- [Preface](#)
 - Welcome to the Book! i
 - The Book's Structure i
 - ***The Trails*** ***ii***
 - About the Updates viii
 - ***What's New in Version 7.1?*** ***viii***
 - ***Warescription*** ***viii***
 - ***Extending Your Warescription*** ***ix***
 - Source Code and Its License xi
 - ***Creative Commons and the Four-to-Free (42F) Guarantee*** ***xi***
 - Acknowledgments xii
- [Key Android Concepts](#)
 - Android Applications 1
 - Android Devices 7
 - Don't Be Scared 10
- [Choosing Your Development Toolchain](#)
 - Android Studio 11
 - Eclipse 11
 - IntelliJ IDEA 12
 - Command-Line Builds via Gradle for Android 12
 - Yet Other Alternatives 12
 - IDEs... And This Book 13
 - What We Are Not Covering 13
- [Tutorial #1 - Installing the Tools](#)
 - Step #1 - Checking Your Hardware Requirements 15
 - Step #2 - Setting Up Java and 32-Bit Linux Support 16
 - Step #3 - Install the Developer Tools 16
 - ***Step #4 - Install the SDKs and Add-Ons*** ***17***
 - In Our Next Episode... 26
- [Android and Projects](#)
 - Common Concepts 27
 - Projects and Android Studio 28
 - Starter Project Generators 35
- [Tutorial #2 - Creating a Stub Project](#)
 - About Our Tutorial Project 37

- About the Rest of the Tutorials 38
- About Our Tools 38
- Step #1: Creating the Project 38
- Step #2 - Set Up the Emulator 40
- Step #3 - Set Up the Device 46
- Step #4: Running the Project 49
- In Our Next Episode... 51
- [Getting Around Android Studio](#)
 - Navigating The Project Explorer 53
 - Running Projects 56
 - Viewing Output 57
 - Accessing Android Tools 58
 - Android Studio and Release Channels 62
 - Visit the Trails! 63
- [Contents of Android Projects](#)
 - What You Get, In General 65
 - The Contents of an Android Studio Project 67
 - The Contents of an Eclipse Project 69
 - What You Get Out Of It 70
 - Projects and this Book 70
- [Introducing Gradle and the Manifest](#)
 - Gradle: The Big Questions 71
 - Obtaining Gradle 74
 - Versions of Gradle and Gradle for Android 76
 - Gradle Environment Variables 77
 - Examining the Gradle Files 77
 - Introducing the Manifest 79
 - Things In Common Between the Manifest and Gradle 80
 - Other Gradle Items of Note 83
 - Where's the GUI? 85
 - The Rest of the Manifest 85
 - Learning More About Gradle 87
 - Visit the Trails! 88
- [Tutorial #3 - Changing Our Manifest \(and Gradle File\)](#)
 - Some Notes About Relative Paths 89
 - Step #1: Supporting Screens 90
 - Step #2: Adding our Minimum and Target SDK Versions 90
 - In Our Next Episode... 91
- [Some Words About Resources](#)
 - String Theory 94
 - Got the Picture? 98

- Dimensions 103
- The Resource That Shall Not Be Named... Yet 105
- [Tutorial #4 - Adjusting Our Resources](#)
 - Step #1: Changing the Name 107
 - Step #2: Changing the Icon 108
 - Step #3: Running the Result 111
 - In Our Next Episode... 113
- [The Theory of Widgets](#)
 - What Are Widgets? 115
 - Size, Margins, and Padding 117
 - What Are Containers? 117
 - The Absolute Positioning Anti-Pattern 118
 - The Theme of This Section: Themes 119
- [The Android User Interface](#)
 - The Activity 123
 - Dissecting the Activity 124
 - Using XML-Based Layouts 125
- [Basic Widgets](#)
 - Common Concepts 131
 - Assigning Labels 134
 - A Commanding Button 144
 - Fleeting Images 149
 - **Fields of Green. Or Other Colors.** **156**
 - More Common Concepts 162
 - **Visit the Trails!** **164**
- [Debugging Your App](#)
 - Get Thee To a Stack Trace 166
 - The Case of the Confounding Class Cast 170
 - Point Break 171
- [LinearLayout and the Box Model](#)
 - Concepts and Properties 173
 - Android Studio Graphical Layout Editor 177
 - Eclipse Graphical Layout Editor 178
- [Other Common Widgets and Containers](#)
 - Just a Box to Check 181
 - Don't Like Checkboxes? How About Toggles or Switches? 186
 - Turn the Radio Up 191
 - All Things Are Relative 195
 - **Tabula Rasa** **202**
 - Scrollwork 209
 - Making Progress with ProgressBars 212

◦ <i>Visit the Trails!</i>	213
• Tutorial #5 - Making Progress	
◦ Step #1: Removing The “Hello, World”	215
◦ Step #2: Adding a ProgressBar	216
◦ Step #3: Seeing the Results	217
◦ In Our Next Episode...	218
• GUI Building, Continued	
◦ Making Your Selection	219
◦ Including Includes	220
◦ Wrap It Up (In a Container)	222
◦ Morphing Widgets	223
◦ Preview of Coming Attractions	224
• AdapterViews and Adapters	
◦ Adapting to the Circumstances	225
◦ Lists of Naughty and Nice	227
◦ Clicks versus Selections	229
◦ Spin Control	233
◦ Grid Your Lions (Or Something Like That...)	236
◦ Fields: Now With 35% Less Typing!	239
◦ Customizing the Adapter	243
◦ Visit the Trails!	251
• The WebView Widget	
◦ Role of WebView	253
◦ WebView and WebKit	254
◦ The Android System WebView	254
◦ Adding the Widget	255
◦ Loading Content Via a URL	255
◦ Links and Redirects	257
◦ Supporting JavaScript	257
◦ Alternatives for Loading Content	258
◦ Listening for Events	259
◦ Addressing the Link/Redirect Behavior	262
◦ Visit the Trails!	263
• Defining and Using Styles	
◦ Styles: DIY DRY	265
◦ Elements of Style	267
◦ Themes: Would a Style By Any Other Name...	270
◦ What Happens If You Have No Theme	270
◦ Android Studio’s Theme Editor	271
• JARs and Library Projects	
◦ The Dalvik VM, and a Bit of ART	278

◦ Getting the Library	278
◦ The Outer Limits	280
◦ JAR Dependency Management	281
◦ OK, So What is a Library Project?	281
◦ Using a Library Project	282
◦ Library Projects: What You Get	283
◦ The Android Support Package	284
• Tutorial #6 - Adding a Library	
◦ Step #1: Attaching the Android Support Package	289
◦ Step #2: Attaching the Third-Party Dependencies	290
◦ In Our Next Episode...	291
• The Action Bar	
◦ Bar Hopping	293
◦ Yet Another History Lesson	299
◦ Your Action Bar Options	300
◦ Setting the Target	302
◦ Defining the Resource	303
◦ Applying the Resource	305
◦ Responding to Events	306
◦ The Rest of the Sample Activity	307
◦ MENU Key, We Hardly Knew Ye	313
◦ Action Bars, Live in Living Color!	314
◦ Visit the Trails!	323
• Tutorial #7 - Setting Up the Action Bar	
◦ Step #1: Acquiring Some Icons	325
◦ Step #2: Defining Some Options	327
◦ Step #3: Loading and Responding to Our Options	328
◦ Step #4: Trying It Out	329
◦ In Our Next Episode...	332
• Android's Process Model	
◦ When Processes Are Created	333
◦ BACK, HOME, and Your Process	334
◦ Termination	335
◦ Foreground Means "I Love You"	336
◦ You and Your Heap	336
• Activities and Their Lifecycles	
◦ Creating Your Second (and Third and...) Activity	338
◦ Warning! Contains Explicit Intents!	344
◦ Using Implicit Intents	346
◦ Extra! Extra!	351
◦ Pondering Parcelable	353

◦	Asynchronicity and Results	354
◦	Schroedinger’s Activity	354
◦	<i>Life, Death, and Your Activity</i>	355
◦	When Activities Die	357
◦	Walking Through the Lifecycle	358
◦	Recycling Activities	361
◦	Application: Transcending the Activity	362
◦	The Case of the Invisible Activity	363
•	Tutorial #8 - Setting Up An Activity	
◦	<i>Step #1: Creating the Stub Activity Class and Manifest Entry</i>	365
◦	Step #2: Launching Our Activity	367
◦	In Our Next Episode...	367
•	The Tactics of Fragments	
◦	The Six Questions	369
◦	Where You Get Your Fragments From	372
◦	Your First Fragment	372
◦	The Fragment Lifecycle Methods	375
◦	Your First Dynamic Fragment	376
◦	Fragments and the Action Bar	379
◦	Fragments Within Fragments: Just Say “Maybe”	380
◦	Fragments and Multiple Activities	381
•	Tutorial #9 - Starting Our Fragments	
◦	<i>Step #1: Create a SimpleContentFragment</i>	383
◦	Step #2: Examining SimpleContentFragment	385
◦	In Our Next Episode...	386
•	Swiping with ViewPager	
◦	Swiping Design Patterns	387
◦	Pieces of a Pager	388
◦	Paging Fragments	388
◦	Paging Other Stuff	393
◦	Indicators	394
•	Tutorial #10 - Rigging Up a ViewPager	
◦	Step #1: Add a ViewPager to the Layout	399
◦	Step #2: Obtaining Our ViewPager	400
◦	Step #3: Creating a ContentsAdapter	401
◦	Step #4: Setting Up the ViewPager	401
◦	In Our Next Episode...	404
•	Resource Sets and Configurations	
◦	What’s a Configuration? And How Do They Change?	405
◦	Configurations and Resource Sets	406
◦	Screen Size and Orientation	407

◦ Coping with Complexity	410
◦ Choosing The Right Resource	411
◦ API-Versioned Resources	415
◦ Default Change Behavior	417
◦ State Saving Scenarios	418
◦ Your Options for Configuration Changes	420
◦ Blocking Rotations	431
◦ And Now, a Word From the Android Project View	431
• Material Design Basics	
◦ Your App, in Technicolor!	435
• Dealing with Threads	
◦ The Main Application Thread	443
◦ Getting to the Background	445
◦ Asyncing Feeling	445
◦ Alternatives to AsyncTask	454
◦ And Now, The Caveats	455
◦ Event Buses	456
◦ Visit the Trails!	463
• Requesting Permissions	
◦ Frequently-Asked Questions About Permissions	466
◦ Characteristics of Permissions	471
◦ New Permissions in Old Applications	474
◦ Android 6.0+ Runtime Permission System	475
• Tutorial: Runtime Permission Support	
◦ Step #0: Install the Android 6.0 SDK	490
◦ Step #1: Import and Review the Starter Project	491
◦ Step #2: Update Gradle for Android 6.0	498
◦ Step #3: Review the Planned UX	500
◦ Step #4: Detect the First Run	501
◦ Step #5: On First Run, Ask For Permissions	502
◦ Step #6: Check for Permissions Before Taking a Picture	506
◦ Step #7: Detect If We Should Show Some Rationale	507
◦ Step #8: Add a Rationale UI and Re-Request Permissions	508
◦ Step #9: Check for Permissions Before Recording a Video	514
◦ Step #10: Detect If We Should Show Some Rationale (Again)	515
◦ Step #11: Support Configuration Changes	517
• Assets, Files, and Data Parsing	
◦ Packaging Files with Your App	525
◦ Files and Android	527
◦ Working with Internal Storage	528
◦ Working with External Storage	536

◦ Multiple User Accounts	541
◦ Linux Filesystems: You Sync, You Win	542
◦ StrictMode: Avoiding Janky Code	544
◦ <i>Files, and Your Development Machine</i>	546
◦ XML Parsing Options	549
◦ JSON Parsing Options	550
◦ Visit the Trails!	550
• Tutorial #11 - Adding Simple Content	
◦ Step #1: Adding Some Content	551
◦ Step #2: Using SimpleContentFragment	552
◦ Step #3: Launching Our Activities, For Real This Time	553
◦ Step #4: Getting a Bit More Material	554
◦ Step #5: Seeing the Results	555
◦ In Our Next Episode...	558
• Tutorial #12 - Displaying the Book	
◦ Step #1: Adding a Book	559
◦ Step #2: Creating a ModelFragment	560
◦ Step #3: Defining Our Model	561
◦ Step #4: Examining Our Model	563
◦ Step #5: Defining Our Event	563
◦ Step #6: Loading Our Model	564
◦ Step #7: Registering for Events	566
◦ Step #8: Adapting the Content	567
◦ Step #9: Showing the Content When Loaded	568
◦ Step #10: Attaching our ModelFragment	568
◦ Step #11: Showing the Content After a Configuration Change	570
◦ Step #12: Setting Up StrictMode	570
◦ In Our Next Episode...	571
• Using Preferences	
◦ Getting What You Want	573
◦ Stating Your Preference	574
◦ Collecting Preferences with PreferenceFragment	575
◦ Types of Preferences	582
• Tutorial #13 - Using Some Preferences	
◦ Step #1: Defining the Preference XML Files	589
◦ Step #2: Creating Our Preference Activity	590
◦ Step #3: Adding To Our Action Bar	591
◦ Step #4: Launching the Preference Activity	592
◦ Step #5: Loading the Preferences	594
◦ Step #6: Saving the Last-Read Position	597
◦ Step #7: Restoring the Last-Read Position	598

◦	Step #8: Keeping the Screen On	599
◦	In Our Next Episode... ..	601
•	SQLite Databases	
◦	Introducing SQLite	603
◦	Thinking About Schemas	604
◦	Start with a Helper	604
◦	Getting Data Out	609
◦	The Rest of the CRUD	615
◦	Hey, What About Hibernate?	620
◦	Visit the Trails!	620
•	Tutorial #14 - Saving Notes	
◦	Step #1: Adding a DatabaseHelper	621
◦	Step #2: Examining DatabaseHelper	622
◦	Step #3: Creating a NoteFragment	623
◦	Step #4: Examining NoteFragment	626
◦	Step #5: Creating the NoteActivity	627
◦	Step #6: Examining NoteActivity	628
◦	Step #7: Add Notes to the Action Bar	628
◦	Step #8: Defining a NoteLoadedEvent	629
◦	Step #9: Loading a Note from the Database	630
◦	Step #10: Loading the Note Into the Fragment	631
◦	Step #11: Updating the Database	632
◦	Step #12: Saving the Note	633
◦	Step #13: Adding a Delete Action Bar Item	635
◦	Step #14: Closing the NoteFragment When Deleted	636
◦	In Our Next Episode... ..	640
•	Internet Access	
◦	DIY HTTP	641
◦	HTTP via DownloadManager	651
◦	Using Third-Party JARs	651
◦	SSL	652
◦	Using HTTP Client Libraries	652
◦	Visit the Trails	675
•	Intents, Intent Filters	
◦	What's Your Intent?	677
◦	Stating Your Intent(ions)	679
◦	Responding to Implicit Intents	679
◦	Requesting Implicit Intents	682
◦	ShareActionProvider	686
•	Broadcasts and Broadcast Receivers	
◦	The Stopped State	693

◦ Example System Broadcasts	694
◦ The Order of Things	702
◦ Keeping It Local	703
◦ Visit the Trails!	704
• Tutorial #15 - Sharing Your Notes	
◦ Step #1: Adding a ShareActionProvider	705
◦ Step #2: Sharing the Note	706
◦ Step #3: Testing the Result	708
◦ In Our Next Episode...	710
• Services and the Command Pattern	
◦ Why Services?	711
◦ Setting Up a Service	712
◦ Communicating To Services	714
◦ Scenario: The Music Player	716
◦ Communicating From Services	719
◦ Scenario: The Downloader	721
◦ Services and Configuration Changes	726
• Tutorial #16 - Updating the Book	
◦ Step #1: Adding a Stub DownloadCheckService	727
◦ Step #2: Tying the Service Into the Action Bar	728
◦ Step #3: Defining Our Event	729
◦ Step #4: Defining Our JSON	729
◦ Step #5: Defining Our Retrofit Interface	730
◦ Step #6: Retrieving Our JSON Via Retrofit	731
◦ Step #7: Downloading the Update	732
◦ Step #8: Unpacking the Update	734
◦ Step #9: Using the Update	736
◦ In Our Next Episode...	741
• Large-Screen Strategies and Tactics	
◦ Objective: Maximum Gain, Minimum Pain	743
◦ The Fragment Strategy	743
◦ Fragment Example: The List-and-Detail Pattern	752
◦ Other Master-Detail Strategies	764
◦ Showing More Pages	776
◦ Fragment FAQs	781
◦ Screen Size and Density Tactics	782
◦ Other Considerations	786
• Tutorial #17 - Supporting Large Screens	
◦ Step #1: Creating Our Layouts	789
◦ Step #2: Loading Our Sidebar Widgets	793
◦ Step #3: Opening the Sidebar	793

◦ Step #4: Loading Content Into the Sidebar	794
◦ Step #5: Removing Content From the Sidebar	796
• Backwards Compatibility Strategies and Tactics	
◦ Think Forwards, Not Backwards	803
◦ Aim Where You Are Going	805
◦ A Target-Rich Environment	805
◦ Lint: It's Not Just For Belly Buttons	806
◦ A Little Help From Your Friends	807
◦ Avoid the New on the Old	807
◦ Testing	811
◦ Keeping Track of Changes	811
• System Services	
◦ What is a System Service?	813
◦ What System Services Are There?	814
• Google Play Services	
◦ What Is Google Play Services?	817
◦ What Is In the Play Services SDK?	818
◦ Adding Play Services to Your Project	826
• Getting Help	
◦ Questions. Sometimes, With Answers.	837
◦ Heading to the Source	838
◦ Getting Your News Fix	839
• Working with Library Projects	
◦ Prerequisites	841
◦ Creating a Library Project	841
◦ Using a Library Project, Part II	845
◦ Library Projects and the Manifest	845
◦ Limitations of Library Projects	846
• Gradle and Eclipse Projects	
◦ Prerequisites and Warnings	847
◦ "Legacy"?	847
◦ Creating Your Gradle Build File	848
◦ Examining the Gradle File	853
• Gradle and Tasks	
◦ Key Build-Related Tasks	855
◦ Results	857
• Gradle and the New Project Structure	
◦ Prerequisites and Warnings	859
◦ Objectives of the New Project Structure	860
◦ Terminology	860
◦ Creating a Project in the New Structure	864

◦ What the New Project Structure Looks Like	864
◦ Configuring the Stock Build Types	867
◦ Adding Build Types	872
◦ Adding Product Flavors and Getting Build Variants	873
◦ Doing the Splits	878
◦ Revisiting the Legacy Gradle File	880
◦ Working with the New Project Structure in Android Studio	881
◦ Flavors, Build Types, and the Project Structure Dialog	884
• Gradle and Dependencies	
◦ Prerequisites and Warnings	885
◦ “Dependencies”?	886
◦ A Tale of Two Dependencies Closures	886
◦ Depending Upon a JAR	886
◦ Depending Upon NDK Binaries	888
◦ Depending Upon an Android Library Project	888
◦ Depending Upon Sub-Projects	890
◦ Depending Upon Artifacts	891
◦ Creating Android JARs from Gradle	898
◦ A Property of Transitive (Dependencies)	899
◦ Dependencies By Build Type	900
◦ Dependencies By Flavor	900
◦ Examining Some CWAC Builds	901
◦ Dependencies and the Project Structure Dialog	906
• Manifest Merger Rules	
◦ Prerequisites	907
◦ Manifest Scenarios	908
◦ Pieces of Manifest Generation	909
◦ Examining the Merger Results	911
◦ Merging Elements and Attributes	912
◦ Employing Placeholders	918
• Signing Your App	
◦ Prerequisites	923
◦ Role of Code Signing	923
◦ What Happens In Debug Mode	924
◦ Production Signing Keys	925
• Distribution	
◦ Prerequisites	941
◦ Get Ready To Go To Market	941
• Advanced Gradle for Android Tips	
◦ Prerequisites	947
◦ Gradle, DRY	947

- Automating APK Version Information 953
- Adding to BuildConfig 955
- Down and Dirty with the DSL 957
- [JUnit and Android](#)
 - Prerequisites 959
 - JUnit Basics 959
 - Pondering Gradle for Android 960
 - Where Your Test Code Lives 961
 - Where Your Test Code Runs 965
 - Writing Your Test Cases 966
 - Your Test Suite 971
 - Running Your Tests 971
 - Testing Android Library Projects 978
 - Test Dependencies 979
 - Testing Legacy Project Structures with Gradle for Android 980
- [Testing with JUnit4](#)
 - Prerequisites 983
 - The AndroidJUnitRunner 983
 - JUnit4 986
- [MonkeyRunner and the Test Monkey](#)
 - Prerequisites 995
 - MonkeyRunner 995
 - **Monkeying Around** 997
- [Testing with UI Automator](#)
 - Prerequisites 1001
 - What Is UI Automator? 1001
 - Why Choose UI Automator Over Alternatives? 1002
 - Gradle and Android Studio Settings 1002
 - Creating a Test Case 1003
 - Running Your Tests 1010
 - Finding Your Widgets 1010
 - Using the UI Automator Viewer 1011
- [Notifications](#)
 - What's a Notification? 1015
 - Showing a Simple Notification 1018
 - The Activity-Or-Notification Scenario 1022
 - Big (and Rich) Notifications 1023
 - Foreground Services 1030
 - Disabled Notifications 1033
- [Advanced Notifications](#)
 - Prerequisites 1037

◦ Being a Good Citizen	1037
◦ Wear? There!	1038
◦ Stacking Notifications	1043
◦ Avoiding Wear	1049
◦ Other Wear-Specific Notification Options	1050
◦ Lockscreen Notifications	1063
◦ Priority, and Heads-Up Notifications	1072
◦ Full-Screen Notifications	1074
◦ Custom Views	1077
◦ Seeing It In Action	1078
◦ Progress Notifications	1084
◦ Life After Delete	1086
◦ The Mysterious Case of the Missing Number	1087
◦ Changes in API Level 23	1087
• Introducing GridLayout	
◦ Prerequisites	1089
◦ Issues with the Classic Containers	1089
◦ The New Contender: GridLayout	1091
◦ GridLayout and the Android Support Package	1091
◦ Eclipse and GridLayout	1093
◦ Trying to Have Some Rhythm	1093
◦ Our Test App	1094
◦ Replacing the Classics	1096
◦ Implicit Rows and Columns	1102
◦ Row and Column Spans	1103
• The Percent Support Library	
◦ Prerequisites	1109
◦ What Percent Gives Us	1110
◦ Using Percent	1111
◦ About Those Performance Gains	1116
◦ Maintaining Aspect Ratio	1127
◦ Other Problems	1127
• Dialogs and DialogFragments	
◦ Prerequisites	1129
◦ DatePickerDialog and TimePickerDialog	1129
◦ AlertDialog	1135
◦ DialogFragments	1135
◦ DialogFragment: The Other Flavor	1139
◦ Dialogs: Modal, Not Blocking	1140
• Advanced ListView	
◦ Prerequisites	1141

◦ Multiple Row Types, and Self Inflation	1141
◦ Choice Modes and the Activated Style	1147
◦ Custom Mutable Row Contents	1148
◦ From Head To Toe	1153
◦ Enter RecyclerView	1156
• Action Bar Navigation	
◦ Prerequisites	1157
◦ List Navigation	1157
◦ Tabs (And Sometimes List) Navigation	1162
◦ Custom Navigation	1168
• Action Modes	
◦ Prerequisites	1170
◦ A Matter of Context	1170
◦ Manual Action Modes	1171
◦ Multiple-Choice-Modal Action Modes	1176
◦ Long-Click To Initiate an Action Mode	1179
• Other Advanced Action Bar Techniques	
◦ Prerequisites	1187
◦ Action Layouts	1187
◦ Action Views and Action Providers	1188
◦ Searching with SearchView	1189
◦ Floating Action Bars	1194
• Toolbar	
◦ Prerequisites	1199
◦ Basic Toolbar Mechanics	1199
◦ Use Case #1: Split Action Bar	1200
◦ Use Case #2: Contextual Actions	1205
◦ Use Case #3: Replacement Action Bar	1214
• AppCompat: The Official Action Bar Backport	
◦ Prerequisites	1217
◦ Ummm... Why?	1217
◦ <i>The Basics of Using AppCompat</i>	1220
◦ Other AppCompat Effects	1226
◦ Toolbar and AppCompat	1232
◦ To Material, or Not to Material	1235
• ActionBarSherlock	
◦ Prerequisites	1239
◦ Installation	1240
◦ Code Changes	1240
• RecyclerView	
◦ Prerequisites	1244

◦ AdapterView and its Discontents	1244
◦ Enter RecyclerView	1244
◦ <i>A Trivial List</i>	1245
◦ <i>Divider Options</i>	1253
◦ Handling Click Events	1259
◦ What About Cursors?	1265
◦ Grids	1269
◦ Varying the Items	1272
◦ Mutable Row Contents	1284
◦ Changing the Contents	1304
◦ <i>The Order of Things</i>	1310
◦ Other Bits of Goodness	1317
◦ <i>The March of the Libraries</i>	1318
• Implementing a Navigation Drawer	
◦ Prerequisites	1321
◦ What is a Navigation Drawer?	1321
◦ A Simple Navigation Drawer	1323
◦ Alternative Row Layouts	1329
◦ Additional Considerations	1331
◦ What Should Not Be in the Drawer	1340
◦ Independent Implementations	1340
• The Android Design Support Library	
◦ Prerequisites	1342
◦ GUIs and the Support Package	1342
◦ Adding the Library... and What Comes With It	1343
◦ Some Notes About Icons	1343
◦ Snackbars: Sweeter than Toasts	1343
◦ Absolutely FABulous	1349
◦ Material Tabs with TabLayout	1365
◦ Floating Labels	1375
• Advanced Uses of WebView	
◦ Prerequisites	1383
◦ Friends with Benefits	1383
◦ Turnabout is Fair Play	1389
◦ Navigating the Waters	1393
◦ Settings, Preferences, and Options (Oh, My!)	1393
◦ Security and Your WebView	1394
◦ <i>Chrome Custom Tabs</i>	1397
• The Input Method Framework	
◦ Prerequisites	1399
◦ Keyboards, Hard and Soft	1399

- Tailored To Your Needs 1400
- Tell Android Where It Can Go 1405
- Fitting In 1407
- Jane, Stop This Crazy Thing! 1409
- [Fonts](#)
 - Prerequisites 1411
 - Love The One You're With 1411
 - Yeah, But Do We Really Have To Do This in Java? 1415
 - Here a Glyph, There a Glyph 1416
- [Rich Text](#)
 - **Prerequisites** **1419**
 - The Span Concept 1419
 - Loading Rich Text 1421
 - Editing Rich Text 1424
 - Saving Rich Text 1428
 - Manipulating Rich Text 1429
- [Animators](#)
 - Prerequisites 1431
 - ViewPropertyAnimator 1431
 - The Foundation: Value and Object Animators 1436
 - Animating Custom Types 1438
 - Hardware Acceleration 1440
 - The Three-Fragment Problem 1441
- [Legacy Animations](#)
 - Prerequisites 1453
 - It's Not Just For Toons Anymore 1453
 - A Quirky Translation 1454
 - Fading To Black. Or Some Other Color. 1458
 - When It's All Said And Done 1460
 - Loose Fill 1461
 - Hit The Accelerator 1461
 - Animate. Set. Match. 1462
 - Active Animations 1463
- [Custom Drawables](#)
 - Prerequisites 1465
 - **Where Do These Things Go?** **1466**
 - ColorDrawable 1467
 - AnimationDrawable 1467
 - StateListDrawable 1471
 - ColorStateList 1472
 - LayerDrawable 1474

◦ TransitionDrawable	1475
◦ LevelListDrawable	1476
◦ ScaleDrawable and ClipDrawable	1477
◦ InsetDrawable	1486
◦ Vectors	1487
◦ ShapeDrawable	1493
◦ VectorDrawable	1503
◦ BitmapDrawable	1504
◦ Composite Drawables	1511
◦ A Stitch In Time Saves Nine	1514
• Mapping with Maps V2	
◦ Prerequisites	1523
◦ A Brief History of Mapping on Android	1524
◦ Where You Can Use Maps V2	1524
◦ Licensing Terms for Maps V2	1525
◦ What You Need to Start	1525
◦ The Book Samples... And You!	1529
◦ Setting Up a Basic Map	1530
◦ Playing with the Map	1535
◦ Map Tiles	1538
◦ Placing Simple Markers	1538
◦ Seeing All the Markers	1541
◦ Flattening and Rotating Markers	1543
◦ Sprucing Up Your “Info Windows”	1547
◦ Images and Your Info Window	1551
◦ Setting the Marker Icon	1557
◦ Responding to Taps	1559
◦ Dragging Markers	1560
◦ The “Final” Limitations	1562
◦ A Bit More About IPC	1565
◦ Finding the User	1566
◦ Dealing with Runtime Permissions	1571
◦ Drawing Lines and Areas	1573
◦ Gestures and Controls	1576
◦ Tracking Camera Changes	1577
◦ Maps in Fragments and Pagers	1579
◦ Animating Marker Movement	1583
◦ Maps, of the Indoor Variety	1593
◦ Taking a Snapshot of a Map	1593
◦ MapFragment vs. MapView	1594
◦ About That AbstractMapActivity Class...	1595

◦ Helper Libraries for Maps V2	1599
◦ Problems with Maps V2 at Runtime	1603
◦ Problems with Maps V2 Deployment	1603
◦ What Non-Compliant Devices Show	1603
◦ Mapping Alternatives	1604
◦ News and Getting Help	1604
• Crafting Your Own Views	
◦ Prerequisites	1607
◦ Pick Your Poison	1607
◦ Colors, Mixed How You Like Them	1608
◦ ReverseChronometer: Simply a Custom Subclass	1618
◦ AspectLockedFrameLayout: A Custom Container	1624
◦ Mirror and MirroringFrameLayout: Draw It Yourself	1627
• Advanced Preferences	
◦ Prerequisites	1639
◦ Introducing PreferenceActivity	1639
◦ Intents for Headers or Preferences	1643
◦ Conditional Headers	1644
◦ Dependent Preferences	1649
◦ Nested Screens	1651
◦ Listening to Preference Changes	1654
◦ Defaults, and Defaults	1657
◦ Listening to Preference Value Changes	1658
• Custom Dialogs and Preferences	
◦ Prerequisites	1659
◦ Your Dialog, Chocolate-Covered	1659
◦ Preferring Your Own Preferences, Preferably	1663
• Progress Indicators	
◦ Prerequisites	1669
◦ Progress Bars	1669
◦ ProgressBar and Threads	1673
◦ Tailoring Progress Bars	1675
◦ Progress Dialogs	1685
◦ Title Bar and Action Bar Progress Indicators	1687
◦ Direct Progress Indication	1689
• More Fun with Pagers	
◦ Prerequisites	1691
◦ Hosting ViewPager in a Fragment	1691
◦ Pages and the Action Bar	1693
◦ ViewPagers and Scrollable Contents	1695
◦ Using ViewPagerIndicator	1696

◦ Columns for Large, Pages for Small	1700
◦ Introducing ArrayAdapter	1706
◦ Columns for Large Landscape, Pages for the Rest	1709
◦ Adding, Removing, and Moving Pages	1714
◦ Inside ArrayAdapter	1718
• Focus Management and Accessibility	
◦ Prerequisites	1731
◦ Prepping for Testing	1732
◦ Controlling the Focus	1732
◦ Accessibility and Focus	1741
◦ Accessibility Beyond Focus	1741
◦ Accessibility Beyond Impairment	1751
• Miscellaneous UI Tricks	
◦ Prerequisites	1753
◦ Full-Screen and Lights-Out Modes	1753
◦ Offering a Delayed Timeout	1764
• Event Bus Alternatives	
◦ Prerequisites	1769
◦ A Brief Note About the Sample Apps	1769
◦ Standard Intents as Event Bus	1769
◦ LocalBroadcastManager as Event Bus	1770
◦ Square’s Otto	1780
◦ Revisiting greenrobot’s EventBus	1786
• Tasks	
◦ Prerequisites	1791
◦ First, Some Terminology	1791
◦ And Now, a Bit About Task Killers	1797
◦ A Canary for the Task’s Coal Mine	1804
◦ The Default User Experience	1806
◦ Explaining the Default Behavior	1810
◦ Basic Scenarios for Changing the Behavior	1814
◦ Dealing with the Persistent Tasks	1827
◦ Documents As Tasks	1829
◦ Other Task-Related Activity Properties	1833
◦ Other Task-Related Activity Methods	1841
• The Assist API (“Now On Tap”)	
◦ Prerequisites	1844
◦ What Data Gets Disclosed	1844
◦ Adding to the Data	1846
◦ Removing from the Data	1848
◦ Blocking Assist as a User	1851

- *Implementing Your Own Assistant* 1854
- [The Data Binding Framework](#)
 - *Prerequisites* 1866
 - *The What, Now?* 1866
 - *The Basic Steps* 1867
 - *The Extended Layout Resource* 1873
 - *The Binding Expression Language* 1876
 - *Observables and Updating the Binding* 1879
 - *Other Features of Note* 1892
- [Desktop Android Apps](#)
 - Prerequisites 1916
 - *Android Desktop Possibilities* 1916
 - *What Users Expect From Desktop Apps* 1918
 - *The Known Unknowns* 1923
 - *Getting Ready for the Desktop* 1924
- [Home Screen App Widgets](#)
 - Prerequisites 1929
 - App Widgets and Security 1929
 - *The Big Picture for a Small App Widget* 1930
 - Crafting App Widgets 1931
 - Another and Another 1937
 - App Widgets: Their Life and Times 1938

 - One Size May Not Fit All 1939
 - Lockscreen Widgets 1945
 - Preview Images 1951
 - Being a Good Host 1953
- [Adapter-Based App Widgets](#)
 - Prerequisites 1955
 - AdapterViews for App Widgets 1955
 - Building Adapter-Based App Widgets 1956
- [Content Provider Theory](#)
 - Prerequisites 1971
 - Using a Content Provider 1971
 - Building Content Providers 1979
 - Issues with Content Providers 1986
- [Content Provider Implementation Patterns](#)
 - Prerequisites 1989
 - The Single-Table Database-Backed Content Provider 1989
 - *The Local-File Content Provider* 1996
 - The Protected Provider 2004

◦ The Stream Provider	2006
◦ FileProvider	2009
◦ StreamProvider	2014
• The Loader Framework	
◦ Prerequisites	2017
◦ Cursors: Issues with Management	2018
◦ Introducing the Loader Framework	2018
◦ Honeycomb... Or Not	2020
◦ Using CursorLoader	2020
◦ What Else Is Missing?	2022
◦ Issues, Issues, Issues	2023
◦ Loaders Beyond Cursors	2023
◦ What Happens When...?	2023
• The ContactsContract and CallLog Providers	
◦ Prerequisites	2027
◦ Introducing You to Your Contacts	2028
◦ Pick a Peck of Pickled People	2029
◦ Spin Through Your Contacts	2031
◦ Makin' Contacts	2036
◦ Looking at the CallLog	2040
• The CalendarContract Provider	
◦ Prerequisites	2046
◦ You Can't Be a Faker	2046
◦ Do You Have Room on Your Calendar?	2046
◦ Penciling In an Event	2051
• The MediaStore Provider	
◦ Prerequisites	2053
◦ What Is the MediaStore?	2054
◦ MediaStore and "Other" External Storage	2055
◦ How Does My Content Get Indexed?	2056
◦ How Do I Retrieve Video from the MediaStore?	2056
• Consuming Documents	
◦ Prerequisites	2065
◦ The Storage Access... What?	2065
◦ The Storage Access Framework Participants	2067
◦ Picking How to Pick (a Peck of Pickled Pepper Photos)	2067
◦ Opening a Document	2068
◦ The Rest of the CRUD	2071
◦ Pondering Persistent Permissions	2072
• Providing Documents	
◦ Prerequisites	2075

- Have Your Content, and Provide it Too 2075
- Key Provider Concepts 2077
- Pieces of a Provider 2078
- Optional Provider Capabilities 2092
- [Encrypted Storage](#)
 - Prerequisites 2100
 - Scenarios for Encryption 2100
 - Obtaining SQLCipher 2100
 - Using SQLCipher 2101
 - SQLCipher Limitations 2102
 - Passwords and Sessions 2103
 - About Those Passphrases... 2104
 - Encrypted Preferences 2111
 - IOCipher 2113
- [Packaging and Distributing Data](#)
 - Prerequisites 2115
 - Packing a Database To Go 2115
- [Advanced Database Techniques](#)
 - Prerequisites 2119
 - Full-Text Indexing 2119
- [Data Backup](#)
 - Prerequisites 2135
 - First, Some Terminology 2136
 - Differing Definitions of “Backup” 2136
 - Implementing IT-Style Backup 2138
 - ***The Google Backup Bootstrap*** **2160**
 - Boosting Backup Security 2168
 - Alternative Approaches 2169
- [Embedding a Web Server](#)
 - Prerequisites 2173
 - Why a Web Server? 2173
 - Introducing AsyncHttpServer 2175
 - Embedding a Simple Server 2175
 - Template-Driven Responses, with Handlebars 2190
 - Supporting WebSockets 2195
 - Securing the Web Server 2200
 - ***Towards a Reusable Web Server Service*** **2206**
- [Miscellaneous Network Capabilities](#)
 - Prerequisites 2217
 - ***Downloading Files*** **2217**
- [Audio Playback](#)

- Prerequisites 2231
- Get Your Media On 2231
- MediaPlayer for Audio 2232
- Other Ways to Make Noise 2237
- [Audio Recording](#)
 - Prerequisites 2241
 - Recording by Intent 2241
 - Recording to Files 2244
 - Recording to Streams 2247
 - Raw Audio Input 2250
 - Requesting the Microphone 2250
- [Video Playback](#)
 - Prerequisites 2251
 - Moving Pictures 2251
- [Using the Camera via 3rd-Party Apps](#)
 - Prerequisites 2257
 - Being Specific About Features 2257
 - Still Photos: Letting the Camera App Do It 2258
 - Scanning with ZXing 2261
 - Videos: Letting the Camera App Do It 2262
 - CWAC-Cam2: A CameraActivity Of Your Own 2264
 - Directly Working with the Camera 2271
- [Working Directly with the Camera](#)
 - Prerequisites 2273
 - Notes About the Code Snippets 2273
 - A Tale of Two APIs 2274
 - ***Performing Basic Camera Operations*** **2275**
 - And Now, The Problems 2298
- [Media Routes](#)
 - Prerequisites 2303
 - Terminology 2303
 - A Tale of Two MediaRouters 2304
 - Attaching to MediaRouter 2305
 - User Route Selection with MediaRouteActionProvider 2307
 - Using Live Video Routes 2322
 - Using Remote Playback Routes 2322
- [Supporting External Displays](#)
 - Prerequisites 2341
 - ***A History of External Displays*** **2341**
 - What is a Presentation? 2342
 - Playing with External Displays 2343

- Detecting Displays 2349
- A Simple Presentation 2350
- A Simpler Presentation 2356
- Presentations and Configuration Changes 2361
- Presentations as Fragments 2362
- Another Sample Project: Slides 2372
- Device Support for Presentation 2379
- Presentations from a Service 2379
- Hey, What About Chromecast? 2382
- [Google Cast and Chromecast](#)
 - Prerequisites 2385
 - Here a Cast, There a Cast 2385
 - Common Chromecast Development Notes 2387
 - Your API Choices 2387
 - Senders and Receivers 2388
 - Supported Media Types 2389
 - Cast SDK Dependencies 2390
 - Developing Google Cast Apps 2392
- [The “Ten-Foot UI”](#)
 - Prerequisites 2393
 - What is the “Ten-Foot UI”? 2394
 - Overscan 2394
 - Navigation 2395
 - Stylistic Considerations 2396
 - The Leanback UI 2398
 - Testing Your Theories 2411
- [Putting the TVs All Together: Decktastic](#)
 - Prerequisites 2414
 - Introducing Decktastic 2414
 - Trying Decktastic Yourself 2418
 - Implementing Decktastic 2418
- [Creating a MediaRouteProvider](#)
 - Prerequisites 2449
 - Terminology 2449
 - DIY Chromecast 2450
 - Creating the MediaRouteProvider 2452
 - Consuming the MediaRouteProvider 2462
 - Implementing This “For Realz” 2465
- [Screenshots and Screen Recordings](#)
 - Prerequisites 2469
 - Requesting Screenshots 2469

- Recording the Screen 2483
- [SSL](#)
 - Prerequisites 2503
 - Basic SSL Operation 2503
 - Common SSL Problems 2504
 - TrustManagers 2505
 - TrustManagerBuilder 2507
 - About That Man in the Middle 2511
 - Self-Signed Certificates, Revisited 2513
 - Certificate Memorizing 2513
 - Pinning 2518
 - NetCipher 2518
 - **Improvements in Android 6.0** **2519**
- [Advanced Permissions](#)
 - Prerequisites 2525
 - Securing Yourself 2525
 - Signature Permissions 2528
 - The Custom Permission Vulnerability 2529
 - Finding the Available Permissions 2540
- [Restricted Profiles and UserManager](#)
 - Prerequisites 2551
 - Android Tablets and Multiple User Accounts 2551
 - Determining What the User Can Do 2557
 - Impacts of Device-Level Restrictions 2559
 - Enabling Custom Restrictions 2560
 - Implicit Intents May Go “Boom” 2570
- [Tapjacking](#)
 - Prerequisites 2573
 - What is Tapjacking? 2573
 - Detecting Potential Tapjackers 2577
 - Defending Against Tapjackers 2580
 - Why Is This Being Discussed? 2583
 - What Changed in 4.0.3? 2584
- [Miscellaneous Security Techniques](#)
 - Prerequisites 2585
 - Public Key Validation 2585
 - Choosing Your Signing Keysize 2596
 - Avoiding Accidental APIs 2597
 - Other Ways to Expose Data 2602
- [AlarmManager and the Scheduled Service Pattern](#)
 - Scenarios 2605

◦ Options	2606
◦ A Simple Example	2608
◦ The Five set...() Varieties	2610
◦ The Four Types of Alarms	2612
◦ When to Schedule Alarms	2612
◦ Archetype: Scheduled Service Polling	2614
◦ Staying Awake at Work	2617
◦ Warning: Not All Android Devices Play Nice	2621
◦ Debugging Alarms	2622
◦ WakefulBroadcastReceiver	2625
◦ Android 6.0 and the War on Background Processing	2628
• PowerManager and WakeLocks	
◦ Prerequisites	2629
◦ Keeping the Screen On, UI-Style	2629
◦ The Role of the WakeLock	2630
◦ What WakefulIntentService Does	2631
• JobScheduler	
◦ Prerequisites	2633
◦ The Limitations of AlarmManager	2633
◦ Enter the JobScheduler	2634
◦ Employing JobScheduler	2634
◦ Pondering Backoff Criteria	2646
◦ Other JobScheduler Features	2648
◦ Android 6.0 and “the War on Background Processing”	2649
◦ GCM Network Manager	2663
• Accessing Location-Based Services	
◦ Prerequisites	2665
◦ Location Providers: They Know Where You’re Hiding	2666
◦ Finding Yourself	2666
◦ On the Move	2668
◦ Are We There Yet? Are We There Yet? Are We There Yet?	2669
◦ Testing... Testing...	2670
◦ Alternative Flavors of Updates	2670
◦ The Fused Option	2672
• The Fused Location Provider	
◦ Prerequisites	2673
◦ Why Use the Fused Location Provider?	2673
◦ Why Not Use the Fused Location Provider?	2674
◦ Finding Our Location, Once	2674
◦ Requesting Location Updates	2680
◦ I Can Haz Location?	2682

- [Working with the Clipboard](#)
 - Prerequisites 2691
 - Using the Clipboard on Android 1.x/2.x 2691
 - Advanced Clipboard on Android 3.x and Higher 2694
 - Monitoring the Clipboard 2699
 - The Android 4.3 Clipboard Bug 2701
- [Telephony](#)
 - Prerequisites 2703
 - Report To The Manager 2704
 - You Make the Call! 2704
 - No, Really, You Make the Call! 2707
- [Working With SMS](#)
 - Prerequisites 2709
 - Sending Out an SOS, Give or Take a Letter 2710
 - Monitoring and Receiving SMS 2716
 - The SMS Inbox 2723
 - Asking to Change the Default 2724
 - SMS and the Emulator 2725
- [NFC](#)
 - Prerequisites 2727
 - What Is NFC? 2727
 - To NDEF, Or Not to NDEF 2729
 - NDEF Modalities 2729
 - NDEF Structure and Android's Translation 2730
 - The Reality of NDEF 2731
 - Sources of Tags 2733
 - Writing to a Tag 2733
 - Responding to a Tag 2741
 - Expected Pattern: Bootstrap 2742
 - Mobile Devices are Mobile 2743
 - Enabled and Disabled 2743
 - Android Beam 2743
 - Beaming Files 2750
 - Another Sample: SecretAgentMan 2752
 - Additional Resources 2760
- [Device Administration](#)
 - Prerequisites 2761
 - Objectives and Scope 2761
 - Defining and Registering an Admin Component 2762
 - Going Into Lockdown 2768
 - Passwords and Device Administration 2775

- Getting Along with Others 2779
- [Basic Use of Sensors](#)
 - Prerequisites 2781
 - The Sensor Abstraction Model 2781
 - Considering Rates 2782
 - Reading Sensors 2783
 - Batching Sensor Readings 2792
- [Printing and Document Generation](#)
 - Prerequisites 2796
 - The Android Print System 2796
 - About the Sample App 2797
 - Printing a Bitmap 2798
 - Printing an HTML Document 2800
 - Printing a PDF File 2804
 - Printing Using a Canvas 2812
 - Print Jobs 2814
 - Printing, Threads, and Services 2814
 - Printing Prior to Android 4.4 2817
 - HTML Generation 2817
 - PDF Generation Options 2821
- [Dealing with Different Hardware](#)
 - Prerequisites 2823
 - Filtering Out Devices 2823
 - Runtime Capability Detection 2826
 - Dealing with Device Bugs 2827
- [Writing and Using Parcelables](#)
 - Prerequisites 2829
 - The Role of Parcelable 2829
 - Writing a Parcelable 2830
 - The Limitations of Parcelable 2836
- [Responding to URLs](#)
 - Prerequisites 2841
 - Manifest Modifications 2841
 - Creating a Custom URL 2843
 - Reacting to the Link 2844
 - App Links 2846
- [Plugin Patterns](#)
 - Prerequisites 2857
 - Definitions, Scenarios, and Scope 2857
 - ***The Keys to Any Plugin System*** **2858**
 - Case Study: DashClock 2866

- Other Plugin Examples 2869
- [PackageManager Tricks](#)
 - Prerequisites 2887
 - Asking Around 2887
 - Preferred Activities 2891
 - Middle Management 2895
- [Remote Services and the Binding Pattern](#)
 - Prerequisites 2899
 - The Binding Pattern 2900
 - When IPC Attacks! 2906
 - Service From Afar 2908
 - Tightening Up the Security 2914
 - Servicing the Service 2918
 - **Thinking About Security** **2922**
 - The “Everlasting Service” Anti-Pattern 2923
- [Advanced Manifest Tips](#)
 - Prerequisites 2925
 - Just Looking For Some Elbow Room 2925
 - Using an Alias 2934
 - Getting Meta (Data) 2936
- [Miscellaneous Integration Tips](#)
 - Prerequisites 2941
 - **Direct Share** **2941**
 - Take the Shortcut 2950
 - Homing Beacons for Intents 2956
 - Integrating with Text Selection 2956
- [Reusable Components](#)
 - Prerequisites 2969
 - Where Do I Find Them? 2969
 - How Are They Packaged? 2970
 - How Do I Create Them? 2971
 - Other Considerations for Publishing Reusable Code 2974
- [Android Studio Editors and Dialogs](#)
 - Prerequisites 2977
 - Project Structure 2977
 - Translations Editor 2987
- [Advanced Emulator Capabilities](#)
 - Prerequisites 2993
 - x86 Images 2993
 - 64-Bit Emulators 2995
 - Hardware Graphics Acceleration 2995

◦ Keyboard Behavior	2996
◦ Headless Operation	2997
• Lint and the Support Annotations	
◦ Prerequisites	2999
◦ What It Is	3000
◦ When It Runs	3000
◦ What to Fix	3001
◦ What to Configure	3002
◦ Support Annotations	3005
• Using Hierarchy View	
◦ Prerequisites	3019
◦ Launching Hierarchy View	3019
◦ Viewing the View Hierarchy	3020
◦ ViewServer	3023
• Screenshots and Screencasts	
◦ Prerequisites	3025
◦ Collecting from Android Studio	3025
◦ Screencasts	3029
◦ Collecting from the Command Line	3029
◦ Collecting from Another App	3031
◦ Tips and Tricks	3032
• ADB Tips and Tricks	
◦ Prerequisites	3033
◦ This is the Droid That You Are Looking For	3033
◦ Installing and Uninstalling Apps	3034
◦ Playing with Permissions	3034
◦ Starting and Stopping Components	3035
◦ Killing Processes and Clearing Data	3036
◦ Changing Display Metrics	3036
• Issues with Speed	
◦ Prerequisites	3041
◦ Getting Things Done	3041
◦ Your UI Seems... Janky	3042
◦ Not Far Enough in the Background	3042
◦ Playing with Speed	3043
• Finding CPU Bottlenecks	
◦ Prerequisites	3045
◦ Android Studio Monitors	3046
◦ Method Tracing	3047
◦ Other General CPU Measurement Techniques	3055
◦ UI “Jank” Measurement	3056

- [Focus On: NDK](#)
 - Prerequisites 3073
 - The Role of the NDK 3074
 - NDK Installation and Project Setup 3077
 - Writing Your Makefile(s) 3081
 - Building Your Library 3082
 - Using Your Library Via JNI 3083
 - Building and Deploying Your Project 3088
 - Gradle and the NDK 3089
- [Improving CPU Performance in Java](#)
 - Prerequisites 3097
 - Reduce CPU Utilization 3097
 - ***Reduce Time on the Main Application Thread*** **3102**
 - Improve Throughput and Responsiveness 3110
- [Finding and Eliminating Jank](#)
 - Prerequisites 3113
 - The Case: ThreePaneDemoBC 3113
 - Are We Janky? 3114
 - Finding the Source of the Jank 3114
 - Where Things Went Wrong 3124
 - Removing the Jank 3125
- [Issues with Bandwidth](#)
 - Prerequisites 3127
 - You're Using Too Much of the Slow Stuff 3128
 - You're Using Too Much of the Expensive Stuff 3128
 - You're Using Too Much of Somebody Else's Stuff 3129
 - You're Using Too Much... And There Is None 3130
- [Focus On: TrafficStats](#)
 - Prerequisites 3131
 - TrafficStats Basics 3131
 - Example: TrafficMonitor 3133
 - Other Ways to Employ TrafficStats 3141
- [Measuring Bandwidth Consumption](#)
 - Prerequisites 3143
 - On-Device Measurement 3143
 - Off-Device Measurement 3147
 - Android Studio Network Monitor 3149
- [Being Smarter About Bandwidth](#)
 - Prerequisites 3151
 - Bandwidth Savings 3151
 - Bandwidth Shaping 3155

- Avoiding Metered Connections 3159
- [Issues with Application Heap](#)
 - Prerequisites 3161
 - You Are in a Heap of Trouble 3162
 - Determining Your Heap Size At Runtime 3163
 - **Fragments of Memory** **3163**
 - Getting a Trim 3164
 - **Warning: Contains Graphic Images** **3165**
 - Releasing SQLite Memory 3176
 - **Cheating** **3176**
- [Finding Memory Leaks](#)
 - Prerequisites 3179
 - Android Studio Realtime Monitor 3180
 - Getting Heap Dumps 3182
 - Analyzing Heap Dumps in Android Studio 3183
 - **Common Leak Scenarios** **3190**
 - **A Canary in a Leaky Coal Mine** **3198**
- [Issues with System RAM](#)
 - Prerequisites 3207
 - Can't We All Just Get Along? 3207
 - Contributors to System RAM Consumption 3208
 - Measuring System RAM Consumption: Tools 3209
 - Measuring System RAM Consumption: Runtime 3224
 - **Learn To Let Go (Of Your Heap)** **3225**
- [Issues with Battery Life](#)
 - Prerequisites 3227
 - You're Getting Blamed 3228
 - Not All Batteries Are Created Equal 3229
 - Stretching Out the Last mWh 3229
- [Power Measurement Options](#)
 - Prerequisites 3231
 - **batterystats and the Battery Historian** **3232**
 - The Qualcomm Tool (That Must Not Be Named) 3242
 - PowerTutor 3243
 - Battery Screen in Settings Application 3247

Preface

Welcome to the Book!

Thanks!

Thanks for your interest in developing applications for Android! Android has grown from nothing to arguably the world's most popular smartphone OS in a few short years. Whether you are developing applications for the public, for your business or organization, or are just experimenting on your own, I think you will find Android to be an exciting and challenging area for exploration.

And, most of all, thanks for your interest in this book! I sincerely hope you find it useful and at least occasionally entertaining.

The Book's Structure

As you may have noticed, this is a rather large book.

To make the equivalent of ~3,500+ pages of material manageable, the chapters are divided into the *core* chapters and a series of *trails*.

The core chapters represent many key concepts that Android developers need to understand in order to build an app. While an occasional “nice to have” topic will drift into the core — to help illustrate a point, for example — the core chapters generally are fairly essential.

The core chapters are designed to be read in sequence and will interleave both traditional technical book prose with tutorial chapters, to give you hands-on experience with the concepts being discussed. Most of the tutorials can be skipped,

PREFACE

though the first two — covering setting up your SDK environment and creating a project – everybody should read.

The bulk of the chapters are divided into trails, covering some particular general topic, from data storage to advanced UI effects to performance measurement and tuning. Each trail will have several chapters. However, those chapters, and the trails themselves, are not necessarily designed to be read in any order. Each chapter in the trails will point out prerequisite chapters or concepts that you will want to have covered in advance. Hence, these chapters are mostly reference material, for when you specifically want to learn something about a specific topic.

The core chapters will link to chapters in the trails, to show you where you can find material related to the chapter you just read. So between the book's table of contents, this preface, the search tool in your digital book reader, and the cross-chapter links, you should have plenty of ways of finding the material you want to read.

You are welcome to read the entire book front-to-back if you wish. The trails will appear after the core chapters. Those trails will be in a reasonably logical order, though you may have to hop around a bit to cover all of the prerequisites.

The Trails

Here is a list of all of the trails and the chapters that pertain to those trails, in order of appearance (except for those appearing in the list multiple times, where they span major categories):

Code Organization and Gradle

- [Working with Library Projects](#)
- [Gradle and Legacy Projects](#)
- [Gradle and Tasks](#)
- [Gradle and the New Project Structure](#)
- [Gradle and Dependencies](#)
- [Manifest Merger Rules](#)
- [Signing Your App](#)
- [Distribution](#)
- [Advanced Gradle for Android Tips](#)

Testing

- [JUnit and Android](#)
- [Testing with JUnit4](#)
- [MonkeyRunner and the Test Monkey](#)
- [Testing with UIAutomator](#)

Advanced UI

- [Notifications](#)
- [Advanced Notifications](#)
- [Introducing GridLayout](#)
- [The Percent Support Library](#)
- [Dialogs and DialogFragments](#)
- [Advanced ListViews](#)
- [Action Bar Navigation](#)
- [Action Modes and Context Menus](#)
- [Other Advanced Action Bar Techniques](#)
- [Toolbar](#)
- [AppCompat: The Official Action Bar Backport](#)
- [ActionBarSherlock](#)
- [RecyclerView](#)
- [Implementing a Navigation Drawer](#)
- [The Android Design Support Library](#)
- [Advanced Uses of WebView](#)
- [The Input Method Framework](#)
- [Fonts](#)
- [Rich Text](#)
- [Animators](#)
- [Legacy Animations](#)
- [Custom Drawables](#)
- [Mapping with Maps V2](#)
- [Crafting Your Own Views](#)
- [Advanced Preferences](#)
- [Custom Dialogs and Preferences](#)
- [Progress Indicators](#)
- [More Fun with Pagers](#)
- [Focus Management and Accessibility](#)
- [Miscellaneous UI Tricks](#)
- [Event Bus Alternatives](#)

- [Tasks](#)
- [The Assist API \(“Now On Tap”\)](#)
- [Data Binding](#)
- [Desktop Android Apps](#)

Home Screen Effects

- [Home Screen App Widgets](#)
- [Adapter-Based App Widgets](#)

Data Storage and Retrieval

- [Content Provider Theory](#)
- [Content Provider Implementation Patterns](#)
- [The Loader Framework](#)
- [The ContactsContract Provider](#)
- [The CalendarContract Provider](#)
- [The MediaStore Provider](#)
- [Consuming Documents](#)
- [Providing Documents](#)
- [Encrypted Storage](#)
- [Packaging and Distributing Data](#)
- [Advanced Database Techniques](#)
- [Data Backup](#)

Advanced Network Topics

- [SSL](#)
- [Embedding a Web Server](#)
- [Miscellaneous Network Capabilities](#)

Media

- [Audio Playback](#)
- [Audio Recording](#)
- [Video Playback](#)
- [Using the Camera via 3rd-Party Apps](#)
- [Working Directly with the Camera](#)
- [The MediaStore Provider](#)
- [Media Routes](#)

PREFACE

- [Supporting External Displays](#)
- [Google Cast and ChromeCast](#)
- [The “10 Foot UI”](#)
- [Putting the TVs All Together: Decktastic](#)
- [Creating a MediaRouteProvider](#)
- [Screenshots and Screen Recordings](#)

Security

- [SSL](#)
- [Encrypted Storage](#)
- [Advanced Permissions](#)
- [Restricted Profiles and UserManager](#)
- [Tapjacking](#)
- [Miscellaneous Security Techniques](#)

Hardware and System Services

- [AlarmManager and the Scheduled Service Pattern](#)
- [PowerManager and WakeLocks](#)
- [JobScheduler](#)
- [Accessing Location-Based Services](#)
- [The Fused Location Provider](#)
- [Working with the Clipboard](#)
- [Telephony](#)
- [Working With SMS](#)
- [NFC](#)
- [Device Administration](#)
- [Basic Use of Sensors](#)
- [Printing and Document Generation](#)
- [Dealing with Different Hardware](#)

Integration and Introspection

- [Writing and Using Parcelables](#)
- [Responding to URLs](#)
- [Plugin Patterns](#)
- [PackageManager Tricks](#)
- [Remote Services and the Binding Pattern](#)
- [Advanced Manifest Tips](#)

- [Miscellaneous Integration Tips](#)
- [Reusable Components](#)

Other Tools

- [Android Studio Dialogs and Editors](#)
- [Advanced Emulator Capabilities](#)
- [Lint and the Support Annotations](#)
- [Using Hierarchy View](#)
- [Screenshots and Screencasts](#)
- [ADB Tips and Tricks](#)
- [Finding CPU Bottlenecks](#)
- [Finding Memory Leaks](#)

Tuning Android Applications

- [Issues with Speed](#)
- [Finding CPU Bottlenecks](#)
- [NDK](#)
- [Improving CPU Performance in Java](#)
- [Finding and Eliminating Jank](#)
- [Issues with Bandwidth](#)
- [Focus On: TrafficStats](#)
- [Measuring Bandwidth Consumption](#)
- [Being Smarter About Bandwidth](#)
- [Issues with Application Heap](#)
- [Finding Memory Leaks](#)
- [Issues with System RAM](#)
- [Issues with Battery Life](#)
- [Other Power Measurement Options](#)
- [Sources of Power Drain](#)
- [Addressing Application Size Issues](#)

Scripting Languages

- [The Role of Scripting Languages](#)
- [The Scripting Layer for Android](#)
- [JVM Scripting Languages](#)

Alternatives for App Development

- [The Role of Alternative Environments](#)
- [HTML5](#)
- [PhoneGap](#)
- [Other Alternative Environments](#)

Miscellaneous Topics

- [Crash Reporting with ACRA](#)
- [In-App Diagnostics](#)
- [Anti-Patterns](#)

Widget Catalog

- [AdapterViewFlipper](#)
- [CalendarView](#)
- [DatePicker](#)
- [ExpandableListView](#)
- [SeekBar](#)
- [SlidingDrawer](#)
- [StackView](#)
- [TabHost](#)
- [TimePicker](#)
- [ViewFlipper](#)

Device Catalog

- [Chrome and Chrome OS](#)
- [Kindle Fire](#)
- [BlackBerry](#)
- [Wrist Wearables](#)
- [Google TV](#)
- [Amazon Fire TV](#)

Appendices

- [Appendix A: CWAC Libraries](#)

About the Updates

This book is updated frequently, typically every 2-3 months.

Each release has notations to show what is new or changed compared with the immediately preceding release:

- The Table of Contents shows sections with changes in bold-italic font
- Those sections have changebars on the right to denote specific paragraphs that are new or modified

What's New in Version 7.1?

For those of you who have read previous editions of this book, here are some of the highlights of what is new in Version 7.1:

- Added [a large chapter on the data binding framework](#)
- Added more samples of leaks, and a section on LeakCanary, to [the chapter on memory leaks](#)
- Added a section on Volley to [the chapter on Internet access](#)
- Added a new chapter on [Android on the desktop](#)
- Repaired the material on Android 6.0's automatic "backup" solution and got it working (with the assistance of an eagle-eyed reader!)
- Moved all of the material that had been in the Android 6.0 appendix into more permanent locations in the main body of the book
- Updated [the chapter on BlackBerry](#) to mention the Priv
- Added material on path-traversal bugs to [one of the chapters on ContentProvider](#)
- Lots of bug fixes and general improvements, particularly to older chapters

Warescription

You (hopefully) are reading this digital book by means of a Warescription.

The Warescription entitles you, for the duration of your subscription, to digital editions of this book and its updates, in PDF, EPUB, and Kindle (MOBI/KF8) formats. You also have access to a version of the book as its own Android APK file, complete with high-speed full-text searching. You also have access to other titles that CommonsWare may publish during that subscription period.

PREFACE

Each subscriber gets personalized editions of all editions of each title. That way, your books are never out of date for long, and you can take advantage of new material as it is made available. For example, when new releases of the Android SDK are made available, this book will be quickly updated to be accurate with changes in the APIs.

However, you can only download the books while you have an active Warescription. There is a grace period after your Warescription ends: you can still download the book until the next book update comes out after your Warescription ends. After that, you can no longer download the book. Hence, **please download your updates as they come out**. You can find out when new releases of this book are available via:

1. The [CommonsWare](#) Twitter feed
2. The [CommonsBlog](#)
3. The Warescription newsletter, which you can subscribe to off of your [Warescription](#) page
4. Just check back on the [Warescription](#) site every month or two

Subscribers also have access to other benefits, including:

- “Office hours” — online chats to help you get answers to your Android application development questions. You will find a calendar for these on your Warescription page.
- A Stack Overflow “bump” service, to get additional attention for a question that you have posted there that does not have an adequate answer.

Extending Your Warescription

In addition to renewing your Warescription through normal means (i.e., paying for it), there are a few programs offered to subscribers to help you keep your Warescription going for longer for free.

Book Bug Bounty

Find a problem in one of our books? Let us know!

Be the first to report a unique concrete problem in the current digital edition, and we will extend your Warescription by six months as a bounty for helping us deliver a better product.

PREFACE

By “concrete” problem, we mean things like:

1. Typographical errors
2. Sample applications that do not work as advertised, in the environment described in the book
3. Factual errors that cannot be open to interpretation

By “unique”, we mean ones not yet reported. Be sure to check [the book’s errata page](#), though, to see if your issue has already been reported. One coupon is given per email containing valid bug reports.

We appreciate hearing about “softer” issues as well, such as:

1. Places where you think we are in error, but where we feel our interpretation is reasonable
2. Places where you think we could add sample applications, or expand upon the existing material
3. Samples that do not work due to “shifting sands” of the underlying environment (e.g., changed APIs with new releases of an SDK)

However, those “softer” issues do not qualify for the formal bounty program.

Questions about the bug bounty, or problems you wish to report for bounty consideration, should be sent to bounty@commonsware.com.

Referral Program

If you link to the CommonsWare site, you can include a referral code on the link. If somebody visits the CommonsWare site through your link, and they subscribe, you get a month extension tacked onto the end of your existing Warescription.

On the Warescription site, visit “Other Stuff” > Settings in the navigation bar. This page has a panel named “Referral Programs” where you can set up a referral code and track your payout dates for any successful referrals.

Book Review Bounty

Active subscribers can get a free month just for posting a review of the book.

To qualify, write an original review (no plagiarism, please) and publish it on your blog or similar site. The review needs to have a regular (not a nofollow) link to the

PREFACE

CommonsWare home page (<https://commonsware.com>). If you want, you can also include your referral link described in the previous section.

You can submit up to two reviews per year under this program. However, if you submit more than one, they have to make logical sense to whoever follows your blog or other site. The first review can be a general review of the book overall, but any future reviews should be about something new, such as reviews of book updates.

Once you have a review posted somewhere, send an email to reviews@commonsware.com, including your Warescription user ID and the link to your review. Assuming that your review qualifies, and that you have an active (non-expired) Warescription, you will get an extra month tacked onto the end of your Warescription. If, however, your review URL stops qualifying (e.g., you delete the blog post containing the review), your free month will be retracted.

If you have questions about this program, send an email to reviews@commonsware.com.

Source Code and Its License

The source code samples shown in this book are available for download from the [book's GitHub repository](#). All of the Android projects are licensed under the [Apache 2.0 License](#), in case you have the desire to reuse any of it.

If you wish to use the source code from the GitHub repository, please follow the instructions on that repository's home page for details of how to use the projects in various development environments, notably Android Studio.

Copying source code directly from the book, in the PDF editions, works best with Adobe Reader, though it may also work with other PDF viewers. Some PDF viewers, for reasons that remain unclear, foul up copying the source code to the clipboard when it is selected.

Creative Commons and the Four-to-Free (42F) Guarantee

Each CommonsWare book edition will be available for use under the [Creative Commons Attribution-Noncommercial-ShareAlike 3.0](#) license as of the fourth

PREFACE

anniversary of its publication date, or when 4,000 copies of the edition have been sold, whichever comes first. That means that, once four years have elapsed (perhaps sooner!), you can use this prose for non-commercial purposes. That is our Four-to-Free Guarantee to our readers and the broader community. For the purposes of this guarantee, new Warescriptions and renewals will be counted as sales of this edition, starting from the time the edition is published.

This edition of this book will be available under the aforementioned Creative Commons license on *1 February 2020*. Of course, watch the CommonsWare Web site, as this edition might be relicensed sooner based on sales.

For more details on the Creative Commons Attribution-Noncommercial-ShareAlike 3.0 license, visit [the Creative Commons Web site](#)

Note that future editions of this book will become free on later dates, each four years from the publication of that edition or based on sales of that specific edition. Releasing one edition under the Creative Commons license does not automatically release *all* editions under that license.

Acknowledgments

I would like to thank the Android team, not only for putting out a good product, but for invaluable assistance on the Android Google Groups and Stack Overflow.

I would also like to thank the thousands of readers of past editions of this book, for their feedback, bug reports, and overall support.

Of course, thanks are also out to the overall Android ecosystem, particularly those developers contributing their skills to publish libraries, write blog posts, answer support questions, and otherwise contribute to the strength of Android.

Portions of this book are reproduced from work created and shared by the Android Open Source Project and used according to terms described in the Creative Commons 2.5 Attribution License.

Core Chapters

Key Android Concepts

No doubt, you are in a hurry to get started with Android application development. After all, you are reading this book, aimed at busy coders.

However, before we dive into getting tools set up and starting in on actual programming, it is important that we “get on the same page” with respect to several high-level Android concepts. This will simplify further discussions later in the book.

Android Applications

This book is focused on writing Android applications. An application is something that a user might install from the Play Store or otherwise download to their device. That application should have some user interface, and it might have other code designed to work in the background (multi-tasking).

This book is not focused on modifications to the Android firmware, such as writing device drivers. For that, you will need to seek [other resources](#).

This book assumes that you have some hands-on experience with Android devices, and therefore you are familiar with buttons like HOME and BACK, the built-in Settings application, the concept of a home screen and launcher, and so forth. If you have never used an Android device, you are strongly encouraged to get one (e.g., a used one on eBay, Craigslist, etc.) and spend some time with it before starting in on learning Android application development.

Programming Language

The vast majority of Android applications are written exclusively in Java. Hence, that is what this book will spend most of its time on and will demonstrate with a seemingly infinite number of examples.

However, there are other options:

- You can write parts of the app in C/C++, for performance gains, porting over existing code bases, etc.
- You can write an entire app in C/C++, mostly for games using OpenGL for 3D animations
- You can write the guts of an app in HTML, CSS, and JavaScript, using tools to package that material into an Android application that can be distributed through the Play Store and similar venues
- And so on

Coverage of these non-Java alternatives will be found in the trails of this book, as the bulk of this book is focused on Java.

The author assumes that you know Java at this point. If you do not, you will need to learn Java before you go much further. You do not need to know *everything* about Java, as Java is vast. Rather, focus on:

- [Language fundamentals](#) (flow control, etc.)
- [Classes and objects](#)
- [Methods and data members](#)
- [Public, private, and protected](#)
- [Static and instance scope](#)
- [Exceptions](#)
- [Threads](#)
- [Collections](#)
- [Generics](#)
- [File I/O](#)
- [Reflection](#)
- [Interfaces](#)

The links are to Wikibooks material on those topics, though there are countless other Java resources for you to consider.

Components

When you first learned Java — whether that was yesterday or back when dinosaurs roamed the Earth — you probably started off with something like this:

```
class SillyApp {  
    public static void main(String[] args) {  
        System.out.println("Hello World!");  
    }  
}
```

In other words, the entry point into your application was a `public static void` method named `main()` that took a `String` array of arguments. From there, you were responsible for doing whatever was necessary.

However, there are other patterns used elsewhere in Java. For example, you do not usually write a `main()` method when writing a Java servlet. Instead, you extend a particular class supplied by a framework (e.g., `HttpServlet`) to create a component, then write some metadata that enumerates your components and tell the framework when and how to use them (e.g., `WEB.XML`).

Android apps are closer in spirit to the servlet approach. You will not write a `public static void main()` method. Instead, you will create subclasses of some Android-supplied base classes that define various application components. In addition, you will create some metadata that tells Android about those subclasses.

There are four types of components, all of which will be covered extensively in this book:

Activities

The building block of the user interface is the *activity*. You can think of an activity as being the Android analogue for the window or dialog in a desktop application, or the page in a classic Web app. It represents a chunk of your user interface and, in some cases, a discrete entry point into your app (i.e., a way for other apps to link to your app).

Normally, an activity will take up most of the screen, leaving space for some “chrome” bits like the clock, signal strength indicators, and so forth.

KEY ANDROID CONCEPTS

Figure 1: Activity on the screen

Services

Activities are short-lived and can be shut down at any time, such as when the user presses the BACK button. *Services*, on the other hand, are designed to keep running, if needed, independent of any activity, for a moderate period of time. You might use a service for checking for updates to an RSS feed, or to play back music even if the controlling activity is no longer operating. You will also use services for scheduled tasks (akin to Linux or OS X “cron jobs”) and for exposing custom APIs to other applications on the device, though the latter is a relatively advanced capability.

Content Providers

Content providers provide a level of abstraction for any data stored on the device that is accessible by multiple applications. The Android development model encourages you to make your own data available to other applications, as well as your own — building a content provider lets you do that, while maintaining a degree of control over how your data gets accessed.

Broadcast Receivers

The system, or applications, will send out *broadcasts* from time to time, for everything from the battery getting low, to when the screen turns off, to when connectivity changes from WiFi to mobile data. A broadcast receiver can arrange to listen for these broadcasts and respond accordingly.

Widgets, Containers, Resources, and Fragments

Most of the focus on Android application development is on the UI layer and activities. Most Android activities use what is known as “the widget framework” for rendering their user interface, though you are welcome to use the 2D (Canvas) and 3D (OpenGL) APIs as well for more specialized GUIs.

In Android terms, a *widget* is the “micro” unit of user interface. Fields, buttons, labels, lists, and so on are all widgets. Your activity’s UI, therefore, is made up of one or more of these widgets. For example, here we see label (TextView), field (EditText), and push-button (Button) widgets:

Figure 2: Activity with widgets

If you have more than one widget — which is fairly typical — you will need to tell Android how those widgets are organized on the screen. To do that, you will use

KEY ANDROID CONCEPTS

various container classes referred to as *layout managers*. These will let you put things in rows, columns, or more complex arrangements as needed.

To describe how the containers and widgets are connected, you will typically create a *layout resource file*. *Resources* in Android refer to things like images, strings, and other material that your application uses but is not in the form of some programming language source code. UI layouts are another type of resource. You will create these layouts either using a structured tool, such as an IDE's drag-and-drop GUI builder, or by hand in XML form.

Sometimes, your UI will work across all sorts of devices: phones, tablets, televisions, etc. Sometimes, your UI will need to be tailored for different environments. You will be able to put resources into *resource sets* that indicate under what circumstances those resources can be used (e.g., use these for normal-sized screens, but use those for larger screens).

We will be examining all of these concepts, in much greater detail, as we get deeper into the book.

Apps and Packages

Given a bucket of source code and a basket of resources, the Android build tools will give you an application as a result. The application comes in the form of an *APK file*. It is that APK file that you will upload to the Play Store or distribute by other means.

Each Android application has a package name, also referred to as an application ID. A package name must fulfill three requirements:

1. It must be a valid Java package name, as some Java source code will be generated by the Android build tools in this package
2. No two applications can exist on a device at the same time with the same application ID
3. No two applications can be uploaded to the Play Store having the same application ID

When you create your Android project — the repository of that source code and those resources — you will declare what package name is to be used for your app. Typically, you will pick a package name following the Java package name “reverse domain name” convention (e.g., `com.commonsware.android.foo`). That way, the domain name system ensures that your package name prefix (`com.commonsware`) is

unique, and it is up to you to ensure that the rest of the package name distinguishes one of your apps from any other.

Android Devices

There are well in excess of one billion Android devices in use today, representing thousands of different models from dozens of different manufacturers. Android itself has evolved since Android 1.0 in 2008. Between different device types and different Android versions, many a media pundit has lobbed the term “fragmentation” at Android, suggesting that creating apps that run on all these different environments is impossible.

In reality, it is not that bad. Some apps will have substantial trouble, but most apps will work just fine if you follow the guidance presented in this book and in other resources.

Types

Android devices come in all shapes, sizes, and colors. However, there are four dominant “form factors”:

- the phone
- the tablet
- the television (TV)
- the wearable (smart watches, Google Glass, etc.)

You will often hear developers and pundits refer to these form factors, and this book will do so from time to time as well. However, it is important that you understand that Android has no built-in concept of a device being a “phone” or a “tablet” or a “TV”. Rather, Android distinguishes devices based on capabilities and features. So, you will not see an `isPhone()` method anywhere, though you can ask Android:

- what is the screen size?
- does the device have telephony capability?
- etc.

Similarly, as you build your applications, rather than thinking of those four form factors, focus on what capabilities and features you need. Not only will this help you line up better with how Android wants you to build your apps, but it will make it easier for you to adapt to other form factors that will come about such as:

- airplane seat-back entertainment centers
- in-car navigation and entertainment devices
- and so on

The Emulator

While there are over a billion Android devices representing thousands of models, probably you do not have one of each model. You may only have a single piece of Android hardware. And if you do not even have that, you most certainly will want to acquire one before trying to publish an Android app.

To help fill in the gaps between the devices you have and the devices that are possible, the Android developer tools ship an *emulator*. The emulator behaves like a piece of Android hardware, but it is a program you run on your development machine. You can use this emulator to emulate many different devices, with different screen sizes and Android OS versions, by creating one or more Android virtual devices, or *AVDs*.

In [an upcoming chapter](#), we will discuss how you install the Android developer tools and how you will be able to [create these AVDs and run the emulator](#).

OS Versions and API Levels

Android has come a long way since the early beta releases from late 2007. Each new Android OS version adds more capabilities to the platform and more things that developers can do to exploit those capabilities.

Moreover, the core Android development team tries very hard to ensure forwards and backwards compatibility. An app you write today should work unchanged on future versions of Android (forwards compatibility), albeit perhaps missing some features or working in some sort of “compatibility mode”. And there are well-trod paths for how to create apps that will work both on the latest and on previous versions of Android (backwards compatibility).

To help us keep track of all the different OS versions that matter to us as developers, Android has *API levels*. A new API level is defined when an Android version ships that contains changes that affect developers. When you create an emulator AVD to test your app, you will indicate what API level that emulator should emulate. When you distribute your app, you will indicate the oldest API level your app supports, so the app is not installed on older devices.

KEY ANDROID CONCEPTS

At the time of this writing, the API levels of significance to most Android developers are:

- API Level 16 (Android 4.1)
- API Level 17 (Android 4.2)
- API Level 19 (Android 4.4)
- API Level 21 (Android 5.0)
- API Level 22 (Android 5.1)

Here, “of significance” refers to API levels that have a reasonable number of Android devices — 5% or more, as reported by [the “Platform Versions” dashboard chart](#).

The latest production API level for most form factors is 23, representing Android 6.0.

Note that API Level 20 was used for the version of Android 4.4 running on the first-generation Android Wear devices. Unless you are specifically developing apps for Wear, you will not be worrying much about API Level 20.

Dalvik

In terms of Android, Dalvik is a virtual machine (VM). Virtual machines are used by many programming languages, such as Java, Perl, and Smalltalk. The Dalvik VM is designed to work much like a Java VM, but optimized for embedded Linux environments.

So, what really goes on when somebody writes an Android application is:

1. Developers write Java-syntax source code, leveraging class libraries published by the Android project and third parties.
2. Developers compile the source code into Java VM bytecode, using the `javac` compiler that comes with the Java SDK.
3. Developers translate the Java VM bytecode into Dalvik VM bytecode, which is packaged with other files into a ZIP archive with the `.apk` extension (the APK file).
4. An Android device or emulator runs the APK file, causing the bytecode to be executed by an instance of a Dalvik VM.

From your standpoint, most of this is hidden by the build tools. You pour Java source code into the top, and the APK file comes out the bottom.

However, there will be places from time to time where the differences between the Dalvik VM and the traditional Java VM will affect application developers, and this book will point out some of them where relevant.

Note that Android is moving to a new runtime environment, called ART. However, the “Dalvik” term will still be used for the bytecode that is generated as part of building an APK.

Processes and Threads

When your application runs, it will do so in its own process. This is not significantly different than any other traditional operating system. Part of Dalvik’s magic is making it possible for many processes to be running many Android applications at one time without consuming ridiculous amounts of RAM.

Android will also set up a batch of threads for running your app. The thread that your code will be executed upon, most of the time, is variously called the “main application thread” or the “UI thread”. You do not have to set it up, but, as we will see later in the book, you will need to pay attention to what you do and do not do on that thread. You are welcome to fork your own threads to do work, and that is fairly common, though in some places Android handles that for you behind the scenes.

Don’t Be Scared

Yes, this chapter threw a lot of terms at you. We will be going into greater detail on all of them in this book. However, Android is like a jigsaw puzzle with lots of interlocking pieces. To be able to describe one concept in detail, we will need to at least reference some of the others. Hence, this chapter was meant to expose you to terms, in hopes that they will sound vaguely familiar as we dive into the details.

Choosing Your Development Toolchain

Before you go much further in your Android endeavors (or, possibly, endeavours, depending upon your preferred spelling), you will need to determine what toolchain you will use to build your Android applications.

Android Studio

The next-generation Google-backed Android IDE is Android Studio. Based off of [IntelliJ IDEA](#), Android Studio is the new foundation of Google's efforts to give Android developers top-notch development tools. While it only reached a version 1.0 status in December 2014, Android Studio had been in use for ~18 months prior to that in various early-access and beta stages. While it still has bugs, it is certainly stable enough for app development.

The [next chapter](#) contains a section with instructions on how to set up Android Studio.

Eclipse

Eclipse is also a popular IDE, particularly for Java development. Eclipse was Google's original IDE for Android development, by means of the Android Developer Tools (ADT) add-in, which gives the core of Eclipse awareness of Android. The ADT add-in, in essence, takes regular Eclipse operations and extends them to work with Android projects.

Note, though, that Google has discontinued maintenance of ADT. The Eclipse Foundation is setting up the “Andmore” project to try to continue work on allowing Eclipse to build Android apps. This book does not cover the Andmore project at this time, and developers are **strongly** encouraged to not use the ADT-enabled Eclipse from Google.

IntelliJ IDEA

While Android Studio is based on IntelliJ IDEA, you can still use the original IntelliJ IDEA for Android app development. A large subset of the Android Studio capabilities are available in the Android plugin for IDEA. Plus, the commercial IDEA Ultimate Edition will go beyond Android Studio in many areas outside of Android development.

Command-Line Builds via Gradle for Android

And, of course, you do not need to use an IDE at all. While this may sound sacrilegious to some, IDEs are not the only way to build applications. Much of what is accomplished via the ADT can be accomplished through command-line equivalents, meaning a shell and an editor is all you truly need. For example, the author of this book did not use an IDE for Android development until 2011.

The recommended way to build Android apps outside of an IDE is by means of Gradle. Google has published a Gradle plugin that teaches Gradle how to build Android apps. Android Studio itself uses Gradle for its builds, so a single build configuration (e.g., `build.gradle` files) can be used both from an IDE and from a build automation tool like a continuous integration server.

An [upcoming chapter](#) gets into more about what Gradle (and the Android Plugin for Gradle) are all about.

Yet Other Alternatives

Other IDEs have their equivalents of the ADT, albeit with minimal assistance from Google. For example, NetBeans has support via the NBAndroid add-on, and reportedly this has advanced substantially in the past few years.

You will also hear reference to using Apache Ant for doing command-line builds of Android apps. This has largely been supplanted by Gradle for Android at this time,

and support for Apache Ant will end soon. Newcomers to Android are encouraged to not invest time in new work with Apache Ant for Android development projects.

IDEs... And This Book

You are welcome to use Android Studio or Eclipse as you work through this book. You are welcome to use another IDE if you wish. You are even welcome to skip the IDE outright and just use an editor.

This book is focused primarily on demonstrating Android capabilities and the APIs for exploiting those capabilities. Hence, the sample code will work with any IDE. However, this book will cover some Android Studio- and Eclipse-specific instructions, since they are the predominant answers today.

The tutorials will have instructions for both Android Studio and Eclipse.

What We Are Not Covering

In the beginning (a.k.a., 2007), we were lucky to have any means of creating an Android app.

Nowadays, there seems to be no end to the means by which we can create an Android app.

There are a few of these “means”, though, that are specifically out of scope for this book.

App Inventor

You may also have heard of a tool named App Inventor and wonder where it fits in with all of this.

App Inventor was originally created by an education group within Google, as a means of teaching students how to think about programming constructs (branches, loops, etc.) and create interesting output (Android apps) without classic programming in Java or other syntax-based languages. App Inventor is purely drag-and-drop, both of widgets *and application logic*, the latter by means of “blocks” that snap together to form logic chains.

App Inventor was donated by Google to MIT, which has recently re-opened it [to the public](#).

However, App Inventor is a closed system — at the present time, it does not somehow generate Java code that you can later augment. That limits you to whatever App Inventor is natively capable of doing, which, while impressive in its own right, offers a small portion of the total Android SDK capabilities.

App Generators

There are a seemingly infinite number of “app generators” available as online services. These are designed mostly for creating apps for specific vertical markets, such as apps for restaurants or apps for grocers. The resulting apps are mostly “brochure-ware”, with few capabilities beyond a mobile Web site, yet still requiring the user to find, download, and install the app. Few of these generators provide the source code to the generated app, to allow the apps to be customized beyond what the generator generates.

Tutorial #1 - Installing the Tools

Now, let us get you set up with the pieces and parts necessary to build an Android app.

NOTE: The instructions presented here are accurate as of the time of this writing. However, the tools change rapidly, and so these instructions may be out of date by the time you read this. Please refer to the [Android Developers Web site](#) for current instructions, using this as a base guideline of what to expect.

Step #1 - Checking Your Hardware Requirements

Compiling and building an Android application, on its own, is not especially hardware-intensive, except for very large projects. However, there are two commonly-used tools that demand more from your development machine: your IDE and the Android emulator. Of the two, the emulator poses the bigger problem.

The more RAM you have, the better. 8GB or higher is a very good idea if you intend to use an IDE and the emulator together.

A faster CPU is also a good idea. However, the Android emulator only utilizes a single core from your development machine. Hence, it is the single-core speed that matters. The best CPU to use is one that can leverage multiple cores to give what amounts to a faster single core, such as Intel's Core i7 with Turbo Boost. For an emulator simulating a larger-screened device (e.g., tablet, television), a Core i7 that can "boost" up to 3.4GHz makes development much more pleasant. Conversely, a CPU like a Core 2 Duo with a 2.5GHz clock speed results in a tablet emulator that is nearly unusable.

Step #2 - Setting Up Java and 32-Bit Linux Support

When you write Android applications, you typically write them in Java source code. That Java source code is then turned into the stuff that Android actually runs (Dalvik bytecode in an APK file).

You need to obtain and install the official Sun/Oracle Java SE SDK (JDK). You can obtain this from the [Oracle Java Web site](#) for Windows, OS X, and Linux. The plain JDK (sans any “bundles”) should suffice. Follow the instructions supplied by Oracle or Apple for installing it on your machine. At the time of this writing, Android supports Java 6 and Java 7, though Java 7 is required for certain scenarios and therefore is recommended. Java 8 works, though you may have to do additional work to configure your IDE to have Java 8 emit Java 7-compatible bytecode.

