebook, or other sources). As a result, modern Android apps should **not** be using Contacts in general — use ContactsContract.

Pick a Peck of Pickled People

Back in the chapter on resource sets and configurations, we saw a series of examples of handling configuration changes. Those samples allowed the user to pick a contact and view a contact. There, we focused on the configuration change aspect. Here, let's examine the actual pick and view logic a bit more closely.

Picking a Contact

When the user picks a contact, we call startActivityForResult() with an ACTION_PICK Intent:

```
public void pickContact(View v) {
  Intent i=
      new Intent(Intent.ACTION_PICK,
                 ContactsContract.Contacts.CONTENT_URI);

  startActivityForResult(i, PICK_REQUEST);
}
```

The Intent has ContactsContract.Contacts.CONTENT_URI as its Uri. Here, ContactsContract.Contacts.CONTENT_URI is defined by the Android SDK and points to the contacts "table" inside the ContactsContract "database", as it were. Whether there is really a database or a table involved is up to the implementation of ContactsContract, of course.

When we call startActivityForResult(), Android needs to find an activity to fulfill this request. However, at the outset, all it has is an action string and a Uri. There could be all sorts of activities on the device that advertise that they can pick from a collection identified by a Uri starting with the content scheme.

To help refine the request, Android asks the ContactsContract ContentProvider what the MIME type is for this Uri. Then, Android knows an action string, a MIME type, and a Uri. It so happens that the contacts apps that ship on Android have an activity that has an <intent-filter> that indicates that it can handle ACTION_PICK of the relevant MIME type from a `content` `Uri`. And so that is the activity that the user sees.

The `Uri` that we get back in `onActivityResult()` not only points to the contact that the user picked, but also gives us *temporary read access* to that contact's personally identifying information. In effect, it is as if the normal `READ_CONTACTS` permission requirement was suspended, for this one `Uri`, for our app alone. Once our process terminates, we may no longer have the ability to get at details about that contact via its `Uri`, as this read access is temporary.

Viewing a Contact

As it turns out, the sample app does not take advantage of the temporary read access. Instead, when the user clicks the "View" button, the app just brings up an activity to go view that contact:

```
public void viewContact(View v) {
  startActivity(new Intent(Intent.ACTION_VIEW, contact));
}
```

Once again, Android has an action string (`ACTION_VIEW`) and a `Uri` (the one that we got in response to the `ACTION_PICK` request). And, once again, Android asks `ContactsContract` for the MIME type of the data associated with this `Uri`, so that the MIME type can help identify the right activity to handle this request. The contacts app that comes on the device should have an activity that complies, and so we can view the contact.

In truth, the only reason why we as developers can count on these activities existing is because of Google Play Services and the Play Store. The Compatibility Definition Document (CDD) that manufacturers must comply with to get Google's proprietary Android apps requires that the device ship with apps that fulfill all of the `<intent-filter>` elements supported by the apps in the Android Open Source Project (AOSP). Hence, for devices that legitimately have the Play Store on them, there should always be an app that offers activities to allow users to pick and view contacts. However, on devices that do *not* legitimately have the Play Store, those activities might not exist. Manufacturers who eschew Google's proprietary apps *should* still aim to comply with the CDD as much as possible, if they want third-party apps like yours to work successfully on those devices. However, there is no contractual requirement that they do, and so, as the saying goes, your mileage may vary (YMMV).

Spin Through Your Contacts

The preceding example allows you to work with contacts, yet not actually have any contact data other than a transient Uri. All else being equal, it is best to use the contacts system this way, as it means you do not need any extra permissions that might raise privacy issues.

Of course, all else is rarely equal.

Your alternative, therefore, is to execute queries against the contacts ContentProvider to get actual contact detail data back, such as names, phone numbers, and email addresses. The Contacts/Spinners sample application will demonstrate this technique.

Contact Permissions

Since contacts are privileged data, you need certain permissions to work with them. Specifically, you need the READ_CONTACTS permission to query and examine the ContactsContract content and WRITE_CONTACTS to add, modify, or remove contacts from the system. This only holds true if your code will have access to personally-identifying information, which is why the Pick sample above — which just has an opaque Uri — does not need any permission.

For example, here is the manifest for the Contacts/Spinners sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  android:versionCode="1"
  android:versionName="1.0"
  package="com.commonsware.android.contacts.spinners"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <uses-permission android:name="android.permission.READ_CONTACTS"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="18"/>

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"/>

  <application
    android:icon="@drawable/cw"
    android:label="@string/app_name">
    <activity
```

```
      android:label="@string/app_name"
      android:name=".ContactSpinners">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>
        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

Pre-Joined Data

While the database underlying the ContactsContract content provider is private, one can imagine that it has several tables: one for people, one for their phone numbers, one for their email addresses, etc. These are tied together by typical database relations, most likely 1:N, so the phone number and email address tables would have a foreign key pointing back to the table containing information about people.

To simplify accessing all of this through the content provider interface, Android pre-joins queries against some of the tables. For example, you can query for phone numbers and get the contact name and other data along with the number — you do not have to do this join operation yourself.

The UI

The ContactSpinners activity is simply a ListActivity, though it sports a Spinner to go along with the obligatory ListView:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
  <Spinner android:id="@+id/spinner"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:drawSelectorOnTop="true"
  />
  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
  />
</LinearLayout>
```

In onCreate() of the activity, we load up the Spinner:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    Spinner spin=(Spinner)findViewById(R.id.spinner);
    spin.setOnItemSelectedListener(this);

    ArrayAdapter<String> aa=new ArrayAdapter<String>(this,
                                 android.R.layout.simple_spinner_item,
                                 getResources().getStringArray(R.array.options));

    aa.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);
    spin.setAdapter(aa);
```

In particular, we populate the `Spinner` based on a `<string-array>` resource from the `res/values/arrays.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="options">
    <item>Contact Names</item>
    <item>Contact Names &amp; Numbers</item>
    <item>Contact Names &amp; Email Addresses</item>
  </string-array>
</resources>
```

Reacting to the Spinner

We set up the activity to be the `OnItemSelectedListener` for the `Spinner`, which means that we have to implement `onItemSelected()` and `onNothingSelected()`:

```
  @Override
  public void onItemSelected(AdapterView<?> parent,
                             View v, int position, long id) {
    getLoaderManager().initLoader(position, null, this);
  }

  @Override
  public void onNothingSelected(AdapterView<?> parent) {
    // ignore
  }
```

When the user selects something in the `Spinner` — and for the default selection — we will use the `Loader` framework and use a `CursorLoader` to query the `ContactsContract ContentProvider`. In this case, though, we want three different `Cursor` values, one for each option in the `Spinner`. That will mean that we need three different `CursorLoader` objects. To identify which loader we are going to initialize, we pass in the `position` of the `Spinner` to `initLoader()`, so the 0/1/2 value that we get as the `position` forms our loader ID.

Loading the Data

In onCreateLoader() of our LoaderCallbacks, we need to return a CursorLoader for whichever loaderId was passed in. What varies is the Uri that we want to query and the "projection" of "columns" that we want to get back. So, onCreateLoader() uses a switch statement to decide what Uri and projection to use, then creates a CursorLoader based upon that:

```
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
  String[] projection;
  Uri uri;

  switch (loaderId) {
    case LOADER_NAMES:
      projection=PROJECTION_NAMES;
      uri=ContactsContract.Contacts.CONTENT_URI;
      break;

    case LOADER_NAMES_NUMBERS:
      projection=PROJECTION_NUMBERS;
      uri=ContactsContract.CommonDataKinds.Phone.CONTENT_URI;
      break;

    default:
      projection=PROJECTION_EMAILS;
      uri=ContactsContract.CommonDataKinds.Email.CONTENT_URI;
      break;
  }

  return(new CursorLoader(this, uri, projection, null, null,
                          ContactsContract.Contacts.DISPLAY_NAME));
}
```

The two case values are just constants tied to the positions from the Spinner, defined as static data members:

```
private static final int LOADER_NAMES=0;
private static final int LOADER_NAMES_NUMBERS=1;
```

Similarly, the three projections are defined as static data members:

```
private static final String[] PROJECTION_NAMES=new String[] {
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
};
private static final String[] PROJECTION_NUMBERS=new String[] {
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] PROJECTION_EMAILS=new String[] {
    ContactsContract.Contacts._ID,
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Email.DATA
};
```

For the "names" Spinner entry, we are going to retrieve the ID and display name of the contact, using the standard ContactsContract.Contacts.CONTENT_URI Uri value.

For the "names and phone numbers" Spinner entry, we still want the display name of the contact, but we also want phone numbers. Fortunately, as mentioned earlier, ContactsContract denormalizes its data in response to queries, so we can get the display name of the contact even when we are querying the "table" of phone numbers, via ContactsContract.CommonDataKinds.Phone.CONTENT_URI. The same basic process holds true for the "names and emails" entry, where we query ContactsContract.CommonDataKinds.Email.CONTENT_URI. Note that we will get somewhat redundant information back — if a contact has two phone numbers, we get two rows in our Cursor, both for the same contact, and one per phone number.

We can sort by DISPLAY_NAME for all three cases, courtesy of the aforementioned denormalization of the data.

Showing the Results

We also have to implement onLoadFinished(), to take in the Cursor that is the result of the query against ContactsContract and put the results in the ListView. Once again, the rendering will differ a bit based upon whether we are showing just names or names along with other data (e.g., phone numbers). So, we have another switch statement, where we determine what columns we want, what layout ID to use, and what roster of widgets in that layout map to those columns:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
  String[] columns;
  int layoutId;
  int[] views;

  switch(loader.getId()) {
    case LOADER_NAMES:
      columns=COLUMNS_NAMES;
      layoutId=android.R.layout.simple_list_item_1;
      views=VIEWS_ONE;
      break;

    case LOADER_NAMES_NUMBERS:
      columns=COLUMNS_NUMBERS;
      layoutId=android.R.layout.simple_list_item_2;
```

```
        views=VIEWS_TWO;
        break;

      default:
        columns=COLUMNS_EMAILS;
        layoutId=android.R.layout.simple_list_item_2;
        views=VIEWS_TWO;
        break;
    }

    setListAdapter(new SimpleCursorAdapter(this, layoutId, c,
                                            columns, views, 0));
  }
```

The lists of columns and views are defined as static data members and map positionally (i.e., the first view is for the first column):

```
private static final String[] COLUMNS_NAMES=new String[] {
  ContactsContract.Contacts.DISPLAY_NAME
};
private static final String[] COLUMNS_NUMBERS=new String[] {
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Phone.NUMBER
};
private static final String[] COLUMNS_EMAILS=new String[] {
    ContactsContract.Contacts.DISPLAY_NAME,
    ContactsContract.CommonDataKinds.Email.DATA
};
private static final int[] VIEWS_ONE=new int[] {
    android.R.id.text1
};
private static final int[] VIEWS_TWO=new int[] {
    android.R.id.text1,
    android.R.id.text2
};
```

Then, we create a `SimpleCursorAdapter` wrapped around that information and use that to populate the `ListView`, thereby showing the contacts and the requested information about those contacts.

Makin' Contacts

Let's now take a peek at the reverse direction: adding contacts to the system. This was never particularly easy and now is… well, different.

First, we need to distinguish between sync providers and other apps. Sync providers are the guts underpinning the accounts system in Android, bridging some existing source of contact data to the Android device. Hence, you can have sync providers for Exchange, Facebook, and so forth. These will need to create raw contacts for newly-added contacts to their backing stores that are being sync'd to the device for the first time. Creating sync providers is outside of the scope of this book for now.

It is possible for other applications to create contacts. These, by definition, will be phone-only contacts, lacking any associated account, no different than if the user added the contact directly. The recommended approach to doing this is to collect the data you want, then spawn an activity to let the user add the contact — this avoids your application needing the WRITE_CONTACTS permission and all the privacy/data integrity issues that creates. In this case, we will stick with the new ContactsContract content provider, to simplify our code, at the expense of requiring Android 2.0 or newer.

To that end, take a look at the Contacts/Inserter sample project. It defines a simple activity with a two-field UI, with one field apiece for the person's first name and phone number:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1"
  >
  <TableRow>
    <TextView
      android:text="First name:"
    />
    <EditText android:id="@+id/name"
    />
  </TableRow>
  <TableRow>
    <TextView
      android:text="Phone:"
    />
    <EditText android:id="@+id/phone"
      android:inputType="phone"
    />
  </TableRow>
  <Button android:id="@+id/insert" android:text="Insert!" />
</TableLayout>
```

The trivial UI also sports a button to add the contact:

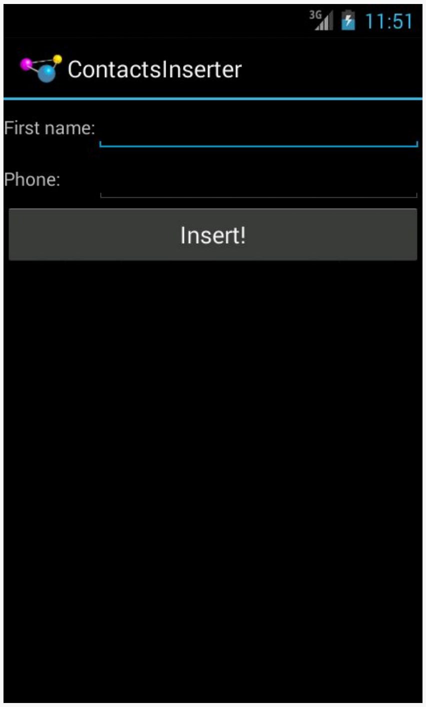

Figure 649: The ContactInserter sample application

When the user clicks the button, the activity gets the data and creates an `Intent` to be used to launch the add-a-contact activity. This uses the `ACTION_INSERT_OR_EDIT` action and a couple of extras from the `ContactsContract.Intents.Insert` class:

```
package com.commonsware.android.inserter;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.Intents.Insert;
import android.view.View;
import android.widget.Button;
import android.widget.EditText;

public class ContactsInserter extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    Button btn=(Button)findViewById(R.id.insert);

    btn.setOnClickListener(onInsert);
  }

  View.OnClickListener onInsert=new View.OnClickListener() {
    public void onClick(View v) {
      EditText fld=(EditText)findViewById(R.id.name);
      String name=fld.getText().toString();

      fld=(EditText)findViewById(R.id.phone);

      String phone=fld.getText().toString();
      Intent i=new Intent(Intent.ACTION_INSERT_OR_EDIT);

      i.setType(Contacts.CONTENT_ITEM_TYPE);
      i.putExtra(Insert.NAME, name);
      i.putExtra(Insert.PHONE, phone);
      startActivity(i);
    }
  };
}
```

We also need to set the MIME type on the `Intent` via `setType()`, to be `CONTENT_ITEM_TYPE`, so Android knows what sort of data we want to actually insert. Then, we call `startActivity()` on the resulting `Intent`. That brings up an add-or-edit activity:

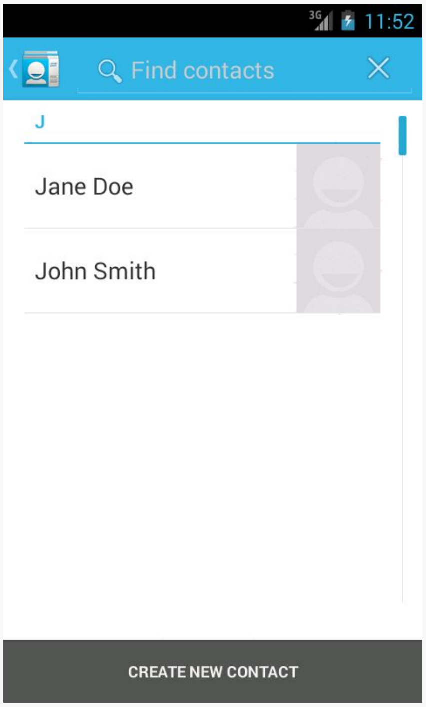

Figure 650: The add-or-edit-a-contact activity

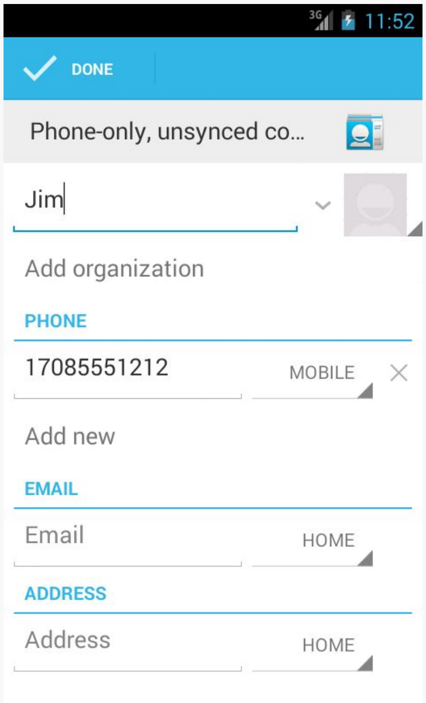
… where if the user chooses "Create new contact", they are taken to the ordinary add-a-contact activity, with our data pre-filled in:



Jim

17085551212 MOBILE

Figure 651: The edit-contact form, showing the data from the ContactInserter activity

Note that the user could choose an existing contact, rather than creating a new contact. If they choose an existing contact, the first name of that contact will be overwritten with the data supplied by the `ContactsInserter` activity, and a new phone number will be added from those `Intent` extras.

Looking at the CallLog

A closely-related `ContentProvider` to `ContactsContract` is `CallLog`. As the name suggests, it contains a log of calls for this device, including things like the date/time of the call, the call duration, and the other party on the call (e.g., a phone number).

If you wish to give the user another look at their calls, independent from the UI available on the device (e.g., Dialer app), you might wish to query the `CallLog`, as we do in the `Contacts/CallLog` sample application

Pondering Permissions

To read the CallLog, you need to hold the READ_CONTACTS permission. This may seem a bit odd, in that there is no READ_CALL_LOG permission, which would appear to be a better match.

The reason for the READ_CONTACTS permission is that the CallLog denormalizes the data, copying into its own table contact data about the other party.

The reason for this is so that the CallLog can remain independent of ContactsContract. For example, suppose that you call somebody who is a friend of yours on Facebook and therefore is in your list of contacts. The CallLog wants to keep track of who this other party is. However, some weeks or months after placing the call, you "un-friend" the person on Facebook, so they are no longer in your list of contacts. If CallLog merely held some ID of the contact in ContactsContract, that ID would be invalid, and we would lose information about the contact. Instead, CallLog will copy into its own table the name of the contact at the time of the call, so that even if the other party is not in your contacts list later, the call log still shows who it was.

Since querying the CallLog provider can return to you contact names, you need to hold READ_CONTACTS when querying it.

Contents of CallLog.Calls

The sample app requests the READ_CONTACTS permission, so it can query the CallLog:

```
<uses-permission android:name="android.permission.READ_CONTACTS" />
```

The app has one Java class, CallLogConsumerActivity, which is the launcher activity.

In onCreate() — among other bits of work that we will explore shortly – we call getLoaderManager().initLoader(), to query the CallLog via a CursorLoader. The activity itself implements the LoaderManager.LoaderCallbacks interface needed by initLoader(), and so the activity has the three required LoaderCallbacks methods:

```
@Override
public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
  return(new CursorLoader(this, CallLog.Calls.CONTENT_URI,
                          PROJECTION, null, null, CallLog.Calls.DATE
                              + " DESC"));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
  adapter.swapCursor(cursor);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
  adapter.swapCursor(null);
}
```

Here, we retrieve the data from the `CallLog.Calls` "table" via its `CONTENT_URI`, asking for the "columns" indicated by the `PROJECTION`:

```
  private static final String[] PROJECTION=new String[] {
      CallLog.Calls._ID, CallLog.Calls.NUMBER, CallLog.Calls.DATE };
```

We sort the data descending by date. It would be nice if the documentation for `CallLog` included some indication that this approach was endorsed and supported. Based on the `CallLog` implementation, it should be stable.

The `Cursor` itself is passed into a `SimpleCursorAdapter` (named `adapter`) via `swapCursor()` calls.

Showing the CallLog

In `onCreate()`, we want to set up that `SimpleCursorAdapter` for mapping the phone number and date of a call to corresponding `TextView` widgets in a row layout:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    adapter=
        new SimpleCursorAdapter(this, R.layout.row, null, new String[] {
            CallLog.Calls.NUMBER, CallLog.Calls.DATE }, new int[] {
            R.id.number, R.id.date }, 0);

    adapter.setViewBinder(this);
    setListAdapter(adapter);
    getLoaderManager().initLoader(0, null, this);
  }
```

Here, we create the `SimpleCursorAdapter` on a `null` `Cursor` at the outset, to indicate that we do not yet have our data, and we will show the `Cursor` delivered to `onLoadFinished()` at that time.

However we will run into a problem with the date. In the `CallLog` provider, the date is stored as "milliseconds since the Unix epoch", the same time system used by `System.currentTimeMillis()`. That is a really long number, one that ordinary people will not recognize. If we blindly just convert that into a string and put it in the `TextView`, users will be unable to understand that column.

To get a chance to convert that value into something more useful, the activity implements the `SimpleCursorAdapter.ViewBinder` interface and calls `setViewBinder(this)` on the `adapter`. A `ViewBinder` will get control every time the `SimpleCursorAdapter` tries binding a value from the `Cursor` to a widget, so we can handle that ourselves where needed.

The `ViewBinder` interface requires a `setViewValue()` method where we do that work:

```
@Override
public boolean setViewValue(View view, Cursor cursor, int columnIndex) {
  if (columnIndex==2) {
    long time=cursor.getLong(columnIndex);
    String formattedTime=DateUtils.formatDateTime(this, time,
                            DateUtils.FORMAT_ABBREV_RELATIVE);

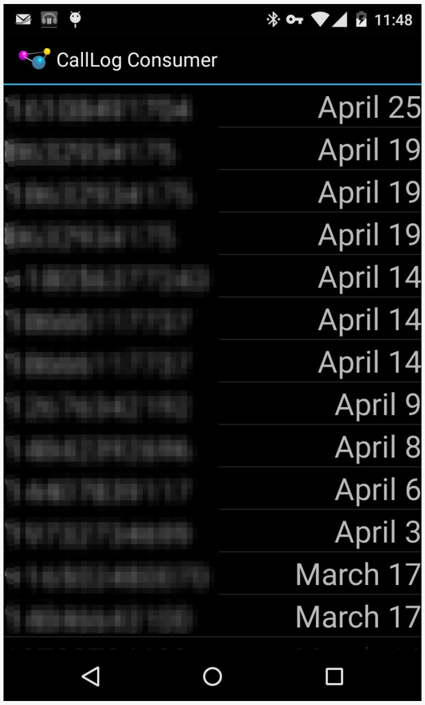
    ((TextView)view).setText(formattedTime);

    return(true);
  }

  return(false);
}
```

If `setViewValue()` returns `false`, that indicates that the `SimpleCursorAdapter` should handle that column normally. Our implementation does that for everything other than column 2, which in our `PROJECTION` is the date. For the date, we get the `long` value of the date and use `DateUtils.formatDateTime()` to convert it into a string representation that will be more human-readable. We put that string into the `TextView` and return `true` to indicate that we have handled this widget binding ourselves.

The results is a list of calls by date and phone number:



CallLog Consumer

Figure 652: CallLog Sample App

The CalendarContract Provider

The Android Open Source Project (AOSP) has had a Calendar application from its earliest days. This application originally was designed to sync with Google Calendar, later extended to other sync sources, such as Microsoft's Exchange. However, this application was not part of the Android SDK, so there was no way to access it from your Android application.

At least, no officially documented and supported way.

Many developers poked through the AOSP source code and found that the Calendar application had a `ContentProvider`. Moreover, this `ContentProvider` was exported (by default). So many developers used undocumented and unsupported means for accessing calendar information. This occasionally broke, as Google modified the Calendar app and changed these pseudo-external interfaces.

Android 4.0 added official SDK support for interacting with the Calendar application via its `ContentProvider`. As part of the SDK, these new interfaces should be fairly stable — if nothing else, they should be supported indefinitely, even if new and improved interfaces are added sometime in the future. So, if you want to tie into the user's calendars, you can. Bear in mind, though, that the new `CalendarContract` `ContentProvider` is not identical to the older undocumented providers, so if you are aiming to support pre-4.0 devices, you have some more work to do.

Of course, similar to the `ContactsContract` `ContentProvider`, the `CalendarContract` `ContentProvider` is severely lacking in documentation, and anything not documented is subject to change.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- content provider theory
- content provider implementations

You Can't Be a Faker

While the Android emulator has the `CalendarContract` `ContentProvider`, it will do you little good. While you can define a Google account on the emulator, the emulator lacks any ability to sync content with that account. Hence, you cannot see any events for your calendars in the Calendar app, and you cannot access any calendar data via `CalendarContract`.

You may be able to use an `outlook.com` account, to sync with an Outlook calendar.

Otherwise, in order to test your use of `CalendarContract`, you will need to have hardware that runs Android 4.0 (or higher), with one or more accounts set up that have calendar data.

Do You Have Room on Your Calendar?

As a `ContentProvider`, `CalendarContract` is not significantly different from any other such provider that Android supplies or that you write yourself, in that there are `Uri` values representing collections of data, upon which you can query, insert, update, and delete as needed.

The Collections

The two main collections of data that you are likely to be interested in are `CalendarContract.Calendars` (the collection of all defined calendars) and `CalendarContract.Events` (the collection of all defined events across all calendars). Each of those has a `CONTENT_URI` static data member that you would use with `ContentResolver` or a `CursorLoader` to perform operations on those collections. An entry in `CalendarContract.Events` points back to its corresponding calendar via a `CALENDAR_ID` column that you can query upon; the remaining columns on `CalendarContract.Events` have names apparently designed to match with the iCalendar specification (e.g., DTSTART and DTEND for the start and end times of the event).

Three other collections may be of interest:

1. CalendarContract.Instances has one entry per occurrence of an event, so recurring events get multiple rows
2. CalendarContract.Attendees has information about each attendee of an event
3. CalendarContract.Reminders has information about each reminder scheduled for an event (e.g., when to remind the user), for those events with associated reminders

Each of those ties back to its associated CalendarContract.Events row via an EVENT_ID column.

Calendar Permissions

There are two permissions for working with CalendarContract: READ_CALENDAR and WRITE_CALENDAR. As you might expect, querying CalendarContract requires the READ_CALENDAR permission; modifying CalendarContract data requires the WRITE_CALENDAR permission.

These permissions have existed since Android's earliest days, even in the SDK, as a side effect of the "meat cleaver" approach the core Android team employed to create the initial SDK. Hence, you can request these permissions in the manifest with any Android build target, without compiler errors. Of course, actually referring to CalendarContract will require a build target (i.e., compileSdkVersion in Android Studio) of API Level 14 or higher.

Querying for Events

For example, let's populate a ListView with the roster of all events the user has across all calendars, using a CursorLoader, showing the name of each event, the event's start date, and the event's end date. You can find this in the Calendar/Query sample project in the book's source code.

Our manifest has the READ_CALENDARS permission, as you would expect:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.cal.query"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk android:minSdkVersion="14"/>

  <uses-permission android:name="android.permission.READ_CALENDAR"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".CalendarQueryActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

We will use a simple `ListActivity` and so therefore do not need an activity layout. Our row layout (`res/layout/row.xml`) has three `TextView` widgets for the three pieces of data that we want to display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/linearLayout1"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <TextView
    android:id="@+id/title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:layout_marginLeft="4dip"
    android:layout_marginRight="4dip"
    android:layout_weight="1"
    android:ellipsize="end"
    android:textSize="20sp"/>

  <LinearLayout
    android:id="@+id/linearLayout2"
    android:layout_width="wrap_content"
    android:layout_height="match_parent"
    android:layout_marginRight="4dip"
    android:orientation="vertical">

    <TextView
      android:id="@+id/dtstart"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="top"
      android:textSize="10sp"/>
    <TextView
      android:id="@+id/dtend"
      android:layout_width="wrap_content"
      android:layout_height="wrap_content"
      android:layout_gravity="bottom"
      android:textSize="10sp"/>
  </LinearLayout>

</LinearLayout>
```

In our activity (CalendarQueryActivity), in onCreate(), we set up a SimpleCursorAdapter on a null Cursor at the outset and define the activity as being the adapter's ViewBinder:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    adapter=
        new SimpleCursorAdapter(this, R.layout.row, null, ROW_COLUMNS,
                                ROW_IDS);
    adapter.setViewBinder(this);
    setListAdapter(adapter);

    getLoaderManager().initLoader(0, null, this);
  }
```

A ViewBinder is a way to tailor how Cursor data is poured into row widgets, without subclassing the SimpleCursorAdapter. Implementing the SimpleCursorAdapter.ViewBinder interface requires us to implement a setViewValue() method, which will be called when the adapter wishes to pour data from one column of a Cursor into one widget. We will examine this method shortly.

The SimpleCursorAdapter will pour data from the ROW_COLUMNS in our Cursor into the ROW_IDS widgets in our row layout:

```
  private static final String[] ROW_COLUMNS=
      new String[] { CalendarContract.Events.TITLE,
          CalendarContract.Events.DTSTART,
          CalendarContract.Events.DTEND };
  private static final int[] ROW_IDS=
      new int[] { R.id.title, R.id.dtstart, R.id.dtend };
```

Our onCreate() also initializes the Loader framework, triggering a call to onCreateLoader(), where we create and return a CursorLoader:

```
  public Loader<Cursor> onCreateLoader(int loaderId, Bundle args) {
    return(new CursorLoader(this, CalendarContract.Events.CONTENT_URI,
                            PROJECTION, null, null,
                            CalendarContract.Events.DTSTART));
  }
```

We query on CalendarContract.Events.CONTENT_URI, asking for a certain set of columns indicated by our PROJECTION static data member:

```
private static final String[] PROJECTION=
    new String[] { CalendarContract.Events._ID,
        CalendarContract.Events.TITLE,
        CalendarContract.Events.DTSTART,
        CalendarContract.Events.DTEND };
```

The ROW_COLUMNS we map are a subset of the PROJECTION, skipping the _ID column that SimpleCursorAdapter needs but will not be displayed. Our query is also set up to sort by the start date (CalendarContract.Events.DTSTART).

When the query is complete, we pop it into the adapter in onLoadFinished() and remove it in onLoaderReset():

```
public void onLoadFinished(Loader<Cursor> loader, Cursor cursor) {
  adapter.swapCursor(cursor);
}

public void onLoaderReset(Loader<Cursor> loader) {
  adapter.swapCursor(null);
}
```

Our setViewValue() implementation then converts the DTSTART and DTEND values into formatted strings by way of DateUtils and the formatDateTime() method:

```
@Override
public boolean setViewValue(View view, Cursor cursor, int columnIndex) {
  long time=0;
  String formattedTime=null;

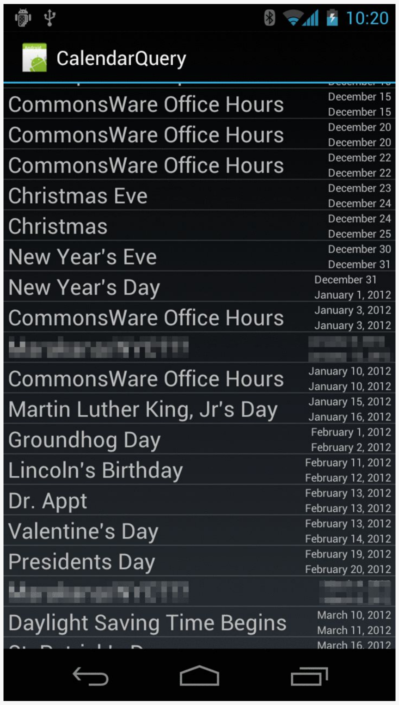
  switch (columnIndex) {
    case 2:
    case 3:
      time=cursor.getLong(columnIndex);
      formattedTime=
          DateUtils.formatDateTime(this, time,
                                   DateUtils.FORMAT_ABBREV_RELATIVE);
      ((TextView)view).setText(formattedTime);
      break;

    default:
      return(false);
  }

  return(true);
}
}
```

The `setViewValue()` method should return `true` for any columns it handles and `false` for columns it does not — skipped columns are handled by `SimpleCursorAdapter` itself.

If you run this on a device with available calendar data, you will get a list of those events:



10:20

Figure 653: The Calendar Query sample application, with some events redacted

Penciling In an Event

What is rarely documented in the Android SDK is what activities might exist that support the MIME types of a given `ContentProvider`. In part, that is because device manufacturers have the right to remove or replace many of the built-in applications.

The Calendar application is considered by Google to be a "core" application. Quoting the Android 2.3 version of the Compatibility Definition Document (CDD):

> The Android upstream project defines a number of core applications, such as a phone dialer, calendar, contacts book, music player, and so on. Device implementers MAY replace these applications with alternative versions.

> However, any such alternative versions MUST honor the same Intent patterns provided by the upstream project. For example, if a device contains an alternative music player, it must still honor the Intent pattern issued by third-party applications to pick a song.

Hence, in theory, so long as the CDD does not change and device manufacturers correctly honor it, those Intent patterns described by the Calendar application's manifest should be available across Android 4.0 devices. The Calendar application appears to support `ACTION_INSERT` and `ACTION_EDIT` for both the collection MIME type (`vnd.android.cursor.dir/event`) and the instance MIME type (`vnd.android.cursor.item/event`). Notably, there is no support for `ACTION_PICK` to pick a calendar or event, the way you can use `ACTION_PICK` to pick a contact.

The MediaStore Provider

Playing back media is a popular pastime on Android devices, one in which your app may want to participate. The easiest way for you to find out what media is available for you to display, edit, or otherwise work with is via the `MediaStore` content provider. `MediaStore` is part of the Android framework and allows you to query for images, audio files, and video files that are indexed on the device.

This chapter will review the general workings of `MediaStore`, plus work through an example of getting video files — and their thumbnails — from `MediaStore`.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- content provider theory
- content provider implementations

It is also a pretty good idea to have read the chapters on media recording and playback that might be of relevance, depending on what you intend to do with the `MediaStore`:

- Audio Playback
- Audio Recording
- Video Playback
- Using the Camera via 3rd-Party Apps
- Working Directly with the Camera

You might also wish to consider skimming through the chapter on files again, as it will be cross-referenced in several places in this chapter.

What Is the MediaStore?

The documentation for `MediaStore` describes it this way:

> The Media provider contains meta data for all available media on both internal and external storage devices.

This definition… leaves a bit to be desired.

From our standpoint as Android developers, the `MediaStore` is a `ContentProvider`, supplied by Android. We can use it much like we use other system-supplied providers, like `ContactsContract` and `CalendarContract`. In this case, the primary role of `MediaStore` is for us to find media, just as the primary role of `ContactsContract` is for us to find contacts.

The "meta data" reference in the documentation refers to the fact that `MediaStore` itself does not store the media, even though that's what the name `MediaStore` would suggest. `MediaMetadataStore` would be a more accurate description. We can learn *about* available media — names, durations, etc. — and we can get a `Uri` from `MediaStore` pointing to the media, but the media itself lives as a file somewhere else.

Indexed Media

`MediaStore` has media as a primary focus. Here, "media" refers to:

- Images (typically photos)
- Audio (music, podcasts, etc.)
- Video (whether recorded by the device, downloaded from somewhere, etc.)

`MediaStore` has intrinsic knowledge of these, particularly for the file formats and codecs that Android supports. As a result, the index maintained by `MediaStore` will contain some metadata in common for all file types, such as:

- title
- MIME type
- dates (when the file was added, when the file was modified)

…and other metadata that will be unique to one or two of the major types, such as:

- duration for audio and video (but not images)

- height and width for images and video (but not audio)
- geotagging for images and video (but not audio)

Indexed Non-Media

As was mentioned in passing in the chapter on files, Android uses MTP for Android 4.0+ as the USB protocol for sharing files with a desktop or notebook computer.

To power this, Android does not go straight to the filesystem, but rather works with `MediaStore`. `MediaStore` maintains an index of *all* files, not just "media". Whatever shows up in `MediaStore` is what shows up to the user in their Windows drive letter, OS X mounted volume, etc.

You too can query `MediaStore` for non-media files. Android will try to maintain a MIME type — probably based on file extensions — and so you can find all indexed PDF files, for example, by querying `MediaStore`.

MediaStore and "Other" External Storage

In the chapter on files, we covered the difference between internal storage and external storage. Primarily, `MediaStore` maintains an index of external storage.

However, many Android devices today have multiple locations that could be considered "external storage". While the vast majority of Android devices have "external storage" as a portion of on-board flash memory, Android device manufacturers are welcome to add other options, such as:

- card slots (typically microSD)
- USB host ports (capable of mounting thumb drives and the like)

From the standpoint of the Android SDK, such secondary storage locations are off-limits, in that there is nothing in the Android SDK to tell us if there are any such locations, where they are located (in terms of `File` objects to their roots), whether they can be read from, or whether they can be written to. You will find various blog posts and Stack Overflow answers where developers have attempted to catalog all of the possibilities, using a mix of low-level Linux information and manufacturer-based heuristics, but these techniques will be generally unreliable across thousands of device models.

However, many manufacturers who have added such secondary storage options will arrange to have that storage be indexed and be part of MediaStore. So, if the user slides in a microSD card containing audio files, on many devices, when you query MediaStore for available audio files, you will find those on the microSD card in addition to those on "traditional" external storage. From the user's standpoint, in terms of consuming media, this is sufficient.

How Does My Content Get Indexed?

As was noted back in the chapter on files, if you write files to external storage, you will want to use MediaScannerConnection to ensure that those files get indexed. In that chapter, the focus was on ensuring that your files would be visible to attached desktops/notebooks via MTP. However, what *really* happens is that MediaScannerConnection updates MediaStore, which in turn drives the MTP-served content.

Even if you fail to index content manually, at some point, Android is likely to pick up the files. For example, Android will scan external storage after a reboot. However, using MediaScannerConnection to "tap Android on the shoulder" and have it index your file means that it will show up in MediaStore more quickly. This is very important for multimedia assets — if you downloaded some media, you want that to be indexed as soon as possible, so the user can turn around and consume that media, whether through your app or another one on the user's device.

How Do I Retrieve Video from the MediaStore?

Video players will need to find out what videos are available on the device, eligible for playback. They may wish to retrieve other details, such as the video title, duration, and so forth. And, of course, they will need something that they can use to actually play back the video itself.

In this section, we will work through the Media/VideoList sample project. This project has a VideosFragment that will show the roster of available videos; tapping on a video in the list will launch the user's video player to watch that video.

Requesting Permission

Starting on API Level 19 devices, you need to hold the READ_EXTERNAL_STORAGE or WRITE_EXTERNAL_STORAGE permissions to be able to work with the MediaStore.

Hence, the VideoList sample app has the READ_EXTERNAL_STORAGE permission in its manifest, as it has no need to write to external storage:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.video.list"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="false"
    android:xlargeScreens="true"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="17"/>

  <uses-permission android:name="android.permission.READ_EXTERNAL_STORAGE" />

  <application
    android:allowBackup="false"
    android:hardwareAccelerated="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

Querying for Video

VideosFragment uses the Loader framework, since MediaStore is a ContentProvider and Loader is a convenient way to asynchronously load content from a ContentProvider. VideosFragment implements the LoaderManager.LoaderCallbacks interface and, in onActivityCreated(), calls getLoaderManager().initLoader() to initialize its Loader.

That triggers a call to onCreateLoader(), where VideosFragment creates a CursorLoader to query the MediaStore for videos:

```
  @Override
  public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(
                              getActivity(),
                              MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                              null, null, null,
                              MediaStore.Video.Media.TITLE));
  }
```

The `Uri` for video content from `MediaStore` is `MediaStore.Video.Media.EXTERNAL_CONTENT_URI`. Passing in `null` for the list of columns to return will return all available columns — not the most efficient approach, but it is convenient. The sort order of `MediaStore.Video.Media.TITLE` has the results sorted by the `TITLE` column, so the videos are returned alphabetically.

Back up in `onActivityCreated()`, we initialized a `SimpleCursorAdapter` to handle our results, passing in the `TITLE` and `_ID` columns into our custom row layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal"
  android:padding="8dp">

  <ImageView
    android:id="@+id/thumbnail"
    android:layout_width="64dp"
    android:layout_height="64dp"
    android:contentDescription="@string/thumbnail"/>

  <TextView
    android:id="@android:id/text1"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginLeft="8dp"
    android:layout_gravity="center_vertical"
    android:textSize="24sp"/>

</LinearLayout>
```

`onActivityCreated()` also attaches a custom `ViewBinder`, `ThumbnailBinder`, that we will cover in the next section, before eventually attaching the initially-empty `SimpleCursorAdapter` to the `ListView` of our `ListFragment`:

```
  @Override
  public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    String[] from=
        { MediaStore.Video.Media.TITLE, MediaStore.Video.Media._ID };
    int[] to= { android.R.id.text1, R.id.thumbnail };
    SimpleCursorAdapter adapter=
        new SimpleCursorAdapter(getActivity(), R.layout.row, null,
                                  from, to, 0);

    adapter.setViewBinder(this);
    setListAdapter(adapter);

    getLoaderManager().initLoader(0, null, this);
  }
```

The rest of our `LoaderManager.LoaderCallbacks` methods are fairly conventional, using `swapCursor()` to load in the results of the query (or `null` if the loader is reset):

```
  @Override
  public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((CursorAdapter)getListAdapter()).swapCursor(c);
  }

  @Override
  public void onLoaderReset(Loader<Cursor> loader) {
    ((CursorAdapter)getListAdapter()).swapCursor(null);
  }
```

Showing the Thumbnails

If you have used a video player on Android, most have an activity (or fragment) akin to the one we are implementing in this section. And, most of those will show thumbnail images of the videos in question.

However, retrieving and showing those thumbnails is a bit complicated, because Android may need to *generate* the thumbnail, if there is not already a thumbnail for the video, or if its cache of thumbnails was cleared. Generating a thumbnail takes time, time that we do not want to spend on the main application thread.

So we need to load this image asynchronously. Picasso reportedly supports this, but at the time of this writing, it remains undocumented and hence may not be reliable.

Instead, this sample app will use another popular image loading library: the Universal Image Loader (UIL).

Preparing the ImageLoader

UIL works off of an `ImageLoader` to handle the asynchronous loading of images for some scope, such as for a fragment. Hence, our fragment holds an `ImageLoader` instance, which we configure in `onAttach()`, as we need an `Activity` to set up the loader:

```
@Override
public void onAttach(Activity host) {
  super.onAttach(host);

  ImageLoaderConfiguration ilConfig=
      new ImageLoaderConfiguration.Builder(getActivity()).build();

  imageLoader=ImageLoader.getInstance();
  imageLoader.init(ilConfig);
}
```

UIL supports many configuration options for the ImageLoader, all of which we are ignoring here, settling for the defaults.

Attaching the ViewBinder

Next, the thumbnail will need to be displayed using some sort of ImageView. Since SimpleCursorAdapter cannot populate an ImageView directly, we need some other way to fill in the ImageView. To handle this, we create an implementation of a ViewBinder, named ThumbnailBinder — that is what we attached to our SimpleCursorAdapter via setViewBinder() back in onActivityCreated().

A ViewBinder is a way to tailor how Cursor data is poured into row widgets, without subclassing the SimpleCursorAdapter. Implementing the SimpleCursorAdapter.ViewBinder interface requires us to implement a setViewValue() method, which will be called when the adapter wishes to pour data from one column of a Cursor into one widget:

```
@Override
public boolean setViewValue(View v, Cursor c, int column) {
  if (column == c.getColumnIndex(MediaStore.Video.Media._ID)) {
    Uri video=
        ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            c.getInt(column));
    DisplayImageOptions opts=new DisplayImageOptions.Builder()
        .showImageOnLoading(R.drawable.ic_media_video_poster)
        .build();

    imageLoader.displayImage(video.toString(), (ImageView)v, opts);

    return(true);
  }

  return(false);
}
```

If our ViewBinder is being asked to bind the video ID column (MediaStore.Video.Media._ID), we first construct the Uri to the video using ContentUris.withAppendedId(). Then, we create a UIL-supplied

DisplayImageOptions object, where we can provide details for how to handle the image load. In this case, we supply a drawable resource to use as a placeholder image while the thumbnail is being loaded. Finally, we tell the imageLoader we set up in onAttach() to display the image. UIL recognizes the Uri structure for a video from MediaStore and uses utility methods like getThumbnail() on MediaStore.Video.Thumbnails to actually retrieve the thumbnail.

The net result is that when we populate our ListView with our ViewBinder-enhanced SimpleCursorAdapter, the ListView rows will initially have the placeholder image, replaced by the actual video thumbnails as they get loaded.

Playing the Selection

VideosFragment extends a version of ContractListFragment, as was used in the EU4You samples earlier in this book. The activity that hosts this fragment is obligated to implement the VideosFragment.Contract interface, which in turn requires an onVideoSelected() method.

In onListItemClick() of VideosFragment, the fragment calls onVideoSelected() on the Contract, supplying:

- the String representation of the Uri that points to the video itself, pulled from the MediaStore.Video.Media.DATA column of the Cursor we loaded from the MediaStore
- the MIME type of that video, pulled from the MediaStore.Video.Media.MIME_TYPE column of that same Cursor

```
  public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    String[] from=
        { MediaStore.Video.Media.TITLE, MediaStore.Video.Media._ID };
    int[] to= { android.R.id.text1, R.id.thumbnail };
    SimpleCursorAdapter adapter=
        new SimpleCursorAdapter(getActivity(), R.layout.row, null,
                                from, to, 0);

    adapter.setViewBinder(this);
```

The main activity — surprisingly named MainActivity — loads up a VideosFragment as a static fragment via the res/layout/main.xml resource:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/videos"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:name="com.commonsware.android.video.list.VideosFragment"
/>
```

`MainActivity` implements `VideosFragment.Contract` and therefore has an `onVideoSelected()` method. It simply constructs an `Intent` to view the video and starts an activity with it:

```
package com.commonsware.android.video.list;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import java.io.File;

public class MainActivity extends Activity implements
    VideosFragment.Contract {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  @Override
  public void onVideoSelected(String uri, String mimeType) {
    Uri video=Uri.fromFile(new File(uri));
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(video, mimeType);
    startActivity(i);
  }
}
```

The Results

Running this on a device with videos available should show the list of those videos, complete with title and thumbnail:

Figure 654: The Video List Demo App

Tapping on any entry in the list should bring up a video player on your device, assuming that one or more such players (that are capable of supporting `content://` `Uri` values) are installed.

Consuming Documents

Android has long offered the ability for an app to pick some file or stream from another app and consume it. However, the original options were designed around an app loading content from another app. Even though our *code* would be requesting content based on abstractions like MIME types, the *implementation* and user experience would be based on the traditional "pick an app to fulfill this request" chooser.

Google, given its clear interest in cross-cutting storage engines like Google Drive, wanted something better. In Android 4.4, they added the Storage Access Framework (SAF) to provide a better user experience, with only modest changes to client code.

In this chapter, we will examine what it takes to consume documents published via the SAF.

Prerequisites

This chapter assumes that you have read the chapter on `ContentProvider` patterns or have equivalent experience with consuming streams published by a `ContentProvider`.

The Storage Access… What?

Let's think about photos for a minute.

A person might have photos managed as:

- on-device photos, mediated by an app like a gallery

- photos stored online in a photo-specific service, like Instagram
- photos stored online in a generic file-storage service, like Google Drive or Dropbox

Now, let's suppose that person is in an app that allows the user to pick a photo, such as to attach to an email.

The classic Android solution would be for the user to have to first choose the app to use to find the photo (e.g., Gallery, Instagram, Google Drive, Dropbox), then find the photo using that app. Then, if all goes well, the original app would receive a `Uri` to that photo and be able to make use of it.

However, this flow has three main problems:

1. From the user's standpoint, they need to know where they have the photo before they can go looking for it. Given the prominence of generic file-storage services, the user might not remember where the photo is stored, but might remember enough details about the photo (e.g., timeframe when taken, tags that might have been attached to the photo) to find it… but the user has to sequentially search each possible photo-storing app until the right one is found.
2. From the client app developer's standpoint, too many apps screw up handling the classic `ACTION_PICK` and `ACTION_GET_CONTENT` activities, failing to return a result in all cases. Users then are as likely to blame the client app for the mistake as they are to blame the photo-storing app, or Android itself.
3. None of this was designed with online file-sharing services in mind. What happens if an app knows about a possible file, but the file is not available on the device right now, because it has not been downloaded from the online service?

The Storage Access Framework is designed to address these issues. It provides its own "picker" UI to allow users to find a file of interest that matches the MIME type that the client app wants. File providers simply publish details about their available files — including those that may not be on the device but could be retrieved if needed. The picker UI allows for easy browsing and searching across all possible file providers, to streamline the process for the user. And, since Android is the one providing the picker, the picker should more reliably give a result to the client app based upon the user's selection (if any).

The Storage Access Framework Participants

Providers are specialized ContentProvider implementations, usually extending DocumentsProvider, that can tell Android about the documents that are published by an app. This includes providing any sort of organizational structure (directory tree, tag cloud, etc.)

The **clients** are apps that wish to consume (or create) documents managed by providers. Clients will indicate what sort of document they want, in the form of a MIME type, where applicable.

The **picker** is the system UI that allows the user to pick a document (or documents) from among the documents published by all providers that meet the criteria established by a client requesting access to the document(s).

Picking How to Pick (a Peck of Pickled Pepper Photos)

ACTION_PICK would seem to be the Intent action to use to pick something. It works, but it is designed for the case where you know the specific collection of "somethings" you want to pick from. Use this, for example, to pick a contact specifically out of ContactsContract.

In cases where you know the MIME type you want, but you do not particularly know or care about the exact source of the file, use ACTION_GET_CONTENT on API Level 18 and below for everything.

For MIME types that clearly represent a document, file, or other sort of stream, use ACTION_OPEN_DOCUMENT (and the SAF) on API Level 19+. The SAF picker will incorporate both full-fledged SAF-compliant providers' documents along with apps that only support ACTION_GET_CONTENT. However, since ACTION_OPEN_DOCUMENT is only available on API Level 19+ devices, if you are supporting older devices, you will need to check Build.VERSION.SDK_INT and choose an Intent action accordingly.

For MIME types that represent entries in a database (e.g., a calendar entry), use ACTION_GET_CONTENT, even on API Level 19+. Google also recommends using ACTION_GET_CONTENT on API Level 19+ "if you want your app to simply read/import data", though it is unclear why they make this recommendation or why the user experience should differ based upon how the bytes would be used.

Opening a Document

Technically, we do not "open" a document using ACTION_OPEN_DOCUMENT. Instead, we are requesting a Uri pointing to some document that the user chooses.

To do that, create an Intent with:

- ACTION_OPEN_DOCUMENT as the action
- CATEGORY_OPENABLE as the category
- your desired MIME type

Then, use that Intent with startActivityForResult().

For example, the Documents/Consumer sample application contains a ConsumerFragment that adds an "Open" item to the action bar overflow. Clicking on "Open" triggers a call to the open() method on the fragment. And, for API Level 19+ devices, that will in turn request to "open" a document:

```
  @TargetApi(Build.VERSION_CODES.KITKAT)
  private void open() {
    Intent i=new Intent().setType("image/*");

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
      startActivityForResult(i.setAction(Intent.ACTION_OPEN_DOCUMENT)
                              .addCategory(Intent.CATEGORY_OPENABLE),
                             REQUEST_OPEN);
    }
    else {
      startActivityForResult(i.setAction(Intent.ACTION_GET_CONTENT),
                             REQUEST_GET);
    }
  }
}
```

This open() method also gracefully degrades for older devices, falling back to ACTION_GET_CONTENT. In both cases, we are trying to allow the user to pick some image (MIME type of image/*). The two startActivityForResult() calls use different request IDs (REQUEST_OPEN versus REQUEST_GET), so that we can distinguish the sort of result that we get in onActivityResult():

```
  @Override
  public void onActivityResult(int requestCode, int resultCode,
                               Intent resultData) {
    if (resultCode == Activity.RESULT_OK) {
      Uri uri=null;

      if (resultData != null) {
        uri=resultData.getData();
        logToTranscript(uri.toString());

        if (requestCode == REQUEST_OPEN) {
          Cursor c=
              getActivity().getContentResolver().query(uri, null, null,
                                                       null, null);

          if (c != null && c.moveToFirst()) {
            int displayNameColumn=
                c.getColumnIndex(OpenableColumns.DISPLAY_NAME);

            if (displayNameColumn >= 0) {
              logToTranscript("Display name: "
                  + c.getString(displayNameColumn));
            }

            int sizeColumn=c.getColumnIndex(OpenableColumns.SIZE);

            if (sizeColumn < 0 || c.isNull(sizeColumn)) {
              logToTranscript("Size not available");
            }
            else {
              logToTranscript(String.format("Size: %d",
                                            c.getInt(sizeColumn)));
            }
          }
          else {
            logToTranscript("...no metadata available?");
          }
        }
      }
    }
  }
```

Both ACTION_GET_CONTENT and ACTION_OPEN_DOCUMENT should supply a Uri in the result Intent that points to the document the user chose, if the user actually chose one and we got RESULT_OK as the result code. This sample logs that Uri value to a "transcript" (TextView inside of a ScrollView) to show what we get back.

If the result is from an ACTION_OPEN_DOCUMENT request (REQUEST_OPEN request code), we can try to get some metadata about the document. The provider should support a query on the returned Uri that will give us the display name (OpenableColumns.DISPLAY_NAME) and possibly the size of the file (OpenableColumns.SIZE). So, we use a ContentResolver to run this query, and if we get results back, we try to read out these two values and record them to the transcript as well. Note, though, that:

- There is no guarantee that either column will be in the result set, or that the result set will have any rows
- The size might not be known, particularly if the file is not presently resident on the device (e.g., it is being downloaded now, given that the user chose the

file), and so we need to call `isNull()` on the `Cursor` to see if we actually have a `SIZE` value before trying to get it as an integer

The user is presented with the system's picker, to choose an image, complete with a navigation drawer to get to various spots within the picker:

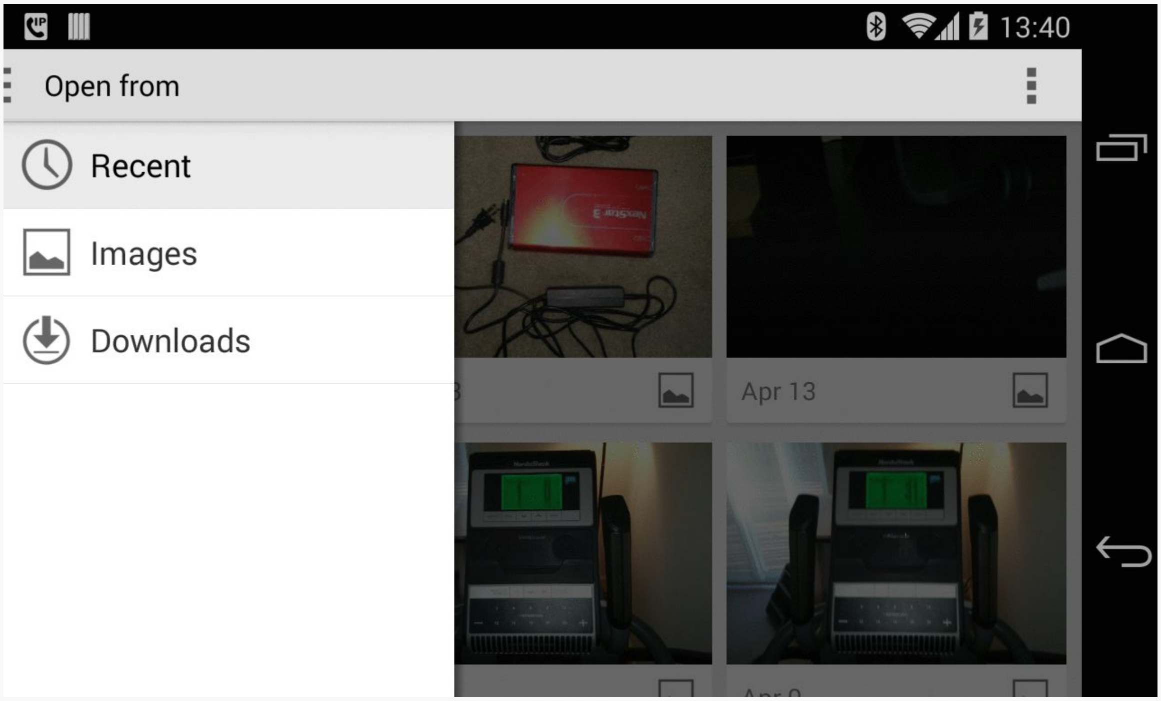

Figure 655: Storage Access Framework Picker, Showing Images

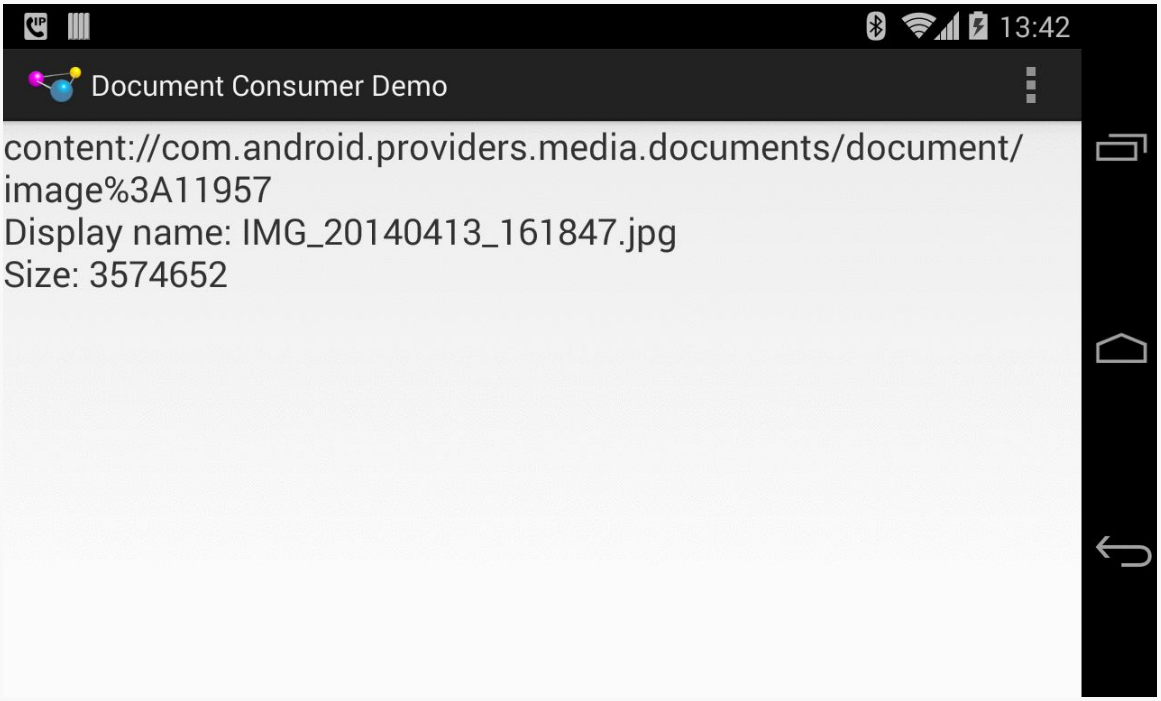
When the user taps on an image, the results wind up in our transcript UI:



content://com.android.providers.media.documents/document/image%3A11957
Display name: IMG_20140413_161847.jpg
Size: 3574652

Figure 656: Uri, Display Name, and Size of Chosen File

Note that the default behavior of `ACTION_OPEN_DOCUMENT` is to let the user choose a single file. If your `Intent` includes `EXTRA_ALLOW_MULTIPLE`, set to `true`, then the user can choose multiple documents. Rather than getting their `Uri` values via `getData()` on the result `Intent`, you will need to call `getClipData()` on the `Intent` and iterate over the "clipboard entries".

The `Uri` itself can then be used to get an `InputStream` or `OutputStream` for the contents, using `openInputStream()` and `openOutputStream()` on `ContentResolver`, respectively. Note, though, that you cannot pass the `Uri` to other applications, as they may not have rights to work with that document the way that you do.

The Rest of the CRUD

`ACTION_OPEN_DOCUMENT` will give you a `Uri` for a document that you can open for reading — the "R" in "CRUD".

However, the other CRUD operations are also entirely possible.

Create

ACTION_CREATE_DOCUMENT will give you a Uri for a document that you can open for writing, as it is your document.

To do this, construct an Intent with:

- an action of ACTION_CREATE_DOCUMENT
- a category of CATEGORY_OPENABLE
- the MIME type of the content you wish to write
- an extra, named EXTRA_TITLE, containing your desired filename

Then, invoke startActivityForResult() on that Intent, and use the Uri supplied in the result Intent delivered to onActivityResult().

Update

The Uri returned from an ACTION_OPEN_DOCUMENT request may be writable. If it is, you can use openOutputStream() on a ContentResolver to write to that document. You can determine if a document is writable by examining the COLUMN_FLAGS value returned from a query() on the Uri — if it includes FLAG_SUPPORTS_WRITE, you can write to the document.

Delete

Similarly, if the COLUMN_FLAGS value includes FLAG_SUPPORTS_DELETE, you can delete the document by calling the static deleteDocument() method on the DocumentsContract class, supplying a ContentResolver plus the Uri of the document to be deleted.

Pondering Persistent Permissions

By default, you will have the rights to read (and optionally write) to the document represented by the Uri until the device is rebooted. That may be sufficient for your needs.

If, however, you need the rights to survive a reboot, you can call takePersistableUriPermission() on a ContentResolver, indicating the Uri of the document and the permissions (FLAG_GRANT_READ_URI_PERMISSION and/or

FLAG_GRANT_WRITE_URI_PERMISSION) that you want persisted. Those rights will then survive a reboot. However:

- They will not survive the document being deleted, so just because you have a saved Uri, do not assume that the Uri will still be valid
- You can revoke those rights by calling releasePersistableUriPermission() later on

In addition, you can call getPersistedUriPermissions() to find out what persisted permissions your app has. This returns a List of UriPermission objects, where each one of those represents a Uri, what persisted permissions (read or write) you have, and when the permissions were persisted.

Providing Documents

The Storage Access Framework gives developers access to `ACTION_OPEN_DOCUMENT` and related `Intent` actions to perform operations on a document provider.

However, what if you want to *be* a document provider?

To do that, you will need to create a subclass of `DocumentsProvider`, override some abstract methods, and perhaps put up with some really obtuse error messages.

This chapter will help you in setting up your `DocumentsProvider`. With luck, you will escape without encountering errors.

Prerequisites

This chapter assumes that you have read the preceding chapter on consuming documents, along with its prerequisites.

Have Your Content, and Provide it Too

Most apps will not need to implement a document provider. They might not even consume documents, let alone provide them to other apps.

However, if your app has document-style content, and that content is of a MIME type that could reasonably be manipulated by other apps, you should consider implementing a document provider to allow the user to manipulate that content using those other apps.

Historically, developers had two main approaches for content:

1. Store it on internal storage
2. Store it on external storage

The internal storage route would be for content that would not normally be user-accessible, while external storage would be for user-accessible content.

In either of those cases, you will want to consider creating a document provider. In the case of internal storage, the user has no way to get to that content except through your app, and so if your app does not offer some capabilities that other apps do for that content, you limit your user by not having a document provider. In the case of external storage, while users in theory could use a file manager or something to try to get other apps to recognize the content, it will be easier for users if you provide a document provider to proactively publish this content to consuming apps.

However, bear in mind that your app does not have to store its content in either of these places. It could store the content in *somebody else's* document provider, using the mechanisms discussed in the preceding chapter on consuming documents. In this case, you would not need to publish a document provider yourself, as the content is available through the same provider that your code is using.

It may also be the case that while your app is the one directly storing the content on internal or external storage, that content would not reasonably be used by other apps. Perhaps it is in some non-standard format that other apps are unlikely to support. Perhaps the files are not to be used by other apps for security reasons. In these cases, skipping the document provider is reasonable, though not exactly ideal from the user's standpoint. In particular, it restricts them from using those files with apps that can work with any file, such as attaching them to email messages.

So, for example:

- If you are implementing a camera app, and you are not storing the photos in the standard `DIRECTORY_DCIM` location for photos, but you are storing the photos yourself in files consider implementing a document provider so users can get at the photos you are taking. But, if you are implementing a camera app, you might elect to allow the user to indicate some place in somebody else's document provider where you could save the photo on their behalf.
- If you are implementing some sort of network-synced file service (e.g., DropBox, Bittorrent Sync), or some sort of on-device version control system, consider implementing a document provider so users can manipulate the documents that you are managing on their behalf.

Key Provider Concepts

Creating a document provider is significantly more complex than is creating a document consumer. To help make sense of what is required, here are some key terms that you will need to understand.

Roots

A document provider can publish one or more "roots". Basically, a "root" points to a tree of documents. Many providers will have just one root, but it is entirely possible for your provider to have more than one.

Documents

Documents, in turn, represent what in filesystem terms would be considered files and directories. A document can either have children (e.g., a directory) or it can have content (e.g., a file), but not both.

A root *also* is a document — here, "root" refers to the root of a tree of documents.

Root and Document IDs

Each root has an ID unique to your app to identify that root as being distinct from any other root. This is a string.

Each document — files and directories alike — will have a string document ID to uniquely identify that document within its root. If you have some natural identifier (e.g., a primary key in some table), feel free to use it. Otherwise, you might consider your document ID to be some path to get to the document.

And, since a root is also a document, a root will have both a root ID and a document ID.

These document IDs need to be durable. Clients, or the Storage Access Framework itself, may wind up caching these IDs. Hence, pick something that not only uniquely identifies this document, but will *continue* to uniquely identify the document even after the document has been modified.

Pieces of a Provider

The Documents/Provider sample application implements a document provider, one that serves documents baked into the app itself in assets/. Of course, this is a rather artificial scenario — usually, a document provider will be working with a read/write data store, like internal storage.

The Activity

A document provider app probably needs a real UI. Perhaps that UI is for broader functionality that the app provides on top of serving documents. Perhaps that UI is merely to configure the document store, such as providing account credentials for the online storage service that the document provider exposes on Android.

If nothing else, you will need a do-nothing activity for the user to run, to ensure that your app is moved out of the stopped state.

In the sample app, this is handled by MainActivity, which uses Theme.NoDisplay to eschew a UI and just shows a Toast to indicate that the provider is now activated:

```
package com.commonsware.android.documents.provider;

import android.app.Activity;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class MainActivity extends Activity {
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
    finish();
  }
}
```

The API Level Resources

The document provider itself comes courtesy of a subclass of DocumentsProvider. However, the DocumentsProvider class only exists on API Level 19 and higher — our subclass is useless on older devices. To ensure that our provider is only used on API Level 19 and higher, we should only enable it on API Level 19+ devices.

To that end, in `res/values/bools.xml`, we have a boolean resource named `min19`, set to `false`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="min19">false</bool>
</resources>
```

In `res/values-v19/bools.xml`, we redefine that boolean resource to be `true`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <bool name="min19">true</bool>
</resources>
```

Hence, when we refer to the `min19` boolean resource, we will get `true` or `false` depending upon whether we are on API Level 19 or not.

The Manifest

Since `DocumentsProvider` is a subclass of `ContentProvider`, we will need a `<provider>` element in the manifest pointing to our subclass of `DocumentsProvider`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.documents.provider"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="19"
    android:targetSdkVersion="19"/>

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name="MainActivity"
      android:label="@string/app_name"
            android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
```

```
        <provider
            android:name=".DemoDocumentsProvider"
            android:authorities="com.commonsware.android.documents.provider"
            android:grantUriPermissions="true"
            android:exported="true"
            android:permission="android.permission.MANAGE_DOCUMENTS"
            android:enabled="@bool/min19">
            <intent-filter>
                <action android:name="android.content.action.DOCUMENTS_PROVIDER" />
            </intent-filter>
        </provider>
    </application>

</manifest>
```

That element:

- Uses our `@bool/min19` resource from above to indicate that this component should only be enabled on API Level 19 and higher
- Is exported, but requires that applications looking to talk to our provider hold the `MANAGE_DOCUMENTS` permission, which can only be held by the firmware (or apps signed with the firmware's signing key)
- Sets the `android:grantUriPermissions` attribute to `true`, as that will be used by `DocumentsProvider` to allow third-party apps limited, conditional access to our documents
- Has your standard `android:name` and `android:authorities` attributes, as with any other `<provider>`

In addition, the `<provider>` has a nested `<intent-filter>` element. This may seem odd, as this used to be impossible, and it is not intuitively obvious what it would mean for a `ContentProvider` to have an `IntentFilter`. It also is [not documented as being allowed on `<provider>`], so we have no official explanation of what this means. Most likely, the magic `android.content.action.DOCUMENTS_PROVIDER` filter is being used simply as a marker, to indicate to Android that this particular `<provider>` is part of the Storage Access Framework and implements a `DocumentsProvider`.

The DocumentsProvider

The real business logic of publishing documents comes from your subclass of `DocumentsProvider`. As this class is new to API Level 19, your build target (e.g., `compileSdkVersion` in `build.gradle`) needs to be 19 or higher.

A minimal `DocumentsProvider` implementation will typically need five methods, outlined below.

onCreate()

As with any ContentProvider, your DocumentsProvider can override onCreate() to perform initialization work. Technically, this is not required, but the odds are very good that you will have *something* that you need to initialize.

In the case of our sample DocumentsProvider — named DemoDocumentsProvider — onCreate() simply obtains access to an AssetManager instance that can be used for serving documents:

```
private AssetManager assets;

@Override
public boolean onCreate() {
  assets=getContext().getAssets();

  return(true);
}
```

queryRoots()

Your queryRoots() method needs to return information about the root(s) that your provider will provide.

However, rather than returning this in the form of some clean object model (e.g., a List of Document.Root objects or some such), the return value is a Cursor. While in principle this Cursor could come from a database, in many cases it will be a MatrixCursor, which is a Cursor interface over a two-dimensional array representing the rows and columns.

From here, you should return all *presently valid* roots. The “presently valid” part is because a root might exist but not be usable at the present time. For example, suppose that you are writing a DocumentsProvider that provides a document interface to an Internet-hosted storage service. In this case, you may need the user to authenticate in order to allow access to those files, such as to pass that authentication data along to the Web service to be able to retrieve directory and file data. If the user is not presently logged in, though, not only can you not talk to the Web service right now, but you do not have the ability to force the user to authenticate right now. Instead, you will have to cull the root(s) governed by those authentication credentials. This may mean that the Cursor you return has no rows, as you simply do not have anything that can be published right now.

The Cursor that you return will have one row per presently valid root. The columns will be ones defined on the DocumentsContract.Root class. Your queryRoots() method is passed a String array representing the columns requested by the Storage Access Framework. As your app may not support all of those columns, you will need to determine the intersection between the requested columns and the ones you support.

The sample app defines a SUPPORTED_ROOT_PROJECTION static data member to list the DocumentsContract.Root columns that are supported in general:

```
private static final String[] SUPPORTED_ROOT_PROJECTION=new String[] {
    Root.COLUMN_ROOT_ID, Root.COLUMN_FLAGS, Root.COLUMN_TITLE,
    Root.COLUMN_DOCUMENT_ID, Root.COLUMN_ICON };
```

And the demo provider has a private netProjection() utility method that computes the intersection between the requested columns and the supported ones:

```
private static String[] netProjection(String[] requested, String[] supported) {
  if (requested==null) {
    return(supported);
  }

  ArrayList<String> result=new ArrayList<String>();

  for (String request : requested) {
    for (String support : supported) {
      if (request.equals(support)) {
        result.add(request);
        break;
      }
    }
  }

  return(result.toArray(new String[0]));
}
```

That net projection is used in the MatrixCursor constructor, to teach it the available columns, as part of the queryRoots() implementation:

```
@Override
public Cursor queryRoots(String[] projection)
    throws FileNotFoundException {
  String[] netProjection=
      netProjection(projection, SUPPORTED_ROOT_PROJECTION);
  MatrixCursor result=new MatrixCursor(netProjection);
  MatrixCursor.RowBuilder row=result.newRow();

  row.add(Root.COLUMN_ROOT_ID, ROOT_ID);
  row.add(Root.COLUMN_ICON, R.drawable.ic_launcher);
  row.add(Root.COLUMN_FLAGS, Root.FLAG_LOCAL_ONLY);
  row.add(Root.COLUMN_TITLE, getContext().getString(R.string.root));
```

```
    row.add(Root.COLUMN_DOCUMENT_ID, ROOT_DOCUMENT_ID);

    return(result);
  }
```

queryRoots() then adds a row to the MatrixCursor, through a MatrixCursor.RowBuilder, containing five columns:

1. DocumentsContract.Root.COLUMN_ROOT_ID is the root ID for this root, as described earlier in this chapter.
2. DocumentsContract.Root.COLUMN_ICON, which is a reference to a drawable resource that may be used in Storage Access Framework UI to help visually represent this root. In principle, this could be anything; in practice, you will probably choose your launcher icon, as it is the icon that the user will recognize.
3. DocumentsContract.Root.COLUMN_FLAGS, indicating which optional capabilities this root supports. In this case, the only flag we are setting is FLAG_LOCAL_ONLY, indicating that network I/O is not required to browse the contents of the provider. Our sample app indicates that it is local-only, as its documents are all packaged in assets/. A provider backed by a Web service, though, would not include this flag, so the Storage Access Framework knows that calls to some of the other methods (e.g., queryChildDocuments()) may take a significant amount of time.
4. DocumentsContract.Root.COLUMN_TITLE, which is a string identifying this root. The title and icon will tend to be included in Storage Access Framework-supplied UIs. In this case, with only a single root, the title is hard-coded to be a string resource. In other cases, this might be some other human-grokkable display name (e.g., the name of some storage service account).
5. DocumentsContract.Root.COLUMN_DOCUMENT_ID, which returns the document ID representing the document tree for this root.

In this case, the document IDs for this DocumentsProvider are the relative paths within assets/ of the files, starting from a root docs/ directory. So, while the root ID could be anything, the root document ID should be consistent with the other document ID values. In this case, the sample app uses:

```
  private static final String ROOT_ID="thisIsMyBoomstick";
  private static final String ROOT_DOCUMENT_ID="docs";
```

queryChildDocuments()

As noted previously, some documents will represent a directory, while others will represent files. For those that represent a directory, `queryChildDocuments()` will need to return the document information for the contents of the directory.

`queryChildDocuments()` is passed:

- the document ID of the directory
- the columns, defined on the `DocumentsContract.Document` class, that the Storage Access Framework wants
- the sort order, expressed as a SQL-style `ORDER BY` clause (minus the actual `ORDER BY` part), that you might use to help control the order in which to return the child documents (or ignore if you wish)

As with `queryRoots()`, we need to come up with the intersection of the columns that the requester asks for and the columns that we support. There is a `static` string array named `SUPPORTED_DOCUMENT_PROJECTION` that represents the columns that we support:

```
private static final String[] SUPPORTED_DOCUMENT_PROJECTION=
    new String[] { Document.COLUMN_DOCUMENT_ID, Document.COLUMN_SIZE,
        Document.COLUMN_MIME_TYPE, Document.COLUMN_DISPLAY_NAME,
        Document.COLUMN_FLAGS};
```

The `queryChildDocuments()` method then uses the same `netProjection()` helper method that `queryRoots()` did to determine the intersection:

```
@Override
public Cursor queryChildDocuments(String parentDocId,
                                  String[] projection,
                                  String sortOrder)
    throws FileNotFoundException {
  String[] netProjection=
      netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);
  MatrixCursor result=new MatrixCursor(netProjection);

  try {
    String[] children=assets.list(parentDocId);

    for (String child : children) {
      addDocumentRow(result, child,
                     parentDocId + File.separator + child);
    }
  }
  catch (IOException e) {
    Log.e(getClass().getSimpleName(),
          "Exception reading asset dir", e);
  }
```

```
    return(result);
  }
```

As with `queryRoots()`, the return value of `queryChildDocuments()` is a `Cursor` representing the documents contained in this directory. Once again, we use a `MatrixCursor` to build up an in-memory `Cursor`, this time for all files within the `assets/` directory denoted by `parentDocId`, using the `list()` method on `AssetManager` to find out what those files are.

The logic to populate the `MatrixCursor` is delegated to an `addDocumentRow()` private method, as we will be using it elsewhere in this `DocumentsProvider` implementation. `addDocumentRow()` creates a `MatrixCursor.RowBuilder` and fills in the supported columns:

```
  private void addDocumentRow(MatrixCursor result, String child,
                              String assetPath) throws IOException {
    MatrixCursor.RowBuilder row=result.newRow();

    row.add(Document.COLUMN_DOCUMENT_ID, assetPath);

    if (isDirectory(assetPath)) {
      row.add(Document.COLUMN_MIME_TYPE, Document.MIME_TYPE_DIR);
    }
    else {
      String ext=MimeTypeMap.getFileExtensionFromUrl(assetPath);

      row.add(Document.COLUMN_MIME_TYPE,
          MimeTypeMap.getSingleton().getMimeTypeFromExtension(ext));
      row.add(Document.COLUMN_SIZE, getAssetLength(assetPath));
    }

    row.add(Document.COLUMN_DISPLAY_NAME, child);
    row.add(Document.COLUMN_FLAGS, 0);
  }
```

Of note:

- the document ID of the child is simply its relative path within `assets/`
- the MIME type is a special one if the child document represents a directory, or else is looked up using `MimeTypeMap` if the child document represents a file
- the "display name" could be something special (e.g., the `<title>` of a Web page), but in this case is just the filename

To determine if an asset path represents a directory, the `isDirectory()` utility method just sees if `list()` returns a non-empty list:

```
private boolean isDirectory(String assetPath) throws IOException {
  return(assets.list(assetPath).length>=1);
}
```

To find the size of a document — to fill in the `COLUMN_SIZE` column in the output — we can ask the `AssetManager` for a `FileDescriptor` on the asset, then obtain the length from that descriptor, as seen in the `getAssetLength()` utility method:

```
private long getAssetLength(String assetPath) throws IOException {
  return(assets.openFd(assetPath).getLength());
}
```

The net result is that, given the name of a directory in `assets/`, we return a `Cursor` with one row per child of that directory, with columns indicating details of that child.

queryDocument()

`queryDocument()` is similar to `queryChildDocuments()`. Both return a `Cursor` with the same sorts of columns as output. The difference: `queryDocument()` provides you with the document ID of a file, and you return details of that file. By contrast, `queryChildDocuments()` gives you the document ID of a directory, and you return the details of all documents within that directory.

This is why `addDocumentRow()` was implemented as a separate method, as we need the same business logic (populate a `MatrixCursor` row based on an asset path) from `queryDocument()`:

```
@Override
public Cursor queryDocument(String documentId, String[] projection)
    throws FileNotFoundException {
  String[] netProjection=
      netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);
  MatrixCursor result=new MatrixCursor(netProjection);

  try {
    addDocumentRow(result, Uri.parse(documentId).getLastPathSegment(),
        documentId);
  }
  catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception reading asset dir", e);
  }

  return(result);
}
```

In this case, the only thing different is that we need to get the bare filename, for use in the DISPLAY_NAME field. Here, we cheat a bit and use getLastPathSegment() on Uri to obtain the filename.

openDocument()

The openDocument() method behaves much like the openFile() method of a classic streaming ContentProvider: given a path, you return a ParcelFileDescriptor representing the file contents. For documents that are true files on the filesystem, you can use the static open() method on ParcelFileDescriptor. For documents that are not files on the filesystem — such as documents that are assets in the APK — you will need to set up a ParcelFileDescriptor pipe and stream the content that way.

That is what DemoDocumentsProvider does, using logic copied from the book's streaming ContentProvider samples:

```
@Override
public ParcelFileDescriptor openDocument(String documentId,
                                         String mode,
                                         CancellationSignal signal)

    throws FileNotFoundException {
  ParcelFileDescriptor[] pipe=null;

  try {
    pipe=ParcelFileDescriptor.createPipe();
    AssetManager assets=getContext().getResources().getAssets();

    new TransferThread(assets.open(documentId),
        new ParcelFileDescriptor.AutoCloseOutputStream(pipe[1])).start();
  }
  catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
    throw new FileNotFoundException("Could not open pipe for: "
        + documentId);
  }

  return(pipe[0]);
}
```

openDocument() is passed three parameters:

1. The document ID of the document to stream back
2. A file mode (r, w, or wt) indicating what sort of operations the client wants to perform on the stream
3. A CancellationSignal that we can use to find out that our streaming is being interrupted

In this case:

- `openDocument()` ignores the `mode`, because it did not return `FLAG_SUPPORTS_WRITE` in either `queryChildDocuments()` or `queryDocument()` to indicate that writing is an option, so the `mode` should always be `r`
- `openDocument()` ignores the `CancellationSignal`, though in reality it should pay attention to it when streaming back the content and stop streaming when requested

The `TransferThread` that does the actual streaming is, once again, the same as the one used earlier in this book for a streaming `ContentProvider`:

```
static class TransferThread extends Thread {
  InputStream in;
  OutputStream out;

  TransferThread(InputStream in, OutputStream out) {
    this.in=in;
    this.out=out;
  }

  @Override
  public void run() {
    byte[] buf=new byte[8192];
    int len;

    try {
      while ((len=in.read(buf)) >= 0) {
        out.write(buf, 0, len);
      }

      in.close();
      out.flush();
      out.close();
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(),
          "Exception transferring file", e);
    }
  }
}
```

The Results

If you have both this sample app and the one from the previous chapter, then run the one from the previous chapter to bring up the Storage Access Framework UI, you will see our provider among the list of available providers:

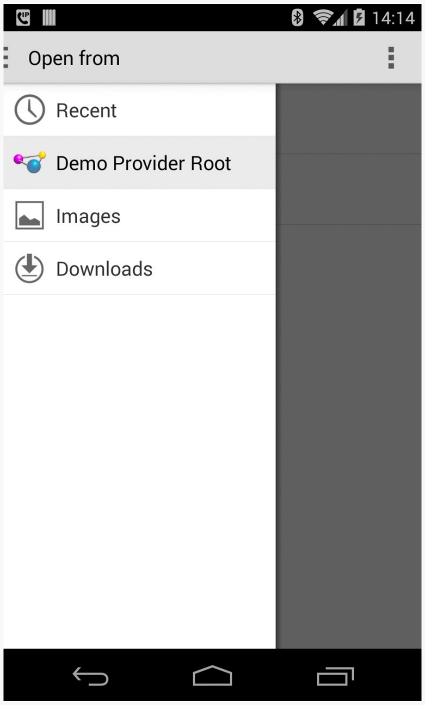


Figure 657: Storage Access Framework Picker, Showing Custom Provider

The provider's `assets/docs/` directory contains three files, one just off the root and two in a `bar/` subdirectory:

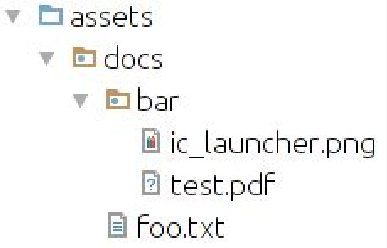

Figure 658: DocumentsProvider Sample Documents

Hence, tapping on our provider in the Storage Access Framework picker brings up the contents of the root document:

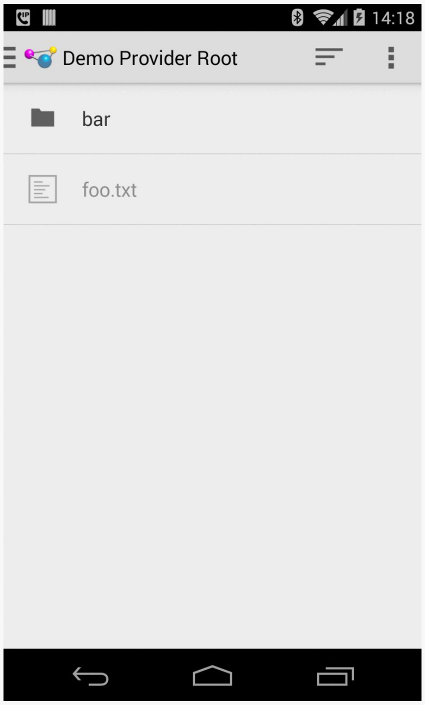

Figure 659: Storage Access Framework Picker, Showing Documents in Root

Tapping on the `bar/` directory brings up its contents in turn:

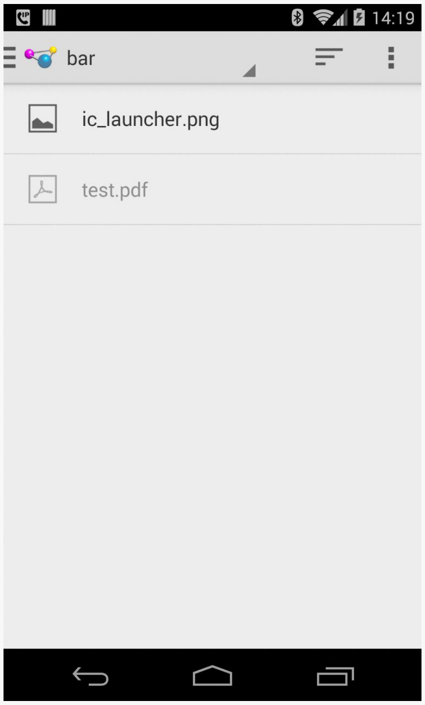

Figure 660: Storage Access Framework Picker, Showing Yet More Documents

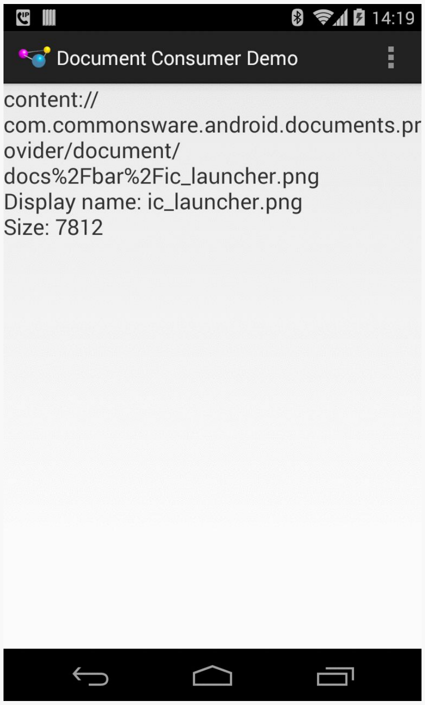
Tapping on one of the files brings up the details for that file:



content://
com.commonsware.android.documents.pr
ovider/document/
docs%2Fbar%2Fic_launcher.png
Display name: ic_launcher.png
Size: 7812

Figure 661: Document Consumer, Showing Details of Picked Document

Optional Provider Capabilities

A `DocumentsProvider` can do a fair bit more than what the above sample app demonstrates. While the sample will suffice for the basics, it is reasonably likely that a production-grade `DocumentsProvider` will need to implement and provide some other optional capabilities, such as those described in this section.

Other CRUD Operations

CRUD — Create, Read, Update, and Delete — is a standard shorthand for the basic operations one can perform on data. The sample app handles the “Read” portion of CRUD, but a `DocumentsProvider` can support all of them if desired.

Create

It may be that your `DocumentsProvider` is only going to serve up documents that were created in your app, or were created outside of the Android device (e.g., on a Web app). If, however, you want consumers of your provider to be able to use

ACTION_CREATE_DOCUMENT to create new documents in your provider, you will need to do a few things.

First, in the COLUMN_FLAGS for the relevant root(s) returned by queryRoots(), you will need to include FLAG_SUPPORTS_CREATE, defined on DocumentsContract.Root. This indicates that at least one directory within that root supports creating new documents. Without this flag, your root(s) will be shown for ACTION_OPEN_DOCUMENT requests but not ACTION_CREATE_DOCUMENT requests.

Next, in one or more directories returned as part of queryDocument() and queryChildDocuments() calls, in the COLUMN_FLAGS column, you will need to include FLAG_DIR_SUPPORTS_CREATE, defined on DocumentsContract.Documents. This indicates that this document is a directory that supports creating new documents inside of it. Otherwise, a directory will be assumed to not support creating new documents. Note that this flag is only used for documents representing directories, not documents representing files.

Finally, you will need to implement createDocument() in your DocumentsProvider. This will be called if a consumer app used ACTION_CREATE_DOCUMENT and the user chose your provider and one of your directories for the new document. You are passed in:

- the document ID of the directory
- the MIME type of the new file
- a suggested display name to use for the new file, though you can modify this if needed

Your job, in createDocument(), is to create the document and return the document ID for the newly-created document. For example, if your documents are held in internal storage, you might create a new file for the document itself plus a database row in some documents table to hold the MIME type and display name.

Update

For something like files, an "update" is replacing the current contents with something new. In the case of a streaming protocol like DocumentsProvider, this implies that your provider can support output as well as input.

This too requires a few changes to your provider.

First, for the file(s) that can be updated, in the results for queryDocument() and queryChildDocuments(), you will need to include FLAG_SUPPORTS_WRITE in COLUMN_FLAGS, to indicate that writing to this file should work.

Then, you will need to pay attention to the mode passed into openDocument(). If the mode is w or wt, you would need to arrange to support writing the file, where your background thread reads from an InputStream on the pipe and writes the data to wherever your data is being stored.

Delete

For any documents that the consumer can delete, include FLAG_SUPPORTS_DELETE in COLUMN_FLAGS in the results for queryDocument() and queryChildDocuments().

You will also need to implement deleteDocument() in your DocumentsProvider. You are supplied the document ID to delete, and your job is to delete it.

If the document represents a directory, you may also need to delete all of its children. That really depends on how you are leveraging the "directory" construct in DocumentsProvider:

- If the "directory" is like a filesystem directory, where children have only one parent, you will want to delete the children when you delete the parent
- If the "directory" is more like a category, such as a tag, where children could have multiple parents, you will need to decide how to handle the children that would be orphaned by your deleting the last parent (delete the children? move them to some other default parent? something else?)

Change Notification

If the data served by your provider changes, it is incumbent upon you to let possible consumers know about the change. For example, if you elect to delete children when you delete their parent, you should let consumers know that those children were deleted. This is not necessary for direct operations performed by consumers (e.g., writing to a document), but is necessary for anything else.

To do that, you call notifyChange() on a ContentResolver, just as you would for changes to the data in a ContentProvider. However, notifyChange() takes a Uri as a parameter, to indicate the scope of the change. There are static utility methods on DocumentsContract that will return a Uri that you can use. Notably:

- `buildDocumentUri()`, given your authority and a document ID, provides a `Uri` that points to that document
- `buildChildDocumentsUri()`, given your authority and a document ID, provides a `Uri` that represents the collection of children of that document

So, for example, if by deleting a parent you also delete the children, you would use `buildChildDocumentsUri()` with `notifyChange()` to ensure that consumers know that those children were modified. The Storage Access Framework will use methods like `queryChildDocuments()` to determine that the children were deleted in this case.

Thumbnails

By default, the Storage Access Framework will use stock icons for directories and files. You can supply your own thumbnails instead, though, if you want. To do this:

- Include `FLAG_SUPPORTS_THUMBNAIL` in the `COLUMN_FLAGS` for the affected document(s) in `queryDocument()` and `queryChildDocuments()`
- Implement `openDocumentThumbnail()` in your `DocumentsProvider`

`openDocumentThumbnail()` is provided the document ID of the document whose thumbnail is required, along with a `Point` object providing a requested size. While your thumbnail does not have to exactly match that size — for example, the aspect ratio that is requested may not match the thumbnail — it should be close.

However, the return value for `openDocumentThumbnail()` is an `AssetFileDescriptor`, which is a wrapper around a `ParcelFileDescriptor`. If your image exists as a file that happens to be the right size, return it by using the static `open()` method on `ParcelFileDescriptor` is fairly straightforward. If, however, you need to scale your source image to fit the desired size, implementing this via a pipe will be moderately tedious.

Recent Documents

If your app has its own concept of recent documents, you can expose that roster to the Storage Access Framework, which can incorporate it as part of its UI. To do this:

- Have your `queryRoots()` method include `FLAG_SUPPORTS_RECENTS` in the `COLUMN_FLAGS` value for the root(s) that support recent documents
- Implement `queryRecentDocuments()` on your `DocumentsProvider`, where you are given the root ID (*not* a document ID!) of one of your roots, and you

need to return the same sort of `Cursor` as you would from `queryChildDocuments()`, but representing the recent documents for that root

The two constraints upon the returned `Cursor` are:

- It should be sorted descending based on last-modified date (e.g., the `COLUMN_LAST_MODIFIED` column in your rows)
- It should be capped at 64 rows, though it can be less if desired

Note that you can, if you wish, have the `Cursor` return rows reflecting both files and directories — you are not limited to one or the other.

Search

If your provider has its own search capability, you can expose that to the Storage Access Framework, which in turn can make it available to users looking for a certain document. To support this:

- Have your `queryRoots()` method include `FLAG_SUPPORTS_SEARCH` in the `COLUMN_FLAGS` value for the root(s) that support searching
- Implement `querySearchDocuments()` on your `DocumentsProvider`, where you are given the root ID (*not* a document ID!) of one of your roots, and you need to return the same sort of `Cursor` as you would from `queryChildDocuments()`, but representing the results of a search

`querySearchDocuments()` is passed a `String` representing the search expression entered by the user. It is up to you to decide what that expression means. It is also up to you to determine where you are searching for that expression (filenames? file contents?).

Note that the `Cursor` you return should only contain documents that reflect files, not documents that point to directories.

Other Flags

There are a few other flags that are available to you on `DocumentsContract.Document` that you can use in `COLUMN_FLAGS` for `Cursor` results representing a document or collection of documents, such as the results of `queryDocument()` and `queryChildDocuments()`:

- If the document represents a directory, and you are supporting thumbnails, and you would like the contents of this directory to be represented in a thumbnail grid as opposed to a list, include `FLAG_DIR_PREFERS_GRID`
- If the document represents a directory, and you feel that users will be better served showing the documents in descending order based upon `COLUMN_LAST_MODIFIED`, rather than alphabetical by display name, include `FLAG_DIR_PREFERS_LAST_MODIFIED`

Encrypted Storage

SQLite databases, by default, are stored on internal storage, accessible only to the app that creates them.

At least, that is the theory.

In practice, it is conceivable that others could get at an app's SQLite database, and that those "others" may not have the user's best interests at heart. Hence, if you are storing data in SQLite that should remain confidential despite extreme measures to steal the data, you may wish to consider encrypting the database.

Perhaps the simplest way to encrypt a SQLite database is to use SQLCipher. SQLCipher is a SQLite extension that encrypts and decrypts database pages as they are written and read. However, SQLite extensions need to be compiled into SQLite, and the stock Android SQLite does not have the SQLCipher extension.

SQLCipher for Android, therefore, comes in the form of a replacement implementation of SQLite that you add as an NDK library to your project. It also ships with replacement editions of the `android.database.sqlite.*` classes that use the SQLCipher library instead of the built-in SQLite. This way, your app can be largely oblivious to the actual database implementation, particularly if it is hidden behind a `ContentProvider` or similar abstraction layer.

SQLCipher for Android is a joint initiative of Zetetic (the creators of SQLCipher) and the Guardian Project (home of many privacy-enhancing projects for Android). SQLCipher for Android is open source, under the Apache License 2.0.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- database access

Scenarios for Encryption

So, why might you want to encrypt a database?

Some developers probably are thinking that this is a way of protecting the app's content against "those pesky rooted device users". In practice, this is unlikely to help. As with most encryption mechanisms, SQLCipher uses an encryption key. If the app has the key, such as being hard-coded into the app itself, anyone can get the key by reverse-engineering the app.

Rather, encrypted databases are to help the user defend their data against other people seeing it when they should not. The classic example is somebody leaving their phone in the back of a taxi — if that device winds up in the hands of some group with the skills to root the device, they can get at any unencrypted content they want. While some users will handle this via the whole-disk encryption available since Android 3.0, others might not.

If the database is going anywhere other than internal storage, there is all the more reason to consider encrypting it, as then it may not even require a rooted device to access the database. Scenarios here include:

1. Databases stored on external storage
2. Databases backed up using external storage, BackupManager, or another Internet-based solution
3. Databases explicitly being shared among a user's devices, or between a user's device and a desktop (note that SQLCipher works on many operating systems, including desktops and iOS)

Obtaining SQLCipher

SQLCipher is available from Zetitec. As of October 2015, the current shipping version was 3.3.1.

NOTE: If you have been using SQLCipher prior to version 2.2.1, please upgrade to 3.0.x! Some modifications were made in July 2013 "to address a compatibility issue with an upcoming Android OS release" (presumably Android 4.4). You can read more in the SQLCipher project's blog post about the upgrade.

NOTE #2: If you have been using SQLCipher prior to version 3.0.x, and you have deployed your app in production, you will have some additional work to do to upgrade your database to the new file format. This is covered later in this chapter.

In Android Studio, to add SQLCipher for Android to your project, just add the official AAR dependency, which Zetitec started publishing in October 2015:

```
dependencies {
    compile 'net.zetetic:android-database-sqlcipher:3.3.1-2@aar'
}
```

Using SQLCipher

If you have existing code that uses classic Android SQLite, you will need to change your import statements to pick up the SQLCipher for Android equivalents of the classes. For example, you obtain `SQLiteDatabase` now from `net.sqlcipher.database.sqlcipher`, not `android.database.sqlite`. Similarly, you obtain `SQLException` from `net.sqlcipher.database` instead of `android.database`. Unfortunately, there is no complete list of which classes need this conversion — `Cursor`, for example, does not. Try converting everything from `android.database` and `android.database.sqlite`, and leave alone those that do not exist in the SQLCipher for Android equivalent packages.

Before starting to use SQLCipher for Android, you need to call `SQLiteDatabase.loadLibs()`, supplying a suitable `Context` object as a parameter. This initializes the necessary libraries. If you are using a `ContentProvider`, just call this in `onCreate()` before actually using anything else with your database. If you are not using a `ContentProvider`, you probably will want to create a custom subclass of `Application` and make this call from that class' `onCreate()`, and reference your custom `Application` class in the `android:name` attribute of the `<application>` element in your manifest. Either of these approaches will help ensure that the libraries are ready before you try doing anything with the database.

Finally, when calling `getReadableDatabase()` or `getWritableDatabase()` on `SQLiteDatabase`, you need to supply the encryption key to use. For the purposes of book examples, a hard-coded passphrase is sufficient. However, those can be trivially reverse-engineered, and so they offer little real-world protection. But, they keep the code simple, which is useful when examining APIs.

The Database/ConstantsSecure-AndroidStudio sample app is yet another variation of the ConstantsBrowser sample that we have been using for most of the database examples. From the standpoint of the ConstantsBrowser activity and ConstantsFragment UI, nothing is different. However, DatabaseHelper uses SQLCipher, rather than SQLite.

In the DatabaseHelper constructor, we call loadLibs() on the SQLiteDatabase class, which is a required initialization step to get the native libraries set up:

```
public DatabaseHelper(Context context) {
  super(context, DATABASE_NAME, null, SCHEMA);

  SQLiteDatabase.loadLibs(context);
}
```

It also offers zero-argument getReadableDatabase() and getWritableDatabase() methods, akin to those offered by the regular SQLiteOpenHelper. However, the DatabaseHelper editions turn around and invoke the one-argument equivalents on the SQLCipher edition of SQLiteOpenHelper:

```
SQLiteDatabase getReadableDatabase() {
  return(super.getReadableDatabase(PASSPHRASE));
}

SQLiteDatabase getWritableDatabase() {
  return(super.getWritableDatabase(PASSPHRASE));
}
```

Here, the PASSPHRASE is just a hard-coded string:

```
private static final String PASSPHRASE=
    "hard-coding passphrases is only for sample code;"+
    "nobody does this in production";
```

That is all the changes that are needed to use SQLCipher.

SQLCipher Limitations

Alas, SQLCipher for Android is not perfect.

It will add a few MB to the size of your APK file per CPU architecture. For most modern Android devices, this extra size will not be a huge issue, though it will be an impediment for older devices with less internal storage, or for apps that are getting close to the size limits imposed by the Play Store or other distribution mechanisms. The chapter on the NDK contains a section about a technology called `libhoudini` that can help reduce this bloat, albeit with a significant performance penalty.

However, the size is mostly from code, and that may cause a problem for Eclipse users. Eclipse may crash with its own `OutOfMemoryError` during the final build process. To address that, find your `eclipse.ini` file (location varies by OS and installation method) and increase the `-Xmx` value shown on one of the lines (e.g., change it to `-Xmx512m`).

Other code that expects to be using native SQLite databases will require alteration to work with SQLCipher for Android databases. For example, the `SQLiteAssetHelper` described elsewhere in this book would need to be ported to use the SQLCipher for Android implementations of `SQLiteOpenHelper`, `SQLiteDatabase`, etc. This is not too difficult for an open source component like `SQLiteAssetHelper`.

Passwords and Sessions

Given an encrypted database, there are several ways that an attacker can try to access the data, including:

1. Use a brute-force attack via the app itself
2. Use a brute-force attack on the database directly, by copying it to some other machine
3. Obtain the password by the strategic deployment of a $5 wrench

The classic way to prevent the first approach is by having business logic that prevents lots of failed login attempts in a short period of time. This can be built into your login dialog (or the equivalent), tracking the number and times of failed logins and introducing delays, forced app exits, or something to add time and hassle for trying lots of passwords.

Since manually trying passwords is nasty, brutish, and long, many attackers would automate the process by copying the SQLCipher database to another machine (e.g., desktop) and running a brute-force attack on it directly. SQLCipher for Android has many built-in protections to help defend against this. So long as you are using a sufficiently long and complex encryption key, you should be fairly well-protected against such attacks.

Defending against wrenches is decidedly more difficult and is beyond the scope of this book.

About Those Passphrases…

Having a solid encryption algorithm, like the AES-256 used by default with SQLCipher for Android, is only half the battle. The other half is in using a high-quality passphrase, one that is unlikely to be guessed by anyone looking to break the encryption.

Upgrading to Encryption

Suppose you have an app already out on the market, and you decide that you want to add the option for encryption. It is fairly likely that the user will be miffed if they lose all their data in the process of switching to an encrypted database. Therefore, you will want to try to retain their data.

SQLCipher for Android does not support in-place encryption of database. However, it *does* support working with unencrypted databases and encrypted databases simultaneously, giving you the option of migration.

The approach boils down to:

- Open the unencrypted database in SQLCipher for Android, using an empty passphrase
- Use the `ATTACH` statement to open the encrypted database inside the same SQLCipher for Android session
- Use a supplied `sqlcipher_export()` function to migrate most of the data
- Copy the Android database schema version between the databases
- `DETACH` the encrypted database
- Close the unencrypted database (and, presumably, delete it)
- Use the encrypted database from this point forward

Since both database files will exist at one time, you will find it simplest to use separate names for them (e.g., `stuff.db` and `stuff-encrypted.db`).

To see how this works, take a look at the `Database/SQLCipherPassphrase-AndroidStudio`, which is a variation of the original, non-`ContentProvider` “constants” sample app, this time using SQLCipher for

Android and supporting an upgrade from a non-encrypted database to an encrypted one.

The bulk of the logic for handling the encryption upgrade is in a static `encrypt()` method on our `DatabaseHelper`:

```
static void encrypt(Context ctxt) {
  SQLiteDatabase.loadLibs(ctxt);

  File dbFile=ctxt.getDatabasePath(DATABASE_NAME);
  File legacyFile=ctxt.getDatabasePath(LEGACY_DATABASE_NAME);

  if (!dbFile.exists() && legacyFile.exists()) {
    SQLiteDatabase db=
        SQLiteDatabase.openOrCreateDatabase(legacyFile, "", null);

    db.rawExecSQL(String.format("ATTACH DATABASE '%s' AS encrypted KEY '%s';",
                                dbFile.getAbsolutePath(), PASSPHRASE));
    db.rawExecSQL("SELECT sqlcipher_export('encrypted')");
    db.rawExecSQL("DETACH DATABASE encrypted;");

    int version=db.getVersion();

    db.close();

    db=SQLiteDatabase.openOrCreateDatabase(dbFile, PASSPHRASE, null);
    db.setVersion(version);
    db.close();

    legacyFile.delete();
  }
}
```

First, we initialize SQLCipher for Android by calling `loadLibs()` on the SQLCipher version of `SQLiteDatabase`. We could do this someplace else, but for this sample, this is as good a spot as any.

We then create `File` objects pointing at the locations of the old, unencrypted database (with a name represented by a `LEGACY_DATABASE_NAME` static data member) and the new encrypted database (`DATABASE_NAME`). To get the `File` locations of those databases, we use `getDatabasePath()`, a method on `Context`, which returns the correct location for a database file given its name.

If the encrypted database exists, there is nothing that we need to do. Similarly, if it does not exist but the unencrypted database *also* does not exist, there is nothing that we *can* do. In either of those cases, we skip over the rest of the logic. In the first case, we already did the conversion (presumably); in the latter case, this is a new installation, and our `SQLiteOpenHelper` `onCreate()` logic will handle that. But, in the case where we do not have the encrypted database but do have the unencrypted one, we can create the encrypted database from the unencrypted data, which is what the bulk of the `encrypt()` method does.

To that, we:

- Use `openOrCreateDatabase()` to open the already-existing unencrypted database file *in SQLCipher for Android*, using `""` as the passphrase.
- Use a `rawExecSQL()` method available on the SQLCipher for Android version of `SQLiteDatabase` to `ATTACH` the encrypted database, given its path, to our database session, using the supplied passphrase. This means that we can access the tables from both databases simultaneously, though we need to prefix all references to the attached database via its handle, `encrypted`.
- Use `rawExecSQL()` to execute `SELECT sqlcipher_export('encrypted')`, which copies most of our data from the unencrypted database (the database we have open) into the `encrypted` database (the one we attached). The big thing that `sqlcipher_export()` does *not* copy is the schema version number that Android maintains.
- Use `rawExecSQL()` to `DETACH` the attached `encrypted` database, as we no longer need it.
- Call `getVersion()` on the `SQLiteDatabase` representing the unencrypted database, to retrieve the schema version number that Android maintains.
- Close the unencrypted database and open the encrypted one using `openOrCreateDatabase()`.
- Use `setVersion()` on `SQLiteDatabase` to set the schema version of the encrypted database to the value we had from the unencrypted database.
- Close the encrypted database and delete the unencrypted database file. Note that on API Level 16+, we could use the `deleteDatabase()` method on `SQLiteDatabase` to cleanly delete everything associated with SQLite.

The combination of doing all of that migrates our data from an unencrypted database to an encrypted one.

Then, we simply need to call `encrypt()` before we try loading our constants, from `doInBackground()` of our `LoadCursorTask`:

```
private class LoadCursorTask extends BaseTask<Void> {
  private final Context ctxt;

  LoadCursorTask() {
    this.ctxt=getActivity().getApplicationContext();
  }

  @Override
  protected Cursor doInBackground(Void... params) {
    DatabaseHelper.encrypt(ctxt);
    return(doQuery());
  }
}
```

To test this upgrade logic, you will need to:

- Run the original unencrypted version of this sample, found in the Database/Constants sample application
- Add a new constant using the unencrypted version of the app
- Run the encrypted version of the sample from this section, which shares the same package name as the original and therefore will replace it on your emulator

You will see your added constant appear along with all of the standard ones, yet if you examine /data/data/com.commonsware.android.constants/databases on your ARM emulator via DDMS, you will see that your database is now named constants-crypt.db instead of constants.db, as we have replaced the unencrypted database with an encrypted one.

Changing Encryption Passphrases

Another thing the user might wish to do is change their passphrase. Perhaps they fear that their existing passphrase has been compromised (e.g., a narrow escape from a $5 wrench). Perhaps they rotate their passphrases as a matter of course. Perhaps they simply keep typing in their current one incorrectly and want to switch to one they think they can enter more accurately.

SQLCipher for Android supports a rekey PRAGMA that can accomplish this. Given an open encrypted database db — opened using the old passphrase – you can change the password to a newPassword string variable via:

```
db.execSQL(String.format("PRAGMA rekey = '%s'", newPassword));
```

Note that this may take some time, as SQLCipher for Android needs to re-encrypt the entire database.

Dealing with the Version 3.0.x Upgrade

If you are starting with SQLCipher for Android with the 3.0.x release, all is good.

If you have been using SQLCipher for Android from previous releases, but you are still in development mode, all is still good, so long as you can wipe out your old databases.

If you have apps in production using SQLCipher for Android from previous releases, you will have a small headache: the database structure has changed. SQLCipher for Android provides us with a `PRAGMA cipher_migrate` that we can run to upgrade the database in place to the new structure, once we have opened the database with our passphrase. However:

1. There is no great built-in place to put the code for calling this pragma
2. You do not want to blindly call this pragma every time you open the database, as it results in extra processing time

SQLCipher for Android, in an attempt to help with this, offers a modified version of methods like `openOrCreateDatabase()` on `SQLiteDatabase`, ones that take a `SQLiteDatabaseHook` implementation as the last parameter. This interface requires two methods:

1. `preKey()`, called after the database is opened but before the passphrase is applied
2. `postKey()`, called after the database is opened and after the passphrase is applied, but before anything else is done (e.g., standard `SQLiteOpenHelper` schema version checking)

Both methods are passed the `SQLiteDatabase` as a parameter, for you to do with as needed. So, for example, you could have a `postKey()` implementation that does the `postKey()` call only if needed:

```
public class SQLCipherV3Hook implements SQLiteDatabaseHook {
  private static final String PREFS=
      "net.sqlcipher.database.SQLCipherV3Helper";

  public static void resetMigrationFlag(Context ctxt, String dbPath) {
    SharedPreferences prefs=
        ctxt.getSharedPreferences(PREFS, Context.MODE_PRIVATE);
    prefs.edit().putBoolean(dbPath, false).commit();
  }

  @Override
  public void preKey(SQLiteDatabase database) {
    // no-op
  }

  @Override
  public void postKey(SQLiteDatabase database) {
    SharedPreferences prefs=
        getContext().getSharedPreferences(PREFS, Context.MODE_PRIVATE);
    boolean isMigrated=prefs.getBoolean(database.getPath(), false);

    if (!isMigrated) {
      database.rawExecSQL("PRAGMA cipher_migrate;");
      prefs.edit().putBoolean(database.getPath(), true).commit();
    }
  }
}
```

You can also pass a `SQLiteDatabaseHook` implementation into the `SQLiteOpenHelper` constructor as the fifth parameter, which will be used when `SQLiteOpenHelper` works with the underlying `SQLiteDatabase`.

Multi-Factor Authentication

Another way to effectively boost the strength of your security is to implement your own multi-factor authentication. In this case, the passphrase is not obtained solely through the user typing in the whole thing, but instead is synthesized from two or more sources. So, in addition to some `EditText` widget for entering in a portion of the passphrase, the rest could come from things like:

- A value written to an NFC tag that the user must tap
- A value encoded in a QR code that the user must scan
- A value obtained by some Bluetooth-connected device via a custom protocol

You, in code, would concatenate the pieces together, possibly using delimiters that cannot be typed in (e.g., ASCII characters below 32) to denote the sources of each segment of the passphrase. The result would be the actual passphrase you would use with SQLCipher for Android.

The objective is to make it easier for users to have more complex passphrases, while not having to type in something complex every time. Tapping an NFC tag is much faster than tapping out a passphrase on a typical phone keyboard, for example. Also, the “something you know and something you have” benefit of multi-factor authentication can help with defending against $5 wrench attacks: if the NFC tag was destroyed, and the user never knew the portion of the passphrase stored on it, the user cannot divulge it.

Of course, this adds risks, such as the NFC tag being destroyed accidentally (e.g., “my dog ate it”). This can be mitigated in some cases by some “admin” being able to reset the password or supply a new NFC tag. In that case, getting the credentials requires *two* kidnappings and *two* $5 wrenches (or the serial application of a single

$5 wrench, if budgets preclude buying two such wrenches), adding to the degree of difficulty for breaking the encryption by that means.

Detecting Failed Logins

If you try to decrypt a database using the incorrect passphrase — whether an attempt by outsiders to use the app, or the user “fat-fingering” the passphrase and making a typo — you will get an exception:

```
11-19 09:17:22.700: E/SQLiteOpenHelper(1634):
net.sqlcipher.database.SQLiteException: file is encrypted or is not a
database
```

Alas, this is not a specific exception, making it a bit difficult to detect failed passphrases specifically. Your options are:

- Assume that your testing is sound and that exceptions when opening a database represent invalid passphrases, or
- Use a generic error message that hints at an invalid passphrase but leaves open the possibility of something else being wrong, or
- Read into the exception’s message looking for “file is encrypted or is not a database”, though this is fragile in the face of changes to SQLCipher for Android

SQLCipher for Android and Performance

Some developers worry about the overhead that encryption will place on the database I/O, and therefore worry that SQLCipher for Android will make their app unacceptably slow.

The impact of SQLCipher is not that bad, particularly for hardware with faster CPUs. Encryption is CPU-intensive, so faster CPUs reduce the overhead of the encryption. Also, since the disk I/O is comparable between SQLite and SQLCipher, the fact that flash memory is slow will mean that disk I/O, not decryption speed, will be the primary determinant of the speed of your queries. Similarly, disk I/O will count for more than CPU speed for the encryption needed for INSERT/UPDATE/DELETE operations.

For example, porting one relatively crude benchmark to use SQLCipher for Android showed no statistically significant performance difference from the SQLite edition on a Nexus 5 running Android 4.4.2.

To the extent that encryption adds overhead, it will tend to magnify existing problems. For example, anything that involves a "table scan" (i.e., a non-indexed lookup of database contents) will need more pages to be decrypted and, therefore, more decryption time. If your database I/O is well-tuned for SQLite, such as adding appropriate indexes, then your SQLCipher for Android overhead should be nominal.

Of course, the worse the CPU, the worse the story, and so older/cheaper devices may fare worse with SQLCipher for Android by comparison.

Encrypted Preferences

There are effectively three forms of data storage in Android:

- SQLite databases
- `SharedPreferences`
- Arbitrary files, in whatever format you want

You can encrypt SQLite via SQLCipher for Android, as seen in this chapter. You can encrypt arbitrary files as part of your data format, such as via `javax.crypto`.

What is not supported, out of the box, is a way to encrypt `SharedPreferences`.

There are two approaches for encrypting the contents of `SharedPreferences`:

1. Encrypt the container in which the `SharedPreferences` are stored
2. Encrypt each preference value as you store it in the `SharedPreferences`, and decrypt it when you read the value back out

Encryption via Custom SharedPreferences

`SharedPreferences` is an interface. Hence, you can create other implementations of that interface that store their data in something other than unencrypted XML files.

`CWSharedPreferences` is one such implementation. You can find it in the [`cwac-prefs` project on GitHub].

`CWSharedPreferences` handles the `SharedPreferences` and `SharedPreferences.Editor` interfaces, along with the in-memory representations of the preferences. It then delegates the work of *storing* the preferences to a strategy object, implementing a strategy interface (`CWSharedPreferences.StorageStrategy`).

Two such strategy implementations are supplied in the project: one using ordinary SQLite, and one using SQLCipher for Android.

The basic recipe for using `CWSharedPreferences` is:

- Create the strategy object, such as

```
new SQLCipherStrategy(getContext(), NAME, "atestpassword", LoadPolicy.SYNC)
```

(here, `NAME` is the name of the set of preferences, `"atestpassword"` is your passphrase, and `LoadPolicy.SYNC` indicates that the preferences should be loaded from disk immediately, not on a background thread)

- Create a `CWSharedPreferences` that employs your chosen strategy:

```
new CWSharedPreferences(yourStrategyObjectGoesHere);
```

- Use the `CWSharedPreferences` as you would any other `SharedPreferences` implementation
- Call `close()` on the strategy object, to release any resources that it might hold (e.g., open database connection)

Encryption via Custom Preference UI and Accessors

The big drawback to the custom `SharedPreferences` is the fact that you cannot get the `PreferenceScreen` system to work with it. The preference UI is hard-wired to use the stock implementation of `SharedPreferences` and does not appear to support any way to substitute in some other implementation.

Hence, another approach is to keep things in standard `SharedPreferences`' XML files, but encrypt text values on a preference-by-preference basis. Since the data type needs to remain the same, most likely you would restrict this to encrypting strings (e.g., `EditTextPreference`, `ListPreference`) rather than numbers, booleans, etc.

To do this, you would need to:

- Implement static methods somewhere for your encryption and decryption algorithms
- Subclass the `Preference` classes of interest and override methods that would deal with the raw preference data, like `onDialogClosed()`, to encrypt the values you persist and decrypt the values you read in, using the static methods mentioned above

- Use your extended Preference classes in your preference XML as needed
- Use those static methods as part of reading (or writing) the preference values directly via SharedPreferences

The downsides to this approach include:

- Only certain preferences are encrypted, rather than all of them
- You lose some of the low-level encryption power of SQLCipher for Android, such as automatic hashing of passphrases, which you would have to handle yourself
- There may not be a library that supplies these extended Preference classes, forcing you to roll your own

IOCipher

SQLCipher for Android is also used as the backing store for IOCipher. IOCipher is a virtual file system (VFS) for Android, allowing you to write code that looks and works like it uses normal file I/O, yet all of the files are actually saved as BLOBs in a SQLCipher for Android database. The result is a fully-encrypted VFS, inheriting all of SQLCipher's security features, such as default AES-256 encryption. This may be easier for you to use than encrypting and decrypting files individually via javax.crypto, for example.

IOCipher is considered to be in pre-alpha state as of November 2012.

Packaging and Distributing Data

Sometimes, you not only want to ship your code and simple resources with your app, but you also want to ship other types of data, such as an initial database that your app will use when first run. This chapter will examine the means by which you can do those sorts of things.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- database access
- content provider theory
- content provider implementations

Packing a Database To Go

Android's support for databases is focused on databases you create and populate entirely at runtime. Even if you want some initial data in the database, the expectation is that you would add that via Java code, such as the series of `insert()` calls we made in the `DatabaseHelper` of the various flavors of the `ConstantsBrowser` sample application.

However, that is tedious and slow for larger initial data sets, even if you make careful use of transactions to minimize the disk I/O.

What would be nice is to be able to ship a pre-populated database with your app. While Android does not offer built-in support for this, there are a few ways you can accomplish it yourself. One of the easiest, though, is to use existing third-party code that supports this pattern, such as Jeff Gilfelt's SQLiteAssetHelper, available via a GitHub repository.

Eclipse users can download a JAR. Android Studio users can add a compile statement to the dependencies closure in build.gradle to pull in com.readystatesoftware.sqliteasset:sqliteassethelper:... (for some version indicated by ...) from mavenCentral() or jcenter().

SQLiteAssetHelper replaces your existing SQLiteOpenHelper subclass with one that handles database creation and upgrading for you. Rather than you writing a lot of SQL code for each of those, you provide a pre-populated SQLite database (for creation) and a series of SQL scripts (for upgrades). SQLiteAssetHelper then does the work to set up your pre-populated database when the database is first accessed and running your SQL scripts as needed to handle schema changes. And, SQLiteAssetHelper is open source, licensed under the same Apache License 2.0 that is used for Android proper.

To examine SQLiteAssetHelper in action, let's look at the Database/ConstantsAssets-AndroidStudio sample project. This is yet another rendition of the same app as the other flavors of ConstantsBrowser, but one where we use a pre-populated database.

Create and Pack the Database

Whereas normally you create your SQLite database at runtime from Java code in your app, you now create your SQLite database using whatever tools you like, at development time. Whether you use the command-line sqlite3 utility, the SQLite Manager extension for Firefox, or anything else, is up to you. You will need to set up all of your tables, indexes, and so forth.

Then, you need to:

1. Create an assets/databases/ directory in your project
2. Copy your database into this directory (or put it there in the first place, if you prefer)

If your minSdkVersion is less than 11, you will instead need to have a ZIP or GZIP archive containing the database. The archive should have the same name as the database file, just with the .zip or .gz extension. The reason for the ZIP compression comes from an Android 1.x/2.x limitation – assets that are compressed by the Android build tools have a file-size limitation (around 1MB). Hence, you need to store larger files in a file format that will not be compressed by the Android build tools, and those tools will not try to compress a .zip file.

In the ConstantsAssets project, you will see an assets/databases/constants.db file, containing a copy of the SQLite database with our constants table and pre-populated values.

Unpack the Database, With a Little Help(er)

Your compressed database will ship with your APK. To get it into its regular position on internal storage, you use SQLiteAssetHelper. Simply create a subclass of SQLiteAssetHelper and override its constructor, supplying the same values as you would for a SQLiteOpenHelper subclass, notably the database name and schema revision number. Note that the database name that you use must match the filename of the compressed database (minus the .zip extension, if you needed that).

So, for example, our new DatabaseHelper looks like this:

```
package com.commonsware.android.dbasset;

import android.content.Context;
import com.readystatesoftware.sqliteasset.SQLiteAssetHelper;

class DatabaseHelper extends SQLiteAssetHelper {
  static final String TITLE="title";
  static final String VALUE="value";
  static final String TABLE="constants";
  private static final String DATABASE_NAME="constants.db";

  public DatabaseHelper(Context context) {
    super(context, DATABASE_NAME, null, 1);
  }
}
```

SQLiteAssetHelper will then copy your database out of assets and set it up for conventional use, as soon as you call getReadableDatabase() or getWritableDatabase() on an instance of your SQLiteAssetHelper subclass.

Upgrading Sans Java

Traditionally, with SQLiteOpenHelper, to handle a revision in your schema, you override onUpgrade() and do the upgrade work in there. With SQLiteAssetHelper, there is a built-in onUpgrade() method that uses SQL scripts in your APK to do the upgrade work instead.

These scripts will also reside in your `assets/databases/` directory of your project. The name of the file will be `$NAME_upgrade_$FROM-$TO.sql`, where you replace `$NAME` with the name of your database (e.g., `constants.db`), `$FROM` with the old schema version number (e.g., `1`) and `$TO` with the new schema version number (e.g., `2`). Hence, you wind up with files like `assets/databases/constants.db_upgrade_1-2.sql`. This should contain the SQL statements necessary to upgrade your schema between the versions.

`SQLiteAssetHelper` will chain these together as needed. Hence, to upgrade from schema version 1 to 3, you could either have a single dedicated 1->3 script, or a 1->2 script and a 2->3 script.

Limitations

The biggest limitation comes with disk space. Since APK files are read-only at runtime, you cannot delete the copy of the database held as an asset in your APK file once `SQLiteAssetHelper` has unpacked it. This means that the space taken up by your ZIP file will be taken up indefinitely. Note, though, that you could use this to your advantage, offering the user a “start over from scratch” option that deletes their existing database, so `SQLiteAssetHelper` will unpack a fresh original copy on the next run. Or, you could implement a `SQLiteDownloadHelper` that follows the `SQLiteAssetHelper` approach but obtains its database from the Internet instead of from assets.

In principle, SQLite could change their file format. If that ever happens, you will need to make sure that you create a SQLite database in the file format that can be used by Android, more so than what can be used by the latest SQLite standalone tools.

Advanced Database Techniques

This chapter offers tips and techniques for working with SQLite beyond what the previous chapters in the book have covered.

Prerequisites

This chapter assumes that you have read the core chapters, particularly the ones on databases and Internet access.

Also, please read the chapter on advanced action bar techniques, particularly the section on `SearchView`, as that is used in one of the sample apps.

Full-Text Indexing

Standard SQL databases are great for ordinary queries. In particular, when it comes to text, SQL databases are great for finding rows where a certain column value matches a particular string. They are usually pretty good about finding when a column value matches a particular string prefix, if there is an index on that column. Things start to break down when you want to search for an occurrence of a string in a column, as this usually requires a "table scan" (i.e., iteratively examining each row to see if this matches). And getting more complex than that is often impossible, or at least rather difficult.

SQLite, in its stock form, inherits all those capabilities and limitations. However, SQLite also offers full-text indexing, where we can search our database much like how we use a search engine (e.g., "find all rows where this column has both `foo` and `bar` in it somewhere"). While a full-text index takes up additional disk space, the speed of the full-text searching is quite impressive.

For example, if you are reading this book using the Android APK edition (instead of the PDF, EPUB, or Kindle/MOBI editions), tap on the `SearchView` action bar item and search for `FTS4`. You will get a list of matches back almost instantaneously, despite the fact that you are searching a multi-megabyte book. That is because this book ships a SQLite-powered full-text index of the book's contents, specifically to power your use of `SearchView`.

In this section, we will review how you can add full-text indexing to your SQLite database and how you can let the user take advantage of that index using a `SearchView`.

First, a Word About SQLite Versions

SQLite has evolved since Android's initial production release in 2008.

In many cases, Android does not incorporate updates to third-party code, for backwards-compatibility reasons (e.g., Apache's HttpClient). In the case of SQLite, newer Android versions do take on newer versions of SQLite… but the exact version of SQLite that a given version of Android uses is undocumented. Worse, some device manufacturers replace the stock SQLite for a version of Android with a different one.

This Stack Overflow answer contains a mapping of Android OS releases to SQLite versions, including various "anomalies" where manufacturers have elected to ship something else.

In many cases, the SQLite version does not matter. Core SQLite capabilities will have existed since the earliest days of Android. However, full-text indexing did not exist in the first SQLite used by Android, meaning that you will have to pay attention to your `minSdkVersion` and aim high enough that devices should support the full-text indexing option you choose.

Note that you could use an external SQLite implementation, one that gives you a newer SQLite engine than what might be on the device. For example, SQLCipher for Android ships its own copy of SQLite (with the SQLCipher extensions compiled in), one that is often newer than the one that is baked into the firmware of any given device.

FTS3 and FTS4

There are two full-text indexing options available in SQLite: FTS3 and FTS4. FTS4 can be much faster on certain queries, though overall the speed of the two implementations should be similar. FTS4 has two key limitations:

1. It may take a bit more disk space for its indexes.
2. It was added to SQLite 3.7.4, which was only introduced into standard Android in API Level 11.

The sample app for this section will demonstrate FTS4, as that is available on most Android devices.

Note that the Android developer documentation does not cover FTS3 or FTS4 full-text indexing. The details for the SQL syntax to support these options can be found in the SQLite documentation.

Creating a Full-Text Indexed Table

A full-text indexed table, using FTS3 or FTS4, uses SQLite's `CREATE VIRTUAL TABLE` syntax. This indicates that you are opting into some special table-storage behavior, rather than the stock stuff.

In the `Database/FTS` sample project, the `onCreate()` method of our `SQLiteOpenHelper` subclass (`DatabaseHelper`) creates such a virtual table, using FTS4 for full-text indexing:

```
@Override
public void onCreate(SQLiteDatabase db) {
  db.execSQL("CREATE VIRTUAL TABLE questions USING fts4("
                +"_id INTEGER PRIMARY KEY, title TEXT, "
                +"link TEXT, profileImage TEXT, creationDate INTEGER, "
                +"order=DESC);");
}
```

There are a few differences here from a typical `CREATE TABLE` statement, beyond the introduction of the `VIRTUAL` keyword:

- The `USING fts4` indicates that the virtual table is employing the FTS4 full-text indexing engine. To use FTS3, just replace `fts4` with `fts3`.
- You can have key-value pairs in the column list, separated by equals signs, to provide options for configuring the virtual table. In this case, it will provide options for configuring the FTS4 indexing behavior. In this case, we are

providing order=DESC, to indicate that the full-text index should be optimized for returning items in descending order. Note that these options only exist for FTS4, not FTS3. The full roster of available options is covered in the SQLite documentation.

This gives us a table that supports normal table operations but also has a full-text index for its columns. However, there are some limitations, notably that these tables ignore constraints. So, for example, the PRIMARY KEY constraint applied to the _id column is ignored.

Populating a Full-Text Indexed Table

Adding content to an FTS3 or FTS4 table uses the same INSERT statements that you might use for a regular table. For example, the DatabaseHelper in the sample app has an insertQuestions() method that deletes all existing rows in the questions table, then inserts a bunch of rows based on a supplied List of Item objects:

```
void insertQuestions(Context app, List<Item> items) {
  SQLiteDatabase db=getDb(app);

  db.beginTransaction();

  db.delete("questions", null, null);

  try {
    for (Item item : items) {
      Object[] args={ item.id, item.title, item.link,
                      item.owner.profileImage, item.creationDate};

      db.execSQL("INSERT INTO questions (_id, title, "
                    +"link, profileImage, creationDate) "
                    +"VALUES (?, ?, ?, ?, ?)",
                  args);
    }

    db.setTransactionSuccessful();
  }
  finally {
    db.endTransaction();
  }
}
```

If those Item objects look familiar, that is because this app is a modified version of the Stack Overflow questions apps profiled in the chapter on Internet access.

The reason why we are deleting everything before inserting is just to keep the sample simple. The database table will hold all of the questions pulled from the Stack Exchange API. Each time we run the app, we get the latest questions from that

API. The vision was to use INSERT OR REPLACE or INSERT OR IGNORE statements to be able to merge content into the table. However, FTS3 and FTS4 tables ignore all constraints, as noted above, which prevents the conflict resolution options (e.g., OR REPLACE) from working. Hence, rather than manually sifting through to find if there is an existing row or not for a given ID value, this sample simply gets rid of all existing rows. A production-grade app would likely apply a more sophisticated algorithm.

Querying a Full-Text Indexed Table

While you can query a full-text indexed table using normal SELECT statements, usually the point is to apply the MATCH operator, as is seen in the loadQuestions() method from DatabaseHelper:

```
Cursor loadQuestions(Context app, String match) {
  SQLiteDatabase db=getDb(app);

  if (TextUtils.isEmpty(match)) {
    return(db.rawQuery("SELECT * FROM questions ORDER BY creationDate DESC",
                       null));
  }

  String[] args={ match };

  return(db.rawQuery("SELECT * FROM questions WHERE title "
                     +"MATCH ? ORDER BY creationDate DESC", args));
}
```

The MATCH operator supports a wide range of query structures, including:

- Keyword matches (e.g., Android)
- Prefix matches (e.g., SQL*)
- Phrase matches (e.g., "open source")
- NEAR, AND, OR, and NOT operators (e.g., sqlite AND database)

The result is the same sort of Cursor that you would get from a regular SELECT statement against a non-full-text-indexed table.

Some Notes About the Rest of the Sample App

As noted previously, this sample app is a revised version of the Stack Overflow questions list from the chapter on Internet access. It is specifically derived from the Picasso version of the sample. However, this version is designed to allow the user to full-text search the downloaded question data (e.g., title), above and beyond just seeing the list of latest questions.

This, in turn, requires a few more changes than those outlined so far. The following sections outline some of the highlights.

Adding a ModelFragment

The original sample had a very simple data model: a list of questions retrieved via Retrofit. Hence, the sample did not include much in the way of model management.

The FTS sample needs a database, which implies more local disk I/O that we are responsible for, which in turn leads us in the direction of implementing a model fragment (`ModelFragment`), much as the tutorials and a few other samples do:

```
package com.commonsware.android.fts;

import android.app.Activity;
import android.app.Fragment;
import android.content.Context;
import android.database.Cursor;
import android.os.Bundle;
import android.util.Log;
import de.greenrobot.event.EventBus;
import retrofit.RestAdapter;

public class ModelFragment extends Fragment {
  private Context app=null;

  @Override
  public void onCreate(Bundle state) {
    super.onCreate(state);

    setRetainInstance(true);
  }

  @Override
  public void onAttach(Activity host) {
    super.onAttach(host);

    EventBus.getDefault().register(this);

    if (app==null) {
      app=host.getApplicationContext();
      new FetchQuestionsThread().start();
    }
  }

  @Override
  public void onDetach() {
    EventBus.getDefault().unregister(this);

    super.onDetach();
  }

  public void onEventBackgroundThread(SearchRequestedEvent event) {
    try {
      Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, event.match);

      EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(),
          "Exception searching database", e);
    }
  }

  class FetchQuestionsThread extends Thread {
    @Override
    public void run() {
      RestAdapter restAdapter=
          new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
              .build();
      StackOverflowInterface so=
          restAdapter.create(StackOverflowInterface.class);

      SOQuestions questions=so.questions("android");

      try {
        DatabaseHelper
            .getInstance(app)
            .insertQuestions(app, questions.items);
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception populating database", e);
      }

      try {
        Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, null);

        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception populating database", e);
      }
    }
  }
}
```

In `onCreate()`, we mark this fragment as retained, as that is key to the model fragment pattern, so the fragment retains the model data across configuration changes.

In `onAttach()`, we register for the greenrobot EventBus, plus kick off a `FetchQuestionsThread` if we have not done so already (i.e., this is the first `onAttach()` call we have received). `onDetach()` unregisters us from the event bus.

FetchQuestionsThread, in turn, uses Retrofit to download the questions from Stack Overflow, then uses DatabaseHelper to insert the questions into the FTS-enabled database table, then uses the DatabaseHelper again to retrieve all existing questions in the form of a Cursor, which it wraps in a ModelLoadedEvent and posts to the EventBus. This time, though, it posts it as a sticky event.

That sticky event is consumed by a revised version of the QuestionsFragment, in its onEventMainThread() method:

```
public void onEventMainThread(ModelLoadedEvent event) {
  ((SimpleCursorAdapter)getListAdapter()).changeCursor(event.model);

  if (sv!=null) {
    sv.setEnabled(true);
  }
}
```

But because this is a sticky event, we will get this event both when it is raised (because the data is loaded) and any time thereafter when the fragment registers with the EventBus. This allows QuestionsFragment to *not* be retained, as it will get back the bulk of its model data automatically from greenrobot's EventBus.

QuestionsFragment also is modified from the Picasso sample to deal with the fact that its model data is now a Cursor, so it uses SimpleCursorAdapter to populate the list. To handle loading avatar images from the URLs, QuestionsFragment adds a QuestionBinder implementation of ViewBinder to the SimpleCursorAdapter, where QuestionBinder handles the Picasso logic from before:

```
private class QuestionBinder implements SimpleCursorAdapter.ViewBinder {
  int size;

  QuestionBinder() {
    size=getActivity()
            .getResources()
            .getDimensionPixelSize(R.dimen.icon);
  }

  @Override
  public boolean setViewValue (View view, Cursor cursor, int columnIndex) {
    switch (view.getId()) {
      case R.id.title:
        ((TextView)view).setText(Html.fromHtml(cursor.getString(columnIndex)));

        return(true);

      case R.id.icon:
        Picasso.with(getActivity()).load(cursor.getString(columnIndex))
            .resize(size, size).centerCrop()
            .placeholder(R.drawable.owner_placeholder)
            .error(R.drawable.owner_error).into((ImageView)view);
        return(true);
    }

    return(false);
  }
}
```

The main activity (`MainActivity`) sets up the `ModelFragment` in `onCreate()`, at least when one does not already exist due to a configuration change:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
    getFragmentManager().beginTransaction()
                        .add(android.R.id.content,
                             new QuestionsFragment()).commit();
  }

  model=(ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

  if (model==null) {
    model=new ModelFragment();
    getFragmentManager().beginTransaction().add(model, MODEL).commit();
  }
}
```

This description, though, has skipped over the `onEventBackgroundThread()` method on the `ModelFragment`, which we will get to later in this overview.