Android also supports the OpenJDK, particularly on Linux environments.

What Android does *not* support are any other Java compilers, including the GNU Compiler for Java (GCJ).

If your development OS is Linux, make sure that you can run 32-bit Linux binaries. This may or may not already be enabled in your Linux distro. For example, on Ubuntu 14.10, you may need to run the following to get the 32-bit binary support installed that is needed by the Android build tools:

```
sudo apt-get install lib32z1 lib32ncurses5 lib32stdc++6
```

You may also need `lib32bz2-1.0`, depending on your version of Linux.

Step #3 - Install the Developer Tools

As noted in the previous chapter, there are a few developer tools that you can choose from.

This book’s tutorials focus on Android Studio. You are welcome to attempt to use Eclipse, another IDE, or no IDE at all for building Android apps. However, you will need to translate some of the tutorials’ IDE-specific instructions to be whatever is needed for your development toolchain of choice.

TUTORIAL #1 - INSTALLING THE TOOLS

With that in mind, visit [the Android Studio download page](#), download the ZIP file for your platform, and unZIP it to some likely spot on your hard drive. Windows users who choose to download the self-installing EXE can just run that file.

Android Studio can then be run from the `studio` batch file or shell script from your Android Studio installation's `bin/` directory.

At the time of this writing, the current production version of Android Studio is 1.4.x, and this book covers that version. If you are reading this in the future, you may be on a newer version of Android Studio, and there may be some differences between what you have and what is presented here.

Step #4 - Install the SDKs and Add-Ons

Next, we need to review what pieces of the Android SDK we have already and perhaps install some new items. To do that, you need to access the SDK Manager.

When you first run Android Studio, you may be asked if you want to import settings from some other prior installation of Android Studio:

Figure 3: Android Studio First-Run Settings Migration Dialog

For most users, particularly those using Android Studio for the first time, the “I do not have...” option is the correct choice to make.

Then, after a short splash screen, you will be taken to the Android Studio Setup Wizard:

TUTORIAL #1 - INSTALLING THE TOOLS

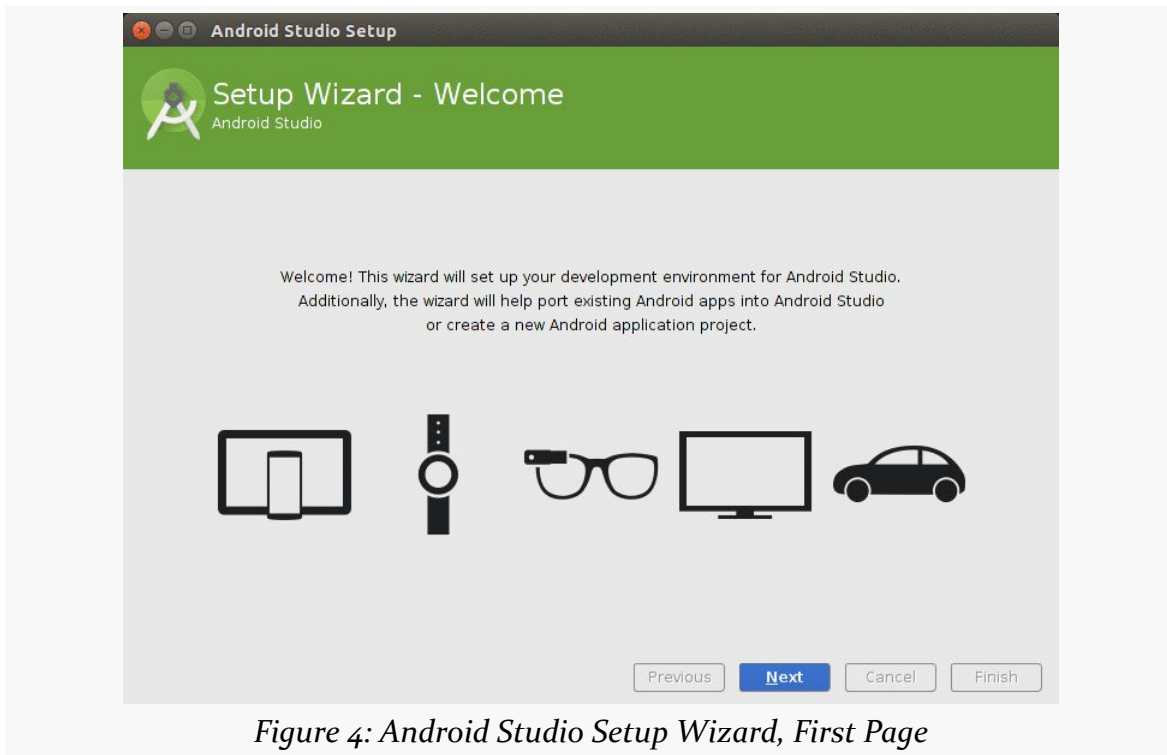

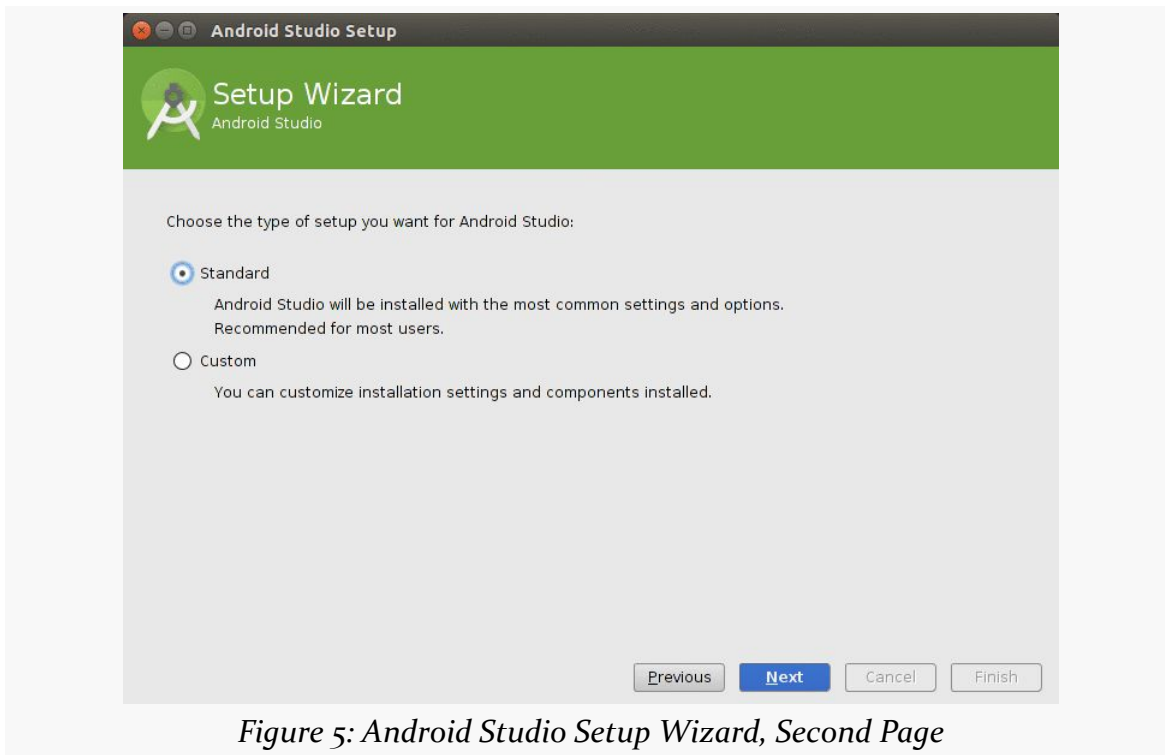

Figure 4: Android Studio Setup Wizard, First Page

Just click “Next” to advance to the second page of the wizard:

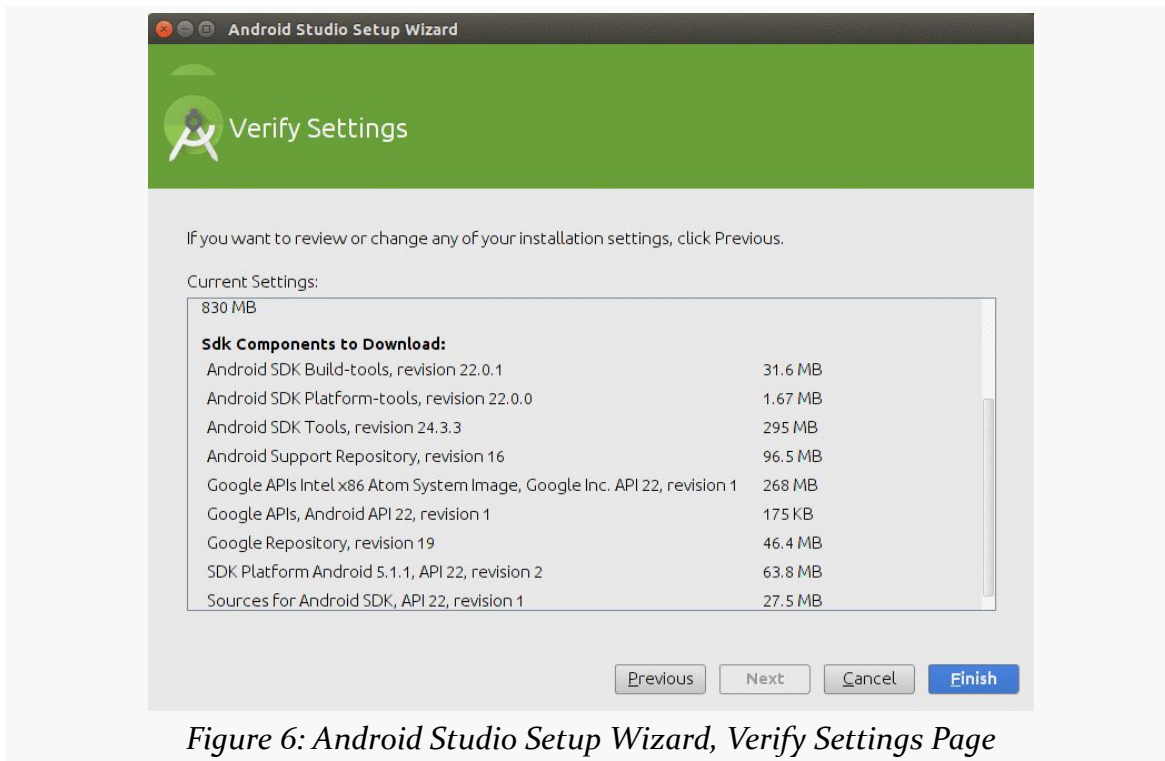

TUTORIAL #1 - INSTALLING THE TOOLS

Here, you have a choice between “Standard” and “Custom” setup modes. Most likely, right now, the “Standard” route will be fine for your environment.

If you go the “Standard” route and click “Next”, you should be taken to a wizard page to verify what will be downloaded and installed:

TUTORIAL #1 - INSTALLING THE TOOLS

Clicking Next may take you to a wizard page explaining some information about the Android emulator:

TUTORIAL #1 - INSTALLING THE TOOLS

What is explained on this page may not make much sense to you. That is perfectly normal, and we will get into what this page is trying to say later in the book. Just click “Finish” to begin the setup process. This will include downloading a copy of the Android SDK and installing it into a directory adjacent to where Android Studio itself is installed.

If you are running Linux, and your installation crashes with an “Unable to run mkshcard SDK tool” error, go back to [Step #2](#) and set up 32-bit support on your Linux environment.

When that is done, after clicking “Finish” one last time, you will be taken to the Android Studio Welcome dialog:

TUTORIAL #1 - INSTALLING THE TOOLS

Figure 8: Android Studio Welcome Dialog

In your case, the contents of the “Recent Projects” list will be empty, as you have not created or opened any projects yet.

In very tiny print at the bottom of that dialog is a “Check for updates now” link. Click that, and if there are updates available, install them. This will automatically restart Android Studio. Android Studio *should* have downloaded the latest updates as part of the initial setup, so most likely this will indicate that nothing more is needed.

Then, in the welcome dialog, click Configure, to bring up a configuration sub-menu:

TUTORIAL #1 - INSTALLING THE TOOLS

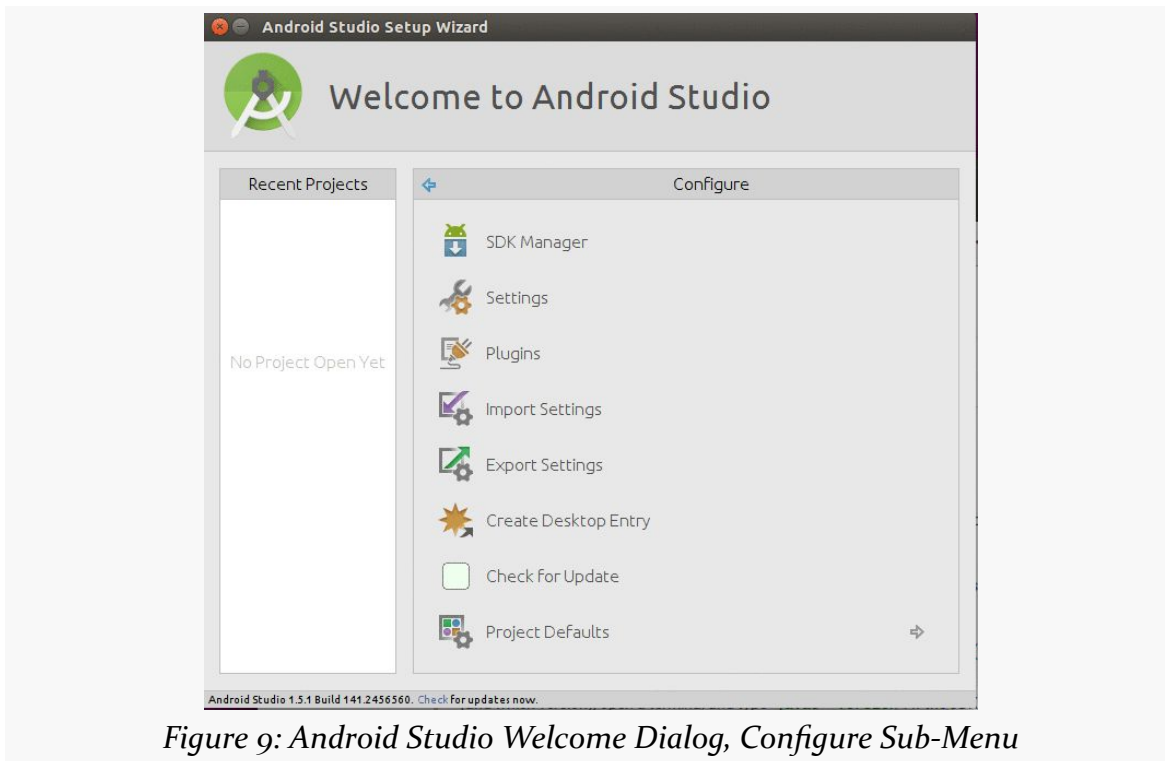

Figure 9: Android Studio Welcome Dialog, Configure Sub-Menu

There, tap on SDK Manager to bring up the SDK Manager.

Using SDK Manager and Updating Your Environment

You should now have the SDK Manager open, as part of the overall default settings for Android Studio:

TUTORIAL #1 - INSTALLING THE TOOLS

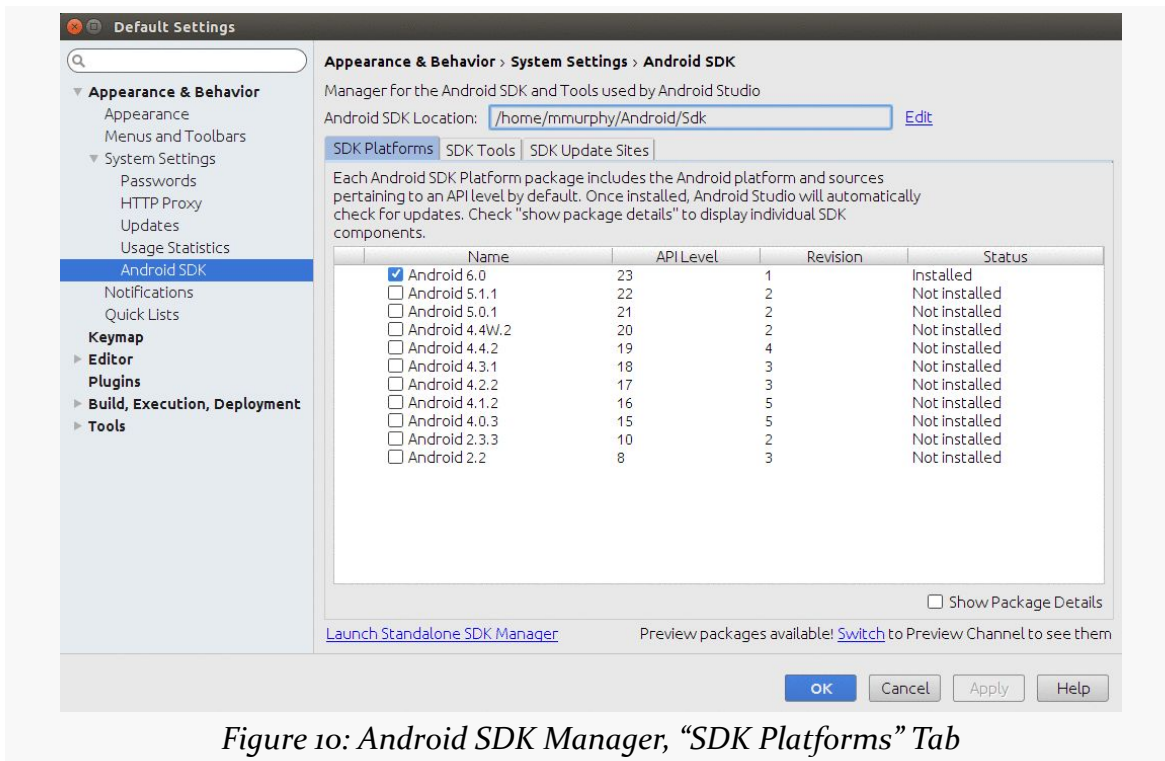

Figure 10: Android SDK Manager, “SDK Platforms” Tab

The “SDK Platforms” tab lists the versions of Android that you can compile against. The latest version of Android is usually installed when you set up Android Studio initially. However, for the tutorials, please also check “Android 4.4.2” and “Android 5.1.1” in the list, and then click the “Apply” button to download and install those versions.

When that has completed, you will be returned to the SDK Manager. Click on the “SDK Tools” tab:

TUTORIAL #1 - INSTALLING THE TOOLS

This lists tools and related materials for Android development, other than the emulator (which is set up and configured separately). Android Studio usually has the right set up of stuff checked and installed already for you. You may wish to install the “Documentation for Android SDK”, which amounts to an offline copy of most of the material found at <http://developer.android.com>. The other items in here are a bit more esoteric, and you will not be needing them for most of this book.

Some items may be marked with a status indicating that an update is available, in which case you may wish to apply those updates. Conversely, if anything labeled “preview” is checked, uncheck and uninstall it. Those items would be related to an outstanding developer preview of a new version of Android. While developer previews are useful, they add complexity for newcomers to Android.

When you are done making these adjustments, you can close up the SDK Manager by clicking the OK button.

In Our Next Episode...

... we will [create an Android project](#) that will serve as the basis for all our future tutorials, plus set up our emulator and device.

Android and Projects

When you work on creating an app for Android, you will do so by working in a “project”. The project is a directory containing your source code and other files, like images and UI definitions. Your IDE or other build tools will take what is in your project and generate an Android app (APK) as output.

The details of how you get started with a project vary based upon what IDE you are using, so this chapter goes through the various possibilities.

Common Concepts

The various ways we set up Android projects have some common elements.

The “Application Name” is the initial name of your project as seen by the user, in places like your home screen launcher icon and the list of installed applications.

The “Project Name” is the name of the project as it is represented inside of the IDE. As you type in an application name, the project name will automatically be filled in to match the application name, with whitespace and other invalid characters removed. Of course, you can change this as you see fit. In the case of Android Studio, the project name also forms the name of the directory that will hold the project.

The “Package Name” refers to a Java package name (e.g., `com.commonware.empublite`). This package name will be used for generating some Java source code, and it also is used as a unique identifier of this package, as was mentioned [earlier in this book](#).

The “Minimum Required SDK” refers to how far back in Android’s version history you are willing to support. The lower the value you specify here, the more Android devices can run your app, but the more work you will have to do to test whether your app really does support those devices. Nowadays, for new development, a minimum required SDK of 15 is reasonable, and you can change your chosen value later on if needed.

The “Target SDK”, roughly speaking, is the version of Android you were thinking of when you were writing the code for this app. Usually, you will set this to be the latest shipping Android API level, then change it over time as new versions of Android are released and you decide that you are ready for some of those changes. We will be exploring the ramifications of target SDK versions throughout the book.

The “Compile With” (a.k.a., “build SDK” or `compileSdkVersion`) is the version of Android whose classes and methods you want to compile against. This can be newer than the minimum required SDK, and it often is newer. On newer devices running newer versions of Android, you might want to take advantage of some new features, and you will “route around” that code on older devices to maintain backwards compatibility. Hence, typically, your build SDK is set to a fairly new version of Android, certainly one new enough to support all of the classes and methods from the Android SDK that you want to use. Note that to set this to API Level 21 or higher, you will need to be using Java 7 or higher for your Java compiler.

The “Theme” is a general statement of the look and feel of your app, particularly in terms of color scheme. The current default (“Holo Light with Dark Action Bar”) means that the body of your UI will be dark text on a light background, except for the “action bar” across the top, which will be light text on a dark background. You will be able to create your own custom themes, overriding various characteristics from one of these stock themes, to set up your own color scheme and the like. We will explore that process [later in the book](#).

Projects and Android Studio

You may have chosen to use [Android Studio](#) as your IDE.

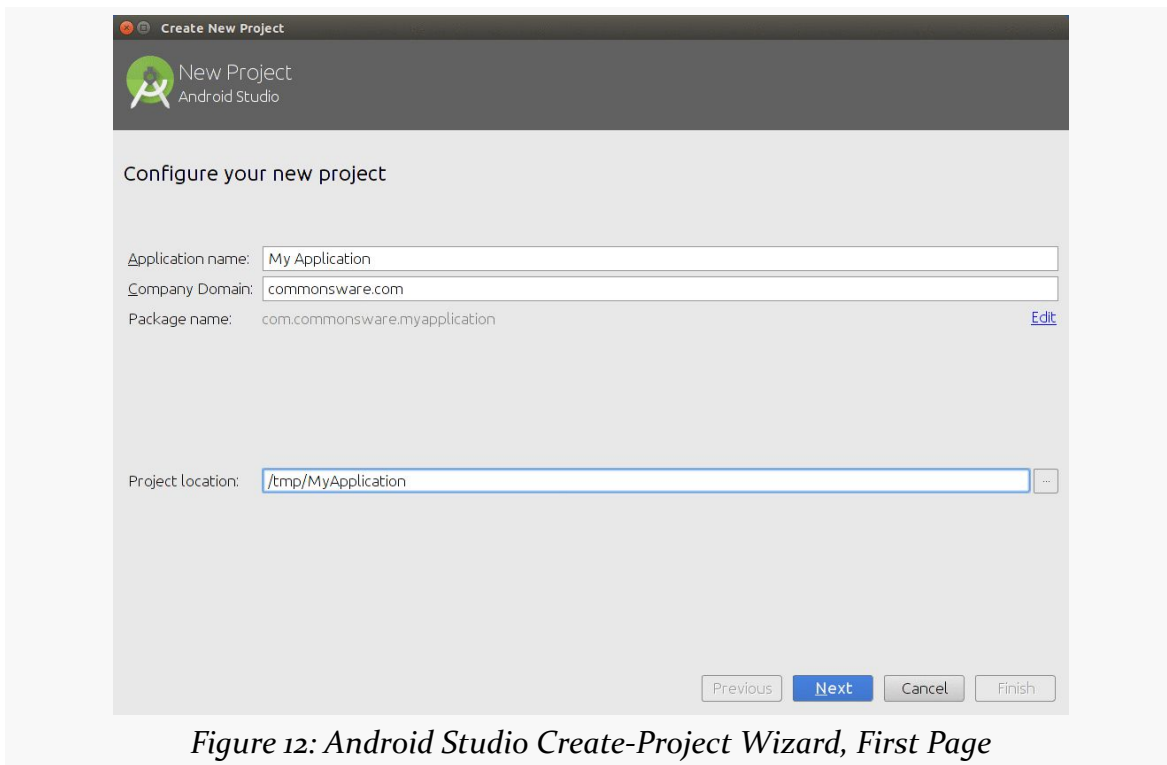

With Android Studio, to work on a project, you can either create a new project from scratch, you can copy an existing Android Studio project to a new one, or you can import an existing Android project into Android Studio. The following sections will review the steps needed for each of these.

Creating a New Project

You can create a project from one of two places:

- If you are at the initial dialog that you first encountered when you opened Android Studio, choose the “Start a new Android Studio project...” menu item
- If you are inside the Android Studio IDE itself, choose File > Create Project... from the main menu

This brings up the new-project wizard:

The first page of the wizard is where you can specify:

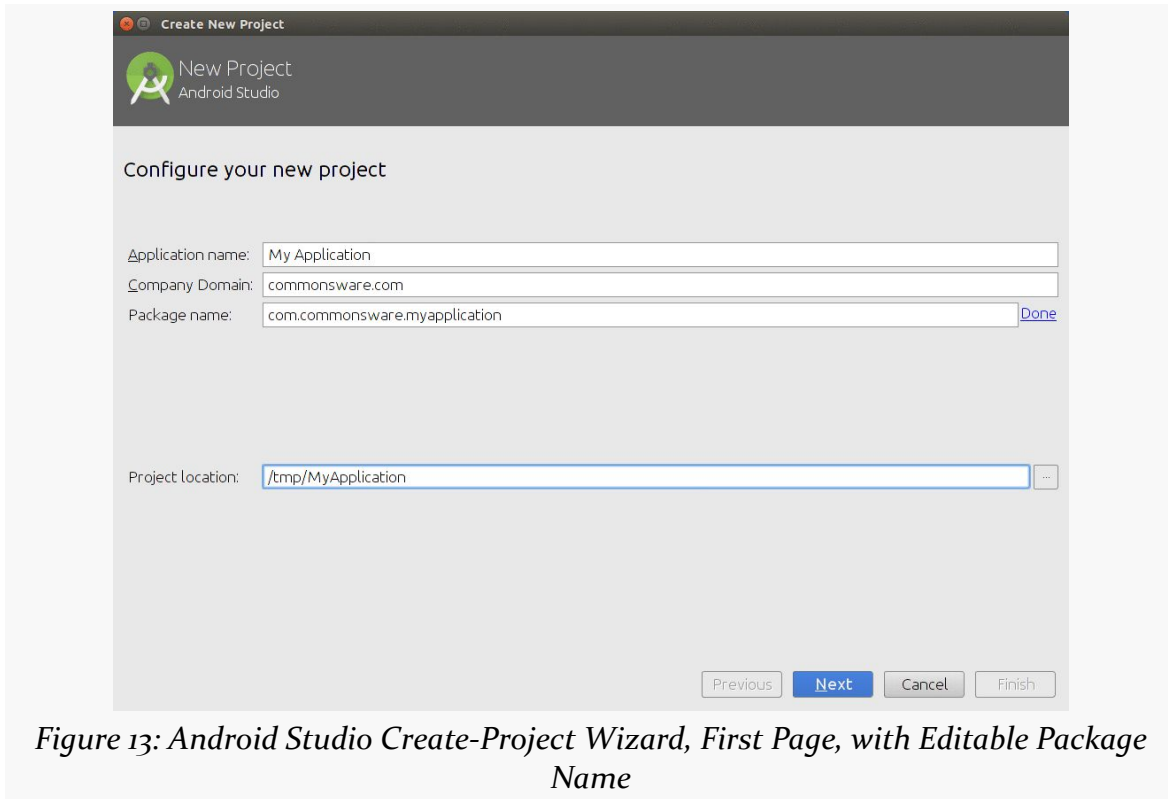

- The application name
- The package name
- The directory where you want the project files to go

By default, the package name will be made up of two pieces:

ANDROID AND PROJECTS

1. The domain name that you specify in the “Company Domain” field
2. The application name, converted into all lowercase with no spaces or other punctuation

If this is not what you want, click the tiny “Edit” link on the far right side of the proposed package name, which will now allow you to edit the package name directly:

Clicking “Next” will advance you to a wizard page where you indicate what sort of project you are creating, in terms of intended device type (phones/tablets, TVs, etc.) and minimum required SDK level:

ANDROID AND PROJECTS

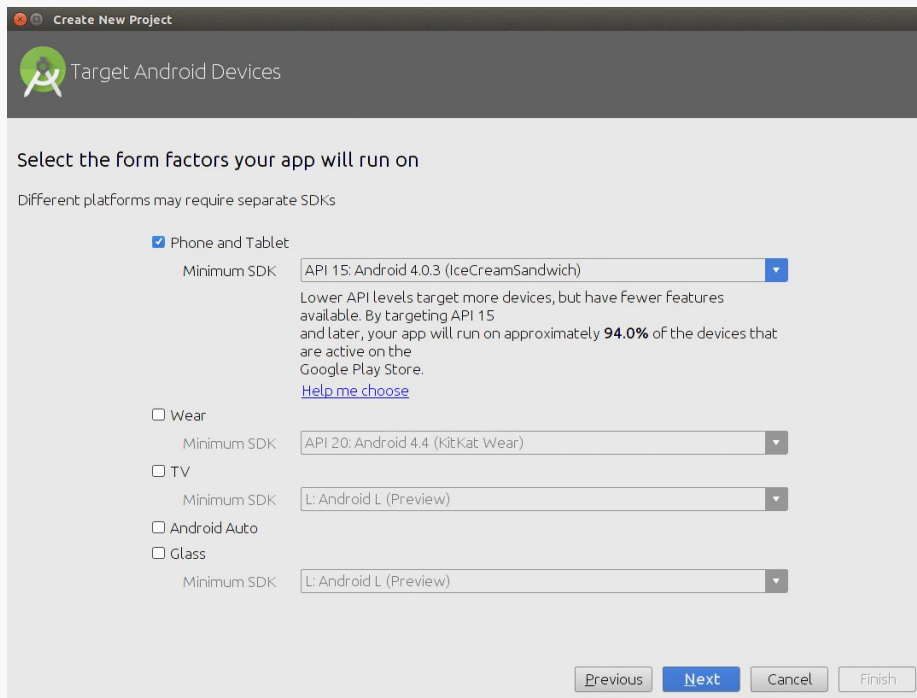

Figure 14: Android Studio Create-Project Wizard, Second Page

Developers just starting out on Android should only check “Phone and Tablet” as the device type. The default “Minimum SDK” value also usually is a good choice, and it can be changed readily in your project, as we will see later in the book.

Clicking “Next” advances you to the third page of the wizard, where you can choose if Android Studio should create an initial activity for you, and if so, based on what template:

ANDROID AND PROJECTS

Figure 15: Android Studio Create-Project Wizard, Third Page

None of these templates are especially good, as they add a lot of example material that you will wind up replacing. “Empty Activity” is the best of the available options for first-time Android developers, simply because it adds the least amount of this “cruft”.

If you choose any option other than “Add No Activity”, clicking “Next” will advance you to a page in the wizard where you can provide additional details about the activity to be created:

What options appear here will vary based upon the template you chose in the previous page. Common options include “Activity Name” (the name of the Java class for your activity) and “Layout Name” (the base name of an XML file that will contain a UI definition of your activity).

Clicking “Finish” will generate your project files.

Copying a Project

Android Studio projects are simply directories of files, with no special metadata held elsewhere (as is the case with Eclipse). Hence, to copy a project, just copy its directory.

Importing a Project

You can import a project from one of two places:

- If you are at the initial dialog that you first encountered when you opened Android Studio, choose the “Import Project...” menu item

ANDROID AND PROJECTS

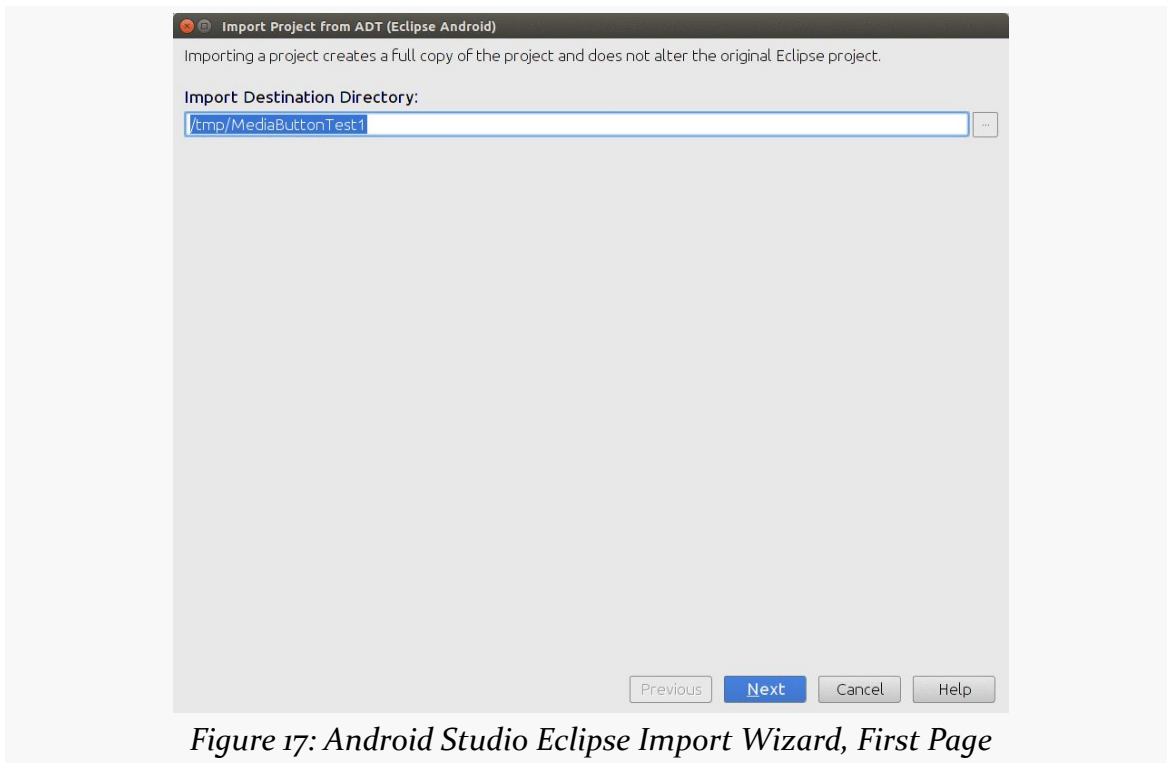

- If you are inside the Android Studio IDE itself, choose File > New... > Import Project... from the main menu

Then, choose the directory containing the project to be imported.

What happens now depends upon the nature of the project. If the project was already set up for use with Android Studio, or at least with Gradle for Android, the Android Studio-specific files will be created (or updated) in the project directory.

However, if the project was not set up for Android Studio or Gradle for Android, but does have Eclipse project files (or at least a `project.properties` file), you will be led through an Eclipse import wizard.

The first page of that wizard is where you specify where Android Studio should make a copy of the project, so it does not modify anything with the original directory:

Clicking “Next” will bring up a page where you can configure some automatic fixes that the import wizard will apply to the imported project code. The details of what is

going on here are well past what we have covered so far in the book. Normally, the defaults are fine.

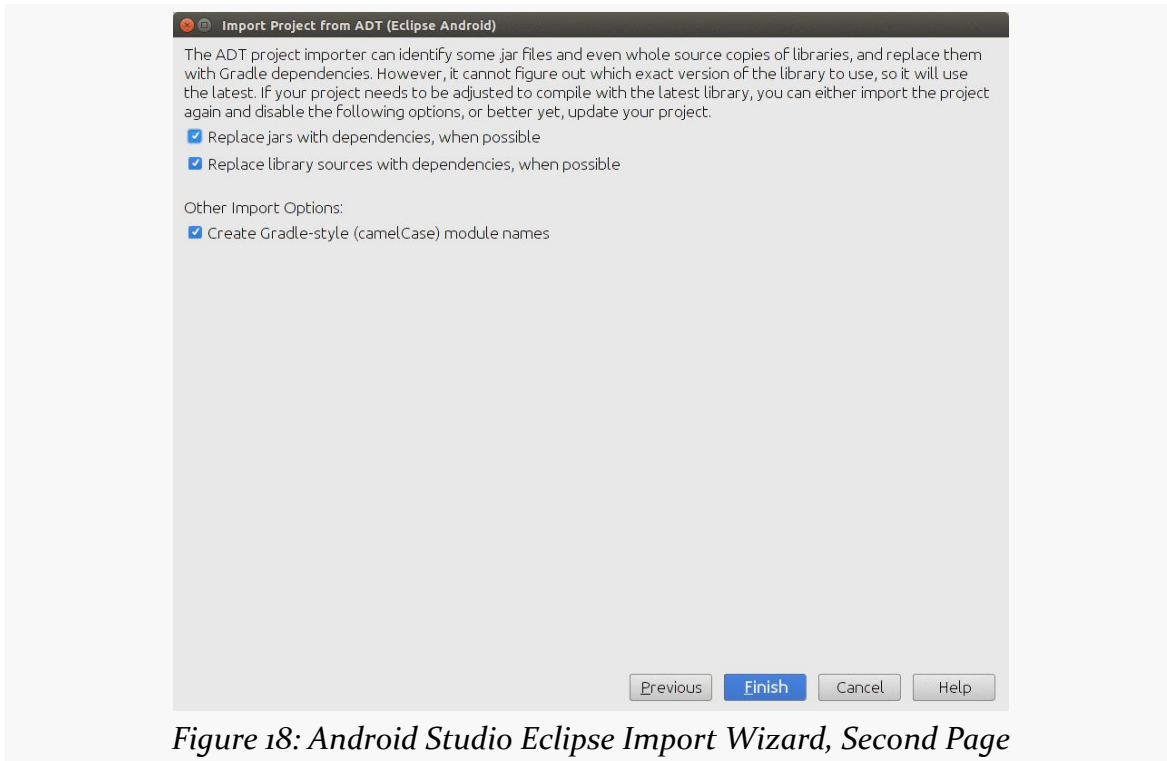

Figure 18: Android Studio Eclipse Import Wizard, Second Page

Clicking “Finish” will perform the project conversion. Android Studio will open up an `import-summary.txt` file outlining some details of how the conversion was accomplished. At this point, the copied-and-modified project is ready for use.

Starter Project Generators

In addition to creating projects through an IDE’s new-project wizard, there are various Web sites that offer online project generators:

- [Android Bootstrap](#)
- [Android Kickstart](#)

On those sites, you provide basic configuration data, such as your application’s package name, and they generate a complete starter project for you. These projects tend to be significantly more advanced than what you get from the IDE wizards. On the plus side, you get a more elaborate “scaffold” on which you can “hang” your own

ANDROID AND PROJECTS

business logic. However, understanding what those generators create and how to change the generated code requires a fair bit of Android development experience.

Tutorial #2 - Creating a Stub Project

Creating an Android application first involves creating an Android “project”. As with many other development environments, the project is where your source code and other assets (e.g., icons) reside. And, the project contains the instructions for your tools for how to convert that source code and other assets into an Android APK file for use with an emulator or device, where the APK is Android’s executable file format.

Hence, in this tutorial, we kick off development of a sample Android application, to give you the opportunity to put some of what you are learning in this book in practice.

About Our Tutorial Project

The application we will be building in these tutorials is called EmPubLite. EmPubLite will be a digital book reader, allowing users to read a digital book like the one that you are reading right now.

EmPubLite will be a partial implementation of [the EmPub reader](#) used for the APK version of this book. EmPub itself is a fairly extensive application, so EmPubLite will have only a subset of its features.

The “Em” of EmPub and EmPubLite stands for “embedded”. These readers are not designed to read an arbitrary EPUB or MOBI formatted book that you might download from somewhere. Rather, the contents of the book (largely an unpacked EPUB file) will be “baked into” the reader APK itself, so by distributing the APK, you are distributing the book.

About the Rest of the Tutorials

Of course, you may have little interest in writing a digital book reader app.

The tutorials presented in this book are certainly optional. There is no expectation that you have to write any code in order to get value from the book. These tutorials are here simply as a way to help those of you who “learn by doing” have an opportunity to do just that.

Hence, there are any number of ways that you can use these tutorials:

- You can ignore them entirely. That is not the best answer, but you are welcome to do it.
- You can read the tutorials but not actually do any of the work. This is the best low-effort answer, as it is likely that you will learn things from the tutorials that you might have missed by simply reading the non-tutorial chapters.
- You can follow along the steps and actually build the EmPubLite app.
- You can [download the answers](#) from the book’s GitHub repository. There, you will find one directory per tutorial, showing the results of having done the steps in that tutorial. For example, you will find a T2-Project/ directory containing a copy of the EmPubLite sample app after having completed the steps found in this tutorial. You can import these projects into your IDE, examine what they contain, cross-reference them back to the tutorials themselves, and run them.

Any of these are valid options — you will need to choose for yourself what you wish to do.

About Our Tools

The instructions in the remaining tutorials should be accurate for Android Studio 1.5.x. The instructions *may* work for other versions of this IDE, but there may also be some differences.

Step #1: Creating the Project

We need to create the Android project for EmPubLite.

TUTORIAL #2 - CREATING A STUB PROJECT

First, visit [the book's GitHub repository's "releases" area](#) and download the `EmPubLiteStarter-AndroidStudio.zip` file that corresponds with this version of the book.

Then, unZIP that ZIP archive into some directory on your development machine outside of where your IDE resides. The ZIP archive will expand into a set of files and subdirectories. Most likely, you will want to place those into an empty existing directory. Eclipse users should **NOT** unZIP the archive directly into the Eclipse workspace, as Eclipse gets confused easily.

In Android Studio, you can import a project from one of two places:

- If you are at the initial “welcome” dialog that you first encountered when you opened Android Studio, choose the “Import project (Eclipse ADT, Gradle, etc.)” menu item. Note that this was back on the first screen (“Quick Start”) of the “welcome” dialog, so if you are on the “Configure” screen with options for “SDK Manager” and such, click the left arrow icon to return to the “Quick Start” screen.
- If you are inside the Android Studio IDE itself, choose `File > New > Import Project...` from the main menu.

Then, just choose the `EmPubLite/` directory inside where you unzipped `EmPubLiteStarter-AndroidStudio.zip`.

Since this project is already set up for use with Android Studio, you should be taken right into the main IDE.

You may get an error showing up in the Messages view, with a message like “failed to find Build Tools revision ...”. Android Studio and the Android SDK evolve between editions of the book. Each Android project contains information about the version of the build tools that it would like to use. While the starter project that you are importing was referring to the latest build tools at the time this book update was published, that may be different than the version of those tools that you got from Android Studio. If this error message does appear, it should also have a link, with a message like “Install Build Tools ... and sync project”. Click that link and wait a bit while Android Studio downloads the missing bits and sets them up with your project.

Android Studio has two ways of viewing the contents of Android projects. The default one, that you are presented with when importing the project, is known as the “Android project view”:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 19: Android Studio “Android Project View”

While you are welcome to navigate your project using it, the tutorial chapters in this book, where they have screenshots of Android Studio, will show the classic project view:

Figure 20: Android Studio “Classic Project View”

To switch to this classic view — and therefore match what the tutorials will show you — click on the drop-down list that currently shows “Android” as selected and choose “Project” instead.

Step #2 - Set Up the Emulator

The Android tools include an emulator, a piece of software that pretends to be an Android device. This is very useful for development — not only does it mean you can get started on Android without a device, but the emulator can help test device configurations that you do not own.

Your first decision to make is whether or not you want to bother setting up an emulator image right now. If you have an Android device, you may prefer to start testing your app on it, and come back to set up the emulator at a later point.

TUTORIAL #2 - CREATING A STUB PROJECT

Your second decision to make is whether you want to go ahead and set up the x86 emulator support. The vast majority of Android devices have ARM CPUs, while the vast majority of development machines have x86 CPUs. The ARM emulator is *slow* on x86 machines, as every ARM instruction must be translated into corresponding x86 instruction(s) before it can be executed. However, setting up the x86 emulator support is a bit complicated, and your development machine may not be able to support it. If you wish to try to set up the x86 emulator right away, there are instructions for doing that [later in the book](#) that you can review and follow.

The Android emulator can emulate one or several Android devices. Each configuration you want is stored in an “Android virtual device”, or AVD. The AVD Manager is where you create these AVDs.

Note that Android Studio now has its own implementation of the AVD Manager that is separate from the one Android developers have traditionally used. You may see screenshots of the older AVD Manager in blog posts, Stack Overflow answers, and the like. The AVD Manager still fills the same role, but it has a different look and feel.

To open the AVD Manager in Android Studio, choose Tools > Android > AVD Manager from the main menu.

Starting with Android Studio 1.4, it appears that no emulator images are set up for you in advance, the way there had been in previous versions of Android Studio. Instead, you are taken to “welcome”-type screen:

TUTORIAL #2 - CREATING A STUB PROJECT

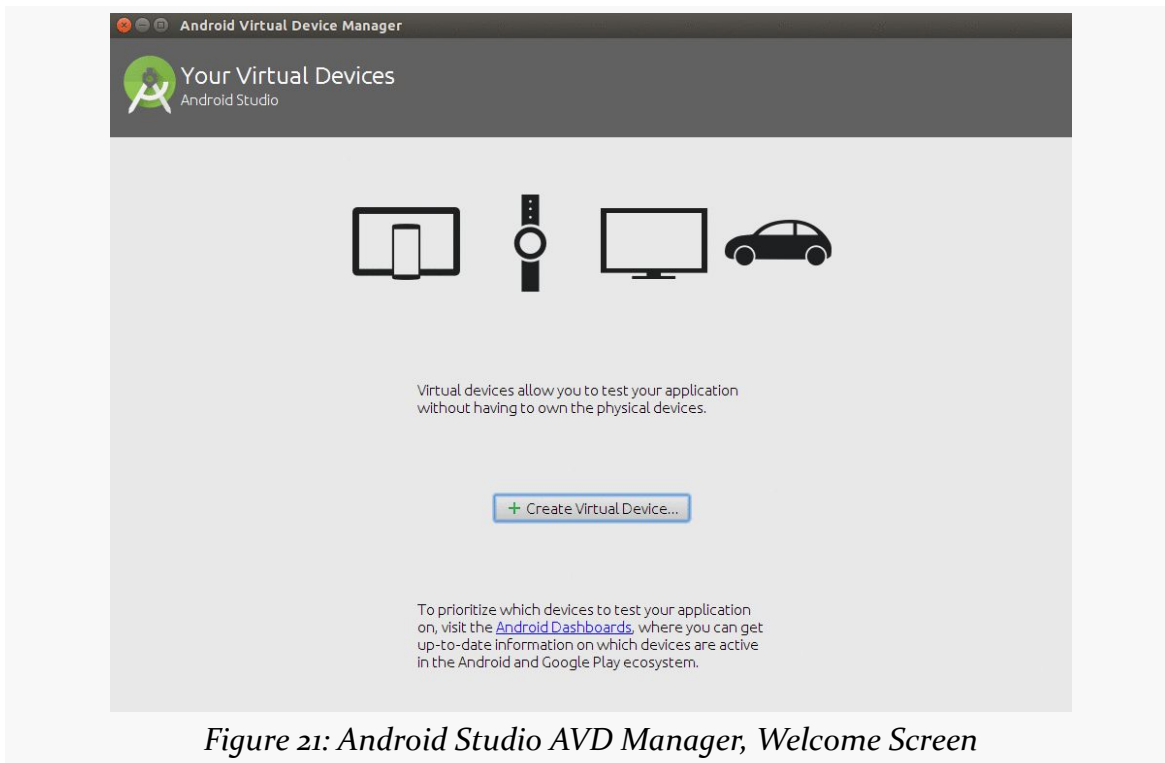

Figure 21: Android Studio AVD Manager, Welcome Screen

Or, you might see a table of available virtual devices (AVDs), possibly including one already set up for you:

TUTORIAL #2 - CREATING A STUB PROJECT

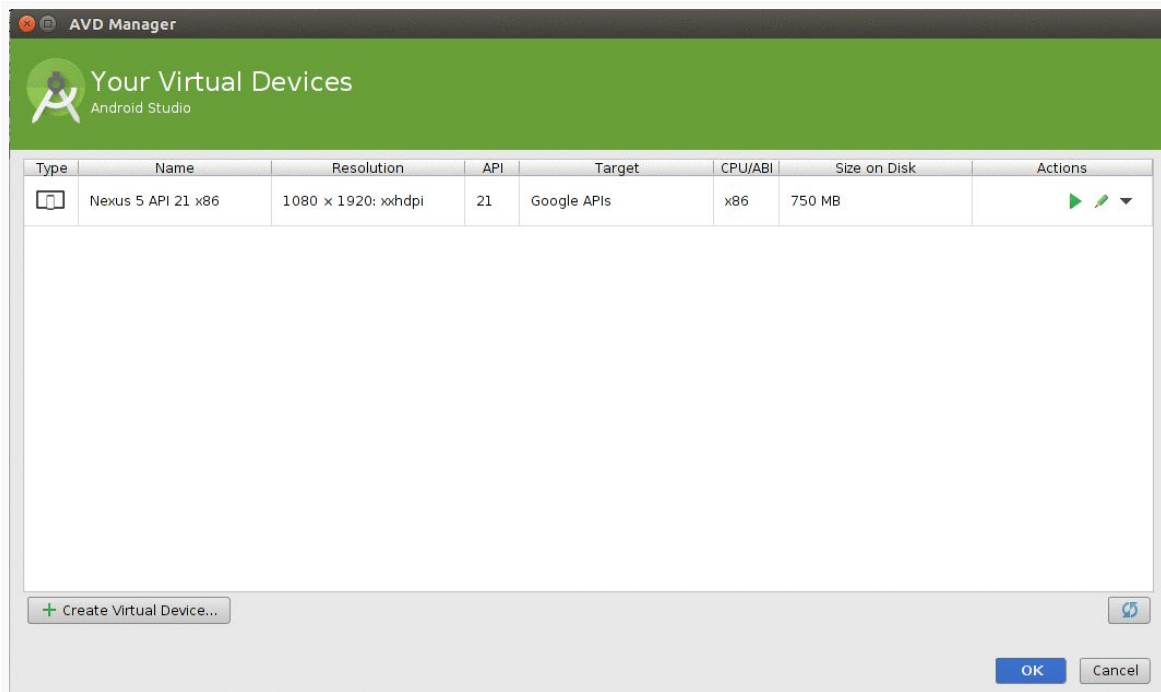

Figure 22: Android Studio AVD Manager, First Page

Regardless of where you start, to define a new AVD, click the “Create Virtual Device” button, which brings up a “Virtual Device Configuration” wizard:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 23: Android Studio Virtual Device Configuration Wizard, First Page

The first page of the wizard allows you to choose a device profile to use as a starting point for your AVD. The “New Hardware Profile” button allows you to define new profiles, if there is no existing profile that meets your needs.

Since emulator speeds are tied somewhat to the resolution of their (virtual) screens, you generally aim for a device profile that is on the low end but is not completely ridiculous. For example, an 800x480 phone would be considered by many people to be fairly low-resolution. However, there are plenty of devices out there at that resolution (or lower), and it makes for a reasonable starting emulator.

If you want to create a new device profile based on an existing one — to change a few parameters but otherwise use what the original profile had — click the “Clone Device” button once you have selected your starter profile.

However, in general, at the outset, using an existing profile is perfectly fine.

Clicking “Next” allows you to choose an emulator image to use:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 24: Android Studio Virtual Device Configuration Wizard, Second Page

Those that need to be downloaded have a blue “Download” link; clicking that link will download the image.

For the tutorials in this book, you want an API Level 18, 19, 21, 22, or 23 image, and for the armeabi-v7 CPU architecture (unless you have gone ahead and configured [x86 emulator support](#)). You do not need one with the “Google APIs” — those are for emulators that have Google Play Services in them and related apps like Google Maps. The ones with “Download” next to them will trigger a one-time download of the files necessary to create AVDs for that particular API level and CPU architecture combination.

Clicking “Next” allows you to finalize the configuration of your AVD:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 25: Android Studio Virtual Device Configuration Wizard, Third Page

A default name for the AVD is suggested, though you are welcome to replace this with your own value. The rest of the default values should be fine.

Clicking “Finish” will return you to the main AVD Manager, showing your new AVD. You can then close the AVD Manager window.

Step #3 - Set Up the Device

You do not need an Android device to get started in Android application development. Having one is a good idea before you try to ship an application (e.g., upload it to the Play Store). And, perhaps you already have a device – maybe that is what is spurring your interest in developing for Android.

If you do not have an Android device that you wish to set up for development, skip this step.

The first step to make your device ready for use with development is to go into the Settings application on the device. What happens now depends a bit on your Android version:

TUTORIAL #2 - CREATING A STUB PROJECT

- On Android 1.x/2.x, go into Applications, then into Development
- On Android 3.0 through 4.1, go into “Developer options” from the main Settings screen
- On Android 4.2 and higher, go into About, tap on the build number seven times, then press BACK, and go into “Developer options” (which was formerly hidden)

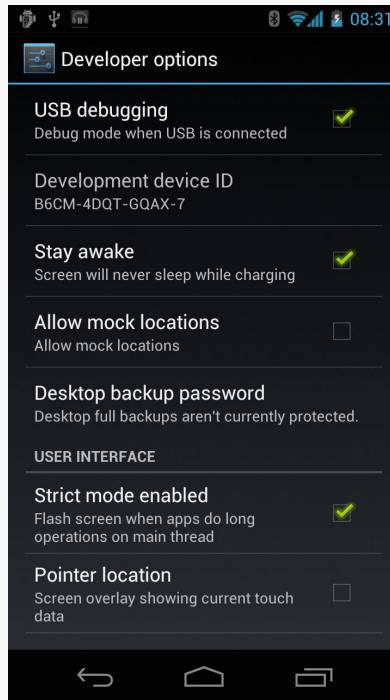

Figure 26: Android device development settings

You may need to slide a switch in the upper-right corner of the screen to the “ON” position to modify the values on this screen.

Generally, you will want to enable USB debugging, so you can use your device with the Android build tools. You can leave the other settings alone for now if you wish, though you may find the “Stay awake” option to be handy, as it saves you from having to unlock your phone all of the time while it is plugged into USB.

Note that on Android 4.2.2 and higher devices, before you can actually use the setting you just toggled, you will be prompted to allow USB debugging with your *specific* development machine via a dialog box:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 27: Allow USB Debugging Dialog

This occurs when you plug in the device via the USB cable and have the driver appropriately set up. That process varies by the operating system of your development machine, as is covered in the following sections.

Windows

When you first plug in your Android device, Windows will attempt to find a driver for it. It is possible that, by virtue of other software you have installed, that the driver is ready for use. If it finds a driver, you are probably ready to go.

If the driver is not found, here are some options for getting one.

Windows Update

Some versions of Windows (e.g., Vista) will prompt you to search Windows Update for drivers. This is certainly worth a shot, though not every device will have supplied its driver to Microsoft.

Standard Android Driver

In your Android SDK installation, if you chose to install the “Google USB Driver” package from the SDK Manager, you will find an `extras/google/usb_driver/` directory, containing a generic Windows driver for Android devices. You can try pointing the driver wizard at this directory to see if it thinks this driver is suitable for your device. This will often work for Nexus devices.

Manufacturer-Supplied Driver

If you still do not have a driver, the [OEM USB Drivers](#) in the developer documentation may help you find one for download from your device manufacturer. Note that you may need the model number for your device, instead of the model

TUTORIAL #2 - CREATING A STUB PROJECT

name used for marketing purposes (e.g., GT-P3113 instead of “Samsung Galaxy Tab 2 7.0”).

OS X and Linux

Odds are decent that simply plugging in your device will “just work”. You can see if Android recognizes your device via running `adb devices` in a shell (e.g., OS X Terminal), where `adb` is in your `platform-tools/` directory of your SDK. If you get output similar to the following, the build tools detected your device:

```
List of devices attached
HT9CPP809576 device
```

If you are running Ubuntu (or perhaps other Linux variants), and this command did not work, you may need to add some udev rules. For example, here is a `51-android.rules` file that will handle the devices from a handful of manufacturers:

```
SUBSYSTEM=="usb", SYSFS{idVendor}=="0bb4", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="22b8", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="18d1", MODE="0666"
SUBSYSTEMS=="usb", ATTRS{idVendor}=="18d1", ATTRS{idProduct}=="0c01", MODE="0666",
OWNER="[me]"
SUBSYSTEM=="usb", SYSFS{idVendor}=="19d2", SYSFS{idProduct}=="1354", MODE="0666"
SUBSYSTEM=="usb", SYSFS{idVendor}=="04e8", SYSFS{idProduct}=="681c", MODE="0666"
```

Drop that in your `/etc/udev/rules.d` directory on Ubuntu, then either reboot the computer or otherwise reload the udev rules (e.g., `sudo service udev reload`). Then, unplug and re-plug in the device and see if it is detected.

The CyanogenMod project maintains [a page on their wiki](#) with more on these udev rules, including rules from a variety of manufacturers and devices.

Step #4: Running the Project

Now, we can confirm that our project is set up properly by running it on a device or emulator.

To do that in Android Studio, just press the Run toolbar button (usually depicted as a green rightward-pointing triangle).

You will then be presented with a dialog indicating where you want the app to run: on some existing device or emulator, or on some newly-launched emulator:

TUTORIAL #2 - CREATING A STUB PROJECT

Figure 28: Android Studio Device Chooser Dialog

If you do not have an emulator running, choose one from the drop-down menu towards the bottom of the dialog, then click OK. Android Studio will launch your emulator for you.

And, whether you start a new emulator instance or reuse an existing one, your app should appear on it:

TUTORIAL #2 - CREATING A STUB PROJECT

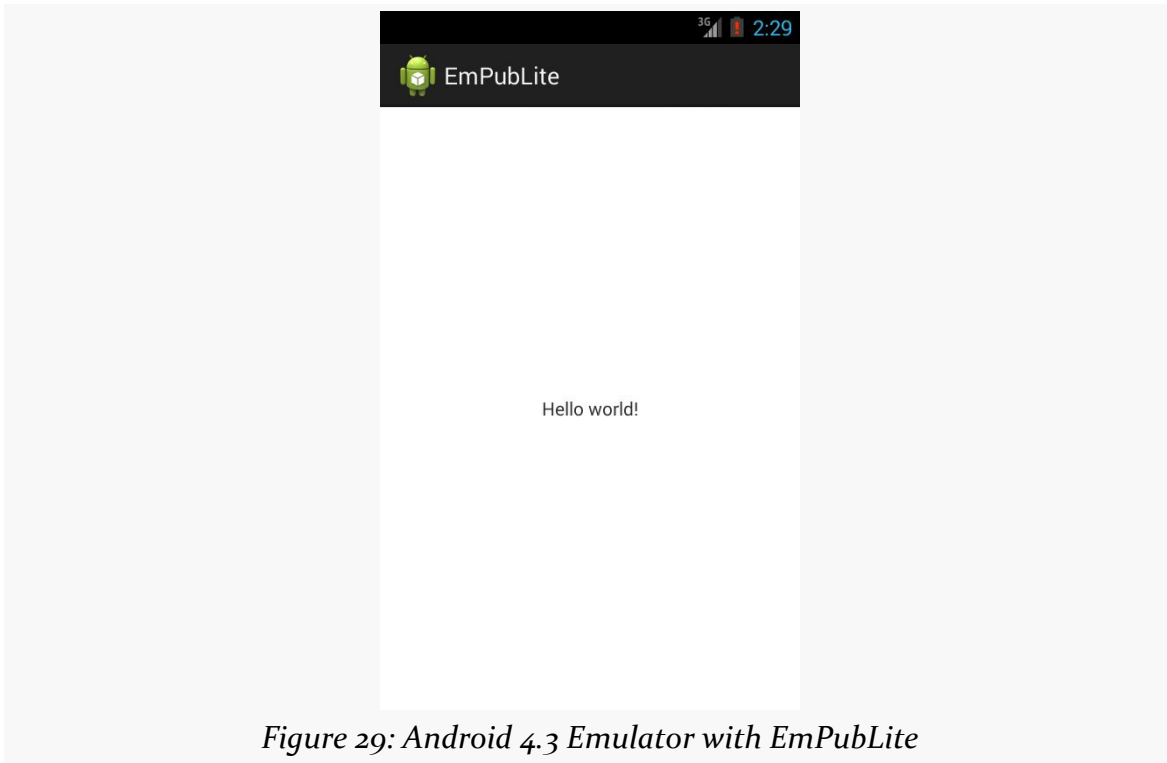

Figure 29: Android 4.3 Emulator with EmPubLite

Note that you may have to unlock your device or emulator to actually see the app running. It will not unlock automatically for you, except the very first time that you run the emulator.

In Our Next Episode...

... we will [modify the AndroidManifest.xml file](#) of our tutorial project.

Getting Around Android Studio

Eclipse has been around for a very long time and has proven to be a very popular IDE. As a result, there is quite a bit of material written about it, from books and blogs to Stack Overflow questions and official project documentation.

Android Studio shares a lot of functionality with its parent, IntelliJ IDEA. However, IDEA itself has not achieved Eclipse's level of popularity, even though it has long been the IDE of choice for many "power developers". And Android Studio's changes to IDEA are largely undocumented.

Hence, this chapter will serve as a quick tour of the Android Studio IDE, to help you get settled in. Other Android-specific capabilities of Android Studio will be explored in the chapters that follow.

Navigating The Project Explorer

After the main editing area — where you will modify your Java source code, your resources, and so forth — the piece of Android Studio you will spend the most time with is the project explorer, usually available on the left side of the IDE window:

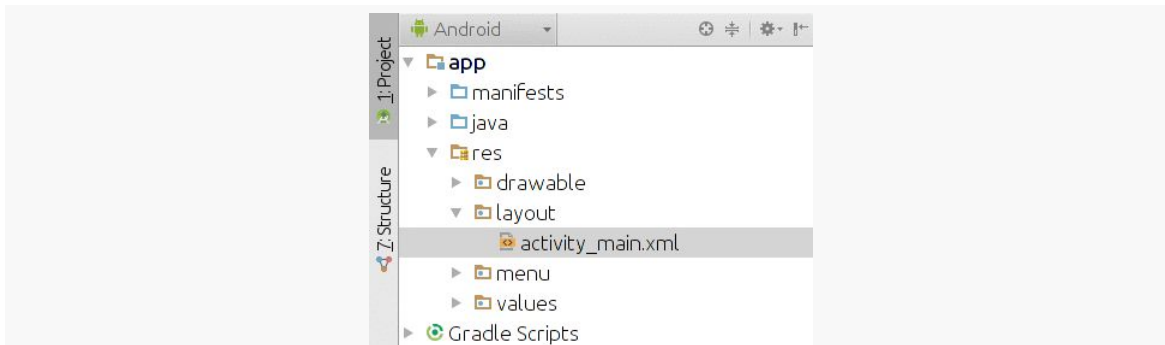

Figure 30: Android Studio Project Explorer, Showing Android Project View

This explorer pane has two main “project views” that an Android developer will use: the Android project view and the classic project view.

Android Project View

By default, when you create or import a project, you will wind up in the Android project view.

In theory, the Android project view is designed to simplify working with Android project files. In practice, it may do so, but only for some advanced developers. On the whole, it makes the IDE significantly more complicated for newcomers to Android, as it is rather difficult to see where things are and what relates to what.

We will return to the Android project view a bit later in the book and explain its benefits relative to [resources](#) and [Gradle’s sourcesets](#).

However, for most of the book — most importantly, for the tutorials – we will use the classic project view.

Classic Project View

To switch to the classic project view, click the drop-down just above the tree in the explorer, and choose Project:

Figure 31: Android Studio Project Explorer, Showing Project View Drop-Down

This will change the contents of the tree to show you all of the files, in their associated directories:

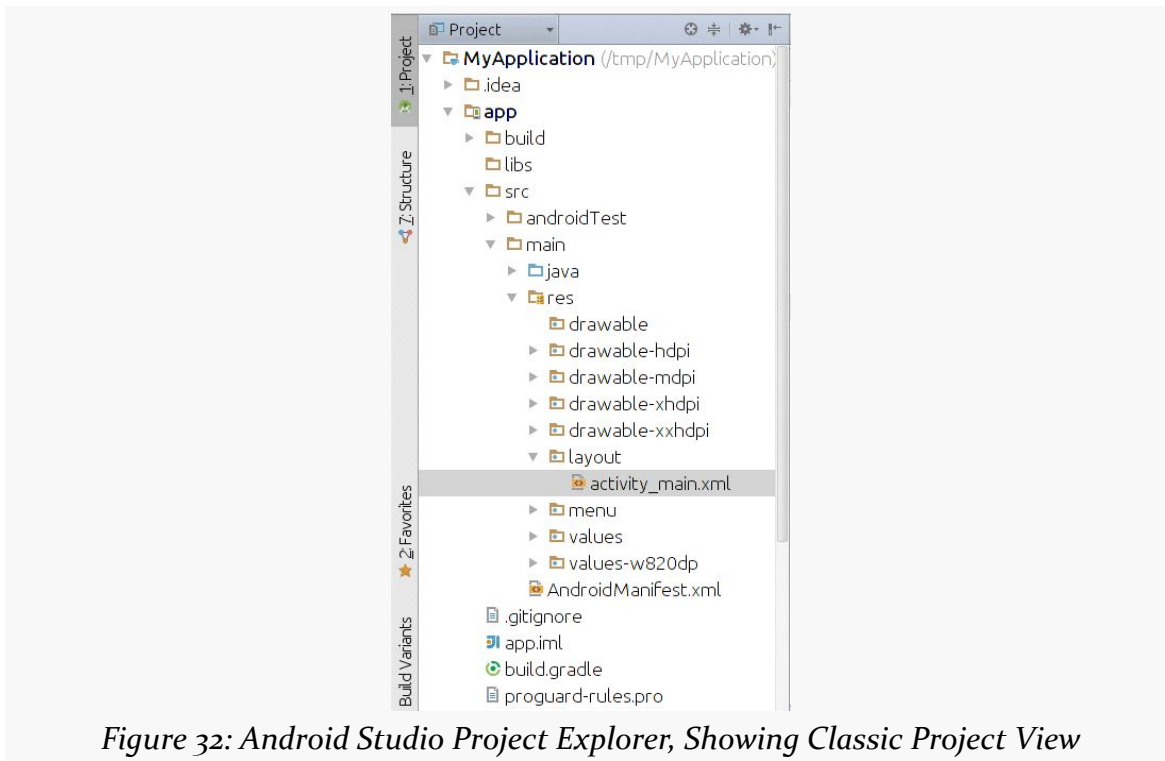

Figure 32: Android Studio Project Explorer, Showing Classic Project View

This project view is much like its equivalent in other IDEs, allowing you to find all of the pieces of your Android project. We will be exploring what those pieces are, and how their files are organized in our projects, in [the next chapter](#).

Context Menus in the Explorer

Right-clicking over a directory or file in the explorer will give you a context menu with a variety of options. Some of these will be typical of any sort of file manager, such as “cut”, “copy”, and/or “paste” options. Some of these will be organized according to how IntelliJ IDEA manages application development, such as the “Refactor” sub-menu, where you can rename or move files around. Yet others will be specific to Android Studio, such as the ability to invoke wizards to create certain types of Android components or other Java classes.

Running Projects

As noted in [Tutorial #2](#), to run your project, just press the Run toolbar button (usually depicted as a green rightward-pointing triangle). You will then be presented

with a dialog indicating where you want the app to run: on some existing device or emulator, or on some newly-launched emulator:

Figure 33: Android Studio Device Chooser Dialog

If you do not have an emulator running, choose one from the drop-down menu towards the bottom of the dialog, then click OK. Android Studio will launch your emulator for you. Whether you start a new emulator instance, reuse an existing one, or request that your app run on an attached Android device, your app should appear on it.

Viewing Output

Beyond your app itself, Android Studio will generate other sorts of diagnostic output, in the form of “console”-style transcripts of things that have occurred. The two of these that probably will matter most for you are the Gradle console and LogCat.

Gradle Console

By default, docked in the lower-right corner of your Android Studio window is a “Gradle Console” item. Tapping on that will open up a pane showing the output of attempts to build your application:

GETTING AROUND ANDROID STUDIO

Figure 34: Android Studio Gradle Console

This may automatically appear from time to time, if specific build problems are detected, and you can always go examine it whenever you need.

Click on the “Gradle Console” item again to collapse the view and get it out of your way.

LogCat

Messages that appear at runtime — including the all-important Java stack traces triggered by bugs in your code — are visible in LogCat. The “Android” item docked towards the lower-left corner of your Android Studio window will display LogCat when tapped:

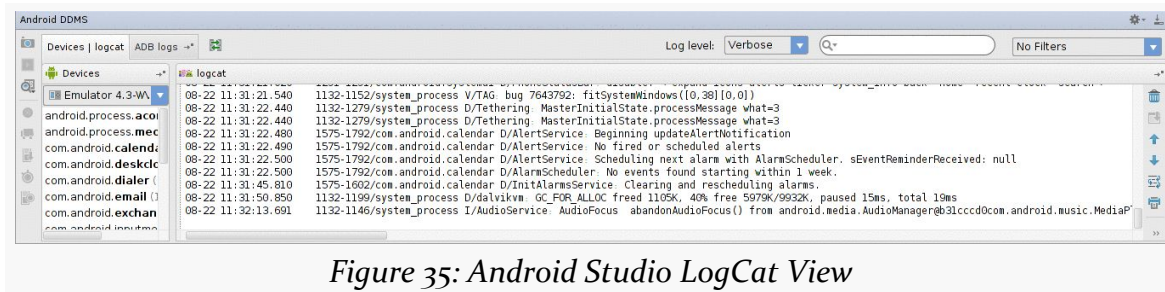

Figure 35: Android Studio LogCat View

LogCat is explained in greater detail [a bit later in this book](#).

Accessing Android Tools

Not everything related to Android is directly part of Android Studio itself. In some cases, tools need to be shared between users of Android Studio, users of Eclipse, and users of “none of the above”. In some cases, while the long term direction may be to

incorporate the tools' functionality directly into Android Studio, that work simply has not been completed to date.

Here are some noteworthy Android-related tools that you can access via the Tools > Android main menu option.

SDK and AVD Managers

As we saw in [Tutorial #1](#), the SDK Manager is Android's tool for downloading pieces of the Android SDK, including:

- “SDK Platform” editions, allowing us to compile against a particular API level
- ARM and (sometimes) x86 emulator images
- Documentation
- Updates to the core build tools
- Etc.

You can launch the SDK Manager via Tools > Android > SDK Manager from the Android Studio main menu, or by clicking on the “droid in a box” toolbar button:

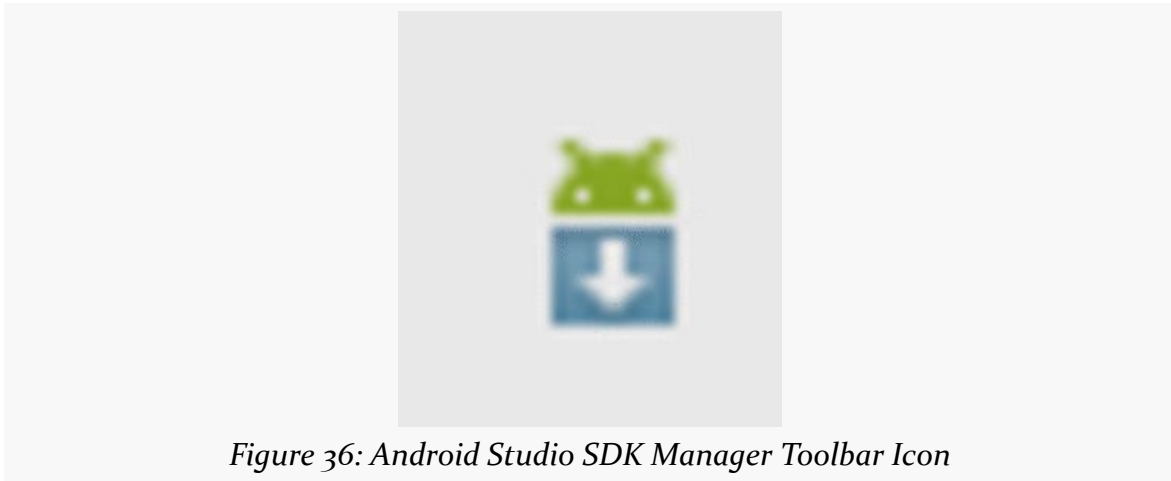

Figure 36: Android Studio SDK Manager Toolbar Icon

The AVD Manager is the tool for creating emulators that emulate certain Android environments, based upon API level, screen size, and other characteristics.

You can launch the AVD Manager via Tools > Android > AVD Manager from the Android Studio main menu, or by clicking the “droid and a screen” toolbar button:

Figure 37: Android Studio AVD Manager Toolbar Icon

Android Device Monitor

Elsewhere in this book, you will see references to tools associated with the Dalvik Debug Monitor Server (DDMS), such as using it to help inspect your running apps for memory or threading issues. You will also see references to tools like Hierarchy View, for trying to make sense of your UI as it appears at runtime, after you have programmatically made lots of changes to it.

In Eclipse, DDMS and Hierarchy View are “perspectives”, added to Eclipse via the ADT plugin.

For everyone not using Eclipse — including Android Studio users — DDMS and Hierarchy View are available via the Android Device Monitor standalone tool. Android Studio users can launch the Monitor via Tools > Android > Android Device Monitor from the main menu.

This will first bring up a splash screen:

GETTING AROUND ANDROID STUDIO

Figure 38: Android Device Monitor Splash Screen

followed by the Monitor itself:

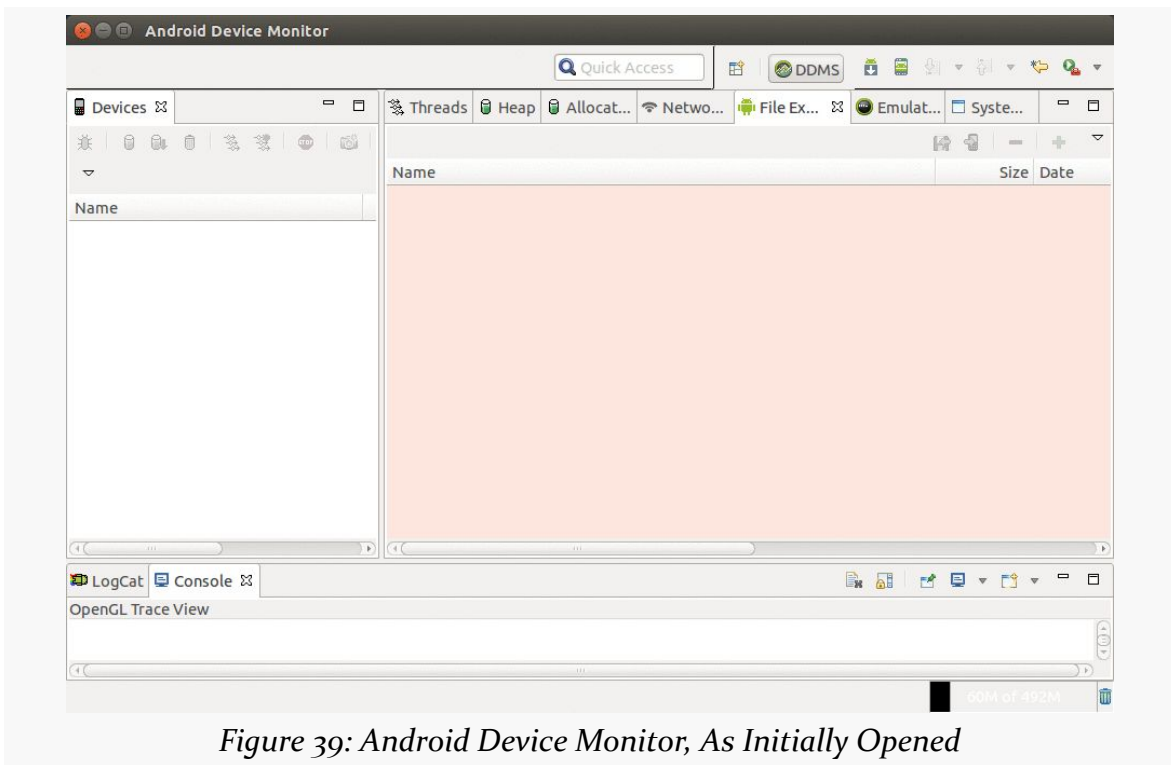

Figure 39: Android Device Monitor, As Initially Opened

If you read about things available from DDMS or Hierarchy View online, such as in blog posts or Stack Overflow answers, most of those capabilities should be available to you via the Android Device Monitor.

Android Studio and Release Channels

When you install Android Studio for the first time, your installation will be set up to get updates on the “stable” release channel. Here, a “release channel” is a specific set of possible upgrades. The “stable” release channel means that you are getting full production-ready updates. Android Studio will check for updates when launched, and you can manually check for updates via the main menu (e.g., Help > Check for Update... on Windows and Linux).

If an update is available, you will be presented with a dialog box showing you details of the update:

Choosing “Release Notes” will bring up a Web page with release notes for the new release. Clicking “Update and Restart” does pretty much what the button name suggests: it downloads the update and restarts the IDE, applying the update along the way.

Clicking the “Updates” hyperlink in the dialog brings up yet another dialog, allowing you to choose which release channel you want to subscribe to:

GETTING AROUND ANDROID STUDIO

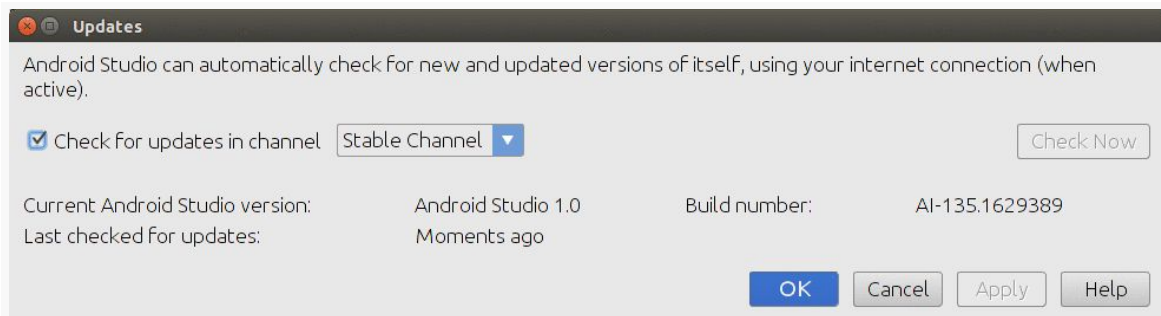

Figure 41: Android Studio Update Release Channel Dialog

You have four channels to choose from:

- Stable, which is appropriate for most developers
- Beta, which will get updates that are slightly ahead of stable
- Dev, which is even more ahead than is the beta channel
- Canary, which is updated *very* early (and the name, suggestive of a “canary in a coal mine”, indicates that you are here to help debug the IDE)

Visit the Trails!

Android Studio’s Project Structure dialog and Translations Editor are covered [later in this book](#).

Contents of Android Projects

The Android build system is organized around a specific directory tree structure for your Android project, much like any other Java project. The specifics, though, are fairly unique to Android — the Android build tools do a few extra things to prepare the actual application that will run on the device or emulator.

Making things more complicated is that the default structure is different for the current tools (e.g., Android Studio) and the legacy tools (e.g., Eclipse with the ADT plugin).

Here is a quick primer on the project structure, to help you make sense of it all, particularly for the sample code referenced in this book.

What You Get, In General

The details of *exactly* what files are in your project depend upon your choice of IDE. However, regardless of whether you go with Android Studio or Eclipse, there are many elements in common.

The Manifest

`AndroidManifest.xml` is an XML file describing the application being built and what components — activities, services, etc. — are being supplied by that application. You can think of it as being the “table of contents” of what your application is about, much as a book has a “table of contents” listing the various parts, chapters, and appendices that appear in the book.

We will examine the manifest a bit more closely starting in [the next chapter](#).

The Java

When you created the project, you supplied the fully-qualified class name of the “main” activity for the application (e.g., `com.commonware.android.SomeDemo`). You will then find that your project’s Java source tree already has the package’s directory tree in place, plus a stub Activity subclass representing your main activity (e.g., `src/com/commonware/android/SomeDemoActivity.java`). You are welcome to modify this file and add Java classes as needed to implement your application, and we will demonstrate that countless times as we progress through this book.

Elsewhere — in directories that you normally do not work with — the Android build tools will also be code-generating some source code for you each time you build your app. One of the code-generated Java classes (`R.java`) will be important for controlling our user interfaces from our own Java code, and we will see many references to this R class as we start building applications in earnest.

The Resources

You will also find that your project has a `res/` directory tree. This holds “resources” — static files that are packaged along with your application, either in their original form or, occasionally, in a preprocessed form. Some of the subdirectories you will find or create under `res/` include:

1. `res/drawable/` for images (PNG, JPEG, etc.)
2. `res/layout/` for XML-based UI layout specifications
3. `res/menu/` for XML-based menu specifications
4. `res/raw/` for general-purpose files (e.g., an audio clip, a CSV file of account information)
5. `res/values/` for strings, dimensions, and the like
6. `res/xml/` for other general-purpose XML files you wish to ship

Some of the directory names may have suffixes, like `res/drawable-hdpi/`. This indicates that the directory of resources should only be used in certain circumstances — in this case, the drawable resources should only be used on devices with high-density screens.

We will cover all of these, and more, later in this book.

The Build Instructions

The IDE needs to know how to take all of this stuff and come up with an Android APK file. Some of this is already “known” to the IDE based upon how the IDE was written. But some details are things that you may need to configure from time to time, and so those details are stored in files that you will edit, by one means or another, from your IDE.

In Android Studio, most of this knowledge is kept in one or more files named `build.gradle`. These are for a build engine known as [Gradle](#), that Android Studio uses to build APKs and other Android outputs.

In Eclipse, this knowledge is scattered among several files, some of which you might edit manually (e.g., `project.properties`) and some of which you would only change through Eclipse itself (e.g., `.classpath`).

The Contents of an Android Studio Project

An Android Studio project is significantly more complex than is an Eclipse project. That complexity is designed to give you more power when you become an expert Android developer.

In the short term, though, it may be a bit confusing.

The Root Directory

In the root directory of your project, the most important item is the `app/` directory, where your application code resides. We will look at that [in the next section](#).

Beyond the `app/` directory, the other noteworthy files in the root of your project include:

- `build.gradle`, which is part of the build instructions for your project, as is described above
- Various other Gradle-related files (`settings.gradle`, `gradle.properties`, and so forth)
- `local.properties`, which indicates where your Android SDK tools reside
- An `.iml` file, where Android Studio holds some additional metadata about your project

The App Directory

The `app/` directory, and its contents, are where you will spend most of your time as a developer. Rarely do you need to manipulate the files in the project root.

The most important thing in the `app/` directory is the `src/` directory, which is the root of your project's sourcesets, which will be described in [the next section](#).

Beyond the `src/` directory, there are a few other items of note in `app/`:

- A `build/` directory, which will hold the outputs of building your app, including your APK file
- A `build.gradle` file, where most of your project-specific Gradle configuration will go, to teach Android Studio how to build your app
- An `app.iml` file, containing more Android Studio metadata

The Sourcesets

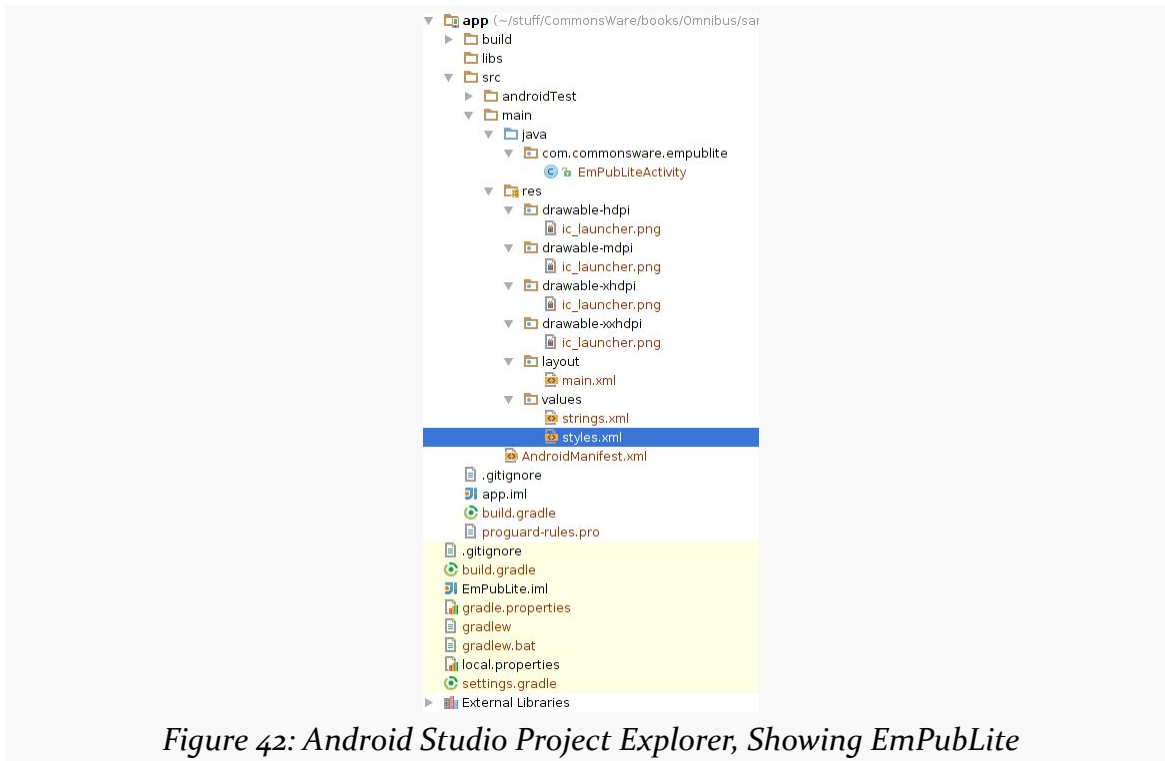

Sourcesets are where the “source” of your project is organized. Here, “source” not only refers to programming language source code (e.g., Java), but other types of inputs to the build, such as your resources.

The sourceset that you will spend most of your time in is `main/`. You will also have a stub sourceset named `androidTest`, for use in creating unit tests, as will be covered [later in the book](#).

Inside of a sourceset, you can have:

- Java code, in a `java/` directory
- Resources, in a `res/` directory
- Assets, in an `assets/` directory, representing other static files you wish packaged with the application for deployment onto the device
- Your `AndroidManifest.xml` file

CONTENTS OF ANDROID PROJECTS

The Contents of an Eclipse Project

When you create a new Android project in Eclipse, you get several items in the project's root directory, including:

1. `AndroidManifest.xml`, as is described above
2. `bin/`, which holds the application once it is compiled (note: this directory will be created when you first build your application)
3. `res/`, which holds your resources, as is described above
4. `src/`, which holds the Java source code for the application

In addition to the files and directories shown above, you may find any of the following in Android projects:

1. `assets/`, which holds other static files you wish packaged with the application for deployment onto the device
2. `gen/`, where Android's build tools will place source code that they generate
3. `libs/`, which holds any third-party Java JARs your application requires
4. `*.properties`, containing configuration data for your builds

5. `proguard.cfg` or `proguard-project.txt`, which are used for integration with [ProGuard](#) for obfuscating your Android code
6. Hidden Eclipse project files (e.g., `.classpath`)

What You Get Out Of It

As part of running your app on a device or emulator, the IDE will generate an APK file. You will find this:

- in the `build/outputs/apk` directory of your Android Studio project, if the project has no modules (e.g., no `app/` directory), or
- in the `build/outputs/apk` directory of your module's directory, (e.g., `app/build/outputs/apk` for a traditional Android Studio project), or
- in the `bin/` directory of your Eclipse project

The APK file is a ZIP archive containing your compiled Java classes, the compiled edition of your resources (`resources.arsc`), any un-compiled resources (such as what you put in `res/raw/`), and the `AndroidManifest.xml` file. If you build a debug version of the application — which is the default — you will have `yourapp-debug.apk` as your APK, for an app named `yourapp`.

Projects and this Book

Projects in this book have a mix of structures. Some use the new Android Studio structure. Others use the older Eclipse structure. The Eclipse-style projects, though, are set up to still be able to be imported into Android Studio — it is just that the files will be in the directory structure used by Eclipse rather than in Android Studio's natural structure.

Slowly, this book is being converted over to having all projects use the Android Studio structure. This process should be completed sometime in 2016.

Introducing Gradle and the Manifest

In the discussion of Android Studio, this book has mentioned something called “Gradle”, without a lot of explanation.

In this chapter, the mysteries of Gradle will be revealed to you.

(well, OK, *some* of the mysteries...)

We also mentioned in passing in the previous chapter the concept of the “manifest”, as being a special file in our Android projects.

On the one hand, Gradle and the manifest are not strictly related. On the other hand, some (but far from all) of the things that we can set up in the manifest can be overridden in Gradle... for Android Studio users. Since Eclipse users are not using Gradle, their definitions will always be in the manifest itself.

So, in this chapter, we will review both what Gradle is, what the manifest is, what each of their roles are, and the basics of how they tie together.

Gradle: The Big Questions

First, let us “set the stage” by examining what this is all about, through a series of fictionally-asked questions (FAQs).

What is Gradle?

[Gradle](#) is software for building software, otherwise known as “build automation software” or “build systems”. You may have used other build systems before in other environments, such as `make` (C/C++), `rake` (Ruby), `Ant` (Java), `Maven` (Java), etc.

These tools know — via intrinsic capabilities and rules that you teach them — how to determine what needs to be created (e.g., based on file changes) and how to create them. A build system does not compile, link, package, etc. applications directly, but instead directs separate compilers, linkers, and packagers to do that work.

Gradle uses a domain-specific language (DSL) built on top of Groovy to accomplish these tasks.

What is Groovy?

There are many programming languages that are designed to run on top of the Java VM. Some of these, like JRuby and Jython, are implementations of other common programming languages (Ruby and Python, respectively). Other languages are unique, and [Groovy](#) is one of those.

Groovy scripts look a bit like a mashup of Java and Ruby. As with Java, Groovy supports:

- Defining classes with the `class` keyword
- Creating subclasses using `extends`
- Importing classes from external JARs using `import`
- Defining method bodies using braces (`{` and `}`)
- Objects are created via the `new` operator

As with Ruby, though:

- Statements can be part of a class, or simply written in an imperative style, like a scripting language
- Parameters and local variables are not typed
- Values can be automatically patched into strings, though using slightly different syntax ("Hello, \$name" for Groovy instead of "Hello, #{name}" for Ruby)

Groovy is an interpreted language, like Ruby and unlike Java. Groovy scripts are run by executing a `groovy` command, passing it the script to run. The Groovy runtime, though, is a Java JAR and requires a JVM in order to operate.

One of Groovy's strengths is in creating a [domain-specific language](#) (or DSL). Gradle, for example, is a Groovy DSL for doing software builds. Gradle-specific capabilities appear to be first-class language constructs, generally indistinguishable

from capabilities intrinsic to Groovy. Yet, the Groovy DSL is largely declarative, like an XML file.

To some extent, we get the best of both worlds: XML-style definitions (generally with less punctuation), yet with the ability to “reach into Groovy” and do custom scripting as needed.

What Does Android Have To Do with Gradle?

Google has published the Android Plugin for Gradle, which gives Gradle the ability to build Android projects. Google is also using Gradle and Gradle for Android as the build system behind Android Studio.

Why Did We Move to Gradle?

Originally, when we would build an app, those builds were done using Eclipse and Ant. Eclipse was the IDE, while Ant was the command-line tool. Eclipse does not use Ant for building Android projects, but rather has its own build system. And we were successfully building a million-plus apps using these tools. Those tools still work today, though Ant support is fading fast.

So, why change?

There appear to be several contributing factors, including:

- Maintaining two separate build systems (Ant and Eclipse’s native approach) was becoming time-consuming, and would become worse with the advent of Android Studio and yet another build system. Hence, Google wishes to standardize on a single build system, based upon Gradle, for IDE and command-line scenarios.
- Getting Ant scripts to do everything that Google needed for builds was getting a bit creaky.
- Ant has no first-class support for “external artifacts” (e.g., libraries) and dependency management of those libraries. While there are ways to graft [Maven](#) onto Ant, or use Maven’s own build system, Google never endorsed that approach. Gradle offers much better support in this area than do Eclipse or Ant, and will help make it easier for developers to reliably consume libraries from a variety of authors.
- Gradle is designed to be integrated into IDEs as a library, much more than Ant is.

As to why Google chose Gradle over Maven... you would have to ask Google.

How Does Gradle Relate to Android Studio?

As noted above, Android Studio uses the new Gradle-based build system as its native approach for building Android projects. While the IntelliJ IDEA IDE that serves as Android Studio's core also has its own build system (much like Eclipse has one), IDEA is more amenable to replaceable build systems.

Over time, this will allow Google to focus on a single build system (Gradle) for all supported scenarios, rather than having to deal with a collection of independent build systems.

How Does Gradle Relate to Eclipse?

At the time of this writing, Eclipse has no ability to use Gradle for Android build scripts, either directly or as a source of project configuration data for imports. The Android Developer Tools (ADT) plugin for Eclipse does have the ability to [export a generated Gradle build file](#) for a project.

It is unclear to what extent that Eclipse will ever get Gradle for Android support. It is best to assume that this will not be possible any time soon.

Obtaining Gradle

As with any build system, to use it, you need the build system's engine itself.

If you will only be using Gradle in the context of Android Studio, the IDE will take care of getting Gradle for you. If, however, you are planning on using Gradle outside of Android Studio (e.g., command-line builds), you will want to consider where your Gradle is coming from. This is particularly important for situations where you want to build the app with no IDE in sight, such as using a continuous integration (CI) server, like Jenkins.

Direct Installation

What most developers looking to use Gradle outside of Android Studio will wind up doing is installing Gradle directly.

The [Gradle download page](#) contains links to ZIP archives for Gradle itself: binaries, source code, or both.

You can unZIP this archive to your desired location on your development machine.

Linux Packages

You may be able to obtain Gradle via a package manager on Linux environments. For example, there is [an Ubuntu PPA for Gradle](#).

The gradlew Wrapper

If you are starting from a project that somebody else has published, you may find a `gradlew` and `gradlew.bat` file in the project root, along with a `gradle/` directory. This represents [the “Gradle Wrapper”](#).

The Gradle Wrapper consists of three pieces:

- the batch file (`gradlew.bat`) or shell script (`gradlew`)
- the JAR file used by the batch file and shell script (in the `gradle/wrapper/` directory)
- the `gradle-wrapper.properties` file (also in the `gradle/wrapper/` directory)

Android Studio uses the `gradle-wrapper.properties` file to determine where to download Gradle from, for use in your project, from the `distributionUrl` property in that file:

```
#Wed Apr 10 15:27:10 PDT 2013
distributionBase=GRADLE_USER_HOME
distributionPath=wrapper/dists
zipStoreBase=GRADLE_USER_HOME
zipStorePath=wrapper/dists
distributionUrl=https\://services.gradle.org/distributions/gradle-2.2.1-all.zip
```

When you create or import a project, or if you change the version of Gradle referenced in the properties file, Android Studio will download the Gradle pointed to by the `distributionUrl` property and install it to a `.gradle/` directory (note the leading `.`) in your project. That version of Gradle will be what Android Studio uses.

RULE #1: Only use a `distributionUrl` that you trust.

If you are importing an Android project from a third party — such as the samples for this book — and they contain the `gradle/wrapper/gradle-wrapper.properties`

file, examine it to see where the `distributionUrl` is pointing to. If it is loading from `services.gradle.org`, or from an internal enterprise server, it is probably trustworthy. If it is pointing to a URL located somewhere else, consider whether you really want to use that version of Gradle, considering that it may have been tampered with.

The batch file, shell script, and JAR file are there to support command-line builds. If you use `gradlew`, it will use a local copy of Gradle installed in `.gradle/` in the project. If there is no such copy of Gradle, `gradlew` will download Gradle from the `distributionUrl`, as does Android Studio. Note that Android Studio does not use `gradlew` for this role — that logic is built into Android Studio itself.

RULE #2: Only use a `gradlew` that you REALLY trust.

It is relatively easy to examine a `.properties` file to check a URL to see if it seems valid. Making sense of a batch file or shell script can be cumbersome. Decompiling a JAR file and making sense of it can be rather difficult. Yet, if you use `gradlew` that you obtained from somebody, that script and JAR are running on your development machine, as is the copy of Gradle that they install. If that code was tampered with, the malware has complete access to your development machine and anything that it can reach, such as servers within your organization.

Note that you do not have to use the Gradle Wrapper at all. If you would rather not worry about it, install a version of Gradle on your development machine yourself and remove the Gradle Wrapper files. You can use the `gradle` command to build your app (if your Gradle's `bin/` directory is in your `PATH`), and Android Studio will use your Gradle installation (if you teach it where to find it, such as via the `GRADLE_HOME` environment variable).

Versions of Gradle and Gradle for Android

The Android Plugin for Gradle that we will use to give Gradle “super Android powers!” is updated periodically. Each update has its corresponding required version of Gradle.

[The rules, according to Google](#), are:

- Android Studio 1.x works with any Android Plugin for Gradle version 1.x, where the values for “x” do not need to match.
- Gradle for Android 1.x should work with all Gradle 2.x versions

If you are using the Gradle Wrapper, you are using an installation of Gradle that is local to the project. So long as the version of Gradle in the project matches the version of Gradle for Android requested in the `build.gradle` file — as will be covered in the next chapter — you should be in fine shape.

If you are not using the Gradle Wrapper, you will need to decide when to take on a new Gradle for Android release and plan to update your Gradle installation and `build.gradle` files in tandem at that point.

Gradle Environment Variables

If you installed Gradle yourself, you will want to define a `GRADLE_HOME` environment variable, pointing to where you installed Gradle, and to add the `bin/` directory inside of Gradle to your `PATH` environment variable.

You may also consider setting up a `GRADLE_USER_HOME` environment variable, pointing to a directory in which Gradle can create a `.gradle` subdirectory, for per-user caches and related materials. By default, Gradle will use your standard home directory.

Examining the Gradle Files

An Android Studio project may have two `build.gradle` files, one at the project level and one at the “module” level (e.g., in the `app/` directory). That split is not required for single-module projects — those could just as easily have one `build.gradle` file for the module and nothing else.

Regardless of whether your `build.gradle` file is in one or two pieces, there are a few common elements that you will find, outlined in this section.

buildscript

The `buildscript` closure (i.e., code section wrapped in braces) in Gradle is where you configure the JARs and such that Gradle itself will use for interpreting the rest of the file. Hence, here you are not configuring your *project* so much as you are configuring *the build itself*.

```
buildscript {
    repositories {
        mavenCentral()
    }
}
```

```
dependencies {  
    classpath 'com.android.tools.build:gradle:1.0.0'  
}  
}
```

The `repositories` closure inside the `buildscript` closure indicates where dependencies can come from, typically in the form of Maven-style repositories. Here, `mavenCentral()` is a built-in method that sets up the repository information for Maven Central, a popular location for obtaining open source dependencies.

The `dependencies` closure indicates what is required to be able to run the rest of the build script. `classpath 'com.android.tools.build:gradle:1.0.0'` is not especially well-documented by the Gradle team. However the `'com.android.tools.build:gradle:1.0.0'` portion means:

- Find the `com.android.tools.build` group of artifacts in a repository
- Find the `gradle` artifact within that group
- Ensure that we have version `1.0.0` of the artifact

The first time you run your build, with the `buildscript` closure as shown above, Gradle will notice that you do not have this dependency. It will then visit [Maven Central](#) and find [the `com.android.tools.build` group](#) and the `gradle` artifact within that group, then download version `1.0.0`.

Sometimes, the last segment of the version is replaced with a `+` sign (e.g., `1.0.+`). This tells Gradle to download the latest version, thereby automatically upgrading you to the latest patch-level (e.g., `1.0.3` at some point).

apply plugin

The `com.android.tools.build:gradle:1.0.0` dependency contains an implementation of the Android Plugin for Gradle, to teach Gradle Android-specific constructs, such as those found in the `android` closure covered [later in this chapter](#). However, just downloading the dependency does not actually apply anything in it.

The `apply plugin: 'com.android.application'` statement actually adds the Android Plugin for Gradle to Gradle for this build. In particular, it indicates that we are building an Android application.

dependencies

The `dependencies` closure in the `buildscript` closure specifies dependencies for the build script. The `dependencies` closure in the root of the `build.gradle` file, by contrast, specifies dependencies for the *app*.

However, the definition of “dependency” is largely the same: it is some library or similar artifact that we need in addition to our project’s source code.

We will get into the concept of these libraries [later in the book](#).

android

The `android` closure contains all of the Android-specific configuration information. This closure is what the Android plugin enables.

But before we get into what is in this closure, we should “switch gears” and talk about the manifest file, as what goes in the `android` closure is related to what goes in the manifest file.

Introducing the Manifest

The foundation for any Android application is the manifest file: `AndroidManifest.xml`. This will be in your project root for Eclipse projects and in your app module’s `src/main/` directory for classic Android Studio projects.

Here is where you declare what is inside your application — the activities, the services, and so on. You also indicate how these pieces attach themselves to the overall Android system; for example, you indicate which activity (or activities) should appear on the device’s main menu (a.k.a., launcher).

When you create your application, you will get a starter manifest generated for you. For a simple application, offering a single activity and nothing else, the auto-generated manifest will probably work out fine, or perhaps require a few minor modifications. On the other end of the spectrum, the manifest file for the Android API demo suite is over 1,000 lines long. Your production Android applications will probably fall somewhere in the middle.

As mentioned previously, some items can be defined in both the manifest and in a `build.gradle` file. The approach of putting that stuff in the manifest still works, and

for Eclipse it is the only option, as Eclipse is not looking at a `build.gradle` file. For Android Studio users, you will probably use the Gradle file and not have those common elements be defined in the manifest.

Things In Common Between the Manifest and Gradle

There are a few key items that can be defined in the manifest and can be overridden in `build.gradle` statements. These items are fairly important to the development and operation of our Android apps as well.

Package Name and Application ID

The root of all manifest files is, not surprisingly, a `manifest` element:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.empublite">
```

Note the `android` namespace declaration. You will only use the namespace on many of the attributes, not the elements (e.g., `<manifest>`, not `<android:manifest>`).

The biggest piece of information you need to supply on the `<manifest>` element is the package attribute.

The package attribute will always need to be in the manifest, even for Android Studio projects. The package attribute will control where some source code is generated for us, notably some `R` and `BuildConfig` classes that we will encounter later in the book.

Since the package value is used for Java code generation, it has to be a valid Java package name. Java convention says that the package name should be based on a reverse domain name (e.g., `com.commonware.empublite`), where you own the domain in question. That way, it is unlikely that anyone else will accidentally collide with the same name.

The package also serves as our app's default "application ID". This needs to be a unique identifier, such that:

- no two apps can be installed on the same device at the same time with the same application ID

- no two apps can be uploaded to the Play Store with the same application ID (and other distribution channels may have the same limitation)

By default, the application ID is the package value, but Android Studio users can override it in their Gradle build files. Specifically, inside of the `android` closure can be a `defaultConfig` closure, and inside of there can be an `applicationId` statement:

```
android {  
    // other stuff  
  
    defaultConfig {  
        applicationId "com.commonware.empublite"  
        // more other stuff  
    }  
}
```

Not only can Android Studio users override the application ID in the `defaultConfig` closure, but there are ways of having different application ID values for different scenarios, such as a debug build versus a release build. We will explore that more [later in the book](#).

minSdkVersion and targetSdkVersion

Your manifest may also contain a `<uses-sdk>` element as a child of the `<manifest>` element, to specify what versions of Android you are supporting. It can contain, among other things, `android:minSdkVersion` and `android:targetSdkVersion` attributes. Eclipse projects will always have this element. Android Studio projects may not have this element, because the values are defined as `minSdkVersion` and `targetSdkVersion` properties in the `defaultConfig` closure, where `applicationId` can be defined.

Of the two, the more critical one is `minSdkVersion`. This indicates what is the oldest version of Android you are testing with your application. The value of the attribute is an integer representing the Android [API level](#). So, if you are only testing your application on Android 4.1 and newer versions of Android, you would set your `minSdkVersion` to be 16.

You can also specify a `targetSdkVersion`. This indicates what version of Android you are thinking of as you are writing your code. If your application is run on a newer version of Android, Android may do some things to try to improve compatibility of your code with respect to changes made in the newer Android. Nowadays, most Android developers should specify a target SDK version of 15 or higher. We will start to explore more about the `targetSdkVersion` as we get deeper

into the book; for the moment, whatever your IDE gives you as a default value is probably a fine starting point.

The XML element looks like:

```
<uses-sdk android:minSdkVersion="15" android:targetSdkVersion="19" />
```

The corresponding entries in `build.gradle` go in the `defaultConfig` closure:

```
android {  
    // other stuff  
  
    defaultConfig {  
        applicationId "com.commonware.empublite"  
        minSdkVersion 15  
        targetSdkVersion 19  
        // more other stuff  
    }  
}
```

Version Code and Version Name

Your manifest can also specify `android:versionName` and `android:versionCode` attributes, up on the root `<manifest>` element. An Android Studio project, though, frequently skips those and defines them via `versionName` and `versionCode` properties in the `defaultConfig` closure.

These two values represent the versions of your application. The `versionName` value is what the user will see for a version indicator in the Applications details screen for your app in their Settings application:

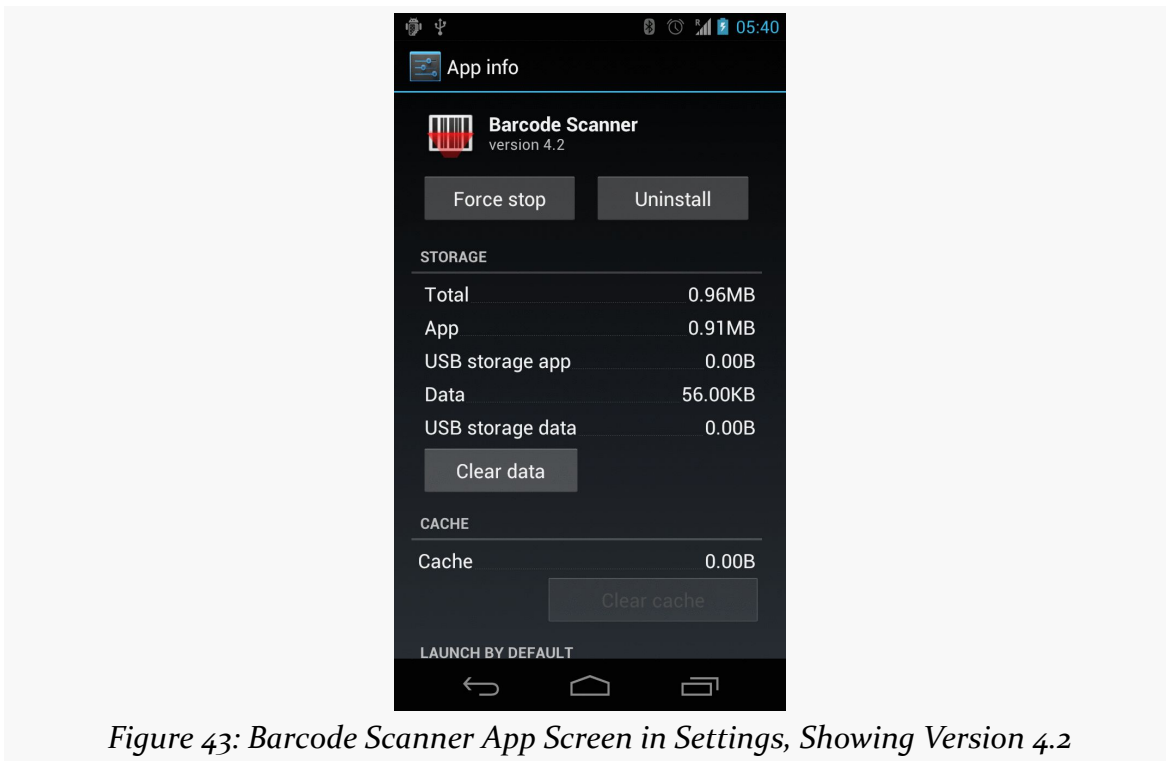

Figure 43: Barcode Scanner App Screen in Settings, Showing Version 4.2

Also, the version name is used by the Play Store listing, if you are distributing your application that way. The version name can be any string value you want.

The `versionCode`, on the other hand, must be an integer, and newer versions must have higher version codes than do older versions. Android and the Play Store will compare the version code of a new APK to the version code of an installed application to determine if the new APK is indeed an update. The typical approach is to start the version code at 1 and increment it with each production release of your application, though you can choose another convention if you wish. During development, you can leave these alone, but when you move to production, these attributes will matter greatly.

Other Gradle Items of Note

You will always have at least two statements directly in the `android` closure: `compileSdkVersion` and `buildToolsVersion`.

```
android {  
    compileSdkVersion 19  
    buildToolsVersion "21.1.2"  
}
```

INTRODUCING GRADLE AND THE MANIFEST

`compileSdkVersion` specifies the API level to be compiled against, usually as a simple API level integer (e.g., 19). An Eclipse project would pull this out of the `project.properties` file in the root of the project directory.

`buildToolsVersion` indicates the version of the Android SDK build tools that you wish to use with this project. While downloading the android plugin from Maven Central gives us parts of what is needed, it is not complete. The rest comes from the “Android SDK Build-tools” entry in the SDK Manager:

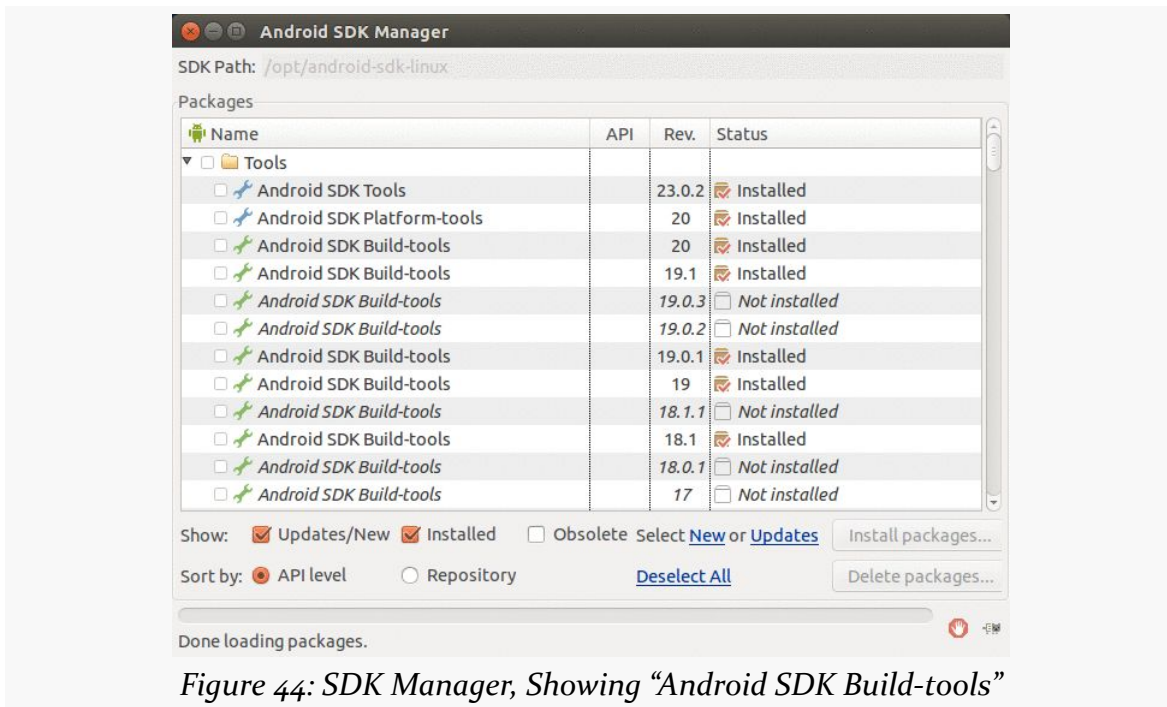

Figure 44: SDK Manager, Showing “Android SDK Build-tools”

Note that the SDK Manager will allow you to download the latest version of the build tools used by Gradle (appearing as 20 in the above screenshot) plus prior versions (e.g., 18.0.1 and 17 in the above screenshot). This corresponds with the `buildToolsVersion` in your `build.gradle` file.

So, your android closure could look like:

```
android {
    compileSdkVersion 19
    buildToolsVersion "20.0.0"

    defaultConfig {
        applicationId "com.commonware.empublite"
        versionCode 1
        versionName "1.0"
    }
}
```

```
    minSdkVersion 15
    targetSdkVersion 18
}
}
```

Eclipse does not really have the notion of a configurable build tools version, so there is no analogue for `buildToolsVersion` in an Eclipse project.

Where's the GUI?

You might wonder why we have to slog through all of this Groovy code and wonder if there is some GUI for affecting Gradle settings.

The answer is yes... and no.

There is [the project structure dialog](#), that allows you to maintain some of this stuff. And you are welcome to try it. However, the more complex your build becomes, the more likely it is that the GUI will not suffice, and you will need to work with the Gradle build files more directly. Hence, this book will tend to focus on the build files.

The Rest of the Manifest

Not everything in the manifest can be overridden in the Gradle build files. Here are a few key items that will always appear in the manifest, regardless of whether this project is to be built by Android Studio, Eclipse, or other means.

An Application For Your Application

In your initial project's manifest, the primary child of the `<manifest>` element is an `<application>` element.

By default, when you create a new Android project, you get a single `<activity>` element inside the `<application>` element:

```
<?xml version="1.0"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.skeleton"
    android:versionCode="1"
    android:versionName="1.0">

    <application>
        <activity
            android:name="Now"
            ...
        >
    </application>
</manifest>
```

```
    android:label="Now">
    <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
    </activity>
</application>
</manifest>
```

This element supplies `android:name` for the class implementing the activity, `android:label` for the display name of the activity, and (sometimes) an `<intent-filter>` child element describing under what conditions this activity will be displayed. The stock `<activity>` element sets up your activity to appear in the launcher, so users can choose to run it. As we'll see later in this book, you can have several activities in one project, if you so choose.

The `android:name` attribute, in this case, has a bare Java class name (`Now`). Sometimes, you will see `android:name` with a fully-qualified class name (e.g., `com.commonware.android.skeleton.Now`). Sometimes, you will see a Java class name with a single dot as a prefix (e.g., `.Now`). Both `Now` and `.Now` refer to a Java class that will be in your project's package — the one you declared in the `package` attribute of the `<manifest>` element.

Supporting Multiple Screens

Android devices come with a wide range of screen sizes, from 2.8" tiny smartphones to 46" TVs. Android divides these into four buckets, based on physical size and the distance at which they are usually viewed:

1. Small (under 3")
2. Normal (3" to around 4.5")
3. Large (4.5" to around 10")
4. Extra-large (over 10")

By default, your application will support small and normal screens. It also will support large and extra-large screens via some automated conversion code built into Android.

To truly support all the screen sizes you want, you should consider adding a `<supports-screens>` element to your manifest. This enumerates the screen sizes you have explicit support for. For example, if you are providing custom UI support for large or extra-large screens, you will want to have the `<supports-screens>` element.

So, while the starting manifest file works, handling multiple screen sizes is something you will want to think about.

You wind up with an element akin to:

```
<supports-screens
  android:largeScreens="true"
  android:normalScreens="true"
  android:smallScreens="false"
  android:xlargeScreens="true" />
```

Much more information about providing solid support for all screen sizes, including samples of the `<supports-screens>` element, will be found later in this book as we cover large-screen strategies.

Other Stuff

As we proceed through the book, you will find other elements being added to the manifest, such as:

- `<uses-permission>`, to tell the user that you need permission to use certain device capabilities, such as accessing the Internet
- `<uses-feature>`, to tell Android that you need the device to have certain features (e.g., a camera), and therefore your app should not be installed on devices lacking such features
- `<meta-data>`, for bits of information needed by particular extensions to Android, such as the Google Play Services library.

These and other elements will be introduced elsewhere in the book.

Learning More About Gradle

This book will go into more about Gradle, both in the core chapters and in the trails. But, the focus will be on Gradle for Android, and Gradle itself offers a lot more than that. The Gradle Web site hosts [documentation](#), links to [Gradle-specific books](#), and links to [other Gradle educational resources](#).

At present, the Gradle for Android documentation is limited and mostly appears on [the Android tools site](#). Of note is [the top-level page about the new build system](#), and [the Gradle plugin user guide](#), though both may be out of date compared to the actual tools themselves.

Visit the Trails!

There are a few more chapters in this book getting into more details about the use of Gradle and Gradle for Android.

- [Gradle and Legacy Projects](#) is for developers who are looking to use Gradle with Eclipse-style projects
- [Gradle and Tasks](#) explains how we ask Gradle to do things on our behalf (“tasks”), such as compile our APK for us
- [Gradle and the New Project Structure](#) gets into why the project structure changed from what we used with Eclipse, and what capabilities we get as a result, including the ability to configure “build types” and “product flavors”
- [Gradle and Dependencies](#) covers more about the “artifacts” mentioned earlier in this chapter, as ways we can get packaged libraries automatically added to our projects via just a couple of lines in our build.gradle files

There is also the [“Advanced Gradle for Android Tips”](#) chapter for other Gradle topics, and [the chapter on manifest merging in Gradle](#).

Tutorial #3 - Changing Our Manifest (and Gradle File)

As we build EmPubLite, we will need to make a number of changes to our project's manifest. In this tutorial, we will take care of a couple of these changes, to show you how to manipulate the `AndroidManifest.xml` file. Future tutorials will make yet more changes.

Android Studio users will also get their first chance to work with the `build.gradle` file.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository.

Some Notes About Relative Paths

In these tutorials, you will see references to relative paths, like `AndroidManifest.xml`, `res/layout/`, and so on.

Android Studio users should interpret these paths as being relative to the `app/src/main/` directory within the project, except as otherwise noted. So, for example, Step #1 below will ask you to open `AndroidManifest.xml` — that file can be found in `app/src/main/AndroidManifest.xml` from the project root.

Step #1: Supporting Screens

Our application will restrict its supported screen sizes. Tablets make for ideal ebook readers. Phones can also be used, but the smaller the phone, the more difficult it will be to come up with a UI that will let the user do everything that is needed, yet still have room for more than a sentence or two of the book at a time.

We will get into screen size strategies and their details [later in this book](#). For the moment, though, we will add a `<supports-screens>` element to keep our application off “small” screen devices (under 3” diagonal size).

Android Studio users can double-click on `AndroidManifest.xml` in the project explorer.

As a child of the root `<manifest>` element, add a `<supports-screens>` element as follows:

```
<supports-screens
  android:largeScreens="true"
  android:normalScreens="true"
  android:smallScreens="false"
  android:xlargeScreens="true"/>
```

Step #2: Adding our Minimum and Target SDK Versions

We also need to teach our IDE our minimum SDK version (how old a version of Android we will support) and our target SDK version (what version of Android we were thinking of when writing our code).

Classically, we would accomplish this by adding a `<uses-sdk>` element to the manifest. Nowadays, Android Studio users *could* do the same, but instead we will follow the Android Studio convention and add those values to `build.gradle`.

Double-click on `app/build.gradle`, off of the project root, in the Project Explorer.

You should see in there a `defaultConfig` closure that looks like:

```
defaultConfig {
    applicationId "com.commonware.empublite"
    versionCode 1
    versionName "1.0"
}
```

TUTORIAL #3 - CHANGING OUR MANIFEST (AND GRADLE FILE)

Add the `minSdkVersion 15` and `targetSdkVersion 18` statements to it, so that it looks like:

```
defaultConfig {
    applicationId "com.commonware.empublite"
    versionCode 1
    versionName "1.0"
    minSdkVersion 15
    targetSdkVersion 18
}
```

You may get a yellow banner at the top of the editor, indicating that a “project sync” is requested. If you do, click the “Sync Now” link in that banner to synchronize the *.iml files with the changes you made to this `build.gradle` file. If you do not get this banner, choose `Tools > Android > Project Sync with Gradle Files` from the main menu to accomplish the same thing. You will want to sync any time you change `build.gradle`, to ensure that the rest of Android Studio is paying attention to your changes.

In Our Next Episode...

... we will [make some changes to the resources](#) of our tutorial project

Some Words About Resources

It is quite likely that by this point in time, you are “chomping at the bit” to get into actually writing some code. This is understandable. That being said, before we dive into the Java source code for our stub project, we really should chat briefly about resources.

Resources are static bits of information held outside the Java source code. Resources are stored as files under the `res/` directory in your Android project layout (whether that is in the project root for Eclipse or in the `main/` sourceset for Android Studio). Here is where you will find all your icons and other images, your externalized strings for internationalization, and more.

These are separate from the Java source code not only because they are different in format. They are separate because you can have *multiple* definitions of a resource, to use in different circumstances. For example, with internationalization, you will have strings for different languages. Your Java code will be able to remain largely oblivious to this, as Android will choose the right resource to use, from all candidates, in a given circumstance (e.g., choose the Spanish string if the device’s locale is set to Spanish).

We will cover all the details of these resource sets [later in the book](#). Right now, we need to discuss the resources in use by our stub project, plus one more.

This chapter will refer to the `res/` directory. Android Studio users will find that in the `app/src/main/` directory of their project, while Eclipse users will find it in the project root directory.

String Theory

Keeping your labels and other bits of text outside the main source code of your application is generally considered to be a very good idea. In particular, it helps with internationalization (I18N) and localization (L10N). Even if you are not going to translate your strings to other languages, it is easier to make corrections if all the strings are in one spot instead of scattered throughout your source code.

Plain Strings

Generally speaking, all you need to do is have an XML file in the `res/values` directory (typically named `res/values/strings.xml`), with a `resources` root element, and one child `string` element for each string you wish to encode as a resource. The `string` element takes a `name` attribute, which is the unique name for this string, and a single text element containing the text of the string:

```
<resources>
  <string name="quick">The quick brown fox...</string>
  <string name="laughs">He who laughs last...</string>
</resources>
```

One tricky part is if the string value contains a quote or an apostrophe. In those cases, you will want to escape those values, by preceding them with a backslash (e.g., These are the times that try men\'s souls). Or, if it is just an apostrophe, you could enclose the value in quotes (e.g., "These are the times that try men's souls.").

For example, a project's `strings.xml` file could look like this:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <string name="app_name">EmPubLite</string>
  <string name="hello_world">Hello world!</string>

</resources>
```

We can reference these string resources from various locations, in our Java source code and elsewhere. For example, the `app_name` string resource often is used in the `AndroidManifest.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.empublite"
  android:versionCode="1"
```

SOME WORDS ABOUT RESOURCES

```
android:versionName="1.0">

<supports-screens
  android:largeScreens="true"
  android:normalScreens="true"
  android:smallScreens="false"
  android:xlargeScreens="true"/>

<uses-sdk
  android:minSdkVersion="15"
  android:targetSdkVersion="18"/>

<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/AppTheme">
  <activity
    android:name="EmPubLiteActivity"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
</application>

</manifest>
```

Here, the `android:label` attribute of the `<application>` element refers to the `app_name` string resource. This will appear in a few places in the application, notably in the list of installed applications in Settings. So, if you wish to change how your application's name appears in these places, simply adjust the `app_name` string resource to suit.

The syntax `@string/app_name` tells Android “find the string resource named `app_name`”. This causes Android to scan the appropriate `strings.xml` file (or any other file containing string resources in your `res/values/` directory) to try to find `app_name`.

Styled Text

Many things in Android can display rich text, where the text has been formatted using some lightweight HTML markup: ``, `<i>`, and `<u>`. Your string resources support this, simply by using the HTML tags as you would in a Web page:

```
<resources>
  <string name="b">This has <b>bold</b> in it.</string>
  <string name="i">Whereas this has <i>italics</i>!</string>
</resources>
```

CDATA. CDATA Run. Run, DATA, Run.

Since a strings resource XML file is an XML file, if your message contains <, >, or & characters (other than the formatting tags listed above), you will need to use a CDATA section:

```
<string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of the TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
</string>
```

The Directory Name

Our string resources in our stub project are in the `res/values/strings.xml` file. Since this directory name (`values`) has no suffixes, the string resources in that directory will be valid for any sort of situation, including any locale for the device. We will need additional directories, with distinct `strings.xml` files, to support other languages. We will cover how to do that [later in this book](#).

Editing String Resources

If you double-click on a string resource file, like `res/values/strings.xml`, in Android Studio, you are presented the XML and edit it that way.

When you double-click on a string resource file in Eclipse, you will be greeted with a list of all the string resources that have been defined:

SOME WORDS ABOUT RESOURCES

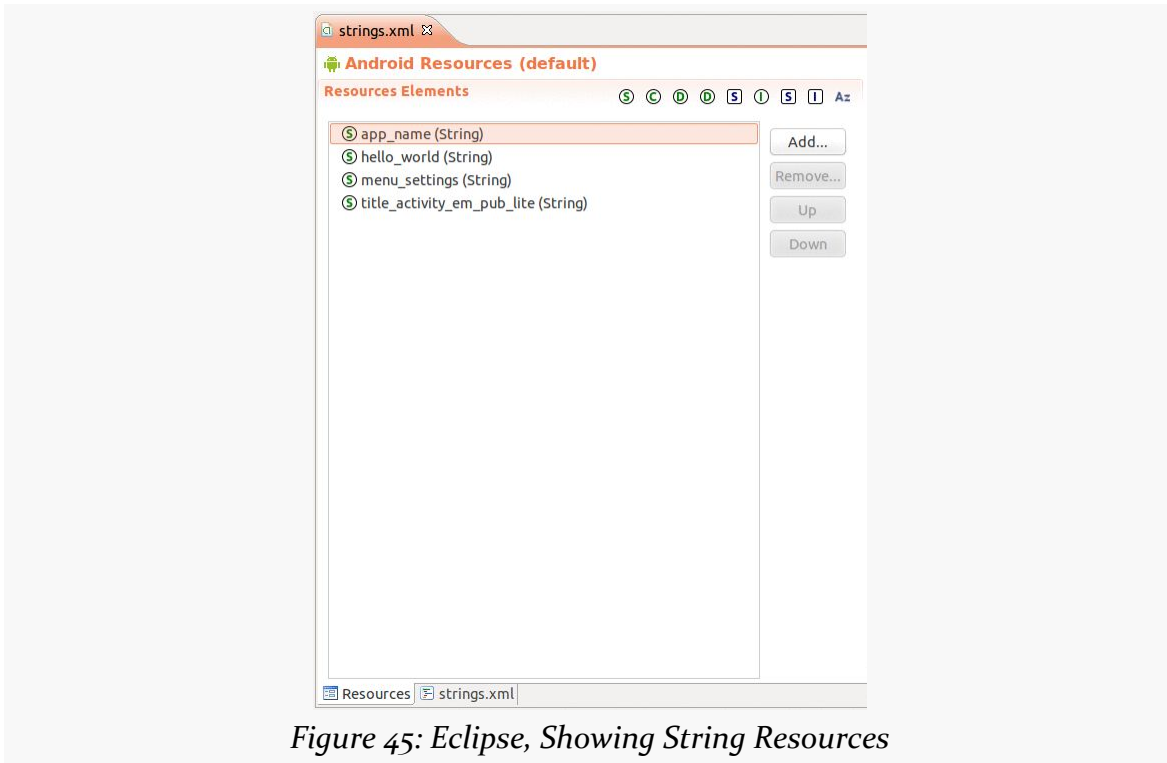

Figure 45: Eclipse, Showing String Resources

Clicking on a resource allows you to edit its name and value:

Figure 46: Eclipse, Editing Existing String Resources

Clicking the “Add...” button to the right of the list of strings brings up a dialog where you can add another resource to this file, typically a string:

SOME WORDS ABOUT RESOURCES

Figure 47: Eclipse, Add String Resource Dialog

Choosing “String” in that dialog and clicking OK will add another (empty) string resource to the list, where you can fill in the name and value.

You can always click on the `strings.xml` sub-tab to bring up an XML editor on the string resources if you prefer.

Got the Picture?

Android supports images in the PNG, JPEG, and GIF formats. GIF is officially discouraged, however; PNG is the overall preferred format. Android also supports some proprietary XML-based image formats, though we will not discuss those at length until later in the book.

The default directory for these so-called drawable resources is `res/drawable/`. Any images found in there can be referenced from Java code or from other places (such as the manifest), regardless of device characteristics.

However, your stub project does not have a `res/drawable/` directory.

Instead, it has directories like `res/drawable-mdpi/` and `res/drawable-hdpi/`.

SOME WORDS ABOUT RESOURCES

These refer to distinct resource sets. The suffixes (e.g., `-mdpi`, `-hdpi`) are filters, indicating under what circumstances the images stored in those directories should be used. Specifically, `-ldpi` indicates images that should be used on devices with low-density screens (around 120 dots-per-inch, or “dpi”). The `-mdpi` suffix indicates resources for medium-density screens (around 160dpi), `-hdpi` indicates resources for high-density screens (around 240dpi), `-xhdpi` indicates resources for extra-high-density screens (around 320dpi), `-xxhdpi` indicates extra-extra-high-density screens (around 480dpi), `-xxxhdpi` indicates extra-extra-extra-high-density screens (around 640dpi), and so on.

Inside each of those directories, you will see an `ic_launcher.png` file (along with perhaps other icons). This is the stock icon that will be used for your application in the home screen launcher. Each of the images is of the same icon, but the higher-density icons have more pixels. The objective is for the image to be roughly the same physical size on every device, using higher densities to have more detailed images.

For example, our `EmPubLite` tutorial project has directories like `res/drawable-hdpi/`, `res/drawable-xhdpi/`, and `res/drawable-mdpi/`. Each could contain a stock launcher icon (`ic_launcher.png`) tailored for that density.

Our `AndroidManifest.xml` file then references our `ic_launcher` icon in the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.empublite"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"
        android:xlargeScreens="true"/>

    <uses-sdk
        android:minSdkVersion="15"
        android:targetSdkVersion="18"/>

    <application
        android:allowBackup="false"
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/AppTheme">
        <activity
            android:name="EmPubLiteActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

SOME WORDS ABOUT RESOURCES

```
        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
</activity>
</application>
</manifest>
```

Note that the manifest simply refers to `@drawable/ic_launcher`, telling Android to find a drawable resource named `ic_launcher`. The resource reference does not indicate the file type of the resource — there is no `.png` in the resource identifier. This means you cannot have `ic_launcher.png` and `ic_launcher.jpg` in the same project, as they would both be identified by the same identifier. You will need to keep the “base name” (filename sans extension) distinct for all of your images.

Also, the `@drawable/ic_launcher` reference does not mention what screen density to use. That is because *Android* will choose the right screen density to use, based upon the device that is running your app. You do not have to worry about it explicitly, beyond having multiple copies of your icon.

If Android detects that the device has a screen density for which you lack an icon, Android will take the next-closest one and scale it.

Ummmm... But I Have “Mipmaps”?

If you create a project through the Android Studio new-project wizard, the resulting project will not have much in the way of `res/drawable-*/` directories, but instead will have “mipmap” directories (e.g., `res/mipmap-hdpi/`).

This is almost completely undocumented. In effect, they are the same as drawables, other than you reference them as `@mipmap/...` instead of `@drawable/...`

(if you are a seasoned Android developer and are reading this section: while drawable resources might be removed when packaging an APK, such as for the Gradle for Android `split` system for making density-specific editions of an app, mipmap resources are left alone, apparently)

For most drawables, put them in `res/drawable-*/` directories, even if you have to create those directories yourself.

Getting Android Drawables

You may be a graphic designer. Or, you may know a graphic designer. In those cases, you can create your own icons, ideally following Google's [design guidelines for iconography](#).

If you are not a graphic designer and do not have ready access to one, you will need to come up with your drawable resources by other means. There are plenty of icon libraries available from third parties, but the following sections outline some of Google's solutions for putting icons in your app.

Android Icon Set Wizard

Both Android Studio and Eclipse offer an icon set wizard. This wizard is designed to take a starter image and give you icons, in a variety of densities, that use that image for a particular image role, such as your home screen launcher icon (the `ic_launcher.png` file we saw earlier in this chapter).

On Eclipse, the Icon Set Wizard will give you drawable resources. On Android Studio, the Image Asset Wizard will give you mipmap resources if you choose to create launcher icons, and it will give you drawable resources if you choose to create other sorts of icons.

Android Asset Studio

The same basic functionality found in the icon set wizard is available outside any IDE (but inside a Chrome browser) in the form of the [Android Asset Studio](#). As with the icon set wizard, you can choose a type of icon (e.g., launcher icons):

SOME WORDS ABOUT RESOURCES

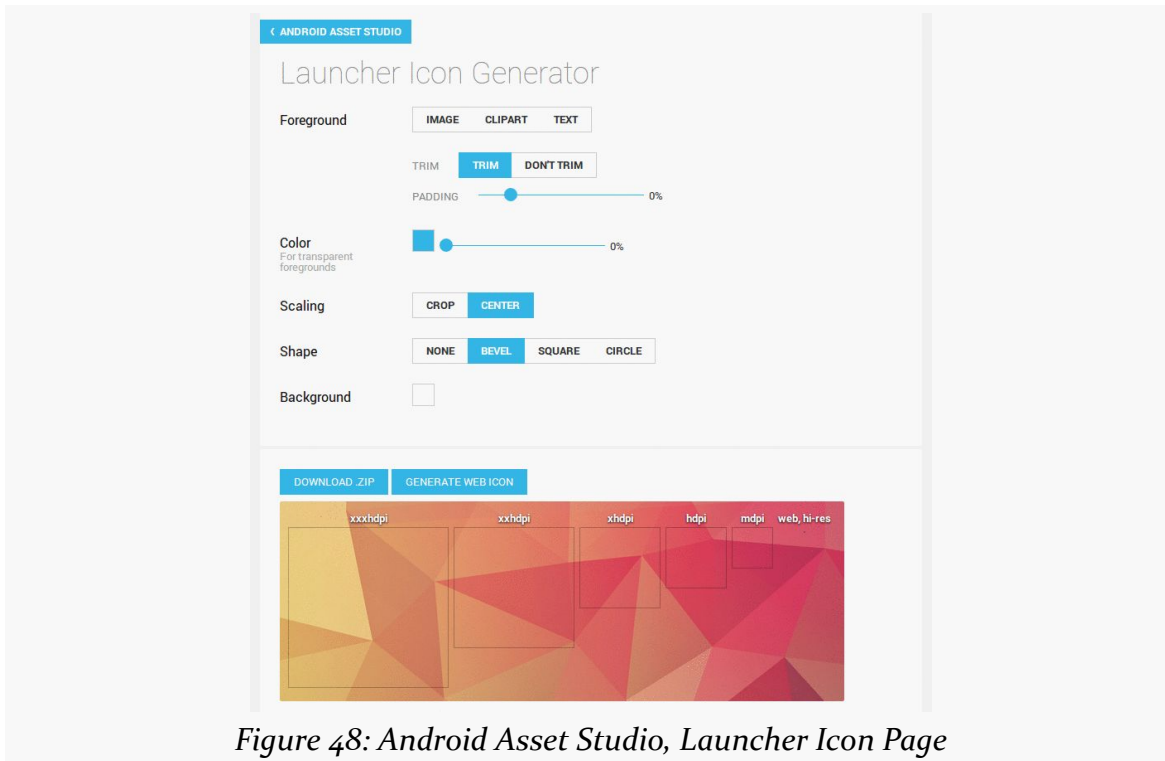

Figure 48: Android Asset Studio, Launcher Icon Page

Then you can specify the source of the base image (uploaded file, canned clipart, or free-form text) and other configuration data. The resulting images, in various densities, can be downloaded at the bottom of the page:

SOME WORDS ABOUT RESOURCES

Figure 49: Android Asset Studio, Launcher Icon Page, with Icons

Editing Existing Drawable Resources

Neither Android Studio nor Eclipse ships with any sort of image editor that you could use for PNG and JPEG files. Hence, you will find yourself editing these images using other tools outside of your IDE.

Dimensions

Dimensions are used in several places in Android to describe distances, such as a widget's size. There are several different units of measurement available to you:

1. px means hardware pixels, whose size will vary by device, since not all devices have the same screen density
2. in and mm for inches and millimeters, respectively, based on the actual size of the screen
3. pt for points, which in publishing terms is 1/72nd of an inch (again, based on the actual physical size of the screen)

SOME WORDS ABOUT RESOURCES

4. dip (or dp) for density-independent pixels — one dip equals one hardware pixel for a ~160dpi resolution screen, but one dip equals two hardware pixels on a ~320dpi screen
5. sp for scaled pixels, where one sp equals one dip for normal font scale levels, increasing and decreasing as needed based upon the user's chosen font scale level in Settings

Dimension resources, by default, are held in a `dimens.xml` file in the `res/values/` directory that also holds your strings.

To encode a dimension as a resource, add a `dimen` element to `dimens.xml`, with a `name` attribute for your unique name for this resource, and a single child text element representing the value:

```
<resources>
  <dimen name="thin">10dip</dimen>
  <dimen name="fat">1in</dimen>
</resources>
```

In a layout, you can reference dimensions as `@dimen/...`, where the ellipsis is a placeholder for your unique name for the resource (e.g., `thin` and `fat` from the sample above). In Java, you reference dimension resources by the unique name prefixed with `R.dimen.` (e.g., `Resources.getDimension(R.dimen.thin)`).

While our stub project does not use dimension resources, we will be seeing them soon enough.

Editing Dimension Resources

As with most types of XML resources, Android Studio just has you edit the XML directly, when you double-click on the resource in the project explorer.

In Eclipse, much like editing string resources, when you double-click on a dimension resource file (e.g., `res/values/dimens.xml`), you will be presented with a list of existing dimensions. Clicking on one will let you change its definition:

SOME WORDS ABOUT RESOURCES

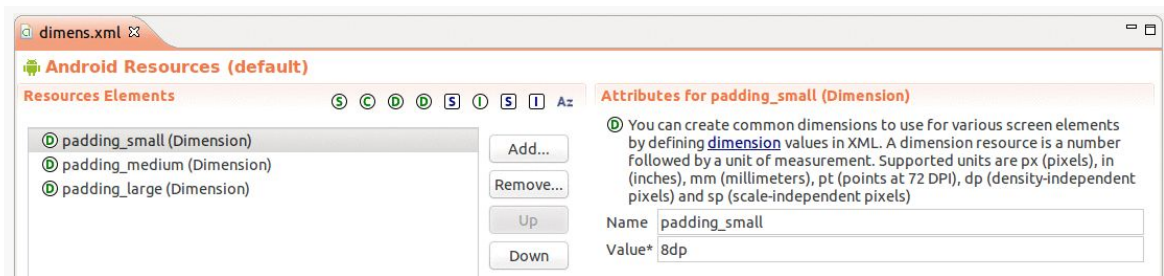

Figure 50: Eclipse, Editing Existing Dimension Resources

Clicking the “Add...” button to the right of the list of dimensions brings up a dialog where you can add another resource to this file, typically a dimension. Choosing “Dimension” and clicking “OK” will add an empty dimension resource to the file, for which you can supply the name and value.

And, as always, you can click on a sub-tab with the name of your file (e.g., `dimens.xml`) to bring up an XML editor on that resource’s content:

Figure 51: Eclipse, Dimension Resources in XML Editor

The Resource That Shall Not Be Named... Yet

Your stub project also has a `res/layout/` directory, in addition to the ones described above. That is for UI layouts, describing what your user interface should look like. We will get into the details of that type of resource as we start examining our user interfaces in [an upcoming chapter](#).

Tutorial #4 - Adjusting Our Resources

Our EmPubLite project has some initial resources. However, the defaults are not what we want for the long term. So, in addition to adding new resources in future tutorials, we will fix the ones we already have in this tutorial.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Step #1: Changing the Name

Our application shows up everywhere as “EmPubLite”:

- In the title bar of our activity
- As the caption under our icon in the home screen launcher
- In the Application list in the Settings app
- And so on

We should change that to be “EmPub Lite”, adding a space for easier reading, and to illustrate that this is a “lite” version of the full EmPub application.

Double-click on the `res/values/strings.xml` file in your project explorer.

In the XML editor for the string resources, you will find an element that looks like:

```
<string name="app_name">EmPubLite</string>
```

Change the text node in this element to EmPub Lite. Then save your changes, giving you something like:

```
<resources>
  <string name="app_name">EmPub Lite</string>
  <string name="hello_world">Hello world!</string>
</resources>
```

Step #2: Changing the Icon

The build tools provide us with a stock icon to use for the launcher — the actual image used varies by Android tools release. However, we can change it to something else. For example, we could use the icon portion of the CommonsWare logo:

Figure 52: CommonsWare

Download the molecule PNG file from [the CommonsWare Web site](http://commonsware.com) and save it somewhere on your development machine.

Then, right-click over the `res/` directory in your main sourceset in the project explorer, and choose `New > Image Asset` from the context menu. That will bring up the Asset Studio wizard:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

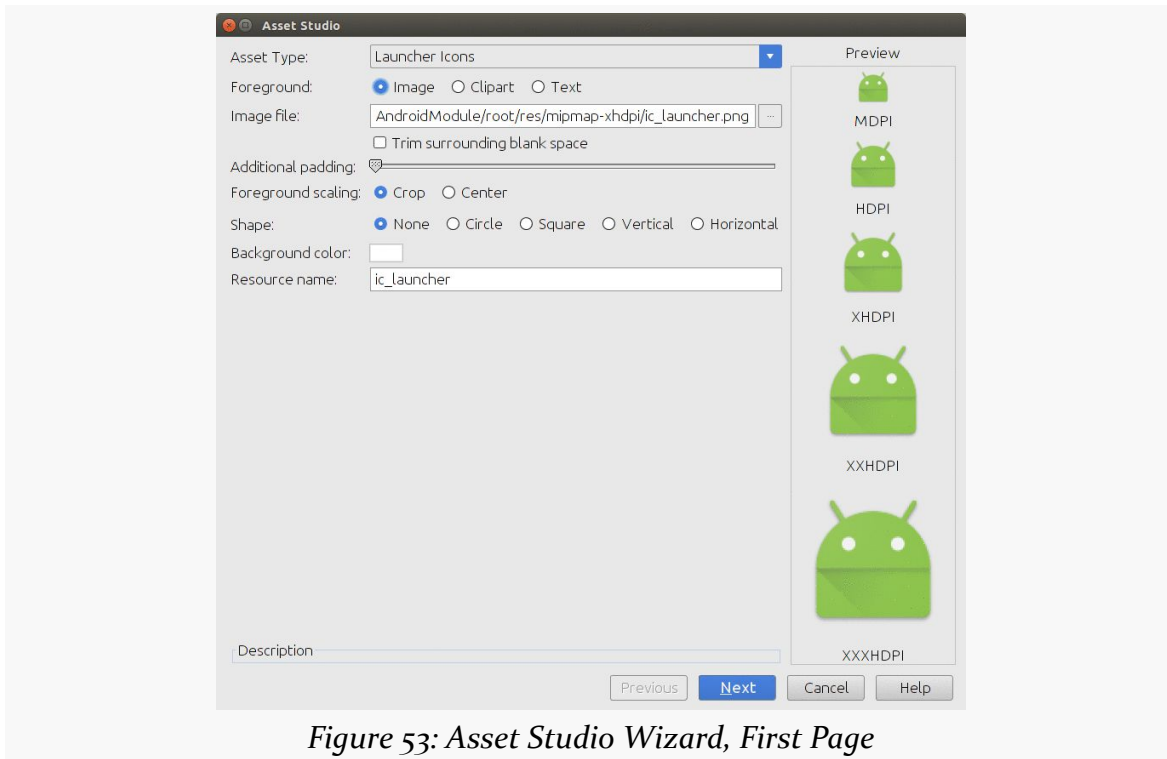

Figure 53: Asset Studio Wizard, First Page

Click the “..” to the right of the “Image file” field and choose the `molecule.png` file that you downloaded. Also, toggle the “Foreground scaling” radio group to “Center” instead of “Crop”. This should give you a preview of what the icons will look like:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

Figure 54: Asset Studio Wizard, First Page, After Loading Image

Leave the rest of the wizard alone, then click Next to proceed to the next page:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

Figure 55: Asset Studio Wizard, Second Page

You should get a red warning towards the bottom, indicating that if you finish the wizard, you will overwrite existing files. This is expected, as we are trying to replace the old `ic_launcher.png` files with new ones. So, go ahead and click **Finish**.

Step #3: Running the Result

If you run the resulting app, you will see that it shows up with the new name and icon, such as in the launcher:

TUTORIAL #4 - ADJUSTING OUR RESOURCES

Figure 56: EmPubLite with New Icons

However, Eclipse users may encounter some problems in running the result. When you wish to run an Android project from Eclipse, you must pay close attention to what part of the Eclipse UI has the focus. The focus *cannot* be on an editor for a resource. So, for example, had you gone back to the string resource editor, done some changes there, then attempted to run the project, nothing would have happened.

Instead, the focus has to be pretty much anywhere else for the Run option in the toolbar to work:

- On the manifest
- On some Java code
- On the Package Explorer

This is a bug, one that will hopefully get fixed someday. However, since that preceding sentence has been in this book for a couple of years, and since Eclipse support is largely abandoned by Google, it is unlikely that the bug will be addressed any time soon.

In Our Next Episode...

... we will [add a progress indicator](#) to the UI of our tutorial project.

The Theory of Widgets

There is a decent chance that you have already done work with widget-based UI frameworks. In that case, much of this chapter will be review, though checking out the section on the [absolute positioning anti-pattern](#) should certainly be worthwhile.

There is a chance, though, that your UI background has come from places where you have not been using a traditional widget framework, where either you have been doing all of the drawing yourself (e.g., game frameworks) or where the UI is defined more in the form of a document (e.g., classic Web development). This chapter is aimed at you, to give you some idea of what we are talking about when discussing the notion of widgets and containers.

What Are Widgets?

Wikipedia has [a nice definition of a widget](#):

In computer programming, a widget (or control) is an element of a graphical user interface (GUI) that displays an information arrangement changeable by the user, such as a window or a text box. The defining characteristic of a widget is to provide a single interaction point for the direct manipulation of a given kind of data. In other words, widgets are basic visual building blocks which, combined in an application, hold all the data processed by the application and the available interactions on this data.

(quote from the 7 March 2014 version of the page)

Take, for example, this Android screen:

THE THEORY OF WIDGETS

Figure 57: A Sample Android Screen

Here, we see:

- some text, like “Phone-only, unsynced co...” and “PHONE”
- an icon of a contact “Rolodex” card
- some data entry fields with hints like “Name” and “Company”
- some “spinner” drop-down lists (the items with the arrowheads pointing southeast)
- some gray divider lines

Everything listed above is a widget. The user interface for most Android screens (“activities”) is made up of one or more widgets.

This does not mean that you cannot do your own drawing. In fact, all the existing widgets are implemented via low-level drawing routines, which you can use for everything from your own custom widgets to games.

This also does not mean that you cannot use Web technologies. In fact, we will see later in this book [a widget designed to allow you to embed Web content](#) into an Android activity.

However, for most non-game applications, your Android user interface will be made up of several widgets.

Size, Margins, and Padding

Widgets have some sort of size, since a zero-pixel-high, zero-pixel-wide widget is not especially user-friendly. Sometimes, that size will be dictated by what is inside the widget itself, such as a label (`TextView`) having a size dictated by the text in the label. Sometimes, that size will be dictated by the size of whatever holds the widget (a “container”, described in the next section), where the widget wants to take up all remaining width and/or height. Sometimes, that size will be a specific set of dimensions.

Widgets can have margins. As with CSS, margins provide separation between a widget and anything adjacent to it (e.g., other widgets, edges of the screen). Margins are really designed to help prevent widgets from running right up next to each other, so they are visually distinct. Some developers, however, try to use margins as a way to hack “absolute positioning” into Android, which is an anti-pattern that we will examine [later in this chapter](#).

Widgets can have padding. As with CSS, padding provides separation between the contents of a widget and the widget’s edges. This is mostly used with widgets that have some sort of background, like a button, so that the contents of the widget (e.g., button caption) does not run right into the edges of the button, once again for visual distinction.

What Are Containers?

Containers are ways of organizing multiple widgets into some sort of structure. Widgets do not naturally line themselves up in some specific pattern — we have to define that pattern ourselves.

In most GUI toolkits, a container is deemed to have a set of children. Those children are widgets, or sometimes other containers. Each container has its basic rule for how it lays out its children on the screen, possibly customized by requests from the children themselves.

Common container patterns include:

- put all children in a row, one after the next
- put all children in a column, one below the next
- arrange the children into a table or grid with some number of rows and columns

- anchor the children to the sides of the container, according to requests made by those children
- anchor the children to other children in the container, according to requests made by those children
- stack all children, one on top of the next
- and so on

In the sample activity above, the dominant pattern is a column, with things laid out from top to bottom. Some of those things are rows, with contents laid out left to right. However, as it turns out, the area with most of those widgets is scrollable.

Android supplies a handful of containers, designed to handle most common scenarios, including everything in the list above. You are also welcome to create your own custom containers, to implement business rules that are not directly supported by the existing containers.

Note that containers also have size, padding, and margins, just as widgets do.

The Absolute Positioning Anti-Pattern

You might wonder why all of these containers and such are necessary. After all, can't you just say that such-and-so widget goes at this pixel coordinate, and this other widget goes at that pixel coordinate, and so on?

Many developers have taken that approach — known as absolute positioning — over the years, to their eventual regret.

For example, many of you may have used Windows apps, back in the 1990's, where when you would resize the application window, the app would not really react all that much. You would expand the window, and the UI would not change, except to have big empty areas to the right and bottom of the window. This is because the developers simply said that such-and-so widget goes at this pixel coordinate, and this other widget goes at that pixel coordinate, **regardless of the actual window size**.

In modern Web development, you see this in the debate over [fixed versus fluid Web design](#). The consensus seems to be that fluid designs are better, though frequently they are more difficult to set up. Fluid Web designs can better handle differing browser window sizes, whether those window sizes are because the user resized their browser window manually, or because those window sizes are dictated by the

screen resolution of the device viewing the Web page. Fixed Web designs — effectively saying that such-and-so element goes at such-and-so pixel coordinate and so on — tend to be easier to build but adapt more poorly to differing browser window sizes.

In mobile, particularly with Android, we have a wide range of possible screen resolutions, from QVGA (320x240) to beyond 1080p (1920x1080), and many values in between. Moreover, any device manufacturer is welcome to create a device with whatever resolution they so desire – there are no rules limiting manufacturers to certain resolutions. Hence, as developers, having the Android equivalent of fluid Web designs is critical, and the way you will accomplish that is by sensible use of containers, avoiding absolute positioning. The containers (and, to a lesser extent, the widgets) will determine how extra space is employed, as the screens get larger and larger.

The Theme of This Section: Themes

In Web development, we have had stylesheets for quite a while. Through such Cascading Style Sheets (CSS) files, we can stipulate various rules about how our Web pages should look. This includes:

- Establishing a default look for certain HTML tags by tag name (e.g., setting the font and size for all `<h1>` and `<h2>` elements)
- Establishing a look for specific HTML elements by class or ID (e.g., setting the width of a specific `<div>` to a certain number of CSS pixels)

In Android, the equivalent concepts can be found in styles and themes. Styles are a collection of values for properties (e.g., have a foreground color of red). These can be applied to specific widgets (e.g., this label should adopt this style), or they can be employed by “themes” that provide the default look for all sorts of widgets and other elements of our UI.

Of course, you do not have to declare any theme for your app. Android will give you a default look-and-feel without any specific theme. That look-and-feel has varied over the years, though, affecting the visual fundamentals of various Android widgets. These themes have names by which we refer to them: `Theme`, `Theme.Holo`, and `Theme.Material`.

In the Beginning, There Was “Theme”, And It Was Meh

Way back in Android 1.0, the default theme was known simply as Theme. Technically, all themes inherit from Theme, much as how later CSS stylesheets effectively “inherit” the settings established by prior stylesheets.

The Theme UI had a particular look to it:

Figure 58: Labels, Fields, and Buttons in Theme

For example:

- At the top of the screen, we had a thin gray “title bar” with the name of our app
- The focused field (an EditText widget) had a bright orange outline, whereas normally it was a plain white rectangle
- The buttons (“OK” and “Cancel”) were... well... buttons

Holo, There!

Android 3.0 (API Level 11) introduced a new default theme, Theme.Holo, with the so-called “holographic widget theme”. This changed the look of our UI somewhat:

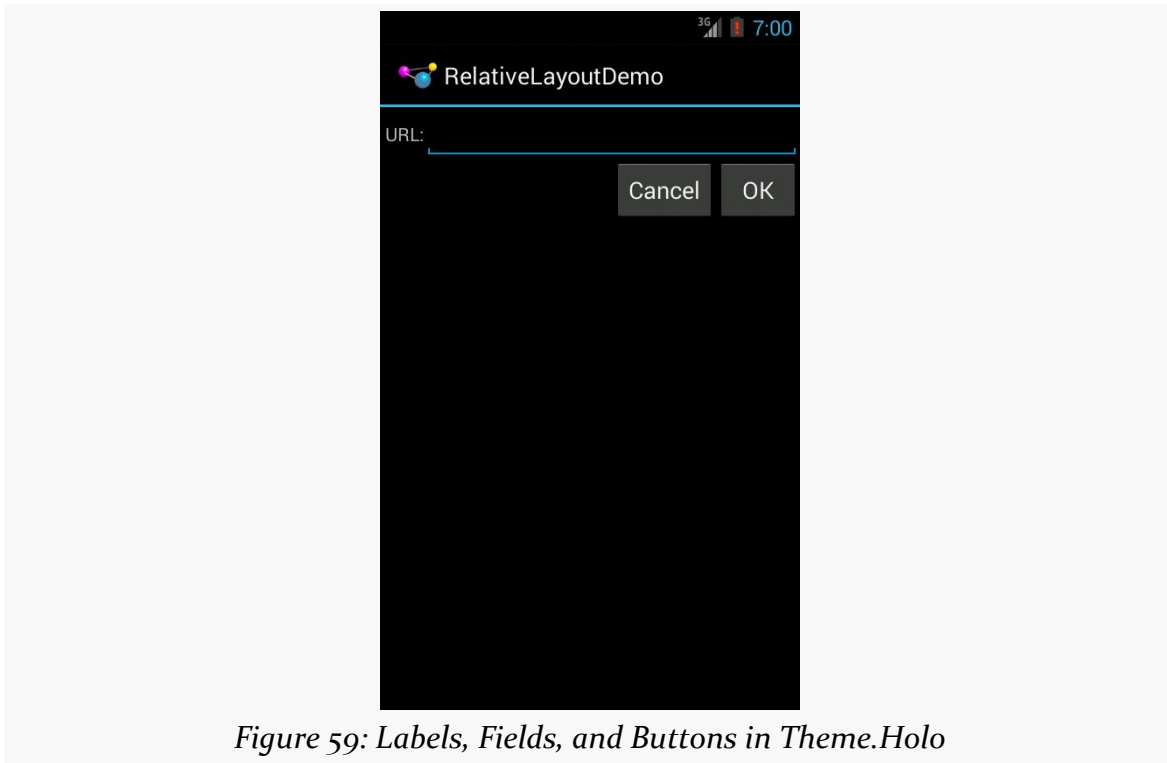

Figure 59: Labels, Fields, and Buttons in Theme.Holo

Now:

- At the top of the screen, we have an “action bar”, containing our app’s logo and name
- The focused field has a blue “underbracket”, whereas normally it is gray
- The buttons are styled slightly differently, with a bigger font, alternative backgrounds, etc.

Considering the Material

Android 5.0 changed the default theme yet again, to `Theme.Material`:

Figure 60: Labels, Fields, and Buttons in Theme.Material

Now:

- The action bar at the top of the screen no longer shows the app icon
- Our field is indicated by an underline, which is teal when focused or gray when unfocused
- The buttons are now forced into all-caps font, with a slightly smaller font size and subtly different background than we had with Theme.Holo

Doing More with Themes

Of course, we can do a lot more than just use these. There are other stock themes, with different characteristics. Furthermore, we can customize the themes, by defining our own (inheriting from a stock theme) and changing some of the properties (e.g., replacing the teal color with something else).

We will get much more into creating custom styles and themes [later in the book](#).

However, we will see the effects of Theme, Theme.Holo, and Theme.Material on stock widgets in [an upcoming chapter](#).

The Android User Interface

The project you created in [an earlier tutorial](#) was just the default files generated by the Android build tools — you did not write any Java code yourself. In this chapter, we will examine the basic Java code and resources that make up an Android activity.

The Activity

The Java source code that you maintain will be in a standard Java-style tree of directories based upon the Java package you chose when you created the project (e.g., `com.commonware.android` results in `com/commonware/android/`). Where those files reside depends upon what tools you are using:

- Android Studio will have that source, by default, in `app/src/main/java/` off of the top-level project root
- Eclipse will have that source be in `src/` off of the top-level project root

If you checked the checkbox in your IDE's new-project wizard to create an activity, you will have, in the innermost directory, a Java source file representing an activity class.

A very simple activity looks like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.os.Bundle;

public class EmPubLiteActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

```
}  
}
```

Dissecting the Activity

Let's examine this Java code piece by piece:

```
package com.commonware.empublite;  
  
import android.app.Activity;  
import android.os.Bundle;
```

By default, the package declaration is the same as the one you used when creating the project. And, like any other Java project, you need to import any classes you reference. Most of the Android-specific classes are in the `android` package.

Remember that not every Java SE class is available to Android programs! Visit the [Android class reference](#) to see what is and is not available.

```
public class EmPubLiteActivity extends Activity {
```

Activities are public classes, inheriting from the `android.app.Activity` base class (or, possibly, from some other class that itself inherits from `Activity`). You can have whatever data members you decide that you need, though the initial code has none.

```
@Override  
protected void onCreate(Bundle savedInstanceState) {  
    super.onCreate(savedInstanceState);  
    setContentView(R.layout.main);  
}
```

The `onCreate()` method is invoked when the activity is started. We will discuss the `Bundle` parameter to `onCreate()` [in a later chapter](#). For the moment, consider it an opaque handle that all activities receive upon creation.

The first thing you normally should do in `onCreate()` is chain upward to the superclass, so the stock Android activity initialization can be done. The only other statement in our stub project's `onCreate()` is a call to `setContentView()`. This is where we tell Android what the user interface is supposed to be for our activity.

This raises the question: what does `R.layout.main` mean? Where did this `R` come from?

To explain that, we need to start thinking about layout resources and how resources are referenced from within Java code.

Using XML-Based Layouts

As noted in the previous chapter, Android uses a series of widgets and containers to describe your typical user interface. These all inherit from an `android.view.View` base class, for things that can be rendered into a standard widget-based activity.

While it is technically possible to create and attach widgets and containers to our activity purely through Java code, the more common approach is to use an XML-based layout file. Dynamic instantiation of widgets is reserved for more complicated scenarios, where the widgets are not known at compile-time (e.g., populating a column of radio buttons based on data retrieved off the Internet).

With that in mind, it's time to break out the XML and learn how to lay out Android activity contents that way.

What Is an XML-Based Layout?

As the name suggests, an XML-based layout is a specification of its widgets' relationships to each other — and to containers — encoded in XML format. Specifically, Android considers XML-based layouts to be resources, and as such layout files are stored in the `res/layout/` directory inside your Android project (or, as we will see later, other layout resource sets, like `res/layout-land/` for layouts to use when the device is held in landscape). As has been noted elsewhere in this book, the location of `res/` is either in the project root for Eclipse or in `app/src/main/` for Android Studio.

Each XML file contains a tree of elements specifying a layout of widgets and containers that make up one `View`. The attributes of the XML elements are properties, describing how a widget should look or how a container should behave. For example, if a `Button` element has an attribute value of `android:textStyle = "bold"`, that means that the text appearing on the face of the button should be rendered in a boldface font style.

For example, here is a `res/layout/main.xml` file that could be used with the aforementioned activity:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
```

```
android:layout_width="match_parent"
android:layout_height="match_parent"
tools:context=".EmPubLiteActivity">

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerHorizontal="true"
    android:layout_centerVertical="true"
    android:text="@string/hello_world"/>

</RelativeLayout>
```

The class name of a widget or container — such as `RelativeLayout` or `TextView` — forms the name of the XML element. Since `TextView` is an Android-supplied widget, we can just use the bare class name. If you create your own widgets as subclasses of `android.view.View`, you would need to provide a full package declaration as well (e.g., `com.commonware.android.MyWidget`).

The root element needs to declare the Android XML namespace (`xmlns:android="http://schemas.android.com/apk/res/android"`). All other elements will be children of the root and will inherit that namespace declaration.

The attributes are properties of the widget or container, describing what it should look and work like. For example, the `android:layout_centerHorizontal="true"` attribute on the `TextView` element indicates that the `TextView` should be centered within its `RelativeLayout` parent.

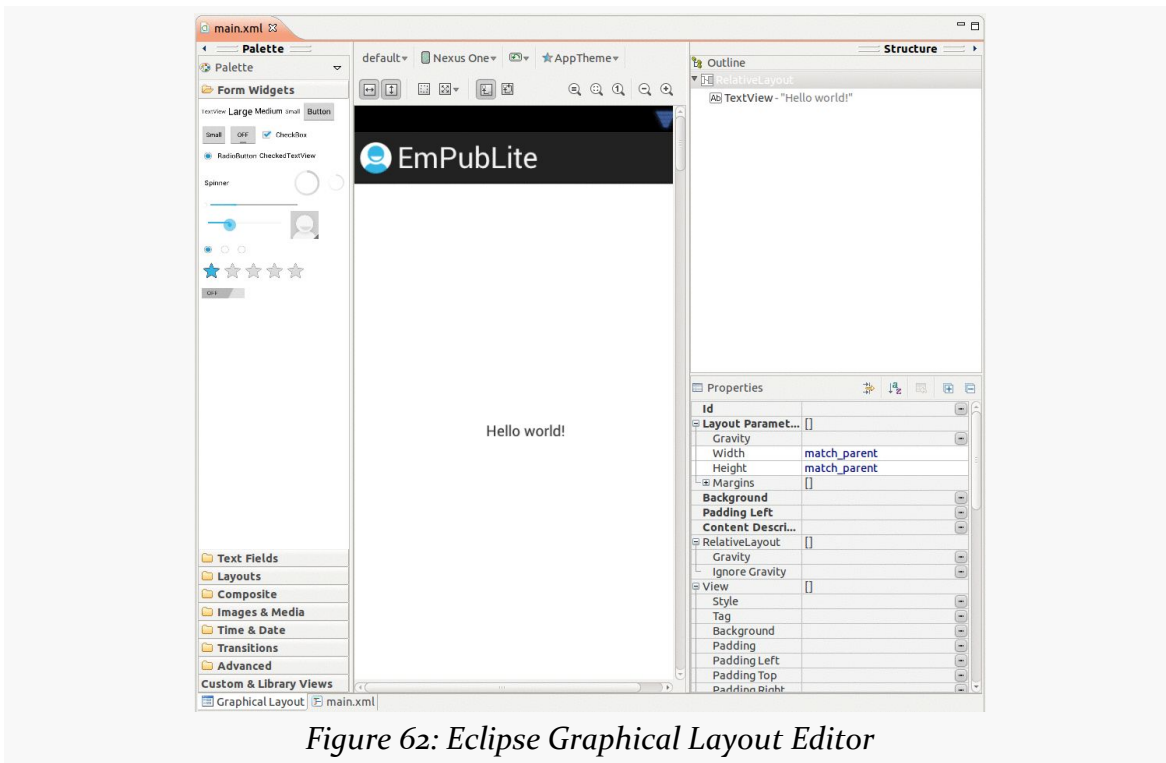

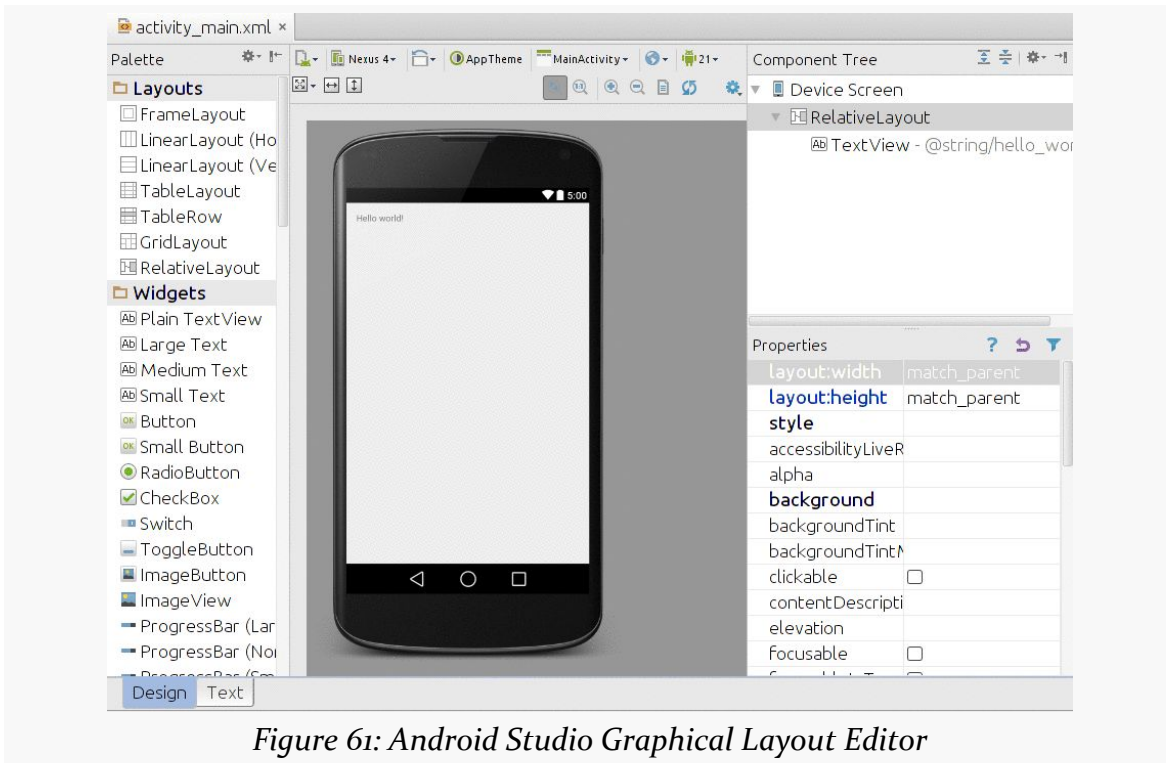

We will get into details about these attributes, their possible values, and their uses, in upcoming chapters. Note that those attributes in the `tools` namespace (e.g., `tools:context`) are there solely to support the Android build tools, and do not affect the runtime execution of your project.

Android's SDK ships with a tool (`aapt`) which uses the layouts. This tool will be automatically invoked by your Android tool chain (e.g., Android Studio, Eclipse). Of particular importance to you as a developer is that `aapt` generates an `R.java` source file, allowing you to access layouts and widgets within those layouts directly from your Java code. In other words, this is where that magic `R` value used in `setContentView()` comes from. We will discuss that a bit more [later in this chapter](#).

XML Layouts and Your IDE

If you are using Android Studio or Eclipse, and you double-click on the `res/layout/main.xml` file in your project, you will not initially see that XML. Instead, you will be taken to the graphical layout editor:

THE ANDROID USER INTERFACE

A sub-tab (e.g., “Text” on Android Studio) will show you the raw XML. The default “Design” or “Graphical Layout” sub-tab, though, shows you a preview of what your layout would look like, if it were to be used for an activity. The “Palette” on the left shows all sorts of widgets and containers, which you can drag into the preview area to add an instance of your chosen widget or container to your layout. Right-clicking over a widget or container will give you an extensive context menu to configure the item, and the toolbar immediately above the preview area will let you configure common properties of a selected widget or container.

We will go into much more detail about using the graphical layout editor in [an upcoming chapter](#), as we start to work more with specific widgets and containers.

Why Use XML-Based Layouts?

Almost everything you do using XML layout files can be achieved through Java code. For example, you could use `setText()` to have a button display a certain caption, instead of using a property in an XML layout. Since XML layouts are yet another file for you to keep track of, we need good reasons for using such files.

Perhaps the biggest reason is to assist in the creation of tools for view definition, such as the aforementioned graphical layout editors in Android Studio and Eclipse. Such GUI builders could, in principle, generate Java code instead of XML. The challenge is re-reading the definition in to support edits — that is far simpler if the data is in a structured format like XML than in a programming language. Moreover, keeping the generated bits separated out from hand-written code makes it less likely that somebody’s custom-crafted source will get clobbered by accident when the generated bits get re-generated. XML forms a nice middle ground between something that is easy for tool-writers to use and easy for programmers to work with by hand as needed.

Also, XML as a GUI definition format is becoming more commonplace. Microsoft’s [XAML](#), Adobe’s [Flex](#), Google’s [GWT](#), and Mozilla’s [XUL](#) all take a similar approach to that of Android: put layout details in an XML file and put programming smarts in source files (e.g., JavaScript for XUL). Many less-well-known GUI frameworks, such as [ZK](#), also use XML for view definition. While “following the herd” is not necessarily the best policy, it does have the advantage of helping to ease the transition into Android from any other XML-centered view description language.

Using Layouts from Java

Given that you have painstakingly set up the widgets and containers for your view in an XML layout file named `main.xml` stored in `res/layout/`, all you need is one statement in your activity's `onCreate()` callback to use that layout, as we saw in our stub project's activity:

```
setContentView(R.layout.main);
```

Here, `R.layout.main` tells Android to load in the layout (layout) resource (R) named `main.xml` (main).

Basic Widgets

Every GUI toolkit has some basic widgets: fields, labels, buttons, etc. Android's toolkit is no different in scope, and the basic widgets will provide a good introduction as to how widgets work in Android activities. We will examine a number of these in this chapter.

Common Concepts

There are a few core features of widgets that we need to discuss at the outset, before we dive into details on specific types of widgets.

Widgets and Attributes

As mentioned in [a previous chapter](#), widgets have attributes that describe how they should behave. In an XML layout file, these are literally XML attributes on the widget's element in the file. Usually, there are corresponding getter and setter methods for manipulating this attribute at runtime from your Java code.

If you visit the JavaDocs for a widget, such as [the JavaDocs for TextView](#), you will see an “XML Attributes” table near the top. This lists all of the attributes defined uniquely on this class, and the “Inherited XML Attributes” table that follows lists all those that the widget inherits from superclasses, such as `View`. Of course, the JavaDocs also list the fields, constants, constructors, and public/protected methods that you can use on the widget itself.