Adding a SearchView

As is covered in the chapter on advanced action bar techniques, a `SearchView` can be used to provide the standard "magnifying glass" search icon in the action bar. When tapped, the action bar item expands into a field where the user can type something, which our code can then receive and use to update the UI. In the `SearchView` sample from the action bar chapter, we saw using a `SearchView` for filtering. This time, we will use a `SearchView` for searching.

For a search, we need to know when the user is done typing, which is usually done by the user clicking a submit button. Hence, our code to configure the `SearchView` (a `configureSearchView()` method in `QuestionsFragment`) calls `setSubmitButtonEnabled(true)`:

```
private void configureSearchView(Menu menu) {
  MenuItem search=menu.findItem(R.id.search);
  search.setOnActionExpandListener(this);
  sv=(SearchView)search.getActionView();
  sv.setOnQueryTextListener(this);
  sv.setSubmitButtonEnabled(true);
  sv.setIconifiedByDefault(true);

  if (initialQuery != null) {
    sv.setIconified(false);
    search.expandActionView();
    sv.setQuery(initialQuery, true);
  }
}
```

This, in turn, means that we need to pay attention to `onQueryTextSubmit()` in our `SearchView.OnQueryTextListener` implementation. That interface is implemented on `QuestionsFragment` itself, and delegates its work to a `doSearch()` method:

```
@Override
public boolean onQueryTextSubmit(String query) {
  doSearch(query);

  return(true);
}
```

That method, in turn, confirms that the search is different than the last one we did (so we do not waste time running the search again), disables the `SearchView`, and posts a `SearchRequestedEvent` on the `EventBus` with the user's search string:

```
private void doSearch(String match) {
  if (!match.equals(lastQuery)) {
    lastQuery=match;

    if (sv != null) {
      sv.setEnabled(false);
    }

    EventBus.getDefault().post(new SearchRequestedEvent(match));
  }
}
```

That event is picked up by `onEventBackgroundThread()` on `ModelFragment`. The method name `onEventBackgroundThread()` means that the event will be delivered to us on an EventBus-supplied background thread, so we can perform database I/O. In it, we call `loadQuestions()` on the `DatabaseHelper` to perform the search, and post another sticky `ModelLoadedEvent` to update the UI with the search results and re-enable the `SearchView`:

```
public void onEventBackgroundThread(SearchRequestedEvent event) {
  try {
    Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, event.match);
```

```
      EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(),
          "Exception searching database", e);
    }
  }
```

When the user clears the `SearchView`, such as by pressing the BACK button a few times, the `onMenuItemActionCollapse()` method of `QuestionsFragment` calls a `clearSearch()` method:

```
  @Override
  public boolean onMenuItemActionCollapse(MenuItem item) {
    clearSearch();

    return(true);
  }
```

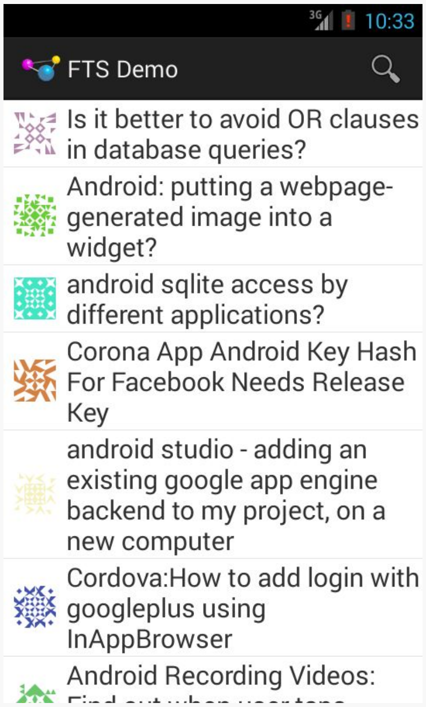
That `clearSearch()` method simply posts another `SearchRequestedEvent`, this time to load a fresh roster of all questions:

```
  private void clearSearch() {
    if (lastQuery!=null) {
      lastQuery=null;

      sv.setEnabled(false);
      EventBus.getDefault().post(new SearchRequestedEvent(null));
    }
  }
```

The Results

When you run the app, you are initially presented with the list of questions pulled from the Stack Exchange API:



Is it better to avoid OR clauses in database queries?

Android: putting a webpage-generated image into a widget?

android sqlite access by different applications?

Corona App Android Key Hash For Facebook Needs Release Key

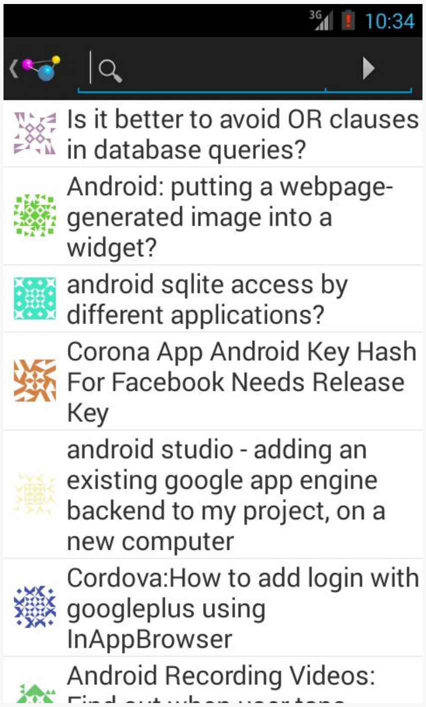
android studio - adding an existing google app engine backend to my project, on a new computer

Cordova:How to add login with googleplus using InAppBrowser

Android Recording Videos:

Figure 662: FTS Demo, As Initially Launched

Tapping on the `SearchView` opens it up, as normal, though this time with the "submit" button (the rightward-pointing arrowhead):



Is it better to avoid OR clauses in database queries?

Android: putting a webpage-generated image into a widget?

android sqlite access by different applications?

Corona App Android Key Hash For Facebook Needs Release Key

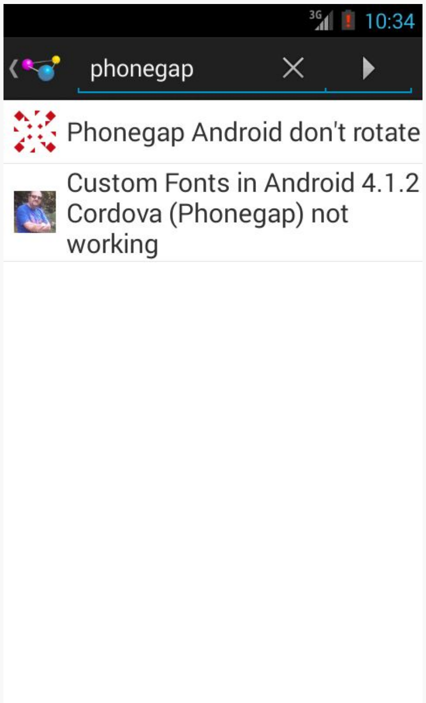
android studio - adding an existing google app engine backend to my project, on a new computer

Cordova:How to add login with googleplus using InAppBrowser

Android Recording Videos:

Figure 663: FTS Demo, with Open SearchView

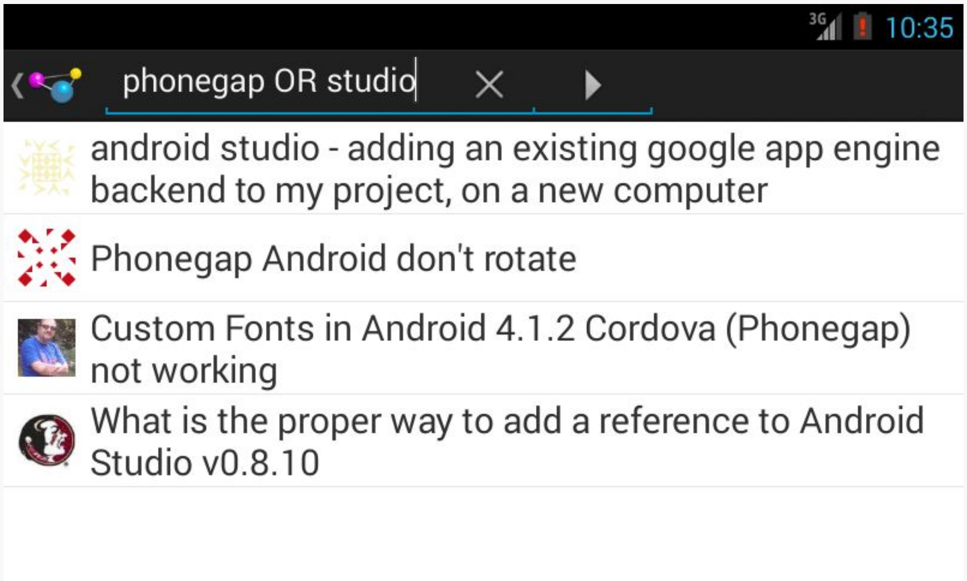
Typing in a search, then tapping the “submit” button, will reload the list with those questions that match the search criteria in the question title:



Phonegap Android don't rotate

Custom Fonts in Android 4.1.2 Cordova (Phonegap) not working

Figure 664: FTS Demo, Showing Basic Search



android studio - adding an existing google app engine backend to my project, on a new computer

Phonegap Android don't rotate

Custom Fonts in Android 4.1.2 Cordova (Phonegap) not working

What is the proper way to add a reference to Android Studio v0.8.10

Figure 665: FTS Demo, Showing Boolean Search

Using the BACK button to get out of the `SearchView` reloads the full list of questions.

Getting Snippets

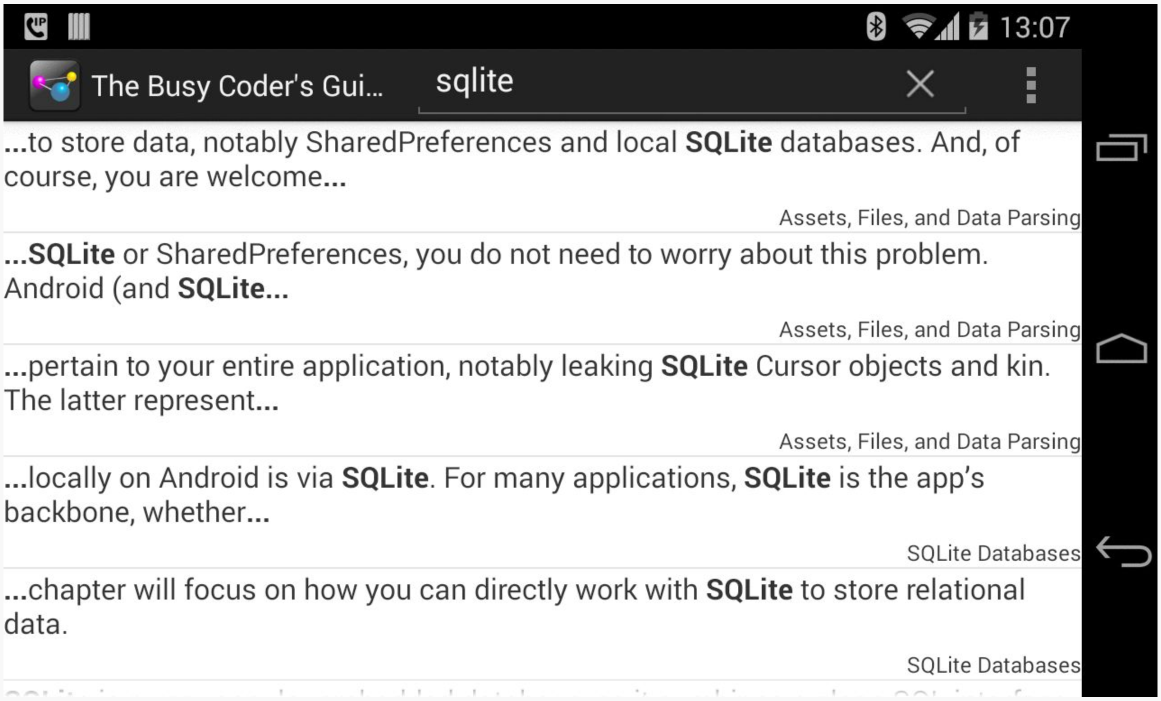
Usually, the content that is being indexed is a lot longer than Stack Overflow question titles. For example, it might be chapters in a book on Android application development. In that case, it would be useful to not only find out what chapters match the search expression, but what the prose is around the search expression, to help the user determine which search results are likely to be useful.

The APK edition of this book stores each paragraph and bullet as a separate entry in a SQLite database in an FTS3-enabled table. The query used when the reader types in a search expression in the app's `SearchView` is:

```
SELECT ROWID as _id, file, node, snippet(booksearch) AS snippet FROM
booksearch WHERE prose MATCH ?
```

Here, `file` and `node` are used to identify where this passage came from within the book, so when the user taps on a search result in the list, the book reader can jump to that particular location.

The `snippet()` auxiliary function will return, as the name suggests, a snippet of the indexed text, with the search match highlighted. It takes the name of the table `booksearch` as a mandatory parameter. It also supports optional parameters for what to bracket the search match with (defaults to `<b>` and `</b>`) and what to use for an ellipsis for extended prose segments (defaults to `<b>...</b>`). In the case of this query, the default formatting of the result is used. The resulting text can then be fed into `Html.fromHtml()` to generate the text for the `ListView` row, showing the search match within the snippet highlighted in bold:



...to store data, notably SharedPreferences and local **SQLite** databases. And, of course, you are welcome...

Assets, Files, and Data Parsing

...**SQLite** or SharedPreferences, you do not need to worry about this problem. Android (and **SQLite...**

SQLite Databases

Figure 666: This Book's Reader App, Showing Search Results

The app also shows the name of the chapter in the lower-right corner of each row, to help provide larger context for where this snippet comes from.

Data Backup

Backing up your PC used to be essential. To some extent, it still is, but as more and more stuff moves to "the cloud", local machine backups become less and less important.

Backing up mobile devices historically has been an afterthought, as a lot of what people use these devices for are gateways to Internet-hosted content and services. However, as more and more stuff becomes local to the device — for disconnected operation, for example — the greater the need for backing up that local data.

Android does not have a full-device backup as part of the OS. It does have some hooks that Google advertises as being "backup", but IT professionals would not consider Google's definition to match their own for "backup". And, what hooks there are exist at the level of an app, not the device, providing opportunity — and requirements — for developers to tailor what gets backed up and, to a lesser extent, how it gets backed up.

This chapter will explore the steps to back up your app's data, with and without Google's assistance.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on file access and Internet access.

Having read the chapters on SSL and SQLCipher for Android are not required but may prove to be useful background for some of the side topics in this chapter.

First, Some Terminology

One key concept when it comes to backups is what, exactly, we are backing up. The general rule is that you focus your backup regimen on the "system of record". This is the one and only system that has the master copy of the data. While it may be one "system", that "system" may be rather complex (e.g., cluster of database servers). However, anything else outside of that system — such as clients for those servers — are not part of the system of record. While they may have some data that is also held by the system of record, that data is considered to be a cached local copy; the system of record has the "real" copy of the data.

Differing Definitions of "Backup"

The problem is that we toss around the term "backup" as though there is a universal canonical definition for that term. Hence, what Google will tell users is "backup" will not necessarily line up with what an IT department will consider "backup" to mean.

What Google Thinks "Backup" Means

Google's focus is on the cloud. Therefore, their focus is on apps using data resident in the cloud, with some servers forming the system of record. Google (presumably) does some sort of backup for their own systems of record, for their own Internet-based services, and Google assumes that other firms are doing the same.

The side-effect of this definition, though, is that Google does not view an app as having much in the way of local data that needs to be backed up. Cached data can always be reloaded from the system of record, after all. What Google expects needs to be backed up will be local preferences and perhaps authentication or authorization credentials for working with the system of record. This dataset is small and does not necessarily change all that often.

Because the dataset does not change that often, Google only really cares about restoring that data in case of a total device replacement. In other words, if your phone gets run over by a bakery truck, and you wind up replacing that phone with another Android phone, Google is interested in making sure that your old phone's apps get restored along with the old phone's last backup of the tiny dataset. After that, you are on your own. In particular, because the dataset does not change that often and does not have much in the way of critical data, Google is not concerned with allowing users to restore app data from backup for any reason *other* than replacing the device outright. In other words, Google is only concerned with disaster recovery.

Google does not offer any configurability for where backups themselves are stored. Whatever Google backs up, Google stores where Google wants. Terms of service and related agreements give Google — at least in Google's eyes — the right to do pretty much anything they want with that data. While they will tout the fact that Android 6.0+ backups are stored in an encrypted fashion, they fail to note that Google — not the developer, not the user – holds the encryption keys. Thus, the security offered by this encryption is nominal, perhaps slowing down somebody who breaks into Google's network, but otherwise not preventing anyone from accessing the data.

Also, there is a 25MB data cap on the size of the backup, so if your app might have data in excess of that, you need to handle backups yourself.

Finally, the author of this book cannot get Google's backup system to work on production hardware, as will be explained a bit more later in this chapter.

What IT Thinks "Backup" Means

Apps may well be the system of record for the data that they work with. There is no requirement that all apps be front-ends for some server, any more than there is a requirement that all desktop OS apps be front-ends for some server. There may be plenty of business or technical reasons why an app will be the system of record for its data, either all of the time or in between specific sync operations with some central data store.

As a result, an IT department will recognize that apps need a much more robust backup and restoration service, one that takes into account conventional IT backup concepts.

Most IT-grade backup regimens have the notion of "backup aging". Rather than Google's approach of considering only one backup to be relevant, an IT department will maintain a series of backups (e.g., 14 days of nightly backups, plus 3 months of weekly backups, plus 5 years of monthly backups), to be able to handle data that might be lost, but where that loss is not detected for some time.

Most IT-grade backups regimens allow data to be restored, in part or completely, at any point, not just in case a device is stepped on by an elephant or otherwise destroyed. Disaster recovery is a *scenario* of a backup regimen, not the sole objective.

IT departments also tend to be very concerned about where their business data goes. The idea that the data should be available, unencrypted, to arbitrary third parties would be an anathema. Business data should be backed up on by IT-supplied technology on IT-supplied backup media, employing whatever security the IT department thinks is necessary.

Suffice it to say, Google's approach to "backup" does not align well with what an IT department will want.

What Your Legal Counsel Thinks "Backup" Means

Legal counsel, at some point, should be brought into the discussion of backups, as, for better or worse, there are legal risks involved in backups.

Particularly with Google-style, send-the-data-to-a-third-party backups, you need to ensure that this will not get you in legal trouble. From European Union privacy laws to HIPAA in the US, there are plenty of laws that prohibit the careless distribution of data.

Beyond that, legal counsel will be worried about "the Ashley Madison scenario". A firm's IT department will be responsible for ensuring that their servers are not hacked into. However, once you start passing data to third parties, now you are at risk of *those* servers getting hacked into. Legal counsel can advise you on what your legal exposure is, in terms of potential lawsuits from people whose data might get leaked by these sorts of attacks.

Implementing IT-Style Backup

So, if we want to add backup and restore capability to our app, what is needed? To explore that, we will use the `Backup/BackupClient` sample project as an illustration. This is a clone of a sample that originally appeared in the chapter on files. We have a three-tab `ViewPager`, with a large `EditText` widget in each tab. The three tabs differ in where they persist their data:

- `getFilesDir()`
- `getExternalFilesDir()`

- DIRECTORY_DOCUMENTS — the user's Documents/ directory on API Level 19+ devices

This revised sample adds backup-and-restore functionality to this app.

The app also has one other change: it stores the most-recently-visited tab in SharedPreferences. To that end, MainActivity has a PrefsLoadThread static inner class that asynchronously loads the SharedPreferences, then delivers them via greenrobot's EventBus:

```
private static class PrefsLoadThread extends Thread {
  private final Context ctxt;

  PrefsLoadThread(Context ctxt) {
    this.ctxt=ctxt.getApplicationContext();
  }

  @Override
  public void run() {
    SharedPreferences prefs=
      PreferenceManager.getDefaultSharedPreferences(ctxt);
    PrefsLoadedEvent event=new PrefsLoadedEvent(prefs);

    EventBus.getDefault().post(event);
  }
}

private static class PrefsLoadedEvent {
  private final SharedPreferences prefs;

  PrefsLoadedEvent(SharedPreferences prefs) {
    this.prefs=prefs;
  }
}
```

MainActivity picks up this event in one version of onEventMainThread(), the one that takes a PrefsLoadedEvent as a parameter, and updates the current page of the ViewPager (named pager):

```
public void onEventMainThread(PrefsLoadedEvent event) {
  this.prefs=event.prefs;

  int lastVisited=prefs.getInt(PREF_LAST_VISITED, -1);

  if (lastVisited>-1) {
    pager.setCurrentItem(lastVisited);
  }
}
```

The PrefsLoadThread is kicked off in onResume(), and the PREF_LAST_VISITED value is saved in onPause(), along with the registration and unregistration from the event bus:

```
@Override
protected void onResume() {
  super.onResume();

  EventBus.getDefault().register(this);

  if (prefs==null) {
    new PrefsLoadThread(this).start();
  }
}

@Override
protected void onPause() {
  EventBus.getDefault().unregister(this);

  if (prefs!=null) {
    prefs
      .edit()
      .putInt(PREF_LAST_VISITED, pager.getCurrentItem())
      .apply();
  }

  super.onPause();
}
```

The net effect is that we retain the last-visited tab across invocations of MainActivity. This forms part of the data that we would like to back up.

Choosing the Backup Scope

The first question is: what exactly are we backing up? Files? Databases? SharedPreferences? Stuff that is out in common areas, like top-level directories on external storage (e.g., DIRECTORY_DOCUMENTS) or the ContactsContract ContentProvider?

Typically, an individual app will focus on backing up only that app's data, which would exclude the common areas from consideration. That does not mean that you *can't* back up common data, but it makes restoration a bit more challenging, as you do not want to overwrite changes to that data that the user made from another app.

In BackupClient, we are backing up:

- the contents of getFilesDir(), which will hold onto one of our tabs' contents

- the contents of `getExternalFilesDir()`, which will hold onto another of our tabs' contents
- some of the contents of the directory that holds the `SharedPreferences` for the app, which will pick up the preference value we are using for the last-visited tab

Notably, we are not backing up the file out on shared storage (the "Public" tab, set to store its data in `Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS)`). Hence, whatever is in that tab will be left alone when we restore the data from the backup.

Choosing a Backup Trigger

The next question is: when are we backing up the data?

There are any number of possibilities:

- A push message, such as through GCM, could request that the app back up its data
- `AlarmManager` or `JobScheduler` could be used to periodically make backups
- You could offer backups on demand, such as through an action bar item

The automated options (push message, `AlarmManager`, `JobScheduler`) are great, so users do not forget to make a backup. On the other hand, there is the risk that the user is using the app at the time the automated backup is supposed to happen, which means you will need some additional logic to ensure that you postpone that backup until a quieter time. It is difficult to back up data that is actively in use.

The `BackupClient` sample will settle for a simple manual trigger, via a "Backup" action bar item in the main activity. We also have a "Restore" action bar item, to request to restore the data from a backup. So, `MainActivity` will load in a menu resource that contains these two options:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/backup"
    android:icon="@drawable/ic_backup_white_24dp"
    android:title="@string/menu_backup"/>
  <item
    android:id="@+id/restore"
    android:icon="@drawable/ic_restore_white_24dp"
    android:title="@string/menu_restore"/>
</menu>
```

It uses a pair of icons culled from Google's material design icon set.

That resource is inflated in `onCreateOptionsMenu()`. If the user chooses the "Backup" option, we start a `BackupService` to do the work:

```
  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.backup) {
      startService(new Intent(this, BackupService.class));

      return(true);
    }
    else if (item.getItemId()==R.id.restore) {
      startActivity(new Intent(this, RestoreRosterActivity.class));

      return(true);
    }

    return(super.onOptionsItemSelected(item));
  }
```

We will get into the restore scenario a bit later in this chapter.

Generating the Dataset

Next, we need to actually collect the data to be backed up and package it in some form to send to a server to serve as the backup dataset.

There are any number of ways to package this sort of data, but a ZIP file seems like a likely candidate:

- It is fairly easy to work with on Android
- It is fairly easy to work with on servers that might need to unpack the data
- It is fairly easy to examine using desktop tools, for development, diagnostics, etc.

It is the job of the `BackupService` to create a ZIP file of our desired data, then send that ZIP file to a backup server.

BackupService itself is an IntentService, as this sort of work is a nice "fire-and-forget" sort of request, where we no longer need the service once the work is done. For a small dataset, with a user-triggered backup, a regular IntentService like this is fine. If, however, you have a lot of data (so backing up and uploading the data may take a while), or if you plan on doing backups without the user around (e.g., triggered by AlarmManager), you will need to consider how to work a WakeLock into the mix, perhaps using a WakefulIntentService as is described in the chapter on AlarmManager.

In onHandleIntent(), we orchestrate the major steps in this process:

```
@Override
protected void onHandleIntent(Intent intent) {
  try {
    File backup=buildBackup();

    uploadBackup(backup);
    backup.delete();

    EventBus.getDefault().post(new BackupCompletedEvent());
  }
  catch (IOException e) {
    Log.e(getClass().getSimpleName(),
      "Exception creating ZIP file", e);
    EventBus.getDefault().post(new BackupFailedEvent());
  }
}
```

We:

- Call a buildBackup() method that creates our backup dataset
- Call an uploadBackup() method to send the dataset to some backup server
- Delete the local backup when that is done, as we no longer need it
- Raise events on an event bus for the UI layer's use, for when a backup succeeds or fails

Those events can then trigger UI responses. In the case of this trivial sample app, they just result in Toast messages to the user:

```
public void onEventMainThread(BackupService.BackupCompletedEvent event) {
  Toast
    .makeText(this, R.string.msg_backup_completed, Toast.LENGTH_LONG)
    .show();
}

public void onEventMainThread(BackupService.BackupFailedEvent event) {
  Toast
    .makeText(this, R.string.msg_backup_failed, Toast.LENGTH_LONG)
```

```
      .show();
  }
```

A production-grade app would do something more sophisticated, particularly for error messages, given that a `Toast` is ephemeral, and so the user might not see it.

`buildBackup()` is responsible for creating a file that contains our desired dataset and returning the `File` object pointing to that file:

```
  private File buildBackup() throws IOException {
    File zipFile=new File(getCacheDir(), BACKUP_FILENAME);

    if (zipFile.exists()) {
      zipFile.delete();
    }

    FileOutputStream fos=new FileOutputStream(zipFile);
    ZipOutputStream zos=new ZipOutputStream(fos);

    zipDir(ZIP_PREFIX_FILES, getFilesDir(), zos);
    zipDir(ZIP_PREFIX_PREFS, getSharedPrefsDir(this), zos);
    zipDir(ZIP_PREFIX_EXTERNAL, getExternalFilesDir(null), zos);
    zos.flush();
    fos.getFD().sync();
    zos.close();

    return(zipFile);
  }
```

We put the backup ZIP file in internal storage cache (`getCacheDir()`), as that is not something that we are backing up, and therefore we do not need to worry about somehow trying to back up the backup file itself.

We then call `zipDir()` three times, one for each directory of data to be backed up. Two of the three locations have SDK-supplied methods to get the `File` object pointing at those directories: `getFilesDir()` and `getExternalFilesDir()`. Unfortunately, the SDK does not provide any direct method that returns a `File` pointing at the directory for `SharedPreferences`. So, we have to hack one ourselves, in the form of `getSharedPrefsDir()`:

```
  static File getSharedPrefsDir(Context ctxt) {
    return(new File(new File(ctxt.getApplicationInfo().dataDir),
      "shared_prefs"));
  }
```

`getApplicationInfo()` returns the `ApplicationInfo` object describing our app. That has a `dataDir` field that points to *all* of our internal storage (whereas `getFilesDir()` points to a subdirectory off of `dataDir`). The `SharedPreferences` are stored in XML files in a `shared_prefs/` directory off of the location pointed to by the dataDir field. This is not an ideal solution, as in theory the SharedPreferences storage location could move. However, this code should work for all API levels from 1 through 23, and therefore it is reasonably likely that it will hold up over time.

zipDir() not only takes the File of data to be backed up and a ZipOutputStream representing where to package the data, but it also takes a path prefix. ZIP files do not really have a directory structure; that structure is faked based on path-style names associated with each entry. The prefix is added to each of those names, giving the effect of putting each directory's contents into a separate "directory" within the ZIP archive. Those three prefixes are defined as simple String constants:

```
static final String ZIP_PREFIX_FILES="files/";
static final String ZIP_PREFIX_PREFS="shared_prefs/";
static final String ZIP_PREFIX_EXTERNAL="external/";
```

zipDir() itself (mostly) is a typical recursive put-the-files-in-the-archive method:

```
private void zipDir(String basePath, File dir,
                    ZipOutputStream zos) throws IOException {
  byte[] buf=new byte[16384];

  if (dir.listFiles()!=null) {
    for (File file : dir.listFiles()) {
      if (file.isDirectory()) {
        String path=basePath+file.getName()+"/";

        zos.putNextEntry(new ZipEntry(path));
        zipDir(path, file, zos);
        zos.closeEntry();
      }
      else if (!file.getName().equals(BACKUP_PREFS_FILENAME)) {
        FileInputStream fin=new FileInputStream(file);
        int length;

        zos.putNextEntry(
          new ZipEntry(basePath+file.getName()));

        while ((length=fin.read(buf))>0) {
          zos.write(buf, 0, length);
        }

        zos.closeEntry();
        fin.close();
      }
    }
  }
}
```

The one wrinkle is that we filter out files with a particular name, denoted by the BACKUP_PREFS_FILENAME constant:

```
private static final String BACKUP_PREFS_FILENAME=
  "com.commonsware.android.backup.BackupService.xml";
```

We will explore what this file is, and why we are not backing it up, later in this chapter.

This backup approach has its flaws, in the interests of keeping the example simple:

- The UI layer is not saving all in-flight data before doing the backup. Hence, any changes in the current tab, since we moved to that tab, are not saved to disk or backed up. And, since we only save what the current tab is in `onPause()`, that too has not been adjusted since our activity moved to the foreground, and so it may be out of date. A production-grade app will need to decide what data that has not been saved through ordinary means should be saved prior to a manual backup, assuming that the app has a manual backup option in the first place.
- The UI layer is not preventing the user from changing data that is being backed up while the backup is happening. In this sample app, the data to be backed up is small enough that it will probably happen quickly enough to not be a problem. A production-grade app, though, should take steps to prevent data entry (though perhaps not navigation through the app) while the backup is going on. Any such steps, though, need to take into account the possibility that the backup may fail — we do not want a failed backup to block the user from working in the app for hours.

Transmitting the Dataset

Given the data to be backed up in a nice convenient package, we need to get that dataset off the device and someplace safe, where we can later download and restore it if needed. There are any number of possible solutions here, including many existing public Web services (Dropbox, Amazon's AWS S3, Google Drive, etc.). If you are only worried about manual backups, you could even consider using `ACTION_SEND` to send the dataset as an email attachment, though size and content limitations on email attachments may make this impractical for many users.

`BackupService` works with some implementation of a particular REST-style API for backing up and restoring the data. This API is fairly lightweight, light enough that it can be implemented in ~70 lines of Ruby code, as will be seen later in this chapter. You could implement the same sort of API in any number of Web frameworks.

For backing up data, there are two REST operations that we need to perform:

- We need to create a new backup entry, via an HTTP POST request to /api/backups on the backup server
- We need to upload the dataset itself, via an HTTP PUT request to /api/backups/.../dataset on the backup server, where the ... is a backup ID that we get from the response to the original POST request

To implement the client side, BackupService employs the OkHttp library profiled in the chapter on Internet access. Specifically, uploadBackup() does both of the HTTP requests necessary to back up the data, given the File pointing to the ZIP archive that is our dataset:

```
private void uploadBackup(File backup) throws IOException {
  Request request=new Request.Builder()
    .url(URL_CREATE_BACKUP)
    .post(RequestBody.create(JSON, "{}"))
    .build();
  Response response=OKHTTP_CLIENT.newCall(request).execute();

  if (response.code()==201) {
    String backupURL=response.header("Location");

    request=new Request.Builder()
      .url(backupURL+RESOURCE_DATASET)
      .put(RequestBody.create(ZIP, backup))
      .build();
    response=OKHTTP_CLIENT.newCall(request).execute();

    if (response.code()==201) {
      String datasetURL=response.header("Location");
      SharedPreferences prefs=
        getSharedPreferences(getClass().getName(),
          Context.MODE_PRIVATE);

      prefs
        .edit()
        .putString(PREF_LAST_BACKUP_DATASET, datasetURL)
        .commit();
    }
    else {
      Log.e(getClass().getSimpleName(),
        "Unsuccessful request to upload backup");
    }
  }
  else {
    Log.e(getClass().getSimpleName(),
      "Unsuccessful request to create backup");
  }
}
```

We create an OkHttp `Request.Builder` representing our `POST` request. The URL is defined as a constant, `URL_CREATE_BACKUP`:

```
private static final String URL_CREATE_BACKUP=
  BuildConfig.URL_SERVER+"/api/backups";
```

This, in turn, is built up from the fixed REST endpoint path (`/api/backups`), with the rest of the URL coming from `BuildConfig.URL_SERVER`. This is defined out in our `build.gradle` file, allowing us to have different backup server locations based upon build types (or, in principle, product flavors):

```
buildTypes {
  debug {
      buildConfigField "String", "URL_SERVER", '"http://10.0.2.2:4567"'
  }

  release {
    buildConfigField "String", "URL_SERVER", '"http://10.0.2.2:4567"'
  }
}
```

Here, they happen to both point to the same value at the moment, the IP address that, on an Android emulator, represents `localhost` of your development machine. However, you could easily change the `release` build type to point to some production instance of a backup server.

The body of the `POST` request is a JSON object containing whatever we want, in case we need to provide some sort of identifiers with the backup for server-side use or analysis. In this case, we are passing an empty JSON object (`{}`), using the `JSON` `MediaType` declared as another constant:

```
private static final MediaType JSON=
  MediaType.parse("application/json; charset=utf-8");
```

We then use an instance of an `OkHttpClient` object to perform the request, getting the `Response` synchronously (since we are already on a background thread). If multiple components in your app will all be using OkHttp, the recommendation is to use a singleton instance of `OkHttpClient`, here defined on `BackupService` itself:

```
static final OkHttpClient OKHTTP_CLIENT=new OkHttpClient();
```

The REST protocol to the backup server is that a 201 response code ("Created") means that our backup metadata has been saved and an ID has been generated for our backup. The `Location` header in the response contains a REST URL pointing to the backup itself (`/api/backups/...` for some value of `...`). We then use that to generate the URL for the dataset (`/api/backups/.../dataset`), and perform a `PUT` request for the dataset, using the `ZIP` `MediaType` defined as yet another constant:

```
  private static final MediaType ZIP=
    MediaType.parse("application/zip");
```

Once again, a 201 response indicates that our resource was created, and the `Location` header provides the URL for the backup dataset. We stuff that URL in a `SharedPreferences` object unique to `BackupService`, under a `PREF_LAST_BACKUP_DATASET` key. We will use that — at least, in theory – if we are restored from a Google disaster recovery process. We will explore that more later in the chapter.

If we get an unexpected response from the server, the sample app logs a message to LogCat and otherwise quietly fails. A production-grade app would handle these scenarios better, including informing the user about the problem.

Of course, a production-grade backup implementation might want more than what we have here, such as better security. For apps being publicly distributed through the Play Store or similar channels, you may want to offer multiple ways of saving off the backup, through some common API with multiple implementations. That way, users can choose whether to back up data via a private server or a public one (e.g., Amazon S3) or some other means that you offer.

Initiating a Restore

Unfortunately, on occasion, the user may have a need to restore the app's data from a backup.

There are three primary possible triggers for this work to be done:

- The user could ask for data to be restored manually, through some option in the app's UI, such as an action bar item
- The request to restore the data could be pushed to the device, such as through GCM, perhaps in response to an IT department staff member initiating a remote restore
- The user could have gotten a new device, and if the user had chosen automatic disaster recovery "backups" on their old device, they could have our app and its data automatically restored onto the new device

There is also the question of *which* backup to restore. Frequently, the user will want the most recent backup, but that is not always the case. The user might realize that the data has been wrong for days and needs to restore an earlier backup than the most recent one.

To that end, the BackupClient demo app will allow the user to manually request that data be restored, via a "Restore" action bar item. We will fetch a list of available backups from the backup server, so the user can choose what backup to restore from.

The "Restore" action bar item in MainActivity simply launches a RestoreRosterActivity, to allow the user to choose the backup to restore. That activity merely sets up a dynamic fragment, RestoreRosterFragment, in onCreate():

```
package com.commonsware.android.backup;

import android.app.Activity;
import android.os.Bundle;

public class RestoreRosterActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager()
      .findFragmentById(android.R.id.content)==null) {
      getFragmentManager().beginTransaction()
        .add(android.R.id.content,
          new RestoreRosterFragment()).commit();
    }
  }
}
```

RestoreRosterFragment has fairly basic implementations of the onCreate(), onResume(), and onPause() lifecycle methods, to mark the fragment as being a retained fragment, plus to register and unregister from the event bus:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
  }

  @Override
  public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);
  }

  @Override
  public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
  }
```

RestoreRosterFragment is a ListFragment, so the ListView will be set up automatically in the inherited implementation of onCreateView(). In onViewCreated(), we can kick off a REST request to pull down the list of backups from the backup server. This client assumes that the REST server has an /api/backups endpoint that will return a JSON roster of the available backups, so we can use OkHttp to perform the GET request for that data:

```
  @Override
  public void onViewCreated(View view,
                            Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    Request request=new Request.Builder()
      .url(URL_BACKUPS)
      .build();

    BackupService.OKHTTP_CLIENT.newCall(request).enqueue(this);
  }
```

Here, we use the same OkHttpClient instance as BackupService uses — since this is a static data member that is automatically initialized, it does not matter whether or not we have used BackupService already in this process. The endpoint URL is found in the URL_BACKUPS constant:

```
  private static final String URL_BACKUPS=
    BuildConfig.URL_SERVER+"/api/backups";
```

Since this is being driven by the UI, and we are calling OkHttp from the main application thread, we use enqueue() instead of execute(), to schedule the request to be performed on a background thread supplied and managed by OkHttp. RestoreRosterFragment implements the required Callback interface needed by enqueue(). That interface, in turn, requires two methods. One is onFailure(), to be called if there is a problem in executing the HTTP request. Here, we just inform the user about the problem in a Toast, though a production-grade app would do something more sophisticated:

```
  @Override
  public void onFailure(Request request, IOException e) {
    Toast.makeText(getActivity(), R.string.msg_roster_failure,
      Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(),
      "Exception retrieving backup roster", e);
  }
```

The more important method is `onResponse()`, called when we get a valid-looking response from the server:

```
  @Override
  public void onResponse(Response response) throws IOException {
    Gson gson=new GsonBuilder()
      .setDateFormat("yyyy-MM-dd'T'HH:mm:ssZZZZZ")
      .create();

    Type listType=new TypeToken<List<BackupMetadata>>() {}.getType();

    EventBus
      .getDefault()
      .post(
        gson.fromJson(response.body().charStream(), listType));
  }
```

This sample *could* use Retrofit for performing this REST-style `GET` request, in which case Retrofit would work with OkHttp and Google's Gson to parse our response. In this case, we are using OkHttp directly, and so we need to arrange to have Gson parse the response.

To that end, we:

- Create a `Gson` instance through a `GsonBuilder`, teaching it that the JSON data to be mapped to `Date` objects in our results have a particular serialized format
- Create a `Type` object wrapping our expected response: a `List` of `BackupMetadata` objects
- Get the JSON from the response (`response.body().charStream`), and pass that to the `Gson` object for parsing

And, since `onResponse()` is called on a background thread, we use the event bus to deliver that `List` of `BackupMetadata` objects to the fragment itself, so we can pick up that event on the main application thread.

The JSON we get back will be a JSON array containing a list of JSON objects, with each of those objects being mapped to a `BackupMetadata` instance by Gson:

```
package com.commonsware.android.backup;

import java.util.Date;

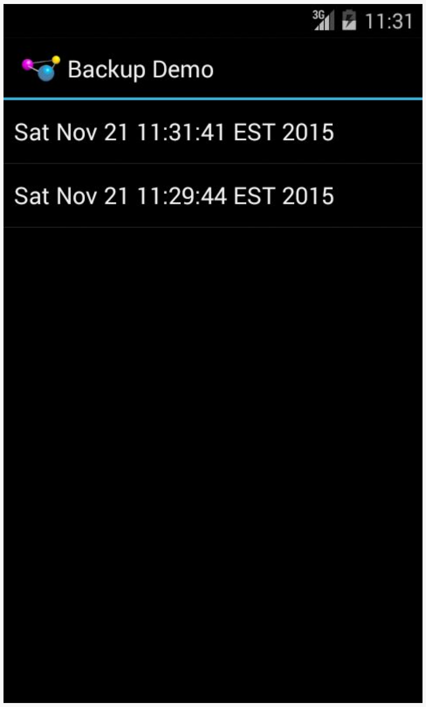
public class BackupMetadata {
  Date timestamp;
  String dataset;

  @Override
  public String toString() {
    return(timestamp.toString());
  }
}
```

RestoreRosterFragment then has an onEventMainThread() method, to pick up the List of BackupMetadata, to wrap that in an ArrayAdapter and put those results in the fragment's ListView:

```
  public void onEventMainThread(List<BackupMetadata> roster) {
    adapter=new ArrayAdapter<BackupMetadata>(getActivity(),
      android.R.layout.simple_list_item_1, roster);

    setListAdapter(adapter);
  }
```



Sat Nov 21 11:31:41 EST 2015

Sat Nov 21 11:29:44 EST 2015

Figure 667: RestoreRosterFragment, Showing Two Backups

Starting the Restore Activity

When the user clicks on an available backup in the ListView, onListItemClick() gets called:

```
  public void onEventMainThread(List<BackupMetadata> roster) {
    adapter=new ArrayAdapter<BackupMetadata>(getActivity(),
      android.R.layout.simple_list_item_1, roster);

    setListAdapter(adapter);
  }
```

The BackupMetadata has a relative URL to the backup's dataset, so we combine that with BuildConfig.URL_SERVER to get a fully-qualified URL. Then, we start up a RestoreProgressActivity, which will be responsible for kicking off the restore and showing some form of progress indicator along the way.

The tricky part with restoring your app's data is that you cannot have any app components running that rely upon that data, as the data will be changing out from underneath those components. In our case, we need to get rid of our MainActivity.

To do that, we attach a few flags to the Intent used to start up the RestoreProgressActivity:

- FLAG_ACTIVITY_NEW_TASK
- FLAG_ACTIVITY_CLEAR_TASK
- FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS

These will get rid of all of our previous activities (including the currently-active RestoreRosterActivity) and will prevent the RestoreProgressActivity from showing up in the overview screen.

RestoreProgressActivity has a simple layout with a large centered ProgressBar:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ProgressBar
    style="@android:style/Widget.ProgressBar.Large"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center"/>
</FrameLayout>
```

In onCreate() of RestoreProgressActivity, in addition to showing that ProgressBar, we kick off a RestoreService to actually download and restore the backup. We are passed the URL to the backup dataset in the Intent used to start

RestoreProgressActivity, and we just pass that same URL along (as a Uri) to the service:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.progress);

  if (savedInstanceState==null) {
    Intent i=
      new Intent(this, RestoreService.class)
        .setData(getIntent().getData());

    startService(i);
  }
}
```

However, we only do that if we are not being recreated after a configuration change, so this only happens on the first invocation of the activity.

RestoreProgressActivity also registers for events on the event bus, using the typical onPause()/onResume() pattern:

```
@Override
protected void onResume() {
  super.onResume();

  EventBus.getDefault().register(this);
}

@Override
protected void onPause() {
  EventBus.getDefault().unregister(this);

  super.onPause();
}
```

Downloading and Restoring the Dataset

Meanwhile, over in RestoreService, we download and unpack the dataset:

```
package com.commonsware.android.backup;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;
import com.squareup.okhttp.Request;
import com.squareup.okhttp.Response;
import java.io.File;
import de.greenrobot.event.EventBus;
import okio.BufferedSink;
import okio.Okio;
```

```
public class RestoreService extends IntentService {
  public RestoreService() {
    super("RestoreService");
  }

  @Override
  protected void onHandleIntent(Intent i) {
    Request request=new Request.Builder()
      .url(i.getData().toString())
      .build();

    try {
      Response response=
        BackupService.OKHTTP_CLIENT.newCall(request).execute();
      File toRestore=new File(getCacheDir(), "backup.zip");

      if (toRestore.exists()) {
        toRestore.delete();
      }

      BufferedSink sink = Okio.buffer(Okio.sink(toRestore));

      sink.writeAll(response.body().source());
      sink.close();

      ZipUtils.unzip(toRestore, getFilesDir(),
        BackupService.ZIP_PREFIX_FILES);
      ZipUtils.unzip(toRestore,
        BackupService.getSharedPrefsDir(this),
        BackupService.ZIP_PREFIX_PREFS);
      ZipUtils.unzip(toRestore, getExternalFilesDir(null),
        BackupService.ZIP_PREFIX_EXTERNAL);

      EventBus.getDefault().post(new RestoreCompletedEvent());
    }
    catch (Exception e) {
      Log.e(getClass().getSimpleName(),
        "Exception restoring backup", e);
      EventBus.getDefault().post(new RestoreFailedEvent());
    }
  }

  static class RestoreCompletedEvent {

  }

  static class RestoreFailedEvent {

  }
}
```

The URL for the dataset is coming in via the `Intent` passed into `onHandleIntent()`. We use that to build the OkHttp `Request`, then do a synchronous call via `execute()` to get the `Response`.

Previous uses of OkHttp in this chapter focused on REST responses, where we could either just use `Location` headers or pass the text of the response over to Gson. Here, we are expecting a ZIP file, and possibly a large one. The right way to get that written to disk (so we can unpack it) is to stream the data down and write that data out to disk, rather than attempting to read everything into memory first.

To that end, we take advantage of the fact that OkHttp itself is built atop Square's Okio library, which offers a nice Java API for handling streams, based on sinks and sources. The recipe for streaming an HTTP response to disk involves:

- Creating a sink for the destination file (in this case, a `backup.zip` file placed in `getCacheDir()`)
- Wrapping that in a `BufferedSink`
- Telling the sink to write everything from the `source()` we get from OkHttp representing the ZIP data
- Closing the sink

At that point, we need to unpack the dataset into the places we got the data from in the first place when we backed it up:

- `getFilesDir()`
- the directory for `SharedPreferences`
- `getExternalFilesDir()`

To that end, we use a slightly modified version of the `ZipUtils` class first referenced in the tutorials. The one used in the tutorials comes from the CWAC-Security library. However, that `ZipUtils` class does not handle two things that we need here:

- Unpacking a subset of the files, from one virtual directory within the ZIP archive
- Restoring them to an already-existing directory without deleting and recreating that directory.

The `BackupClient` project has its own modified version of `ZipUtils` that handles those cases. Beyond that, the `unzip()` method is the same as before, taking:

- The ZIP file to unpack
- The filesystem directory where the unpacked files should go
- The virtual directory within the ZIP archive that we want (as opposed to the entire contents)

When that is done, we post a `RestoreCompletedEvent`. If there is some problem, we post a `RestoreFailedEvent`, in addition to logging details to LogCat.

`RestoreProgressActivity` listens for both of those events:

```
  public void onEventMainThread(RestoreService.RestoreCompletedEvent event) {
    startActivity(new Intent(this, MainActivity.class));
    finish();
  }

  public void onEventMainThread(RestoreService.RestoreFailedEvent event) {
    Toast.makeText(this, R.string.msg_restore_failed,
      Toast.LENGTH_LONG).show();
    finish();
  }
```

In the success case, we can now start up a fresh `MainActivity` (since the original was destroyed as part of launching `RestoreProgressActivity`), and it can read the restored data.

In the failure case… we are really screwed. We may have partially restored the data, but perhaps not all of it, and there is no telling what state the data is in. A production-grade app would handle this by:

- Moving all of the existing data to a safe location on the device
- Attempting to restore the data
- If there is an unhandled exception in the restoration process, deleting the partially-restored data and moving the original data back into position

This would reduce the odds of some catastrophic problem wiping out the app. In this sample, though, we just show a `Toast`, `finish()` the activity (thereby exiting the app, as we have no other active activities), and hoping the user uninstalls and reinstalls the app, or just uninstalls the app, or something.

Trying This Yourself… With a Little Help from Ol' Blue Eyes

Everything discussed so far assumes the existence of some REST-style Web server that we can interact with for backups. As it so happens, the `BackupClient` project has a crude implementation of such a server, in the form of a Ruby script using the Sinatra gem:

```
require 'fileutils'
require 'time'
require 'sinatra'
require 'json'
```

```
BACKUP_ROOT='/tmp/backups'

get '/' do
  'Hello world!'
end

get '/api/backups' do
  result=[]

  if File.exist?(BACKUP_ROOT)
    Dir.foreach(BACKUP_ROOT) do |item|
      next if item == '.' or item == '..'

      subdir=File.join(BACKUP_ROOT, item)

      if File.directory?(subdir)
        f=File.join(subdir, "metadata.json")

        if File.exist?(f)
          metadata=JSON.load(open(f))
          metadata['dataset']="/api/backups/#{item}/dataset"

          result << metadata
        end
      end
    end
  end

  result.sort_by!{|metadata| metadata['timestamp']}
  result.reverse!

  JSON.pretty_generate(result)
end

post '/api/backups' do
  id=SecureRandom.uuid
  dir=File.join(BACKUP_ROOT, id)
  FileUtils.mkdir_p(dir)
  f=File.join(dir, "metadata.json")
  metadata={'timestamp'=>Time.new.xmlschema}
  File.open(f, 'w') {|io| io.write(JSON.generate(metadata))}

  redirect to('/api/backups/'+id), 201
end

put '/api/backups/:id/dataset' do
  dir=File.join(BACKUP_ROOT, params[:id])

  if File.exist?(dir)
    f=File.join(dir, "backup.zip")
    File.open(f, 'w') {|io| io.write(request.body.read)}

    redirect to("/api/backups/#{params[:id]}/dataset"), 201
  else
    status 404
  end
end

get '/api/backups/:id/dataset' do
```

```
  dir=File.join(BACKUP_ROOT, params[:id])
  f=File.join(dir, "backup.zip")

  if File.exist?(f)
    send_file f
  else
    status 404
  end
end
```

If you have familiarity with Ruby, you can:

- install the `sinatra` and `json` gems in your environment
- run the script (`ruby server.rb`)

That will give you a server, listening to `localhost:4567`… which happens to be what the `BackupClient` Android app is looking to talk to, if that app is running on an emulator. If you want to test with an actual Android device, the `-o` switch lets you specify the IP address to listen to, and `-p` lets you change up the port number if you wish.

The Google Backup Bootstrap

Once you get your real backup system going, then, if you wish, you can play around with Google's disaster recovery bootstrap. By opting into what Google terms "backup", you can have some of your data automatically backed up, then restored when the user replaces their device.

Unfortunately, there is little evidence that this really works, particularly during testing. Multiple bugs were reported during the M Developer Preview period without adequate resolution. The author of this book cannot get the full backup documented procedures to work, and others have their own problems getting it to work. And since the actual backup engine — a class called `GmsBackupTransport` — is not part of the Android SDK, but instead is part of the Play Services framework, there is no support for it.

Hence, while this section will discuss some implementation issues under the theory that *somebody* out there actually gets this stuff to work, bear in mind that there may be yet more issues that would be uncovered when actually trying this.

What to Bootstrap?

The biggest decision that you will need to make is what should be included in Google's bootstrap backup and what should not.

The primary considerations are privacy and security. Any data included in the bootstrap is visible to other parties. If that data is not encrypted with a user-supplied passphrase, other parties will be able to do what they want with the data, without much recourse.

One option, therefore, is to opt out of these bootstrap backups entirely, and handle disaster recovery like any other restore process.

Another is to only include some identifiying information in the bootstrap backup, to help expedite the restore process, but without really compromising security much. In the context of the `BackupClient` sample shown earlier in this chapter, if the backup server was adequately secured, including a dataset URL in the bootstrap backup would not be much of a problem. Having the URL itself is probably not that useful, and if only authorized users can download datasets from those URLs, attackers would not gain anything from peeking at the bootstrap. `BackupClient` itself has very little security, to keep the sample (reasonably) simple, but you can imagine requiring user accounts or similar means to try to lock down access to the backup server.

The far other end of the spectrum is to allow Android to backup "the whole shootin' match" (i.e., everything), on the grounds that the data you have is not especially private.

You and your qualified legal counsel will need to make this decision before deciding what to do for implementing the bootstrap backup itself.

Bootstrap Backup on Android 6.0+

Android has had a backup API since Android 2.2. However, not only did developers have to opt into the backups, but they had to write special code to assist in those backups. As such, that API was not used that much.

Android 6.0 has gone the other direction, with opt-out backups of all likely data, if your `targetSdkVersion` is 23 or higher. Specifically:

- Your app's internal storage (getFilesDir(), SharedPreferences, getDatabaseDir(), etc.) gets backed up, with the exception of getCacheDir() and getNoBackupFilesDir() (the latter introduced in API Level 21)
- getExternalFilesDir() is backed up, but not other locations on external storage

Backups occur approximately once per day, if the device is idle, charging, and on WiFi.

Configuring the Backup

If what you want to back up is different than what Android 6.0+ will back up by default, you can add manifest entries to better control what is and is not backed up.

To opt out entirely, add android:allowBackup="false" to your <application> element in the manifest:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/AppTheme"
  tools:replace="android:allowBackup">
  <!-- other cool stuff here -->
</application>
```

Here, the tools:replace ensures that no library attempts to override your allowBackup value.

Conversely, if you want to participate in the bootstrap backup, but you want to change the roster of what gets backed up, use the android:fullBackupContent attribute on the <application> element. This needs to point to an XML resource that describes what it is that you do and do not want backed up.

The BackupClient sample has this configured. The <application> element points to a res/xml/backup_rules.xml resource:

```
  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme"
    android:fullBackupContent="@xml/backup_rules">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
    <activity android:name=".RestoreRosterActivity"/>
    <activity android:name=".RestoreProgressActivity"/>

    <service android:name=".BackupService"/>
    <service android:name=".RestoreService"/>
  </application>
```

That XML resource can contain `<include>` and `<exclude>` elements, inside of a root `<full-backup-content>` element. The rules are:

- If there are no `<include>` elements — only `<exclude>` elements – then all the files that get backed up by default will get backed up, except those blocked by those `<exclude>` elements.
- If there are one or more `<include>` elements (perhaps along with `<exclude>` elements), then *none* of the files that get backed up by default will be backed up. Instead, only the files listed in the `<include>` elements (and not blocked by any `<exclude>` elements) will be backed up.

The `BackupClient` sample has a single `<include>` element, in effect saying that only what is cited in this element should be backed up:

```
<?xml version="1.0" encoding="utf-8"?>
<full-backup-content>
  <include
    domain="shared_prefs"
    path="com.commonsware.android.backup.BackupService.xml"/>
</full-backup-content>
```

The `<include>` and `<exclude>` elements must have a `domain` attribute and a `path` attribute. These combine to indicate what is being included or excluded.

The `domain` attribute indicates one of five locations relative to your app:

- `root` points to all of your internal storage
- `file` points to the subset of your internal storage used for ordinary files (i.e., `getFilesDir()`)
- `database` points to the subset of your internal storage used for databases (i.e., `getDatabasePath()`)
- `sharedpref` points to the subset of your internal storage used for `SharedPreferences`
- `external` points to the location used by `getExternalFilesDir(null)`

The path attribute then provides a relative path, from the base location indicated by domain, for the item to be included or excluded.

Hence, the BackupClient backup rules say to include a specific SharedPreferences file. This is the one written to by BackupService on every backup, holding a single value, keyed by lastBackupDataset, with the URL to the last backup dataset. Because this SharedPreferences file is included in the bootstrap backup, it should be restored in case the user replaces the device. However, it is the *only* thing that is supposed to be backed up — everything else in the app should be left alone.

Note that the documentation does not state clearly if the path attribute is required. It is possible that the path attribute is optional, where if it is missing, it means you want to include or exclude everything in the cited domain.

Testing the Backup and Restore Steps

In theory, to test your backup configuration, you can run three commands on the command line:

```
adb shell setprop log.tag.BackupXmlParserLogging VERBOSE
adb shell bmgr run
adb shell bmgr fullbackup ...
```

where ... is the application ID of the app to be backed up.

(the above assumes that you have adb in your PATH)

You can then manually initiate a restore operation via:

```
adb shell bmgr fullbackup ...
```

for the same value of .... Presumably, you would do this after modifying or clearing the backed-up data, so you can confirm that the data was restored properly.

The author has gotten these steps to work on an Android 6.0 x86 emulator image (one without Play Services, otherwise known as the “Google APIs”). As of the time of this writing, the author has not gotten this to work on production hardware.

Bootstrap Backup on Android 2.2-5.1

Prior to Android 6.0, Android had a "backup service", inaugurated in Android 2.2. As with the Android 6.0 approach, the original backup service was mostly for disaster recovery.

Unlike with Android 6.0's approach, you needed to opt into having these backups. Partly, this opt-in was accomplished via code, as you had to extend a `BackupAgentHelper` and register it in your manifest as the `android:backupAgent`, via the `<application>` element. The `BackupAgentHelper` subclass would indicate what should be backed up, by instantiating one or more `BackupHelper` objects (e.g., `FileBackupHelper`), configuring them to back up certain items, then registering them with the `BackupAgentHelper` via an `addHelper()` method.

Partly, though, the opt-in was accomplished via registering for an API key. This process was never integrated into the rest of the Play Services architecture, which now has a standardized approach for registering for various API keys and agreeing to the terms of service for each.

Instead, you would need to visit an obscure Web page, agree to the terms of service, provide information about your app (notably the application ID), get the API key, and add it to your manifest via a `<meta-data>` element.

However, those terms of service contain some interesting clauses, ones that may give your legal counsel some concern, such as:

- "the form and nature" of the backup service "may change from time to time without prior notice to you"
- "Google may stop… providing the Service (or any features within the Service) to you or to users generally at Goolgle's sole discretion, without prior notice to you"
- You "agree to use the Service only for purposes that are permitted by… any applicable law… in the relevant jurisdictions (including any laws regarding the export of data or software to and from the United States or other relevant countries)" without ever disclosing what those "relevant countries" are
- You agree to not "sell… access to the Service", which would seem to preclude its use by paid apps or apps using in-app purchases to upgrade to some "pro" edition that enabled backups

- "you are responsible for maintaining the security… of the Backup Service Key(s)", despite the fact that these have to be published in the manifest and therefore are readable by anyone
- "you will not transmit any Content through the Service that is copyrighted, protected by trade secret or otherwise subject to third party proprietary rights", despite the fact that developers have no means of validating these rights for user-supplied content
- "Google may need to change these Terms from time to time… Once the modified Terms are posted, the changes will become effective immediately, and you are deemed to have accepted the modified Terms if you continue to use the Service", despite the fact that developers have no means of finding out exactly when the terms change or somehow instantaneously preventing installed copies of their apps from using the service

Beyond this, there are no statements about where the data is actually backed up, other than opening it up to just about anyone that Google wishes to characterize as "Subsidiaries and Affiliates".

Please discuss these terms with legal counsel before registering for this service and integrating it within your app.

Additional documentation about this form of backup, should you choose to pursue it, can be found online.

Boosting Backup Security

Backups, in effect, are intentional data leaks. You want something other than the device to have access to your app's data. Hence, it is important to take reasonable steps to ensure that those backups are secure, secure enough that nobody is going to be able to exploit them for uses that go against the user's wishes. Rest assured that people will try to exploit backups and will succeed if your security is insufficient.

Securing Access to the Dataset

The backup dataset that you transfer off the device needs to be secure from attack. Unauthorized people should not be able to get at the dataset.

For a backup system like the one outlined in this chapter, the big thing to secure is access to the dataset via its URL. If anyone who gets the URL can download the dataset, now all an attacker needs to do is determine how to get that URL, such as by exploiting flaws in Google's bootstrap backup. Or, for that matter, Google staff could get at the URL, at least in principle.

In this case, the URL alone must be insufficient. It would need to be combined with other information from the user, such as some sort of site authentication, where that other information is not retained.

If you are holding onto backup datasets yourself, on your own servers, you will also need to ensure that only authorized staff can get at those datasets and that such access is highly visible. Otherwise, you are at risk of an insider attack, whether through so-called "social engineering" or just good old-fashioned extortion.

Securing Transmission of the Dataset

Another way that an attacker could get at the dataset is to copy the data in motion, as it is sent from your app to the backup server. Make sure that you are using suitable security here:

- HTTPS with certificate pinning
- Corporate VPN
- etc.

Bear in mind that users may wind up making a backup from any sort of network, ranging from your office network to the free WiFi at a local coffee shop. In principle, you could detect this and refuse to back up the data when you do not recognize the network. However, this reduces the value of the backup system, as the user might not be able to make a manual backup at some point when they need it (e.g., on business travel).

Encrypting the Dataset

The ultimate in protection for the user is to have the data be encrypted by a user-supplied passphrase. Then, even *you* cannot access the data without the user's assistance. There are ways of addressing this, perhaps involving brute force attacks or other sorts of brute force attacks. However, it certainly slows attackers down.

The simplest way to have encrypted backups — from the standpoint of the person writing the backup code — is to encrypt the data itself. For example, you do not necessarily need to re-encrypt a SQLCipher for Android database as part of a backup dataset, as it is already encrypted. Note, though, that having encrypted data at rest does not mean you can skip encrypting the data in motion, as it is sent to your backup server. While attackers would not be able to *read* the backed-up data readily, they could *replace* the backed-up data sent over the unencrypted communications channel and perhaps cause problems that way.

If, however, you are not in position to encrypt the data at rest within your app, you may wish to consider asking the user for a passphrase and using that to encrypt the backup dataset. Note that this passphrase requirement largely eliminates the ability for you to do unattended automated backups, as you either do not have the passphrase then (and so cannot encrypt the backups) or you are *saving* the passphrase (and so have just made it trivial for somebody to get it and decrypt the data).

Alternative Approaches

Backing up local data is essential where the device is the system of record, to be able to deal with catastrophe (e.g., the user accidentally uninstalls the app).

That being said, there are a few ways of dealing with backing up local data that might not necessarily seem to the user as though it is a backup process.

Data Versioning

Beyond the accidental wiping of data, such as through an erroneous install, a backup can also help recover from more fine-grained errors, like accidentally deleting a bit of data (e.g., a row or set of rows from database tables).

One way to address that is to use some sort of data versioning approach. Many software developers are familiar with this in the form of source code version control, such as `git`. Here, you never really "delete" anything forever. Instead, you delete (or change) things in your working copy of the data, with the versioning system tracking changes to the data, so you can roll back to some earlier version if the need arises.

This is not limited to source code or similar sorts of documents. One simple example of versioning that has been used for decades is to not actually delete database rows, but instead set some `is_deleted` column to a known value. Then, when you query the database, you filter out the "deleted" rows by excluding from the query those rows where `is_deleted` is set to that specific value. Recovering those deleted rows is then a matter of showing all the deleted ones to the user and clearing `is_deleted` for the ones to be restored.

Obviously, this gets much more complicated once you get into foreign key constraints (i.e., how can you restore X if it depends on Y that was also deleted?). And it is not a full replacement for a backup-and-restore system, since anything that damages or deletes the entire database cannot be recovered via this sort of versioning. But, if you are looking to implement a robust disk-based "undo" facility for users, just bear in mind that it also helps out for some sorts of cases where you might ordinarily think of restoring from a backup.

Import and Export

Another feature that you can add that has some relationship to data backups is data import and export. Whatever is exported can be backed up by the user by some other means; if the master copy of the app's data gets damaged, you might be able to recover from that damage via importing a previous export.

Of course, import and export are also used for data exchange with foreign systems (e.g., exporting tabular data in a format that can be read in by a desktop spreadsheet program). Also, traditionally, import and export are tasks that are manually requested by users. However, you might consider giving the user an option of performing an automatic export as a replacement for, or adjunct to, some other form of regular backup.

Data Synchronization

The ultimate solution for not having to mess with a robust device-based backup system is to not have the device be the system of record. Instead, some server is the system of record, with the device holding what amounts to a persistent cache of some of that data:

- Data that you retrieved previously, so you do not necessarily have to keep downloading the same data from the server
- Data that the user has modified that you are planning on sending to the server at some time in the future (e.g., during the nightly sync, or when the Internet is available again).

Trail: Advanced Network Topics

Embedding a Web Server

Usually, Android devices are mobile. Usually, servers are not mobile.

However, occasionally, you may have a valid reason to want to have your Android app expose some sort of open TCP/IP port to other apps, the user, or (eek!) the Internet at large. The “eek!” is because allowing foreign devices access to stuff inside a user’s device is fraught with security issues, as usually Android devices lack configurable firewalls and the other protection measures associated with production-grade servers.

In this chapter, we will explore some reasons for having such a TCP daemon as part of your app, focusing on the most common scenario: serving Web content from your app. We will then examine more closely one embeddable Web server implementation and how you can use it — carefully – in your Android apps.

Prerequisites

In addition to having read the core chapters of this book, you should have some familiarity with setting up a Web server and a Web application. This chapter is not a primer on these topics, but instead focuses on how to do them in the context of an Android app.

Why a Web Server?

Some people reading this chapter might wonder what role a Web server would ever have being in an Android app. Sure, we *talk* to Web servers all the time, particularly those hosting Web services. But *publishing* a Web server is uncommon, to say the least.

However, “uncommon” does not mean “completely ridiculous”. Even though there are security concerns with having Web servers embedded in Android apps, there are plenty of use cases as well.

Development Uses

One way to mitigate the security issues is to use the Web server only in constrained situations. One common situation is “development”: if the Web server is only used in, say, debug builds, we do not have to worry about security concerns affecting ordinary users. This reduces the potential audience of those who might be affected by some attacker.

One popular example of this is Facebook’s Stetho, which extends Chrome DevTools to be able to examine Android apps, including:

- Examining the view hierarchy in much the same was as you view the DOM of a loaded Web page
- Optionally using OkHttp interceptors to monitor network requests in much the same way as you can view network activity by a Web page
- Examine SQLite databases much as you might examine cookies, local storage, or other Web client-side storage mechanisms

Stetho accomplishes this through an embedded HTTP daemon that Chrome DevTools communicates with.

This book’s chapter on custom in-app diagnostic tools will examine how you can use the techniques outlined in this chapter to build your own Stetho-style diagnostics.

Other tools, like Opersys’ Binder Explorer, serve up Web content from a device, but are standalone tools, not designed to be embedded in an app.

Production Uses

Running Web servers on end-user devices is a bit frightening. Not only do normal Android security measures, like permissions, play much of a role, but we lack most of the security infrastructure seen with traditional Web servers.

The counterbalance is that mobile devices rarely have public IP addresses. This limits the scope of potential attackers to those on the same network. Later in this chapter, we will explore various ways of securing these sorts of servers from this limited attacker audience.

Putting the security issues aside for a moment, there is one main reason why one might want to run a Web server on a mobile device: you want other things, outside the device, to talk to your app. There are many possible use cases here, such as:

- Wanting to serve media stored on the device to playback devices, like having Chromecast play a movie stored on a phone
- Wanting to allow users to work with device-resident data from their desktop or notebook computers, via a Web app, instead of having to have that data be synchronized to some third-party Web site
- Exposing Web services to access device-resident data, such as having native programs on desktops or notebooks talk to your app and have access to its data
- Serving content to a small group, such as meeting participants at a neutral site, perhaps from a device more dedicated to that role (e.g., an Android HDMI dongle, as opposed to any one person's phone or tablet)

Introducing AsyncHttpServer

There are a variety of HTTP servers available for Android. Some are standalone programs, such as Opersys' cross-compiled node.js used for their Binder Explorer. Others are embeddable, designed to be used from Android apps. One of the more prominent of these comes from Koushik Dutta's AndroidAsync project.

Among the TCP/IP clients and servers in AndroidAsync is `AsyncHttpServer`. As the name suggests, it is an implementation of an HTTP server, offering a reasonable range of features:

- Pluggable providers of content for particular URL routes, for implementing Web app-style interfaces, including "out of the box" support for serving directories containing files
- WebSockets support, for pushing data to clients in addition to responding to incoming HTTP requests
- Configurable ports (other than the standard Linux/Android limitation that you cannot use ports below 1024, since you do not have superuser privileges)
- SSL support via a configurable `SSLContext`

Embedding a Simple Server

From the standpoint of `AsyncHttpServer`, getting the server going is almost trivial. The `AsyncHttpServer` documentation shows examples like this:

```
AsyncHttpServer server = new AsyncHttpServer();

server.get("/", new HttpServerRequestCallback() {
    @Override
    public void onRequest(AsyncHttpServerRequest request, AsyncHttpServerResponse
response) {
        response.send("Hello!!!");
    }
});

// listen on port 5000
server.listen(5000);
// browsing http://localhost:5000 will return Hello!!!
```

However, there is more to using `AsyncHttpServer` when you start to take into account things like UI controls, foreground services, and the like.

The `WebServer/Simple` sample application demonstrates a fairly minimal complete app that uses `AsyncHttpServer` to serve up some content.

The Dependencies

This app uses three dependencies:

- AndroidAsync, for obvious reasons
- greenrobot's EventBus, so the service hosting the `AsyncHttpServer` can let the UI layer know — if the UI exists — about changes in the state of the server
- `support-v13`, mostly for `NotificationCompat`, used for creating the foreground service

```
apply plugin: 'com.android.application'

dependencies {
    compile 'com.koushikdutta.async:androidasync:2.1.6'
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.android.support:support-v13:23.0.0'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.0"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 23
        versionCode 1
        versionName "1.0"
    }

    aaptOptions {
        noCompress 'html'
    }

    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'),
'proguard-rules.pro'
        }
    }
}
```

The Service

The bulk of the functionality lies in WebServerService, the awkwardly-named Android Service subclass that hosts the AsyncHttpServer.

The objective of WebServerService is to serve some Web content, specifically some content baked into the app via an assets/ directory.

Setting Up the AsyncHttpServer

onCreate() on WebServerService does the basic plumbing of setting up the AsyncHttpServer:

```
  @Override
  public void onCreate() {
    super.onCreate();

    server=new AsyncHttpServer();
    server.get("/.*", new AssetRequestCallback());
    server.listen(4999);

    raiseStartedEvent();
    foregroundify();
  }
```

The server field holds our AsyncHttpServer, instantiated as part of onCreate().

The get() call tells the AsyncHttpServer that we want to support HTTP GET requests on a particular URL regular expression. In this case, we use a wildcard to say that we are willing to entertain all URLs. AssetRequestCallback is an object that will be given control when a matching GET request comes in and will handle sending back the response — we will examine this callback shortly. Note that AsyncHttpServer also has a post() convenience method (for HTTP POST requests) plus a more generic addAction() method for registering to support other sorts of HTTP operations (e.g., HEAD).

Once configured, we can call `listen()` on the `AsyncHttpServer` to set up the server to listen on the designated TCP/IP port (4999 in this case). There is also `listenSecure()` for supporting SSL, where you provide a `SSLContext` in addition to the port. Note that the server will be listening on all eligible network interfaces. For most Android devices, that will either be WiFi or mobile data.

The `raiseStartedEvent()` and `foregroundify()` calls will be explained in upcoming sections.

Serving Pages from Assets

`AsyncHttpServer` offers `directory()` methods that allow you to teach the server to automatically serve content from directories that you can access, such as some subdirectory of `getFilesDir()`.

If you want to serve anything else, you will need to create an implementation of `HttpServerRequestCallback` and use that in your `get()`, `post()`, or `addAction()` calls. That callback object will be called with `onRequest()` whenever an HTTP request arrives that matches the HTTP verb and URI pattern you specified. You get an `AsyncHttpServerRequest` object that represents the request, and an `AsyncHttpServerResponse` that represents your response. Your job is to interpret the request and generate that response.

In the sample app, `AssetRequestCallback` is a `HttpServerRequestCallback` that looks in `assets/`, via `AssetManager`, for matching files and serves them:

```
private class AssetRequestCallback
  implements HttpServerRequestCallback {
  private final AssetManager assets;

  AssetRequestCallback() {
    assets=getAssets();
  }

  @Override
  public void onRequest(AsyncHttpServerRequest request,
                        AsyncHttpServerResponse response) {
    String path=request.getPath();

    try {
      if (path.length()==0 || "/".equals(path)) {
        path="index.html";
      }
      else if (path.startsWith("/")) {
        path=path.substring(1);
      }
```

```
        AssetFileDescriptor afd=getAssets().openFd(path);

        response.sendStream(afd.createInputStream(), afd.getLength());
      }
      catch (IOException e) {
        handle404(response, path);
      }
    }

    private void handle404(AsyncHttpServerResponse response,
                           String path) {
      Log.e(getClass().getSimpleName(),
        "Invalid URL: "+path);
      response.code(404);
      response.end();
    }
  }
```

If your URI pattern contains wildcards — such as the `/.*` we used with the `get()` call in `onCreate()` — you can use `getPath()` on the `AsyncHttpServerRequest` to get the full path to the resource that the HTTP client is requesting. In this case, we normalize it a bit:

- If the path is empty or is purely `/`, we interpret this as trying to load the "home page" of the Web server and map that to an `index.html` file in `assets/`
- If the path begins with a `/`, we remove it, as `AssetManager` does not accept leading slashes when we later try to retrieve the asset using the `open()` method.

After that, we are in position to build our response. Ideally, for serving something out of assets, we would stream it right from storage, as opposed to reading the whole thing into memory first. `AsyncHttpServerResponse` has a `sendStream()` method for just this purpose, taking an `InputStream` and the length of data to stream out.

It's that length that poses a problem. `AssetManager` has no direct way to get the length of an asset. So, while we could get our `InputStream` from the `AssetManager`, we still lack the length.

Instead, we use `openFd()` on `AssetManager` to open the asset as an `AssetFileDescriptor`. This has a `length()` method, to go along with the `createInputStream()` method. These we turn around and pass to `sendStream()`.

However, there is one big limitation here: the asset cannot be compressed. Otherwise, we will get an exception when trying to determine the length. By default, HTML files stored as assets will be compressed. So, back in our `app/` module's `build.gradle` file, we disable this:

```
aaptOptions {
  noCompress 'html'
}
```

This tells `aapt` (the tool responsible for putting stuff into the APK) not to compress files with a `.html` file extension.

Alternative options for sending results include:

- `send()`, which takes the MIME type and a `String` of the data for that MIME type
- `sendFile()`, which works great if the data to be returned is an existing file on the filesystem

`AsyncHttpServer` will attempt to guess a MIME type if you do not provide one, but it has a relatively limited list of known MIME types. You can use `setContentType()` to provide a MIME type separately, if you know it. Fortunately, in this case, it knows that `.html` files have a MIME type of `text/html`.

If we get an `IOException`, presumably the path that was requested does not match anything in assets, so we use the `code()` and `end()` methods on the `AsyncHttpServerResponse` to return an HTTP 404 (file not found) response.

Making a Foreground Service

Sometimes, you will only have your Web server running while your app is in the foreground. However, more often than not, you will want the Web server available longer than that. For example, when serving media to Chromecast for playback, you do not want to all of a sudden stop serving just because the user started doing something else on their device and your process was terminated while it was in the background.

Hence, there will be times when you will want your service to be a foreground service, so that Android is less likely to terminate it due to old age. The `foregroundify()` method that we called in `onCreate()` has a fairly basic recipe for setting up a foreground service:

```
  private void foregroundify() {
    NotificationCompat.Builder b=
      new NotificationCompat.Builder(this);
    Intent iActivity=new Intent(this, MainActivity.class);
    PendingIntent piActivity=
      PendingIntent.getActivity(this, 0, iActivity, 0);
    Intent iReceiver=new Intent(this, StopReceiver.class);
    PendingIntent piReceiver=
      PendingIntent.getBroadcast(this, 0, iReceiver, 0);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(getString(R.string.app_name))
      .setContentIntent(piActivity)
      .setSmallIcon(R.mipmap.ic_launcher)
      .setTicker(getString(R.string.app_name))
      .addAction(R.drawable.ic_stop_white_24dp,
        getString(R.string.notify_stop),
        piReceiver);

    startForeground(1337, b.build());
  }
```

Note that there are two `PendingIntent` objects associated with the `Notification`. If the user taps on the main portion of the notification tray tile, we will bring back the `MainActivity` to the foreground. However, we also add a "stop" action, tied to a `StopReceiver`. This manifest-registered `BroadcastReceiver` just calls `stopService()`, to shut down our service directly from the `Notification`:

```
package com.commonsware.android.webserver.simple;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;

public class StopReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    context.stopService(new Intent(context, WebServerService.class));
  }
}
```

Raising Status Events

We want to let the UI layer know — if the UI layer exists at the moment – that the Web server has started and stopped. That way, the UI can adjust its presentation to reflect that fact, such as toggling action bar items between "play" and "stop" icons.

Also, when the Web server is started, we need to let the user know what URL(s) will work to communicate with that Web server. Devices do not usually get domain names, and it is aggravating for a user to find out the IP address(es) of the device. It would be simpler if our UI could inform the user of URLs that can reach the service, so that the user can more readily type those URLs in on a desktop Web browser (or whatever).

To that end, `WebServerService` has a pair of `static` classes that serve as events for EventBus: `ServerStartedEvent` and `ServerStoppedEvent`:

```
static class ServerStartedEvent {
  private ArrayList<String> urls=new ArrayList<String>();

  void addUrl(String url) {
    urls.add(url);
  }

  ArrayList<String> getUrls() {
    return (urls);
  }
}

static class ServerStoppedEvent {

}
```

`ServerStartedEvent` not only is the indication that the Web server has started, but it also contains the URLs that the UI can display to the user.

The `raiseStartedEvent()` method called from `onCreate()` is responsible for raising the `ServerStartedEvent`:

```
private void raiseStartedEvent() {
  ServerStartedEvent event=new ServerStartedEvent();

  try {
    for (Enumeration<NetworkInterface> enInterfaces=
         NetworkInterface.getNetworkInterfaces();
         enInterfaces.hasMoreElements(); ) {
      NetworkInterface ni=enInterfaces.nextElement();

      for (Enumeration<InetAddress> enAddresses=
           ni.getInetAddresses();
           enAddresses.hasMoreElements(); ) {
        InetAddress addr=enAddresses.nextElement();

        if (addr instanceof Inet4Address) {
          event.addUrl(
            "http://"+addr.getHostAddress()+":4999");
        }
      }
    }
  }
  catch (SocketException e) {
    Log.e(getClass().getSimpleName(), "Exception in IP addresses", e);
  }

  EventBus.getDefault().removeAllStickyEvents();
```

```
    EventBus.getDefault().postSticky(event);
  }
```

The bulk of this method is involved in determining the IP addresses for the device:

- Iterate over all of the network interfaces
- For each network interface, iterate over all of its IP addresses
- For each IP address, see if it is an IPv4 address
- For each IPv4 address, construct the proper URL (with scheme and port) and add it to a running list of URLs inside the `ServerStartedEvent`

In terms of the event itself, both `ServerStartedEvent` and `ServerStoppedEvent` will be sent using sticky events. These will allow our activity to be destroyed and recreated, yet still find out the status of the Web server. However, we only want *one* of these events to be outstanding — if the user starts, stops, then starts the Web server again, we do not want three sticky events floating around.

So, we remove all existing sticky events (if any), then use `postSticky()` to raise the `ServerStartedEvent`.

The Rest of the Lifecycle

`ServerStoppedEvent` is posted from `onDestroy()`:

```
  @Override
  public void onDestroy() {
    EventBus.getDefault().removeAllStickyEvents();
    EventBus.getDefault().postSticky(new ServerStoppedEvent());
    server.stop();
    AsyncServer.getDefault().stop(); // no, really, I mean stop

    super.onDestroy();
  }
```

As was the case with `ServerStartedEvent`, we wipe out any existing sticky events (such as the `ServerStartedEvent` that should have been posted earlier), then post the `ServerStoppedEvent`.

To stop the Web server, we have to do two things:

1. Call `stop()` on the `AsyncHttpServer`, which ideally would be enough
2. Call `stop()` on the default `AsyncServer`, which is an unfortunately-required minor hassle

While we will use startService() to start the service, we are not using the command pattern to send commands to the service. In principle, that means we could skip the onStartCommand() method. However, the default implementation of onStartCommand() returns START_STICKY, which means that Android will keep trying to restart our service after our process gets terminated. This is a ridiculous default value and goes a long way towards explaining Android's memory issues. So, we override onStartCommand() to return START_NOT_STICKY, to indicate that if the process is terminated, do *not* automatically restart the service:

```
@Override
public int onStartCommand(Intent i, int flags, int startId) {
  return(START_NOT_STICKY);
}
```

And, since this service does not support the binding pattern, we have a stub implementation of onBind() to satisfy the compiler, since onBind() is an abstract method on Service:

```
@Override
public IBinder onBind(Intent intent) {
  throw new UnsupportedOperationException("Go away");
}
```

The Activity

The main activity — surprisingly enough, named MainActivity — is not that complicated, though it does have a couple of interesting wrinkles.

The activity itself is a ListActivity, where the URLs that are supplied in the ServerStartedEvent will be displayed as rows in the list. This particular app has no need for anything else in the content area, so we just inherit the full-screen ListView and skip onCreate() entirely.

As with many other samples using greenrobot's EventBus, MainActivity registers with the bus in onResume() and unregisters in onPause():

```
@Override
protected void onResume() {
  super.onResume();

  EventBus.getDefault().registerSticky(this);
}

@Override
protected void onPause() {
  EventBus.getDefault().unregister(this);
```

```
    super.onPause();
  }
```

Note that since we are looking to use sticky events, we have to use `registerSticky()` rather than the ordinary `register()` method.

The user will be able to start and stop the Web server through action bar items, defined in `res/menu/actions.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/start"
    android:icon="@drawable/ic_phone_android_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_record"
    android:visible="true"/>
  <item
    android:id="@+id/stop"
    android:icon="@drawable/ic_stop_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_stop"
    android:visible="false"/>
</menu>
```

The icons come from Google's material design icon roster.

The vision is that the `start` item will be visible when the Web server is not running, while the `stop` item will be visible when the Web server is running. That means we need to know whether the Web server is running when the activity is created, in addition to finding out changes in the Web server's state (e.g., user stopped it via the `Notification`). You might think that the Web server would not be running when the activity is created, but that ignores:

- Configuration changes (e.g., screen rotation)
- The user exiting the activity via BACK while the Web server is running, then returning to the activity via the launcher icon, overview screen (a.k.a., recent-tasks list), `Notification`, etc.

While our `ServerStartedEvent` is sticky, `onResume()` is called before `onCreateOptionsMenu()`. The `registerSticky()` call will immediately hand us the sticky event (if there is one). However, if we want to change the state of the two action bar items when the events arrive, we might not *have* those action bar items yet, if `onCreateOptionsMenu()` has not yet been called.

To handle all of this, we have the two `MenuItem` objects for those action bar items (`start` and `stop`) defined as fields on `MainActivity`, and they are populated in `onCreateOptionsMenu()` as normal:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
  getMenuInflater().inflate(R.menu.actions, menu);

  start=menu.findItem(R.id.start);
  stop=menu.findItem(R.id.stop);

  WebServerService.ServerStartedEvent event=
    EventBus.getDefault().getStickyEvent(WebServerService.ServerStartedEvent.class);

  if (event!=null) {
    handleStartEvent(event);
  }

  return(super.onCreateOptionsMenu(menu));
}
```

However, we *also* check to see if we have a sticky `ServerStartedEvent`; if yes, we call a private `handleStartEvent()` to toggle the state of the two action bar items plus load our URLs into the `ListView`:

```
private void handleStartEvent(WebServerService.ServerStartedEvent event) {
  start.setVisible(false);
  stop.setVisible(true);

  setListAdapter(new ArrayAdapter<String>(this,
    android.R.layout.simple_list_item_1, event.getUrls()));
}
```

We also call `handleStartEvent()` from `onEventMainThread()`, if and only if we have our action bar items set up (i.e., if `start` is not `null`):

```
public void onEventMainThread(WebServerService.ServerStartedEvent event) {
  if (start!=null) {
    handleStartEvent(event);
  }
}
```

We also need to watch for `ServerStoppedEvent` events, so we can flip the action bar items and clear the list:

```
public void onEventMainThread(WebServerService.ServerStoppedEvent event) {
  if (start!=null) {
    start.setVisible(true);
    stop.setVisible(false);
    setListAdapter(null);
  }
}
```

However, since the stopped state is also the natural initial state of our activity, we do not need to do anything special to check for that event manually at startup.

If the user taps on either of those action bar items, we start or stop the service, in `onOptionsItemSelected()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  Intent i=new Intent(this, WebServerService.class);

  if (item.getItemId()==R.id.start) {
    startService(i);
  }
  else {
    stopService(i);
  }

  return(super.onOptionsItemSelected(item));
}
```

And, if the user happens to tap on one of those `ListView` rows containing a URL for the Web server, we will go start up a Web browser on the device itself to go view that URL, in `onListItemClick()`:

```
@Override
protected void onListItemClick(ListView l, View v, int position, long id) {
  startActivity(new Intent(Intent.ACTION_VIEW,
    Uri.parse(getListAdapter().getItem(position).toString())));
}
```

The Results

Running the app brings up the initial UI, largely empty:

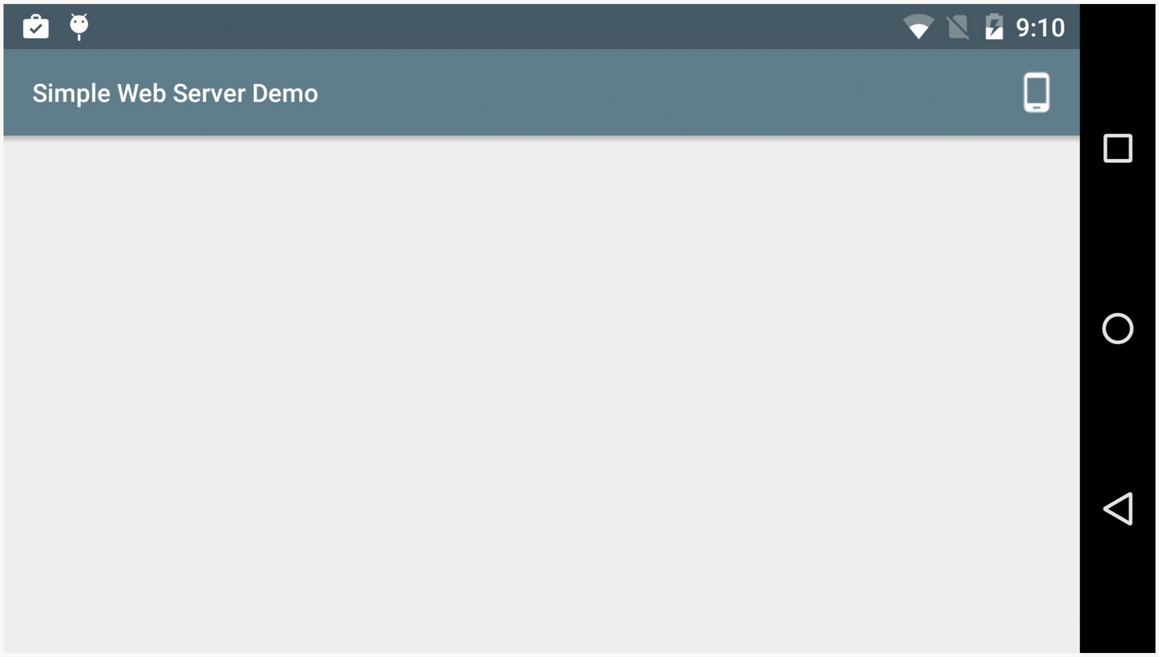


Figure 668: Simple Web Server Demo, As Initially Launched

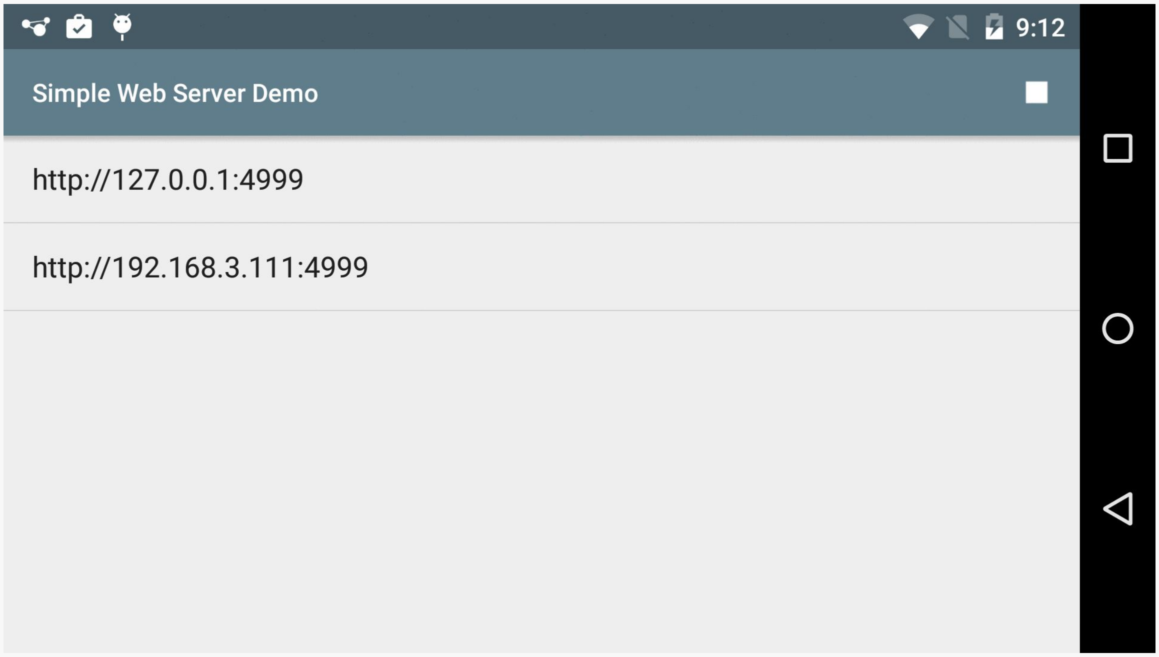
Tapping the action bar item (icon looks like a phone) will start the Web server, and the UI will show the available URLs:

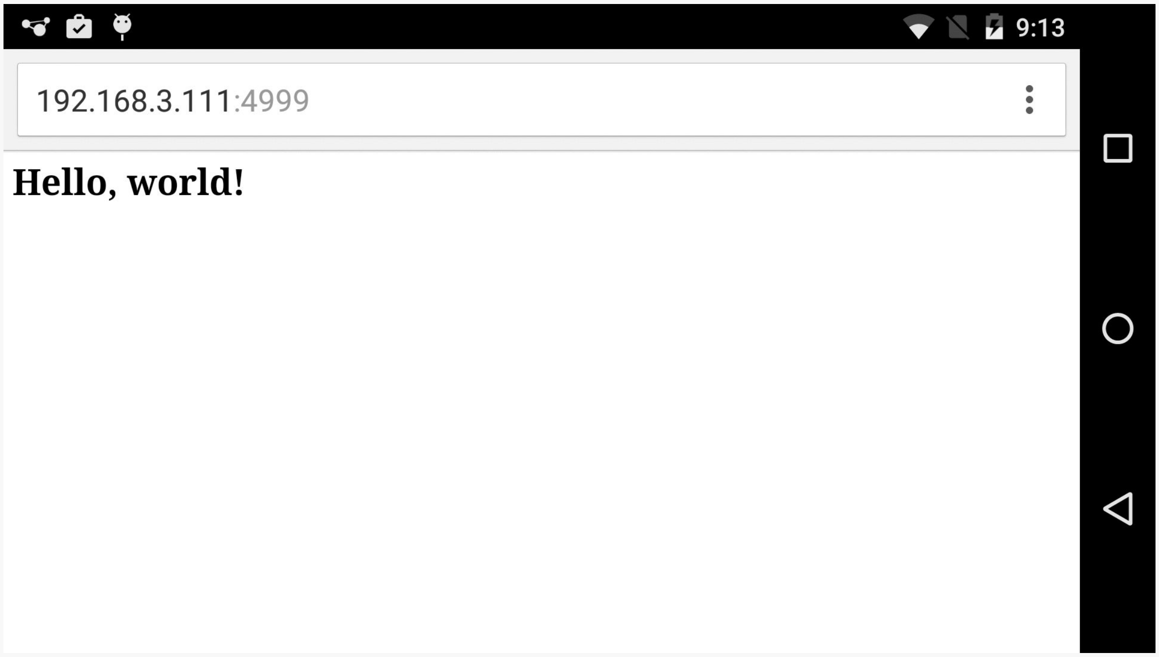


http://127.0.0.1:4999

http://192.168.3.111:4999

Figure 669: Simple Web Server Demo, With Web Server Running

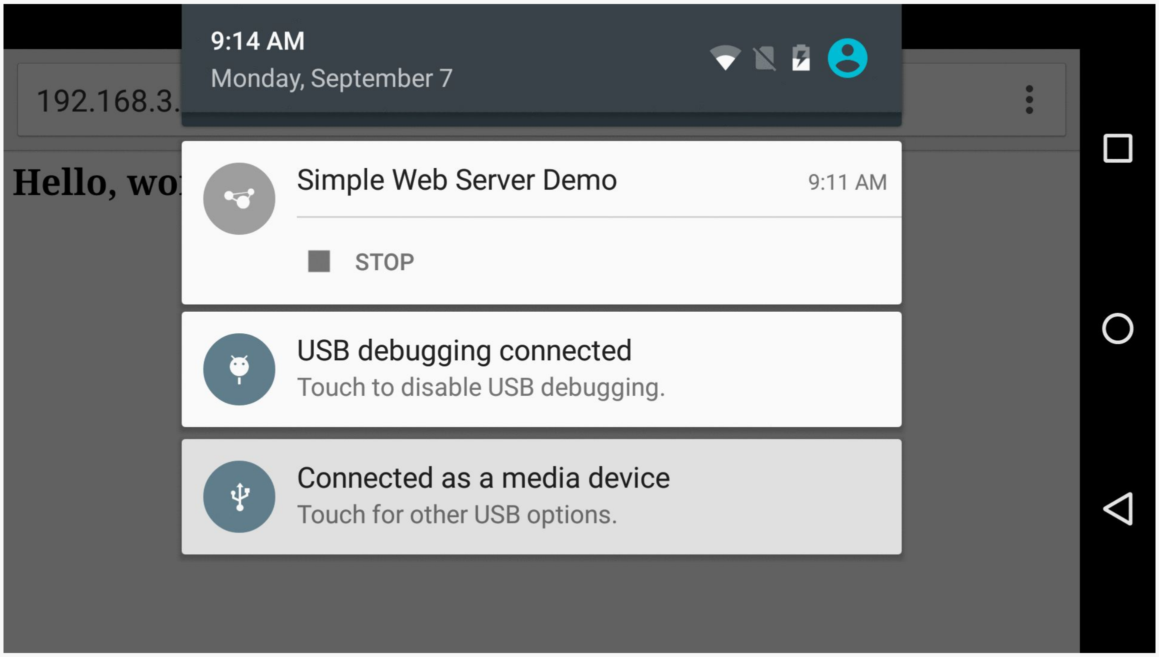
If you are running this on hardware, you should be able to visit the Web server using the non-`localhost` URL (i.e., the one that is not for an IP address of `127.0.0.1`). Or, tap on any of the URLs in the UI to bring up a Web browser on the device or emulator for that URL:



Hello, world!

Figure 670: Web Page Served by Simple Web Server Demo

You can stop the server either by tapping the “stop” action bar item, or by clicking the “stop” action in the foreground `Notification`:



9:14 AM
Monday, September 7

Simple Web Server Demo 9:11 AM
■ STOP

USB debugging connected
Touch to disable USB debugging.

Connected as a media device
Touch for other USB options.

Template-Driven Responses, with Handlebars

Many times, you will want to generate the HTML that you send back from the Web server to the browser, rather than use simple files or assets. From the standpoint of `AsyncHttpServer`, this is mostly a matter of having another `HttpServerRequestCallback` that handles the HTML generation process.

The sky is the (proverbial) limit in terms of how you generate that HTML, as you have the full power of Java at your disposal. However, in many cases, you will want to take advantage of template engines to simplify your work. Rather than concatenating together a seemingly infinite number of strings to assemble your HTML from parts, you have a template that pulls in dynamic bits as needed.

In the chapter on printing, you will see how to use the jmustache template engine for building HTML on the fly. The name "jmustache" is based on a popular template language syntax, using "mustaches" (braces) to represent the dynamic bits. So, `Hello, {{ username }}` would pull `username` from some supplied context and put it after `Hello,` in the resulting string.

Another engine that uses the same basic syntax, but with a bit more power behind it, is handlebars. The original handlebars implementation is in JavaScript, but there is a Java port of it that we can use in our Android apps. In this section, we will look at how to add handlebars support to our miniature Web server, to return template-driven HTML content, as shown in the `WebServer/Template` sample application.

Adding the Handlebars Dependency

Edgar Espina's Handlebars.java library will be our template library. This library is available on Maven Central and so only requires that we add one line to `build.gradle` to pull in this dependency:

```
dependencies {
    compile 'com.koushikdutta.async:androidasync:2.1.6'
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.android.support:support-v13:23.0.0'
    compile 'com.github.jknack:handlebars:2.2.2'
}
```

Loading Handlebars Templates

In `onCreate()` of the revised `WebServerService`, we need to initialize the template engine, by creating an instance of the `Handlebars` class, where we store that instance in a field of the service:

```
public class WebServerService extends Service {
  private AsyncHttpServer server;
  private Handlebars handlebars;
  private Template t;

  @Override
  public void onCreate() {
    super.onCreate();

    handlebars=new Handlebars(new AssetTemplateLoader(getAssets()));

    try {
      t=handlebars.compile("demo.hbs");
      server=new AsyncHttpServer();
      server.get("/demo", new TemplateRequestCallback());
      server.get("/.*", new AssetRequestCallback());
      server.listen(4999);

      raiseReadyEvent();
      foregroundify();
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(),
        "Exception starting Web server", e);
    }
  }
```

The parameter to the Handlebars constructor is a TemplateLoader that is responsible for loading templates from some data store. The library comes with loaders that can load from simple files. However, reminiscent of the previous sample, it would be nice if we could package our templates as assets, so that they ship with our app. Handlebars.java knows nothing about Android and assets, so we have to create our own AssetTemplateLoader that implements the TemplateLoader interface. We do this by extending the AbstractTemplateLoader base class and override sourceAt(). sourceAt() takes a String representation of the location of the template, and it is our job to return a TemplateSource that encapsulates the template itself. As there is no AssetTemplateSource, the simplest way to do this is to read the template into memory and wrap it in StringTemplateSource, which is what AssetTemplateLoader does:

```
private static class AssetTemplateLoader
  extends AbstractTemplateLoader {
  private final AssetManager mgr;

  AssetTemplateLoader(AssetManager mgr) {
    this.mgr=mgr;
  }

  @Override
  public TemplateSource sourceAt(String s) throws IOException {
    return(new StringTemplateSource(s, slurp(mgr.open(s))));
  }
}

// inspired by http://stackoverflow.com/a/309718/115145

public static String slurp(final InputStream is) throws IOException {
  final char[] buffer=new char[1024];
  final StringBuilder out=new StringBuilder();
  final InputStreamReader in=new InputStreamReader(is, "UTF-8");

  while (true) {
    int rsz=in.read(buffer, 0, buffer.length);
    if (rsz < 0)
      break;
    out.append(buffer, 0, rsz);
  }

  return(out.toString());
}
```

By using AssetTemplateLoader when we create the Handlebars instance, we will be able to load templates out of the main sourceset's assets/ folder, such as demo.hbs:

```
<html>
    <head><title>Display Metrics</title></head>
    <body>
        <h1>Display Metrics</h1>
        <table>
```

```
            <tr><th>Density DPI</th><td>{{ densityDpi }}</td></tr>
            <tr><th>Density xDPI</th><td>{{ xdpi }}</td></tr>
            <tr><th>Density yDPI</th><td>{{ ydpi }}</td></tr>
            <tr><th>Dimensions</th><td>{{ widthPixels }} x {{ heightPixels }}</td></tr>
        </table>
    </body>
</html>
```

In that file, you will see a few table cells that will be filled in by dynamic data (e.g., `{{ densityDpi }}`). What this HTML page represents is a report of some of the key values from a `DisplayMetrics` object, providing details of resolution and density of the Android device's screen.