Those attributes can be modified by a “Properties” view in the graphical layout editor of the IDE:

BASIC WIDGETS

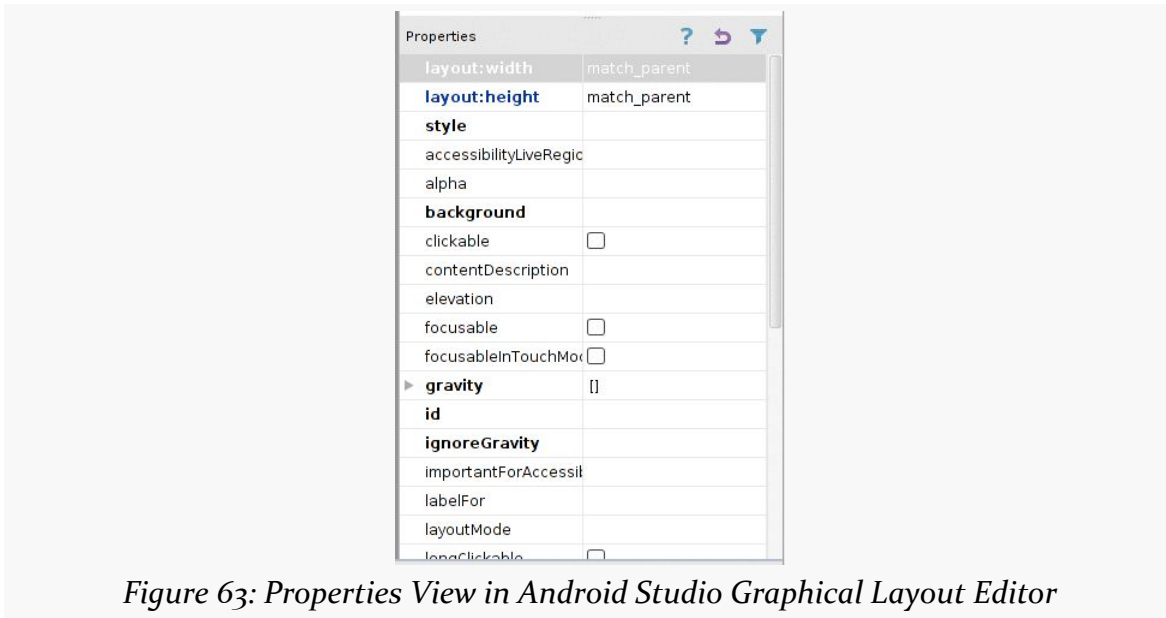

Figure 63: Properties View in Android Studio Graphical Layout Editor

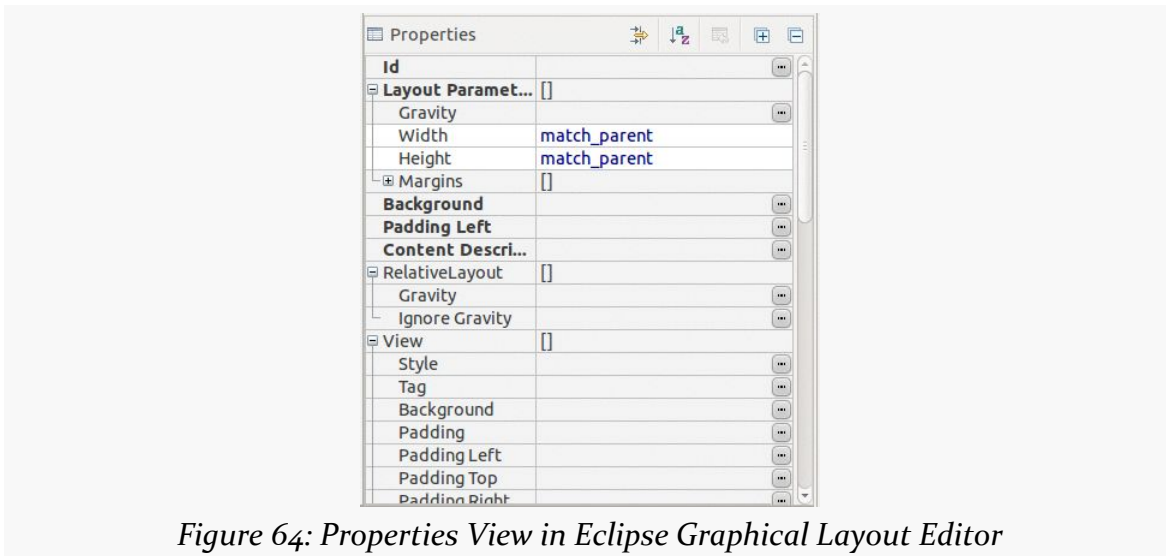

Figure 64: Properties View in Eclipse Graphical Layout Editor

This book does not attempt to explain each and every attribute on each and every widget. We will, however, cover the most popular widgets and the most commonly-used attributes on those widgets.

Referencing Widgets By ID

Many widgets and containers only need to appear in the XML layout file and do not need to be referenced in your Java code. For example, a static label (`TextView`) frequently only needs to be in the layout file to indicate where it should appear.

Anything you *do* want to use in your Java source, though, needs an `android:id`.

The convention is to use `@+id/...` as the `id` value, where the `...` represents your locally-unique name for the widget in question, for the first occurrence of a given `id` value in your layout file. The second and subsequent occurrences in the same layout file should drop the `+` sign.

Android provides a few special `android:id` values, of the form `@android:id/...` — we will see some of these in various chapters of this book.

To access our identified widgets, use `findViewById()`, passing it the numeric identifier of the widget in question. That numeric identifier was generated by Android in the `R` class as `R.id.something` (where `something` is the specific widget you are seeking).

This concept will become important as we try to attach listeners to our widgets (e.g., finding out when a checkbox is checked) or when we try referencing widgets from other widgets in a layout XML file (e.g., with `RelativeLayout`). All of this will be covered later in this chapter.

Size

Most of the time, we need to tell Android how big we want our widgets to be. Occasionally, this will be handled for us — we will see an example of that with `TableLayout` in [an upcoming chapter](#). But generally we need to provide this information ourselves.

To do that, you need to supply `android:layout_width` and `android:layout_height` attributes on your widgets in the XML layout file. These attributes' values have three flavors:

1. You can provide a specific dimension, such as `125dip` to indicate the widget should take up exactly a certain size (here, 125 density-independent pixels)

2. You can provide `wrap_content`, which means the widget should take up as much room as its contents require (e.g., a `TextView` label widget's content is the text to be displayed)
3. You can provide `match_parent`, which means the widget should fill up all remaining available space in its enclosing container

The latter two flavors are the most common, as they are independent of screen size, allowing Android to adjust your view to fit the available space.

Note that you will also see `fill_parent`. This is an older synonym for `match_parent`. `match_parent` is the recommended value going forward, but `fill_parent` will certainly work.

This chapter focuses on individual widgets. Size becomes much more important when we start combining multiple widgets on the screen at once, and so we will be spending more time on sizing scenarios in later chapters.

The `layout_` prefix on these attributes means that these attributes represent requests by the widget to its enclosing container. Whether those requests will be truly honored will depend a bit on what other widgets there are in the container and what *their* requests are.

Assigning Labels

The simplest widget is the label, referred to in Android as a `TextView`. Like in most GUI toolkits, labels are bits of text not editable directly by users. Typically, they are used to identify adjacent widgets (e.g., a “Name:” label before a field where one fills in a name).

In Java, you can create a label by creating a `TextView` instance. More commonly, though, you will create labels in XML layout files by adding a `TextView` element to the layout, with an `android:text` property to set the value of the label itself. If you need to swap labels based on certain criteria, such as internationalization, you may wish to use a string resource reference in `android:text` instead (e.g., `@string/label`).

For example, in [our last tutorial](#), we still are using the automatically-generated `res/layout/main.xml` file, containing, among other things, a `TextView`:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
```

BASIC WIDGETS

```
android:layout_width="match_parent"
android:layout_height="match_parent"
tools:context=".EmPubLiteActivity">

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_centerHorizontal="true"
    android:layout_centerVertical="true"
    android:text="@string/hello_world"/>

</RelativeLayout>
```

Android Studio Graphical Layout Editor

The TextView widget is available in the “Widgets” category of the Palette in the Android Studio graphical layout editor:

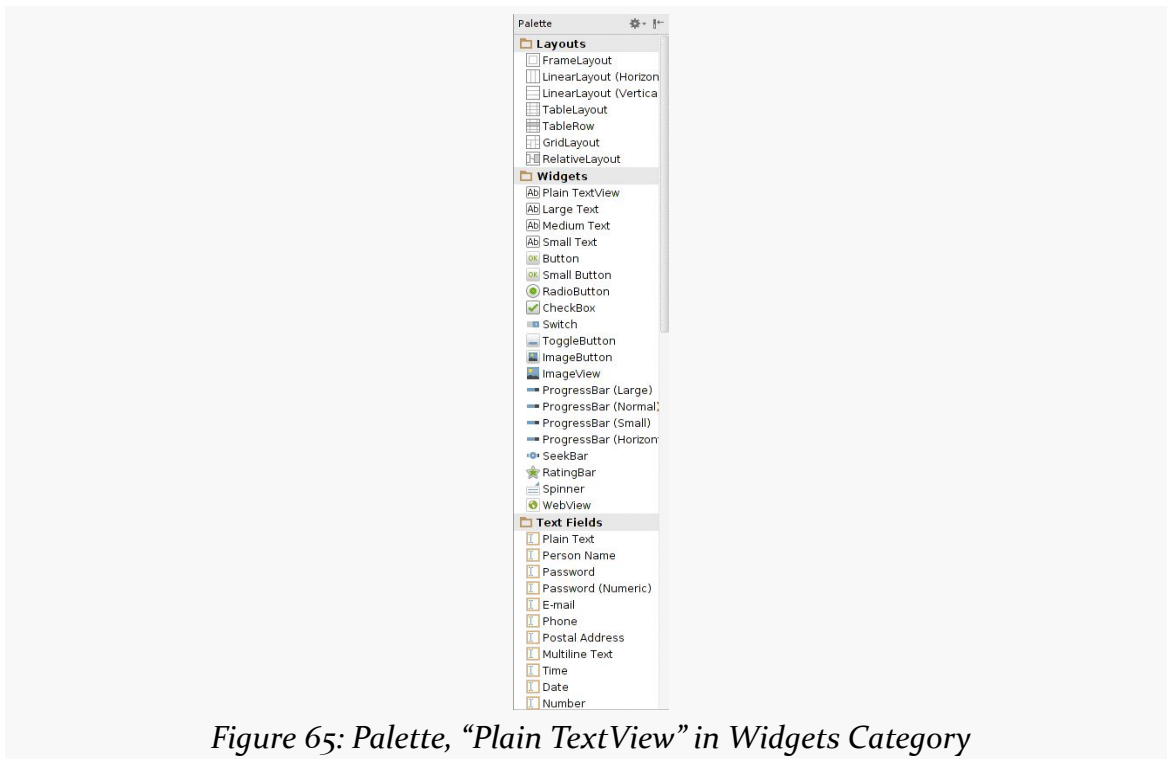

Figure 65: Palette, “Plain TextView” in Widgets Category

The “Large Text”, “Medium Text”, and “Small Text” items beneath “Plain TextView” are also TextView widgets, with different default font sizes.

You can drag that TextView from the palette into a layout file in the main editing area to add the widget to the layout. Or, drag it over the top of some container you

BASIC WIDGETS

see in the Component Tree pane of the editor to add it as a child of that specific container:

Figure 66: Component Tree Pane

Clicking on the resulting TextView in the Component Tree pane, or in the preview area, will set up the Properties pane with the various attributes of the widget, ready for you to change as needed:

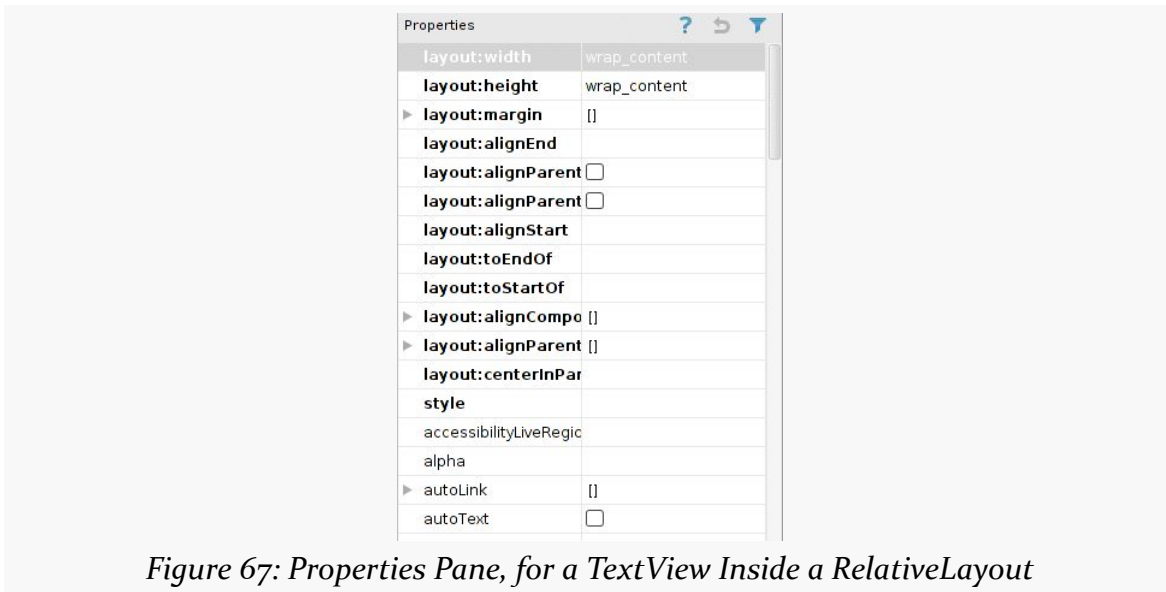

Figure 67: Properties Pane, for a TextView Inside a RelativeLayout

Editing the Text

The “Text” property will allow you to choose or define a string resource to serve as the text to be displayed:

BASIC WIDGETS

Figure 68: Properties Pane, with TextView “text” Property Selected

Clicking on the value will allow the property to be edited:

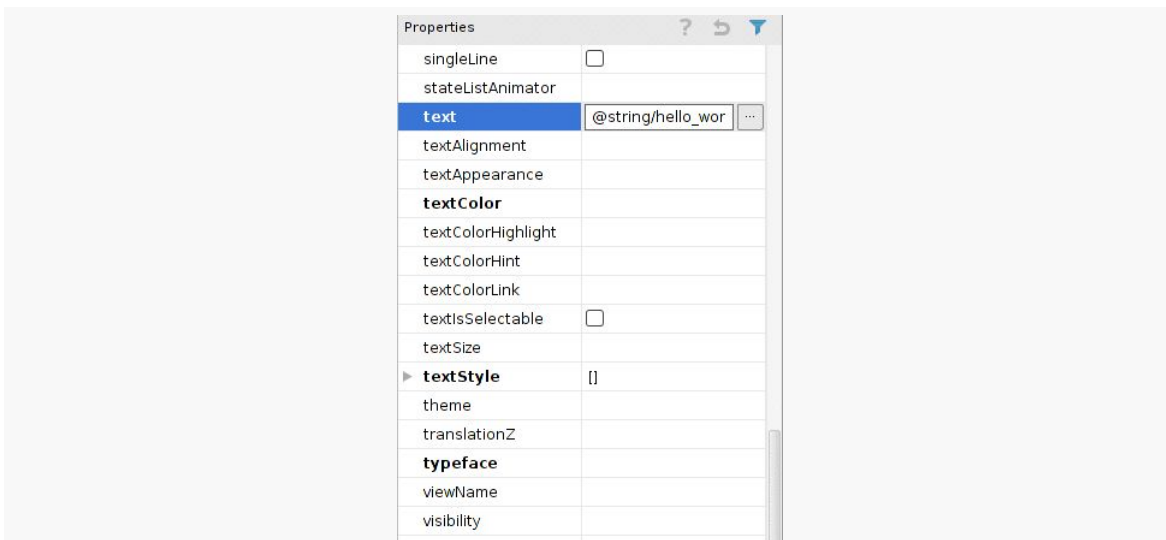

Figure 69: Properties Pane, with TextView “text” Property Editable

You can either type a literal string right in the Properties pane row, or you can click the “...” button to the right of the field to pick a string resource:

BASIC WIDGETS

Figure 70: String Resources Dialog

You can highlight one of those resources and click “OK” to use it. Or, in the bottom of that dialog, there is a “New Resource” drop-down. When viewing string resources, that drop-down will contain a single command: “New String Value...”. Choosing it will allow you to define a new string resource via another dialog:

BASIC WIDGETS

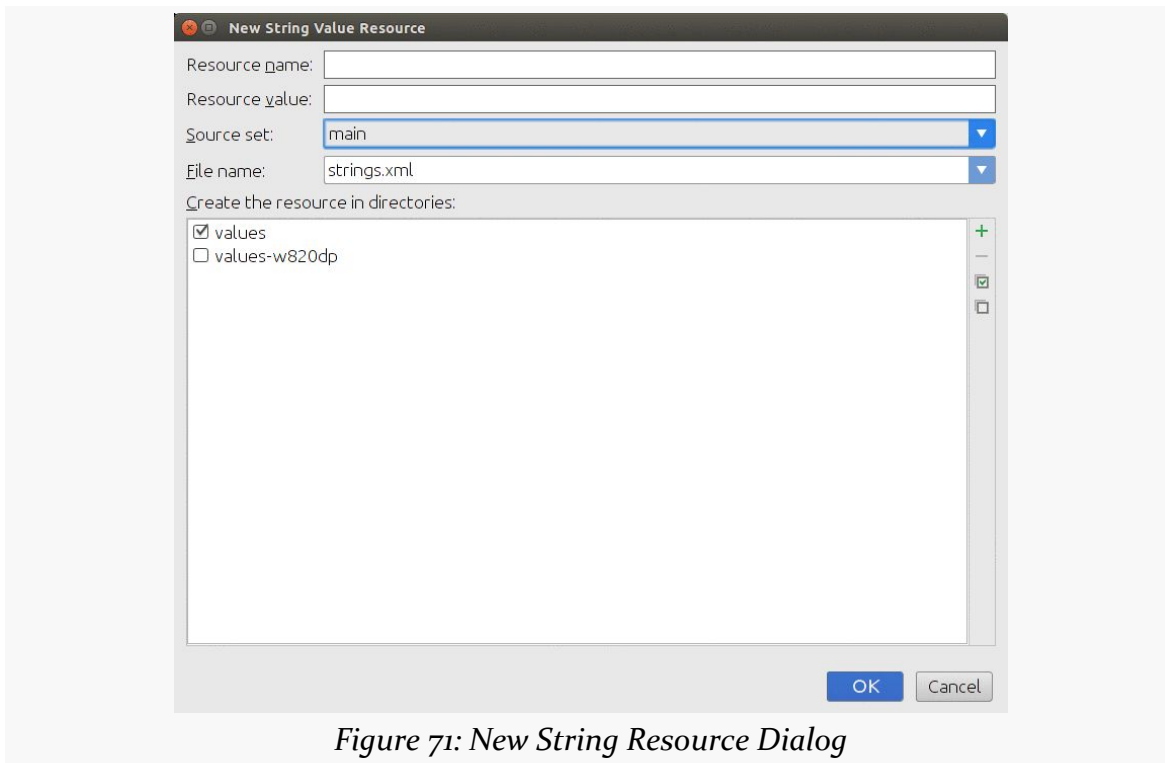

Figure 71: New String Resource Dialog

You can give your new string resource a name, the actual text of the string itself, the filename in which the string resource should reside (`strings.xml` by default), and which `values/` directory the string should go into (`values` by default). You will also choose the “source set” — for now, that will just be `main`. Once you accept the dialog, your new string resource will be applied to your `TextView`.

Editing the ID

The “id” property will allow you to change the `android:id` value of the widget:

BASIC WIDGETS

Figure 72: Properties Pane, with TextView “id” Property Selected

The value you fill in here is what goes after the `@+id/` portion (e.g., `textView2`).

Eclipse Graphical Layout Editor

The `TextView` widget is available in the “Form Widgets” portion of the Palette in the Eclipse graphical layout editor:

BASIC WIDGETS

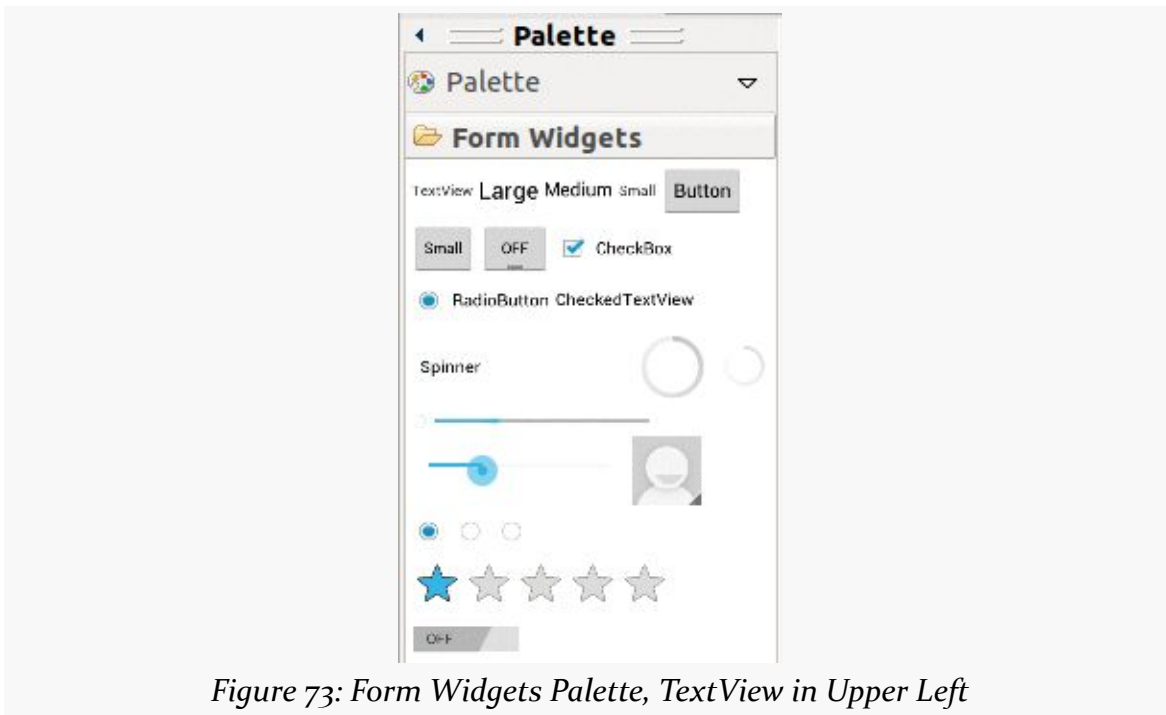

Figure 73: Form Widgets Palette, TextView in Upper Left

You can drag that TextView from the palette into a layout file in the main editing area to add the widget to the layout. Or, drag it over the top of some container you see in the Outline pane of the editor to add it as a child of that specific container:

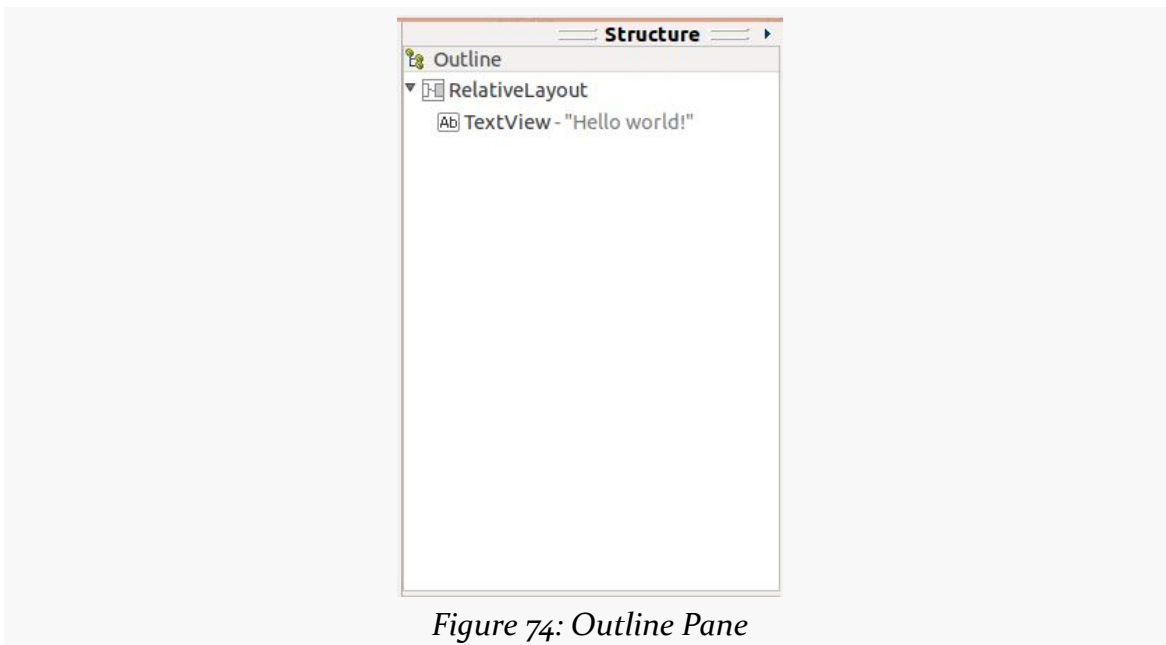

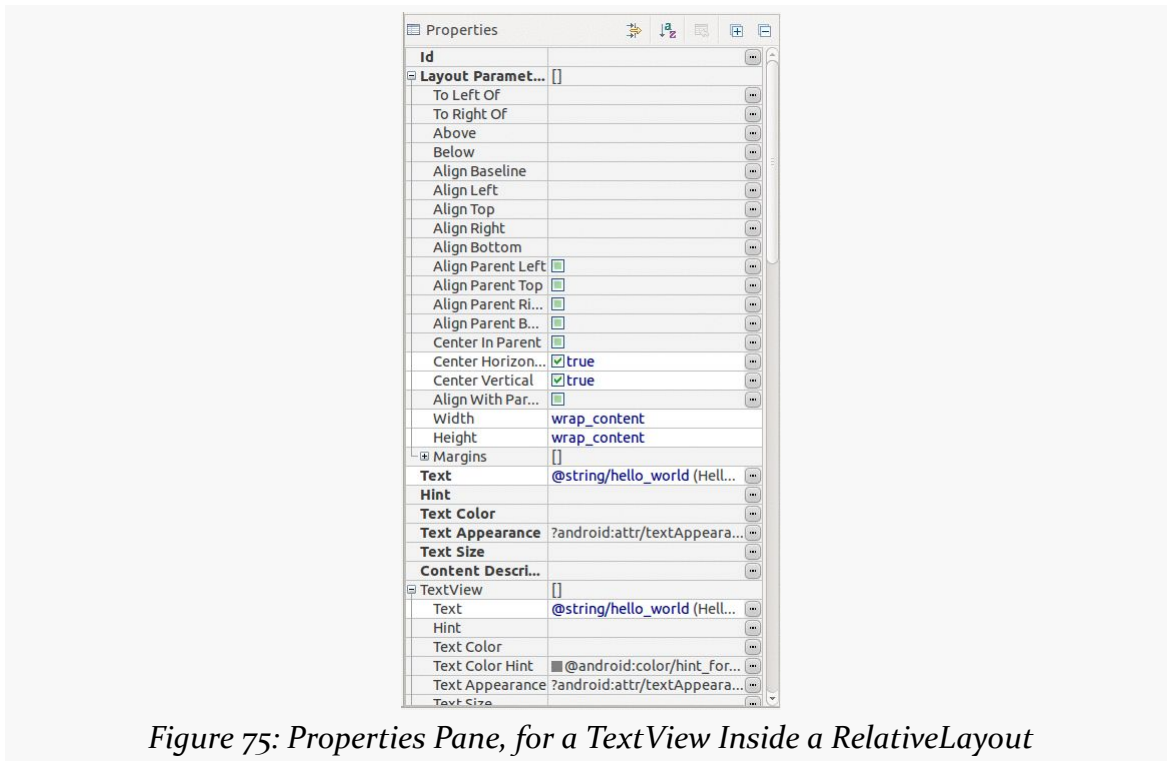

Figure 74: Outline Pane

BASIC WIDGETS

Clicking on the resulting `TextView` in the Outline pane, or in the preview area, will set up the Properties pane with the various attributes of the widget, ready for you to change as needed:

Editing the Text

The “Text” property will allow you to choose or define a string resource to serve as the text to be displayed. By default, it brings up a list of existing string resources:

Figure 76: String Resource Chooser

You can highlight one of those resources and click “OK” to use it, or you can click the “New String...” button to define a brand-new string resource.

Editing the ID

The “id” property will allow you to change the `android:id` value of the widget. Be sure to include the `@+id/` prefix, as Eclipse will not add that automatically for you.

Notable TextView Attributes

TextView has numerous other attributes of relevance for labels, such as:

1. `android:typeface` to set the typeface to use for the label (e.g., monospace)
2. `android:textStyle` to indicate that the typeface should be made bold (bold), italic (italic), or bold and italic (bold_italic)
3. `android:textColor` to set the color of the label’s text, in RGB hex format (e.g., `#FF0000` for red) or ARGB hex format (e.g., `#88FF0000` for a translucent red)

These attributes, like most others, can be modified through the Properties pane.

BASIC WIDGETS

For example, in the [Basic/Label](#) sample project, you will find the following layout file:

```
<?xml version="1.0" encoding="utf-8"?>
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/profound"
/>
```

Just that layout alone, with the stub Java source provided by Android's project builder (e.g., `android create project`) and appropriate string resources, gives you:

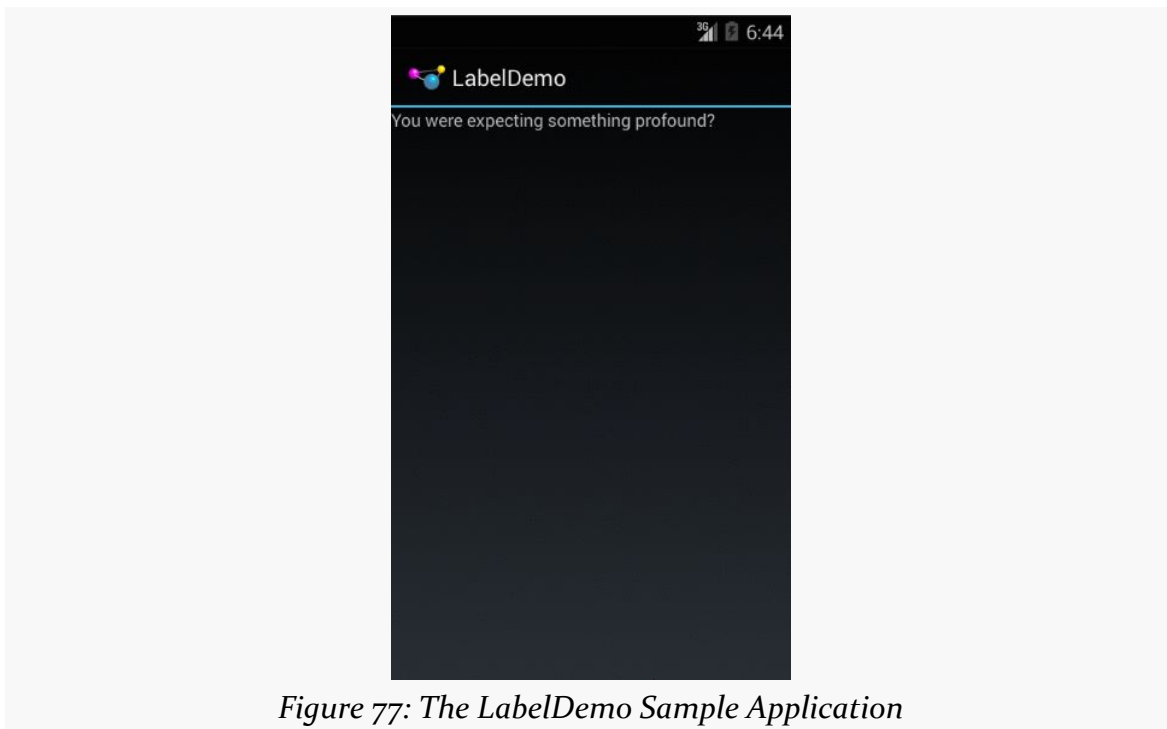

Figure 77: The LabelDemo Sample Application

A Commanding Button

Android has a `Button` widget, which is your classic push-button “click me and something cool will happen” widget. As it turns out, `Button` is a subclass of `TextView`, so everything discussed in the preceding section in terms of formatting the face of the button still holds.

For example, in the [Basic/Button](#) sample project, you will find the following layout file:

BASIC WIDGETS

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/button1"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/button" />

</LinearLayout>
```

Just that layout alone, with the stub Java source provided by Android's project builder (e.g., `android create project`) and appropriate string resources, gives you:

Figure 78: Button Widget, in Theme

BASIC WIDGETS

Figure 79: Button Widget, in Theme.Holo

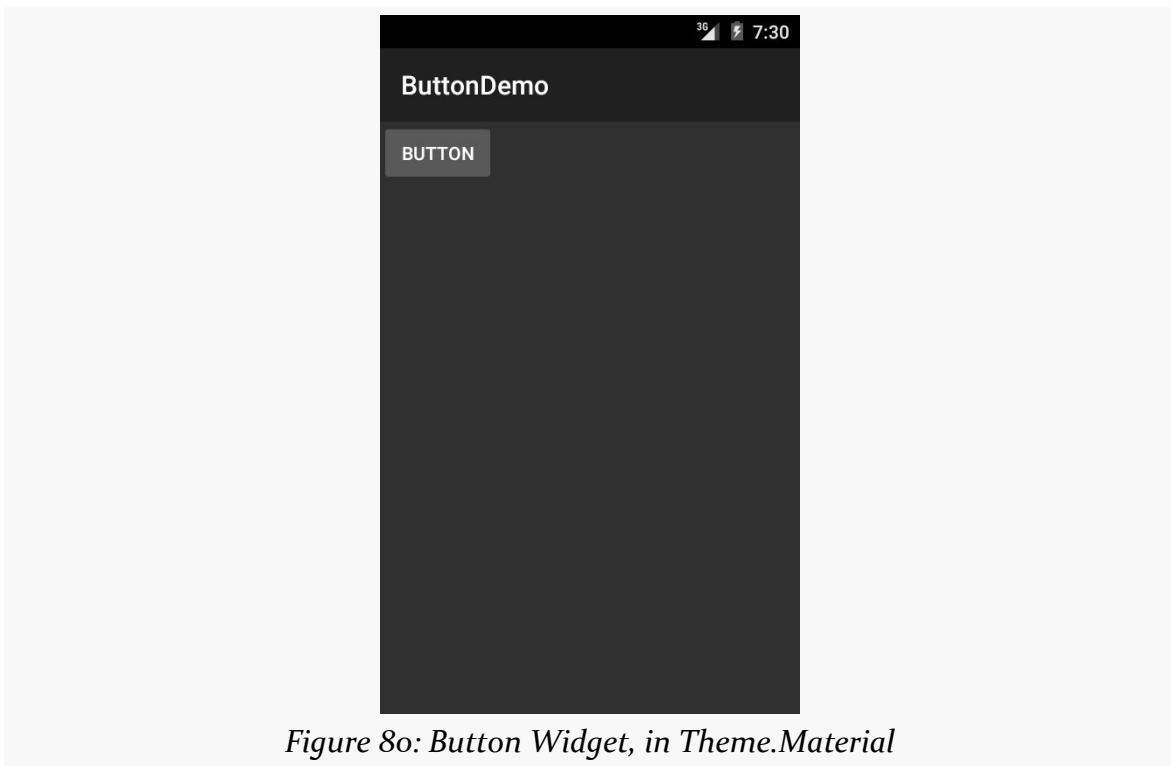

Figure 80: Button Widget, in Theme.Material

Android Studio Graphical Layout Editor

As with the `TextView` widget, the `Button` widget is available in the “Widgets” portion of the Palette in the Android Studio graphical layout editor:

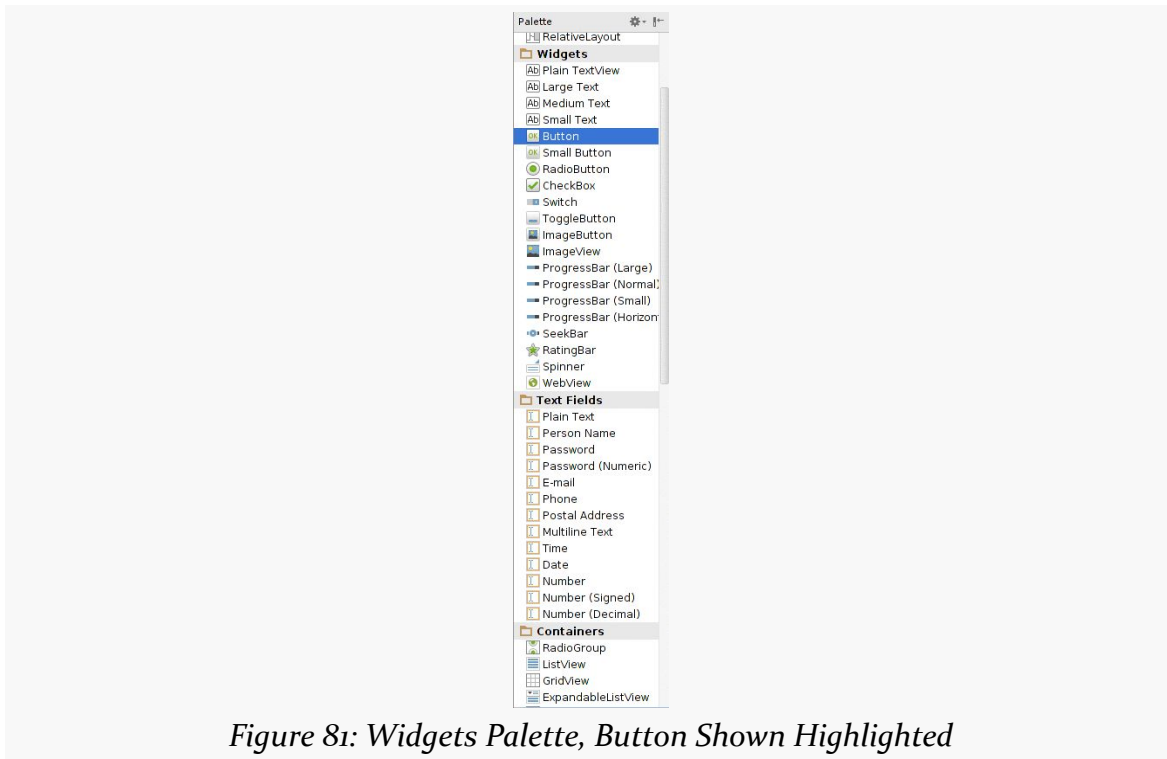

Figure 81: Widgets Palette, Button Shown Highlighted

You can drag that `Button` from the palette into a layout file in the main editing area to add the widget to the layout. The Properties pane will then let you adjust the various attributes of this `Button`. Since `Button` inherits from `TextView`, most of the options are the same (e.g., “Text”).

Eclipse Graphical Layout Editor

As with the `TextView` widget, the `Button` widget is available in the “Form Widgets” portion of the Palette in the Eclipse graphical layout editor:

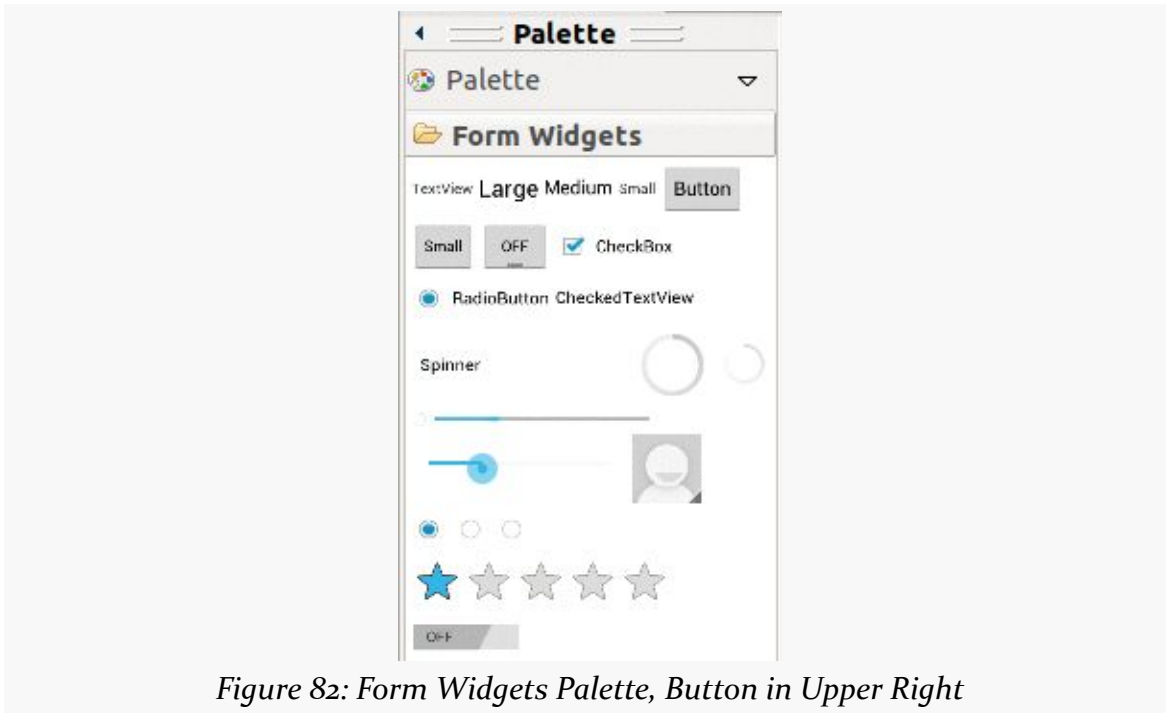

Figure 82: Form Widgets Palette, Button in Upper Right

You can drag that `Button` from the palette into a layout file in the main editing area to add the widget to the layout. The Properties pane will then let you adjust the various attributes of this `Button`. Since `Button` inherits from `TextView`, most of the options are the same (e.g., “Text”).

Tracking Button Clicks

Buttons are command widgets — when the user presses a button, they expect something to happen.

To define what happens when you click a `Button`, you can:

1. Define some method on your `Activity` that holds the button that takes a single `View` parameter, has a `void` return value, and is `public`
2. In your layout XML, on the `Button` element, include the `android:onClick` attribute with the name of the method you defined in the previous step

For example, we might have a method on our `Activity` that looks like:

```
public void someMethod(View theButton) {  
    // do something useful here  
}
```

Then, we could use this XML declaration for the Button itself, including `android:onClick`:

```
<Button
  android:onClick="someMethod"
  ...
/>
```

This is enough for Android to “wire together” the Button with the click handler. When the user clicks the button, `someMethod()` will be called.

Another approach is to skip `android:onClick`, instead calling `setOnClickListener()` on the Button object in Java code. When a Button is used directly by an activity, this is not typically used — `android:onClick` is a bit cleaner. However, when we start to [talk about fragments](#), you will see that `android:onClick` does not work that well with fragments, and so we will use `setOnClickListener()` at that point.

Fleeting Images

Android has two widgets to help you embed images in your activities: `ImageView` and `ImageButton`. As the names suggest, they are image-based analogues to `TextView` and `Button`, respectively.

Each widget takes an `android:src` attribute (in an XML layout) to specify what picture to use. These usually reference a drawable resource (e.g., `@drawable/icon`).

`ImageButton`, a subclass of `ImageView`, mixes in the standard `Button` behaviors, for responding to clicks and whatnot.

For example, take a peek at the `main.xml` layout from the [Basic/ImageView](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<ImageView xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/icon"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:adjustViewBounds="true"
  android:src="@drawable/molecule"/>
```

The result, just using the code-generated activity, is simply the image:

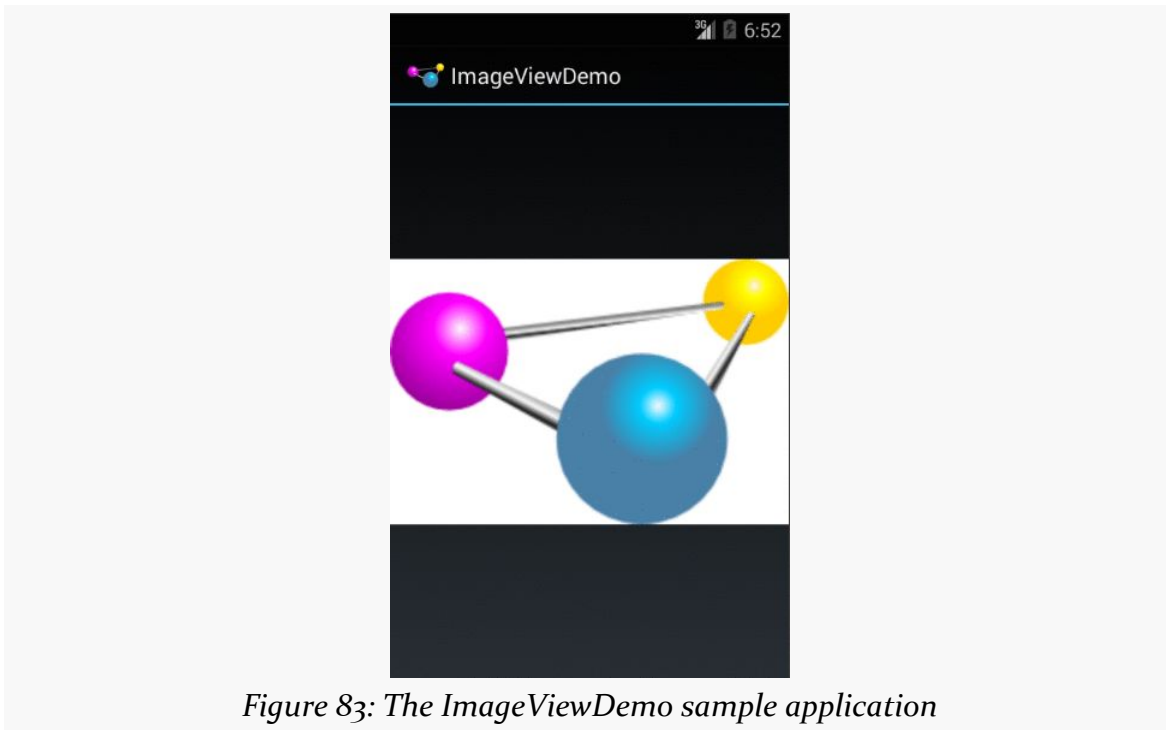

Figure 83: The ImageViewDemo sample application

Android Studio Graphical Layout Editor

The `ImageView` widget can be found in the “Widgets” portion of the Palette in the Android Studio Graphical Layout editor:

BASIC WIDGETS

Figure 84: Widgets Palette, ImageView Shown Highlighted

ImageButton appears alongside ImageView in that tool palette.

You can drag these into a layout file, then use the Properties pane to set their attributes. Like all widgets, you will have an “id” option to set the android:id value for the widget. Two others of importance, though, are more unique to ImageView and ImageButton:

- “src” allows you to choose a drawable resource to use as the image to be displayed
- “scaleType” opens a drop-down menu where you can choose how the image is to be scaled:

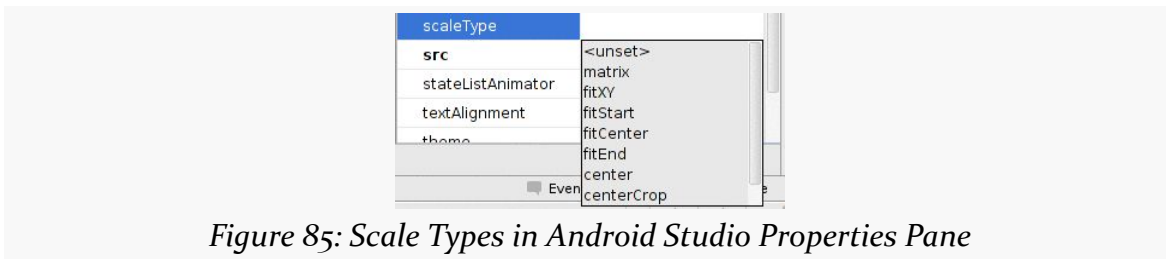

Figure 85: Scale Types in Android Studio Properties Pane

We will examine those scale types more [later in this chapter](#).

Eclipse Graphical Layout Editor

The ImageView widget can be found in the “Images & Media” portion of the Palette in the Graphical Layout editor:

The ImageButton widget is adjacent to the ImageView widget in the Palette.

You can drag these into a layout file, then use the Properties pane to set their attributes. Like all widgets, you will have an “Id” option to set the `android:id` value for the widget. Two others of importance, though, are more unique to ImageView and ImageButton:

- “Src” allows you to choose a drawable resource to use as the image to be displayed
- “Scale Type” opens a drop-down menu where you can choose how the image is to be scaled:

BASIC WIDGETS

Figure 87: Scale Types in Eclipse Properties Pane

We will examine those scale types more in the next section.

Scaling Images

It is possible, perhaps even probable, that our `ImageView` size will not exactly match the size of the images that we are trying to display. `ImageView` supports a variety of “scale types” that indicate how Android should try to deal with the discrepancy between the size/aspect ratio of the image and the size/aspect ratio of the `ImageView` itself.

These values can be seen in the JavaDocs in [the `ImageView.ScaleType` class](#). The default (“`fitCenter`”) simply scales up the image to best fit the available space.

Of note, a choice of “`center`” will center the image in the available space but will not scale up the image:

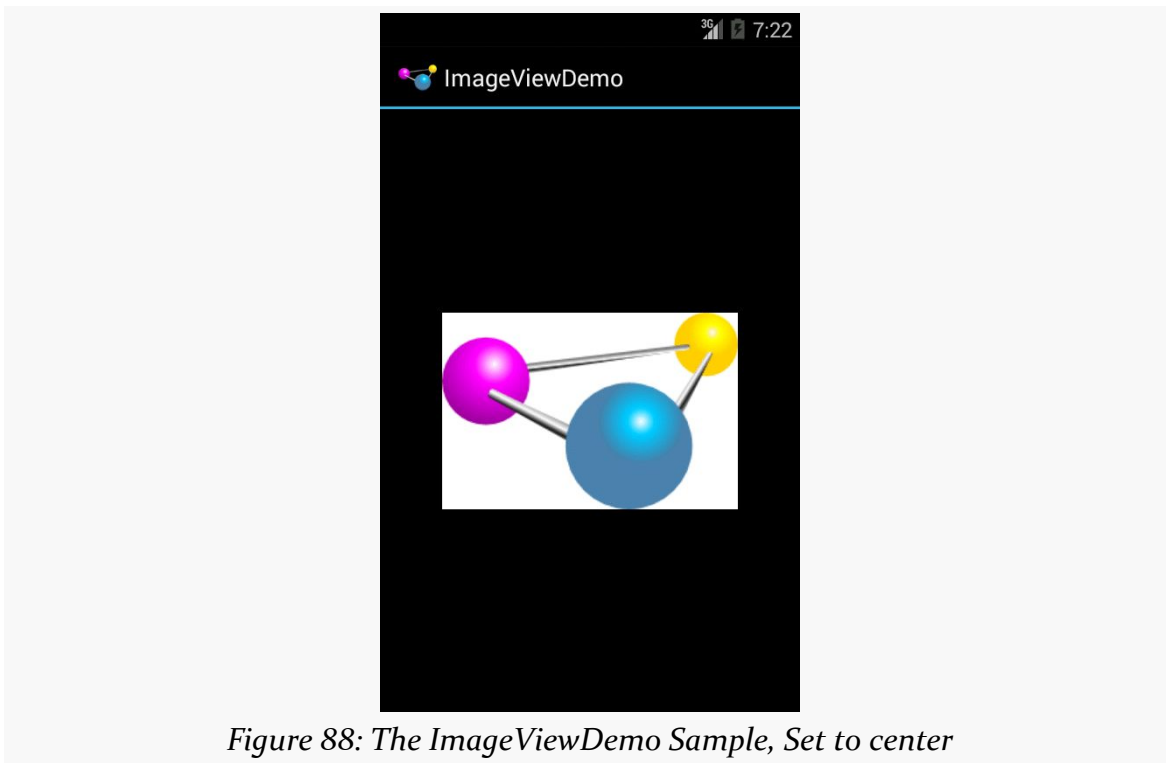

Figure 88: The ImageViewDemo Sample, Set to center

A choice of “centerCrop” will scale the image so that its shortest dimension fills the available space and crops the rest:

Figure 89: The ImageViewDemo Sample, Set to centerCrop

A choice of “fitXY” will scale the image to fill the space, ignoring the aspect ratio:

Figure 90: The `ImageViewDemo` Sample, Set to `fitXY`

Fields of Green. Or Other Colors.

Along with buttons and labels, fields are the third “anchor” of most GUI toolkits. In Android, they are implemented via the `EditText` widget, which is a subclass of the `TextView` used for labels.

Along with the standard `TextView` attributes (e.g., `android:textStyle`), `EditText` has others that will be useful for you in constructing fields, notably `android:inputType`, to describe what sort of input your `EditText` expects (numbers? email addresses? phone numbers?). A thorough explanation of `android:inputType` and its interaction with input method editors (a.k.a., “soft keyboards”) will be discussed in an [upcoming chapter](#).

For example, from the [Basic/Field](#) sample project, here is an XML layout file showing an `EditText`:

```
<?xml version="1.0" encoding="utf-8"?>
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/field"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

BASIC WIDGETS

```
android:inputType="textMultiLine"  
android:text="@string/license"  
</>
```

Note that we have `android:inputType="textMultiLine"`, so users will be able to enter in several lines of text. We also have defined the initial text to be the value of a license string resource.

The result, once built and installed into the emulator, is:

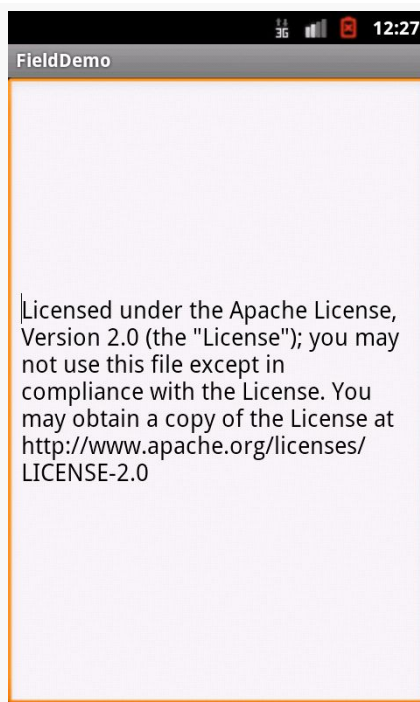

Figure 91: FieldDemo, in Theme

BASIC WIDGETS

Figure 92: FieldDemo, in Theme.Holo

Figure 93: FieldDemo, in Theme.Material

Android Studio Graphical Layout Editor

The Android Studio Graphical Layout's Palette has a whole section dedicated primarily to `EditText` widgets, named "Text Fields":

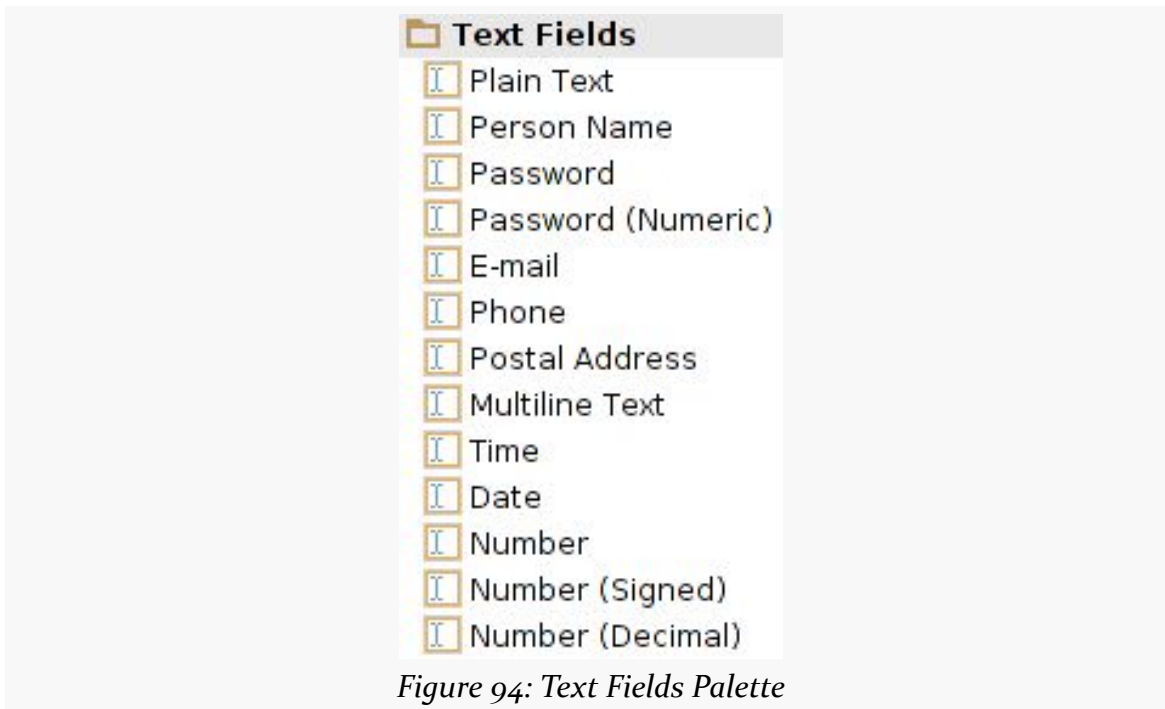

Figure 94: Text Fields Palette

The first entry is a general-purpose `EditText`. The rest come pre-configured for various scenarios, such as a person's name or a password.

You can drag any of these into your layout, then use the Properties pane to configure relevant attributes. The "Id" and "Text" attributes are the same as found on `TextView`, as are many other properties, as `EditText` inherits from `TextView`.

Eclipse Graphical Layout Editor

The Graphical Layout's Palette has a whole section dedicated primarily to `EditText` widgets, named "Text Fields":

Figure 95: Text Fields Palette

The first entry is a general-purpose `EditText`. The rest come pre-configured for various scenarios, such as a person’s name or a postal address.

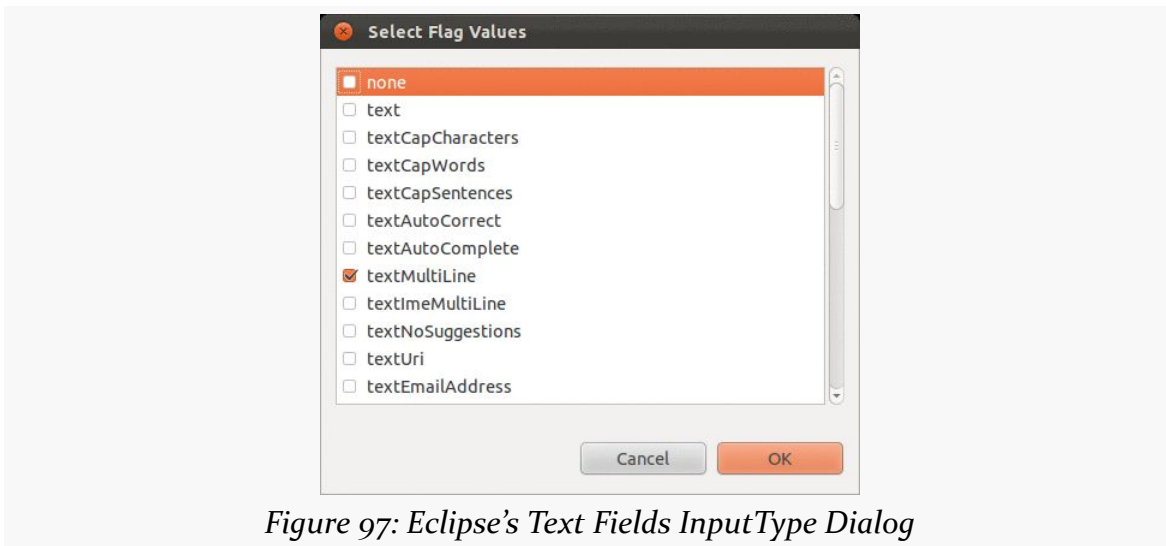

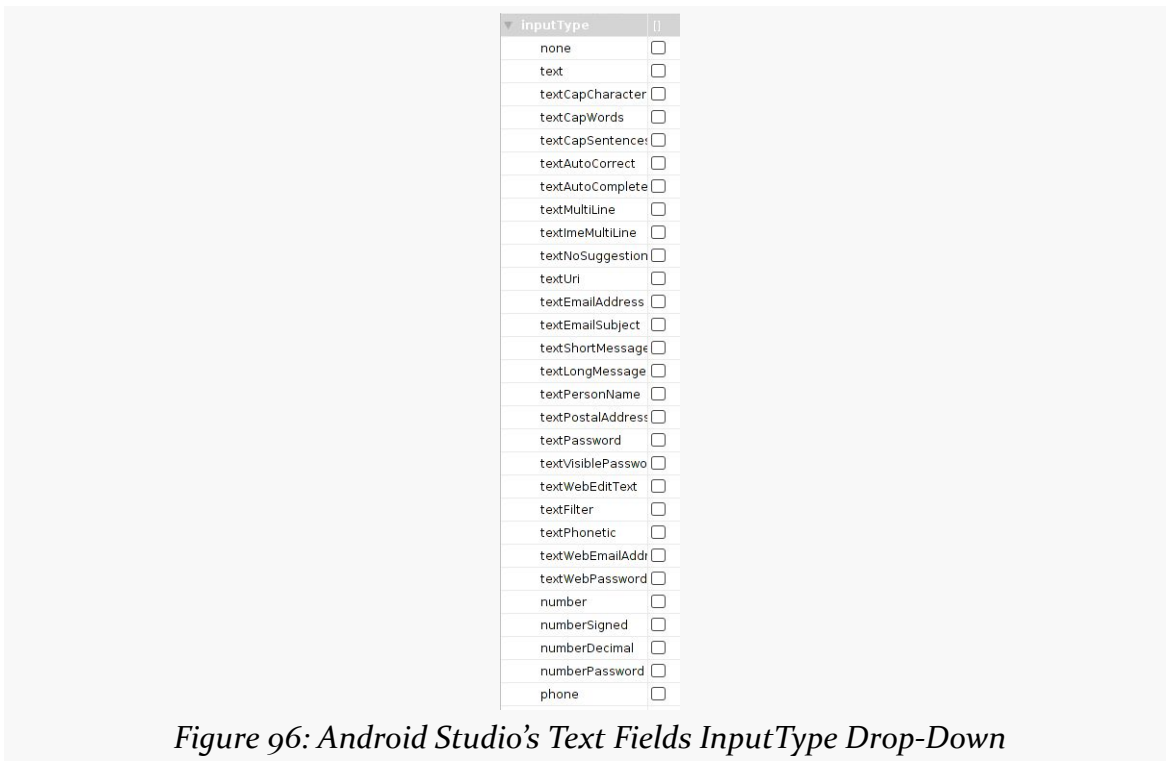

You can drag any of these into your layout, then use the Properties pane to configure relevant attributes. The “Id” and “Text” attributes are the same as found on `TextView`, as are many other properties, as `EditText` inherits from `TextView`.

Notable `EditText` Attributes

The “Hint” item in the Properties pane allows you to set a “hint” for this `EditText`. The “hint” text will be shown in light gray in the `EditText` widget when the user has not entered anything yet. Once the user starts typing into the `EditText`, the “hint” vanishes. This might allow you to save on screen space, replacing a separate label `TextView`.

The “Input Type” item in the Properties pane allows you to describe what sort of input you are expecting to receive in this `EditText`, lining up with many of the types of fields you can drag from the Palette into the layout:

BASIC WIDGETS

The inputType attribute will be covered in greater detail in an [upcoming chapter](#).

More Common Concepts

All widgets, including the ones shown above, extend `View`. The `View` base class gives all widgets an array of useful attributes and methods beyond those already described.

Padding

Widgets have a minimum size, one that may be influenced by what is inside of them. So, for example, a `Button` will expand to accommodate the size of its caption. You can control this size using padding. Adding padding will increase the space between the contents (e.g., the caption of a `Button`) and the edges of the widget.

Padding can be set once in XML for all four sides (`android:padding`) or on a per-side basis (`android:paddingLeft`, etc.). Padding can also be set in Java via the `setPadding()` method.

The value of any of these is a dimension — a combination of a unit of measure and a count. So, `10dip` is 10 density-independent pixels, `2mm` is 2 millimeters, etc.

Margins

By default, widgets are tightly packed, one next to the other. You can control this via the use of margins, a concept that is reminiscent of the padding described previously.

The difference between padding and margins comes in terms of the background. For widgets with a transparent background — like the default look of a `TextView` — padding and margins have similar visual effect, increasing the space between the widget and adjacent widgets. However, for widgets with a non-transparent background — like a `Button` — padding is considered inside the background while margins are outside. In other words, adding padding will increase the space between the contents (e.g., the caption of a `Button`) and the edges, while adding margin increases the empty space between the edges and adjacent widgets.

Margins can be set in XML, either on a per-side basis (e.g., `android:layout_marginTop`) or on all sides via `android:layout_margin`. Once again, the value of any of these is a dimension — a combination of a unit of measure and a count, such as `5dp` for 5 density-independent pixels.

Colors

There are two types of color attributes in Android widgets. Some, like `android:background`, take a single color (or a drawable to serve as the background). Others, like `android:textColor` on `TextView` (and subclasses) can take a `ColorStateList`, including via the Java setter (in this case, `setTextColor()`).

A `ColorStateList` allows you to specify different colors for different conditions. For example, when you get to selection widgets in an upcoming chapter, you will see how a `TextView` has a different text color when it is the selected item in a list compared to when it is in the list but not selected. This is handled via the default `ColorStateList` associated with `TextView`.

If you wish to change the color of a `TextView` widget in Java code, you have two main choices:

- Use `ColorStateList.valueOf()`, which returns a `ColorStateList` in which all states are considered to have the same color, which you supply as the parameter to the `valueOf()` method. This is the Java equivalent of the `android:textColor` approach, to make the `TextView` always be a specific color regardless of circumstances.
- Create a `ColorStateList` with different values for different states, either via the constructor or via an XML drawable resource. This will be covered [much later in the book](#).

Other Useful Attributes

Some additional attributes on `View` most likely to be used include:

1. `android:visibility`, which controls whether the widget is initially visible
2. `android:nextFocusDown`, `android:nextFocusLeft`, `android:nextFocusRight`, and `android:nextFocusUp`, which control the focus order if the user uses the D-pad, trackball, or similar pointing device
3. `android:contentDescription`, which is roughly equivalent to the `alt` attribute on an HTML `` tag, and is used by accessibility tools to help people who cannot see the screen navigate the application — this is very important for widgets like `ImageView`

We will see more about the focus attributes and `android:contentDescription` in [the chapter on focus management and accessibility](#), later in this book.

Useful Methods

You can toggle whether or not a widget is enabled via `setEnabled()` and see if it is enabled via `isEnabled()`. One common use pattern for this is to disable some widgets based on a `CheckBox` or `RadioButton` checked state. We will explore `CheckBox`, `RadioButton`, and similar sorts of widgets [a bit later in the book](#).

You can give a widget focus via `requestFocus()` and see if it is focused via `isFocused()`. You might use this in concert with disabling widgets as mentioned above, to ensure the proper widget has the focus once your disabling operation is complete.

To help navigate the tree of widgets and containers that make up an activity's overall view, you can use:

1. `getParent()` to find the parent widget or container
2. `findViewById()` to find a child widget with a certain ID
3. `getRootView()` to get the root of the tree (e.g., what you provided to the activity via `setContentView()`)

Visit the Trails!

You can learn more about Android's input method framework — what you might think of as soft keyboards — [in a later chapter](#).

Another chapter in the trails covers [the use of fonts](#), to tailor your `TextView` widgets (and those that inherit from them, like `Button`).

Yet another chapter in the trails covers [rich text formatting](#), both for presenting formatted text in a `TextView` (e.g., inline **boldface**) and for collecting formatted text from the user via a customized `EditText`.

Debugging Your App

Now that we are starting to manipulate layouts and Java code more significantly, the odds increase that we are going to somehow do it wrong, and our app will crash.

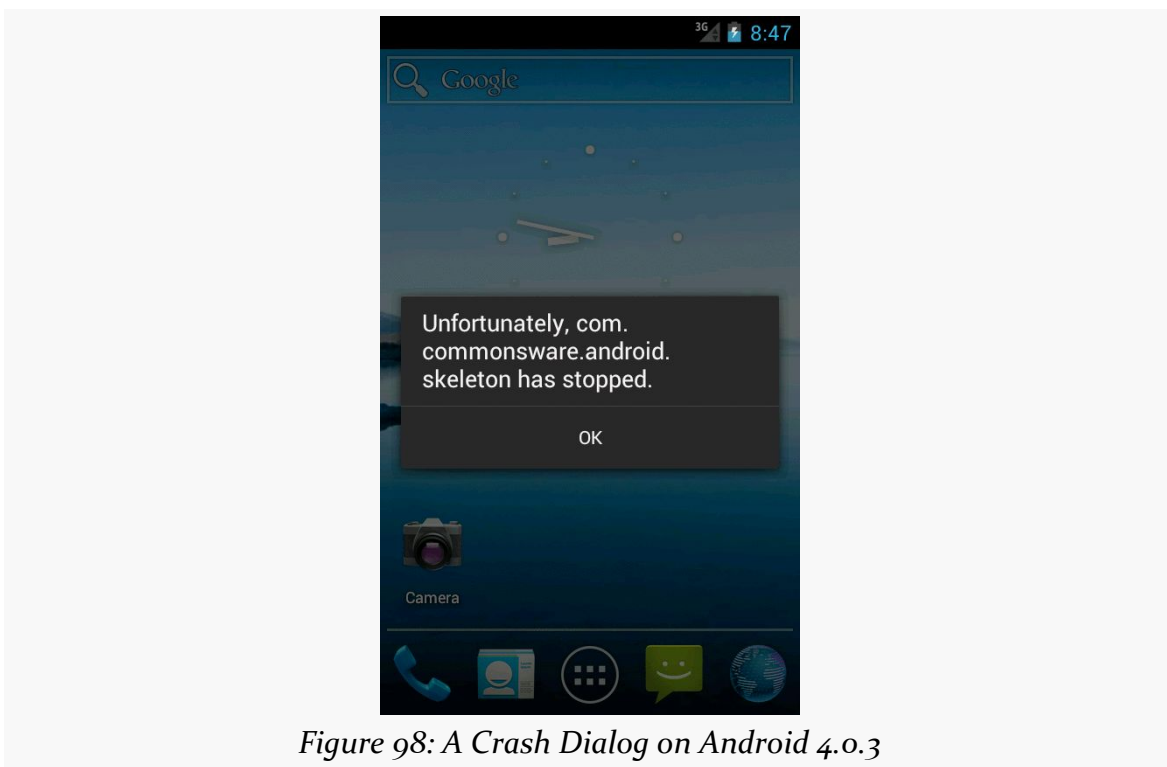

Figure 98: A Crash Dialog on Android 4.0.3

In this chapter, we will cover a few tips on how to debug these sorts of issues.

Get Thee To a Stack Trace

If you see one of those “Force Close” or “Has Stopped” dialogs, the first thing you will want to do is examine the Java stack trace that is associated with this crash. These are logged to a facility known as LogCat, on your device or emulator.

To view LogCat, you have three choices:

1. Use the `adb logcat` command at the command line (or something that uses `adb logcat`, such as various colorizing scripts available online)
2. Use the LogCat tab in the standalone Android Device Monitor utility (run `monitor` from the command line)
3. Use the LogCat view in your IDE (Eclipse or Android Studio)

There are also LogCat apps on the Play Store, such as aLogCat, that will display the contents of LogCat. However, for security and privacy reasons, on Jelly Bean and higher devices, such apps will only be able to show you *their* LogCat entries, not those from the system, your app, or anyone else. Hence, for development purposes, it is better to use one of the other alternatives outlined above.

LogCat in Android Studio

The LogCat view is available at any time, from pretty much anywhere in Android Studio, by means of clicking on the Android tool window entry, usually docked at the bottom of your IDE window:

Figure 99: Minimized Tool Windows in Android Studio, Showing Android Tool Window Entry

Tapping on that will bring up some Android-specific logs in an “Android DDMS” tool window, with a tab for “Devices | logcat”:

DEBUGGING YOUR APP

Figure 100: Android DDMS Tool Window, Showing LogCat

LogCat will show your stack traces, diagnostic information from the operating system, and anything you wish to include via calls to static methods on the `android.util.Log` class. For example, `Log.e()` will log a message at error severity, causing it to be displayed in red.

If you want to send something from LogCat to somebody else, such as via an issue tracker, just highlight the text and copy it to the clipboard, as you would with any text editor.

The “trash can” icon atop the tool strip on the right is the “clear log” tool. Clicking it will appear to clear LogCat. It definitely clears your LogCat view, so you will only see messages logged after you cleared it. Note, though, that this does not actually clear the logs from the device or emulator.

In addition, you can:

- Use the “Log level” drop-down to filter lines based on severity, where messages for your chosen severity or higher will be displayed
- Use the search field to the right of the “Log level” drop-down to filter items based on a search string
- Set up more permanent filters via the drop-down to the right of the search field

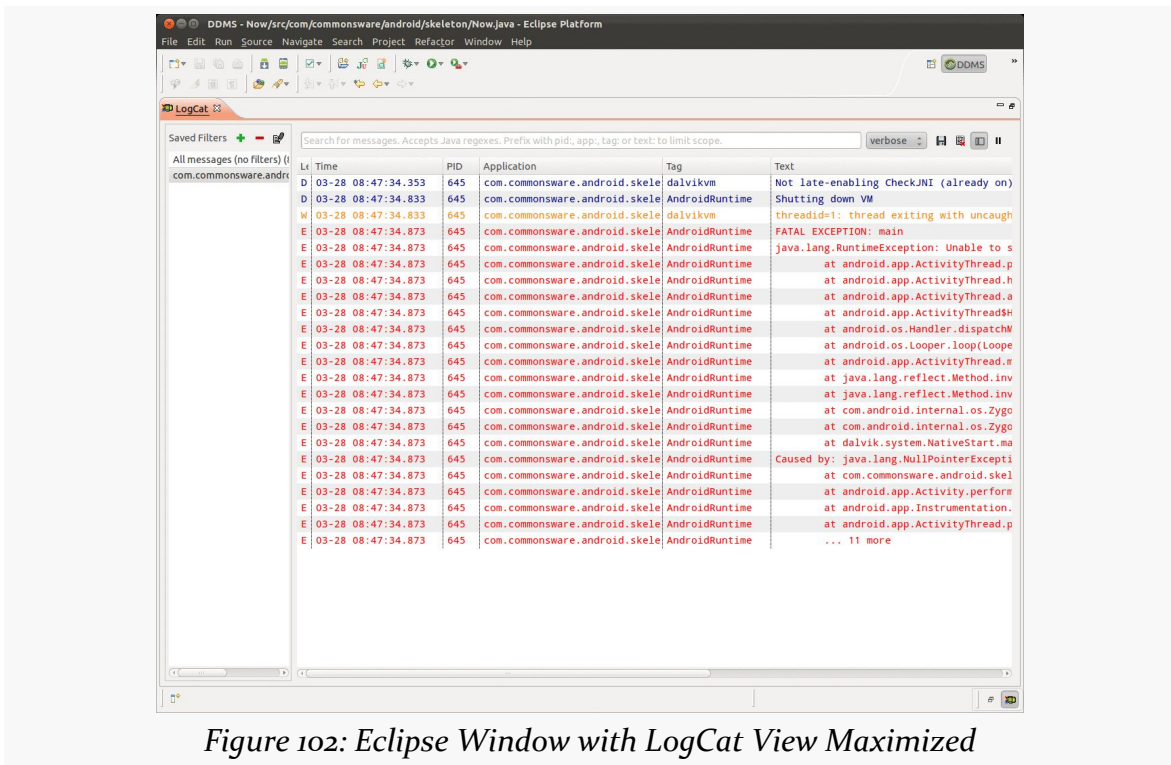

LogCat in Eclipse

The LogCat view is available at any time, from pretty much anywhere in Eclipse, by means of clicking on the LogCat icon in the status bar of your Eclipse window:

DEBUGGING YOUR APP

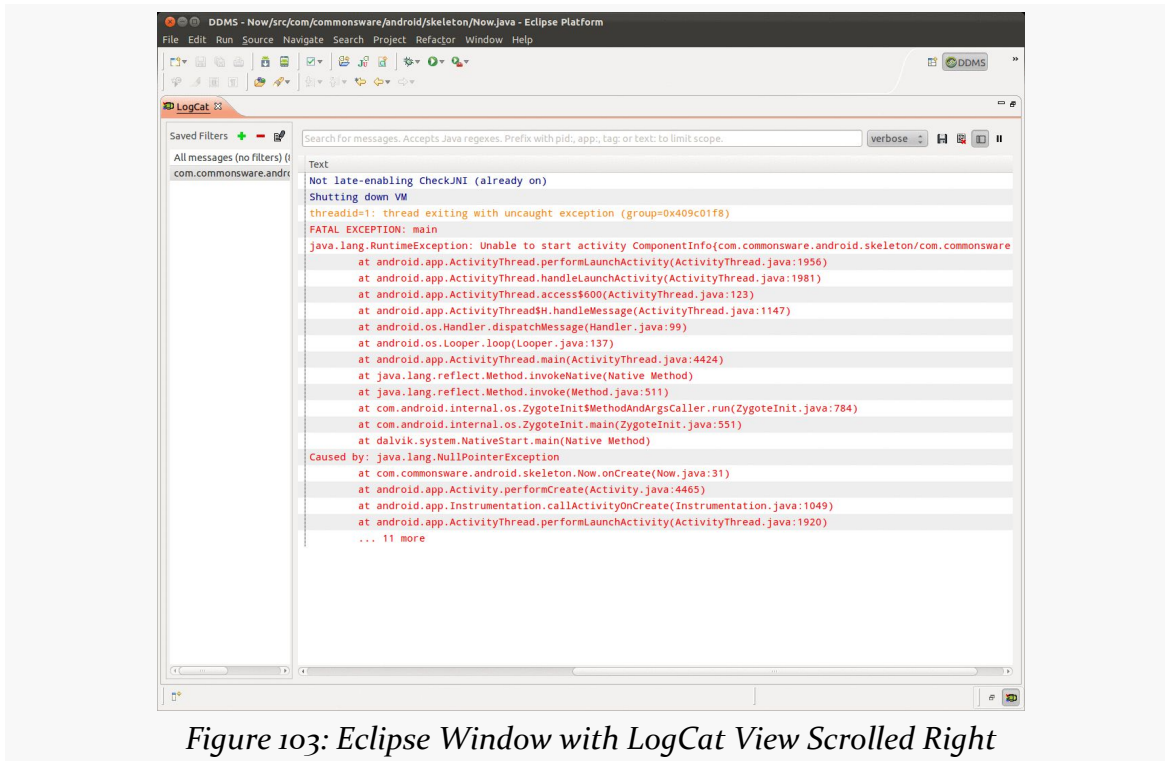

LogCat will show your stack traces, diagnostic information from the operating system, and anything you wish to include via calls to static methods on the `android.util.Log` class. For example, `Log.e()` will log a message at error severity, causing it to be displayed in red.

By default, when developing your app, if your app crashes, LogCat will display messages from your app alone, via a filter on the left, with the name of your app's package (e.g., `com.commonware.android.skeleton`). Switching the filter to "All messages (no filters)" will show all LogCat messages, regardless of origin.

DEBUGGING YOUR APP

There is a scrollbar towards the bottom of the main log area that will let you see more of your stack trace:

Your stack trace will typically consist of two or more “stanzas”. Your own code will typically be in the last of these. So, in the screenshot above, we have `java.lang.RuntimeException: Unable to start activity...`, followed by `Caused by: java.lang.NullPointerException`, as a pair of stanzas. The point where our code crashed shows up in that second stanza (at `com.commonsware.android.skeleton.Now.onCreate(Now.java:31)`).

If you double-click on a line in the stack trace corresponding with your code, you will be taken to a Java editor on that source file and line, so you can see what code triggered the exception.

If you wish to save one of these stack traces as a file, to attach to an issue in an issue tracker or something, highlight the lines you want in LogCat (click on the first line, then `<Shift>`-click on the last line), then click on the “Export Selected Items to Text File” icon (looks like a 3.5-inch floppy disk or a classic “save” icon). This will bring up your platform’s “Save As” dialog, where you can specify where to write out the file.

The icon immediately to the right is the “clear” icon:

Clicking it will appear to clear LogCat. It definitely clears your LogCat *view*, so you will only see messages logged after you cleared it. Note, though, that this does not actually clear the logs from the device or emulator.

The Case of the Confounding Class Cast

If you crash, the stack trace might suggest that there is a problem tied to your resources. One common flavor of this is a `ClassCastException` when you call `findViewById()`. For example, you might call `(Button)findViewById(R.id.button)`, yet get a `ClassCastException: android.widget.LinearLayout` as a result, indicating that while you thought your `findViewById()` call would return a `Button`, it really returned a `LinearLayout`.

Often times, this is not your fault. Sometimes, the R values get out of sync with pre-compiled classes from previous builds. This most often occurs just after you change your mix of resources (e.g., add a new layout).

To resolve this, you need to clean your project:

- In Android Studio, choose “Build > Clean Project” from the main menu
- In Eclipse, select the project, then choose Project > Clean from the main menu

So, if you get a strange crash that seems like it might be related to resources, clean your project. If the problem goes away, you are set — if the problem persists, you will need to do a bit more debugging.

Point Break

One of the hallmarks of Java IDEs is the ability to do real-time debugging, using breakpoints and the like. In that respect, Android Studio and Eclipse work for Android apps in the same way that IntelliJ IDEA and Eclipse work for Java apps. You can debug on an emulator or any Android device for which you enabled USB debugging (as you may have done in Tutorial #1).

Lacking any Android Studio-specific documentation, you will wind up referring to [the documentation for IntelliJ IDEA](#) to learn how to use its debugger. Similarly, you can turn to [the documentation for Eclipse](#) for details of how to use the Eclipse debugger.

Note that if you set up Eclipse to catch all unhandled exceptions, those exceptions will not be logged to LogCat unless you allow execution to proceed past the point of the exception. While this may not matter much to you during development, the LogCat stack trace is often easier for other developers to read, away from your Eclipse environment. So, if you wish to post a stack trace on an issue or on a support forum (e.g., Stack Overflow), use the LogCat stack trace.

LinearLayout and the Box Model

LinearLayout represents Android's approach to a box model — widgets or child containers are lined up in a column or row, one after the next.

Some GUI toolkits use the box as their primary unit of layout. If you want, you can use LinearLayout in much the same way, eschewing some of the other containers. Getting the visual representation you want is mostly a matter of identifying where boxes should nest and what properties those boxes should have, such as alignment with respect to other boxes.

Concepts and Properties

To configure a LinearLayout, you have four main areas of control besides the container's contents: the orientation, the fill model, the weight, the gravity.

Orientation

Orientation indicates whether the LinearLayout represents a row or a column. Just add the `android:orientation` property to your LinearLayout element in your XML layout, setting the value to be `horizontal` for a row or `vertical` for a column.

The orientation can be modified at runtime by invoking `setOrientation()` on the LinearLayout, supplying it either `HORIZONTAL` or `VERTICAL`.

Fill Model

The point behind a LinearLayout — or any of the Android container classes — is to organize multiple widgets. Part of organizing those widgets is determining how much space each gets.

LinearLayout takes an “eldest child wins” approach towards allocating space. So, if we have a LinearLayout with three children, the first child will get its requested space. The second child will get its requested space, if there is enough room remaining, and likewise for the third child. So if the first child asks for all the space (e.g., this is a horizontal LinearLayout and the first child has `android:layout_width="match_parent"`), the second and third children will wind up with zero width.

Weight

But, what happens if we have two or more widgets that should split the available free space? For example, suppose we have two multi-line fields in a column, and we want them to take up the remaining space in the column after all other widgets have been allocated their space.

To make this work, in addition to setting `android:layout_width` (for rows) or `android:layout_height` (for columns), you must also set `android:layout_weight`. This property indicates what proportion of the free space should go to that widget. If you set `android:layout_weight` to be the same non-zero value for a pair of widgets (e.g., 1), the free space will be split evenly between them. If you set it to be 1 for one widget and 2 for another widget, the second widget will use up twice the free space that the first widget does. And so on.

The weight for a widget is zero by default.

Another pattern for using weights is if you want to allocate sizes on a percentage basis. To use this technique for, say, a horizontal layout:

1. Set all the `android:layout_width` values to be 0 for the widgets in the layout
2. Set the `android:layout_weight` values to be the desired percentage size for each widget in the layout
3. Make sure all those weights add up to 100

If you want to have space left over, not allocated to any widget, you can add an `android:weightSum` attribute to the LinearLayout, and ensure that the sum of the `android:layout_weight` attributes of the children are less than that sum. The children will each get space allocated based upon the ratio of their `android:layout_weight` compared to the `android:weightSum`, not compared to the sum of the weights. And there will be empty space that takes up the rest of the room not allocated to the children.