Back up in `onCreate()`, we go ahead and load this template, via a call to `compile()` on the `Handlebars` object. This `Template` instance is then ready to generate a custom page for us, once we give it the data to feed into that page.

Handlebars' Context (No, Not *That* Context)

The data for the handlebars-delimited macros in the template file (e.g., `{{ densityDpi }}`) comes from what Handlebars refers to as its context. To render a template, you create a context and apply it to the template.

Back up in `onCreate()`, when we set up our routes on our Web server, we added one for `/demo`, pointing to a `TemplateRequestCallback`:

```
      server.get("/demo", new TemplateRequestCallback());
```

This means that whenever the server gets a `/demo` request, `TemplateRequestCallback` is responsible for it, through the same sort of `onRequest()` callback method that we used in `AssetRequestCallback`:

```
  private class TemplateRequestCallback implements HttpServerRequestCallback {
    @Override
    public void onRequest(AsyncHttpServerRequest request, AsyncHttpServerResponse
response) {
      try {
        DisplayMetrics metrics=new DisplayMetrics();
        WindowManager wmgr=(WindowManager)getSystemService(WINDOW_SERVICE);

        wmgr.getDefaultDisplay().getMetrics(metrics);

        Context ctxt=Context
          .newBuilder(metrics)
          .resolver(FieldValueResolver.INSTANCE)
          .build();

        response.send(t.apply(ctxt));
        ctxt.destroy();
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(),
          "Exception serving Web page", e);
      }
    }
  }
```

Here, we first get our hands on a `DisplayMetrics` instance, as that is the source of the data that we want to pour into the response.

We then build a context, through a class unfortunately named `Context`. Since you cannot have two imports for `Context`, you will either be able to import `android.app.Context` *or* `com.github.jknack.handlebars.Context`, and you would have to refer to the other `Context` via the fully-qualified class name. In this case, `WebServerService` did not need `android.app.Context`, so a bare `Context` class name is referring to `com.github.jknack.handlebars.Context`.

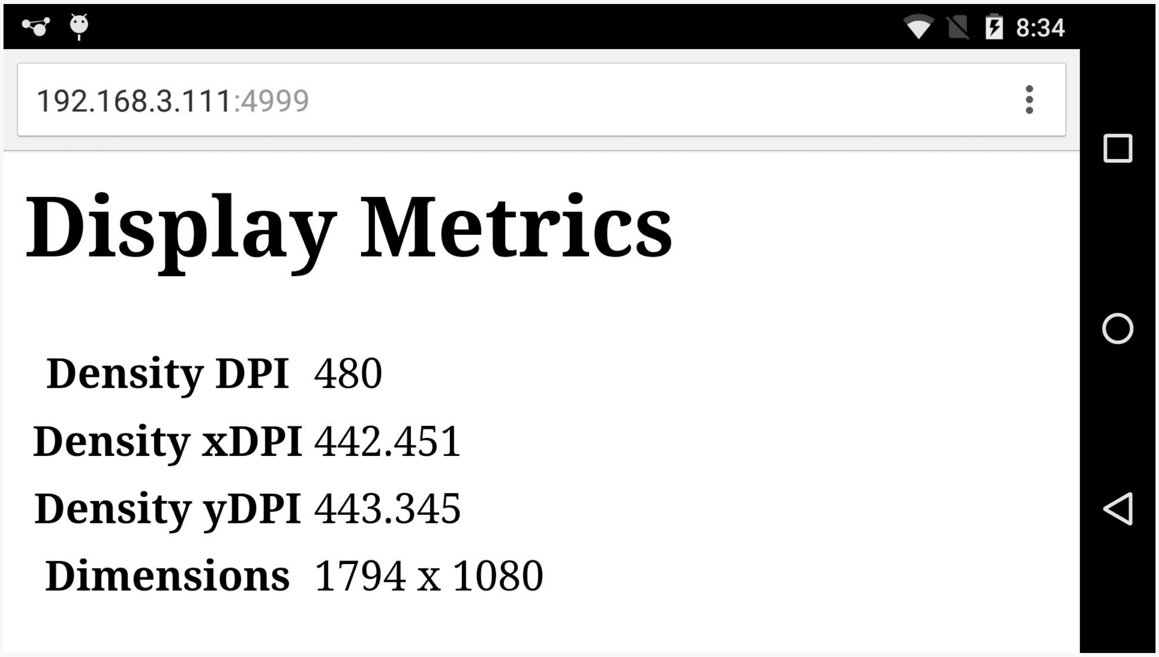
There are many ways to populate a Handlebars `Context`. For the purposes of this example, we only need one source of data: the `DisplayMetrics` instance. `newBuilder()` is a factory method on `Context` that creates a `Context` builder object, providing some data source as a starting point. You can then further configure the builder, before eventually calling `build()` to get the `Context`. In this case, we call `resolver()` on the builder, to indicate how the contents of a macro translate into operations against our data source. Here, we are using `FieldValueResolver.INSTANCE`, which says that a macro like `{{ displayDpi }}` should be interpreted as a reference to a field on the data source instance.

We then use the `Context` to generate our result from the `Template` via the `apply()` method, and `send()` that result.

When you are done with a `Context`, call `destroy()` on it, per the Handlebars documentation.

The Results

If you run the app, start the server, and view the `/demo` page, you will see some values culled from `DisplayMetrics` on the device:



192.168.3.111:4999

Display Metrics

Density DPI	480
Density xDPI	442.451
Density yDPI	443.345
Dimensions	1794 x 1080

Figure 672: Template Web Server Demo, /demo URL Response, Zoomed

Supporting WebSockets

Given sufficient time and effort, there is nothing stopping you from building a full-fledged Web app served via an Android-hosted Web server.

One thing that many Web apps use today is a WebSocket. A WebSocket is a bi-directional data channel between client and server. In particular, it is used for “server push”, where the server sends messages to the client, perhaps related to some data changes on the server.

`AsyncHttpServer` not only supports serving HTTP requests, but is also offers WebSocket support as well. The [`WebServer/WebSockets`](#) sample application builds upon the server created in the first sample app in this chapter, adding in a push channel so the server can asynchronously update the client.

Registering the WebSocket Listener

Just as AndroidAsync has `HttpServerRequestCallback` for handling HTTP requests, it also has `AsyncHttpServer.WebSocketRequestCallback` for handling incoming WebSocket connections. And, just as you register instances of

`HttpServerRequestCallback` with an `AsyncHttpServer` to handle various HTTP request types (e.g., `get()`, `post()`), you register `AsyncHttpServer.WebSocketRequestCallback` instances with an `AsyncHttpServer` to handle those WebSocket connections.

This sample app's `WebServerService` has a slightly different `onCreate()` method than does the original. It calls `websocket()` on the `AsyncHttpServer` to tie a custom `WebSocketClientCallback` instance to the server, bound to a `/ss` URL. It also starts up a `ScheduledExecutorService` to get control every three seconds:

```
public class WebServerService extends Service implements Runnable {
  private AsyncHttpServer server;
  final private ArrayList<WebSocket> sockets=new ArrayList<WebSocket>();
  final private ScheduledExecutorService timer=
    Executors.newSingleThreadScheduledExecutor();

  @Override
  public void onCreate() {
    super.onCreate();

    server=new AsyncHttpServer();
    server.websocket("/ss", new WebSocketClientCallback());
    server.get("/.*", new AssetRequestCallback());
    server.listen(4999);

    raiseStartedEvent();
    foregroundify();

    timer.scheduleAtFixedRate(this, 3000, 3000, TimeUnit.MILLISECONDS);
  }
```

We will use the `ScheduledExecutorService` as the trigger for sending messages over the WebSockets to any connected clients.

`WebSocketClientCallback` is an implementation of the `AsyncHttpServer.WebSocketRequestCallback` interface. It requires only one method: `onConnected()`, which is called when a new WebSocket connection has been requested by a client:

```
  private class WebSocketClientCallback
    implements AsyncHttpServer.WebSocketRequestCallback {
    @Override
    public void onConnected(final WebSocket ws,
                            AsyncHttpServerRequest request) {
      sockets.add(ws);

      ws.setClosedCallback(new CompletedCallback() {
        @Override
        public void onCompleted(Exception ex) {
          if (ex!=null) {
            Log.e(getClass().getSimpleName(),
              "Exception with WebSocket", ex);
          }

          sockets.remove(ws);
        }
      });
    }
  }
```

Here, we do two things:

1. Add the `WebSocket` that we are passed to an `ArrayList` of outstanding `WebSocket` instances, being tracked in the service via a `sockets` field
2. Add a `CompletedCallback` to the `WebSocket`, to be notified if and when the client disconnects, so we can remove the `WebSocket` from the `sockets` `ArrayList` and, if there was some sort of exception that triggered the `WebSocket` to be closed, log that `Exception` to LogCat

Here, we are treating all outstanding `WebSocket` instances as equal. If you have the notion of different clients needing different messages pushed to them, you would need to hold onto the `WebSocket` instances in some other data structure (e.g., a `HashMap`, keyed by something, to allow you to find the `WebSocket` associated with a given client).

Posting Messages to Clients

Sending a message on a `WebSocket` is trivial: call `send()` on the `WebSocket` instance, passing a string representing the message to be sent.

In `onCreate()`, we called `scheduleAtFixedRate()` to arrange to get control every three seconds. Our `WebServerService` implements the `Runnable` interface, so it can get control directly on those three-second intervals, in a `run()` method:

```
  @Override
  public void run() {
    for (WebSocket socket : sockets) {
      socket.send(new Date().toString());
    }
  }
```

Once again, we are treating all of the `WebSocket` instances the same, sending the same message to each: the current date and time. Obviously, a more sophisticated app might do something more elaborate here, such as sending over a JSON-formatted string containing a complex data structure.

Receiving Messages on the Client

In this sample app, we want the client to be a Web browser, one that is viewing our `index.html` page, courtesy of the normal Web serving feature of `AsyncHttpServer`. That `index.html` is a bit different than the one we used in the first sample:

```
<html>
<head>
    <title>CommonsWare Android WebSocket Server Demo</title>
</head>
<body>
<h1>Messages from Server</h1>
<ul id="transcript"></ul>
<script src="app.js"></script>
</body>
</html>
```

Of note:

- We have an empty bulleted list, with an `id` of `transcript`
- We load an `app.js` file from the same server, where that file contains our WebSocket client code:

```
window.onload = function() {
    var ws_url=location.href.replace('http://', 'ws://')+'ss';
    var socket=new WebSocket(ws_url);

    socket.onopen = function(event) {
      // console.log(event.currentTarget.url);
    };

    socket.onerror = function(error) {
      console.log('WebSocket error: ' + error);
    };

    socket.onmessage = function(event) {
      var li=document.createElement("li");

      li.appendChild(document.createTextNode(event.data));
      document.getElementById("transcript").appendChild(li);
    };
}
```

This book is not here to provide an extensive description of JavaScript-based WebSocket client development. What this snippet of JavaScript does is arrange to get control when the page is loaded (`window.onload`). At that point, it derives the URL for the WebSocket endpoint on the server, by changing the scheme (from `http` to `ws`, the official IETF scheme for WebSockets) and appending the `ss` to the end of the URL.

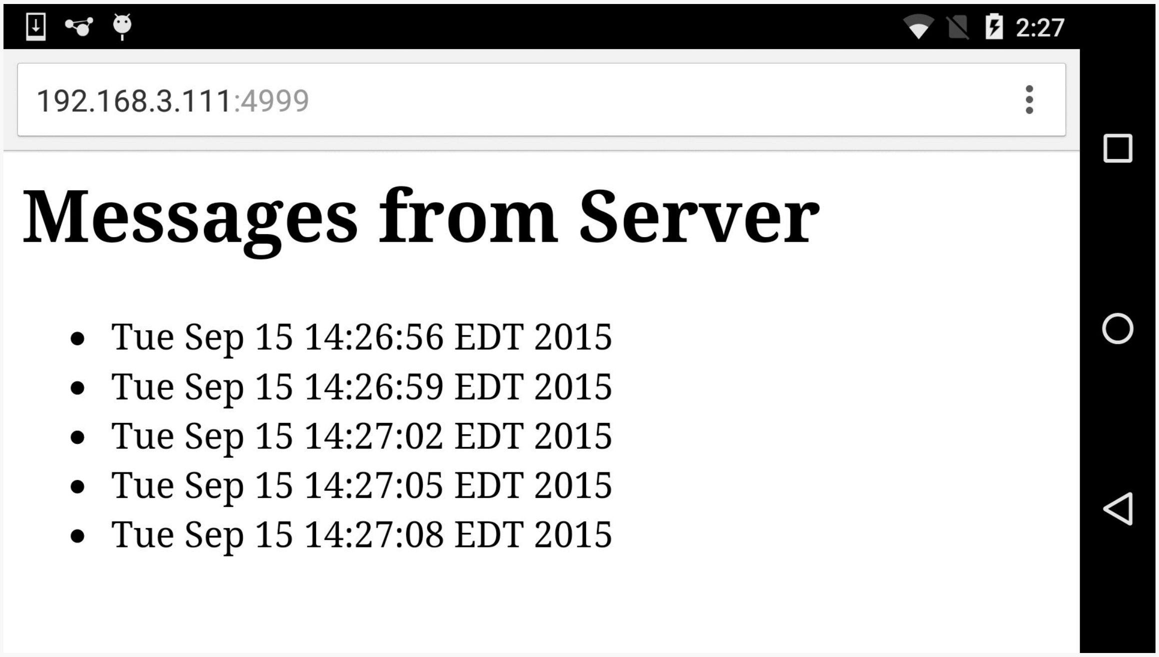
NOTE: this code is very simplistic and assumes that the URL used to load this Web page is simply the home page (e.g., `http://AAA.BBB.CCC.DDD/`, where AAA.BBB.CCC.DDD is the Android device's IP address). A more robust implementation would do a better job.

After creating a `WebSocket` object for that URL, we register three event handlers:

- `onopen`, which is called when we have opened the WebSocket successfully
- `onerror`, which is called if there is some sort of problem with the WebSocket
- `onmessage`, which is called when we receive a message from the server

In `onmessage`, we create a `<li>` element, slap the message from the server into the the text of that element, and append it to the `transcript`.

The result, if you load the home page in a reasonably modern browser, is the timestamps of when the server got control via the `ScheduledExecutorService`, showing up in a bulleted list, in chronological order:



Messages from Server

- Tue Sep 15 14:26:56 EDT 2015
- Tue Sep 15 14:26:59 EDT 2015
- Tue Sep 15 14:27:02 EDT 2015
- Tue Sep 15 14:27:05 EDT 2015
- Tue Sep 15 14:27:08 EDT 2015

Figure 673: WebSocket Server Demo, Zoomed

Reversing the Communications Flow

Of course, nothing is stopping you from having data flow in the other direction, from the client to the server.

In JavaScript, there is a `send()` method on the `WebSocket` object that you can use to send a `String` to the server.

On the server side, you can call `setStringCallback()` to register a `StringCallback` implementation, which will be called with `onStringAvailable()` whenever a string message arrives from that WebSocket's client.

Implementing a WebSocket Client in Android

While this sample was focused on a browser as a client, AndroidAsync also has a WebSocket client API. Some sort of same-LAN peer-to-peer Android app might use this with another Android app's WebSocket server. Or, you could communicate with arbitrary WebSocket servers out on the Internet.

The AndroidAsync documentation has more on this process.

Securing the Web Server

However, as has been emphasized throughout this chapter, security is an issue any time you have open ports on a mobile device. Even if you think that your use of this Web server will be only for debugging purposes, developers are people too, and people make mistakes.

We can do a bit more to "harden" the Web server, to make it a bit more robust in the face of threats and user error. The `WebServer/Secure` sample application — starting from the `WebServer/Simple` project – demonstrates a few of the techniques.

Disabling on Mobile Data Connections

There are several types of network connection supported by Android. The two that get the most attention are WiFi and mobile data, but some devices offer others (e.g., wired Ethernet).

The one connection type that is the riskiest from a security standpoint is the mobile data connection. With WiFi, usually you will be behind some firewall, or at the very least a NAT-equipped router, which will limit the scope of attacks to anyone that can get to that WiFi LAN segment. Usually, that will only be people on that same WiFi network, which limits the scope of who could attack you.

With mobile data, though, at best you are part of a network with arbitrary other people on it (other mobile subscribers), and at worst you are given a *public* IP address and anyone in the world can reach your server.

Besides, usually mobile data is not a useful connection type for a mobile Web server. If the IP address given to the device by the mobile carrier is a private IP address, most browsers cannot get to that device, such as the user's own desktop browser.

Hence, it seems reasonable to block attempts to start the server when we are on a mobile network. It also seems reasonable to block attempts to start the server if we have no network connection at all, as the server may not be that useful in this state.

So, `onCreate()` of `WebServerService` checks to see what we are on and reacts accordingly:

```
    ConnectivityManager mgr=(ConnectivityManager)getSystemService(CONNECTIVITY_SERVICE);
    NetworkInfo ni=mgr.getActiveNetworkInfo();

    if (ni==null || ni.getType()==ConnectivityManager.TYPE_MOBILE) {
      EventBus.getDefault().post(new ServerStartRejectedEvent());
      stopSelf();
    }
```

We use `ConnectivityManager` to check for the active network (`getActiveNetworkInfo()`). If we have no connection (`getActiveNetworkInfo()` returns `null`) or it is a mobile data connection (`getType()` returns `TYPE_MOBILE`), we raise a `ServerStartRejectedEvent` and stop the service. Our activity can register for a `ServerStartRejectedEvent` and do something to let the user know that the Web server is not running.

Note that there is an `else` following the `if` from the above code – we will examine the full `onCreate()` method a bit later in this chapter.

Implementing an Inactivity Timeout

What happens if the user fails to stop the Web server? The longer the server is running, the more likely it is that somebody will discover and attempt to attack it.

However, we can implement an inactivity timeout. If we do not receive a valid HTTP request within X period of time, we automatically stop the service.

`WebServerService` defines a `MAX_IDLE_TIME_SECONDS` constant for how long we can go without a valid request before we stop the service:

```
  private static final int MAX_IDLE_TIME_SECONDS=60;
```

`WebServerService` also has a Java `ScheduledExecutorService`, which will keep track of when the timeout period is reached:

```
  private ScheduledExecutorService timer=
    Executors.newSingleThreadScheduledExecutor();
```

In `onCreate()` — if we did not stop the service due to being on the wrong network — we arrange to get control at the designated time using the `ScheduledExecutorService`:

```
      timeoutFuture=timer.schedule(onTimeout,
        MAX_IDLE_TIME_SECONDS, TimeUnit.SECONDS);
```

We hold on to the response from `schedule()` — a `ScheduledFuture` object — in a field for later use. The `onTimeout` parameter is a simple `Runnable` that will be invoked `MAX_IDLE_TIME_SECONDS` from when `schedule()` was called:

```
  private Runnable onTimeout=new Runnable() {
    @Override
    public void run() {
      stopSelf();
    }
  };
```

The net effect is that `MAX_IDLE_TIME_SECONDS` from when the service is created, we stop it.

However, so long as the Web server is active, we do *not* want to stop it. To handle that, `onRequest()` of `AssetRequestCallback` reschedules the timeout, if we have a successful request (e.g., not a 404):

```
        timeoutFuture.cancel(false);
        timeoutFuture=timer.schedule(onTimeout,
          MAX_IDLE_TIME_SECONDS, TimeUnit.SECONDS);
```

So, the service will stop `MAX_IDLE_TIME_SECONDS` from either when the service starts or from our last valid HTTP request, whichever comes last.

If you run the sample, start the server, and let it sit for a while, you will see that the server automatically stops. Since our logic for updating the UI is triggered by onDestroy(), we do not need to do anything special for this timeout shutdown.

Supporting Random URLs

Another thing we can do is change up our URLs. Rather than using simple paths like / or /index.html, we can add a dynamically-generated random prefix, like /AG78. This will make it more difficult for an attacker to get a valid page in response to some HTTP request, as they will have to guess the prefix in addition to the rest of the path. It makes things incrementally harder for the user, as they will have to enter in a few additional characters for the URL, but since navigating the content should be through hyperlinks and the like once the initial URL is used, the cost should not be too bad.

To do this, the revised WebServerService employs SecureRandom, a class that ties into high-quality (on newer versions of Android) random number generation algorithms. We also track the prefix in a String named rootPath:

```
private SecureRandom rng=new SecureRandom();
private String rootPath;
```

The onCreate() method then uses the SecureRandom object to generate a 20-bit BigInteger and converts that into a base-24 string. 20 bits means about a million possible prefix values, which should be enough. Using base-24 instead of base-10 reduces the number of characters that the user has to type, while avoiding any potential O (capital O) versus 0 (zero) confusion, as the letters used will be in the range from A through N.

```
@Override
public void onCreate() {
  super.onCreate();

  ConnectivityManager mgr=(ConnectivityManager)getSystemService(CONNECTIVITY_SERVICE);
  NetworkInfo ni=mgr.getActiveNetworkInfo();

  if (ni==null || ni.getType()==ConnectivityManager.TYPE_MOBILE) {
    EventBus.getDefault().post(new ServerStartRejectedEvent());
    stopSelf();
  }
  else {
    rootPath=
      "/"+new BigInteger(20, rng).toString(24).toUpperCase();

    server=new AsyncHttpServer();
    server.get("/.*", new AssetRequestCallback());
    server.listen(4999);
```

```
      raiseReadyEvent();
      foregroundify();
      timeoutFuture=timer.schedule(onTimeout,
        MAX_IDLE_TIME_SECONDS, TimeUnit.SECONDS);
    }
  }
```

`onRequest()` in the `AssetRequestCallback` needs to remove this `rootPath` if the requested URL begins with it, so we do not try using it as part of looking up the associated asset. Conversely, if the requested URL does *not* begin with `rootPath`, it is an invalid URL, so we can return a 404 response to the request.

```
    @Override
    public void onRequest(AsyncHttpServerRequest request,
                          AsyncHttpServerResponse response) {
      String path=request.getPath();

      try {
        if (path.startsWith(rootPath)) {
          path=path.substring(rootPath.length()+1);
        }
        else {
          handle404(response, path, null);
          return;
        }

        if (path.length()==0 || "/".equals(path)) {
          path="index.html";
        }
        else if (path.startsWith("/")) {
          path=path.substring(1);
        }

        AssetFileDescriptor afd=getAssets().openFd(path);

        response.sendStream(afd.createInputStream(),
          afd.getLength());
        timeoutFuture.cancel(false);
        timeoutFuture=timer.schedule(onTimeout,
          MAX_IDLE_TIME_SECONDS, TimeUnit.SECONDS);
        invalidRequestCount=0;
      }
      catch (IOException e) {
        handle404(response, path, e);
      }
    }
```

The `invalidRequestCount` referred to late in the `onRequest()` implementation is part of some code for detecting attackers, which we get into in the next section.

Detecting Attacks

Having a random prefix makes it more difficult for an attacker to get a valid URL. However, if they can just keep trying, eventually they will hit upon the same prefix that we are using and will be able to get Web pages from the server.

The obvious defense would be to block requests from clients that seem to be attempting to guess URLs, by counting the number of invalid requests that they make and rejecting future requests outright once they exceed some threshold.

In the sample app, we take an even more draconian approach: if somebody is attacking us, stop the service entirely. This has the side effect of stopping legitimate requests as well, of course.

In the sample app, there are two types of invalid request:

1. Requests with the proper prefix but asking for a path within there that does not match any of our assets
2. Requests without the proper prefix

Given that our `AssetRequestCallback` is handling the wildcard path (`/.*`), both types of invalid request will come to `AssetRequestCallback`. And, in both cases, `handle404()` is called.

So, `WebServerService` has a field named `invalidRequestCount`, to track how many sequential invalid requests are made. In `handle404()`, we increment that count by calling a `trackInvalidRequests()` method back up on `WebServerService`:

```
  private void handle404(AsyncHttpServerResponse response,
                         String path, Exception e) {
    Log.e(getClass().getSimpleName(), "Invalid URL: "+path, e);
    response.code(404);
    response.end();
    trackInvalidRequests();
  }
```

`trackInvalidRequests()` increments the count and, if the value exceeds a certain threshold, stops the service:

```
private void trackInvalidRequests() {
  invalidRequestCount++;

  if (invalidRequestCount>MAX_SEQUENTIAL_INVALID_REQUESTS) {
    stopSelf();
    }
  }
```

The `invalidRequestCount=0` line at the bottom of `onRequest()` resets this counter, as we are tracking *sequential* invalid requests. This means that a user who fumbles around a bit trying to enter the URL is not harmed long-term, once the correct URL is used. However, since most attackers tend to make attempts in rapid-fire fashion, several consecutive failures will trip the detection algorithm and shut down the server.

Here, the threshold is `MAX_SEQUENTIAL_INVALID_REQUESTS`, defined as 10:

```
  private static final int MAX_SEQUENTIAL_INVALID_REQUESTS=10;
```

One key limitation with this approach is that it requires that all URLs be handled by some code of ours. There is no obvious way with `AsyncHttpServer` to find out if URLs we elect to have the server handle itself fail with a 404 or other error. With luck, this will be added in the future.

What About SSL?

In principle, you could have the embedded Web server use SSL for encrypting its traffic. `AsyncHttpServer` has a `listenSecure()` method that takes an `SSLContext` as a parameter, where you would configure the SSL certificates to use for your server.

However, in practice, SSL is not going to be that useful, except in select scenarios. Android devices do not generally have domain names, and traditional SSL certificates are tied to a domain name. While you could create a self-signed certificate, Web browsers will raise all sorts of warnings when users try visiting that site using a regular Web browser, harming usability.

The primary situation where using a self-signed certificate can work well is when non-browser code is serving as as the client, particularly if that client code is your own app running on another device. Your app, serving in the role of the client, can validate that the served-up self-signed certificate is indeed the proper one, rather than simply failing or otherwise rejecting the self-signed certificate.

Towards a Reusable Web Server Service

A few samples in this book use an embedded Web server for a separate input and control surface, showing output or collecting input from a developer in a browser so as not to interfere with what is going on with the device itself. Rather than have each of those samples roll its own embedded Web server, we can combine the elements of the samples from this chapter into a reusable library module that the other projects can pull in and extend. The WebServer/Reusable project contains a `webserver` module that serves in this role.

Gradle Changes

Previous editions of this code were in application projects. Now, we need a library project.

Hence, the module's `build.gradle` file not only contains references to all of the dependencies needed from all of the preceding samples, but it also uses the `com.android.library` Android Plugin for Gradle:

```
apply plugin: 'com.android.library'

dependencies {
    compile 'com.koushikdutta.async:androidasync:2.1.6'
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.android.support:support-v13:23.0.0'
    compile 'com.github.jknack:handlebars:2.2.2'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.0"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 23
    }
}
```

Configuration via Abstract Methods

Hard-coded constants are not a great solution for reusable code, as those constants cannot be changed by somebody reusing the code. There are any number of patterns that can be used for configuration (e.g., `Builder` object populating some configuration data structure).

In this case, since we are providing a base class for others to override, we can use the simple approach of `abstract` methods.

So, in this version of the sample, `WebServerService` is `abstract` and defines five `abstract` methods:

```
abstract public class WebServerService extends Service {
  abstract protected void buildForegroundNotification(NotificationCompat.Builder b);
  abstract protected boolean configureRoutes(AsyncHttpServer server);
  abstract protected int getPort();
  abstract protected int getMaxIdleTimeSeconds();
  abstract protected int getMaxSequentialInvalidRequests();
```

buildForegroundNotification()

It used to be that `foregroundify()` configured the entire `Notification` used for the foreground service. Now, some of that stuff should be configured by the subclass, such as text and icons.

The revised `foregroundify()` will call out to `buildForegroundNotification()`, where the subclass can add in basic stuff to the `NotificationCompat.Builder`:

```
  private void foregroundify() {
    NotificationCompat.Builder b=
      new NotificationCompat.Builder(this);

    Intent iReceiver=new Intent(this, StopReceiver.class);
    PendingIntent piReceiver=
      PendingIntent.getBroadcast(this, 0, iReceiver, 0);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL);

    buildForegroundNotification(b);

    b.addAction(R.drawable.ic_stop_white_24dp,
      getString(R.string.notify_stop),
      piReceiver);

    startForeground(NOTIFY_ID, b.build());
  }
```

Things configured on the `Builder` before calling `buildForegroundNotification()` could be overridden by the subclass. Things configured on the `Builder` *after* calling `buildForegroundNotification()`, on the other hand, are enforced by the base `WebServerService` class. In particular, we ensure that the "stop" action is there, pointing at our `StopReceiver`.

configureRoutes()

`onCreate()` used to handle everything with respect to configuring the routes of the Web server (i.e., what paths route to what handlers). Now, that is mostly to be handled by subclasses, via a `configureRoutes()` method:

```
@Override
public void onCreate() {
  super.onCreate();

  ConnectivityManager mgr=(ConnectivityManager)getSystemService(CONNECTIVITY_SERVICE);
  NetworkInfo ni=mgr.getActiveNetworkInfo();

  if (ni==null || ni.getType()==ConnectivityManager.TYPE_MOBILE) {
    EventBus.getDefault().post(new ServerStartRejectedEvent());
    stopSelf();
  }
  else {
    handlebars=new Handlebars(new AssetTemplateLoader(getAssets()));
    rootPath=
      "/"+new BigInteger(20, rng).toString(24).toUpperCase();

    server=new AsyncHttpServer();

    if (configureRoutes(server)) {
      server.get("/.*", new AssetRequestCallback());
    }

    server.listen(getPort());

    raiseReadyEvent();
    foregroundify();
    timeoutFuture=timer.schedule(onTimeout,
      getMaxIdleTimeSeconds(), TimeUnit.SECONDS);
  }
}
```

If `configureRoutes()` returns `true`, that means that `WebServerService` should add the all-wildcard route, pulling matching content from `assets/`, and tracking failures for the consecutive-invalid-request defense.

getPort() and getMaxIdleTimeSeconds()

The `onCreate()` code shown above also shows two more `abstract` methods that subclasses provide:

- `getPort()`, to return the port to use to run the Web server
- `getMaxIdleTimeSeconds()`, to return how long the server can be idle before it is automatically shut down

These replace constants found in earlier versions of the sample.

getMaxSequentialInvalidRequests()

Similarly, the subclass needs to supply a `getMaxSequentialInvalidRequests()` implementation, to return how many consecutive invalid requests are allowed before the Web server shuts down as a defensive measure. This is used by the slightly-revised `trackInvalidRequests()` method:

```
protected void trackInvalidRequests() {
  invalidRequestCount++;

  if (invalidRequestCount>getMaxSequentialInvalidRequests()) {
    stopSelf();
  }
}
```

Integrating WebSocket and Handlebars

The support for WebSockets was pulled over into the `Reusable` project largely as-is from its original implementation. The idea is that the `WebServerService` would handle basic registration of clients, leaving the subclass to push messages to them. To that end, the `sockets` collection of outstanding `WebSocket` instances is exposed to subclasses via a `protected` `getWebSockets()` method.

Also, since not all uses of `WebServerService` need WebSocket support, subclasses need to call a `serveWebSockets()` method to set up the WebSocket route. This method takes two parameters:

- the relative path, under the randomly-generated root path, to use for WebSocket registration, and
- a `WebSocketRequestCallback` instance for handling those registrations, or `null` to use the standard implementation supplied by `WebServerService`

```
protected void serveWebSockets(String relpath,
                               AsyncHttpServer.WebSocketRequestCallback cb) {
  StringBuilder route=new StringBuilder(rootPath);

  if (!relpath.startsWith("/")) {
    route.append('/');
  }

  route.append(relpath);

  if (cb==null) {
    cb=new WebSocketClientCallback();
  }

  server.websocket(route.toString(), cb);
}
```

`WebServerService` also integrates Handlebars support, creating the `Handlebars` instance in `onCreate()`, pulling the `Handlebars` templates from assets as before.

However, rather than having a dedicated route for Handlebars templates, the stock `AssetRequestCallback` now knows that paths ending in `.hbs` represent Handlebars templates. `AssetRequestCallback` will call a `getContextForPath()` method, supplying the path to the template (minus the randomly-generated root path), so subclasses can prepare and return the appropriate `Context` for resolving any macros encoded in the template:

```
private class AssetRequestCallback
  implements HttpServerRequestCallback {
  private final AssetManager assets;

  AssetRequestCallback() {
    assets=getAssets();
  }

  @Override
  public void onRequest(AsyncHttpServerRequest request,
                        AsyncHttpServerResponse response) {
    String path=request.getPath();

    try {
      if (path.startsWith(rootPath)) {
        path=path.substring(rootPath.length()+1);
      }
      else {
        handle404(response, path, null);
        return;
      }

      if (path.length()==0 || "/".equals(path)) {
        path="index.html";
      }
      else if (path.startsWith("/")) {
        path=path.substring(1);
      }

      if (path.endsWith(".hbs")) {
        Template t=handlebars.compile(path);
        Context ctxt=getContextForPath(path);

        response.send(t.apply(ctxt));
        response.setContentType("text/html");
        ctxt.destroy();
      }
      else {
        AssetFileDescriptor afd=assets.openFd(path);

        response.sendStream(afd.createInputStream(),
          afd.getLength());
      }

      resetTimeout();
      invalidRequestCount=0;
    }
    catch (IOException e) {
      handle404(response, path, e);
    }
  }
```

However, `getContextForPath()` is not `abstract`, so subclasses that do not need Handlebars support do not need to worry about it. Instead, the stock implementation just throws an `IllegalStateException`, to make it obvious to developers that they need to override this method if they have `.hbs` files that are being served:

```
protected Context getContextForPath(String relpath) {
  throw new IllegalStateException("You need to override this if using Handlebars!");
}
```

Stopping the Service

Mostly, stopping the subclass of `WebServerService` is not a problem. The service can call `stopSelf()`, or activities of apps that reuse `WebServerService` can call `stopService()` with an `Intent` identifying the subclass.

However, there is one problem area: `StopReceiver`. This `BroadcastReceiver` is used to handle the "stop" action added to the foreground `Notification`. It cannot call `stopSelf()`, as it is not the service. However, the original implementation of `StopReceiver` also does not work, as it calls `stopService()` on an `Intent` identifying `WebServerService`, and that is not the running service — some subclass of `WebServerService` is.

There are any number of possible solutions to this problem:

- We could skip the "stop" action altogether and have apps using this library deal with it. However, some developers might skip having a "stop" action, and that action is important for users.
- We could have another `abstract` method, where subclasses have to provide an `Intent`, or possibly just a Java `Class`, identifying the service.
- We could use Java reflection to try to find subclasses of `WebServerService` in our VM and stop those. This would require the least work on behalf of users of the library. However, this is an Android book, and so it would be nice to find a more "Android-y" solution.

This sample takes another approach: manual `Intent` resolution.

Apps using the library should have their `<service>` have an `<intent-filter>` in the manifest with an `<action>` of `com.commonsware.android.webserver.WEB_SERVER_SERVICE`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonsware.andprojector"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <uses-permission android:name="android.permission.INTERNET"/>
  <uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"/>

  <application
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".MainActivity"
      android:theme="@style/AppTheme">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <service
      android:name=".ProjectorService"
      android:exported="false">
      <intent-filter>
        <action android:name="com.commonsware.android.webserver.WEB_SERVER_SERVICE"/>
      </intent-filter>
    </service>
  </application>

</manifest>
```

`StopReceiver` then uses `PackageManager` to find all services in this package that implement that action string, creates `Intent` objects identifying them, and stops those services:

```
package com.commonsware.android.webserver;

import android.content.BroadcastReceiver;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;

public class StopReceiver extends BroadcastReceiver {
  @Override
  public void onReceive(Context context, Intent intent) {
    Intent i=
      new Intent(context.getString(R.string.service_action))
```

```
        .setPackage(context.getPackageName());

    PackageManager mgr=context.getPackageManager();

    for (ResolveInfo ri : mgr.queryIntentServices(i, 0)) {
      ComponentName cn=
        new ComponentName(ri.serviceInfo.applicationInfo.packageName,
          ri.serviceInfo.name);
      Intent stop=new Intent().setComponent(cn);

      context.stopService(stop);
    }
  }
}
```

You might wonder why the `<action>` element does not refer to the same string resource that `StopReceiver` uses when creating the `Intent`. Ideally, it would. However, this is not supported — action strings must be literal strings, not references to string resources.

Trimming Back the Project

Since `WebServerService` is `abstract`, we do not need it in our manifest. And, since the overall project is now a library project, we can trim the manifest back a fair bit:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonsware.android.webserver"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <uses-permission android:name="android.permission.INTERNET"/>
  <uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"/>

  <application>
    <receiver android:name=".StopReceiver"/>
  </application>

</manifest>
```

Similarly, the library no longer has its activity (to be supplied by the apps using the library) or any of its resources.

Reusing the Module via Relative Paths

In theory, this library project could be published as an AAR in an artifact repository. That could be a local repo, or a remote one; the remote one could be public (e.g., Maven Central) or private to an organization.

A lightweight, though somewhat clunky, alternative is to have an app wishing to use the library have what amounts to a "virtual module" for the library.

In an project's settings.gradle, you normally just list the modules in the project itself. However, it is also possible to list modules that live somewhere else, updating the default location for that module to point to the proper spot:

```
include ':app', ':webserver'

project(':webserver').projectDir=new File('../../WebServer/Reusable/webserver')
```

Here, we declare that the project not only has an app module in its default location (app/), but that we have a webserver module whose files are in a location relative to the current project. Note that the path is relative to the project root and must point to the module we wish to reference (webserver/), not just the project containing that module.

Then, modules inside the project can pull in the virtual module as if it were just another library module in the same project:

```
dependencies {
    compile project(':webserver')
}
```

This has the advantage of allowing you to make changes to the library module and have it automatically be pulled in by multiple application projects, without having to fuss with version numbers, artifact repositories, and the like. However, in practice, most production-grade apps would benefit from having the library itself be versioned, as that helps decouple the release schedule of the library from the release schedules of the apps using that library. Use this technique only for lightweight experimental projects… like book sample apps.

Seeing the Reuse In Action

This reusable Web server module will be reused in a few sample projects, including:

- Having a Web app in debug builds to give you information about your running app without disturbing the app itself
- Using a Web app for viewing the output of screenshots taken by an app

Miscellaneous Network Capabilities

This chapter is a catch-all for various Android capabilities related to network I/O and the Internet, beyond what is covered elsewhere in the book.

(yes, this chapter could have a more exciting rationale for existing, but the author is subject to "Truth in Advertising" laws…)

Prerequisites

Readers of this chapter should have read the core chapters of the book.

Downloading Files

Android 2.3 introduced a `DownloadManager`, designed to handle a lot of the complexities of downloading larger files, such as:

1. Determining whether the user is on WiFi or mobile data, and if so, whether the download should occur
2. Handling when the user, previously on WiFi, moves out of range of the access point and "fails over" to mobile data
3. Ensuring the device stays awake while the download proceeds

`DownloadManager` itself is less complicated than the alternative of writing all of that stuff yourself. However, it does present a few challenges. In this section, we will examine the [`Internet/Download`] sample project, one that uses `DownloadManager`.

The Permissions

To use `DownloadManager`, you will need to hold the `INTERNET` permission. You will also need the `WRITE_EXTERNAL_STORAGE` permission, as `DownloadManager` can only download to external storage. Note that you need to hold `WRITE_EXTERNAL_STORAGE` even if you are trying to have `DownloadManager` write to some location where that permission might not be needed (e.g., `getExternalFilesDir()` on an Android 4.4+ device). `DownloadManager` is requiring you to hold that permission, more so than the

Android framework, and `DownloadManager` requires that permission for all API levels at the present time.

For example, here is the manifest for the `Internet/Download` application, where we request these two permissions:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.downmgr"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="14"/>

  <uses-permission android:name="android.permission.INTERNET"/>
  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
      android:name=".DownloadDemo"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

The Layout

Our sample application has a simple layout, consisting of three buttons:

1. One to kick off a download
2. One to query the status of a download
3. One to display a system-supplied activity containing the roster of downloaded files

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button
    android:id="@+id/start"
    android:text="@string/start_download"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
  <Button
    android:id="@+id/query"
    android:text="@string/query_status"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
    android:enabled="false"
  />
  <Button android:id="@+id/view"
    android:text="@string/view_log"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
</LinearLayout>
```

Requesting the Download

To kick off a download, we first need to get access to the DownloadManager. This is a so-called "system service". You can call getSystemService() on any activity (or other Context), provide it the identifier of the system service you want, and receive the system service object back. However, since getSystemService() supports a wide range of these objects, you need to cast it to the proper type for the service you requested.

So, for example, here is the onCreateView() method of the DownloadFragment, in which we get the DownloadManager:

```
  @Override
  public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                           Bundle savedInstanceState) {
    mgr=
        (DownloadManager)getActivity().getSystemService(Context.DOWNLOAD_SERVICE);

    View result=inflater.inflate(R.layout.main, parent, false);

    query=result.findViewById(R.id.query);
    query.setOnClickListener(this);
    start=result.findViewById(R.id.start);
    start.setOnClickListener(this);

    result.findViewById(R.id.view).setOnClickListener(this);

    return(result);
  }
```

Most of these managers have no `close()` or `release()` or `goAwayPlease()` sort of methods — you can just use them and let garbage collection take care of cleaning them up.

Given the manager, we can now call an `enqueue()` method to request a download. The name is relevant — do not assume that your download will begin immediately, though often times it will. The `enqueue()` method takes a `DownloadManager.Request` object as a parameter. The `Request` object uses the builder pattern, in that most methods return the `Request` itself, so you can chain a series of calls together with less typing.

For example, the top-most button in our layout is tied to a `startDownload()` method in `DownloadFragment`, shown below:

```
private void startDownload(View v) {
  Uri uri=Uri.parse("https://commonsware.com/misc/test.mp4");

  Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS)
             .mkdirs();

  DownloadManager.Request req=new DownloadManager.Request(uri);

  req.setAllowedNetworkTypes(DownloadManager.Request.NETWORK_WIFI
                                 | DownloadManager.Request.NETWORK_MOBILE)
     .setAllowedOverRoaming(false)
     .setTitle("Demo")
     .setDescription("Something useful. No, really.")
     .setDestinationInExternalPublicDir(Environment.DIRECTORY_DOWNLOADS,
                                        "test.mp4");

  lastDownload=mgr.enqueue(req);

  v.setEnabled(false);
  query.setEnabled(true);
}
```

We are downloading a sample MP4 file, and we want to download it to the external storage area. To do the latter, we are using `getExternalStoragePublicDirectory()` on `Environment`, which gives us a directory suitable for storing a certain class of content. In this case, we are going to store the download in the `Environment.DIRECTORY_DOWNLOADS`, though we could just as easily have chosen `Environment.DIRECTORY_MOVIES`, since we are downloading a video clip. Note that the File object returned by getExternalStoragePublicDirectory() may point to a not-yet-created directory, which is why we call mkdirs() on it, to ensure the directory exists.

We then create the DownloadManager.Request object, with the following attributes:

1. We are downloading the specific URL we want, courtesy of the Uri supplied to the Request constructor
2. We are willing to use either mobile data or WiFi for the download (setAllowedNetworkTypes()), but we do not want the download to incur roaming charges (setAllowedOverRoaming())
3. We want the file downloaded as test.mp4 in the downloads area on the external storage (setDestinationInExternalPublicDir())

We also provide a name (setTitle()) and description (setDescription()), which are used as part of the notification drawer entry for this download. The user will see these when they slide down the drawer while the download is progressing.

The enqueue() method returns an ID of this download, which we hold onto for use in querying the download status.

Keeping Track of Download Status

If the user presses the Query Status button, we want to find out the details of how the download is progressing. To do that, we can call query() on the DownloadManager. The query() method takes a DownloadManager.Query object, describing what download(s) you are interested in. In our case, we use the value we got from the enqueue() method when the user requested the download:

```
private void queryStatus(View v) {
  Cursor c=
      mgr.query(new DownloadManager.Query().setFilterById(lastDownload));

  if (c == null) {
    Toast.makeText(getActivity(), R.string.download_not_found,
                   Toast.LENGTH_LONG).show();
  }
  else {
    c.moveToFirst();

    Log.d(getClass().getName(),
          "COLUMN_ID: "
              + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_ID)));
    Log.d(getClass().getName(),
          "COLUMN_BYTES_DOWNLOADED_SO_FAR: "
              +
c.getLong(c.getColumnIndex(DownloadManager.COLUMN_BYTES_DOWNLOADED_SO_FAR)));
      Log.d(getClass().getName(),
            "COLUMN_LAST_MODIFIED_TIMESTAMP: "
                +
c.getLong(c.getColumnIndex(DownloadManager.COLUMN_LAST_MODIFIED_TIMESTAMP)));
      Log.d(getClass().getName(),
            "COLUMN_LOCAL_URI: "
                + c.getString(c.getColumnIndex(DownloadManager.COLUMN_LOCAL_URI)));
      Log.d(getClass().getName(),
            "COLUMN_STATUS: "
                + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_STATUS)));
      Log.d(getClass().getName(),
            "COLUMN_REASON: "
                + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_REASON)));

      Toast.makeText(getActivity(), statusMessage(c), Toast.LENGTH_LONG)
           .show();

      c.close();
    }
  }
```

The `query()` method returns a `Cursor`, containing a series of columns representing the details about our download. There is a series of constants on the `DownloadManager` class outlining what is possible. In our case, we retrieve (and dump to LogCat):

1. The ID of the download (`COLUMN_ID`)
2. The amount of data that has been downloaded to date (`COLUMN_BYTES_DOWNLOADED_SO_FAR`)
3. What the last-modified timestamp is on the download (`COLUMN_LAST_MODIFIED_TIMESTAMP`)
4. Where the file is being saved to locally (`COLUMN_LOCAL_URI`)
5. What the actual status is (`COLUMN_STATUS`)
6. What the reason is for that status (`COLUMN_REASON`)

Note that `COLUMN_LOCAL_URI` may be unavailable, if the user has deleted the downloaded file between when the download completed and the time you try to access the column.

There are a number of possible status codes (e.g., `STATUS_FAILED`, `STATUS_SUCCESSFUL`, `STATUS_RUNNING`). Some, like `STATUS_FAILED`, may have an accompanying reason to provide more details.

Note that you really should close this `Cursor` when you are done with it. `StrictMode`, for example, will complain if you do not.

Download Broadcasts

To find out about the results of the download, we need to register a BroadcastReceiver, to watch for two actions used by DownloadManager:

1. ACTION_DOWNLOAD_COMPLETE, to let us know when the download is done
2. ACTION_NOTIFICATION_CLICKED, to let us know if the user taps on the Notification displayed on the user's device related to our download

So, in onResume() of our fragment, we register a single BroadcastReceiver for both of those events:

```
  @Override
  public void onResume() {
    super.onResume();

    IntentFilter f=
        new IntentFilter(DownloadManager.ACTION_DOWNLOAD_COMPLETE);

    f.addAction(DownloadManager.ACTION_NOTIFICATION_CLICKED);

    getActivity().registerReceiver(onEvent, f);
  }
```

That BroadcastReceiver is unregistered in onPause():

```
  @Override
  public void onPause() {
    getActivity().unregisterReceiver(onEvent);

    super.onPause();
  }
```

The BroadcastReceiver implementation examines the action string of the incoming Intent (via a call to getAction() and either displays a Toast (for ACTION_NOTIFICATION_CLICKED) or enables the start-download Button:

```
    public void onReceive(Context ctxt, Intent i) {
      if (DownloadManager.ACTION_NOTIFICATION_CLICKED.equals(i.getAction())) {
        Toast.makeText(ctxt, R.string.hi, Toast.LENGTH_LONG).show();
      }
      else {
        start.setEnabled(true);
      }
    }
  };
}
```

What the User Sees

The user, upon launching the application, sees our three pretty buttons:

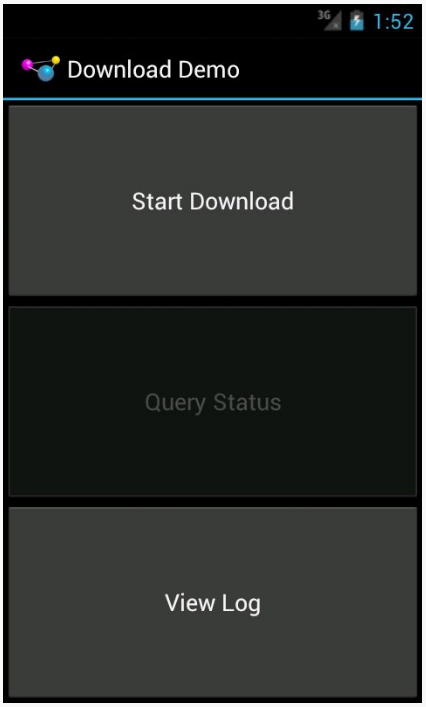


Figure 674: The Download Demo Sample, As Initially Launched

Clicking the first disables the button while the download is going on, and a download icon appears in the status bar (though it is a bit difficult to see, given the poor contrast between Android's icon and Android's status bar):

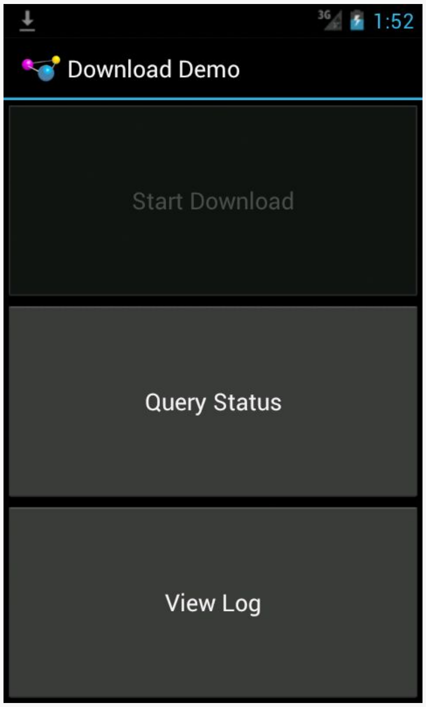

Figure 675: The Download Demo Sample, Downloading

Sliding down the notification drawer shows the user the progress in the form of a `ProgressBar` widget:

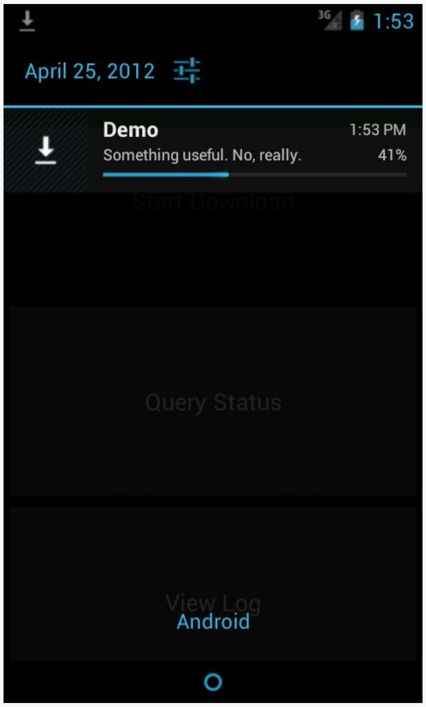

Figure 676: The DownloadManager Notification

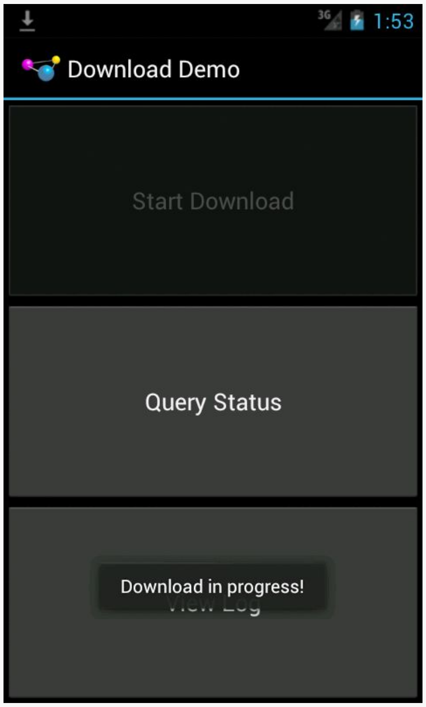
Tapping on the entry in the notification drawer returns control to our original activity, where they see a `Toast`, raised by our `BroadcastReceiver`.

If they tap the middle button during the download, a different `Toast` will appear indicating that the download is in progress:



Download in progress!

Figure 677: The Download Demo, Showing Download Status

Additional details are also dumped to LogCat:

```
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_ID: 12
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_BYTES_DOWNLOADED_SO_FAR: 615400
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_LAST_MODIFIED_TIMESTAMP: 1291988696232
12-10 08:45:01.289: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_LOCAL_URI: file:///mnt/sdcard/Download/test.mp4
12-10 08:45:01.299: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_STATUS: 2
12-10 08:45:01.299: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_REASON: 0
```

Once the download is complete, tapping the middle button will indicate that the download is, indeed, complete, and final information about the download is emitted to LogCat:

```
12-10 08:49:27.360: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_ID: 12
12-10 08:49:27.360: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_BYTES_DOWNLOADED_SO_FAR: 6219229
12-10 08:49:27.370: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_LAST_MODIFIED_TIMESTAMP: 1291988713409
12-10 08:49:27.370: DEBUG/com.commonsware.android.download.DownloadDemo(372):
```

```
COLUMN_LOCAL_URI: file:///mnt/sdcard/Download/test.mp4
12-10 08:49:27.370: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_STATUS: 8
12-10 08:49:27.370: DEBUG/com.commonsware.android.download.DownloadDemo(372):
COLUMN_REASON: 0
```

Tapping the bottom button brings up the activity displaying all downloads, including both successes and failures:

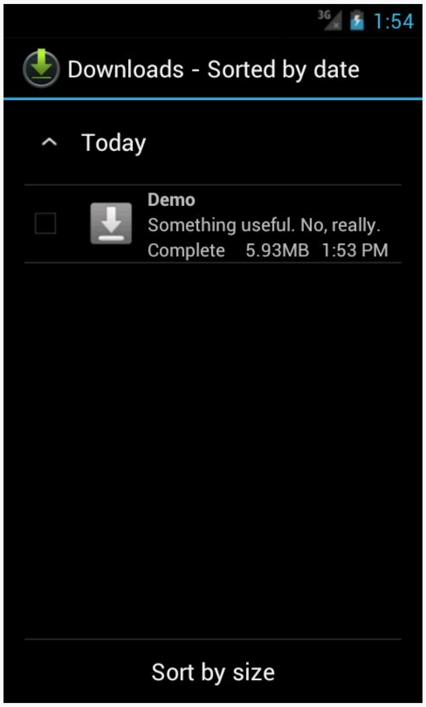


Figure 678: The DownloadManager Results

And, of course, the file is downloaded.

Limitations

While `DownloadManager` nowadays supports HTTPS (SSL) URLs, that was not the case when it was introduced back in Android 2.3. You will want to test any HTTPS URLs you intend to use with `DownloadManager` if you are supporting older versions of Android.

If you display the list of all downloads, and your download is among them, it is a really good idea to make sure that some activity (perhaps one of yours) is able to respond to an `ACTION_VIEW Intent` on that download's MIME type. Otherwise, when the user taps on the entry in the list, they will get a `Toast` indicating that there is nothing available to view the download. This may confuse users. Alternatively, use `setVisibleInDownloadsUi()` on your request, passing in `false`, to suppress it from this list.

Trail: Media

Audio Playback

Whether it comes in the form of simple beeps or in the form of symphonies (or gangster rap or whatever), Android applications often need to play audio. A few things in Android can play audio automatically, such as a `Notification`. However, once you get past those, you are on your own.

Fortunately for you, Android offers support for audio playback, and we will examine some of the options in this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Get Your Media On

In Android, you have five different places you can pull media clips from — one of these will hopefully fit your needs:

- You can package audio clips as raw resources (`res/raw` in your project), so they are bundled with your application. The benefit is that you're guaranteed the clips will be there; the downside is that they cannot be replaced without upgrading the application.
- You can package audio clips as assets (`assets/` in your project) and reference them via `file:///android_asset/` URLs in a `Uri`. The benefit over raw resources is that this location works with APIs that expect `Uri` parameters instead of resource IDs. The downside — assets are only replaceable when the application is upgraded — remains.

- You can store media in an application-local directory, such as content you download off the Internet. Your media may or may not be there, and your storage space isn't infinite, but you can replace the media as needed.
- You can store media — or make use of media that the user has stored herself — that is on an SD card. There is likely more storage space on the card than there is on the device, and you can replace the media as needed, but other applications have access to the SD card as well.
- You can, in some cases, stream media off the Internet, bypassing any local storage

Remember that on Android 1.x/2.x devices, internal storage space is at a premium. That means you should only package small clips in your app (`assets/` or `res/raw/`) and download larger clips to external storage.

MediaPlayer for Audio

If you want to play back music, particularly material in MP3 format, you will want to use the `MediaPlayer` class. With it, you can feed it an audio clip, start/stop/pause playback, and get notified on key events, such as when the clip is ready to be played or is done playing.

You have three ways to set up a `MediaPlayer` and tell it what audio clip to play:

- If the clip is a raw resource, use `MediaPlayer.create()` and provide the resource ID of the clip
- If you have a `Uri` to the clip, use the `Uri`-flavored version of `MediaPlayer.create()`
- If you have a string path to the clip, just create a `MediaPlayer` using the default constructor, then call `setDataSource()` with the path to the clip

Next, you need to call `prepare()` or `prepareAsync()`. Both will set up the clip to be ready to play, such as fetching the first few seconds off the file or stream. The `prepare()` method is synchronous; as soon as it returns, the clip is ready to play. The `prepareAsync()` method is asynchronous — more on how to use this version later.

Once the clip is prepared, `start()` begins playback, `pause()` pauses playback (with `start()` picking up playback where `pause()` paused), and `stop()` ends playback. One caveat: you cannot simply call `start()` again on the `MediaPlayer` once you have called `stop()` — we'll cover a workaround a bit later in this section.

To see this in action, take a look at the Media/Audio sample project. The layout is pretty trivial, with three buttons and labels for play, pause, and stop:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
  <LinearLayout
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:padding="4dip"
  >
    <ImageButton android:id="@+id/play"
      android:src="@drawable/play"
      android:layout_height="wrap_content"
      android:layout_width="wrap_content"
      android:paddingRight="4dip"
      android:enabled="false"
    />
    <TextView
      android:text="Play"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:gravity="center_vertical"
      android:layout_gravity="center_vertical"
      android:textAppearance="?android:attr/textAppearanceLarge"
    />
  </LinearLayout>
  <LinearLayout
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:padding="4dip"
  >
    <ImageButton android:id="@+id/pause"
      android:src="@drawable/pause"
      android:layout_height="wrap_content"
      android:layout_width="wrap_content"
      android:paddingRight="4dip"
    />
    <TextView
      android:text="Pause"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:gravity="center_vertical"
      android:layout_gravity="center_vertical"
      android:textAppearance="?android:attr/textAppearanceLarge"
    />
  </LinearLayout>
  <LinearLayout
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:padding="4dip"
  >
```

```
    <ImageButton android:id="@+id/stop"
      android:src="@drawable/stop"
      android:layout_height="wrap_content"
      android:layout_width="wrap_content"
      android:paddingRight="4dip"
    />
    <TextView
      android:text="Stop"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
      android:gravity="center_vertical"
      android:layout_gravity="center_vertical"
      android:textAppearance="?android:attr/textAppearanceLarge"
    />
  </LinearLayout>
</LinearLayout>
```

The Java, of course, is where things get interesting:

```
package com.commonsware.android.audio;

import android.app.Activity;
import android.app.AlertDialog;
import android.content.Context;
import android.content.SharedPreferences;
import android.media.MediaPlayer;
import android.os.Bundle;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.ImageButton;
import android.widget.Toast;

public class AudioDemo extends Activity
  implements MediaPlayer.OnCompletionListener {

  private ImageButton play;
  private ImageButton pause;
  private ImageButton stop;
  private MediaPlayer mp;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    setContentView(R.layout.main);

    play=(ImageButton)findViewById(R.id.play);
    pause=(ImageButton)findViewById(R.id.pause);
    stop=(ImageButton)findViewById(R.id.stop);

    play.setOnClickListener(new View.OnClickListener() {
      public void onClick(View view) {
        play();
      }
    });

    pause.setOnClickListener(new View.OnClickListener() {
      public void onClick(View view) {
        pause();
      }
    });

    stop.setOnClickListener(new View.OnClickListener() {
      public void onClick(View view) {
        stop();
      }
    });

    setup();
  }

  @Override
  public void onDestroy() {
    super.onDestroy();

    if (stop.isEnabled()) {
      stop();
    }
  }

  public void onCompletion(MediaPlayer mp) {
    stop();
  }

  private void play() {
    mp.start();

    play.setEnabled(false);
    pause.setEnabled(true);
    stop.setEnabled(true);
  }

  private void stop() {
    mp.stop();
    pause.setEnabled(false);
    stop.setEnabled(false);

    try {
      mp.prepare();
      mp.seekTo(0);
      play.setEnabled(true);
    }
    catch (Throwable t) {
      goBlooey(t);
    }
  }

  private void pause() {
    mp.pause();

    play.setEnabled(true);
    pause.setEnabled(false);
    stop.setEnabled(true);
  }

  private void loadClip() {
    try {
      mp=MediaPlayer.create(this, R.raw.clip);
      mp.setOnCompletionListener(this);
    }
    catch (Throwable t) {
      goBlooey(t);
    }
  }

  private void setup() {
    loadClip();
    play.setEnabled(true);
    pause.setEnabled(false);
    stop.setEnabled(false);
  }

  private void goBlooey(Throwable t) {
    AlertDialog.Builder builder=new AlertDialog.Builder(this);

    builder
      .setTitle("Exception!")
      .setMessage(t.toString())
      .setPositiveButton("OK", null)
      .show();
  }
}
```

In onCreate(), we wire up the three buttons to appropriate callbacks, then call setup(). In setup(), we create our MediaPlayer, set to play a clip we package in the project as a raw resource. We also configure the activity itself as the completion listener, so we find out when the clip is over. Note that, since we use the static create() method on MediaPlayer, we have already implicitly called prepare(), so we do not need to call that separately ourselves.

The buttons simply work the MediaPlayer and toggle each others' states, via appropriately-named callbacks. So, play() starts MediaPlayer playback, pause() pauses playback, and stop() stops playback and resets our MediaPlayer to play again. The stop() callback is also used for when the audio clip completes of its own accord.

To reset the MediaPlayer, the stop() callback calls prepare() on the existing MediaPlayer to enable it to be played again and seekTo() to move the playback point to the beginning. If we were using an external file as our media source, it would be better to call prepareAsync().

The UI is nothing special, but we are more interested in the audio in this sample, anyway:

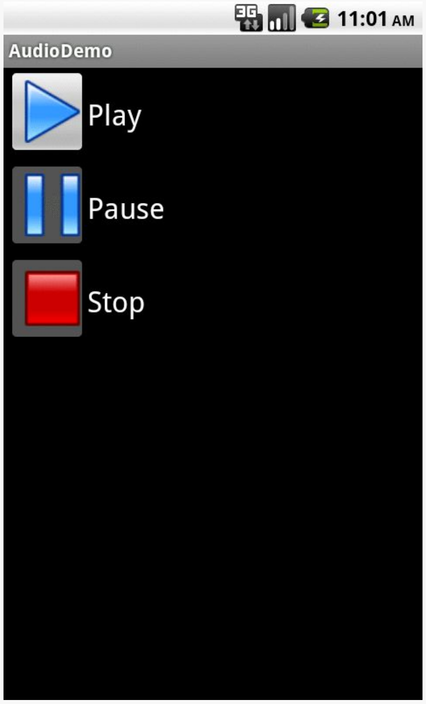

Figure 679: The AudioDemo sample application

Streaming Limitations

You can use the same basic code for streaming media, using an `http://` or `rtsp://` URL. However, bear in mind that Android does not support streaming MP3 over RTSP, as that exceeds the relevant RTSP specifications. That being said, there *are* MP3-over-RTSP streams in the world, and clients and servers that have negotiated an ad-hoc extension to the specification to accommodate this. Android cannot play these streams.

Other Ways to Make Noise

While `MediaPlayer` is the primary audio playback option, particularly for content along the lines of MP3 files, there are other alternatives if you are looking to build other sorts of applications, notably games and custom forms of streaming audio.

SoundPool

The SoundPool class's claim to fame is the ability to overlay multiple sounds, and do so in a prioritized fashion, so your application can just ask for sounds to be played and SoundPool deals with each sound starting, stopping, and blending while playing.

This may make more sense with an example.

Suppose you are creating a first-person shooter. Such a game may have several sounds going on at any one time:

1. The sound of the wind whistling amongst the trees on the battlefield
2. The sound of the surf crashing against the beach in the landing zone
3. The sound of booted feet crunching on the sand
4. The sound of the character's own panting as the character runs on the beach
5. The sound of orders being barked by a sergeant positioned behind the character
6. The sound of machine gun fire aimed at the character and the character's squad mates
7. The sound of explosions from the gun batteries of the battleship providing suppression fire

And so on.

In principle, SoundPool can blend all of those together into a single audio stream for output. Your game might set up the wind and surf as constant background sounds, toggle the feet and panting on and off based on the character's movement, randomly add the barked orders, and tie the gunfire based on actual game play.

In reality, your average smartphone will lack the CPU power to handle all of that audio without harming the frame rate of the game. So, to keep the frame rate up, you tell SoundPool to play at most two streams at once. This means that when nothing else is happening in the game, you will hear the wind and surf, but during the actual battle, those sounds get dropped out — the user might never even miss them — so the game speed remains good.

AudioTrack

The lowest-level Java API for playing back audio is AudioTrack. It has two main roles:

1. Its primary role is to support streaming audio, where the streams come in some format other than what `MediaPlayer` handles. While `MediaPlayer` can handle RTSP, for example, it does not offer SIP. If you want to create a SIP client (perhaps for a VOIP or Web conferencing application), you will need to convert the incoming data stream to PCM format, then hand the stream off to an `AudioTrack` instance for playback.
2. It can also be used for "static" (versus streamed) bits of sound that you have pre-decoded to PCM format and want to play back with as little latency as possible. For example, you might use this for a game for in-game sounds (beeps, bullets, or "boing"s). By pre-decoding the data to PCM and caching that result, then using `AudioTrack` for playback, you will use the least amount of overhead, minimizing CPU impact on game play and on battery life.

ToneGenerator

If you want your phone to sound like… well… a phone, you can use `ToneGenerator` to have it play back dual-tone multi-frequency (DTMF) tones. In other words, you can simulate the sounds played by a regular "touch-tone" phone in response to button presses. This is used by the Android dialer, for example, to play back the tones when users dial the phone using the on-screen keypad, as an audio reinforcement.

Note that these will play through the phone's earpiece, speaker, or attached headset. They do not play through the outbound call stream. In principle, you might be able to get `ToneGenerator` to play tones through the speaker loud enough to be picked up by the microphone, but this probably is not a recommended practice.

Audio Recording

Most Android devices have microphones. On such devices, it might be nice to get audio input from those microphones, whether to record locally, process locally (e.g., speech recognition), or to stream out over the Internet (e.g., voice over IP).

Not surprisingly, Android has some capabilities in this area. Also, not surprisingly, there are multiple APIs, with varying mixes of power and complexity, to allow you to capture microphone input. In this chapter, we will examine `MediaRecorder` for recording audio files and `AudioRecord` for raw microphone input.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on audio playback is probably also a good idea. And, for the section on playing back local streams, you will want to have read up on content providers, particularly the chapter on provider patterns.

Recording by Intent

Just as the easiest way to take a picture with the camera is to use the device's built-in camera app, the easiest way to record some audio is to use a built-in activity for it. And, as with using the built-in camera app, the built-in audio recording activity has some significant limitations.

Requesting the built-in audio recording activity is a matter of calling `startActivityForResult()` for a `MediaStore.Audio.Media.RECORD_SOUND_ACTION` action. You can see this in the `Media/SoundRecordIntent` sample project, specifically the `MainActivity`:

```
package com.commonsware.android.soundrecord;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.MediaStore;
import android.widget.Toast;

public class MainActivity extends Activity {
  private static final int REQUEST_ID=1337;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    Intent i=new Intent(MediaStore.Audio.Media.RECORD_SOUND_ACTION);

    startActivityForResult(i, REQUEST_ID);
  }

  @Override
  protected void onActivityResult(int requestCode, int resultCode,
                                  Intent data) {
    if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
      Toast.makeText(this, "Recording finished!", Toast.LENGTH_LONG)
           .show();
    }

    finish();
  }
}
```

As with a few other sample apps in this book, the Media/SoundRecordIntent uses a Theme.NoDisplay activity, eschewing its own UI. Instead, in onCreate(), we immediately call startActivityForResult() for MediaStore.Audio.Media.RECORD_SOUND_ACTION. That will bring up a recording activity:

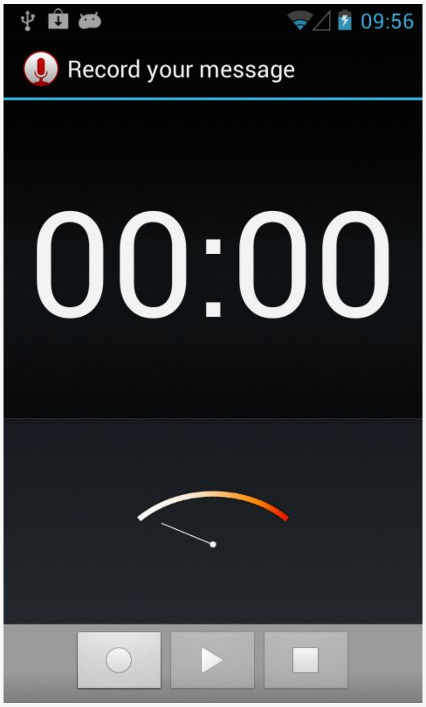

Figure 680: Built-In Sound Recording Activity

If the user records some audio via the "record" `ImageButton` (one with the circle icon) and the "stop" `ImageButton` (one with the square icon), you will get control back in `onActivityResult()`, where you are passed an `Intent` whose `Uri` (via `getData()`) will point to this audio recording in the `MediaStore`.

However:

- You have no control over where the file is stored or what it is named. It appears that, by default, these files are dumped unceremoniously in the root of external storage.
- You have no control over anything about the way the audio is recorded, such as codecs or bitrates. For example, it appears that, by default, the files are recorded in AMR format.
- `ACTION_VIEW` may not be able to play back this audio (leastways, it failed to in testing on a few devices). Whether that is due to codecs, the way the data is put in `MediaStore`, or the limits of the default audio player on Android, is unclear.

Hence, in many cases, while this works, it may not work well enough — or controlled enough — to meet your needs. In that case, you will want to handle the recording yourself, as will be described in the next couple of sections.

Recording to Files

If your objective is to record a voice note, a presentation, or something along those lines, then `MediaRecorder` is probably the class that you want. It will let you specify what sort of media you wish to record, in what format, and to what location. It then handles the actual act of recording.

To illustrate this, let us review the [Media/AudioRecording] sample project.

Our activity's layout consists of a single `ToggleButton` widget named `record`:

```
<ToggleButton xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/record"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:textAppearance="?android:attr/textAppearanceLarge"/>
```

In `onCreate()` of `MainActivity`, we load the layout and set the activity itself up as the `OnCheckedChangedListener`, to find out when the user toggles the button:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ((ToggleButton)findViewById(R.id.record)).setOnCheckedChangeListener(this);
  }
```

Also, in `onResume()`, we initialize a `MediaRecorder`, setting the activity up as being the one to handle info and error events about the recording. Similarly, we `release()` the `MediaRecorder` in `onPause()`, to reduce our overhead when we are not in the foreground:

```
  @Override
  public void onResume() {
    super.onResume();

    recorder=new MediaRecorder();
    recorder.setOnErrorListener(this);
    recorder.setOnInfoListener(this);
  }

  @Override
  public void onPause() {
    recorder.release();
    recorder=null;

    super.onPause();
  }
```

Most of the work occurs in `onCheckedChanged()`, where we get control when the user toggles the button. If we are now checked, we begin recording; if not, we stop the previous recording:

```
  @Override
  public void onCheckedChanged(CompoundButton buttonView,
                               boolean isChecked) {
    if (isChecked) {
      File output=
          new File(
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS),
                   BASENAME);

      recorder.setAudioSource(MediaRecorder.AudioSource.MIC);
      recorder.setOutputFormat(MediaRecorder.OutputFormat.THREE_GPP);
      recorder.setOutputFile(output.getAbsolutePath());

      if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD_MR1) {
        recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AAC);
        recorder.setAudioEncodingBitRate(160 * 1024);
      }
      else {
        recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AMR_NB);
      }

      recorder.setAudioChannels(2);

      try {
        recorder.prepare();
        recorder.start();
      }
      catch (Exception e) {
        Log.e(getClass().getSimpleName(),
              "Exception in preparing recorder", e);
        Toast.makeText(this, e.getMessage(), Toast.LENGTH_LONG).show();
      }
    }
    else {
      try {
        recorder.stop();
      }
      catch (Exception e) {
        Log.w(getClass().getSimpleName(),
              "Exception in stopping recorder", e);
        // can fail if start() failed for some reason
      }

      recorder.reset();
  }
}
```

To record audio, we:

- Create a File object representing where the recording should be stored, in this case using Environment.getExternalStoragePublicDirectory() to find a location on external storage
- Tell the MediaRecorder that we wish to record from the microphone, through a call to setAudioSource(), that we wish to record a 3GP file via a call to setOutputFormat(), and that we wish to record the results to our File via a call to setOutputFile()
- If we are running on Android 2.3.3 or higher, we can also configure our encoder to be AAC via setAudioEncoder() and set our requested bitrate to 160Kbps via setAudioEncodingBitRate() — otherwise, we use setAudioEncoder() to request AMR narrowband
- Indicate how many audio channels we want via setAudioChannels(), such as 2 to attempt to record in stereo
- Kick off the actual recording via calls to prepare() (to set up the output file) and record()

Stopping the recording, when the user toggles off the button, is merely a matter of calling stop() on the MediaRecorder.

Because we told the MediaRecorder that our activity was our OnErrorListener and OnInfoListener, we have to implement those interfaces on the activity and implement their required methods (onError() and onInfo(), respectively). In the normal course of events, neither of these should be triggered. If they are, we are passed an int value (typically named what) that indicates what happened:

```
@Override
public void onInfo(MediaRecorder mr, int what, int extra) {
  String msg=getString(R.string.strange);

  switch (what) {
    case MediaRecorder.MEDIA_RECORDER_INFO_MAX_DURATION_REACHED:
      msg=getString(R.string.max_duration);
      break;

    case MediaRecorder.MEDIA_RECORDER_INFO_MAX_FILESIZE_REACHED:
      msg=getString(R.string.max_size);
      break;
  }

  Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}
```

```
@Override
public void onError(MediaRecorder mr, int what, int extra) {
  Toast.makeText(this, R.string.strange, Toast.LENGTH_LONG).show();
}
```

Here, we just raise a `Toast` in either case, with either a generic message or a specific message for the cases where the maximum time duration or the maximum file size for our recording has been reached.

We also need to hold the `RECORD_AUDIO` and `WRITE_EXTERNAL_STORAGE` permissions. `RECORD_AUDIO`, in particular, is needed to let the user know that we intend to record information off of the microphone.

The results are that we get a recording on external storage (typically in a `Downloads` directory) after we toggle the button on, record some audio, then toggle the button off.

`MediaRecorder` is rather fussy about the order of method calls for its configuration. For example, you must call `setAudioEncoder()` *after* the call to `setOutputFormat()`.

Also, the available codecs and file types are rather limited. Notably, Android lacks the ability to record to MP3 format, perhaps due to patent licensing issues.

On the flip side, `MediaRecorder` also supports recording video, a topic which is not presently covered in this book.

Recording to Streams

The nice thing about recording to files is that Android handles all of the actual file I/O for us. The downside is that because Android handles all of the actual file I/O for us, it can only write files that are accessible to it and our process, meaning external storage. This may not be suitable in all cases, such as wanting to record to some form of private encrypted storage.

The good news is that Android does support recording to streams, in the form of a pipe created by `ParcelFileDescriptor` and `createPipe()`. This follows the same basic pattern that we saw in the chapter on content provider patterns, where we served a stream via a pipe. However, as you will see, there are some limits on how well we can do this.

To demonstrate and explain, let us examine the Media/AudioRecordStream sample project. This is nearly a complete clone of the previous sample, so we will only focus on the changes in this section.

The author would like to thank Lucio Maciel for his assistance in getting this example to work.

Setting Up the Stream

The biggest change, by far, is in our setOutputFile() call. Before, we supplied a path to external storage. Now, we supply the write end of a pipe:

```
      recorder.setOutputFile(getStreamFd());
```

Our getStreamFd() method looks a lot like the openFile() method of our pipe-providing provider:

```
  private FileDescriptor getStreamFd() {
    ParcelFileDescriptor[] pipe=null;

    try {
      pipe=ParcelFileDescriptor.createPipe();

      new TransferThread(new AutoCloseInputStream(pipe[0]),
                         new FileOutputStream(getOutputFile())).start();
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
    }

    return(pipe[1].getFileDescriptor());
  }
```

We create our pipe with createPipe(), spawn a TransferThread to copy the recording from an InputStream to a FileOutputStream, and return the write end of the pipe. However, setOutputFile() on MediaRecorder takes the actual integer file descriptor, not a ParcelFileDescriptor, so we use getFileDescriptor() to retrieve the file descriptor and return that.

Our TransferThread is similar to the one from the content provider sample, except that we pass over a FileOutputStream, so we can not only flush() but also sync() when we are done writing:

```
  static class TransferThread extends Thread {
    InputStream in;
    FileOutputStream out;
    TransferThread(InputStream in, FileOutputStream out) {
      this.in=in;
      this.out=out;
    }

    @Override
    public void run() {
      byte[] buf=new byte[8192];
      int len;

      try {
        while ((len=in.read(buf)) >= 0) {
          out.write(buf, 0, len);
        }

        in.close();

        out.flush();
        out.getFD().sync();
        out.close();
      }
      catch (IOException e) {
        Log.e(getClass().getSimpleName(),
              "Exception transferring file", e);
      }
    }
  }
```

Changes in Recording Configuration

The biggest limitation of a pipe's stream is that it is *purely* a stream. You cannot rewind re-read earlier bits of data. In other words, the stream is not seekable.

That is a problem with MediaRecorder in some configurations. For example, a 3GP file contains a header with information about the overall file, information that MediaRecorder does not know until the recording is complete. In the case of a file, MediaRecorder can simply rewind and update the header with the final data when everything is done. However, that is not possible with a pipe-based stream.

However, some configurations will work, notably "raw" ones that just have the recorded audio, with no type of header. That is what we use in this sample.

Specifically, we now write to a .amr file:

```
  private static final String BASENAME="recording-stream.amr";
```

We also set our output format to RAW_AMR, and our encoder to AMR_NB:

```
      recorder.setAudioSource(MediaRecorder.AudioSource.MIC);
      recorder.setOutputFormat(MediaRecorder.OutputFormat.RAW_AMR);
```

```
    recorder.setOutputFile(getStreamFd());
    recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AMR_NB);
    recorder.setAudioChannels(2);
```

This combination works. Other combinations might also work. But our approach of writing the 3GP file, as in the file-based example, will not work.

Raw Audio Input

Just as AudioTrack allows you to play audio supplied as raw 8- or 16-bit PCM input, AudioRecord allows you to record audio from the microphone, supplied to you in PCM format. It is then up to you to actually do something with the raw byte PCM data, including converting it to some other format and container as needed.

Note that you need RECORD_AUDIO to work with AudioRecord, just as you need it to work with MediaRecorder.

Requesting the Microphone

As noted in the opening paragraph of this chapter, most Android devices have microphones. The key word there is *most*. Not all Android devices will have microphones, as only some tablets (and fewer Android TV devices) will support microphone input.

As with most of this optional hardware, the solution is to use <uses-feature>. In that case, you would request the android.hardware.microphone feature, with android:required="false" if you felt that you do not absolutely *need* a microphone. In that case, you would use hasSystemFeature() on PackageManager to determine at runtime if you do indeed have a microphone.

Note that the RECORD_AUDIO permission implies that you need a microphone. Hence, even if you skip the <uses-feature> element, your app will still only ship to devices that have a microphone. If the microphone is optional, be sure to include android:required="false", so your app will be available to devices that lack a microphone.

Video Playback

Just as Android supports audio playback, it also supports video playback of local and streaming content. Unlike audio playback – which supports a mix of high-level and low-level APIs – video playback offers a purely high-level interface, in the form of the same `MediaPlayer` class you used for audio playback. To keep things a bit simpler, though, Android does offer a `VideoView` widget you can drop in an activity or fragment to play back video.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with [the chapter on audio playback](#).

Moving Pictures

Video clips get their own widget, the `VideoView`. Put it in a layout, feed it an MP4 video clip, and you get playback!

For example, take a look at this layout, from the [`Media/Video`](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
  <VideoView
     android:id="@+id/video"
      android:layout_width="match_parent"
      android:layout_height="match_parent"
    />
</LinearLayout>
```

The layout is simply a full-screen video player. Whether it will use the full screen will be dependent on the video clip, its aspect ratio, and whether you have the device (or emulator) in portrait or landscape mode.

Wiring up the Java is almost as simple:

```
package com.commonsware.android.video;

import java.io.File;
import android.app.Activity;
import android.graphics.PixelFormat;
import android.os.Bundle;
import android.os.Environment;
import android.widget.MediaController;
import android.widget.VideoView;

public class VideoDemo extends Activity {
  private VideoView video;
  private MediaController ctlr;

  @Override
  public void onCreate(Bundle icicle) {
    super.onCreate(icicle);
    getWindow().setFormat(PixelFormat.TRANSLUCENT);
    setContentView(R.layout.main);

    File clip=new File(Environment.getExternalStorageDirectory(),
                        "test.mp4");

    if (clip.exists()) {
      video=(VideoView)findViewById(R.id.video);
      video.setVideoPath(clip.getAbsolutePath());

      ctlr=new MediaController(this);
      ctlr.setMediaPlayer(video);
      video.setMediaController(ctlr);
      video.requestFocus();
      video.start();
    }
  }
}
```

Here, we:

1. Confirm that our video file exists on external storage
2. Tell the `VideoView` which file to play
3. Create a `MediaController` pop-up panel and cross-connect it to the `VideoView`
4. Give the `VideoView` the focus and start playback

The biggest trick with `VideoView` is getting a video clip onto the device. While `VideoView` does support some streaming video, the requirements on the MP4 file are fairly stringent. If you want to be able to play a wider array of video clips, you need to have them on the device, preferably on an SD card.

The crude `VideoDemo` class assumes there is an MP4 file named `test.mp4` in the root of external storage on your device or emulator. Once there, the Java code shown above will give you a working video player:

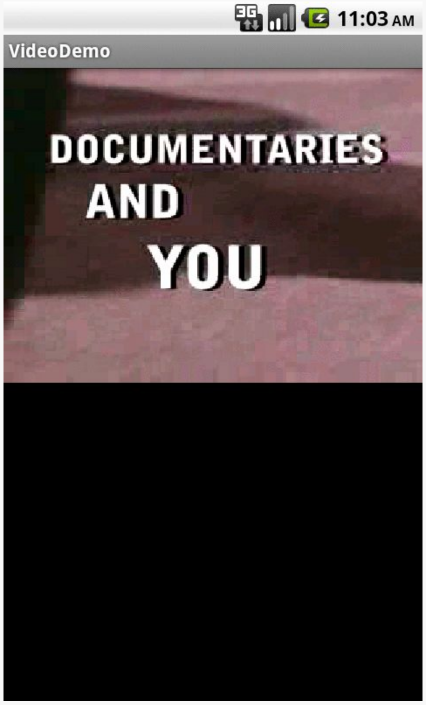

Figure 681: The VideoDemo sample application, showing a Creative Commons-licensed video clip

Tapping on the video will pop up the playback controls:

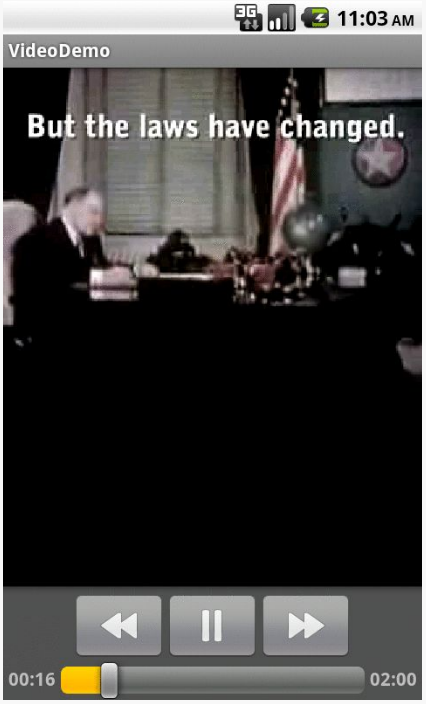

Figure 682: The VideoDemo sample application, with the media controls displayed

The video will scale based on space, as shown in this rotated view of the emulator (`<Ctrl>-<F12>`):

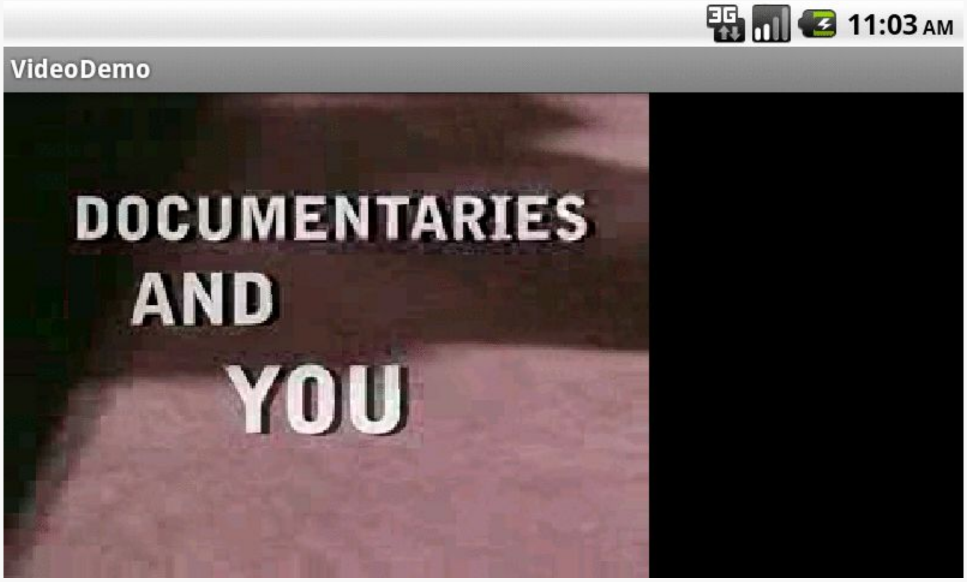

Figure 683: The VideoDemo sample application, in landscape mode, with the video clip scaled to fit

NOTE: playing video on the Android emulator may work for you, but it is not terribly likely. Video playback requires graphic acceleration to work well, and the emulator does not have graphics acceleration — regardless of the capabilities of the actual machine the emulator runs on. Hence, if you try playing back video in the emulator, expect problems. If you are serious about doing Android development with video playback, you definitely need to acquire a piece of Android hardware.

Using the Camera via 3rd-Party Apps

Most Android devices will have a camera, since they are fairly commonplace on mobile devices these days. You, as an Android developer, can take advantage of the camera, for everything from snapping tourist photos to scanning barcodes. If you wish to let other apps do the “heavy lifting” for you, working with the camera can be fairly straightforward. If you want more control, you can work with the camera directly, though this control comes with greater complexity.

You can also record videos using the camera. Once again, you have the option of either using a third-party activity, or doing it yourself.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the material on implicit `Intents`.

Being Specific About Features

If your app needs a camera — by any of the means cited in this chapter – you should include a `<uses-feature>` element in the manifest indicating your requirements. However, you need to be fairly specific about your requirements here.

For example, the Nexus 7 (2012) has a camera… but only a front-facing camera. This facilitates apps like video chat. However, the `android.hardware.camera` implies that you need a high-resolution rear-facing camera, even though this is undocumented. Hence, to work with the Nexus 7’s camera, you need to:

- Require the `CAMERA` permission (if you are using the `Camera` directly)

- Not require the android.hardware.camera feature (android:required="false")
- Optionally require the android.hardware.camera.front feature (if your app definitely needs a front-facing camera)

At runtime, you would use hasSystemFeature() on PackageManager, or interrogate the Camera class for available cameras, to determine what you have access to.

Note that if you want to record audio when recording videos, you should also consider the android.hardware.microphone feature.

Still Photos: Letting the Camera App Do It

The easiest way to take a picture is to not take the picture yourself, but let somebody else do it. The most common implementation of this approach is to use an ACTION_IMAGE_CAPTURE Intent to bring up the user's default camera application, and let it take a picture on your behalf.

To see this in use, take a look at the Camera/Content sample project. This trivial app will use system-supplied activities to take a picture, then view the result, without actually implementing any of its own UI.

The Implementation

Of course, we still need an activity, so our code can be launched by the user. We just set it up with Theme.NoDisplay, so no UI will be created for it:

```
    <activity
      android:name=".CameraContentDemoActivity"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
```

The activity itself — CameraContentDemoActivity — consists solely of onCreate() and onActivityResult() methods:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    Intent i=new Intent(MediaStore.ACTION_IMAGE_CAPTURE);
    File dir=
        Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DCIM);

    output=new File(dir, "CameraContentDemo.jpeg");
    i.putExtra(MediaStore.EXTRA_OUTPUT, Uri.fromFile(output));

    startActivityForResult(i, CONTENT_REQUEST);
  }

  @Override
  protected void onActivityResult(int requestCode, int resultCode,
                                  Intent data) {
    if (requestCode == CONTENT_REQUEST) {
      if (resultCode == RESULT_OK) {
        Intent i=new Intent(Intent.ACTION_VIEW);

        i.setDataAndType(Uri.fromFile(output), "image/jpeg");
        startActivity(i);
        finish();
      }
    }
  }
}
```

In onCreate(), we create our ACTION_IMAGE_CAPTURE Intent. We add an extra, keyed as MediaStore.EXTRA_OUTPUT, indicating where we want the app to save the resulting picture. In our case, we store that in a CameraContentDemo.jpeg file in the default external storage directory for photos (identified by Environment.DIRECTORY_DCIM). The documentation for ACTION_IMAGE_CAPTURE indicates that this needs to be in the form of a Uri object, which is why we use Uri.fromFile() to convert our string path into the Uri.

At that point, we call startActivityForResult() to bring up the user's chosen camera app to take our picture. We next get control in onActivityResult(). There, we create an ACTION_VIEW Intent, pointing at our output file, indicating the MIME type is image/jpeg, and start up an activity for that. This should bring up the Gallery or another app capable of displaying the photo on the screen.

The Caveats

There are several downsides to this approach.

First, you have no control over the camera app itself. You do not even really know what app it is. You cannot dictate certain features that you would like (e.g., resolution, color effects). You simply blindly ask for a photo and get the result.

Also, since you do not know what the camera app is or behaves like, you cannot document that portion of your application's flow very well. You can say things like "at this point, you can take a picture using your chosen camera app", but that is about as specific as you can get.

It is possible that your app's process will be terminated while your app is not in the foreground, because the user is taking a picture using the third-party camera app. Whether or not this happens depends on how much system RAM the camera app uses and what else is all going on with the device. But, it does happen. Now, your app should be able to cope with such things, but many developers do not expect their process to be replaced between a call to `startActivityForResult()` and the corresponding `onActivityResult()` callback.

Finally, some camera apps misbehave, returning odd results, such as a thumbnail-sized image rather than a max-resolution image. There is little you can do about this.

So, while this approach is easy, it may pose some quality-control issues.

OK, One More Caveat: Permissions

Your app's behavior on Android 6.0+ with respect to `ACTION_IMAGE_CAPTURE` will depend on your permissions.

If you do not request the `CAMERA` permission (i.e., you do not have `<uses-permission>` for the `CAMERA` permission in your manifest), `ACTION_IMAGE_CAPTURE` will work as described above.

If you request the `CAMERA` permission, and you go through the Android 6.0 runtime permission system to have the user agree to that permission, `ACTION_IMAGE_CAPTURE` will work as described above.

If, on the other hand, you request the `CAMERA` permission, but the user has not granted it at runtime — for example, you have not asked for it — `ACTION_IMAGE_CAPTURE` requests will result in a `SecurityException`.

What complicates matters is that it is not only the manifest that is in your `app/` module that counts, but also any manifests that are merged in from libraries. So if a library (e.g., `play-services-vision` from the Play Service SDK) has the `CAMERA` permission in *its* manifest, your app is requesting that permission, even if your code does not do anything directly with the camera.

Scanning with ZXing

If your objective is to scan a barcode, it is *much* simpler for you to integrate Barcode Scanner into your app than to roll it yourself.

Barcode Scanner – one of the most popular Android apps of all time — can scan a wide range of 1D and 2D barcode types. They offer an integration library that you can add to your app to initiate a scan and get the results. The library will even lead the user to the Play Store to install Barcode Scanner if they do not already have the app.

One limitation is that while the ZXing team (the authors and maintainers of Barcode Scanner) make the integration library available, they only do so in source form.

That sample project — `Camera/ZXing` – has a UI dominated by a "Scan!" button. Clicking the button invokes a `doScan()` method in our sample activity:

```
public void doScan(View v) {
  (new IntentIntegrator(this)).initiateScan();
}
```

This passes control to Barcode Scanner by means of the integration JAR and the `IntentIntegrator` class. `initiateScan()` will validate that Barcode Scanner is installed, then will start up the camera and scan for a barcode.

Once Barcode Scanner detects a barcode and decodes it, the activity invoked by `initiateScan()` finishes, and control returns to you in `onActivityResult()` (as the Barcode Scanner scanning activity was invoked via `startActivityForResult()`). There, you can once again use `IntentIntegrator` to find out details of the scan, notably the type of barcode and the encoded contents:

```
public void onActivityResult(int request, int result, Intent i) {
  IntentResult scan=IntentIntegrator.parseActivityResult(request,
                                                         result,
                                                         i);

  if (scan!=null) {
    format.setText(scan.getFormatName());
    contents.setText(scan.getContents());
  }
}
```

To use `IntentIntegrator` and `IntentResult`, the sample project has two modules: the `app/` module for the app, and a `zxing/` module containing those two classes (and a rump AndroidManifest.xml to make the build tools happy). The app/ module depends upon the zxing module via a compile project(':zxing') dependency directive.

Some notes:

- Barcode Scanner's scanning activity only works in landscape
- Even though you are not using the camera directly yourself, you should consider including the <uses-feature> element declaring that you need a camera, if your app cannot function without barcodes
- If you wish to add Barcode Scanner logic directly to your app, and avoid the dependency on the third-party APK, that is possible, but the process for doing it is not well documented or supported

Videos: Letting the Camera App Do It

Just as ACTION_IMAGE_CAPTURE can be used to have a third-party app supply you with still images, there is an ACTION_VIDEO_CAPTURE on MediaStore that can be used as an Intent action for asking a third-party app capture a video for you. As with ACTION_IMAGE_CAPTURE, you use startActivityForResult() with ACTION_VIDEO_CAPTURE to find out when the video has been recorded.

There are two extras of note for ACTION_VIDEO_CAPTURE:

- MediaStore.EXTRA_OUTPUT, which indicates where on external storage the video should be written, and
- MediaStore.EXTRA_VIDEO_QUALITY, which should be an integer, either 0 for low quality/low size videos or 1 for high quality

If you elect to skip EXTRA_OUTPUT, the video will be written to the default directory for videos on the device (typically a "Movies" directory in the root of external storage), and the Uri you receive on the Intent in onActivityResult() will point to this file.

The impacts of skipping EXTRA_VIDEO_QUALITY are undocumented.

The Media/VideoRecordIntent sample project is a near-clone of the Camera/Content sample from earlier in this chapter. Instead of requesting a third-party app take a still image, though, this sample requests that a third-party app record a video:

```
package com.commonsware.android.videorecord;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.os.Environment;
import android.provider.MediaStore;
import java.io.File;

public class MainActivity extends Activity {
  private static final int REQUEST_ID=1337;
  private Uri result=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    File video=
        new File(
Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_MOVIES),
                 "sample.mp4");

    if (video.exists()) {
      video.delete();
    }

    Intent i=new Intent(MediaStore.ACTION_VIDEO_CAPTURE);

    result=Uri.fromFile(video);
    i.putExtra(MediaStore.EXTRA_OUTPUT, result);
    i.putExtra(MediaStore.EXTRA_VIDEO_QUALITY, 1);

    startActivityForResult(i, REQUEST_ID);
  }

  @Override
  protected void onActivityResult(int requestCode, int resultCode,
                                  Intent data) {
    if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
      Intent view=
          new Intent(Intent.ACTION_VIEW).setDataAndType(result,
                                                       "video/mp4");

      startActivity(view);
    }

    finish();
  }
}
```

onCreate() of MainActivity starts by setting up a File object pointing to a sample.mp4 file in the standard location for movies on the device. If the file already exists, onCreate() deletes it. Then, onCreate() sets up the Intent to request that a third-party app record a movie to that location, at high quality (EXTRA_VIDEO_QUALITY set to 1).

The call to startActivityForResult() will trigger the third-party app to record the video. When control returns to MainActivity, onActivityResult() creates an ACTION_VIEW Intent for the same file, then calls startActivity() to request that some app play back the video.

CWAC-Cam2: A CameraActivity Of Your Own

Relying upon third-party applications for taking pictures does introduce some challenges:

- Not all camera apps are created equal. Some implement ACTION_IMAGE_CAPTURE and ACTION_VIDEO_CAPTURE well… and others do not. Some might only ever give you a thumbnail, or some might not support all valid Uri values for writing out the output, and so on.
- Even within "valid" output, there can be variances. One common variation is how portrait images are handled. Some camera apps will write out an image that is actually in portrait mode. Some camera apps will write out an image that is set up for landscape, but with an "EXIF header" in the JPEG data that tells image viewers to rotate the image to portrait. Unfortunately, not everything honors those headers, such as Android's own BitmapFactory.
- If the camera app uses a lot of system RAM, your app may be kicked out of RAM while the user is taking a picture. This should not be a problem, as your app's process is eligible to be terminated at any point when you are not in the foreground. However, it is a bit unexpected to think that taking a picture may cause you to have to switch to a fresh process.

The alternative to relying upon a third-party app is to implement camera functionality within your own app. For that, you have three major options:

1. Use the android.hardware.Camera API, added to Android way back in API Level 1, but marked as deprecated in API Level 21
2. Use the android.hardware.camera2 API, added to Android in API Level 21 as a replacement for android.hardware.Camera, but therefore is only useful on its own if your minSdkVersion is 21 or higher
3. Use some third-party library that wraps around one or both of those APIs

The author of this book has written two such libraries. One works but has a lot of compatibility issues. Plus, that library relied upon the android.hardware.Camera API, and device manufacturers may not test that API quite as much in the future, given that it is now deprecated.

The replacement library is CWAC-Cam2. The API for this library is designed to generally mimic ACTION_IMAGE_CAPTURE and ACTION_VIDEO_CAPTURE, making it easier for you to switch to this library, or even offer support for both third-party camera apps (via ACTION_IMAGE_CAPTURE and ACTION_VIDEO_CAPTURE) or your own built-in camera support.

This section outlines how to use CWAC-Cam2. Note, though, that this library is very young and under active development, so there may be changes to this API that are newer than the prose in this section. Be sure to read the project documentation as well to confirm what is and is not supported.

Adding the Dependency

The recipe for adding CWAC-Cam2 to your Android Studio project is similar to the recipe used by other CWAC libraries: add the CWAC repository, then add the artifact itself as a dependency. That involves adding the following snippet to your module's build.gradle file:

```
repositories {
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:cam2:0.1.+'
}
```

If HTTPS is unavailable to you, you can downgrade the URL to HTTP.

The CameraActivity should be added to your manifest automatically, courtesy of Gradle for Android's manifest merger process.

Taking Pictures

To take still images, you create an Intent to launch the CameraActivity and implement onActivityResult(), just as you would do with ACTION_IMAGE_CAPTURE. However, CameraActivity provides an IntentBuilder that makes it a bit easier to assemble the Intent with the features that you want, as CameraActivity supports much more than the limited roster of extras documented for ACTION_IMAGE_CAPTURE.

Building the Intent

To create the Intent to pass to startActivityForResult() and take the picture, create an instance of CameraActivity.IntentBuilder, call zero or more configuration methods to describe the picture that you want to take, then call build() to build the Intent.

By default, the Intent created by IntentBuilder will give you a thumbnail version of the image. If you want to get a full-size image written to some file, call to() on the IntentBuilder, supplying a File or a Uri to write to. Note that since this activity is in your app, you should be able to write the image to internal storage if you so choose.

In addition:

- If you want the MediaStore to index the newly-taken picture, call updateMediaStore() on the IntentBuilder.
- By default, the user will be given a preview of the taken picture and given an opportunity to re-take the picture. Call skipConfirm() on the IntentBuilder to skip this confirmation screen
- By default, the rear-facing camera will be used at the outset, though the user can switch cameras as desired. Call facing(CameraSelectionCriteria.Facing.FRONT) to start with the front-facing camera. Note that the activity will ignore your requested Facing value if there is no such camera.

So, for example, you could have the following code somewhere in one of your activities, to allow the user to take a picture:

```
Intent i=new CameraActivity.IntentBuilder(this)
    .facing(CameraSelectionCriteria.Facing.FRONT)
    .to(new File(getFilesDir(), "picture.jpg"))
    .skipConfirm()
    .build();

startActivityForResult(i, REQUEST_PICTURE);
```

What the User Sees

When the `CameraActivity` starts, the user is greeted with a large preview, with a pair of floating buttons over the bottom right side:

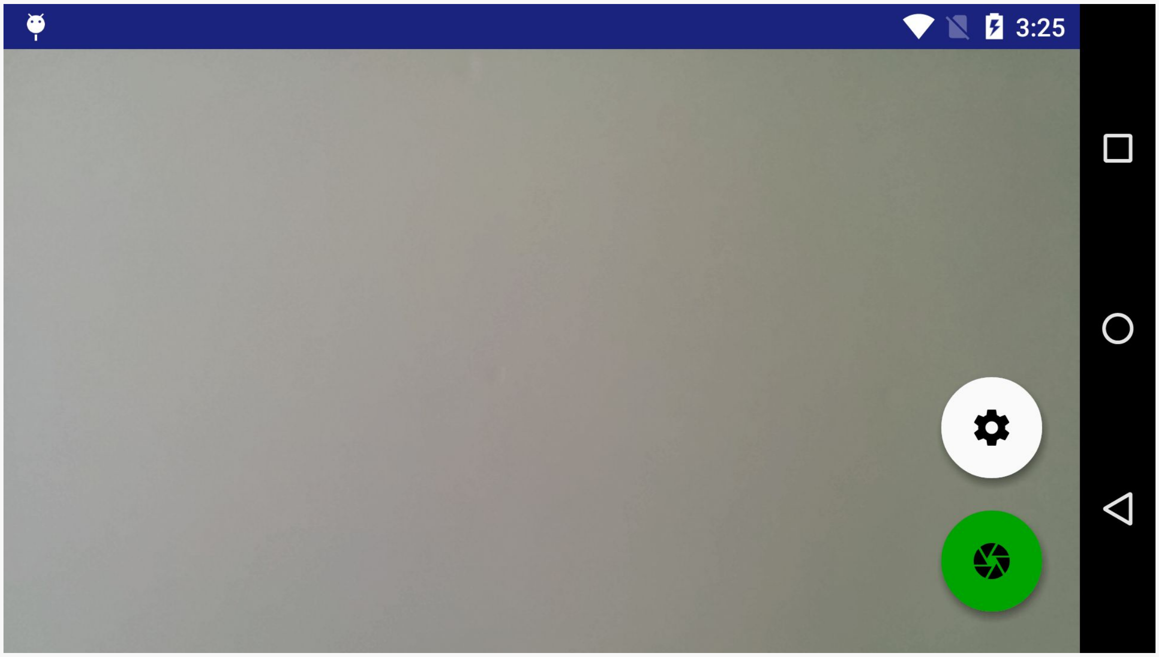

Figure 684: CWAC-Cam2 CameraActivity

The green button will take a picture. The "settings" button above it is a floating action menu — when tapped, the menu exposes other smaller buttons for specific actions, such as switching between the rear-facing and front-facing cameras (where available):

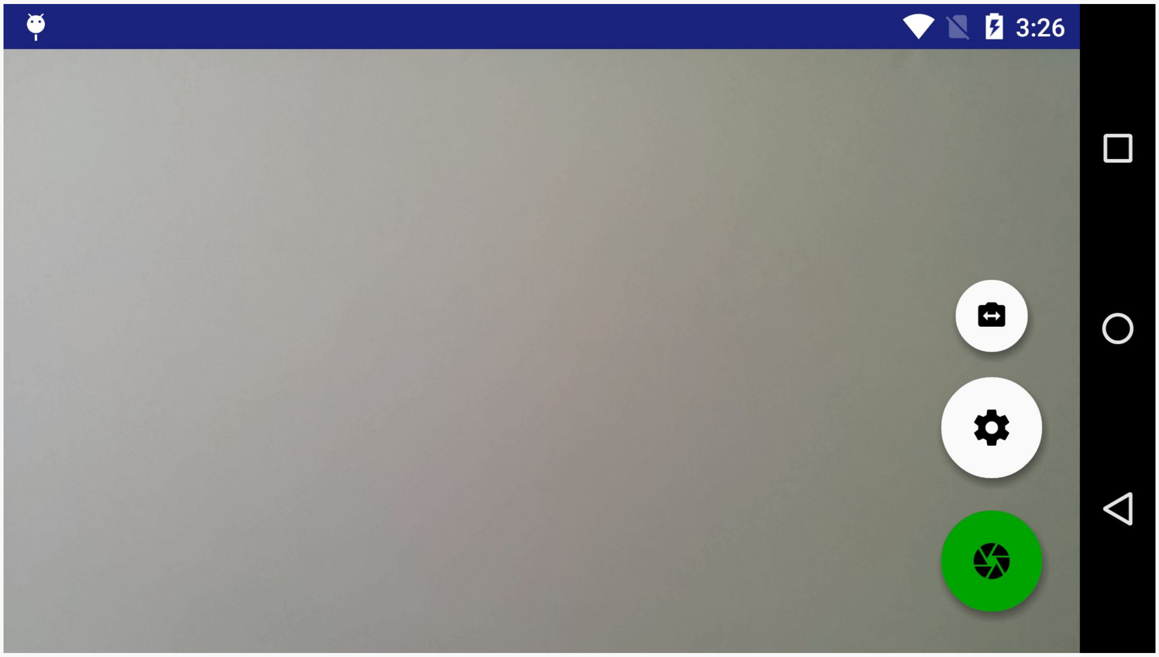

Figure 685: CWAC-Cam2 CameraActivity, Showing Camera Switch Button

Tapping the green button takes the picture and returns control to your activity.

Processing the Results

Handling the results of the `startActivityForResult()` call works much like that for `ACTION_IMAGE_CAPTURE`. If the request code passed to `onActivityResult()` is the one you supplied to the corresponding `startActivityForResult()` call (e.g., `REQUEST_PICTURE`), check the result code.

If the result code is `Activity.RESULT_CANCELED`, that means that the user did not take a picture. It could be that the device does not have a camera (use `<uses-feature>` elements to better control this) or that the user declined to take a picture and pressed BACK to exit the `CameraActivity`.

If the result code is `Activity.OK`, and you did not call `to()` on the `IntentBuilder`, call `data.getParcelableExtra("data")` to get the thumbnail `Bitmap` of the picture taken by the user.

If the result code is `Activity.OK`, and you did call `to()`, your image should be written to the location that you designated in that `to()` call. For convenience, this same value is returned in the `Intent` handed to `onActivityResult()` — call `getData()` on that `Intent` to get your `Uri` value.

Recording Videos

As seen earlier in this chapter, `MediaStore` offers `ACTION_VIDEO_CAPTURE`, as the video counterpart to `ACTION_PICTURE_CHAPTER`. CWAC-Cam2 also supports video capture, via the `VideoRecorderActivity` as a counterpart to the `CameraActivity`. The basic flow is the same: build the `Intent`, call `startActivityForResult()`, and deal with the video when the recording is complete.

Building the Intent

`VideoRecorderActivity` has its own `IntentBuilder` that supports many of the same methods as does `CameraActivity.IntentBuilder`, including `facing()` and `updateMediaStore()`. It also supports the version of the `to()` method that takes a `File`, but not one that takes a `Uri`, due to limitations in the underlying video recording code. Note that `to()` is required for `VideoRecorderActivity`, as videos are always written to files.

It also offers a few new builder-style methods, including:

- `quality()`, into which you can pass `Quality.HIGH` or `Quality.LOW`. `Quality.HIGH` will aim to give you the best possible resolution, while `Quality.LOW` will aim to give you something low-resolution, suitable for stuff like MMS messages.
- `sizeLimit()`, which will aim to cap the video size at around the supplied size in bytes
- `durationLimit()`, which will aim to cap the video duration at around the supplied duration in seconds

So, you could have:

```
Intent i=new VideoRecorderActivity.IntentBuilder(this)
    .facing(CameraSelectionCriteria.Facing.FRONT)
    .to(new File(getFilesDir(), "test.mp4"))
    .quality(VideoRecorderActivity.Quality.HIGH)
    .build();

startActivityForResult(i, REQUEST_VIDEO);
```

What the User Sees

The VideoRecorderActivity UI is very similar to the CameraActivity UI, with a pair of FABs:

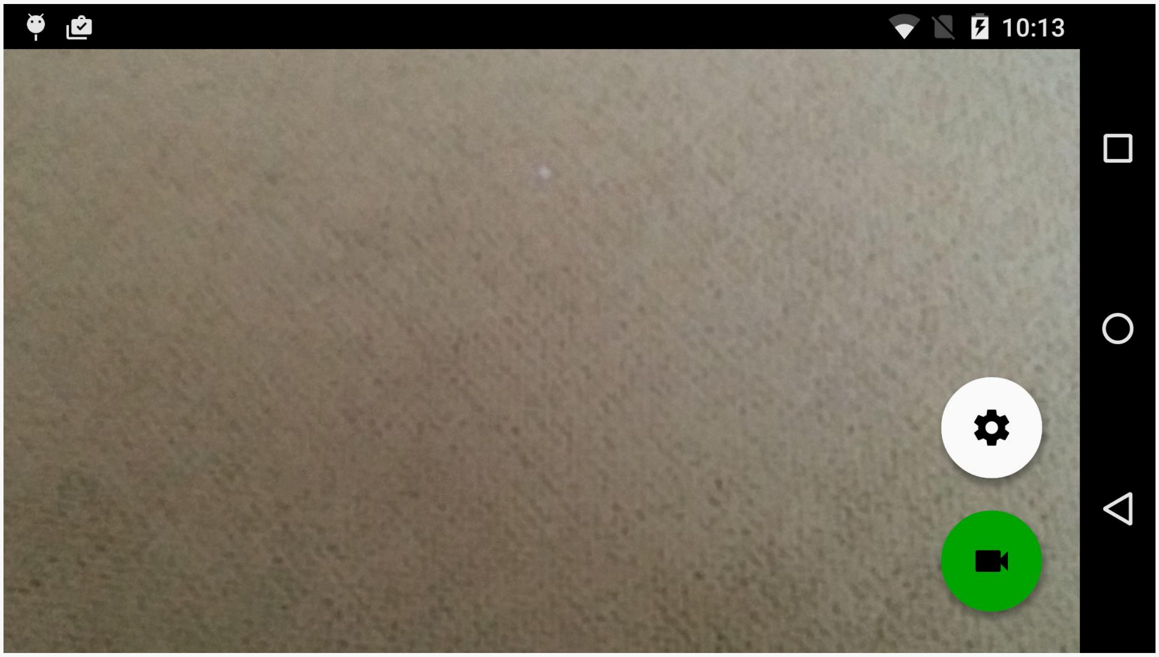

Figure 686: CWAC-Cam2 VideoRecorderActivity

However, the main FAB is green and shows a video camera icon. Tapping that begins recording, and the FAB switches to a red background with a stop icon. Tapping the FAB again stops recording and control returns to whatever activity had started the VideoRecorderActivity.

Processing the Results

As with CameraActivity, handling the results of the startActivityForResult() call works much like that for ACTION_VIDEO_CAPTURE. If the request code passed to onActivityResult() is the one you supplied to the corresponding startActivityForResult() call (e.g., REQUEST_VIDEO), check the result code.

If the result code is Activity.RESULT_CANCELED, that means that the user did not take a picture, either because the device does not have a camera or the user pressed BACK without recording a video.

If the result code is `Activity.OK`, your video should be written to the location that you designated in your `to()` call on the builder. For convenience, this same value is returned in the `Intent` handed to `onActivityResult()` — call `getData()` on that `Intent` to get your `Uri` value.

Directly Working with the Camera

Of course, you can bypass these third-party apps and libraries, electing instead to work directly with the camera if you so choose. This is very painful, as will be illustrated in the next chapter.

Working Directly with the Camera

Letting third-party apps take the pictures and videos for you is all well and good, but there will be times where you need more control than that. It is possible for you to work directly with the device cameras. However, doing is exceptionally complicated.

Part of that complexity is because Android presently has three separate APIs for working with the camera:

- `android.hardware.Camera` for taking still photos
- `android.hardware.camera2` for taking still photos on Android 5.0+ devices
- `MediaRecorder` for recording videos

This chapter will attempt to outline the basic steps for using these APIs.

Prerequisites

This chapter assumes that you have read the previous chapter covering `Intent`-based uses of the camera and the chapter on audio recording.

Notes About the Code Snippets

The code snippets shown in this chapter are here purely to illustrate how to call certain APIs. They are not from any particular sample project, as a sample project small enough to fit in a book would be riddled with bugs and limitations.

A Tale of Two APIs

As noted in the introduction to this chapter, there are three APIs for working with the camera. One — `MediaRecorder` — is focused purely on recording videos. It relies on you using one of the other two APIs for setting up the camera preview, so the user can see what will be recorded. Those other two APIs exist for taking still photos, where one (`android.hardware.camera2`) is substantially newer.

android.hardware.Camera

The original camera API is based around the `android.hardware.Camera` class.

(NOTE: there is another `Camera` class, in `android.graphics`, that is not directly related to taking pictures)

Instances of this class represent an open camera, where you call methods on the `Camera` to do things like take pictures. You also work extensively with a `Camera.Parameters` object, where you can determine a number of key characteristics about the camera (e.g., what the available resolutions are for pictures) and set up the particular results that you want.

This API works on all Android devices.

android.hardware.camera2

The original camera API worked, albeit with some difficulty. However, it was fairly limited, as it was designed primarily around the smartphone camera capabilities of 2005-2010. Nowadays, device manufacturers have access to much more powerful camera modules from chipset manufacturers like Qualcomm. Android needed a more powerful API to accommodate the current hardware, and a more flexible API to be able to adjust to changes over time.

Hence, Android 5.0 brought a new API, based on a series of classes in the `android.hardware.camera2` package. On the plus side, these offer much greater capability. They are also designed with asynchronous work in mind, off-loading slow or complex operations onto background threads for you. However, on the whole, the API is more complicated, much less documented, and substantially different than the original API.

It is also only available on Android 5.0 devices. If your `minSdkVersion` is 21 or higher, that is not a problem. If, however, you are aiming to support older devices than that, you have two choices:

1. Stick with the original API for all devices
2. Use the original API for older devices and the newer API for newer devices

The latter might allow you to offer more features to users of those newer devices, but it does roughly double the work required to implement camera logic in your app.

MediaRecorder

`MediaRecorder` is responsible for both audio recording and video recording. `MediaRecorder` has a fairly limited API, one that has not changed substantially since 2011. However, if you use it carefully, it works. It works in tandem with either camera API — you use the camera APIs to show the user what will be recorded, and you use `MediaRecorder` to actually do the recording.

However, `MediaRecorder` has a number of issues, such as a fair bit of delay between when you ask it to begin recording and when it actually *does* begin recording. This makes it a poor choice for fast-twitch video recording purposes. Some apps, notably Vine, have elected to skip using `MediaRecorder`. Instead, they use the regular camera APIs. These APIs, among other things, give you access to the preview frames that are used to show the user what is visible through the camera lens. With a fair amount of work, you can stitch those together into a video. Needless to say, this is a beyond-advanced topic that is well outside the scope of this book.

The APIs That You (Probably) Can't Use

The aforementioned APIs are all part of the Android SDK. For camera apps that ship with devices, those apps are not limited to these APIs. Device manufacturers are welcome to create apps that use internal proprietary APIs for their devices.

Hence, when it comes to determining what is and is not possible through the camera APIs, it is important to compare to other third-party camera apps, more so than manufacturer-supplied apps. Manufacturers can "cheat"; you cannot.

Performing Basic Camera Operations

Cameras have some key functionality:

- Showing a preview to the user, so the user can see in real time what the camera lens sees, so the user can frame a picture
- Take a still picture
- Record a video

In the following sections, we will outline what is required to perform these operations using the various APIs.

Permissions

First, you need permission to use the camera. That way, when end users install your application, they will be notified that you intend to use the camera, so they can determine if they deem that appropriate for your application.

You simply need the `CAMERA` permission in your `AndroidManifest.xml` file, along with whatever other permissions your application logic might require.

If you plan to record video, using `MediaRecorder`, you will also want to request the `RECORD_AUDIO` permission.

And, if you were planning on storing pictures or videos out on external storage, you probably need the `WRITE_EXTERNAL_STORAGE` permission. The exception would be if your `minSdkVersion` is 19 or higher and you are only storing those files in locations that are automatically read/write for your app, such as `getExternalFilesDir()` or `getExternalCacheDir()`.

Note that all three of these permissions (`CAMERA`, `RECORD_AUDIO`, and `WRITE_EXTERNAL_STORAGE`) are part of the Android M runtime permission system. If your app has a `targetSdkVersion` of M or higher, you will need to request those permissions at runtime. If your app has a lower `targetSdkVersion`, while you will not have to do anything special for your app, bear in mind that the user can still revoke your access to those capabilities, and so you may find lots of devices that claim to support a camera but just do not seem to have any cameras available when you try to use one.

Features

Your manifest also should contain one or more `<uses-feature>` elements, declaring what you need in terms of camera hardware. By default, asking for the `CAMERA` permission indicates that you *need* a camera. More specifically, asking for the `CAMERA` permission indicates that you need an *auto-focus* camera.

The following sections outline some common scenarios and how to handle them.

A Camera is Optional

If you would like a camera, but having one is not essential for the use of your app, put the following `<uses-feature>` element in your manifest:

```
<uses-feature android:name="android.hardware.camera" android:required="false" />
```

This indicates that you would like a camera, but it is not required. This reverses the default established by the `CAMERA` permission.

A Camera is Required

Technically, you would not need any `<uses-feature>` element in your manifest to indicate that you need a camera, as the `CAMERA` permission would handle that for you. However, it is good form to explicitly declare it anyway:

```
<uses-feature android:name="android.hardware.camera" android:required="true" />
```

Not only does that make your manifest more self-documenting, but it also helps protect you in case the default behavior of the `CAMERA` permission changes.

Other Camera Features

There are three other camera features that you could consider having `<uses-feature>` elements for:

1. `android.hardware.camera.autofocus`, to indicate whether or not the device needs a camera with auto-focus capability.
2. `android.hardware.camera.flash`, to indicate whether or not the device must support a camera flash
3. `android.hardware.camera.front`, to indicate whether or not the app needs a front-facing camera specifically (`android.hardware.camera` requests a rear-facing camera)

Of these, the only one you should definitely include in your app is `android.hardware.camera.autofocus`, once again because of the default effects of requesting the `CAMERA` permission. In particular, if you do not absolutely need auto-focus capabilities, you can use `android:required="false"` to reverse the `CAMERA` default requirement.

Finding Out What Cameras Exist

Some devices will have just a rear-facing camera. Some will have just a front-facing camera. Some will have both cameras. Some will have no cameras. And, in theory at least, some could have yet more camera options.

At some point, you are likely to need to find out what cameras exist on the device that you are running on. Perhaps you need a particular camera (e.g., a front-facing camera for your "selfie"-focused app). Or, perhaps you want to allow your users to switch between cameras on the fly.

android.hardware.Camera

The simplest way to choose a camera is to not choose at all, and arrange to open the default camera. That default camera is the first rear-facing camera on the device. However, devices that have *no* rear-facing cameras effectively have no default camera, and so going with the default is rarely the correct choice. Instead, you should iterate over the available cameras, to find the one that you want.

To find out how many cameras there are for the current device, you can call the static `getNumberOfCameras()` method on the `Camera` class.

To find out details about a particular camera, you can call the static `getCameraInfo()` method on `Camera`. This takes two parameters:

- the ID of the camera to open, which will be a number from 0 to the number of available camera minus 1
- a `Camera.CameraInfo` object, into which `getCameraInfo()` will pour details about the camera

The most notable field on `Camera.CameraInfo` is `facing`, which tells you if this is a rear-facing (`Camera.CameraInfo.CAMERA_FACING_BACK`) or front-facing (`Camera.CameraInfo.CAMERA_FACING_FRONT`) camera.

For example, the following code snippet could be used to identify the first front-facing camera:

```
int chosen=-1;
int count=Camera.getNumberOfCameras();
Camera.CameraInfo info=new Camera.CameraInfo();

for (int cameraId=0; cameraId < count; cameraId++) {
  Camera.getCameraInfo(cameraId, info);

  if (info.facing==Camera.CameraInfo.CAMERA_FACING_FRONT) {
    chosen=cameraId;
    break;
  }
}
```

If chosen remains at a value of -1, you know that there is no front-facing camera available to you, and you would need to decide how you wish to proceed, if you really wanted such a camera.

android.hardware.camera2

With the original camera API, your main entry point is the Camera class. With the Android 5.0+ camera API, your main entry point is a CameraManager. This is another system service, one you can retrieve by calling getSystemService() on a Context, asking for the CAMERA_SERVICE:

```
CameraManager mgr=
    (CameraManager)ctxt.
        getApplicationContext().
        getSystemService(Context.CAMERA_SERVICE);
```

You will notice here that we are specifically calling getSystemService() on the Application context. That is because there is a bug in Android 5.0 where CameraManager leaks theContext that creates it. This bug has been fixed in Android 5.1. However, to be safe, you are better off retrieving this system service via the singleton Application object, as there is no risk of a memory leak (singletons are "pre-leaked", as it were).

Given a CameraManager, you can call getCameraIdList() to get a list of camera IDs. These are strings, not integers as they were with the original camera API.

To learn more about the camera, you can ask the CameraManager to give you a CameraCharacteristics object for a given camera ID. The CameraCharacteristics object has all sorts of information about the camera, including what direction it is facing. CameraCharacteristics behaves a lot like a HashMap, in that you use get() and a key to retrieve a value, such as CameraCharacteristics.LENS_FACING to determine the camera's facing direction.

So, the code snippet for the first front-facing camera using a CameraManager named mgr, would be something like:

```
String chosen=null;

for (String cameraId : mgr.getCameraIdList()) {
  CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);

  if
(cc.get(CameraCharacteristics.LENS_FACING)==CameraCharacteristics.LENS_FACING_FRONT) {
    chosen=cameraId;
    break;
  }
}
```

Here, a value of `null` would indicate that there is no available front-facing camera.

Opening and Closing a Camera

Once you decide which camera you wish to use, you will eventually need to "open" it. This gives your app access to that camera, and blocks other app's access while you have it open. You need to open a camera before you can use that camera to take pictures, record video, etc.

Eventually, when you are done with the camera, you should close it, to allow other apps to have access to the camera again. If you fail to close it, until your process is terminated, the camera is inaccessible.

android.hardware.Camera

Old code samples would open the camera by calling a zero-parameter static `open()` method on the `Camera` class. This opens the default camera, and as noted above, this is rarely a good idea. However, it is your only option on API Level 8 and below, if you are still supporting such devices, as those devices only supported a single camera.

Instead, if you have the ID of the camera that you wish to open, call the one-parameter static `open()` method, passing in the ID of the camera.

Both flavors of `open()` return an instance of `Camera`, which you can hold onto in your activity or fragment that is working with the camera.

While you have access to this camera, no other process can. Hence, it is important to release the camera when you are no longer needing it. To release the camera, call `release()` on your `Camera` instance, after which it is no longer safe to use the camera. A common pattern is to `open()` the camera in `onStart()` or `onResume()` and `release()` it in `onPause()` or `onStop()`, so you tie up the camera only while you are in the foreground.

android.hardware.camera2

Opening and closing a camera is a *lot* more complicated with the Android 5.0+ camera API.

Partly, that complexity seems to be due to a threading limitation with CameraManager — while we want to do long tasks related to the camera on background threads, CameraManager itself is not free-threaded when it comes to opening and closing cameras. Hence, we need to use some form of thread synchronization to make sure that we are not trying to open and close cameras simultaneously.

Partly, that complexity is that the way that CameraManager deals with background operations is via a Handler tied to a HandlerThread. HandlerThread, as the name suggests, is a Thread which has all the associated bits to support a Handler. The main application thread itself is a HandlerThread (or, close enough), but we specifically want to use a background thread, so we do not tie up the main application thread. So, we need to create and manage our own HandlerThread and Handler.

So, the first thing you will need to do is set up a HandlerThread, such as in a data member of some class:

```
final private HandlerThread handlerThread=new HandlerThread(NAME,
    android.os.Process.THREAD_PRIORITY_BACKGROUND);
```

Here, NAME is some string to identify this thread (used in places like the list of running threads in DDMS). The second parameter is the thread priority; in general, you want your own HandlerThread instances to have background priority.

Creating the HandlerThread instance does not actually start the thread, any more than creating a Thread object starts the thread. Instead, you need to call start() when you want the thread to begin working its message loop. Any time after this point, it is safe to create a Handler for that HandlerThread, by getting the Looper from the HandlerThread and passing it to the Handler constructor:

```
handlerThread.start();
handler=new Handler(handlerThread.getLooper());
```

(You might wonder why a class named HandlerThread, designed to work with a Handler, lacks any methods to give you such a Handler. Lots of people wonder this, so you are not alone.)

Next, to actually open the camera, you will need to call openCamera() on your CameraManager, supplying:

- the ID of the camera that you wish to open
- a CameraDevice.StateCallback instance
- the Handler that you created for your HandlerThread

But, we want to make sure that we are not trying to open or close another camera while all of this is going on, so we need to use some sort of Java thread synchronization for that, such as a Semaphore:

```
final private Semaphore lock=new Semaphore(1);
```

Then, we can consider opening the camera, once we obtain the lock:

```
if (!lock.tryAcquire(2500, TimeUnit.MILLISECONDS)) {
  throw new RuntimeException("Time out waiting to lock camera opening.");
}

mgr.openCamera(cameraId, new DeviceCallback(), handler);
```

You will notice that we do not release the lock here, as we need to keep the lock until the camera has completed opening.

CameraDevice.StateCallback is an abstract class, so we usually have to create some dedicated subclass for it. There are three abstract methods that we will need to implement: onOpened(), onError(), and onDisconnected(). Plus, we will typically want to implement onClosed(), even though there is a default implementation of this callback.

onOpened() will be called when the camera is open and is ours to use. We are passed a CameraDevice object representing our open camera, and it is our job to hold onto this device while we have the camera open. The big thing that we need to do in onOpened() is release that lock that we obtained when we tried opening the camera. This is also a fine time to consider starting to show camera previews to the user, and we will see how to do that in upcoming sections of the book.

onError() will be called if there is some serious error when trying to open or use the camera. We are passed an error code to indicate what sort of problem we encountered. It could be that the camera is already in use (ERROR_CAMERA_IN_USE), or that while the camera exists, we do not have access to it due to device policy (ERROR_CAMERA_DISABLED), or that there was a general problem with this specific camera (ERROR_CAMERA_DEVICE) or with the overall camera engine (ERROR_CAMERA_SERVICE).

onDisconnected() will be called if we no longer can use the camera, for reasons other than our closing it ourselves. We are supposed to close the CameraDevice, if we have one, as the camera is no longer usable.

To close the camera, whether in response to onDisconnected() or because you are simply done with the camera, call close() on the CameraDevice, inside of the lock:

```
try {
  lock.acquire();
  cameraDevice.close();
  cameraDevice=null;
}
finally {
  lock.release();
}
```

Note that close() is a synchronous call, and so we can release() our lock in a finally block.

Our CameraDevice.StateCallback will be called with onClosed(), to let us know that the close operation has completed.

Setting Up a Preview Surface

The camera preview is basically a stream of images, taken by the camera, usually at less than full resolution. Mostly, that stream is to be presented to the user on the screen, to help them "see what the camera sees", so they can line up the right picture.

For presenting the preview stream to the user, there are two typical solutions: SurfaceView and TextureView.

SurfaceView for the Camera

SurfaceView is used as a raw canvas for displaying all sorts of graphics outside of the realm of your ordinary widgets. In this case, Android knows how to display a live look at what the camera sees on a SurfaceView, to serve as a preview pane. A SurfaceView is also used for video playback, and a variation of SurfaceView called GLSurfaceView is used for OpenGL animations.

That being said, SurfaceView is a subclass of View, and so it can be added to your UI the same as any other widget:

- Include it in a layout
- Return it as the View from onCreateView() of a Fragment
- Instantiate it in Java and add it to some container via addView()
- Etc.

If your app will support API Level 10 and older, you will want to call getSurfaceHolder().getType(SurfaceHolder.SURFACE_TYPE_PUSH_BUFFERS) on the SurfaceView. A "push buffers" SurfaceView is one designed to have images pushed to the surface, usually from video playback or camera previews. A SurfaceHolder is a quasi-controller object for the SurfaceView — most interactions with the SurfaceView come by way of the SurfaceHolder. This bit of configuration is not needed on API Level 11 and higher, as Android handles it for us automatically as the SurfaceView is put to use.

TextureView for the Camera

SurfaceView, however, has some limitations. This is mostly tied back to the way it works, by "punching a hole" in the UI to allow some lower-level component (like the camera) to render stuff into it. While there is a transparent layer on top of this "hole", for use in alpha-compositing in any overlapping widgets, the SurfaceView *content* is not rendered as part of the normal view hierarchy. The net effect is that you cannot readily move, animate, or otherwise transform a SurfaceView.

TextureView was added in API Level 14 and works for camera previews as of API Level 15. TextureView serves much the same role as does SurfaceView, for showing camera previews, playing videos, or rendering OpenGL scenes. However, TextureView behaves as a regular View and so therefore can be animated and such without issue.

However, the cost is in performance. TextureView relies upon the GPU to do more work, and therefore TextureView is a bit less performant than is a SurfaceView. Most camera apps will not show a difference.

Showing the Previews

To show previews, you need to create your surface (SurfaceView or TextureView) and have it be part of your UI. Then, you can teach your opened camera to show previews on that surface.

android.hardware.Camera

The biggest thing that we need to do in the original camera API is to configure the preview is determine what size of preview images should be used. Devices cannot support arbitrary-sized previews. Instead, we need to ask the camera what preview sizes it supports, choose one, then configure the camera to use that specific preview size.

To do any of this, we need the Camera.Parameters associated with our chosen and open Camera. Camera.Parameters serves two roles:

- It tells us what is possible, in terms of camera capabilities, above and beyond the limited information reported by Camera.Info
- It is where we stipulate what behavior we want, by updating the parameters and associating the updated parameters with the Camera

Getting the Camera.Parameters object from a Camera is a simple matter of calling getParameters().

To find out what the valid preview sizes are, we can call getSupportedPreviewSizes() on the Camera.Parameters object. This will return a List of Camera.Size objects, with each Camera.Size holding a width and a height as integers.

Choosing a preview size is a bit of an art form. Too big of a preview size is wasteful from a performance standpoint. Too small of a preview size results in a grainy preview. And, as will be seen later in this chapter, the difference in aspect ratio between your surface and your preview size will need to be taken into account. We will explore choosing preview sizes a bit more later in this chapter. For the moment, assume that we have sifted through the available preview sizes and have chosen something suitable. Whatever size you choose, you can pass to setPreviewSize() on the Camera.Parameters.

Then, you can call setParameters() on the Camera, passing in your modified Camera.Parameters object, to affect this change.

You will wind up with a block of code resembling:

```
Camera.Parameters parameters=camera.getParameters();
Camera.Size
previewSize=figureOutWhatPreviewSizeYouWant(parameters.getSupportedPreviewSizes());

parameters.setPreviewSize(previewSize.width, previewSize.height);

camera.setParameters(parameters);
```

Given that, in principle, there are just three more steps:

1. Attach your preview surface to the `Camera` by calling `setPreviewDisplay()` (if you are using a `SurfaceView`) or `setPreviewTexture()` (if you are using a `SurfaceTexture`)
2. Show the preview on-screen by calling `startPreview()` on the `Camera`
3. Stop showing the preview by calling `stopPreview()` on the `Camera`

However, timing is important.

You also cannot call `setPreviewDisplay()` or `startPreview()` before your preview surface is ready. To know when *that* is, you will need to register a listener with your surface:

- You can register a `SurfaceHolder.Callback` with the `SurfaceHolder` of your `SurfaceView` by calling `addCallback()` on the `SurfaceHolder`. Your `SurfaceHolder.Callback` will be called with `surfaceChanged()` when the surface is ready for use, at which point it is safe to call `setPreviewDisplay()` and `startPreview()`.
- You can register a `TextureView.SurfaceTextureListener` with your `TextureView` by means of the `setSurfaceTextureListener()` call. Your `TextureView.SurfaceTextureListener` will be called with `onSurfaceTextureAvailable()` at the point in time when it is safe to call `setPreviewTexture()` and `startPreview()`.

You also need to stop the preview before you `release()` the `Camera`. And, as we will see later in this chapter, you also need to restart your preview after taking a photo.

android.hardware.camera2

Once the camera is opened — even right from within the `onOpened()` method of your `CameraDevice.StateCallback` — you can request to have preview frames be pushed to your desired preview surface.

First, strangely enough, you are going to need to choose the resolution of the picture that you wish to take. You might think that this would be delayed until a later point, such as when we actually go to take a picture, but the API seems to want it right away.

To find out the possible resolutions, you need to request a `StreamConfigurationMap` from the `CameraCharacteristics`:

```
CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map=
  cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
```

(where `cameraId` is the ID of the camera that you are working with)

From there, you can get an array of `Size` objects via a call to `getOutputSizes()`. Curiously, `getOutputSizes()` takes a Java class object, identifying the use case for the frames to be generated by the camera. So, passing `SurfaceTexture.class` would give you preview frame resolutions, but passing `ImageFormat.JPEG` would give you picture resolutions (at least, for images to be encoded in JPEG format).

So, you can get your roster of available picture sizes via:

```
CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map=
  cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
Size[] rawSizes=map.getOutputSizes(ImageFormat.JPEG);
```

From there, you will need to choose a size. This process can be a bit interesting; some notes about it appear later in this chapter. But, for example, you might choose the size that is the highest resolution, as determined by the total area (width times height).

Next, you are going to need to set up an `ImageReader`. Typically this is done via the `newInstance()` factory method, which takes four parameters:

- The width and height of the desired resolution of the *picture* that you wish to later take with the camera
- The image format to use (e.g., `ImageFormat.JPEG`) for those pictures
- How many simultaneous frames will be needed (typical value: 2)

```
ImageReader reader=ImageReader.newInstance(pictureSize.getWidth(),
          pictureSize.getHeight(), pictureFormat, 2);
```

Then, you need a Surface associated with your preview surface. For example, you can call getSurfaceTexture() on a TextureView to get a SurfaceTexture, then pass it to the Surface constructor to get the associated Surface object.

Next, you can call createCaptureSession() on the CameraDevice representing the opened camera. This takes three parameters:

- An ArrayList of Surface objects, for every places that the camera driver needs to route frames towards. Typically, you will have two elements in this list: the Surface for your preview surface and the Surface that you get from your ImageReader by calling getSurface() on it.
- A CameraCaptureSession.StateCallback instance, to be notified about state changes in the frame-capturing process
- The Handler tied to your HandlerThread

```
cameraDevice
  .createCaptureSession(Arrays.asList(surface, reader.getSurface()),
                        new PreviewCaptureSession(), handler);
```

(where PreviewCaptureSession is some subclass of CameraCaptureSession.StateCallback)

That actually does not begin the previews. Instead, it configures the camera to indicate that it is possible to do previews.

To continue the work for getting the previews rolling, in the onConfigured() callback method on your CameraCaptureSession.StateCallback, you can create a CaptureRequest.Builder that you can use for configuring the camera to capture preview frames. You get one of those by calling createCaptureRequest() on the CameraDevice, passing in an int indicating the general type of request that you are creating, such as TEMPLATE_PREVIEW for preview frames:

```
CaptureRequest.Builder b=
  cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);
```

You then call setTarget() on the Builder, supplying the Surface onto which the captured frames will be written. For previews, that target is the Surface associated with your preview surface.

You can also call set() on the Builder to configure various options that you would like for the camera, such as auto-focus modes, flash modes, and the like. The code snippet shown below demonstrates setting up "continuous picture" auto-focus mode and having the auto-exposure mode engage the flash as needed.

Eventually, you ask the CaptureRequest.Builder to build() you a CaptureRequest, and you pass that to setRepeatingRequest() on the CameraCaptureSession that is passed into onConfigure() of your CameraCaptureSession.StateCallback:

```
@Override
public void onConfigured(CameraCaptureSession session) {
  try {
    CaptureRequest.Builder b=
      cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);

    b.addTarget(surface);
    b.set(CaptureRequest.CONTROL_AF_MODE,
            CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
    b.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

    // other Builder configuration goes here

    CaptureRequest previewRequest=b.build();

    session.setRepeatingRequest(previewRequest, null, handler);
  }
  catch (CameraAccessException e) {
    // do something
  }
  catch (IllegalStateException e) {
    // do something
  }
}
```

setRepeatingRequest() takes three parameters:

- the CaptureRequest created by the Builder
- an optional CameraCaptureSession.CaptureCallback object to be notified about frame captures
- the Handler associated with your HandlerThread

Note that you will want to hold onto the CaptureRequest.Builder that you created here, as you will want it again when it comes time to take a picture.

When you go to close() the CameraDevice, before you do so, you must also close up the previews. You do this by calling close() on the CameraCaptureSession and close() on your ImageReader.

Taking a Picture

At some point, you will want to take a picture. Typically, this is based on user input, though it would not have to be. Taking a picture not only involves telling the camera to capture a picture (typically at a different resolution than the previews), but also to arrange to get that written out to disk somewhere as a JPEG file.

android.hardware.Camera

Taking a photo with a `Camera` is a matter of calling `takePicture()` on the `Camera` object. There are two flavors of `takePicture()`, for which three parameters are in common:

- a `Camera.ShutterCallback`, which will be called the moment the picture is taken, so that you can customize the "shutter" sound
- two `Camera.PictureCallback` objects, for raw (uncompressed) and JPEG photo data, where relatively few devices support raw images using the original camera API

The four-parameter version of `takePicture()` also takes a third `Camera.PictureCallback`, to be called when "a scaled, fully processed postview image is available". This explanation probably means something to somebody, but the author of this book has no idea what it means.

You cannot call `takePicture()` until *after* `startPreview()` has been called to set up a preview pane. `takePicture()` will automatically stop the preview. At some point, if you want to be able to take another photo, you will need to call `startPreview()` again. Note, though, that you *cannot* call `startPreview()` until after the final compressed photo has been delivered to your `Camera.PictureCallback` object.

Before you call `takePicture()`, you are going to want to adjust the `Camera.Parameters` to configure how the photo should be taken. The primary setting to adjust is the size of the picture to take. Just as you ask `Camera.Parameters` for available preview sizes and choose one, you can call `getSupportedPictureSizes()`, which returns a `List` of `Camera.Size` objects. You can then choose a size and pass its width and height to `setPictureSize()` on the `Camera.Parameters`. Other things to potentially adjust include:

- flash mode (`getSupportedFlashModes()` and `setFlashMode()`)
- focus mode (`getSupportedFocusModes()` and `setFocusMode()`)
- white balance (`getSupportedWhiteBalance()` and `setWhiteBalance()`)
- geo-tagging (`setGpsLatitude()`, `setGpsLongitude()`, `setGpsAltitude()`, etc.)
- JPEG image quality (`setJpegQuality()`)
- and so on

Note that calling setParameters() multiple times seems to lead to camera instability. Ideally, you collect all your desired settings from the user up front, then call setParameters() once when you set up your preview size. If you need to change parameters, you may wish to consider closing and re-opening the camera.

The Camera.PictureCallback will be called with onPictureTaken() and will be handed a byte array representing the picture. Typically, you will supply a PictureCallback for JPEG images, and so the byte array will represent the photo encoded in JPEG. At this point, you can hand that byte array off to a background thread to write it to disk, upload it to some server, or whatever else you planned to do with the picture.

Note that one thing you cannot readily do with the picture is hand it to another activity. There is a 1MB limit on the size of an Intent used with startActivity(), and usually the JPEG will be bigger than that. Hence, you cannot readily pass the picture via an Intent extra to another activity. If at all possible, use fragments or something else to keep all your relevant bits of UI together in a single activity, rather than try to get the images from activity to activity.

android.hardware.camera2

First, you should attach an ImageReader.OnImageAvailableListener instance to your ImageReader, using setOnImageAvailableListener(). ImageReader.OnImageAvailableListener is an interface; you will be called with onImageAvailable() when a new image is delivered to the ImageReader. We will come back to that onImageAvailable() method after quite a bit of additional coding.

Next, given the CaptureRequest.Builder you created when you set up the previews, you need to adjust the builder to lock the auto-focus (assuming that auto-focus is enabled):

```
b.set(CaptureRequest.CONTROL_AF_TRIGGER,
        CameraMetadata.CONTROL_AF_TRIGGER_START);
```

At that point, you can build() a fresh CaptureRequest and call setRepeatingRequest() on the CameraCaptureSession, to change the previews to switch to a locked focus:

```
captureSession.setRepeatingRequest(b.build(),
              new RequestCaptureTransaction(),
              handler);
```

Here, RequestCaptureTransaction is a subclass of CameraCaptureSession.CaptureCallback, so you can be notified of how the auto-focus locking is proceeding. You wind up having to implement a fairly convoluted state machine to eventually find out it is time to take a picture… or possibly to ask for a "precapture trigger" to start on the auto-exposure system:

```
private class RequestCaptureTransaction extends CameraCaptureSession.CaptureCallback {
  private final Session s;
  boolean isWaitingForFocus=true;
  boolean isWaitingForPrecapture=false;
  boolean haveWeStartedCapture=false;

  RequestCaptureTransaction(CameraSession session) {
    this.s=(Session)session;
  }

  @Override
  public void onCaptureProgressed(CameraCaptureSession session,
                                  CaptureRequest request, CaptureResult partialResult) {
    capture(partialResult);
  }

  @Override
  public void onCaptureFailed(CameraCaptureSession session, CaptureRequest request,
CaptureFailure failure) {
    // TODO: raise event
  }

  @Override
  public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest request,
TotalCaptureResult result) {
    capture(result);
  }

  private void capture(CaptureResult result) {
    if (isWaitingForFocus) {
      isWaitingForFocus=false;

      int autoFocusState=result.get(CaptureResult.CONTROL_AF_STATE);

      if (CaptureResult.CONTROL_AF_STATE_FOCUSED_LOCKED == autoFocusState ||
          CaptureResult.CONTROL_AF_STATE_NOT_FOCUSED_LOCKED == autoFocusState) {
        Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

        if (state == null ||
            state == CaptureResult.CONTROL_AE_STATE_CONVERGED) {
          isWaitingForPrecapture=false;
          haveWeStartedCapture=true;
          capture(s);
        }
        else {
          isWaitingForPrecapture=true;
          precapture();
        }
      }
    }
    else if (isWaitingForPrecapture) {
      Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

      if (state == null ||
          state == CaptureResult.CONTROL_AE_STATE_PRECAPTURE ||
          state == CaptureRequest.CONTROL_AE_STATE_FLASH_REQUIRED) {
        isWaitingForPrecapture=false;
      }
    }
    else if (!haveWeStartedCapture) {
      Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

      if (state == null ||
          state != CaptureResult.CONTROL_AE_STATE_PRECAPTURE) {
        haveWeStartedCapture=true;
        capture();
      }
    }
  }

  private void precapture() {
    try {
      b.set(CaptureRequest.CONTROL_AE_PRECAPTURE_TRIGGER,
          CaptureRequest.CONTROL_AE_PRECAPTURE_TRIGGER_START);
      s.captureSession.capture(b.build(), this, handler);
    }
    catch (Exception e) {
      // do something
    }
  }

  private void capture() {
    try {
      CaptureRequest.Builder captureBuilder=
          cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_STILL_CAPTURE);

      captureBuilder.addTarget(reader.getSurface());
      captureBuilder.set(CaptureRequest.CONTROL_AF_MODE,
          CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
      captureBuilder.set(CaptureRequest.CONTROL_AE_MODE,
          CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

      captureSession.stopRepeating();
      captureSession.capture(captureBuilder.build(),
          new CapturePictureTransaction(), null);
    }
    catch (Exception e) {
      // do something
    }
  }
}
```

The author of this book wishes he understood what all this stuff is for.

But, eventually, it will be time to take the picture, represented by the `capture()` method in the above code dump. Here, we create a new `CaptureRequest.Builder`, this time using TEMPLATE_STILL_CAPTURE to indicate that we are trying to take a picture. We set up our target (via addTarget()) to be the Surface from the ImageReader. We re-establish our desired auto-focus and auto-exposure modes. Then, we stop the previews, by calling stopRepeating() on the CameraCaptureSession, undoing the prior setRepeatingRequest() call where we asked for previews. Then, we call capture() on the CameraCaptureSession, requesting a single-frame capture rather than a repeating request. This, like setRepeatingRequest(), takes our CaptureRequest from the Builder, a CameraCaptureSession.CaptureCallback to find out the results of the capture work, and our Handler.

The primary job of this CameraCaptureSession.CaptureCallback is to restart the previews, in onCaptureCompleted(). First, we use the preview edition of the CaptureRequest.Builder to undo some of the changes made during the camera capture process. Then, given the original preview CaptureRequest, we call setRepeatingRequest() again, to get the previews showing once more:

```
@Override
public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest request,
TotalCaptureResult result) {
  try {
    b.set(CaptureRequest.CONTROL_AF_TRIGGER,
        CameraMetadata.CONTROL_AF_TRIGGER_CANCEL);
    b.set(CaptureRequest.CONTROL_AE_MODE,
        CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);
    s.captureSession.capture(b.build(), null, handler);
    s.captureSession.setRepeatingRequest(previewRequest, null, handler);
  }
  catch (CameraAccessException e) {
    // do something
  }
  catch (IllegalStateException e) {
    // do something
  }
}
```

As part of all of this work, your onImageAvailable() method on your ImageReader.OnImageAvailableListener will be called when the picture is ready. The recipe for getting your JPEG image looks like this:

```
@Override
public void onImageAvailable(ImageReader imageReader) {
  Image image=imageReader.acquireNextImage();
  ByteBuffer buffer=image.getPlanes()[0].getBuffer();
  byte[] bytes=new byte[buffer.remaining()];

  buffer.get(bytes);
  image.close();
  // do something with the byte[] of JPEG data
}
```

Here, you are subject to the same sorts of limitations as were described in the section on taking pictures with the original camera API. Notably, that `byte` array may be large, too large to put into an `Intent` extra and pass to another activity.

Recording a Video

Traditional Android video recording is handled via `MediaRecorder`. This means that we need to hand control over the camera from the regular camera API that we are using to `MediaRecorder`, record the video, and then return control back to the camera API (e.g., for previews).

`MediaRecorder` itself then has its own API for configuring the recorder, starting the recording, and stopping the recording.

android.hardware.Camera

To retain the camera access for your app, but allow `MediaRecorder` to take over the camera, call `stopPreview()`, then `unlock()`, on the `Camera` object:

```
camera.stopPreview();
camera.unlock();
```

When the recording is complete, you reverse the process, by calling `reconnect()` and `startPreview()`:

```
camera.reconnect();
camera.startPreview();
```

In between the `unlock()` and `reconnect()` calls is when you use the `MediaRecorder` API.

android.hardware.camera2

This particular combination (video recording with the Android 5.0+ camera API) will be covered in a future edition of this chapter.

Using MediaRecorder

Creating a MediaRecorder instance is simple enough: just use the zero-argument constructor.

You then need to tell it what camera to use. With the original camera API, that is a matter of calling setCamera() on the MediaRecorder, passing in your Camera object.

```
MediaRecorder recorder=new MediaRecorder();

recorder.setCamera(camera);
```

Next, call setAudioSource() and setVideoSource() to indicate where the audio and video to be recorded are coming from. The typical value to use for the audio source is CAMCORDER. For the original camera API, you will need to use CAMERA as the video source:

```
recorder.setAudioSource(MediaRecorder.AudioSource.CAMCORDER);
recorder.setVideoSource(MediaRecorder.VideoSource.CAMERA);
```

Next, you need to configure how the video should be recorded, in terms of things like resolution. The typical approach using the original camera API is to use setProfile(), passing in a CamcorderProfile to the MediaRecorder. You can find out what profiles are supported by calling methods like hasProfile() on CamcorderProfile. There are some fairly generic profiles, like QUALITY_HIGH and QUALITY_LOW, and some fairly specific profiles, like QUALITY_2160P for 2K video. Not all devices will support all profiles, based on Android version and camera driver capabilities. So, you will need to be responsive to varying cameras and gracefully degrade from the profile you want to a profile that you can get. For example, the following code snippet tries QUALITY_HIGH, falls back to QUALITY_LOW if QUALITY_HIGH is not available, and bails out if neither of those profiles exist:

```
boolean canGoHigh=CamcorderProfile.hasProfile(cameraId,
    CamcorderProfile.QUALITY_HIGH);
boolean canGoLow=CamcorderProfile.hasProfile(cameraId,
    CamcorderProfile.QUALITY_LOW);

if (canGoHigh) {
  recorder.setProfile(CamcorderProfile.get(cameraId,
      CamcorderProfile.QUALITY_HIGH));
}
else if (canGoLow) {
  recorder.setProfile(CamcorderProfile.get(cameraId,
      CamcorderProfile.QUALITY_LOW));
}
else {
  throw new IllegalStateException(
      "cannot find valid CamcorderProfile");
}
```

Here, `cameraId` is the `int` identifying your open camera.

Then, you can configure:

- the file path to which the resulting video should be written
- the maximum file size you want, after which recording will automatically stop (optional)
- the maximum duration that you want, after which recording will automatically stop (optional)
- a hint for what orientation the video should be recorded in (optional)

```
recorder.
  setOutputFile(new File(getExternalFilesDir(null), FILENAME).getAbsolutePath());
recorder.setMaxFileSize(5000000); // ~5MB max
recorder.setMaxDuration(10000); // ~10 seconds max
recorder.setOrientationHint(90); // rotate output 90 degrees
```

Optionally, you can call `setInfoListener()` and `setErrorListener()`, supplying objects that will be invoked when certain events occur. Notably, if you use `setMaxFileSize()` or `setMaxDuration()`, the `OnInfoListener` object will be notified when recording automatically stops due to reaching one of those limits.

You then call `prepare()`, followed by `start()`, and your video recording will commence:

```
recorder.prepare();
recorder.start();
```

When it comes time to stop the recording manually (e.g., user taps a "stop" button), just call `stop()`, then `release()`, on the `MediaRecorder`.

And Now, The Problems

Of course, taking pictures is not nearly this simple. The preceding sections glossed over all sorts of problems that you will run into in practice when trying to implement these APIs. The following sections outline a few of those problems, particularly ones that will affect both camera APIs.

Choosing a Preview Size

Camera drivers are capable of delivering preview images to your preview surface in one of several resolutions. You have to sift through a roster of resolutions and choose one.

Your gut instinct might be to choose the highest-available resolution. After all, that should result in the highest-quality previews. However, this can be wasteful, if the preview images are significantly bigger than your preview surface. Plus, the larger the preview frames, the slower the camera driver will be to deliver them, reducing your possible frames-per-second (fps) for the previews. You might instead elect to choose the largest preview that is smaller than the surface, or some algorithm like that.

Previews and Aspect Ratios

Compounding the problem of choosing preview sizes is that the resolutions of available preview sizes bear no relationship at all to the size of your preview surface. After all, you might have a `TextureView` that fills the screen, or you might have a `TextureView` that is rather tiny. That is up to you from a UI design standpoint; the camera driver is oblivious to such considerations.

In particular, the aspect ratios (width divided by height) of the preview frames do not necessarily have to match the aspect ratio of your preview surface. For example, few camera drivers support square previews, yet for aesthetic reasons you might be aiming for a square preview surface.

You have two main approaches for dealing with this: letterboxing and cropping.

Letterboxing is where your preview frames retain their aspect ratio, but do not fill up all the available space in the preview surface. Instead, part of the preview surface is unused. For example, if your preview surface is square, and your preview frames have a landscape aspect ratio (width is greater than the height), letterboxing would show the landscape aspect ratio within the square box of the preview surface, with black bars for the unused portion of the square's height. Typically, using gravity, you try to have the preview frames be centered and the unused portion of the surface be split to either side of the frames.

If you want to fill the preview surface, then letterboxing is not a viable option. However, if you just take the preview frames and try to put them into the surface, the surface will stretch the frames to fit the surface. If the aspect ratio of the frames is significantly different than is the aspect ratio of the surface, the subject matter in the preview will seem significantly stretched, either vertically or horizontally.

The trick to deal with this, on API Level 14+ (with graphics acceleration enabled, as is the default), is to have the surface be *bigger* than what you really want, but then to have something overlapping the surface and causing it to be visually cropped. You have your new, larger surface match the aspect ratio of the preview frames, so there is no stretching. However, now what the user sees in your preview surface may differ substantially from what winds up in the picture or video, as you are cropping off portions that do not fit your preview surface, where those cropped areas might well show up in final output.

Choosing a Picture or Video Size

Choosing a picture or video size is reminiscent of choosing a preview size. While many cases will call for as high of a resolution as you can muster, some use cases will lead you towards choosing a lower resolution. For example, situations requiring a rapid upload of the resulting media might select a lower resolution, as that will reduce the file size and make the upload process that much faster.

Also, bear in mind that the aspect ratio of the available picture or video sizes do not necessarily match the aspect ratio of *either* the preview frames *or* your preview surface. Emphasize to your users that the preview surface is for *aiming* the camera; what actually gets recorded may be somewhat different in scope but should be centered on the same spot.

Picture Orientation

Your app may wish to take pictures in both landscape and portrait modes. However, the camera drivers are designed around taking pictures in landscape, particularly for rear-facing cameras.

You can hint to the camera driver what orientation you think the resulting picture should have, such as via `setRotation()` on the `Camera.Parameters` in the original camera API. However, as the documentation for that method states:

> The camera driver may set orientation in the EXIF header without rotating the picture. Or the driver may rotate the picture and the EXIF thumbnail. If the Jpeg picture is rotated, the orientation in the EXIF header will be missing or 1 (row #0 is top and column #0 is left side).

Many camera drivers take the approach of leaving the image alone and setting the Orientation EXIF header. That header tells image viewers to rotate the image. Unfortunately, not all image viewers or image decoding libraries pay attention to this. Notably, *Android* usually does not pay attention to this, as BitmapFactory ignores this EXIF header. As a result, when you go to load in your own picture that you took, your result may come out mis-oriented.

You have two major choices:

1. Put more smarts in any logic that you are using to display images that you take with the camera, where you read the EXIF headers yourself and you arrange to rotate the image as needed, perhaps by rotating the ImageView you are using to show the image.
2. As part of post-processing the image before saving it, you rotate the image based upon what is in the EXIF header, and save the image with the proper rotation and no EXIF header. This has the advantage of making the image "correct" for all image viewers. However, rotating full-resolution photos is rather memory-intensive and slow. Using NDK code, such as this library, may be able to help.

Storage Considerations

Bear in mind that if you wish to save pictures or videos in common locations on external storage, such as the standard location for digital camera output (Environment.DIRECTORY_DCIM), you will need the WRITE_EXTERNAL_STORAGE permission on all relevant API levels. As of Android M, this is a dangerous permission handled via the runtime permission system, so you will need to have the <uses-permission> element in the manifest *and* ask the user for that permission at runtime.

Also, files written out to external storage will not be picked up immediately by MediaStore, and so "gallery" and related apps that rely upon the MediaStore will not see your pictures or videos. You can use MediaScannerConnection to proactively have the MediaStore add your newly-created files to the index, as was covered earlier in the book.

Configuration Changes

Opening and closing a camera each takes a fair amount of time. As a result, if your app wants to support taking pictures and videos in either portrait or landscape, this is a case where you will want to strongly consider using a retained fragment to hold onto your `Camera` (or combination of `CameraManager` and `CameraDevice`) across a configuration change. That way, Android will not destroy and recreate the fragment, and you can keep the camera open during the change.

Camera Peeking Attacks

(NOTE: this section is based upon a blog post from the author)

A research paper points out an interesting Android attack vector, resulting in a possible leak of private information. The paper's authors refer to it as the "camera peeking" attack.

An Android camera driver can only be used by one app at a time. The attack is simple:

- monitor for when an app that might use the camera for something important comes to the foreground
- at that point, start watching for the camera to become unavailable
- once the camera is unavailable, then available again, grab the camera and take a picture, in hopes that the camera is still pointing at the private information

The example cited by the paper's authors is to watch for a banking app taking a photo of a check, to try to take another photo of the check to send to those who might use the information for various types of fraud.

Polling for camera availability is slow, simply because the primary way to see if the camera is available is to open it, and that takes hundreds of milliseconds. The paper's specific technique helped to minimize the polling, by knowing when the right activity was in the foreground and therefore the camera was probably already in use. Then, it would be a matter of polling until the camera is available again and taking a picture. Even without the paper's specific attack techniques, this general attack is possible, and there may be more efficient ways to see if the camera is in use.

On the other hand, the defense is simple: if your app is taking pictures, and those pictures may be of sensitive documents, ask the user to point the camera somewhere else before you release the camera. So long as you have exclusive control over the camera, nothing else can use it, including any attackers.

A sophisticated implementation of this might use image-recognition techniques to see, based upon preview frames plus the taken picture, if the camera is pointing somewhere else. For example, a banking app offering check-scanning might determine if the dominant color in the camera field significantly changes, as that would suggest that the camera is no longer pointed at a check, since checks are typically fairly monochromatic.

Or, just ask the user to point the camera somewhere else, then close the camera after some random number of seconds.

General-purpose camera apps might offer an "enhanced security" mode that does this sort of thing, but having that on by default might annoy the user trying to take pictures at the zoo, or at a sporting event. However, document-scanning apps might want to have this mode on by default, and check-scanning apps might simply always use this mode.

Media Routes

Android can send audio and video to a variety of places, such as:

- Bluetooth headsets or headphones
- External displays, like a TV or monitor
- External devices that themselves play back media, such as a Chromecast

There is a common API for determining which of these “places” are available and allowing the user to choose which of these “places” should be used for a given bit of media. This common API centers around a `MediaRouter`, which is the focus of this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book. In addition, you should read the chapters on advanced action bar techniques and the AppCompat action bar backport.

Terminology

First, we need to establish some common ground in terms of…, well, terms.

Media

In this chapter, “media” refers to audio or video. This includes both media that may be stored on the device as well as media that may be streamed from some other source, frequently over the Internet.

Route

A route indicates where media should be played. There are three categories of routes that concern us:

- Where should we be playing live audio, in terms of speakers or headphones or other things connected to the device?
- Where should we be playing live video: on the device's own screen or on some other screen connected via a cable?
- Is there any sort of "remote playback" device available, such as a Chromecast, that can play back media on its own under our direction, rather than requiring our own app to play back the media itself

MediaRouter

`MediaRouter` is the name of a class (actually, two classes) that know what routes are possible given the current environment and what routes are selected for the different categories (by default or by user choice).

A Tale of Two MediaRouters

`MediaRouter` and its related classes represent a curious API. There are two versions of the `MediaRouter` class related support classes that will concern you as a developer.

android.media

`MediaRouter` debuted in Android in API Level 16, through classes added to the `android.media` package. This version of `MediaRouter` can work with live audio and live video routes, but not the Chromecast-style remote playback routes.

`android.media` also contains other classes that pertain to routes, such as `MediaRouteActionProvider`, a way to allow the user to choose media routes via an action bar item. The version of these classes in `android.media` work with native API Level 11 versions of the action bar and fragments.

android.support.v7.media

In 2013, an update to the Android Support package was released that contained another version of `MediaRouter` and kin, in `android.support.v7` packages. These are contained in a dedicated Android library project that you can add to your app, found in the extras/android/support/v7/mediarouter directory of your Android SDK installation, if you have a current Android Support package installed.

While the native version of MediaRouter is a system service — obtained via getSystemService() – the v7 version of MediaRouter is a singleton, obtained from a static getInstance() method on the MediaRouter class.

The good news is that this updated version of MediaRouter can work with all three categories of routes, including the Chromecast-style remote playback routes.

However, the bad news is that the v7 version of MediaRouter's support classes only support the Android Support backports of fragments and the action bar. This requires you to inherit from ActionBarActivity and use the v4 version of Fragment and kin. This is a rather annoying limitation, considering that many developers have specifically started dropping support for older API levels to be able to *avoid* using this backport.

Attaching to MediaRouter

To be able to take advantage of all that MediaRouter has to offer, we need to obtain an instance of it and connect to that instance, via method calls and registering callbacks.

Getting a MediaRouter Instance

To get an instance of the android.support.v7.media.MediaRouter flavor of MediaRouter, call getInstance() on MediaRouter.

This is in contrast to the android.media.MediaRouter variant, which is a system service, obtained by calling getSystemService().

Note that the android.support.v7.media.MediaRouter flavor is global for your process, but weakly held from a garbage collection standpoint. You need to ensure that you hold onto your instance of MediaRouter as long as you need it. Once your application code lets go of the MediaRouter instance, it becomes eligible for garbage collection, disposing of any registered callbacks and such along the way.

Working with Routes

MediaRouter has a getSelectedRoute() method that returns the media route chosen by the user, or the overall default if the user has not yet had a chance in your app to choose a route. This method returns a MediaRouter.RouteInfo object, containing details about the route. In particular, you can call supportsControlCategory() to determine if the route is a live audio route, a live video route, or a remote playback route, so you can take advantage of it accordingly.

There is also getDefaultRoute(), which, as the name suggests, returns the MediaRouter.RouteInfo instance that is the overall default for your app.

You can call getRoutes() to obtain a list of all routes known at the present time. You might use this to allow the user to choose a route, though MediaRouteActionProvider is generally a better choice, as will be seen later in this chapter.

Given that you have a MediaRouter.RouteInfo instance from somewhere, you can call selectRoute() to make this route the active one, replacing whatever the previously-selected route was.

Registering a Callback

You can also call addCallback() to provide a MediaRouter.Callback instance that will be invoked at various points in time based on the changes in media routes. addCallback() also takes a MediaRouteSelector, which describes what sorts of routes you are interested in. We will examine MediaRouteSelector in greater detail in the coverage of MediaRouteActionProvider later in this chapter.

There are two flavors of addCallback(). Both take the MediaRouteSelector and the MediaRouter.Callback, but one also takes an int supplying flags to control the behavior of addCallback(). One flag of particular importance is CALLBACK_FLAG_REQUEST_DISCOVERY. This tells MediaRouter to not only set up the callback, but to attempt to find new routes previously unknown to it. Mostly, this is for remote callback routes, which require network I/O to find and are not necessarily known if not specifically scanned for.

MediaRouter.Callback is a class, not an interface. You create your own subclass of MediaRouter.Callback and override the callback methods that interest you. Some noteworthy callback methods include:

- onRouteAdded() and onRouteRemoved(), which are called when routes are newly detected or have been lost, such as when a user plugs in or unplugs an HDMI cable from the device
- onRouteSelected() is called when a new route is selected, either by the user (e.g., via MediaRouteActionProvider) or by you (e.g., via selectRoute())
- onRouteUnselected() is also called when a new route is selected, but in this case, you are notified about the *old* route being unselected

When you are done with the callback, call removeCallback() on the MediaRouter, passing in the same MediaRouter.Callback instance you supplied to addCallback().

We will see examples of using MediaRouter.Callback in the next section.

User Route Selection with MediaRouteActionProvider

To give the user some measure of control over where media is played, you can add a MediaRouteActionProvider to your action bar. This will add a button that, when tapped, will allow the user to choose routes of relevance to your app (live audio, live video, remote playback).

However, this does not really work the way you (or the user) might expect, simply because some routes are automatically applied by the OS. Depending upon what the Android device is connected to will determine what routes are automatically applied and which ones the user can choose via MediaRouteActionProvider. For example, while Android will route live video to an HDMI-connected external display automatically, the user must opt into connecting to a Chromecast for remote playback capability.

This section outlines how to use MediaRouteActionProvider — both the Google and CWAC versions — and what the user will see for various circumstances. Most of the sections will be focusing on the MediaRouter/ActionProvider sample project, which uses the Google version of MediaRouteActionProvider.

The Basic Project and Dependencies

The project has dependency on the mediarouter Android library project. Projects that need mediarouter will need to have access to the Android Support library from the SDK Manager and follow the instructions to add it to your project. Since mediarouter depends upon appcompat, you will need both library projects.

The AppCompat backport of the action bar requires that your activities use a theme extending from `Theme.AppCompat`. Hence, we have a `res/values/styles.xml` resource that defines `AppTheme` in the context of `Theme.AppCompat.Light.DarkActionBar`:

```
<resources>

  <style name="AppBaseTheme" parent="@style/
Theme.AppCompat.Light.DarkActionBar"></style>

  <style name="AppTheme" parent="AppBaseTheme">
    <!-- All customizations that are NOT specific to a particular API-level can go
here. -->
  </style>

</resources>
```

And our `<activity>` in the manifest, pointing to `MainActivity`, refers to that theme:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.mrap"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="18"/>

  <application
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name="com.commonsware.android.mrap.MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

The Menu Resource

Since `MediaRouteActionProvider` is an action provider, we can add it to our action bar via an `actionProviderClass` attribute in a menu resource. And, since the Google implementation of `MediaRouteActionProvider` works with the AppCompat action bar backport, we specifically need to use the AppCompat approach to adding `actionProviderClass`, putting it in our app's custom XML namespace:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/route_provider"
    android:title="@string/route_provider_title"
    app:actionProviderClass="android.support.v7.app.MediaRouteActionProvider"
    app:showAsAction="always"/>

</menu>
```

Initializing the MediaRouter and Selector

Our activity (`MainActivity`) is an `ActionBarActivity` subclass, following the rules for using the AppCompat action bar backport:

```
package com.commonsware.android.mrap;

import android.os.Bundle;
import android.support.v4.view.MenuItemCompat;
import android.support.v7.app.ActionBarActivity;
import android.support.v7.app.MediaRouteActionProvider;
import android.support.v7.media.MediaControlIntent;
import android.support.v7.media.MediaRouteSelector;
import android.support.v7.media.MediaRouter;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.TextView;

public class MainActivity extends ActionBarActivity {
  private MediaRouteSelector selector=null;
  private MediaRouter router=null;
  private TextView selectedRoute=null;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);
    selectedRoute=(TextView)findViewById(R.id.selected_route);

    router=MediaRouter.getInstance(this);
    selector=
        new
MediaRouteSelector.Builder().addControlCategory(MediaControlIntent.CATEGORY_LIVE_AUDIO)

.addControlCategory(MediaControlIntent.CATEGORY_LIVE_VIDEO)

.addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
                                        .build();

  }
  @Override
  public void onStart() {
    super.onStart();

    router.addCallback(selector, cb,
                       MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
  }

  @Override
  public void onStop() {
    router.removeCallback(cb);

    super.onStop();
  }

  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.main, menu);

    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

    provider.setRouteSelector(selector);

    return(true);
  }

  private MediaRouter.Callback cb=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
                                MediaRouter.RouteInfo route) {
      selectedRoute.setText(route.toString());
    }
  };
}
```

In `onCreate()` we obtain an instance of `MediaRouter`. More specifically, we obtain an instance of `android.support.v7.media.MediaRouter`.

We also will need a `MediaRouteSelector` instance. `MediaRouteSelector` expresses rules for what sorts of media routes we are interested in. The simplest way to set up a `MediaRouteSelector` is to use the `MediaRouteSelector.Builder` inner class, which follows the fluent API style of other Android `Builder` classes (e.g., `Notification.Builder`, `AlertDialog.Builder`). Here, we call `addControlCategory()` three times, indicating three categories of routes that we are interested in:

- `MediaControlIntent.CATEGORY_LIVE_AUDIO`
- `MediaControlIntent.CATEGORY_LIVE_VIDEO`
- `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK`

Calling build() on the resulting Builder gives us our MediaRouteSelector, which we will use elsewhere in the activity.

Configuring the ActionProvider

In onCreateOptionsMenu() of MainActivity, we inflate our menu resource and pull out the MediaRouteActionProvider. To obtain an action provider from the AppCompat action bar, the simplest solution is to use the MenuItemCompat helper class from the Android Support package, calling its static getActionProvider() method. This will work both with the AppCompat backport of the action bar *and* with the native API Level 11+ action bar, though you do not need to use MenuItemCompat for the latter if you do not want.

We then call the setRouteSelector() method on our MediaRouteActionProvider instance, passing in the MediaRouteSelector we configured back in onCreate(). This tells the action provider what routes the user should be able to configure. In our case, that is all three major categories of routes (live audio, live video, and remote playback).

Registering for Route Changes

Interestingly enough, that is insufficient to make the MediaRouteActionProvider work. We *also* need to register a MediaRouter.Callback with the MediaRouter, to be informed about events related to media routes. Our cb private data member is an instance of an anonymous inner class extending MediaRouter.Callback, overriding the onRouteSelected() method. This method will be called whenever a new route is selected, telling us the MediaRouter.RouteInfo of the newly-selected route. In our case, we just update a TextView that is our activity's UI with the details of that route, courtesy of calling toString() on the RouteInfo object.

To inform MediaRouter about our desire for such callbacks, we need to call addCallback() on the MediaRouter, and later on call removeCallback() when we no longer need to know about such events. In MainActivity, these steps are done in onStart() and onStop(), respectively.

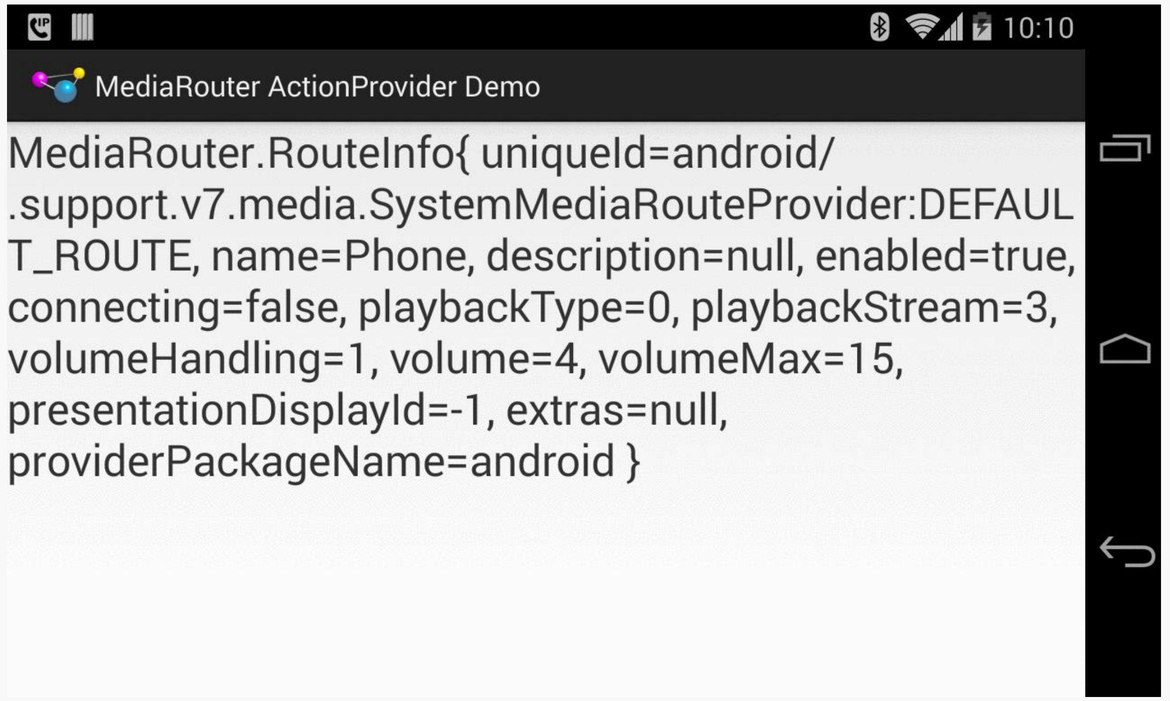
Note that we provide the CALLBACK_FLAG_REQUEST_DISCOVERY flag in the addCallback() method, to trigger a search for any Chromecast or other remote playback-capable devices that can serve as media routes.

The Results

Running this on an emulator is largely pointless, as emulators do not emulate media routes.

Running this on a device will give varying results, depending upon what other media-related accessories are available to that device. If there are no user-selectable media routes available, the `MediaRouteActionProvider` is marked as invisible, so the user does not see the icon and perhaps get confused by why tapping on it has no effect.

However, our `TextView` will show some initial route that was chosen by the device:

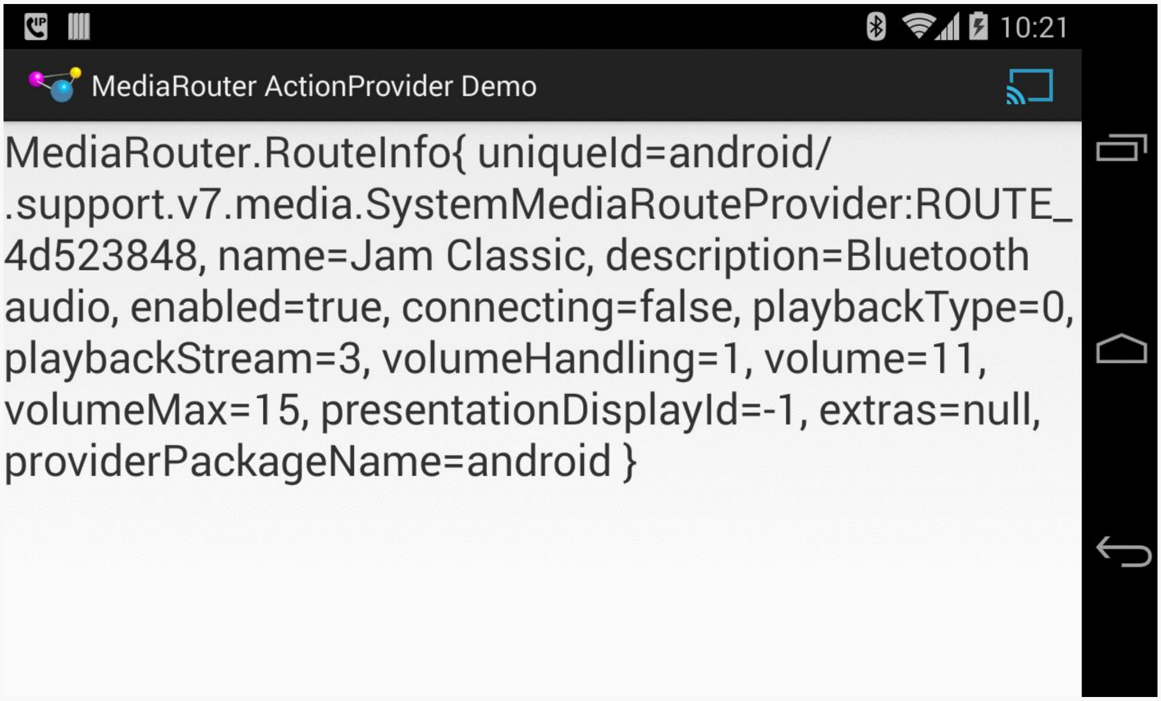


MediaRouter.RouteInfo{ uniqueId=android/.support.v7.media.SystemMediaRouteProvider:DEFAULT_ROUTE, name=Phone, description=null, enabled=true, connecting=false, playbackType=0, playbackStream=3, volumeHandling=1, volume=4, volumeMax=15, presentationDisplayId=-1, extras=null, providerPackageName=android }

Figure 687: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route

Live Audio Routes

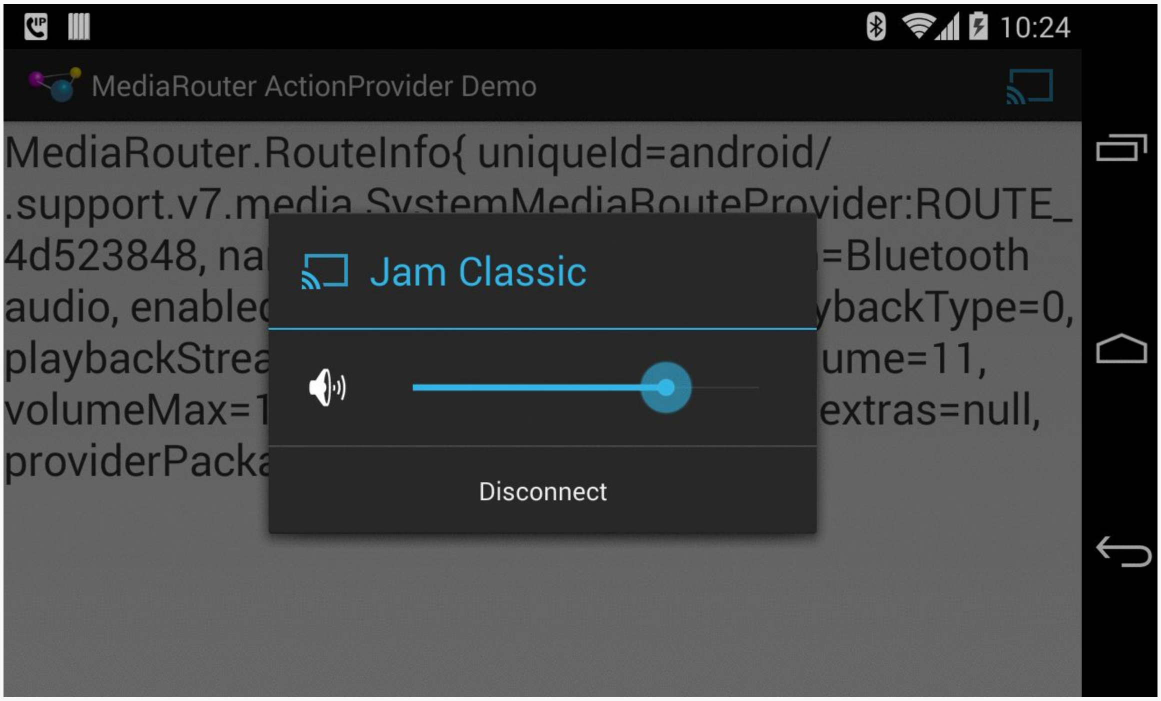
If you launch the demo with some form of external headset or speakers attached, such as via Bluetooth, you will see the route for that is automatically selected:



MediaRouter.RouteInfo{ uniqueId=android/.support.v7.media.SystemMediaRouteProvider:ROUTE_4d523848, name=Jam Classic, description=Bluetooth audio, enabled=true, connecting=false, playbackType=0, playbackStream=3, volumeHandling=1, volume=11, volumeMax=15, presentationDisplayId=-1, extras=null, providerPackageName=android }

Figure 688: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Audio Route

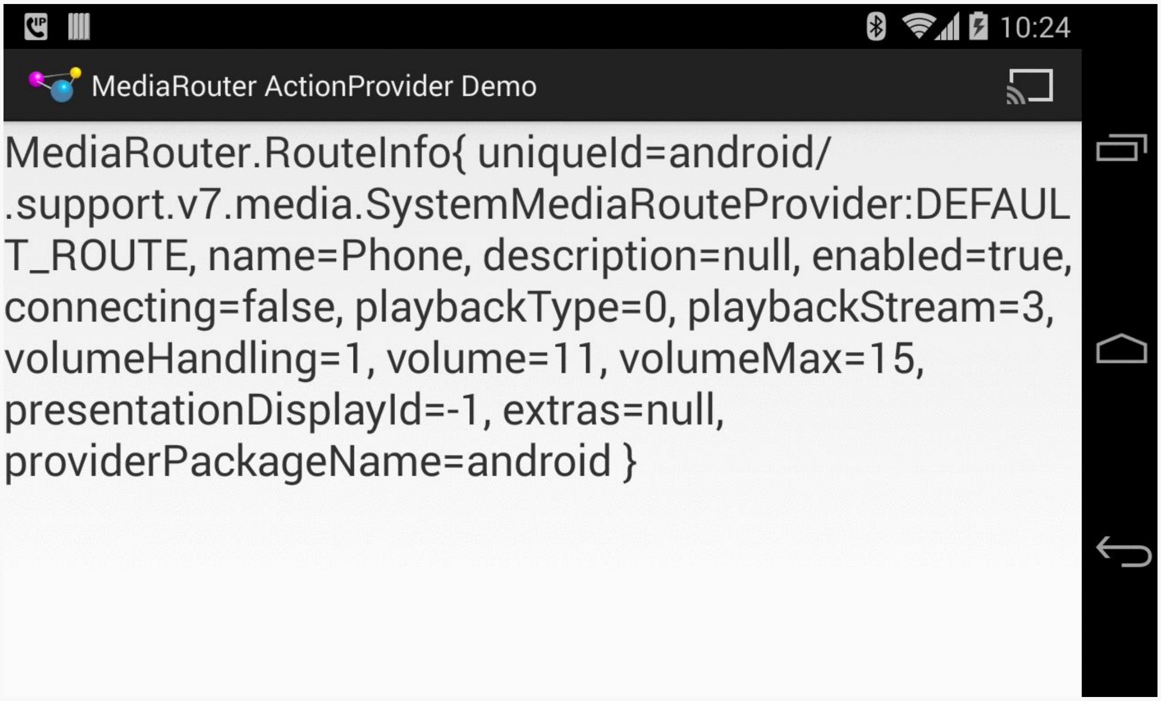
The `MediaRouteActionProvider` appears, with a blue highlight, indicating an active selected route. More importantly, the blue highlight indicates that the route is configurable by tapping on it to bring up a dialog:



MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.media.SystemMediaRouteProvider:ROUTE_
4d523848, na =Bluetooth
audio, enabled ybackType=0,
playbackStrea ume=11,
volumeMax=1 extras=null,
providerPacka

Figure 689: MediaRouter ActionProvider Demo, on a Nexus 4, Live Audio Route Configuration

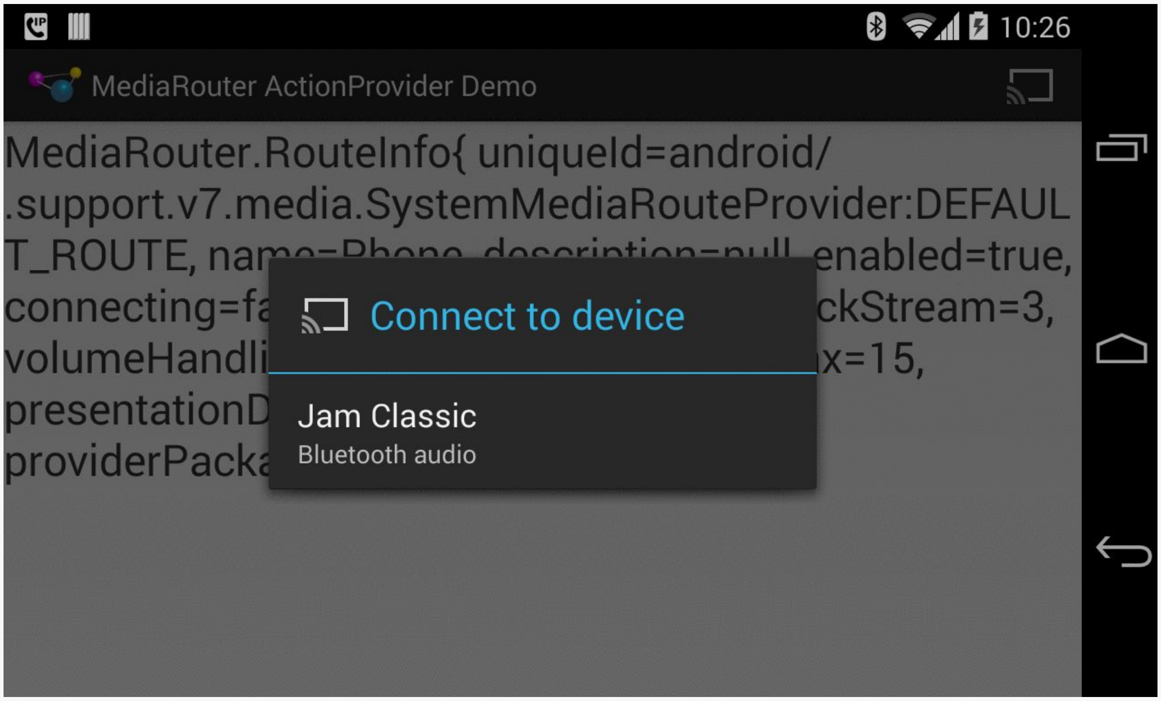
Here, we can adjust the volume, plus disconnect from the route. Disconnecting shows our `MediaRouteActionProvider` with the default white highlight:



```
MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.media.SystemMediaRouteProvider:DEFAUL
T_ROUTE, name=Phone, description=null, enabled=true,
connecting=false, playbackType=0, playbackStream=3,
volumeHandling=1, volume=11, volumeMax=15,
presentationDisplayId=-1, extras=null,
providerPackageName=android }
```

Figure 690: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route and Provider

The white highlight means that there are possible routes, though none in use. Tapping the icon brings up a connection dialog:



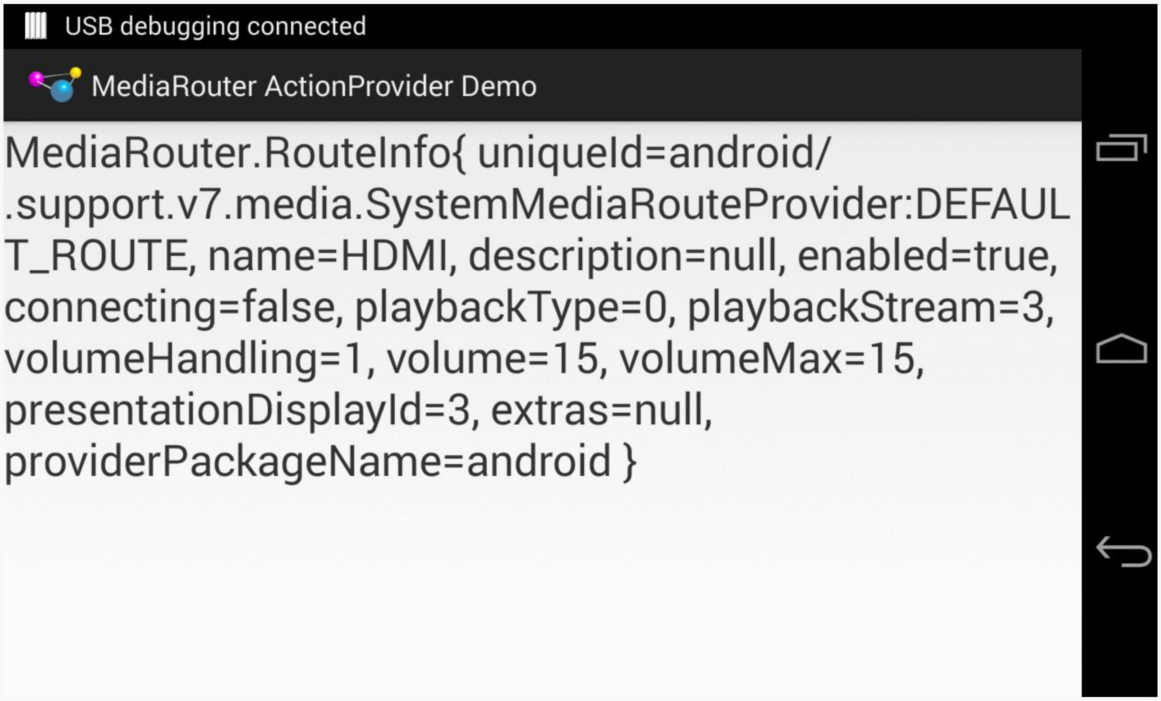
```
MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.media.SystemMediaRouteProvider:DEFAUL
T_ROUTE, nam                          enabled=true,
connecting=fa                         ckStream=3,
volumeHandli                          x=15,
presentationD
providerPacka
```

Figure 691: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Routes

Live Video Routes

If you launch the demo with some form of external display attached — HDMI, MHL, SlimPort, etc. — you still will not see the `MediaRouteActionProvider`, as live video routes are automatically selected, at least if there is only one such route.

However, `onRouteSelected()` will still be called as part of starting up the activity, so the `TextView` will reflect the live video route:

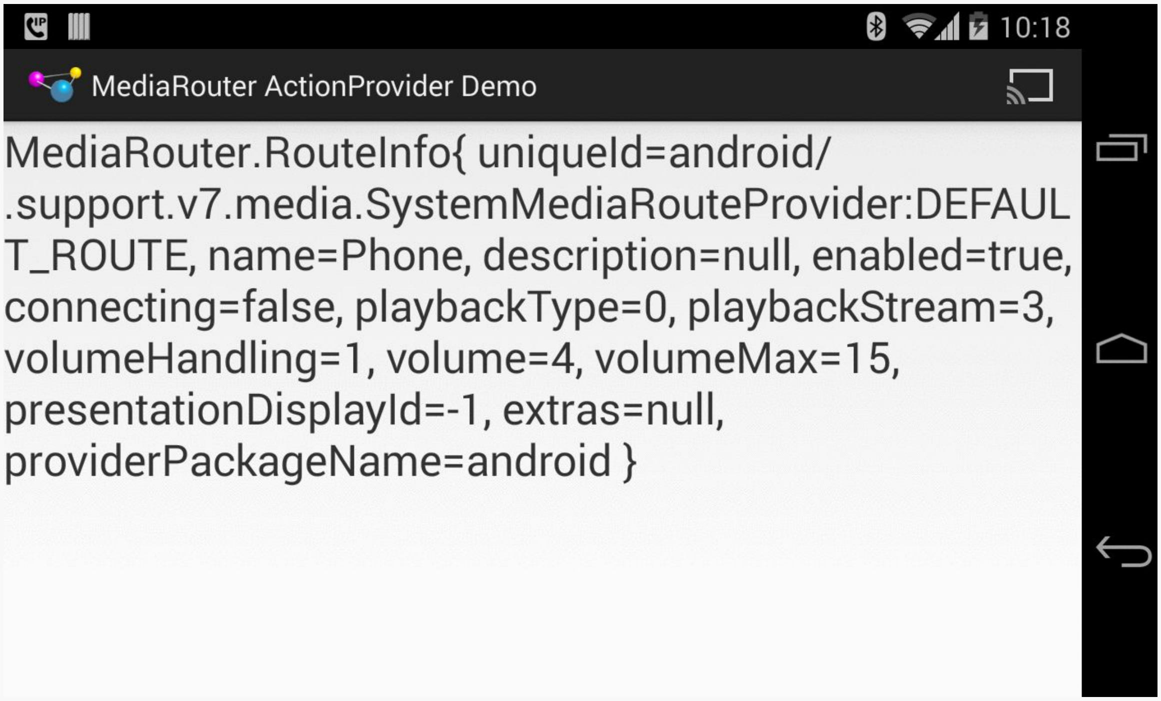


```
MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.media.SystemMediaRouteProvider:DEFAUL
T_ROUTE, name=HDMI, description=null, enabled=true,
connecting=false, playbackType=0, playbackStream=3,
volumeHandling=1, volume=15, volumeMax=15,
presentationDisplayId=3, extras=null,
providerPackageName=android }
```

Figure 692: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Video Route

Remote Playback Routes

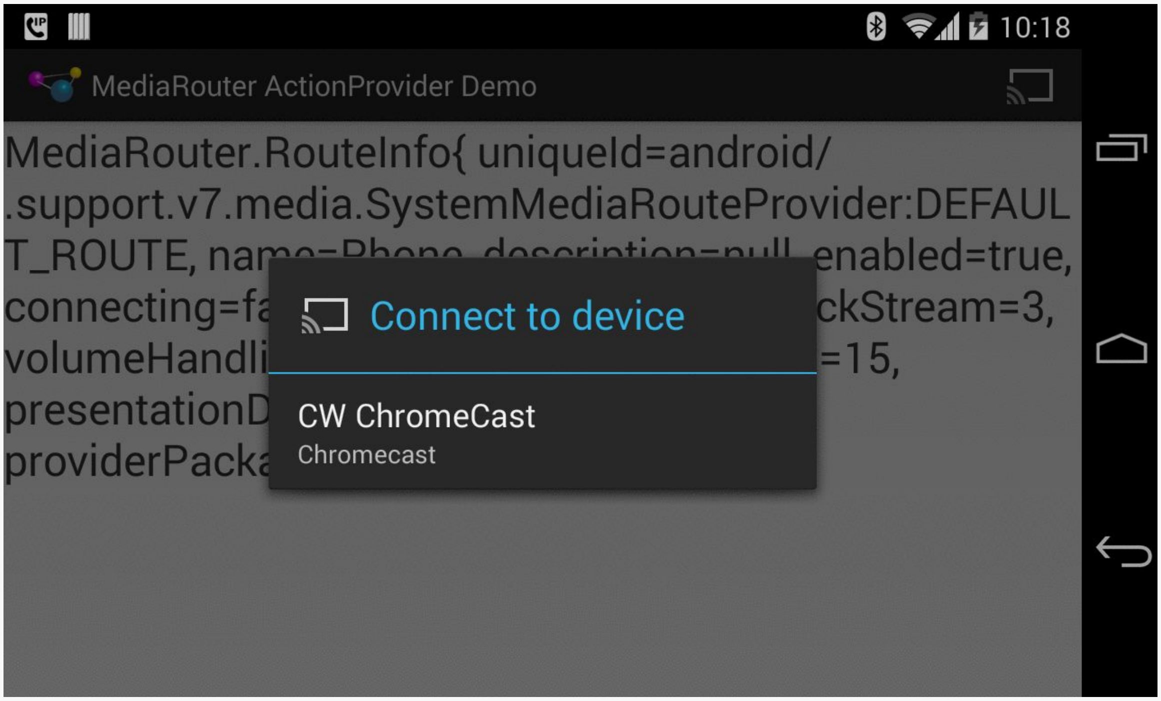
Since the user has to opt into remote playback media routes, the `MediaRouteActionProvider` *will* appear if you configure it to show such routes and a route is available:



```
MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.media.SystemMediaRouteProvider:DEFAUL
T_ROUTE, name=Phone, description=null, enabled=true,
connecting=false, playbackType=0, playbackStream=3,
volumeHandling=1, volume=4, volumeMax=15,
presentationDisplayId=-1, extras=null,
providerPackageName=android }
```

Figure 693: MediaRouter ActionProvider Demo, on a Nexus 4, Showing ActionProvider

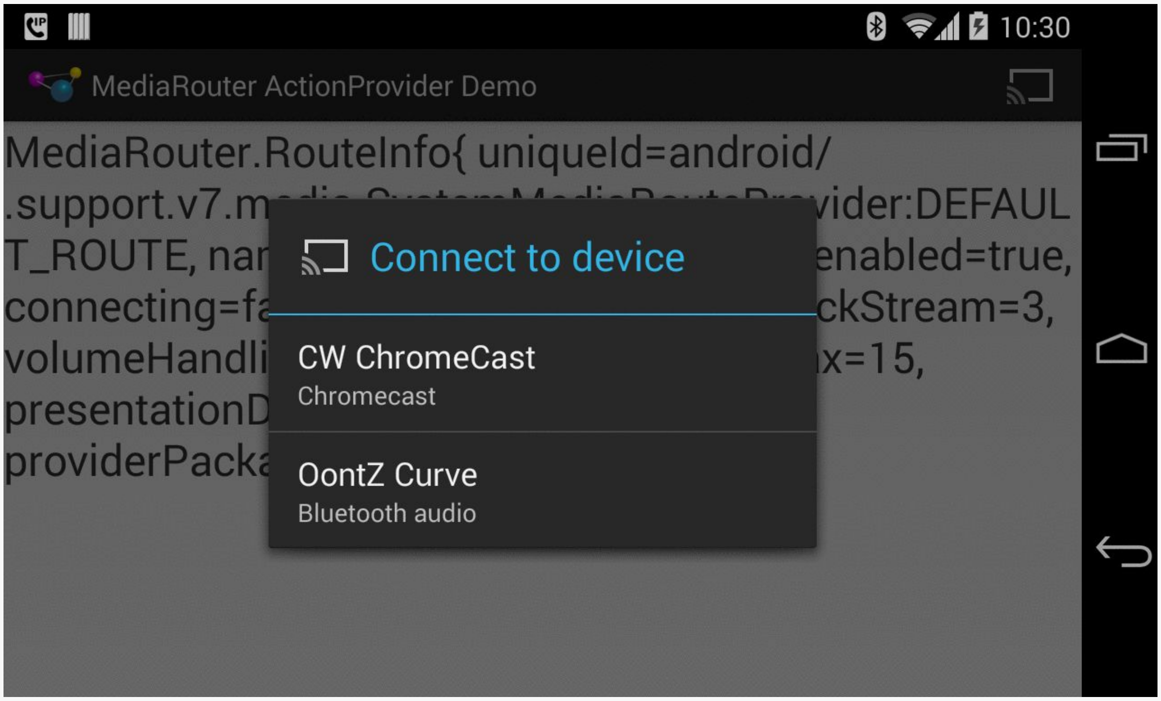
The `MediaRouteActionProvider`, when tapped, will pop up a dialog of available routes that the user can select:



```
MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.media.SystemMediaRouteProvider:DEFAUL
T_ROUTE, nam                              enabled=true,
connecting=fa                              ckStream=3,
volumeHandli                               =15,
presentationD
providerPacka
```

Figure 694: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Chromecast Route

Note that if the device has both a Bluetooth audio connection *and* access to a remote playback route (like a Chromecast), and you requested both live audio and remote playback routes, then the route selection dialog could have multiple choices:



10:30

MediaRouter ActionProvider Demo

MediaRouter.RouteInfo{ uniqueId=android/
.support.v7.m vider:DEFAUL
T_ROUTE, nar enabled=true,
connecting=fa ckStream=3,
volumeHandli x=15,
presentationD
providerPacka

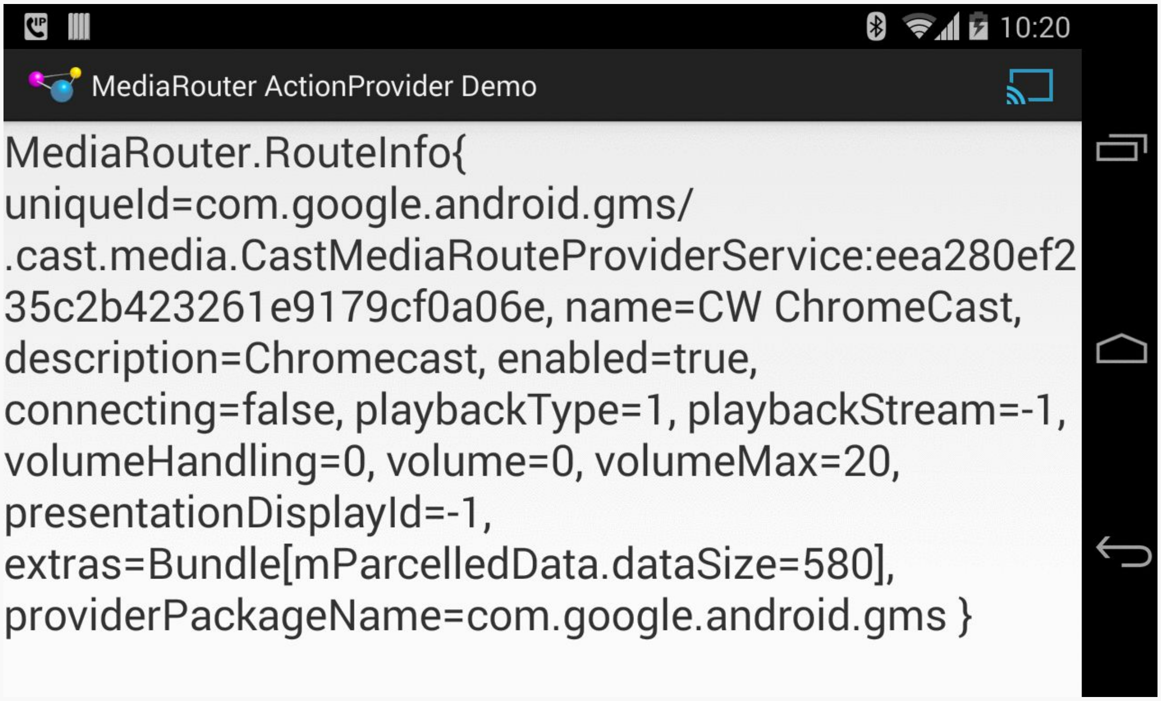
Connect to device

CW ChromeCast
Chromecast

OontZ Curve
Bluetooth audio

Figure 695: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Multiple Available Routes

If the user chooses a route from the dialog, our `onRouteSelected()` method will be called to reflect the new selection:

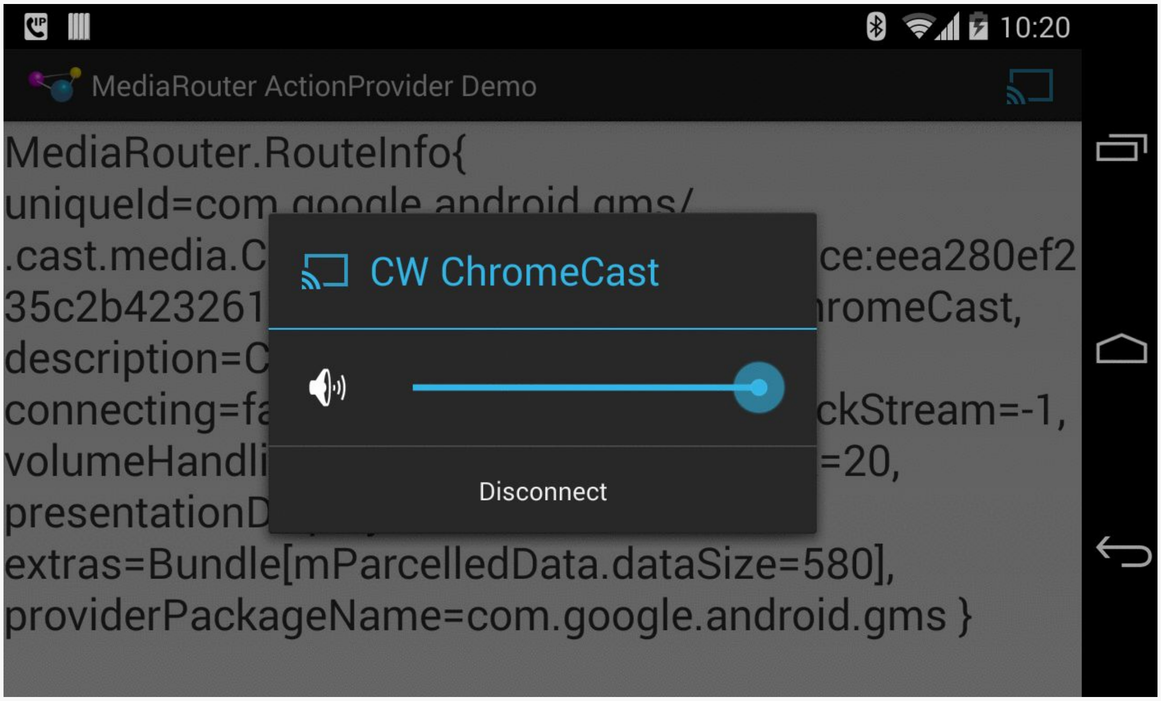


MediaRouter.RouteInfo{ uniqueId=com.google.android.gms/.cast.media.CastMediaRouteProviderService:eea280ef235c2b423261e9179cf0a06e, name=CW ChromeCast, description=Chromecast, enabled=true, connecting=false, playbackType=1, playbackStream=-1, volumeHandling=0, volume=0, volumeMax=20, presentationDisplayId=-1, extras=Bundle[mParcelledData.dataSize=580], providerPackageName=com.google.android.gms }

Figure 696: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Selected Chromecast Route

Also note that the `MediaRouteActionProvider` color changes from white to blue, indicating an altered route.

Tapping the action provider again pops up a dialog to control the volume of the route, plus a "Disconnect" button:



```
MediaRouter.RouteInfo{
uniqueId=com.google.android.gms/
.cast.media.C                    ce:eea280ef2
35c2b423261                     romeCast,
description=C
connecting=fa                    ckStream=-1,
volumeHandli                     =20,
presentationD
extras=Bundle[mParcelledData.dataSize=580],
providerPackageName=com.google.android.gms }
```

Figure 697: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Route Dialog

Tapping that "Disconnect" button returns everything to its original state.

Using Live Video Routes

A live video route is designed to be used with `Presentation`, a class that enables you to render your own content on the external display, much like how you would render your own content in a `Dialog`.

The use of `Presentation` is covered in an upcoming chapter.

Using Remote Playback Routes

In principle, `RemotePlaybackClient` allows you to work with remote playback routes, to specify `Uri` values to play back.

In practice, not even Google's own sample code for `RemotePlaybackClient` works reliably, let alone as documented.

That being said, let's take a look at the MediaRouter/RemotePlayback sample project, to see how RemotePlaybackClient works and where the current problems lie.

Setting Up MediaRouteActionProvider

Much of the basic setup of this application mirrors the MediaRouteActionProvider sample shown earlier in this chapter. One difference is that the UI is now encapsulated in a PlaybackFragment, with MainActivity simply setting up that fragment when needed:

```
package com.commonsware.android.remoteplayback;

import android.os.Bundle;
import android.support.v7.app.ActionBarActivity;

public class MainActivity extends ActionBarActivity {
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
      getSupportFragmentManager().beginTransaction()
                                 .add(android.R.id.content,
                                      new PlaybackFragment()).commit();
    }
  }
}
```

PlaybackFragment, when it is created, opts into being retained on configuration changes, tells Android that it wishes to add items to the action bar, and sets up a MediaRouteSelector for CATEGORY_REMOTE_PLAYBACK routes:

```
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    setHasOptionsMenu(true);
    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK).build();
  }
```

Then, in onAttach() — called when the PlaybackFragment is attached to the hosting activity — we obtain a MediaRouter instance:

```
  @Override
  public void onAttach(Activity host) {
    super.onAttach(host);
    router=MediaRouter.getInstance(host);
  }
```

In `onStart()`, we hook a `cb` data member — an instance of `MediaRouter.Callback` up to the `MediaRouter`, also requesting that the `MediaRouter` initiate discovery of available routes. We remove our callback in `onStop()`:

```
  @Override
  public void onStart() {
    super.onStart();

    router.addCallback(selector, cb,
                       MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
  }

  @Override
  public void onStop() {
    router.removeCallback(cb);

    super.onStop();
  }
```

We will examine `cb`'s declaration later in this section.

Later on, as part of our `onCreateOptionsMenu()` processing, we configure the `MediaRouteActionProvider` as before:

```
    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

    provider.setRouteSelector(selector);
```

All of this is very similar to the earlier examples. From here, though, we will actually use the route once the user selects it, to play back some media.

The Rest of the User Interface

The UI of the `PlaybackFragment` — other than the action bar — consists of a "transcript". This is a `TextView` inside of a `ScrollView`:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <TextView
    android:id="@+id/transcript"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:textSize="20sp"/>
```

```
</ScrollView>
```

As with most fragments, we inflate this layout in `onCreateView()`, holding onto the `TextView` and `ScrollView` widgets:

```
@Override
public View onCreateView(LayoutInflater inflater,
                         ViewGroup container,
                         Bundle savedInstanceState) {
  scroll=
      (ScrollView)inflater.inflate(R.layout.activity_main, container,
                                   false);

  transcript=(TextView)scroll.findViewById(R.id.transcript);

  logToTranscript("Started");

  return(scroll);
}
```

The `logToTranscript()` method will append a `String` to the `TextView` contents on a new line, plus scroll to the bottom to ensure that the new text is visible:

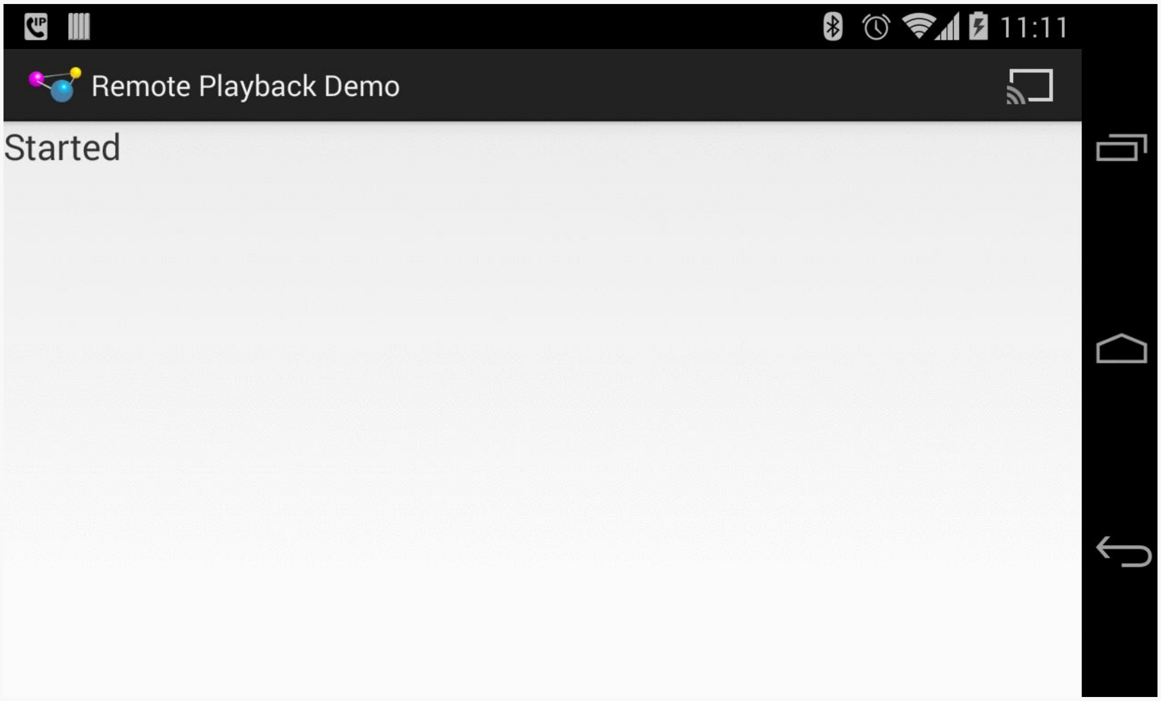
```
private void logToTranscript(String msg) {
  if (client != null) {
    String sessionId=client.getSessionId();

    if (sessionId != null) {
      msg="(" + sessionId + ") " + msg;
    }
  }

  transcript.setText(transcript.getText().toString() + msg + "\n");
  scroll.fullScroll(View.FOCUS_DOWN);
}
```

The `client` data member referred to in `logToTranscript()` is our `RemotePlaybackClient` instance, which will be covered in the next section.

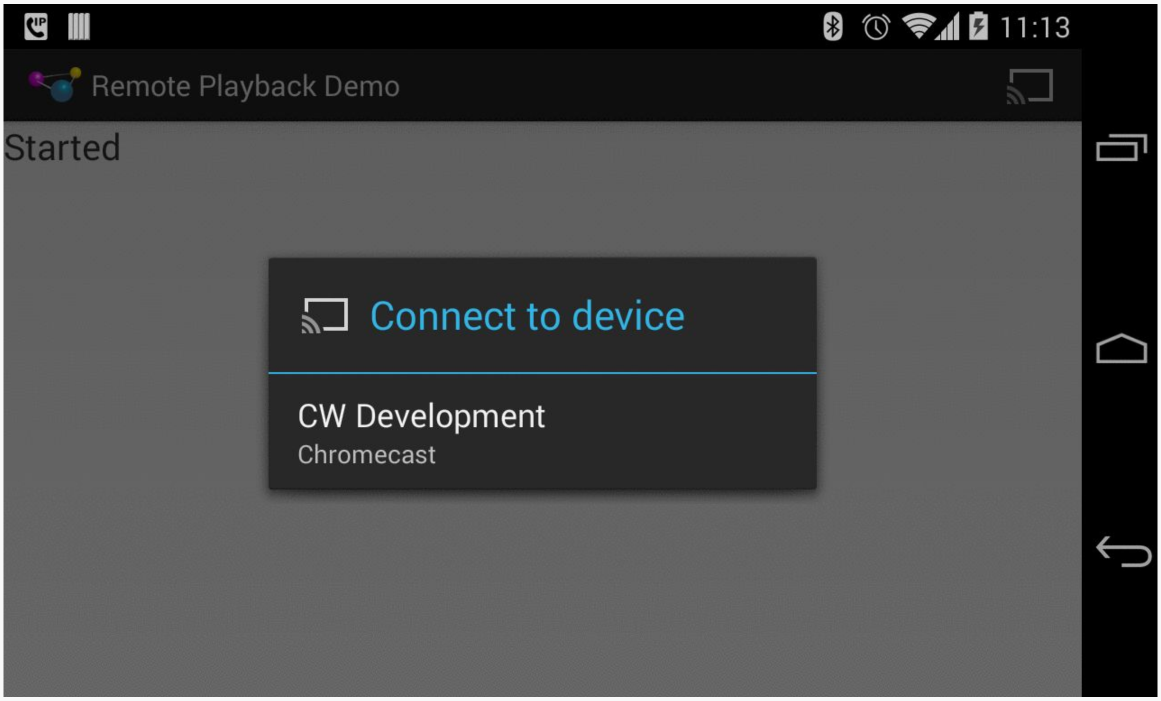
What the user sees when first running the sample is the action bar (with our `MediaRouteActionProvider`) and the transcript, with a simple "Started" message:



Started

Figure 698: RemotePlaybackClient Demo, on a Nexus 4, As Initially Launched

As before, tapping on the "cast" action bar item pops up our dialog of available routes:



11:13

Remote Playback Demo

Started

Connect to device

CW Development

Chromecast

Figure 699: RemotePlaybackClient Demo, on a Nexus 4, Showing Available Routes

Connecting and Session Management

When the user selects a route, our `MediaRouter.Callback` (cb) is called with `onRouteSelected()`. Similarly, if the user elects to disconnect via the `MediaRouteActionProvider`, our `Callback` is called with `onRouteUnselected()`. In the `MediaRouter.Callback` implementation inside `PlaybackFragment`, those events route to `connect()` and `disconnect()` methods, respectively, after logging a message to the transcript:

```
private MediaRouter.Callback cb=new MediaRouter.Callback() {
  @Override
  public void onRouteSelected(MediaRouter router,
                              MediaRouter.RouteInfo route) {
    logToTranscript(getActivity().getString(R.string.route_selected));
    connect(route);
  }

  @Override
  public void onRouteUnselected(MediaRouter router,
                                MediaRouter.RouteInfo route) {
    logToTranscript(getActivity().getString(R.string.route_unselected));
    disconnect();
  }
};
```

The `connect()` method handles connecting to the remote playback device and starting a session:

```
private void connect(MediaRouter.RouteInfo route) {
  client=
      new RemotePlaybackClient(getActivity().getApplication(), route);

  if (client.isRemotePlaybackSupported()) {
    logToTranscript(getActivity().getString(R.string.connected));

    if (client.isSessionManagementSupported()) {
      client.startSession(null, new SessionActionCallback() {
        @Override
        public void onResult(Bundle data, String sessionId,
                             MediaSessionStatus sessionStatus) {
          logToTranscript(getActivity().getString(R.string.session_started));
          updateMenu();
        }

        @Override
        public void onError(String error, int code, Bundle data) {
          logToTranscript(getActivity().getString(R.string.session_failed));
        }
      });
    }
    else {
      getActivity().supportInvalidateOptionsMenu();
    }
  }
  else {
    logToTranscript(getActivity().getString(R.string.remote_playback_not_supported));
    client=null;
  }
}
```

All of that, though, requires a bit more explanation.

What's a Session?

The objective of the `connect()` method is to establish a "session" with the `RemotePlaybackClient`. In Android's terms, a "session" is the state associated with an application's interactions with the remote playback client. In principle, the session could be shared among several instances of the app, such as several people contributing tracks to a dynamic playlist for audio playback at a party. Here, though, we are simply focused on having this one application instance have a session.

In principle, not all remote playback clients may support session management. In those cases, everybody is considered to be part of the same session. The test device for this sample (Chromecast) does support session management, however.

Connecting the Client

Connecting to the remote playback device is simply a matter of creating an instance of RemotePlaybackClient, specifying the route to connect to:

```
    client=
        new RemotePlaybackClient(getActivity().getApplication(), route);
```

Here, we use getActivity().getApplication() in the RemotePlaybackClient constructor. That is because we want to hold onto this RemotePlaybackClient instance across configuration changes, so we can easily maintain our session. Since we do not know what RemotePlaybackClient may hold onto given the supplied Context, and since we do not want to leak our activity by retaining a reference to it, we use the global Application instance, for a "leak-resistant" Context.

We also call isRemotePlaybackSupported() to confirm that, indeed, the RemotePlaybackClient is connected to something that supports remote playback. This should always return true in this case, as we are only interested in remote playback routes. But, a little defensive programming never hurts.

Assuming that is all OK, we log a "connected" message to the transcript and continue on to start our session.

Starting a Session

isSessionManagementSupported() on RemotePlaybackClient will indicate if the device supports explicit session management or not. If not, we will use the default implicit session and just continue on.

Otherwise, we call startSession() to explicitly start a session. This takes an optional Bundle of additional information to send in the start-session request to the device (or null if unused), plus a SessionActionCallback. The SessionActionCallback is supposed to be called when the session is ready for use. Surprisingly enough, this actually works… for startSession().

The SessionActionCallback will be called with onResult() for success and onError() for failure. In either case, we log a message to the transcript indicating the status.

In addition, if we have a session — either explicitly created via `startSession()` or implicitly created for devices without explicit session management — we call an `updateMenu()` method to update the action bar items.

About the Action Bar

The fragment maintains two `boolean` values representing key states in the operation of the playback:

1. `isPlaying` indicates if playback was started and not yet stopped
2. `isPaused` indicates if playback was paused and not yet resumed

The aforementioned `updateMenu()` implementation uses those, plus the existence of a non-`null` `client`, to configure the action bar items:

```
private void updateMenu() {
  if (menu != null) {
    menu.findItem(R.id.stop).setVisible(client != null && isPlaying);
    menu.findItem(R.id.pause).setVisible(client != null && isPlaying
                                          && !isPaused);
    menu.findItem(R.id.play)
        .setVisible(client != null && (!isPlaying || isPaused));
  }
}
```

Specifically:

- When we are not playing, the `play` item is visible; when we *are* playing, the `stop` item is visible
- When we are not paused, the `pause` item is visible (`play` serves "double duty", handling starting playback from a stopped state and resuming playback from a paused state)

This is based on a cached copy of the `Menu` object, saved in `onCreateOptionsMenu()` as part of setting up the action bar:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
  this.menu=menu;
  inflater.inflate(R.menu.main, menu);

  updateMenu();

  MenuItem item=menu.findItem(R.id.route_provider);
  MediaRouteActionProvider provider=
      (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);
```

```
    provider.setRouteSelector(selector);
  }
```

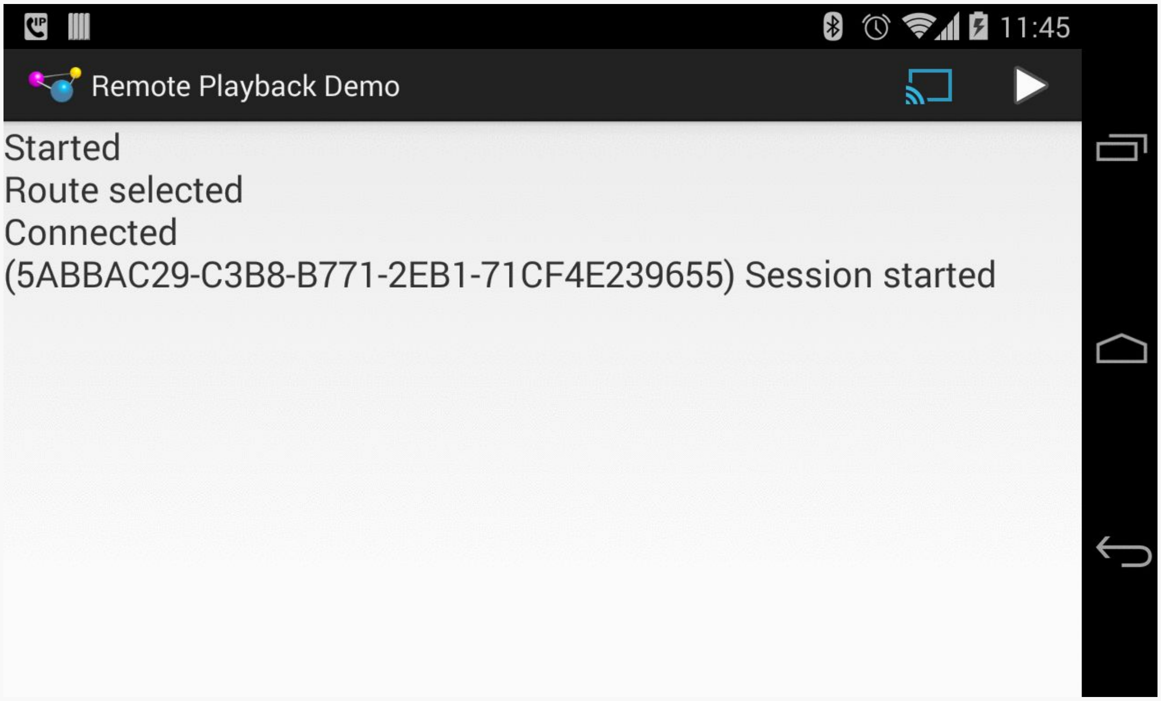
This is also where the logic shown previously for configuring the `MediaRouteActionProvider` resides.

Session IDs

A session has a `String` identifier. In principle, this can be shared with other instances of your application, to allow for shared management of the session.

In the case of this sample, the session ID is merely logged to the transcript for all messages that are tied to an active session.

Hence, when the user chooses a remote playback route from the `MediaRouteActionProvider`, the resulting UI should resemble:



```
Started
Route selected
Connected
(5ABBAC29-C3B8-B771-2EB1-71CF4E239655) Session started
```

Figure 700: RemotePlaybackClient Demo, on a Nexus 4, Showing an Active Session

We see that we have connected to the client and started our session, and the `play` action bar item is now available to start playback of some media.