LINEARLAYOUT AND THE BOX MODEL

To see `android:layout_weight` in action, take a look at the [Containers/LinearPercent](#) sample project. Here, we have a `res/layout/main.xml` file containing a vertical `LinearLayout` with three `Button` widgets as children:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="50"
        android:text="@string/fifty_percent"/>

    <Button
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="30"
        android:text="@string/thirty_percent"/>

    <Button
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="20"
        android:text="@string/twenty_percent"/>

</LinearLayout>
```

Each of the three `Button` widgets declares its height to be `0dip`. However, each also has an `android:layout_weight` attribute, with the top `Button` requesting a weight of 50, the middle `Button` a weight of 30, and the bottom `Button` a weight of 20.

The result is that the `Button` widgets' heights are allocated based solely upon those weights:

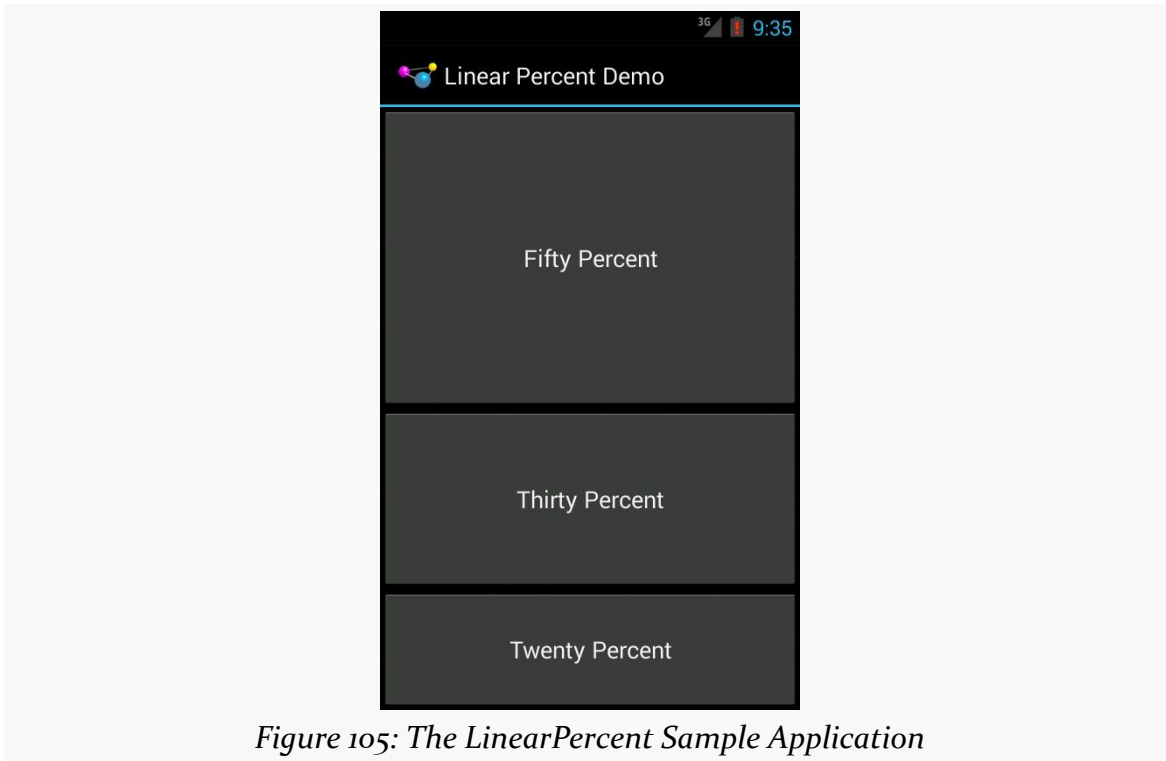

Figure 105: The LinearPercent Sample Application

Gravity

By default, everything in a `LinearLayout` is left- and top-aligned. So, if you create a row of widgets via a horizontal `LinearLayout`, the row will start flush on the left side of the screen.

If that is not what you want, you need to specify a gravity. Unlike the physical world, Android has two types of gravity: the gravity of a widget within a `LinearLayout`, and the gravity of the contents of a widget or container.

The `android:gravity` property of some widgets and containers — which also can be defined via `setGravity()` in Java — tells Android to slide the contents of the widget or container in a particular direction. For example, `android:gravity="right"` says to slide the contents of the widget to the right; `android:gravity="right|bottom"` says to slide the contents of the widget to the right and the bottom.

Here, “contents” varies. `TextView` supports `android:gravity`, and the “contents” is the text held within the `TextView`. `LinearLayout` supports `android:gravity`, and the “contents” are the widgets inside the container. And so on.

LINEARLAYOUT AND THE BOX MODEL

Children of a `LinearLayout` also have the option of specifying `android:layout_gravity`. Here, the child is telling the `LinearLayout` “if there is room, please slide me (and me alone) in this direction”. However, this only works in the direction *opposite* the orientation of the `LinearLayout` – the children of a vertical `LinearLayout` can use `android:layout_gravity` to control their positioning horizontally (left or right), but not vertically.

For a row of widgets, the default is for them to be aligned so their texts are aligned on the baseline (the invisible line that letters seem to “sit on”), though you may wish to specify a gravity of `center_vertical` to center the widgets along the row’s vertical midpoint.

Android Studio Graphical Layout Editor

The `LinearLayout` container can be found in the “Layouts” portion of the Palette of the Android Studio graphical layout editor:

Figure 106: Layouts Palette in Android Studio Graphical Layout Editor

You can drag either the “`LinearLayout (Vertical)`” or “`LinearLayout (Horizontal)`” into a layout XML resource, then start dragging in children to go into the container.

When your `LinearLayout` is the selected widget, a few new toolbar buttons will appear over the preview:

Figure 107: LinearLayout Toolbar Buttons

LINEARLAYOUT AND THE BOX MODEL

The left two buttons toggle the width and height between `match_parent` and `wrap_content`, while the third button changes the gravity of the `LinearLayout`.

When one of the *children* of the `LinearLayout` is the selected widget, the toolbar changes:

Figure 108: LinearLayout Toolbar Buttons, For Selected Child

From left to right, the buttons:

- Toggle the parent `LinearLayout` between horizontal and vertical orientations
- Align the child widgets' baselines (where a "baseline" is the invisible line that text appears to sit upon)
- Change the `android:layout_gravity` value for the child
- Toggle the width between `match_parent` and `wrap_content`
- Toggle the height between `match_parent` and `wrap_content`
- Distribute the weights of the selected children evenly
- Assign this widget all of the weight, at the expense of other children of the `LinearLayout`
- Set the weight to a specific value
- Clear the weights from the children

The Properties pane for the selected widget also allows you to get to the `LinearLayout` container to make adjustments to its attributes.

Eclipse Graphical Layout Editor

The `LinearLayout` container can be found in the "Layouts" portion of the Palette of the Eclipse graphical layout editor:

LINEARLAYOUT AND THE BOX MODEL

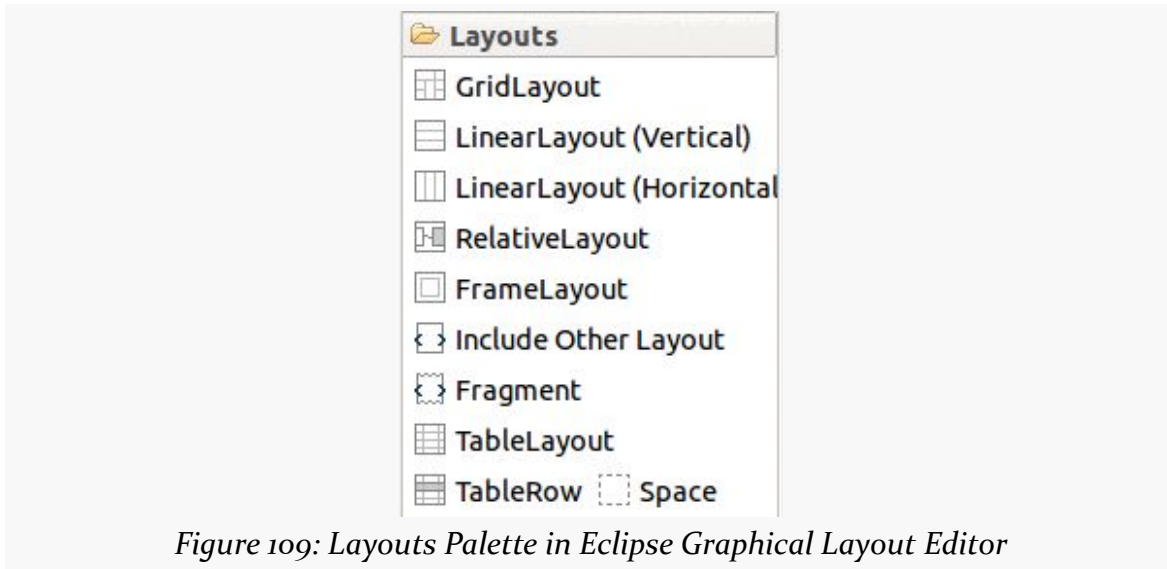

Figure 109: Layouts Palette in Eclipse Graphical Layout Editor

You can drag either the “LinearLayout (Vertical)” or “LinearLayout (Horizontal)” into a layout XML resource, then start dragging in children to go into the container.

When your LinearLayout is the selected widget, a toolbar will appear over the preview:

Figure 110: LinearLayout Toolbar in Eclipse Graphical Layout Editor

The left two buttons toggle your LinearLayout between vertical and horizontal modes. The two immediately to the right of the divider toggle the width and height between match_parent and wrap_content.

When one of the *children* of the LinearLayout is the selected widget, the toolbar changes:

Figure 111: LinearLayout Contents Toolbar in Eclipse Graphical Layout Editor

The left two buttons still toggle the orientation of the LinearLayout. The width and height buttons to their right toggle the width and height of the selected widget.

The right-most six buttons, from left to right, allow you to:

LINEARLAYOUT AND THE BOX MODEL

- Change the margins on the selected widget
- Change the gravity of the selected widget
- Give all widgets in the `LinearLayout` equal weight
- Give the selected widget all the weight
- Manually assign the weight to the selected widget
- Clear all weights from all widgets in the `LinearLayout`

The Properties pane for the selected widget also allows you to get to the `LinearLayout` container to make adjustments to its attributes.

Other Common Widgets and Containers

In [the chapter on basic widgets](#), we left out all of the classic “two-state” widgets, such as checkboxes and radio buttons. We will examine those and other related widgets in this chapter.

Beyond `LinearLayout`, Android supports a range of containers providing different layout rules. In this chapter, we will look at two other commonly-used containers: `RelativeLayout` (a rule-based model) and `TableLayout` (the grid model), along with `ScrollView` and `HorizontalScrollView`, containers that allow their contents to scroll. We will examine all of these containers in this chapter as well.

Just a Box to Check

The classic checkbox has two states: checked and unchecked. Clicking the checkbox toggles between those states to indicate a choice (e.g., “Add rush delivery to my order”).

In Android, there is a `CheckBox` widget to meet this need. It has `TextView` as an ancestor, so you can use `TextView` properties like `android:textColor` to format the widget.

Within Java, you can invoke:

1. `isChecked()` to determine if the checkbox has been checked
2. `setChecked()` to force the checkbox into a checked or unchecked state
3. `toggle()` to toggle the checkbox as if the user clicked upon it

OTHER COMMON WIDGETS AND CONTAINERS

Also, you can register a listener object (in this case, an instance of `OnCheckedChangeListener`) to be notified when the state of the checkbox changes.

For example, from [the Basic/CheckBox sample project](#), here is a simple checkbox layout:

```
<?xml version="1.0" encoding="utf-8"?>
<CheckBox xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/check"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/unchecked"/>
```

The corresponding `CheckBoxDemo.java` retrieves and configures the behavior of the checkbox:

```
package com.commonware.android.checkbox;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CheckBox;
import android.widget.CompoundButton;

public class CheckBoxDemo extends Activity implements
    CompoundButton.OnCheckedChangeListener {
    CheckBox cb;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        cb=(CheckBox)findViewById(R.id.check);
        cb.setOnCheckedChangeListener(this);
    }

    public void onCheckedChanged(CompoundButton buttonView,
        boolean isChecked) {
        if (isChecked) {
            cb.setText(R.string.checked);
        }
        else {
            cb.setText(R.string.unchecked);
        }
    }
}
```

Note that the activity serves as its own listener for checkbox state changes since it implements the `OnCheckedChangeListener` interface (set via `cb.setOnCheckedChangeListener(this)`). The callback for the listener is `onCheckedChanged()`, which receives the checkbox whose state has changed and

OTHER COMMON WIDGETS AND CONTAINERS

what the new state is. In this case, we update the text of the checkbox to reflect what the actual box contains.

The result? Clicking the checkbox immediately updates its text, as shown below:

Figure 113: CheckBoxDemo Sample App, in Theme.Holo, with CheckBox Checked

Figure 114: CheckBoxDemo Sample App, in Theme, with CheckBox Checked

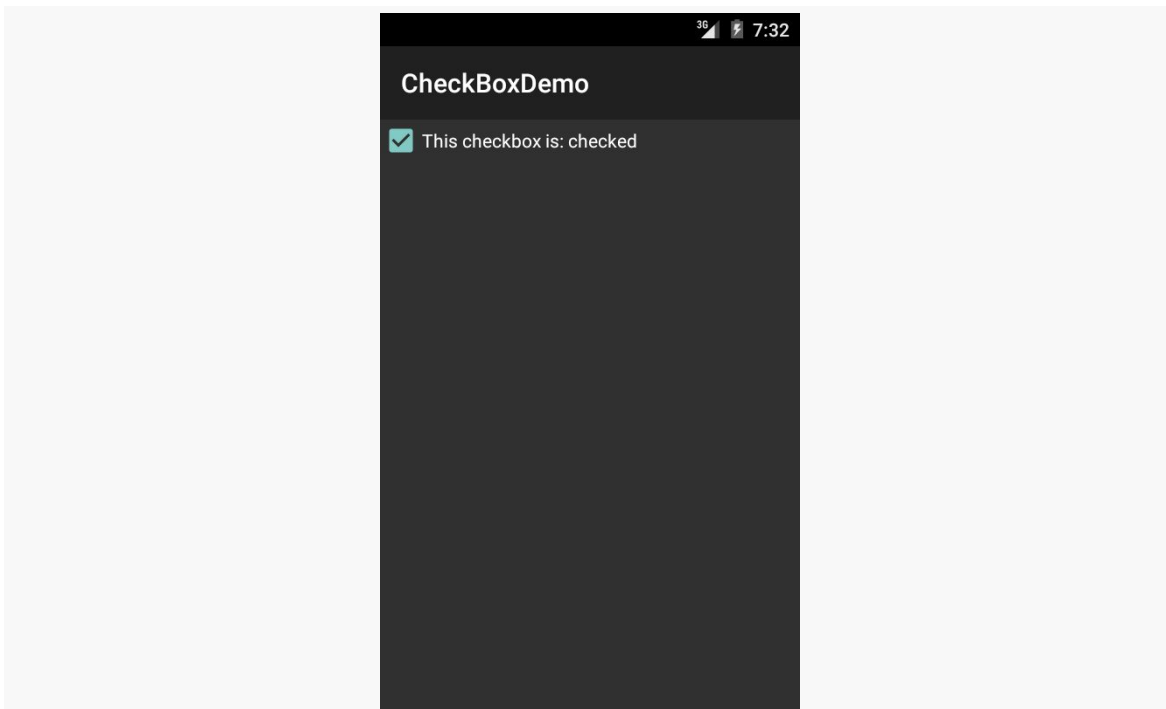

Figure 115: CheckBoxDemo Sample App, in Theme.Material, with CheckBox Checked

Android Studio Graphical Layout Editor

The CheckBox widget can be found in the “Widgets” portion of the Palette in the Android Studio Graphical Layout editor:

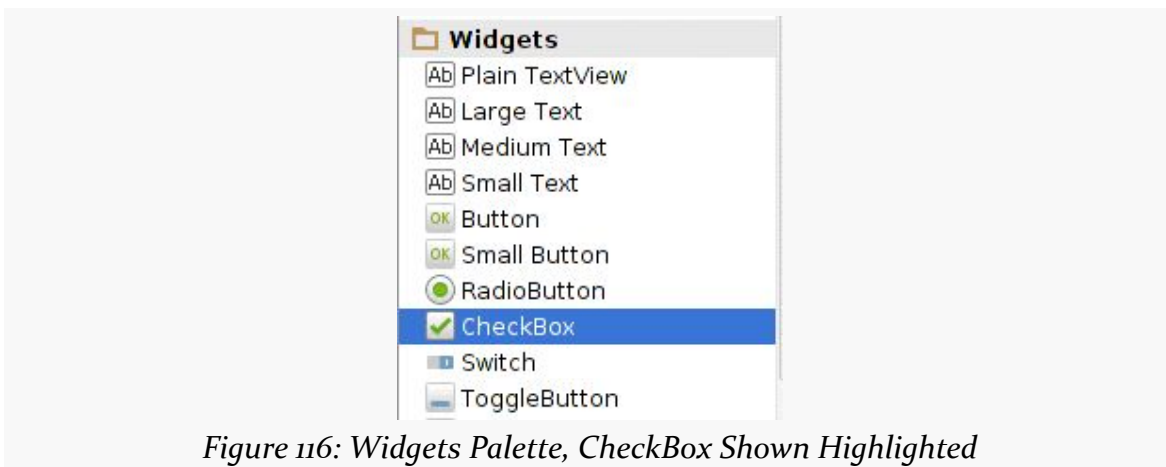

Figure 116: Widgets Palette, CheckBox Shown Highlighted

You can drag it into the layout and configure it as desired using the Properties pane. As `CheckBox` inherits from `TextView`, most of the settings are the same as those you would find on a regular `TextView`.

Eclipse Graphical Layout Editor

The `CheckBox` widget appears in the “Form Widgets” section of the Palette in the Graphical Layout editor. You can drag it into the layout and configure it as desired using the Properties pane. As `CheckBox` inherits from `TextView`, most of the settings are the same as those you would find on a regular `TextView`.

Don't Like Checkboxes? How About Toggles or Switches?

A similar widget to `CheckBox` is `ToggleButton`. Like `CheckBox`, `ToggleButton` is a two-state widget that is either checked or unchecked. However, `ToggleButton` has a distinct visual appearance:

Figure 117: ToggleButtonDemo Sample, Unchecked, in Theme.Holo

Otherwise, `ToggleButton` behaves much like `CheckBox`. You can put it in a layout file, as seen in [the Basic/ToggleButton sample](#):

```
<?xml version="1.0" encoding="utf-8"?>
<ToggleButton xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

You can also set up an `OnCheckedChangeListener` to be notified when the user changes the state of the `ToggleButton`.

Similarly, Android has a `Switch` widget, showing the state via a small “ON/OFF” slider:

OTHER COMMON WIDGETS AND CONTAINERS

Figure 119: SwitchDemo Sample, Unchecked, in Theme.Holo

Figure 120: SwitchDemo Sample, Checked, in Theme.Holo

Figure 121: SwitchDemo Sample, Unchecked, in Theme.Material

Figure 122: SwitchDemo Sample, Checked, in Theme.Material

OTHER COMMON WIDGETS AND CONTAINERS

Switch, like CheckBox and ToggleButton, inherits from CompoundButton, and therefore shares a common API, for methods like `toggle()`, `isChecked()`, and `setChecked()`. And, as with the others, you can put it in a layout file, as seen in [the Basic/Switch sample](#):

```
<?xml version="1.0" encoding="utf-8"?>
<Switch xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

The biggest limitation with Switch is that it was only added to the Android SDK in API Level 14. If your `minSdkVersion` is set to 14 or higher, you are welcome to use Switch. If your `minSdkVersion` is set to something lower than 14, though, you will either need to choose something else or get into more complicated scenarios, like using a library that offers a backport of Switch. We will cover those more complicated scenarios later in the book; for now, it is simplest to only use Switch if your `minSdkVersion` is set to 14 or higher.

Android Studio Graphical Layout Editor

The ToggleButton and Switch widgets can be found in the “Widgets” portion of the Palette in the Android Studio Graphical Layout editor, just beneath the CheckBox widget:

Figure 123: Widgets Palette, ToggleButton and Switch At Bottom

You can drag either widget into the layout and configure it as desired using the Properties pane.

Eclipse Graphical Layout Editor

Like `CheckBox`, the `ToggleButton` and `Switch` widgets appear in the “Form Widgets” section of the Palette in the Graphical Layout editor. You can drag either widget into the layout and configure it as desired using the Properties pane.

Turn the Radio Up

As with other implementations of radio buttons in other toolkits, Android’s radio buttons are two-state, like checkboxes, but can be grouped such that only one radio button in the group can be checked at any time.

`CheckBox`, `ToggleButton`, `Switch`, and `RadioButton` all inherit from `CompoundButton`, which in turn inherits from `TextView`. Hence, all the standard `TextView` properties for font face, style, color, etc. are available for controlling the look of radio buttons. Similarly, you can call `isChecked()` on a `RadioButton` to see if it is selected, `toggle()` to change its checked state, and so on, like you can with a `CheckBox`.

Most times, you will want to put your `RadioButton` widgets inside of a `RadioGroup`. The `RadioGroup` is a `LinearLayout` that indicates a set of radio buttons whose state is tied, meaning only one button out of the group can be selected at any time. If you assign an `android:id` to your `RadioGroup` in your XML layout, you can access the group from your Java code and invoke:

1. `check()` to check a specific radio button via its ID (e.g., `group.check(R.id.radio1)`)
2. `clearCheck()` to clear all radio buttons, so none in the group are checked
3. `getCheckedRadioButtonId()` to get the ID of the currently-checked radio button (or `-1` if none are checked)

Note that the mutual-exclusion feature of `RadioGroup` only applies to `RadioButton` widgets that are immediate children of the `RadioGroup`. You cannot have other containers between the `RadioGroup` and its `RadioButton` widgets.

For example, from [the Basic/RadioButton sample application](#), here is an XML layout showing a `RadioGroup` wrapping a set of `RadioButton` widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RadioGroup
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
```

OTHER COMMON WIDGETS AND CONTAINERS

```
android:layout_height="match_parent"
>
<RadioButton android:id="@+id/radio1"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="@string/rock" />

<RadioButton android:id="@+id/radio2"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="@string/scissors" />

<RadioButton android:id="@+id/radio3"
  android:layout_width="wrap_content"
  android:layout_height="wrap_content"
  android:text="@string/paper" />
</RadioGroup>
```

Using the stock Android-generated Java for the project and this layout, you get:

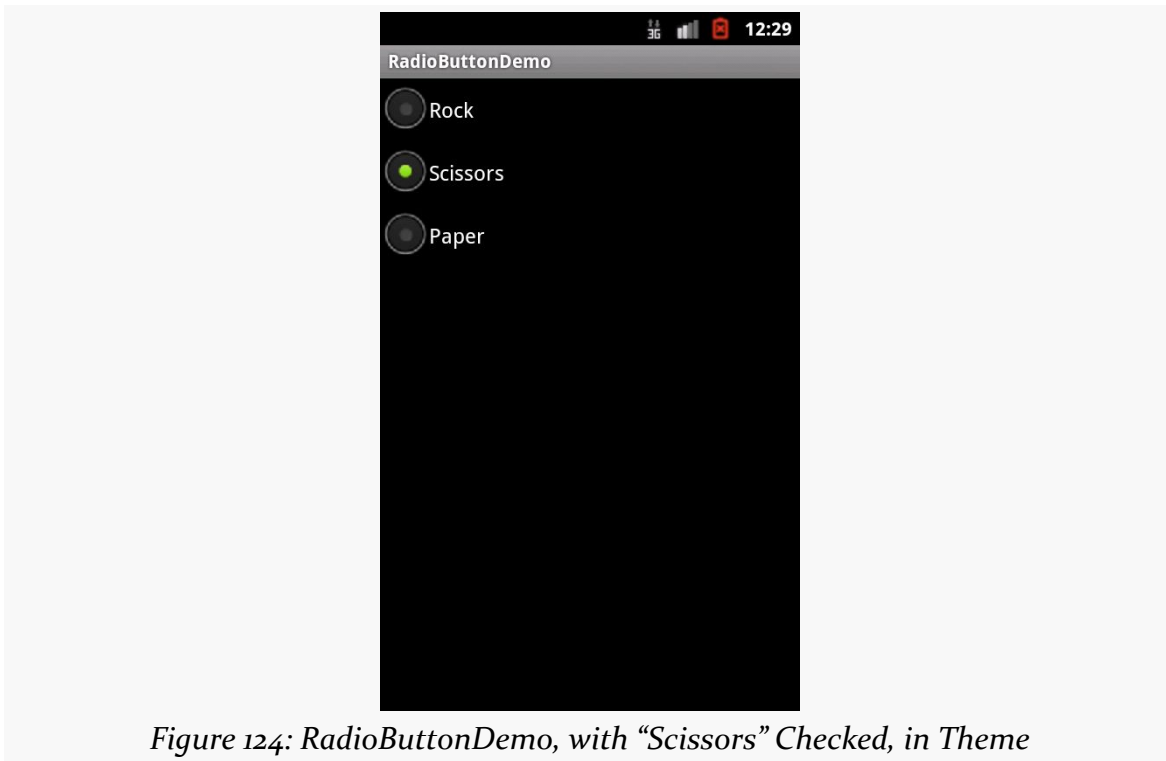

Figure 124: RadioButtonDemo, with “Scissors” Checked, in Theme

OTHER COMMON WIDGETS AND CONTAINERS

Figure 125: RadioButtonDemo, with “Scissors” Checked, in Theme.Holo

Figure 126: RadioButtonDemo, with “Scissors” Checked, in Theme.Material

OTHER COMMON WIDGETS AND CONTAINERS

Note that the radio button group is initially set to be completely unchecked at the outset. To preset one of the radio buttons to be checked, use either `setChecked()` on the `RadioButton` or `check()` on the `RadioGroup` from within your `onCreate()` callback in your activity. Alternatively, you can use the `android:checked` attribute on one of the `RadioButton` widgets in the layout file.

Android Studio Graphical Layout Editor

The `RadioGroup` container can be found in the “Containers” portion of the Palette in the Android Studio Graphical Layout editor:

Figure 127: Widgets Palette, RadioGroup Highlighted

Dragging a `RadioGroup` into the preview works much like dragging a `LinearLayout` into the preview. You get a box into which you can drag other widgets, such as the `RadioButton` found in the “Widgets” section of the Palette.

Eclipse Graphical Layout Editor

Both `RadioButton` and `RadioGroup` appear in the “Form Widgets” section of the Palette in the Graphical Layout editor. The `RadioButton` widget has a radio button with the text “`RadioButton`” to the right. The `RadioGroup` widget looks like three radio buttons (sans text) side-by-side.

Since `RadioGroup` extends `LinearLayout`, when you drag it into the layout, you will get the same sorts of options as a vertical `LinearLayout`, such as setting the gravity. Note, though, that dragging a `RadioGroup` into a layout automatically gives you three

RadioButton child widgets — a departure from any other container in the Palette. You can configure those RadioButton widgets, delete them, add more, etc.

All Things Are Relative

RelativeLayout, as the name suggests, lays out widgets based upon their relationship to other widgets in the container and the parent container. You can place Widget X below and to the left of Widget Y, or have Widget Z's bottom edge align with the bottom of the container, and so on.

Concepts and Properties

To make all this work, we need ways to reference other widgets within an XML layout file, plus ways to indicate the relative positions of those widgets.

Positions Relative to Container

The easiest relations to set up are tying a widget's position to that of its container:

1. `android:layout_alignParentTop` says the widget's top should align with the top of the container
2. `android:layout_alignParentBottom` says the widget's bottom should align with the bottom of the container
3. `android:layout_alignParentLeft` says the widget's left side should align with the left side of the container
4. `android:layout_alignParentRight` says the widget's right side should align with the right side of the container
5. `android:layout_centerHorizontal` says the widget should be positioned horizontally at the center of the container
6. `android:layout_centerVertical` says the widget should be positioned vertically at the center of the container
7. `android:layout_centerInParent` says the widget should be positioned both horizontally and vertically at the center of the container

All of these properties take a simple boolean value (true or false).

Note that the padding of the widget is taken into account when performing these various alignments. The alignments are based on the widget's overall cell (combination of its natural space plus the padding).

Relative Notation in Properties

The remaining properties of relevance to `RelativeLayout` take as a value the identity of a widget in the container. To do this:

- Put identifiers (`android:id` attributes) on all elements that you will need to address
- Address these widgets from other widgets using the identifiers

The first occurrence of an `id` value should have the plus sign (`@+id/widget_a`); the second and subsequent times that `id` value is used in the layout file should drop the plus sign (`@id/widget_a`). This allows the build tools to better help you catch typos in your widget `id` values — if you do not have a plus sign for a widget `id` value that has not been seen before, that will be caught at compile time. For example, if Widget A appears in the `RelativeLayout` before Widget B, and Widget A is identified as `@+id/widget_a`, Widget B can refer to Widget A in one of its own properties via the identifier `@id/widget_a`.

Positions Relative to Other Widgets

There are four properties that control position of a widget *vis-à-vis* other widgets:

1. `android:layout_above` indicates that the widget should be placed above the widget referenced in the property
2. `android:layout_below` indicates that the widget should be placed below the widget referenced in the property
3. `android:layout_toLeftOf` indicates that the widget should be placed to the left of the widget referenced in the property
4. `android:layout_toRightOf` indicates that the widget should be placed to the right of the widget referenced in the property

Beyond those four, there are five additional properties that can control one widget's alignment relative to another:

1. `android:layout_alignTop` indicates that the widget's top should be aligned with the top of the widget referenced in the property
2. `android:layout_alignBottom` indicates that the widget's bottom should be aligned with the bottom of the widget referenced in the property
3. `android:layout_alignLeft` indicates that the widget's left should be aligned with the left of the widget referenced in the property

OTHER COMMON WIDGETS AND CONTAINERS

4. `android:layout_alignRight` indicates that the widget's right should be aligned with the right of the widget referenced in the property
5. `android:layout_alignBaseline` indicates that the baselines of the two widgets should be aligned (where the "baseline" is that invisible line that text appears to sit on)

The last one is useful for aligning labels and fields so that the text appears "natural". Since fields have a box around them and labels do not, `android:layout_alignTop` would align the top of the field's box with the top of the label, which will cause the text of the label to be higher on-screen than the text entered into the field.

So, if we want Widget B to be positioned to the right of Widget A, in the XML element for Widget B, we need to include `android:layout_toRightOf = "@id/widget_a"` (assuming `@id/widget_a` is the identity of Widget A).

Example

With all that in mind, let's examine a typical "form" with a field, a label, plus a pair of buttons labeled "OK" and "Cancel".

Here is the XML layout, pulled from [the Containers/Relative sample project](#):

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">

  <TextView
    android:id="@+id/label"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignBaseline="@+id/entry"
    android:layout_alignParentLeft="true"
    android:layout_marginLeft="4dip"
    android:text="@string/url"/>

  <EditText
    android:id="@+id/entry"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_alignParentTop="true"
    android:layout_toRightOf="@+id/label"
    android:inputType="text"/>

  <Button
    android:id="@+id/ok"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignRight="@+id/entry"
```

OTHER COMMON WIDGETS AND CONTAINERS

```
        android:layout_below="@id/entry"
        android:text="@string/ok"/>

<Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignTop="@id/ok"
    android:layout_toLeftOf="@id/ok"
    android:text="@string/cancel"/>

</RelativeLayout>
```

First, we open up the `RelativeLayout`. In this case, we want to use the full width of the screen (`android:layout_width = "match_parent"`) and only as much height as we need (`android:layout_height = "wrap_content"`).

Next, we define the label as a `TextView`. We indicate that we want its left edge aligned with the left edge of the `RelativeLayout` (`android:layout_alignParentLeft="true"`) and that we want its baseline aligned with the baseline of the yet-to-be-defined `EditText`. Since the `EditText` has not been declared yet, we use the + sign in the ID (`android:layout_alignBaseline="@+id/entry"`).

After that, we add in the field as an `EditText`. We want the field to be to the right of the label, have the field be aligned with the top of the `RelativeLayout`, and for the field to take up the rest of this “row” in the layout. Those are handled by three properties:

1. `android:layout_toRightOf = "@id/label"`
2. `android:layout_alignParentTop = "true"`
3. `android:layout_width = "match_parent"`

Then, the OK button is set to be below the field (`android:layout_below = "@id/entry"`) and have its right side align with the right side of the field (`android:layout_alignRight = "@id/entry"`). The Cancel button is set to be to the left of the OK button (`android:layout_toLeft = "@id/ok"`) and have its top aligned with the OK button (`android:layout_alignTop = "@id/ok"`).

With no changes to the auto-generated Java code, the emulator gives us:

Figure 128: The RelativeLayoutDemo sample application

Overlap

RelativeLayout also has a feature that LinearLayout lacks — the ability to have widgets overlap one another. Later children of a RelativeLayout are “higher in the Z axis” than are earlier children, meaning that later children will overlap earlier children if they are set up to occupy the same space in the layout.

This will be clearer with an example. Here is a layout, [from the Containers/RelativeOverlap sample](#), with a RelativeLayout holding two Button widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:text="@string/big"
        android:textSize="120dip"
        android:textStyle="bold"/>

    <Button
        android:layout_width="wrap_content"
```

OTHER COMMON WIDGETS AND CONTAINERS

```
android:layout_height="wrap_content"  
android:layout_centerInParent="true"  
android:text="@string/small"/>
```

```
</RelativeLayout>
```

The first Button is set to fill the screen. The second Button is set to be centered inside the parent, but only take up as much space as is needed for its caption. Hence, the second Button will appear to “float” over the first Button:

Figure 129: The RelativeLayout sample application

Both Button widgets can still be clicked, though clicking on the smaller Button does not also click the bigger Button. Your clicks will be handled by the widget on top in the case of an overlap like this.

Android Studio Graphical Layout Editor

You will find RelativeLayout in the “Layouts” section of the Palette in the Android Studio Graphical Layout editor. You can drag that into your layout XML resource.

OTHER COMMON WIDGETS AND CONTAINERS

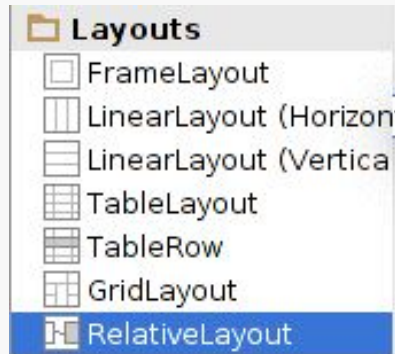

Figure 130: Layouts Section of Palette, RelativeLayout Highlighted

As you drag other widgets into your RelativeLayout, you will see a popup indicator of the RelativeLayout rules that will be applied if you were to drop the widget at the current mouse pointer position:

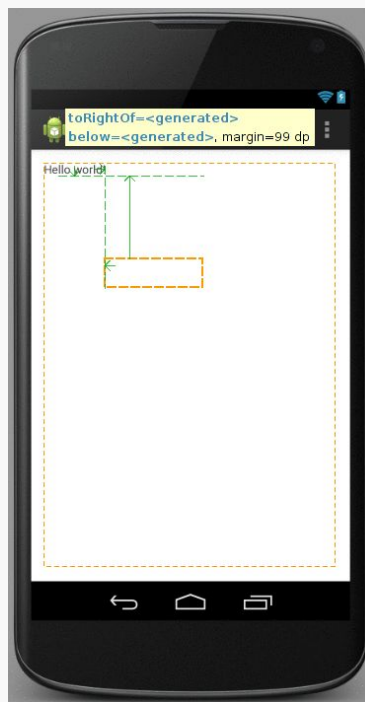

Figure 131: Dragging a Widget in a RelativeLayout

Getting the rules that you *want* may or may not be possible purely through drag-and-drop. You may need to just drop the widget into the RelativeLayout and manually adjust the rules, whether by using the Properties pane or by editing the XML directly.

NOTE: There is [a bug in the layout editor](#) that renders the `RelativeLayout` incorrectly on Android Studio, if your preview is set to API Level 21. If you drop the preview to API Level 19, the `RelativeLayout` renders correctly. And, running the app on a device shows that the `RelativeLayout` renders correctly, even on Android 5.0.

Eclipse Graphical Layout Editor

You will find `RelativeLayout` in the “Layouts” section of the Palette in the Eclipse Graphical Layout editor. You can drag that into your layout XML resource.

As with Android Studio, when you drag a widget into a `RelativeLayout`, a popup will indicate the `RelativeLayout` rules that will be applied if you drop the widget at the current location. Sometimes, you cannot get the rules that you really want, forcing you to modify the `RelativeLayout` XML directly via the other editor sub-tab or via the Properties pane to get it set up properly.

Tabula Rasa

If you like HTML tables, you will like Android’s `TableLayout`. It allows you to position your widgets in a grid to your specifications. You control the number of rows and columns, which columns might shrink or stretch to accommodate their contents, and so on.

`TableLayout` works in conjunction with `TableRow`. `TableLayout` controls the overall behavior of the container, with the widgets themselves poured into one or more `TableRow` containers, one per row in the grid.

Concepts and Properties

For all this to work, we need to figure out how widgets work with rows and columns, plus how to handle widgets that live outside of rows.

Putting Cells in Rows

Rows are declared by you, the developer, by putting widgets as children of a `TableRow` inside the overall `TableLayout`. You, therefore, control directly how many rows appear in the table.

The number of columns are determined by Android; you control the number of columns in an indirect fashion.

OTHER COMMON WIDGETS AND CONTAINERS

First, there will be at least one column per widget in your longest row. So if you have three rows, one with two widgets, one with three widgets, and one with four widgets, there will be at least four columns.

However, a widget can take up more than one column by including the `android:layout_span` property, indicating the number of columns the widget spans. This is akin to the `colspan` attribute one finds in table cells in HTML:

```
<TableRow>
  <TextView android:text="URL:" />
  <EditText
    android:id="@+id/entry"
    android:layout_span="3" />
</TableRow>
```

In the above XML layout fragment, the field spans three columns.

Ordinarily, widgets are put into the first available column. In the above fragment, the label would go in the first column (column 0, as columns are counted starting from 0), and the field would go into a spanned set of three columns (columns 1 through 3). However, you can put a widget into a different column via the `android:layout_column` property, specifying the 0-based column the widget belongs to:

```
<TableRow>
  <Button
    android:id="@+id/cancel"
    android:layout_column="2"
    android:text="Cancel" />
  <Button android:id="@+id/ok" android:text="OK" />
</TableRow>
```

In the preceding XML layout fragment, the Cancel button goes in the third column (column 2). The OK button then goes into the next available column, which is the fourth column.

Non-Row Children of `TableLayout`

Normally, `TableLayout` contains only `TableRow` elements as immediate children. However, it is possible to put other widgets in between rows. For those widgets, `TableLayout` behaves a bit like `LinearLayout` with vertical orientation. The widgets automatically have their width set to `match_parent`, so they will fill the same space that the longest row does.

Stretch, Shrink, and Collapse

By default, each column will be sized according to the “natural” size of the widest widget in that column (taking spanned columns into account). Sometimes, though, that does not work out very well, and you need more control over column behavior.

You can place an `android:stretchColumns` property on the `TableLayout`. This lists the column or columns that should absorb any extra space on the row, if the natural width of the columns collectively is narrower than the available horizontal space. You can:

- List a single column to be stretched (e.g., `android:stretchColumns="0"` to stretch the first column)
- Provide a comma-delimited list of columns to be stretched (e.g., `android:stretchColumns="0,1"` to stretch the first two columns)
- Use `*` to indicate that all columns should be stretched, akin to using equal `android:layout_weight` values in a horizontal `LinearLayout` (e.g., `android:stretchColumns="*"`)

Conversely, you can place an `android:shrinkColumns` property on the `TableLayout`. Again, this should be a single column number, a comma-delimited list of column numbers, or `*` as shorthand for referring to all columns. The columns listed in this property will try to word-wrap their contents to reduce the effective width of the column — by default, widgets are not word-wrapped. This helps if you have columns with potentially wordy content that might cause some columns to be pushed off the right side of the screen.

You can also leverage an `android:collapseColumns` property on the `TableLayout`, again with a column number or comma-delimited list of column numbers (`*` is not documented as an available option). These columns will start out “collapsed”, meaning they will be part of the table information but will be invisible. Programmatically, you can collapse and un-collapse columns by calling `setColumnCollapsed()` on the `TableLayout`. You might use this to allow users to control which columns are of importance to them and should be shown versus which ones are less important and can be hidden.

You can also control stretching and shrinking at runtime via `setColumnStretchable()` and `setColumnShrinkable()`.

Example

The XML layout fragments shown above, when combined, give us a `TableLayout` rendition of the “form” we created for `RelativeLayout`, with the addition of a divider line between the label/field and the two buttons (found in [the Containers/Table demo](#)):

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="1">

    <TableRow>

        <TextView
            android:layout_marginLeft="4dip"
            android:text="@string/url"/>

        <EditText
            android:id="@+id/entry"
            android:layout_span="3"
            android:inputType="text"/>
    </TableRow>

    <View
        android:layout_height="2dip"
        android:background="#0000FF"/>

    <TableRow>

        <Button
            android:id="@+id/cancel"
            android:layout_column="2"
            android:text="@string/cancel"/>

        <Button
            android:id="@+id/ok"
            android:text="@string/ok"/>
    </TableRow>
</TableLayout>
```

When compiled against the generated Java code and run on the emulator, we get:

Figure 132: The *TableLayoutDemo* sample application

Android Studio Graphical Layout Editor

You will find `TableLayout` in the “Layouts” section of the Palette in the Android Studio Graphical Layout editor. You can drag that into your layout XML resource.

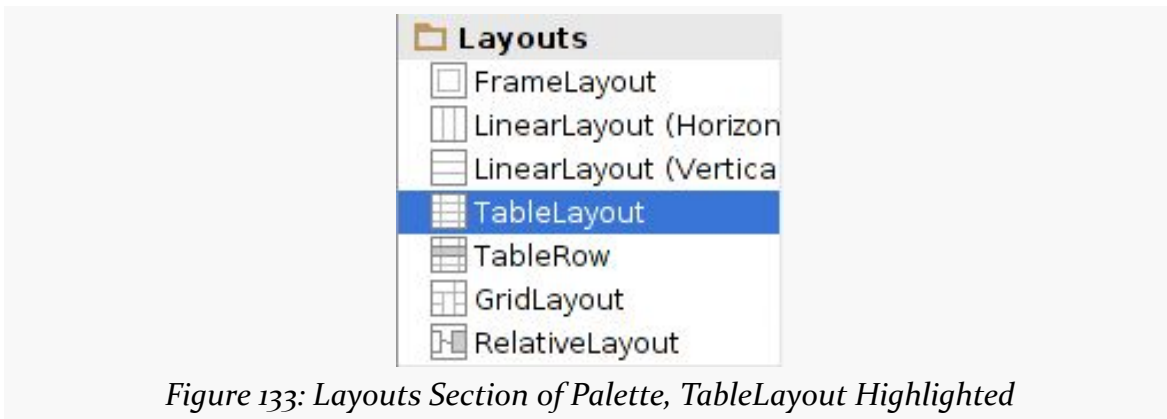

Figure 133: Layouts Section of Palette, *TableLayout* Highlighted

You might expect that you would then drag in `TableRow` containers as needed for your rows, then drag widgets into the `TableRow` containers. That’s not how Android Studio chose to implement the `TableLayout` drag-and-drop support.

OTHER COMMON WIDGETS AND CONTAINERS

Instead, you drag widgets directly into the `TableLayout`, which will switch to a “grid mode”, allowing you to indicate where in a table you want this widget to reside as a cell:

Figure 134: *TableLayout Drag-and-Drop in Android Studio*

Dropping the widget in a given cell position will:

- Add any necessary `TableRow` widgets, both for the row you requested and any prior rows that were not already set up, and
- Add the widget into the `TableRow`, with an `android:layout_column` value if needed to put the widget into the desired column in that row

For example, if you start with an empty `TableLayout`, then drag a `CheckBox` into “row 2, column 2”, you wind up with the following layout XML:

```
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:paddingLeft="@dimen/activity_horizontal_margin"
  android:paddingRight="@dimen/activity_horizontal_margin"
  android:paddingTop="@dimen/activity_vertical_margin"
  android:paddingBottom="@dimen/activity_vertical_margin"
  tools:context=".MyActivity">
```

```
<TableRow
    android:layout_width="fill_parent"
    android:layout_height="fill_parent"></TableRow>

<TableRow
    android:layout_width="fill_parent"
    android:layout_height="fill_parent"></TableRow>

<TableRow
    android:layout_width="fill_parent"
    android:layout_height="fill_parent">

    <CheckBox
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="New CheckBox"
        android:id="@+id/checkBox2"
        android:layout_column="2" />

</TableRow>
</TableLayout>
```

Three TableRow widgets were added (for rows 0, 1, and 2), and the CheckBox is given `android:layout_column="2"` to put it in column 2.

Eclipse Graphical Layout Editor

You will find TableLayout in the “Layouts” section of the Palette in the Eclipse Graphical Layout editor. You can drag that into your layout XML resource and start configuring it via the context menu, notably editing the `android:stretchColumns` and `android:shrinkColumns` values.

In addition, the toolbar above the layout will now sport an add-row button:

Figure 135: Eclipse Layout Toolbar for TableLayout

Clicking that adds a TableRow child to the TableLayout, though you will not necessarily see a visible change. However, now if you start dragging in other widgets, they will go in that row.

Once you have started to populate the row and can select it, you will get some more toolbar buttons:

Figure 136: Eclipse Layout Toolbar for TableLayout, with Row Selected

The icon immediately to the right of the add-row button will remove the selected row from the table. On the far right side of the toolbar are buttons to allow you to toggle the height and width of the row, plus toggle on and off baseline alignment for the contents of the row (enabled by default).

Scrollwork

Phone screens tend to be small, which requires developers to use some tricks to present a lot of information in the limited available space. One trick for doing this is to use scrolling, so only part of the information is visible at one time, the rest available via scrolling up or down.

ScrollView is a container that provides scrolling for its contents. You can take a layout that might be too big for some screens, wrap it in a ScrollView, and still use your existing layout logic. It just so happens that the user can only see part of your layout at one time, the rest available via scrolling.

For example, here is a ScrollView used in an XML layout file (from [the Containers/Scroll demo](#)):

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content">
  <TableLayout
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:stretchColumns="0">
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#000000"/>
      <TextView android:text="#000000"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
    <TableRow>
      <View
        android:layout_height="80dip"
        android:background="#440000" />
      <TextView android:text="#440000"
        android:paddingLeft="4dip"
        android:layout_gravity="center_vertical" />
    </TableRow>
  </TableLayout>
</ScrollView>
```

```
</TableRow>
<TableRow>
  <View
    android:layout_height="80dip"
    android:background="#884400" />
  <TextView android:text="#884400"
    android:paddingLeft="4dip"
    android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
  <View
    android:layout_height="80dip"
    android:background="#aa8844" />
  <TextView android:text="#aa8844"
    android:paddingLeft="4dip"
    android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
  <View
    android:layout_height="80dip"
    android:background="#ffaa88" />
  <TextView android:text="#ffaa88"
    android:paddingLeft="4dip"
    android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
  <View
    android:layout_height="80dip"
    android:background="#ffffaa" />
  <TextView android:text="#ffffaa"
    android:paddingLeft="4dip"
    android:layout_gravity="center_vertical" />
</TableRow>
<TableRow>
  <View
    android:layout_height="80dip"
    android:background="#ffffff" />
  <TextView android:text="#ffffff"
    android:paddingLeft="4dip"
    android:layout_gravity="center_vertical" />
</TableRow>
</TableLayout>
</ScrollView>
```

Without the `ScrollView`, the table would take up at least 560 density-independent pixels (7 rows at 80 dips each, based on the `View` declarations). There may be some devices with screens capable of showing that much information, but many will be smaller. The `ScrollView` lets us keep the table as-is, but only present part of it at a time.

On the stock Android emulator, when the activity is first viewed, you see:

Figure 137: The ScrollViewDemo sample application

Notice how only five rows and part of the sixth are visible. You can scroll up and down to see the remaining rows. Also note how the right side of the content gets clipped by the scrollbar — be sure to put some padding on that side or otherwise ensure your own content does not get clipped in that fashion.

Android also has `HorizontalScrollView`, which works like `ScrollView`... just horizontally. This would be good for forms that might be too wide rather than too tall. Note that `ScrollView` only scrolls vertically and `HorizontalScrollView` only scrolls horizontally.

Also, note that you cannot put scrollable items into a `ScrollView`. For example, a `ListView` widget — which we will see in [an upcoming chapter](#) — already knows how to scroll. You do not need to put a `ListView` in a `ScrollView`, and if you were to try, it would not work very well.

And, a `ScrollView` or `HorizontalScrollView` can only have one child — if you want more than one, wrap the children in a suitable container class (e.g., a `LinearLayout`) and put that inside the `ScrollView` or `HorizontalScrollView`.

Android Studio Graphical Layout Editor

The `ScrollView` and `HorizontalScrollView` widgets appear in the “Containers” section of the Palette in the Graphical Layout editor. You can drag one of these into your layout XML resource, then drag *one* child into it.

Eclipse Graphical Layout Editor

The `ScrollView` and `HorizontalScrollView` widgets appear in the “Composite” section of the Palette in the Graphical Layout editor. You can drag one of these into your layout XML resource, then drag *one* child into it.

Making Progress with ProgressBars

If you are going to fork background threads to do work on behalf of the user, you will want to think about keeping the user informed that work is going on. This is particularly true if the user is effectively waiting for that background work to complete.

The typical approach to keeping users informed of progress is some form of progress bar, like you see when you copy a bunch of files from place to place in many desktop operating systems. Android supports this through the `ProgressBar` widget.

A `ProgressBar` keeps track of progress, defined as an integer, with 0 indicating no progress has been made. You can define the maximum end of the range — what value indicates progress is complete — via `setMax()`. By default, a `ProgressBar` starts with a progress of 0, though you can start from some other position via `setProgress()`.

If you prefer your progress bar to be indeterminate — meaning that it will show a general animated effect, rather than a specific amount of progress — use `setIndeterminate()`, setting it to true.

In your Java code, you can either positively set the amount of progress that has been made (via `setProgress()`) or increment the progress from its current amount (via `incrementProgressBy()`). You can find out how much progress has been made via `getProgress()`.

We will see a `ProgressBar` in action in [the next chapter](#), another one of our tutorials.

Visit the Trails!

The trails portion of the book contains [a widget catalog](#), providing capsule descriptions and samples for a number of widgets not described elsewhere in this book.

You might also be interested in [GridLayout](#), which is an alternative to the classic `LinearLayout`, `RelativeLayout`, and `TableLayout` containers.

Tutorial #5 - Making Progress

When we actually get around to opening the digital book for display, there will be a slight delay as the HTML and other assets are read into memory. To help assure the user that their device has not frozen, we will add a `ProgressBar` to our user interface in this tutorial.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Step #1: Removing The “Hello, World”

Right now, our user interface consists of a highly-sophisticated “Hello, World” string, shown in a `TextView`. While no doubt it is eligible for many design awards, this is not the user interface we need. So, we need to get rid of it.

Double-click on the `res/layout/main.xml` file. This should bring up the graphical layout editor on your initial layout:

TUTORIAL #5 - MAKING PROGRESS

Figure 138: main.xml Layout in Android Studio

Click on the “Hello, world!” TextView in the middle of that layout to highlight it, then press the Delete key to delete it. At this point, you can save your file.

Also, we no longer need the hello_world string resource. To remove it, open the res/values/strings.xml file. Find the <string> element that has a name of hello_world, delete that element, and save the file.

The resulting XML should resemble:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string name="app_name">EmPub Lite</string>
</resources>
```

Step #2: Adding a ProgressBar

Now that the TextView is out of the way, we can add our ProgressBar in its place.

TUTORIAL #5 - MAKING PROGRESS

Go back to `res/layout/main.xml` in Android Studio. In the “Widgets” portion of the tool palette, you will see a few `ProgressBar` widget entries:

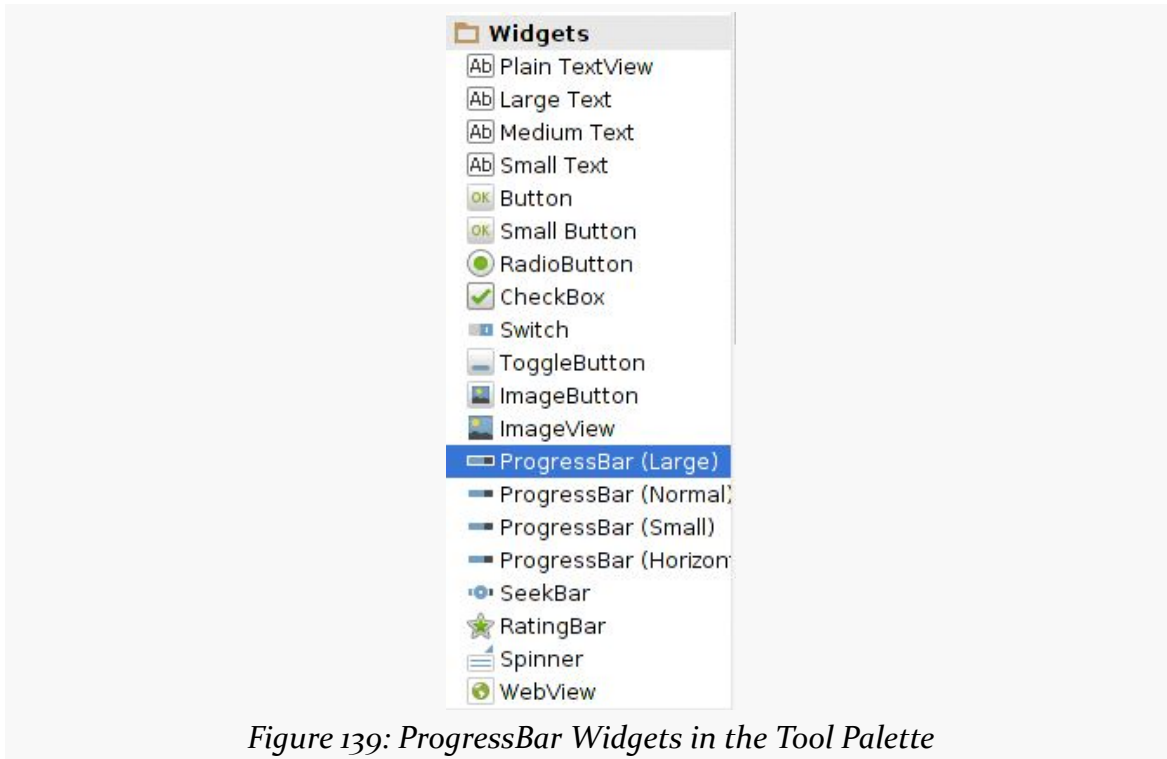

Figure 139: ProgressBar Widgets in the Tool Palette

Drag the “Large” one out of the palette and onto the preview of our activity. You will see a tooltip pointing out the `RelativeLayout` rules that the drag-and-drop operation will apply if you drop the widget in its current location. Slide the `ProgressBar` around until you center it and the tooltip shows that it will use `centerHorizontal` and `centerVertical` rules. If you wind up with `centerInParent` instead of those other two settings, that is fine as well.

In the Properties list on the right, find the “id” row, and change the value for the “id” to `progressBar1` (to match what Eclipse’s drag-and-drop GUI builder uses, to keep the two sets of instructions synchronized).

Step #3: Seeing the Results

If you run the app in a device or emulator, you will see your `ProgressBar` widget, sitting there, all alone, waiting for somebody to write more code in support of it:

Figure 140: EmPubLite, With ProgressBar

Note that if you have not yet set up the x86 emulator, you might wish to consider doing so, as we will become increasingly dependent upon the emulator, and the ARM emulator is slow. There is a section [later in the book](#) that covers how to set up the x86 emulator.

In Our Next Episode...

... we will [attach a third-party library](#) to our tutorial project.

GUI Building, Continued

If you are using an IDE, and you have been experimenting with the graphical layout editor and drag-and-drop GUI building, this chapter will cover some other general features of this editor that you may find useful.

Even if you are not using an IDE, you may want to at least skim this chapter, as you will find a few tricks that will be relevant for you as well.

Making Your Selection

Clicking on a widget makes it the selected widget, meaning that the toolbar buttons will affect that widget (or, sometimes, its container, depending upon the button). Selected widgets have a thin blue border with blue square “grab handles” for adjusting its size and position.

Figure 141: Android Studio, Selected Widget in Graphical Layout Editor

Clicking on a container also selects it. However, there may or may not be a blue border — in particular, containers that fill the screen (`match_parent` for width and height) do not seem to get the border.

Sometimes, though, you want to select a container that you cannot reach, because its contents are completely filled with widgets. That occurs with the `LinearPercent` sample from [a previous chapter](#) – the entire `LinearLayout` is filled with the three `Button` widgets. In these cases, click on the widget or container in the Component Tree (Android Studio) or Outline (Eclipse) pane to select it.

Including Includes

Sometimes, you have a widget or a collection of widgets that you want to reuse across multiple layout XML resources. Android supports the notion of an “include” that allows this. Simply create a dedicated layout XML resource that contains the widget(s) to reuse, then add them to your main layouts via an `<include>` element:

```
<include layout="@layout/thing_we_are_reusing" />
```

GUI BUILDING, CONTINUED

You can even assign the `<include>` element a width or height if needed, as if it were just a widget or container.

The IDE makes it easy for you to take widgets from an existing layout XML resource and extract them into a separate layout XML resource, replacing them with an `<include>` element.

In Android Studio, select the widget(s) that you want to reuse, then choose Refactor > Extract Layout from the context menu. This will display a dialog where you can fill in the file name of your resulting resource:

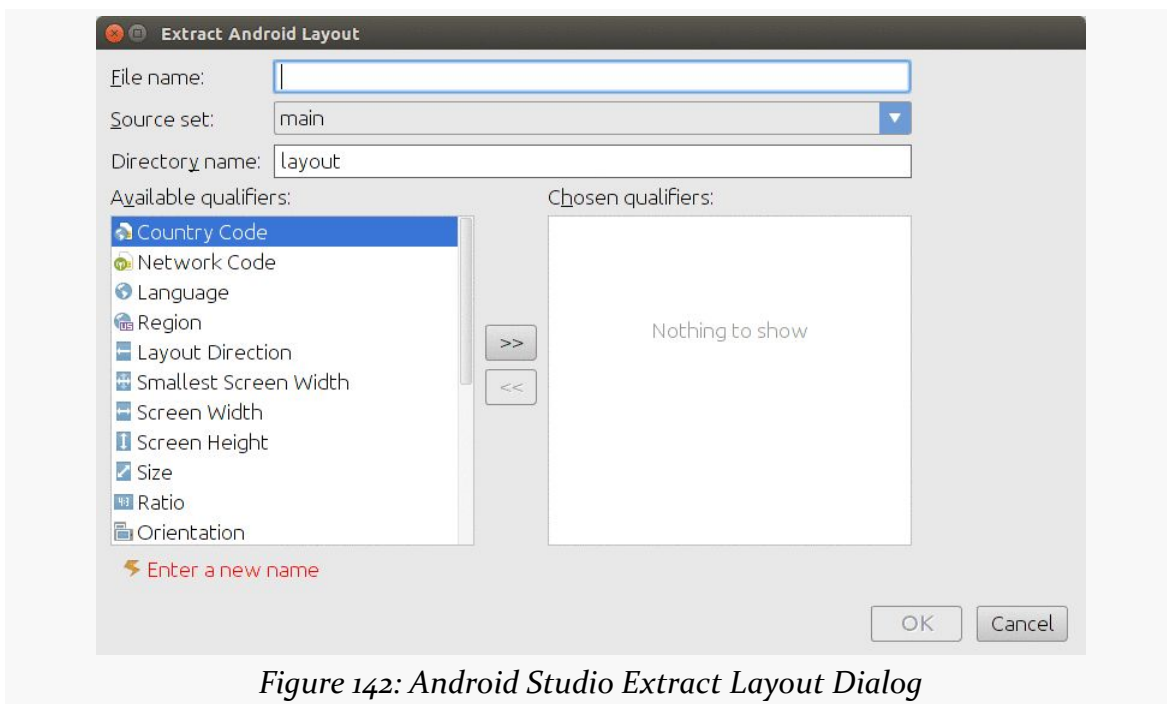

Figure 142: Android Studio Extract Layout Dialog

In Eclipse, select the widget(s) that you want to reuse, then right-click over them and choose “Extract Include” from the context menu. This will bring up a dialog where you can specify a name to give the new layout XML resource:

By default, Eclipse will search *all* your layout files for these widgets and replace them with the `<include>`, though you can uncheck the checkbox to disable this behavior and only affect the layout XML resource you are presently editing.

If you are extracting multiple widgets that are not wrapped in their own container, the IDE will automatically wrap them in a `<merge>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<merge xmlns:android="http://schemas.android.com/apk/res/android">
  <!-- widgets go here -->
</merge>
```

This is necessary purely from an XML standpoint — you cannot have multiple root elements in an XML file. When the `<merge>` is added to another layout via `<include>`, the `<merge>` element itself evaporates, leaving behind its children.

Wrap It Up (In a Container)

Sometimes, after you have added a widget to your layout, you later determine that you really needed it to be in some sort of container. For example, perhaps you thought you only needed one `TextView` but later decided to stack two `TextView` widgets in a vertical `LinearLayout`, in which case you somehow need to introduce this `LinearLayout` into the mix.

In Eclipse, the simplest way to do that is to right-click over the widget that needs a new container (in the preview pane or the Outline pane) and choose “Wrap In Container...” from the context menu. This will bring up a dialog allowing you to choose the class of the container (with a reasonable default pre-selected) and give the container an `android:id` value (which, for some strange reason, is mandatory).

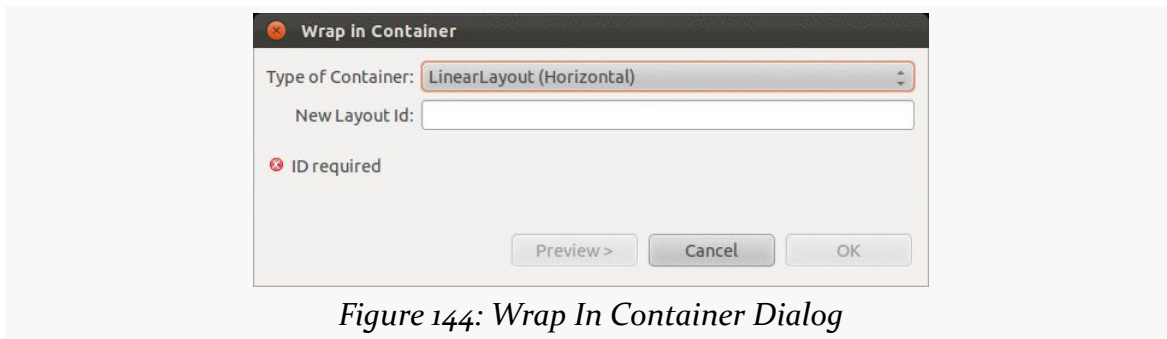

Figure 144: Wrap In Container Dialog

Similarly, if a widget is wrapped in a container, where the container is no longer necessary, “Remove Container” will get rid of the container.

Note that Android Studio does not offer this feature.

Morphing Widgets

Occasionally, you might configure a widget, only to decide later on that you really want it to be a different type of widget. For example, perhaps you start with a `CheckBox` and later want to switch it to be a `ToggleButton`.

To do this in Android Studio, right-click over the widget (in the preview pane or the Component Tree pane) and choose Morphing from the context menu. This brings up a fly-out menu of possible alternative classes; choosing one will automatically convert your widget into the selected type.

To do this in Eclipse, right-click over the widget (in the preview pane or the Outline pane) and choose “Change Widget Type” from the context menu. This will bring up a dialog box for you to choose a replacement widget class, with a likely candidate pre-selected for you:

Figure 145: Change Widget Type

After making the selection, Eclipse will alter your element to the new widget type. Note that you may need to make other changes yourself, for attributes that you no longer need or now need to add.

Preview of Coming Attractions

At the top of the graphical layout editor, you will find a series of drop-downs that allow you to tailor what the preview looks like:

Figure 146: Android Studio Preview Controls

Figure 147: Eclipse Preview Controls

Your IDE will choose some likely defaults based upon your project settings, but you are welcome to change them as you see fit. Notable changes include:

- What version of Android is used for the preview (as widget styling changes from time to time in Android releases)
- What language is used for your string resources?
- What size and resolution of screen is used?
- Is it displayed in portrait or landscape?

These only affect the preview, so they show you (approximately) what your layout will look like under those conditions, but they do not modify anything about your layout XML itself.

AdapterViews and Adapters

If you want the user to choose something out of a collection of somethings, you could use a bunch of `RadioButton` widgets. However, Android has a series of more flexible widgets than that, ones that this book will refer to as “selection widgets”.

These include:

- `ListView`, which is your typical “list box”
- `Spinner`, which (more or less) is a drop-down list
- `GridView`, offering a two-dimensional roster of choices
- `ExpandableListView`, a limited “tree” widget, supporting two levels in the hierarchy

and many more.

At their core, these are ordinary widgets. You will find them in your tool palette of your IDE’s graphical layout editor, and can drag them and position them as you see fit.

The key is that these all have a common superclass: `AdapterView`, so named because they partner with objects implementing the `Adapter` interface to determine what choices are available for the user to choose from.

Adapting to the Circumstances

An `Adapter` is your bridge between your model data and that data’s visual representation in the `AdapterView`:

- an Adapter might “adapt” an Invoice into a View that would serve as a row in a `ListView`
- an Adapter might “adapt” a Book into a View that would serve as a cell in a `GridView`
- and so on

Android ships with several Adapter classes ready for your use, where the different adapter classes are designed to “adapt” different sorts of collections (e.g., arrays versus results of database queries). Android also has a `BaseAdapter` class that can serve as the foundation for your own Adapter implementation, if you need to “adapt” a collection of data that does not fit any of the Adapter classes supplied by Android.

Using ArrayAdapter

The easiest adapter to use is `ArrayAdapter` — all you need to do is wrap one of these around a Java array or `java.util.List` instance, and you have a fully-functioning adapter:

```
String[] items={"this", "is", "a", "really", "silly", "list"};
new ArrayAdapter<String>(this,
    android.R.layout.simple_list_item_1,
    items);
```

One flavor of the `ArrayAdapter` constructor takes three parameters:

1. The Context to use (typically this will be your activity instance)
2. The resource ID of a view to use (such as a built-in system resource ID, as shown above)
3. The actual array or list of items to show

By default, the `ArrayAdapter` will invoke `toString()` on the objects in the list and wrap each of those strings in the view designated by the supplied resource. `android.R.layout.simple_list_item_1` simply turns those strings into `TextView` objects. Those `TextView` widgets, in turn, will be shown in the list or spinner or whatever widget uses this `ArrayAdapter`. If you want to see what `android.R.layout.simple_list_item_1` looks like, you can find a copy of it in your SDK installation — just search for `simple_list_item_1.xml`.

We will see in a [later section](#) how to subclass an Adapter and override row creation, to give you greater control over how rows and cells appear.

Lists of Naughty and Nice

The classic listbox widget in Android is known as `ListView`. Include one of these in your layout, invoke `setAdapter()` to supply your data and child views, and attach a listener via `setOnItemSelectedListener()` to find out when the selection has changed. With that, you have a fully-functioning listbox.

However, if your activity is dominated by a single list, you might well consider creating your activity as a subclass of `ListActivity`, rather than the regular `Activity` base class. If your main view is just the list, you do not even need to supply a layout — `ListActivity` will construct a full-screen list for you. If you do want to customize the layout, you can, so long as you identify your `ListView` as `@android:id/list`, so `ListActivity` knows which widget is the main list for the activity.

For example, here is a layout pulled from [the Selection/List sample project](#):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent" >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content" />
    <ListView
        android:id="@android:id/list"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        />
</LinearLayout>
```

It is just a list with a label on top to show the current selection.

The Java code to configure the list and connect the list with the label is:

```
package com.commonware.android.list;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.ArrayAdapter;
import android.widget.ListView;
import android.widget.TextView;

public class ListViewDemo extends ListActivity {
    private TextView selection;
```

ADAPTERVIEWS AND ADAPTERS

```
private static final String[] items={"lorem", "ipsum", "dolor",
    "sit", "amet",
    "consectetuer", "adipiscing", "elit", "morbi", "vel",
    "ligula", "vitae", "arcu", "aliquet", "mollis",
    "etiam", "vel", "erat", "placerat", "ante",
    "porttitor", "sodales", "pellentesque", "augue", "purus"};

@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);
    setContentView(R.layout.main);
    setListAdapter(new ArrayAdapter<String>(this,
        android.R.layout.simple_list_item_1,
        items));
    selection=(TextView)findViewById(R.id.selection);
}

@Override
public void onItemClick(ListView parent, View v, int position,
    long id) {
    selection.setText(items[position]);
}
}
```

With `ListActivity`, you can set the list adapter via `setListAdapter()` — in this case, providing an `ArrayAdapter` wrapping an array of Latin strings. To find out when the list selection changes, override `onItemClick()` and take appropriate steps based on the supplied child view and position (in this case, updating the label with the text for that position).

The results?

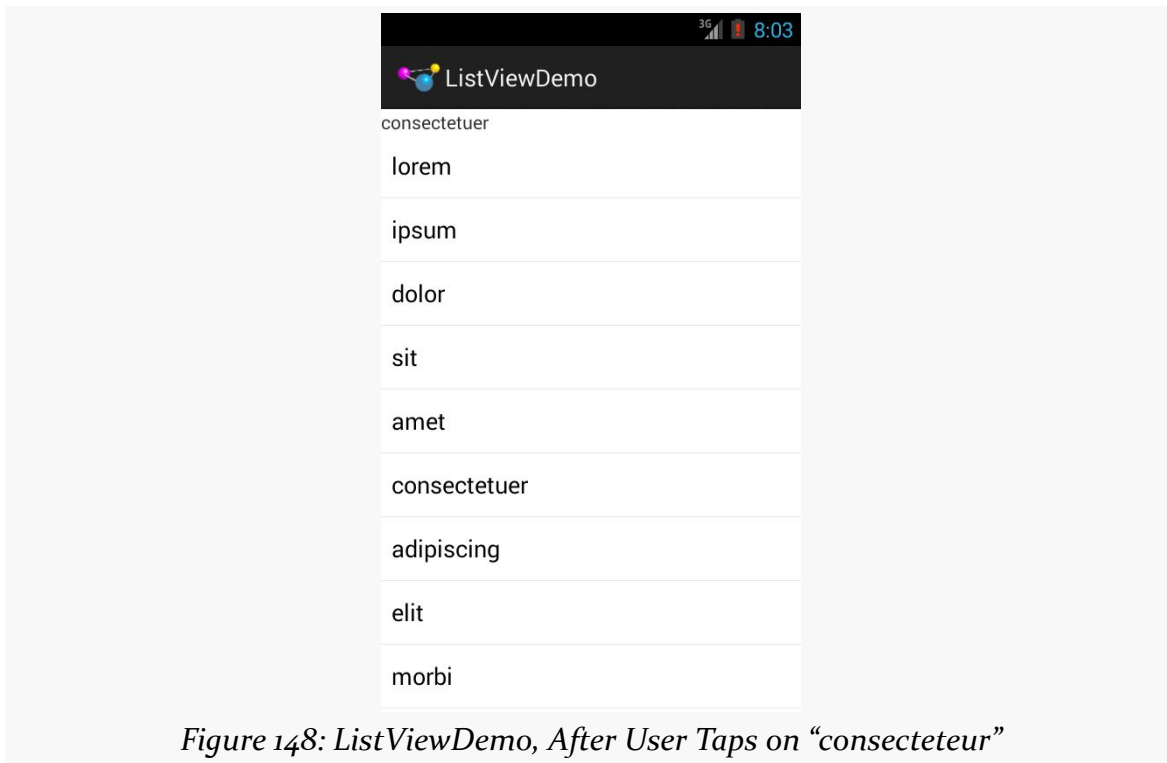

Figure 148: ListViewDemo, After User Taps on “consectetuer”

The second parameter to our `ArrayAdapter` — `android.R.layout.simple_list_item_1` — controls what the rows look like. The value used in the preceding example provides the standard Android list row: a big font with lots of padding to offer a large touch target for the user.

Clicks versus Selections

One thing that can confuse some Android developers is the distinction between clicks and selections. One might think that they are the same thing — after all, clicking on something selects it, right?

Well, no. At least, not in Android. At least not all of the time.

Android is designed to be used with touchscreen devices and non-touchscreen devices. Historically, Android has been dominated by devices that only offered touchscreens. However, there are various devices powered by Android and connected to TVs. Most TVs are not touchscreens, and so users of those TV-using Android devices will use some sort of remote control to drive Android. And some

Android devices offer both touchscreens and some other sort of pointing device — D-pad, trackball, arrow keys, etc.

To accommodate both styles of device, Android sometimes makes a distinction between selection events and click events. Widgets based on the “spinner” paradigm — including `Spinner` — treat everything as selection events. Other widgets — like `ListView` and `GridView` — treat selection events and click events differently. For these widgets, selection events are driven by the pointing device, such as using arrow keys to move a highlight bar up and down a list. Click events are when the user either “clicks” the pointing device (e.g., presses the center D-pad button) or taps on something in the widget using the touchscreen.

Choice Modes

By default, `ListView` is set up simply to collect clicks on list entries. Sometimes, though, you want a list that tracks a user’s choice, or possibly multiple choices. `ListView` can handle that as well, but it requires a few changes.

First, you will need to call `setChoiceMode()` on the `ListView` in Java code to set the choice mode, classically supplying either `CHOICE_MODE_SINGLE` or `CHOICE_MODE_MULTIPLE` as the value. You can get your `ListView` from a `ListActivity` via `getListView()`. You can also declare this via the `android:choiceMode` attribute in your layout XML.

Then, rather than use `android.R.layout.simple_list_item_1` as the layout for the list rows in your `ArrayAdapter` constructor, you can use either `android.R.layout.simple_list_item_single_choice` or `android.R.layout.simple_list_item_multiple_choice` for single-choice or multiple-choice lists, respectively.

For example, here is an activity layout from [the Selection/Checklist sample project](#):

```
<?xml version="1.0" encoding="utf-8"?>
<ListView
xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:drawSelectorOnTop="false"
    android:choiceMode="multipleChoice"
/>
```

ADAPTERVIEWS AND ADAPTERS

It is a full-screen `ListView`, with the `android:choiceMode="multipleChoice"` attribute to indicate that we want multiple choice support.

Our activity just uses a standard `ArrayAdapter` on our list of Latin words, but uses `android.R.layout.simple_list_item_multiple_choice` as the row layout:

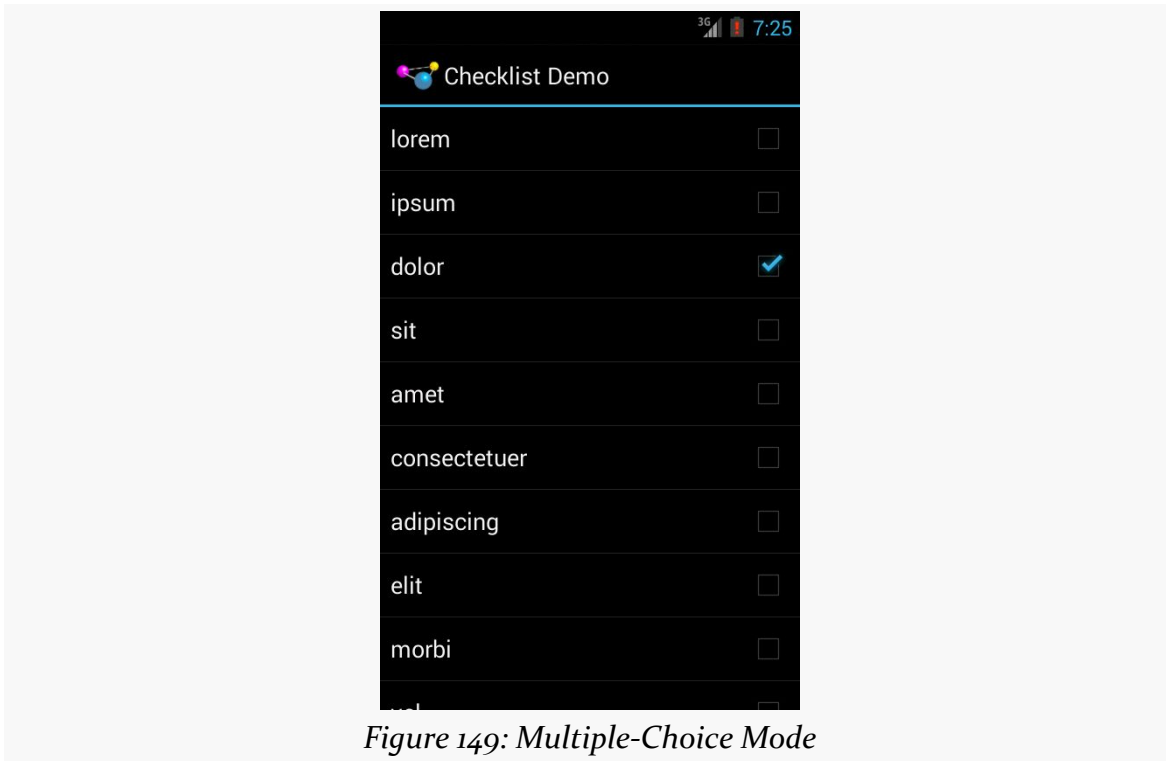

```
package com.commonware.android.checklist;

import android.app.ListActivity;
import android.os.Bundle;
import android.widget.ArrayAdapter;

public class ChecklistDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_multiple_choice,
            items));
    }
}
```

What the user sees is the list of words with checkboxes down the right edge:

If we wanted, we could call methods like `getCheckedItemPositions()` on our `ListView` to find out which items the user checked, or `setItemChecked()` if we wanted to check (or un-check) a specific entry ourselves.

Clicks versus Selections, Revisited

If the user clicks a row in a `ListView`, a click event is registered, triggering things like `onListItemClick()` in an `OnItemClickListener`. If the user uses a pointing device to change a selection (e.g., pressing up and down arrows to move a highlight bar in the `ListView`), that triggers `onItemSelected()` in an `OnItemSelectedListener`.

Many times, particularly if the `ListView` is the entire UI at present, you only care about clicks. Sometimes, particularly if the `ListView` is adjacent to something else (e.g., on a TV, where you have more screen space *and* do not have a touchscreen), you will care more about selection events. Either way, you can get the events you need.

Spin Control

In Android, the Spinner is the equivalent of the drop-down selector you might find in other toolkits. Clicking the Spinner drops down a list for the user to choose an item from. You basically get the ability to choose an item from a list without taking up all the screen space of a `ListView`, at the cost of an extra click to make a change.

As with `ListView`, you provide the adapter for data and child views via `setAdapter()` and hook in a listener object for selections via `setOnItemSelectedListener()`.

To tailor the view used when displaying the drop-down perspective, you need to configure the adapter, not the Spinner widget. Use the `setDropDownViewResource()` method to supply the resource ID of the view to use.

For example, culled from [the Selection/Spinner sample project](#), here is an XML layout for a simple view with a Spinner:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
    <Spinner android:id="@+id/spinner"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
</LinearLayout>
```

This is the same view as shown in [a previous section](#), just with a Spinner instead of a `ListView`.

To populate and use the Spinner, we need some Java code:

```
public class SpinnerDemo extends Activity
    implements AdapterView.OnItemSelectedListener {
    private TextView selection;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
```

ADAPTERVIEWS AND ADAPTERS

```
        "etiam", "vel", "erat", "placemat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);
    selection=(TextView)findViewById(R.id.selection);

    Spinner spin=(Spinner)findViewById(R.id.spinner);
    spin.setOnItemSelectedListener(this);

    ArrayAdapter<String> aa=new ArrayAdapter<String>(this,
                                                    android.R.layout.simple_spinner_item,
                                                    items);

    aa.setDropDownViewResource(
        android.R.layout.simple_spinner_dropdown_item);
    spin.setAdapter(aa);
}

@Override
public void onItemClick(AdapterView<?> parent,
                        View v, int position, long id) {
    selection.setText(items[position]);
}

@Override
public void onNothingSelected(AdapterView<?> parent) {
    selection.setText("");
}
}
```

Here, we attach the activity itself as the selection listener (`spin.setOnItemSelectedListener(this)`), as Spinner widgets only support selection events, not click events. This works because the activity implements the `OnItemSelectedListener` interface. We configure the adapter not only with the list of fake words, but also with a specific resource to use for the drop-down view (via `aa.setDropDownViewResource()`). Also note the use of `android.R.layout.simple_spinner_item` as the built-in View for showing items in the spinner itself. Finally, we implement the callbacks required by `OnItemSelectedListener` to adjust the selection label based on user input.

What we get is:

Figure 150: SpinnerDemo, as Initially Launched

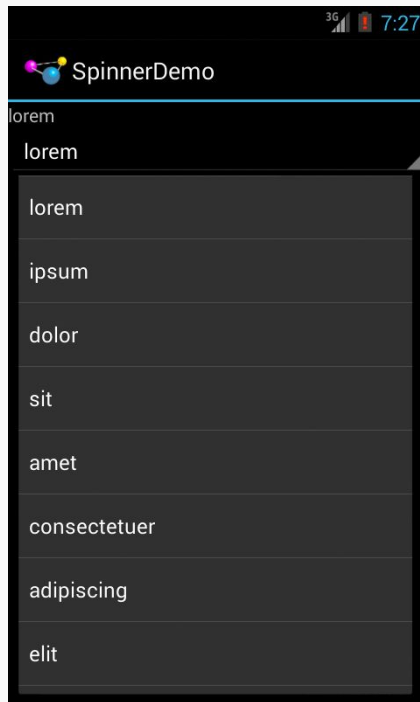

Figure 151: SpinnerDemo, with Spinner Drop-Down List Displayed

Grid Your Lions (Or Something Like That...)

As the name suggests, `GridView` gives you a two-dimensional grid of items to choose from. You have moderate control over the number and size of the columns; the number of rows is dynamically determined based on the number of items the supplied adapter says are available for viewing.

There are a few properties which, when combined, determine the number of columns and their sizes:

1. `android:numColumns` spells out how many columns there are, or, if you supply a value of `auto_fit`, Android will compute the number of columns based on available space and the properties listed below.
2. `android:verticalSpacing` and `android:horizontalSpacing` indicate how much whitespace there should be between items in the grid.
3. `android:columnWidth` indicates how wide each column should be, in terms of some dimension value (e.g., `40dp` or `@dimen/grid_column_width`).
4. `android:stretchMode` indicates, for grids with `auto_fit` for `android:numColumns`, what should happen for any available space not taken up by columns or spacing — this should be `columnWidth` to have the columns take up available space or `spacingWidth` to have the whitespace between columns absorb extra space.

Otherwise, the `GridView` works much like any other selection widget — use `setAdapter()` to provide the data and child views, invoke `setOnItemClickListener()` to find out when somebody clicks on a cell in the grid, etc.