Playing

The play action bar item is tied to a play() method via onOptionsItemSelected(), if we are not paused:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  switch (item.getItemId()) {
    case R.id.play:
      if (isPlaying && isPaused) {
        resume();
      }
      else {
        play();
      }

      return(true);

    case R.id.stop:
      stop();
      return(true);

    case R.id.pause:
      pause();
      return(true);
  }

  return(super.onOptionsItemSelected(item));
}
```

play(), in turn, uses the play() method on RemotePlaybackClient to play back a copy of [“Elephants Dream”](), a Creative Commons-licensed video, hosted on CommonsWare’s corner of the Amazon S3 service:

```
private void play() {
  logToTranscript(getActivity().getString(R.string.play_requested));

  ItemActionCallback playCB=new ItemActionCallback() {
    @Override
    public void onResult(Bundle data, String sessionId,
                         MediaSessionStatus sessionStatus,
                         String itemId, MediaItemStatus itemStatus) {
      logToTranscript(getActivity().getString(R.string.playing));
      isPlaying=true;
      updateMenu();
    }

    @Override
    public void onError(String error, int code, Bundle data) {
      logToTranscript(getActivity().getString(R.string.play_error)
          + error);
    }
  };

  client.play(Uri.parse("http://misc.commonsware.com/ed_hd_512kb.mp4"),
              "video/mp4", null, 0, null, playCB);
}
```

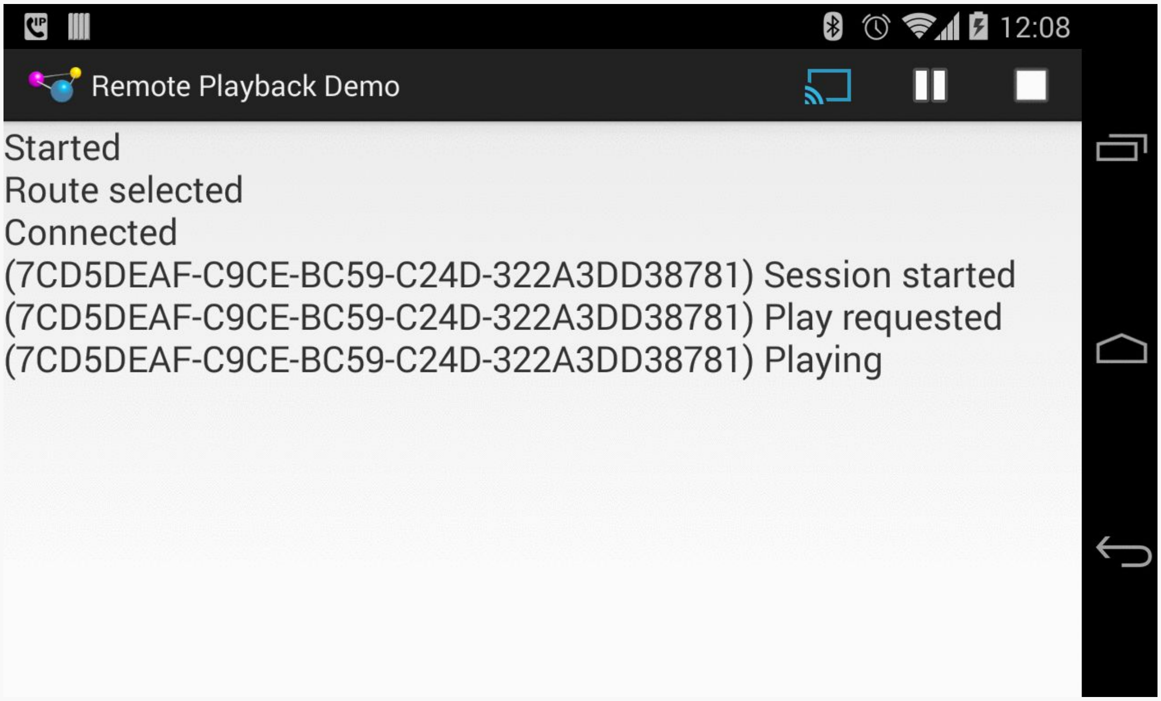
The `play()` method on `RemotePlaybackClient` takes a few parameters:

- The `Uri` of the media to be played back
- The MIME type of that media (or `null` if you do not know the MIME type)
- An optional `Bundle` of metadata about the media to be played, where the `Bundle` keys come from `MediaItemMetadata` class (or `null` if none)
- The starting offset in the media to begin playback from (use `0` to start from the beginning)
- An optional `Bundle` of additional data to pass to the device
- An instance of `ItemActionCallback` to be notified when playback has started or has failed

`ItemActionCallback` is reminiscent of `SessionActionCallback`, in that `onResult()` will be called when playback begins and `onError()` will return when playback ends. The method signature of `onResult()` is slightly different, offering an ID and status of this particular media item.

In our case, we log a message to the transcript before requesting playback, then again on success or failure. On success, we also update `isPlaying` to be `true` and refresh the action bar.

Hence, once the user begins playback by tapping the `play` action bar item, the UI will look like this:



Started
Route selected
Connected
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Session started
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Play requested
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Playing

Figure 701: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Started

And, of course, the movie should be showing up on your remote playback device.

Stopping, and a Bug

The `stop()` action bar item is tied to a `stop()` method in `PlaybackFragment`. You would think that this would be very similar to starting playback — call some `stop()` method on `RemotePlaybackClient` and update the UI after playback has stopped.

And, indeed, that is what we do… except that we have to deal with a bug:

```
private void stop() {
  logToTranscript(getActivity().getString(R.string.stop_requested));

  StopCallback stopCB=new StopCallback();

  client.stop(null, stopCB);
  transcript.postDelayed(stopCB, 1000);
}
```

The stop() Call, and the Bug

`stop()` on `RemotePlaybackClient` takes an optional `Bundle` (here, `null`) and a `SessionActionCallback`. The `SessionActionCallback` is supposed to be called when playback has stopped (`onResult()`) or if there was some error in processing the request (`onError()`).

In practice, neither happen when testing this on a Chromecast. This same behavior can be seen with Google's own sample code, so it would not appear to be a problem with the author's own sample.

What actually happens is that playback is indeed stopped, but the `SessionActionCallback` is not called with `onResult()` or `onError()`.

The Workaround: RunnableSessionActionCallback

Since we cannot rely upon `onResult()` to be called for us, if we have work that we need to do in that case, we have to have some sort of fallback mechanism. One crude fallback is to assume that the request succeeded if we have not received a specific response after a period of time (say, 1000 milliseconds).

To that end, this sample has `RunnableSessionActionCallback`, a `SessionActionCallback` that implements `Runnable`:

```
abstract class RunnableSessionActionCallback extends
    SessionActionCallback implements Runnable {
  abstract protected void doWork();

  private boolean hasRun=false;

  @Override
  public void onResult(Bundle data, String sessionId,
                       MediaSessionStatus sessionStatus) {
    transcript.removeCallbacks(this);
    run();
  }

  @Override
  public void run() {
    if (!hasRun) {
      hasRun=true;
      doWork();
    }
  }
}
```

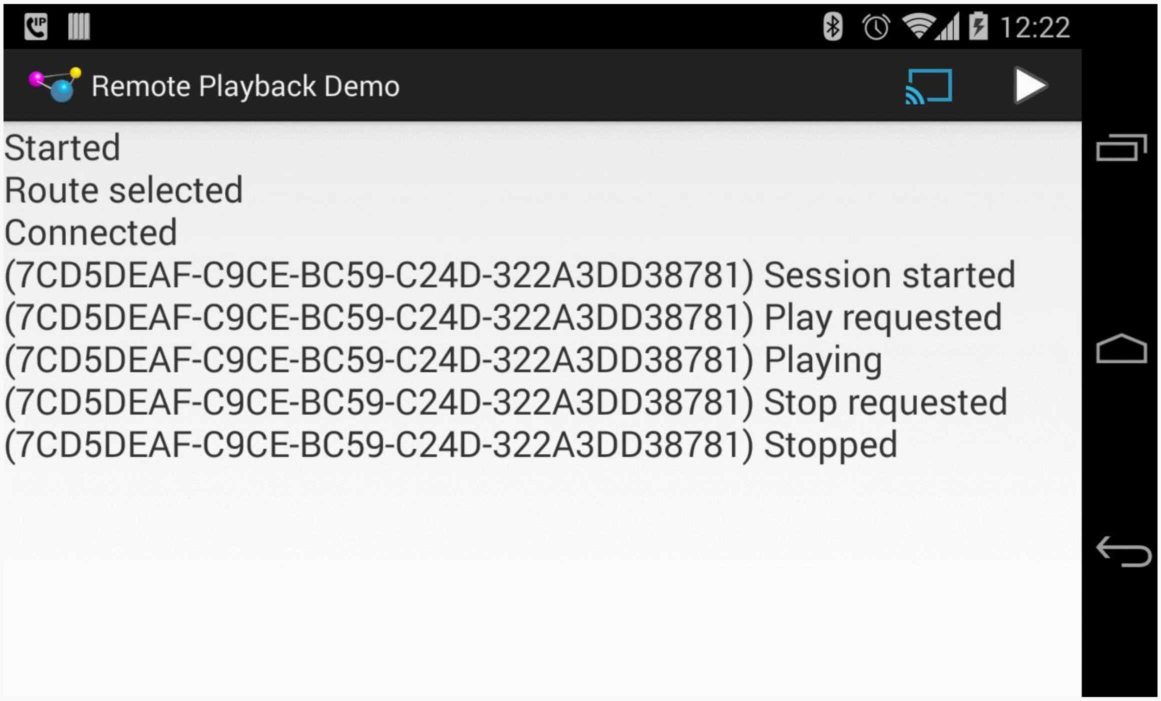
The run() method sees whether or not the callback has already been run from a previous run() call. If not, it does the work specified by the abstract doWork() method, to be implemented in subclasses.

StopCallback, as seen in the stop() method above, extends RunnableSessionActionCallback and overrides doWork():

```
private class StopCallback extends RunnableSessionActionCallback {
  @Override
  protected void doWork() {
    isPlaying=false;
    isPaused=false;
    updateMenu();
    logToTranscript(getActivity().getString(R.string.stopped));
  }
}
```

stop() then not only passes the StopCallback to the stop() implementation on RemotePlaybackClient, but also schedules it as a Runnable to be invoked in 1000 milliseconds, via a call to postDelayed() on the TextView portion of the transcript. The onResult() implementation in RunnableSessionActionCallback calls removeCallbacks(), so we do not bother invoking the posted Runnable if that is not needed.

The doWork() implementation in StopCallback updates our flags, refreshes the action bar, and logs a message to the transcript. The result will look like:



Started
Route selected
Connected
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Session started
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Play requested
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Playing
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Stop requested
(7CD5DEAF-C9CE-BC59-C24D-322A3DD38781) Stopped

Figure 702: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Stopped

This sample also does not handle the case where the media completes playback on its own, insofar as this event is not detected, to update the action bar. This will be added in a future version of this sample, if further bugs allow such support to actually work.

Pausing and Resuming

Similarly, the pause action bar item forwards to a `pause()` method that calls `pause()` on the `RemotePlaybackClient`:

```
private void pause() {
  logToTranscript(getActivity().getString(R.string.pause_requested));

  PauseCallback pauseCB=new PauseCallback();

  client.pause(null, pauseCB);
  transcript.postDelayed(pauseCB, 1000);
}
```

That, in turn, uses `PauseCallback`:

```
private class PauseCallback extends RunnableSessionActionCallback {
  @Override
```

```
    protected void doWork() {
      isPaused=true;
      updateMenu();
      logToTranscript(getActivity().getString(R.string.paused));
    }
  }
```

This updates the action bar and logs messages to the transcript, similar to the `stop()` behavior. It also should successfully pause playback on the remote device.

The `play` action bar item routes to `resume()` if playback is paused:

```
  private void resume() {
    logToTranscript(getActivity().getString(R.string.resume_requested));

    ResumeCallback resumeCB=new ResumeCallback();

    client.resume(null, resumeCB);
    transcript.postDelayed(resumeCB, 1000);
  }
```

That, in turn, uses `ResumeCallback`:

```
  private class ResumeCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
      isPaused=false;
      updateMenu();
      logToTranscript(getActivity().getString(R.string.resumed));
    }
  }
```

This too updates the action bar and logs messages to the transcript, in addition to resuming playback on the remote device.

Disconnecting

A call to `disconnect()` on `PlaybackFragment` is triggered from two locations:

- `onRouteUnselected()` in our `MediaRouter.Callback`, such as when the user uses the `MediaRouteActionProvider` to disconnect from the route
- `onDestroy()`, as part of general cleanup of the fragment

`disconnect()` should reverse the work done in `connect()`, ending our session and releasing the client:

```
  private void disconnect() {
    isPlaying=false;
    isPaused=false;
    if (client != null) {
      logToTranscript(getActivity().getString(R.string.session_ending));
      EndSessionCallback endCB=new EndSessionCallback();

      if (client.isSessionManagementSupported()) {
        client.endSession(null, endCB);
      }

      transcript.postDelayed(endCB, 1000);
    }
  }
```

This simply calls the `endSession()` method on the `RemotePlaybackClient`, supplying an `EndSessionCallback` to be notified (theoretically) of when the session has been torn down. But it only calls `endSession()` if session management is supported; otherwise, we would get a runtime error.

To be sure we complete the disconnection, though, we schedule the `EndSessionCallback` as seen in the `stop()`, `pause()`, and `resume()` methods. `EndSessionCallback` calls `release()` on the `RemotePlaybackClient`, to indicate that we are done with it, before setting `client` to `null`, refreshing the action bar, and logging something to the transcript:

```
  private class EndSessionCallback extends
      RunnableSessionActionCallback {
    @Override
    protected void doWork() {
      client.release();
      client=null;

      if (getActivity() != null) {
        updateMenu();
        logToTranscript(getActivity().getString(R.string.session_ended));
      }
    }
  }
```

Other Remote Playback Features

There are other things that `RemotePlaybackClient` offers that are not shown in this sample:

- `enqueue()` allows you to build up a queue of media to be played back in the current session. This could be used by an individual or, in principle, by several people using the same app with a shared session ID. `remove()` allows you to remove specific items from the playback queue. These methods only work if `isQueueingSupported()` returns `true`.

- `getStatus()` will return information about the currently-playing piece of media, while `getSessionStatus()` will return information about the overall session. You can also find out about these changes on the fly by registering with `setStatusCallback()`.
- `seek()` allows you to move the playback to a new offset within the media, for "rewind" and "fast-forward" functionality. The status APIs (above) can tell you where you are in the playback, so you can determine the appropriate offset to seek to.

Supporting External Displays

Android 4.2 inaugurated support for applications to control what appears on an external or "secondary" display (e.g., TV connected via HDMI), replacing the default screen mirroring. This is largely handled through a `Presentation` object, where you declare the UI that goes onto the external display, in parallel with whatever your activity might be displaying on the primary screen.

In this chapter, we will review how Android supports these external displays, how you can find out if an external display is attached, and how you can use `Presentation` objects to control what is shown on that external display.

The author would like to thank Mark Allison, whose "Multiple Screens" blog post series helped to blaze the trail for everyone in this space.

Prerequisites

In addition to the core chapters, you should read the chapter on dialogs and the chapter on `MediaRouter` before reading this chapter.

A History of External Displays

In this chapter, "external displays" refers to a screen that is temporarily associated with an Android device, in contrast with a "primary screen" that is where the Android device normally presents its user interface. So, most Android devices connected to a television via HDMI would consider the television to be a "external display", with the touchscreen of the device itself as the "primary screen". However, a Android TV box or a Fire TV connected to a television via HDMI would consider the television to be the "primary screen", simply because there is no other screen. Some devices themselves may have multiple screens, such as the Sony Tablet P — what those devices do with those screens will be up to the device.

Historically, support for external displays was manufacturer-dependent. Early Android devices had no ability to be displayed on an external display except through so-called "software projectors" like Jens Riboe's Droid@Screen. Some Android 2.x devices had ports that allowed for HDMI or composite connections to a television or projector. However, control for what would be displayed resided purely in the hands of the manufacturer. Some manufacturers would display whatever was on the touchscreen (a.k.a., "mirroring"). Some manufacturers would do that, but only for select apps, like a built-in video player.

Android 3.0 marked the beginning of Android's formal support for external displays, as the Motorola XOOM supported mirroring of the LCD's display via an micro-HDMI port. This mirroring was supplied by the core OS, not via device-dependent means. Any Android 3.0+ device with some sort of HDMI connection (e.g., micro-HDMI port) should support this same sort of mirroring capability.

However, mirroring was all that was possible. There was no means for an application to have something on the external display (e.g., a video) and something *else* on the primary screen (e.g., playback controls plus IMDB content about the movie being watched).

Android 4.2 changed that, with the introduction of `Presentation`.

What is a Presentation?

A `Presentation` is a container for displaying a UI, in the form of a `View` hierarchy (like that of an activity), on an external display.

You can think of a `Presentation` as being a bit like a `Dialog` in that regard. Just as a `Dialog` shows its UI separate from its associated activity, so does a `Presentation`. In fact, as it turns out, `Presentation` *inherits from* `Dialog`.

The biggest difference between a `Presentation` and an ordinary `Dialog`, of course, is where the UI is displayed. A `Presentation` displays on an external display; a `Dialog` displays on the primary screen, overlaying the activity. However, this difference has a profound implication: the *characteristics* of the external display, in terms of size and density, are likely to be different than those of a primary screen.

Hence, the resources used by the UI on an external display may be different than the resources used by the primary screen. As a result, **the `Context` of the `Presentation` is not the** `Activity`. Rather, it is a separate `Context`, one whose `Resources` object will use the proper resources based upon the external display characteristics.

This seemingly minor bit of bookkeeping has some rippling effects on setting up your `Presentation`, as we will see as this chapter unfolds.

Playing with External Displays

To write an app that uses an external display via a `Presentation`, you will need Android 4.2 or higher.

Beyond that, though, you will also need an external display of some form. Presently, you have three major options: emulate it, use a screen connected via some sort of cable, or use Miracast for wireless external displays.

Emulated

Even without an actual external display, you can lightly test your `Presentation`-enabled app via the Developer Options area of Settings on your Android 4.2 device. There, in the Drawing category, you will see the “Simulate secondary displays” preference:

1280x720 tvdpi

Strict mode enabled ☑
Flash screen when apps do long operations on main thread

Show CPU usage ☐
Screen overlay showing current CPU usage

Profile GPU rendering ☐
Measure rendering time in adb shell dumpsys gfxinfo

Enable OpenGL traces

Figure 705: Nexus 10, Simulating a 720p external display

Normally, that will show a mirrored version of the primary screen, but with a `Presentation`-enabled app, it will show what is theoretically shown on the real external display.

However, there are limits with this technology:

- You will see this option on an Android emulator, but it may not work, particularly if you are not capable of using the "Host GPU Support" option. At the time of this writing, it works on the x86 Android 4.2 emulator image, but not the x86 Android 4.3 or 4.4 emulator image, and the ARM emulators are likely to be far too slow.
- The external display is rather tiny, making it difficult for you to accurately determine if everything is sized appropriately.
- The external display occludes part of the screen, overlaying your activities, though you can at least drag it around the screen to move it out of your way as needed.

In practice, before you ship a `Presentation`-capable app, you will want to test it with an actual physical external display.

HDMI

If you have a device with HDMI-out capability, and you have the appropriate cable, you can simply plug that cable between your device and the display. “Tuning” the display to use that specific HDMI input port should cause your device’s screen contents to be mirrored to that display. Once this is working, you should be able to control the contents of that display using `Presentation`.

MHL

Mobile High-Definition Link, or MHL for short, is a relatively new option for connections to displays. On many modern Android devices, the micro USB port supports MHL as well. Some external displays have MHL ports, in which case a male-to-male MHL direct cable will connect the device to the display. Otherwise, MHL can be converted to HDMI via adapters, so an MHL-capable device can attach to any HDMI-compliant display.

SlimPort

SlimPort is another take on the overload-the-micro-USB-port-for-video approach. MHL is used on substantially more devices, but SlimPort appears on several of the Nexus-series devices (Nexus 4, Nexus 5, and the 2013 generation of the Nexus 7). Hence, while users will be more likely to have an MHL device, *developers* may be somewhat more likely to have a SlimPort device, given the popularity of Nexus devices among Android app developers.

From the standpoint of your programming work, MHL and SlimPort are largely equivalent — there is nothing that you need to do with your `Presentation` to address either of those protocols, let alone anything else like native HDMI.

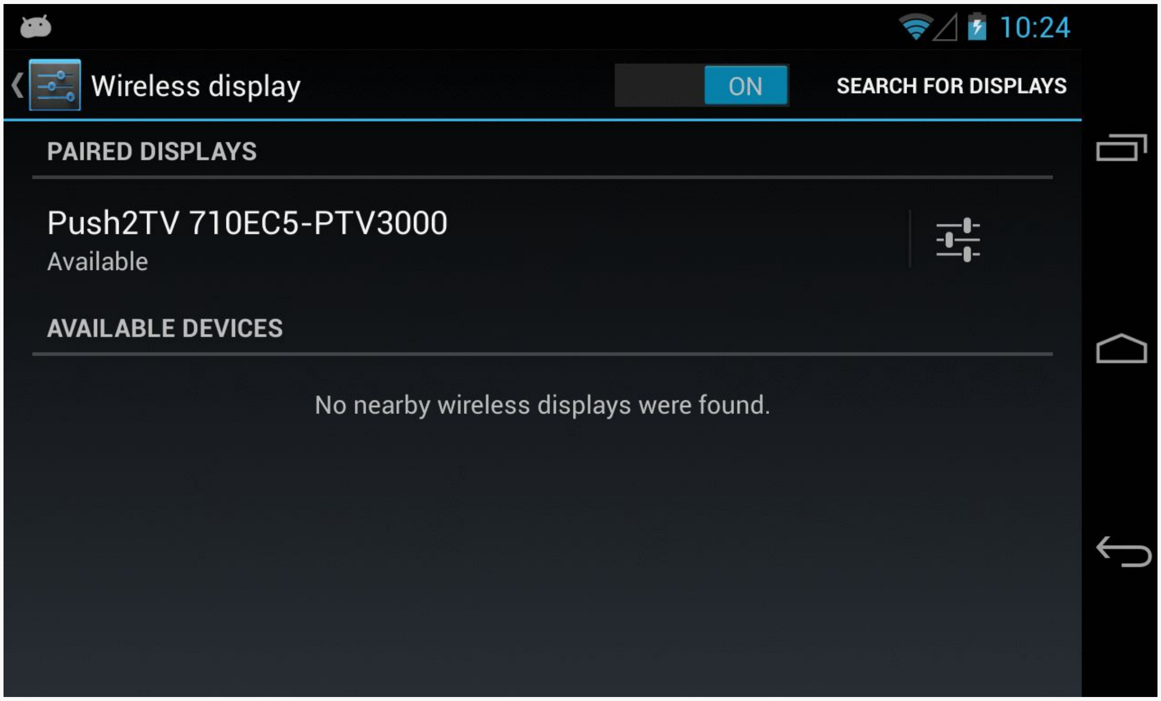
USB 3.1 Type C

The new USB 3.1 Type C specification has enough hooks for video display that we may see Android devices starting to use it (along with USB->HDMI adapters) for supporting external displays.

Miracast

There are a few wireless display standards available. Android 4.2 supports Miracast, based upon WiFiDirect. This is also supported by some devices running earlier versions of Android, such as some Samsung devices (where Miracast is sometimes referred to as "AllShare Cast"). However, unless and until those devices get upgraded to Android 4.2, you cannot control what they display, except perhaps through some manufacturer-specific APIs.

On a Miracast-capable device, going into Settings > Displays > Wireless display will give you the ability to toggle on wireless display support and scan for available displays:



Wireless display

ON

SEARCH FOR DISPLAYS

PAIRED DISPLAYS

Push2TV 710EC5-PTV3000
Available

AVAILABLE DEVICES

No nearby wireless displays were found.

Figure 706: Nexus 4 Wireless Display Settings

You can then elect to attach to one of the available wireless displays and get your screen mirrored, and later use this with your `Presentation`-enabled app.

Of course, you also need some sort of Miracast-capable display. As of early 2013, there were few of these. However, you can also get add-on boxes that connect to normal displays via HDMI and make them available via Miracast. One such box is the Netgear PTV3000, whose current firmware supports Miracast along with other wireless display protocols.

Note that Miracast uses a compressed protocol, to minimize the bandwidth needed to transmit the video. This, in turn, can cause some lag.

Note that Intel's WiDi is an extended version of Miracast.

WirelessHD

An up-and-coming competitor to Miracast is WirelessHD. WirelessHD has greater bandwidth requirements. On the other hand, it avoids compression, and therefore the lag that you experience with Miracast. At the time of this writing, though, no WirelessHD-native Android devices are available.

Detecting Displays

Of course, we can only present a `Presentation` on an external display if there is, indeed, such a screen available. There are two approaches for doing this: using `DisplayManager` and using `MediaRouter`. We examined `MediaRouter` for detecting live video routes in a preceding chapter, so let's focus here on `DisplayManager`.

`DisplayManager` is a system service, obtained by calling `getSystemService()` and asking for the `DISPLAY_SERVICE`.

Once you have a `DisplayManager`, you can ask it to give you a list of all available displays (`getDisplays()` with zero arguments) or all available displays in a certain category (`getDisplays()` with a single `String` parameter). As of API Level 17, the only available display category is `DISPLAY_CATEGORY_PRESENTATION`. The difference between the two flavors of `getDisplays()` is just the sort order:

- The zero-argument `getDisplays()` returns the `Display` array in arbitrary order
- The one-argument `getDisplays()` will put the `Display` objects matching the identified category earlier in the array

These would be useful if you wanted to pop up a list of available displays to ask the user which `Display` to use.

You can also register a `DisplayManager.DisplayListener` with the `DisplayManager` via `registerDisplayListener()`. This listener will be called when displays are added (e.g., HDMI cable was connected), removed (e.g., HDMI cable was disconnected), or changed. It is not completely clear what would trigger a "changed" call, though possibly an orientation-aware display might report back the revised height and width.

Note that while DisplayManager was added in API Level 17, Display itself has been around since API Level 1, though some additions have been made in more recent Android releases. But, this may mean that you can pass the Display object around to code supporting older devices without needing to constantly check for SDK level or add the @TargetApi() annotation.

Also note that the support-v4 library contains a DisplayManagerCompat, allowing you to call DisplayManager-like methods going all the way back to API Level 4. This does not give older devices the ability to work with external displays — that would require a time machine — but it can make it incrementally easier for you to write your app, without having to worry about API level. DisplayManagerCompat just gracefully degrades to returning information only about the device's standard touchscreen.

A Simple Presentation

Let's take a look at a small sample app that demonstrates how we can display custom content on an external display using a Presentation. The app in question can be found in the Presentation/Simple sample project.

The Presentation Itself

Since Presentation extends from Dialog, we provide the UI to be displayed on the external display via a call to setContentView(), much like we would do in an activity. Here, we just create a WebView widget in Java, point it to some Web page, and use it:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private class SimplePresentation extends Presentation {
  SimplePresentation(Context ctxt, Display display) {
    super(ctxt, display);
  }

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    WebView wv=new WebView(getContext());

    wv.loadUrl("https://commonsware.com");

    setContentView(wv);
  }
}
```

However, there are two distinctive elements of our implementation:

- Our constructor takes a `Context` (typically the `Activity`), along with a `Display` object indicating where the UI should be presented.
- Our call to the `WebView` constructor uses `getContext()`, instead of the `Activity` object. In this case, that may have no real-world effect, as `WebView` is not going to be using any of our resources. But, had we used a `LayoutInflater` for inflating our UI, we would need to use one created from `getContext()`, not from the activity itself.

Detecting the Displays

We need to determine whether there is a suitable external display when our activity comes into the foreground. We also need to determine if an external display was added or removed while we are in the foreground.

So, in `onStart()`, if we are on an Android 4.2 or higher device, we will get connected to the `MediaRouter` to handle those chores:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onStart() {
  super.onStart();

  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
    if (cb==null) {
      cb=new RouteCallback();
      router=(MediaRouter)getSystemService(MEDIA_ROUTER_SERVICE);
    }

    handleRoute(router.getSelectedRoute(MediaRouter.ROUTE_TYPE_LIVE_VIDEO));
    router.addCallback(MediaRouter.ROUTE_TYPE_LIVE_VIDEO, cb);
  }
}
```

Specifically, we:

- Create an instance of `RouteCallback`, an inner class of our activity that extends `SimpleCallback`
- Use `getSystemService()` to obtain a `MediaRouter`
- Call a `handleRoute()` method on our activity that will update our UI based upon the current video route, obtained by calling `getSelectedRoute()` on the `MediaRouter`
- Register the `RouteCallback` object with the `MediaRouter` via `addCallback()`

The RouteCallback object simply overrides onRoutePresentationDisplayChanged(), which will be called whenever there is a change in what screens are available and considered to be the preferred modes for video. There, we just call that same handleRoute() method that we called in onStart():

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN)
private class RouteCallback extends SimpleCallback {
  @Override
  public void onRoutePresentationDisplayChanged(MediaRouter router,
                                                RouteInfo route) {
    handleRoute(route);
  }
}
```

Hence, our business logic for showing the presentation is isolated in one method, handleRoute().

Our onStop() method will undo some of the work done by onStop(), notably removing our RouteCallback. We will examine that more closely in the next section.

Showing and Hiding the Presentation

Our handleRoute() method will be called with one of two parameter values:

- The RouteInfo of the active route we should use for displaying the Presentation
- null, indicating that there is no route for such content, other than the primary screen

If we are passed the RouteInfo, it may represent the route we are already using, or possibly it may represent a different route entirely.

We need to handle all of those cases, even if some (switching directly from one route to another) may not necessarily be readily testable.

Hence, our handleRoute() method does its best:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void handleRoute(RouteInfo route) {
  if (route == null) {
    clearPreso();
  }
  else {
    Display display=route.getPresentationDisplay();
```

```
      if (route.isEnabled() && display != null) {
        if (preso == null) {
          showPreso(route);
          Log.d(getClass().getSimpleName(), "enabled route");
        }
        else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
          clearPreso();
          showPreso(route);
          Log.d(getClass().getSimpleName(), "switched route");
        }
        else {
          // no-op: should already be set
        }
      }
      else {
        clearPreso();
        Log.d(getClass().getSimpleName(), "disabled route");
      }
    }
  }
```

There are five possibilities handled by this method:

- If the route is `null`, then we should no longer be displaying the `Presentation`, so we call a `clearPreso()` method that will handle that
- If the route exists, but is disabled or is not giving us a `Display` object, we also assume that we should no longer be displaying the `Presentation`, so we call `clearPreso()`
- If the route exists and seems ready for use, and we are not already showing a `Presentation` (our `preso` data member is `null`), we need to show the `Presentation`, which we delegate to a `showPreso()` method
- If the route exists, seems ready for use, but we are already showing a `Presentation`, and the ID of the new `Display` is different than the ID of the `Display` our `Presentation` had been using, we use *both* `clearPreso()` and `showPreso()` to switch our `Presentation` to the new `Display`
- If the route exists, seems ready for use, but we are already showing a `Presentation` on this `Display`, we do nothing and wonder why `handleRoute()` got called

Showing the `Presentation` is merely a matter of creating an instance of our `SimplePresentation` and calling `show()` on it, like we would a regular `Dialog`:

```
  @TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
  private void showPreso(RouteInfo route) {
    preso=new SimplePresentation(this, route.getPresentationDisplay());
    preso.show();
  }
```

Clearing the `Presentation` calls `dismiss()` on the `Presentation`, then sets the `preso` data member to `null` to indicate that we are not showing a `Presentation`:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void clearPreso() {
  if (preso != null) {
    preso.dismiss();
    preso=null;
  }
}
```

Our `onPause()` uses `clearPreso()` and `removeCallback()` to unwind everything:

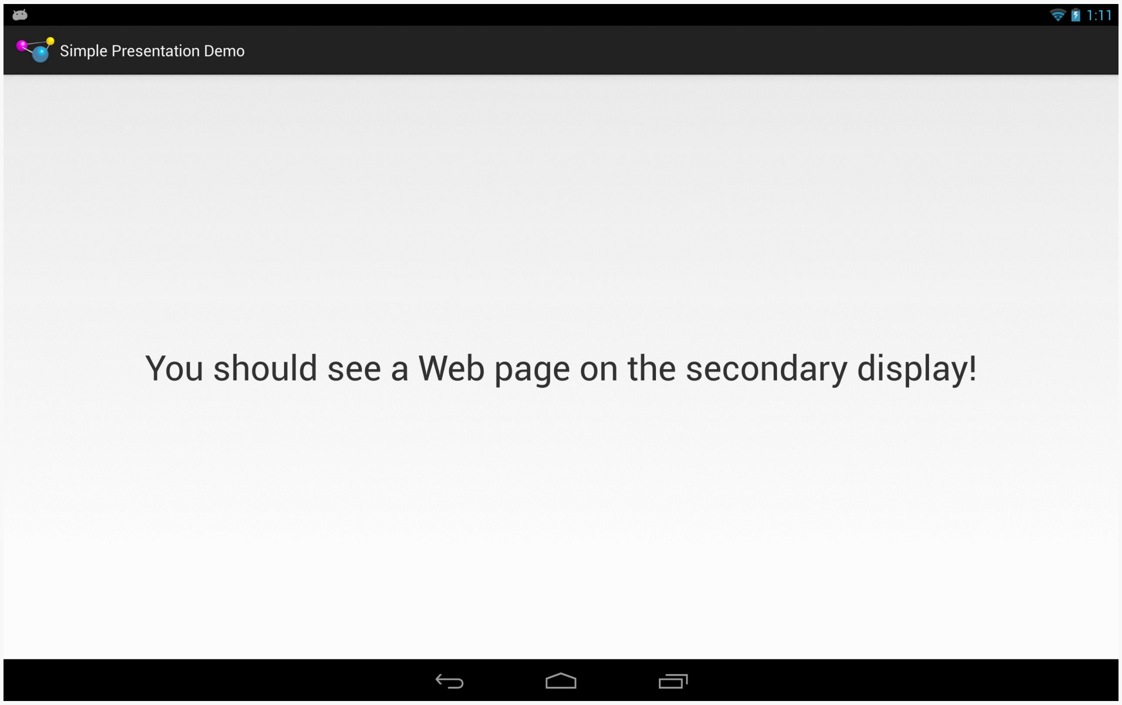
```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onStop() {
  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
    clearPreso();

    if (router != null) {
      router.removeCallback(cb);
    }
  }

  super.onStop();
}
```

The Results

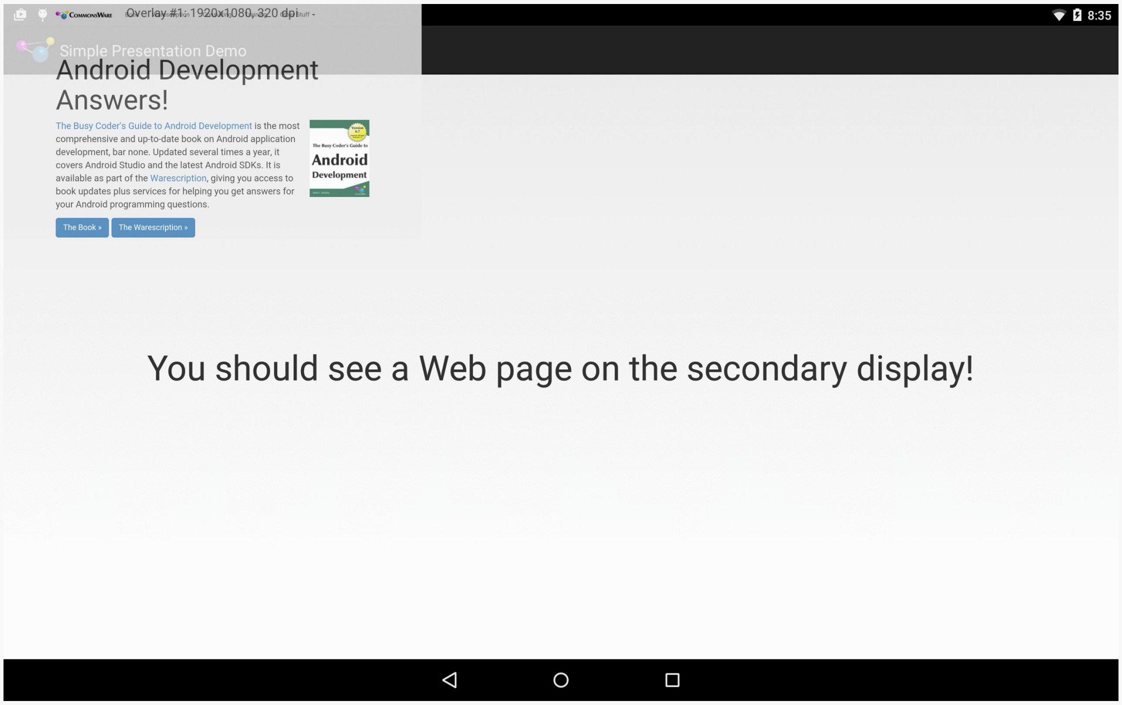
If you run this with no external display, you will just see a plain `TextView` that is the UI for our primary screen:



You should see a Web page on the secondary display!

Figure 707: Nexus 10, No Emulated Secondary Display, Showing Sample App

If you run this *with* an external display, the external display will show our `WebView`:



Overlay #1: 1920x1080, 320 dpi

Simple Presentation Demo

Android Development Answers!

The Busy Coder's Guide to Android Development is the most comprehensive and up-to-date book on Android application development, bar none. Updated several times a year, it covers Android Studio and the latest Android SDKs. It is available as part of the Warescription, giving you access to book updates plus services for helping you get answers for your Android programming questions.

You should see a Web page on the secondary display!

Figure 708: Nexus 10, With Emulated Secondary Display, Showing Sample App

A Simpler Presentation

There was a fair bit of code in the previous sample for messing around with `MediaRouter` and finding out about changes in the available displays.

To help simplify apps using `Presentation`, the author of this book maintains a library, [`CWAC-Presentation`](), with various reusable bits of code for managing `Presentations`.

One piece of this is `PresentationHelper`, which isolates all of the display management logic in a single reusable object. In this section, we will examine how to use `PresentationHelper`, then how `PresentationHelper` itself works, using `DisplayManager` under the covers.

Getting a Little Help

Our [Presentation/Simpler]() sample project uses the CWAC-Presentation artifact:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:presentation:0.4.+'
}
```

This gives us access to `PresentationHelper`. Our `MainActivity` in the sample creates an instance of `PresentationHelper` in `onCreate()`, stashing the object in a data member:

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);
    helper=new PresentationHelper(this, this);
  }
```

The constructor for `PresentationHelper` takes two parameters:

- a `Context` object, one that should be valid for the life of the helper, typically the `Activity` that creates the helper, and
- a implementation of `PresentationHelper.Listener` — in this case, the interface is implemented on `MainActivity` itself

The activity that creates the helper must forward `onPause()` and `onResume()` lifecycle methods to the equivalent methods on the helper:

```
  @Override
  public void onResume() {
    super.onResume();
    helper.onResume();
  }

  @Override
  public void onPause() {
    helper.onPause();
    super.onPause();
  }
```

The implementer of `PresentationHelper.Listener` also needs to have `showPreso()` and `clearPreso()` methods, much like the ones from the original `Presentation` sample in this chapter. `showPreso()` will be passed a `Display` object and should arrange to display a `Presentation` on that `Display`:

```
  @Override
  public void showPreso(Display display) {
    preso=new SimplerPresentation(this, display);
    preso.show();
  }
```

`clearPreso()` should get rid of any outstanding `Presentation`. It is passed a `boolean` value, which will be `true` if we simply lost the `Display` we were using (and so the activity might want to display the `Presentation` contents elsewhere, such as in the activity itself), or `false` if the activity is moving to the background (triggered via `onPause()`):

```
  @Override
  public void clearPreso(boolean showInline) {
    if (preso != null) {
      preso.dismiss();
      preso=null;
    }
  }
```

The implementations here are pretty much the same as the ones used in the previous example. `PresentationHelper` has handled all of the `Display`-management events – our activity can simply focus on showing or hiding the `Presentation` on demand.

Help When You Need It

In many respects, the `PresentationHelper` from the CWAC-Presentation project works a lot like the logic in the original `Presentation` sample's `MainActivity`, detecting various states and calling `showPreso()` and `clearPreso()` accordingly. However, `PresentationHelper` uses a different mechanism for this — `DisplayManager`.

The `PresentationHelper` constructor just stashes the parameters it is passed in data members and obtains a `DisplayManager` via `getSystemService()`, putting it in another data member:

```
  public PresentationHelper(Context ctxt, Listener listener) {
    this.listener=listener;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
      mgr=
          (DisplayManager)ctxt.getSystemService(Context.DISPLAY_SERVICE);
    }
  }
```

`onResume()` calls out to a private `handlePreso()` method to initialize our state, and tells the `DisplayManager` to let it know as displays are attached and detached from the device, by means of `registerDisplayListener()`:

```
public void onResume() {
  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
    handleRoute();
    mgr.registerDisplayListener(this, null);
  }
}
```

The `PresentationHelper` itself implements the `DisplayListener` interface, which requires three callback methods:

- `onDisplayAdded()` is called when a new output display is available
- `onDisplayChanged()` is called when an existing attached display changes its characteristics
- `onDisplayRemoved()` is called whenever a previously-attached output display has been detached

In our case, all three methods route to the same `handleRoute()` method, to update our state:

```
@Override
public void onDisplayAdded(int displayId) {
  handleRoute();
}

@Override
public void onDisplayChanged(int displayId) {
  handleRoute();
}

@Override
public void onDisplayRemoved(int displayId) {
  handleRoute();
}
```

`handleRoute()` is where the bulk of the "business logic" of `PresentationHelper` resides:

```
private void handleRoute() {
  if (isEnabled()) {
    Display[] displays=
        mgr.getDisplays(DisplayManager.DISPLAY_CATEGORY_PRESENTATION);

    if (displays.length == 0) {
      if (current != null || isFirstRun) {
        listener.clearPreso(true);
        current=null;
      }
    }
    else {
      Display display=displays[0];

      if (display != null && display.isValid()) {
        if (current == null) {
          listener.showPreso(display);
          current=display;
        }
        else if (current.getDisplayId() != display.getDisplayId()) {
          listener.clearPreso(true);
          listener.showPreso(display);
          current=display;
        }
        else {
          // no-op: should already be set
        }
      }
      else if (current != null) {
        listener.clearPreso(true);
        current=null;
      }
    }

    isFirstRun=false;
  }
}
```

We get the list of attached displays from the `DisplayManager` by calling `getDisplays()`. By passing in `DISPLAY_CATEGORY_PRESENTATION`, we are asking for returned array of `Display` objects to be ordered such that the preferred display for presentations is the first element.

If the array is empty, and we already had a `current` `Display` from before (or if this is the first time `handlePreso()` has run), we call `clearPreso()` to inform the listener that there is no `Display` for presentation purposes.

If we do have a valid `Display`:

- If we were not displaying anything before, we call `showPreso()` to inform the listener to start displaying things, plus keep track of the `current` `Display` in a data member
- If we were displaying something before, but now the preferred `Display` for a `Presentation` is different (the ID value of the `Display` objects differ), we call `clearPreso()` and `showPreso()` to get the listener to switch to the new `Display`
- Otherwise, this was a spurious call to `handlePreso()`, so we do not do anything of note

If, for whatever reason, the best `Display` is not valid, we do the same thing as if we had no `Display` at all: call `clearPreso()`.

Finally, in onPause(), we call clearPreso() to ensure that we are no longer attempting to display anything, plus call unregisterDisplayListener() so we are no longer informed about changes to the mix of Display objects that might be available:

```
public void onPause() {
  if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
    listener.clearPreso(false);
    current=null;

    mgr.unregisterDisplayListener(this);
  }
}
```

Presentations and Configuration Changes

One headache when using Presentation comes from the fact that it is a Dialog, which is owned by an Activity. If the device undergoes a configuration change, the activity will be destroyed and recreated by default, forcing you to destroy and recreate your Dialog. This, in turn, causes flicker on the external display, as the display briefly reverts to mirroring while this goes on.

Devices that support external displays may be orientation-locked to landscape when an external display is attached (e.g., an HDMI cable is plugged in). This reduces the odds of a configuration change considerably, as the #1 configuration change is an orientation change. However, that is not a guaranteed “feature” of Android external display support, and there are other configuration changes that could go on (e.g., devices gets plugged into a keyboard dock).

You can either just live with the flicker, or use android:configChanges to try to avoid the destroy/re-create cycle for the configuration change. As was noted back in the chapter on configuration changes, this is a risky approach, as it requires you to remember all your resources that might change on the configuration change and reset them to reflect the configuration change.

A “middle ground” approach is to ensure that your activity running the Presentation is orientation-locked to landscape mode, by adding android:orientation="landscape" to your <activity> in the manifest, then use android:configChanges to handle the configuration changes related to orientation:

- orientation
- keyboardHidden
- screenSize

- `screenLayout`

For those configuration changes, nothing should be needed to be modified in your activity, since you want to be displaying in landscape all of the time, and so you will not need to modify your use of resources. This leaves open the possibility of other configuration changes that would cause flicker on the external display, but those are relatively unlikely to occur while your activity is in the foreground, and so it may not be worth trying to address the flicker in all those cases.

Yet another possibility is to have your presentation be delivered by a service, as we will discuss later in this chapter.

Presentations as Fragments

Curiously, the support for `Presentation` is focused on `View`. There is nothing built into Android 4.2 that ties a `Presentation` to a `Fragment`. However, this can be a useful technique, one we can roll ourselves… with a bit of difficulty.

The Reuse Reality

There will be a few apps that will only want to deliver content if there is a external display on which to deliver it. However, the vast majority of apps supporting external displays will do so optionally, still supporting regular Android devices with only primary screens.

In this case, though, we have a problem: we need to show that UI *somewhere* if there is no external display to show it on. Our only likely answer is to have it be part of our primary UI.

Fragments would seem to be tailor-made for this. We could "throw" a fragment to the external display if it exists, or incorporate it into our main UI (e.g., as another page in a `ViewPager`) if the external display does not exist, or even have it be shown by some separate activity on smaller-screen devices like phones. Our business logic will already have been partitioned between the fragments — it is merely a question of where the fragment shows up.

Presentations as Dialogs

The nice thing is that `Presentation` extends `Dialog`. We already have a `DialogFragment` as part of Android that knows how to display a `Dialog` populated by a Fragment implementation of onCreateView(). DialogFragment even knows how to handle either being part of the main UI *or* as a separate dialog.

Hence, one could imagine a PresentationFragment that extends DialogFragment and adds the ability to either be part of the main UI on the primary screen *or* shown on an external display, should one be available.

And, in truth, it is possible to create such a PresentationFragment, though there are some limitations.

The Context Conundrum

The biggest limitation comes back to the Context used for our UI. Normally, there is only one Context of relevance: the Activity. In the case of Presentation, though, there is a separate Context that is tied to the display characteristics of the external display.

This means that PresentationFragment must manipulate *two* Context values:

- The Activity, if the fragment should be part of our main UI
- Some other Context supplied by the Presentation, if the fragment should be displayed in the Presentation on the external display

This makes creating a PresentationFragment class a bit tricky… though not impossible. After all, if it *were* impossible, these past several paragraphs would not be very useful.

A PresentationFragment (and Subclasses)

The [Presentation/Fragment](#) sample project has the same UI as the Presentation/Simple project, if there is an external display. If there is only the primary screen, though, we will elect to display the WebView side-by-side with our TextView in the main UI of our activity. And, to pull this off, we will create a PresentationFragment based on DialogFragment.

Note that this sample project has its android:minSdkVersion set to 17, mostly to cut down on all of the "only do this if we are on API Level 17" checks and @TargetApi() annotations. Getting this code to work on earlier versions of Android is left as an exercise for the reader.

In a simple DialogFragment, we might just override onCreateView() to provide the contents of the dialog. The default implementation of onCreateDialog() would create an empty Dialog, to be populated with the View returned by onCreateView().

In our PresentationFragment subclass of DialogFragment, though, we need to override onCreateDialog() to use a Presentation instead of a Dialog… if we have a Presentation to work with:

```
package com.commonsware.android.preso.fragment;

import android.app.Dialog;
import android.app.DialogFragment;
import android.app.Presentation;
import android.content.Context;
import android.os.Bundle;
import android.view.Display;

abstract public class PresentationFragment extends DialogFragment {
  private Display display=null;
  private Presentation preso=null;

  @Override
  public Dialog onCreateDialog(Bundle savedInstanceState) {
    if (preso == null) {
      return(super.onCreateDialog(savedInstanceState));
    }

    return(preso);
  }

  public void setDisplay(Context ctxt, Display display) {
    if (display == null) {
      preso=null;
    }
    else {
      preso=new Presentation(ctxt, display, getTheme());
    }

    this.display=display;
  }

  public Display getDisplay() {
    return(display);
  }

  protected Context getContext() {
    if (preso != null) {
      return(preso.getContext());
    }

    return(getActivity());
  }
}
```

We also expose getDisplay() and setDisplay() accessors, to supply the Display object to be used if this fragment will be thrown onto an external display. setDisplay() also creates the Presentation object wrapped around the display, using the three-parameter Presentation constructor that supplies the theme to be used (in this case, using the getTheme() method, which a subclass could override if desired).

PresentationFragment also implements a getContext() method. If this fragment will be used with a Display and Presentation, this will return the Context from the Presentation. If not, it returns the Activity associated with this Fragment.

This project contains a WebPresentationFragment, that pours the same basic Android source code used elsewhere in this book for a WebViewFragment into a subclass of PresentationFragment:

```
package com.commonsware.android.preso.fragment;

import android.annotation.TargetApi;
import android.os.Build;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebView;

public class WebPresentationFragment extends PresentationFragment {
  private WebView mWebView;
  private boolean mIsWebViewAvailable;

  /**
   * Called to instantiate the view. Creates and returns the
   * WebView.
   */
  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    if (mWebView != null) {
      mWebView.destroy();
    }

    mWebView=new WebView(getContext());
    mIsWebViewAvailable=true;
    return mWebView;
  }

  /**
   * Called when the fragment is visible to the user and
   * actively running. Resumes the WebView.
   */
  @TargetApi(11)
  @Override
  public void onPause() {
    super.onPause();

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
      mWebView.onPause();
    }
  }

  /**
   * Called when the fragment is no longer resumed. Pauses
   * the WebView.
   */
  @TargetApi(11)
  @Override
  public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
      mWebView.onResume();
    }

    super.onResume();
  }

  /**
   * Called when the WebView has been detached from the
   * fragment. The WebView is no longer available after this
   * time.
   */
  @Override
  public void onDestroyView() {
    mIsWebViewAvailable=false;
    super.onDestroyView();
  }

  /**
   * Called when the fragment is no longer in use. Destroys
   * the internal state of the WebView.
   */
  @Override
  public void onDestroy() {
    if (mWebView != null) {
      mWebView.destroy();
      mWebView=null;
    }
    super.onDestroy();
  }

  /**
   * Gets the WebView.
   */
  public WebView getWebView() {
    return mIsWebViewAvailable ? mWebView : null;
  }
}
```

(note: the flawed comments came from the original Android open source code from which this fragment was derived)

The only significant difference, besides the superclass, is that the `onCreateView()` method uses `getContext()`, not `getActivity()`, as the `Context` to use when creating the `WebView`.

And, the project has a `SamplePresentationFragment` subclass of `WebPresentationFragment`, where we use the factory-method-and-arguments pattern to pass a URL into the fragment to use for populating the `WebView`:

```
package com.commonsware.android.preso.fragment;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class SamplePresentationFragment extends WebPresentationFragment {
  private static final String ARG_URL="url";

  public static SamplePresentationFragment newInstance(Context ctxt,
                                                       Display display,
                                                       String url) {
    SamplePresentationFragment frag=new SamplePresentationFragment();

    frag.setDisplay(ctxt, display);

    Bundle b=new Bundle();

    b.putString(ARG_URL, url);
    frag.setArguments(b);

    return(frag);
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    View result=
        super.onCreateView(inflater, container, savedInstanceState);

    getWebView().loadUrl(getArguments().getString(ARG_URL));

    return(result);
  }
}
```

Using PresentationFragment

Our activity's layout now contains not only a `TextView`, but also a `FrameLayout` into which we will slot the `PresentationFragment` if there is no external display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="horizontal"
  tools:context=".MainActivity">

  <TextView
    android:id="@+id/prose"
    android:layout_width="0px"
    android:layout_height="wrap_content"
    android:layout_gravity="center"
    android:layout_weight="1"
    android:gravity="center"
    android:text="@string/secondary"
    android:textSize="40sp"/>

  <FrameLayout
    android:id="@+id/preso"
    android:layout_width="0px"
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:visibility="gone"/>

</LinearLayout>
```

Note that the `FrameLayout` is initially set to have `gone` as its `visibility`, meaning that only the `TextView` will appear. Based on the widths and weights, the `TextView` will take up the full screen when the `FrameLayout` is `gone`, or they will split the screen in half otherwise.

In the `onCreate()` implementation of our activity (`MainActivity`), we inflate that layout and grab both the `TextView` and the `FrameLayout`, putting them into data members:

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);

    inline=findViewById(R.id.preso);
    prose=(TextView)findViewById(R.id.prose);
  }
```

Our `onStart()` method, and our `RouteCallback`, are identical to those from the previous sample. Our `handleRoute()` method is *nearly* identical to the original, as is our `onStop()` method. The difference is that we need to distinguish whether we have lost an external display (and therefore want to move the Web page into the main UI) or if we are going away entirely (and therefore just wish to clean up the external display, if any). Hence, `clearPreso()` takes a `boolean` parameter (`switchToInline`), `true` if we want to show the fragment in the main UI, `false` otherwise. And, our `onStop()` and `handleRoute()` methods pass the appropriate value to `clearPreso()`:

```
@Override
protected void onStop() {
  clearPreso(false);

  if (router != null) {
    router.removeCallback(cb);
  }

  super.onStop();
}

private void handleRoute(RouteInfo route) {
  if (route == null) {
    clearPreso(true);
  }
  else {
    Display display=route.getPresentationDisplay();

    if (route.isEnabled() && display != null) {
      if (preso == null) {
        showPreso(route);
        Log.d(getClass().getSimpleName(), "enabled route");
      }
      else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
        clearPreso(true);
        showPreso(route);
        Log.d(getClass().getSimpleName(), "switched route");
      }
      else {
        // no-op: should already be set
      }
    }
    else {
      clearPreso(true);
      Log.d(getClass().getSimpleName(), "disabled route");
    }
  }
}
```

`showPreso()` is called when we want to display the `Presentation` on the external display. Hence, we need to remove the `WebPresentationFragment` from the main UI if it is there:

```
private void showPreso(RouteInfo route) {
  if (inline.getVisibility() == View.VISIBLE) {
    inline.setVisibility(View.GONE);
    prose.setText(R.string.secondary);

    Fragment f=getFragmentManager().findFragmentById(R.id.preso);

    getFragmentManager().beginTransaction().remove(f).commit();
  }
```

```
    preso=buildPreso(route.getPresentationDisplay());
    preso.show(getFragmentManager(), "preso");
  }
```

Creating the actual `PresentationFragment` is delegated to a `buildPreso()` method, which employs the `newInstance()` method on the `SamplePresentationFragment`:

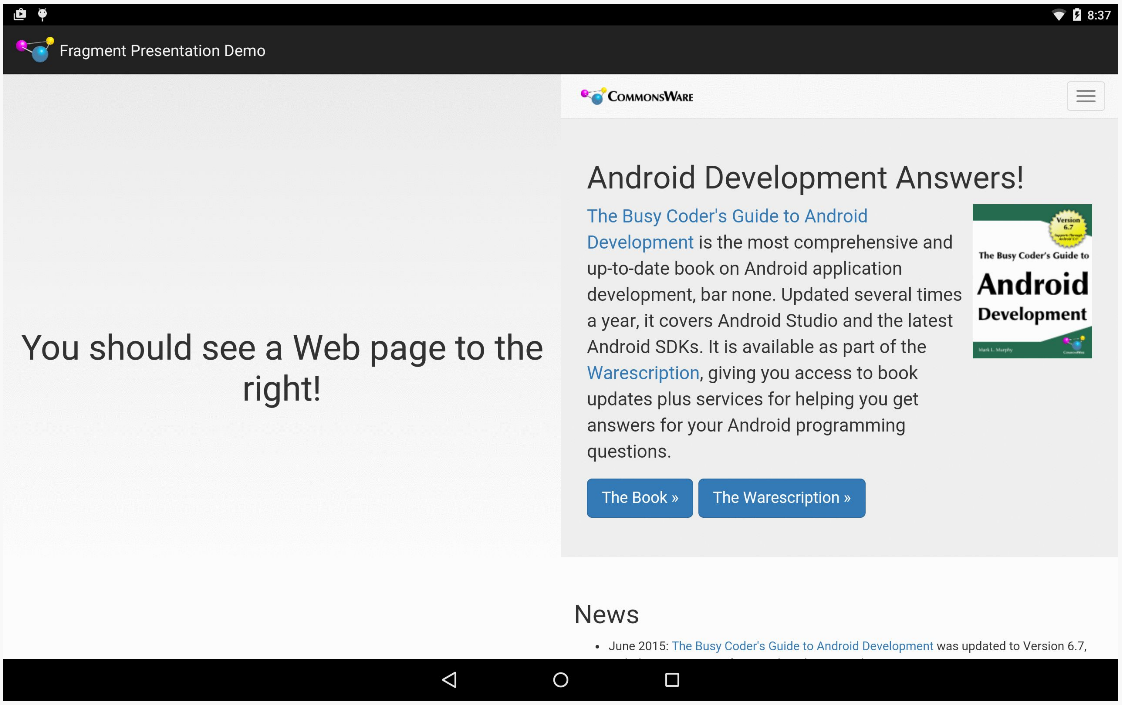
```
  private PresentationFragment buildPreso(Display display) {
    return(SamplePresentationFragment.newInstance(this, display,
                                                  "https://commonsware.com"));
  }
```

`clearPreso()` is responsible for *adding* the `PresentationFragment` to the main UI, if `switchToInline` is `true`:

```
  private void clearPreso(boolean switchToInline) {
    if (switchToInline) {
      inline.setVisibility(View.VISIBLE);
      prose.setText(R.string.primary);
      getFragmentManager().beginTransaction()
                          .add(R.id.preso, buildPreso(null)).commit();
    }

    if (preso != null) {
      preso.dismiss();
      preso=null;
    }
  }
```

With an external display, the results are visually identical to the original sample. Without an external display, though, our UI is presented side-by-side:



You should see a Web page to the right!

Android Development Answers!

The Busy Coder's Guide to Android Development is the most comprehensive and up-to-date book on Android application development, bar none. Updated several times a year, it covers Android Studio and the latest Android SDKs. It is available as part of the Warescription, giving you access to book updates plus services for helping you get answers for your Android programming questions.

News

- June 2015: The Busy Coder's Guide to Android Development was updated to Version 6.7,

Figure 709: Nexus 10, With Inline PresentationFragment

Limits

This implementation of `PresentationFragment` has its limitations, though.

First, we cannot reuse the same fragment *instance* for both the inline UI and the `Presentation` UI, as they use different `Context` objects. Hence, production code will need to arrange to get data out of the old fragment instance and into the new instance when the screen mix changes. You might be able to leverage `onSaveInstanceState()` for that purpose, with a more-sophisticated implementation of `PresentationFragment`.

Also, depending upon the device and the external display, you *may* see multiple calls to `handleRoute()`. For example, attaching an external display may trigger three calls to your `RouteCallback`, for an attach, a detach, and another attach event. It is unclear why this occurs. However, it may require some additional logic in your app to deal with these events, if you encounter them.

Another Sample Project: Slides

At the 2013 Samsung Developer Conference, the author of this book delivered a presentation on using Presentation. Rather than use a traditional presentation package driven from a notebook, the author used the Presentation/Slides sample app. This sample app shows how to show slides on an external display, controlled by a ViewPager on a device's touchscreen.

What the audience saw, through most of the presentation, were simple slides. What the presenter saw was a ViewPager, with tabs, along with action bar items for various actions:

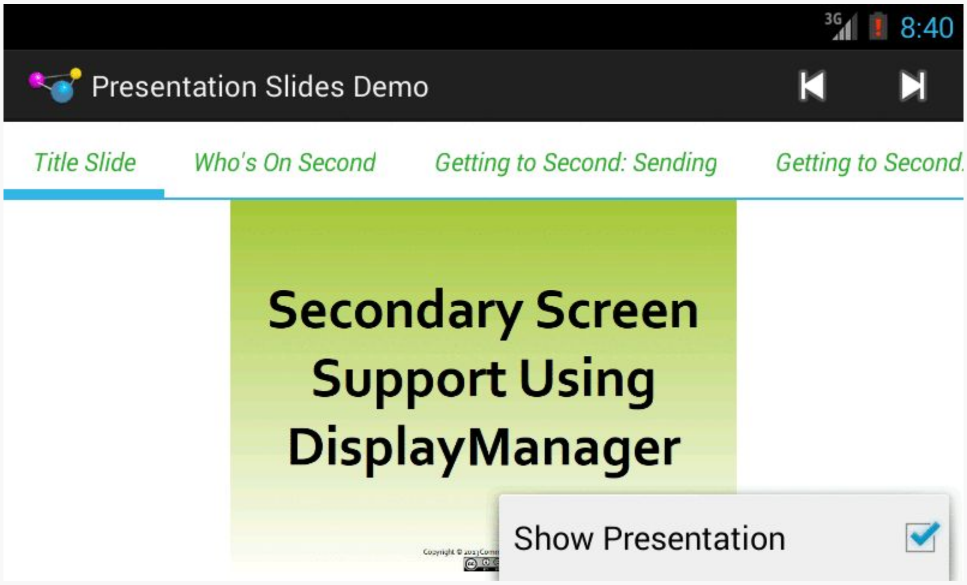


Figure 710: PresentationSlidesDemo, Showing Overflow

The Slides

The slides themselves are a series of 20 drawable resources (img0, img1, etc.), put into the res/drawable-nodpi/ resource directory, as there is no intrinsic "density" that the slides were prepared for. As we use the slides in ImageView widgets, their images will be resized to fit the available ImageView space alone, not taking screen density into account.

There is a matching set of 20 string resources (`title0`, `title1`, etc.) containing a string representation of the slide titles, for use with `getPageTitle()` of a `PagerAdapter`.

The PagerAdapter

That `PagerAdapter`, named `SlidesAdapter`, has each slide be visually represented by an `ImageView` widget. In this case, `SlidesAdapter` extends `PagerAdapter` directly, skipping fragments:

```java
package com.commonsware.android.preso.slides;

import android.content.Context;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;

class SlidesAdapter extends PagerAdapter {
  private static final int[] SLIDES= { R.drawable.img0,
      R.drawable.img1, R.drawable.img2, R.drawable.img3,
      R.drawable.img4, R.drawable.img5, R.drawable.img6,
      R.drawable.img7, R.drawable.img8, R.drawable.img9,
      R.drawable.img10, R.drawable.img11, R.drawable.img12,
      R.drawable.img13, R.drawable.img14, R.drawable.img15,
      R.drawable.img16, R.drawable.img17, R.drawable.img18,
      R.drawable.img19 };
  private static final int[] TITLES= { R.string.title0,
      R.string.title1, R.string.title2, R.string.title3,
      R.string.title4, R.string.title5, R.string.title6,
      R.string.title7, R.string.title8, R.string.title9,
      R.string.title10, R.string.title11, R.string.title12,
      R.string.title13, R.string.title14, R.string.title15,
      R.string.title16, R.string.title17, R.string.title18,
      R.string.title19 };
  private Context ctxt=null;

  SlidesAdapter(Context ctxt) {
    this.ctxt=ctxt;
  }

  @Override
  public Object instantiateItem(ViewGroup container, int position) {
    ImageView page=new ImageView(ctxt);

    page.setImageResource(getPageResource(position));
    container.addView(page,
                      new ViewGroup.LayoutParams(
                                                 ViewGroup.LayoutParams.MATCH_PARENT,
                                                 ViewGroup.LayoutParams.MATCH_PARENT));

    return(page);
  }
  @Override
  public void destroyItem(ViewGroup container, int position,
                          Object object) {
    container.removeView((View)object);
  }

  @Override
  public int getCount() {
    return(SLIDES.length);
  }

  @Override
  public boolean isViewFromObject(View view, Object object) {
    return(view == object);
  }

  @Override
  public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
  }

  int getPageResource(int position) {
    return(SLIDES[position]);
  }
}
```

The data for the SlidesAdapter consists of a pair of static int arrays, one holding the drawable resource IDs, one holding the string resource IDs.

Of note, SlidesAdapter has a getPageResource() method, to return the drawable resource ID for a given page position, which is used by instantiateItem() for populating the position's ImageView.

The PresentationFragment

We also want to be able to show the slide on an external display via a Presentation. As with the preceding sample app, this one uses a PresentationFragment, here named SlidePresentationFragment:

```
package com.commonsware.android.preso.slides;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.commonsware.cwac.preso.PresentationFragment;

public class SlidePresentationFragment extends PresentationFragment {
  private static final String KEY_RESOURCE="r";
  private ImageView slide=null;
  public static SlidePresentationFragment newInstance(Context ctxt,
                                                      Display display,
                                                      int initialResource) {
    SlidePresentationFragment frag=new SlidePresentationFragment();

    frag.setDisplay(ctxt, display);

    Bundle b=new Bundle();

    b.putInt(KEY_RESOURCE, initialResource);
    frag.setArguments(b);

    return(frag);
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    slide=new ImageView(getContext());

    setSlideContent(getArguments().getInt(KEY_RESOURCE));

    return(slide);
  }

  void setSlideContent(int resourceId) {
    slide.setImageResource(resourceId);
  }
}
```

Here, in addition to the sort of logic seen in the preceding sample app, we also need to teach the fragment which image it should be showing at any point in time. We do this in two ways:

1. We pass in an `int` named `initialResource` to the factory method, where `initialResource` represents the image to show when the fragment is first displayed. That value is packaged into the arguments `Bundle`, and `onCreateView()` uses that value.
2. Actually putting the drawable resource into the `ImageView` for this `Presentation` is handled by `setSlideContent()`. This is called by `onCreateView()`, passing in the `initialResource` value.

The Activity

The rest of the business logic for this application can be found in its overall entry point, `MainActivity`.

Setting Up the Pager

onCreate() of MainActivity is mostly focused on setting up the ViewPager:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  setContentView(R.layout.activity_main);

  TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

  pager=(ViewPager)findViewById(R.id.pager);
  adapter=new SlidesAdapter(this);
  pager.setAdapter(adapter);
  tabs.setViewPager(pager);
  tabs.setOnPageChangeListener(this);

  helper=new PresentationHelper(this, this);
}
```

The ViewPager and our SampleAdapter are saved in data members of the activity, for later reference. We also wire in a TabPageIndicator, from the ViewPagerIndicator library, and arrange to get control in our OnPageChangeListener methods when the page changes (whether via the tabs or via a swipe on the ViewPager itself).

onCreate() also hooks up a PresentationHelper, following the recipe used elsewhere in this chapter. And, as PresentationHelper requires, we forward along the onResume() and onPause() events to it:

```
@Override
public void onResume() {
  super.onResume();
  helper.onResume();
}

@Override
public void onPause() {
  helper.onPause();
  super.onPause();
}
```

Setting Up the Presentation

In the showPreso() method, required by the PresentationHelper.Listener interface, we create an instance of SlidePresentationFragment, passing in the resource ID of the current slide, as determined by the ViewPager:

```
@Override
public void showPreso(Display display) {
  int drawable=adapter.getPageResource(pager.getCurrentItem());

  preso=
      SlidePresentationFragment.newInstance(this, display, drawable);
  preso.show(getFragmentManager(), "preso");
}
```

We then show() the PresentationFragment, causing it to appear on the attached Display.

The corresponding clearPreso() method follows the typical recipe of calling dismiss() on the PresentationFragment, if one exists:

```
  @Override
  public void clearPreso(boolean showInline) {
    if (preso != null) {
      preso.dismiss();
      preso=null;
    }
  }
```

Controlling the Presentation

However, the SlidesPresentationFragment now is showing the slide that was current when the Display was discovered or attached. What happens if the user changes the slide, using the ViewPager?

In that case, our OnPageChangeListener onPageSelected() method will be called, and we can update the SlidesPresentationFragment to show the new slide:

```
  @Override
  public void onPageSelected(int position) {
    if (preso != null) {
      preso.setSlideContent(adapter.getPageResource(position));
    }
  }
```

Offering an Action Bar

The activity also sets up the action bar with three items:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/first"
    android:icon="@android:drawable/ic_media_previous"
    android:showAsAction="always"
    android:title="@string/first">
  </item>
  <item
    android:id="@+id/last"
    android:icon="@android:drawable/ic_media_next"
    android:showAsAction="always"
    android:title="@string/last">
  </item>
    <item
    android:id="@+id/present"
    android:checkable="true"
    android:checked="true"
    android:showAsAction="never"
    android:title="@string/show_presentation">
  </item>

</menu>
```

Two, `first` and `last`, simply set the `ViewPager` position to be the first or last slide, respectively. This will also update the `SlidesPresentationFragment`, as `onPageSelected()` is called when we call `setCurrentItem()` on the `ViewPager`.

```
  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    return(super.onCreateOptionsMenu(menu));
  }

  @Override
  public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
      case R.id.present:
        boolean original=item.isChecked();

        item.setChecked(!original);

        if (original) {
          helper.disable();
        }
        else {
          helper.enable();
        }

        break;

      case R.id.first:
        pager.setCurrentItem(0);
        break;

      case R.id.last:
        pager.setCurrentItem(adapter.getCount() - 1);
        break;
    }

    return(super.onOptionsItemSelected(item));
  }
```

The other action bar item, `present`, is a checkable action bar item, initially set to be checked. This item controls what we are showing on the external display:

- If it is checked, we want to show our `Presentation`
- If it is unchecked, we want to revert to default mirroring

The theory here is that, in a presentation, we could switch from showing the slides to showing the audience what the presenter has been seeing all along.

Switching between `Presentation` and default mirroring is a matter of calling `enable()` (to show a `Presentation`) or `disable()` (to revert to mirroring) on the `PresentationHelper`.

Device Support for Presentation

Alas, there is a problem: not all Android 4.2 devices support `Presentation`, even though they support displaying content on external displays. Non-`Presentation` devices simply support classic mirroring.

Generally speaking, it appears that devices that *shipped* with Android 4.2 and higher will support `Presentation`, assuming that they have some sort of external display support (e.g., MHL). Devices that were *upgraded* to Android 4.2 are less likely to support `Presentation`.

Unfortunately, at the present time, there is no known way to detect whether or not `Presentation` will work, let alone any means of filtering on this capability in the Play Store via `<uses-feature>`. With luck, this issue will be addressed in the future.

Presentations from a Service

Since `Presentation` inherits from `Dialog`, it also “inherits” one of the limitations of `Dialog`: you can only show one from an `Activity`. In many cases, that is not a big problem. If you are using the external display as an adjunct to your own app’s use of the primary touchscreen, you would be using an activity anyway. However, it does prevent one from using `Presentation` to, say, implement a video player app that plays on an external display but does not tie up the touchscreen, so the user can use other apps while the video plays.

However, as it turns out, it *is* possible to drive the content of an external display from a background app… just not by using a `Presentation`.

The details of this are a bit tricky, derived from one Stack Overflow answer and another Stack Overflow question.

However, you do not need to deal with all of the details, courtesy of PresentationService.

PresentationService is a class in the CWAC-Presentation library. PresentationService clones some of the logic from Presentation and Dialog, enough to allow you to define a View that will be shown on external display, driven by a Service. PresentationService is an abstract base class for you to extend, where PresentationService handles showing your content on an external display, and you simply manage that content.

The CWAC-Presentation library has a demoService/ directory containing a sample use of PresentationService. The recipe is fairly simple and is outlined in the following sections.

Step #1: Attach the Libraries

The CWAC-Presentation README contains instructions for attaching the libraries to your project, whether via Gradle dependencies, downloading a pair of JARs, or using the source form of the Android library project.

Step #2: Create a Stub PresentationService

As is noted above, PresentationService is an abstract class, so you will need to create your own concrete subclass of it, under whatever name you wish. And, as with any service, you will need a <service> element in the manifest. None of this is especially unusual.

The sample app is a service-based rendition of the Presentation/Slides sample app described earlier in this chapter. It has a SlideshowService that will display the slideshow on an external display from the background, switching slides every five seconds.

Step #3: Return the Theme

One of the abstract methods that you will need to implement is getThemeId(). This should return the value of the style resource that represents the theme that you wish to use for the widgets you are going to show on the external display.

For example, if your project uses the `@style/AppTheme` approach that is code-generated for you, you can simply return `R.style.AppTheme` from `getThemeId()`, as the sample app does:

```
@Override
protected int getThemeId() {
  return(R.style.AppTheme);
}
```

Step #4: Build the View

The other `abstract` method you need to implement is `buildPresoView()`. You are passed a `Context` and a `LayoutInflater`, and your job is to use those to build your UI for the external display, returning the root view. The `LayoutInflater` is already set up to use the theme you provided via `getThemeId()`.

Since this will be called shortly before showing the result on the external display, you can also take this time to initialize other aspects of your presentation. For example, the `SlideshowService` implements `Runnable` and has a `Handler` for the main application thread, initialized in `onCreate()`:

```
private Handler handler=null;

@Override
public void onCreate() {
  handler=new Handler(Looper.getMainLooper());
  super.onCreate();
}
```

`buildPresoView()` not only returns an `ImageView` for the slides, but also calls `run()`, which populates the `ImageView` and calls `postDelayed()` on the `Handler` to schedule `run()` to be called again in five seconds, thereby arranging to update the slide every five seconds:

```
@Override
protected View buildPresoView(Context ctxt, LayoutInflater inflater) {
  iv=new ImageView(ctxt);
  run();

  return(iv);
}

@Override
public void run() {
  iv.setImageResource(SLIDES[iteration % SLIDES.length]);
  iteration+=1;

  handler.postDelayed(this, 5000);
}
```

`onDestroy()` calls `removeCallbacks()` to break the `Handler` `postDelayed()` loop:

```
@Override
public void onDestroy() {
  handler.removeCallbacks(this);

  super.onDestroy();
}
```

Step #5: Start and Stop the Service

Calling `startService()` on your service will then trigger the presentation. Or, more accurately, it will trigger `PresentationService` to work with a `PresentationHelper` to determine when a presentation should be shown. `PresentationService` will then use `buildPresoView()` to populate the external display. Conversely, calling `stopService()` will stop the presentation.

It is up to you to determine what is the trigger for these calls. The sample app simply starts the service immediately when run and stops the service in response to an action bar item click.

While the service is running, you are welcome to use an event bus or other means to control the contents of the presentation, by manipulating the widgets you created in `buildPresoView()`.

Note that it is safe to call `startService()` on the service multiple times, if you do not know whether the service is already running and need to ensure that it is running now.

Hey, What About Chromecast?

In February 2014, Google released a long-awaited SDK to allow anyone to write an app that connects to Chromecast, Google's streaming-media HDMI stick. This Cast SDK also works with other Google Cast-capable devices, like some Android TV models. A natural question coming out of that is whether `Presentation` and `DisplayManager` work with Chromecast.

The answer is: that depends on how you look at the problem.

While Chromecast may physically resemble a wireless display adapter, in truth it is its own device, running a customized mashup of Android and ChromeOS.

Chromecast's strength is in playing streaming media from any source, primarily directly off of the Internet.

The classic approach for the Google Cast SDK is that apps are telling the Chromecast what to stream from, not streaming to the Chromecast itself. As such, the Cast API is distinctly different from that of `Presentation`, and while the two both deal with what the Android device would consider an external display, they are not equivalent solutions.

However:

- A Chromecast can also serve as a Miracast endpoint; if a user sets that up, then your app can use `Presentation` with a Chromecast
- In 2015, the Cast SDK added a `Presentation`-workalike API, one that presumably works with Chromecast without having to go through the Miracast setup

More coverage of Chromecast can be found in the next chapter.

Google Cast and Chromecast

A popular target for MediaRouter, in some countries, is Chromecast, Google's lightweight streaming media player for televisions and other HDMI displays. Originally, Chromecast was a "closed box", with no official support for third-party apps (and active work to block unofficial support). In early 2014, though, Google finally opened up Chromecast to developers.

This chapter covers what it takes to enable an Android app to "cast" content to a Chromecast, possibly as part of a broader external display strategy.

Prerequisites

In addition to the core chapters, you should read the chapter on MediaRouter before reading this chapter.

Here a Cast, There a Cast

You will see two terms used in this chapter and in the online literature regarding all of this: Chromecast and "Google Cast". Despite the similarities in their names, these are fairly distinct items.

What is Chromecast?

Chromecast, as noted earlier in this chapter, is a streaming media receiver, sold by Google under their own brand.

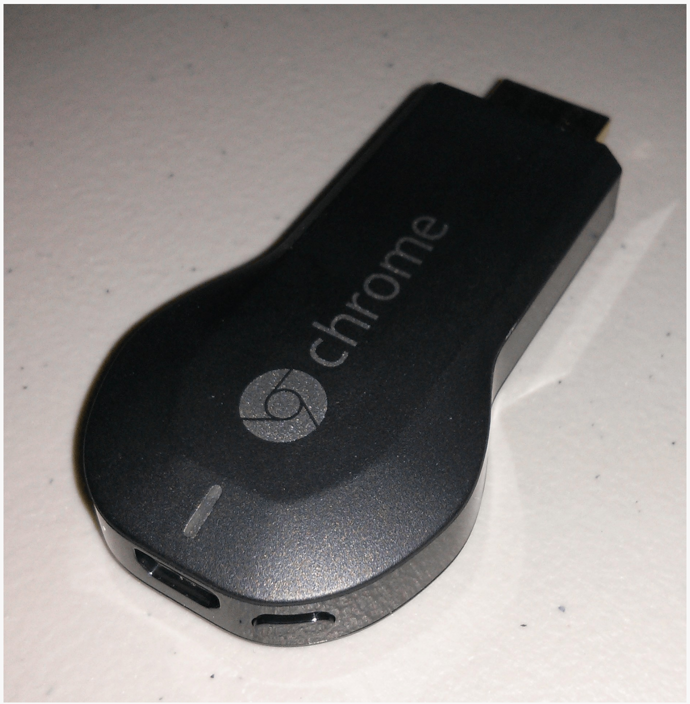

Figure 711: Google Chromecast

It plugs into an HDMI port of a television or similar display, plus uses micro USB for supplying power.

However, rather than other streaming media receivers, that use Bluetooth or IR (infrared) peripherals for controlling the playback, Chromecast appears to use WiFi, designed to be controlled by a smartphone, tablet, or Chrome Web browser.

Chromecast itself runs its own OS, apparently a hybrid of Android and ChromeOS.

What is Google Cast?

Google Cast can be thought of as a control protocol for Google Cast-enabled receivers. Through a Google-supplied SDK (or other means), Google Cast client apps ("senders") can direct a Google Cast-enabled receiver to play, pause, rewind, fast-forward, etc. a stream.

Google Cast could, in theory, be "baked into" displays (such as a television), in addition to being supported by dedicated media receivers like the Chromecast.

Google Cast does assume that, in general, the media receiver runs its own OS and is capable of playing streaming media without ongoing assistance from the Google Cast client. Hence, the client is not "locked into" having to keep feeding content to the Google Cast client, allowing the user to go off and do other things with that client while playback is going on.

Common Chromecast Development Notes

Chromecast goes to sleep if it detects that it is plugged into a television or monitor that is turned off (or perhaps even not accepting input from the HDMI port the Chromecast is using). While it is in this sleep mode, it may not appear as an available route. You may need to keep the display active to allow Chromecast to work properly. A 720p-capable pico projector, such as the Vivitek Qumi series, can be a handy way to have a test display for Chromecast (or for live video media routes) at your development station, without the bulk of another monitor, if you have a handy surface to project upon.

Also, note that a Chromecast "uses Google's DNS regardless of what you have defined locally", according to a Google engineer. That will preclude you from using any local domains on an organization's own DNS server, without some tricky firewall configuration to route Google DNS requests to the in-house DNS server. Similarly, you cannot use machine names as pseudo-domain names, the way you might be able to using a regular Web browser.

Your API Choices

Chromecast offers up remote playback media routes and works with `RemotePlaybackClient`, as is discussed in the chapter on `MediaRouter`. The sample app for `RemotePlaybackClient` was tested on a Chromecast.

If you want greater control than is offered via `RemotePlaybackClient`, though, you can use the Cast SDK. This SDK is part of the Play Services framework, not part of Android itself. It also works solely with Google Cast devices, of which Chromecast is the only known example, whereas other sorts of devices are able to publish remote playback media routes. Hence, using the Cast SDK will tie you to Google Cast — and some of its restrictions, both technical and legal — but will give you greater developer control over the behavior of both the Google Cast device and your app.

This chapter will focus on the Cast SDK. See the chapter on `MediaRouter` for coverage of `RemotePlaybackClient`.

Senders and Receivers

There are three major components to the Google Cast environment:

- The sources of streaming media, usually out on the Internet
- The software on the playback device that plays that streaming media ("receiver")
- The software on the control device (phone, tablet, Chrome Web browser) that directs the receiver about what to play and when ("sender")

The Sender App

The sender app is responsible for allowing the user to choose some media to play, then to control the actual playback (pause, start, stop, rewind, fast-forward, etc.).

The details of how to choose some media will depend heavily on the nature of the sender app. For example, a subscription-based streaming video service, such as Netflix, would allow the user to browse and search eligible content hosted by Netflix itself. Netflix presumably has its own Web service APIs that its own sender app would use for this purpose, and it is up to Netflix to offer a sensible UI for choosing a piece of media to watch.

Passing a reference (e.g., URL) to the receiver, and issuing control commands, will either be handled by `RemotePlaybackClient` (on Android) or via a Google-supplied SDK (for Android, iOS, or Chrome Web apps).

The Receiver

The details of how a receiver is implemented is up to the manufacturer of the Google Cast-enabled device. In the case of Chromecast, it is a version of the Chrome Web browser. In principle, the implementation could be anything; in practice, it is likely that the same basic software stack will be used, courtesy of licensing Google Cast technology from Google for streaming media devices.

Official Google Cast receiver software comes in three flavors: default, styled, and custom.

Default Receiver

The default receiver is what you get by default, as you might have guessed. If you do nothing else, your sender will be communicating with the default receiver. In effect, the default receiver is a specific Chrome Web app, running on the Chrome browser inside of the Chromecast, that is responsible for playback of your chosen media.

Other than providing the URLs to the media, plus requests to pause, start, stop, etc. the playback, you have no control over the default receiver, particularly from a look-and-feel standpoint.

Styled Receiver

A styled receiver is one where you, the developer, supply light branding information that is applied to what otherwise is the default receiver, such as a logo.

Whereas using the default receiver requires no explicit registration with Google, using the styled receiver does require you to register your sender app with Google, at which point you will be able to provide a URL pointing to a CSS file that contains the custom styles.

Custom Receiver

If you would rather replace the default receiver functionality with your own, either to offer more functionality, or to consume media types that may require additional configuration (e.g., DRM), you can create a custom receiver. This, in effect, is a Chrome Web app, where you provide not only CSS, but the HTML and JavaScript as well. This is substantially more complicated, and it requires registration with Google (as with the styled receiver). However, you have far greater control over what appears on the television.

Supported Media Types

The list of supported media types is likely to change over time. At present, Google Cast-enabled devices are supposed to support major media types, such as:

- MP4 and VP8 for video
- MP3, AAC, and Ogg Vorbis for audio
- PNG, JPEG, GIF, BMP, and WEBP for still images (e.g., photos)
- HLS and MPEG-DASH for streaming

Cast SDK Dependencies

Using the Cast SDK to develop for Google Cast devices has a fair number of dependencies… and not just dependencies on particular libraries.

Developer Registration

If you are going to be using the default receiver, *and* you do not need to have debugging access to the device (e.g., to examine JavaScript logs from the Web rendering engine on the Google Cast device), you are welcome to develop your apps independently.

However, if you will use a styled or custom receiver, or you wish to gain debugging access to the device, you will need to register with Google.

This process will involve you agreeing to some terms of service (see below), along with paying a $5 registration fee.

The Terms of Service

The Google Cast SDK has separate Developer Terms of Service from anything else. If you are going to use the Google Cast SDK, you will be expected to agree to these terms as part of the registration processes. You are strongly encouraged to review these terms with qualified legal counsel. Failure to comply with the terms may cause your app (or, more accurately, your styled or custom receivers) to "be de-registered", presumably meaning that it will no longer work.

These terms contain some curious clauses, worth discussing with your attorney, including a requirement to adhere to a massive design checklist, controlling the look-and-feel of your sender and receiver. This includes a specific requirement for the precise icon to be used for initiating communications with the Google Cast receiver. Those agreeing to these terms are also barred from doing things that might allow others to display content on a Google Cast receiver without using the SDK or breaking through any access controls on the Google Cast device (e.g., creating an exploit that roots it).

Device Registration and Development Setup

While registering your device is optional, it may be handy for custom receivers, so that you can debug your custom HTML and JavaScript that is being rendered by the Google Cast device.

First, you should configure your device to publish its serial number to Google when it checks for Google Cast software updates. For the Chromecast, this involves using whatever means you used to configure the Chromecast in the first place for your network (e.g., the Chromecast Android app). There should be an option for "Send this Chromecast's serial number when checking for updates" — in the Chromecast Android app, this will be in the "Share Data" section of the device's settings screen.

Once you have registered as a Cast SDK developer, the Google Cast SDK Developer Console will have an option for you to "Add New Device". You will need the Google Cast device's serial number — in the case of the Chromecast, this is etched on the underside of the device.

Note that it may take some time before your device registration will be complete, as the device will not find out about the registration until it checks for another update, and there does not appear to be a way to trigger this. Hence, you may need to wait a few hours. You will know that you have access once you can successfully connect, via a Web browser, to port 9222 on the IP address of the Google Cast device. For the Chromecast, the easiest way to get that IP address is through your Chromecast configuration tool (e.g., the Chromecast Android app). Note that the Web page may not be much (e.g., "Inspectable WebContents"), but it will not return a 404 or similar error code.

If you wish to use a styled or custom receiver, you will also need to register your application, in the same Cast SDK Console area. This will be covered in a future edition of this book.

The Official Libraries

You will need the Google Play Services SDK, which you may have used already for other portions of the Play Services framework, such as GCM, Maps V2, and so on.

You will also need the same `mediarouter` Android library project covered in the chapter on `MediaRouter`, along with its dependencies (e.g., the `support-v4` library and the `appcompat` library).

The CastCompanionLibrary… Or Not

The Play Services SDK (and its dependencies) is all that you need to write Cast SDK applications. However, Google has also published the Cast Companion Library (CCL), containing a lot of helper code to make it a bit easier for you to write apps that adhere to the design checklist

Developing Google Cast Apps

Coverage of the Cast SDK, including sample apps, will be added to this chapter in a future edition of this book.

The “Ten-Foot UI”

Increasingly, Android devices are being used to drive screens that are somewhat larger than those found on your average phone or tablet:

- Many Android phones and tablets can directly deliver content to TVs, monitors, and projectors via HDMI, MHL, SlimPort, Miracast, and similar technologies
- Android devices can control the behavior of non-Android presentation engines, like Chromecast
- Some Android devices themselves use a TV or other display as their primary screen, from big names (Google and Amazon), mid-range firms (OUYA), and firms you have never heard of (various Android “HDMI sticks” available on eBay, Alibaba, etc.)

Technically, writing for these displays is a bit different than you would do for a phone or tablet. In some cases, such as with Google Cast, writing for these displays is more substantially different.

However, in all cases, the design of the UI needs to be different, owing to different physical and usage characteristics of large screens. This chapter will focus on this so-called “ten-foot UI” and help you understand what sorts of changes will need to be considered.

Prerequisites

Understanding this chapter requires that you have read the chapter on focus management.

The sample of the "leanback" UI is a revised version of a sample app profiled in the chapter on the MediaStore ContentProvider.

What is the "Ten-Foot UI"?

The "ten-foot UI" is not referring to a UI that is 3.048 meters high or 9.87789527 by 10^-17 parsecs wide.

Rather, the distance referred to by the "ten-foot UI" indicates the approximate distance between the viewer and the screen. People usually sit farther from TVs, monitors, and projectors than they do phones or tablets when using them. Partly, that is because the screens are a lot bigger, so they do not need to sit as closely. Partly, that is because often times the screens are being "used" by more than one person (e.g., an audience watching a presentation on a projector), and everybody needs to be able to see the screen.

The expression "ten-foot UI" refers to the design constraints inherent in developing user interfaces to be used across such a distance. Even though the screen may be bigger, the *apparent* screen size (or "visual angle" may be no bigger than phones or tablets, or sometimes even less. That, plus user input differences, technical differences between TVs and other displays, and so on all go into the "ten-foot UI" design guidance that UI experts give us.

Overscan

Television standards have been with us for several decades. Television sets from the dawn of television had significantly lower and more variable quality than today's devices. The delivery of the signal at the outset had significantly lower and more variable quality than today's over-the-air HDTV or cable connections. As a result of these two characteristics, the engineers devising television standards made some decisions that, while necessary at the time, add some complexity to delivering apps to televisions, in the form of overscan.

Simply put, not all televisions show exactly the same picture. Depending on device and signal, a television may show up to 12% less of the picture, as measured horizontally and vertically. Hence, the theoretical ideal screen size (e.g., 720p = 1280 x 720 pixels) may be achieved in some cases, but you may get less (e.g., 1128 x 634 pixels) in other cases.

Android TV and Fire TV ignore overscan, relying upon developers to take it into account. As a result, the reported screen resolution is *not* necessarily available to you. Instead, you need to avoid putting anything important in the outer ~10% of the screen, centering the important stuff within the available space.

So, for example, you might have a background for your game (e.g., a starfield). Make sure that there is nothing essential on the background image that the user must see that is along the outside edge. Then, if part of the background is lost due to overscan, there is no particular problem.

The bigger issue, of course, is standard foreground widgets and containers. Android developers are used to being able to have layouts that work edge-to-edge, with just a minor amount of margin so text, icons, and the like do not run right into the edge of the screen. Now, you need more than a "minor amount" of margin. Google and Amazon recommend a `27dp` margin on the top and bottom sides of your activities, and a `48dp` margin on the left and right sides of your activities.

For activity and fragment layouts that are dedicated for TV presentation, you could elect to put those margins in those layouts, or add them via a theme. However, for activity and fragment layouts that may be used both for a touchscreen device (phone or tablet) and a television, adding the margin on the touchscreen device may be unsuitable.

For that, you could use dimension resources in different resource sets. Define `overscan_horizontal` and `overscan_vertical` to be both `0dp` (or whatever) in `res/values/dimens.xml`. Define them to be `48dp` and `27dp`, respectively, in `res/values-television/dimens.xml`, where `-television` is a resource set qualifier that will be used in Android TV and other TV-based Android devices. Then, you can refer to `@dimen/overscan_horizontal` and `@dimen/overscan_vertical` in activity/fragment layouts, to take overscan into account conditionally.

Navigation

Most televisions, monitors, and projectors are not touchscreens. Users will be changing what is shown either by using some sort of remote control (e.g., Fire TV, Android TV) or by using an app that runs on a touchscreen device (e.g., direct monitor connection, Chromecast).

In the remote control scenarios, in-screen navigation becomes important. Those remote controls usually focus on some sort of D-pad or arrow keys for moving focus and clicking on widgets. This forces users into a sequential-access model (e.g., click “left” three times then “enter” once) rather than the random-access model that touchscreens offer.

The chapter on focus management covers these sorts of concerns. Bear in mind that getting focus management implemented properly in your app not only helps with the “ten-foot UI”, but also can help other sorts of users, such as the visually impaired or motion impaired who cannot readily use touchscreens.

Also note that text input is a significant chore when you try to do it using a remote control. Hence, even to the extent it is possible, try to limit the number of places that users *have* to type into `EditText` widgets and the like in your UI. If possible, offer a way for users to do that sort of thing via a separate app on their phone or tablet, or perhaps through a Web browser that pushes the information to the TV set-top box.

Stylistic Considerations

In addition to structural issues like overscan and focus management, there are some stylistic issues that you will need to take into account when designing your ten-foot UI.

Fonts

With phones and tablets, if the user has some difficulty reading a bit of text, they can usually fix the problem just by moving their hand a bit, to bring the screen closer.

That becomes less likely of a solution as you get into larger screens. People get annoyed if they have to get up off of their sofa to squint and try to read text on a television. In a presentation setting, people may be unable to move into a better viewing position.

To combat this:

- Err on the side of larger fonts, with a medium weight (i.e., not too light or too heavy of strokes that make up the letters)
- Aim to use simpler fonts, particularly sans-serif fonts, as those tend to be more readable at a distance

- Where practical, give the user control over font size within your application, or allow some other sort of "zoom" mechanism, to help see details that they might otherwise be unable to see
- Light text on a dark background tends to be easier to read on televisions, so consider using a theme that supports this (e.g., `Theme.Holo` as opposed to `Theme.Holo.Light`)
- Use fewer words
- Use more line spacing (e.g., via `android:lineSpacingMultiplier` on a `TextView`), so descenders from one line are clearly distinguished from the tops of characters on the next line

Padding and Margins

In addition to adding more line spacing, consider adding more padding and margins to your ten-foot UIs.

Bear in mind that screen density calculations start to go astray as the user moves further away from the screen. We are used to making those calculations based on actual pixels on phones and tablets (a.k.a., "two-foot UI"). The *apparent* size of a television may be no bigger than that of a tablet, once the user's distance from the screen is taken into account. However, screen density has no good way to take that distance into account, other than by effectively hard-coding the density (e.g., Fire TV considering everything to be `-xhdpi`). Hence, particularly for padding and margins, you may need to "finesse" your values a bit on televisions and the like.

In cases where Android is directly talking to the television (e.g., HDMI/MHL from a phone or tablet, Fire TV, Android TV, Android HDMI sticks), you can use `-notouch` qualifiers on resource sets to provide different values for dimension resources.

Colors

Usually, with the ten-foot UI, we treat televisions, monitors, and projectors equally. They do differ in one key area: color management.

Televisions, for historical reasons, tend to have different color responses than do monitors or projectors. As Google puts it:

> TV screens have higher contrast and saturation levels than computer monitors

Even to the extent that those settings could be adjusted, if the television will be used *as a television*, the factory settings may be the proper ones. Beyond that, few television owners think about changing such things.

As a result, you need to be careful with your color choices:

- Pure white (`#FFFFFF`) can cause problems, such as "ghosting", so use a very light gray (e.g., `#F1F1F1`, `#EBEBEB`) instead. Pure black (`#000000`) is not a problem.
- Aim for more muted colors, particularly in the blue/green/violet end of the color spectrum, as opposed to bright red or orange. Warm colors tend to bleed more than cool colors.

Aspect Ratio

Bear in mind that different TVs (or other displays) may have different aspect ratios. While many will be 16:9, also consider 4:3 and 21:9 (also known as 2.35:1).

The Leanback UI

In 2014, Google added the `leanback-v17` library to the Android Support package. This contains code to help you create TV-focused user interfaces. While the intention is for this library to help you create UIs for Android TV, there is nothing strictly tied to the Android TV platform in `leanback-v17`. Your user interfaces can work just fine on other TV environments (e.g., Amazon Fire TV). And they still support touchscreen events, and so they can be used on phones and tablets as well, though perhaps not optimally.

Where to Get Leanback

Android Studio users can add a dependency on the `leanback-v17` artifact from the Android Repository:

```
dependencies {
    compile 'com.nostra13.universalimageloader:universal-image-loader:1.9.3'
    compile 'com.android.support:leanback-v17:21.0.3'
}
```

This particular bit of Gradle configuration comes from the [`Leanback/VideoBrowse`] sample application, which will be the focus of this "leanback" UI section. This project depends not only upon `leanback-v17`, but also upon the [Universal Image Loader]() (UIL), another image-loading library, akin to Picasso.

If you read through [the chapter on `MediaStore`](), this sample app will seem familiar. In the `MediaStore` chapter, we created a sample app that would present a list of videos available on the device in a `ListView`, using UIL for handling the video thumbnails. The `VideoBrowse` "leanback" sample app is the same app, adjusted to use a "leanback" UI instead of a `ListView`.

BrowseFragment

The primary UI element that we get from `leanback-v17` is `BrowseFragment`. `BrowseFragment` is a fragment designed to allow browsing of a roster of content through a two-dimensional scrolling interface. There is a list of "headers" (e.g., categories of videos), and within each header is a horizontal scrolling list of items within that header.

This sort of UI pattern is fairly commonplace in TV-centric apps, as it works well with TV-style remotes:

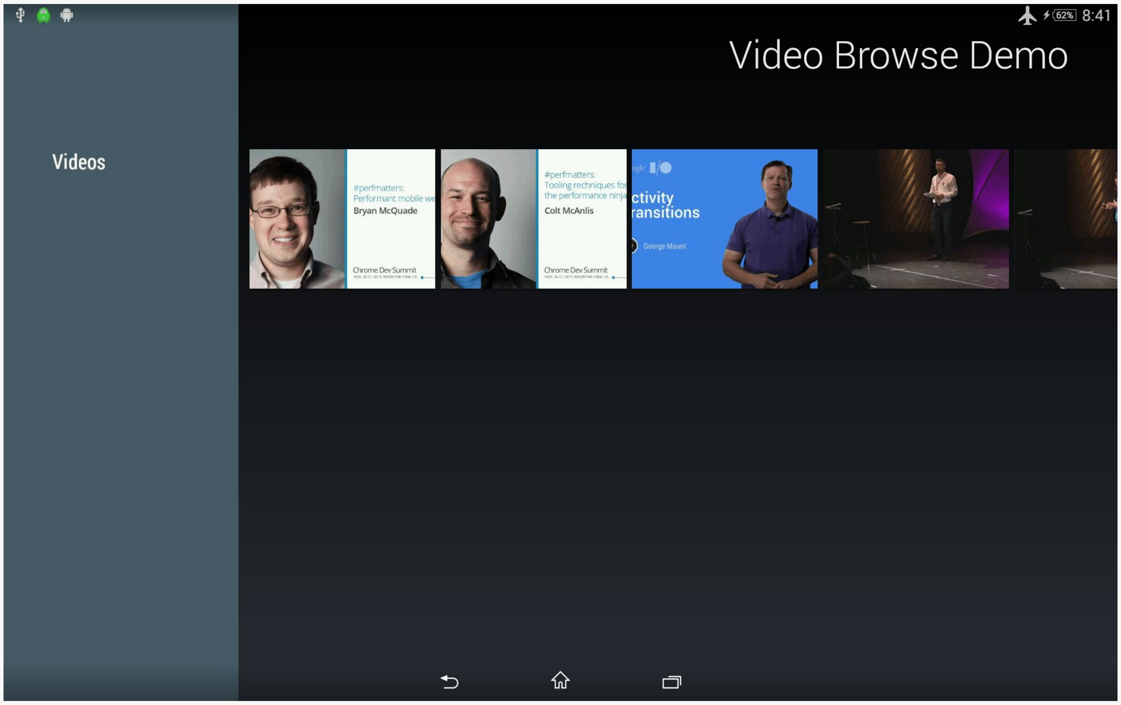

Figure 712: VideoBrowse Sample App, As Initially Launched

The VideoBrowse sample application consists of one activity, hosting a BrowseFragment, that will display the roster of available videos on the device. Clicking on an individual video will bring up the device's default video player app, just as the VideoList sample did in the chapter on the MediaStore.

Theme and Activity

There is very little specifically required of an activity that hosts a BrowseFragment, particularly on the Java side. So long as the activity gets the BrowseFragment onto the screen, the key work is done.

In the case of our MainActivity, it uses a res/layout/main.xml file, pointing to our VideosFragment, which is a subclass of BrowseFragment:

```xml
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/videos"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:name="com.commonsware.android.video.browse.VideosFragment"
/>
```

The Java code simply loads up the layout containing that static fragment, plus has an onVideoSelected() method that will be called if the user clicks on a video:

```java
package com.commonsware.android.video.browse;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import java.io.File;

public class MainActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
  }

  public void onVideoSelected(String uri, String mimeType) {
    Uri video=Uri.fromFile(new File(uri));
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(video, mimeType);
    startActivity(i);
  }
}
```

However, there are two other requirements of the activity, in terms of what goes in the manifest:

- The activity needs to use a theme that is, or inherits from, `Theme.Leanback`
- To show up as the "launcher activity" for an Android TV device, the activity needs to have an `<action>` of `MAIN` and a `<category>` of `LEANBACK_LAUNCHER`:

```
  <application
    android:allowBackup="false"
    android:hardwareAccelerated="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="MainActivity"
      android:label="@string/app_name"

android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
      android:screenOrientation="sensorLandscape"
      android:theme="@style/Theme.Leanback">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
        <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
```

In our case, we match on either the `LAUNCHER` or the `LEANBACK_LAUNCHER` category, as this particular activity can work on either form factor family (touchscreens or TVs). However, other apps might have separate "launcher activity" implementations for phones/tablets versus televisions, and so having a separate `LEANBACK_LAUNCHER` category allows us to indicate which activities serve which role.

This activity also sets its `screenOrientation` to `sensorLandscape`, indicating that it will always present itself in landscape mode, no matter how the device is held. It also uses a `configChanges` attribute to opt out of configuration changes due to orientation changes, as the UI is not changing in those cases.

Loading the Videos

`VideosFragment` is responsible for showing the roster of available videos on the device, using a `BrowseFragment` two-dimensional structure. This means, though, that `VideosFragment` needs to be able to find out what videos are available. As with the `VideoList` sample in the MediaStore chapter, `VideosFragment` will query the `MediaStore` `ContentProvider` to find out about the videos, by means of a `CursorLoader`.

In onViewCreated(), VideosFragment calls initLoader() to start loading the videos, in addition to indicating that the fragment itself will serve as the controller handling clicks on individual videos, via the setOnItemViewClickedListener() interface:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  getLoaderManager().initLoader(0, null, this);
  setOnItemViewClickedListener(this);
}
```

For those calls to work, VideosFragment needs to implement the LoaderManager.LoaderCallbacks<Cursor> interface (for initLoader()) and the OnItemViewClickedListener (for setOnItemViewClickedListener()).

The initLoader() call triggers a call to our onCreateLoader() method, which queries the MediaStore roster of videos for all videos, ordered by title:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
  return(new CursorLoader(
                          getActivity(),
                          MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                          null, null, null,
                          MediaStore.Video.Media.TITLE));
}
```

That, in turn, will eventually trigger a call to onLoadFinished():

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
  mapCursorToModels(c);

  setHeadersState(BrowseFragment.HEADERS_ENABLED);
  setTitle(getString(R.string.app_name));

  ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
  ArrayObjectAdapter listRowAdapter=
      new ArrayObjectAdapter(new VideoPresenter(getActivity()));

  for (Video v : videos) {
    listRowAdapter.add(v);
  }

  HeaderItem header=new HeaderItem(0, "Videos", null);

  rows.add(new ListRow(header, listRowAdapter));
  setAdapter(rows);
}
```

We will get to much of the code in onLoadFinished() a bit later in this chapter. However, the first thing that onLoadFinished() does is call a mapCursorToModels() method. This method will be responsible for taking the data from the Cursor we get back from MediaStore and using it to populate some model objects that will drive what the BrowseFragment displays to the user. BrowseFragment's API is not especially well-suited for working with a Cursor directly; it is simpler to have a separate collection of model objects representing the results of the database query.

In our case, the model object will be a Video:

```
package com.commonsware.android.video.browse;

class Video {
  int id;
  String uri;
  String mimeType;
  String title;

  Video(int id, String uri, String mimeType, String title) {
    this.id=id;
    this.uri=uri;
    this.mimeType=mimeType;
    this.title=title;
  }

  @Override
  public String toString() {
    return(title);
  }
}
```

There are four pieces of data we need to track for the video:

- Its unique id, so we can get a thumbnail of the video later on
- Its Uri (here, held in a string representation), to be used to play back the video
- Its MIME type, also to be used to play back the video
- Its title, which will be used along with its thumbnail when rendering the video as part of the BrowseFragment roster of content

VideosFragment holds onto a collection of these Video objects in a data member named videos:

```
  private ArrayList<Video> videos=new ArrayList<Video>();
```

mapCursorToModels() iterates over the Cursor rows and creates a Video object for each row, adding the Video to the videos, and closing the Cursor when done:

```
private void mapCursorToModels(Cursor c) {
  videos.clear();

  int idColumn=c.getColumnIndex(MediaStore.Video.Media._ID);
  int uriColumn=c.getColumnIndex(MediaStore.Video.Media.DATA);
  int mimeTypeColumn=
      c.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
  int titleColumn=
      c.getColumnIndex(MediaStore.Video.Media.TITLE);

  for (c.moveToFirst(); !c.isAfterLast(); c.moveToNext()) {
    videos.add(new Video(c.getInt(idColumn),
                         c.getString(uriColumn),
                         c.getString(mimeTypeColumn),
                         c.getString(titleColumn)));
  }

  c.close();
}
```

Headers and Contents

So, let’s look at the full `onLoadFinished()` method, called when we have our `Cursor` of videos:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
  mapCursorToModels(c);

  setHeadersState(BrowseFragment.HEADERS_ENABLED);
  setTitle(getString(R.string.app_name));

  ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
  ArrayObjectAdapter listRowAdapter=
      new ArrayObjectAdapter(new VideoPresenter(getActivity()));

  for (Video v : videos) {
    listRowAdapter.add(v);
  }

  HeaderItem header=new HeaderItem(0, "Videos", null);

  rows.add(new ListRow(header, listRowAdapter));
  setAdapter(rows);
}
```

As mentioned, the first thing that we do is map the `Cursor` contents to `Video` objects.

We then make two general changes to the look of the `BrowseFragment`:

- We enable the headers. In truth, that would not make sense for this particular application, as we only have one header. However, we are enabling the headers to show what that looks like, as many uses of BrowseFragment will need the full two-dimensional browsing experience.

- We set the title to be the app_name string resource. This title goes in the upper-right corner and is used to remind the user of what app they are in, much like the title in an action bar would on a phone or tablet.

We then build up the two-dimensional data model and rendering rules for the browsing experience. This involves creating instances of an ObjectAdapter base class, supplied by leanback-v17. ObjectAdapter fills a role reminiscent of Adapter with AdapterView, insofar as it organizes model data and helps with the rendering. However, whereas Adapter does that all itself, ObjectAdapter splits the roles out: it handles the model data and delegates to Presenter implementations for rendering individual items from the model data.

In the two-dimensional browsing model, we need an ObjectAdapter that represents our rows, where each row has a header and a nested ObjectAdapter for the items to appear in that row.

Just as ArrayAdapter is the easiest Adapter class to use, ArrayObjectAdapter is the easiest ObjectAdapter to use. ArrayObjectAdapter adapts arrays of objects, where in this case, "array" really means ArrayList.

Unlike ArrayAdapter, where we primarily build up our array and hand it to the adapter, ArrayObjectAdapter has us populate the "array" via methods like add() on the ArrayObjectAdapter.

So, after calling setHeadersState() and setTitle() as described above, we:

- Create an ArrayObjectAdapter, named rows, that uses the ListRowPresenter supplied by leanback-v17 to render the row
- Create another ArrayObjectAdapter, named listRowAdapter, that uses a custom VideoPresenter that we will examine later in this chapter
- Iterate over the Video roster and add each to the listRowAdapter
- Create an instance of a HeaderItem, supplied by leanback-v17, that represents the header entry itself, with a title for that header
- Create an instance of a ListRow, supplied by leanback-v17, that wraps around the HeaderItem and the listRowAdapter for the items to show in that row
- Put the ListRow in the rows ArrayObjectAdapter, and pass rows to setAdapter() to tell the BrowseFragment what to display

A more complex app might have several ListRow objects in rows, one per header. For example, you might group videos by some sort of categorization scheme, where each HeaderItem names the category and the ListRow also contains the videos specific to that category.

Of the classes cited here, all are stock implementations from leanback-v17, with the exception of VideoPresenter, which is responsible for rendering a Video as an item in the horizontal list of videos.

Presenting the Presenters

A Presenter, in the leanback-v17 system, is an object responsible for converting some model object (e.g., a Video) into a visual representation that will be used for an ObjectAdapter.

The Presenter abstract class enforces a "view holder" approach. A view holder is simply a data structure holding onto a basket of widgets. The idea is that the view holder represents all the widgets for a particular instance of the Presenter. So, we now have two levels of indirection over the Adapter approach used by ListView and kin: not only does ObjectAdapter not do the rendering, but Presenter alone does not do the rendering, but instead involves a view holder.

As a result, a Presenter implementation will tend to be artificially complex.

First, let's look at the view holder, implemented as a static class inside VideoPresenter, named Holder, that extends the stock Presenter.ViewHolder class:

```
static class Holder extends Presenter.ViewHolder {
  private final ImageLoader imageLoader;
  private final ImageCardView cardView;
  private final ImageSize targetSize;

  public Holder(View view, ImageLoader imageLoader) {
    super(view);

    cardView=(ImageCardView)view;
    this.imageLoader=imageLoader;

    Resources res=view.getContext().getResources();

    targetSize=
        new ImageSize((int)res.getDimension(R.dimen.card_width),
                      (int)res.getDimension(R.dimen.card_height));
  }

  protected void updateCardViewImage(String path) {
    DisplayImageOptions opts=new DisplayImageOptions.Builder()
```

```
          .showImageOnLoading(R.drawable.ic_media_video_poster)
          .build();

      imageLoader.loadImage(path, targetSize, opts,
                            new SimpleImageLoadingListener() {
        @Override
        public void onLoadingComplete(String uri, View v, Bitmap bmp) {
          Drawable bmpDrawable=
              new BitmapDrawable(cardView.getContext().getResources(),
                                 bmp);

          cardView.setMainImage(bmpDrawable);
        }
      });
    }
  }
```

The Presenter will set up the UI, in the form of an ImageCardView – another stock class provided by leanback-v17 that is an ImageView with an associated caption. As we will want to pour video thumbnails into the ImageView, this sample app uses the Universal Image Loader (UIL), the same way the VideoList sample does. Here, the ImageLoader instance is created by the Presenter, to be shared among its Holder instances, and we pass in the ImageLoader to the Holder and, um, hold it in a data member.

We also determine how big the thumbnail should be, creating an ImageSize object for UIL's use in eventually resizing the thumbnail bitmap. That ImageSize is based on a pair of dimension resources, card_width and card_height:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="card_width">400dp</dimen>
  <dimen name="card_height">300dp</dimen>
</resources>
```

The updateCardViewImage() will be called when we are ready to use this ViewHolder to present the contents of some particular Video. We receive the Uri to the video (in a String representation, as that is what UIL will use). We set up a UIL DisplayImageOptions object to indicate that we want to show a placeholder image while the thumbnail is loading.

Then, since UIL has no knowledge of how to work with an ImageCardView from leanback-v17, we have to use a different version of loadImage(), one that takes:

- the path to the video (for which UIL knows how to retrieve thumbnails),
- the desired thumbnail size,
- the DisplayImageOptions, and

- a SimpleImageLoadingListener that takes the Bitmap retrieved by UIL, wraps it in a BitmapDrawable, and pops that into the ImageCardView

Now, given the Holder, we can set up the rest of VideoPresenter, starting with its constructor:

```
VideoPresenter(Context ctxt) {
  super();

  this.ctxt=ctxt;

  ImageLoaderConfiguration ilConfig=
      new ImageLoaderConfiguration.Builder(ctxt).build();

  imageLoader=ImageLoader.getInstance();
  imageLoader.init(ilConfig);
}
```

Here, mostly, we are setting up the ImageLoader from UIL, using the same basic recipe as was used in the VideoList sample app.

At the point in time that the VideoPresenter needs to create a view holder to use for rendering an item, onCreateViewHolder() will be called:

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
  ImageCardView cardView=new ImageCardView(ctxt);

  cardView.setFocusable(true);
  cardView.setFocusableInTouchMode(true);

  return(new Holder(cardView, imageLoader));
}
```

Here, we set up an ImageCardView, marking it as focusable both for the D-pad and for touchscreens, and wrap that in our custom Holder.

At the point in time when we are ready to show a Video using the widgets managed by the Holder, onBindViewHolder() is called:

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
                             Object item) {
  Video video=(Video)item;
  Holder h=(Holder)viewHolder;
  Resources res=ctxt.getResources();

  h.cardView.setTitleText(video.toString());
  h.cardView.setMainImageDimensions((int)res.getDimension(R.dimen.card_width),
                                    (int)res.getDimension(R.dimen.card_height));
```

```
    Uri thumbnailUri=
        ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            video.id);

    h.updateCardViewImage(thumbnailUri.toString());
  }
```

We are passed in a generic `Object` that is the model data from our `ObjectAdapter` — in this case, it will be a `Video`, as we are using `VideoPresenter` with an `ArrayObjectAdapter` that holds the `Video` instances. We update the `ImageCardView` caption based on the title of the `Video`, then set the size of the `ImageView` based upon the same dimension resources as we used with UIL's `ImageSize`. We construct a `Uri` pointing to the video as known to `MediaStore` (given the video's id), and pass the `String` representation of that into the `Holder`, which will handle the UIL work.

There is one other abstract method that we need to override to satisfy `Presenter`: `onUnbindViewHolder()`:

```
  @Override
  public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
  }
```

`onUnbindViewHolder()` can often be skipped. However, if you have memory-intensive stuff in the view holder — like the bitmap in an `ImageView` — this is a fine time to take steps to release that memory. In our case, we `null` out the image in the `ImageCardView`. Ideally, we would somehow work with UIL to arrange to recycle this `Bitmap` object, since all of our `Bitmap` objects should be the same size.

Handling Clicks

`BrowseFragment` automatically handles a lot of input events, such as:

- arrow key events in the list of headers, to move a selection bar up and down the list
- click events on a header, to allow navigation into the row of items for that header
- arrow key events on an item, to navigate to the next or previous item
- BACK button events on an item, to return to the list of headers

It also captures the click event on an item and routes that to the `onItemClicked()` method of the `BrowseFragment`, which we override in `VideosFragment`:

```
@Override
public void onItemClicked(Presenter.ViewHolder viewHolder,
                          Object o,
                          RowPresenter.ViewHolder rowViewHolder,
                          Row row) {
  Video video=(Video)o;
  ((MainActivity)getActivity()).onVideoSelected(video.uri,
                                                video.mimeType);
}
```

The `Object` passed as the second parameter to `onItemClicked()` is the `Object` in our `ObjectAdapter` for the clicked-upon item. In our case, the `ObjectAdapter` is our `ArrayObjectAdapter` wrapped around our `Video` objects, and so the `Object` passed into `onItemClicked()` is a `Video`. Given that, we can call out to the hosting activity and its `onVideoSelected()` to go play back the selected video.

The Results

Launching the app shows our list of headers (with just the one header), thumbnails of videos in that header, and the "Video Browse Demo" title:

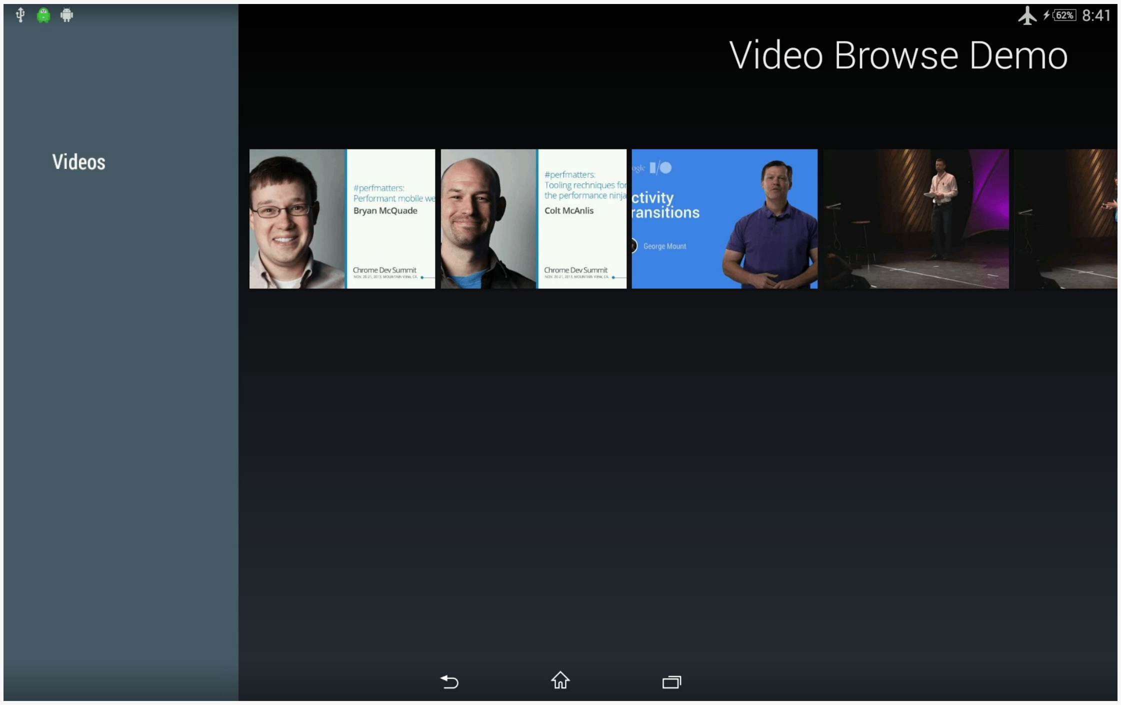

Figure 713: VideoBrowse Sample App, As Initially Launched

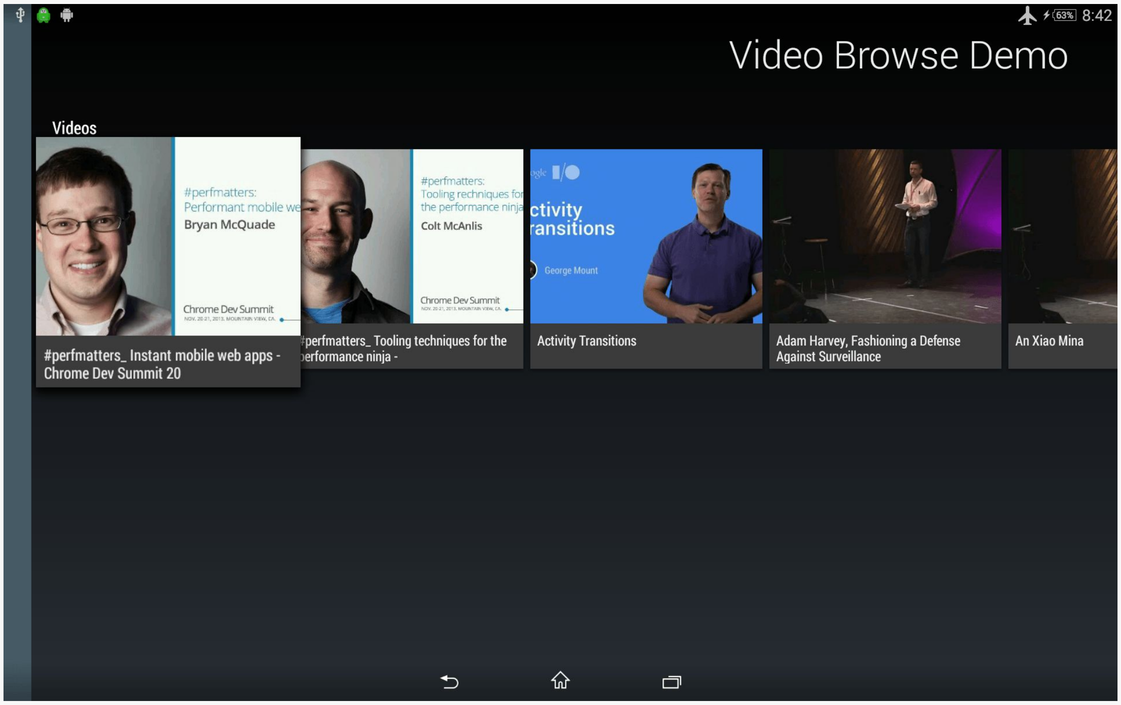
Selecting a video slides the headers out of the way and shows the full card for the video, including the video's title:



8:42

Activity Transitions
Adam Harvey, Fashioning a Defense Against Surveillance
An Xiao Mina

Figure 714: VideoBrowse Sample App, With First Video Selected

Clicking on the selected video brings up the default video player for the device.

Note that this UI is not tied strictly to TV-style displays. For example, the screenshots shown in this section came from an Android tablet, as you can tell by the status bar and navigation bar. The `BrowseFragment` UI is not completely out of place on a tablet, and it works with touch events as well as the key events that would be emitted by a TV-style remote control. On a phone, the `BrowseFragment` UI gets a bit cramped, particularly in portrait, though it still works.

Testing Your Theories

Ideally, you test your ten-foot UI in a ten-foot experience, using something connected to a television.

This does not have to be expensive:

- If you have a phone or tablet that can connect to a TV via HDMI, MHL, or Miracast, at most you might need a cable or a Miracast adapter
- Android "HDMI sticks" or other Android set-top boxes can be found on eBay, Alibaba, or elsewhere
- Chromecast and the Fire TV Stick are available in some markets fairly inexpensively

Any of those will cost $10-75. At the $100 price point, you can start looking at the Fire TV or Nexus Player as well.

If you need to develop using more traditional hardware (phone or a tablet) or an emulator, the big thing will be to make sure that you are estimating the screen size properly. For example, a 10" tablet, held fully at arm's length, will have the same visual angle as a modest television (~26") at a comfortable seating distance. While this will not help with color saturation, using remote controls, or other aspects of the ten-foot UI, you can at least get a sense of whether your text and UI controls will be large enough to be usable.

Putting the TVs All Together: Decktastic

This book profiles many ways of getting content to a TV:

- By means of `Presentation` and related classes, for touchscreen-enabled devices that also happen to presently have a connection to an external display
- By means of `RemotePlaybackClient`, for use with devices like the Chromecast
- By means of directly displaying output on a TV, for devices where the TV is the primary display (e.g., Android TV devices, Amazon's Fire TV and Fire TV Stick)

It is entirely possible to create one app that can support all of these modes from one code base, though you are constrained by the most limited option. In this case, `RemotePlaybackClient` is the most limited option, as its API is designed to tell some external device to play some media, whereas the other options can support comparatively arbitrary user interfaces rendered through normal Android widgets.

In this chapter, we will review the `Presentation/Decktastic` sample application. This app is designed to give the user a roster of slide-based presentations to choose from, then deliver one of those presentations. The presentation will appear on the external display (e.g., TV or projector), while the presenter will be able to control the presentation either from a touchscreen-equipped Android device or a remote control.

Prerequisites

You should read the following chapters before this one:

- Supporting External Displays
- Google Cast and ChromeCast
- The “10 Foot UI”

Reading up on specific hardware, like the Amazon Fire TV, is a good idea but not as critical.

Introducing Decktastic

Before we get into discussing the implementation of Decktastic, we should first review what the app looks like and how it functions.

Launcher UI

If you were to set up Decktastic on some test device and run it, the first thing that you would see is a media browsing UI built from the `leanback-v17` support library, showing you a roster of the available presentations to choose from:

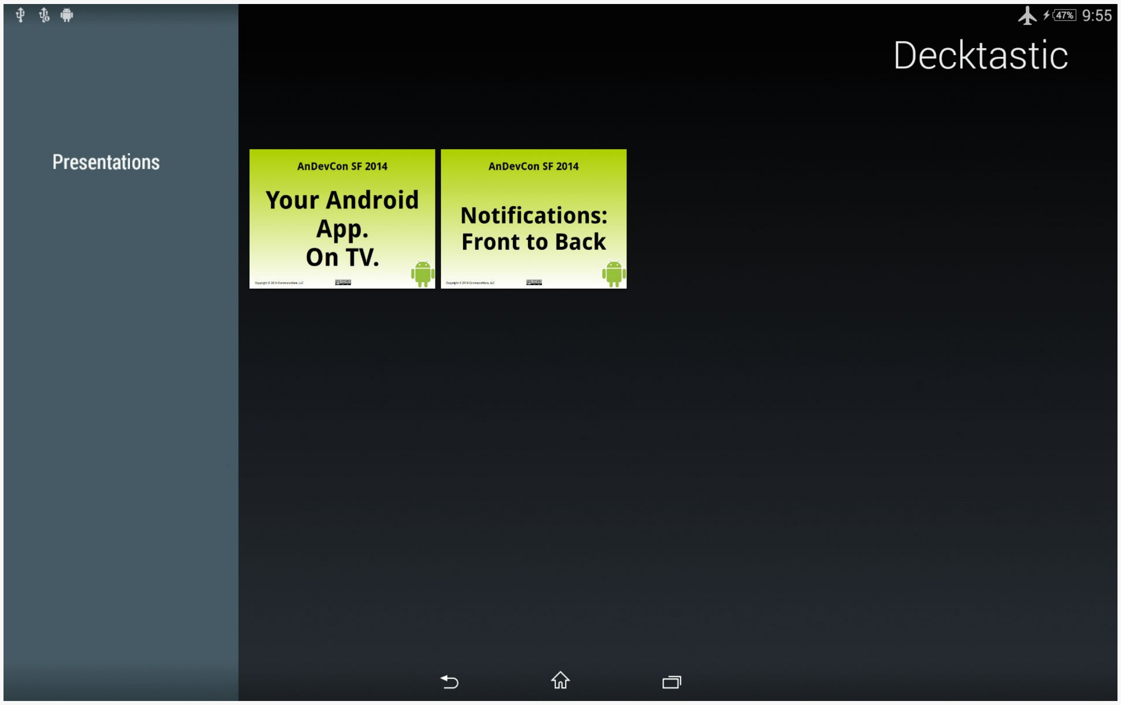

Figure 715: Decktastic Media Browser

This UI works fine on TVs and on tablets. On phones… it gets a bit cramped.

Tapping on a presentation selects it:

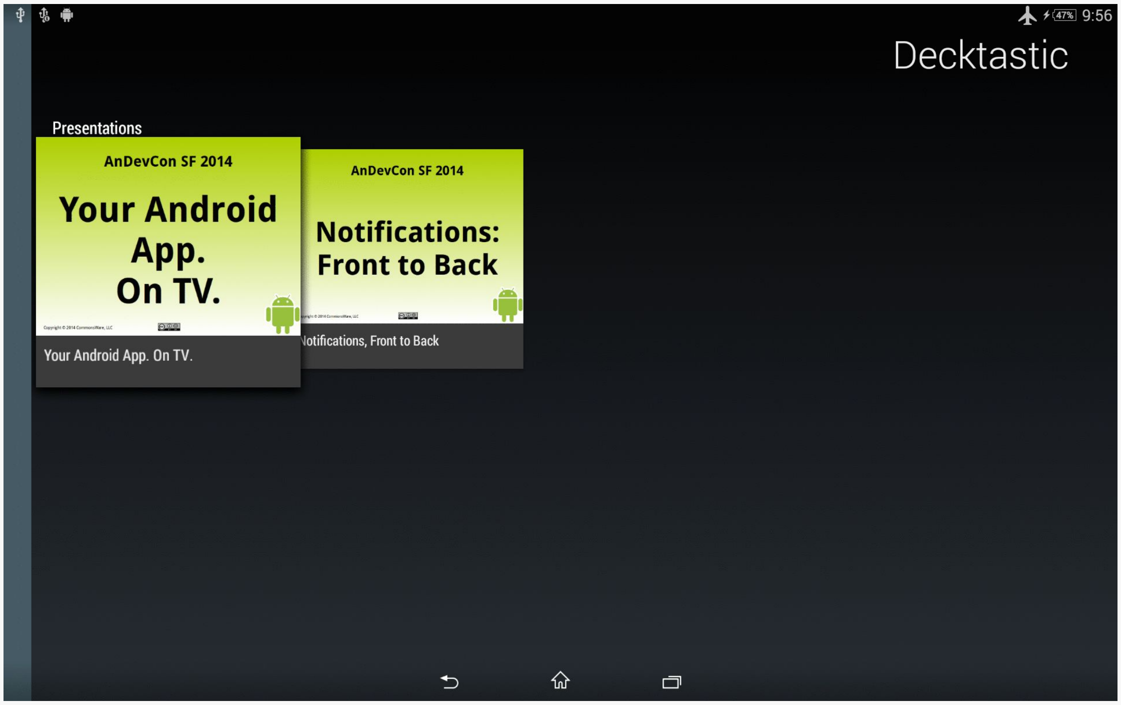

Figure 716: Decktastic Media Browser, With Selected Presentation

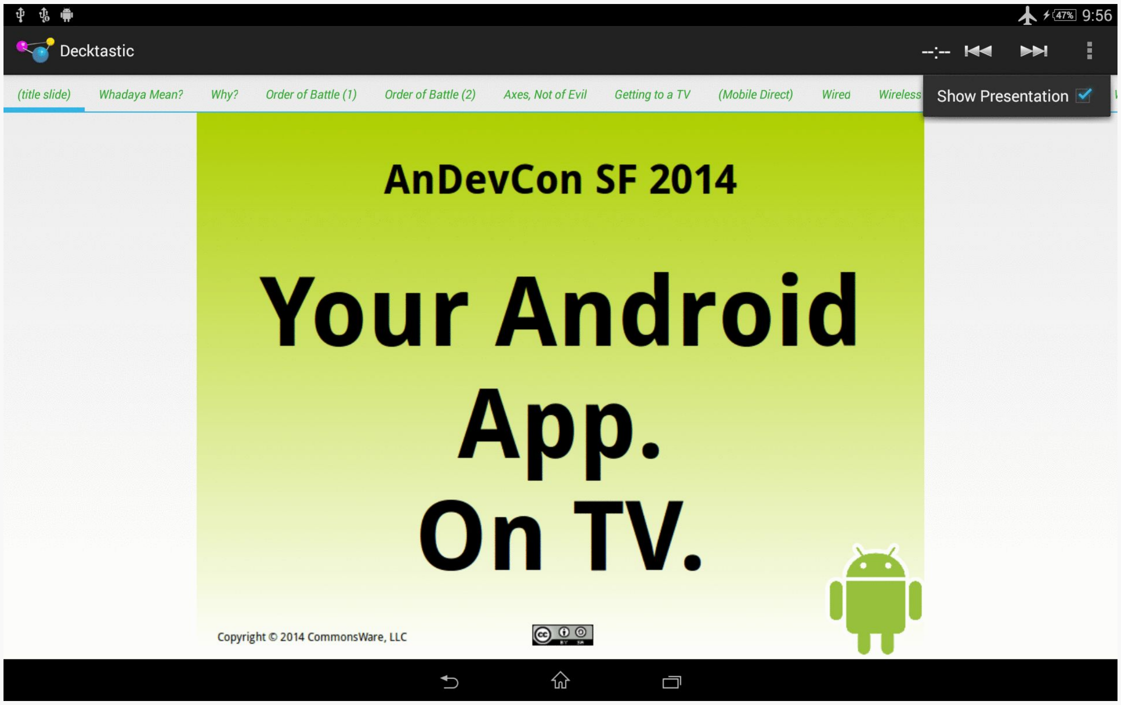
Presentation UI

Tapping on the presentation again opens it up into a `ViewPager`-based UI for the presenter:



Show Presentation ☑

AnDevCon SF 2014

Your Android App. On TV.

Copyright © 2014 CommonsWare, LLC

Figure 717: Decktastic Main UI, Showing Presentation and Open Overflow

However, who sees what depends a bit upon the available hardware:

- If you are running this standalone on a phone or tablet, you will see the `ViewPager`-based UI
- If you are running this on a phone or tablet with a connection to an external display, *you* will see the `ViewPager`-based UI, but the *audience* (those looking at the external display) will, by default, just see the slides
- If you are running this on a phone or tablet with a connection to a Chromecast or similar remote playback device, we get the same results as with the external display (you see the full UI, the audience sees the slides)
- If you are running this on an Android TV, Fire TV, or similar device, both you and the audience only see the slides

To move through the slides, you can:

- Swipe the `ViewPager`
- Use the `ViewPager` tabs
- Use right or down keys to move forward, or left or up keys to move backward, whether on a QWERTY keyboard (e.g., Bluetooth) or via the D-

pad on some form of remote (for TV-centric scenarios, like Android TV or Fire TV)

Trying Decktastic Yourself

Most of the sample applications in this book stand alone, so all you need to do is run them. Decktastic requires presentations, which means it requires a bit of setup.

If you want to see Decktastic work, you should:

- Run Decktastic once (e.g., from Android Studio). This will show that there are no available presentations. Press BACK to destroy the launcher activity.
- Download this ZIP archive containing a pair of Decktastic-compatible presentations.
- UnZIP the archive, and copy the contents (not the ZIP file itself) into `Android/data/com.commonsware.android.preso.decktastic/files` on your Android device or emulator's external storage.
- Run Decktastic again. This should give you one full presentation ("Your Android App. On TV" from the 2014 AnDevCon San Francisco conference) and one stub presentation (enough to get you a second entry in the list of presentations, but not the full slide set)

Implementing Decktastic

Decktastic is a pair of activities that "stand upon the shoulders of giants", in the form of using eight third-party libraries that provide a lot of the utility code.

The Gradle Dependencies

This project is designed to be built by Android Studio, and therefore it declares all of its dependencies in `build.gradle`. The file structure is suitable for Eclipse, but Eclipse developers would need to attach all of the appropriate dependencies manually.

The project's `build.gradle` file specifies a fair number of dependencies:

```
repositories {
    maven {
      url "http://dl.bintray.com/populov/maven"
    }
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
    mavenCentral()
}

dependencies {
    compile 'com.viewpagerindicator:library:2.4.1@aar'
    compile 'com.commonsware.cwac:presentation:0.4.+'
    compile 'com.android.support:support-v13:21.0.3'
    compile 'com.google.code.gson:gson:2.3'
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.commonsware.cwac:mediarouter:0.2.+'
    compile 'com.android.support:leanback-v17:21.0.3'
    compile 'com.squareup.picasso:picasso:2.4.0'
}
```

The project uses:

- Two CWAC libraries, `cwac-presentation` for `PresentationHelper` and `cwac-mediarouter` for the cross-port of the `MediaRouteActionProvider` to the native action bar
- `support-v13`, to pull in `ViewPager` and related classes
- The ViewPagerIndicator library
- Google's Gson
- greenrobot's EventBus
- Google's `leanback-v17` library, for "ten-foot UI" elements used in our launcher activity
- Square's Picasso, for asynchronously loading images

NOTE: `cwac-mediarouter` has been discontinued, as it is no longer practical to maintain a cross-port of the `mediarouter-v7` library.

The Presentation Format

A Decktastic presentation consists of a JSON file and a series of image files. The image files are the slides themselves, perhaps exported from a traditional presentation package like LibreOffice Impress. The JSON file spells out what the image files are and their order of appearance.

For example, here is a JSON file from the stub presentation included in the aforementioned ZIP archive:

```
{
    "title": "Notifications, Front to Back",
    "duration": 70,
    "baseURL": "http://misc.commonsware.com/andevcon2014/preso2/",
    "slides": [
        {
            "title": "(title slide)",
            "image": "img0.png"
        },
        {
            "title": "Order of Battle",
            "image": "img1.png"
        }
    ]
}
```

The `title` is used on the initial "leanback" activity as part of displaying the available presentations.

The `duration` is how long the presentation should run, in minutes. This will be used for a countdown timer to help the presenter know how much time remains in the presentation.

The `baseURL` is a URL to a directory on a Web server somewhere that contains the same slide images as are available locally. This is needed to support `RemotePlaybackClient`, as Chromecast and similar devices need to be able to download their content over the network. We do not have an easy way to deliver that content from the phone or tablet that runs Decktastic and so we need a network-hosted copy of the slides as well. If you were willing to dispense with Chromecast support, you would not need this `baseURL` property.

The `slides` array contains JSON objects, each of which provides the title for a slide and the image associated with that slide. The title will be used for the `ViewPager` tabs, so the presenter knows the upcoming slides and can rapidly switch to a specific slide. The images, of course, are what the presenter and the audience see. Of particular importance is the first slide in the array, as this will be used as the "title slide", shown on the initial "leanback" activity.

The Model Classes

Given that JSON, we need a model class that will represent it, caching the parsed JSON so that we can use that information to render the presentation. We also need a model class that represents the collection of parsed presentations, so that we have the information necessary to render the "leanback" activity that allows the user to find the presentation to display.

There are two model classes in the book that handle this: `PresoContents` and `PresoRoster`.

PresoContents

`PresoContents` represents the parsed JSON, along with a few other bits of information about the presentation:

```
package com.commonsware.android.preso.decktastic;

import java.io.File;
import java.util.List;

public class PresoContents {
  String title;
  List<Slide> slides;
  int duration;
  String baseURL;
  File baseDir;
  int id=-1;

  static class Slide {
    String image;
    String title;
  }

  @Override
  public String toString() {
    return(title);
  }

  File getSlideImage(int position) {
    return(new File(baseDir, slides.get(position).image));
  }

  String getSlideTitle(int position) {
    return(slides.get(position).title);
  }

  String getSlideURL(int position) {
    return(baseURL+slides.get(position).image);
  }
}
```

The `title`, `slides`, `duration`, and `baseURL` fields come straight from the JSON. The `baseDir` field represents the directory in which the presentation was loaded; all images will be assumed to be relative to this directory. Finally, each presentation is given an `id`, so we can distinguish one presentation from another in our collection of presentations.

`PresoContents` also has getter methods to retrieve the local image file (`getSlideImage()`), title (`getSlideTitle()`), and remote image URL (`getSlideURL()`) for a slide given its `position` in the array of slides.

PresoRoster

`PresoRoster` is a singleton collection of the available presentations. It also contains the model logic for loading the collection of presentations and parsing the JSON to create an individual `PresoContents` object for a single presentation:

```
package com.commonsware.android.preso.decktastic;

import android.util.Log;
import com.google.gson.Gson;
import java.io.BufferedReader;
import java.io.File;
import java.io.FileInputStream;
import java.io.FilenameFilter;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.ArrayList;
import java.util.List;

class PresoRoster {
  private static final PresoRoster INSTANCE=new PresoRoster();
  private List<PresoContents> presos=new ArrayList<PresoContents>();

  static PresoRoster getInstance() {
    return(INSTANCE);
  }

  private PresoRoster() {}

  int getPresoCount() {
    return(presos.size());
  }

  PresoContents getPreso(int position) {
    return(presos.get(position));
  }

  PresoContents getPresoById(int id) {
    return(getPreso(id));
  }

  void load(File base) {
    base.mkdirs();

    String[] presoDirs=base.list(new FilenameFilter() {
      @Override
      public boolean accept(File orig, String name) {
        return(new File(orig, name).isDirectory());
      }
    });

    Gson gson=new Gson();

    for (String presoDir : presoDirs) {
      PresoContents c=loadPreso(gson, new File(base, presoDir));
      if (c!=null) {
        c.id=presos.size();
        presos.add(c);
      }
    }
  }

  private PresoContents loadPreso(Gson gson, File base) {
    PresoContents result=null;

    try {
      InputStream is=new FileInputStream(new File(base, "preso.json"));
      BufferedReader reader=
          new BufferedReader(new InputStreamReader(is));

      result=gson.fromJson(reader, PresoContents.class);
      result.baseDir=base;
      is.close();
    }
    catch (IOException e) {
      Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }

    return(result);
  }
}
```

The class includes:

- Getters to retrieve a presentation by index in the array of presentations (`getPreso()`) and to retrieve a presentation by the ID of the presentation (`getPresoById()`)
- A `getPresoCount()` method that indicates how many presentations were found
- A `load()` method that will scan for subdirectories under a given directory, then attempt to parse a `preso.json` file in the subdirectory (in a private `loadPreso()` method) using Gson

The result of `load()` is that the `PresoRoster` should be populated with all known presentations under the specified root directory. Note, though, that this work is done on the current thread, and therefore `load()` needs to be called on a background thread. Also note that `PresoRoster` makes no attempt at thread synchronization, and so `load()` should be called before anything attempts to use the `PresoRoster` getter methods like `getPresoCount()`.

The Launcher Activity: LeanbackActivity

As noted previously, our launcher activity is one that implement's Google's "leanback" user interface, specifically a `BrowseFragment` for browsing media content. In this case, that content consists of the roster of available presentations.

The `LeanbackActivity` itself is fairly short:

```
package com.commonsware.android.preso.decktastic;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class LeanbackActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
      getFragmentManager()
          .beginTransaction()
          .add(android.R.id.content, new RosterFragment()).commit();
    }
  }

  public void showPreso(PresoContents preso) {
    startActivity(new Intent(this, MainActivity.class)
                    .putExtra(MainActivity.EXTRA_PRESO_ID,
                              preso.id));
  }
}
```

All it does is add a `RosterFragment` to the UI managed by the activity, plus add a `showPreso()` method that will be called by that `RosterFragment` when a presentation is selected. `showPreso()`, in turn, will start a separate activity (`MainActivity`), supplying `EXTRA_PRESO_ID` with the ID of the selected presentation, so `MainActivity` knows what presentation to show.

Manifest Entry

To work properly with the `leanback-v17` classes like `BrowseFragment`, `LeanbackActivity` needs to use `Theme.Leanback`, supplied by `leanback-v17`:

```
        <activity
            android:name="com.commonsware.android.preso.decktastic.LeanbackActivity"

android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
            android:label="@string/app_name"
            android:screenOrientation="sensorLandscape"
            android:theme="@style/Theme.Leanback">
          <intent-filter>
            <action android:name="android.intent.action.MAIN" />

            <category android:name="android.intent.category.LAUNCHER" />
            <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
          </intent-filter>
        </activity>
```

Other noteworthy items in the `<activity>` element in the manifest include:

- Locking the screen orientation to `sensorLandscape`, as we want to stick with a landscape-style orientation, but it could either be "regular" or "reverse" landscape without issue
- Handling orientation-related configuration changes, which are not needed since we are locking the screen orientation to `sensorLandscape`, and therefore the UI does not change on an orientation change
- Having the `LEANBACK_LAUNCHER` category as an option in the `<intent-filter>`, as this will cause this activity to appear on Android TV's home screen launcher (as opposed to the `LAUNCHER` category used by normal Android devices)

RosterFragment

`RosterFragment` is a `BrowseFragment`, designed to provide the two-dimensional navigation of headers and items in a header. In this case, we will have just one header, "Presentations", containing all of the presentations found by `PresoRoster`.

In `onAttach()`, we check to see how many presentations are known about. If there are none, we make two assumptions:

1. That this is the first time we have needed to look for presentations, and
2. That there are presentations to be found

So, we fork a `LoadThread` to go load those presentations:

```
@Override
public void onAttach(Activity host) {
  super.onAttach(host);

  if (PresoRoster.getInstance().getPresoCount()==0) {
    new LoadThread(host).start();
  }
}
```

Of course, those assumptions are a gross simplification. It could be that the user launched our `LeanbackActivity`, pressed BACK, then launched it again for some reason, and therefore the first `LoadThread` did not yet finish before we go and fork a second one. Or, it could be that there are no presentations to be found, in which case we scan unnecessarily. A production-grade version of this app should have a more sophisticated means of ensuring a one- (and only one-) time initialization.

`LoadThread` drops our thread priority to background levels, then tells the `PresoRoster` to load presentations from our app's standard spot on external storage. Then, we raise a `RosterLoadedEvent` on greenrobot's EventBus:

```
  private static class LoadThread extends Thread {
    private Context ctxt=null;

    LoadThread(Context ctxt) {
      super();

      this.ctxt=ctxt.getApplicationContext();

android.os.Process.setThreadPriority(android.os.Process.THREAD_PRIORITY_BACKGROUND);
    }

    @Override
    public void run() {
      PresoRoster.getInstance().load(ctxt.getExternalFilesDir(null));

      EventBus.getDefault().postSticky(new RosterLoadedEvent());
    }
  }
```

You will notice that we call `postSticky()`, not `post()` on the `EventBus` instance. This says that we not only want to deliver this event to any current registrants, but that the `EventBus` should cache this event and hand it to future registrants.

To respond to the `RosterLoadedEvent`, we register the `RosterFragment` on the bus in `onResume()` and unregister in `onPause()`:

```
  @Override
  public void onResume() {
    super.onResume();

    EventBus.getDefault().registerSticky(this);
  }

  @Override
  public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
  }
```

Specifically, we register using `registerSticky()`. This, in conjunction with `postSticky()`, means that if events were sticky-posted in the past, we are delivered those immediately, in addition to future events. This will allow us to handle configuration changes — even though our activity and fragment might be destroyed on a locale change, or if our device is put into some sort of desk dock, we will get the `RosterLoadedEvent` when our fragment is created anew.

In particular, we have `onEventMainThread()` set up to listen for `RosterLoadedEvent`. At this point, we know that we have our data model and should render it on the screen:

```
public void onEventMainThread(RosterLoadedEvent event) {
  setHeadersState(BrowseFragment.HEADERS_ENABLED);
  setTitle(getString(R.string.app_name));

  ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
  PresoRoster roster=PresoRoster.getInstance();
  ArrayObjectAdapter listRowAdapter=new ArrayObjectAdapter(new PresoPresenter());

  for (int i=0; i < roster.getPresoCount(); ++i) {
    listRowAdapter.add(roster.getPreso(i));
  }

  HeaderItem header=new HeaderItem(0, "Presentations", null);
  rows.add(new ListRow(header, listRowAdapter));

  setAdapter(rows);
}
```

In `onEventMainThread()`, we:

- Indicate that we do want headers (though, in reality, since this app only has one header, you could easily skip the headers)
- Set the title to appear in the upper-right corner
- Create an `ArrayObjectAdapter` for the `rows` that make up the entirety of the `BrowseFragment` contents, using the standard `ListRowPresenter` for our headers and rows
- Create another `ArrayObjectAdapter`, wrapped around a `PresoPresenter`, that will manage the presentations in our one-and-only row
- Pour our `PresoContents` instances insto the `ArrayObjectAdapter` for our row
- Attach the "Presentations" title to the row via a standard `ListRow` object
- Tell the `RosterFragment` that the `rows` represents what it should render

This is all covered in greater detail in the chapter on the "ten-foot" UI.

In `onViewCreated()` of `RosterFragment`, we indicate that the `RosterFragment` itself should be the listener for click events on items (in our case, presentations):

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
  super.onViewCreated(view, savedInstanceState);

  setOnItemViewClickedListener(this);
}
```

This works because `RosterFragment` implements the `OnItemViewClickedListener` interface and therefore implements the `onItemClicked()` method:

```
@Override
public void onItemClicked(Presenter.ViewHolder viewHolder,
                          Object o,
                          RowPresenter.ViewHolder rowViewHolder,
                          Row row) {
  ((LeanbackActivity)getActivity()).showPreso((PresoContents)o);
}
```

Here, we ask the hosting `LeanbackActivity` to show the clicked-upon presentation, which causes `LeanbackActivity` to launch a `MainActvity` to do just that.

PresoPresenter

The role of `PresoPresenter` is to render the individual items shown in the `BrowseFragment`. In this case, the items are `PresoContents` model objects; `PresoPresenter` will pour the presentation information into `ImageCardView` widgets. `ImageCardView` is supplied by the `leanback-v17` library and is designed to be used for rendering items in a `BrowseFragment`.

The `Presenter` abstract class — which `PresoPresenter` extends — enforces the view holder pattern. A `Presenter` is really responsible for creating and updating `Presenter.ViewHolder` instances, which in turn are responsible for updating the actual widgets themselves. To that end, the `PresoPresenter.Holder` static class is a subclass of `Presenter.ViewHolder`, one that is responsible for pouring a `PresoContents` into an `ImageCardView`:

```
static class Holder extends Presenter.ViewHolder {
  private ImageCardView cardView;
  private PicassoImageCardViewTarget viewTarget;

  public Holder(View view) {
    super(view);

    cardView=(ImageCardView)view;
```

```
      viewTarget=new PicassoImageCardViewTarget(cardView);
    }

    protected void updateCardViewImage(String path) {
      Picasso.with(cardView.getContext())
              .load("file://" + path)
              .resize(convertDpToPixel(cardView.getContext(), CARD_WIDTH),
                  convertDpToPixel(cardView.getContext(), CARD_HEIGHT))
              .into(viewTarget);
    }
  }
```

Here, we are going to use Picasso to load the initial slide off of disk and put it in the `ImageCardView`. However, Picasso has no built-in knowledge of `ImageCardView`, the way it has built-in knowledge of `ImageView`. We need to teach Picasso how to populate an `ImageCardView`. Picasso's mechanism for this is to define a `Target` implementation (`PicassoImageCardViewTarget` in this case) that is responsible for taking a loaded bitmap and updating the UI with it:

```
  private static class PicassoImageCardViewTarget implements Target {
    private ImageCardView imageCardView;

    public PicassoImageCardViewTarget(ImageCardView imageCardView) {
      this.imageCardView=imageCardView;
    }

    @Override
    public void onBitmapLoaded(Bitmap bmp, Picasso.LoadedFrom lf) {
      Drawable bmpDrawable=
          new BitmapDrawable(imageCardView.getContext().getResources(),
                             bmp);

      imageCardView.setMainImage(bmpDrawable);
    }

    @Override
    public void onBitmapFailed(Drawable d) {
      imageCardView.setMainImage(d);
    }

    @Override
    public void onPrepareLoad(Drawable d) {
      imageCardView.setMainImage(d);
    }
  }
```

`Target` requires implementations of:

- `onBitmapLoaded()`, where we take the image and put it as the "main image" of the `ImageCardView` by means of `setMainImage()`
- `onBitmapFailed()`, where we are given a failure `Drawable` and need to use it, once again by setting it as the `ImageCardView` main image

- onPrepareLoad(), where we are given a "loading" Drawable and need to use it, once more by setting it as the ImageCardView main image

The PresoPresenter.Holder class creates an instance of a PicassoImageCardViewTarget and uses that for the into() method of the Picasso RequestBuilder (created via the with() static method on the Picasso class).

The other thing interesting about our use of Picasso is in the resize() call. Particularly since Picasso does not know about ImageCardView and how big the image should be, we need to manually tell Picasso what size to make the image. Here, we hard-code the sizes of the card width and height in density-independent pixels:

```
private static final int CARD_WIDTH=400;
private static final int CARD_HEIGHT=300;
```

We then use a static convertDpToPixel() method to get the actual number of hardware pixels to use, based upon the current screen density:

```
static int convertDpToPixel(Context ctxt, int dp) {
  float density=ctxt.getResources().getDisplayMetrics().density;

  return(Math.round((float)dp*density));
}
```

Back up in PresoPresenter itself, the Presenter abstract class requires us to override onCreateViewHolder(), where we are responsible for creating a Presenter.ViewHolder. In the case of PresoPresenter, that comes in the form of the aforementioned PresoPresenter.Holder:

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
  ImageCardView cardView=new ImageCardView(parent.getContext());

  cardView.setFocusable(true);
  cardView.setFocusableInTouchMode(true);

  return(new Holder(cardView));
}
```

We also have to override onBindViewHolder(), where we are given an eligible Presenter.ViewHolder and need to populate its widgets from a supplied item:

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
                             Object item) {
  PresoContents preso=(PresoContents)item;
  Holder h=(Holder)viewHolder;
```

```
    h.cardView.setTitleText(preso.toString());
    h.cardView.setMainImageDimensions(CARD_WIDTH, CARD_HEIGHT);
    h.updateCardViewImage(preso.getSlideImage(0).getAbsolutePath());
  }
```

Here, the item is a `PresoContents` and the `Presenter.ViewHolder` is a `PresoPresenter.Holder`. We update the `ImageCardView` title and image size based on the presentation, plus tell the `Holder` to update the image itself, calling the `updateCardViewImage()` method that contained our Picasso request.

Note that we are passing the density-independent pixels values (`CARD_WIDTH`, `CARD_HEIGHT`) to `setMainImageDimensions()`. Unfortunately, this method is undocumented, and so what the units of measure should be are not disclosed.

The `Presenter` abstract class also requires implementations of `onUnbindViewHolder()` (called when we should no longer be populating those widgets) and `onViewAttachedToWindow()` (called when the widgets associated with a `Presenter.ViewHolder` are now "live"):

```
  @Override
  public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
  }

  @Override
  public void onViewAttachedToWindow(Presenter.ViewHolder viewHolder) {
    // no-op
  }
```

The Guts: MainActivity

All of the above was just to handle the launcher activity, to allow the user to choose a presentation. `MainActivity` is where we actually show the presentation itself.

This is based upon the `Presentation/Slides` sample app. profiled in the chapter on `Presentation`. Some of the basic logic, for managing the `ViewPager` and displaying the current slide on an external display, is identical to that sample. However, the Decktastic app also supports direct-to-TV devices (e.g., Fire TV, Android TV) and remote playback devices (e.g., Chromecast), and so it blends in some of the techniques covered elsewhere in this book.

Basic Setup

`onCreate()` of `MainActivity` in responsible for basic setup.

```
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    preso=PresoRoster.getInstance()
                     .getPresoById(getIntent()
                                    .getIntExtra(EXTRA_PRESO_ID, 0));

    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    helper=new PresentationHelper(this, this);

    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
            .build();
    router=MediaRouter.getInstance(this);
    router.addCallback(selector, routeCB,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);

    if (isDirectToTV()) {
      getActionBar().hide();
    }

    setupPager();
  }
```

First, we take the EXTRA_PRESO_ID value received via an Intent extra and uses that to find the PresoContents object representing the presentation to be shown. That PresoContents object is then referenced by a data member named preso.

Next, we load up the activity_main layout resource, containing our ViewPager and a TabPageIndicator:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical"
    android:keepScreenOn="true">

  <com.viewpagerindicator.TabPageIndicator
    android:id="@+id/titles"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:visibility="gone"/>

  <android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
  </android.support.v4.view.ViewPager>

</LinearLayout>
```

Then, we create a `PresentationHelper`, so that we find out when we should and should not be displaying a `Presentation`. As before, `MainActivity` itself is the `PresentationHelper.Listener` for finding out about these events. We will explore that more later in this chapter.

We then go through some logic for setting up remote playback device support (`MediaRouteSelector.Builder` and kin) and direct-to-TV device support (calling `isDirectToTV()`). Those will be explored later in this chapter, in sections on remote playback device support and direct-to-TV device support.

Finally, we call `setupPager()`, to populate our `ViewPager`.

The ViewPager

The `setupPager()` method is responsible for putting a `SlidesAdapter` into the `ViewPager` and otherwise setting things up to allow the presenter to control what slide is shown and for us to find out what slide the presenter selects:

```
private void setupPager() {
  durationInSeconds=preso.duration * 60;

  if (rc!=null) {
    rc.setOverallDuration(durationInSeconds);
  }

  adapter=new SlidesAdapter(this, preso);
  pager.setAdapter(adapter);

  TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

  tabs.setViewPager(pager);
  tabs.setOnPageChangeListener(this);

  if (isDirectToTV()) {
    tabs.setVisibility(View.GONE);
  }
  else {
    tabs.setVisibility(View.VISIBLE);
  }
}
```

Some of this — specifically the `SlidesAdapter` and `TabPageIndicator` logic — is standard `ViewPager` setup work. The `durationInSeconds` stuff at the top is for setting up a `ReverseChronometer`, as will be discussed later in this chapter. The `isDirectToTV()` call and `if` block will be explained more in the section on direct-to-TV device support later in this chapter.

`SlidesAdapter` is a fragment-free edition of a `PagerAdapter`, as the slides are purely `ImageView` widgets:

```
package com.commonsware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class SlidesAdapter extends PagerAdapter {
  private PresoContents preso;
  private Context ctxt;

  SlidesAdapter(Context ctxt, PresoContents preso) {
    this.ctxt=ctxt;
    this.preso=preso;
  }

  @Override
  public Object instantiateItem(ViewGroup container, int position) {
    ImageView page=new ImageView(ctxt);

    container.addView(page,
                      new ViewGroup.LayoutParams(
                                                ViewGroup.LayoutParams.MATCH_PARENT,
                                                ViewGroup.LayoutParams.MATCH_PARENT));

    Picasso.with(ctxt).load(getSlideImageUri(position)).into(page);

    return(page);
  }

  @Override
  public void destroyItem(ViewGroup container, int position,
                          Object object) {
    container.removeView((View)object);
  }

  @Override
  public int getCount() {
    return(preso.slides.size());
  }

  @Override
  public boolean isViewFromObject(View view, Object object) {
    return(view == object);
  }

  @Override
  public String getPageTitle(int position) {
    return(preso.getSlideTitle(position));
  }

  Uri getSlideImageUri(int position) {
    return(Uri.fromFile(preso.getSlideImage(position)));
  }
}
```

Of note:

- `instantiateItem()` creates the `ImageView`, adds it to the supplied `container` (set to fill that container), and tells Picasso to go load the image asynchronously into the `ImageView`
- `destroyItem()` removes the `ImageView` from the container
- `getCount()` returns the number of pages, based on the number of slides in the `PresoContents` supplied to the `SlidesAdapter` via its constructor
- `getPageTitle()` returns the page title, obtained from the `PresoContents` object
- `getSlideImageUri()` gets a `Uri` pointing to a local file from the `PresoContents`, for use both by `instantiateItem()` and by the `Presentation` object that we will use for external display support (as will be covered later in this chapter)

Supporting the Direct-to-TV Scenario

To determine whether or not our activity is natively displaying on a TV-style screen, we check to see whether the device has either `FEATURE_TELEVISION` or `FEATURE_LEANBACK`, in the private `isDirectToTV()` method on `MainActivity`:

```
  private boolean isDirectToTV() {
    return(getPackageManager().hasSystemFeature(PackageManager.FEATURE_TELEVISION)
        || getPackageManager().hasSystemFeature(PackageManager.FEATURE_LEANBACK));
  }
```

Admittedly, not all Android direct-to-TV devices may advertise that they have one of these features. In particular, minor-brand Android HDMI sticks might just be using a fairly vanilla Android device profile, culled from a tablet. There is no good way of detecting such a scenario, though Decktastic could provide some manual option (e.g., checkable action item) to go into direct-to-TV mode if this proved to be important.

We use `isDirectToTV()` in two places. First, in `onCreate()`, we hide the action bar if we are going direct to a TV:

```
    if (isDirectToTV()) {
      getActionBar().hide();
    }
```

Second, in `setupPager()`, we hide the `TabPagerIndicator` if we are going direct to a TV:

```
    if (isDirectToTV()) {
      tabs.setVisibility(View.GONE);
    }
    else {
      tabs.setVisibility(View.VISIBLE);
    }
```

This eliminates the "chrome" from our activity, leaving us with just the contents of the `ViewPager` itself, in the form of our slides. On the plus side, this gives us the visual output we want. However, it comes at a cost: there is no means for the presenter to change slides. After all, there is no touchscreen in this scenario, and so even though the `ViewPager` could be swiped, that is not possible without a touchscreen.

To support standard presentation remotes and similar mechanisms, `MainActivity` overrides `onKeyDown()`:

```
  @Override
  public boolean onKeyDown(int keyCode, KeyEvent event) {
    switch(keyCode) {
      case KeyEvent.KEYCODE_SPACE:
      case KeyEvent.KEYCODE_DPAD_RIGHT:
      case KeyEvent.KEYCODE_DPAD_DOWN:
      case KeyEvent.KEYCODE_PAGE_DOWN:
      case KeyEvent.KEYCODE_MEDIA_NEXT:
        if (pager.canScrollHorizontally(1)) {
          pager.setCurrentItem(pager.getCurrentItem()+1, true);
        }

        return(true);

      case KeyEvent.KEYCODE_DPAD_LEFT:
      case KeyEvent.KEYCODE_DPAD_UP:
      case KeyEvent.KEYCODE_PAGE_UP:
      case KeyEvent.KEYCODE_MEDIA_PREVIOUS:
        if (pager.canScrollHorizontally(-1)) {
          pager.setCurrentItem(pager.getCurrentItem()-1, true);
        }

        return(true);
    }

    return(super.onKeyDown(keyCode, event));
  }
```

Here, we will advance to the next slide if the user presses:

- the space bar or the Page Down key on a QWERTY keyboard

- right or down arrow keys, D-pad buttons, or the like
- a "next" media button on a media remote

Conversely, we will return to the preceding slide if the user presses:

- the Page Up key on a QWERTY keyboard
- left or up arrow keys, D-pad buttons, or the like
- a "previous" media button on a media remote

This should allow most remotes for direct-to-TV devices to control our slides. Note that we are passing `true` as the second parameter to the `setCurrentItem()` method, and therefore the audience will see an animated transition to the next slide. That may or may not be desirable; an enhanced edition of Decktastic might allow that to be configured (e.g., via a checkable action item).

Note that this is still a bit limited compared to having touchscreen access, as our `onKeyDown()` method only moves a slide at a time. There is no facility to jump to an arbitrary spot, the way you could by swiping and tapping upon `ViewPager` tabs on a touchscreen.

Supporting External Displays

As noted earlier, in `onCreate()` of `MainActivity`, we create an instance of `PresentationHelper`, supplying the activity itself as both the `Context` and the `PresentationHelper.Listener` for presentation-related events:

```
    helper=new PresentationHelper(this, this);
```

That, in turn, requires us to forward along `onPause()` and `onResume()` events from our activity to the `PresentationHelper`:

```
  @Override
  public void onResume() {
    super.onResume();
    helper.onResume();
  }

  @Override
  public void onPause() {
    helper.onPause();
    super.onPause();
  }
```

We also have to implement `showPreso()` and `clearPreso()` methods to satisfy the `PresentationHelper.Listener` interface:

```
  @Override
  public void clearPreso(boolean showInline) {
    if (presoFrag != null) {
      presoFrag.dismiss();
      presoFrag=null;
    }
  }

  @Override
  public void showPreso(Display display) {
    Uri slide=adapter.getSlideImageUri(pager.getCurrentItem());

    presoFrag=
        SlidePresentationFragment.newInstance(this, display, slide);
    presoFrag.show(getFragmentManager(), "presoFrag");
  }
```

In `showPreso()`, we obtain the `Uri` for the current slide by calling the `getSlideImageUri()` method we conveniently implemented on the `SlidesAdapter`. Then, we create an instance of a `SlidePresentationFragment`, handing it the slide `Uri`, and we `show()` that fragment. We only `dismiss()` the fragment in `clearPreso()`.

The fragment itself is a `PresentationFragment`, with an `ImageView` as the fragment's UI, populated using Picasso, with the `Uri` being transferred from the `newInstance()` factory method to the fragment itself via the arguments `Bundle`:

```
package com.commonsware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.commonsware.cwac.preso.PresentationFragment;
import com.squareup.picasso.Picasso;

public class SlidePresentationFragment extends PresentationFragment {
  private static final String KEY_URI="u";
  private ImageView slide=null;

  public static SlidePresentationFragment newInstance(Context ctxt,
                                                      Display display,
                                                      Uri slideUri) {
    SlidePresentationFragment frag=new SlidePresentationFragment();

    frag.setDisplay(ctxt, display);

    Bundle b=new Bundle();

    b.putParcelable(KEY_URI, slideUri);
    frag.setArguments(b);

    return(frag);
  }

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    slide=new ImageView(getContext());

    setSlideContent((Uri)getArguments().getParcelable(KEY_URI));

    return(slide);
  }

  void setSlideContent(Uri slideUri) {
    Picasso.with(getContext()).load(slideUri).into(slide);
  }
}
```

This arranges to show the *current* slide, for whatever the current slide is at the time `showPreso()` is called on `MainActivity`. However, we need to update this fragment to reflect changes in the current slide. To accomplish this, we set up `MainActivity` to implement the `OnPageChangeListener` interface, then call `setOnPageChangelListener()` on the `ViewPager` in `setupPager()` to have it forward page-change events to the activity. Of those events, we pay particular attention to `onPageSelected()`, updating the `SlidePresentationFragment` if there is one around:

```
  @Override
  public void onPageScrollStateChanged(int arg0) {
    // ignored
  }

  @Override
  public void onPageScrolled(int arg0, float arg1, int arg2) {
    // ignored
  }

  @Override
  public void onPageSelected(int position) {
    if (presoFrag != null) {
      presoFrag.setSlideContent(adapter.getSlideImageUri(position));
    }

    if (client!=null) {
      String url=preso.getSlideURL(position);

      client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
  }
```

We will get into the `client` stuff from `onPageSelected()` in the next section, as that pertains to supporting remote playback devices.

Supporting Chromecast and Remote Playback Devices

The key limitation of Chromecast and other remote playback devices is that they can only play back media that they can access. While Chromecast supports mirroring, that is handled via the `Presentation` API discussed previously; devices limited to the `RemotePlaybackClient` API need URLs to media files. That is why our JSON for the presentation contains a URL pointing to a copy of each slide up on some public Web server. To push those URLs over to the Chromecast at the appropriate points, we need to set up the `RemotePlaybackClient` system.

First, in `onCreate()`, we define a `MediaRouteSelector` for remote playback devices, set up a `MediaRouter`, and add a callback to find out about selected route changes, asking `MediaRouter` to scan for possible routes along the way:

```
    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
            .build();
    router=MediaRouter.getInstance(this);
    router.addCallback(selector, routeCB,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
```

All of this is using the `mediarouter-v7` portion of the Android Support package, as the native `MediaRouter` and kin do not support remote playback devices.

Our menu resource for our action bar contains, among other things, a `MediaRouteActionProvider`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
      xmlns:android="http://schemas.android.com/apk/res/android"
      tools:ignore="AppCompatResource">

  <item
      android:id="@+id/countdown"
      android:actionViewClass=
        "com.commonsware.android.preso.decktastic.ReverseChronometer"
      android:showAsAction="always"
      android:title="This Should Not Be Needed">
  </item>
  <item
    android:id="@+id/route_provider"
    android:title="@string/media_route_provider"
    android:actionProviderClass=
      "com.commonsware.cwac.mediarouter.app.MediaRouteActionProvider"
    android:showAsAction="always"/>
  <item
      android:id="@+id/first"
      android:icon="@android:drawable/ic_media_previous"
      android:showAsAction="always"
      android:title="@string/first">
  </item>
  <item
    android:id="@+id/last"
    android:icon="@android:drawable/ic_media_next"
    android:showAsAction="always"
    android:title="@string/last">
  </item>
  <item
      android:id="@+id/present"
      android:checkable="true"
      android:checked="true"
      android:showAsAction="never"
      android:title="@string/show_presentation">
  </item>

</menu>
```

As part of our work in setting up the action bar in `onCreateOptionsMenu()`, we retrieve the `MediaRouteActionProvider` and configure it with the same `MediaRouteSelector` that we used for the `MediaRouter` callback:

```
  @Override
  public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    rc=(ReverseChronometer)menu.findItem(R.id.countdown)
                               .getActionView();

    rc.setWarningDuration(5 * 60);
    rc.setOnClickListener(this);
    rc.setOnLongClickListener(this);
    rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
    rc.setTextColor(Color.WHITE);

    if (durationInSeconds>0) {
      rc.setOverallDuration(durationInSeconds);
    }

    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)item.getActionProvider();

    provider.setRouteSelector(selector);

    return(super.onCreateOptionsMenu(menu));
  }
```

(the lines in `onCreateOptionsMenu()` pertaining to the `ReverseChronometer` will be explained later in this chapter)

If the user interacts with the `MediaRouteActionProvider` and elects to connect to a remote playback device, our `MediaRouter.Callback` will be notified about the change of route:

```
private MediaRouter.Callback routeCB=new MediaRouter.Callback() {
  @Override
  public void onRouteSelected(MediaRouter router,
                              MediaRouter.RouteInfo route) {
    connect(route);
  }

  @Override
  public void onRouteUnselected(MediaRouter router,
                                MediaRouter.RouteInfo route) {
    disconnect();
  }
};
```

Here, we just delegate the `onRouteSelected()` and `onRouteUnselected()` callbacks to `connect()` and `disconnect()` methods on `MainActivity`. `MediaRouter.Callback` is an abstract class, not an interface — otherwise, we would simply have implemented the interface on `MainActivity` and bypassed this anonymous inner class instance.

The `connect()` method on `MainActivity` is responsible for sending over the current slide to the remote playback device:

```
private void connect(MediaRouter.RouteInfo route) {
  client=
      new RemotePlaybackClient(getApplicationContext(), route);

  if (client.isRemotePlaybackSupported()) {
    String url=preso.getSlideURL(pager.getCurrentItem());

    client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
  }
  else {
    client=null;
  }
}
```

Here, we:

- Create an instance of `RemotePlaybackClient`
- Confirm that the remote playback device supports the remote playback protocol (`isRemotePlaybackSupported()`)
- Call `play()`, passing over a URL pointing to the same slide that the `ViewPager` is showing from a local file

The `play()` call requires an `ItemActionCallback` as the last parameter. We really do not need the callback, but passing `null` does not work. So, we have a do-nothing `ItemActionCallback` named `playCB` that we use:

```
ItemActionCallback playCB=new ItemActionCallback() {
  @Override
  public void onResult(Bundle data, String sessionId,
                       MediaSessionStatus sessionStatus,
                       String itemId, MediaItemStatus itemStatus) {
  }

  @Override
  public void onError(String error, int code, Bundle data) {
  }
};
```

That will show the slide that was current as of the time the user connected to the remote playback device. We need to show a new slide when the presenter switches to a new slide, just as we did in the `Presentation` scenario. This too is handled in `onPageSelected()`, where we make the same sort of `play()` call that we did in `connect()`:

```
@Override
public void onPageSelected(int position) {
  if (presoFrag != null) {
    presoFrag.setSlideContent(adapter.getSlideImageUri(position));
  }

  if (client!=null) {
    String url=preso.getSlideURL(position);

    client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
  }
}
```

Not only is `disconnect()` called from `MediaRouter.Callback`, but it is also called from `onDestroy()` of `MainActivity`, where we also remove that callback from the `MediaRouter`:

```
@Override
public void onDestroy() {
  disconnect();
  router.removeCallback(routeCB);
  super.onDestroy();
}
```

`disconnect()` releases the `RemotePlaybackClient` and ensures that we are back on our default route:

```
private void disconnect() {
  if (client != null) {
    client.release();
    client=null;
  }
```

```
    router.getDefaultRoute().select();
  }
```

The net effect of all of this is that the slides will update on the remote playback device as the presenter switches slides, in addition to when the presenter connects to the remote playback device originally. We are not in control of any transition effects — we simply provide the slides, and it is up to the remote playback device to download and show them, however that device wishes.

The Rest of the Story

One common need of a presenter is to know how much time is remaining in which to deliver the presentation. Presentations are usually time-limited, to fit conference agendas and the like. The JSON structure for a presentation contains the duration of the presentation, and it would be useful to let the presenter know how much of that duration is remaining.

The chapter on custom views has a section outlining the implementation of a `ReverseChronometer` widget. `Chronometer` is a standard Android SDK class for counting up time (e.g., a stopwatch). `ReverseChronometer` is for counting *down* time.

Decktastic puts a `ReverseChronometer` in the action bar as a custom view, courtesy of our menu XML:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
      xmlns:android="http://schemas.android.com/apk/res/android"
      tools:ignore="AppCompatResource">

  <item
      android:id="@+id/countdown"
      android:actionViewClass=
        "com.commonsware.android.preso.decktastic.ReverseChronometer"
      android:showAsAction="always"
      android:title="This Should Not Be Needed">
  </item>
  <item
    android:id="@+id/route_provider"
    android:title="@string/media_route_provider"
    android:actionProviderClass=
      "com.commonsware.cwac.mediarouter.app.MediaRouteActionProvider"
    android:showAsAction="always"/>
  <item
      android:id="@+id/first"
      android:icon="@android:drawable/ic_media_previous"
      android:showAsAction="always"
      android:title="@string/first">
  </item>
  <item
    android:id="@+id/last"
    android:icon="@android:drawable/ic_media_next"
    android:showAsAction="always"
    android:title="@string/last">
  </item>
  <item
      android:id="@+id/present"
      android:checkable="true"
      android:checked="true"
      android:showAsAction="never"
      android:title="@string/show_presentation">
  </item>

</menu>
```

We customize the `ReverseChronometer` through a handful of lines in the `onCreateOptionsMenu()` method:

```
    rc=(ReverseChronometer)menu.findItem(R.id.countdown)
                               .getActionView();

    rc.setWarningDuration(5 * 60);
    rc.setOnClickListener(this);
    rc.setOnLongClickListener(this);
    rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
    rc.setTextColor(Color.WHITE);

    if (durationInSeconds>0) {
      rc.setOverallDuration(durationInSeconds);
    }
```

Here we:

- Retrieve the `ReverseChronometer` from the action item
- Have it change to a "warning" presentation with five minutes remaining
- Set up the activity to respond to click and long-click events
- Set the appearance to be `24sp` white text

And, if we already know the presentation's overall duration, via the `durationInSeconds` data member, we pour that into the `ReverseChronometer` as well.

`durationInSeconds` is populated via a few lines at the top of `setupPager()`:

```
    durationInSeconds=preso.duration * 60;

    if (rc!=null) {
      rc.setOverallDuration(durationInSeconds);
    }
```

This way, no matter whether `setupPager()` or `onCreateOptionsMenu()` is called first, we pour the duration into the `ReverseChronometer`.

By default, that `ReverseChronometer` does nothing other than show the remaining time… which remains fixed by default. That is where the click and long-click event handlers come into play:

```
@Override
public void onClick(View v) {
  ReverseChronometer rc=(ReverseChronometer)v;

  if (rc.isRunning()) {
    rc.stop();
  }
  else {
    if (isFirstRCClick) {
      isFirstRCClick=false;
      rc.reset();
    }

    rc.run();
  }
}

@Override
public boolean onLongClick(View v) {
  ReverseChronometer rc=(ReverseChronometer)v;

  rc.reset();

  return(true);
}
```

There are three possibilities when the user taps on the `ReverseChronometer`:

- It was never clicked before (`isFirstRCClick` is `true`), in which case we ensure that the `ReverseChronometer` is reset to the overall duration before calling `run()` to start the countdown
- It is already running, in which case we call `stop()` to pause the countdown
- It was not already running (but was clicked before), in which case we call `run()` again to resume the countdown

This gives us what from a media standpoint would be play, pause, and resume logic.

A long-click will `reset()` the `ReverseChronometer`, returning the time remaining to the overall duration.

Our action bar also has a few other action items, handled in `onOptionsItemSelected()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  switch (item.getItemId()) {
    case R.id.present:
      boolean original=item.isChecked();

      item.setChecked(!original);

      if (original) {
        helper.disable();
      }
      else {
        helper.enable();
      }

      break;

    case R.id.first:
      pager.setCurrentItem(0);
      break;

    case R.id.last:
      pager.setCurrentItem(adapter.getCount() - 1);
      break;
  }

  return(super.onOptionsItemSelected(item));
}
```

Specifically:

- There is a checkable action item to determine whether or not we should be showing a `Presentation`. If this is unchecked, and an external display is attached, we still disable the `PresentationHelper`. This will cause normal display mirroring to begin, and the audience will see the same UI that the presenter does, complete with the `ViewPager`, action bar, and so on. Checking it re-enables the `PresentationHelper`, so if an external display is available, we start showing the slides again.
- The `first` and `last` action bar items are "fast-forward" and "rewind" options, allowing the presenter to quickly jump to the first or the last slide in the presentation. This happens via calls to `setCurrentItem()` on the `ViewPager`, which will in turn invoke `onPageSelected()`, causing us to update our `PresentationFragment` or remote playback device, if needed.

Note that since the direct-to-TV mode hides the action bar, none of these options are available to the presenter on a device like Android TV or a Fire TV. This will require the presenter to use something else to track the remaining time in a presentation, such as a countdown timer app running on a separate Android device.

Creating a MediaRouteProvider

As was noted earlier in the book, you can use `MediaRouter` to identify media routes, such as those published by devices like Google's Chromecast. Specifically, remote playback routes let you write apps that tell other devices, like the Chromecast, to play back media on your behalf.

However, not only can you write *clients* for remote playback routes, you can write *providers* of those routes. Perhaps you are working with a hardware manufacturer that is creating a Chromecast-like device. Perhaps you want to allow your app, running on a Fire TV or an Android HDMI stick, to be controlled by a user's phone or tablet. Or perhaps you are trying to tie Android into specialized media hardware that does not communicate by conventional means (e.g., wireless speakers that do not use normal Bluetooth profiles).

This chapter will outline how you can create code that will publish media routes to users of `MediaRouter`, so that you can then take those requests and forward them to a remote device.

Prerequisites

This chapter assumes that you have read the chapter on `MediaRouter`.

Terminology

For the purposes of this chapter:

- The "client device" refers to a phone or tablet that runs an app that should be able to direct what is shown on a streaming media player

- The “player device” refers to the streaming media player itself, which may or may not be running Android
- The “player app” refers to an Android app running on an Android-powered player device

DIY Chromecast

Google’s Chromecast is a nice little device. However, it has issues:

- The device itself is not especially open.
- The Cast SDK that Google encourages for writing Chromecast-enabled apps is not especially open.
- The terms and conditions for using the Cast SDK may be troublesome for many developers.
- Chromecast is not available globally.
- Chromecast is only one device, and there are plenty of other streaming media devices available that need to be considered.

Some of these issues can be mitigated by the use of `MediaRouter` and `RemotePlaybackClient` instead of the proprietary Cast SDK. You are not bound by any particular license terms (beyond the norm for Android development) and the implementation of the media framework is open.

However, to make this work, the client device needs to know how to talk to the player device.

The good news is that the media routing framework in Android supports plug-in media route providers for just this purpose. The OS ships with such a provider for the Chromecast, and you can create your own providers to talk to whatever else you would like to talk to. The user can then install a small app on their client device that implements this media route provider, and *any* apps already on their client device that use classes like `RemotePlaybackClient` will automatically be able to cast their desired content to the player device.

MediaRouteProvider

The guts of this come in the form of a `MediaRouteProvider`. Your custom subclass of `MediaRouteProvider` will:

- Tell Android what general capabilities you support, such as remote playback, session management, and the like
- Advertise what sorts of content your player device is capable of playing (e.g., certain video MIME types, certain URL schemes like `http` and `rtsp`)
- Serve as the recipient of commands from `MediaRouter`, `RemotePlaybackClient`, and the like, for you to forward along asynchronously to the player device

Depending upon your use case, you could elect to keep the `MediaRouteProvider` private to your application. That way, your app can cast to the player device, but no other apps can. Or, you can make your `MediaRouteProvider` available to all apps on the device, with the media routing framework taking care of the IPC details to have those apps tell your `MediaRouteProvider` what the player device should do.

Player Device… and Maybe a Player App

Of course, this assumes the existence of some player device that is not supported by Android out of the box. Since Android only really supports Chromecast, external displays (e.g., HDMI, MHL, Miracast), and some Bluetooth options (e.g., external speakers) for media routes, there are countless player devices that need additional help. These will run the gamut from devices from major players (e.g., Amazon's Fire TV) to no-name devices (e.g., Android HDMI "sticks").

Some player devices will run Android. In that case, you would be writing a player app that would run on the player device that would be the recipient of commands sent to it from your `MediaRouteProvider` on the client device. For example, if you write a video player app, you could augment it with remote control capability driven by a `MediaRouteProvider` on a client device, turning your player app and anything it can run on (e.g., Fire TV, OUYA game console) into a Chromecast-like environment.

Some player devices will not run Android. If they offer some existing remote control over-the-air protocol, you could create a `MediaRouteProvider` that speaks that protocol. Or, perhaps the player devices are programmable, just not via Android (e.g., a Linux program for XMBC), in which case you might be able to write both ends of the communications channel.

Communications Protocol

Somehow, the data from the MediaRouteProvider needs to get to the player device (and, where relevant, the player app). Likely candidates include Bluetooth, regular WiFi (if both devices are on the same network), and WiFi Direct.

However, in principle, anything is possible. For example, there is nothing stopping you from sending MediaRouteProvider commands to some Web server out on the Internet, which forwards them to some distant location for use. That would be a bit unusual – normally, the user of the client device is controlling something she can see — but it certainly could be done.

The biggest thing to watch out for is the addressability of the media to be played back. There is little point in connecting a MediaRouteProvider to some player device, then not have the ability for the player device to access the media that the client device is requesting. The expected pattern is that the media is hosted in some (relatively) central location, like a Web server. However, once again, anything is possible. If you want to have some sort of server on the client device, to allow the player device to play back media from it, and you believe that you can adequate secure this, you are welcome to do so.

Creating the MediaRouteProvider

As noted earlier, the core of all of this is a custom MediaRouteProvider. Google supplies a sample application for creating such a MediaRouteProvider. However, it is overly complex, and it is undocumented.

This chapter will focus instead on the MediaRouter/RouteProvider sample project. This is a clone of the MediaRouter/RemotePlayback sample project covered earlier in this book, with the addition of a custom MediaRouteProvider.

Defining the Supported Actions

A MediaRouteProvider advertises — whether to its own app's MediaRouter or to the entire device — what sorts of actions it can perform. For example, a remote playback route provider needs to support actions like play, pause, resume, and stop of some piece of media.

The way this is handled in the media routing framework is via a series of IntentFilter objects.

Since IntentFilter objects do not need a Context to be created, it is safe to define them statically, if desired. That's what we do in DemoRouteProvider, a custom subclass of MediaRouteProvider. It declares a pair of static final IntentFilter objects, ifPlay and ifControl, which are then configured in a static initialization block:

```
private static final IntentFilter ifPlay=new IntentFilter();
private static final IntentFilter ifControl=new IntentFilter();

static {
  ifPlay.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
  ifPlay.addAction(MediaControlIntent.ACTION_PLAY);
  ifPlay.addDataScheme("http");
  ifPlay.addDataScheme("https");
  ifPlay.addDataScheme("rtsp");

  try {
    ifPlay.addDataType("video/*");
  }
  catch (MalformedMimeTypeException e) {
    throw new RuntimeException("Exception setting MIME type", e);
  }

  ifControl.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
  ifControl.addAction(MediaControlIntent.ACTION_PAUSE);
  ifControl.addAction(MediaControlIntent.ACTION_RESUME);
  ifControl.addAction(MediaControlIntent.ACTION_STOP);
  ifControl.addAction(MediaControlIntent.ACTION_GET_STATUS);
  ifControl.addAction(MediaControlIntent.ACTION_SEEK);
}
```

Both stipulate that they are looking for Intent objects in the MediaControlIntent.CATEGORY_REMOTE_PLAYBACK category. This category is used for all media routing Intents that form the foundation of the routing framework.

ifPlay is defined as supporting MediaControlIntent.ACTION_PLAY, stating that we know how to play back some content. The qualifications for "some content" are handled via scheme and type constraints placed on the IntentFilter. Here, we limit the content to be URLs that might be reachable by a playback device (http, https, rtsp) and have a MIME type matching video/*. Hence, we are stating that we can play back streaming video.

ifControl sets up the remaining actions that we support:

- MediaControlIntent.ACTION_PAUSE
- MediaControlIntent.ACTION_RESUME
- MediaControlIntent.ACTION_STOP
- MediaControlIntent.ACTION_GET_STATUS

- MediaControlIntent.ACTION_SEEK

These are placed on an independent IntentFilter because, technically, we can support these actions on any type of media. In the case of this specific example, the only media we support is streaming video. But, we could configure other IntentFilter objects, like ifPlay was, stating yet other media types that we handle.

To fully comply with the RemotePlaybackClient API, we must advertise that we handle all of those actions… even if our intended client will not use all of them.

We could also:

- Advertise that we support session management actions, like MediaControlIntent.ACTION_START_SESSION
- Advertise that we support the "enqueue" operation for stacking up media to be played (e.g., MediaControlIntent.ACTION_ENQUEUE) and manipulating that queue (e.g., MediaControlIntent.ACTION_REMOVE)
- Define a custom category for other actions that we support that are "out of band" with respect to the standard media routing actions

All of those are demonstrated in Google's sample app.

Creating the Descriptors

Just because we have some static IntentFilter objects does not mean that anything will pay attention to them. We need to actually register them with the media routing framework, wrapped in a pair of "descriptor" objects. DemoRouteProvider calls a private handleDiscovery() method from the constructor, where handleDiscovery() sets up the descriptors:

```
private void handleDiscovery() {
  MediaRouteDescriptor.Builder mrdBuilder=
      new MediaRouteDescriptor.Builder(DEMO_ROUTE_ID, "Demo Route");

  mrdBuilder.setDescription("The description of a demo route")
            .addControlFilter(ifPlay)
            .addControlFilter(ifControl)
            .setPlaybackStream(AudioManager.STREAM_MUSIC)
            .setPlaybackType(MediaRouter.RouteInfo.PLAYBACK_TYPE_REMOTE)
            .setVolumeHandling(MediaRouter.RouteInfo.PLAYBACK_VOLUME_FIXED);

  MediaRouteProviderDescriptor.Builder mrpdBuilder=
      new MediaRouteProviderDescriptor.Builder();

  mrpdBuilder.addRoute(mrdBuilder.build());
```

```
    setDescriptor(mrpdBuilder.build());
  }
```

In the end, we need to provide a `MediaRouteProviderDescriptor` to the `MediaRouteProvider` by means of a `setDescriptor()` method. `MediaRouteProviderDescriptor` is, in effect, metadata about the `MediaRouteProvider` itself. At the present time, the only thing this holds is a set of `MediaRouteDescriptor` objects, one for each media route that the `MediaRouteProvider` claims to support.

A `MediaRouteProvider` is made up of several pieces of information, including:

- The `IntentFilter`(s) representing the supported actions and, where relevant, MIME types and schemes
- A locally-unique ID of the route, to distinguish it from any other one that we might configure
- A name and description, which the user will see when they try to connect to this route (e.g., via a `MediaRouteActionProvider`)
- What audio stream is being used for the playback, from the standpoint of volume management, audio ducking, and the like
- Whether the playback is occurring locally on the device to some peripheral (e.g., speaker) or if the playback is occurring remotely on a player device (e.g., Chromecast)
- Whether playback volume is controlled here on the client device or on the player device
- Etc.

These are all configured on a `MediaRouteProvider` by creating a `MediaRouteProvider.Builder` and supplying the values either in the `Builder` constructor or via fluent setter methods. In the particular case of our simple demo provider, we:

- Use various strings for the ID, name, and description
- Use the two `IntentFilter` objects defined earlier to indicate what actions we can perform
- Indicate that the playback stream is `STREAM_MUSIC`, that the playback type is `PLAYBACK_TYPE_REMOTE`, and that the volume handling is `PLAYBACK_VOLUME_FIXED` (i.e., volume should be managed on the TV or whatever the media is being played upon)

It is very likely that you will elect to have several MediaRouteDescriptor objects for different client application scenarios. Google's sample app uses a total of four MediaRouteDescriptor objects:

- One set up largely like the one in this sample
- One set up with PLAYBACK_VOLUME_VARIABLE (so volume is controllable by a client app)
- One set up with variable volume plus queuing actions
- One set up with variable volume plus queuing and session management actions

Receiving the Actions

Now, we have told the media routing framework what actions we support. Some app will then try to use RemotePlaybackClient and ask us to perform those actions. Hence, we need to find out when this happens, so we can do the actual work of having the playback device actually play back the media, pause the media, etc.

To do this, we need to create a custom subclass of MediaRouteProvider.RouteController. This contains a series of callback methods which we can override to find out when various events occur.

There are four such callback methods that the DemoRouteController subclass of MediaRouteProvider.RouteController implements:

- onSelect(), which will be called when a client app has selected our MediaRouteProvider to handle some media on behalf of that client app
- onUnselect() and onRelease(), which will be called when the client app disconnects from our MediaRouteProvider
- onControlRequest(), which will be called when some specific action that we advertised is requested, such as playing back a piece of media

The DemoRouteController just logs a message to LogCat for the first three callbacks:

```
@Override
public void onRelease() {
  Log.d(getClass().getSimpleName(), "released");
}

@Override
public void onSelect() {
  Log.d(getClass().getSimpleName(), "selected");
}
```

```
@Override
public void onUnselect() {
  Log.d(getClass().getSimpleName(), "unselected");
}
```

The `onControlRequest()` method is a bit more complex, as *all* control requests route through here: play, pause, resume, stop, etc. `onControlRequest()` is passed the `Intent` identifying the particular action that should be performed, and we can examine the `Intent` action string to determine what needs to be done. In this case, `onControlRequest()` delegates the real work to action-specific methods like `onPlayRequest()`:

```
@Override
public boolean onControlRequest(Intent i, ControlRequestCallback cb) {
  if (i.hasCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)) {
    if (MediaControlIntent.ACTION_PLAY.equals(i.getAction())) {
      return(onPlayRequest(i, cb));
    }
    else if (MediaControlIntent.ACTION_PAUSE.equals(i.getAction())) {
      return(onPauseRequest(i, cb));
    }
    else if (MediaControlIntent.ACTION_RESUME.equals(i.getAction())) {
      return(onResumeRequest(i, cb));
    }
    else if (MediaControlIntent.ACTION_STOP.equals(i.getAction())) {
      return(onStopRequest(i, cb));
    }
    else if (MediaControlIntent.ACTION_GET_STATUS.equals(i.getAction())) {
      return(onGetStatusRequest(i, cb));
    }
    else if (MediaControlIntent.ACTION_SEEK.equals(i.getAction())) {
      return(onSeekRequest(i, cb));
    }
  }

  Log.w(getClass().getSimpleName(), "unexpected control request"
      + i.toString());

  return(false);
}
```

`onControlRequest()` should return `true` if we agree to perform the action and will use the supplied `ControlRequestCallback` object to asynchronously deliver our results. If `onControlRequest()` returns `false`, that means that we are rejecting the action for some reason, such as it being one that is unrecognized. In `DemoRouteController`, that will occur if the category or the action on the `Intent` is not one of the supported options.

Note that if you opted into variable volume, there are `onSetVolume()` and `onUpdateVolume()` callback methods that will give you access to those events.

Handling the Actions

For those actions that you advertise and receive in onControlRequest(), you need to actually do the work for those actions. The details of this will vary widely depending upon your playback device and playback app that you are supporting. For example, you might establish a WiFi Direct connection in onSelect(), then use that connection in handling play, pause, etc. actions.

However, a few aspects of handling these actions will be in common across all implementations:

- onControlRequest() must return true or false as was described in the preceding section
- You must call onResult() or onError() on the ControlRequestCallback object to indicate if the action succeeded or failed
- You must supply an appropriate Bundle to those methods, particularly to onResult(), containing the right set of values to provide more details about the results of the action

The details of what that Bundle must contain are documented on the MediaControlIntent class, on the definition of each action string (e.g., ACTION_PLAY).

With that in mind, let's look at the six actions supported by DemoRouteController.

Play

The Bundle passed to onResult() of the ControlRequestCallback, when the action is ACTION_PLAY, needs three values:

- EXTRA_SESSION_ID: if you are implementing session management, this will be the unique session ID (String) for the session you are playing the media in. If you are not implementing session management, then what you are supposed to return is undocumented and (hopefully) unused
- EXTRA_ITEM_ID: if you are implementing "enqueue" support, this will be the item ID (String) for managing this item in the queue of available items. If you are not supporting a playback queue, then what you are supposed to return is undocumented and (hopefully) unused

- EXTRA_ITEM_STATUS: this should point to a Bundle created from a MediaItemStatus object where you indicate what the status is of the playback of this item

You create a MediaItemStatus object via a MediaItemStatus.Builder, where you can pass into the constructor a value indicating the overall status (e.g., MediaItemStatus.PLAYBACK_STATE_PLAYING), plus use fluent setter methods to define additional characteristics of the status, such as the current seek position.

The DemoRouteController logic for ACTION_PLAY, in the onPlayRequest() method, logs the event to LogCat and crafts a valid-but-meaningless result Bundle for use with onResult():

```
private boolean onPlayRequest(Intent i, ControlRequestCallback cb) {
  Log.d(getClass().getSimpleName(), "play: "
      + i.getData().toString());

  MediaItemStatus.Builder statusBuilder=
      new MediaItemStatus.Builder(
                                  MediaItemStatus.PLAYBACK_STATE_PLAYING);

  Bundle b=new Bundle();

  b.putString(MediaControlIntent.EXTRA_SESSION_ID, DemoRouteProvider.DEMO_SESSION_ID);
  b.putString(MediaControlIntent.EXTRA_ITEM_ID, DemoRouteProvider.DEMO_ITEM_ID);
  b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
              statusBuilder.build().asBundle());

  cb.onResult(b);

  return(true);
}
```

Pause, Resume, and Stop

The Bundle passed to onResult() of the ControlRequestCallback, when the action is ACTION_PAUSE, ACTION_RESUME, or ACTION_STOP, does not need any particular values at the present time. Hence, the DemoRouteController methods for those actions just log the event to LogCat and pass an empty Bundle to onResult():

```
private boolean onPauseRequest(Intent i, ControlRequestCallback cb) {
  Log.d(getClass().getSimpleName(), "pause");

  cb.onResult(new Bundle());

  return(true);
}

private boolean onResumeRequest(Intent i, ControlRequestCallback cb) {
  Log.d(getClass().getSimpleName(), "resume");
```

```
    cb.onResult(new Bundle());

    return(true);
  }

  private boolean onStopRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "stop");

    cb.onResult(new Bundle());

    return(true);
  }
```

Get Status and Seek

The `Bundle` passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_GET_STATUS` or `ACTION_SEEK`, must contain the same sort of `MediaItemStatus`-built nested `Bundle` representing the current status. For `ACTION_GET_STATUS`, the only “work” to be done is to pass back the status; for `ACTION_SEEK`, you should move the playback position to the location indicated by an extra on the `Intent`, then return the revised status.

In the case of `DemoRouteController`, both just log a message to LogCat and return a fairly pointless status:

```
  private boolean onGetStatusRequest(Intent i,
                                     ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "get-status");

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
                                   MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
                statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
  }

  private boolean onSeekRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "seek");

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
                                   MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();
    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
                statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
  }
```

Publishing the Controller

While we have defined our `RouteController`, we still need to teach our `MediaRouteProvider` about it. That is through overriding the `onCreateRouteController()` method and returning an instance of `RouteController`:

```
  @Override
  public RouteController onCreateRouteController(String routeId) {
    return(new DemoRouteController());
  }
```

`onCreateRouteController()` is passed the route ID `String` used in the `MediaRouteDescriptor`. You can either use that to instantiate a different `RouteProvider`, pass the `String` into a common `RouteProvider` so it knows what to do, or ignore it entirely if you have only one published route. In the case of `DemoRouteProvider`, we ignore the route ID and always return a `DemoRouteController`.

Handling Discovery Requests

`DemoRouteProvider` is always available, largely because it does not do much of anything.

In the real world, your `MediaRouteProvider` may not always be relevant. For example, the TV you are set up to talk to may be powered down. Or, the user may not be at home where the TV is, so the client device and the TV are not on the same network.

Rather than constantly polling the outside world to see if a route is possible, we only do this when a client app requests “route discovery”, such as by providing the `MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY` flag on an `addCallback()` call to a `MediaRouter`. That in turn triggers an `onDiscoveryRequestChanged()` call on our `MediaRouteProvider`.

There, and in our constructor-triggered setup, we should do work to determine if a route is currently possible and set up our descriptors. This work should be done in a background thread if it involves network I/O.

Note that `onDiscoveryRequestChanged()` is passed a `MediaRouteDiscoveryRequest` object, describing what the consuming app is looking for. If the request is irrelevant for your provider (e.g., the app wants a local audio route, and you provide remote playback routes), simply ignore it.

The `onDiscoveryRequestChanged()` implementation in `DemoRouteProvider` just calls the same `handleDiscovery()` method that the constructor does.

Consuming the MediaRouteProvider

Having a `MediaRouteProvider` is nice, but it is useless if apps are not going to know about it.

You have two main options for consuming the `MediaRouteProvider`: use it only within your own app, or publish it to all apps on the device.

Private Provider

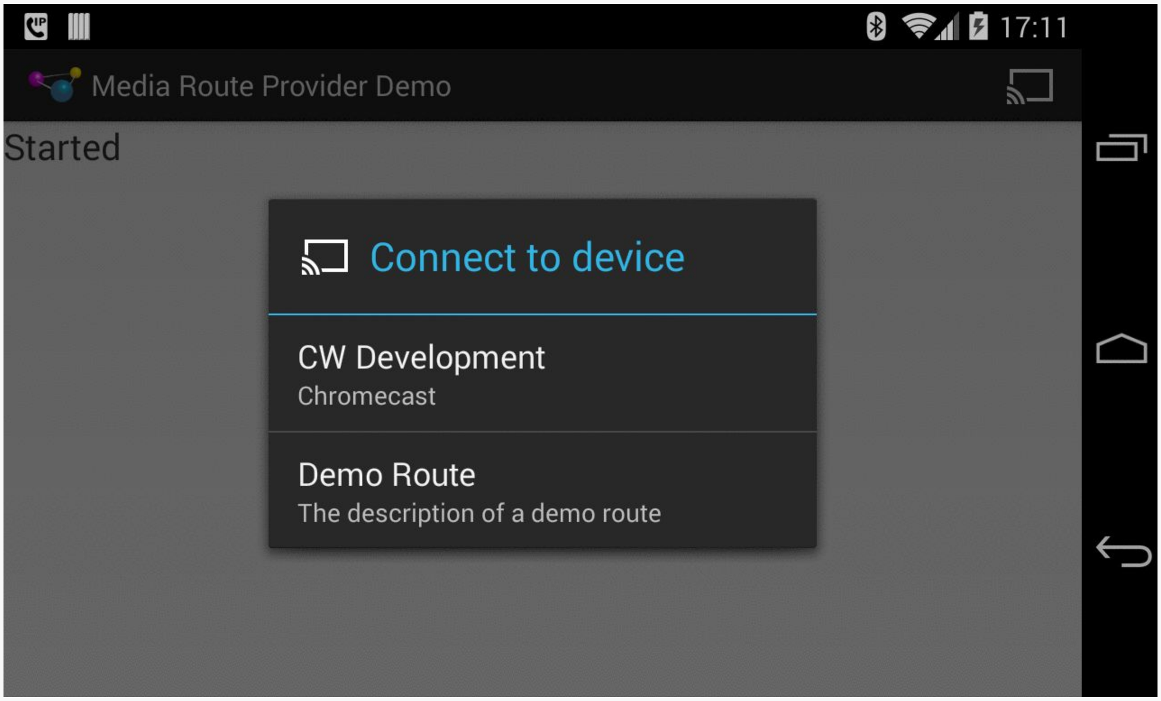
Using a `MediaRouteProvider` for your own app is very simple. Just add a single call to `addProvider()` on your `MediaRouter`, supplying an instance of your `MediaRouteProvider`.

Since our sample project is a fork of the original `RemotePlaybackClient` sample, we still have a `PlaybackFragment` that sets up the `MediaRouter` and `MediaRouteActionProvider`. In `onAttach()` of that `PlaybackFragment`, we can configure our `MediaRouterProvider` after obtaining the `MediaRouter` instance:

```
@Override
public void onAttach(Activity host) {
  super.onAttach(host);

  router=MediaRouter.getInstance(host);
  provider=new DemoRouteProvider(getActivity());
  router.addProvider(provider);
}
```

At this point, our `DemoRouteProvider` will be available as an option for the user, along with any other eligible media routes:



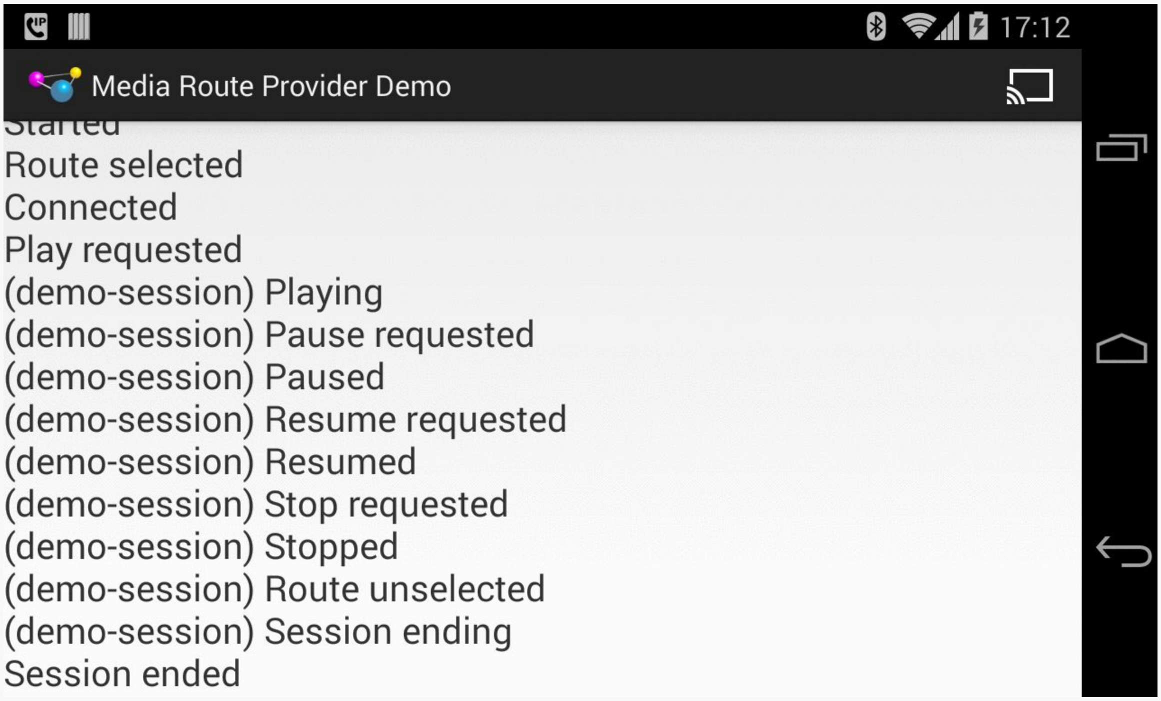
Connect to device

CW Development
Chromecast

Demo Route
The description of a demo route

Figure 718: MediaRouteProvider Demo, on a Nexus 4, Showing Available Routes

Choosing the `DemoRouteProvider` ("Demo Route" in the screenshot) will allow you to use it just like you do a Chromecast… if you do not mind the fact that nothing shows up on your television:



Started
Route selected
Connected
Play requested
(demo-session) Playing
(demo-session) Pause requested
(demo-session) Paused
(demo-session) Resume requested
(demo-session) Resumed
(demo-session) Stop requested
(demo-session) Stopped
(demo-session) Route unselected
(demo-session) Session ending
Session ended

Figure 719: MediaRouteProvider Demo, on a Nexus 4, After Several Commands

As it turns out, the `DemoRouteProvider` works better than Google's own `MediaRouteProvider` for the Chromecast, insofar as more of the callbacks work. Specifically, we actually receive callbacks for pause, resume, and stop events, as opposed to having to just assume that those events completed.

Also, we remove the demo provider in `onDetach()`:

```
@Override
public void onDetach() {
  router.removeProvider(provider);

  super.onDetach();
}
```

Among other things, this allows us to correctly handle configuration changes — if we fail to call `removeProvider()` and blindly add another provider in `onAttach()`, we wind up with multiple providers, because our `MediaRouter` is a framework-provided singleton and is not re-created with the new fragment.

Public Provider

If you want your MediaRouteProvider to be used by other apps, you will need to create one more Java class: a subclass of MediaRouteProviderService. This requires only one method, onCreateMediaRouteProvider(), where you return an instance of your MediaRouteProvider:

```
package com.commonsware.android.mrp;

import android.support.v7.media.MediaRouteProvider;
import android.support.v7.media.MediaRouteProviderService;

public class DemoRouteProviderService extends MediaRouteProviderService {
  @Override
  public MediaRouteProvider onCreateMediaRouteProvider() {
    return(new DemoRouteProvider(this));
  }
}
```

This also needs to be added to your manifest, like any other Service. Give it an <intent-filter> looking for the android.media.MediaRouteProviderService action, so the media routing framework knows that it can obtain a MediaRouteProvider from it:

```
<service
  android:name="DemoRouteProviderService"
  tools:ignore="ExportedService">
  <intent-filter>
    <action android:name="android.media.MediaRouteProviderService"/>
  </intent-filter>
</service>
```

However, do *not* do both addProvider() *and* have the <service> element. If you use the <service> element, your app can use the MediaRouteProvider, just as can any other app on the device. Hence, in the published source code for this sample, the <service> element is commented out — you will need to uncomment it, and comment out the addProvider() call, to test the DemoRouteProvider with other apps.

Implementing This "For Realz"

Of course, DemoRouteProvider is just a demo and does not actually play any media anywhere. It is here to give you the basic steps for responding to RemotePlaybackClient requests. For a production MediaRouteProvider, in addition to the usual tightening-up of the code (e.g., better exception handling), you will need to work on other areas as well, ones that are beyond the scope of the sample app.

Communicating with the Playback Device

Of course, the big one is passing the actions over to the playback device, so you actually *do* play back media.

If you are the developer of the playback device and its protocols (e.g., it is an Android device, and you are writing the playback app for it), then you can choose how you wish to handle the communications. You can work with low-level socket protocols directly, or you can leverage libraries like AllJoyn or ZeroMQ.

If the playback device "is what it is", and you cannot change it, then you will need to determine what protocols it offers and how best to map the `MediaControlIntent` actions to that protocol.

Also note that `onControlRequest()` is designed for asynchronous operation. The sample app just invoked the `ControlRequestCallback` during the `onControlRequest()` processing. Usually, though, your communications with the playback device will not be as fast as a call to `Log.d()`. You should arrange to do those communications in a background thread, perhaps via a single-thread thread pool as an `ExecutorService`. Simply pass the `ControlRequestCallback` to that thread along with the rest of the action's data (e.g., the URL of the media to load), and the thread can call `onResult()` or `onError()` as needed.

Handling Other Actions/Protocols

As was noted in the description of the sample app, that app eschews:

- volume control
- session management
- queue management

Any of those may be of interest to your users, and so you may need to consider offering them at some point. Also note that some potential client apps might need those capabilities and therefore will not see or use your published media routes without them.

Custom Actions

When setting up the MediaRouteProvider, we create one or more MediaRouteDescriptor objects wrapped around one or more IntentFilter objects. Those IntentFilter objects indicate what actions we support. The DemoRouteProvider uses standard actions (e.g., ACTION_PLAY) in a standard category (CATEGORY_REMOTE_PLAYBACK).

However, you are not limited to that.

You are welcome to also support custom actions in a custom category, to represent other things that your particular MediaRouteProvider offers. You can then use those actions from your own client app, or document them for use by third-party apps.

The client app can use supportsControlRequest() and sendControlRequest() to determine whether a particular media route supports a particular Intent that represents an action to be performed by that route's MediaRouteProvider. This way, a client app can work both with your custom MediaRouteProvider (taking advantage of your custom actions) and with regular providers that lack such support, assuming that the client can gracefully degrade its functionality.

Google's sample app defines a custom ACTION_GET_STATISTICS action that their sample client requests where available and their sample provider implements.

Screenshots and Screen Recordings

Android 5.0 debuted the ability for Android apps to take screenshots of whatever is in the foreground. It further allows apps to record full-resolution video of whatever is in the foreground, for screencasts, product demo videos, and the like. For whatever reason, this is called "media projection", and is based around classes like `MediaProjectionManager`.

In this chapter, we will explore how to use the media projection APIs to record screenshots and screencast-style videos.

Prerequisites

Understanding this chapter requires that you have read the core chapters, plus the chapter on embedding a Web server in your app for debug and diagnostic purposes.

Having read the chapter on using the camera APIs would not be a bad idea, particularly for video recording, though it is not essential.

Requesting Screenshots

Here, "screenshot" (or "screen capture") refers to generating an ordinary image file (e.g., PNG) of the contents of the screen. Most likely, you have created such screenshots yourself for a desktop OS (e.g., using the PrtSc key on Windows or Linux). Android's development tools allow you to take screenshots of devices and emulators, and there is a cumbersome way for users to take screenshots using the volume and power keys.

The media projection APIs allow you to take a screenshot of whatever is in the foreground… which does not necessarily have to be your own app. Indeed, you can take screenshots of any app, plus of system-supplied UI, such as the pull-down notification shade.

Not surprisingly, this has privacy and security issues. As such, in order to be able to take screenshots, the user must agree to allow it. In particular, instead of a durable permission that the user might grant once and forget about, the user has to agree to allow your app to take screenshots every time you want to do so.

Introducing andprojector

In 2009, the author of this book wrote a utility called DroidEx. This tool ran on a desktop or notebook and served as a "software projector" for an Android device, as opposed to the hardware projectors (e.g., ELMO) usually needed to show an Android screen to a large audience. Under the covers, DroidEx used the same protocol that Android Studio and DDMS use for screenshots, requesting screenshots as fast as possible, drawing them to a Swing `JFrame`. Later, Jens Riboe took DroidEx a bit further, adding more of a Swing control UI, in the form of Droid@Screen.

The `MediaProjection/andprojector` sample project has the same objective as did DroidEx: be able to show the contents of an Android screen to an audience. Nowadays, you might be able to do that straight from hardware, using things like an MHL->HDMI adapter. However, sometimes that option is not available (e.g., the projector you are using for your notebook is limited to VGA). andprojector differs from DroidEx in a few key ways:

- It is an Android app, not a program that you run on your notebook, and so it can be used without a notebook that has the Android SDK on it (which DroidEx required)
- It "projects" the screen using an embedded Web server to push PNG files to a Web browser, as opposed to DroidEx's use of a Swing `JFrame` to display the projection in a desktop OS window
- It uses the media projection APIs, which is the point of this chapter

On the device, the UI resembles that of the Web server apps profiled elsewhere in this book. When launched, the screen is mostly empty, except for a phone action bar item:

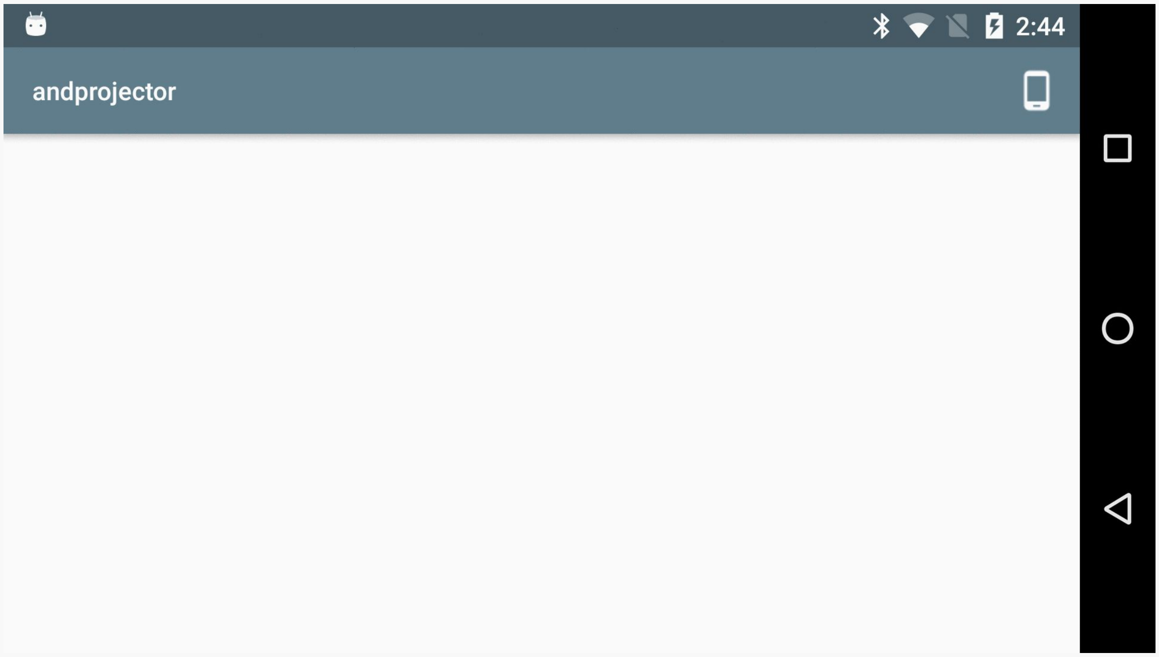


Figure 720: andprojector, As Initially Launched

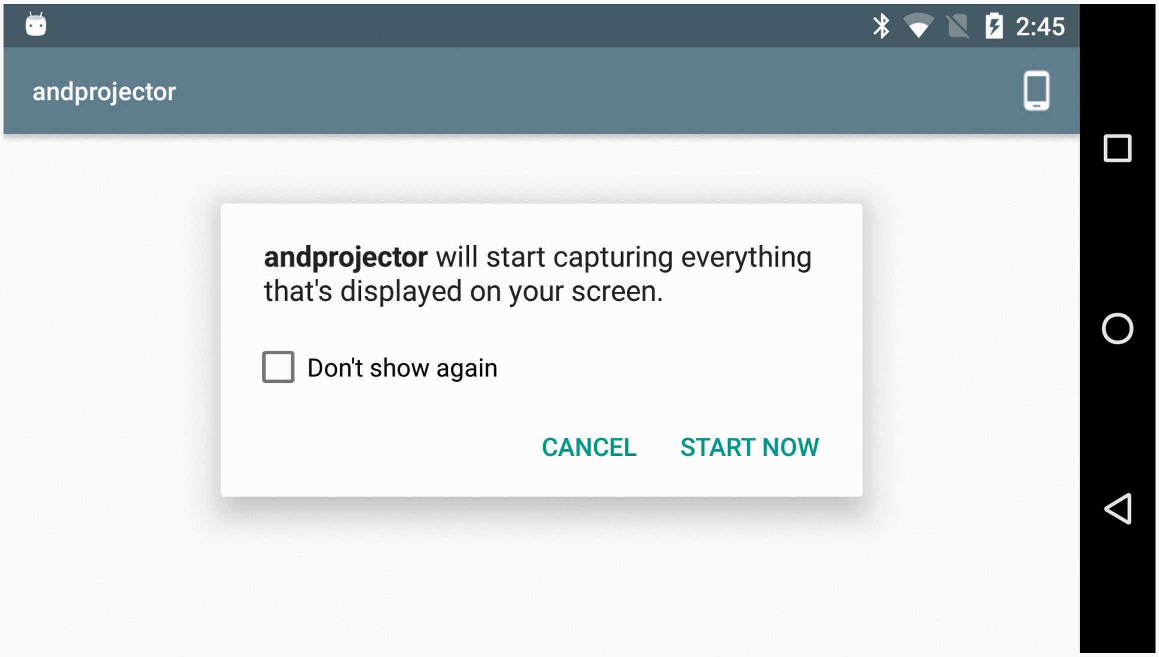
When you tap the action bar item, a system-supplied dialog appears, asking for permission to take screenshots:

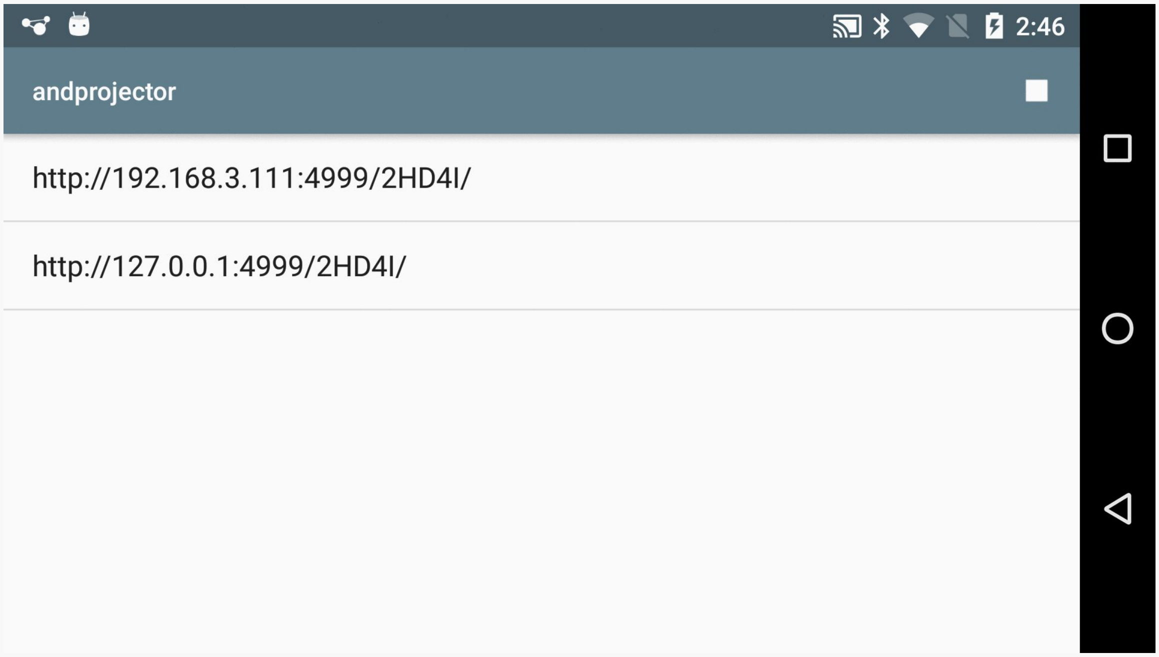


andprojector will start capturing everything that's displayed on your screen.

☐ Don't show again

Figure 721: andprojector, Showing Permission Dialog

If you grant permission, you will see URLs that can be used to view what is on the device screen:



http://192.168.3.111:4999/2HD4I/

http://127.0.0.1:4999/2HD4I/

Figure 722: andprojector, Showing URLs

Entering one of those (including the trailing slash!) in a Web browser on some other machine on the same WiFi network will cause it to start showing the contents of the device screen. This can be done in either orientation, though it tends to work better in landscape.

Clicking the "stop" action bar item — which replaced the device action bar item when permission was granted — will stop the presentation and return the app to its original state.

With that in mind, let's see how andprojector pulls off this bit of magic.

Asking for Permission

In the `MainActivity` that houses our UI, in `onCreate()`, we get our hands on a `MediaProjectionManager` system service, in addition to fussing with Material-style coloring for the status bar:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  Window window=getWindow();
  window.addFlags(WindowManager.LayoutParams.FLAG_DRAWS_SYSTEM_BAR_BACKGROUNDS);
  window.clearFlags(WindowManager.LayoutParams.FLAG_TRANSLUCENT_STATUS);
  window.setStatusBarColor(
    getResources().getColor(R.color.primary_dark));

  mgr=(MediaProjectionManager)getSystemService(MEDIA_PROJECTION_SERVICE);
}
```

`MediaProjectionManager`, at the time of this writing (October 2015), has a grand total of *two* methods. When the user taps on the device action bar item, we invoke fully 50% of the `MediaProjectionManager`, calling `createScreenCaptureIntent()`. This will return an `Intent`, designed to be used with `startActivityForResult()`, that brings up the screenshot permission dialog:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
  if (item.getItemId()==R.id.start) {
    startActivityForResult(mgr.createScreenCaptureIntent(),
        REQUEST_SCREENSHOT);
  }
  else {
    stopService(new Intent(this, ProjectorService.class));
  }

  return super.onOptionsItemSelected(item);
}
```

In `onActivityResult()`, if our request for permission was granted, we pass the details along via `Intent` extras to a `ProjectorService` that we start using `startService()`:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
  if (requestCode==REQUEST_SCREENSHOT) {
    if (resultCode==RESULT_OK) {
      Intent i=
          new Intent(this, ProjectorService.class)
              .putExtra(ProjectorService.EXTRA_RESULT_CODE,
                resultCode)
              .putExtra(ProjectorService.EXTRA_RESULT_INTENT,
                data);

      startService(i);
    }
  }
}
```

The rest of the `MainActivity` is mostly doing the same sort of work as was seen in the sample apps from the chapter on embedding a Web server, including populating the `ListView` with the URLs for our projection.

Creating the MediaProjection

`ProjectorService` extends `WebServerService`, our reusable embedded Web server. However, most of its business logic — along with code extracted into a separate `ImageTransmogrifier` — involves fetching screenshots using the media projection APIs, generating PNGs for them, and pushing them over to the Web browser.

In `onCreate()` of `ProejctorService`, we:

- get our hands on a `MediaProjectionManager` and a `WindowManager` system service
- set up a `HandlerThread` and create an associated `Handler` for it, as the media projection process wants a `Handler`

```
  @Override
  public void onCreate() {
    super.onCreate();

    mgr=(MediaProjectionManager)getSystemService(MEDIA_PROJECTION_SERVICE);
    wmgr=(WindowManager)getSystemService(WINDOW_SERVICE);

    handlerThread.start();
    handler=new Handler(handlerThread.getLooper());
  }
```

That `HandlerThread` is created in an initializer, since it does not directly depend on a `Context`:

```
  final private HandlerThread handlerThread=new
HandlerThread(getClass().getSimpleName(),
      android.os.Process.THREAD_PRIORITY_BACKGROUND);
```

In `onStartCommand()`, we then use the remaining 50% of the `MediaProjectionService` API to get a `MediaProjection`, using the values that were passed to `onActivityResult()` from our permission request which, in turn, were passed to `ProjectorService` via `Intent` extras:

```
    projection=
        mgr.getMediaProjection(i.getIntExtra(EXTRA_RESULT_CODE, -1),
            (Intent)i.getParcelableExtra(EXTRA_RESULT_INTENT));
```

We then create an instance of `ImageTransmogrifier`, passing in the `ProjectorService` itself as a constructor parameter:

```
    it=new ImageTransmogrifier(this);
```

ImageTransmogrifier, in its constructor, sets about determining the screen size (using WindowManager and getDefaultDisplay()). Since high-resolution displays will wind up with *very* large bitmaps, and therefore slow down the data transfer, we scale the width and height until such time as each screenshot will contain no more than 512K pixels.

```
public class ImageTransmogrifier implements ImageReader.OnImageAvailableListener {
  private final int width;
  private final int height;
  private final ImageReader imageReader;
  private final ProjectorService svc;
  private Bitmap latestBitmap=null;

  ImageTransmogrifier(ProjectorService svc) {
    this.svc=svc;

    Display display=svc.getWindowManager().getDefaultDisplay();
    Point size=new Point();

    display.getSize(size);

    int width=size.x;
    int height=size.y;

    while (width*height > (2<<19)) {
      width=width>>1;
      height=height>>1;
    }

    this.width=width;
    this.height=height;

    imageReader=ImageReader.newInstance(width, height,
        PixelFormat.RGBA_8888, 2);
    imageReader.setOnImageAvailableListener(this, svc.getHandler());
  }
```

Finally, we create a new ImageReader, which boils down to a class that manages a bitmap Surface that can be written to, using our specified width, height, and bit depth. In particular, we are saying that there are two possible outstanding bitmaps at a time, courtesy of the 2 final parameter, and that we should be notified when a new image is ready, by registering the ImageTransmogrifier as the listener. The Handler is used so that we are informed about image availability on our designated background HandlerThread.

Back over in ProjectorService, we then as the MediaProjection to create a VirtualDisplay, tied to the ImageTransmogrifier and its ImageReader:

```
    vdisplay=projection.createVirtualDisplay("andprojector",
        it.getWidth(), it.getHeight(),
        getResources().getDisplayMetrics().densityDpi,
        VIRT_DISPLAY_FLAGS, it.getSurface(), null, handler);
```

We need to provide:

- a name for this virtual display, primarily for logging purposes
- the size of the virtual display, in terms of width and height, where we use the scaled width and height computed by the `ImageTransmogrifier`
- the density of the virtual display, which we set to match the density of the actual device screen
- a set of flags (`VIRT_DISPLAY_FLAGS`), where the magic values that seem to work are `VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY` and `VIRTUAL_DISPLAY_FLAG_PUBLIC`:

```
  static final int VIRT_DISPLAY_FLAGS=
      DisplayManager.VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY |
      DisplayManager.VIRTUAL_DISPLAY_FLAG_PUBLIC;
```

- a `Surface` representing the virtual display, in this case retrieved from the `ImageReader` inside the `ImageTransmogrifier`

```
  Surface getSurface() {
    return(imageReader.getSurface());
  }
```

- an optional `VirtualDisplay.Callback` to be notified about events in the lifecycle of the `VirtualDisplay` (unused here, so we pass `null`)
- a `Handler` from a `HandlerThread`, to be used for that callback (presumably unused here, but since we have the right `Handler` anyway, we use it)

We also need to know about events surrounding the `MediaProjection` itself, so we create and register a `MediaProjection.Callback`, as part of the full `onStartCommand()` implementation:

```
  @Override
  public int onStartCommand(Intent i, int flags, int startId) {
    projection=
        mgr.getMediaProjection(i.getIntExtra(EXTRA_RESULT_CODE, -1),
            (Intent)i.getParcelableExtra(EXTRA_RESULT_INTENT));

    it=new ImageTransmogrifier(this);

    MediaProjection.Callback cb=new MediaProjection.Callback() {
      @Override
      public void onStop() {
        vdisplay.release();
      }
    };
    vdisplay=projection.createVirtualDisplay("andprojector",
        it.getWidth(), it.getHeight(),
        getResources().getDisplayMetrics().densityDpi,
        VIRT_DISPLAY_FLAGS, it.getSurface(), null, handler);
    projection.registerCallback(cb, handler);

    return(START_NOT_STICKY);
  }
```

And, at this point, the device will start collecting screenshots for us.

Processing the Screenshots

Of course, it would be useful if we could actually receive those screenshots and do something with them.

We find out when when a screenshot is available via the `ImageReader.Callback` we set up in `ImageTransmogrifier`, specifically its `onImageAvailable()` callback. Since `ImageTransmogrifier` itself is implementing the `ImageReader.Callback` interface, `ImageTransmogrifier` has the `onImageAvailable()` implementation:

```
  @Override
  public void onImageAvailable(ImageReader reader) {
    final Image image=imageReader.acquireLatestImage();

    if (image!=null) {
      Image.Plane[] planes=image.getPlanes();
      ByteBuffer buffer=planes[0].getBuffer();
      int pixelStride=planes[0].getPixelStride();
      int rowStride=planes[0].getRowStride();
      int rowPadding=rowStride - pixelStride * width;
      int bitmapWidth=width + rowPadding / pixelStride;

      if (latestBitmap == null ||
          latestBitmap.getWidth() != bitmapWidth ||
          latestBitmap.getHeight() != height) {
        if (latestBitmap != null) {
          latestBitmap.recycle();
        }

        latestBitmap=Bitmap.createBitmap(bitmapWidth,
            height, Bitmap.Config.ARGB_8888);
      }

      latestBitmap.copyPixelsFromBuffer(buffer);

      if (image != null) {
        image.close();
      }

      ByteArrayOutputStream baos=new ByteArrayOutputStream();
      Bitmap cropped=Bitmap.createBitmap(latestBitmap, 0, 0,
        width, height);
      cropped.compress(Bitmap.CompressFormat.PNG, 100, baos);

      byte[] newPng=baos.toByteArray();

      svc.updateImage(newPng);
    }
  }
```

This is complex.

First, we ask the `ImageReader` for the latest image, via `acquireLatestImage()`. If, for some reason, there is no image, there is nothing for us to do, so we skip all the work.

Otherwise, we have to go through some gyrations to get the actual bitmap itself from `Image` object. The recipe for that probably makes sense to somebody, but that "somebody" is not the author of this book. Suffice it to say, the first six lines of the main `if` block in `onImageAvaialble()` get access to the bytes of the bitmap (as a `ByteBuffer` named `buffer`) and determine the width of the bitmap that was handed to us (as an `int` named `bitmapWidth`).

Because `Bitmap` objects are large and therefore troublesome to allocate, we try to reuse one where possible. If we do not have a `Bitmap` (`latestBitmap`), or if the one we have is not the right size, we create a new `Bitmap` of the appropriate size. Otherwise, we use the `Bitmap` that we already have. Regardless of where the `Bitmap` came from, we use `copyPixelsFromBuffer()` to populate it from the `ByteBuffer` we got from the `Image.Plane` that we got from the `Image` that we got from the `ImageReader`.

You might think that this `Bitmap` would be the proper size. However, it is not. For inexplicable reasons, it will be a bit larger, with excess unused pixels on each row on the end. This is why we need to use `Bitmap.createBitmap()` to create a cropped edition of the original `Bitmap`, for our actual desired width.

We then `compress()` the cropped `Bitmap` into a PNG file, get the `byte` array of pixel data from the compressed result, and hand that off to the `ProjectorService` via `updateImage()`.

`updateImage()`, in turn, holds onto this most-recent PNG file in an `AtomicReference` wrapped around the `byte` array:

```
private AtomicReference<byte[]> latestPng=new AtomicReference<byte[]>();
```

This way, when some Web server thread goes to serve up this PNG file, we do not have to worry about thread contention with the `HandlerThread` we are using for the screenshots themselves.

Then, we iterate over all connected browsers' WebSocket connections and send a unique URL to them, where the uniqueness (from `SystemClock.uptimeMillis()`) is designed as a "cache-busting" approach to ensure the browser always requests the image

```
void updateImage(byte[] newPng) {
  latestPng.set(newPng);

  for (WebSocket socket : getWebSockets()) {
    socket.send("screen/"+Long.toString(SystemClock.uptimeMillis()));
  }
}
```

Those WebSockets are enabled by `ProjectorService` calling `serveWebSockets()` on its `WebServerService` superclass, in the `configureRoutes()` callback:

```
@Override
protected boolean configureRoutes(AsyncHttpServer server) {
  serveWebSockets("/ss", null);

  server.get(getRootPath()+"/screen/.*",
    new ScreenshotRequestCallback());

  return(true);
}
```

The `ScreenshotRequestCallback` is an inner class of `ProjectorService`, one that serves the PNG file itself in response to a request:

```
private class ScreenshotRequestCallback
    implements HttpServerRequestCallback {
  @Override
  public void onRequest(AsyncHttpServerRequest request,
                        AsyncHttpServerResponse response) {
    response.setContentType("image/png");

    byte[] png=latestPng.get();
    ByteArrayInputStream bais=new ByteArrayInputStream(png);

    response.sendStream(bais, png.length);
  }
}
```

The result is that, whenever a screenshot is ready, we create the PNG file and tell the browser "hey! we have an update!".

The HTML

The Web content that is served to the browser is reminiscent of the HTML and JavaScript used in the section on implementing WebSockets. There, the messages being pushed to the browser were timestamps, shown in a list. Here, the messages being pushed to the browser are URLs to load a fresh screenshot.

Hence, the HTML just has an `<img>` tag for that screenshot, with an `id` of `screen`, loading `screen/0` at the outset to bootstrap the display:

```
<html>
<head>
    <title>andprojector</title>
</head>
<body>
<img id="screen"
  style="height: 100%; width: 100%; object-fit: contain"
  src="screen/0">
<script src="js/app.js"></script>
</body>
</html>
```

The JavaScript registers for a WebSocket connection, then updates that `<img>` with a fresh URL when such a URL is pushed over to the browser:

```
window.onload = function() {
    var screen=document.getElementById('screen');
    var ws_url=location.href.replace('http://', 'ws://')+'ss';
    var socket=new WebSocket(ws_url);

    socket.onopen = function(event) {
      // console.log(event.currentTarget.url);
    };

    socket.onerror = function(error) {
      console.log('WebSocket error: ' + error);
    };

    socket.onmessage = function(event) {
      screen.src=event.data;
    };
}
```

Of course, in principle, there could be much more to the Web UI, including some ability to stop all of this when it is no longer needed. Speaking of which…

Shutting Down

The user can stop the screenshot collection and broadcasting either via the action bar item or the action in the `Notification` that is raised in support of the foreground service. In either case, in `onDestroy()`, in addition to chaining to `WebServerService` to shut down the Web server, `ProjectorService` stops the `MediaProjection`:

```
@Override
public void onDestroy() {
  projection.stop();

  super.onDestroy();
}
```

This should also trigger our `VirtualDisplay.Callback`, causing us to release the `VirtualDisplay`.

Dealing with Configuration Changes

However, there is one interesting wrinkle we have to take into account: what happens if the user rotates the screen? We need to update our `VirtualDisplay` and `ImageReader` to take into account the new screen height and width.

`ProjectorService` will be called with `onConfigurationChanged()` when any configuration change occurs. This could be due to a screen rotation or other triggers (e.g., putting the device into a car dock). So, we need to see if the screen height or width changed — if not, we do not need to do anything. So, we create a new `ImageTransmogrifier` and compare its height and width to the current height and width:

```
@Override
public void onConfigurationChanged(Configuration newConfig) {
  super.onConfigurationChanged(newConfig);

  ImageTransmogrifier newIt=new ImageTransmogrifier(this);

  if (newIt.getWidth()!=it.getWidth() ||
    newIt.getHeight()!=it.getHeight()) {
    ImageTransmogrifier oldIt=it;

    it=newIt;
    vdisplay.resize(it.getWidth(), it.getHeight(),
      getResources().getDisplayMetrics().densityDpi);
    vdisplay.setSurface(it.getSurface());

    oldIt.close();
    }
  }
```

If a dimension has changed, we tell the `VirtualDisplay` to resize to the new height and width, attach a new `Surface` from the new `ImageReader`, and switch over to the new `ImageTransmogrifier`, closing the old one.

This solution is not perfect — there is a bit of a race condition if a screenshot is taken while the configuration change is going on – but for a non-production-grade app it will suffice.

Recording the Screen

Here, a "screencast" refers to a full-motion video of what goes on the screen. You can think of it as a series of screenshots all written to one video file (e.g., an MP4). Many apps on the Play Store have screencasts as part of their product profile, so you can see what the app looks like when it is run.

Android's media projection APIs allow you to capture screencasts, using a mechanism similar to the one used to take screenshots. You have to ask permission from the user to be able to record the screen, and that permission will last for the duration of one screen recording. During that period of time, you can direct Android to make a duplicate copy of what goes on the screen to a video file. This winds up using the `MediaRecorder` API along with dedicated media projection APIs, which is a bit awkward, since `MediaRecorder` is really aimed at using the device camera to record videos of the world outside the device.

Jake Wharton, with his open source Telecine app, helped blaze the trail in how these APIs are supposed to work, since the documentation, as usual, is limited.

This chapter will examine a separate app, `MediaProjection/andcorder`, that offers screen recording through the media projection APIs. In the end, andcorder does the same basic stuff as does Telecine, with fewer bells and whistles. Also, the control channel is different: Telecine uses a screen overlay, while andcorder uses a foreground `Notification` or the command line.

Requesting Media Projection… Without a GUI

The andprojector sample app profiled earlier in this chapter used the media projection APIs, just as andcorder does. Both have to do the same work at the outset: ask the user for permission to record the screen. In the case of andprojector, while we had a foreground `Notification` to stop the projection, starting the projection was done through the andprojector activity, via an action bar item. The andcorder app, on the other hand, will demonstrate a different approach to this… and highlight a regression introduced in Android 6.0.

`MainActivity` is designed to be an invisible activity, like a few others used elsewhere in this book. We want a launcher icon in the home screen to be able to initialize the app, but we do not need an activity's UI to control it.

So, we skip the `setContentView()` call, and in `onCreate()` just callstartActivityForResult(), using theIntentsupplied by createScreenCaptureIntent()from aMediaProjectionManager`:

```java
package com.commonsware.android.andcorder;

import android.app.Activity;
import android.content.Intent;
import android.media.projection.MediaProjectionManager;
import android.os.Bundle;

public class MainActivity extends Activity {
  private static final int REQUEST_SCREENCAST=59706;
  private MediaProjectionManager mgr;

  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    mgr=(MediaProjectionManager)getSystemService(MEDIA_PROJECTION_SERVICE);

    startActivityForResult(mgr.createScreenCaptureIntent(),
      REQUEST_SCREENCAST);
  }

  @Override
  protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (requestCode==REQUEST_SCREENCAST) {
      if (resultCode==RESULT_OK) {
        Intent i=
            new Intent(this, RecorderService.class)
                .putExtra(RecorderService.EXTRA_RESULT_CODE, resultCode)
                .putExtra(RecorderService.EXTRA_RESULT_INTENT, data);

        startService(i);
      }
    }

    finish();
  }
}
```

In onActivityResult(), we just pass the data along to a RecorderService, which is responsible for starting and stopping the screen recording. Then, we finish() the activity, as it is no longer needed.

This looks simple enough. It even works well, on Android 5.0 and 5.1. On Android 6.0, though, we have some problems.

The activity is designed to be used with Theme.NoDisplay, as the other "invisible activity" book samples use. Most of those samples will work just fine on Android 6.0. In particular, a Theme.NoDisplay activity that does its work in onCreate() and then calls finish() should be just fine on Android 6.0.

But sometimes the work that needs to be done is a bit more involved than that. In particular, calling startActivityForResult(), with an eye towards calling finish() in onActivityResult(), will cause your app to crash with an IllegalStateException saying that your activity "did not call finish() prior to onResume() completing". This, apparently, is a requirement of Theme.NoDisplay activities on Android 6.0+.

So, we have to things a bit differently, to accommodate this undocumented regression in behavior.

Rather than refer to Theme.NoDisplay directly in the manifest, we refer to a custom Theme.Apptheme resource instead:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonsware.android.andcorder"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <application
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".MainActivity"
      android:theme="@style/AppTheme">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <service
      android:name=".RecorderService"
      android:exported="true"/>

  </application>
```

```
</manifest>
```

This custom theme inherits from `Theme.NoDisplay` by default, in `res/values/styles.xml`:

```
<resources>

  <style name="AppTheme" parent="android:Theme.NoDisplay">
  </style>

</resources>
```

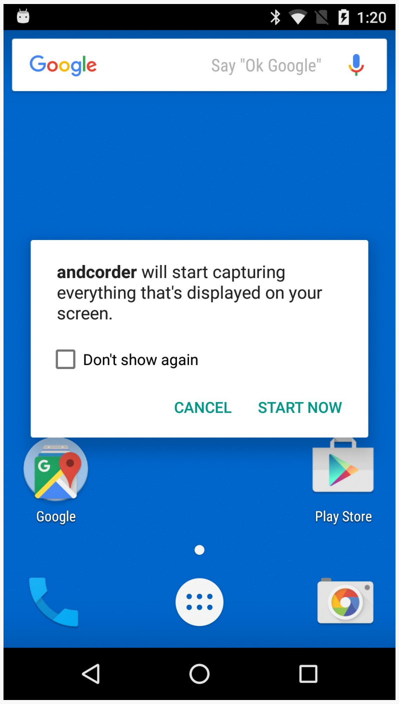
But, on Android 6.0 and higher (API Level 23+), it inherits from `Theme.Translucent.NoTitleBar`

```
<resources>

  <style name="AppTheme" parent="android:Theme.Translucent.NoTitleBar">
  </style>

</resources>
```

This gives the same basic visual result as using `Theme.NoDisplay`, but it behaves better on Android 6.0:



andcorder will start capturing everything that's displayed on your screen.

□ Don't show again

Figure 723: andcorder, As Initially Launched

Technically, this extra theme-related work is not necessary here, as the regression only occurs if your `targetSdkVersion` is set to 23 or higher. Right now, this project sets `targetSdkVersion` to 22. However, not only is the theme setup here to show you how to do it, but it also ensures that this app will survive having its `targetSdkVersion` increased in some future edition of this book, should that prove necessary.

Implementing a Control Channel… Without a GUI

We need to be able to tell andcorder to start and stop screen recording. If we are going to have an invisible activity, we need some other way to tell andcorder what it is supposed to do.

One approach used in andcorder is a `Notification`, tied to the foreground service that manages the actual screen recording.

We will use action strings, in the `Intent` used to start the `RecorderService`, to indicate what is to be done. Those action strings will be the application ID plus a segment at the end that is the specific operation we want:

```
static final String ACTION_RECORD=
  BuildConfig.APPLICATION_ID+".RECORD";
static final String ACTION_STOP=
  BuildConfig.APPLICATION_ID+".STOP";
static final String ACTION_SHUTDOWN=
  BuildConfig.APPLICATION_ID+".SHUTDOWN";
```

Here, we use `BuildConfig.APPLICATION_ID`, a faster, no-`Context` way to get our application ID, as part of building up these strings. We have three actions: to start recording (`RECORD`), to stop recording (`STOP`), and to shut down the `RecorderService` (`SHUTDOWN`). An `Intent` with *no* action string will be used on the initial launch of the service, from `MainActivity`.

`onStartCommand()` is where all of these commands, triggered by `startService()` calls, will come in:

```
@Override
public int onStartCommand(Intent i, int flags, int startId) {
  if (i.getAction()==null) {
    resultCode=i.getIntExtra(EXTRA_RESULT_CODE, 1337);
    resultData=i.getParcelableExtra(EXTRA_RESULT_INTENT);

    if (recordOnNextStart) {
      startRecorder();
    }

    foregroundify(!recordOnNextStart);
    recordOnNextStart=false;
  }
  else if (ACTION_RECORD.equals(i.getAction())) {
    if (resultData!=null) {
      foregroundify(false);
      startRecorder();
    }
    else {
      Intent ui=
        new Intent(this, MainActivity.class)
          .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK);

      startActivity(ui);
      recordOnNextStart=true;
    }
  }
  else if (ACTION_STOP.equals(i.getAction())) {
    foregroundify(true);
    stopRecorder();
  }
  else if (ACTION_SHUTDOWN.equals(i.getAction())) {
    stopSelf();
  }

  return(START_NOT_STICKY);
}
```

If we have no action string, this should be the command from `MainActivity`, so we grab the `resultCode` and `resultData` out of the `Intent` and stash them in simple fields on the service:

```
private int resultCode;
private Intent resultData;
private boolean recordOnNextStart=false;
```

We also:

- Call `startRecorder()` if `recordOnNextStart` is set to `true`
- Call `foregroundify()`, with a `boolean` that indicates whether we should give the user the option to begin recording (`true`) or to stop existing recording (`false`)
- Clear the `recordOnNextStart` flag

We will discuss more about that `recordOnNextStart`, its role, and why it exists, later in this chapter.

If, instead, a `RECORD` action string was on the `Intent`, then ideally we should begin recording the screen contents. The "ideally" part is because there will be scenarios in which the `RECORD` action is invoked before we actually have permission from the user to record the screen (more on this later).

So, if a `RECORD` action comes in, *and* we have permission from the user to record the screen (`resultData` is not `null`), we call `startRecorder()` to start recording, plus call `foregroundify()` to put up a `Notification` with an action for `STOP`. If, on the other hand, we do not presently have permission from the user (`resultData` is `null`), we start up `MainActivity` to get that permission, plus set `recordOnNextStart` to `true`.

The other two cases are simpler:

- If we get a `STOP Intent`, we call `stopRecorder()`, plus call `foregroundify()` to change the foreground service `Notification` to one that has an action for `RECORD`
- If we get a `SHUTDOWN Intent`, we call `stopSelf()` to go away entirely

`foregroundify()` is invoked for most of those cases, to put the service in the foreground (if it is not in the foreground already) and show a `Notification` with the appropriate mix of actions:

```
  private void foregroundify(boolean showRecord) {
    NotificationCompat.Builder b=
      new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL);

    b.setContentTitle(getString(R.string.app_name))
      .setSmallIcon(R.mipmap.ic_launcher)
      .setTicker(getString(R.string.app_name));

    if (showRecord) {
      b.addAction(R.drawable.ic_videocam_white_24dp,
        getString(R.string.notify_record), buildPendingIntent(ACTION_RECORD));
    }
    else {
      b.addAction(R.drawable.ic_stop_white_24dp,
        getString(R.string.notify_stop), buildPendingIntent(ACTION_STOP));
    }

    b.addAction(R.drawable.ic_eject_white_24dp,
      getString(R.string.notify_shutdown), buildPendingIntent(ACTION_SHUTDOWN));

    if (isForeground) {
      NotificationManager
mgr=(NotificationManager)getSystemService(NOTIFICATION_SERVICE);

      mgr.notify(NOTIFY_ID, b.build());
    }
    else {
      startForeground(NOTIFY_ID, b.build());
      isForeground=true;
    }
  }
```

In addition to generic NotificationCompat.Builder configuration, we:

- add an action to shut down the service, tied to the SHUTDOWN action string
- either add an action to RECORD or STOP the recording, based upon the boolean passed into foregroundify()
- either use startForeground() to move the service into the foreground and show the Notification or use NotificationManager to update the existing Notification (if we are already in the foreground)

The latter distinction may not be necessary. Calling startForeground() multiple times does not seem to have any harm, and it also updates the foreground Notification. Using NotificationManager directly for the already-in-the-foreground scenario, though, may be superfluous.

The addAction() calls delegate to a buildPendingIntent() method, to create the PendingIntent to be triggered when the action is tapped:

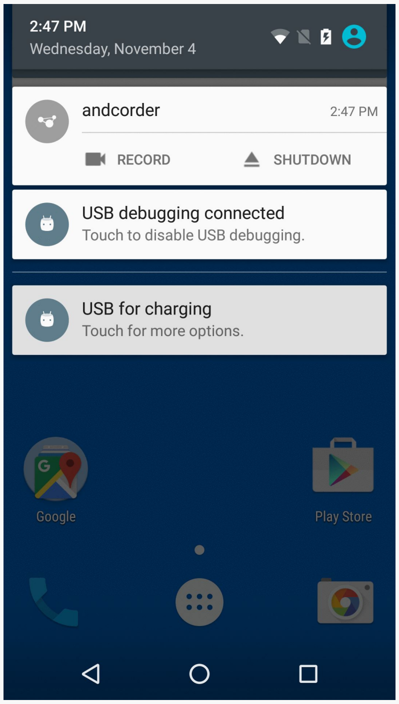
```
private PendingIntent buildPendingIntent(String action) {
  Intent i=new Intent(this, getClass());

  i.setAction(action);

  return(PendingIntent.getService(this, 0, i, 0));
}
```

This creates an explicit `Intent`, tied to `RecorderService` itself, but also adds the action string. This `Intent` will always resolve to our `RecorderService`; the action string is just part of the payload.

That foreground `Notification` provides the visual way of starting recording:



2:47 PM
Wednesday, November 4

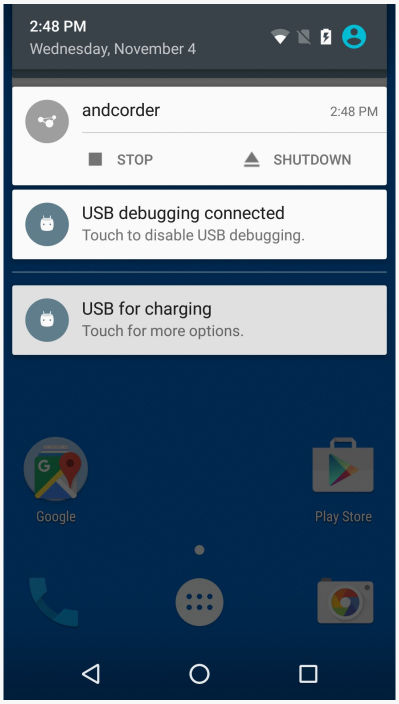
andcorder 2:47 PM

USB debugging connected
Touch to disable USB debugging.