For example, here is an XML layout from [the Selection/Grid sample project](#), showing a `GridView` configuration:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView
    android:id="@+id/selection"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <GridView
    android:id="@+id/grid"
```

ADAPTERVIEWS AND ADAPTERS

```
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:verticalSpacing="40dip"
    android:horizontalSpacing="5dip"
    android:numColumns="auto_fit"
    android:columnWidth="100dip"
    android:stretchMode="columnWidth"
    android:gravity="center"
  />
</LinearLayout>
```

For this grid, we take up the entire screen except for what our selection label requires. The number of columns is computed by Android (`android:numColumns = "auto_fit"`) based on our horizontal spacing (`android:horizontalSpacing = "5dip"`) and columns width (`android:columnWidth = "100dip"`), with the columns absorbing any “slop” width left over (`android:stretchMode = "columnWidth"`).

The Java code to configure the GridView is:

```
package com.commonware.android.grid;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.GridView;
import android.widget.TextView;

public class GridDemo extends Activity
    implements AdapterView.OnItemClickListener {
    private TextView selection;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
        selection=(TextView)findViewById(R.id.selection);

        GridView g=(GridView) findViewById(R.id.grid);
        g.setAdapter(new ArrayAdapter<String>(this,
            R.layout.cell,
            items));
        g.setOnItemClickListener(this);
    }

    @Override
    public void onItemClick(AdapterView<?> parent, View v,
        int position, long id) {
        selection.setText(items[position]);
    }
}
```

ADAPTERVIEWS AND ADAPTERS

```
}  
}
```

The grid cells are defined by a separate `res/layout/cell.xml` file, referenced in our `ArrayAdapter` as `R.layout.cell`:

```
<?xml version="1.0" encoding="utf-8"?>  
<TextView  
  xmlns:android="http://schemas.android.com/apk/res/android"  
  android:layout_width="wrap_content"  
  android:layout_height="wrap_content"  
  android:textSize="14dip"  
>
```

With the vertical spacing from the XML layout (`android:verticalSpacing = "40dip"`), the grid overflows the boundaries of the emulator's screen:

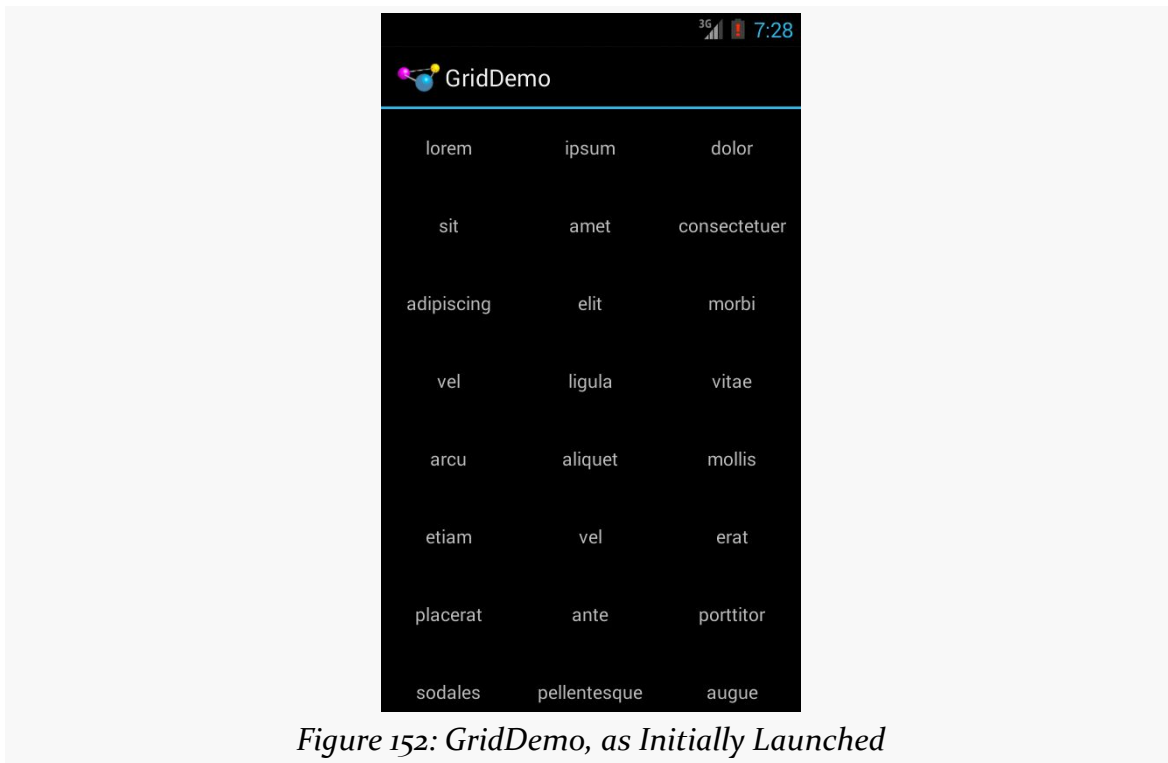

Figure 152: GridDemo, as Initially Launched

Figure 153: GridDemo, Scrolled to the Bottom of the Grid

GridView, like ListView, supports both click events and selection events. In this sample, we register an `OnItemClickListener` to listen for click events.

Fields: Now With 35% Less Typing!

The `AutoCompleteTextView` is sort of a hybrid between the `EditText` (field) and the `Spinner`. With auto-completion, as the user types, the text is treated as a prefix filter, comparing the entered text as a prefix against a list of candidates. Matches are shown in a selection list that folds down from the field. The user can either type out an entry (e.g., something not in the list) or choose an entry from the list to be the value of the field.

`AutoCompleteTextView` subclasses `EditText`, so you can configure all the standard look-and-feel aspects, such as font face and color.

In addition, `AutoCompleteTextView` has an `android:completionThreshold` property, to indicate the minimum number of characters a user must enter before the list filtering begins.

ADAPTERVIEWS AND ADAPTERS

You can give `AutoCompleteTextView` an adapter containing the list of candidate values via `setAdapter()`. However, since the user could type something not in the list, `AutoCompleteTextView` does not support selection listeners. Instead, you can register a `TextWatcher`, like you can with any `EditText`, to be notified when the text changes. These events will occur either because of manual typing or from a selection from the drop-down list.

Below we have a familiar-looking XML layout, this time containing an `AutoCompleteTextView` (pulled from [the Selection/AutoComplete sample application](#)):

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <TextView
        android:id="@+id/selection"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        />
    <AutoCompleteTextView android:id="@+id/edit"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:completionThreshold="3"/>
</LinearLayout>
```

The corresponding Java code is:

```
package com.commonware.android.auto;

import android.app.Activity;
import android.os.Bundle;
import android.text.Editable;
import android.text.TextWatcher;
import android.widget.ArrayAdapter;
import android.widget.AutoCompleteTextView;
import android.widget.TextView;

public class AutoCompleteDemo extends Activity
    implements TextWatcher {
    private TextView selection;
    private AutoCompleteTextView edit;
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
```

ADAPTERVIEWS AND ADAPTERS

```
super.onCreate(icle);
setContentView(R.layout.main);
selection=(TextView)findViewById(R.id.selection);
edit=(AutoCompleteTextView)findViewById(R.id.edit);
edit.addTextChangedListener(this);

edit.setAdapter(new ArrayAdapter<String>(this,
    android.R.layout.simple_dropdown_item_1line,
    items));
}

@Override
public void onTextChanged(CharSequence s, int start, int before,
    int count) {
    selection.setText(edit.getText());
}

@Override
public void beforeTextChanged(CharSequence s, int start,
    int count, int after) {
    // needed for interface, but not used
}

@Override
public void afterTextChanged(Editable s) {
    // needed for interface, but not used
}
}
```

This time, our activity implements `TextWatcher`, which means our callbacks are `onTextChanged()`, `beforeTextChanged()`, and `afterTextChanged()`. In this case, we are only interested in the first, and we update the selection label to match the `AutoCompleteTextView`'s current contents.

Here we have the results:

Figure 154: AutoCompleteDemo, as Initially Launched

Figure 155: AutoCompleteDemo, After Entering a Few Matching Letters

Figure 156: AutoCompleteDemo, After Auto-Complete Value Was Selected

Note that the red underline in the preceding screenshot is due to spelling correction. Like `EditText`, `AutoCompleteTextView` supports hinting at spelling errors. The emulator's language is set to English, as there is no option in it for Latin.

Customizing the Adapter

The humble `ListView` is one of the most important widgets in all of Android, simply because it is used so frequently. Whether choosing a contact to call or an email message to forward or an ebook to read, `ListView` widgets are employed in a wide range of activities.

Of course, it would be nice if they were more than just plain text.

The good news is that they can be as fancy as you want, within the limitations of a mobile device's screen, of course. However, making them more elaborate takes some work.

Note that while this section will be using `ListView` as the `AdapterView`, the same techniques hold for *any* `AdapterView`.

The Single Layout Pattern

The simplest way of creating custom `ListView` rows (or `GridView` cells or whatever) is when they all have the same basic structure and can be created from the same layout XML resource. This does not mean they have to be strictly identical, but that you can make whatever changes you need just by configuring the widgets (e.g., make some things `VISIBLE` or `GONE`).

This is not especially difficult, though it does take a few more steps than what we have seen previously.

Step #0: Get Things Set Up Simply

First, create your activity (e.g., `ListActivity`), get your data (e.g., array of Java strings), and set up your `AdapterView` with a simple adapter following the steps outlined in the preceding sections.

Here, we will examine [the Selection/Dynamic sample project](#). We will use a simple `ListActivity` (taking the default layout of a full-screen `ListView`) and use the same list of 25 Latin words used in earlier samples. However, this time, we want to have a more elaborate row, taking into account the length of the Latin word.

Step #1: Design Your Row

Next, create a layout XML resource that will represent one row in your `ListView` (or cell in your `GridView` or whatever).

For example, our `res/layout/row.xml` resource will use a pair of nested `LinearLayout` containers to organize two `TextView` widgets and an `ImageView`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal">

    <ImageView
        android:id="@+id/icon"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center_vertical"
        android:padding="2dip"
        android:src="@drawable/ok"
        android:contentDescription="@string/icon"/>
```

```
<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"/>
</LinearLayout>
```

```
</LinearLayout>
```

The ImageView will use one of two drawable resources, one for short words, and another for long words.

Step #2: Extend ArrayAdapter

If you just used `R.layout.row` with a regular `ArrayAdapter`, it would work, insofar as it would not crash. However, `ArrayAdapter` only knows how to update a single `TextView` in a row, so it would ignore our other `TextView`, let alone the `ImageView`.

So, we need to create our own `ListAdapter`, by creating our own subclass of `ArrayAdapter`.

Since an `Adapter` is tightly coupled to the `AdapterView` that uses it, it is typically simplest to make the custom `ArrayAdapter` subclass be an inner class of whoever manages the `AdapterView`. Hence, in our sample, we will create an `IconicAdapter` inner class of our `ListActivity`.

Step #3: Override the Constructor and `getView()`

The `IconicAdapter` constructor can chain to the superclass and supply the necessary data, such as our Java array of Latin words. The real fun comes when we override `getView()`:

```
package com.commonware.android.fancylists.three;

import android.app.ListActivity;
import android.os.Bundle;
```

ADAPTERVIEWS AND ADAPTERS

```
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.ImageView;
import android.widget.TextView;

public class DynamicDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setListAdapter(new IconicAdapter());
    }

    class IconicAdapter extends ArrayAdapter<String> {
        IconicAdapter() {
            super(DynamicDemo.this, R.layout.row, R.id.label, items);
        }

        @Override
        public View getView(int position, View convertView,
            ViewGroup parent) {
            View row=super.getView(position, convertView, parent);
            ImageView icon=(ImageView)row.findViewById(R.id.icon);

            if (items[position].length()>4) {
                icon.setImageResource(R.drawable.delete);
            }
            else {
                icon.setImageResource(R.drawable.ok);
            }

            TextView size=(TextView)row.findViewById(R.id.size);

            size.setText(String.format(getString(R.string.size_template),
                items[position].length()));

            return(row);
        }
    }
}
```

Our `getView()` implementation does three things:

- It chains to the superclass' implementation of `getView()`, which returns to us an instance of our row View, as prepared by `ArrayAdapter`. In particular, our word has already been put into one `TextView`, since `ArrayAdapter` does that normally.

ADAPTERVIEWS AND ADAPTERS

- It finds our `ImageView` and applies a business rule to set which icon should be used, referencing one of two drawable resources (`R.drawable.ok` and `R.drawable.delete`).
- It finds our other `TextView` and populates it as well, by pulling in the value of a string resource and using `String.format()` to pour in our word length.

Note that we call `findViewById()` not on the activity, but rather on the row returned by the superclass' implementation of `getView()`. **Always call `findViewById()` on something that is guaranteed to give you a unique result.** In the case of an `AdapterView`, there will be many rows, cells, etc. — calling `findViewById()` on the activity might return widgets with the right name but from other rows or cells.

This gives us:

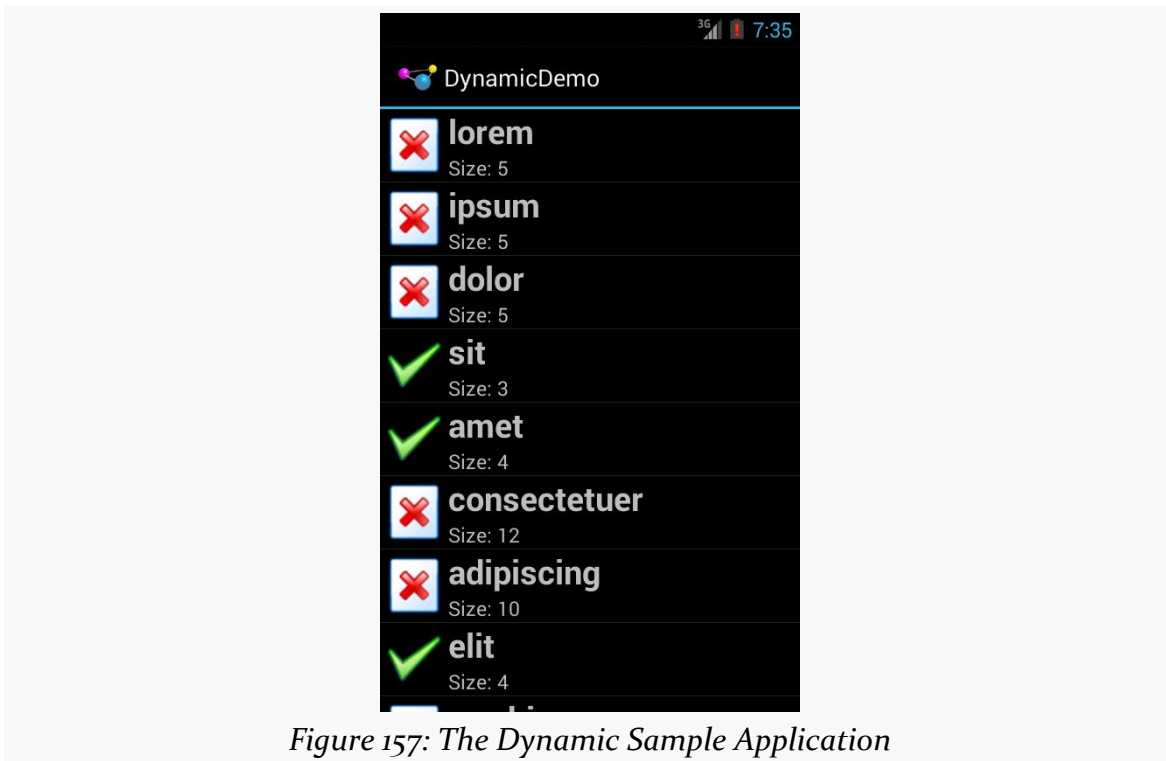

Figure 157: The Dynamic Sample Application

The approach of overriding `getView()` works for `ArrayAdapter`, but some other types of adapters would have alternatives. We will see that mostly with `CursorAdapter`, profiled in upcoming chapters.

Optimizing with the ViewHolder Pattern

A somewhat expensive operation we do a lot with more elaborate list rows is call `findViewById()`. This dives into our row and pulls out widgets by their assigned identifiers, so we can customize the widget contents (e.g., change the text of a `TextView`, change the icon in an `ImageView`). Since `findViewById()` can find widgets anywhere in the tree of children of the row's root `View`, this could take a fair number of instructions to execute, particularly if we keep having to re-find widgets we had found once before.

In some GUI toolkits, this problem is avoided by having the composite `View` objects, like our rows, be declared totally in program code (in this case, Java). Then, accessing individual widgets is merely the matter of calling a getter or accessing a field. And you can certainly do that with Android, but the code gets rather verbose. What would be nice is a way where we can still use the layout XML yet cache our row's key child widgets so we only have to find them once.

That's where the holder pattern comes into play, in a class we will call `ViewHolder`.

All `View` objects have `getTag()` and `setTag()` methods. These allow you to associate an arbitrary object with the widget. What the holder pattern does is use that "tag" to hold an object that, in turn, holds each of the child widgets of interest. By attaching that holder to the row `View`, every time we use the row, we already have access to the child widgets we care about, without having to call `findViewById()` again.

So, let's take a look at one of these holder classes (taken from [the Selection/ViewHolder sample project](#), a revised version of the Selection/Dynamic sample from before):

```
package com.commonware.android.fancylists.five;

import android.view.View;
import android.widget.ImageView;
import android.widget.TextView;

class ViewHolder {
    ImageView icon=null;
    TextView size=null;

    ViewHolder(View row) {
        this.icon=(ImageView)row.findViewById(R.id.icon);
        this.size=(TextView)row.findViewById(R.id.size);
    }
}
```

ADAPTERVIEWS AND ADAPTERS

ViewHolder holds onto the child widgets, initialized via `findViewById()` in its constructor. The widgets are simply package-protected data members, accessible from other classes in this project... such as a `ViewHolderDemo` activity. In this case, we are only holding onto two widgets — the icon and the second label — since we will let `ArrayAdapter` handle our first label for us. In our case, we are holding onto the `TextView` and `ImageView` widgets that we want to populate in `getView()`.

Using `ViewHolder` is a matter of creating an instance whenever we inflate a row and attaching said instance to the row `View` via `setTag()`, as shown in this rewrite of `getView()`, found in `ViewHolderDemo`:

```
@Override
public View getView(int position, View convertView,
                    ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    ViewHolder holder=(ViewHolder)row.getTag();

    if (holder==null) {
        holder=new ViewHolder(row);
        row.setTag(holder);
    }

    if (getModel(position).length(>4) {
        holder.icon.setImageResource(R.drawable.delete);
    }
    else {
        holder.icon.setImageResource(R.drawable.ok);
    }

    holder.size.setText(String.format(getString(R.string.size_template),
items[position].length()));

    return(row);
}
```

If the call to `getTag()` on the row returns `null`, we know we need to create a new `ViewHolder`, which we then attach to the row via `setTag()` for later reuse. Then, accessing the child widgets is merely a matter of accessing the data members on the holder.

This takes advantage of the fact that rows in a `ListView` get *recycled* — a 25,000-row list does not create 25,000 rows. The recycling itself is handled for us by `ArrayAdapter`, so we simply have to create our `ViewHolder` when needed and reuse the existing `ViewHolder` when a row gets recycled. The first time the `ListView` is displayed, all new rows need to be created, and we wind up creating a `ViewHolder` for each. As the user scrolls, rows get recycled, and we can reuse their corresponding `ViewHolder` widget caches. We will cover this recycling process in greater detail [in a later chapter](#).

ADAPTERVIEWS AND ADAPTERS

Note that the `getModel()` method shown here retrieves our model `String` for a given position, by using `getListAdapter()` (to retrieve our `IconicAdapter` from the activity's `ListView`) and `getItem()` (to retrieve the data, held by the adapter, represented by the position):

```
private String getModel(int position) {  
    return(((IconicAdapter)getListAdapter()).getItem(position));  
}
```

Dealing with Multiple Row Layouts

The story gets significantly more complicated if our mix of rows is more complicated. For example, here is the Sound screen in the Settings application:

Figure 158: Sound Settings Screen

It may not look like it, but that is a `ListView`. However, not all the rows look the same:

- Some have one line of text (e.g., “Volumes”)
- Some have two lines of text (e.g., “Silent mode” plus “Off”)
- Some have one line of text and a `CheckBox` (e.g., “Vibrate and ring”)

- Some are headings with totally different text formatting (e.g., “RINGTONE & NOTIFICATIONS”)

This is handled by having more than one row layout XML resource used by the adapter. The complexity comes not only in managing those different resources and determining which to use when, but in just having more than one resource – after all, we only teach ArrayAdapter how to use one. We will examine how to handle this scenario [in a later chapter](#).

Visit the Trails!

To learn more about ListView, you can turn to [Advanced ListViews](#), which covers other tricks you can do with a ListView.

RecyclerView is a more powerful (and more complex) replacement for ListView and GridView. You can read more about [what it does and how you can use it](#).

The WebView Widget

HTML has come a *long* way from Sir Tim Berners-Lee's original vision of using it to publish physics papers.

Not surprisingly, displaying HTML, CSS, and JavaScript in mobile applications is fairly popular, not only for creating full-fledged Web browsers, but for rendering HTML content from RSS/Atom feeds, from HTML-formatted email messages, ebooks (like the one you are reading), and so forth.

There are a couple of ways to display HTML in Android, with the most powerful being the `WebView` widget, the focus of this chapter.

Role of WebView

If your HTML is fairly limited in scope, such as what you might find in the body of a status update on Twitter, you can use the static `fromHtml()` method on the `Html` utility class to parse an HTML-formatted string into something that you can put into a `TextView`. `TextView` can render simple formatting like styles (bold, italic, etc.), font faces (serif, sans serif, etc.), colors, links, and so forth.

However, sometimes your needs for HTML transcend what `TextView` can handle. You will not be browsing Facebook using `TextView`, for example.

In those cases, `WebView` will be the more appropriate widget, as it can handle a *much* wider range of HTML tags. `WebView` can also handle CSS and JavaScript, which `Html.fromHtml()` would simply ignore. `WebView` can also assist you with common “browsing” metaphors, such as history list of visited URLs to support backwards and forwards navigation.

On the other hand, `WebView` is a much more expensive widget to use, in terms of memory consumption, than is `TextView`.

WebView and WebKit

The reason for the memory cost of `WebView` is the fact that `WebView` is powered by a fairly complete copy of [WebKit](#) (for Android 4.3 and older) or [Blink](#) (for Android 4.4+). `WebKit` is an open source Web rendering engine that forms the heart of major Web browsers, such as Safari, while `Blink` is used for Google's Chrome and Chromium browsers. While the version of `WebKit/Blink` that lives in Android is one optimized for mobile use, it still represents a fairly substantial code base, and rendering complex Web pages takes up a fair amount of RAM (as anyone with lots of browser tabs on their desktop knows all too well).

Because `WebView` is powered by `WebKit/Blink`, content that renders in Chrome and Safari *probably* renders the same in `WebView`. The emphasis on the word “probably” is for a few reasons:

- As mentioned, `WebKit/Blink` in Android is a mobile-optimized version, which introduces some differences compared to its desktop brethren
- `WebKit/Blink`, like any software project, has its own upgrade cycles and versioning, so different browsers (Chrome vs. Safari vs. `WebView`) will use different versions of the `WebKit` engine, introducing some differences
- Android has tweaked `WebKit/Blink` for its own purposes, introducing yet other potential differences

The Android System WebView

Starting in Android 5.0, the implementation of `WebView` can be updated by Google through the Play Store. The “Android System `WebView`” app contains this implementation. This does not affect your code, as the framework detects that you are running on Android 5.0+ or not, delegating to the right implementation in either case.

Having the `WebView` implementation be updated at any time has its pros and its cons.

On the plus side, if a security flaw is found, Google can quickly roll out a fix and millions of people will get it in short order.

However, *any* change that Google makes will get out to millions of people quickly... including new bugs, as we will see later in this chapter.

Adding the Widget

For simple stuff, WebView is not significantly different than any other widget in Android — pop it into a layout, tell it what URL to navigate to via Java code, and you are done.

As you can see in [the WebKit/Browser1 sample application](#), here is a simple layout with a WebView:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/webkit"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

As with any other widget, you need to tell it how it should fill up the space in the layout (in this case, it fills all remaining space).

And, just as with other widgets, you can add it using your IDE's graphical layout editor. An Android Studio user can drag a WebView out of the “Layouts” section of the tool palette, while an Eclipse user can drag a WebView out of the “Composite” section of the Eclipse tool palette.

Note that WebView knows how to scroll its own contents, so you do not need to put it in a ScrollView or HorizontalScrollView.

Loading Content Via a URL

There are a number of ways to load HTML content into a WebView widget.

The simplest is to use the `loadUrl()` method, which takes a URL and retrieves its contents over the Internet. For example, here is the activity source code for the WebKit/Browser1 sample application:

```
package com.commonware.android.browser1;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;
```

THE WEBVIEW WIDGET

```
public class BrowserDemo1 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        browser=(WebView)findViewById(R.id.webkit);

        browser.loadUrl("https://commonsware.com");
    }
}
```

However, we also have to make one change to `AndroidManifest.xml`, adding a line where we request permission to access the Internet:

```
<uses-permission android:name="android.permission.INTERNET"/>
```

If we fail to add this permission, the browser will refuse to load pages. We will discuss more about this “permission” concept [in a later chapter](#).

The resulting activity looks like a Web browser, just with hidden scrollbars:

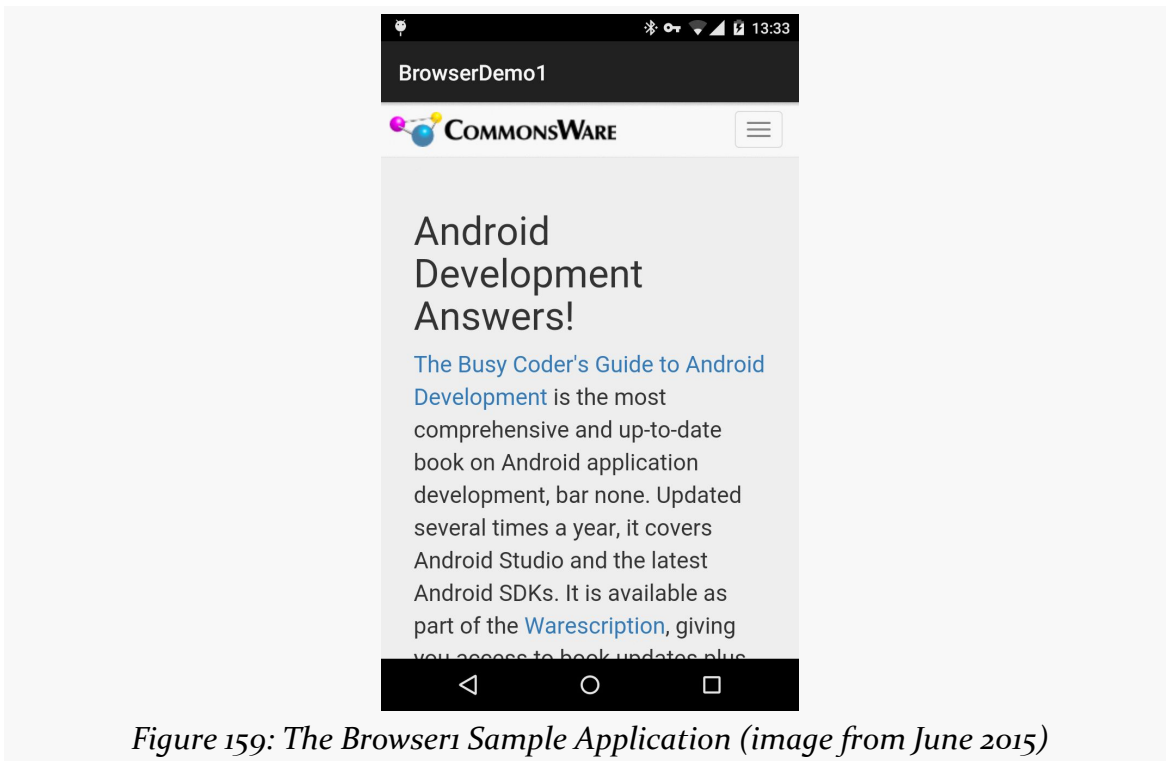

Figure 159: The Browser1 Sample Application (image from June 2015)

As with a regular Android Web browser, you can pan around the page by dragging it, while the directional pad moves you around all the focusable elements on the page.

What is missing is all the extra stuff that make up a Web browser, such as a navigational toolbar. `WebView` does not provide any of that — if you want those sorts of UI features, you will need to implement those yourself (e.g., use an `EditText` or `AutoCompleteTextView` for a browser address bar).

Links and Redirects

The sample shown above loads the CommonsWare home page. The links in that page are clickable. Exactly what happens when you click on the link, though, depends upon circumstances.

Traditionally, the default behavior for when the user clicks on a link in a `WebView` is for the linked-to Web page to be launched in a Web browser. However, the “Android System `WebView`” released in early June 2015 changed that default behavior, so now the linked-to Web page opens up in the `WebView` itself. Since Android 4.4 and older devices do not have the “Android System `WebView`”, this means that the default behavior of link clicks varies by device, which is not fun.

Also, if you try loading a page using `loadUrl()`, and the server issues a server-side redirect (e.g. HTTP 301 or 304 response), the default behavior is the same as a simple click of a link:

- On devices with “Android System `WebView`” 43.0.2357.121 or newer, the redirected-to page shows up in the `WebView`
- Everywhere else, the redirected-to page appears in a separate Web browser app

We will cover how to address this problem later in this chapter.

Supporting JavaScript

Now, you may be tempted to replace the URL in the above source code with something else, such as Google’s home page or something else that relies upon JavaScript. You will find that such pages do not work especially well by default. That is because, by default, JavaScript is turned off in `WebView` widgets.

If you want to enable JavaScript, call `getSettings().setJavaScriptEnabled(true);` on the `WebView` instance. At this point, any JavaScript referenced by your Web page should work normally.

There are some fancy tricks you can perform with `WebView` and JavaScript, such as having JavaScript call Java code or vice versa. These techniques will be covered [in a later chapter](#).

Alternatives for Loading Content

`loadUrl()` works with:

- `http://` and `https://` URLs
- `file://` URLs pointing to the local filesystem
- `file:///android_asset/` URLs pointing to one of your application's assets, as will be discussed [later in this book](#)
- `content://` URLs pointing to a `ContentProvider` that is publishing content available for streaming, as will be discussed [much later in this book](#)

Instead of `loadUrl()`, you can also use `loadData()`. Here, you supply the HTML for the `WebView` to display. You might use this to:

1. display a manual that was installed as a file with your application package
2. display snippets of HTML you retrieved as part of other processing, such as the description of an entry in an Atom feed
3. generate a whole user interface using HTML, instead of using the Android widget set

There are two flavors of `loadData()`. The simpler one allows you to provide the content, the MIME type, and the encoding, all as strings. Typically, your MIME type will be `text/html` and your encoding will be `UTF-8` for ordinary HTML.

For example, if you replace the `loadUrl()` invocation in the previous example with the following:

```
browser.loadData("<html><body>Hello, world!</body></html>",  
                "text/html", "UTF-8");
```

You get:

THE WEBVIEW WIDGET

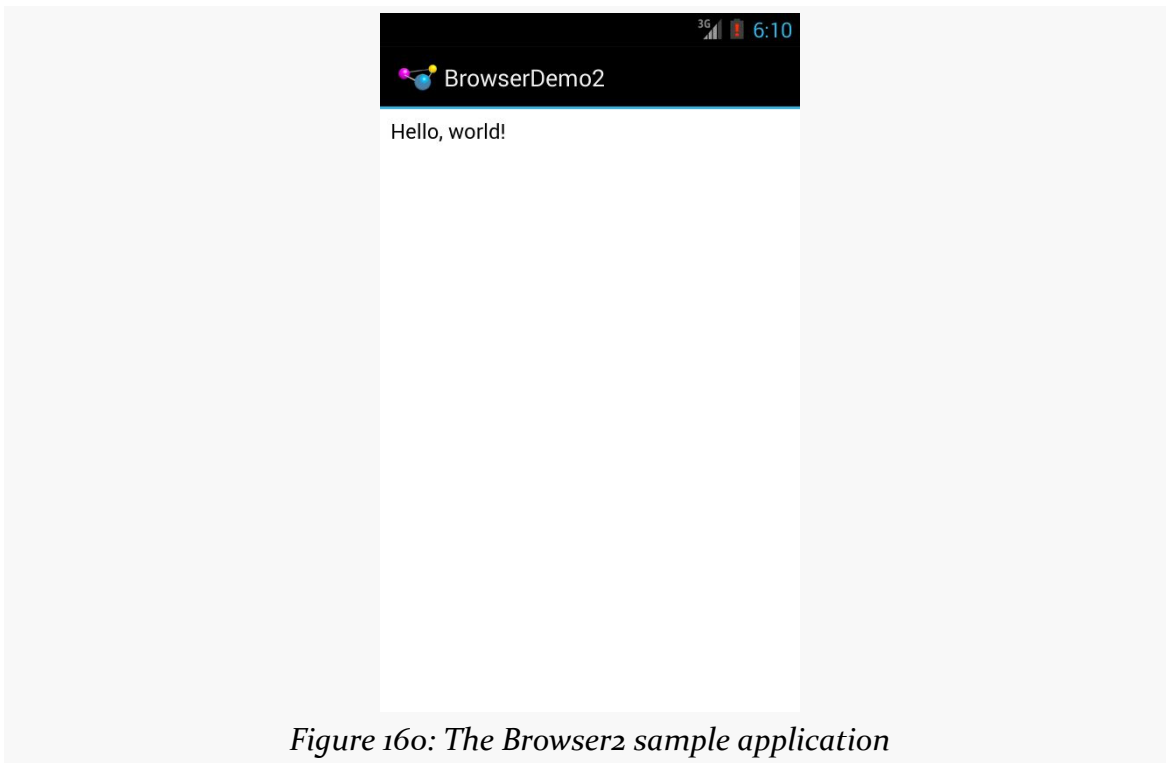

Figure 160: The Browser2 sample application

This is also available as a fully-buildable sample, as [WebKit/Browser2](#).

There is also a `loadDataWithBaseURL()` method. This takes, among other parameters, the “base URL” to use when resolving relative URLs in the HTML. Any relative URL (e.g., ``) will be interpreted as being relative to the base URL supplied to `loadDataWithBaseURL()`. If you find that you have content that refuses to load properly with `loadData()`, try `loadDataWithBaseURL()` with a null base URL, as sometimes that works better, for unknown reasons.

Listening for Events

Particularly if you are going to use the `WebView` as a local user interface (vs. browsing the Web), you will want to be able to get control at key times, particularly when users click on links. You will want to make sure those links are handled properly, either by loading your own content back into the `WebView`, by submitting an `Intent` to Android to open the URL in a full browser, or by some other means. We will discuss using an `Intent` to launch a Web browser [in a later chapter](#).

THE WEBVIEW WIDGET

One hook into the `WebView` activity is via `setWebViewClient()`, which takes an instance of a `WebViewClient` implementation as a parameter. The supplied callback object will be notified of a wide range of events, ranging from when parts of a page have been retrieved (`onPageStarted()`, etc.) to when you, as the host application, need to handle certain user- or circumstance-initiated events, such as:

1. `onTooManyRedirects()`
2. `onReceivedHttpAuthRequest()`
3. etc.

A common hook will be `shouldOverrideUrlLoading()`, where your callback is passed a URL (plus the `WebView` itself) and you return `true` if you will handle the request or `false` if you want default handling (e.g., actually fetch the Web page referenced by the URL). In the case of a feed reader application, for example, you will probably not have a full browser with navigation built into your reader, so if the user clicks a URL, you probably want to use an `Intent` to ask Android to load that page in a full browser. But, if you have inserted a “fake” URL into the HTML, representing a link to some activity-provided content, you can update the `WebView` yourself.

For example, let’s amend the first browser example to be an application that, upon a click, shows the current time.

From [WebKit/Browser3](#), here is the revised Java:

```
package com.commonware.android.webkit;

import android.app.Activity;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import java.util.Date;

public class BrowserDemo3 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        browser=(WebView)findViewById(R.id.webkit);
        browser.setWebViewClient(new Callback());

        loadTime();
    }

    void loadTime() {
        String page=
```

THE WEBVIEW WIDGET

```
        "<html><body><a href='http://webview.used.to.be.less.annoying/clock'>"
        + DateUtils.formatDateTime(this, new Date().getTime(),
                                   DateUtils.FORMAT_SHOW_DATE
                                   | DateUtils.FORMAT_SHOW_TIME)
        + "</a></body></html>";

    browser.loadData(page, "text/html", "UTF-8");
}

private class Callback extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView view, String url) {
        loadTime();

        return(true);
    }
}
```

Here, we load a simple Web page into the browser (`loadTime()`) that consists of the current time, made into a hyperlink to a fake URL. We also attach an instance of a `WebViewClient` subclass, providing our implementation of `shouldOverrideUrlLoading()`. In this case, no matter what the URL, we want to just reload the `WebView` via `loadTime()`.

Running this activity gives us:

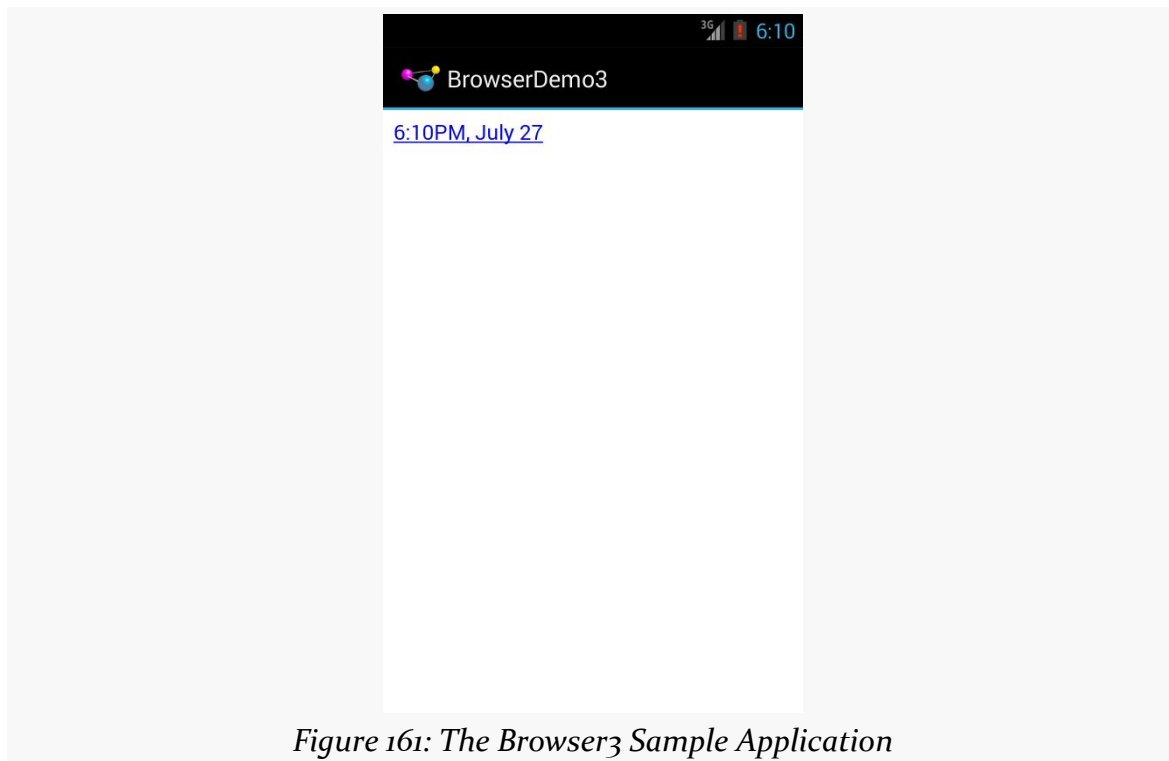

Figure 161: The Browser3 Sample Application

Clicking the link will cause us to rebuild the page with the new time.

Note that we are using a `DateUtils` utility class supplied by Android for formatting our date and time. The big advantage of using `DateUtils` is that this class is aware of the user's settings for how they prefer to see the date and time (e.g., 12- versus 24-hour mode).

There is also a `WebChromeClient` that you can register with a `WebView` via a call to `setWebChromeClient()`. This object will be called when various things occur in the `WebView` that might pertain to a browser's "chrome" (i.e., the things outside the HTML rendering area). For example, `onJsAlert()` will be called on your `WebChromeClient` when JavaScript code calls `alert()`.

Addressing the Link/Redirect Behavior

Given that Google, through "Android System WebView" 43.0.2357.121, has changed the default behavior for when users click on links or redirects, it is in your best interests to *avoid the default*, since the default varies.

To do this, you can use `WebViewClient` and `shouldOverrideUrlLoading()`, as indicated above.

The [WebKit/Browser4](#) is a clone of the original sample from this chapter, with one change: adding in a `WebViewClient` to force all link clicks to alter the `WebView` contents, regardless of what version of Android or the "Android System WebView" we are using:

```
package com.commonware.android.browser4;

import android.app.Activity;
import android.os.Bundle;
import android.webkit.WebView;
import android.webkit.WebViewClient;

public class BrowserDemo4 extends Activity {
    WebView browser;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        browser=(WebView)findViewById(R.id.webkit);

        browser.setWebViewClient(new WebViewClient() {
            @Override
            public boolean shouldOverrideUrlLoading(WebView view, String url) {
                view.loadUrl(url);
            }
        });
    }
}
```

THE WEBVIEW WIDGET

```
        return(true);
    }
});

browser.loadUrl("https://commonsware.com");
}
```

Here, the `WebViewClient` is an instance of an anonymous inner class, and `shouldOverrideUrlLoading()` just turns around and calls `loadUrl()` on the `WebView` to handle the new URL. `shouldOverrideUrlLoading()` returns `true` to indicate that it is handling the event.

Visit the Trails!

You can learn more about powerful tricks with `WebView`, including integrating the Java and JavaScript environments, in [a later chapter](#).

You can also create apps that run totally in the browser using [HTML5](#), or app frameworks that use `WebView` to render their UI, such as [PhoneGap](#).

Defining and Using Styles

As noted in [an earlier chapter](#), Android offers styles and themes, filling the same sort of role that CSS does in Web development. In that earlier chapter, we covered the basic roles of styles and themes, plus introduced the three classic theme families:

- Theme
- Theme.Holo
- Theme.Material

In this chapter, we will take a slightly “deeper dive” into styles and themes, exploring how you can create your own and apply them to your app’s UI.

Styles: DIY DRY

The purpose of styles is to encapsulate a set of attributes that you intend to use repeatedly, conditionally, or otherwise wish to keep separate from your layouts proper. The primary use case is “don’t repeat yourself” (DRY) — if you have a bunch of widgets that look the same, use a style to use a single definition for “look the same”, rather than copying the look from widget to widget.

And that paragraph will make a bit more sense if we look at an example, specifically [the Styles/NowStyled sample project](#). This is a trivial project, with a full-screen button that shows the date and time of when the activity was launched or when the button was pushed. This time, though, we want to change the way the text on the face of the button appears, and we will do so using a style.

The `res/layout/main.xml` file in this project has a style attribute on the `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
```

DEFINING AND USING STYLES

```
android:id="@+id/button"
android:text=""
android:layout_width="match_parent"
android:layout_height="match_parent"
style="@style/bigred"
/>
```

Note that the `style` attribute is part of stock XML and therefore is not in the `android` namespace, so it does not get the `android:` prefix.

The value, `@style/bigred`, points to a style resource. Style resources are values resources and can be found in the `res/values/` directory in your project, or in other resource sets (e.g., `res/values-v11/` for values resources only to be used on API Level 11 or higher). The convention is for style resources to be held in a `styles.xml` file, such as the one from the `NowStyled` project:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="bigred">
    <item name="android:textSize">30sp</item>
    <item name="android:textColor">#FFFF0000</item>
  </style>
</resources>
```

The `<style>` element supplies the name of the style, which is what we use when referring to the style from a layout. The `<item>` children of the `<style>` element represent values of attributes to be applied to whatever the style is applied towards — in our example, our `Button` widget. So, our `Button` will have a comparatively large font (`android:textSize` set to `30sp`) and have the text appear in red (`android:textColor` set to `#FFFF0000`).

Just defining the style and applying it to the widget gives us the desired results:

Figure 162: The Styles/NowStyled sample application

Elements of Style

There are four elements to consider when applying a style:

- Where do you put the style attributes to say you want to apply a style?
- What attributes can you define via a style?
- How do you inherit from a previously-defined style (one of your own or one from Android)?
- What values can those attributes have in a style definition?

Where to Apply a Style

The style attribute can be applied to a widget, to only affect that widget.

The style attribute can be applied to a container, to affect that container. However, doing this does not automatically style its children. For example, suppose `res/layout/main.xml` looked instead like this:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
```

```
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        style="@style/bigred">
    <Button
        android:id="@+id/button"
        android:text=""
        android:layout_width="match_parent"
        android:layout_height="match_parent"
    />
</LinearLayout>
```

The resulting UI would not have the Button text in a big red font, despite the style attribute. The style only affects the container, not the contents of the container.

You can also apply a style to an activity or an application as a whole, though then it is referred to as a “theme”, which will be covered [a bit later in this chapter](#).

The Available Attributes

When styling a widget or container, you can apply any of that widget’s or container’s attributes in the style itself. So, if it shows up in the “XML Attributes” or “Inherited XML Attributes” portions of the Android JavaDocs, you can put it in a style.

Note that Android will ignore invalid styles. So, had we applied the bigred style to the LinearLayout as shown above, everything would run fine, just with no visible results. Despite the fact that LinearLayout has no `android:textSize` or `android:textColor` attribute, there is no compile-time failure nor a runtime exception.

Also, layout directives, such as `android:layout_width`, can be put in a style.

Inheriting a Style

You can also indicate that you want to inherit style attributes from another style, by specifying a parent attribute on the `<style>` element.

For example, take a look at this style resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <style name="activated" parent="android:Theme.Holo">
        <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
    </style>
</resources>
```

(note: in some renditions of this book, you may see the `<item>` element split over two lines — this is caused by word-wrapping, as this element should be all on one line)

Here, we are indicating that we want to inherit the `Theme.Holo` style from within Android. Hence, in addition to all of our own attribute definitions, we are specifying that we want all of the attribute definitions from `Theme.Holo` as well.

In many cases, this will not be necessary. If you do not specify a parent, your attribute definitions will be blended into whatever default style is being applied to the widget or container.

That `?android:attr` looks a bit bizarre, but we will get into what that syntax means in the next section.

The Possible Values

Typically, the value that you will give those attributes in the style will be some constant, like `30sp` or `#FFFF0000`.

Sometimes, though, you want to perform a bit of indirection — you want to apply some other attribute value from the theme you are inheriting from. In that case, you will wind up using the somewhat cryptic `?android:attr/` syntax, along with a few related magic incantations.

For example, let's look again at this style resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

Here, we are indicating that the value of `android:background` is not some constant value, or even a reference to a drawable resource (e.g., `@drawable/my_background`). Instead, we are referring to the value of some other attribute — `activatedBackgroundIndicator` — from our inherited theme. Whatever the theme defines as being the `activatedBackgroundIndicator` is what our background should be.

This portion of the Android style system is very under-documented, to the point where Google itself recommends you look at the [Android source code listing the various styles](#) to see what is possible.

This is one place where inheriting a style becomes important. In the example shown in this section, we inherited from `Theme.Holo`, because we specifically wanted the `activatedBackgroundIndicator` value from `Theme.Holo`. That value might not exist in other styles, or it might not have the value we want.

Themes: Would a Style By Any Other Name...

Themes are styles, applied to an activity or application, via an `android:theme` attribute on the `<activity>` or `<application>` element. If the theme you are applying is your own, just reference it as `@style/...`, just as you would in a style attribute of a widget. If the theme you are applying, though, comes from Android, typically you will use a value with `@android:style/` as the prefix, such as `@android:style/Theme.Holo.Dialog` or `@android:style/Theme.Holo.Light`.

In a theme, your focus is not so much on styling widgets, but styling the activity itself. For example, here is the definition of `@android:style/Theme.Holo.NoActionBar.Fullscreen`:

```
<!-- Variant of the default (dark) theme that has no title bar and  
fills the entire screen -->  
<style name="Theme.Holo.NoActionBar.Fullscreen">  
  <item name="android:windowFullscreen">true</item>  
  <item name="android:windowContentOverlay">@null</item>  
</style>
```

It specifies that the activity should take over the entire screen, removing the status bar on phones (`android:windowFullscreen` set to `true`). It also specifies that the “content overlay” — a layout that wraps around your activity’s content view — should be set to nothing (`android:windowContentOverlay` set to `@null`), having the effect of removing the title bar.

What Happens If You Have No Theme

Most of the sample apps that we have examined so far have not defined a theme, either at the `<application>` level or the `<activity>` level. What happens here then depends upon the device that your app runs upon:

- On an Android 1.x or 2.x device, you will get `Theme` as your theme

DEFINING AND USING STYLES

- On an Android 3.x or 4.x device, if your `minSdkVersion` or `targetSdkVersion` is 11 or higher, you will get `Theme.Holo` as your theme; otherwise, you will stick with `Theme` as your theme
- On an Android 5.0+ device, if your `targetSdkVersion` is 14 or higher, you will get `Theme.Material` as your theme; otherwise, your app behaves as in the 3.x/4.x scenario above

As a result, your app is far from “broken”, despite the lack of an explicit theme. It does mean, though, that your app will have a different look on those different Android OS levels, a look that will tend to have your app blend in more with other apps on that same device.

However, once you want to start customizing your theme, you will now run into a problem: having different themes for different OS versions. An Android 2.x device knows nothing about `Theme.Material`, for example, so you cannot simply create a custom theme based on `Theme.Material` and expect it to work. As we will see [in a later chapter](#), the solution winds up being *versioned resources*, where you have different theme definitions for different API levels.

Of course, if your `minSdkVersion` is high enough, resource versioning is less of an issue. For example, if your `minSdkVersion` is 21, all devices that your app runs upon should know about `Theme.Material`, just as if your `minSdkVersion` were 11 or higher, all devices that your app would run on would know about `Theme.Holo`.

Android Studio’s Theme Editor

On Android Studio 1.5 and higher, there is a dedicated theme editor, which allows you to (somewhat) preview your theme and (somewhat) modify it visually.

When you open a style or theme resource, you will get a banner across the top of the XML editor, offering to open the theme in the theme editor:

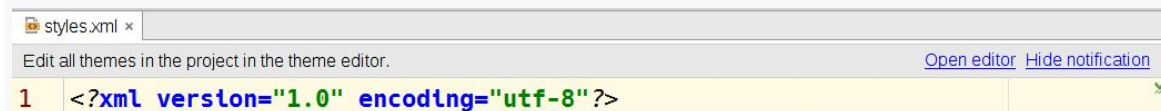

Figure 163: The Styles/NowStyled Style Resource, with Banner

Clicking the “Open editor” link in that banner will bring up the Theme Editor tab:

DEFINING AND USING STYLES

Figure 164: The Android Studio Theme Editor

If the style resource does not define a style being used as a theme – as is the case with the `NowStyled` sample app, you wind up with a pretty, albeit read-only, way of seeing how colors and settings in the theme will affect the action bar (labeled here as the “app bar”), buttons, and so forth.

If you open the Theme Editor on a style resource that is being used as a theme, you may get a preview of that custom theme:

DEFINING AND USING STYLES

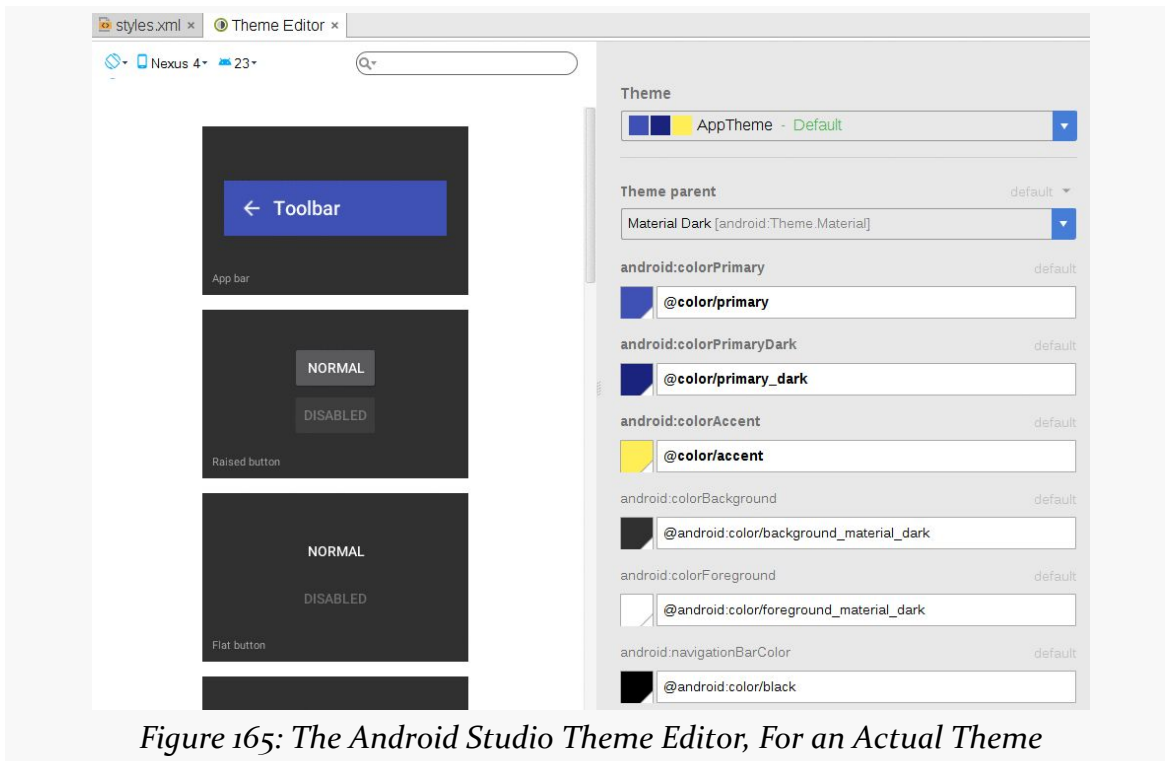

Figure 165: The Android Studio Theme Editor, For an Actual Theme

In places where you have overridden certain colors, such as the `android:colorPrimary` attribute for a `Theme.Material`-based theme, you can use a color picker to replace that color with a different value:

DEFINING AND USING STYLES

Figure 166: The Android Studio Theme Editor's Color Picker Dialog

As the dialog notes, if you change the color in the dialog, the editor will update the associated resources to match, and show you the revised value in the preview:

DEFINING AND USING STYLES

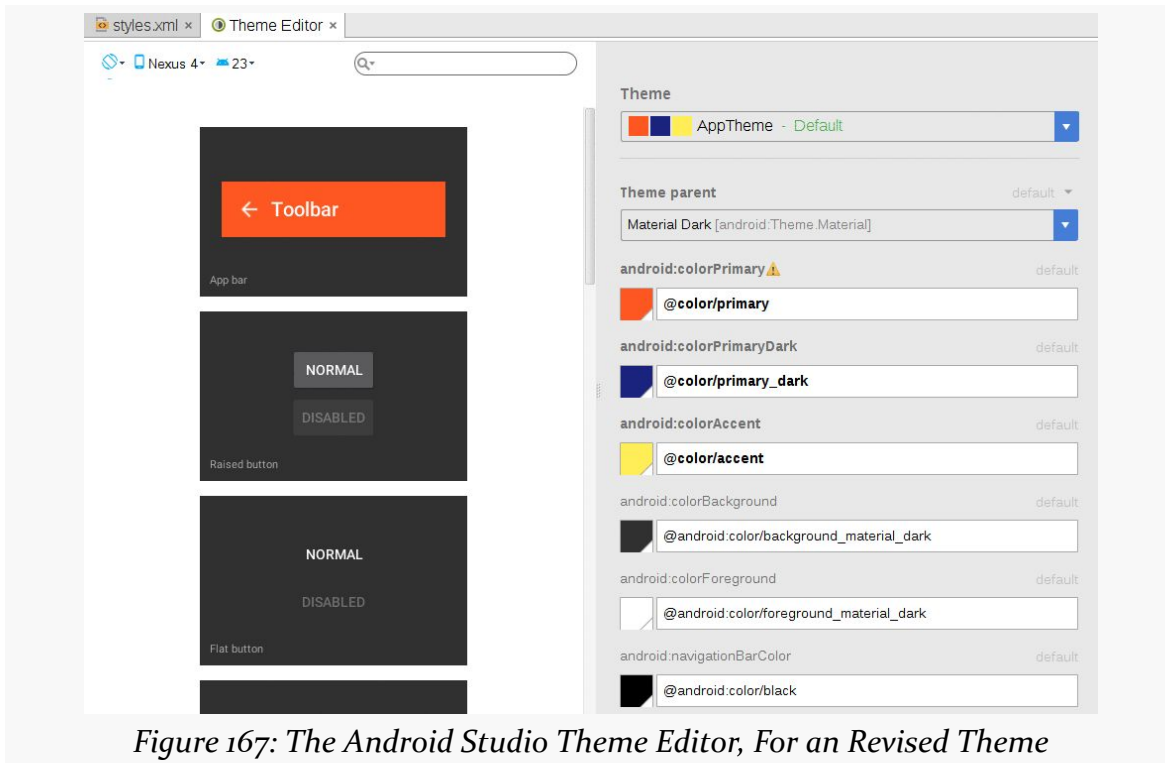

Figure 167: The Android Studio Theme Editor, For an Revised Theme

It is possible that this tool will gain greater utility in the years to come.

JARs and Library Projects

Java has as many, if not more, third-party libraries than any other modern programming language. Here, “third-party libraries” refer to the innumerable JARs that you can include in a server or desktop Java application — the things that the Java SDKs themselves do not provide.

In the case of Android, the virtual machine (VM) at its heart is not precisely Java, and what it provides in its SDK is not precisely the same as any traditional Java SDK. That being said, many Java third-party libraries still provide capabilities that Android lacks natively and therefore may be of use to you in your project, for the ones you can get working with Android’s flavor of Java. This chapter explains what it will take for you to leverage such libraries and the limitations on Android’s support for arbitrary third-party code.

You might think that JARs are the primary model of code reuse within Android. That’s not really the case. The primary model of code reuse within Android is the Android library project. Many reusable components and frameworks are distributed as library projects, and we will see several in the course of this book.

The example described in this chapter is the Android Support package, a key piece of reusable code from Google itself, distributed partly as JARs and partly as an Android library project.

But first, let’s talk a bit more about Android and VMs.

The Dalvik VM, and a Bit of ART

When you are writing Android applications, you are writing Java source code. You might be thinking that your Android device is running Java bytecode, just as your Web browser might when it runs a Java applet.

Alas, you would be mistaken.

Android does not have a Java VM. Android has the Dalvik VM or ART.

The Dalvik VM is a virtual machine, along the lines of the Java VM, the Parrot VM (Perl), Microsoft's CLR, and so forth. Since each VM has its own bytecode, the Dalvik VM bytecode is not the same as the Java VM bytecode (or the Parrot VM bytecode, etc.).

When you build your project, your Java source code is initially compiled using the standard `javac` compiler. Then, however, the Java VM bytecodes created by `javac` are cross-compiled into Dalvik VM bytecodes, and it is *those* bytecodes that are packaged into your APK file and are executed by Android.

Most of the time, you will not notice the difference. Every now and then, though, you will encounter some issues related to Android's use of Dalvik, and the most prominent of these comes when you try repurposing existing Java code.

ART is a new runtime, available for developer testing in Android 4.4. ART still uses Dalvik bytecodes, but uses them as input for an ahead-of-time (AOT) compiler. Rather than relying on a just-in-time (JIT) compiler, as the Dalvik VM does, to translate Dalvik bytecodes into CPU-specific instructions, ART's AOT compiler converts *all* the bytecodes to instructions at installation time.

Getting the Library

You have two easy choices for integrating third-party Java code into your project: use JARs or use an artifact in a repository. The latter approach is for Android Studio users; any IDE can use JARs. The details vary by IDE.

Android Studio

Ideally, the documentation for the third-party library will tell you how to get it as an artifact and add it to your Android Studio project. Specifically, it should tell you a

JARS AND LIBRARY PROJECTS

line that you should add to your dependencies closure of your app's `build.gradle` file, such as `compile 'com.squareup.retrofit:retrofit:1.6.1'`. We will get into the details of what this line means [much later in the book](#).

The documentation should also indicate what artifact repository this artifact comes from. It may tell you that the artifact comes from “Maven” or “Maven Central”, in which case you will need a `mavenCentral()` line in your `repositories` closure:

```
repositories {
    mavenCentral()
}
```

Or, it may tell you something else to use, if the artifact is from another repository, such as:

```
repositories {
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}
```

So, for example, you might wind up with the following in your app's `build.gradle` file:

```
repositories {
    mavenCentral()
}

dependencies {
    compile 'com.squareup.retrofit:retrofit:1.6.1'
}
```

If you have an artifact name (e.g., `com.squareup.retrofit:retrofit:1.6.1`), and you have no indication of where the artifact comes from, try the `mavenCentral()` option.

If all you have is a JAR file, put it in a `libs/` directory in your project's `app/` folder, and then make sure that your dependencies closure has the `compile fileTree...` line in it to pull JARs from `libs/`:

```
dependencies {
    compile fileTree(dir: 'libs', include: ['*.jar'])
}
```

Much more about Android Studio, Gradle, and dependencies can be found [later in the book](#), but this should help you get started.

Eclipse

If you choose to use an existing JAR, place the JAR in the `libs/` directory in your Android project. And that's it, at least for Eclipse. Your JAR will be automatically added to your build path, and your JAR will be automatically bundled into the APK file that is your Android application. Note that other IDEs might require other steps – please consult the documentation for that IDE.

Also note that the R22 version of the ADT plugin for Eclipse may force you to make some adjustments to the “Order & Export” portion of your project's build path. If it seems like your JAR is not being picked up (e.g., you try referring to classes from the JAR and you get runtime `ClassNotFoundException`s), then try this recipe:

- Right-click on the project in Eclipse's Package Explorer and choose Build Path > Configure Build Path from the context menu
- Switch to the “Order and Export” tab
- Check the “Android Private Libraries” entry in the list, if it is not already checked

The Outer Limits

Not all available Java code will work well with Android. There are a number of factors to consider, including:

- *Expected Platform APIs*: Does the code assume a newer JVM than the one Android is based on? Or, does the code assume the existence of Java APIs that ship with J2SE but not with Android, such as Swing?
- *Size*: Existing Java code designed for use on desktops or servers need not worry too much about on-disk size, or, to some extent, even in-RAM size. Android, of course, is short on both. Using third-party Java code, particularly when pre-packaged as JARs, may balloon the size of your application.
- *Performance*: Does the Java code effectively assume a much more powerful CPU than what you may find on many Android devices? Just because a desktop can run it without issue does not mean your average mobile phone will handle it well.
- *Interface*: Does the Java code assume a console interface? Or is it a pure API that you can wrap your own interface around?
- *Operating System*: Does the Java code assume the existence of certain console programs? Does the Java code assume it can use a Windows DLL?

- *Language Version*: Was the JAR compiled with an older version of Java (1.4.2 or older)? Was the JAR compiled with a different compiler than the official one from Sun (e.g., GCJ)? Was the JAR compiled with Java 8, so it has Java 8 bytecodes rather than those compatible with Java 6?
- *Dependencies*: Does the Java code depend on other third-party JARs that might have some of these problems as well? Does the Java code depend upon third-party libraries (e.g., the `org.json` JSON library) that are built into Android, but the third party expects a different version of that library?

One trick for addressing some of these concerns is to use open source Java code, and actually work with the code to make it more Android-friendly. For example, if you are only using 10% of the third-party library, maybe it's worthwhile to recompile the subset of the project to be only what you need, or at least removing the unnecessary classes from the JAR. The former approach is safer, in that you get compiler help to make sure you are not discarding some essential piece of code, though it may be more tedious to do.

JAR Dependency Management

One challenge with reusing JARs is that JARs sometimes depend upon other JARs.

If you are using Android Studio, this is handled for you automatically, if you are using artifacts from a repository as the source of the JARs (e.g., pulling from Maven Central).

If you are using Eclipse, you will need to identify and download all relevant dependent JARs, placing them in `libs/` along with the JARs you originally obtained.

OK, So What is a Library Project?

An Android library project is a special type of Android project designed to share code and resources between Android application projects. It is specifically aimed at developers or teams creating multiple applications from the same code base. Library projects can also be used for reusable components, such as distributing custom widgets, activities, or frameworks to third parties.

The biggest difference between an Android library project and a JAR is that an Android library project is designed to distribute *resources* and *manifest entries* as well as Java code. If all you are looking to distribute is Java code, a JAR works just as

well as an Android library project. But if you need to distribute layouts, themes, activities, and the like, an Android library project is the better solution.

A [later chapter](#) will describe how to create an Android library project.

Using a Library Project

Given that you have a library project — or have identified one you want to use — you can attach it to a regular Android project, so the regular Android project has access to everything in the library. As you might expect, how you accomplish this depends upon your choice of IDE.

Android Studio

Hopefully, the library project that you are wishing to use is being distributed as an AAR — an Android archive file that contains a compiled version of the library's source code, along with the resources and, if supplied, manifest.

More specifically, hopefully the library project that you are wishing to use is being distributed as an AAR as an artifact in a repository. If so, you can integrate it using the same approach as is described [earlier in this chapter](#) for JARs — just add the necessary `compile` statement to the `dependencies` closure.

For example, to add [the CWAC-ColorMixer library project](#) to your Android Studio app, you would use:

```
repositories {
    maven {
        url "https://repo.commonware.com.s3.amazonaws.com"
    }
}

dependencies {
    compile 'com.commonware.cwac:colormixer:0.5.+'
```

If the Android library project is being distributed in any other way, adding it to Android Studio becomes substantially more complicated. Those scenarios will be examined in greater detail in upcoming chapters on [library projects](#) and [Gradle dependencies](#). In that chapter, we will also go into more details about the structure of that `compile` statement and the versioning rules (e.g., `0.5.+`).

Eclipse

To add a reference to an Android library project in Eclipse, you must first have it in your Eclipse workspace, such as via importing the project. Then, go into the project properties window (e.g., right-click on the project and choose Properties). Click on the Android entry in the list on the left, then click the “Add” button in the Library area. This will let you browse to the directory where your library project resides. You can add multiple libraries and control their ordering with the “Up” and “Down” buttons, or remove a library with the “Remove” button.

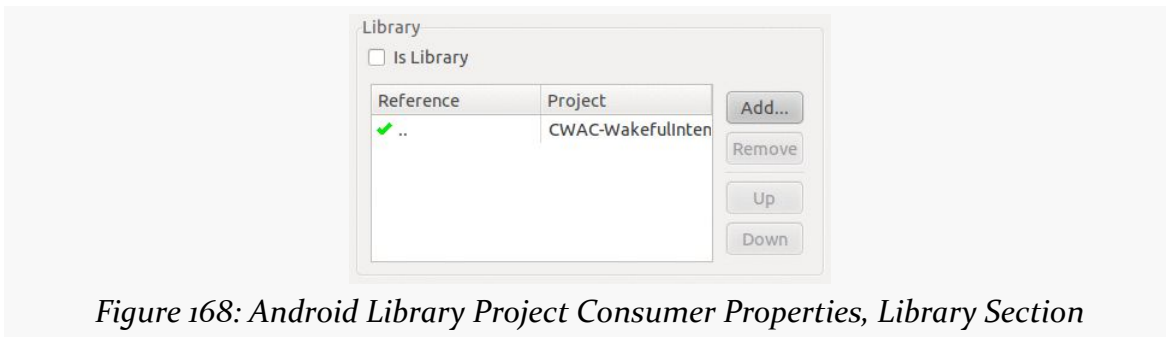

Figure 168: Android Library Project Consumer Properties, Library Section

Library Projects: What You Get

Now, if you build the main project, the Android build tools will:

- Include the `src/` directories of the main project and all of the libraries (`libs/`) in the source being compiled.
- Include all of the resources of the projects, with the caveat that if more than one project defines the same resource (e.g., `res/layout/main.xml`), the highest priority project’s resource is included. The main project is top priority, and the priority of the remainder are determined by their order as defined in the build rules (e.g., order in dependencies in Android Studio; order in `project.properties` for Eclipse).

This means you can safely reference `R.` constants (e.g., `R.layout.main`) in your library source code, as at compile time it will use the value from the main project’s generated `R` class(es).

You may also have some manifest entries automatically injected into your manifest, to add items from a manifest supplied by the library.

The Android Support Package

The Android Support package is distributed by Google, containing classes (in JARs and Android library projects) that are not part of the Android SDK, but are available to Android developers.

What's In There?

You can roughly divide the contents of the Android Support package into two major areas:

1. “Backports” of capabilities added to newer versions of Android and the Android SDK, so they can be used on older devices as well. By using the backported classes, you can get the same abilities on a wider range of devices than you could if you only used the classes in the Android SDK.
2. New widgets, containers, or other classes that are not going to be in the Android SDK (for ill-defined reasons) but that Google wishes to make available for Android developers.

More specifically, the most commonly-used pieces of the Android Support package include:

- `support-v4`, which contains backports and miscellaneous UI classes, working back to API Level 4
- `support-v13`, which is identical to `support-v4` but *also* contains a few classes that only work on API Level 13 and higher
- `appcompat-v7`, which is a backport of the action bar, a concept that we will discuss [in an upcoming chapter](#)
- `recyclerview-v7`, which is the home of [the RecyclerView widget](#) that serves as an alternative to `ListView` and `GridView`
- `mediarouter-v7`, which provides a re-implementation of [MediaRouter and related classes](#)

About the Names

What this book refers to as the “Android Support package” has many names.

It was originally referred to as the Android Compatibility Library, at a time when it only contained backports. Once Google started adding in things that were not strictly related to “compatibility”, they started changing the name to try to be more

JARS AND LIBRARY PROJECTS

generic. Right now, “Android Support” seems to be fairly consistent, either used standalone or in the form of “Android Support package” or “Android Support Library”.

For the purposes of this book, “Android Support package” refers to the entire family of these libraries.

-v4 Versus -v13

Any given project needs *either* support-v4 *or* support-v13 (or sometimes neither), not both. If your `minSdkVersion` is 13 or higher, choose the support-v13 library over the support-v4 library, as support-v13 is a clear superset of what is in support-v4.

Getting It

You will find the Android Support package in your SDK Manager, in the “Extras” category towards the bottom of the tree:

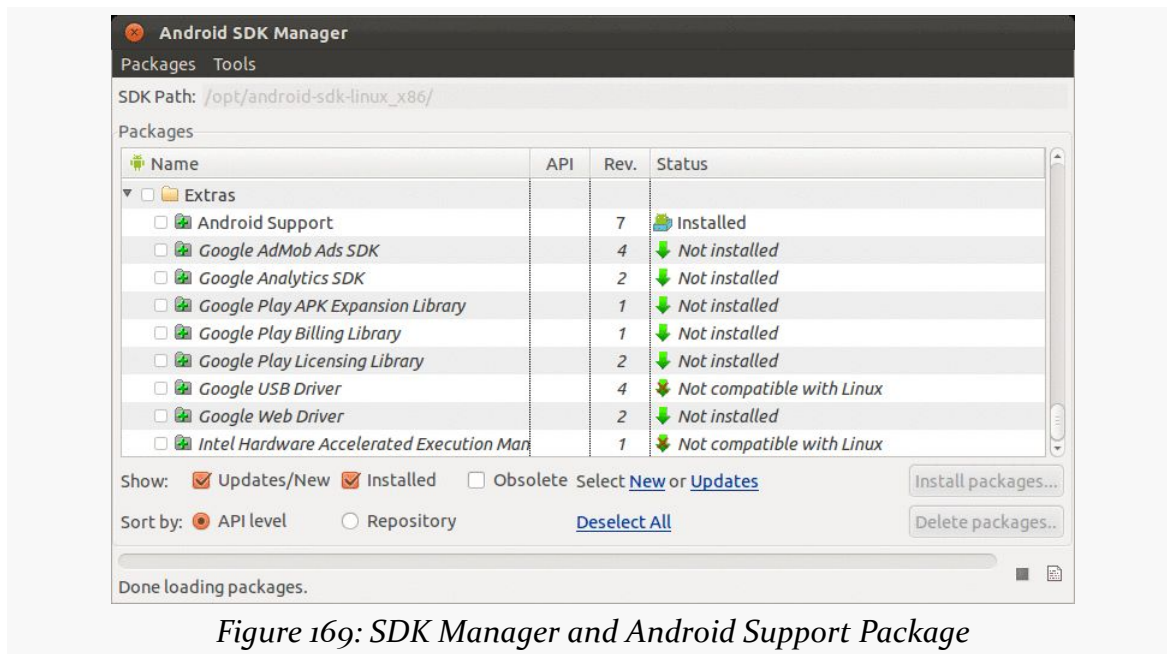

Figure 169: SDK Manager and Android Support Package

To install it, check the checkbox and click the “Install” button, just as you might install an SDK itself.

This will add an `extras/` directory to wherever your SDK installation resides, and the Android Support package will go into subdirectories inside of `extras/`.

Android Studio users will also want to download the “Android Repository” from the “Extras” area, as this makes the Android Support package’s libraries available to you in a local artifact repository, to simplify adding it to your project.

Attaching It To Your Project

As with many things in Android, how you attach Android Support package libraries to your app depends upon your choice of IDE.

Android Studio

You can add references to the Android Support package’s libraries — whether those libraries are simple JARs or Android library projects — via a few lines in your dependencies closure, referencing the artifacts from the Android Repository.

Here are the `compile` statements for many artifacts in the now-current version of the Android Support package:

```
compile 'com.android.support:appcompat-v7:23.1.1'  
compile 'com.android.support:cardview-v7:23.1.1'  
compile 'com.android.support:design:23.1.1'  
compile 'com.android.support:gridlayout-v7:23.1.1'  
compile 'com.android.support:leanback-v17:23.1.1'  
compile 'com.android.support:mediarouter-v7:23.1.1'  
compile 'com.android.support:palette-v7:23.1.1'  
compile 'com.android.support:recyclerview-v7:23.1.1'  
compile 'com.android.support:support-annotations:23.1.1'  
compile 'com.android.support:support-v13:23.1.1'  
compile 'com.android.support:support-v4:23.1.1'
```

Also, while you *could* add all of these to your project, that is not necessary. Only attach dependencies for libraries that you are actually using. Having unused libraries in your project just increases your APK size for no good reason. Hence, most projects will have only a subset of the aforementioned lines.

Note that, in general, when using the Android Support libraries, you should set your `compileSdkVersion` to be the same as the major version of the library. So, for a 23.1.0 version of the library, your `compileSdkVersion` should be 23.

Eclipse

For `support-v4` or `support-v13`, find the `android-support-v4.jar` or `android-support-v13.jar` file installed in your `extras/` directory tree of your SDK installation and add a copy to your project’s `libs/` directory.

JARS AND LIBRARY PROJECTS

The others are distributed as Android library projects. You will need to import the project(s) you want from the Android SDK's extras/ area, then attach them to your project as is described [earlier in this chapter](#).

Tutorial #6 - Adding a Library

We will want to use some third-party libraries in our project, to ease development of the app:

- the [Android Support library](#), specifically its android-support-v13 JAR
- greenrobot's [EventBus](#), for communication between various pieces of our app
- Google's [GSON](#) parser of JSON data
- Square's [Retrofit](#), for retrieving JSON data from Web services
- Square's [OkHttp](#), for general HTTP request, like downloading a ZIP archive
- the [CWAC-Security library](#), by the author of this book, which contains some code for securely unpacking a ZIP archive

Right now, we will just focus on arranging for our project to be able to use the libraries. Later in the book, we will actually put the libraries to use.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Step #1: Attaching the Android Support Package

First, we need one of the pieces of the Android Support package, specifically the support-v13 library, for some classes that we will be using from it later on, such as ViewPager.

Open the app/build.gradle file, off of the project root directory. Find the dependencies closure, which should look like this:

TUTORIAL #6 - ADDING A LIBRARY

```
dependencies {
    compile fileTree(dir: 'libs', include: ['*.jar'])
}
```

Replace that implementation with:

```
dependencies {
    compile 'com.android.support:support-v13:23.1.1'
}
```

This means that we will no longer be loading JAR files out of a `libs/`, so you can delete that `libs/` directory from the `app/` directory of your project. It also tells Android Studio to incorporate the `support-v13` library from your local Android Repository, which you installed back in [Tutorial #1](#).

Step #2: Attaching the Third-Party Dependencies

We also need some third-party components for our application eventually, but we can set them up now.

Four of the third-party components we are going to set up now all are available from Maven Central and JCenter. However, the CWAC-Security library is not, and so we will need to teach Gradle how to find that library.

To do that, add the following code to your `app/build.gradle` file, above the `dependencies` closure:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}
```

Then, add five more lines to the `dependencies` closure, identifying the libraries that we need:

```
dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.google.code.gson:gson:2.3.1'
    compile 'com.squareup.retrofit:retrofit:1.9.0'
    compile 'com.squareup.okhttp:okhttp:2.4.0'
    compile 'com.commonsware.cwac:security:0.5.2'
    compile 'com.android.support:support-v13:23.1.1'
}
```

At this point, your `app/build.gradle` file should look something like:

TUTORIAL #6 - ADDING A LIBRARY

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.2"

    defaultConfig {
        applicationId "com.commonware.empublite"
        versionCode 1
        versionName "1.0"
        minSdkVersion 15
        targetSdkVersion 18
    }
}

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
}

dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.google.code.gson:gson:2.3.1'
    compile 'com.squareup.retrofit:retrofit:1.9.0'
    compile 'com.squareup.okhttp:okhttp:2.4.0'
    compile 'com.commonware.cwac:security:0.5.2'
    compile 'com.android.support:support-v13:23.1.1'
}
```

You may get a yellow banner at the top of the editor, indicating that a “project sync” is requested. If you do, click the “Sync Now” link in that banner to synchronize the *.iml files with the changes you made to this build.gradle file. If you do not, choose Tools > Android > Sync Project with Gradle Files to force that resync.

In Our Next Episode...

... we will [configure the action bar](#) on our tutorial project

The Action Bar

The action bar — that bar that runs across the top of your activity — is the backbone of your UI. Here, you can provide actions for the user to perform related to the current activity (e.g., “edit the contact that you are viewing”) or related to the application as a whole (e.g., “here is the documentation”). Sometimes, these actions will appear as toolbar buttons or other widgets in the action bar. Sometimes, these actions will appear in the “overflow”, which amounts to a menu.

This chapter introduces the concept of the action bar and how to add actions to it.

Bar Hopping

Android has had many patterns for various “bars” as part of its UI. So, to help explain what an action bar is, it helps if we review the history and role of Android’s various bars.

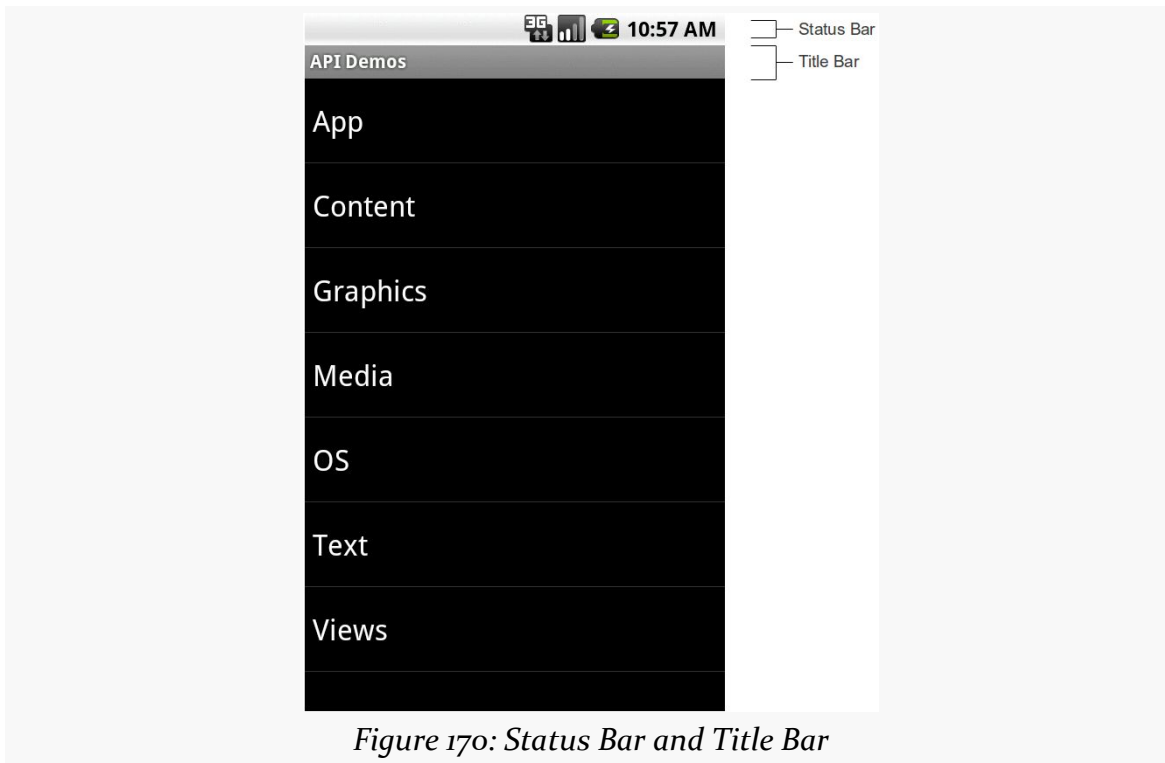

Android 1.x/2.x

In the beginning, there was the status bar and the title bar.

The status bar was a thin strip across the top of the screen, used for things like the clock, signal strength, battery charge, and notification icons (for events like new unread email messages). This bar is technically part of the OS, not your app’s UI.

The title bar was a thin gray strip beneath the status bar that, by default, would hold the name of your application, much like the title bar of a browser might show the name of a Web site.

THE ACTION BAR

Android 3.0-4.1, Tablets

When official support for tablets arrived with Android 3.0 in February 2011, the story changed.

The status bar was replaced by the system bar, appearing at the bottom of the screen. This had all of the contents of the old status bar, but also had the soft keys for BACK, HOME, etc. Android 1.x and 2.x required that devices have off-screen affordances for those operations; now, device manufacturers could skip those and have the system bar offer them.

The action bar, by default, appears at the top of your activity, replacing the old title bar. You can define what goes in the action bar (icon, title, toolbar buttons, etc.).

THE ACTION BAR

Figure 171: Action Bar and System Bar

The icon on the far left of the action bar also serves as a toolbar button, if you wish. A common pattern for using this is take the user back to the “main” or “home” activity of your application.

Sometimes, the far right side of the action bar will contain a “...” affordance. This is known as the “action overflow” or “overflow menu”:

THE ACTION BAR

Figure 172: Action Bar with Open Overflow Menu

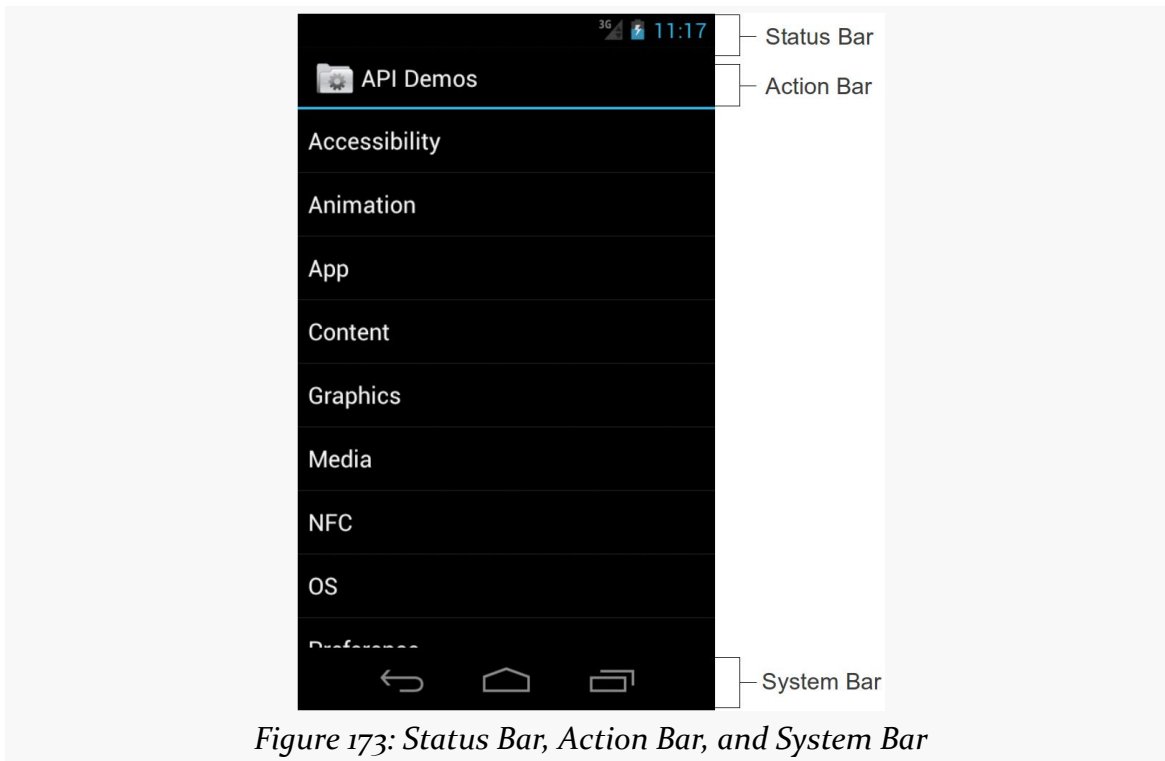

Tapping it will give the user access to actions that might have been toolbar buttons on a larger screen, but there was insufficient room. Also, low-priority actions may be tucked into the overflow, rather than clutter up the screen with too many toolbar buttons.

Android 4.0-4.4, Phones

Phone-sized devices were not supported by Android 3.x. They jumped from Android 2.3 to 4.0, and along the way adopted some of the Android 3.x UI features:

- Phone apps could have an action bar, like their tablet counterparts
- Device manufacturers could skip the BACK, HOME, etc. buttons and let a partial system bar handle those
- The status bar remained intact from the Android 2.x approach

THE ACTION BAR

Android 4.2-4.4, Tablets

The Nexus 7, introduced in the summer of 2012, was a 7" tablet that did not follow the tablet UI structure that all other standard Android tablets used. Instead, it looked a bit like a really large phone, having a top status bar along with a bottom system bar solely for the navigation buttons (BACK, HOME, etc.). Apps, as before, could have an action bar as well.

Initially, it was thought that the Nexus 7 was going to be distinctive in that regard. Instead, with Android 4.2, Google switched all tablets to this model, restoring the status bar and relegating the system bar purely for navigation buttons.

THE ACTION BAR

Figure 174: Status Bar, Action Bar, and System Bar, on Nexus 7 Emulator

Android 5.0+

Functionally, the action bar is much the same in Android 5.0 as it was in previous releases. However, aesthetically, it has dropped the icon and made other minor stylistic adjustments.

THE ACTION BAR

Figure 175: Action Bar on Android 5.0 Emulator

Yet Another History Lesson

Back in the dawn of Android time, referred to by some as “the year 2007”, we had options menus. These would rise up from the bottom of the screen based on the user pressing a MENU key:

THE ACTION BAR

Figure 176: Legacy Options Menu

This is why you will see references to “options menu” scattered throughout the Android SDK.

The action bar pattern was first espoused by Google at the 2010 Google I/O conference. However, at the time, there was no actual implementation of this, except in scattered apps, and definitely not in the Android SDK.

Android 3.0 — a.k.a., API Level 11 — added the action bar to the SDK, and apps targeting that API level will get an action bar when running on such devices.

Your Action Bar Options

There are several implementations of the action bar floating about. You will probably be using the one that is part of Android itself, starting with API Level 11. However, there are a couple of backports of the action bar if you need them.

Pure Native

As mentioned above, devices running Android 3.0 and higher have support for the action bar as part of their firmware, and that support is exposed through the Android SDK. For example, there is an `ActionBar` class, and you can get an instance of it for your activity's action bar via `getActionBar()`.

However, this only works on devices running Android 3.0 and higher. If you try calling `getActionBar()` on an older device, you will crash with a `VerifyError` runtime exception. `VerifyError` is Android's way of telling you "while you compiled fine, something your compiled code refers to does not exist".

If your `minSdkVersion` is 11 or higher, you will be able to use the native action bar, and that approach will be used in most of this book.

Backports

If your `minSdkVersion` is lower than 11, you have three major choices:

1. Use the "menu" APIs in Android, which will add stuff to the action bar on newer devices, but will result in the classic "options menu" on older devices.
2. Use the `appcompat-v7` backport of the action bar, published by Google in the Android Support package in August 2013.
3. Use `ActionBarSherlock`, an independent backport of the action bar, published by Jake Wharton in 2011, after Android 3.0 was released.

This chapter assumes that your `minSdkVersion` is set to 11 or higher and you will use the native action bar. Separate chapters in the trails cover the use of [appcompat-v7](#) and [ActionBarSherlock](#).

Note that, as of October 2014, the `appcompat-v7` library not only backports the action bar, but also attempts to backport part of Google's Material Design styling. Normally, Material Design only comes from Android 5.0 and the use of `Theme.Material`. The [appcompat-v7 chapter](#) will cover the library's effects both to the action bar and to other aspects of your app's UI.

A Quick Note About Toasts

In the sample app that follows, we use a `Toast` to let the user know some work has been completed.

THE ACTION BAR

A Toast is a transient message, meaning that it displays and disappears on its own without user interaction. Moreover, it does not take focus away from the currently-active Activity, so if the user is busy writing the next Great Programming Guide, they will not have keystrokes be “eaten” by the message.

Since a Toast is transient, you have no way of knowing if the user even notices it. You get no acknowledgment from them, nor does the message stick around for a long time to pester the user. Hence, the Toast is mostly for advisory messages, such as indicating a long-running background task is completed, the battery has dropped to a low-but-not-too-low level, etc.

Making a Toast is fairly easy. The Toast class offers a static `makeText()` method that accepts a String (or string resource ID) and returns a Toast instance. The `makeText()` method also needs the Activity (or other Context) plus a duration. The duration is expressed in the form of the `LENGTH_SHORT` or `LENGTH_LONG` constants to indicate, on a relative basis, how long the message should remain visible. Once your Toast is configured, call its `show()` method, and the message will be displayed.

Setting the Target

If you want proper action bar support, you will want to target API Level 14 or higher at runtime. That involves setting the `targetSdkVersion` property in your `build.gradle` file (for Android Studio users) or setting the `android:targetSdkVersion` attribute of the `<uses-sdk>` element of your manifest (for Eclipse users, or Android Studio users maintaining Eclipse compatibility with their projects).

We see this in the manifest of the [ActionBar/ActionBarDemoNative](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.inflation"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="10"
        android:targetSdkVersion="19"/>

    <application
```

THE ACTION BAR

```
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name=".ActionBarDemoActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>
</manifest>
```

Specifically, we have `android:targetSdkVersion` set to 19. While 11 or higher will give you an action bar, 14 or higher will solve a particular UI quirk related to menu choices. Some Android 4.0+ devices, but not all, will show *two* ways of getting at overflow menu items if you have your `android:targetSdkVersion` set to a value between 11 and 13. You will have the “...” item in the action bar itself *and* a second one in the system bar, on devices that have one. Setting `android:targetSdkVersion` to 14 or higher resolves this.