USB for charging
Touch for more options.

Figure 724: andcorder Notification, Showing Record and Shutdown Actions

…and stopping recording once started:



2:48 PM
Wednesday, November 4

andcorder 2:48 PM
STOP SHUTDOWN

USB debugging connected
Touch to disable USB debugging.

USB for charging
Touch for more options.

Figure 725: andcorder Notification, Showing Stop and Shutdown Actions

In addition, `onDestroy()` stops the recording and removes us from the foreground, plus we have the obligatory `onBind()` implementation:

```
@Override
public void onDestroy() {
  stopRecorder();
  stopForeground(true);

  super.onDestroy();
}

@Override
public IBinder onBind(Intent intent) {
  throw new IllegalStateException("go away");
}
```

Using the Control Channel… From the Command Line

The downside of relying upon a foreground `Notification` is that the user has to interact with that `Notification` to start and stop the recording. As a result, that `Notification` — and the rest of the notification tray — will be visible at the beginning and the end of the recording. While this could be addressed by editing the video, video editors can be difficult to use. It would be nice to be able to operate andcorder without affecting the screen.

Fortunately, we can, courtesy of `adb`.

As is covered in the chapter on ADB, it is possible to use the `adb shell am` command to start an activity, start a service, and send a broadcast. In this case, since we are using a service for managing the recording process, we can use `adb shell am` to trigger the same actions that the `Notification` does.

This, however, requires that our `RecorderService` be exported. For the `PendingIntent` objects used in the `Notification`, we would not need to export the service. Invoking the service from the command line, however, does require an exported service, since the command line is not the app itself and therefore is considered to be a third-party client of the app. Moreover, there is no obvious way to validate that the commands were sent from `adb shell am`, which means that when andcorder is installed, any app could send commands to `RecorderService`.

From a security standpoint, this is not great. The user still has to be involved to grant permission to record the screen, which limits the security risk a little bit. However, in general, **you should not run andcorder on your own personal device**, due to this security hole. Or, at minimum, run andcorder, then uninstall it immediately when you are done with it, so it does not linger where malware might try to use it.

The andcorder project contains three `bash` scripts to invoke the `RecorderService`. These should be able to be trivially converted to Windows command files; the proof of this is left as an exercise for the reader.

All three scripts use `adb shell am startservice`, and all point to the same component (`-n com.commonsware.android.andcorder/.RecorderService`). What varies is the action string supplied to the `-a` switch.

NOTE: the shell script code listings are word-wrapped due to line length limitations in the books; the files themselves have the `adb shell` commands all on one line.

So, the `record` script, for example, passes `com.commonsware.android.andcorder.RECORD` as the action string:

```
#!/bin/bash
```

```
adb shell am startservice -n com.commonsware.android.andcorder/.RecorderService
-a com.commonsware.android.andcorder.RECORD
```

The `stop` script passes the `STOP` action string; the `shutdown` script passes the `SHUTDOWN` action string.

These, therefore, replicate the `Intent` structures used in the `PendingIntent` objects for the `Notification` actions.

However, there is one key usage difference: it would be nice to be able to run the `record` script without having to think about whether or not you ran andcorder from the home screen launcher or not. The `RECORD` action cannot actually do the recording without the result data from the `startActivityForResult()` call in `MainActivity`.

This is why the `RECORD` action logic detects this case and starts up `MainActivity` — so we can can just run the `record` script and, if we do not presently have screen-recording permission, request it from the user.

The `recordOnNextStart` flag indicates whether or not `RECORD` started up `MainActivity`. If it did, when we get the result data in the no-action `onStartCommand()` call, we should go ahead and begin recording. This prevents the user from having to run the `record` script twice, once to pop up the permission dialog and once to actually begin recording.

Starting the Recording

The `startRecorder()` method on `RecorderService` is called when it is time to begin screen recording, either because the user asked us to record just now or the user asked us to record (via the command-line script) and we just now got permission from the user to do that.

```
  synchronized private void startRecorder() {
    if (session==null) {
      MediaProjectionManager mgr=
        (MediaProjectionManager)getSystemService(MEDIA_PROJECTION_SERVICE);
      MediaProjection projection=
        mgr.getMediaProjection(resultCode, resultData);

      session=
        new RecordingSession(this, new RecordingConfig(this),
          projection);
      session.start();
    }
  }
```

Here, as with the andprojector sample, we use a `MediaProjectionManager` to turn the `resultCode` `int` and `resultData` `Intent` into a `MediaProjection`. Then, we create a `RecordingSession`, wrapped around a `RecordingConfig` and the `MediaProjection`, and call `start()` on the `RecordingSession`.

Both `RecordingSession` and `RecordingConfig` are classes that are part of the app, not the Android SDK. `RecordingConfig` holds onto information about the nature of what is being recorded (notably, the video resolution) to capture. `RecordingSession` handles the stateful work of actually recording the video.

Of the two, you might expect `RecordingSession` to be far more complex. In truth, it is decidedly more straightforward than is `RecordingConfig`. Determining the resolution and other information about our screen recording is annoyingly complicated.

Deciding How Big Our Recording Is

The job of `RecordingConfig` is to derive and hold onto five pieces of data regarding the screen recording that we are about to initiate:

- The width and height of the video, in pixels
- The bit rate at which the video should be recorded
- The frame rate (frames per second) at which the video should be recorded
- The screen density

These are held in five `final int` fields, as `RecordingConfig` is designed to be immutable:

```
final int width;
final int height;
final int frameRate;
final int bitRate;
final int density;
```

All five of these values will be initialized in the constructor (since they are `final`). In fact, all the business logic for `RecordingSession` is just in the constructor, to derive these five values.

That constructor starts off simple enough:

```
RecordingConfig(Context ctxt) {
  DisplayMetrics metrics=new DisplayMetrics();
  WindowManager wm=(WindowManager)ctxt.getSystemService(Context.WINDOW_SERVICE);
```

```
    wm.getDefaultDisplay().getRealMetrics(metrics);

    density=metrics.densityDpi;

    Configuration cfg=ctxt.getResources().getConfiguration();

    boolean isLandscape=
      (cfg.orientation==Configuration.ORIENTATION_LANDSCAPE);
```

Here, we:

- Populate a DisplayMetrics data structure, given a WindowManager
- Save the screen density in its final field
- Get the current Configuration and determine if we are in landscape mode or not

Where things start to get messy is with the other four fields, as they need to be populated based on the device's video recording capabilities. For various reasons, screen recording is actually handled mostly by MediaRecorder, the same class used to record videos from a device camera. Hence, we are limited by not only the actual resolution of the screen but by the capabilities of the video recording engine.

The classic way to handle this is by using CamcorderProfile objects. These standardize video recording support for various resolutions. We can find out which of these profiles the device supports and use that to help determine our video resolution, frame rate, and bitrate.

However, we also have to take into account the resolution of the screen itself. If MediaRecorder is capable of 1080p (1920 x 1080) video recording, but the device has a low-end WXGA (1280 x 800) screen, we will waste a lot of space recording that screen at 1080p. What we want is the smallest resolution that is bigger than the screen, to minimize wasted space while not losing data. If, for some reason, we do not have a CamcorderProfile that is bigger than the screen, we will have to settle for one that is as big as we can manage.

To that end, the CAMCORDER_PROFILES static field on RecordingConfig lists the major CamcorderProfile IDs, in descending order based on resolution:

```
  private static final int[] CAMCORDER_PROFILES={
    CamcorderProfile.QUALITY_2160P,
    CamcorderProfile.QUALITY_1080P,
    CamcorderProfile.QUALITY_720P,
    CamcorderProfile.QUALITY_480P,
    CamcorderProfile.QUALITY_CIF,
    CamcorderProfile.QUALITY_QVGA,
    CamcorderProfile.QUALITY_QCIF
  };
```

If we simply iterate over this list and choose either the first one we find, or one that is smaller yet is bigger than the screen, we will get the right `CamcorderProfile` for our use case:

```
    CamcorderProfile selectedProfile=null;

    for (int profileId : CAMCORDER_PROFILES) {
      CamcorderProfile profile=null;

      try {
        profile=CamcorderProfile.get(profileId);
      }
      catch (Exception e) {
        // not documented to throw anything, but does
      }

      if (profile!=null) {
        if (selectedProfile==null) {
          selectedProfile=profile;
        }
        else if (profile.videoFrameWidth>=metrics.widthPixels &&
          profile.videoFrameHeight>=metrics.heightPixels) {
          selectedProfile=profile;
        }
      }
    }
```

To get a `CamcorderProfile` given its ID, you call the static `get()` method on `CamcorderProfile`. This is supposed to return the `CamcorderProfile` if it is supported or `null` if it is not. In actuality, it may throw an exception if the profile is not supported, which is why we have to wrap the `get()` call in a `try/catch` block. Then, if profile exists, we hold onto it as the `selectedProfile` if either:

- `selectedProfile` is `null`, meaning this is the largest available profile, or
- the profile has a resolution bigger than the screen on both axes

If, after all that is done, we have a `null` `selectedProfile`, that means that *none* of the `CamcorderProfile` values were available. That is very strange, and rather than take a random guess as to what will work, we just blow up with an `IllegalStateException`. Obviously, a production-grade app would need to blow up more nicely.

Otherwise, we can collect our remaining data… which once again is more complex than you might expect:

```
    if (selectedProfile==null) {
      throw new IllegalStateException("No CamcorderProfile available!");
    }
    else {
      frameRate=selectedProfile.videoFrameRate;
      bitRate=selectedProfile.videoBitRate;

      int targetWidth, targetHeight;

      if (isLandscape) {
        targetWidth=selectedProfile.videoFrameWidth;
        targetHeight=selectedProfile.videoFrameHeight;
      }
      else {
        targetWidth=selectedProfile.videoFrameHeight;
        targetHeight=selectedProfile.videoFrameWidth;
      }

      if (targetWidth>=metrics.widthPixels &&
        targetHeight>=metrics.heightPixels) {
        width=metrics.widthPixels;
        height=metrics.heightPixels;
      }
      else {
        if (isLandscape) {
          width=targetHeight*metrics.widthPixels/metrics.heightPixels;
          height=targetHeight;
        }
        else {
          width=targetWidth;
          height=targetWidth*metrics.heightPixels/metrics.widthPixels;
        }
      }
    }
```

Getting the frame rate and the bitrate are easy enough, as they are just fields on the `CamcorderProfile`. Where things start to get strange is in determining what we should tell the `MediaRecorder` that we want recorded in terms of resolution.

Partly, this is a problem of orientation. `MediaRecorder` thinks that everything is recorded in landscape, but we may well want to record the screen held in portrait mode.

Partly, this is a problem of aspect ratios. There is no requirement that the `MediaRecorder` advertise support for resolutions that match the screen size, or even match the screen's aspect ratio. So, if the `MediaRecorder` is capable of recording our full screen, we ask it to record the full screen (as determined from the `DisplayMetrics`). If, however, we are on some odd device whose `MediaRecorder` is not capable of recording video at the screen's own resolution, we try to at least maintain the aspect ratio of the screen when deriving the resolution to use for recording.

The net of all that work is that we have the details of how we want the screen recording to be done, encapsulated in the RecordingConfig object, ready for use by the RecordingSession.

Actually Recording Stuff

None of that actually records the screen, though. That is the responsibility of the RecordingSession.

In the RecordingSession constructor, we:

- Hold onto the RecordingConfig and MediaProjection
- Hold onto the application Context, as we will need a Context later on
- Create an instance of a ToneGenerator to use for audible feedback about the state of the recording
- Create a File object pointing at our desired output: an andcorder.mp4 file in our app's portion of external storage

```
RecordingSession(Context ctxt, RecordingConfig config,
                 MediaProjection projection) {
  this.ctxt=ctxt.getApplicationContext();
  this.config=config;
  this.projection=projection;
  this.beeper=new ToneGenerator(
    AudioManager.STREAM_NOTIFICATION, 100);

  output=new File(ctxt.getExternalFilesDir(null), "andcorder.mp4");
  output.getParentFile().mkdirs();
}
```

The actual work to record the video is handled in the start() method on RecordingSession, where we set up the MediaRecorder and a VirtualDisplay, the latter being the same thing that we used in the andprojector sample:

```
void start() {
  recorder=new MediaRecorder();
  recorder.setVideoSource(MediaRecorder.VideoSource.SURFACE);
  recorder.setOutputFormat(MediaRecorder.OutputFormat.MPEG_4);
  recorder.setVideoFrameRate(config.frameRate);
  recorder.setVideoEncoder(MediaRecorder.VideoEncoder.H264);
  recorder.setVideoSize(config.width, config.height);
  recorder.setVideoEncodingBitRate(config.bitRate);
  recorder.setOutputFile(output.getAbsolutePath());

  try {
    recorder.prepare();
    vdisplay=projection.createVirtualDisplay("andcorder",
      config.width, config.height, config.density,
      VIRT_DISPLAY_FLAGS, recorder.getSurface(), null, null);
    beeper.startTone(ToneGenerator.TONE_PROP_ACK);
    recorder.start();
  }
  catch (IOException e) {
    throw new RuntimeException("Exception preparing recorder", e);
  }
}
```

First, we create an instance of MediaRecorder and configure it. As is discussed in the chapter on working with the camera, MediaRecorder is a *very* fussy class, requiring a fairly specific order of method calls to configure it without messing things up too bad. The values for the configuration come from:

- the RecordingConfig, notably the requested resolution, frame rate, and bitrate
- the output File created in the RecordingSession constructor
- hardcoded values for the video source, output format, and encoder format

Of particular interest is the call to setVideoSource(). Usually, you would set this to CAMERA, to record from a device-supplied camera. Here, though, we set it to SURFACE, indicating that MediaRecorder should supply a Surface onto which we can render what should get recorded.

We then:

- Prepare the MediaRecorder, which might throw an IOException if there is some problem with the output file
- Create a VirtualDisplay, as we did in andprojector, tied to the details of the display we got from DisplayMetrics by way of the RecordingConfig
- Play a tone using ToneGenerator to let the user know that recording has begun
- Actually begin the recording, via a call to start() on the MediaRecorder

The VIRT_DISPLAY_FLAGS used here are the same ones used for andprojector:

```
  static final int VIRT_DISPLAY_FLAGS=
    DisplayManager.VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY |
      DisplayManager.VIRTUAL_DISPLAY_FLAG_PUBLIC;
```

And, at this point, the screen is being recorded.

Stopping the Recording

Eventually, we will want to stop that recording, whether triggered via the Notification or the command-line script. That eventually results in a call to stopRecorder() on the RecorderService, which just calls stop on the RecordingSession before setting the field to null:

```
synchronized private void stopRecorder() {
  if (session!=null) {
    session.stop();
    session=null;
  }
}
```

The stop() method on RecordingSession unwinds everything we set up, via stop() and release() calls on the MediaProjection, MediaRecorder, and VirtualDisplay. stop() also calls scanFile() on MediaScannerConnection, so that our video gets indexed by the MediaStore and therefore can be seen in on-device video players and via the MTP connection to your developer machine:

```
void stop() {
  projection.stop();
  recorder.stop();
  recorder.release();
  vdisplay.release();

  MediaScannerConnection.scanFile(ctxt,
    new String[]{output.getAbsolutePath()}, null, this);
}

@Override
public void onScanCompleted(String path, Uri uri) {
  beeper.startTone(ToneGenerator.TONE_PROP_NACK);
}
```

When the scan is complete, another beep signals to the user that the screen recording is finished.

Usage Notes

On the plus side, andcorder has no built-in duration limitation, the way that adb shell screenrecord does.

Trail: Security

SSL

The traditional approach to securing HTTP operations is by means of SSL. Android supports SSL, much as ordinary Java does. Most of the time, you can just allow Android to do its thing with respect to SSL, and you will be fine. However, there may be times when you have to play a more direct role in SSL communications, to handle arbitrary SSL-encrypted endpoints, or to help ensure that your app is not the victim of a man-in-the-middle attack.

This chapter will explore various SSL scenarios and how to address them.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on Internet access.

Basic SSL Operation

Generally speaking, SSL “just works”, for ordinary sites with ordinary certificates.

If you use an `https:` URL with `HttpUrlConnection` or `WebView`, SSL handshaking will happen automatically, and assuming the certificates check out OK, you will get your result, just as if you had requested an `http:` URL.

However, originally, requesting a download via `DownloadManager` with an `https:` scheme would result in `java.lang.IllegalArgumentException: Can only download HTTP URIs`. As of Android 4.0, SSL is supported. Hence, you need to be careful about making SSL requests via `DownloadManager` if your `minSdkVersion` is less than 14.

For example, the Retrofit and Picasso sample apps from the chapter on Internet access both use `https://api.stackexchange.com` for their service endpoint. As a result, those requests — for the API JSON, at least — will go over SSL. You would need to log the URLs used for the image avatars to see whether StackExchange gives you `https` URLs or not.

Common SSL Problems

It would be nice if SSL always worked, rather than only generally worked. Alas, there are problems that you may well encounter while setting up SSL support, beyond having to deal with possible man-in-the-middle attacks.

This section will outline some of these common problems.

Self-Signed Certificate

SSL certificates used for public Web sites are usually backed by a “root certificate authority” that is well-known. That is not always the case.

One case is when the certificate is “self-signed”, meaning that it was generated by somebody without involving a certificate authority. If you have shipped a production Android app, you created a self-signed certificate when you created your production key store. And you have been using a system-generated self-signed certificate throughout your development, known as the “debug signing key”.

Self-signed certificates are rarely used on public-facing Web sites, as Web browsers are taught to warn users when such certificates are encountered. However, self-signed certificates might be used on internal servers, particularly test servers and other non-production environments.

There are even some benefits for using a self-signed certificate for production servers, if those servers will be talking only to your own apps and not arbitrary Web browsers. This technique will be reviewed later in this chapter.

Wildcard Certificate

Some certificates are difficult to validate because they use wildcards.

For example, Amazon S3 is a file storage and serving “cloud” solution from Amazon.com. They allow you to define “buckets” containing “objects”, where each object then has its own URL. That URL is based on the name of the bucket and the name of the object. One option is for you to have the domain name of the URL be based on the name of the bucket, leaving the path to be solely the name of the object. This works, even with SSL, but Amazon needed to use a "wildcard SSL certificate", one that matches `*.s3.amazonaws.com`, not just a single domain name. By default, this will fail on Android, as Android's stock `TrustManager` will not validate wildcards for multiple domain name segments (e.g., `http://misc.commonsware.com.s3.amazonaws.com/foo.txt`). You will get an exception akin to:

```
javax.net.ssl.SSLHandshakeException: java.security.cert.CertificateException:
No subject alternative DNS name matching misc.commonsware.com.s3.amazonaws.com found
```

Custom Certificate Authority

Some larger organizations have set up their own certificate authority. Sometimes, they aspire to become a recognized root certificate authority, but have not been adopted by many browsers. Sometimes, they simply want to have more structure than a pure self-signed certificate but do not necessarily want to have all certificates go through a root certificate authority, perhaps due to expense.

In these cases, Android will reject the SSL certificate, for the same reason it rejects self-signed ones: it cannot validate the certificate chain all the way back to a known root certificate authority. But, with a little work, you can enable Android to support these as well.

TrustManagers

Our work in handling these common problems — and some other enhancements that help with other sorts of attacks — revolves around a `TrustManager`. You may already be familiar with these from standard Java development. Otherwise, this section reviews what a `TrustManager` is and how you apply one in your Android HTTP operations. Later on, we will discuss where you can get a `TrustManager` that works the way *you* want.

What is a TrustManager?

In Java, a `TrustManager` is responsible for determining if an SSL certificate chain is valid or not for a given request.

An SSL certificate chain, in turn, represents a series of SSL certificates that, as the name suggests, are chained together. Sometimes, the chain will only have one entry (e.g., a self-signed certificate). More often, the chain will have a few entries, starting with the server's certificate, which may chain to some intermediate certificate(s), eventually leading to a certificate that might be from a root certificate authority.

In truth, we often use a collection of `TrustManager` instances, represented as a simple Java array. And, of course, courtesy of design patterns like the composite pattern, one `TrustManager` might delegate decision-making to other `TrustManager` instances.

How Do We Use One?

For the moment, let us assume that we get a `TrustManager` array handed to us by magic. How would we use it?

The answer depends on what you are using for your HTTP stack, as is outlined below.

HttpsURLConnection

Normally, when using a `java.net.URL`, you open a connection and do not pay much attention to whether the connection object you get back is an `HttpURLConnection` or an `HttpsURLConnection`. If, however, you want to tailor the SSL processing with a custom `TrustManager` array, you will need to explicitly use `HttpsURLConnection`:

```
SSLContext ssl=SSLContext.getInstance("TLS")

ssl.init(null, builders, null);

HttpsURLConnection conn=(HttpsURLConnection)new URL(url).openConnection();

conn.setSSLSocketFactory(ssl.getSocketFactory());

// conn.getInputStream() and other work to process the HTTPS call
```

(here, `builders` is the array of `TrustManager` instances)

OkHTTP

Square's OkHttp works along the same lines:

```
SSLContext ssl=SSLContext.getInstance("TLS")
```

```
ssl.init(null, builders, null);

OkHttpClient okHttpClient=new OkHttpClient();

okHttpClient.setSslSocketFactory(ssl.getSocketFactory());

HttpURLConnection conn=okHttpClient.open(new URL(url));

// conn.getInputStream() and other work to process the HTTPS call
```

Something Else

Other HTTP stacks, or libraries that in turn use HTTP directly or indirectly, should offer similar facilities. If not, you may wish to switch to something that does.

What Not To Do

You will find various blog posts, Stack Overflow answers, and the like that suggest that you simply disable SSL certificate validation, by implementing an "accept-all" `TrustManager`. Such a `TrustManager` basically implements the interface with empty stubs for methods like `checkServerTrusted()`, not throwing any exceptions.

Technically, this works. And, *if* you are using this only early on in development and *if* you swear upon a stack of `$RELIGIOUS_TEXTS` that you will replace this hack by the time you go to production, it is difficult to complain about this technique.

However, in production, ignoring SSL certificate validation errors opens your app up to man-in-the-middle attacks. We will explore man-in-the-middle attacks in greater detail later in this chapter.

If you think that this is not important, bear in mind that the US Federal Trade Commission (FTC) has sued firms for blindly accepting all SSL certificates. It is not out of the question for class action suits, or legal action by other nations, to be forthcoming.

Please do not implement an "accept-all" `TrustManager`**!**

TrustManagerBuilder

To simplify handling some of these scenarios, the author of this book has written a `TrustManagerBuilder`, as part of the CWAC-Security library. The objective of this library is to bundle up some good SSL hygiene practices in an easy-to-use builder-style API. You create an instance of `TrustManagerBuilder`, call a series of methods on it to configure your desired SSL behavior, then call `buildArray()` to get the `TrustManager` array to pass into your `init()` call on the `SSLSocket`, as described above.

The following sections are based in part on [the `TrustManagerBuilder` documentation].

Basic Configuration

There are two `TrustManagerBuilder` constructors: a zero-argument constructor and a one-parameter constructor, taking a `Context`. Use the one-parameter constructor if you plan on using the builder-style methods that take a raw resource ID or a path into `assets/` as parameters.

Of course, the real work is done in the `// configure builder here` parts, using the following builder-style methods:

- `useDefault()`: this tells `TrustManagerBuilder` to use the system default `TrustManager` for validating incoming SSL certificates
- `selfSigned()`: this tells `TrustManagerBuilder` to allow a specific self-signed SSL certificate, based upon a supplied keystore file and password
- `allowCA()`: this tells `TrustManagerBuilder` to accept certificates signed by a custom certificate authority, based upon a supplied certificate file
- `denyAll()`: this tells `TrustManagerBuilder` to reject all certificates (mostly for testing purposes)
- `memorize()`: this tells `TrustManagerBuilder` to only accept SSL certificates approved by the user
- `addAll()`: this tells `TrustManagerBuilder` to add other trust managers that you may have implemented yourself or obtained from other libraries

In addition, `or()` tells `TrustManagerBuilder` to logically OR any subsequent configuration with whatever came previously in the build, while `and()` indicates that subsequent configuration should be logically AND-ed with whatever came previously.

Supporting Self-Signed Certificates

Perhaps you are using self-signed certificates for an in-house server, such as a test server for development purposes.

selfSigned() will help with that. The simple form of the method takes two parameters. The first parameter is either:

- a File pointing to a keystore for your self-signed certificate on the local file system,
- an int raw resource ID, if you wish to package the keystore in your app in res/raw/, or
- a String pointing to a relative path in assets/ where you have placed your keystore

The second parameter is a char array for the password for the keystore. If you are dynamically retrieving that password (e.g., the user types it in), you can clear out the char array (e.g., set all elements in the array to x), to quickly get rid of the password from memory. If your password is more static, just call toCharArray() on a String to get the char array that you need.

The default selfSigned() expect that keystore to be in BKS format; if your keystore is in some other format supported by Android's edition of KeyStore, use the three-parameter version of selfSigned() that takes the KeyStore format name as the last parameter.

If you want to *only* support a specific self-signed certificate, you could set up a TrustManagerBuilder as follows:

```
new TrustManagerBuilder(this).selfSigned(R.raw.selfsigned, "foobar".toCharArray());
```

(where this is a Context, like the IntentService in which you are making a SSL-encrypted Web service call)

Here, the BKS-formatted keystore would reside in res/raw/selfsigned.bks (though the file extension could vary).

If you want to support more than one self-signed certificate — such as when you plan on switching your old certificate to a new one — you could do:

```
new TrustManagerBuilder(this)
  .selfSigned(R.raw.selfsigned, "foobar".toCharArray())
  .or()
  .selfSigned(R.raw.selfsigned2, "snicklefritz".toCharArray());
```

If you want to use a single TrustManagerBuilder for both your self-signed scenario and regular certificate authority-based certificates, you could do:

```
new TrustManagerBuilder(this)
  .selfSigned(R.raw.selfsigned, "foobar".toCharArray())
  .or()
  .useDefault();
```

Getting the self-signed certificate keystore, and employing the self-signed certificate on your server, is up to you. For example, you could use `openssl` to generate a 4,096-bit self-signed certificate, with a lifespan of 10,000 days:

```
openssl req -new -newkey rsa:4096 -sha1 -days 10000 -nodes -x509 -keyout selfsigned.key
-out selfsigned.crt
```

(note: this should all be on one line; it is split over multiple lines here to fit the page)

That will give you something that you could use with your server. To get a BKS file for use with `TrustManagerBuilder`, you can use the JAR for The Legion of the Bouncy Castle in conjunction with the `keytool` command. For example, the following command will take the self-signed certificate from above and create `selfsigned.bks` as output, using `foobar` as the password, assuming that the `bcprov-jdk16-146.jar` JAR file is in the current working directory:

```
keytool -import -file selfsigned.crt -keystore selfsigned.bks -storetype BKS -provider
org.bouncycastle.jce.provider.BouncyCastleProvider -providerpath bcprov-jdk16-146.jar
-storepass foobar
```

(note: this should all be on one line; it is split over several lines here to fit the page)

Supporting Custom Certificate Authorities

The Android developer documentation has some sample code for validating an SSL certificate against a custom certificate authority (CA). That same technique is integrated into `TrustManagerBuilder`.

```
new TrustManagerBuilder(getContext()).allowCA("uwash-load-der.crt")
```

Here, `uwash-load-der.crt` is the CA's root certificate (in this case, from the University of Washington). The parameter to `allowCA()` is similar to the parameter to `selfSigned()`:

- a `File` pointing to the CA's root certificate on the local file system,
- an `int` raw resource ID, if you wish to package the CA's root certificate in your app in `res/raw/`, or
- a `String` pointing to a relative path in `assets/` where you have placed your CA's root certificate

By default, the one-parameter version of `allowCA()` assumes an X.509 certificate file. If your certificate file is in some other format that is supported by Android's edition of the `CertificateFactory` class, you can use the two-parameter version of `allowCA()` that takes the format name as a `String` in the second parameter.

And, of course, `allowCA()` can be combined with the others as well, such as a configuration that supports the default certificate authorities or a custom one:

```
new TrustManagerBuilder(this)
  .allowCA("uwash-load-der.crt")
  .or()
  .useDefault();
```

About That Man in the Middle

Man-in-the-middle (MITM) attacks are a common way of trying to intercept SSL encrypted communications. The "man" in the "middle" might be a proxy server, a different Web site you wind up communicating with via DNS poisoning, etc. The objective of the "man" is to pretend to be the actual Web site or Web service you are trying to communicate with. If your app "falls for it", your app will open an encrypted channel to the attacker, not your site, and the attacker will have access to the unencrypted data you send over that channel.

Unfortunately, Android apps have a long history of being victims of man-in-the-middle attacks.

"Why Eve and Mallory Love Android: An Analysis of Android SSL (In)Security", an analysis of possible man-in-the-middle attacks on Android, is depressing. One in six surveyed apps explicitly ignored SSL certificate validation issues, mostly by means of do-nothing `TrustManager` implementations as noted above. Out of a selected 100 apps, 41 could be successfully attacked using man-in-the-middle techniques, yielding a treasure trove of credit card information, account credentials for all the major social networks, and so forth.

Their paper outlines a few ways in which apps can screw up SSL management — the following sections outline some of them.

Disabling SSL Certificate Validation

As mentioned above, if you disable SSL certificate validation, by implementing and using a do-nothing `TrustManager`, you are wide open for man-in-the-middle attacks.

A simple transparent proxy server can pretend to be the real endpoint — apps ignoring SSL validation entirely will trust that the transparent proxy is the real endpoint and, therefore, perform SSL key exchange with the proxy rather than the real site. The proxy, as a result, gets access to everything the app sends.

Ignoring Domain Names

A related flaw is when you disable hostname verification. The "common name" (CN) of the SSL certificate should reflect the domain name being requested. Requesting `https://www.foo.com/something` and receiving an SSL certificate for `xkcdhatguy.com` would be indicative of a mis-configured Web server at best and a man-in-the-middle attack at worst.

By default, this is checked, and if there is no match, you will get errors like:

```
javax.net.ssl.SSLException: hostname in certificate didn't match: <...>
```

where the `...` is replaced by whatever domain name you were requesting.

But some developers disable this check. Perhaps during development they were accessing the server using a private IP address, and they were getting `SSLExceptions` when trying to access that server. It is very important to allow Android to check the hostname for you, which is the default behavior.

Hacked CAs

The truly scary issue is when the problem stems from the CA itself.

Comodo, TURKTRUST, and other certificate authorities have been hacked, where nefarious parties gained the ability to create arbitrary certificates backed by the CA. For example, in the TURKTRUST case, Google found that somebody had created a `*.google.com` certificate that had TURKTRUST as the root CA. Any browser — or Android app — that implicitly trusted TURKTRUST-issued certificates would believe that this certificate was genuine. This is the ultimate in man-in-the-middle attacks, as code that is ordinarily fairly well-written will believe the CA and therefore happily communicate with the attacker.

Self-Signed Certificates, Revisited

As Moxie Marlinspike points out, one way to avoid having your app be the victim of a man-in-the-middle attack due to a hijacked certificate authority is to simply *not use a certificate authority*.

Certificate authorities are designed for use by general-purpose clients (e.g., Web browsers) hitting general-purpose servers (e.g., Web servers). In the case where you control both the client *and* the server, you don't need a certificate authority. You merely need to have a self-signed certificate that both ends know about.

This works well if the Web server is solely functioning as a Web service to deliver data to your Android app, or perhaps other native apps on other platforms for which you can also support self-signed certificates. Depending upon your server's capabilities, you might be able to arrange to have the same server-side application logic be available both from a self-signed certificate on one domain (for use with apps) and from a CA-rooted certificate for another domain (for use with Web browsers).

However, it is very possible that the staff who manage the servers will reject the notion of using a self-signed certificate, perhaps in an effort to minimize the complexity of supporting multiple SSL paths (for browsers and apps). Or, you may not control the server well enough to go with a self-signed certificate, such as if you are using a cloud computing provider.

Certificate Memorizing

If your app needs to connect to arbitrary SSL servers — perhaps ones configured by the user (e.g., email client) or are intrinsic to the app's usage (e.g., URLs in a Web browser) — detecting man-in-the-middle attacks boils down to proper SSL certificate validation… and praying for no hacked CA certificates.

However, one way to incrementally improve security is to use certificate memorizing. With this technique, each time you see a certificate that you have not seen before, or perhaps a different certificate for a site visited previously, you ask the user to confirm that it is OK to proceed.

The idea here is that even if we cannot tell, absolutely, whether a given certificate is genuine or from an attacker, we can detect *differences in certificates over time*. So, if the user has been seeing certificate A, and now all of a sudden receives certificate B instead, there are two main possibilities:

1. The HTTPS server changed certificates for legitimate reasons
2. An attacker is providing an alternative certificate

So, what we do is check certificates against a roster that the user has approved before. If the newly-received certificate is not in that roster, we fail the HTTPS request, but raise a custom exception so that your code can detect this case and ask the user for approval to proceed.

Technically savvy users may be able to deduce whether the certificate is indeed genuine; slightly less-savvy users might simply contact the site to see if this is expected behavior. The downside is that technically unsophisticated users might be baffled by the question of whether or not they should accept the certificate and may take their confusion out on you, the developer of the app that is asking the question.

The Standalone Solution

There is a standalone implementation of a `MemorizingTrustManager` that you could consider using. It has been around for a few years, with a slow-but-steady set of updates.

However, that library handles asking the user for acceptance of the certificates for you, rather than raising some event that your app can handle itself. In order to tailor the UI, you would need to modify the library itself.

Moreover, the library attempts to handle this UI *while your SSL request is in process*, by blocking the background thread upon which you are making the HTTPS request. A side-effect of this is that `MemorizingTrustManager` has some fairly unpleasant code for trying to block this thread while interacting with the user on the main application thread. And, if the user takes too long, your request to the server may time out anyway.

The TrustManagerBuilder Solution

The author of this book has created a separate `MemorizingTrustManager` that is part of the `TrustManagerBuilder` of the CWAC-Security library. It will simply throw a custom exception if a certificate is not memorized. Your code that request the HTTPS operation is already needing to catch various exceptions. If your code detects this special `CertificateNotMemorizedException`, you can handle asking the user what to do yourself, integrated into your own UI, without threading concerns. If the user elects to proceed, you can have TrustManagerBuilder memorize the certificate, after which you can try your HTTPS request again.

This requires a bit more configuration and management than much of the rest of TrustManagerBuilder. There is a dedicated demo project in the demoMemo/ directory of the CWAC-Security repository that demonstrates how to use certificate memorization. The sections that follow explain how to set up certificate memorization, and are based upon the TrustManagerBuilder documentation.

Configuring the TrustManagerBuilder

In addition to other builder methods, you can call memorize() on a TrustManagerBuilder to indicate that you want to enable certificate memorization. This method takes an instance of a MemorizingTrustManager.Options object to configure how memorization works.

The constructor for MemorizingTrustManager.Options takes three parameters:

1. A Context, used only for the duration of the constructor itself — this Context is not retained after the constructor returns.
2. A String representing a relative path to a directory, inside of getFilesDir(), for working files for certificate memorization. This directory will be created for you if it does not already exist.
3. A String that is the password to use for the KeyStore that will hold the memorized certificates.

While MemorizingTrustManager.Options offers a builder-style API for configuring the options, no other methods are required beyond the constructor for basic use.

The memorize() call should be towards the end of the configuration, after an and() call, to say "we will accept SSL certificates that match other criteria *and* are ones that are memorized".

```
options=
    new MemorizingTrustManager.Options(this, "memorize", "snicklefritz");

try {
  builder=
      new TrustManagerBuilder(this).useDefault().and().memorize(options);
}
catch (Exception e) {
  // do something useful
}
```

Detecting Memorization Exceptions

When you perform an HTTPS operation, you may get an `SSLHandshakeException`. That should wrap another exception, retrieved via `getCause()`.

If the wrapped exception is `CertificateNotMemorizedException`, that means that we found a certificate that matched your other criteria (e.g., valid root CA), but was not found in the memorized roster of certificates. The `CertificateNotMemorizedException` contains the certificate chain, retrieved via `getCertificateChain()`.

At this point, you should tell the user that the request failed because of the unrecognized certificate, and ask the user how to proceed. You are welcome to use the contents of the certificate chain to provide technical details regarding the unrecognized certificates to the user, if you so choose.

Bear in mind that your users may be non-technical. Throwing up a dialog with a lot of SSL gibberish may not be effective. Instead, ideally, you should steer them for how to contact somebody who can indicate if it is safe to proceed.

There are three possible avenues that the user could take:

1. The user could elect to not proceed, under the premise that the SSL communications may be compromised. How you handle that is up to you.
2. The user could elect to proceed, but not remember this certificate for very long ("Allow once").
3. The user could elect to proceed, with you remembering the certificate for a long time, if the certificate is thought to be valid.

Memorizing the Certificate

In cases #2 and #3 above, you can call methods on your `TrustManagerBuilder` to update the memorized roster with the certificate chain that had failed previously. Use `allowCertOnce()` to remember the certificate for the lifetime of your process, and use `memorizeCert()` to remember the certificate indefinitely. Both of these methods take the `X509Certificate` array that is the certificate chain that you got from calling `getCertificateChain()` on the `CertificateNotMemorizedException`.

After you do this, you can re-try your request that failed due to the unrecognized certificate, and it should succeed.

Clearing the Certificate Roster

At any point, you can call `clearMemorizedCerts()` on the `TrustManagerBuilder` to get rid of the certificate roster. Pass `false` as the parameter to only get rid of the "transient" certificates (i.e., the ones you registered via `allowCertOnce()`). Pass `true` as the parameter to get rid of both the transient and the persistent certificates (i.e., the ones you registered via `memorizeCert()`).

Notes on Threading

Because certificate memorization involves reading from and writing to files, setup and use of the `TrustManagerBuilder` should be performed on a background thread. Of course, your network I/O should be on a background thread, anyway.

If you will have several threads that are all performing HTTPS operations, they should *share* a `TrustManagerBuilder` instance, so that there is a central spot for updating the certificate roster. The `MemorizingTrustManager` should be thread-safe; please file issues if you run into threading-related problems.

Using Trust-on-First-Use

The default behavior of certificate memorization is to fail on every unrecognized certificate. The downside of this is that the user will immediately get a failure the first time the user uses the app, because no certificates will have been memorized by that point.

You have three courses of action to handle this:

1. Live with it.
2. Manage it yourself, by determining when you believe it is safe to memorize the certificate without user involvement.
3. Call `trustOnFirstUse()` on the `MemorizingTrustManager.Options` object when you create it, to indicate that the *first* unrecognized certificate should be memorized automatically, with failures being reported for all subsequent unrecognized certificates.

About CertificateMemorizationException

If you encounter a `CertificateMemorizationException` — in a crash log, for example — that indicates that the library encountered some problem when attempting to save a certificate that is being saved automatically via the trust-on-first-use feature. This exception is unlikely to occur.

Pinning

One way to limit the possible damage from hacked CAs is to recognize that most apps do not need to communicate with arbitrary servers. Web browsers, email clients, chat clients, and the like might need to be able to communicate with whatever server the user elects to configure. But many apps just need to communicate back to their developer's own server, such as a native client adjunct to a regular Web app.

In this case, the app does not need to accept arbitrary SSL certificates. The developer knows the actual SSL certificate used by the developer's server, so the developer can arrange to accept only that one certificate. Or, the developer knows the CA that they get their SSL certificates from and can only accept certificates issued by that CA, and not other CAs. This reduces security a bit, but makes it easier for you to handle SSL certificate expiration and replacement without major headaches.

This technique is referred to as "pinning". Chrome is perhaps the most well-known implementer of pinning: when you access services like Gmail from Chrome, Google (who wrote the browser) knows the valid certificates for Google (who wrote the server) and can toss out anything that is invalid… such as the TURKTRUST fake certificate mentioned earlier in this chapter.

Nikolay Elenkov has another blog post outlining certificate pinning support in Android 4.2+. Moxie Marlinspike has an implementation of pinning, with a description in a blog post, and has also released a pinning library offering a `PinningTrustManager` that you can use following his guidelines.

NetCipher

The Guardian Project has released an Android library project called NetCipher — formerly known as OnionKit — designed to help boost Internet security for Android applications.

In particular, NetCipher helps your application integrate with Orbot, a Tor proxy. Tor ("The Onion Router") is designed to help with anonymity, having your Internet requests go through a series of Tor routers before actually connecting to your targeted server through some Tor endpoint. Tor is used for everything from mitigating Web site tracking to helping dissidents bypass national firewalls. NetCipher helps your app:

- Detect if Orbot is installed, and help the user install it if it is not
- Detect if Orbot is running, and help you start it if it is not
- Make HTTP requests by means of Orbot instead of directly over the Internet

Advanced Permissions

Adding basic permissions to your app to allow it to, say, access the Internet, is fairly easy. However, the full permissions system has many capabilities beyond simply asking the user to let you do something. This chapter explores other uses of permissions, from securing your own components to using signature-level permissions (your own or Android's).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on permissions and the chapter on signing your app. The discussion of signature-level permissions will make a bit more sense if you read through the chapter on plugins as well.

Securing Yourself

Principally, at least initially, permissions are there to allow the user to secure their device. They have to agree to allow you to do certain things, such as reading contacts, that they might not appreciate.

The other side of the coin, of course, is to secure your own application. If your application is mostly activities, security may be just an "outbound" thing, where you request the right to use resources of other applications. If, on the other hand, you put content providers or services in your application, you will want to implement "inbound" security to control which applications can do what with the data.

Note that the issue here is less about whether other applications might "mess up" your data, but rather about privacy of the user's information or use of services that might incur expense. That is where the stock permissions for built-in Android applications are focused – can you read or modify contacts, can you send SMS, etc. If your application does not store information that might be considered private, security is less an issue. If, on the other hand, your application stores private data, such as medical information, security is much more important.

The first step to securing your own application using permissions is to declare said permissions, once again in the `AndroidManifest.xml` file. In this case, instead of `uses-permission`, you add `permission` elements. Once again, you can have zero or more `permission` elements, all as direct children of the root `manifest` element.

Declaring a permission is slightly more complicated than using a permission. There are three pieces of information you need to supply:

- The symbolic name of the permission. To keep your permissions from colliding with those from other applications, you should use your application's Java namespace as a prefix
- A label for the permission: something short that would be understandable by users
- A description for the permission: something a wee bit longer that is understandable by your users

```
<permission
  android:name="vnd.tlagency.sekrits.SEE_SEKRITS"
  android:label="@string/see_sekrits_label"
  android:description="@string/see_sekrits_description" />
```

This does not enforce the permission. Rather, it indicates that it is a possible permission; your application must still flag security violations as they occur.

Enforcing Permissions via the Manifest

There are two ways for your application to enforce permissions, dictating where and under what circumstances they are required. The easier one is to indicate in the manifest where permissions are required.

Activities, services, and receivers can all declare an attribute named `android:permission`, whose value is the name of the permission that is required to access those items:

```
<activity
  android:name=".SekritApp"
  android:label="Top Sekrit"
  android:permission="vnd.tlagency.sekrits.SEE_SEKRITS">
  <intent-filter>
    <action android:name="android.intent.action.MAIN" />
    <category
      android:name="android.intent.category.LAUNCHER"
/>
  </intent-filter>
</activity>
```

Only applications that have requested your indicated permission will be able to access the secured component. In this case, "access" means:

1. Activities cannot be started without the permission
2. Services cannot be started, stopped, or bound to an activity without the permission
3. Intent receivers ignore messages sent via `sendBroadcast()` unless the sender has the permission

Enforcing Permissions Elsewhere

In your code, you have two additional ways to enforce permissions.

Your services can check permissions on a per-call basis via `checkCallingPermission()`. This returns `PERMISSION_GRANTED` or `PERMISSION_DENIED` depending on whether the caller has the permission you specified. For example, if your service implements separate read and write methods, you could require separate read versus write permissions in code by checking those methods for the permissions you need from Java.

Also, you can include a permission when you call `sendBroadcast()`. This means that eligible broadcast receivers must hold that permission; those without the permission are ineligible to receive it. We will examine `sendBroadcast()` in greater detail elsewhere in this book.

Requiring Standard System Permissions

While normally you require your own custom permissions using the techniques described above, there is nothing stopping you from reusing a standard system permission, if it would fit your needs.

For example, suppose that you are writing YATC (Yet Another Twitter Client). You decide that in addition to YATC having its own UI, you will design YATC to be a "Twitter engine" for use by third party apps:

- Send timeline updates via broadcast `Intents`
- Publish the timeline, the user's own tweets, @-mentions, and the like via a `ContentProvider`
- Offer a command-based service interface for posting updates to the timeline
- And so on

You could, and perhaps should, implement your own custom permission. However, since any app can get to Twitter just by having the `INTERNET` permission, one could argue that a third-party app should just need that same `INTERNET` permission to use your API (rather than integrating JTwitter or another third-party JAR).

Signature Permissions

Each permission in Android is assigned a protection level, via an `android:protectionLevel` attribute on the `<permission>` element. By default, permissions are at a `normal` level, but they can also be flagged as `dangerous`, `signatureOrSystem`, or `signature`. In the latter two cases, "signature" means that the app requesting the permission and the app requiring the permission should have be signed by the same signing key. In the case of `signatureOrSystem` — only used by the firmware – the app requesting the permission either needs to be signed by the firmware's signing key or reside on the system partition (e.g., come pre-installed with the device).

Firmware-Only Permissions

Most of Android's permissions mentioned in this book are ones that any SDK application can hold, if they ask for them and the user grants them. `INTERNET`, `READ_CONTACTS`, `ACCESS_FINE_LOCATION`, and kin all are normal permissions.

`BRICK` is not.

There was a permission in Android, named `BRICK`, that, in theory, allows an application to render a phone inoperable (a.k.a., "brick" the phone). While there is no `brickMe()` method in the Android SDK tied to this permission, presumably there might be something deep in the firmware that was protected by this permission. Though, since Android 6.0 removed the `BRICK` permission from the SDK, it is clearly not something Google expects us to use.

The `BRICK` permission could not be held by ordinary Android SDK applications. You could request it all you want, and it will not be granted.

However, applications that are signed with the same signing key that signed the firmware *could* hold the BRICK permission.

That is because the system's own manifest used to have the following <permission> element:

```
<permission android:name="android.permission.BRICK"
        android:label="@string/permlab_brick"
        android:description="@string/permdesc_brick"
        android:protectionLevel="signature" />
```

Your Own Signature Permissions

You too can require signature-level permissions. That will restrict the holders of that permission to be other apps signed by your signing key. This is particularly useful for inter-process communication between apps in a suite — by using signature permissions, you ensure that only your apps will be able to participate in those communications.

This is what was used in the ContentProvider-based plugin sample from elsewhere in this book. The plugin required a permission that was declared with android:protectionLevel="signature", and the host application requested that permission.

One nice thing about these sorts of signature-level permissions is that the user is not bothered with them. It is assumed that the user will agree to the communication between the apps signed by the same signing key. Hence, the user will not see signature-level permissions at install or upgrade time.

Since in some cases, you may not be sure which app will be installed first, it is best to have all apps in the suite include the *same* <permission> element, in addition to the corresponding <uses-permission> element. That way, no matter which app is installed first, it can declare the permission that all will share.

Though, that has its own problems, as you will see in the next section.

The Custom Permission Vulnerability

NOTE: Some of the material in this section originally appeared in material hosted in the CWAC-Security project repository. In addition, the author would like to thank Mark Carter and "Justin Case" for their contributions in this topic area).

Unfortunately, custom permissions have some undocumented limitations that make them intrinsically risky. Specifically, custom permissions can be defined by anyone, at any time, and "first one in wins", which opens up the possibility of unexpected behavior.

Here, we will walk through some scenarios and show where the problems arise, plus discuss how to mitigate them as best we can.

Scenarios

All of the following scenarios focus on three major app profiles.

App A is an app that defines a custom permission in its manifest, such as:

```
<permission
  android:name="com.commonsware.cwac.security.demo.OMG"
  android:description="@string/perm_desc"
  android:label="@string/perm_label"
  android:protectionLevel="normal"/>
```

App A also defends a component using the `android:permission` attribute, referencing the custom permission:

```
<provider
  android:name="FileProvider"
  android:authorities="com.commonsware.cwac.security.demo.files"
  android:exported="true"
  android:grantUriPermissions="false"
  android:permission="com.commonsware.cwac.security.demo.OMG">
  <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

App B has a `<uses-permission>` element to declare to the user that it wishes to access components defended by that permission:

```
<uses-permission android:name="com.commonsware.cwac.security.demo.OMG"/>
```

App C has the same `<uses-permission>` element. The difference is that App B *also* has the `<permission>` element, just as App A does, albeit with different descriptive information (e.g., `android:description`) and, at times, a different protection level.

All three apps are signed with different signing keys, because in the real world they would be from different developers.

So, to recap:

- A defines a permission and uses it for defense
- B defines the same permission and requests to hold it
- C just requests to hold this permission

With all that in mind, let's walk through some possible scenarios, focusing on two questions:

1. What is the user told, when the app is installed through normal methods (i.e., not via `adb`), regarding this permission?
2. What access, if any, does App B or App C have to the `ContentProvider` from App A?

The Application SDK Case (A, Then C)

Suppose the reason why App A has defined a custom permission is because it wants third-party apps to have the ability to access its secured components… but only with user approval. By defining a custom permission, and having third-party apps request that permission, the user should be informed about the requested permission and can make an informed decision.

Conversely, if an app tries to access a secured component but has not requested the permission, the access attempt should fail.

App C has requested the custom permission via the `<uses-permission>` element. If the permission — defined by App A — has an `android:protectionLevel` of `normal` or `dangerous`, the user will be informed about the requested permission at install time. If the user continues with the installation, App C can access the secured component.

If, however, the `android:protectionLevel` is `signature`, the user is not informed about the requested permission at install time, as the system can determine on its own whether or not the permission should be granted. In this case, App A and App C are signed with different signing keys, so Android silently ignores the permission request. If the user continues with installation, then App C tries to access App A's secured component, App C crashes with a `SecurityException`.

In other words, this all works as expected.

The Application SDK Problem Case (C, Then A)

However, in many cases, there is nothing forcing the user to install App A before App C. This is particularly true for publicly-distributed apps on common markets, like the Play Store.

When the user installs App C, the user is not informed about the request for the custom permission, presumably because that permission has not yet been defined. If the user later installs App A, App C is not retroactively granted the permission, and so App C's attempts to use the secured component fail.

This works as expected, though it puts a bit of a damper on custom permissions. One way to work around this would be for the user to uninstall App C, then install it again (with App A already installed). This returns us to the original scenario from the preceding section. However, if the user has data in App C, losing that data may be a problem (as in a "let's give App C, or perhaps App A, one-star ratings on the Play Store" sort of problem).

The Peer Apps Case, Part One (A, Then B)

Suppose now we augment our SDK-consuming app (formerly App C) to declare the same permission that App A does, in an attempt to allow the two apps to be installed in either order. That is what App B is: the same app as App C, but where it has the same `<permission>` element as does App A in its manifest.

This scenario is particularly important where both apps could be of roughly equal importance to the user. In cases where App C is some sort of plugin for App A, it is not unreasonable for the author of App A to require App A to be installed first. But, if Twitter and Facebook wanted to access components of each others' apps, it would be unreasonable for either of those firms to mandate that their app must be installed first. After all, if Twitter wants to be installed first, and Facebook wants to be installed first, one will be disappointed.

If the user installs App A (the app defending a component with the custom permission) before App B, the user will be notified at install time about App B's request for this permission. Notably, the information shown on the installation security screen will contain App A's description of the permission. And, if the user goes ahead and installs App B, App B can indeed access App A's secured component, since it was granted permission by the user.

Once again, everything is working as expected. Going back to the two questions:

1. The user is informed when App B or App C requests the permission defined by App A.
2. App B and App C can hold that permission if and only if they meet the requirements of the protection level

The Peer Apps Case, Part Two (B, Then A)

What happens if we reverse the order of installation? After all, if App A and App B are peers, from the standpoint of the user, there is roughly a 50% chance that the user will install App B before App A.

Here is where things go off the rails.

The user is not informed about App B's request for the custom permission.

The user will be informed about any platform permissions that the app requests via other `<uses-permission>` elements. If there are none, the user is told that App B requests no permissions… despite the fact that it does.

When the user installs App A, the same thing occurs. Of course, since App A does not have a `<uses-permission>` element, this is not all that surprising.

However, at this point, **even though the user was not informed**, App B holds the custom permission and can access the secured component.

This is bad enough when both parties are ethical. App B could be a piece of malware, though, designed to copy the data from App A, ideally without the user's knowledge. And, if App B is installed before App A, that would happen.

So, going to the two questions:

1. The user is **not** informed about App B's request for the permission…
2. …but App B gets it anyway and can access the secured component

The Downgraded-Level Malware Case (B, Then A, Again)

You might think that the preceding problem would only be for `normal` or `dangerous` protection levels. If App A defines a permission as requiring a matching `signature`, and App A marks a component as being defended by that permission, Android must require the signature match, right?

Wrong.

The behavior is identical to the preceding case. Android does not use the *defender's* protection level. It uses the *definer's* protection level, meaning the protection level of whoever was installed first and had the `<permission>` element.

So, if App A has the custom permission defined as `signature`, and App B has the custom permission defined as `normal`, if App B is installed first, the behavior is as shown in the preceding section:

1. The user is **not** informed about App B's request for the permission…
2. …but App B gets it anyway and can access the secured component, despite the signatures not matching

The Peer Apps Case With a Side Order of C

What happens if we add App C back into the mix? Specifically, what if App B is installed first, then App A, then App C?

When App C eventually gets installed, the user is prompted for the custom permission that App C requests via `<uses-permission>`. However, the description that the user sees is from App B, the one that first defined the custom `<permission>`. Moreover, the protection level is whatever App B defined it to be. So if App B downgraded the protection level from App A's intended `signature` to be `normal`, App C can hold that permission and access the secured App A component, even if it is signed by another signing key.

Not surprisingly, the same results occur if you install App B, then App C, then App A.

Behavior Analysis

The behavior exhibited in these scenarios is consistent with two presumed implementation "features" of Android's permission system:

1. First one in wins. In other words, the first app (or framework, in the case of the OS's platform permissions) that defines a `<permission>` for a given `android:name` gets to determine what the description is and what the protection level is.

2. The user is only prompted to confirm a permission if the app being installed has a `<uses-permission>` element, the permission was already defined by some other app, and the protection level is not `signature`.

Risk Assessment

The “first one in wins” rule is a blessing and a curse. It is a curse, insofar as it opens up the possibility for malware to hold a custom permission without the user’s awareness of that, and even to downgrade a `signature`-level permission to `normal`. However, it is a blessing, in that the malware would have to be installed first; if it is installed second, either its request to hold the permission will be seen by the user (`normal` or `dangerous`) or the request to hold the permission will be rejected (`signature`).

This makes it somewhat unlikely for a piece of malware to try to sneakily make off with data. Eventually, if enough users start to ask publicly why App B needs access to App A’s data (for cases where App A was installed first and the user knows about the permission request), somebody in authority may eventually realize that this is a malware attack. Of course, “eventually” may be a rather long time.

However, there are some situations where Android’s custom permission behavior presents risk even greater than that. If the attacker has a means of being *sure* that their app was installed first, they can hold any permission from any third-party app they want to that was known at install time.

For example:

- Somebody could sell a used Android device, and the buyer could neglect to factory-reset it, and the malware could be installed by the seller
- Somebody could sell a used Android device with a ROM mod preinstalled, based on a normal ROM mod (e.g., CyanogenMod), but with an additional bit of malware installed, to prevent a factory reset from foiling the attack’
- Somebody could distribute devices to users who might think the device is “factory clean” and not laden with malware (e.g., devices given as gifts)
- Somebody could distribute devices to users who might think that the pre-installed malware is actually a legitimate app (e.g., devices given to employees by an employer wishing to monitor usage by examining protected data from third-party apps)

Android 5.0's "Fix"

Android 5.0 now prevents two apps from defining the same `<permission>` ("same" based on `android:name`) unless they are signed by the same signing key. First one in wins; the second app installation will fail.

On the plus side:

- This solves the security problem, as an attacker (B) cannot get at a defender's (A's) data by virtue of having been installed first, as A simply cannot be installed in this case.
- This has no impact on developers using `signature`-level `<permission>` elements for their own app suite.

However, it does pose significant limitations on legitimate public uses of custom `<permission>` elements. Only the defender should have the `<permission>` element now. Some client of the defender's app (C) should not have the `<permission>` element and should simply rely upon the fact that the defender should be installed first. If the client were to define the `<permission>`, then either the client *or* the defender cannot be installed, which is pointless.

This has usability issues:

- A client should check, on first run of their app, if an expected defender (and its `<permission>` element) exists. If not, the client should alert the user to this fact and perhaps stop the app from proceeding further. The user would have to uninstall the client, install the defender, then reinstall the client, to get everything working properly, and the more the user uses the client app, the more painful the uninstall might be.
- It is impossible for two apps to be clients of each other. By definition, one app has to be installed first and the other second, which means only the first-to-be-installed app can have a custom `<permission>`. If Facebook wanted to hold a custom Twitter permission, and Twitter wanted to hold a custom Facebook permission, one of them is out of luck — if Facebook is installed first, it cannot request Twitter's permission (as it does not yet exist) nor can it define Twitter's permission (as if it does, Twitter cannot be installed). This *might* be able to be overcome for apps that are pre-loaded as part of a ROM mod or other custom Android build.

And, of course, this fix is only for Android 5.0 and above.

Mitigation Using PermissionUtils

The “first one in wins” rule also leads us to a mitigation strategy: On first run of our app, see if any other app has defined permissions that we have defined. If that has happened, then we are at risk, and take appropriate steps. If, however, no other app has defined our custom permissions, then the Android permission system should work for us, and we can proceed as normal.

The CWAC-Security library provides some helper code, in the form of the `PermissionUtils` class, to detect other apps defining the same custom permissions that you define.

The idea is that you call `checkCustomPermissions()` — a static method on `PermissionUtils` — on the first run of your app. It will return details about what other apps have already defined custom permissions that your app defines. If `checkCustomPermissions()` returns nothing, you know that everything is fine, and you can move ahead. Otherwise, you can:

- Check to see if the offending app is on some whitelist, or otherwise meets criteria that suggests that it is OK
- Alert the user, indicating that these already-installed apps will have access to your app secured components
- Upload details about the offending apps to your server, so you can try to track down whether they are legitimate users of some API that you are exposing or are malware
- Whatever else you feel is necessary

Example: Permission Proxy

The section on `ContentProvider` proxy plugins involves the use of a custom `signature`-level permission, to secure communications between the proxy and the host app that uses the proxy.

The idea is that the proxy holds some permission (e.g., `READ_CONTACTS`) and proxies data to some `ContentProvider` protected by that proxy (e.g., `CallLog`). The host app, rather than holding the permission and accessing the protected `ContentProvider` directly, can talk to the proxy. That way, the user only needs to grant permission if they elect to install the proxy; otherwise, the host app is blocked from having access to the protected content.

However, to prevent arbitrary other apps from using the proxy themselves, the host and proxy agree on a custom `signature`-level permission. The proxy defends itself using that permission, and the host requests the permission. In theory, this would limit communications with the proxy to only be from the host, or from other apps signed with the same signing key as the proxy and host use.

But, as is described above, another app could define the *same* permission, with a `normal` protection level. If that other app is installed first, not only can any other app access the proxy just by requesting the permission, but the attacker could have requested the same permission that it defined, so the user is unaware that the attacker holds this permission.

Hence, these proxies need to use some defensive measures, and the samples shown in this book employ `PermissionUtils` from the CWAC-Security library to do just that.

What the Proxy Does

The proxy is a `ContentProvider`. Specifically, there is an `AbstractCPProxy` subclass of `ContentProvider` that does the "heavy lifting", and a `CallLogProxy` subclass of `AbstractCPProxy` that handles some of the details of proxying the `CallLog` versus something else.

In `onCreate()` of the `AbstractCPProxy`, we use `PermissionUtils` and `checkCustomPermissions()` to determine whether or not anything was installed before us, that defined our custom permission, *other* than our known host app:

```
 @Override
 public boolean onCreate() {
  SharedPreferences prefs=
    PreferenceManager.getDefaultSharedPreferences(getContext());

  if (prefs.getBoolean(PREFS_FIRST_RUN, true)) {
   SharedPreferences.Editor editor=
     prefs.edit().putBoolean(PREFS_FIRST_RUN, false);

   HashMap<PackageInfo, ArrayList<PermissionLint>> entries=
     PermissionUtils.checkCustomPermissions(getContext());

   for (Map.Entry<PackageInfo, ArrayList<PermissionLint>> entry :
entries.entrySet()) {
    if
(!"com.commonsware.android.cpproxy.consumer".equals(entry.getKey().packageName)) {
     tainted=true;
     break;
    }
   }
```

```
      editor.putBoolean(PREFS_TAINTED, tainted).apply();
    }
    else {
      tainted=prefs.getBoolean(PREFS_TAINTED, true);
    }

    return(true);
  }
```

We use SharedPreferences to hold onto two key pieces of data:

1. Have we already done the check, as determined by PREFS_FIRST_RUN? If yes, we can just look up the results of the previous check. This is not merely an optimization — we do not have to worry about apps installed *after* us somehow redefining our custom permission.
2. When we did the check, did we find some package that had been installed before us, other than the host, that defined our custom permission, as determined by PREFS_TAINTED?

The actual check is accomplished by calling checkCustomPermissions() and iterating over the results. If there is an entry in the HashMap that represents a package other than ours, our environment is tainted.

The implementation in the book then uses the tainted data member in a checkTainted() private method:

```
  private void checkTainted() {
    if (tainted) {
      throw new RuntimeException(getContext().getString(R.string.tainted_abort));
    }
  }
```

This is called at the top of each ContentProvider method that we are proxying, such as insert():

```
  @Override
  public Uri insert(Uri uri, ContentValues values) {
    checkTainted();

    return(getContext().getContentResolver().insert(convertUri(uri),
                                                    values));
  }
```

The result is that if we feel that our environment is compromised, we fail any attempt to use the proxy.

Note that the proxy makes no attempt to confirm that the host app really *is* the host app, versus some other app with the same package name, perhaps distributed through other channels. We could augment the proxy with additional logic to handle that case, covered elsewhere in this book, if we wanted.

Also, we could, in theory, use `Binder.getCallingUid()` to confirm whether the request did come from the host app, and in that case, allow the proxy to do its work, failing in all other cases. We could even consider jettisoning the custom permission in this case, as if we know the UID of the other party, we can validate it instead of relying on a permission as a means of validation. However, that only works well in cases where the list of possible valid callers is knowable inside the app — this is fine for host-and-plugin or similar sorts of "hub-and-spoke" architectures but may be impractical in other cases.

What the Provider Could Do

The proxy has no decent means of alerting the user as to the reason for the lockdown. After all, it is a `ContentProvider`, not an `Activity`. In principle, it could use a `Notification`.

Another approach is to have the host app perform the same sorts of checks as does the proxy, and use that information to inform the user on first run of the app.

Finding the Available Permissions

On the one hand, developers should try to stick to documented permissions.

On the other hand, documentation is sometimes lacking. This is particularly true for permissions other than those defined by the OS itself, ones that come from other apps that change more frequently, including the Play Services SDK and framework.

You might find that you need to determine what permissions have been defined on a given device. Perhaps that need is at runtime — if you request a permission that does not exist, you cannot actually get it, and that may lead to problems in the future. Perhaps that need is just during development itself, to inspect some device and determine what it does and does not have in terms of permissions.

`PackageManager` offers methods to allow you to examine the device's permissions and permission groups. The `Permissions/PermissionReporter` sample app uses these methods to build up a tabbed UI listing the defined permissions, broken down by protection level.

PackageManager and Permission Groups

getAllPermissionGroups() on PackageManager will return a list of PermissionGroupInfo objects. This method takes an int value; 0 generally will be fine for your use cases.

On its own,PermissionGroupInfois not especially useful. However, you can turn around and call queryPermissionsByGroup()onPackageManager, passing in the namefrom thePermissionGroupInfo, to get all of the permissions in that group. This method also takes anintvalue as the second parameter, where once againo` will be fine.

queryPermissionsByGroup() returns a List of PermissionInfo objects. PermissionInfo has a few interesting values:

- name, which is the fully-qualified name of the permission
- descriptionRes, which is the string resource ID from the permission's android:description attribute
- protectionLevel, which is a set of flags indicating the nature of the permission's security

Note that to get the actual text of the description, there is a loadDescription() method on PermissionInfo that will do all the work to find the actual string for the description, based upon the app that defined the permission and the current locale.

To get the details of all the permissions defined on a device, we will have to call queryPermissionsByGroup() for each permission group. Each of those calls will involve IPC, and so this *might* be slow enough to warrant its own thread.

With that in mind, the PermissionReporter sample app has a PermissionLoadThread that collects information about the permissions on the system. That information is aggregated in a PermissionRosterLoadedEvent, which will be used with greenrobot's EventBus to provide the results to the UI when the data is ready:

```
// inspired by https://stackoverflow.com/a/32063384/115145

class PermissionLoadThread extends Thread {
  private final Context ctxt;
  private final PermissionRosterLoadedEvent result=
    new PermissionRosterLoadedEvent();

  PermissionLoadThread(Context ctxt) {
    this.ctxt=ctxt.getApplicationContext();
  }
```

When the thread runs, the `run()` method loops over the permission groups:

```
  @Override
  public void run() {
    PackageManager pm=ctxt.getPackageManager();

    addPermissionsFromGroup(pm, null);

    for (PermissionGroupInfo group :
      pm.getAllPermissionGroups(0)) {
      addPermissionsFromGroup(pm, group.name);
    }

    EventBus.getDefault().postSticky(result);
  }
```

As it turns out, not all permissions are part of a group. To find out the details of these un-grouped permissions, you need to call `queryPermissionsByGroup()` with a `null` permission group name.

For each permission group (plus the magic `null` group), we call a private `addPermissionsFromGroup()` method to collect the details of the permissions in that group:

```
  private void addPermissionsFromGroup(PackageManager pm,
                                       String groupName) {
    try {
      for (PermissionInfo info :
        pm.queryPermissionsByGroup(groupName, 0)) {
        int coreBits=
          info.protectionLevel &
            PermissionInfo.PROTECTION_MASK_BASE;

        switch (coreBits) {
          case PermissionInfo.PROTECTION_NORMAL:
            result.add(PermissionType.NORMAL, info);
            break;

          case PermissionInfo.PROTECTION_DANGEROUS:
            result.add(PermissionType.DANGEROUS, info);
            break;

          case PermissionInfo.PROTECTION_SIGNATURE:
```

```
      result.add(PermissionType.SIGNATURE, info);
      break;

     default:
      result.add(PermissionType.OTHER, info);
      break;
    }
   }
  }
  catch (PackageManager.NameNotFoundException e) {
   throw new IllegalStateException(
    "And you may ask yourself... how did I get here?");
  }
 }
```

The `protectionLevel` field on a `PermissionInfo` contains a number of different sorts of flags. The `PROTECTION_MASK_BASE` is a bitmask that restricts the bits we are looking at to the ones for basic protections. We then divide the permissions into four groups based on protection level:

- normal
- dangerous
- signature
- other (which, on older devices, will include `system` or `signatureOrSystem` permissions)

Those `PermissionInfo` objects are then poured into the `PermissionRosterLoadedEvent` object, with each `PermissionInfo` added to a list based on those four groups:

```
package com.commonsware.android.permreporter;

import android.util.SparseArray;

public enum PermissionType {
 NORMAL(0),
 DANGEROUS(1),
 SIGNATURE(2),
 OTHER(3);

 private static final SparseArray<PermissionType> BY_VALUE=
   new SparseArray<PermissionType>(4);

 static {
  for (PermissionType type : PermissionType.values()) {
   BY_VALUE.put(type.value, type);
  }
 }

 private final int value;

 private PermissionType(int value) {
    this.value=value;
  }

  static PermissionType forValue(int value) {
    return(BY_VALUE.get(value));
  }
}
```

`PermissionType` is an `enum` defined by this project for the four groups and includes some Java shenanigans for being able to convert back and forth between integer values and the `enum` values:

```
package com.commonsware.android.permreporter;

import android.content.pm.PermissionInfo;
import java.util.ArrayList;
import java.util.HashMap;

public class PermissionRosterLoadedEvent {
  HashMap<PermissionType, ArrayList<PermissionInfo>> roster=
      new HashMap<PermissionType, ArrayList<PermissionInfo>>();

  void add(PermissionType type, PermissionInfo info) {
    ArrayList<PermissionInfo> list=roster.get(type);

    if (list==null) {
      list=new ArrayList<PermissionInfo>();
      roster.put(type, list);
    }

    list.add(info);
  }

  ArrayList<PermissionInfo> getListForType(PermissionType type) {
    return(roster.get(type));
  }
}
```

`run()` then posts the `PermissionRosterLoadedEvent` on the event bus.

The Rest of the Sample

Of course, having a `PermissionLoadThread` and `PermissionRosterLoadedEvent` in isolation is not especially useful. Something needs to start the thread and something needs to consume the event. All of that is handled by the sample app's UI layer.

The Activity and ViewPager

The MainActivity has a ViewPager, along with a third-party tab implementation. onCreate() sets up a PermissionTabAdapter as the PagerAdapter and kicks off the PermissionLoadThread:

```
package com.commonsware.android.permreporter;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.ViewPager;
import io.karim.MaterialTabs;

public class MainActivity extends Activity  {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    ViewPager pager=(ViewPager)findViewById(R.id.pager);

    pager.setAdapter(new PermissionTabAdapter(this, getFragmentManager()));

    MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
    tabs.setViewPager(pager);

    new PermissionLoadThread(this).start();
  }
}
```

PermissionTabAdapter sets up four tabs, one per PermissionType, with labels pulled from string resources, and with instances of PermissionListFragment as the tab contents:

```
package com.commonsware.android.permreporter;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class PermissionTabAdapter extends FragmentPagerAdapter {
  private static final int[] TITLES={
      R.string.normal,
      R.string.dangerous,
      R.string.signature,
      R.string.other};
  private final Context ctxt;

  public PermissionTabAdapter(Context ctxt, FragmentManager mgr) {
    super(mgr);

    this.ctxt=ctxt;
  }
  @Override
  public int getCount() {
    return(4);
  }

  @Override
  public Fragment getItem(int position) {
    return(PermissionListFragment.newInstance(PermissionType.forValue(position)));
  }

  @Override
  public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
  }
}
```

The PermissionListFragment instances are provided the PermissionType associated with their position in the ViewPager, courtesy of the forValue() lookup method implemented on PermissionType

The Tab Content

PermissionListFragment uses the factory method pattern to hold onto that PermissionType in the arguments Bundle, so it survives a configuration change:

```
public class PermissionListFragment extends ListFragment {
  private static final String KEY_TYPE="type";

  static PermissionListFragment newInstance(PermissionType type) {
    PermissionListFragment frag=new PermissionListFragment();
    Bundle args=new Bundle();

    args.putSerializable(KEY_TYPE, type);
    frag.setArguments(args);

    return(frag);
  }
```

The PermissionListFragment registers for events on the event bus in onResume() and unregisters in onPause():

```
  @Override
  public void onResume() {
    super.onResume();

    EventBus.getDefault().registerSticky(this);
  }

  @Override
  public void onPause() {
    EventBus.getDefault().unregister(this);
    super.onPause();
  }
```

By using sticky events with greenrobot's EventBus, we do not have to worry about configuration changes, as we can pick up the last-delivered `PermissionRosterLoadedEvent` after the change.

Speaking of that event, there is an `onLoadMainThread()` method to pick up that `PermissionRosterLoadedEvent`, sort the permissions by name, and populate the `ListView` associated with this `ListFragement`:

```
public void onEventMainThread(PermissionRosterLoadedEvent event) {
  PermissionType type=(PermissionType)getArguments().getSerializable(KEY_TYPE);
  ArrayList<PermissionInfo> perms=event.getListForType(type);

  if (perms!=null && perms.size()>0) {
    Collections.sort(perms, new Comparator<PermissionInfo>() {
      @Override
      public int compare(PermissionInfo one, PermissionInfo two) {
        return (one.name.compareTo(two.name));
      }
    });

    setListAdapter(new PermissionAdapter(perms));
  }
  else {
    setListAdapter(new PermissionAdapter(new ArrayList<PermissionInfo>()));
    setEmptyText(getActivity().getString(R.string.msg_no_perms));
  }
}
```

The permissions are shown via a `PermissionAdapter`, which just uses the permission name for the contents:

```
private class PermissionAdapter extends ArrayAdapter<PermissionInfo> {
  PermissionAdapter(ArrayList<PermissionInfo> perms) {
    super(getActivity(), android.R.layout.simple_list_item_1, perms);
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    View result=super.getView(position, convertView, parent);
    TextView tv=(TextView)result.findViewById(android.R.id.text1);

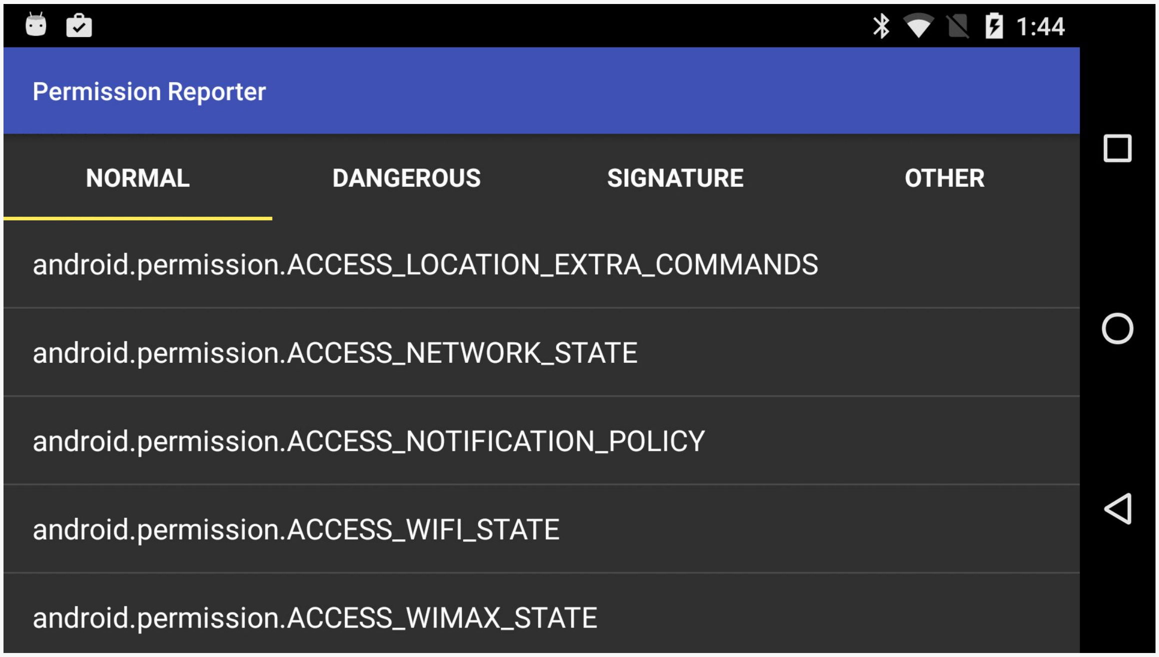
    tv.setText(getItem(position).name);

    return(result);
  }
}
```

This is required because `PermissionInfo` lacks a useful `toString()` implementation, so a simple `ArrayAdapter` is insufficient.

The Results

Running the app gives you four tabs for the four different `PermissionType` values:



android.permission.ACCESS_LOCATION_EXTRA_COMMANDS

android.permission.ACCESS_NETWORK_STATE

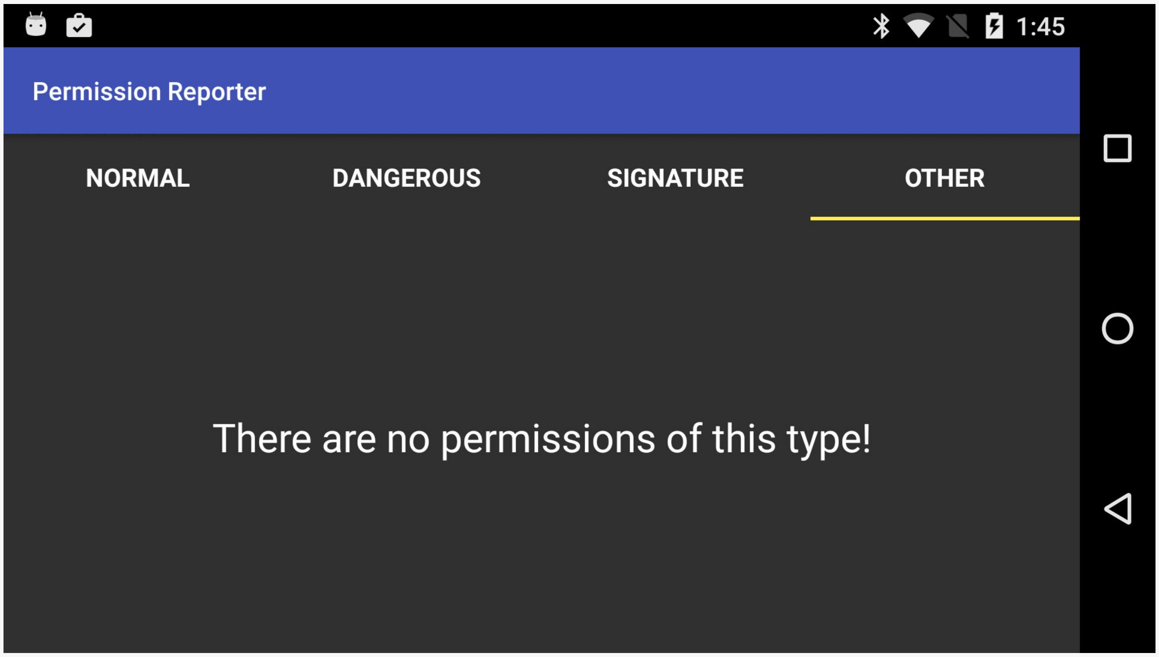
android.permission.ACCESS_NOTIFICATION_POLICY

android.permission.ACCESS_WIFI_STATE

android.permission.ACCESS_WIMAX_STATE

Figure 726: PermissionReporter, Normal Tab, on Android 6.0

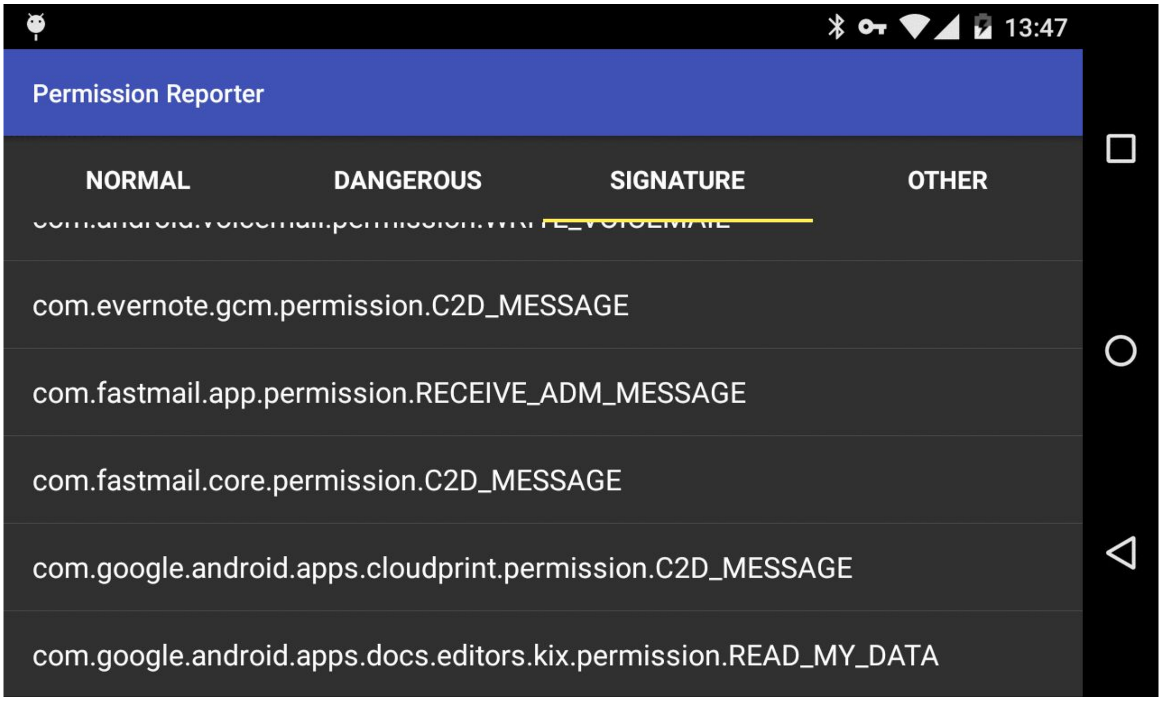
The fourth tab, for "other" permissions, is typicallye empty:



There are no permissions of this type!

Figure 727: PermissionReporter, Other Tab, on Android 6.0

The roster will include both system permissions, Play Services-defined permissions, and third-party permissions:



com.evernote.gcm.permission.C2D_MESSAGE

com.fastmail.app.permission.RECEIVE_ADM_MESSAGE

com.fastmail.core.permission.C2D_MESSAGE

com.google.android.apps.cloudprint.permission.C2D_MESSAGE

com.google.android.apps.docs.editors.kix.permission.READ_MY_DATA

Restricted Profiles and UserManager

Android 4.2 introduced the concept of having multiple distinct users of a tablet. Each user would get their own portion of internal and external storage, as if they each had their own tablet.

Android 4.3 extends this a bit further, with the notion of setting up restricted profiles. As the name suggests, a restricted profile is restricted, in terms of what it can do on the device. Some restrictions will be device-wide (e.g., can the user install apps?), and some restrictions will be per-app. You can elect to allow your app to be restricted, where you define the possible ways in which your app can be restricted, and the one setting up the restricted profile can then configure the desired options for some specific profile.

This chapter will explain how users set up these restricted profiles, what you can learn about the device-wide restrictions, and how you can offer your own restrictions for your own app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on files and its section on multiple user accounts.

Android Tablets and Multiple User Accounts

The theory is that tablets are likely to be shared, whether among family members, among team members in a business, or similar sorts of group settings. There are three levels of "user" in an Android 4.3+ tablet that we will need to consider.

Primary User

The primary user is whoever first set up the tablet after initial purchase. In a family, this is probably a parent; in a corporate setting, this might be an IT administrator.

Prior to Android 4.2, there was only one user per device, and that user could (generally) do anything. In Android 4.2+, the primary user holds this role.

One thing that the primary user can do is set up other users, via the Users option in the Settings app:

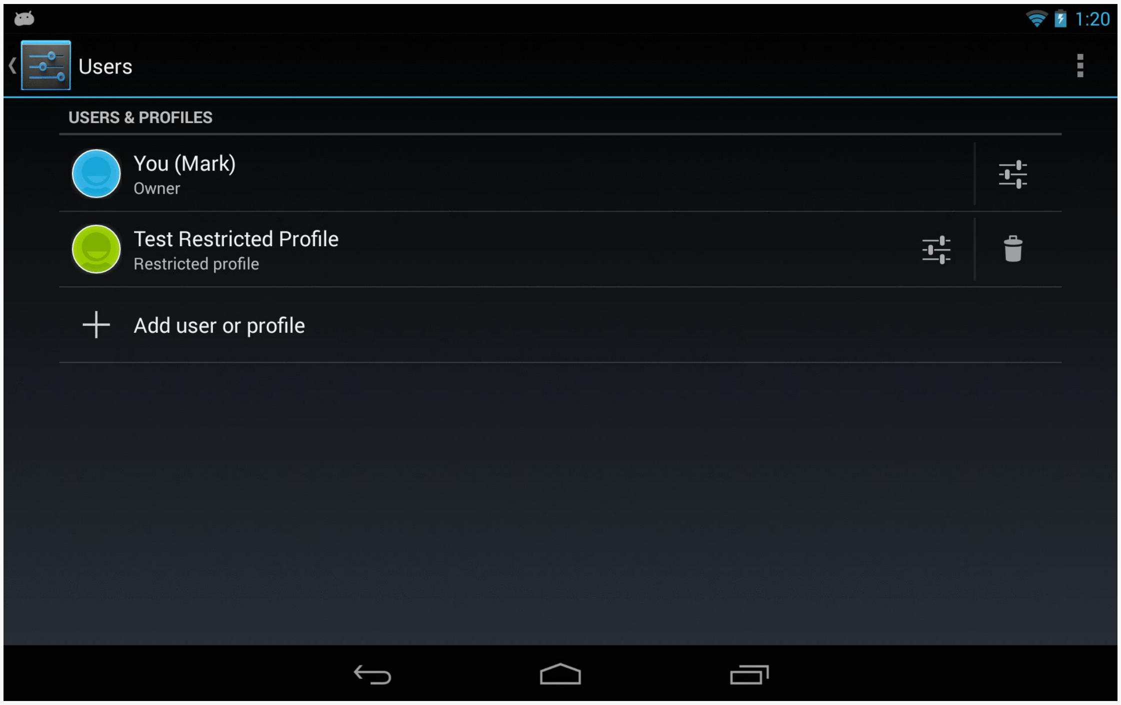


Figure 728: Users Screen in Settings

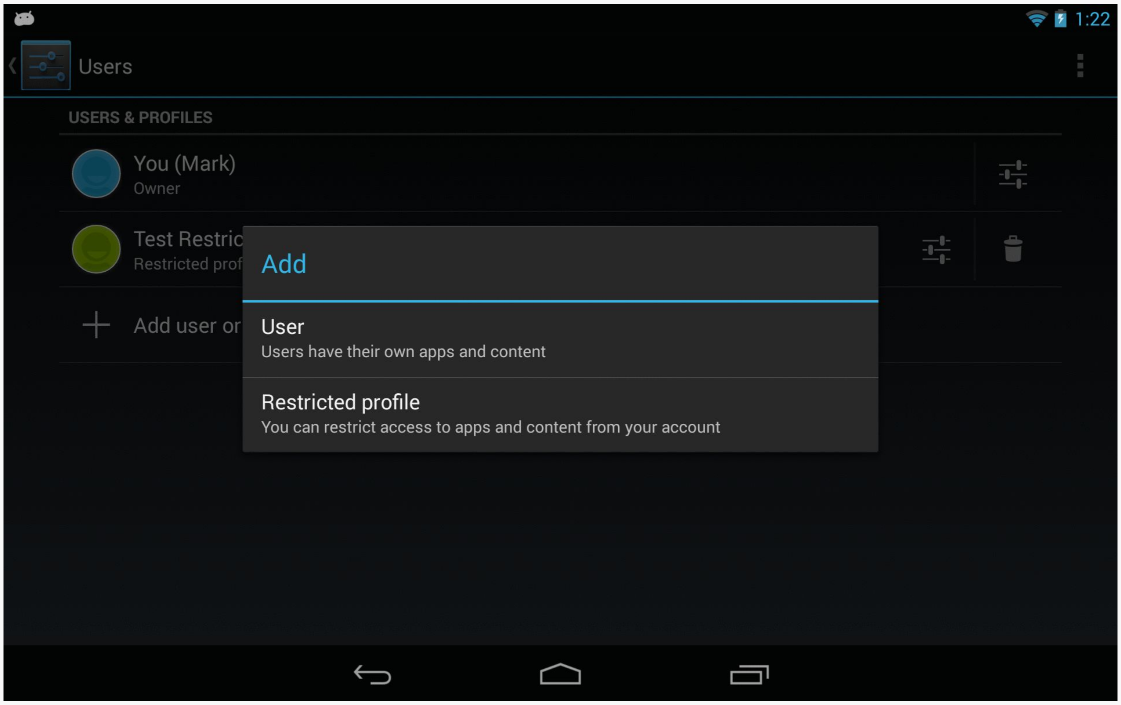
Tapping the "Add user or profile" entry allows the primary user to set up another user or restricted profile:



Add

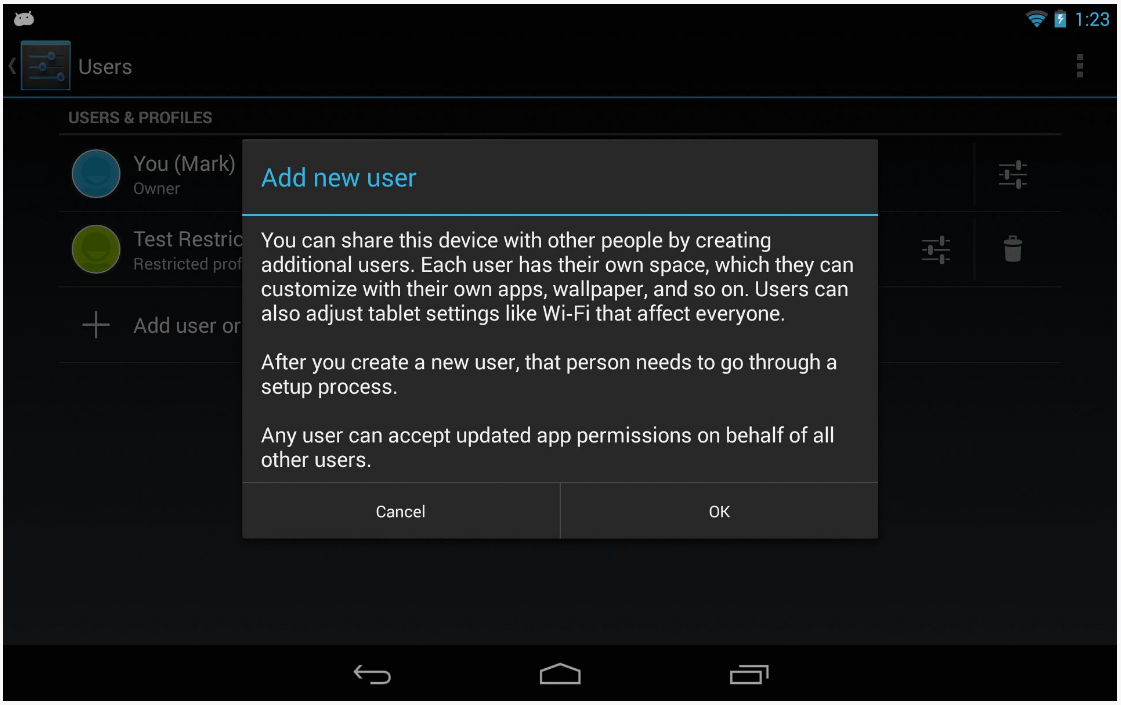
User
Users have their own apps and content

Restricted profile
You can restrict access to apps and content from your account

Figure 729: Add Dialog in Users Screen in Settings

Secondary User

Choosing "User" from the Add dialog will define a secondary user of the device. This user has much of the same control as the primary user, in terms of being able to install and run whatever apps are desired.



Add new user

You can share this device with other people by creating additional users. Each user has their own space, which they can customize with their own apps, wallpaper, and so on. Users can also adjust tablet settings like Wi-Fi that affect everyone.

After you create a new user, that person needs to go through a setup process.

Any user can accept updated app permissions on behalf of all other users.

Figure 730: Add New User Warning Dialog in Users Screen in Settings

Restricted Profile

A restricted profile is akin to a secondary user, in that it gets its own separate portion of internal and external storage. Beyond that, though, the primary user can further configure what the restricted profile can access:

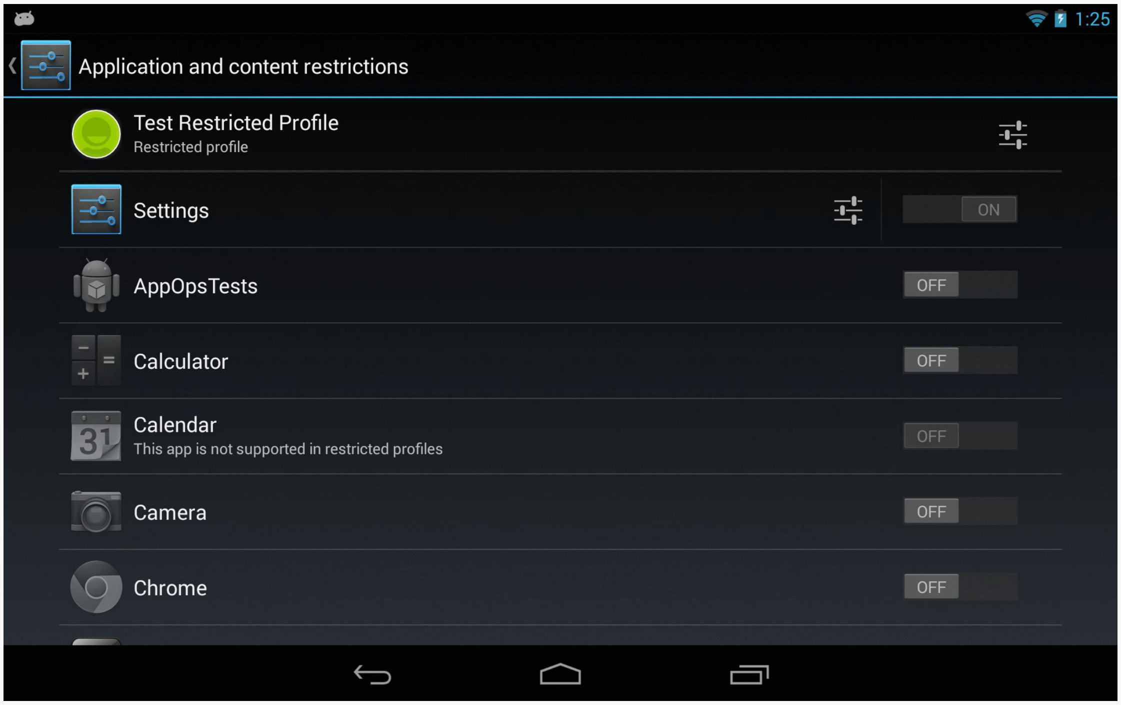


Figure 731: Restricted Profile Configuration Screen in Settings

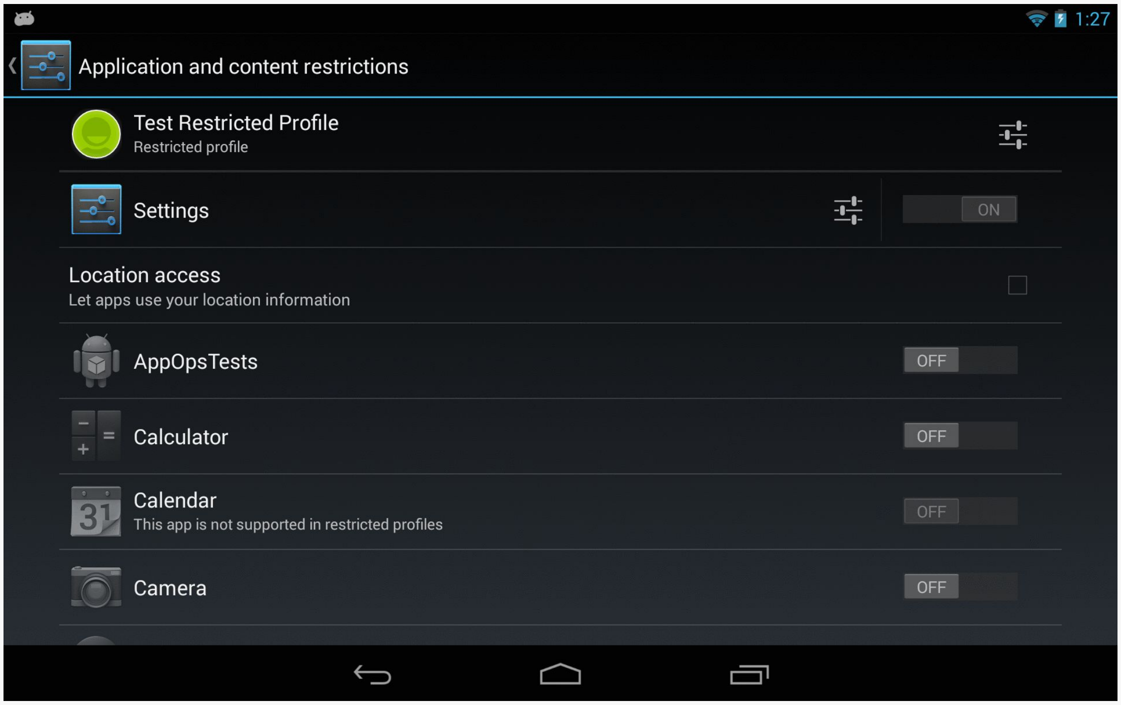
The bulk of the restricted profile configuration screen is a list of apps, with `Switch` widgets to allow the primary user to allow or deny access to each app.

Some apps will have the "settings" icon to the left of the `Switch`. Tapping that will either bring up a dedicated activity for restricting operations within that app, or it will add new rows to the list with individual restriction options for that app. For example, tapping the settings icon for the Settings app adds a row where the primary user can block location sharing:



Application and content restrictions

Test Restricted Profile
Restricted profile

Settings ON

Location access
Let apps use your location information □

AppOpsTests OFF

Calculator OFF

Calendar
This app is not supported in restricted profiles OFF

Camera OFF

Figure 732: Location Sharing Restrictions

The "settings" icon in the first row, for the profile itself, will allow the primary user to control things for the entire profile, notably its name.

Switching to the restricted profile (e.g., via the lockscreen) will show the constrained set of available apps:

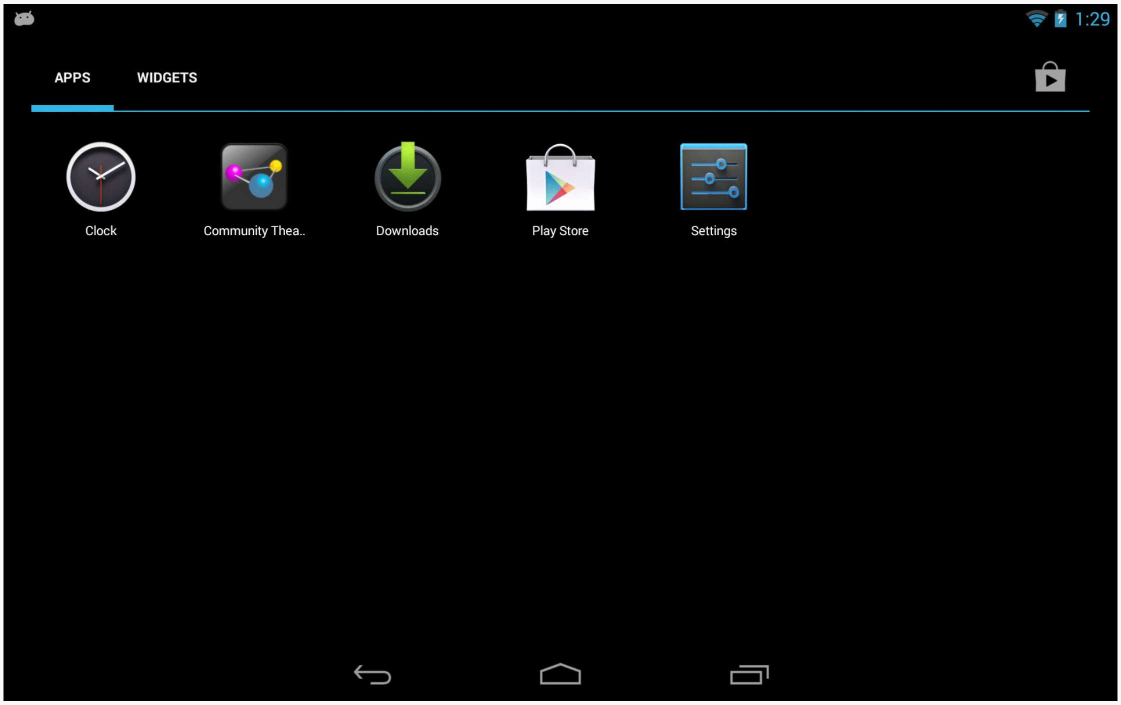


Figure 733: Apps in a Restricted Profile

Determining What the User Can Do

Your app can find out what device-level restrictions were placed on the current user by means of the `UserManager` system service. Specifically, as you can see in `MainActivity` of the [`RestrictedProfiles/Device`]() sample project, all you need to do is:

- Acquire an instance of a `UserManager` by calling `getSystemService()` on a `Context`, passing in `USER_SERVICE` as the service's name
- Calling `getUserRestrictions()` on the `UserManager`:

```
package com.commonsware.android.profile.device;

import android.app.Activity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    UserManager mgr=(UserManager)getSystemService(USER_SERVICE);
    Bundle restrictions=mgr.getUserRestrictions();

    if (restrictions.keySet().size() > 0) {
      setContentView(R.layout.activity_main);

      RestrictionsFragment f=
          (RestrictionsFragment)getFragmentManager().findFragmentById(R.id.contents);

      f.showRestrictions(restrictions);
    }
    else {
      Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
           .show();
      finish();
    }
  }
}
```

`getUserRestrictions()` returns a `Bundle`, whose keys are documented on `UserManager` for various device-level restrictions that theoretically can be placed on the user. Here, "theoretically" means that while `UserManager` documents several `DISALLOW_*` constants, only two seem to be directly accessible to the primary user for configuration via Settings:

- `DISALLOW_MODIFY_ACCOUNTS`, to prevent a restricted profile from, among other things, modifying restricted profiles
- `DISALLOW_SHARE_LOCATION`, to prevent the apps run in this restricted profile from gathering location data

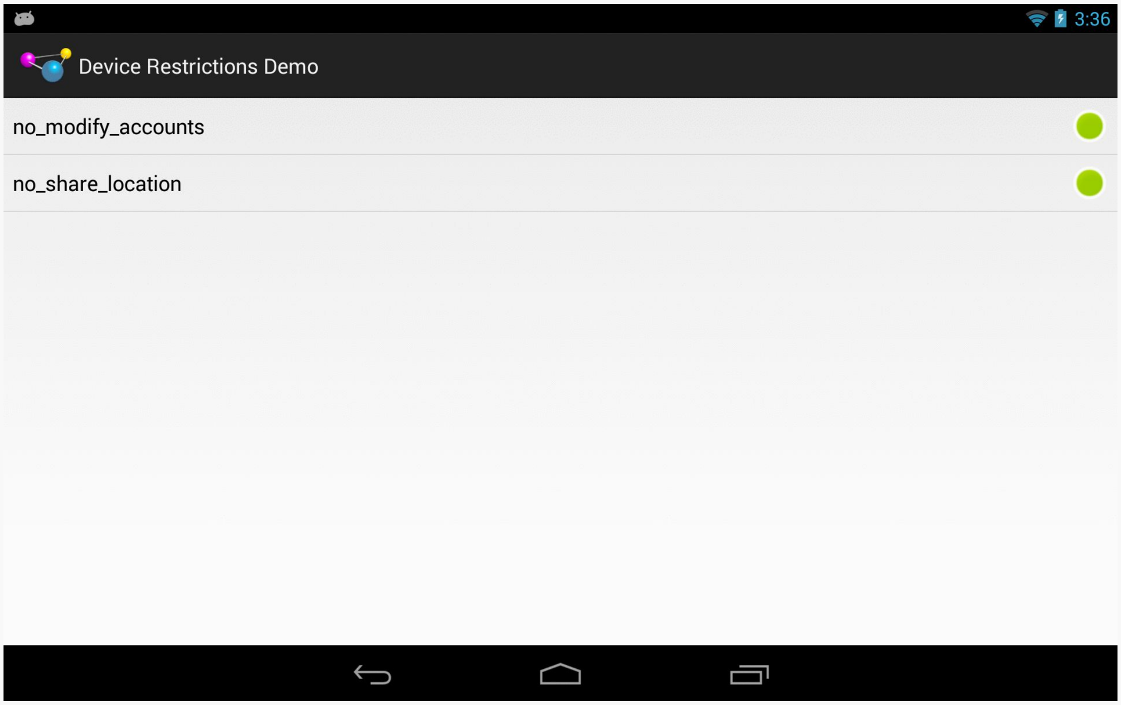
`MainActivity` examines the `Bundle` and, if it is empty, just displays a `Toast` and exits via `finish()`. This is the behavior you will see if you run this sample app on a non-restricted profile, such as the primary user. If, however, the `Bundle` has one or more keys, we inflate an `activity_main` layout that contains a `RestrictionsFragment` in a `<fragment>` element:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/contents"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  class="com.commonsware.android.profile.device.RestrictionsFragment"/>
```

We then retrieve the `RestrictionsFragment` from the `FragmentManager` and call `showRestrictions()` on it, passing in the `Bundle`.

`RestrictionsFragment` is a `ListFragment` employing a custom `RestrictionsAdapter`. The `RestrictionsAdapter` wraps around the `Bundle` and an `ArrayList` of its keys. The `RestrictionsAdapter` constructor creates the `ArrayList` by sorting the `keySet()` of the `Bundle`. `getView()` on `RestrictionsAdapter` lets the superclass handle inflating the row (`android.R.layout.simple_list_item_1`), then puts an icon on the right side by using `setCompoundDrawablesWithIntrinsicBounds()`, which can tuck a drawable resource onto any of the four sides of a `TextView`.

The resulting list will show green icons for keys where the `Bundle` has stored a `true` `Boolean` value, and a red icon for `false`:



no_modify_accounts ●

no_share_location ●

Figure 734: Default Device Restrictions, on a Nexus 7 (2013)

Since the keys are negative in tone (e.g., `DISALLOW_MODIFY_ACCOUNTS`), `true` means that the restriction is enforced and the underlying operation (e.g., modifying accounts) *cannot* be done.

Impacts of Device-Level Restrictions

Your app's functionality may be limited by these device-level restrictions. This section outlines some of the results you should expect from a restricted profile.

Restricting Location Access

If a restricted profile is prevented from sharing the device's location with apps, those apps simply will not receive location updates. There is no good way to detect this via the location API (e.g., `isProviderEnabled()` returns `true`), so you will have to detect this via `getUserRestrictions()` on `UserManager` as noted above.

Uninstalling Apps

Even without specific configuration, the restricted profile can only uninstall apps that they are available to that profile. However, since apps are really shared between profiles, this only removes that app from the restricted profile; it does not actually uninstall the app from the device as a whole.

Enabling Custom Restrictions

As noted earlier, the list of apps that is shown on the restricted profile configuration screen in Settings can have "settings" icons. The Settings app itself will have a settings icon, to allow the primary user to configure device-level restrictions.

But, what if you want *your* app to have such a settings icon? Maybe it makes sense for your app to allow the primary user to restrain restricted profiles from doing certain things within your app:

- Block in-app purchases
- Only show certain categories of content, not the full roster
- Only allow operation during certain times of the day

The means by which the Settings app restricts profiles is also available to you. You can declare to Android what aspects of your app can be restricted. Android will then collect that restriction data for you. Your app, at runtime, can then determine what restrictions are in place (if any) and take appropriate steps.

All of this will be illustrated using the [`RestrictedProfiles/App`] sample project.

Stating Your Restrictions

The biggest thing that you need to do to restrict your app is teach Android how to collect restrictions. In other words, you need to tell Android what to do when the user taps that settings icon in the restricted profile entry for your app.

You have two major options:

- Provide a list of the restrictions that Android should render and collect itself, or
- Provide an Intent that can be used to start up an activity of your own design where you collect those restrictions

Either approach will require you to set up a manifest-registered BroadcastReceiver, set to respond to the android.intent.action.GET_RESTRICTION_ENTRIES action:

```
    <receiver android:name="RestrictionEntriesReceiver">
      <intent-filter>
        <action android:name="android.intent.action.GET_RESTRICTION_ENTRIES"/>
      </intent-filter>
    </receiver>
```

That BroadcastReceiver will be called with sendOrderedBroadcast(), not so much to affect ordering, but to allow the BroadcastReceiver to send back a result via its setResultExtras() method. This provides a Bundle that the broadcaster can eventually retrieve, in this case providing details of what restrictions we wish to collect from the primary user to restrict the profile.

Option #1: RestrictionEntry List

To collect restrictions the way the Settings app does — with restriction rows appearing below your app in the restricted profile screen in Settings – your BroadcastReceiver will need to put an entry into the return Bundle, under the key of EXTRA_RESTRICTIONS_LIST (a constant defined on the Intent class). The value needs to be an ArrayList of RestrictionEntry objects, with each RestrictionEntry describing one restriction to collect.

Another thing that the RestrictionEntry objects contain is their current value. Android itself retains these values and supplies them to your BroadcastReceiver via an EXTRA_RESTRICTIONS_BUNDLE extra on the incoming Intent. Your app needs to use those current values when constructing its list of RestrictionEntry objects to return.

So, let's take a look at RestrictionEntriesReceiver, the receiver we have set up to handle the android.intent.action.GET_RESTRICTION_ENTRIES action for this sample app.

The entry point for RestrictionEntriesReceiver is onReceive(), as it is for any basic BroadcastReceiver:

```
@Override
public void onReceive(Context ctxt, Intent intent) {
  Bundle current=
      (Bundle)intent.getParcelableExtra(Intent.EXTRA_RESTRICTIONS_BUNDLE);
  ArrayList<RestrictionEntry> restrictions=
      new ArrayList<RestrictionEntry>();

  restrictions.add(buildBooleanRestriction(ctxt, current));
  restrictions.add(buildChoiceRestriction(ctxt, current));
  restrictions.add(buildMultiSelectRestriction(ctxt, current));

  Bundle result=new Bundle();

  result.putParcelableArrayList(Intent.EXTRA_RESTRICTIONS_LIST,
                                restrictions);

  setResultExtras(result);
}
```

In onReceive(), RestrictionEntriesReceiver pulls out the Bundle of current restrictions, by retrieving the EXTRA_RESTRICTIONS_BUNDLE extra from the Intent passed into onReceive(). Note that this Bundle could very well be empty, if this is the first time we are being asked for restrictions.

RestrictionEntriesReceiver creates an empty ArrayList of RestrictionEntry objects, then calls a series of builder methods to create a total of three such RestrictionEntry objects, adding each to the list. onReceive() goes on to create a Bundle representing the results to be returned, packages the ArrayList in that Bundle under the EXTRA_RESTRICTIONS_LIST key, and returns that Bundle to the caller by means of setResultExtras().

The three builder methods are each responsible for defining a single RestrictionEntry, including populating it with the current value from the current Bundle.

There are three types of RestrictionEntry, for boolean, single-selection lists ("choice"), and multi-selection lists. The RestrictionEntry constructor takes two parameters:

- The String key under which we will later retrieve this restriction value
- The current value of the restriction

The current value is:

- A boolean for boolean restrictions
- A String for choice restrictions
- A String array for multi-select restrictions

Our first builder, buildBooleanRestriction(), populates and returns a RestrictionEntry designed to collect a boolean value from the primary user, via a CheckBox:

```
private RestrictionEntry buildBooleanRestriction(Context ctxt,
                                                 Bundle current) {
  RestrictionEntry entry=
      new RestrictionEntry(RESTRICTION_BOOLEAN,
                           current.getBoolean(RESTRICTION_BOOLEAN,
                                              false));

  entry.setTitle(ctxt.getString(R.string.boolean_restriction_title));
  entry.setDescription(ctxt.getString(R.string.boolean_restriction_desc));

  return(entry);
}
```

buildBooleanRestriction() retrieves the current value from current Bundle to use with the RestrictionEntry constructor. In this case, if there is no such entry in the Bundle, the overall default value is false.

Each RestrictionEntry can have a title (setTitle()), supplying a string which will be displayed to describe what this restriction is. A boolean restriction can also have a description (setDescription()), containing another string with a bit more text. Note that, at the present time, the other two types of restrictions will ignore any description that you include. Also note that the values supplied to setTitle() and setDescription() need to be strings, and so if you wish to use a string resource, you will need to get the actual string value yourself via getString().

The remaining two builder methods have a similar structure:

```
private RestrictionEntry buildChoiceRestriction(Context ctxt,
                                                Bundle current) {
  RestrictionEntry entry=
      new RestrictionEntry(RESTRICTION_CHOICE,
                           current.getString(RESTRICTION_CHOICE));

  entry.setTitle(ctxt.getString(R.string.choice_restriction_title));
  entry.setChoiceEntries(ctxt, R.array.display_values);
  entry.setChoiceValues(ctxt, R.array.restriction_values);

  return(entry);
}

private RestrictionEntry buildMultiSelectRestriction(Context ctxt,
                                                     Bundle current) {
  RestrictionEntry entry=
      new RestrictionEntry(RESTRICTION_MULTI,
                           current.getStringArray(RESTRICTION_MULTI));

  entry.setTitle("A Multi-Select Restriction");
  entry.setChoiceEntries(ctxt, R.array.display_values);
  entry.setChoiceValues(ctxt, R.array.restriction_values);

  return(entry);
}
```

As with a ListPreference, you provide two string arrays to the RestrictionEntry, representing the values the primary user sees (setChoiceEntries()) and the corresponding values to be supplied to your app based upon the choice(s) (setChoiceValues()). You can supply these either as Java string arrays or as <string-array> resources – RestrictionEntriesReceiver goes with the latter approach.

Option #2: Custom Restriction Activity

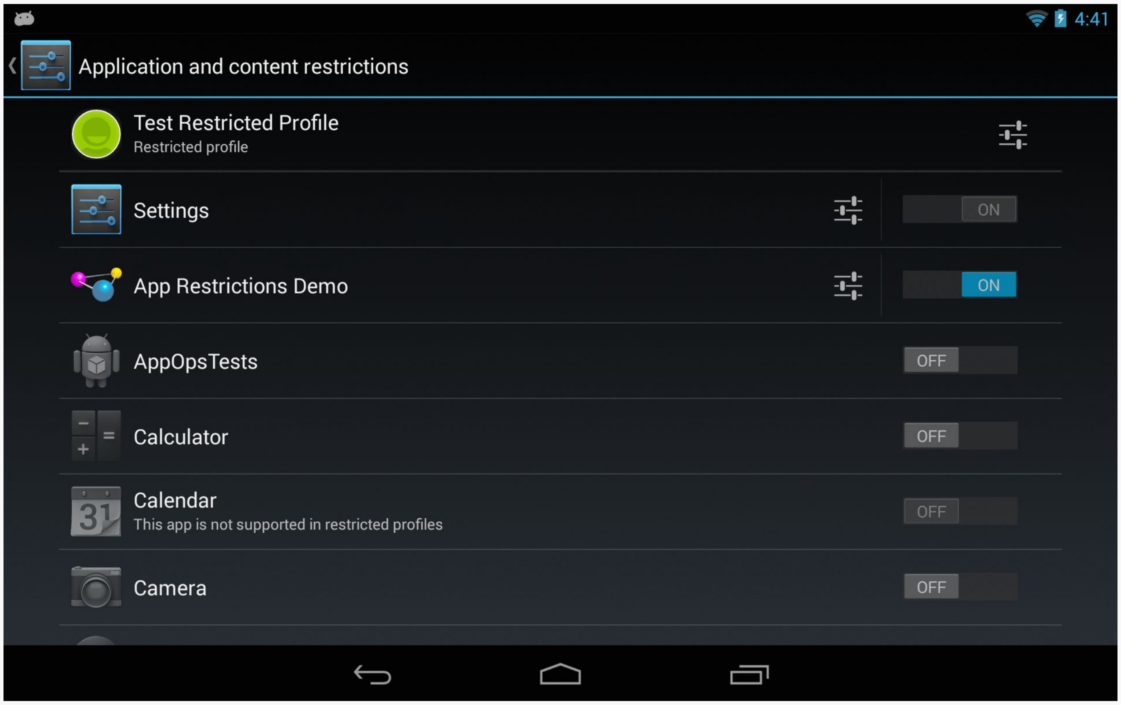
It may be that what you want to collect, in terms of restrictions, cannot readily be represented in the form of Switch widgets and list dialogs. For example, to restrict use of your app based on time, it would be nice to use a TimePickerDialog or the equivalent.

The alternative to returning an EXTRA_RESTRICTIONS_LIST roster of RestrictionEntry objects from your BroadcastReceiver is to have the result Bundle contain EXTRA_RESTRICTIONS_INTENT. This key should point to an Intent that identifies the activity that you want to start up when the user taps the settings icon. Android will call startActivityForResult() on that Intent when the user taps on the settings icon.

Your job is to collect the restrictions from the user, using the EXTRA_RESTRICTIONS_BUNDLE from the incoming Intent to pre-populate your activity, if desired. When the user is done, you should call setResult(), passing in an Intent that contains another EXTRA_RESTRICTIONS_BUNDLE with the revised data, or optionally a EXTRA_RESTRICTIONS_LIST (with the RestrictionEntry objects containing the values to be used).