Doing nothing else but the preceding steps would give us an action bar, but one with no toolbar icons or action overflow menu. While perhaps visually appealing, this is not terribly useful for the user, so we need to do some more work to give the user actions to perform from the action bar.

Note that this manifest has a `minSdkVersion` of 10. This means that the app can run on Android 2.3.3 devices. On those devices, though, the app will not have an action bar, as the action bar did not exist then, and this app is not using a backport like `appcompat-v7`. Instead, the app will have an old-style options menu on API Level 10 devices. There is nothing intrinsically wrong with this, though it does mean that your app will look different on API Level 10 devices.

Defining the Resource

The easiest way to get toolbar icons and action overflow items into the action bar is by way of a menu XML resource. This is called a “menu” resource for historical reasons, as these resources originally were used for things like the options menu.

You can add a `res/menu/` directory to your project and place in there menu XML resources.

THE ACTION BAR

Through Eclipse, if you create a new file in there (e.g., `actions.xml`), you will be able to manipulate the menu items using a structured editor, using the “Add” to add a new item and configuring it via the options on the right:

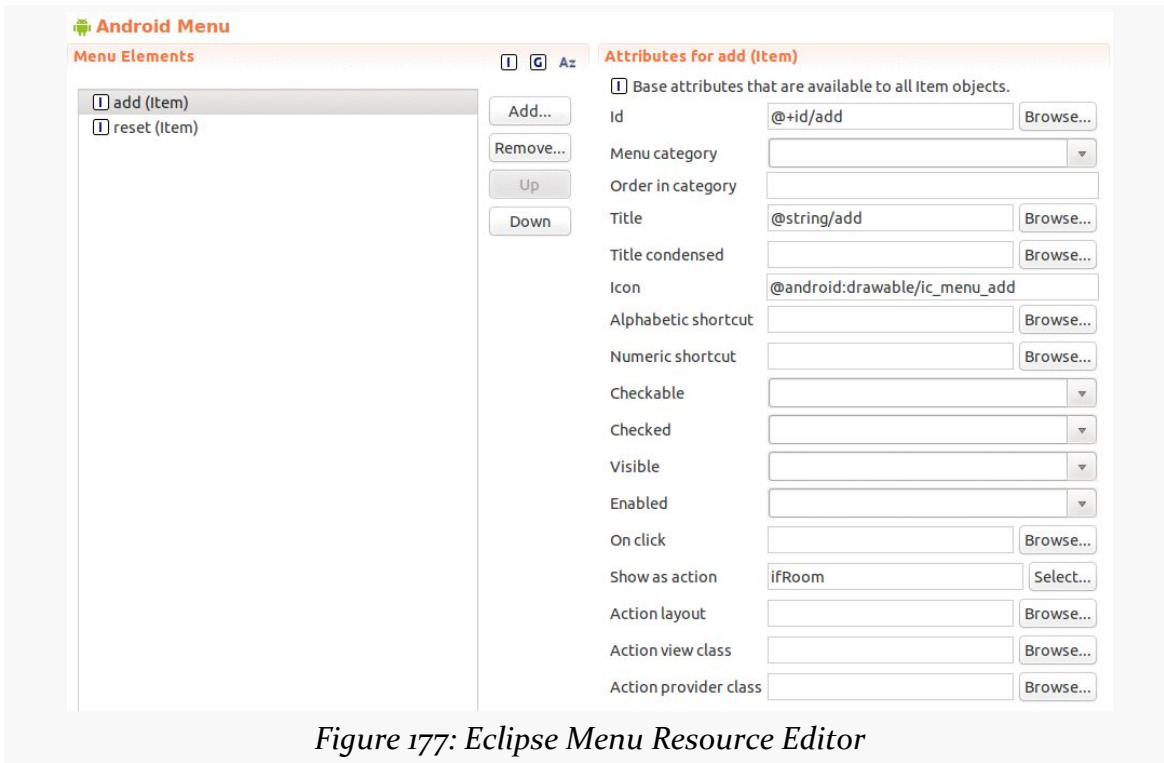

Figure 177: Eclipse Menu Resource Editor

Or, you can work with the raw XML, such as `res/menu/actions.xml` from `ActionBar/ActionBarDemoNative`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/add"
    android:icon="@drawable/ic_action_new"
    android:showAsAction="always"
    android:title="@string/add"/>
  <item
    android:id="@+id/reset"
    android:icon="@drawable/ic_action_refresh"
    android:showAsAction="always|withText"
    android:title="@string/reset"/>
  <item
    android:id="@+id/about"
    android:icon="@drawable/ic_action_about"
    android:showAsAction="never"
    android:title="@string/about">
</item>
```

```
</menu>
```

If you are using Android Studio, you will work with the XML directly.

There are four things you will want to configure on every menu item (`<item>` element in the XML):

1. The ID of the item (via the `Id` field in Eclipse or the `android:id` attribute in XML). This will create another `R.id` value, associated with this menu item, much like the `R.id` values for our widgets in our layouts. We will use this ID to determine when the user clicks on one of our toolbar buttons or action overflow items.
2. The title of the item (via the `Title` field in Eclipse or the `android:title` attribute in XML). If this item winds up in the action overflow menu, or optionally as part of its toolbar button, this text will appear. Also, this title will appear as a “tooltip” on the action item in the action bar itself, if the user long-presses on the icon (something few users know to do). Typically, you will use a string resource reference (e.g., `@string/add`), to better support internationalization.
3. The icon for the item (via the `Icon` field in Eclipse or the `android:icon` attribute in XML). If your item will appear as a toolbar button, this icon is used with that button.
4. Flags indicating how this item should be portrayed in the action bar (via the “Show as action” field in Eclipse or the `android:showAsAction` attribute in XML). You will choose to have it be always a toolbar button, only be a toolbar button `ifRoom`, or have it never be a toolbar button. You can also elect to append `|withText` to either `always` or `ifRoom`, to indicate that you want the toolbar button to be both the icon and the title, not just the icon. Note that `always` is not *guaranteed* to be a toolbar button — if you ask for 100 `always` items, you will not have room for all of them. However, `always` items get priority for space in the action bar over `ifRoom` items.

Applying the Resource

From your activity, you teach Android about these action bar items by overriding an `onCreateOptionsMenu()` method, such as this one from the `ActionBarDemoActivity` of the `ActionBar/ActionBarDemoNative` sample project:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
}
```

```
        return(super.onCreateOptionsMenu(menu));
    }
```

Here, we create a `MenuInflater` and tell it to inflate our menu XML resource (`R.menu.actions`) and pour them into the supplied `Menu` object. We then chain to the superclass, returning its result.

Responding to Events

To find out when the user taps on one of these things, you will need to override `onOptionsItemSelected()`, such as the `ActionBarDemoActivity` implementation shown below:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.add:
            addWord();

            return(true);

        case R.id.reset:
            initAdapter();

            return(true);

        case R.id.about:
            Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
                .show();

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

You will be passed a `MenuItem`. You can call `getItemId()` on it and compare that value to the ones from your menu XML resource (`R.id.add` and `R.id.reset`). If you handle the event, return `true`; otherwise, return the value of chaining to the superclass' implementation of the method.

If you wish to respond to taps on your application icon, on the left of the action bar, compare `getItemId()` to `android.R.id.home`, as that will be the `MenuItem` used for that particular toolbar button. Note that if you have your `android:targetSdkVersion` set to 14 or higher, you will also need to call `setHomeButtonEnabled(true)` on the `ActionBar` (obtained via a call to

`getActionBar()` to enable this behavior. Note that this icon may not exist, particularly if you are using `Theme.Material` on Android 5.0+.

The Rest of the Sample Activity

So, what is it that we really are doing here in `ActionBarDemoActivity`?

In many respects, this is reminiscent of the `ListActivity` demos from [an earlier chapter](#). We have an array of 25 Latin words, and we want to display these in a list.

However, in this case, we are only showing five words at the outset. An “add” action bar item will add additional words out of the main roster of 25 words, until the `ListView` holds all 25. A “reset” action bar item will return us to the original 5 words.

`ActionBarDemoActivity` is a `ListActivity`. However, rather than set up our `ArrayAdapter` directly in the `onCreate()` method as some of the other samples have done, we delegate that work to an `initAdapter()` method. Moreover, that `initAdapter()` method does its work a bit differently than what those other samples did:

```
private void initAdapter() {
    words=new ArrayList<String>();

    for (int i=0;i<5;i++) {
        words.add(items[i]);
    }

    adapter=
        new ArrayAdapter<String>(this,
                                android.R.layout.simple_list_item_1,
                                words);

    setListAdapter(adapter);
}
```

Rather than create the `ArrayAdapter` straight out of the static `items` array, we create a fresh `ArrayList` and pour the 5 elements from `items` into it, then create the `ArrayAdapter` on the `ArrayList`. This may seem superfluous, but we will take advantage of this approach with our action bar items.

When the user clicks the “reset” item in the action bar, we call `initAdapter()` again, which gives our `ListActivity` a fresh set of 5 Latin words to display:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
```

THE ACTION BAR

```
    case R.id.add:
        addWord();

        return(true);

    case R.id.reset:
        initAdapter();

        return(true);

    case R.id.about:
        Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)
            .show();

        return(true);
}

return(super.onOptionsItemSelected(item));
}
```

When the user clicks the “add” item in the action bar, we call an `addWord()` private method, which adds the next word out of the `items` array and appends it to the `ListView`:

```
private void addWord() {
    if (adapter.getCount() < items.length) {
        adapter.add(items[adapter.getCount()]);
    }
}
```

The net result of all of this is that we have an activity with our customized action bar:

THE ACTION BAR

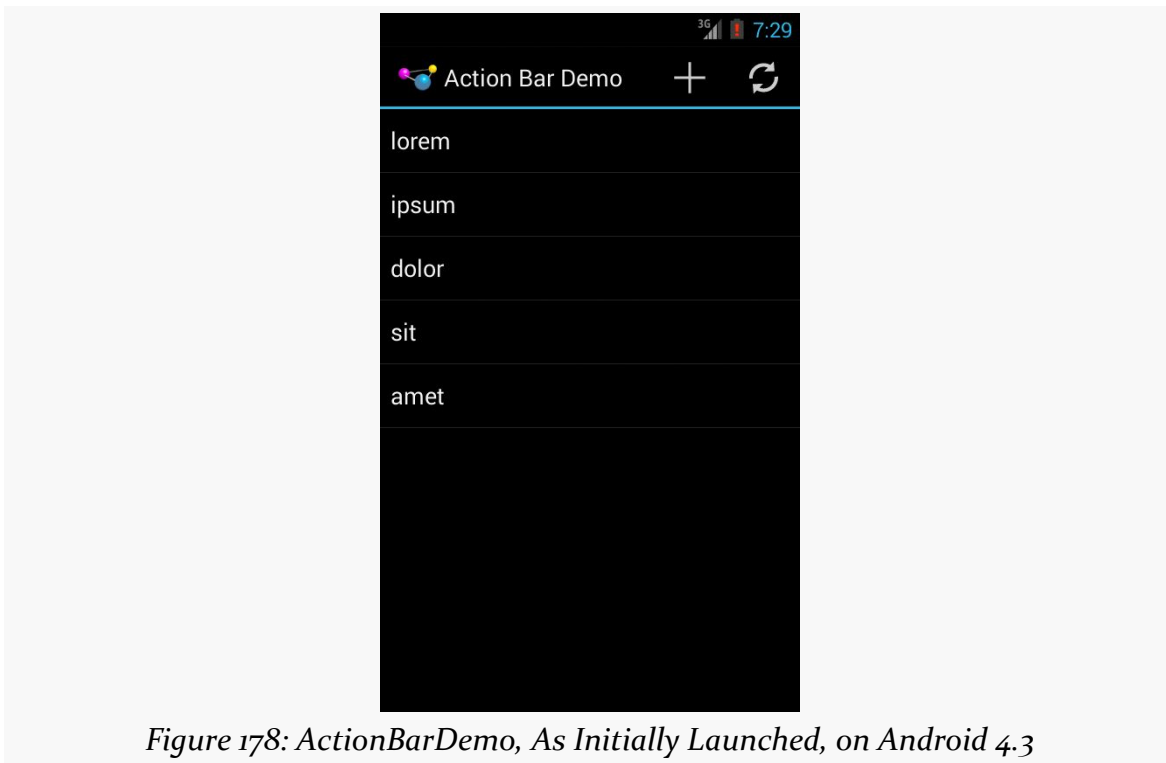

Figure 178: ActionBarDemo, As Initially Launched, on Android 4.3

Among our action bar items is an “about” one that will always be in the overflow menu. This will have three possible visual outcomes.

First, on devices without an off-screen MENU key, the overflow menu is represented by a “...” button, which displays the overflow menu when clicked:

THE ACTION BAR

Figure 179: ActionBarDemo, on Android 4.3 Large Screen, with Overflow

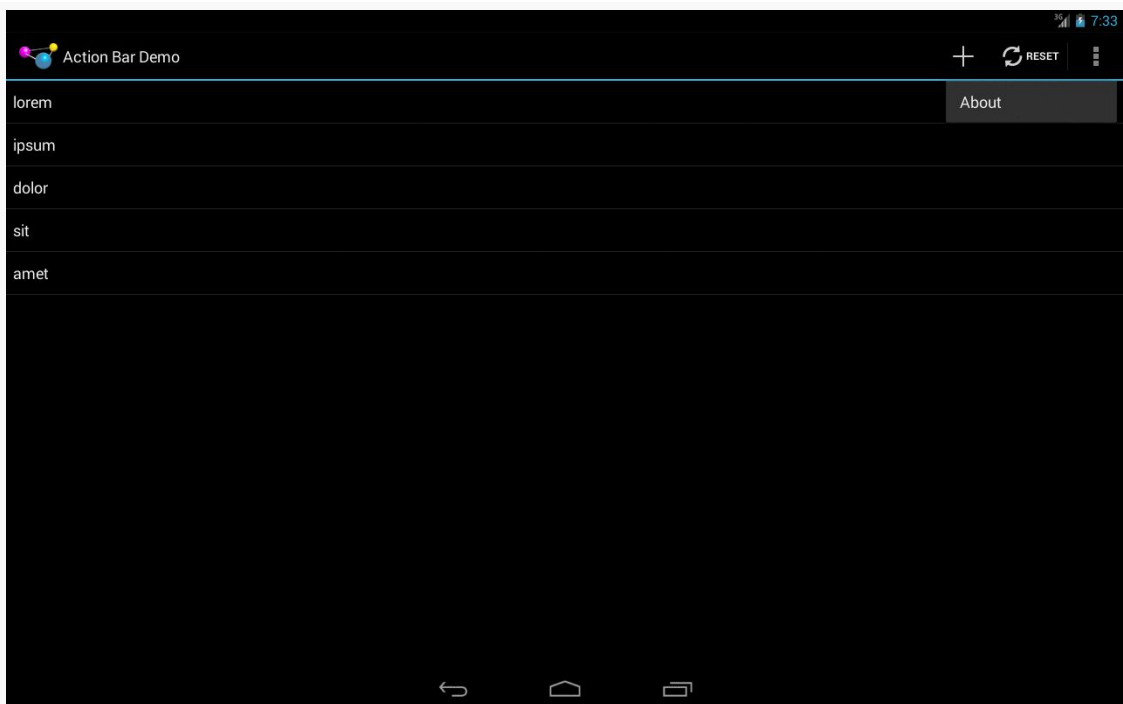

Figure 180: ActionBarDemo, on Android 4.3 Large Screen, with Overflow Open

THE ACTION BAR

On Android 4.x devices with an off-screen MENU key, pressing the MENU key will cause the overflow menu to rise up from the bottom of the screen:

Figure 181: ActionBarDemo, on Android 4.3 Normal Screen, with Overflow

Android 4.4+ devices should always have the “...” button, as is described in the next section.

Android 2.3 devices that run this app will have no action bar:

THE ACTION BAR

Figure 182: ActionBarDemo, on Android 2.3.3 Normal Screen

However, pressing the MENU button will bring up the old-style options menu, where our action items appear:

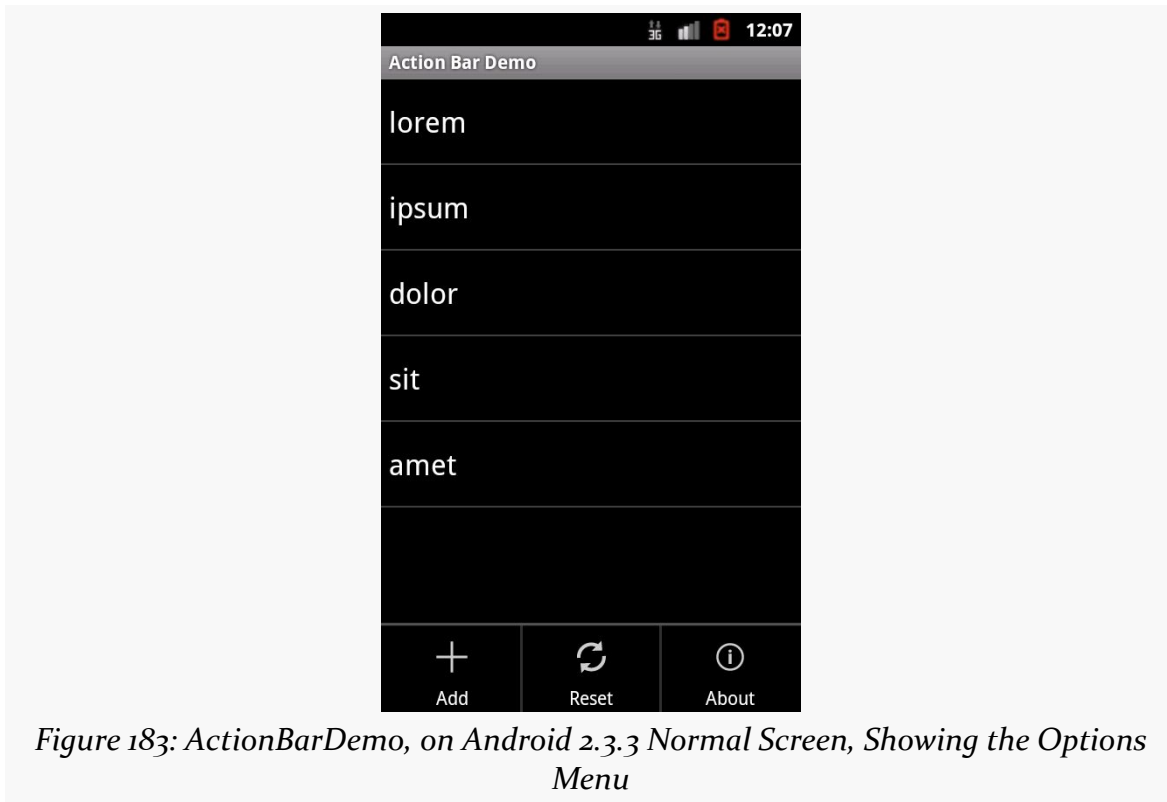

Figure 183: ActionBarDemo, on Android 2.3.3 Normal Screen, Showing the Options Menu

MENU Key, We Hardly Knew Ye

To expand upon the history lessons from earlier in this chapter, all Android 1.x and 2.x devices had a MENU key, used to bring up the options menu. With Android 3.0 and the advent of the system/navigation bar, device manufacturers no longer needed keys for HOME, BACK, and MENU. And, the action bar incorporated a “...” affordance for accessing the overflow, for items that would have been in the options menu and were not promoted to be toolbar buttons in the action bar itself.

Confusion began when we started having devices that *had* a MENU key *and* Android 3.0+. A few Android 2.x devices were upgraded to Android 4.0, and hundreds of millions of Android devices, from manufacturers like Samsung and HTC, shipped with Android 4.x and a MENU key.

To accommodate this, the device would report whether it had a “permanent menu key”, and the action bar would choose whether to show the “...” affordance based upon the existence of this key. Devices with a MENU key would not get the “...”, but instead would use the MENU key to display the overflow.

THE ACTION BAR

This irritated many developers, for much the same reason as why the MENU key irritated those developers back in Android 1.x/2.x: the existence of a menu was not very discoverable. Many users would eventually realize that tapping the MENU key might uncover useful stuff, but not all users would make this connection. However, now developers could see an obvious alternative, in the form of the “...” affordance, and so they sought ways to trick the action bar into showing the “...” even on devices that had a MENU key.

And that was how the world worked... up until Android 4.4.

An [unannounced change in Android 4.4](#) is that the “...” button should now *always* be shown in the action bar. The MENU key, if it exists, will still work, showing the overflow. Ideally, it shows the overflow as dropping down from the “...”, though that is not required. And [the Compatibility Definition Document for Android 4.4](#) more forcefully suggests that the MENU key is obsolete.

None of this should directly affect your code. However:

- When taking screenshots, bear in mind that they will vary between devices that have the “...” button and those that do not
- When writing documentation, or blog posts, or other instructional material, try to phrase references to the overflow that will work for both those users with a “...” button and those that do not

Action Bars, Live in Living Color!

On Android 4.0+, if you are using a `Holo` theme as a base, you may wish to adjust the colors used by your action bar.

On Android 5.0+, if you are using a `Material` theme as a base, you *will* want to adjust the colors used by your action bar. This is Google’s vision for how branding should work, in lieu of having your icon be in the action bar.

The following sections outline some ways to affect the colors of your action bar.

Material Tint Effects

Android 5.0 and `Theme.Material` make action bar colors easy to set up, as part of an overall “tinting” approach.

THE ACTION BAR

The [ActionBar/MaterialColor](#) sample project is a clone of the ActionBarDemoNative sample shown earlier in this chapter, but one where:

- Our `minSdkVersion` is set to 21, so the app will only run on Android 5.0+
- We set up a custom theme, with specific tinting rules, that affect our action bar colors

Color Resources

The theme will need to refer to colors, and the cleanest way to do that is to set up color resources. Like all of our other resources, we give color resources a name and a color value, usually in #RRGGBB or #AARRGGBB format. Color resources are “value” resources, held by default in `res/values/`, with the convention of using a `colors.xml` file for the actual colors.

For example, here is the `res/values/colors.xml` file from the MaterialColor sample application:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="primary">#3f51b5</color>
  <color name="primary_dark">#1a237e</color>
  <color name="accent">#ffee58</color>
</resources>
```

It defines three colors, `primary`, `primary_dark`, and `accent`, with different colors for each. In Android Studio, editing this file shows a tiny color swatch to help you visualize the colors:

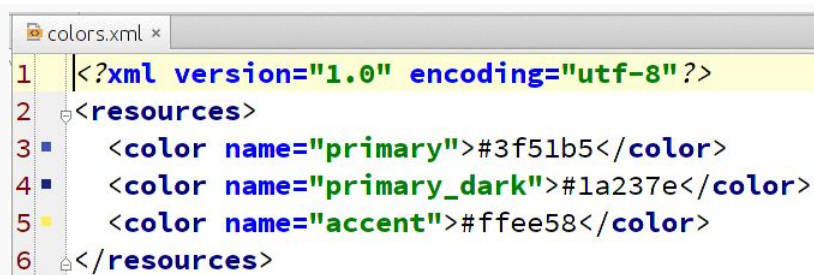

Figure 184: Color Resources in Android Studio

Tinting a Theme

Then, given that we have definitions of our colors, we can apply those colors to a custom theme, found in `res/values/styles.xml`:

THE ACTION BAR

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

Here, our `AppTheme` is inheriting from `Theme.Material` and is overriding three tints: `colorPrimary`, `colorPrimaryDark`, and `colorAccent`, referring to our three color resources in turn.

Note that we could have inherited from `Theme.Material.Light` had we wanted a light “content area” (where our widgets go), or even `Theme.Material.Light.DarkActionBar` for a light content area and a dark action bar (before we start tailoring the action bar colors).

Applying the Theme

The application’s manifest declares that we will use `AppTheme` as the default theme for our `<application>`, so all activities will use that theme unless overridden at the activity level:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.abmatcolor"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <uses-sdk
    android:minSdkVersion="21"
    android:targetSdkVersion="21"/>

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">

    <activity
      android:name="ActionBarDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

THE ACTION BAR

```
</intent-filter>
</activity>
</application>
</manifest>
```

Also note that here is where we specify that `minSdkVersion` is 21. An Android Studio project could do that in `build.gradle`, but since Eclipse does not work with Gradle, we have to define it in the manifest.

The Results

Everything else about the app is the same as the `ActionBarDemoNative` sample, including our activity and the `ListView` that we are populating.

However, when we run this edition on an Android 5.0+ device or emulator, our action bar takes on the requested colors, specifically the `colorPrimary` value for the background color of the action bar:

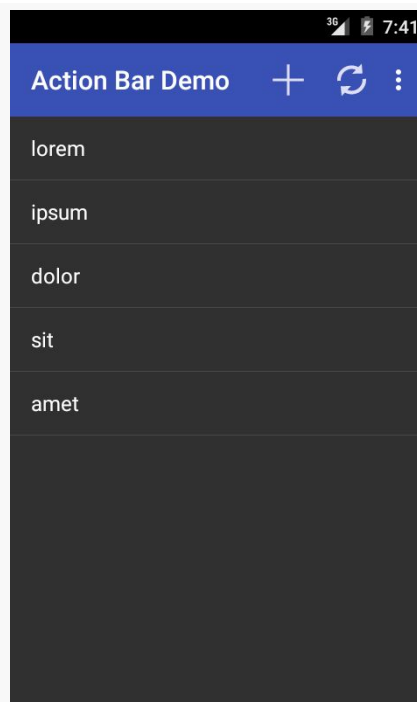

Figure 185: MaterialColor on Android 5.0 Emulator

The custom theme also affects the colors of certain widgets, as will be covered [later in the book](#).

Restoring the Icon (Sort Of)

While the Material Design philosophy skips the application icon that we used to have in the action bar, there is a way to add it back for a `Theme.Material` application, though it requires a little bit of work, as seen in the [ActionBar/MaterialLogo](#) sample project.

The key thing that you need to do is to call `setDisplayHomeAsUpEnabled(true)` on your `ActionBar` object, which you get by calling `getActionBar()` in your `Activity`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    getActionBar().setDisplayHomeAsUpEnabled(true);

    initAdapter();
}
```

This will use whatever icon is set for the `android:icon` attribute in your manifest as the “home” icon in your action bar:

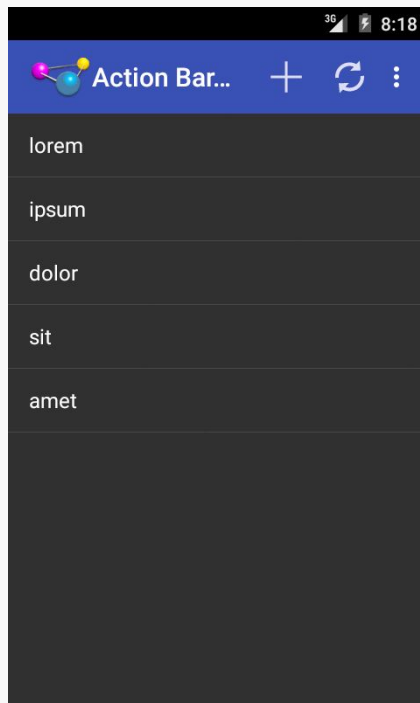

Figure 186: MaterialLogo on Android 5.0 Emulator

THE ACTION BAR

If you would rather use a different icon, such as one that is scaled to fit the action bar a bit better, you can call `setIcon()` on your `ActionBar`, supplying the ID of a drawable resource (e.g., `R.drawable.action_bar_icon`) that should be used instead of the drawable specified in the `android:icon` attribute of your `<activity>` or `<application>` in the manifest.

Action Bar Style Generator

For `Theme.Holo` and `kin`, the tinting rules from `Theme.Material` will not apply. Instead, you will need to do a fair bit of tinkering to get the color scheme set up the way you want.

Or, you can use [Jeff Gilfelt's Action Bar Style Generator](#).

This is a Web site that allows you to design an action bar color scheme, where the site will then generate for you everything that you need to implement that color scheme.

Note that Mr. Gilfelt has marked this site as deprecated, with an eye towards people using `Theme.Material` or the `appcompat-v7` edition of the action bar. The site works, but in all likelihood it will be discontinued at some future date.

Also note that the site works best with Google's Chrome or Chromium browsers, though in testing, a recent edition of Firefox worked as well. As the site indicates, "your mileage may vary with other browsers".

Designing the Scheme

The site is dominated by form for designing the color scheme and a preview area to show what the design will look like:

THE ACTION BAR

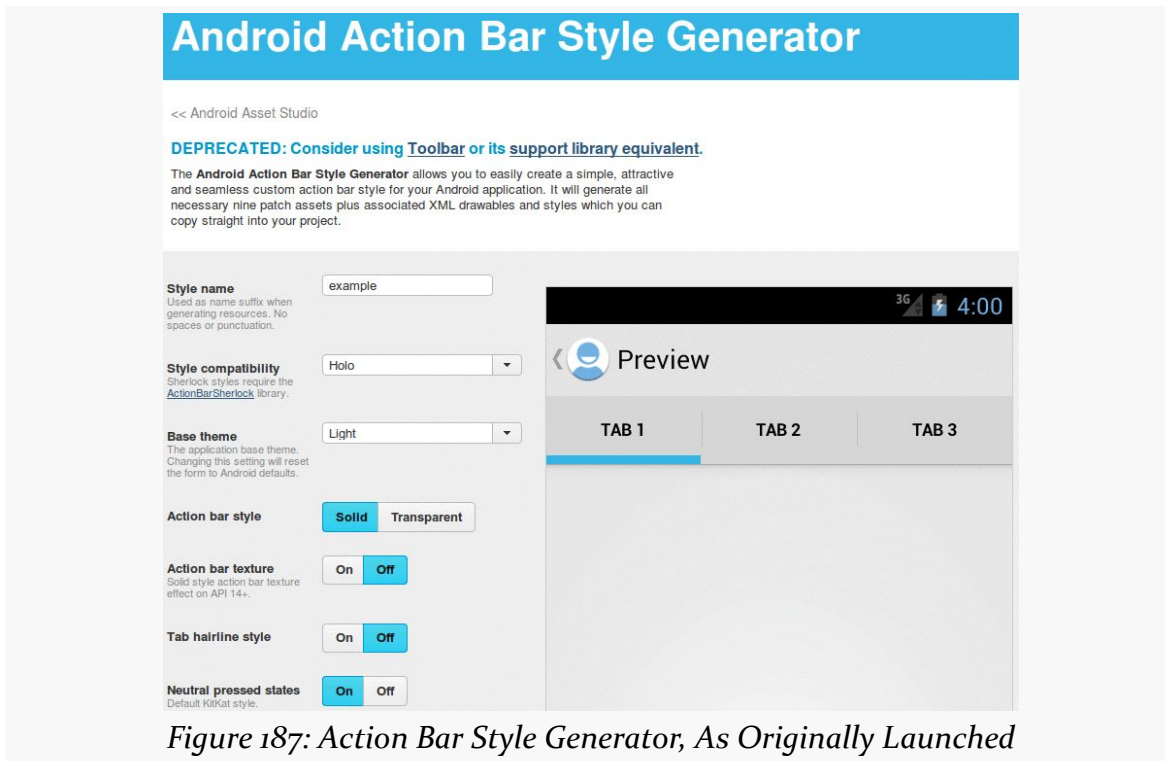

Figure 187: Action Bar Style Generator, As Originally Launched

In the “Style name” field, you can fill in the name you want to give your custom theme. Whatever you fill in will be converted into all lowercase with a leading capital letter, all following Theme. . So, for example, filling in AppTheme will result in a style resource named Theme.Apptheme.

For “Style compatibility”, choose “Holo”. For “Base theme”, choose the base style you want:

- Light
- Dark
- Light with dark action bar

The next four options (“Action bar style”, “Action bar texture”, “Tab hairline style”, “Neutral pressed states”) are for advanced features and can be left at their defaults.

Scrolling further down the page, you will come to seven color pickers, allowing you to tailor the colors to be used in your action bar implementation. Each picker, when opened, allows you to choose a color based on a fixed palette, then refined using a gradient selector. Or, if you know specific colors (e.g., a graphic designer gave them to you), you can fill the color into the supplied field:

THE ACTION BAR

Figure 188: Action Bar Style Generator, Showing “Action bar color” Picker

As you change the colors, you will see what they impact on the preview.

At the bottom of the page is the “Output resources” frame:

Figure 189: Action Bar Style Generator, Showing “Output resources” Frame

Here, you can click on the “DOWNLOAD .ZIP” button to download a ZIP archive containing your custom theme and all the associated resources required to implement it.

Implementing the Scheme

UnZIP the contents of that ZIP archive into your project’s `res/` directory (e.g., in a traditional Android Studio project, unZIP into `src/main/res/` in your app module). It will add a bunch of files, notably including a file in `res/values/` whose name is based upon the name you filled into the Web form for the theme name (e.g., `styles_apptHEME.xml`).

THE ACTION BAR

If you look at that file, you will see that it defines a custom theme for you, named `Theme`. plus whatever you provided to that form (converted into a leading capital letter and the rest lowercase). That file will be rather lengthy, as it designates specific styles to use for various facets of the action bar (e.g., `android:actionBarStyle`).

Here is the theme's primary `<style>` resource element, defining the theme itself:

```
<style name="Theme.Apptheme" parent="@android:style/Theme.Holo">
  <item name="android:actionBarItemBackground">@drawable/
selectable_background_apptheme</item>
  <item name="android:popupMenuStyle">@style/PopupMenu.Apptheme</item>
  <item name="android:dropDownListViewStyle">@style/
DropDownListView.Apptheme</item>
  <item name="android:actionBarTabStyle">@style/ActionBarTabStyle.Apptheme</item>
  <item name="android:actionDropDownStyle">@style/DropDownNav.Apptheme</item>
  <item name="android:actionBarStyle">@style/ActionBar.Solid.Apptheme</item>
  <item name="android:actionModeBackground">@drawable/
cab_background_top_apptheme</item>
  <item name="android:actionModeSplitBackground">@drawable/
cab_background_bottom_apptheme</item>
  <item name="android:actionModeCloseButtonStyle">@style/
ActionButton.CloseMode.Apptheme</item>

</style>
```

To use this theme, just add an `android:theme` attribute to your `<application>` (or perhaps individual `<activity>` elements) in your manifest:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/Theme.Apptheme">
  <activity
    android:name="ActionBarDemoActivity"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
</application>
```

The resulting app will have a color scheme mirroring what you defined on the form:

THE ACTION BAR

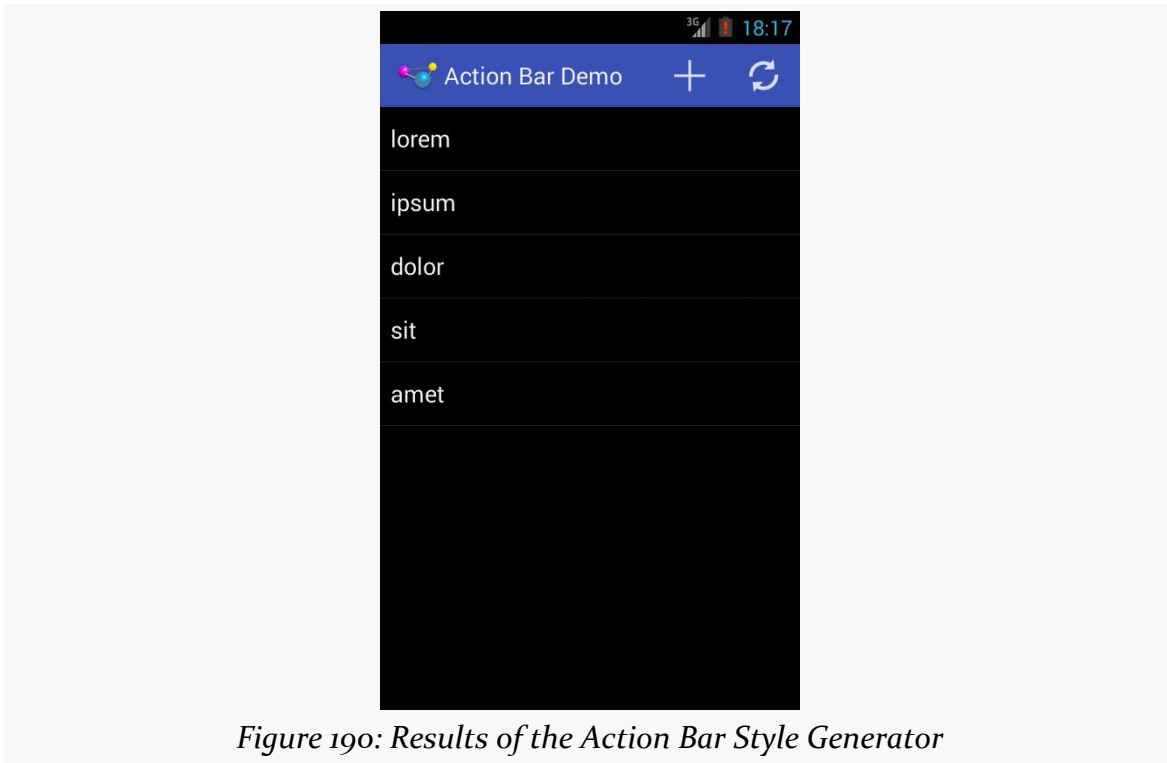

Figure 190: Results of the Action Bar Style Generator

This screenshot, and the code snippets, comes from the [ActionBar/HoloColor](#) sample project, which is the same as the base action bar sample app from this chapter with the custom theme applied.

Visit the Trails!

In addition to this chapter, you can [learn more about advanced action bar techniques](#) and [learn about action modes](#), which temporarily replace the action bar with new items for use with contextual operations.

Tutorial #7 - Setting Up the Action Bar

Next up is to configure the action bar to our EmPubLite application.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Starting in this tutorial, we will now begin editing Java source files. Some useful Android Studio shortcut key combinations are (Windows/Linux syntax shown):

- <Alt>-<Enter> for bringing up quick-fixes for the problem at the code where the cursor is.
- <Ctrl>-<Alt>-<O> will organize your Java import statements, including removing unused imports.
- <Ctrl>-<Alt>-<L> will reformat the Java or XML in the current editing window, in accordance with either the default styles in Android Studio or whatever you have modified them to in Settings.

Step #1: Acquiring Some Icons

As you noticed when running the previous versions of our app, our current action bar is very boring.

Very, very boring.

To make it more useful and worthy of its screen space, we need to start adding some action items. And to do that, we will need some icons.

TUTORIAL #7 - SETTING UP THE ACTION BAR

There are many sources of icons for use in Android apps, but few of them are part of the IDE. In particular, the IDE does not have many icons that are well-suited for use with action bar items.

So, to keep things simple, [download this set of icons](#). These are culled from an icon set that Google used to publish, called the “Action Bar Icon Pack”. In the ZIP archive, inside the root `EmPubLite-Icons/` directory, you will find four subdirectories, one each for icons set up for `-mdpi`, `-hdpi`, `-xxhdpi`, and `-xxxhdpi` densities.

UnZIP the archive somewhere on your development machine. Then, copy the icons from each of those four aforementioned directories into the corresponding drawable directories in your project. Android Studio users can do this by dragging all four directories from your hard drive into the Android Studio project tree view on the left, dropping them into the `src/main/res/` directory of your app/ module. This will merge these new icons into your existing drawable directory structure:

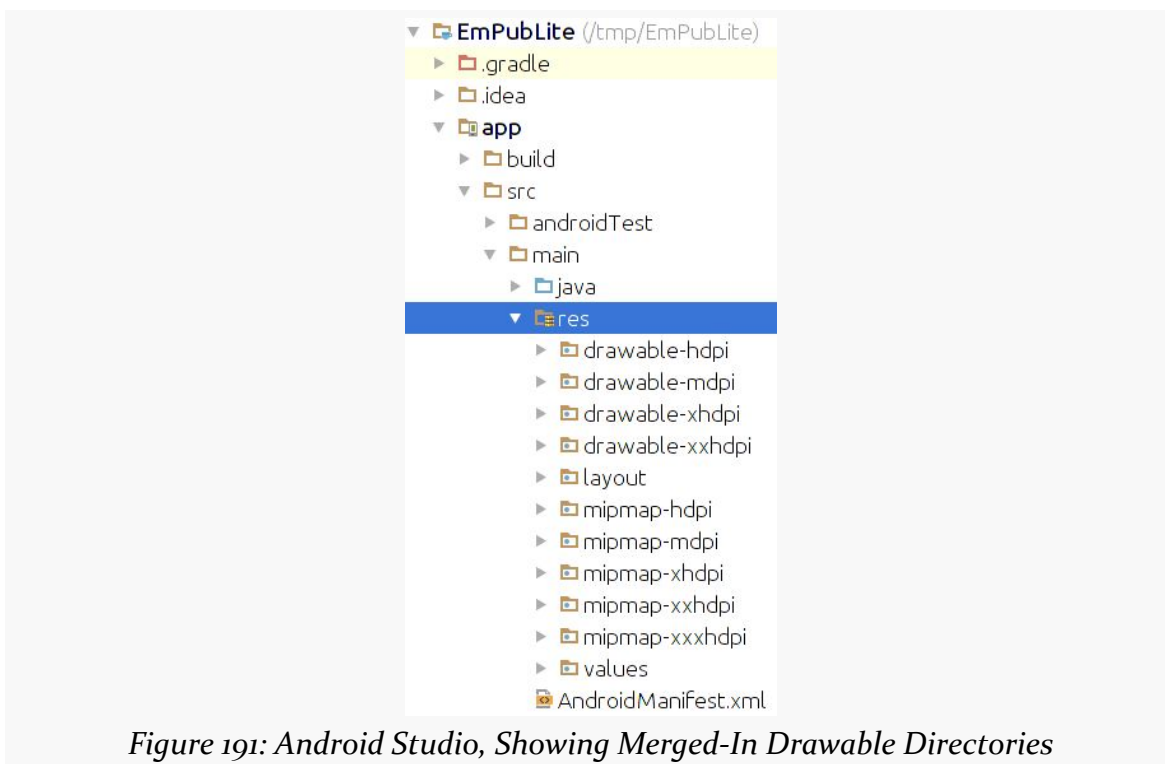

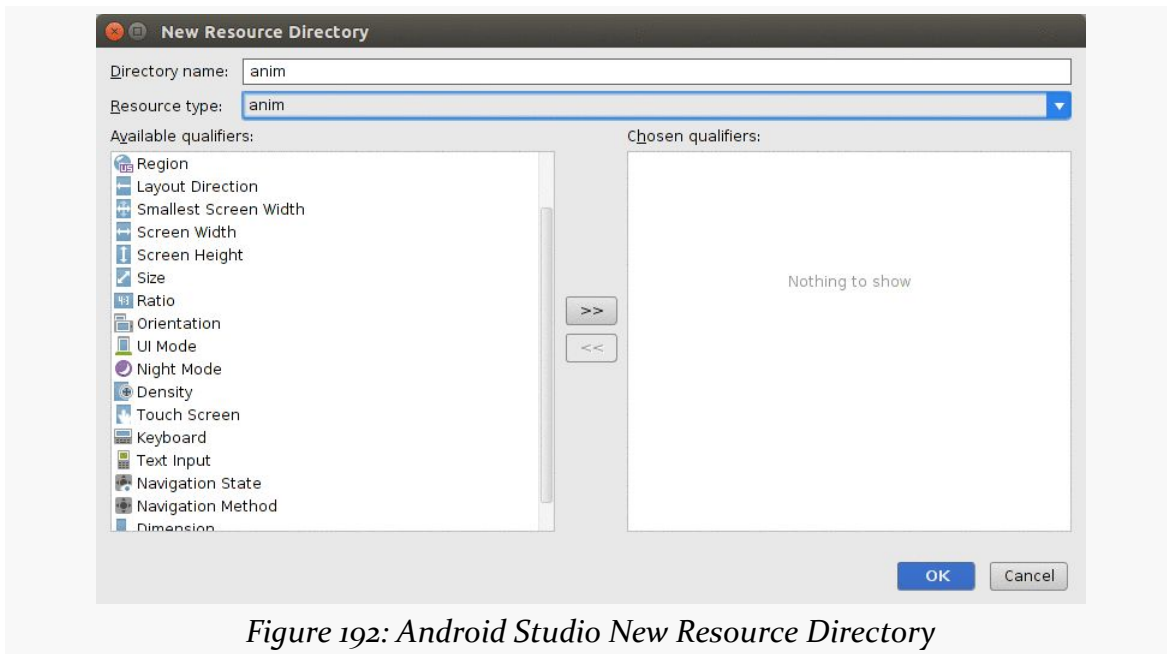

Figure 191: Android Studio, Showing Merged-In Drawable Directories

Step #2: Defining Some Options

Next, we will add a couple of low-priority action items, for a help screen and an “about” screen.

Right click over the `res/` directory in your project, and choose `New > “Android resource directory”` from the context menu. This will bring up a dialog to let you create a new resource directory:

Change the “Resource type” drop-down to be “menu”, then click OK to create the directory.

Then, right-click over your new `res/menu/` directory and choose `New > “Menu resource file”` from the context menu. Fill in `options.xml` in the “New Menu Resource File” dialog:

TUTORIAL #7 - SETTING UP THE ACTION BAR

Then click OK to create the file. It will open up into an XML editor, into which you can paste the following content:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/help"
        android:icon="@drawable/ic_action_help"
        android:title="@string/help">
    </item>
    <item
        android:id="@+id/about"
        android:icon="@drawable/ic_action_about"
        android:title="@string/about">
    </item>

</menu>
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Also, you will need to add string resources for help and about, by adding appropriate <string> elements to your existing res/values/strings.xml file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <string name="app_name">EmPub Lite</string>
    <string name="help">Help</string>
    <string name="about">About</string>

</resources>
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Step #3: Loading and Responding to Our Options

Simply defining res/menu/options.xml is insufficient. We need to actually tell Android to use what we defined in that file, and we need to add code to respond to when the user taps on our items.

To do that, you will need to add an onCreateOptionsMenu() method and an onOptionsItemSelected() method to EmPubLiteActivity, as follows:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.options, menu);
}
```

TUTORIAL #7 - SETTING UP THE ACTION BAR

```
        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        switch (item.getItemId()) {
            case R.id.about:
                return (true);

            case R.id.help:
                return (true);
        }

        return(super.onOptionsItemSelected(item));
    }
}
```

NOTE: Copying and pasting Java code may or may not work, depending on what you are using to read the book. For the PDF, some PDF viewers (e.g., Adobe Reader) should copy the code fairly well; others may do a much worse job. Reformatting the code with <Ctrl>-<Alt>-<L> after pasting it in sometimes helps.

In `onCreateOptionsMenu()`, we are inflating `res/menu/options.xml` and pouring its contents into the supplied `Menu` object, which will be used by Android to populate our action bar.

In `onOptionsItemSelected()`, we examine the supplied `MenuItem` and route to different branches of a `switch` statement based upon the item's ID.

To get this to compile, you will need to add some imports as well:

```
import android.view.Menu;
import android.view.MenuItem;
```

Android Studio users can press <Alt>-<Enter> with the cursor in a class reference that is missing its import to add that import.

Step #4: Trying It Out

If you run this in an Android 4.x device or emulator, you may see no initial difference. That would be for devices or emulators that have a MENU button and are running Android 4.3 or below. To display our options, you would need to press MENU:

TUTORIAL #7 - SETTING UP THE ACTION BAR

Figure 194: EmPubLite, With Options Via the MENU Button

Note that on an emulator, the MENU button is mapped to the PgUp key of your keyboard.

In other cases, the action bar will have a “...” icon on the action bar:

TUTORIAL #7 - SETTING UP THE ACTION BAR

Pressing that brings up a menu showing our items:

TUTORIAL #7 - SETTING UP THE ACTION BAR

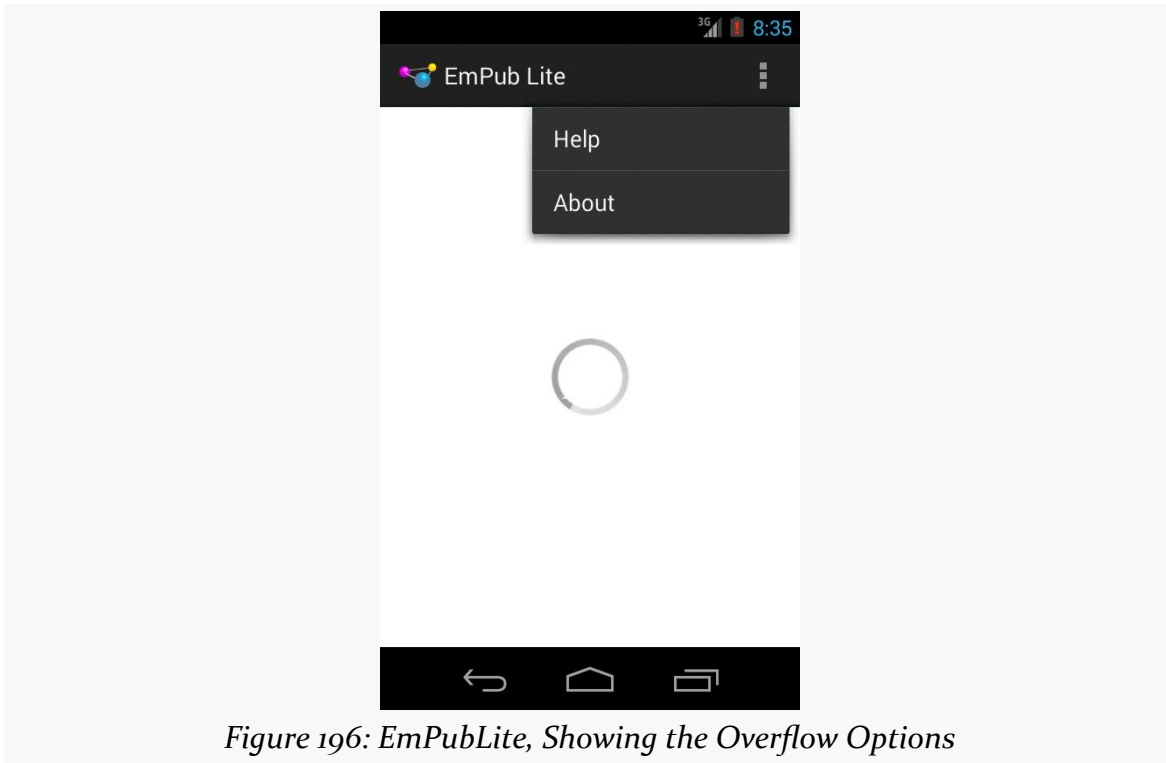

Figure 196: EmPubLite, Showing the Overflow Options

In Our Next Episode...

... we will [define our first new activity](#) on the tutorial project.

Android's Process Model

So far, we have been treating our activity like it is our entire application. Soon, we will start to get into more complex scenarios, involving multiple activities and other types of components, like services and content providers.

But, before we get into a lot of that, it is useful to understand how all of this ties into the actual OS itself. Android is based on Linux, and Linux applications run in OS processes. Understanding a bit about how Android and Linux processes inter-relate will be useful in understanding how our mixed bag of components work within these processes.

When Processes Are Created

A user installs your app, goes to their home screen's launcher, and taps on an icon representing your activity. Your activity dutifully appears on the screen.

Behind the scenes, what happened is that Android forked a copy of a process known as the zygote. As a result of the way your process is forked from the zygote, your process contains:

- A copy of the VM (Dalvik or ART), shared among all such processes via Linux copy-on-write memory sharing
- A copy of the Android framework classes, like Activity and Button, also shared via copy-on-write memory
- A copy of your own classes, loaded out of your APK
- Any objects created by you or the framework classes, such as the instance of your Activity subclass

BACK, HOME, and Your Process

Suppose that you have an app with just one activity. From the home screen's launcher, the user taps on the icon associated with your app's activity. Then, with your activity in the foreground, the user presses BACK.

At this point, the user is telling the OS that she is done with your activity. Control will return to whatever preceded that activity — in this case, the home screen's launcher.

You might think that this would cause your process to be terminated. After all, that is how most desktop operating systems work. Once the user closes the last window of the application, the process hosting that application is terminated.

However, that is not how Android works. Android will *keep* your process around, for a little while at least. This is done for speed and power: if the user happens to want to return to your app sooner rather than later, it is more efficient to simply bring up another copy of your activity again in the existing process than it is to go set up a completely new copy of the process. This does not mean that your process will live forever; we will discuss when your process will go away later in this chapter.

Now, instead of the user pressing BACK, let's say that the user pressed HOME instead. Visually, there is little difference: the home screen re-appears. Depending on the home screen implementation there may be a visible difference, as BACK might return to a launcher whereas HOME might return to something else on the home screen. However, in general, they feel like very similar operations.

The difference is what happens to your activity.

When the user presses BACK, your foreground activity is *destroyed*. We will get into more of what that means [in the next chapter](#). However, the key feature is that the activity itself — the instance of your subclass of Activity — will never be used again, and hopefully is garbage collected.

When the user presses HOME, your foreground activity is *not* destroyed... at least, not immediately. It remains in memory. If the user launches your app again from the home screen launcher, and if your process is still around, Android will simply bring your existing activity instance back to the foreground, rather than having to create a brand-new one (as is the case if the user pressed BACK and destroyed your activity).

What HOME literally is doing is bringing the home screen activity back to the foreground, not otherwise directly affecting your process much.

Termination

Processes cannot live forever. They take up a chunk of RAM, for your classes and objects, and these mobile devices only have so much RAM to work with. Eventually, therefore, Android has to get rid of your process, to free up memory for other applications.

How long your process will stick around depends on a variety of factors, including:

- What else the device is doing, either in the foreground (user using apps) or in the background (e.g., automated checks for new email)
- How much memory the device has
- What is still running inside your process

Going back to the scenario from above, we have an application with a single activity launched from the home screen, where the user can return to the home screen either by pressing BACK or by pressing HOME. You might think that this has no difference at all on when the process would be terminated, but that would be incorrect. Pressing HOME would keep the process around perhaps a bit longer than would pressing BACK.

Why?

When the user presses BACK, your one and only activity is destroyed. When the user presses HOME, your activity is not destroyed. Android will tend to keep processes around longer if they have active (i.e., not destroyed) components in them.

The key word there is “tend”. Android’s algorithms for determining when to get rid of what processes are baked into the OS and are, at best, lightly documented. There is evidence to suggest that other criteria, such as process age, are also taken into account, and so there may be times when a process that has an activity running (but not in the foreground) might be terminated where a process with no running activity might not. However, in general, processes with active (not destroyed) components will stick around a bit longer than processes without such components.

Foreground Means “I Love You”

Just because Android terminates processes to free up memory does not mean that it will terminate just any process to free up memory. A foreground process – the most common of which is a process that has an activity in the foreground – is the least likely of all to be terminated. In fact, you can pretty much assume that if Android has to kill off the foreground process, that the phone is very sick and will crash in a matter of moments.

(and, fortunately, that does not happen very often)

So, if you are in the foreground, you are safe. It is only when you are not in the foreground that you are at risk of having the process be terminated.

You and Your Heap

Processes take up RAM. A significant chunk of that RAM represents the objects you create (a.k.a., “the heap”).

Those of you with significant Java backgrounds know that the Java VM loves RAM (“can’t get enough of it!”). Java VMs routinely grab 64MB or 128MB of heap space upon creating the process and will grow as big as you wish to let them (e.g., `-Xmx` switch to the `java` command).

Android heap sizes are not that big, because Android is designed to run on mobile devices with constrained amounts of RAM.

Your heap limit may be as low as 16MB, though values in the 32-48MB range are more typical with current-generation devices. How much the heap limit will be depends a bit on what version of Android is on the device. It depends quite a lot, though, on the screen size, as bigger screens will tend to want to display bigger bitmap images, and bitmap images can consume quite a bit of RAM.

The key is that the heap is small, and (generally speaking) you cannot adjust it yourself. It is what it is. Small applications will rarely run into a problem with heap space, but larger applications might. We will discuss tools and techniques for measuring and coping with memory problems later in this book.

Activities and Their Lifecycles

An Android application will have multiple discrete UI facets. For example, a calendar application needs to allow the user to view the calendar, view details of a single event, edit an event (including adding a new one), and so forth. And on smaller-screen devices, like most phones, you may not have room to squeeze all of this on the screen at once.

To handle this, you can have multiple activities. Your calendar application may have one activity to display the calendar, another to add or edit an event, one to provide settings for how the calendar should work, another for your online help, etc. Some of these activities might be private to your app, while others might be able to be launched by third parties, such as your “launcher” activity being available to home screens.

All of this implies that one of your activities has the means to start up another activity. For example, if somebody clicks on an event from the view-calendar activity, you might want to show the view-event activity for that event. This means that, somehow, you need to be able to cause the view-event activity to launch and show a specific event (the one the user clicked upon).

This can be further broken down into two scenarios:

- You know what activity you want to launch, probably because it is another activity in your own application
- You have a reference to... something (e.g., a Web page), and you want your users to be able to do... something with it (e.g., view it), but you do not know up front what the options are

This chapter will cover both of those scenarios.

In addition, frequently it will be important for you to understand when activities are coming and going from the foreground, so you can automatically save or refresh data, etc. This is the so-called “activity lifecycle”, and we will examine it in detail as well in this chapter.

Creating Your Second (and Third and...) Activity

Unfortunately, activities do not create themselves. On the positive side, this does help keep Android developers gainfully employed.

Hence, given a project with one activity, if you want a second activity, you will need to add it yourself. The same holds true for the third activity, the fourth activity, and so on.

The sample we will examine in this section is [Activities/Explicit](#). Our first activity, `ExplicitIntentsDemoActivity`, started off as just the default activity code generated by the build tools. Now, though, its layout contains a `Button`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:textSize="20sp"
        android:text="@string/hello"
        android:onClick="showOther"/>

</LinearLayout>
```

That `Button` is tied to a `showOther()` method in our activity implementation, which we will examine shortly.

Defining the Class and Resources

To create your second (or third or whatever) activity, you first need to create the Java class. You need to create a new Java source file, containing a public Java class that extends `Activity` directly or indirectly. You have three basic ways of doing this:

- Just create the class and resources yourself
- Use the Android Studio new-activity wizard
- Use the Eclipse new-activity wizard

Android Studio New-Activity Wizard

Right-click on your `app/src/main/` sourceset directory in the project explorer, and go into the `New > Activity` portion of the context menu. This will give you a submenu of available activity templates — mostly the same roster of templates that we saw back when we created the project in the first place.

If you choose one of those templates, you will be presented with a one-page wizard in which to provide the details for this activity:

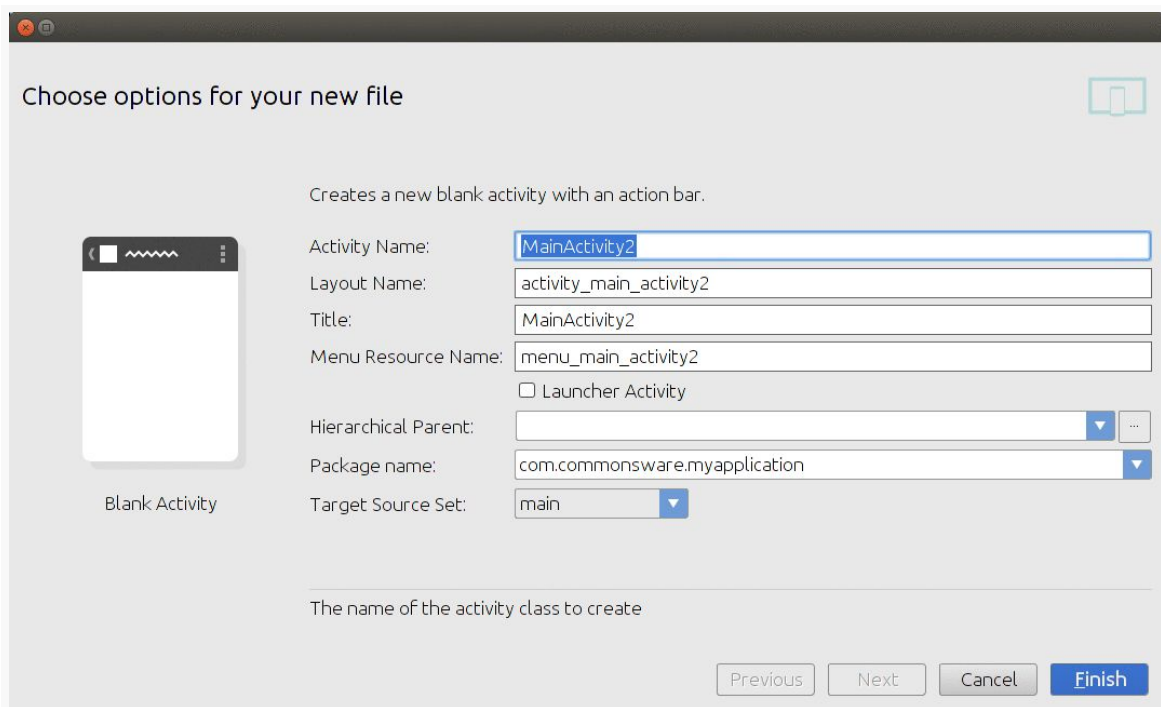

Figure 197: Android Studio New-Activity Wizard

The first few fields will be based upon the template you chose (e.g., activity name, layout XML resource name) and will mirror those we saw back in the new-project wizard. Others, though, are new to this wizard:

- the “Launcher Activity” checkbox which, if checked, will add the appropriate bits to the manifest to tell Android that this activity should get an icon in the home screen’s launcher
- the “Hierarchical Parent” drop-down, which presently is beyond the scope of this book

ACTIVITIES AND THEIR LIFECYCLES

- the “Package name” drop-down, where you can choose the Java package name into which this activity’s class will be added
- the “Target Source Set” drop-down, where you can indicate the Gradle sourceset into which the generated code should go (for now, choose main)

Clicking “Finish” will then create the activity’s Java class, related resources, and manifest entry.

Eclipse New-Activity Wizard

Right-clicking over a project in the Package Explorer, and choosing New > Other from the context menu, brings up a list of things that you can add to your project. One of those, in the Android group, is “Android Activity”:

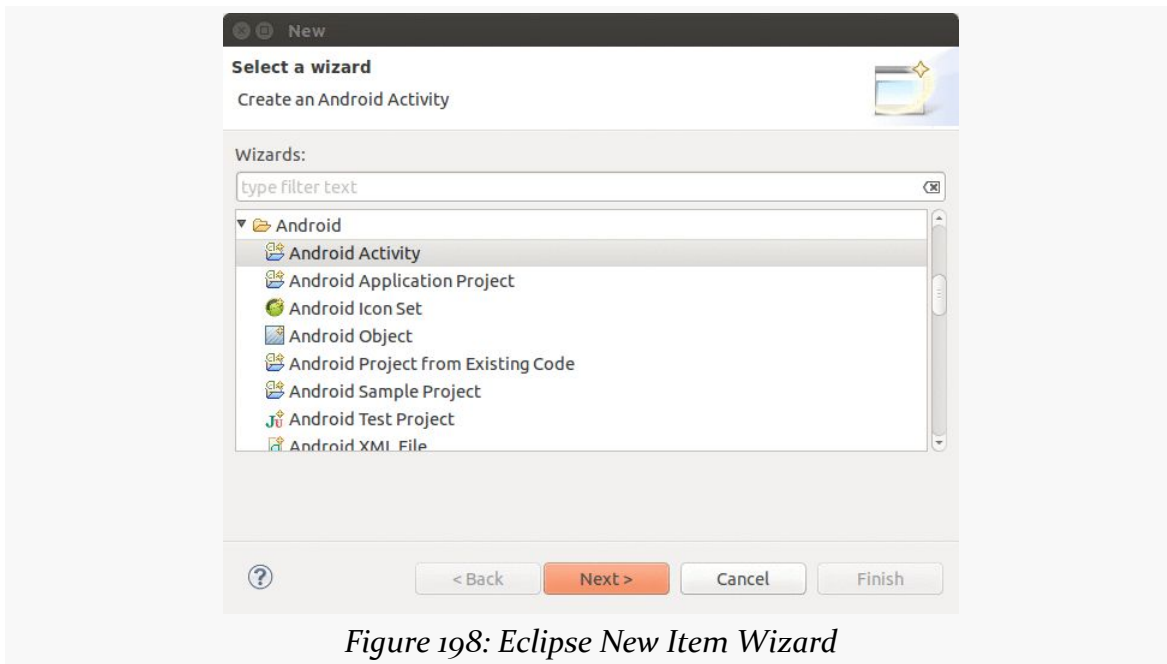

Figure 198: Eclipse New Item Wizard

Choosing “Android Activity” and clicking Next will give you a list of available activity templates:

ACTIVITIES AND THEIR LIFECYCLES

Figure 199: Eclipse New Activity Wizard, First Page

Choosing a template and clicking Next will bring up another wizard page, where you will need to provide additional information about the new activity:

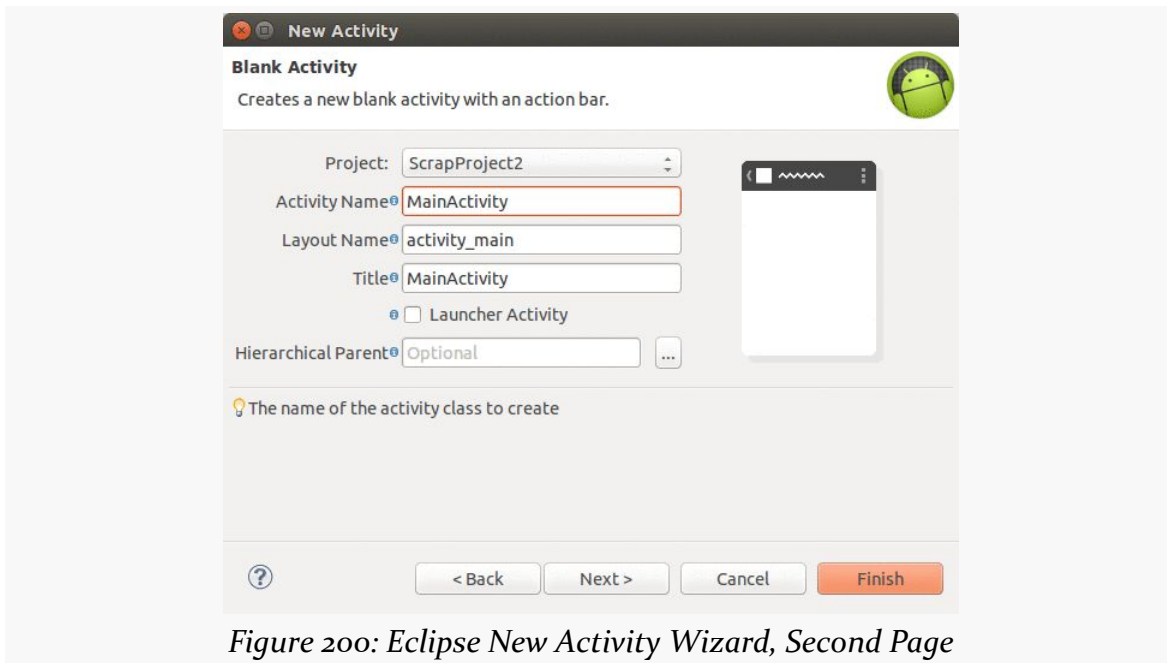

Figure 200: Eclipse New Activity Wizard, Second Page

In addition to the class name and layout name, as we saw in the new-project wizard, we are also asked for some more details:

- the project into which we want this activity created (defaults to the one we right-clicked over)
- the “Title” is the caption that will appear in the action bar for this activity
- the “Launcher Activity” checkbox which, if checked, will add the appropriate bits to the manifest to tell Android that this activity should get an icon in the home screen’s launcher
- the “Hierarchical Parent” drop-down, which presently is beyond the scope of this book

Clicking “Finish” will then create the activity’s Java class, related resources, and manifest entry.

Populating the Class and Resources

Once you have your stub activity set up, you can then add an `onCreate()` method to it (or edit an existing one created by the wizard), filling in all the details (e.g., `setContentView()`), just like you did with your first activity. Your new activity may need a new layout XML resource or other resources, which you would also have to create (or edit those created for you by the wizard).

In `Activities/Explicit`, our second activity is `OtherActivity`, with pretty much the standard bare-bones implementation:

```
package com.commonware.android.exint;

import android.app.Activity;
import android.os.Bundle;

public class OtherActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.other);
    }
}
```

and a similarly simple layout, `res/layout/other.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">
```

```
<TextView
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/other"
    android:textColor="#FFFF0000"
    android:textSize="20sp" />
```

```
</LinearLayout>
```

Augmenting the Manifest

Simply having an activity implementation is not enough. We also need to add it to our `AndroidManifest.xml` file. This is automatically handled for you by the IDEs' respective new-activity wizards. However, if you created the activity "by hand", you will need to add its manifest element, and over time you will need to edit this element in many cases.

Adding an activity to the manifest is a matter of adding another `<activity>` element to the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.exint"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11" />

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true" />

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="ExplicitIntentsDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />

                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
        <activity android:name="OtherActivity" />
    </application>
</manifest>
```

You need the `android:name` attribute at minimum. Note that we do not include an `<intent-filter>` child element, the way the original activity has. For now, take it on faith that the original activity's `<intent-filter>` is what causes it to appear as a launchable activity in the home screen's launcher. We will get into more details of how that `<intent-filter>` works and when you might want your own [in a later chapter](#).

Warning! Contains Explicit Intents!

An Intent encapsulates a request, made to Android, for some activity or other receiver to do something.

If the activity you intend to launch is one of your own, you may find it simplest to create an explicit Intent, naming the component you wish to launch. For example, from within your activity, you could create an Intent like this:

```
new Intent(this, HelpActivity.class);
```

This would stipulate that you wanted to launch the `HelpActivity`. This activity would need to be named in your `AndroidManifest.xml` file.

In `Activities/Explicit`, `ExplicitIntentsDemoActivity` has a `showOther()` method tied to its Button widget's `onClick` attribute. That method will use `startActivity()` with an explicit Intent, identifying `OtherActivity`:

```
package com.commonware.android.exint;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class ExplicitIntentsDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showOther(View v) {
        startActivity(new Intent(this, OtherActivity.class));
    }
}
```

Our launched activity shows the button:

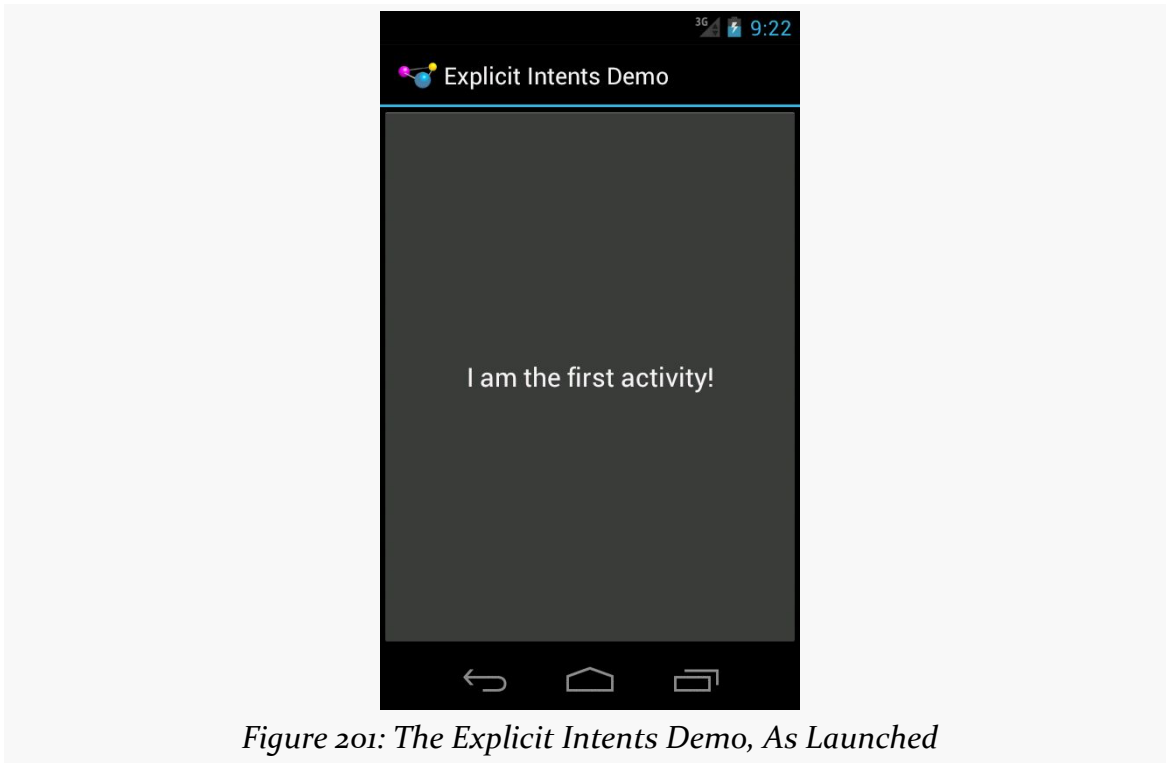

Figure 201: The Explicit Intents Demo, As Launched

Clicking the button brings up the other activity:

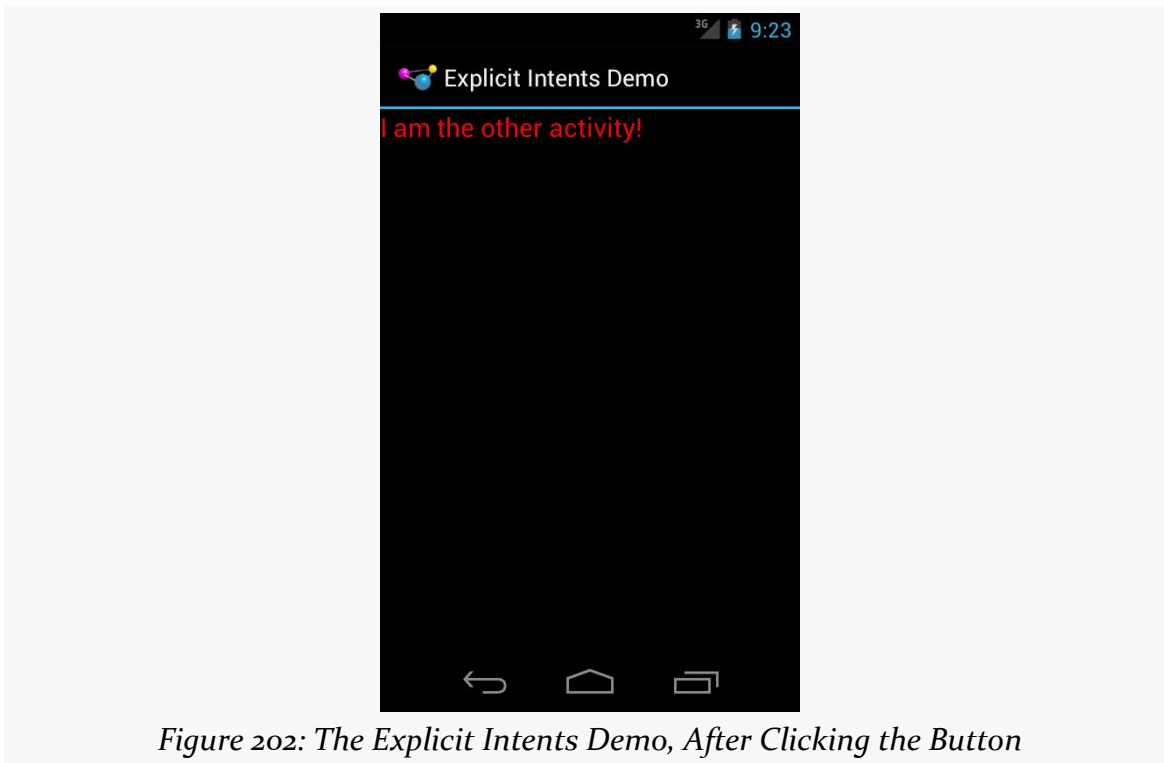

Figure 202: The Explicit Intents Demo, After Clicking the Button

Clicking BACK would return us to the first activity. In this respect, the BACK button in Android works much like the BACK button in your Web browser.

Using Implicit Intents

The explicit Intent approach works fine when the activity to be started is one of yours.

However, you can also start up activities from the operating system or third-party apps. In those cases, though, you will not have a Java Class object representing the other activity in your project, so you cannot use the Intent constructor that takes a Class.

Instead, you will use what are referred as the “implicit” Intent structure, which looks an *awful* lot like how the Web works.

If you have done any work on Web apps, you are aware that HTTP is based on verbs applied to URIs:

ACTIVITIES AND THEIR LIFECYCLES

- We want to GET this image
- We want to POST to this script or controller
- We want to PUT to this REST resource
- Etc.

Android's implicit Intent model works much the same way, just with a *lot* more verbs.

For example, suppose you get a latitude and longitude from somewhere (e.g., body of a tweet, body of a text message). You decide that you want to display a map on those coordinates. There are ways that you can embed a Google Map directly in your app — and we will see how [in a later chapter](#) — but that is complicated and assumes the user wants Google Maps. It would be better if we could create some sort of generic “hey, Android, display an activity that shows a map for this location” request.

Or, in a simpler scenario: we get a URL to a Web page from some source (e.g., Web service call), and we want to open a Web browser on that page. This is illustrated in the [Activities/LaunchWeb](#) sample project.