What the Primary User Sees

Given the `RestrictionEntriesReceiver` described above, when the primary user goes to configure a restriction profile, your app will appear with a settings icon next to it:



Application and content restrictions

Test Restricted Profile
Restricted profile

Settings ON

App Restrictions Demo ON

AppOpsTests OFF

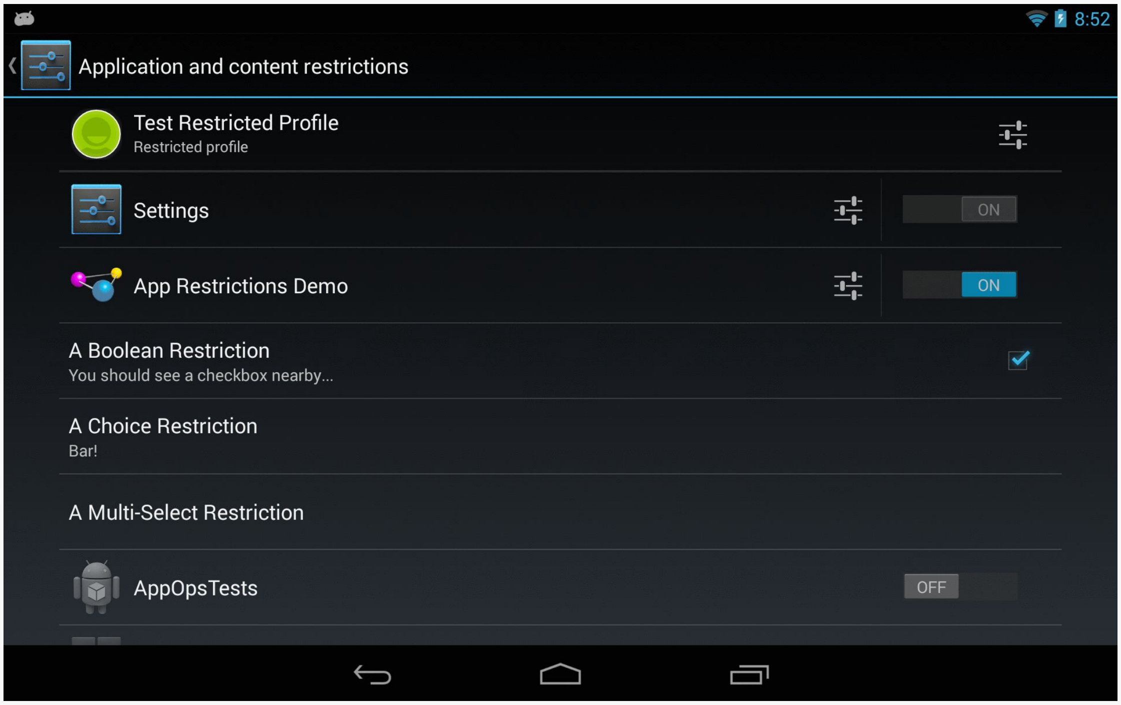
Calculator OFF

Calendar
This app is not supported in restricted profiles OFF

Camera OFF

Figure 735: Restricted Profile, Showing App Settings Icon

Tapping that settings icon will "unfold" and display the restrictions that you configured via the `RestrictionEntry` objects:



8:52

Application and content restrictions

Test Restricted Profile
Restricted profile

Settings — ON

App Restrictions Demo — ON

A Boolean Restriction
You should see a checkbox nearby... ☑

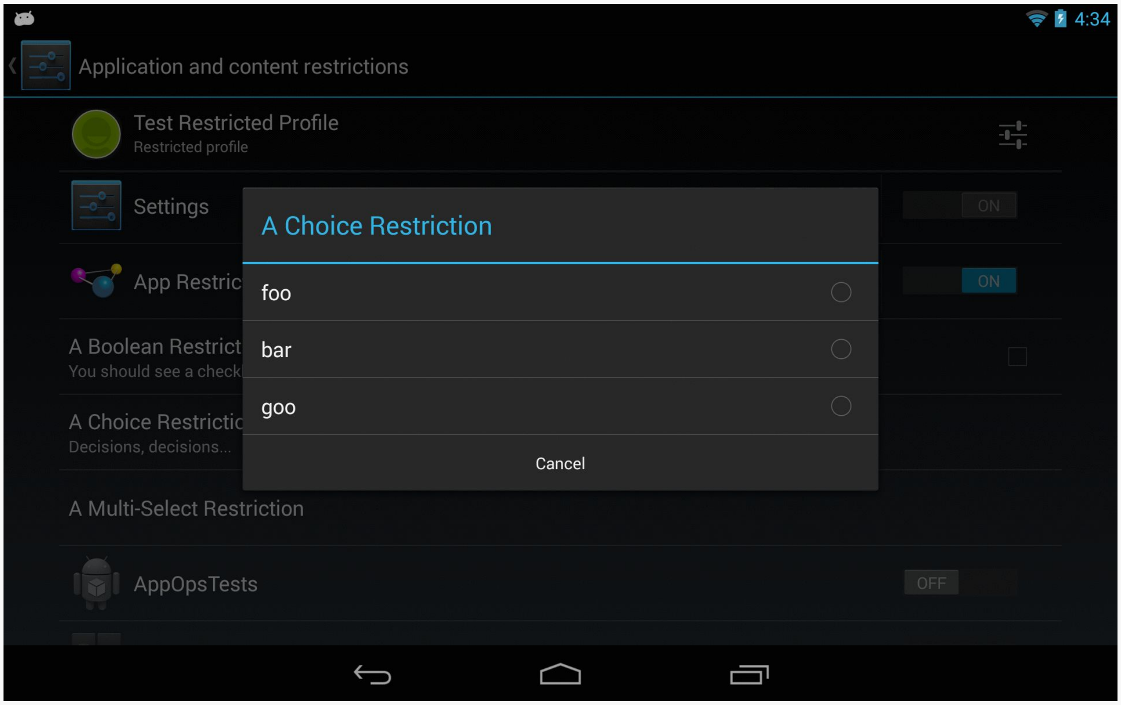
A Choice Restriction
Bar!

A Multi-Select Restriction

AppOpsTests — OFF

Figure 736: Restricted Profile, Showing App Restrictions

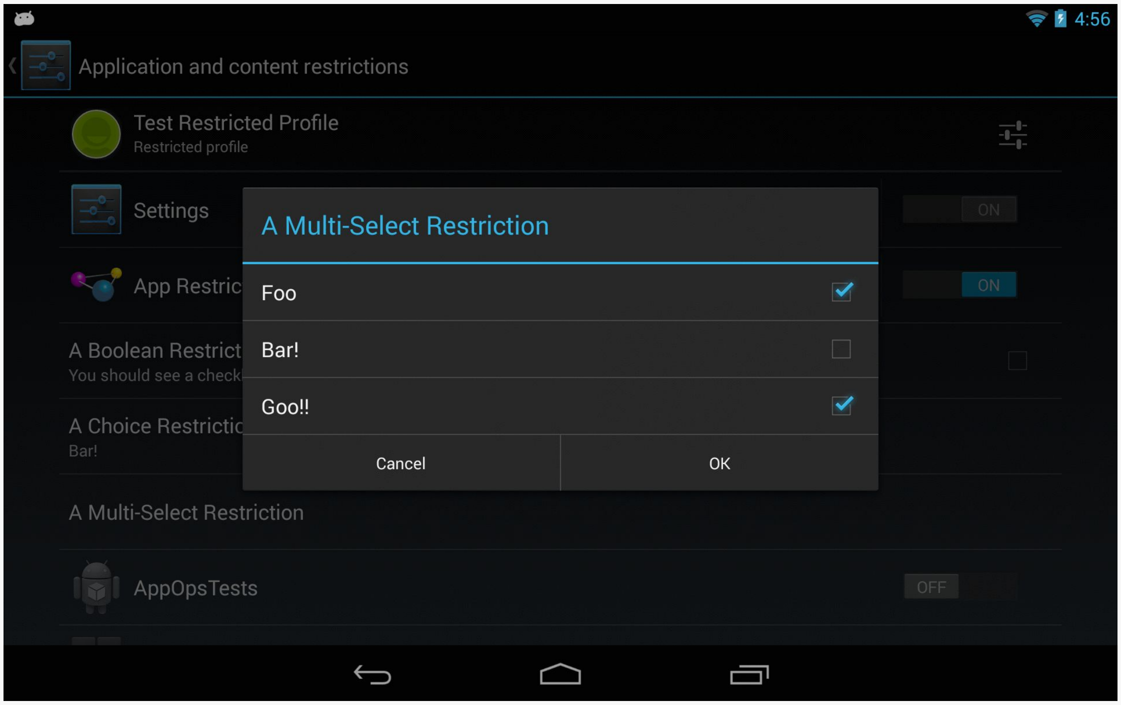
The primary user can then interact with your restrictions, toggling checkboxes and popping up the list dialogs:



A Choice Restriction

- foo ○
- bar ○
- goo ○

Figure 737: Restricted Profile, Showing Choice Restriction



A Multi-Select Restriction

- Foo ☑
- Bar! □
- Goo!! ☑

Figure 738: Restricted Profile, Showing Multi-Select Restriction

Finding Out the Current Restrictions

Now, the rest of your app needs to find out what restrictions are placed upon it, so behavior can be tailored accordingly. To do this, call `getApplicationRestrictions()` on `UserManager`, passing in your package name, as seen here in `MainActivity`:

```
package com.commonsware.android.profile.app;

import android.app.Activity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends Activity {
  @Override
  protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    UserManager mgr=(UserManager)getSystemService(USER_SERVICE);
    Bundle restrictions=
        mgr.getApplicationRestrictions(getPackageName());

    if (restrictions.keySet().size() > 0) {
      setContentView(R.layout.activity_main);

      RestrictionsFragment f=
          (RestrictionsFragment)getFragmentManager().findFragmentById(R.id.contents);

      f.showRestrictions(restrictions);
    }
    else {
      Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
           .show();
      finish();
    }
  }
}
```

This `Bundle` could be empty, or it could have values specified by the primary user to restrict the profile that is running your app.

In the case of this sample, we once again set up a `RestrictionsAdapter` to show the results, if the `Bundle` is not empty. However, our adapter is a bit more complicated, as there are more than boolean restrictions now. `getView()` has been updated to handle all three possible restrictions, showing the icon for the boolean restriction, and showing the value(s) from the lists in the other restrictions:

```
package com.commonsware.android.profile.app;

import android.app.ListFragment;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.TextView;
import java.util.ArrayList;
import java.util.Collections;

public class RestrictionsFragment extends ListFragment {
  public void showRestrictions(Bundle restrictions) {
    setListAdapter(new RestrictionsAdapter(restrictions));
  }

  class RestrictionsAdapter extends ArrayAdapter<String> {
    Bundle restrictions;

    RestrictionsAdapter(Bundle restrictions) {
      super(getActivity(), android.R.layout.simple_list_item_1,
            new ArrayList<String>());

      ArrayList<String> keys=
          new ArrayList<String>(restrictions.keySet());

      Collections.sort(keys);
      addAll(keys);

      this.restrictions=restrictions;
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
      TextView row=
          (TextView)super.getView(position, convertView, parent);
      String key=getItem(position);

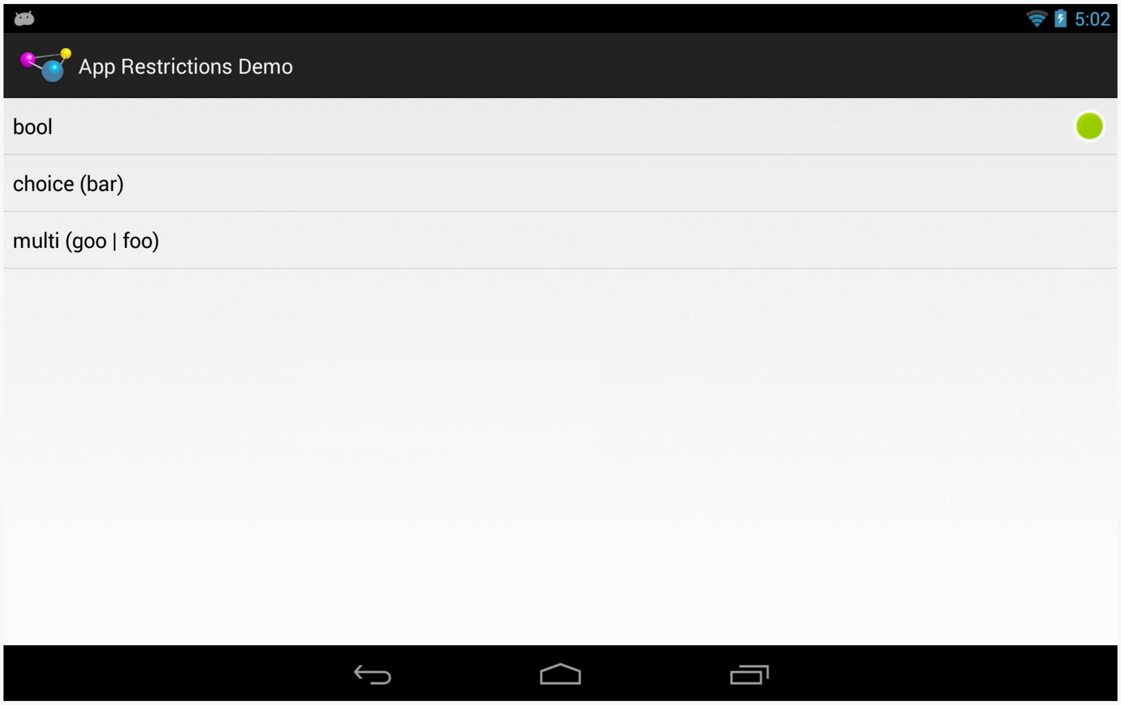
      if (RestrictionEntriesReceiver.RESTRICTION_BOOLEAN.equals(key)) {
        int icon=
            restrictions.getBoolean(key) ? R.drawable.ic_true
                : R.drawable.ic_false;

        row.setCompoundDrawablesWithIntrinsicBounds(0, 0, icon, 0);
      }
      else if (RestrictionEntriesReceiver.RESTRICTION_CHOICE.equals(key)) {
        row.setText(String.format("%s (%s)", key,
                                  restrictions.getString(key)));
      }
      else {
        String value=
            TextUtils.join(" | ", restrictions.getStringArray(key));

        row.setText(String.format("%s (%s)", key, value));
      }

      return(row);
    }
  }
}
```

The result, when run on a restricted profile with restrictions placed upon our app, is to show those restrictions:



App Restrictions Demo

bool ●

choice (bar)

multi (goo | foo)

Figure 739: App Restrictions Demo, on a Restricted Profile

The Uninstall Bug

Note that there appears to be a bug in Android 4.3, where an uninstalled app's restrictions remain intact. Your app may continue to show up in the restricted profile, and if the user reinstalls the app later on, whatever original restrictions were placed on a restricted profile return.

Implicit Intents May Go "Boom"

The primary user of a tablet, when setting up a restricted profile, can control what apps are available to that profile. In many cases, if the user is setting up a restricted profile in the first place, the list of apps available to that profile will be fairly limited, such as only allowing a young child to access a few games and educational apps.

`startActivity()` always has the chance of throwing an `ActivityNotFoundException`. However, for certain `Intent` actions, we often ignore this possibility, because we are certain that there will be an app that can handle our request:

- All Android devices have Web browsers, right?
- All Android devices have some sort of mapping application, right?
- All Android devices let you pick a contact, right?

Now, with restricted profiles, you will need to deal with the `ActivityNotFoundException` case all of the time. You have three basic approaches for this:

1. Wrap all `startActivity()` and `startActivityForResult()` calls in a `try/catch` block that catches `ActivityNotFoundException` and intelligently handle the problem
2. Use `PackageManager` and `resolveActivity()` *before* trying to start the activity, where if `resolveActivity()` returns `null`, you know that there is no activity available to handle your desired operation
3. Switch out some of your `startActivity()` and `startActivityForResult()` calls for implementations in your app (e.g., embed Maps V2 rather than try to launch a potentially-nonexistent activity)

You might consider implementing a `safeStartActivity()` utility method that wraps up your particular plan, so you can debug it once.

Tapjacking

On the whole, Android's security is fairly good for defending an app from another app. Between using Linux users and filesystems for protecting an application's files from other apps, to the use of custom permissions to control access to public interfaces, an application would seem to be relatively protected.

However, there is one attack vector that existed until Android 4.0.3: tapjacking. This chapter outlines what tapjacking is and what you can do about it to protect your app's users, for as long as you are supporting devices older than 4.0.3.

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- broadcast Intents
- service theory

What is Tapjacking?

Tapjacking refers to another program intercepting and inspecting touch events that are delivered to your foreground activity (or related artifacts, such as the input method editor). At its worst, tapjackers could intercept passwords, PINs, and other private data.

The term "tapjacking" seems to have been coined by Lookout Mobile Security, in a blog post that originally demonstrated this issue.

You might be wondering how this is possible. There are a handful of approaches to implementing this. The Lookout blog post cited perhaps the least useful approach: making a transparent `Toast`. The [Tapjacking/Jackalope]() sample application will illustrate a far more troublesome implementation.

World War Z (Axis)

You may recall that there are three axes to consider with Android user interfaces. The X and Y axes are the ones you typically think about, as they control the horizontal and vertical positioning of widgets in an activity. The Z axis — effectively "coming out the screen towards the user's eyes" — can be used in applications for sophisticated techniques, such as a pop-up panel.

Normally, you think of the Z axis within the scope of your activity and its widgets. However, there are ways to display "system alerts" – widgets that can float over the top of any activity. A `Toast` is the one you are familiar with, most likely. A `Toast` displays something on the screen, yet touch events on the `Toast` itself will be passed through to the underlying activity. Lookout demonstrated that it is possible to create a fully-transparent `Toast`. However, the lifetime of a `Toast` is limited (3.5 seconds maximum), which would limit how long it can try to grab touch events.

However, any application holding the `SYSTEM_ALERT_WINDOW` permission can display their own "system alerts" with custom look and custom duration. By making one that is fully transparent and lives as long as possible, a tapjacker can obtain touch events for any application in the system, including lock screens, home screens, and any standard activity.

Enter the Jackalope

To demonstrate this, let's take a look at the Jackalope sample application. It consists of a tiny activity and a service, with the service doing most of the work.

The activity employs `Theme.NoDisplay`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
      android:versionCode="1"
      android:versionName="1.0" package="com.commonsware.android.tj.jackalope">
    <uses-permission android:name="android.permission.SYSTEM_ALERT_WINDOW" />
    <application android:label="Jackalope">
        <activity android:name=".Jackalope"
                  android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
        <service android:name=".Tapjacker" />
    </application>
</manifest>
```

The activity then just starts up the service and finishes:

```
package com.commonsware.android.tj.jackalope;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class Jackalope extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    startService(new Intent(this, Tapjacker.class));
    finish();
  }
}
```

The visible effect is… nothing. Tapping the icon in the launcher appears to have no effect, but it does actually start up the tapjacker. You just cannot see it.

The `Tapjacker` service does its evil work in a handful of lines of code:

```
package com.commonsware.android.tj.jackalope;

import android.app.Service;
import android.content.Intent;
import android.graphics.PixelFormat;
import android.os.IBinder;
import android.util.Log;
import android.view.Gravity;
import android.view.MotionEvent;
import android.view.View;
import android.view.WindowManager;

public class Tapjacker extends Service implements View.OnTouchListener {
  private View v=null;
  private WindowManager mgr=null;

  @Override
  public void onCreate() {
    super.onCreate();

    v=new View(this);
    v.setOnTouchListener(this);
    mgr=(WindowManager)getSystemService(WINDOW_SERVICE);

    WindowManager.LayoutParams params
```

```
      =new WindowManager.LayoutParams(
        WindowManager.LayoutParams.FILL_PARENT,
        WindowManager.LayoutParams.FILL_PARENT,
        WindowManager.LayoutParams.TYPE_SYSTEM_OVERLAY,
        WindowManager.LayoutParams.FLAG_WATCH_OUTSIDE_TOUCH,
        PixelFormat.TRANSPARENT);

    params.gravity=Gravity.FILL_HORIZONTAL|Gravity.FILL_VERTICAL;
    mgr.addView(v, params);

    // stopSelf(); -- uncomment for "component-less" operation
  }

  @Override
  public IBinder onBind(Intent intent) {
    return(null);
  }

  @Override
  public void onDestroy() {
    mgr.removeView(v);  // comment out for "component-less" operation

    super.onDestroy();
  }

  public boolean onTouch(View v, MotionEvent event) {
    Log.w("Tapjacker",
          String.valueOf(event.getX())+":"+String.valueOf(event.getY()));

    return(false);
  }
}
```

In `onCreate()`, we create an invisible `View` in Java code. Note that while you normally create a widget by passing in the Activity to the constructor, any Context will work, and so here we use the `Tapjacker` service itself.

Then, we access the `WindowManager` system service and add the invisible `View` to the system. To do this, we need to supply a `WindowManager.LayoutParams` object, much like you might use `LinearLayout.LayoutParams` or `RelativeLayout.LayoutParams` when putting a `View` inside of one of those containers. In this case, we:

1. Say that the `View` is to fill the screen
2. Indicates that the `View` is to be treated as a "system overlay" (`TYPE_SYSTEM_OVERLAY`), which will be at the top of the Z axis, floating above anything else (activities, dialogs, etc.)
3. Indicates that we are to receive touch events that are beyond the `View` itself (`FLAG_WATCH_OUTSIDE_TOUCH`), such as on the system bar in API Level 11+ devices

We attach the `Tapjacker` service itself as the `OnTouchListener` to the `View`, and simply log all touch events to LogCat. In `onDestroy()`, we remove the system overlay `View`.

The result is that every screen tap results in an entry in LogCat – including data entry via the soft keyboard — even though the user is unaware that anything might be intercepting these events.

Note, though, that this does not intercept regular key events, including those from hardware keyboards. Also note that this does not magically give the malware author access to data entered before the tapjacker was set up. Hence, even if the tapjacker can sniff a password, if they do not know the account name, the user may still be safe.

Thinking Like a Malware Author

So, you have touch events. On the surface, this might not seem terribly useful, since the View cannot see what is being tapped upon.

However, a savvy malware author would identify what activity is in the foreground and log that information along with the tap details and the screen size, periodically dumping that information to some server. The malware author can then scan the touch event dumps to see what interesting applications are showing up. With a minor investment – and possibly collaboration with other malware authors — the author can know what touch events correspond to what keys on various input method editors, including the stock keyboards used by a variety of devices. Loading a pirated version of the APK on an emulator can indicate which activity has the password, PIN, or other secure data. Then, it is merely a matter of identifying the touch events applied to that activity and matching them up with the soft keyboard to determine what the user has entered. Over time, the malware author can perhaps develop a script to help automate this conversion.

Hence, the on-device tapjacker does not have to be very sophisticated, other than trying to avoid detection by the user. All of the real work to leverage the intercepted touch events can be handled offline.

Detecting Potential Tapjackers

Tapjacking seems bad.

This raises the question: can we identify when a tapjacker is running? That would allow users and developers to "route around the damage", such as uninstalling the tapjacker application.

Unfortunately, this does not appear to be possible. There is no obvious way for an application — or the user — to determine if some other application has employed `WindowManager` to add a `TYPE_SYSTEM_OVERLAY` `View` to the screen. Even if there were, there is no way to determine if this `View` represents a tapjacker or somebody exploiting this capability for other, less nefarious ends.

All we can do is identify applications that might pose a problem.

Who Holds a Permission?

The biggest identifier of a possible tapjacker is the `SYSTEM_ALERT_WINDOW` permission. This is required to add a `TYPE_SYSTEM_OVERLAY` `View` to the screen. Relatively few applications request this, since built-in system alerts, like `Toast`, do not require the permission.

Also, a tapjacker probably needs the `INTERNET` permission, to deliver the results to the malware author. In principle, the tapjacker could be split into two applications, one with `SYSTEM_ALERT_WINDOW` and one with `INTERNET`. However, this adds to deployment complexity and therefore may be avoided by malware authors.

An end user can use programs like RL Permissions to examine the applications that have these permissions. A developer can use `PackageManager` to enumerate the installed applications and see which ones hold these permissions. We will examine some code for doing this later in this chapter.

Who is Running?

Of course, a tapjacker is only a threat if it is actually running in the background. Applications might use those two permissions just in the course of normal activity-centric operations, not with an everlasting service trying to maintain the interception `View`.

We can use `ActivityManager` to enumerate the running processes and what packages' code are in each. Any package that holds the permission combination from the previous section and is running in a process is a possible tapjacking threat. We will examine some code for doing this in the next section.

Note that it is important to examine running processes, not running services. For example, the Tapjacker service from earlier in this chapter could add the interception View and immediately exit. You can see this in action by adjusting the code as indicated in the comments in onCreate() and onDestroy(). The interception View will remain intact (with the Tapjacker service object leaked) until the process is terminated. That process might be terminated quickly or slowly, depending on what all is going on with the device. A sophisticated malware author might try to run without a running service to increase stealthiness, at the cost of occasionally losing some data.

Combining the Two: TJDetect

To see these techniques in action, take a look at the Tapjacking/TJDetect sample project. This consists of a single ListActivity, whose list is populated with the applications that hold both SYSTEM_ALERT_WINDOW and INTERNET permissions and are presently running:

```
package com.commonsware.android.tj.detect;

import android.app.ActivityManager;
import android.app.ListActivity;
import android.content.pm.PackageInfo;
import android.content.pm.PackageManager;
import android.os.Bundle;
import android.widget.ArrayAdapter;
import java.util.ArrayList;
import java.util.HashSet;

public class TJDetect extends ListActivity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    ActivityManager am=(ActivityManager)getSystemService(ACTIVITY_SERVICE);
    HashSet<CharSequence> runningPackages=new HashSet<CharSequence>();

    for (ActivityManager.RunningAppProcessInfo proc :
        am.getRunningAppProcesses()) {
      for (String pkgName : proc.pkgList) {
        runningPackages.add(pkgName);
      }
    }

    PackageManager mgr=getPackageManager();
    ArrayList<CharSequence> scary=new ArrayList<CharSequence>();

    for (PackageInfo pkg :
        mgr.getInstalledPackages(PackageManager.GET_PERMISSIONS)) {
      if (PackageManager.PERMISSION_GRANTED==
          mgr.checkPermission(android.Manifest.permission.SYSTEM_ALERT_WINDOW,
                              pkg.packageName)) {
```

```
        if (PackageManager.PERMISSION_GRANTED==
              mgr.checkPermission(android.Manifest.permission.INTERNET,
                                  pkg.packageName)) {
          if (runningPackages.contains(pkg.packageName)) {
            scary.add(mgr.getApplicationLabel(pkg.applicationInfo));
          }
        }
      }
    }

    setListAdapter(new ArrayAdapter(this,
                        android.R.layout.simple_list_item_1,
                        scary));
  }
}
```

To find the unique set of packages that are running across all processes, we iterate over the RunningAppProcessInfo objects returned by ActivityManager from a call to getRunningAppProcesses(). One public data member of RunningAppProcessInfo is a list of all the packages whose code runs in this process (pkgList). We use a simple HashSet to come up with the unique set of packages.

Then, we find all installed packages via a call to getInstalledPackages() on PackageManager. For each package, we use checkPermission() on PackageManager to see if the package in question holds a permission. Packages that pass those two tests are then checked against the HashSet of running packages, and those that are running are recorded in an ArrayList, later wrapped in an ArrayAdapter.

If you run TJDetect, it will not detect Jackalope, since Jackalope lacks the INTERNET permission. And, particularly on production hardware, it will detect several packages that may not be tapjackers at all, but rather are system applications installed in the firmware by the device manufacturer.

Defending Against Tapjackers

OK, so users and developers cannot reliably detect tapjackers. And Android 4.0.3 eliminates this attack vector. Surely, for previous versions of Android, there must be something in the OS that helps defend users and developers against tapjacking, right?

The answer is “yes”, for a generous definition of the term “defend” and an equally generous definition of “users and developers”.

Filtering Touch Events

The only "defense" directly provided by Android is to allow applications to filter out touch events that had been intercepted by a tapjacker, `Toast`, or any other form of system overlay or alert. Those touch events are simply dropped, never delivered to the underlying activity.

Implementing the Filter

The simplest way to implement the touch event filter is to add the `android:filterTouchesWhenObscured` attribute to a widget or container, setting it to true. The equivalent Java setter method on `View` is `setFilterTouchesWhenObscured()`.

For example, take a look at the `res/layout/main.xml` file in the [Tapjacking/RelativeSecure]() sample project:

```xml
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:filterTouchesWhenObscured="true">
  <TextView android:id="@+id/label"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="URL:"
    android:layout_alignBaseline="@+id/entry"
    android:layout_alignParentLeft="true"/>
  <EditText
    android:id="@id/entry"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_toRightOf="@id/label"
    android:layout_alignParentTop="true"/>
  <Button
    android:id="@+id/ok"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/entry"
    android:layout_alignRight="@id/entry"
    android:text="OK" />
  <Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_toLeftOf="@id/ok"
    android:layout_alignTop="@id/ok"
    android:text="Cancel" />
</RelativeLayout>
```

Here, we have android:filterTouchesWhenObscured="true" on the RelativeLayout at the root of the layout resource. This property cascades to a container's children, and so if a tapjacker (or Toast or whatever) is above any of the widgets in the RelativeLayout, none of the touch events will be processed.

More fine-grained control can be achieved in custom widgets by overriding onFilterTouchEventForSecurity(), which gets control before the regular touch event methods. You can determine if a touch event had been intercepted by looking for the FLAG_WINDOW_IS_OBSCURED flag in the MotionEvent passed to onFilterTouchEventForSecurity(), and you can make the decision of how to handle this on an event-by-event basis.

The User Experience and the Hoped-For Security

Normally, the user will not see a difference when interacting with widgets that have this attribute set. However, if a tapjacker is intercepting these events, the user will not see any reaction from the widgets when they are tapped. For example, clicking a Button will have no visual effect (e.g., orange flash).

The hope is that users will realize that the UI is not responding to their touch events and therefore will not complete whatever it is they are doing. For example, they might not complete their PIN entry after realizing that the number pad supplied by the app is not responding to their taps.

For some users and some apps, this will be an effective defense. However, there will be some users who will remain oblivious until after completing the attempt to enter the private information.

The Flaws

The user can still use the soft keyboard to enter data into EditText widgets. While the soft keyboard will not automatically appear in portrait mode (since the EditText will not respond to the tap), if it has the focus, the user can long-press the MENU button to raise the soft keyboard and enter data that way.

Similarly, if the user is in landscape mode and gets the full-screen soft keyboard, since this is not the EditText widget defended by the touch event filtering, everything works normally — including interception by tapjacking. Developers could try to prevent this by adding flagNoFullscreen to the android:imeOptions attribute on the EditText in the layout XML, though this may not be honored by all soft keyboards. Developers could also try to prevent this by locking the activity into portrait mode (`android:screenOrientation="portrait"`), but this would be bad for users with side-slider keyboards, Android TV devices, etc.

And, most importantly, the tapjacking still happens. If users keep trying to enter their credentials despite the lack of UI feedback, they may eventually enter the whole thing and therefore become vulnerable to having that information used for ill ends.

Availability

Filtering touch events when the activity is obscured is supported in API Level 9 and above — in other words, Android 2.3 and newer. At the time of this writing, that leaves out ~25% of active Android devices, based on the June 1, 2012 published edition of the platform versions data from Google.

Detect-and-Warn

You can use the tapjacker detection logic illustrated earlier in this chapter. It is not particularly accurate, but you may feel it is worthwhile.

To minimize hassle for the user, your application should maintain a "whitelist" of approved packages. Any time you detect a package that is not on the approved list, you would raise an `AlertDialog` (or the equivalent) to let the user know of the potential tapjacker. If they elect to continue onward in your app, add the new package(s) to the whitelist, so you do not bother the user again for the same package.

Why Is This Being Discussed?

Some of you are by this time wondering why this book has a chapter on this subject.

Google's security team indicated to the author that `android:filterTouchesWhenObscured` is sufficient security. If so, developers need to realize when to use it, and for that, developers need to understand what tapjacking is to start with. The code to implement tapjacking is sufficiently trivial that "security by obscurity" of the code seems pointless.

It is eminently possible that `android:filterTouchesWhenObscured` is not sufficient security, despite Google's claim. Since Google seems to have changed their mind, eliminating tapjacking in Android 4.0.3, it would appear that Google thinks that Google's original solution was insufficient. In that case, developers may be able to help inform the public about the dangers of applications that request the `SYSTEM_ALERT_WINDOW` permission.

There are legitimate uses for tapjacking techniques. Some apps use this to provide a universal gesture interface, for example, to get control no matter what application is presently in the foreground. Whether the value that such apps provide is worth the risks inherent in tapjacking is up for debate.

If you feel that tapjacking is a problem and that `android:filterTouchesWhenObscured` is inadequate, you may wish to let Google know when you have the opportunity to interact with Google engineers at conferences and similar events. If you come up with other ways to detect and/or prevent tapjacking, you may wish to distribute that knowledge, so other developers can learn from your discovery.

What Changed in 4.0.3?

As of Android 4.0.3, the tapjacking attack is no longer possible, at least through the techniques outlined in this chapter. A `View` of type `TYPE_SYSTEM_OVERLAY` cannot receive touch events.

Miscellaneous Security Techniques

This chapter outlines some additional security measures that you can consider for your applications that do not necessarily warrant a full chapter on their own at this time.

In other words, it's just a pile of interesting security stuff.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, you should review the app signing chapter if you are unfamiliar with the signing process.

Public Key Validation

We sign our apps with signing keys all the time. By default, we are signing with a so-called "debug signing key", created automatically by the build tools. For production, we sign with a different signing key. The primary use of that signing key is to determine equivalence of authorship:

- Is this APK, representing an upgrade to an already-installed app, signed by the same signing key that signed that app?
- Is this APK, that requests firmware-defined `signature`-level permissions, signed by the same signing key that signed the firmware?

However, as it turns out, information about the public key that signed an APK is visible to us, for our own APK as well as for any other APK on the device. We can leverage that to help determine whether a given APK was signed by something we recognize. This goes above and beyond using Android's built-in signature-based defenses (e.g., using a custom `signature`-level permission).

Scenarios

There are several scenarios in which we might imagine that we could employ our own public key validation. How well the technique will work, though, depends on what we are checking and the nature of the attack we are defending against.

Checking Yourself

You might consider checking your own app's public key. After all, if your app is not signed with your production signing key, something very strange is going on, and the natural reaction is that "something strange" is unlikely to be a good thing for you.

However, there are some issues here.

First and foremost, checking your own signing key assumes that whatever caused you to *not* be signed by that key did not also modify your validation algorithm. For example, suppose that you validate your signing key to determine if somebody perhaps reverse-engineered and modified your app, perhaps to remove some license checks. This will only catch an attacker that removed the licensing checks and did not *also* remove your signature validation, or modify the validation to use the attacker's signing key. While it is possible that an attacker will modify one part but not another, it remains unclear how well this defense will work in practice.

Also, bear in mind that you, as a developer, may be opting into services that intentionally change your app's signature. Various providers will "wrap" your app, whether for interstitial ad banners or for quasi-DRM. There are three possible ways that they wrap your app:

1. They sign it with their signing key, which means that your runtime validation of the key will fail, as your app is now signed by their key, not yours. This is also *very* risky, as if for whatever reason you are no longer able to use their service (e.g., they go out of business), you may have difficulty in upgrading your app, as you will not have the right key to use.
2. They sign it with *your* signing key, either one that you upload, or one that they generate for you. In this case, your runtime public key validation logic could still work. On the other hand, now this other firm is perfectly capable

of upgrading your app, or shipping other apps, signed with your production signing key, and this has its own set of risks.

3. They allow you to download the "wrapped" app and have you sign it yourself with your own signing key. This is the best alternative from a security standpoint, but it is the most tedious, as now you have additional work to do to publish your app.

Checking Arbitrary Other Apps

What will tend to be more reliable is to check *other* applications' public keys. While they might have been cracked, it is unlikely that the same attacker also attacked *your* app, and so you can help detect problems in others.

For example, let us consider a specific scenario: a client-side JAR for integration to a third-party app.

This book outlines many forms of IPC, from content providers to remote services to broadcast `Intent` objects. If you are creating an app that offers such IPC endpoints, you may wish to consider also shipping a JAR to make using those endpoints a bit easier. You might create a library that handles all of the details of sending commands to your remote service, or you might create a library that provides a wrapper around the AIDL-generated Java proxy classes for remote binding.

Another thing such a JAR could do is check the integrity of your app. The JAR's code is in the client's app, not yours, and while your app might be cracked, the client's app might not. You could check the validity of the public key of your own app from the client's app, and fail if there is a detected problem.

This might be especially important depending upon the nature of the app and the JAR that is providing access to it. If the app is an app offering on-device payments (e.g., a Google Wallet sort of app), and the app offers an API for other apps to do payments, it is fairly important that those other apps can trust the payment app. By checking the public key, your JAR can help provide that level of trust… or at least ensure that nobody else has done something specifically to degrade that trust.

This is particularly important for avoiding device-hosted man-in-the-middle attacks on your IPC from client apps to your app. In an ideal world, you would only allow IPC via `signature`-level permissions, but that will not work in cases where third parties are writing the clients.

If your IPC is based upon a service (command pattern or binding pattern), if multiple service implementations all advertise the same `<intent-filter>`, Android needs to decide which service will handle the request. First, it will take into account the `android:priority` value on the `<intent-filter>` (even though this behavior is currently undocumented). For multiple services with the same priority (e.g., no priority specified), the first one that was installed will be the one that is chosen. In either case, the client has no way to know, short of examining the service's public key, whether the service that will respond to the requests for IPC is the legitimate service or something else advertising that it supports the same `Intent` action. Even with Android 5.0 blocking your ability to bind via an implicit `Intent`, you wind up with the same sorts of problems when you use `resolveService()` to try to determine the `ComponentName` of the service to make an explicit `Intent` for it.

The Easy Solution: SignatureUtils

The author of this book has published the CWAC-Security library. Among other things, this library has a `SignatureUtils` class that makes it relatively easy for you to compare the signature of some Android app to a known good value.

All you need to do is call the static `getSignatureHash()` method, supplying some `Context` (any will do) and the package name of the app that you wish to check. This will return the SHA-256 hash of the signing key of the app, as a set of capitalized, colon-delimited hex values.

You can get the same sort of hash by running the Java 7 version of `keytool`. Hence, if the app you wish to test is another one of yours, perhaps signed with a different signing key, you can use `keytool` to get the value to compare with the result of `getSignatureHash()`. Or, during development, create a little utility app that will dump the `getSignatureHash()` value for the third-party app, and run it on a device containing a known good version of that app (i.e., one that does not appear to have been replaced by malware).

Ideally, over time, we will be able to get app developers to publish their SHA-256 hashes on their Web sites, as another means of getting a known value of the hash to compare at runtime.

If you determine that `getSignatureHash()` does *not* return the right value, this means that the app that is installed on the device is written by somebody other than the app's original author. Often times, this will mean the app has malware in it. It is up to you to determine how you wish to respond to this scenario:

- Alert the user?
- Send data back to your server, or to your analytics collection point, with details of the bad APK?
- Block usage of your app, or usage of features that depend upon the flawed third party?
- Something else?

Examining Public Keys

Under the covers, SignatureUtils uses PackageManager and related classes to examine what they somewhat erroneously refer to as "signatures". The MiscSecurity/SigDump sample project will allow us to browse the list of installed packages, see a decoded public key on the screen for a package that we select, plus dump the "signature" as a binary file for later comparison using another app.

The UI Structure

In this sample, we use a SlidingPaneLayout for a master-detail pattern presentation, as was demonstrated in the chapter on dealing with multiple screen sizes. The "master" fragment will be the list of packages; the "detail" fragment will be the decoded public key for the selected package.

The master fragment is implemented as PackagesFragment. It implements a typical ListFragment for use with the master/detail pattern, utilizing the activated state to show the context for the detail fragment. The detail will be SignatureFragment, which will display portions of the decoded public key in a TableLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:shrinkColumns="1"
  android:stretchColumns="1">

  <TableRow>

    <TextView
      android:layout_gravity="center"
      android:layout_margin="4dp"
      android:text="@string/subject"
      android:textStyle="bold"/>

    <TextView android:id="@+id/subject"/>
  </TableRow>

  <TableRow>
```

```
    <TextView
      android:layout_gravity="center"
      android:layout_margin="4dp"
      android:text="@string/issuer"
      android:textStyle="bold"/>

    <TextView android:id="@+id/issuer"/>
  </TableRow>

  <TableRow>

    <TextView
      android:layout_gravity="center"
      android:layout_margin="4dp"
      android:text="@string/valid_between"
      android:textStyle="bold"/>

    <TextView android:id="@+id/valid"/>
  </TableRow>

</TableLayout>
```

Listing the Packages

Our PackagesFragment needs the list of packages to display. It expects the hosting activity to supply that, by using the contract pattern, and having a getPackageList() method on its Contract:

```
  interface Contract {
    void onPackageSelected(PackageInfo pkgInfo);

    List<PackageInfo> getPackageList();
  }
```

The hosting activity — MainActivity — retrieves a PackageManager instance in onCreate(), caching it in a mgr data member. getPackageList() then calls getInstalledPackages() on PackageManager, specifically requesting to retrieve signature information via the GET_SIGNATURES flag. The list we get back from getInstalledPackages() can be in any order, so we sort the results before returning it for display purposes:

```
  @Override
  public List<PackageInfo> getPackageList() {
    List<PackageInfo> result=
        mgr.getInstalledPackages(PackageManager.GET_SIGNATURES);

    Collections.sort(result, new Comparator<PackageInfo>() {
      @Override
      public int compare(final PackageInfo a, final PackageInfo b) {
        return(a.packageName.compareTo(b.packageName));
      }
    });
    return(result);
  }
```

Note that this is a `List` of `PackageInfo` objects, so we need an `ArrayAdapter` subclass to handle rendering that. Here, we have a `PackageListAdapter` that knows how to populate list rows using the `packageName` field of a `PackageInfo` object, plus using an activated row layout for API Level 11+ devices:

```
package com.commonsware.android.signature.dump;

import android.annotation.TargetApi;
import android.content.pm.PackageInfo;
import android.os.Build;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.TextView;

class PackageListAdapter extends ArrayAdapter<PackageInfo> {
  PackageListAdapter(PackagesFragment packagesFragment) {
    super(packagesFragment.getActivity(), getRowResourceId(),
          packagesFragment.getContract().getPackageList());
  }

  @Override
  public View getView(int position, View convertView, ViewGroup parent) {
    View result=super.getView(position, convertView, parent);

    ((TextView)result).setText(getItem(position).packageName);

    return(result);
  }

  @TargetApi(Build.VERSION_CODES.HONEYCOMB)
  private static int getRowResourceId() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
      return(android.R.layout.simple_list_item_activated_1);
    }

    return(android.R.layout.simple_list_item_1);
  }
}
```

The result is that our master list is a list of all installed packages, sorted by package name, with the detail `TableLayout` peeking out of the right edge when shown on a phone-sized screen:

com.android.contacts

com.android.customlocale2

Figure 740: Signature Dump Demo, As Initially Launched

Dumping the Key

`onListItemClick()` of our `PackagesFragment` routes control to `onPackageSelected()` of the `Contract` interface, which in our case is `MainActivity`. There, we need to do some useful stuff based upon the fact that the user tapped on a particular package:

```
@Override
public void onPackageSelected(PackageInfo pkgInfo) {
  Signature[] signatures=pkgInfo.signatures;
  byte[] raw=signatures[0].toByteArray();

  sigDisplay.show(raw);
  panes.closePane();

  File output=
      new File(getExternalFilesDir(null),
               pkgInfo.packageName.replace('.', '_') + ".bin");

  new WriteThread(output, raw).start();
}
```

First, we get the `Signature` array from the `PackageInfo` object. While this is an array, usually an app will only be signed once. Signing more than once is not especially useful, as an upgraded app needs to match the count and contents of each signature. Hence, we will only pay attention to the first signature. If you are using these techniques as the basis for your client JAR checking the public key of your app for IPC protection purposes, *and* your app is signed with multiple keys, you will want to check all of those keys.

The public key itself is represented as a byte array in the `Signature`. `onPackageSelected()` does two things with this byte array:

- Writes it to a file on external storage using a background thread, with a filename based on the app's package name, with `.` characters replaced by `_` characters
- Passes the byte array to the detail fragment (a `SignatureFragment`) and updates the `SlidingPaneLayout` to ensure that detail fragment is now visible

Decoding the Key

`SignatureFragment` is mostly comprised of the `show()` method that `MainActivity` uses to pass us the byte array of the "signature" to display:

```
package com.commonsware.android.signature.dump;

import android.app.Fragment;
import android.os.Bundle;
import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.TextView;
import java.io.ByteArrayInputStream;
import java.security.cert.CertificateException;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.Locale;

public class SignatureFragment extends Fragment {
  DateFormat fmt=new SimpleDateFormat("yyyy-MM-dd HH:mm:ss", Locale.US);

  @Override
  public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
                           Bundle savedInstanceState) {
    return(inflater.inflate(R.layout.sig, container, false));
  }

  void show(byte[] raw) {
    CertificateFactory cf=null;
    try {
      cf=CertificateFactory.getInstance("X509");
    }
    catch (CertificateException e) {
      Log.e(getClass().getSimpleName(),
            "Exception getting CertificateFactory", e);
      return;
    }

    X509Certificate c=null;
    ByteArrayInputStream bin=new ByteArrayInputStream(raw);

    try {
      c=(X509Certificate)cf.generateCertificate(bin);
    }
    catch (CertificateException e) {
      Log.e(getClass().getSimpleName(),
            "Exception getting X509Certificate", e);
      return;
    }

    TextView tv=(TextView)getView().findViewById(R.id.subject);

    tv.setText(c.getSubjectDN().toString());

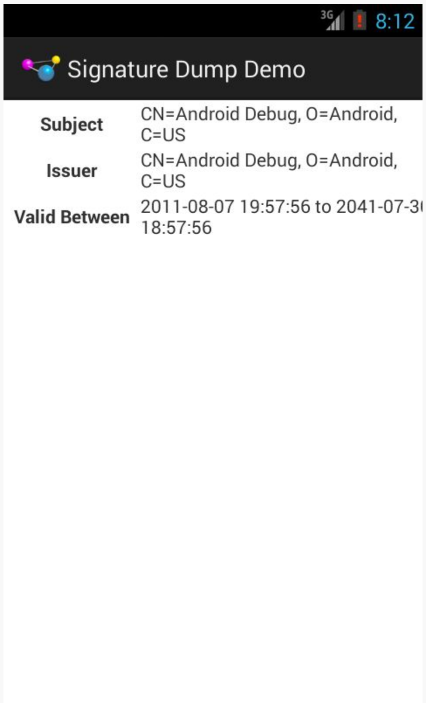
    tv=(TextView)getView().findViewById(R.id.issuer);
    tv.setText(c.getIssuerDN().toString());

    tv=(TextView)getView().findViewById(R.id.valid);
    tv.setText(fmt.format(c.getNotBefore()) + " to "
        + fmt.format(c.getNotAfter()));
  }
}
```

That byte array *really* represents an X509 certificate, serialized to a byte array. `show()` goes through the work to get the `X509Certificate` object representing that same data, assuming the byte array is not corrupted somehow. Then, `show()` populates some `TextView` widgets in our `TableLayout` with the:

- The subject of the signature
- The issuer of the signature
- The range of dates in which this signature is valid

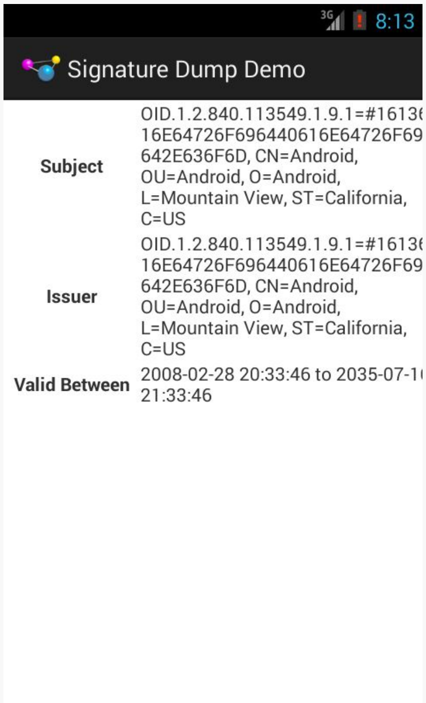
A debug signing key output will resemble:



Subject	CN=Android Debug, O=Android, C=US
Issuer	CN=Android Debug, O=Android, C=US
Valid Between	2011-08-07 19:57:56 to 2041-07-3(18:57:56

Figure 741: Signature Dump Demo, Showing Debug Signing Key

A self-signed production signing key will resemble:



Subject: OID.1.2.840.113549.1.9.1=#1613 16E64726F696440616E64726F69 642E636F6D, CN=Android, OU=Android, O=Android, L=Mountain View, ST=California, C=US

Issuer: OID.1.2.840.113549.1.9.1=#1613 16E64726F696440616E64726F69 642E636F6D, CN=Android, OU=Android, O=Android, L=Mountain View, ST=California, C=US

Valid Between: 2008-02-28 20:33:46 to 2035-07-1 21:33:46

Figure 742: Signature Dump Demo, Showing Production Signing Key

A signing key created by some signing authority would have a subject that is distinct from its issuer.

Choosing Your Signing Keysize

The documentation for app signing contains a small side note about the `-keysize` parameter to `keytool`, the utility used to generate our signing keys:

> The size of each generated key (bits). If not supplied, Keytool uses a default key size of 1024 bits. In general, we recommend using a key size of 2048 bits or higher.

The reason for the 2,048-bit key size recommendation is that 1,024-bit RSA (the `keytool` default) has been considered at risk for a few years.

The recent revelations about state-sponsored decryption research should be hammering this home. Even if today, forging a 1,024-bit digital signature is still impractical for all but the largest security agencies, it is well within reason that this will fall within the reach of large botnets in the not-too-distant future. Once signing keys can be cracked, apps will be able to be replaced with hacked editions, without tripping up the signature check, or `signature`-level permission checks might start passing due to forged signatures.

Switching to a larger keysize is not that hard… for new apps. Just specify `-keysize 4096` when creating your production signing key, and you should be good for a long time, barring a major decryption breakthrough for RSA signatures.

For existing apps with existing signing keys, though, you cannot change the key without breaking your ability to update the app.

Create a new, stronger production signing key, as a separate key from whatever you are using for production. Make note to use that new signing key for any new apps you create. And, if you have other reasons why you are migrating an existing user base to a new app (e.g., free app for which you are now offering a paid-app option), consider using the new signing key.

If you are a consultant, and you create unique signing keys per project, just cut over to using a stronger key for new clients and projects.

And if you are creating apps for which security is paramount, you might consider whether it is worthwhile to move your user base to a new version of the app with a new signing key at some point, just for the added protection.

Avoiding Accidental APIs

One place where developers create their own security problems is with "accidental APIs".

An API, of course, is where one code base exposes some interface that another code base can use. An accidental API is when one code base does not intend to expose an interface, but does anyway, possibly to the app's detriment.

Bear in mind that if your app becomes popular, other developers will poke and prod at it, to see if they can connect to your app by one means or another. Perhaps they want to offer features that you have not gotten to yet. Perhaps they have more nefarious aims. Regardless, making sure that other code can only work with your app the way that *you* intend for such code to work with your app.

Export Only What's Necessary

A component of your app is only reachable by a third-party app if it is exported. Otherwise, it is inaccessible to third-party apps.

(Admittedly, content providers have an exception to this rule, which we will get to shortly)

You normally do not think about exporting components, except when it comes to content providers. However, your choices for how you implement your app may lead you to accidentally export things that you did not realize were exported.

Export Defaults

The official way to declare whether or not a component is exported is to have an `android:exported` attribute for that component in the manifest (e.g., on an `<activity>` element). However, many times, we do not have such an attribute, but instead rely on the default export behavior.

Activities, services, and broadcast receivers have a simple rule for the default: if the component has an `<intent-filter>`, it is exported by default. Otherwise, it is not exported by default.

This, in turn, leads to a fairly simple development rule: only use an `<intent-filter>` and implicit `Intent` objects for working with your components if you *also* want third party apps to work with those components. Otherwise, do not use `<intent-filter>`, and instead communicate with your components using explicit `Intent` objects (e.g., the kind that take a Java class as the second constructor parameter).

For example, the classic `MAIN`/`LAUNCHER` `<intent-filter>` on your launcher activity is specifically there because you *want* a third party app — the launcher — to be able to start your activity. Most, if not all, of your other activities probably do not need an `<intent-filter>`, as they are likely to be private to your app.

The Chooser Bug

Some developers choose to still use an `<intent-filter>` and implicit `Intent` objects for their own private activities, yet then use `android:exported` to enforce the privacy.

This is not a good plan.

The rest of the system, notably `PackageManager`, does not pay much attention to `android:exported` *until the time when the component is to be used*, such as when the activity is to be started. Then, and only then, does Android realize that the component is not exported, and it fails the request, usually with a cryptic `SecurityException`.

A classic example of where this can cause problem came to light in 2012, with the UPS Mobile app. The rest of this section is an excerpt from the author's blog post on this incident:

The UPS Mobile app allows you to track packages and do a handful of other things that you might ordinarily do via the UPS Web site. It generally seems to be well-regarded, but it has an annoying flaw:

It claims to be Barcode Scanner, and does a lousy job at it.

Barcode Scanner, from ZXing, is a favorite among Android developers for its integration possibilities. However, some people do not like having a dependence upon the Barcode Scanner app, so they grab the open source code and attempt to blend it into their own apps. This is neither endorsed nor supported by the ZXing team, but since it is open source, it is also perfectly legitimate.

However, UPS (or whoever they hired to build the app) screwed up. They not only copied the source code, but they copied the manifest entry for the scanning activity. And, their activity has:

```
<intent-filter>
  <action android:name="com.google.zxing.client.android.SCAN" />
  <category android:name="android.intent.category.DEFAULT" />
<intent-filter>
```

This means that on any device that has UPS Mobile installed, they will be an option for handling Barcode Scanner `Intent` objects. What happened was that the person asking the question was manually invoking `startActivityForResult()` to bring up Barcode Scanner, was getting a chooser with UPS Mobile in it, and then was crashing upon choosing UPS Mobile… because UPS Mobile declared this activity to be not exported.

Due to this bug, Android will display non-exported activities in a chooser, despite the fact that they can never be successfully used by the user.

So, what should we learn from this?

First, UPS Mobile should not have used that `<intent-filter>`. As Dianne Hackborn has pointed out, your `<intent-filter>` mix is effectively part of your app's API, and so you need to think long and hard about every `<intent-filter>` you publish. UPS Mobile is not Barcode Scanner and should not be advertising that they handle such `Intent` objects, despite the activity being not exported.

Second, UPS Mobile probably should not have had *any* `<intent-filter>` elements for this activity, if they intend to use it purely internally. They could just as easily use an explicit `Intent` to identify the activity and avoid all of this nonsense.

Third, the person who filed the SO question ideally would have been using ZXing's `IntentIntegrator`. As Sean Owen of the ZXing project noted in a comment on my answer, `IntentIntegrator` ensures that only Barcode Scanner or official brethren will handle any scan requests, so this problem would not have appeared.

Fourth, Android really should not be showing non-exported activities in a chooser, which means probably that `PackageManager` should be filtering out non-exported activities from methods like `queryIntentActivities()`, which I presume lies at the heart of the chooser.

In summary, if your component is truly private, do not have an `<intent-filter>` on it, lest you cause yourself, and your users, problems with other apps.

The ContentProvider Behavior Change

Content providers are a little different… in lots of ways. In the specific scenarios being covered here, there are two primary differences.

First, third-party apps *can* still access a provider that has `android:exported="false"`. However, they can only do so in response to some operation initiated by your application, using `android:grantUriPermissions` and flags like `FLAG_GRANT_READ_URI_PERMISSION`. A third-party app will have no *independent* access to your non-exported provider.

Second, the default value for `android:exported` not only does not depend upon `<intent-filter>` (since few providers use one), but it has changed over the years:

- For apps with `android:minSdkVersion` *and* `android:targetSdkVersion` set to 16 or lower, the provider is exported by default

- All other apps, the provider is *not* exported by default

Lint will complain about your manifest having a `<provider>` without an `android:exported` attribute.

Sanitize Your Input Extras

If you do expose one or more of your components to third-party apps, and you are supporting certain `Intent` extras on any `Intent` objects used to talk to those components, make sure that the extras' values make sense.

Even Google makes this error, as was seen in the `PreferenceActivity` bug. `PreferenceActivity` supports an extra, named `:android:show_fragment`, to indicate that the activity should immediately jump to a specific fragment, rather than start at the top level of the preference navigation. The problem is that `PreferenceActivity` did not — and, at the time, could not — validate that the fragment to be loaded is a fragment that is *supposed* to be loaded. This would allow attackers to force apps, like Settings, to load arbitrary fragments, including those not normally accessible to the current user. This is the reason why we now need to override `isValidFragment()` in our `PreferenceActivity` implementations, so *we* can declare whether or not a particular requested fragment is a legitimate choice or not.

The equivalent behavior for a `ContentProvider` is to sanitize the inputs to methods like `query()`, `update()`, `openFile()`, and so on, to make sure that you do not expose something that you should not. For example, blindly accepting paths to `openFile()` could get you in trouble, if the `Uri` contains relative paths (e.g., `content://your.authority.here/../databases/your-private.db`), perhaps allowing third parties to get at files that you did not intend for them to access.

Secure Your Output Extras

Similarly, if you send broadcasts or otherwise use IPC to talk to third-party apps, bear in mind that others might be able to see some of that interaction, depending on the IPC in question.

The obvious case is with a broadcast `Intent` for an implicit `Intent`. Any app with a registered receiver will be able to "tune into" that broadcast and get whatever data is inside the `Intent`. In cases where you cannot use permissions to limit the scope of the broadcast, you need to make sure that there is nothing in the `Intent` that is private to the user.

Sometimes, though, non-obvious cases will emerge. For a few years, `Intent` extras on activities might be viewed by third-party apps that held the `GET_TASKS` permission, courtesy of the recent-tasks list. The `Intent` used to launch the task is available via `ActivityManager` and `getRecentTasks()`. While this specific problem was resolved in Android 4.1.1, there may be other similar scenarios lurking about.

Other Ways to Expose Data

Sometimes, we expose data to third-party apps by using standard Android APIs. We focus on the normal publisher and consumer of data using those APIs and forget about other apps that might be monitoring those communications. Or, we might not realize that one party in those communications may not have the user's best interests at heart. This section outlines some examples.

App Widgets

Any data that is put into the widgets inside of your `RemoteViews` for an app widget is visible to the home screen, lockscreen, or other app widget host. Those apps are the ones actually converting the `RemoteViews` into a view hierarchy, and they can inspect those views, reading the text in your `TextViews`, and so forth.

As a result, be careful about exposing potentially sensitive data via an app widget.

Notifications

Custom notifications also use `RemoteViews` and therefore could suffer from the same problem.

On the surface, you might not be worried quite so much about this, because the `Notification` object goes to the `NotificationManager`, for display by the OS itself.

However, as of Android 4.3 (API Level 18), apps can register to listen to added and removed notifications via a `NotificationListenerService`. Not only can such a service read the text from your `Notification`, but it can also access your `RemoteViews`. This includes any `RemoteViews` that may be generated for you by the expanded notification classes (e.g., `BigPictureStyle`).

As a result, be careful about exposing potentially sensitive data via a `Notification`.

Clipboard

Any app can retrieve text off of the clipboard. After all, that's the point behind a clipboard.

However, this does mean that you need to be careful what you put on the clipboard in the first place. The quintessential problem case is a password manager: putting a password on the clipboard for easy pasting into an app's `EditText` password field will be popular, but it allows that password to be retrieved by other apps.

You can attempt to help reduce the window of risk by clearing the clipboard after a period of time. However, bear in mind that your process might be terminated before that occurs. Also, only clear the clipboard if the clipboard text is still yours — do not clear the clipboard if another app has already put its own contents there, lest you confuse and irritate the user in the middle of some other paste operation.

ServerSocket and Kin

If you open up any sort of server-style socket connection — TCP/IP, Bluetooth, etc. — bear in mind that the Android security framework may not be able to help you much. You cannot secure a `ServerSocket` with an `android:permission` attribute, for example. It is up to you to validate whether a particular request is expected and allowed, or not.

AlarmManager and the Scheduled Service Pattern

Many applications have the need to get control every so often to do a bit of work. And, many times, those applications need to get control in the background, regardless of what the user may be doing (or not doing) at the time.

The solution, in most cases, is to use `AlarmManager`, which is roughly akin to `cron` on Linux and OS X and Scheduled Tasks in Windows. You teach `AlarmManager` when you want to get control back, and `AlarmManager` will give you control at that time.

Scenarios

The two main axes to consider with scheduled work are frequency and foreground (vs. background).

If you have an activity that needs to get control every second, the simplest approach is to use a `postDelayed()` loop, scheduling a `Runnable` to be invoked after a certain delay, where the `Runnable` reschedules itself to be invoked after the delay in addition to doing some work. We saw this in the chapter on threads. This has the advantages of giving you control back on the main application thread and avoiding the need for any background threads.

On the far other end of the spectrum, you may need to get control on a somewhat slower frequency (e.g., every 15 minutes), and do so in the background, even if nothing of your app is presently running. You might need to poll some Web server for new information, such as downloading updates to an RSS feed. This is the scenario that `AlarmManager` excels at. While `postDelayed()` works *inside* your process (and therefore does not work if you no longer have a process), `AlarmManager` maintains its schedule *outside* of your process. Hence, it can arrange to give you control, even if it has to start up a new process for you along the way.

`JobScheduler`, added to Android 5.0, also does this. If your `minSdkVersion` is 21 or higher, `JobScheduler` is definitely worth considering, as it not only takes time into account, but other environmental factors as well. For example, if you need an Internet connection to do your work, `JobScheduler` will only give you control if there is an Internet connection. `JobScheduler` is covered a bit later in the book.

Options

There are a variety of things you will be able to configure about your scheduled alarms with `AlarmManager`.

Wake Up… Or Not?

The biggest one is whether or not the scheduled event should wake up the device.

A device goes into a sleep mode shortly after the screen goes dark. During this time, nothing at the application layer will run, until something wakes up the device. Waking up the device does not necessarily turn on the screen — it may just be that the CPU starts running your process again.

If you choose a "wakeup"-style alarm, Android will wake up the device to give you control. This would be appropriate if you need this work to occur even if the user is not actively using the device, such as your app checking for critical email messages in the middle of the night. However, it does drain the battery some.

Alternatively, you can choose an alarm that will not wake up the device. If your desired time arrives and the device is asleep, you will not get control until something else wakes up the device.

Repeating… Or Not?

You can create a "one-shot" alarm, to get control once at a particular time in the future. Or, you can create an alarm that will give you control periodically, at a fixed period of your choice (e.g., every 15 minutes).

If you need to get control at multiple times, but the schedule is irregular, use a "one-shot" alarm for the nearest time, where you do your work *and* schedule a "one-shot" alarm for the next-nearest time. This would be appropriate for scenarios like a calendar application, where you need to let the user know about upcoming appointments, but the times for those appointments may not have any fixed schedule.

However, for most polling operations (e.g., checking for new messages every NN minutes), a repeating alarm will typically be the better answer.

Inexact… Or Not?

If you do choose a repeating alarm, you will have your choice over having (relatively) precise control over the timing of event or not.

If you choose an "inexact" alarm, while you will provide Android with a suggested time for the first event and a period for subsequent events, Android reserves the right to shift your schedule somewhat, so it can process your events and others around the same time. This is particularly important for "wakeup"-style alarms, as it is more power-efficient to wake up the device fewer times, so Android will try to combine multiple apps' events to be around the same time to minimize the frequency of waking up the device.

However, inexact alarms are annoying to test and debug, simply because you do not have control over when they will be invoked. Hence, during development, you might start with an exact alarm, then switch to inexact alarms once most of your business logic is debugged.

Note that Android 4.4 changes the behavior of `AlarmManager`, such that it is more difficult to actually create an exact-repeating alarm schedule. This will be examined in greater detail shortly, as we review the various methods and flags for scheduling `AlarmManager` events.

Absolute Time… Or Not?

As part of the alarm configuration, you will tell Android when the event is to occur (for one-shot alarms) or when the event is to *first* occur (for repeating alarms). You can provide that time in one of two ways:

- An absolute "real-time clock" time (e.g., 4am tomorrow), or
- A time relative to now

For most polling operations, particularly for periods more frequent than once per day, specifying the time relative to now is easiest. However, some alarms may need to tie into "real world time", such as alarm clocks and calendar alerts — for those, you will need to use the real-time clock (typically by means of a Java `Calendar` object) to indicate when the event should occur.

What Happens (Or Not???)

And, of course, you will need to tell Android what to do when each of these timer events occurs. You will do that in the form of supplying a `PendingIntent`. First mentioned in the chapter on services, a `PendingIntent` is a `Parcelable` object, one that indicates an operation to be performed upon an `Intent`:

- start an activity
- start a service
- send a broadcast

While the service chapter discussed an Android activity using `createPendingResult()` to craft such a `PendingIntent`, that is usually not very useful for `AlarmManager`, as the `PendingIntent` will only be valid so long as the activity is in the foreground. Instead, there are static factory methods on `PendingIntent` that you will use instead (e.g., `getBroadcast()` to create a `PendingIntent` that calls `sendBroadcast()` on a supplied `Intent`). That being said, our next sample will use `createPendingResult()`, to keep the sample as simple as possible.

A Simple Example

A trivial sample app using `AlarmManager` can be found in `AlarmManager/Simple`.

This application consists of a single activity, `SimpleAlarmDemoActivity`, that will both set up an alarm schedule and respond to alarms:

```
package com.commonsware.android.alarm;

import android.app.Activity;
import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.os.SystemClock;
import android.util.Log;
import android.widget.Toast;
```

```
public class SimpleAlarmDemoActivity extends Activity {
  private static final int ALARM_ID=1337;
  private static final int PERIOD=5000;
  private PendingIntent pi=null;
  private AlarmManager mgr=null;

  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    mgr=(AlarmManager)getSystemService(ALARM_SERVICE);
    pi=createPendingResult(ALARM_ID, new Intent(), 0);
    mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
                     SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
  }

  @Override
  public void onDestroy() {
    mgr.cancel(pi);

    super.onDestroy();
  }

  @Override
  protected void onActivityResult(int requestCode, int resultCode,
                                  Intent data) {
    if (requestCode == ALARM_ID) {
      Toast.makeText(this, R.string.toast, Toast.LENGTH_SHORT).show();
      Log.d(getClass().getSimpleName(), "I ran!");
    }
  }
}
```

In `onCreate()`, in addition to setting up the "hello, world"-ish UI, we:

- Obtain an instance of `AlarmManager`, by calling `getSystemService()`, asking for the `ALARM_SERVICE`, and casting the result to be an `AlarmManager`
- Create a `PendingIntent` by calling `createPendingResult()`, supplying an empty `Intent` as our "result" (since we do not really need it here)
- Calling `setRepeating()` on `AlarmManager`

The call to `setRepeating()` is a bit complex, taking four parameters:

1. The type of alarm we want, in this case `ELAPSED_REALTIME`, indicating that we want to use a relative time base for when the first event should occur (i.e., relative to now) and that we do not need to wake up the device out of any sleep mode
2. The time when we want the first event to occur, in this case specified as a time delta in milliseconds (`PERIOD`) added to "now" as determined by

SystemClock.elapsedRealtime() (the number of milliseconds since the device was last rebooted)

3. The number of milliseconds to occur between events
4. The PendingIntent to invoke for each of these events

When the event occurs, since we used createPendingResult() to create the PendingIntent, our activity gets control in onActivityResult(), where we simply display a Toast (if the event is for our alarm's request ID). This continues until the activity is destroyed (e.g., pressing the BACK button), at which time we cancel() the alarm, supplying a PendingIntent to indicate which alarm to cancel. While here we use the same PendingIntent object as we used for scheduling the alarm, that is not required — it merely has to be an *equivalent* PendingIntent, meaning:

- The Intent inside the PendingIntent matches the scheduled alarm's Intent, in terms of component, action, data (Uri), MIME type, and categories
- The ID of the PendingIntent (here, ALARM_ID) must also match

Running this simply brings up a Toast every five seconds until you BACK out of the activity.

The Five set…() Varieties

There are five methods that you can call on AlarmManager to establish an alarm, including the setRepeating() demonstrated above.

On Android 4.4 (API Level 19) and higher, setExact() is used for a one-shot alarm, where you want to get control at one specific time in the future. This would be used for specific events or for irregular alarm schedules.

On Android 4.3 and below, and for apps whose targetSdkVersion is set to 18 or lower, set() has the same behavior as setExact(). However, on Android 4.4 and above, apps with their targetSdkVersion set to be 19 or higher will have different, *inexact* behavior for set(). The time of the event is considered a minimum — your PendingIntent will not be invoked before your desired time, but it can occur any time thereafter… and you do not have control over how long that delay will be. As with all "inexact" schedules, the objective is for Android to be able to "batch" these events, to do several around the same time, for greater efficiency, particularly when waking up the device.

On Android 4.4 and higher, you have a `setWindow()` option that is a bit of a hybrid between the new-style `set()` and `setExact()`. Here, you specify the time you want the event to occur and an amount of time that Android can "flex" the actual event. So, for example, you might set up an event to occur every hour, with a "window" of five minutes, to allow Android the flexibility to invoke your `PendingIntent` within that five-minute window. This allows for better battery optimization than with `setExact()`, while still giving you some control over how far "off the mark" the event can occur.

On Android 4.3 and below, and for apps whose `targetSdkVersion` is set to 18 or lower, `setRepeating()` is used for an alarm that should occur at specific points in time at a specific frequency. In addition to specifying the time of the first event, you also specify the period for future events. Android will endeavor to give you control at precisely those times, though since Android is not a real-time operating system (RTOS), microsecond-level accuracy is certainly not guaranteed. However, note that as of Android 5.1, your minimum period is one minute (60000ms) — values less than that will be rounded up to one minute. This minimum period is enforced regardless of your `targetSdkVersion` value.

`setInexactRepeating()` is used for an alarm that should occur on a general frequency, such as every 15 minutes. In addition to specifying the time of the first event, you also specify a general frequency, as one of the following public static data members on `AlarmManager`:

- `INTERVAL_FIFTEEN_MINUTES`
- `INTERVAL_HALF_HOUR`
- `INTERVAL_HOUR`
- `INTERVAL_HALF_DAY`
- `INTERVAL_DAY`

Android guarantees that it will give your app control somewhere during that time window, but precisely *when* within that window is up to Android.

Note that on Android 4.4 and above, for apps with their `targetSdkVersion` set to be 19 or higher, `setRepeating()` behaves identically to `setInexactRepeating()` – in other words, all repeating alarms are inexact. The only way to get exact repeating would be to use `setExact()` and to re-schedule the event yourself, rather than relying upon Android doing that for you automatically. Ideally, you use `setInexactRepeating()`, to help extend battery life.

And, note that on Android 5.1 and higher, alarms must be set to occur at least 5 seconds in the future from now. You cannot trigger an alarm to occur in the future sooner than 5 seconds.

The Four Types of Alarms

In the above sample, we used `ELAPSED_REALTIME` as the type of alarm. There are three others:

- `ELAPSED_REALTIME_WAKEUP`
- `RTC`
- `RTC_WAKEUP`

Those with `_WAKEUP` at the end will wake up a device out of sleep mode to execute the `PendingIntent` — otherwise, the alarm will wait until the device is awake for other means.

Those that begin with `ELAPSED_REALTIME` expect the second parameter to `setRepeating()` to be a timestamp based upon `SystemClock.elapsedRealtime()`. Those that begin with `RTC`, however, expect the second parameter to be based upon `System.currentTimeMillis()`, the classic Java "what is the current time in milliseconds since the Unix epoch" method.

When to Schedule Alarms

The sample, though, begs a bit of a question: when are we supposed to set up these alarms? The sample just does so in `onCreate()`, but is that sufficient?

For most apps, the answer is "no". Here are the three times that you will need to ensure that your alarms get scheduled:

When User First Runs Your App

When your app is first installed, none of your alarms are set up, because your code has not yet run to schedule them. There is no means of setting up alarm information in the manifest or something that might automatically kick in.

Hence, you will need to schedule your alarms when the user first runs your app.

As a simplifying measure — and to cover another scenario outlined below — you might be able to simply get away with scheduling your alarms *every* time the user runs your app, as the sample app shown above does. This works for one-shot alarms (using `set()`) and for alarms with short polling periods, and it works because setting up a new alarm schedule for an equivalent `PendingIntent` will replace the old schedule. However, for repeating alarms with slower polling periods, it may excessively delay your events. For example, suppose you have an alarm set to go off every 24 hours, and the user happens to run your app 5 minutes before the next event was to occur — if you blindly reschedule the alarm, instead of going off in 5 minutes, it might not go off for another 24 hours.

There are more sophisticated approaches for this (e.g., using a `SharedPreferences` value to determine if your app has run before or not).

On Boot

The alarm schedule for alarm manager is wiped clean on a reboot, unlike `cron` or Windows Scheduled Tasks. Hence, you will need to get control at boot time to re-establish your alarms, if you want them to start up again after a reboot. We saw how to get control at boot time, via an `ACTION_BOOT_COMPLETED` `BroadcastReceiver`, back in the chapter on broadcasts.

After a Force-Stop

There are other events that could cause your alarms to become unscheduled. The best example of this is if the user goes into the Settings app and presses "Force Stop" for your app. At this point, on Android 3.1+, nothing of your code will run again, until the user manually launches some activity of yours.

If you are rescheduling your alarms every time your app runs, this will be corrected the next time the user launches your app. And, by definition, you cannot do anything until the user runs one of your activities, anyway.

If you are trying to avoid rescheduling your alarms on each run, though, you have a couple of options.

One is to record the time when your alarm-triggered events occur, each time they occur, such as by updating a `SharedPreference`. When the user launches one of your activities, you check the last-event time — if it was too long ago (e.g., well over your polling period), you assume that the alarm had been canceled, and you reschedule it.

Another is to rely on FLAG_NO_CREATE. You can pass this as a parameter to any of the PendingIntent factory methods, to indicate that Android should only return an *existing* PendingIntent if there is one, and not create one if there is not:

```
PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, PendingIntent.FLAG_NO_CREATE);
```

If the PendingIntent is null, your alarm has been canceled — otherwise, Android would already have such a PendingIntent and would have returned it to you. This feels a bit like a side-effect, so we cannot rule out the possibility that, in future versions of Android, this technique could result in false positives (null PendingIntent despite the scheduled alarm) or false negatives (non-null PendingIntent despite a canceled alarm).

Archetype: Scheduled Service Polling

The classic AlarmManager scenario is where you want to do a chunk of work, in the background, on a periodic basis. This is fairly simple to set up in Android, though perhaps not quite as simple as you might think.

The Main Application Thread Strikes Back

When an AlarmManager-triggered event occurs, it is very likely that your application is not running. This means that the PendingIntent is going to have to start up your process to have you do some work. Since everything that a PendingIntent can do intrinsically gives you control on your main application thread, you are going to have to determine how you want to move your work to a background thread.

One approach is to use a PendingIntent created by getService(), and have it send a command to an IntentService that you write. Since IntentService does its work on a background thread, you can take whatever time you need, without interfering with the behavior of the main application thread. This is particularly important when:

- The AlarmManager-triggered event happens to occur when the user happens to have one of your activities in the foreground, so you do not freeze the UI, or
- You want the same business logic to be executed on demand by the user, such as via an action bar item, as once again you do not want to freeze the UI

Examining a Sample

An incrementally-less-trivial sample app using AlarmManager for the scheduled service pattern can be found in AlarmManager/Scheduled.

This application consists of three components: a BroadcastReceiver, a Service, and an Activity.

This sample demonstrates scheduling your alarms at two points in your app:

- At boot time
- When the user runs the activity

For the boot-time scenario, we need a BroadcastReceiver set up to receive the ACTION_BOOT_COMPLETED broadcast, with the appropriate permission. So, we set that up, along with our other components, in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonsware.android.schedsvc"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="11"/>

  <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".ScheduledServiceDemoActivity"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.NoDisplay">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <receiver android:name="PollReceiver">
      <intent-filter>
        <action android:name="android.intent.action.BOOT_COMPLETED"/>
      </intent-filter>
    </receiver>

    <service android:name="ScheduledService">
    </service>
  </application>
```

```
</manifest>
```

The `PollReceiver` has its `onReceive()` method, to be called at boot time, which delegates its work to a `scheduleAlarms()` static method, so that logic can also be used by our activity:

```
package com.commonsware.android.schedsvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
  private static final int PERIOD=5000;

  @Override
  public void onReceive(Context ctxt, Intent i) {
    scheduleAlarms(ctxt);
  }

  static void scheduleAlarms(Context ctxt) {
    AlarmManager mgr=
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Intent i=new Intent(ctxt, ScheduledService.class);
    PendingIntent pi=PendingIntent.getService(ctxt, 0, i, 0);

    mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
                     SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
  }
}
```

The `scheduleAlarms()` method retrieves our `AlarmManager`, creates a `PendingIntent` designed to call `startService()` on our `ScheduledService`, and schedules an exact repeating alarm to have that command be sent every five seconds.

The `ScheduledService` itself is the epitome of “trivial”, simply logging a message to LogCat on each command:

```
package com.commonsware.android.schedsvc;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;

public class ScheduledService extends IntentService {
  public ScheduledService() {
    super("ScheduledService");
  }

  @Override
  protected void onHandleIntent(Intent intent) {
    Log.d(getClass().getSimpleName(), "I ran!");
  }
}
```

That being said, because this is an IntentService, we could do much more in onHandleIntent() and not worry about tying up the main application thread.

Our activity — ScheduledServiceDemoActivity — is set up with Theme.NoDisplay in the manifest, never calls setContentView(), and calls finish() right from onCreate(). As a result, it has no UI. It simply calls scheduleAlarms() and raises a Toast to indicate that the alarms are indeed scheduled:

```
package com.commonsware.android.schedsvc;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class ScheduledServiceDemoActivity extends Activity {
  @Override
  public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    PollReceiver.scheduleAlarms(this);

    Toast.makeText(this, R.string.alarms_scheduled, Toast.LENGTH_LONG)
         .show();
    finish();
  }
}
```

On Android 3.1+, we also need this activity to move our application out of the stopped state and allow that boot-time BroadcastReceiver to work.

If you run this app on a device or emulator, after seeing the Toast, messages will appear in LogCat every five seconds, even though you have no activity running.

Staying Awake at Work

The sample shown above works… most of the time.

However, it has a flaw: the device might fall asleep before our service can complete its work, if we woke it up out of sleep mode to process the event.

To understand where this flaw would appear, and to learn how to address it, we need to think a bit more about the event flows and timing of the code we are executing.

Mind the Gap

For a _WAKEUP-style alarm, Android makes precisely one guarantee: *if* the PendingIntent supplied to AlarmManager for the alarm is one created by getBroadcast() to send a broadcast Intent, Android will ensure that the device will stay awake long enough for onReceive() to be completed. Anything beyond that is not guaranteed.

In the sample shown above, we are not using getBroadcast(). We are taking the more straightforward approach of sending the command directly to the service via a getService() PendingIntent. Hence, Android makes no guarantees about what happens after AlarmManager wakes up the device, and the device could fall back asleep before our IntentService completes processing of onHandleIntent().

The WakefulIntentService

For our trivial sample, where we are merely logging to LogCat, we could simply move that logic out of an IntentService and into a BroadcastReceiver. Then, Android would ensure that the device would stay awake long enough for us to do our work in onReceive().

The problem is that onReceive() is called on the main application thread, so we cannot spend much time in that method. And, since our alarm event might occur when nothing else of our code is running, we need to have our BroadcastReceiver registered in the manifest, rather than via registerReceiver(). A side effect of this is that we cannot fork threads or do other things in onReceive() that might live past onReceive() yet be “owned” by the BroadcastReceiver itself. Besides, Android only ensures that the device will stay awake until onReceive() returns, so even if we did fork a thread, the device might fall asleep before that thread can complete its work.

Enter the WakefulIntentService.

WakefulIntentService is a reusable component, published by the author of this book.

WakefulIntentService allows you to implement “the handoff pattern”:

- You add the JAR, AAR, or library project to your project
- You create a subclass of WakefulIntentService to do your background work, putting that business logic in a doWakefulWork() method instead of onHandleIntent() (though it is still called on a background thread)

- You set up your alarm to route to a `BroadcastReceiver` of your design
- Your `BroadcastReceiver` calls `sendWakefulWork()` on the `WakefulIntentService` class, identifying your own subclass of `WakefulIntentService`
- You add a `WAKE_LOCK` permission to your manifest

`WakefulIntentService` will perform a bit of magic to ensure that the device will stay awake long enough for your work to complete in `doWakefulWork()`. Hence, we get the best of both worlds: the device will not fall asleep, and we will not have to worry about tying up the main application thread.

Android Studio users can add a reference to the CommonsWare Maven artifact repository in their top-level `repositories` closure:

```
repositories {
    mavenCentral()
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}
```

(here shown alongside an existing `mavenCentral()` statement)

Then, adding the `WakefulIntentService` is merely a matter of adding a `compile 'com.commonsware.cwac:wakeful:...'` statement to the top-level `dependencies` closure (for some version of the library, denoted by `...`).

Eclipse users can download a JAR from the project's GitHub repository.

`WakefulIntentService` is open source, licensed under the Apache License 2.0.

The Polling Archetype, Revisited

With that in mind, take a peek at the `AlarmManager/Wakeful` sample project. This is a near-clone of the previous sample, with the primary difference being that we will use `WakefulIntentService`.

The `libs/` directory of the project contains the `CWAC-WakefulIntentService.jar` library, so Eclipse/Ant users can make use of `WakefulIntentService` in our code. Android Studio users, instead, pull the AAR from the CommonsWare artifact repository:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:wakeful:1.0.+'
}
```

Our manifest includes the `WAKE_LOCK` permission:

```
  <uses-permission android:name="android.permission.WAKE_LOCK"/>
```

Our `PollReceiver` will now serve two roles: handling `ACTION_BOOT_COMPLETED` *and* handling our alarm events. We can detect which of these cases triggered `onReceive()` by inspecting the broadcast `Intent`, passed into `onReceive()`. We will use an explicit `Intent` for the alarm events, so any `Intent` with an action string must be `ACTION_BOOT_COMPLETED`:

```
package com.commonsware.android.wakesvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonsware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
  private static final int PERIOD=900000; // 15 minutes
  private static final int INITIAL_DELAY=5000; // 5 seconds

  @Override
  public void onReceive(Context ctxt, Intent i) {
    if (i.getAction() == null) {
      WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
    }
    else {
      scheduleAlarms(ctxt);
    }
  }

  static void scheduleAlarms(Context ctxt) {
    AlarmManager mgr=
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
                     SystemClock.elapsedRealtime() + INITIAL_DELAY,
                     PERIOD, pi);
  }
}
```

If the Intent is our explicit Intent, we call sendWakefulWork() on WakefulIntentService, identifying our ScheduledService class as being the service that contains our business logic.

The other changes to PollReceiver is that we use getBroadcast() to create our PendingIntent, wrapping our explicit Intent identifying PollReceiver itself, and that we use more realistic polling periods (5 second initial delay, every 15 minutes thereafter).

ScheduledService has only two changes: it extends WakefulIntentService and has the LogCat logging in doWakefulWork():

```
package com.commonsware.android.wakesvc;

import android.content.Intent;
import android.util.Log;
import com.commonsware.cwac.wakeful.WakefulIntentService;

public class ScheduledService extends WakefulIntentService {
  public ScheduledService() {
    super("ScheduledService");
  }

  @Override
  protected void doWakefulWork(Intent intent) {
    Log.d(getClass().getSimpleName(), "I ran!");
  }
}
```

How the Magic Works

A WakefulIntentService keeps the device awake by using a WakeLock. A WakeLock allows a “userland” (e.g., Android SDK) app to tell the Linux kernel at the heart of Android to keep the device awake, with the CPU powered on, indefinitely, until the WakeLock is released.

This can be a wee bit dangerous, as you can accidentally keep the device awake much longer than you need to. That is why using a library like WakefulIntentService can be useful — to use more-tested code rather than rolling your own.

Warning: Not All Android Devices Play Nice

Some Android devices take liberties with the way `AlarmManager` works, in ways that may affect your applications.

One example of this today is the SONY Xperia Z. It has a "STAMINA mode" that the user can toggle on via the "Power Management" screen in Settings. This mode will be entered when the device's screen turns off, if the device is not plugged in and charging. The user can add apps to a whitelist ("Apps active in standby"), where STAMINA mode does not affect those apps' behavior.

`_WAKEUP` style alarms do not wake up the device when it is in STAMINA mode. The behavior is a bit reminiscent of non-`_WAKEUP` alarms. Alarms that occur while the device is asleep are suppressed, and you get one invocation of your `PendingIntent` at the point the device wakes back up. At that point, the schedule continues as though the alarms had been going off all along. Apps on the whitelist are unaffected.

Mostly, you need to be aware of this from a support standpoint. If Xperia Z owners complain that your app behaves oddly, and you determine that your alarms are not going off, see if they have STAMINA mode on, and if they do, ask them to add your app to the whitelist.

If you are using "if my alarm has not gone off in X amount of time, the user perhaps force-stopped me, so let me reschedule my alarms" logic, you should be OK. Before one of your activities gets a chance to make that check, your post-wakeup alarm should have been invoked, so you can update your event log and last-run timestamp. Hence, you should not be tripped up by STAMINA and accidentally reschedule your alarms (potentially causing duplicates, depending upon your alarm-scheduling logic).

Other devices with similar characteristics include Sony's Xperia P, Xperia U, Xperia sola, and Xperia go.

Debugging Alarms

If you are encountering issues with your alarms, the first thing to do is to ensure that the alarm schedule in `AlarmManager` is what you expect it to be. To do that, run **`adb shell dumpsys alarm`** from a command prompt. This will dump a report of all the scheduled alarms, including when they are set to be invoked next (with portions replaced by vertical ellipses to keep this listing from being too long):

```
Current Alarm Manager state:

.
.
.
```

You are given details of each outstanding alarm, including the all-important `when` value indicating the time the alarm should be invoked next, if it is not canceled first (e.g., `when=+5d15h10m7s782ms`), along with the package requesting the alarm. You can use this to identify your app's alarms and see when they should be invoked next.

You are also given:

- Per-app details about how frequently their alarms have gone off, which can be useful for battery impact analysis

- A list of "top alarms" by number of occurrences, also for device performance analysis

Note, though, that for inexact alarms, the when value may not indicate when the event will actually occur.

WakefulBroadcastReceiver

The Android Support package has added a WakefulBroadcastReceiver, which offers an alternative to WakefulIntentService for arranging to do work, triggered by a broadcast (such as an AlarmManager event), that may take a while. WakefulBroadcastReceiver has its pros and cons compared to WakefulIntentService, making it worth considering.

Using WakefulBroadcastReceiver

Using WakefulBroadcastReceiver with AlarmManager is slightly different than is using WakefulIntentService. The AlarmManager/WakeCast sample project is a clone of the WakefulIntentService project, but one using WakefulBroadcastReceiver instead.

The activity is unchanged — it simply calls scheduleAlarms() on PollReceiver. scheduleAlarms() itself is unchanged, as it still uses setRepeating() on AlarmManager to arrange to periodically invoke a PendingIntent, targeting the PollReceiver.

But PollReceiver itself is now a WakefulBroadcastReceiver rather than just an ordinary BroadcastReceiver. This in turn requires a slightly different implementation of onReceive():

```
package com.commonsware.android.wakecast;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.WakefulBroadcastReceiver;

public class PollReceiver extends WakefulBroadcastReceiver {
  private static final int PERIOD=900000; // 15 minutes
  private static final int INITIAL_DELAY=5000; // 5 seconds

  @Override
  public void onReceive(Context ctxt, Intent i) {
    if (i.getAction() == null) {
      startWakefulService(ctxt,
                          new Intent(ctxt, ScheduledService.class));
    }
    else {
      scheduleAlarms(ctxt);
    }
  }

  static void scheduleAlarms(Context ctxt) {
    AlarmManager mgr=
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
                     SystemClock.elapsedRealtime() + INITIAL_DELAY,
                     PERIOD, pi);

  }
}
```

Now, when the AlarmManager broadcast arrives, we call startWakefulService(), passing it the Context supplied to onReceive(), plus an Intent identifying the service to start up. Under the covers, this works much like sendWakefulWork() on WakefulIntentService — it starts the identified service, but acquires a WakeLock first.

Our ScheduledService is now a regular IntentService, instead of a WakefulIntentService. This means that our background work moves back to the standard onHandleIntent() method, instead of doWakefulWork(). However, we have one extra bit of bookkeeping to do: we must call the static completeWakefulIntent() method on WakefulBroadcastReceiver (or, as shown, on PollReceiver, as that will point to the same static method):

```
package com.commonsware.android.wakecast;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;

public class ScheduledService extends IntentService {
  public ScheduledService() {
    super("ScheduledService");
  }

  @Override
  protected void onHandleIntent(Intent intent) {
    Log.d(getClass().getSimpleName(), "I ran!");

    PollReceiver.completeWakefulIntent(intent);
  }
}
```

We pass the Intent supplied to onHandleIntent() to completeWakefulIntent(). Behind the scenes, completeWakefulIntent() will release the WakeLock that has been keeping our CPU powered on while we do our work.

Comparing to WakefulIntentService

One might think that WakefulIntentService would now be obsolete with the addition of WakefulBroadcastReceiver. In truth, there are some advantages to the current implementation of WakefulBroadcastReceiver:

- It uses a time-limited WakeLock, one set to auto-release after one minute, so there is no risk of an app somehow failing to release the lock and thereby keeping the CPU on indefinitely.
- To make the time-limited locks work, WakefulBroadcastReceiver uses one WakeLock per request, rather than the single static WakeLock that WakefulIntentService uses, making WakefulBroadcastReceiver incrementally more resilient in the face of various potential problems.
- Because it is not strictly tied to being used with an IntentService, WakefulBroadcastReceiver may offer greater flexibility. For example, an IntentService is not a good choice if the work you do is intrinsically asynchronous, such as trying to find the device's location. Any place where you find yourself registering a listener from a service, an IntentService will not work well, as the IntentService wants to shut down before your listener has received a result. A regular Service can work well, though, in this case, and WakefulBroadcastReceiver might be of use in this pattern (though the author has not tried this yet).

On the other hand:

- WakefulBroadcastReceiver requires an explicit call to completeWakefulIntent(), which a developer can easily forget, possibly causing the WakeLock to be leaked. While this is not disastrous, since the WakeLock will auto-release after a minute, it may still represent wasted power. WakefulIntentService is more "idiot-proof" and therefore avoids this issue.
- The time for the WakefulBroadcastReceiver WakeLock is locked to being one minute — no more, no less. This offers limited flexibility and can cause problems if the work you intend to do could easily exceed a minute. Unfortunately, the implementation of WakefulBroadcastReceiver offers no easy way to override this one-minute timeout value.

- If Android terminates your process and restarts your service, the restarted service will *not* be under the control of a WakeLock, as Android will be starting the service directly, not via WakefulBroadcastReceiver. WakefulIntentService will suffer the same fate, but it will automatically grab a WakeLock for you when it detects this condition. In the case of WakefulBroadcastReceiver, your service will run without a WakeLock, unless you detect this case yourself (via a custom onStartCommand() that examines the passed-in flags, looking for START_FLAG_REDELIVERY) and grab your own WakeLock.

A future generation of WakefulIntentService will aim to adopt some of the advantages of WakefulBroadcastReceiver while avoiding its disadvantages. As it stands, either component is a reasonable choice if you are willing to live within their respective constraints.

Android 6.0 and the War on Background Processing

Android 6.0 introduced some changes to the behavior of AlarmManager that significantly affect its use on Android 6.0+ devices. These changes also affect JobScheduler, and so this topic is covered in grand detail at the end of the JobScheduler chapter.

PowerManager and WakeLocks

There are going to be times when you want the device to keep running, even though it ordinarily would go into a sleep mode, with the CPU powered down and the screen turned off. Sometimes, that will be based upon user interactions, or the lack thereof, such as keeping the screen on while playing back a video. Sometimes, that will be to allow background scheduled work to run to completion, as was introduced in the chapter on `AlarmManager`.

This chapter looks a bit more at the details of this sort of power management, including coverage of how `AlarmManager` works.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on `AlarmManager`.

Keeping the Screen On, UI-Style

If your objective is to keep the screen (and CPU) on while your activity is in the foreground, the simplest solution is to add `android:keepScreenOn="true"` to something in the activity's layout. So long as that widget or container is visible, the screen will stay on.

If you wish to do this conditionally, `setKeepScreenOn()` allows you to toggle this setting at runtime.

Once your activity is no longer in the foreground, or the widget or container is no longer visible, the effect lapses, and screen operation returns to normal.

The Role of the WakeLock

Most of the time in Android, you are developing code that will run while the user is actually using the device. Activities, for example, only really make sense when the device is fully awake and the user is tapping on the screen or keyboard.

Particularly with scheduled background tasks, though, you need to bear in mind that the device will eventually "go to sleep". In full sleep mode, the display, main CPU, and keyboard are all powered off, to maximize battery life. Only on a low-level system event, like an incoming phone call, will anything wake up the device.

Another thing that will partially wake up the phone is an `Intent` raised by the `AlarmManager`. So long as broadcast receivers are processing that `Intent`, the `AlarmManager` ensures the CPU will be running (though the screen and keyboard are still off). Once the broadcast receivers are done, the `AlarmManager` lets the device go back to sleep.

You can achieve the same effect in your code via a `WakeLock`.

One of the changes that the core Android team made to the Linux kernel was to introduce the concept of the "wakelock". In simple terms, a wakelock allows a Linux userland application — such as our Android SDK apps — to control whether or not the CPU can be powered down as part of a sleep mode. While a wakelock is in force, the CPU will remain on and processing instructions from the processes and threads that are on the device.

From the SDK, to access a wakelock, you use a `WakeLock` object, obtained from the `PowerManager` system service. When you call `acquire()` on that `WakeLock`, the CPU will remain on; when you call `release()` on that `WakeLock`, the CPU can fall back asleep, if there are no other outstanding `WakeLocks` from SDK apps or the operating system itself.

There are four types of `WakeLock` objects. All will keep the CPU on. They vary in their effects on the screen (leave it off, have it display with dim backlight, have it display with normal backlight) and any physical keys (ignore or accept). You will pass a flag into `newWakeLock()` on the `PowerManager` system service to indicate what type of `WakeLock` you want. The most common is the `PARTIAL_WAKE_LOCK`, which keeps the CPU on but leaves the screen and keyboard off — ideal for periodic background work triggered by an `AlarmManager` event.

What WakefulIntentService Does

For a _WAKEUP alarm, the AlarmManager will arrange for the device to stay awake, via a WakeLock, for as long as the BroadcastReceiver's onReceive() method is executing. For some situations, that may be all that is needed. However, onReceive() is called on the main application thread, and Android will kill off the receiver if it takes too long.

Your natural inclination in this case is to have the BroadcastReceiver arrange for a Service to do the long-running work on a background thread, since BroadcastReceiver objects should not be starting their own threads. Perhaps you would use an IntentService, which packages up this "start a Service to do some work in the background" pattern. And, given the preceding section, you might try acquiring a partial WakeLock at the beginning of the work and release it at the end of the work, so the CPU will keep running while your IntentService does its thing.

This strategy will work… some of the time.

The problem is that there is a gap in WakeLock coverage, as depicted in the following diagram:

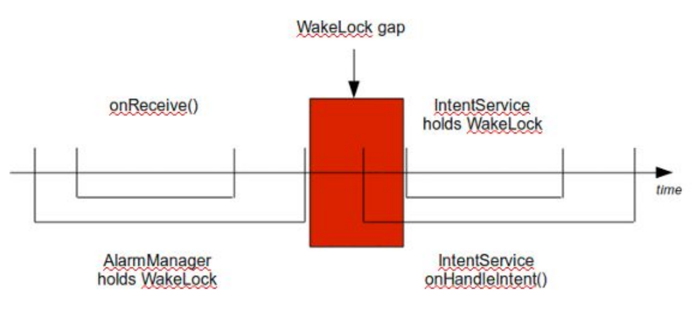

Figure 743: The WakeLock Gap

The BroadcastReceiver will call startService() to send work to the IntentService, but that service will not start up until after onReceive() ends. As a result, there is a window of time between the end of onReceive() and when your IntentService can acquire its own WakeLock. During that window, the device might fall back asleep. Sometimes it will, sometimes it will not.

What you need to do, instead, is arrange for overlapping WakeLock instances. You need to acquire a WakeLock in your BroadcastReceiver, during the onReceive()

execution, and hold onto that WakeLock until the work is completed by the IntentService:

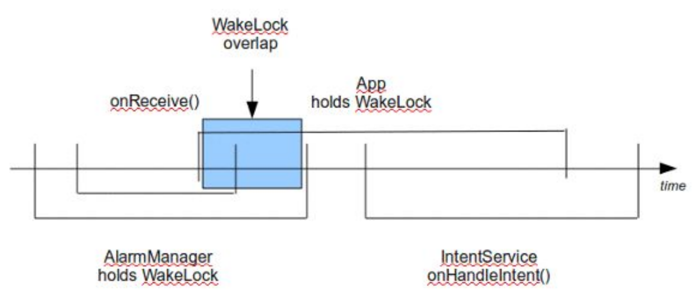

Figure 744: The WakeLock Overlap

Then you are assured that the device will stay awake as long as the work remains to be done.

The WakefulIntentService recipe described in [its chapter]() does not have you manage your own WakeLock. That is because WakefulIntentService handles it for you. One reason why WakefulIntentService exists is to manage that WakeLock, because WakeLocks suffer from one major problem: they are [not Parcelable](), and therefore cannot be passed in an Intent extra. Hence, for our BroadcastReceiver and our WakefulIntentService to use the same WakeLock, they have to be shared via a static data member… which is icky. WakefulIntentService is designed to hide this icky part from you, so you do not have to worry about it.

WakefulIntentService also handles various edge and corner cases, such as:

- What happens if Android elects to get rid of your process due to low memory conditions?
- What happens if your doWakefulWork() crashes, so we do not leak the acquired WakeLock?
- What if your UI also sends commands to the WakefulIntentService, or your processing takes longer than your polling period in AlarmManager, so that we have more than one piece of work outstanding at a point in time?

The one requirement related to a WakeLock that WakefulIntentService imposes upon you is the WAKE_LOCK permission. Any code in your process that is directly manipulating WakeLock objects needs this permission, even if that code is from a third-party JAR like WakefulIntentService.

JobScheduler

AlarmManager was our original solution for doing work on a periodic basis. However, AlarmManager can readily be misused, in ways that impact the battery — this is why API Level 19 put renewed emphasis on “inexact” alarm schedules. Worse, AlarmManager will give us control at points in time that may be useless to us, such as giving us control when there is no Internet access, when the point of the scheduled work is to transfer some data over the Internet.

Android 5.0 introduced JobScheduler, which offers a more sophisticated API for handling these sorts of scenarios. This chapter will explore how to set up JobScheduler and use it for one-off and periodic work.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on AlarmManager. Also, you should have read the chapter on PowerManager and wakelocks.

The Limitations of AlarmManager

AlarmManager does its job, and frequently does it well. However, it is far from perfect:

- It does not persist its alarm schedule across reboots, forcing us to implement an ACTION_BOOT_COMPLETED BroadcastReceiver to re-establish our alarms
- It does not keep the device awake after waking it up with a _WAKEUP alarm, forcing us to use tools like WakefulBroadcastReceiver to make sure that we can get our work done without the device falling back asleep

- It gives us control even if the work we want to do is not possible, such as wanting to download material from the Internet but being woken up at points in time when we lack a working Internet connection (e.g., a WiFi-only tablet in a location for which it does not recognize any access points)
- In cases where the criteria we want cannot be met, we cannot readily implement any sort of back-off policy, except by doing the calculations ourselves and perhaps abandoning the convenient "repeating" API outright

And so on. `AlarmManager` is nice, but it would be better to have another solution.

Enter the JobScheduler

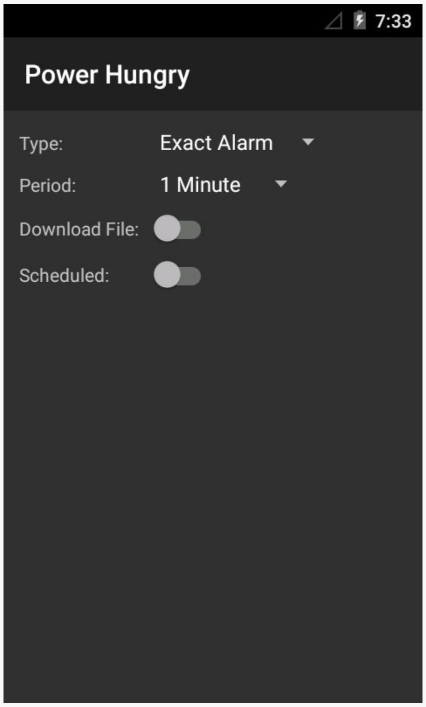
`JobScheduler` was designed to handle those four problems outlined above:

- It persists its roster of jobs and will re-establish them automatically after a reboot. Note, though, that you still have to hold the `ACTION_BOOT_COMPLETED` permission for this to work. Also note that you do not *have* to have jobs be persisted — this is an opt-in capability of `JobScheduler`.
- It handles "wakefulness" for us, via its own `WakeLock`, so we do not have to worry about it ourselves.
- It offers an API where we can specify criteria to be satisfied before we should be given control, notably a criteria indicating that we need a working network connection.
- If our criteria cannot be met, `JobScheduler` implements a configurable back-off policy, so we can slow down our attempts to get control when those attempts are regularly failing.

Employing JobScheduler

The `JobScheduler/PowerHungry` sample project demonstrates the use of `JobScheduler`, by way of comparing its use to that of `AlarmManager`.

The UI for `JobScheduler` allows you to pick from three types of event schedules: exact alarm, inexact alarm, and `JobScheduler`. You can also choose from one of four polling periods: 1 minute, 15 minutes, 30 minutes, and 60 minutes:



Type: Exact Alarm

Period: 1 Minute

Download File:

Scheduled:

Figure 745: PowerHungry Demo, As Initially Launched

A `Switch` (in its `Theme.Material` styling) allows you to determine whether you are simply getting control at those points in time to just log to LogCat, or whether you are going to try to do some work at those points in time. Specifically, the "work" is to download a file, using `HttpUrlConnection`.

The bottom `Switch` toggles on and off the event schedules. When the event schedules are toggled on, you cannot manipulate the rest of the UI — you need to turn off the events in order to change the event configuration.

Note that none of this information is persisted. This is a lightweight demo; it is expected that you are keeping this UI in the foreground while a test is running.

Defining and Scheduling the Job

The "job" is defined as an instance of `JobInfo`, typically created using an instance of `JobInfo.Builder` to configure a `JobInfo` using a fluent builder-style API. We teach the `JobInfo` the work to do and when to do it, then use a `JobScheduler` to actually schedule the job.

In the sample app, this work is mostly accomplished via a `manageJobScheduler()` method on the `MainActivity` class:

```
private void manageJobScheduler(boolean start) {
  if (start) {
    JobInfo.Builder b=new JobInfo.Builder(JOB_ID,
        new ComponentName(this, DemoJobService.class));
    PersistableBundle pb=new PersistableBundle();

    if (download.isChecked()) {
      pb.putBoolean(KEY_DOWNLOAD, true);
      b.setExtras(pb).setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY);
    } else {
      b.setRequiredNetworkType(JobInfo.NETWORK_TYPE_NONE);
    }

    b.setPeriodic(getPeriod()).setPersisted(false)
        .setRequiresCharging(false).setRequiresDeviceIdle(true);

    jobs.schedule(b.build());
  }
  else {
    jobs.cancel(JOB_ID);
  }
}
```

The `start` parameter to `manageJobScheduler()` is driven by the bottom `Switch` widget. A `start` value of `true` means that we should start up the job; a value of `false` means that we should cancel any existing job.

If `start` is `true`, we begin by creating a `JobInfo.Builder`, supplying two key pieces of data:

- an `int` that will serve as the job ID, which needs to be unique to our app but does not have to be unique for the whole device
- a `ComponentName` identifying the `JobService` that will actually implement the work of the job itself

The primary way of passing data from the scheduling code (our activity) and the job-implementing code (`JobService`) is by means of a `PersistableBundle` – a `Bundle`-like object that can be persisted to disk. `PersistableBundle` was introduced in API Level 21, but at that time it inexplicably lacked support for `boolean` values. API Level 22 added `getBoolean()` and `putBoolean()` to `PersistableBundle`, and this sample project has `minSdkVersion` of 22 to be able to take advantage of it. If you wanted to use this sample on API Level 21, you would need to convert the `boolean` into something else, such as `0` and `1` `int` values.

Our `PersistableBundle` can have more data than just this one extra, though that is all we need in this case. We attach the `PersistableBundle` to the `JobInfo` via the `setExtras()` method on the `JobInfo.Builder`.

We can also call methods on the `JobInfo.Builder` to configure the criteria that should be satisfied before giving us control. In our case, one criterion that we need is to have a network connection, but only if we are supposed to be downloading a file. So, we call `setRequiredNetworkType()` in either case, indicating that we either want `ANY` type of network connection (metered or unmetered) or `NONE`.

Other criteria-defining methods that we invoke include `setRequiresCharging()` (set to `false` to indicate we want control even if we are on battery) and `setRequiresDeviceIdle()` (set to `true` to indicate that we want control only if the user is not using it).

In the case of this sample, we want to do this work every so often, based upon the period chosen by the user in the bottom `Spinner` and retrieved via the `getPeriod()` method. So, we call `setPeriodic()` on the `JobInfo.Builder` to request getting control with that frequency, bearing in mind that this is merely a hint, not a requirement, and we may get control more or less frequently than this.

We also call `setPersisted(false)` to indicate that we do not need for this job to be persisted, so it will be lost on a reboot. If we instead called `setPersisted(true)`, the manifest would need to request the `RECEIVE_BOOT_COMPLETED` permission to have the job be re-created at boot time.

Finally, we call `schedule()` on a `JobScheduler` instance named `jobs` to schedule the job.

The `jobs` data member is populated up in `onCreate()` of the activity:

```
    jobs=(JobScheduler)getSystemService(JOB_SCHEDULER_SERVICE);
```

While this may look like an ordinary request for a system service, it has one issue: your version of Android Studio may not know anything about it. In that case, this code will fail a Lint check, complaining that the service is not recognized. This is a bug that should be fixed in Android Studio 0.8.14. The workaround is to add `@SuppressWarnings("ResourceType")` to the method where you are making this `getSystemService()` call to suppress this Lint check.

If the `start` parameter to `manageJobScheduler()` is `false`, we call `cancel()` on the `JobScheduler`, passing in our unique job ID (`JOB_ID`) to indicate what job to cancel. Or, we could have called `cancelAll()`, which would cancel all jobs scheduled by our application.

Implementing the Job

The work for the job itself is handled by a `JobService`. This is a subclass of `Service` that we, in turn, extend ourselves, overriding two job-specific callback methods to actually do the work: `onStartJob()` and `onStopJob()`.

The `JobService` in our sample app is `DemoJobService`:

```
package com.commonsware.android.job;

import android.app.job.JobParameters;
import android.app.job.JobService;
import android.os.PersistableBundle;
import android.util.Log;

public class DemoJobService extends JobService {
  private volatile Thread job=null;

  @Override
  public boolean onStartJob(JobParameters params) {
    PersistableBundle pb=params.getExtras();

    if (pb.getBoolean(MainActivity.KEY_DOWNLOAD, false)) {
      job=new DownloadThread(params);
      job.start();

      return(true);
    }

    Log.d(getClass().getSimpleName(), "job invoked");

    return(false);
  }

  @Override
  synchronized public boolean onStopJob(JobParameters params) {
    if (job!=null) {
      Log.d(getClass().getSimpleName(), "job interrupted");
      job.interrupt();
    }

    return(false);
  }

  synchronized private void clearJob() {
    job=null;
  }
  private class DownloadThread extends Thread {
    private final JobParameters params;

    DownloadThread(JobParameters params) {
      this.params=params;
    }

    @Override
    public void run() {
      Log.d(getClass().getSimpleName(), "job begins");
      new DownloadJob().run();
      Log.d(getClass().getSimpleName(), "job ends");
      clearJob();
      jobFinished(params, false);
    }
  }
}
```

`onStartJob()` is passed a `JobParameters`. This serves both as a "handle" identifying a particular job invocation and giving us access to the job ID (`getJobId()`) and `PersistableBundle` of extras (`getExtras()`) that were set up by our `JobInfo` when we scheduled the job.

`onStartJob()` needs to return `true` if we have successfully forked a background thread to do the work, or `false` if no work needs to be done. In our case, this is determined by whether or not we want to try to download a file. In a production-grade app, this may be determined by whether there is any work to be done (e.g., "do we have entries in the upload queue?").

In `onStartJob()`, we check the `PersistableBundle` to see if we are supposed to download a file. If we are, we fork a `DownloadThread` to do that work, then return `true`. Otherwise, we return `false`.

Because this sample app illustrates the difference in behavior between `JobScheduler` and `AlarmService`, we want to isolate the actual download-the-file logic into a common implementation that can be used from either code path. That takes the form of a `DownloadJob`, which implements `Runnable` and does the download work when it is `run()`:

```
package com.commonsware.android.job;

import android.net.Uri;
import android.os.Environment;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

class DownloadJob implements Runnable {
  static final Uri TO_DOWNLOAD=
      Uri.parse("https://commonsware.com/Android/excerpt.pdf");

  @Override
  public void run() {
    try {
      File root=

Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

      root.mkdirs();

      File output=new File(root, TO_DOWNLOAD.getLastPathSegment());

      if (output.exists()) {
        output.delete();
      }

      URL url=new URL(TO_DOWNLOAD.toString());
      HttpURLConnection c=(HttpURLConnection)url.openConnection();

      FileOutputStream fos=new FileOutputStream(output.getPath());
      BufferedOutputStream out=new BufferedOutputStream(fos);

      try {
        InputStream in=c.getInputStream();
        byte[] buffer=new byte[8192];
        int len=0;

        while ((len=in.read(buffer)) >= 0) {
          out.write(buffer, 0, len);
        }

        out.flush();
      }
      finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
      }
    }
    catch (IOException e2) {
      Log.e("DownloadJob", "Exception in download", e2);
    }
  }
}
```

DownloadThread delegates to DownloadJob to do the actual work. However, when the work is complete, it then calls jobFinished() on the DemoJobService. jobFinished(), as the name suggests, tells the framework that we are finished doing the work associated with this job. If the job succeeded, we pass false as the second parameter, to indicate that this job does not need to be rescheduled. If, on the other hand, we were unable to actually do the work (e.g., we cannot connect to the desired server, perhaps due to server maintenance), we would pass true as the second parameter, to request that this job be rescheduled to be invoked again shortly, so that we can retry the operation.

Our onStopJob() method will be called by Android if environmental conditions have changed and we should stop the background work that we are doing. For example, we asked to do this work when the device was idle — if the user picks up the device and starts using it, we should stop our background work. In this case, if the job thread is still outstanding, we cancel() it. onStopJob() should return true if this job is still needed and should be retried, or false otherwise. Most short-period periodic jobs should return false, to just worry about the next job in the next period, and that is what onStopJob() does here. One-time jobs, or jobs with long periods (e.g., a day), may wish to return true to ensure that they will get another chance to do the desired work. We will cover more about this issue later in this chapter.

Wiring in the Job Service

Since a JobService is a Service, we need the corresponding <service> element in the manifest. For a JobService, the <service> element is perfectly normal… with one exception:

```
        <service
            android:name=".DemoJobService"
            android:permission="android.permission.BIND_JOB_SERVICE"
        />
```

You need to defend the service with the BIND_JOB_SERVICE permission. This only allows code that holds the BIND_JOB_SERVICE permission to start or bind to this service, which should limit it to the OS itself.

The Rest of the Sample

As noted earlier, the UI for our activity is a pair of Spinner widgets, along with a pair of Switch widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<GridLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp"
    android:useDefaultMargins="true">
    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/type_label"
        android:layout_row="0"
        android:layout_column="0"/>

    <Spinner
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/type"
        android:layout_row="0"
        android:layout_column="1"/>

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/period_label"
        android:layout_row="1"
        android:layout_column="0"/>

    <Spinner
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/period"
        android:layout_row="1"
        android:layout_column="1"/>

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/download_label"
        android:layout_row="2"
        android:layout_column="0"/>

    <Switch
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/download"
        android:layout_row="2"
        android:layout_column="1"/>

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/scheduled_label"
        android:layout_row="3"
        android:layout_column="0"/>

    <Switch
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/scheduled"
        android:layout_row="3"
        android:layout_column="1"/>
</GridLayout>
```

`onCreate()` of `MainActivity` sets up the UI, including populating the two `Spinner` widgets based on `<string-array>` resources and hooking up the activity to respond to changes in the checked state of the `scheduled` `Switch` widget:

```
@SuppressWarnings("ResourceType")
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);

  setContentView(R.layout.main);
  type=(Spinner)findViewById(R.id.type);

  ArrayAdapter<String> types=
      new ArrayAdapter<String>(this,
          android.R.layout.simple_spinner_item,
          getResources().getStringArray(R.array.types));

  types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
  type.setAdapter(types);

  period=(Spinner)findViewById(R.id.period);

  ArrayAdapter<String> periods=
      new ArrayAdapter<String>(this,
          android.R.layout.simple_spinner_item,
          getResources().getStringArray(R.array.periods));

  periods.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
  period.setAdapter(periods);

  download=(Switch)findViewById(R.id.download);
  scheduled=(Switch)findViewById(R.id.scheduled);
  scheduled.setOnCheckedChangeListener(this);

  alarms=(AlarmManager)getSystemService(ALARM_SERVICE);
  jobs=(JobScheduler)getSystemService(JOB_SCHEDULER_SERVICE);
}
```

When the user toggles the `scheduled` `Switch` widget, we examine the `type` `Spinner` and route control to a method dedicated for handling that particular type of periodic request, such as the `manageJobScheduler()` method we saw earlier in this chapter:

```
@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
  toggleWidgets(!isChecked);

  switch(type.getSelectedItemPosition()) {
    case 0:
      manageExact(isChecked);
      break;

    case 1:
      manageInexact(isChecked);
      break;
    case 2:
      manageJobScheduler(isChecked);
      break;
  }
}
```

Our onCheckedChanged() for the schedule Switch also calls a toggleWidgets() method that enables or disables the other widgets, depending upon whether the schedule Switch is checked or unchecked:

```
  private void toggleWidgets(boolean enable) {
    type.setEnabled(enable);
    period.setEnabled(enable);
    download.setEnabled(enable);
  }
```

If the user had chosen an exact alarm, onCheckedChanged() routes control to manageExact():

```
  private void manageExact(boolean start) {
    if (start) {
      long period=getPeriod();

      PollReceiver.scheduleExactAlarm(this, alarms, period,
          download.isChecked());
    }
    else {
      PollReceiver.cancelAlarm(this, alarms);
    }
  }
```

It, in turn, routes control over to a PollReceiver, a WakefulBroadcastReceiver that is set up for handling our alarms:

```
package com.commonsware.android.job;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.WakefulBroadcastReceiver;

public class PollReceiver extends WakefulBroadcastReceiver {
  static final String EXTRA_PERIOD="period";
  static final String EXTRA_IS_DOWNLOAD="isDownload";

  @Override
  public void onReceive(Context ctxt, Intent i) {
    boolean isDownload=i.getBooleanExtra(EXTRA_IS_DOWNLOAD, false);
    startWakefulService(ctxt,
        new Intent(ctxt, DemoScheduledService.class)
            .putExtra(EXTRA_IS_DOWNLOAD, isDownload));
    long period=i.getLongExtra(EXTRA_PERIOD, -1);

    if (period>0) {
      scheduleExactAlarm(ctxt,
          (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE),
          period, isDownload);
    }
  }

  static void scheduleExactAlarm(Context ctxt, AlarmManager alarms,
                                 long period, boolean isDownload) {
    Intent i=new Intent(ctxt, PollReceiver.class)
        .putExtra(EXTRA_PERIOD, period)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.setExact(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+period, pi);
  }

  static void scheduleInexactAlarm(Context ctxt, AlarmManager alarms,
                                   long period, boolean isDownload) {
    Intent i=new Intent(ctxt, PollReceiver.class)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.setInexactRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+period, period, pi);
  }

  static void cancelAlarm(Context ctxt, AlarmManager alarms) {
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.cancel(pi);
  }
}
```

This sample app has a `targetSdkVersion` of 21. Hence, on Android 5.0 devices — the ones that have `JobScheduler`, we cannot set up exact repeating alarms. Our only option is to handle the repeating work ourselves.

Hence, `scheduleExactAlarm()` creates a broadcast `PendingIntent`, on an `Intent` pointing at our `PollReceiver`, with a pair of extras indicating the polling period and whether or not we should be downloading a file. It then uses `setExact()` on an `AlarmManager` to schedule a *one-off* event to occur one polling period from now.

That, in turn, will trigger `onReceive()` of the `PollReceiver`. Here, we call `startWakefulService()` to have our work be done by a `DemoScheduledService`. In addition, if we have a polling period, that means that this is an exact alarm, and we call `scheduleExactAlarm()` to set up the next occurrence of this "repeating" event.

DemoScheduledService is simply an IntentService wrapper around the DownloadJob that we used with DemoJobService, logging the fact that it ran and calling completeWakefulIntent() to indicate that the work initiated by the WakefulBroadcastReceiver was done.

cancelAlarm() on PollReceiver — called by manageExact() when we are stopping the repeating event — creates an equivalent PendingIntent to the ones used for the AlarmManager events, and uses that with cancel() on AlarmManager to cancel those events.

If the user had chosen an exact alarm, onCheckedChanged() routes control to manageInexact():

```
private void manageInexact(boolean start) {
  if (start) {
    long period=getPeriod();