We have a LaunchDemo activity that uses a layout containing a EditText widget and a Button, among other things:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <EditText
        android:id="@+id/url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:hint="@string/url"
        android:inputType="textUri"/>

    <Button
        android:id="@+id/browse"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showMe"
        android:text="@string/show_me"/>

</LinearLayout>
```

The Button is tied to a `showMe()` method on the activity itself, where we want to bring up a Web browser on the URL entered into the EditText widget:

ACTIVITIES AND THEIR LIFECYCLES

```
package com.commonware.android.activities;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class LaunchDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showMe(View v) {
        EditText url=(EditText)findViewById(R.id.url);

        startActivity(new Intent(Intent.ACTION_VIEW,
            Uri.parse(url.getText().toString())));
    }
}
```

Here, we take the URL and convert it to a `Uri` via calling `Uri.parse()`. Then, we can use an action called `ACTION_VIEW` to try to display the desired Web page.

When launched, the user is presented with our data entry form:

We can fill in a URL:

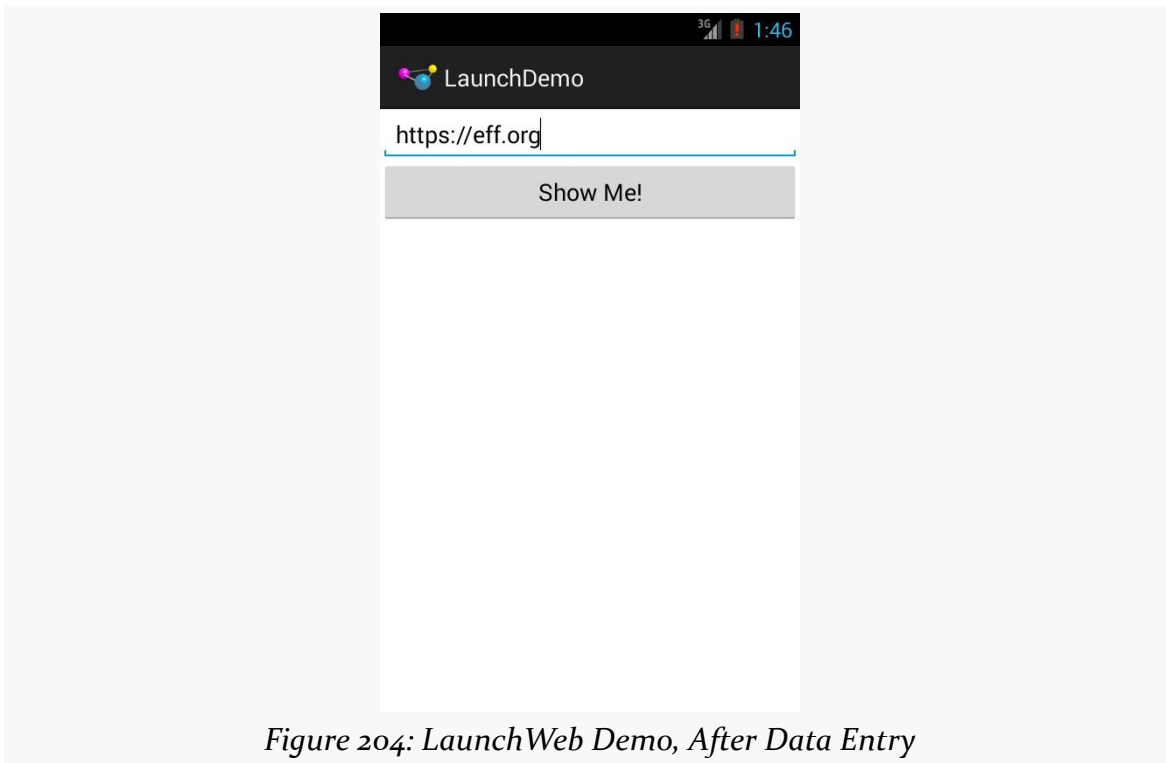

Figure 204: LaunchWeb Demo, After Data Entry

If the device has one app that responds to an `ACTION_VIEW` Intent on an `https:` scheme, clicking the “Show Me!” button will bring up that app, probably a Web browser:

ACTIVITIES AND THEIR LIFECYCLES

Figure 205: EFF Home Page, Launched from LaunchWeb

We will discuss what happens if there are no applications set up to handle this Intent, or if there is more than one, [in a later chapter](#).

Extra! Extra!

Sometimes, we may wish to pass some data from one activity to the next. For example, we might have a `ListActivity` showing a collection of our model objects (e.g., books) and we have a separate `DetailActivity` to show information about a specific model object. Somehow, `DetailActivity` needs to know which model object to show.

One way to accomplish this is via Intent extras.

There is a series of `putExtra()` methods on Intent to allow you to supply key/value pairs of data to be bundled into the Intent. While you cannot pass arbitrary objects, most primitive data types are supported, as are strings and some types of lists. The [next section](#) will explain a bit more about what can go in an Intent extra.

ACTIVITIES AND THEIR LIFECYCLES

Any activity can call `getIntent()` to retrieve the `Intent` used to start it up, and then can call various forms of `get...Extra()` (with the `...` indicating a data type) to retrieve any bundled extras.

For example, let's take a look at the [Activities/Extras](#) sample project.

This is mostly a clone of the `Activities/Explicit` sample from earlier in this chapter. However, this time, our first activity will pass an extra to the second:

```
package com.commonware.android.extra;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class ExtrasDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showOther(View v) {
        Intent other=new Intent(this, OtherActivity.class);

        other.putExtra(OtherActivity.EXTRA_MESSAGE, getString(R.string.other));
        startActivity(other);
    }
}
```

We create the `Intent` as before, but then call `putExtra()`, supplying a key (a static string named `OtherActivity.EXTRA_MESSAGE`) and a value (the `R.string.other` string resource). Then, and only then, do we call `startActivity()`.

Our revised `OtherActivity` then retrieves that extra, along with the inflated `TextView` (via `findViewById()`) and pours that text in:

```
package com.commonware.android.extra;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class OtherActivity extends Activity {
    public static final String EXTRA_MESSAGE="msg";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.other);
    }
}
```

```
TextView tv=(TextView)findViewById(R.id.msg);  
tv.setText(getIntent().getStringExtra(EXTRA_MESSAGE));  
}  
}
```

Visually, the result is the same. Functionally, the text to be shown is passed from one activity to the next.

Pondering Parcelable

As noted above, Intent extras cannot handle arbitrary objects. That is because, most of the time, Intent extras get passed across process boundaries. Even when you are calling `startActivity()` to start up one of your own activities, that request passes from your process to a core OS process and back to your process. The Intent extras come along for the ride.

Hence, Intent extras need to be something that can be converted into a byte array, as part of the inter-process communication (IPC) that handles the passing around of Intent objects. You will see this come up in other flavors of Android IPC as well, such as [remote services](#).

However, there are two ways in which you can try to make your own objects work as Intent extras.

One approach is to implement `Serializable` on your class. This is a classic Java construct, designed to allow instances of your class, and other `Serializable` objects your instances hold onto, to be serialized into files and later read back in.

Another approach is to implement `Parcelable` on your class. This is an Android construct, one that is very similar to `Serializable`. However, `Serializable` is designed for *durable* storage of objects, where the file might be read back in months or years later. As such, `Serializable` has to deal with possible changes to the Java code implementing those classes, and as such needs to have hooks to help with converting old, saved objects into new objects. This adds overhead. `Parcelable` is only concerned with converting objects into byte arrays to pass across process boundaries. It can make the simplifying assumption that the class definition is not changing from when the object is turned into bytes and when the bytes are turned back into an object. As a result, `Parcelable` is faster than `Serializable` for Android's IPC use.

You are welcome to implement `Parcelable` on your own classes if you wish, at which point they can be passed around via Intent extras. Beyond that, though, any Java classes you see in the Android JavaDocs that implement `Parcelable` can be put into Intent extras. So, for example, `Uri` implements `Parcelable`, and so you can put a `Uri` into an Intent extra. Not everything in the Android SDK is `Parcelable`, but some key classes like `Uri` are `Parcelable`.

A lot more detail on `Parcelable`, including how you can implement it on your own classes, appears [later in this book](#).

Asynchronicity and Results

Note that `startActivity()` is asynchronous. The other activity will not show up until sometime after you return control of the main application thread to Android.

Normally, this is not much of a problem. However, sometimes one activity might start another, where the first activity would like to know some “results” from the second. For example, the second activity might be some sort of “chooser”, to allow the user to pick a file or contact or song or something, and the first activity needs to know what the user chose. With `startActivity()` being asynchronous, it is clear that we are not going to get that sort of result as a return value from `startActivity()` itself.

To handle this scenario, there is a separate `startActivityForResult()` method. While it too is asynchronous, it allows the newly-started activity to supply a result (via a `setResult()` method) that is delivered to the original activity via an `onActivityResult()` method. We will examine `startActivityForResult()` in greater detail [in a later chapter](#).

Schroedinger’s Activity

An activity, generally speaking, is in one of four states at any point in time:

1. *Active*: the activity was started by the user, is running, and is in the foreground. This is what you are used to thinking of in terms of your activity’s operation.
2. *Paused*: the activity was started by the user, is running, and is visible, but another activity is overlaying part of the screen. During this time, the user can see your activity but may not be able to interact with it. This is a

relatively uncommon state, as most activities are set to fill the screen, not have a theme that makes them look like some sort of dialog box.

3. *Stopped*: the activity was started by the user, is running, but it is hidden by other activities that have been launched or switched to.
4. *Dead*: the activity was destroyed, perhaps due to the user pressing the BACK button.

Life, Death, and Your Activity

Android will call into your activity as the activity transitions between the four states listed above.

Note that for all of these, you should chain upward and invoke the superclass' edition of the method, or Android may raise an exception.

`onCreate()` and `onDestroy()`

We have been implementing `onCreate()` in all of our Activity subclasses in all the examples. This will get called in two primary situations:

- When the activity is first started (e.g., since a system restart), `onCreate()` will be invoked with a `null` parameter.
- If the activity had been running and you have set up your activity to have different resources based on different device states (e.g., landscape versus portrait), your activity will be re-created and `onCreate()` will be called. We will discuss this scenario in greater detail [later in this book](#).

Here is where you initialize your user interface and set up anything that needs to be done once, regardless of how the activity gets used.

On the other end of the lifecycle, `onDestroy()` may be called when the activity is shutting down, such as because the activity called `finish()` (which “finishes” the activity) or the user presses the BACK button. Hence, `onDestroy()` is mostly for cleanly releasing resources you obtained in `onCreate()` (if any), plus making sure that anything you started up outside of lifecycle methods gets stopped, such as background threads.

Bear in mind, though, that `onDestroy()` may not be called. This would occur in a few circumstances:

- You crash with an unhandled exception
- The user force-stops your application, such as through the Settings app
- Android has an urgent need to free up RAM (e.g., to handle an incoming phone call), wants to terminate your process, and cannot take the time to call all the lifecycle methods

Hence, `onDestroy()` is very likely to be called, but it is not guaranteed.

Also, bear in mind that it may take a long time for `onDestroy()` to be called. It is called quickly if the user presses BACK to finish the foreground activity. If, however, the user presses HOME to bring up the home screen, your activity is not immediately destroyed. `onDestroy()` will not be called until Android does decide to gracefully terminate your process, and that could be seconds, minutes, or hours later.

`onStart()`, `onRestart()`, and `onStop()`

An activity can come to the foreground either because it is first being launched, or because it is being brought back to the foreground after having been hidden (e.g., by another activity, by an incoming phone call).

The `onStart()` method is called in either of those cases. The `onRestart()` method is called in the case where the activity had been stopped and is now restarting.

Conversely, `onStop()` is called when the activity is about to be stopped. It too may not be called, for the same reasons that `onDestroy()` would not be called. However, `onStop()` is usually called fairly quickly after the activity is no longer visible, so the odds that `onStop()` will be called are even higher than that of `onDestroy()`.

`onPause()` and `onResume()`

The `onResume()` method is called just before your activity comes to the foreground, either after being initially launched, being restarted from a stopped state, or after a pop-up dialog (e.g., incoming call) is cleared. This is a great place to refresh the UI based on things that may have occurred since the user last was looking at your activity. For example, if you are polling a service for changes to some information (e.g., new entries for a feed), `onResume()` is a fine time to both refresh the current view and, if applicable, kick off a background thread to update the view (e.g., via a `Handler`).

Conversely, anything that takes over user input — mostly, the activation of another activity — will result in your `onPause()` being called. Here, you should undo anything you did in `onResume()`, such as stopping background threads, releasing any exclusive-access resources you may have acquired (e.g., camera), and the like.

Once `onPause()` is called, Android reserves the right to kill off your activity's process at any point. Hence, you should not be relying upon receiving any further events.

So, what is the difference between `onPause()` and `onStop()`? If an activity comes to the foreground that fills the screen, your current foreground activity will be called with `onPause()` and `onStop()`. If, however, an activity comes to the foreground that does *not* fill the screen, your current foreground activity will only be called with `onPause()`, as it is still visible.

Stick to the Pairs

If you initialize something in `onCreate()`, clean it up in `onDestroy()`.

If you initialize something in `onStart()`, clean it up in `onStop()`.

If you initialize something in `onResume()`, clean it up in `onPause()`.

In other words, stick to the pairs. For example, do not initialize something in `onStart()` and try to clean it up in `onPause()`, as there are scenarios where `onPause()` may be called multiple times in succession (i.e., user brings up a non-full-screen activity, which triggers `onPause()` but not `onStop()`, and hence not `onStart()`).

Which pairs of lifecycle methods you choose is up to you, depending upon your needs. You may decide that you need two pairs (e.g., `onCreate()/onDestroy()` and `onResume()/onPause()`). Just do not mix and match between them.

When Activities Die

So, what gets rid of an activity? What can trigger the chain of events that results in `onDestroy()` being called?

First and foremost, when the user presses the BACK button, the foreground activity will be destroyed, and control will return to the previous activity in the user's

navigation flow (i.e., whatever activity they were on before the now-destroyed activity came to the foreground).

You can accomplish the same thing by calling `finish()` from your activity. This is mostly for cases where some other UI action would indicate that the user is done with the activity (e.g., the activity presents a list for the user to choose from — clicking on a list item might close the activity). However, please do not artificially add your own “exit”, “quit”, or other menu items or buttons to your activity — just allow the user to use normal Android navigation options, such as the BACK button.

If none of your activities are in the foreground any more, your application’s process is a candidate to be terminated to free up RAM. As noted earlier, depending on circumstances, Android may or may not call `onDestroy()` in these cases (`onPause()` and `onStop()` would have been called when your activities left the foreground).

If the user causes the device to go through a “configuration change”, such as switching between portrait and landscape, Android’s default behavior is to destroy your current foreground activity and create a brand new one in its place. We will cover this more in [a later chapter](#).

And, if your activity has an unhandled exception, your activity will be destroyed, though Android will not call any more lifecycle methods on it, as it assumes your activity is in an unstable state.

Walking Through the Lifecycle

To see when these various lifecycle methods get called, let’s examine the [Activities/Lifecycle](#) sample project.

This project is the same as the `Activities/Extras` project, except that our two activities no longer inherit from `Activity` directly. Instead, we introduce a `LifecycleLoggingActivity` as a base class and have our activities inherit from it:

```
package com.commonware.android.lifecycle;

import android.app.Activity;
import android.os.Bundle;
import android.util.Log;

public class LifecycleLoggingActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

ACTIVITIES AND THEIR LIFECYCLES

```
    Log.d(getClass().getSimpleName(), "onCreate()");
}

@Override
public void onRestart() {
    super.onRestart();

    Log.d(getClass().getSimpleName(), "onRestart()");
}

@Override
public void onStart() {
    super.onStart();

    Log.d(getClass().getSimpleName(), "onStart()");
}

@Override
public void onResume() {
    super.onResume();

    Log.d(getClass().getSimpleName(), "onResume()");
}

@Override
public void onPause() {
    Log.d(getClass().getSimpleName(), "onPause()");

    super.onPause();
}

@Override
public void onStop() {
    Log.d(getClass().getSimpleName(), "onStop()");

    super.onStop();
}

@Override
public void onDestroy() {
    Log.d(getClass().getSimpleName(), "onDestroy()");

    super.onDestroy();
}
}
```

All LifecycleLoggingActivity does is override each of the lifecycle methods mentioned above and emit a debug line to LogCat indicating who called what.

When we first launch the application, our first batch of lifecycle methods is invoked, in the expected order:

```
04-01 11:47:21.437: D/ExplicitIntentsDemoActivity(1473): onCreate()
```

ACTIVITIES AND THEIR LIFECYCLES

```
04-01 11:47:21.827: D/ExplicitIntentsDemoActivity(1473): onStart()  
04-01 11:47:21.827: D/ExplicitIntentsDemoActivity(1473): onResume()
```

If we click the button on the first activity to start up the second, we get:

```
04-01 11:47:54.776: D/ExplicitIntentsDemoActivity(1473): onPause()  
04-01 11:47:54.877: D/OtherActivity(1473): onCreate()  
04-01 11:47:54.947: D/OtherActivity(1473): onStart()  
04-01 11:47:54.974: D/OtherActivity(1473): onResume()  
04-01 11:47:55.347: D/ExplicitIntentsDemoActivity(1473): onStop()
```

Notice that our first activity is paused before the second activity starts up, and that `onStop()` is delayed on the first activity until after the second activity has appeared.

If we press the BACK button on the second activity, returning to the first activity, we see:

```
04-01 11:48:54.807: D/OtherActivity(1473): onPause()  
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onRestart()  
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onStart()  
04-01 11:48:54.857: D/ExplicitIntentsDemoActivity(1473): onResume()  
04-01 11:48:55.257: D/OtherActivity(1473): onStop()  
04-01 11:48:55.257: D/OtherActivity(1473): onDestroy()
```

Notice how, once again, going onto the screen happens in between `onPause()` and `onStop()` of the activity leaving the screen. Also notice that `onDestroy()` is called immediately after `onStop()`, because the activity was finished via the BACK button.

If we now press the HOME button, to bring the home screen activity to the foreground, we see:

```
04-01 11:50:30.347: D/ExplicitIntentsDemoActivity(1473): onPause()  
04-01 11:50:32.227: D/ExplicitIntentsDemoActivity(1473): onStop()
```

There is a delay between `onPause()` and `onStop()` as the home screen does its display work, and there is no `onDestroy()`, because the application is still running and nothing finished the activity. Eventually, the device will terminate our process, and if that happens normally, we would see the `onDestroy()` LogCat message.

Recycling Activities

Let us suppose that we have three activities, named A, B, and C. A starts up an instance of B based on some user input, and B later starts up an instance of C through some more user input.

Our “activity stack” is now A-B-C, meaning that if we press BACK from C, we return to B, and if we press BACK from B, we return to A.

Now, let’s suppose that from C, we wish to navigate back to A. For example, perhaps the user pressed the icon on the left of our action bar, and we want to return to the “home activity” as a result, and in our case that happens to be A. If C calls `startActivity()`, specifying A, we wind up with an activity stack that is A-B-C-A.

That’s because starting an activity, by default, creates a new instance of that activity. So, now we have two independent copies of A.

Sometimes, this is desired behavior. For example, we might have a single `ListActivity` that is being used to “drill down” through a hierarchical data set, like a directory tree. We might elect to keep starting instances of that same `ListActivity`, but with different extras, to show each level of that hierarchy. In this case, we would want independent instances of the activity, so the BACK button behaves as the user might expect.

However, when we navigate to the “home activity”, we may not want a separate instance of A.

How to address this depends a bit on what you want the activity stack to look like after navigating to A.

If you want an activity stack that is B-C-A — so the existing copy of A is brought to the foreground, but the instances of B and C are left alone — then you can add `FLAG_ACTIVITY_REORDER_TO_FRONT` to your Intent used with `startActivity()`:

```
Intent i=new Intent(this, HomeActivity.class);
i.setFlags(Intent.FLAG_ACTIVITY_REORDER_TO_FRONT);
startActivity(i);
```

If, instead, you want an activity stack that is just A — so if the user presses BACK, they exit your application — then you would add two flags: `FLAG_ACTIVITY_CLEAR_TOP` and `FLAG_ACTIVITY_SINGLE_TOP`:

```
Intent i=new Intent(this, HomeActivity.class);  
i.setFlags(Intent.FLAG_ACTIVITY_CLEAR_TOP | Intent.FLAG_ACTIVITY_SINGLE_TOP);  
startActivity(i);
```

This will finish all activities in the stack between the current activity and the one you are starting — in our case, finishing C and B.

Application: Transcending the Activity

Activity inherits from a class named Context. Many of the methods that we are calling on our activities, like `startActivity()`, are inherited from Context.

However, Activity is not the only relevant subclass of Context. We will see Service [later in the book](#), for example. And sometimes we will see plain Context objects, such as when we cover BroadcastReceiver [later in the book](#).

Another Context of note is Application. An instance of Application is created when our app starts up. The Application instance is a natural singleton; there should be exactly one instance of Application in our process.

Normally, this singleton is an instance of Application itself. However, we can subclass Application if we wish, then include a reference to our custom application class in an `android:name` attribute on the `<application>` element in the manifest. Then, when Android starts up our app, it will create an instance of our designated Application subclass, rather than creating an instance of the ordinary Application class.

We can retrieve the Application object at any point by calling `getApplicationContext()` on any Context object. `getApplicationContext()` will return a Context; if we need to reference Application or our specific Application subclass, we need to down-cast the returned Context to the appropriate type.

We can use Application in a few ways in Android apps.

First and foremost, if we need to hold onto some other object in a static data member, and that other object needs a Context, we *really* want it to be using the Application, not an Activity, Service, etc. Because Application is a singleton, it is effectively “pre-leaked”. We cannot somehow leak it further by having another indirect static reference to it. In contrast, suppose we have a static data member holding onto an Activity. Now, when that Activity is destroyed, it (and all it holds,

like widgets and listeners) cannot be garbage-collected. This represents a memory leak.

You could even take it one step further and have the `Application` manage this static data, rather than using separate singletons. There are pros and cons to this approach, but on the whole Google is not a big fan of it. That being said, `Application` has an `onCreate()` that is called shortly after it is instantiated, and your subclass of `Application` could override that and use it to initialize some “global” data.

However, while the JavaDocs indicate that there is an `onTerminate()` method on `Application` — suggesting that we find out when the `Application` is going away and our process is being terminated — that method is never called in practice.

The Case of the Invisible Activity

Sometimes, you want an activity that has no UI.

This is rather unusual. Mostly, it will be cases where something else in the system says that *it* needs *you* to have an activity, but where you do not really have anything that you want to display to the user in a traditional activity-style UI.

For example, home screen launcher icons only start up activities. However, you may have a need for a home screen launcher that simply triggers some work to be done in the background, perhaps using a service (as will be discussed [later in the book](#)).

You have two ways of setting up an invisible activity, both involving using a particular `android:theme` value on the `<activity>` element.

The most efficient option is to use `Theme.NoDisplay`. With this value, Android does nothing in terms of setting up a UI for you. However, the key limitation is that all the work the activity is going to do needs to be completed in `onCreate()`, and in there you need to call `finish()` to trigger the activity to be destroyed. Most of the time, this will work just fine.

Occasionally, you need an invisible activity that has to hang around for a few seconds, perhaps waiting on some callback result, before it can be destroyed. Using `Theme.NoDisplay` will still work... but only on older Android devices. On Android 6.0 and higher, using `Theme.NoDisplay` without calling `finish()` in `onCreate()` (or, technically, before `onResume()`) [will crash your app](#).

ACTIVITIES AND THEIR LIFECYCLES

The workaround is to use `Theme.Translucent.NoTitleBar`. This actually does allocate a UI for you, but sets it up to have a transparent background and no action bar. The user may still perceive that the activity is around — for example, it will show up the overview screen (a.k.a., recent-tasks list). Also, since the activity is “really there”, the user may not be able to interact with whatever the user can see, such as the underlying home screen. But, if the activity can `finish()` itself quickly, and is interacting with the user in the meantime (e.g., displaying some system dialog), you may be able to get away with this approach.

Tutorial #8 - Setting Up An Activity

Of course, it would be nice if those “Help” and “About” menu choices that we added [in the previous tutorial](#) actually did something.

In this tutorial, we will define another activity class, one that will be responsible for displaying simple content like our help text and “about” details. And, we will arrange to start up that activity when those action bar items are selected. The activity will not actually display anything meaningful yet, as that will be the subject of the next few tutorials.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book’s GitHub repository.

Step #1: Creating the Stub Activity Class and Manifest Entry

First, we need to define the Java class for our new activity, `SimpleContentActivity`.

Right-click on your `main/` `sourceset` directory in the project explorer, and choose `New > Activity > Empty Activity` from the context menu. This will bring up a new-activity wizard:

TUTORIAL #8 - SETTING UP AN ACTIVITY

Figure 206: Android Studio New Activity Wizard

Fill in `SimpleContentActivity` in the “Activity Name” field and uncheck the “Generate Layout File” checkbox. Leave “Launcher Activity” unchecked. If the package name drop-down is showing the app’s package name, leave it alone. On the other hand, if the package name drop-down is empty, click on it and choose the app’s package name. Then click on Finish.

In the `SimpleContentActivity` class that results, change the superclass to be `Activity` instead of `AppCompatActivity`.

At this point, your `SimpleContentActivity` class should look like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.os.Bundle;

public class SimpleContentActivity extends Activity {

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

Step #2: Launching Our Activity

Now that we have declared that the activity exists and can be used, we can start using it.

Go into `EmPubLiteActivity` and modify `onOptionsItemSelected()` to add in some logic in the `R.id.about` and `R.id.help` branches, as shown below:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.about:
            Intent i=new Intent(this, SimpleContentActivity.class);
            startActivity(i);

            return(true);

        case R.id.help:
            i=new Intent(this, SimpleContentActivity.class);
            startActivity(i);

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

In those two branches, we create an `Intent`, pointing at our new `SimpleContentActivity`. Then, we call `startActivity()` on that `Intent`. Right now, both `help` and `about` do the same thing — we will add some smarts to have them load up different content later in this book.

You will need to add an import for `android.content.Intent` to get this to compile.

If you run this app in a device or emulator, and you choose either the `Help` or `About` menu choices, what appears to happen is that the `ProgressBar` vanishes. In reality, what happens is that our `SimpleContentActivity` appeared, but empty, as we have not given it a full UI yet.

In Our Next Episode...

... we will [begin using fragments](#) in our tutorial project.

The Tactics of Fragments

Fragments are an optional layer you can put between your activities and your widgets, designed to help you reconfigure your activities to support screens both large (e.g., tablets) and small (e.g., phones).

This chapter will cover basic uses of fragments.

The Six Questions

In the world of journalism, the basics of any news story consist of six questions, [the Five Ws and One H](#). Here, we will apply those six questions to help frame what we are talking about with respect to fragments.

What?

Fragments are not activities, though they can be used by activities.

Fragments are not containers (i.e., subclasses of `ViewGroup`), though typically they create a `ViewGroup`.

Rather, you should think of fragments as being units of UI reuse. You define a fragment, much like you might define an activity, with layouts and lifecycle methods and so on. However, you can then host that fragment in one or several activities, as needed.

Android does not precisely implement UI architectures like Model-View-Controller (MVC), Model-View-Presenter (MVP), Model-View-ViewModel (MVVM), etc. To the extent that you wish to shove Android into the MVC architecture, fragments and activities combine to be the controller layer. Fragments serve as a local controller,

focused on their set of widgets, populating them from model data, and handling their events. Activities will serve as more of an orchestration layer, handling cross-fragment communications (e.g., a click in Fragment A needs to cause a change in what is displayed in Fragment B).

Functionally, fragments are Java classes, extending from a base Fragment class. As we will see, there are two versions of the Fragment class, one native to API Level 11 and one supplied by the Android Support package.

Where??

Since fragments are Java classes, your fragments will reside in one of your application's Java packages. The simplest approach is to put them in the same Java package that you used for your project overall and where your activities reside, though you can refactor your UI logic into other packages if needed.

Who?!?

Typically, you create fragment implementations yourself, then tell Android when to use them. Some third-party Android library projects may ship fragment implementations that you can reuse, if you so choose.

When?!?!?

Some developers start adding fragments from close to the outset of application development — that is the approach we will take in the tutorials. And, if you are starting a new application from scratch, defining fragments early on is probably a good idea. That being said, it is entirely possible to “retrofit” an existing Android application to use fragments, though this may be a lot of work. And, it is entirely possible to create Android applications without fragments at all.

Fragments were introduced with Android 3.0 (API Level 11, a.k.a., Honeycomb).

WHY?!?!?

Ah, this is the big question. If we have managed to make it this far through the book without fragments, and we do not necessarily need fragments to create Android applications, what is the point? Why would we bother?

THE TACTICS OF FRAGMENTS

The primary rationale for fragments was to make it easier to support multiple screen sizes.

Android started out supporting phones. Phones may vary in size, from tiny ones with less than 3" diagonal screen size (e.g., Sony Ericsson X10 mini), to monsters that are over 5" (e.g., Samsung Galaxy Note). However, those variations in screen size pale in comparison to the differences between phones and tablets, or phones and TVs.

Some applications will simply expand to fill larger screen sizes. Many games will take this approach, simply providing the user with bigger interactive elements, bigger game boards, etc. Any one of the ever-popular Angry Birds game series, when played on an tablet, gives you bigger birds and bigger pigs, not a phone-sized game area surrounded by ad banners.

However, another design approach is to consider a tablet screen to really be a collection of phone screens, side by side.

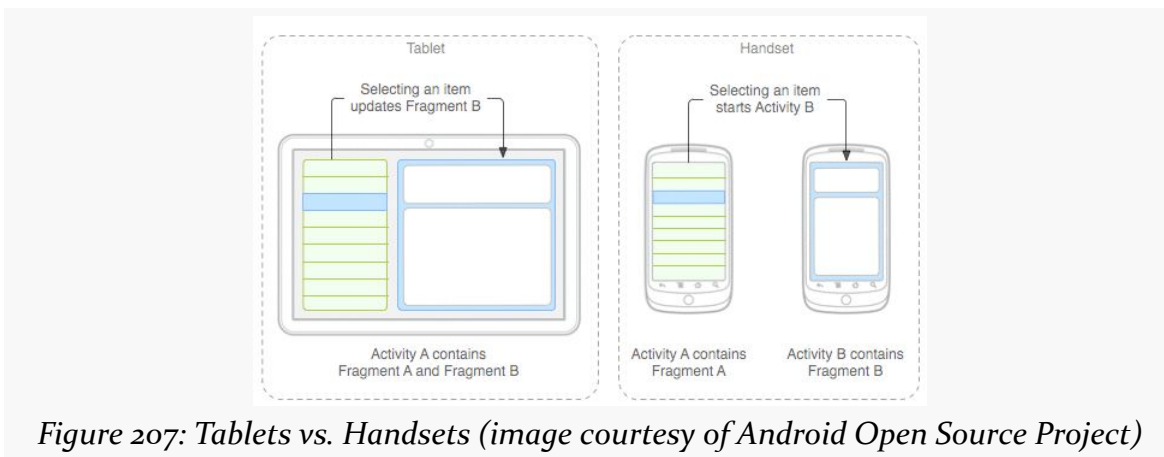

Figure 207: Tablets vs. Handsets (image courtesy of Android Open Source Project)

The user can access all of that functionality at once on a tablet, whereas they would have to flip back and forth between separate screens on a phone.

For applications that can fit this design pattern, fragments allow you to support phones and tablets from one code base. The fragments can be used by individual activities on a phone, or they can be stitched together by a single activity for a tablet.

Details on using fragments to support large screen sizes is a topic for [a later chapter in this book](#). This chapter is focused on the basic mechanics of setting up and using fragments.

OMGOMGOMG, HOW?!?!??

Well, answering that question is what the rest of this chapter is for, plus coverage of more advanced uses of fragments elsewhere in this book.

Where You Get Your Fragments From

Most developers will use the implementation of fragments that has been part of Android since API Level 11. You will use `android.app.Fragment` and have them be hosted by your regular activities.

However, there is a backport of the fragment system available in the Android Support package. This works back to API Level 4, so if your `minSdkVersion` is lower than 11 *and* you want to use fragments, the backport is something that you will wish to consider. You will need to add the `support-v4` JAR to your project (e.g., via `compile 'com.android.support:support-v4:...'` in your dependencies in `build.gradle`, for some value of `...`). You will also need to use `android.support.v4.app.Fragment` instead of `android.app.Fragment`. Also, you will need to host those fragments in an activity inheriting from `android.support.v4.app.FragmentActivity` (as the regular `android.app.Activity` base class does not know about fragments prior to API Level 11).

This book focuses mostly on using the native API Level 11 implementation of fragments, with the occasional example of using the backport where the backport is necessary for one reason or another.

Your First Fragment

In many ways, it is easier to explain fragments by looking at an implementation, more so than trying to discuss them as abstract concepts. So, in this section, we will take a look at the [Fragments/Static](#) sample project. This is a near-clone of the [Activities/Lifecycle](#) sample project from [the previous chapter](#). However, we have converted the launcher activity from one that will host widgets directly itself to one that will host a fragment, which in turn manages widgets.

The Fragment Layout

Our fragment is going to manage our UI, so we have a `res/layout/mainfrag.xml` layout file containing our Button:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/showOther"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/hello"
    android:textSize="20sp"/>
```

Note, though, that we do not use the `android:onClick` attribute. We will explain why we dropped that attribute from the previous editions of this sample shortly.

The Fragment Class

The project has a `ContentFragment` class that will use this layout and handle the `Button`.

As with activities, there is no constructor on a typical `Fragment` subclass. The primary method you override, though, is not `onCreate()` (though, as we will see later in this chapter, that is possible). Instead, the primary method to override is `onCreateView()`, which is responsible for returning the UI to be displayed for this fragment:

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.mainfrag, container, false);

    result.findViewById(R.id.showOther).setOnClickListener(this);

    return(result);
}
```

We are passed a `LayoutInflater` that we can use for inflating a layout file, the `ViewGroup` that will eventually hold anything we inflate, and the `Bundle` that was passed to the activity's `onCreate()` method. While we are used to framework classes loading our layout resources for us, we can “inflate” a layout resource at any time using a `LayoutInflater`. This process reads in the XML, parses it, walks the element tree, creates Java objects for each of the elements, and stitches the results together into a parent-child relationship.

Here, we inflate `res/layout/mainfrag.xml`, telling Android that its contents will eventually go into the `ViewGroup` but not to add it right away. While there are simpler flavors of the `inflate()` method on `LayoutInflater`, this one is required in case the `ViewGroup` happens to be a `RelativeLayout`, so we can process all of the positioning and sizing rules appropriately.

THE TACTICS OF FRAGMENTS

We also use `findViewById()` to find our `Button` widget and tell it that we, the fragment, are its `OnClickListener`. `ContentFragment` must then implement the `View.OnClickListener` interface to make this work. We do this instead of `android:onClick` to route the `Button` click events to the fragment, not the activity.

Since we implement the `View.OnClickListener` interface, we need the corresponding `onClick()` method implementation:

```
@Override
public void onClick(View v) {
    ((StaticFragmentsDemoActivity) getActivity()).showOther(v);
}
```

Any fragment can call `getActivity()` to find the activity that hosts it. In our case, the only activity that will possibly host this fragment is `StaticFragmentsDemoActivity`, so we can cast the result of `getActivity()` to `StaticFragmentsDemoActivity`, so that we can call methods on our activity. In particular, we are telling the activity to show the other activity, by means of calling the `showOther()` method that we saw in the original `Activities/Lifecycle` sample (and will see again shortly).

That is really all that is needed for this fragment. However, `ContentFragment` also overrides many other fragment lifecycle methods, and we will examine these [later in this chapter](#).

The Activity Layout

Originally, the `res/layout/main.xml` used by the activity was where we had our `Button` widget. Now, the `Button` is handled by the fragment. Instead, our activity layout needs to account for the fragment itself.

In this sample, we are going to use a static fragment. Static fragments are easy to add to your application: just use the `<fragment>` element in a layout file, such as our revised `res/layout/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.sfrag.ContentFragment"/>
```

Here, we are declaring our UI to be completely comprised of one fragment, whose implementation (`com.commonware.android.sfrag.ContentFragment`) is identified by the `android:name` attribute on the `<fragment>` element. Instead of `android:name`,

you can use `class`, though most of the Android documentation has now switched over to `android:name`.

Android Studio users can drag a fragment out of the “Custom” section of the graphical layout editor tool palette, if desired, rather than setting up the `<fragment>` element directly in the XML. Eclipse users have a similar option in the “Layouts” section of the tool palette.

The Activity Class

`StaticFragmentsDemoActivity` — our new launcher activity — looks identical to the previous version, with the exception of the class name:

```
package com.commonware.android.sfrag;

import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class StaticFragmentsDemoActivity extends
    LifecycleLoggingActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void showOther(View v) {
        Intent other=new Intent(this, OtherActivity.class);

        other.putExtra(OtherActivity.EXTRA_MESSAGE,
            getString(R.string.other));
        startActivity(other);
    }
}
```

Since the `res/layout/main.xml` file has the `<fragment>` element, the fragment is simply loaded into position in the call to `setContentView()`.

The Fragment Lifecycle Methods

Fragments have lifecycle methods, just like activities do. In fact, they support most of the same lifecycle methods as activities:

- `onCreate()`
- `onStart()` (but not `onRestart()`)
- `onResume()`

- onPause()
- onStop()
- onDestroy()

By and large, the same rules apply for fragments as do for activities with respect to these lifecycle methods (e.g., `onDestroy()` may not be called).

In addition to those and the `onCreateView()` method we examined earlier in this chapter, there are four other lifecycle methods that you can elect to override if you so choose.

`onAttach()` will be called first, even before `onCreate()`, letting you know that your fragment has been attached to an activity. You are passed the Activity that will host your fragment.

`onViewCreated()` will be called after `onCreateView()`. This is particularly useful if you are inheriting the `onCreateView()` implementation but need to configure the resulting views, such as with a `ListFragment` and needing to set up an adapter.

`onActivityCreated()` will be called after `onCreate()` and `onCreateView()`, to indicate that the activity's `onCreate()` has completed. If there is something that you need to initialize in your fragment that depends upon the activity's `onCreate()` having completed its work, you can use `onActivityCreated()` for that initialization work.

`onDestroyView()` is called before `onDestroy()`. This is the counterpart to `onCreateView()` where you set up your UI. If there are things that you need to clean up specific to your UI, you might put that logic in `onDestroyView()`.

`onDetach()` is called after `onDestroy()`, to let you know that your fragment has been disassociated from its hosting activity.

Your First Dynamic Fragment

Static fragments are fairly simple, once you have the Fragment implementation: just add the `<fragment>` element to where you want to have the fragment appear in your activity's layout.

That simplicity, though, does come with some costs. We will review some of those limitations [in the next chapter](#).

THE TACTICS OF FRAGMENTS

Those limitations can be overcome by the use of dynamic fragments. Rather than indicating to Android that you wish to use a fragment by means of a `<fragment>` element in a layout, you will use a `FragmentManager` to add a fragment at runtime from your Java code.

With that in mind, take a look at the [Fragments/Dynamic](#) sample project.

This is the same project as the one for static fragments, except this time we will adjust `OtherActivity` to use a dynamic fragment, specifically a `ListFragment`.

The ListFragment Class

`ListFragment` serves the same role for fragments as `ListActivity` does for activities. It wraps up a `ListView` for convenient use. So, to have a more interesting `OtherActivity`, we start with an `OtherFragment` that is a `ListFragment`, designed to show our favorite 25 Latin words as seen in previous examples.

Just as a `ListActivity` does not need to call `setContentView()`, a `ListFragment` does not need to override `onCreateView()`. By default, the entire fragment will be comprised of a single `ListView`. And just as `ListActivity` has a `setListAdapter()` method to associate an `Adapter` with the `ListView`, so too does `ListFragment`:

```
package com.commonware.android.dfrag;

import android.app.Activity;
import android.app.ListFragment;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.AdapterView;

public class OtherFragment extends ListFragment {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetur", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };

    @Override
    public void onViewCreated(View view, Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);

        setListAdapter(new ArrayAdapter<String>(getActivity(),
            android.R.layout.simple_list_item_1, items));
    }
}
```

We call `setListAdapter()` in `onViewCreated()`, as we know that the `ListView` is now ready for use.

This class also overrides many fragment lifecycle methods, logging their results, akin to our other `Fragment` and `LifecycleLoggingActivity`.

The Activity Class

Now, `OtherActivity` no longer needs to load a layout — we have removed `res/layout/other.xml` from the project entirely. Instead, we will use a `FragmentManager` to add our fragment to the UI:

```
package com.commonware.android.dfrag;

import android.os.Bundle;

public class OtherActivity extends LifecycleLoggingActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new OtherFragment()).commit();
        }
    }
}
```

To work with a `FragmentManager`, you need the `FragmentManager`. This object knows about all of the fragments that exist in your activity. If you are using the native API Level 11 edition of fragments, you can get your `FragmentManager` by calling `getFragmentManager()`. If you are using the Android Support package, you need to call `getSupportFragmentManager()` instead.

Given a `FragmentManager`, you can start a `FragmentManager` by calling `beginTransaction()`, which returns the `FragmentManager` object. `FragmentManager` operates on the builder pattern, so most methods on `FragmentManager` return the `FragmentManager` itself, so you can chain a series of method calls one after the next.

We call two methods on our `FragmentManager`: `add()` and `commit()`. The `add()` method, as you might guess, indicates that we want to add a fragment to the UI. We supply the actual fragment object, in this case by creating a new `OtherFragment`. We also need to indicate where in our layout we want this fragment to reside. Had we loaded a layout, we could drop this fragment in any desired container. In our case, since we did not load a layout, we supply `android.R.id.content` as the ID of the container to hold our fragment's `View`. Here, `android.R.id.content` identifies the

container into which the results of `setContentView()` would go — it is a container supplied by Activity itself and serves as the top-most container for our content.

Just calling `add()` is insufficient. We then need to call `commit()` to make the transaction actually happen.

You might be wondering why we are trying to find a fragment in our `FragmentManager` before actually creating the fragment. We do that to help deal with configuration changes, and we will be exploring that further [in the next chapter](#).

Fragments and the Action Bar

Fragments can add items to the action bar by calling `setHasOptionsMenu(true)` from `onCreate()` (or any other early lifecycle method). This indicates to the activity that it needs to call `onCreateOptionsMenu()` and `onOptionsItemSelected()` on the fragment.

The [Fragments/ActionBarNative](#) sample application demonstrates this. This has the same functionality as does the `ActionBar/ActionBarDemoNative` sample from [the chapter on the action bar](#), just with the activity converted into a dynamic fragment.

In `onCreate()`, we call `setHasOptionsMenu(true)`, to indicate that we are interested in participating in the action bar:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    setHasOptionsMenu(true);
}
```

(we will discuss that `setRetainInstance(true)` call [in a later chapter](#))

That will trigger our fragment's `onCreateOptionsMenu()` and `onOptionsItemSelected()` methods to be called at the appropriate time:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
```

```
switch(item.getItemId()) {
    case R.id.add:
        addWord();

        return(true);

    case R.id.reset:
        initAdapter();

        return(true);
}

return(super.onOptionsItemSelected(item));
}
```

Here, we initialize our action bar from the `R.menu.actions` menu XML resource, including setting up our `EditText` widget, plus the logic to respond to the reset action overflow item.

Our activity does not need to do anything special to allow the fragment to contribute to the action bar — it just sets up the dynamic fragment:

```
package com.commonware.android.abf;

import android.app.Activity;
import android.os.Bundle;

public class ActionBarFragmentActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new ActionBarFragment()).commit();
        }
    }
}
```

Fragments Within Fragments: Just Say “Maybe”

Historically, one major limitation with fragments is that they could not contain other fragments. In most cases, this does not pose a major problem. However, there will be times when you might trip over this limitation, such as when using a `ViewPager`, as will be described in [a later chapter](#).

Android 4.2 — and the Android Support package — added support for nested fragments. Whereas an activity works with fragments via a `FragmentManager`

obtained via `getFragmentManager()` or `getSupportFragmentManager()`, fragments can work with nested fragments via a call to `getChildFragmentManager()`.

However, Android 3.0 through 4.1 have a version of fragments that does not have `getChildFragmentManager()`. Hence, you have two options:

1. Use the Android Support package's backport of fragments, until such time as you can drop support for Android 4.1 and earlier, or
2. Do not use nested fragments for the time being.

We will see how `getChildFragmentManager()` works in [the chapter on ViewPager](#).

Fragments and Multiple Activities

A fragment should handle functionality purely within the fragment itself. Anything outside the fragment should be the responsibility of the calling activity. For example, if the user taps on an item in a `ListFragment`, and the effects of that event might go beyond what is inside the `ListFragment` itself, the `ListFragment` should forward the event to the hosting activity, so it can perhaps perform additional steps (e.g., launch an activity, update another fragment hosted by the activity).

As we will see [in a later chapter](#), it is entirely possible — perhaps even likely — that some of our fragments will be hosted by multiple different activities. For example, we might have a fragment that is hosted in one case by an activity designed for larger screens (e.g., tablets) and in another case by an activity designed for smaller screens (e.g., phones).

In these cases, the fragment does not know at compile time which activity class will be hosting it at runtime. For those cases, you have three major options:

1. Have the activities implement a common interface, and have the fragment cast the result of calling `getActivity()` to that interface, so it can call methods on the hosting activity without knowing its exact implementation.
2. Have the activities supply a listener object, with a common interface, to the fragment via a setter, and have the fragment use that listener for raising events and so on.
3. Use an event bus, as we will explore [later in this book](#).

We will see much more on this subject when we get into large-screen strategies [in a later chapter](#).

Tutorial #9 - Starting Our Fragments

Much of the content of a digital book to be viewed in EmPubLite will be in the form of HTML and related assets (CSS, images, etc.). Hence, we will eventually need to render our content in a WebView widget, for best results with semi-arbitrary HTML content.

To do this, we will set up fragments for the bits of content:

- each chapter (or, in our case, HTML file containing chapters)
- other material, like our “help” and “about” pages

Right now, we will focus on just setting up some of the basic classes for these fragments — we will load them up with content and display them over the next few tutorials.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book’s GitHub repository:

Step #1: Create a SimpleContentFragment

Android has a `WebViewFragment` for the native API Level 11+ implementation of fragments, designed to show some Web content in a `WebView`. In this step, we will create a subclass of `WebViewFragment` that adds in a bit of EmPubLite-specific business logic.

TUTORIAL #9 - STARTING OUR FRAGMENTS

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Fragment > "Fragment (Blank)"` from the context menu. That will bring up a new-fragment dialog:

Fill in `SimpleContentFragment` for the “Fragment Name” and uncheck all three checkboxes. Then, click `Finish` to create the fragment class.

Then, replace the contents of the fragment class with the following code:

```
package com.commonware.empublite;

import android.annotation.SuppressLint;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebViewFragment;

public class SimpleContentFragment extends WebViewFragment {
    private static final String KEY_FILE="file";

    static SimpleContentFragment newInstance(String file) {
        SimpleContentFragment f=new SimpleContentFragment();

        Bundle args=new Bundle();
```

TUTORIAL #9 - STARTING OUR FRAGMENTS

```
args.putString(KEY_FILE, file);
f.setArguments(args);

return(f);
}

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);
}

@SuppressWarnings("SetJavaScriptEnabled")
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {

    View result=
        super.onCreateView(inflater, container, savedInstanceState);

    getWebView().getSettings().setJavaScriptEnabled(true);
    getWebView().getSettings().setSupportZoom(true);
    getWebView().getSettings().setBuiltInZoomControls(true);
    getWebView().loadUrl(getPage());

    return(result);
}

private String getPage() {
    return(getArguments().getString(KEY_FILE));
}
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

You can also delete the `hello_blank_fragment` string from `res/values/strings.xml`.

Step #2: Examining SimpleContentFragment

`SimpleContentFragment` is simple, with a total of four methods:

- `onCreate()`, where we call `setRetainInstance(true)` — the utility of this will be examined in greater detail [in an upcoming chapter](#).
- `onCreateView()`, where we chain to the superclass (to have it create the `WebView`), then configure it to accept JavaScript and support zoom operations. We then have it load some content, retrieved in the form of a URL from a private `getPage()` method. Finally, we return what the

TUTORIAL #9 - STARTING OUR FRAGMENTS

- superclass returned from `onCreateView()` — effectively, we are simply splicing in our own configuration logic.
- a `newInstance()` static factory method. This method creates an instance of `SimpleContentFragment`, takes a passed-in `String` (pointing to the file to load), puts it in a `Bundle` identified as `KEY_FILE`, hands the `Bundle` to the fragment as its arguments, and returns the newly-created `SimpleContentFragment`.
 - `getPage()`, where it returns a value out of the “arguments” `Bundle` supplied to the fragment — specifically the string identified as `KEY_FILE`.

This means that anyone wanting to use `SimpleContentFragment` should use the factory method, to provide the path to the content to load. We will see why we implemented `SimpleContentFragment` this way in [the next chapter](#).

In Our Next Episode...

... we will [set up horizontal swiping](#) of book chapters in our tutorial project.

Swiping with ViewPager

Android, over the years, has put increasing emphasis on UI design and having a fluid and consistent user experience (UX). While some mobile operating systems take “the stick” approach to UX (forcing you to abide by certain patterns or be forbidden to distribute your app), Android takes “the carrot” approach, offering widgets and containers that embody particular patterns that they espouse. The action bar, for example, grew out of this and is now the backbone of many Android activities.

Another example is the ViewPager, which allows the user to swipe horizontally to move between different portions of your content. However, ViewPager is not distributed as part of the firmware, but rather via the Android Support package. Hence, even though ViewPager is a relatively new widget, you can use it on Android 1.6 and up.

This chapter will focus on where you should apply a ViewPager and how to set one up.

Swiping Design Patterns

In 2012, Google released [Android design guidelines](#) as an adjunct to the existing developer documentation. This site outlines many aspects of UI and UX design for Android, from recommended sizing to maintaining platform fidelity instead of mimicking another mobile operating system.

They have [a page dedicated to “swipe views”](#), where they outline the scenario for using horizontal swiping: moving from peer to peer in sequence in a collection of content:

- Email messages in a folder or label

- Chapters in an ebook
- Tabs in a collection of tabs

The primary way to implement this pattern in Android is the `ViewPager`.

Pieces of a Pager

`AdapterView` classes, like `ListView`, work with `Adapter` objects, like `ArrayAdapter`. `ViewPager`, however, is not an `AdapterView`, despite adopting many of the patterns from `AdapterView`. `ViewPager`, therefore, does not work with an `Adapter`, but instead with a `PagerAdapter`, which has a slightly different API.

Android ships two `PagerAdapter` implementations in the Android Support package: `FragmentPagerAdapter` and `FragmentStatePagerAdapter`. The former is good for small numbers of fragments, where holding them all in memory at once will work. `FragmentStatePagerAdapter` is for cases where holding all possible fragments to be viewed in the `ViewPager` would be too much, where Android will discard fragments as needed and hold onto the (presumably smaller) states of those fragments instead.

Paging Fragments

The simplest way to use a `ViewPager` is to have it page fragments in and out of the screen based on user swipes.

To see this in action, this section will examine the [ViewPager/Fragments](#) sample project.

The project has a dependency on the Android Support package, in order to be able to use `ViewPager`. In Android Studio, this is a `compile` statement in the dependencies closure of `build.gradle`:

```
dependencies {  
    compile 'com.android.support:support-v13:21.0.3'  
}
```

In Eclipse, this is a bare JAR in the project's `libs/` directory.

The Activity Layout

The layout used by the activity just contains the ViewPager. Note that since ViewPager is not in the `android.widget` package, we need to fully-qualify the class name in the element:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/
android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
</android.support.v4.view.ViewPager>
```

Note that ViewPager is not available for drag-and-drop in the IDE graphical designers, probably because it comes from the Android Support package and therefore is not available to all projects.

The Activity

As you see, the ViewPagerFragmentDemoActivity itself is blissfully small:

```
package com.commonware.android.pager;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.ViewPager;

public class ViewPagerFragmentDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        pager.setAdapter(new SampleAdapter(getFragmentManager()));
    }
}
```

All we do is load the layout, retrieve the ViewPager via `findViewById()`, and provide a `SampleAdapter` to the ViewPager via `setAdapter()`.

The PagerAdapter

Our `SampleAdapter` inherits from `FragmentPagerAdapter` and implements two required callback methods:

SWIPING WITH VIEWPAGER

- `getCount()`, to indicate how many pages will be in the `ViewPager`, and
- `getItem()`, which returns a `Fragment` for a particular position within the `ViewPager` (akin to `getView()` in a classic `Adapter`)

```
package com.commonware.android.pager;

import android.app.Fragment;
import android.app.FragmentManager;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    public SampleAdapter(FragmentManager mgr) {
        super(mgr);
    }

    @Override
    public int getCount() {
        return(10);
    }

    @Override
    public Fragment getItem(int position) {
        return(EditorFragment.newInstance(position));
    }
}
```

Here, we say that there will be 10 pages total, each of which will be an instance of an `EditorFragment`. In this case, rather than use the constructor for `EditorFragment`, we are using a `newInstance()` factory method. The rationale for that will be explained in the next section.

The Fragment

`EditorFragment` will host a full-screen `EditText` widget, for the user to enter in a chunk of prose, as is defined in the `res/layout/editor.xml` resource:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/editor"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:inputType="textMultiline"
    android:gravity="left|top"
/>
```

We want to pass the position number of the fragment within the `ViewPager`, simply to customize the hint displayed in the `EditText` before the user types in anything. With normal Java objects, you might pass this in via the constructor, but it is not a good idea to implement a constructor on a `Fragment`. Instead, the recipe is to create a static factory method (typically named `newInstance()`) that will create the

Fragment and provide the parameters to it by updating the fragment’s “arguments” (a Bundle):

```
static EditorFragment newInstance(int position) {
    EditorFragment frag=new EditorFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);

    return(frag);
}
```

You might be wondering why we are bothering with this Bundle, instead of just using a regular data member. The arguments Bundle is part of our “saved instance state”, for dealing with things like screen rotations — a concept we will get into [later in the book](#). For the moment, take it on faith that this is a good idea.

In onCreateView() we inflate our R.layout.editor resource, get the EditText from it, get our position from our arguments, format a hint containing the position (using a string resource), and setting the hint on the EditText:

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);
    int position=getArguments().getInt(KEY_POSITION, -1);

    editor.setHint(String.format(getString(R.string.hint), position + 1));

    return(result);
}
```

The Result

When initially launched, the application shows the first fragment:

SWIPING WITH VIEWPAGER

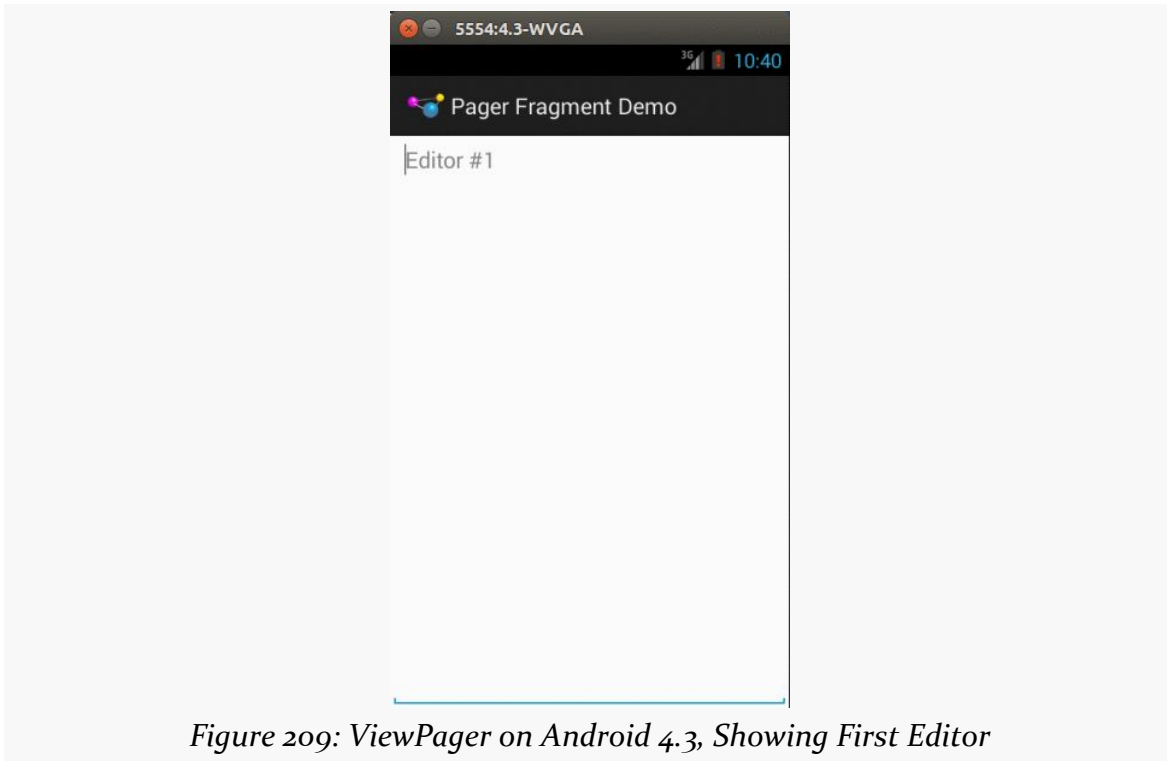

Figure 209: ViewPager on Android 4.3, Showing First Editor

However, you can horizontally swipe to get to the next fragment:

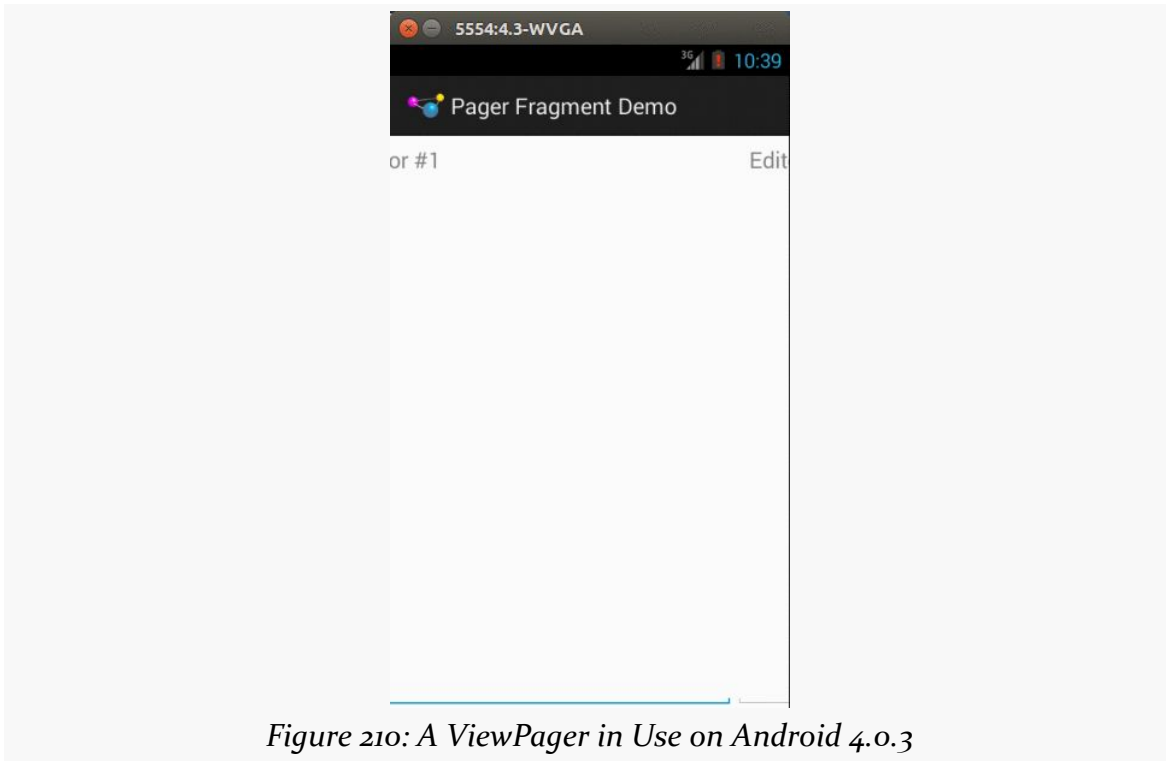

Figure 210: A ViewPager in Use on Android 4.0.3

Swiping works in both directions, so long as there is another page in your desired direction.

Paging Other Stuff

You do not have to use fragments inside a ViewPager. A regular PagerAdapter actually hands View objects to the ViewPager. The supplied fragment-based PagerAdapter implementations get the View from a fragment and use that, but you are welcome to create your own PagerAdapter that eschews fragments.

Hence, if you want ViewPager to page things other than fragments, the solution is to not use FragmentPagerAdapter or FragmentStatePagerAdapter, but instead create your own implementation of the PagerAdapter interface, one that avoids the use of fragments.

We will see an example of this [in a later chapter](#), where we also examine [how to have more than one page of the ViewPager be visible at a time](#).

Indicators

By itself, there is no visual indicator of where the user is within the set of pages contained in the `ViewPager`. In many instances, this will be perfectly fine, as the pages themselves will contain cues as to position. However, even in those cases, it may not be completely obvious to the user how many pages there are, which directions for swiping are active, etc.

Hence, you may wish to attach some other widget to the `ViewPager` that can help clue the user into where they are within “page space”.

PagerTitleStrip and PagerTabStrip

The primary built-in indicator options available to use are `PagerTitleStrip` and `PagerTabStrip`. As the name suggests, `PagerTitleStrip` is a strip that shows titles of your pages. `PagerTabStrip` is much the same, but the titles are formatted somewhat like tabs, and they are clickable (switching you to the clicked-upon page), whereas `PagerTitleStrip` is non-interactive.

To use either of these, you first must add it to your layout, inside your `ViewPager`, as shown in the `res/layout/main.xml` resource of the [ViewPager/Indicator](#) sample project, a clone of the `ViewPager/Fragments` project that adds a `PagerTabStrip` to our UI:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.view.ViewPager xmlns:android="http://schemas.android.com/apk/res/
android"
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <android.support.v4.view.PagerTabStrip
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="top"/>

</android.support.v4.view.ViewPager>
```

Here, we set the `android:layout_gravity` of the `PagerTabStrip` to `top`, so it appears above the pages. You could similarly set it to `bottom` to have it appear below the pages.

Our `SampleAdapter` needs another method: `getPageTitle()`, which will return the title to display in the `PagerTabStrip` for a given position:

SWIPING WITH VIEWPAGER

```
package com.commonware.android.pager2;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(10);
    }

    @Override
    public Fragment getItem(int position) {
        return(EditorFragment.newInstance(position));
    }

    @Override
    public String getPageTitle(int position) {
        return(EditorFragment.getTitle(ctxt, position));
    }
}
```

Here, we call a static `getTitle()` method on `EditorFragment`. That is a refactored bit of code from our former `onCreateView()` method, where we create the string for the hint — we will use the hint text as our page title:

```
package com.commonware.android.pager2;

import android.app.Fragment;
import android.content.Context;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class EditorFragment extends Fragment {
    private static final String KEY_POSITION="position";

    static EditorFragment newInstance(int position) {
        EditorFragment frag=new EditorFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_POSITION, position);
        frag.setArguments(args);

        return(frag);
    }
}
```

SWIPING WITH VIEWPAGER

```
static String getTitle(Context ctxt, int position) {
    return(String.format(ctxt.getString(R.string.hint), position + 1));
}

@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);
    EditText editor=(EditText)result.findViewById(R.id.editor);
    int position=getArguments().getInt(KEY_POSITION, -1);

    editor.setHint(getTitle(getActivity(), position));

    return(result);
}
}
```

Figure 211: ViewPager and PagerTabStrip on Android 4.3, Showing Second Page

Third-Party Indicators

If you want something else for your indicators, besides a strip of page titles, you might wish to check out the [ViewPagerIndicator library](#). This library contains a series of widgets that serve in the same role as PagerTitleStrip, with different looks. We will look at one such indicator, TabPageIndicator, [later in this book](#).

Visit the Trails!

There is [a chapter on advanced ViewPager techniques](#) that may interest you!

Tutorial #10 - Rigging Up a ViewPager

A ViewPager is a fairly slick way to present a digital book. You can have individual portions of the book be accessed by horizontal swiping, with the prose within a portion accessed by scrolling vertically. While not offering “page-at-a-time” models used by some book reader software, it is **much** simpler to set up.

So, that’s the approach we will use with EmPubLite. Which means, among other things, that we need to add a ViewPager to the app.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book’s GitHub repository.

Step #1: Add a ViewPager to the Layout

Right now, the layout for EmPubLiteActivity just has a ProgressBar. We need to augment that to have our ViewPager as well, set up such that we can show either the ProgressBar (while we load the book) or the ViewPager as needed.

Since ViewPager is not available for drag-and-drop through the IDE graphical layout editors, even IDE users are going to have to dive into the layout XML this time.

Open up `res/layout/main.xml` and switch to the Text sub-tab to see the raw XML. As a child of the `<RelativeLayout>`, after the `<ProgressBar>`, add a `<android.support.v4.view.ViewPager>` element as follows:

```
<android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
```

TUTORIAL #10 - RIGGING UP A VIEWPAGER

```
android:layout_height="match_parent"  
android:visibility="gone"/>
```

This adds the ViewPager, also having it fill the parent, but with the visibility initially set to gone, meaning that the user will not see it.

The entire layout should now resemble:

```
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    xmlns:tools="http://schemas.android.com/tools"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    tools:context=".EmPubLiteActivity">  
  
    <ProgressBar  
        style="?android:attr/progressBarStyleLarge"  
        android:layout_width="wrap_content"  
        android:layout_height="wrap_content"  
        android:id="@+id/progressBar1"  
        android:layout_centerVertical="true"  
        android:layout_centerHorizontal="true" />  
  
    <android.support.v4.view.ViewPager  
        android:id="@+id/pager"  
        android:layout_width="match_parent"  
        android:layout_height="match_parent"  
        android:visibility="gone" />  
</RelativeLayout>
```

Step #2: Obtaining Our ViewPager

We will be referencing the ViewPager from a few places in the activity, so we may as well get a reference to it and hold onto it in a data member, for easy access.

Add a field to EmPubLiteActivity:

```
private ViewPager pager=null;
```

You will also need to add an import for `android.support.v4.view.ViewPager` to get this to compile.

Then, in `onCreate()`, after the call to `setContentView(R.layout.main)`, use `findViewById()` to retrieve the ViewPager and store it in the pager data member:

```
pager=(ViewPager)findViewById(R.id.pager);
```

Step #3: Creating a ContentsAdapter

A ViewPager needs a PagerAdapter to populate its content, much like a ListView needs a ListAdapter. We cannot completely construct a PagerAdapter yet, as we still need to learn how to load up our book content from files. But, we can get part-way towards having a useful PagerAdapter now.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `ContentsAdapter` as the name and click OK to create the empty class.

Then, replace the generated `ContentsAdapter.java` file with the following content:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.support.v13.app.FragmentStatePagerAdapter;

public class ContentsAdapter extends FragmentStatePagerAdapter {
    public ContentsAdapter(Activity ctxt) {
        super(ctxt.getFragmentManager());
    }

    @Override
    public Fragment getItem(int arg0) {
        // TODO Auto-generated method stub
        return null;
    }

    @Override
    public int getCount() {
        // TODO Auto-generated method stub
        return 0;
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Step #4: Setting Up the ViewPager

Let's add a few more lines to the bottom of `onCreate()` of `EmPubLiteActivity`, to set up `ContentsAdapter` and attach it to the `ViewPager`:

```
adapter=new ContentsAdapter(this);
pager.setAdapter(adapter);
```

TUTORIAL #10 - RIGGING UP A VIEWPAGER

```
findViewById(R.id.progressBar1).setVisibility(View.GONE);
pager.setVisibility(View.VISIBLE);
```

This will require a new field:

```
private ContentsAdapter adapter=null;
```

It will also require an import for `android.view.View`.

What we are doing is creating our `ContentsAdapter` instance, associating it with the `ViewPager`, and toggling the visibility of the `ProgressBar` (making it `GONE`) and the `ViewPager` (making it `VISIBLE`).

At this point, your `EmPubLiteActivity` should look something like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.view.ViewPager;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;

public class EmPubLiteActivity extends Activity {
    private ViewPager pager=null;
    private ContentsAdapter adapter=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
        pager=(ViewPager)findViewById(R.id.pager);

        adapter=new ContentsAdapter(this);
        pager.setAdapter(adapter);
        findViewById(R.id.progressBar1).setVisibility(View.GONE);
        pager.setVisibility(View.VISIBLE);
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.options, menu);
        return (super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        switch (item.getItemId()) {
            case R.id.about:
                Intent i = new Intent(this, SimpleContentActivity.class);
                startActivity(i);

                return (true);
        }
    }
}
```

TUTORIAL #10 - RIGGING UP A VIEWPAGER

```
case R.id.help:
    i = new Intent(this, SimpleContentActivity.class);
    startActivity(i);

    return (true);
}
return (super.onOptionsItemSelected(item));
}
```

The net effect, if you run this modified version of the app, is that we no longer see the `ProgressBar`. Instead, we have a big blank area, taken up by our empty `ViewPager`:

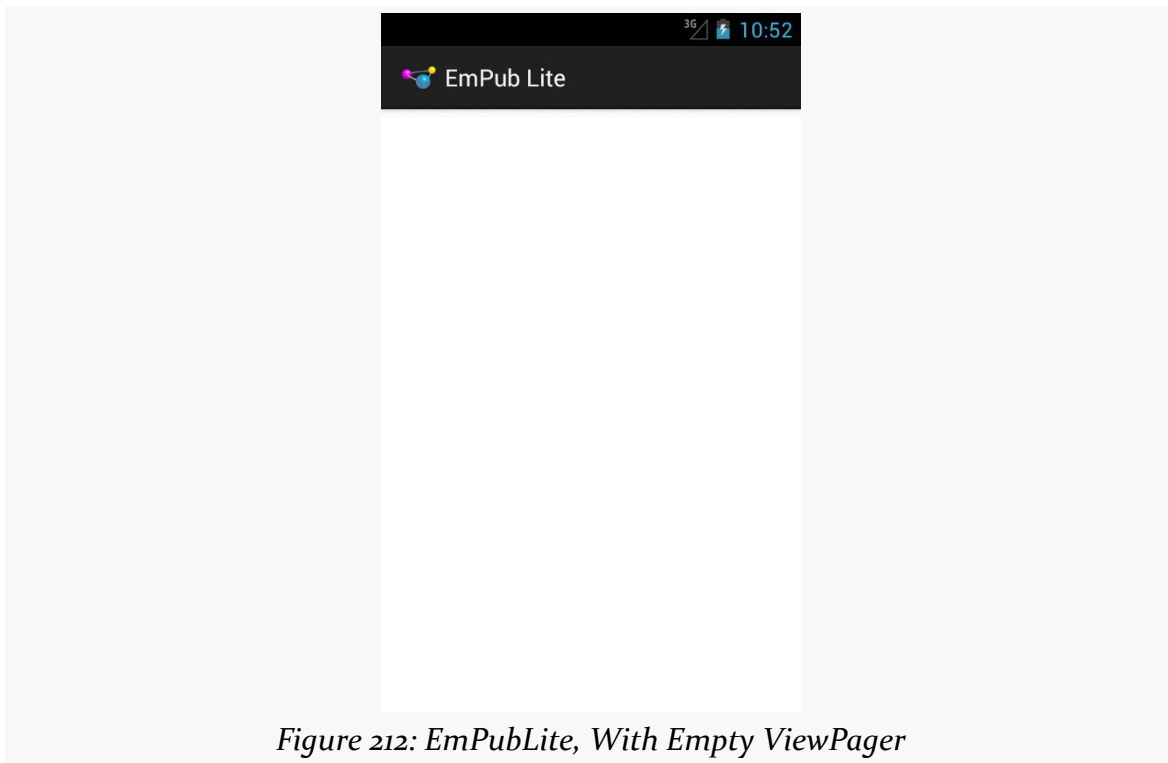

Figure 212: EmPubLite, With Empty ViewPager

The `ViewPager` is empty simply because our `ContentsAdapter` returned 0 from `getCount()`, indicating that there are no pages to be displayed. The `ProgressBar` is no longer visible because we are immediately swapping in the `ViewPager`, but in the future, if it takes some time to get the `ViewPager` set up (e.g., disk I/O), we will see the `ProgressBar` briefly.

In Our Next Episode...

... we will [finish our “help” and “about” screens](#) in our tutorial project.

Resource Sets and Configurations

Devices sometimes change while users are using them, in ways that our application will care about:

- The user might rotate the screen from portrait to landscape, or vice versa
- The user might put the device in a car or desk dock, or remove it from such a dock
- The user might put the device in a “netbook dock” that adds a full QWERTY keyboard, or remove it from such a dock
- The user might switch to a different language via the Settings application, returning to our running application afterwards
- And so on

In all of these cases, it is likely that we will want to change what resources we use. For example, our layout for a portrait screen may be too tall to use in landscape mode, so we would want to substitute in some other layout.

This chapter will explore how to provide alternative resources for these different scenarios — called “configuration changes” — and will explain what happens to our activities when the user changes the configuration while we are in the foreground.

What’s a Configuration? And How Do They Change?

Different pieces of Android hardware can have different capabilities, such as:

- Different screen sizes
- Different screen densities (dots per inch)

- Different number and capabilities of cameras
- Different mix of radios (GSM? CDMA? GPS? Bluetooth? WiFi? NFC? something else?)
- And so on

Some of these, in the eyes of the core Android team, might drive the selection of resources, like layouts or drawables. Different screen sizes might drive the choice of layout. Different screen densities might drive the choice of drawable (using a higher-resolution image on a higher-density device). These are considered part of the device’s “configuration”.

Other differences — ones that do not drive the selection of resources — are not part of the device’s configuration but merely are “features” that some devices have and other devices do not. For example, cameras and Bluetooth and WiFi are features.

Some parts of a configuration will only vary based on different devices. A screen will not change density on the fly, for example. But some parts of a configuration can be changed during operation of the device, such as orientation (portrait vs. landscape) or language. When a configuration switches to something else, that is a “configuration change”, and Android provides special support for such events to help developers adjust their applications to match the new configuration.

Configurations and Resource Sets

One set of resources may not fit all situations where your application may be used. One obvious area comes with string resources and dealing with internationalization (I18N) and localization (L10N). Putting strings all in one language works fine — probably at least for the developer — but only covers one language.

That is not the only scenario where resources might need to differ, though. Here are others:

1. *Screen orientation*: is the screen in a portrait orientation? Landscape?
2. *Screen size*: is this something sized like a phone? A tablet? A television?
3. *Screen density*: how many dots per inch does the screen have? Will we need a higher-resolution edition of our icon so it does not appear too small?
4. *Keyboard*: what keyboard does the user have (QWERTY, numeric, neither), either now or as an option?
5. *Other input*: does the device have some other form of input, like a directional pad or click-wheel?

The way Android currently handles this is by having multiple resource directories, with the criteria for each embedded in their names.

Suppose, for example, you want to support strings in both English and Spanish. Normally, for a single-language setup, you would put your strings in a file named `res/values/strings.xml`. To support both English and Spanish, you could create two folders, `res/values-en/` and `res/values-es/`, where the value after the hyphen is the [ISO 639-1](#) two-letter code for the language you want. Your English-language strings would go in `res/values-en/strings.xml` and the Spanish ones in `res/values-es/strings.xml`. Android will choose the proper file based on the user's device settings. Note that Android 5.0 added support for [BCP 47 three-letter language and locale values](#), though these also require Gradle for Android 1.1.0 (or higher) and Android Studio 1.1.0 (or higher).

However, the **better** approach is for you to consider some language to be your default, and put those strings in `res/values/strings.xml`. Then, create other resource directories for your translations (e.g., `res/values-es/strings.xml` for Spanish). Android will try to match a specific language set of resources; failing that, it will fall back to the default of `res/values/strings.xml`. This way, if your app winds up on a device with a language that you do not expect, you at least serve up strings in your chosen default language. Otherwise, if there is no such default, you will wind up with a `ResourceNotFoundException`, and your application will crash.

This, therefore, is the bedrock resource set strategy: have a complete set of resources in the default directory (e.g., `res/layout/`), and override those resources in other resource sets tied to specific configurations as needed (e.g., `res/layout-land/`).

Note that Android Studio has a [translations editor](#) to help you manage your string resources for your default language and whatever translations you are going to include in your app.

Screen Size and Orientation

Perhaps the most important resource set qualifiers that we have not yet seen are the ones related to screen size and orientation. Here, “orientation” refers to how the device is being held: portrait or landscape.

Orientation is fairly easy, as you can just use `-port` or `-land` as resource set qualifiers to restrict resources in a directory to a specific orientation. The convention is to put landscape resources in a `-land` directory (e.g., `res/layout-land/`) and to put

portrait resource in the default directory (e.g., `res/layout/`). However, this is merely a convention, and you are welcome to use `-port` if you prefer.

Screen size is a bit more complicated, simply because the available approaches have changed over the years.

The Original: Android-Defined Buckets

Way back in the beginning, with Android 1.0, all screen sizes were created equal... mostly because there was only one screen size, and that mostly because there was only one device.

Android 1.5, however, introduced three screen sizes and associated resource set qualifiers, with a fourth (`-xlarge`) added later:

- `-small` for screens at or under 3" in diagonal size
- `-normal` for screens between 3" and 5" in diagonal size
- `-large` for screens between 5" and 10" in diagonal size
- `-xlarge` for screens at or over 10" in diagonal size

As we will see, these resource set qualifiers establish lower bounds for when a directory's worth of resources will be used. So a `res/layout-normal/` directory will not be used for `-small` screens but would be used for `-normal`, `-large`, and `-xlarge` screens.

The Modern: Developer-Defined Buckets

The problem with the classic size buckets is that they were fairly inflexible. What if you think that so-called "phablets", like the Samsung Galaxy Note series, should have layouts more like phones, while larger tablets, such as the 8.9" Kindle Fire HD, should have layouts more like 10" tablets? That was not possible given the fixed buckets.

Android 3.2 gave us more control. We can have our own buckets for screen size, using the somewhat-confusing `-swNNDp` resource set qualifier. Here, the `NNN` is replaced by you with a value, measured in `dp`, for the *shortest width* of the screen. "Shortest width" basically means the width of the screen when the device is held in portrait mode. Hence, rather than measuring based on diagonal screen size, as with the classic buckets, your custom buckets are based on the linear screen size of the shortest screen side.

For example, suppose that you wish to consider a dividing line between resources to be at the 7" point — 7" and smaller devices would get one set of layouts, while larger devices would get a different set of layouts. 7" tablets usually have a shortest width of around 3.5" to 3.75", given common aspect ratios. Since 1 dp is 1/160th of an inch, those shortest widths equate to 560-600 dp. Hence, you might set up a `-sw600dp` resource set for your larger layouts, and put the smaller layouts in a default resource set.

Mashups: Width and Height Buckets

Using `-swNNNdp` does not address orientation, as the shortest width is the same regardless of whether the device is held in portrait or landscape. Hence, you would need to add `-swNNNdp-land` as a resource set for landscape resources for your chosen dividing line.

An alternative is to use `-wNNNdp` or `-hNNNdp`. These resource set qualifiers work much like `-swNNNdp`, particularly in terms of what NNN means. However, whereas `-swNNNdp` refers to the shortest width, `-wNNNdp` refers the *current* width, and `-hNNNdp` refers to the *current* height. Hence, these change with orientation changes.

About That API Level

`-swNNNdp`, `-wNNNdp`, and `-hNNNdp` were added in API Level 13. Hence, older devices will ignore any resource sets with those qualifiers.

In principle, this might seem like a big problem, for those developers still supporting older devices.

In practice, it is less of an issue than you might expect, simply because the *vast* majority of those older devices were phones, not tablets. The only Android 2.x tablets that sold in any significant quantity were three 7" models:

- the original Kindle Fire
- the original Barnes & Noble NOOK series
- the original Samsung Galaxy Tab

Of those, only the Galaxy Tab had the then-Android Market (now the Play Store). Hence, if you are only distributing via the Play Store, you might be in position to simply ignore pre-API Level 13 tablets. Use `-swNNNdp` to create your dividing line for larger devices, and the Galaxy Tab will simply use the layouts for your smaller devices.

If this concerns you, or you are also supporting the Kindle Fire and early NOOKs, you can use layout aliases to minimize code duplication. For example, suppose that you have a `res/layout/main.xml` that you wanted to have different versions for phones and tablets, and you want to use `-swNNDp` for your dividing line as to where the tablet layouts get used, but you also want to have the older tablets, like the Galaxy Tab, use the following recipe:

- Put your tablet-sized layouts in `res/layout/`, but with *different* filenames (e.g., `res/layout/main_to_be_used_for_tablets.xml`)
- In `res/values-swNNDp/layouts.xml`, for your chosen value of `NNN`, put aliases (via `<item>` elements) for the original names (via the `name` attribute) pointing to the resources you want to use for `-swNNDp` devices:

```
<resources>
  <item name="main" type="layout">@layout/main_to_be_used_for_tablets</item>
</resources>
```

- In `res/values-large/layouts.xml`, put those same aliases

Now, both older and newer devices, when referencing the same resource name, will get routed to the right layouts for their screen size.

Coping with Complexity

Where things start to get complicated is when you need to use multiple disparate criteria for your resources.

For example, suppose that you have drawable resources that are locale-dependent, such as a stop sign. You might want to have resource sets of drawables tied to language, so you can substitute in different images for different locales. However, you might also want to have those images vary by density, using higher-resolution images on higher-density devices, so the images all come out around the same physical size.

To do that, you would wind up with directories with multiple resource set qualifiers, such as:

- `res/drawable-ldpi/`
- `res/drawable-mdpi/`
- `res/drawable-hdpi/`
- `res/drawable-xhdpi/`
- `res/drawable-en-rUK-ldpi/`

- res/drawable-en-rUK-mdpi/
- res/drawable-en-rUK-hdpi/
- res/drawable-en-rUK-xhdpi/
- And so on

(with the default language being, say, US English, using a US stop sign)

Once you get into these sorts of situations, though, a few rules come into play, such as:

1. The configuration options (e.g., -en) have a particular order of precedence, and they must appear in the directory name in that order. The [Android documentation](#) outlines the specific order in which these options can appear. For the purposes of this example, screen size is more important than screen orientation, which is more important than screen density, which is more important than whether or not the device has a keyboard.
2. There can only be one value of each configuration option category per directory.
3. Options are case sensitive

For example, you might want to have different layouts based upon screen size and orientation. Since screen size is more important than orientation in the resource system, the screen size would appear in the directory name ahead of the orientation, such as:

- res/layout-sw600dp-land/
- res/layout-sw600dp/
- res/layout-land/
- res/layout/

Choosing The Right Resource

Given that you can have N different definitions of a resource, how does Android choose the one to use?

First, Android tosses out ones that are specifically invalid. So, for example, if the language of the device is -ru, Android will ignore resource sets that specify other languages (e.g., -zh). The exceptions to this are density qualifiers and screen size qualifiers — we will get to those exceptions later.

Then, Android chooses the resource set that has the desired resource and has *the most important distinct qualifier*. Here, by “most important”, we mean the one that appears left-most in the directory name, based upon the directory naming rules [discussed above](#). And, by “distinct”, we mean where no other resource set has that qualifier.

If there is no specific resource set that matches, Android chooses the default set — the one with no suffixes on the directory name (e.g., `res/layout/`).

With those rules in mind, let’s look at some scenarios, to cover the base case plus the aforementioned exceptions.

Scenario #1: Something Simple

Let’s suppose that we have a `main.xml` file in:

- `res/layout-land/`
- `res/layout/`

When we call `setContentView(R.layout.main)`, Android will choose the `main.xml` in `res/layout-land/` if the device is in landscape mode. That particular resource set is valid in that case, and it has the most important distinct qualifier (`-land`). If the device is in portrait mode, though, the `res/layout-land/` resource set does not qualify, and so it is tossed out. That leaves us with `res/layout/`, so Android uses that `main.xml` version.

Scenario #2: Disparate Resource Set Categories

It is possible, though bizarre, for you to have a project with `main.xml` in:

- `res/layout-en/`
- `res/layout-land/`
- `res/layout/`

In this case, if the device’s locale is set to be English, Android will choose `res/layout-en/`, regardless of the orientation of the device. That is because `-en` is a more important resource set qualifier — “Language and region” appears higher in the “Table 2. Configuration qualifier names” from the Android documentation than does “Screen orientation” (for `-land`). If the device is not set for English, though, Android will toss out that resource set, at which point the decision-making process is the same as in Scenario #1 above.

Scenario #3: Multiple Qualifiers

Now let's envision a project with `main.xml` in:

- `res/layout-en/`
- `res/layout-land-v11/`
- `res/layout/`

You might think that `res/layout-land-v11/` would be the choice, as it is more specific, matching on two resource set qualifiers versus the one or none from the other resource sets.

(in fact, the author of this book thought this was the choice for many years)

In this case, though, language is more important than either screen orientation or Android API level, so the decision-making process is the similar to Scenario #2 above: Android chooses `res/layout-en/` for English-language devices, `res/layout-land-v11/` for landscape API Level 11+ devices, or `res/layout/` for everything else.

Scenario #4: Multiple Qualifiers, Revisited

Let's change the resource mix, so now we have a project with `main.xml` in:

- `res/layout-land-night/`
- `res/layout-land-v11/`
- `res/layout/`

Here, while `-land` is the most important resource set qualifier, it is not distinct — we have more than one resource set with `-land`. Hence, we need to check which is the next-most-important resource set qualifier. In this case, that is `-night`, as night mode is a more important category than is Android API level, and so Android will choose `res/layout-land-night/` if the device is in night mode. Otherwise, it will choose `res/layout-land-v11/` if the device is running API Level 11 or higher. If the device is not in night mode and is not running API Level 11 or higher, Android will go with `res/layout/`.

Scenario #5: Screen Density

Now, let's look at the first exception to the rules: screen density.

Android will *always* accept a resource set that contains a screen density, *even if it does not match the density of the device*. If there is an exact density match, of course, Android uses it. Otherwise, it will use what it feels is the next-best match, based upon how far off it is from the device’s actual density and whether the other density is higher or lower than the device’s actual density.

The reason for this is that for drawable resources, Android will downsample or upsample the image automatically, so the drawable will appear to be the right size, even though you did not provide an image in that specific density.

The catch is two-fold:

1. Android applies this logic to all resources, not just drawables, so even if there is no exact density match on, say, a layout, Android will still choose a resource from another density bucket for the layout
2. As a side-effect of the previous bullet, if you include a density resource set qualifier, Android will ignore any lower-priority resource set qualifiers (unless there are multiple directories with the same density resource set qualifier, in which case the lower-priority qualifiers serve as the “tiebreaker”)

So, now let’s pretend that our project has `main.xml` in:

- `res/layout-mdpi/`
- `res/layout-nonnav/`
- `res/layout/`

Android will choose `res/layout-mdpi/`, even for `-hdpi` devices that do not have a “non-touch navigation method”. While `-mdpi` does not match `-hdpi`, Android will still choose `-mdpi`. If we were dealing with drawables resources, Android would upsample the `-mdpi` image.

Scenario #6: Screen Sizes

If you have resource sets tied to screen size, Android will choose the one that is closest to the actual screen size yet smaller than the actual screen size. Resource sets for screen sizes larger than the actual screen size are ignored.

This works for `-swNNDdp`, `-wNNDdp`, and `-hNNDdp` for all devices. On `-large` or `-xlarge` devices, Android applies the same logic for the classic screen size qualifiers (`-small`, `-normal`, `-large`, `-xlarge`). However, Android does *not* apply this logic for `-small` or `-normal` devices — a `-normal` device will not load a `-small` resource.

Now let's pretend that our project has `main.xml` in:

- `res/layout-normal/`
- `res/layout-land/`
- `res/layout/`

Android will choose `res/layout-normal/` if the device is not `-small`. Otherwise, Android will choose `res/layout-land/` if the device is landscape. If all else fails, Android will choose `res/layout/`.

Similarly, if we have:

- `res/layout-w320dp/`
- `res/layout-land/`
- `res/layout/`

Android will choose `res/layout-w320dp/` for devices whose current screen width is 320dp or higher. Otherwise, Android will choose `res/layout-land/` if the device is landscape. If all else fails, Android will choose `res/layout/`.

API-Versioned Resources

As noted previously in this chapter, the `-vNNN` set of suffixes indicate that the resources in that directory are for the stated API level or higher. So, for example, `res/values-v21/` indicates that the resources in that directory should only be used on API Level 21 (Android 5.0) and higher. Devices running older versions of Android will ignore those resources.

This is a particularly important set of suffixes for dealing with major Android version changes. The look and feel of a stock Android app changed significantly at API Level 11 (Android 3.0) and API Level 21 (Android 5.0). You may find that you want to have different resources starting at those API level split points, so that your UI looks appropriately on all versions of Android that you are supporting.

Use Case: Themes by API Level

One big use case for this feature is having different themes by API level.

Even if your `minSdkVersion` is 11 or higher, you may want to have two different themes for your app:

RESOURCE SETS AND CONFIGURATIONS

- One, used from API Level 11-20, based on `Theme.Holo`
- Another, used from API Level 21 onwards, based on `Theme.Material`

Your rough alternative is to use [the `appcompat-v7` backport](#) of the action bar and bits of the Material Design aesthetic. For highly stylized apps, or in cases where you are sure that you want Material Design on pre-Android 5.0 devices, `appcompat-v7` is worth considering. But if you want to blend in better on each major native UI variant, you will want to support `Theme.Holo` on Android 3.x and 4.x and `Theme.Material` after that.

The hard work here is setting up your themes themselves, such as what was outlined back in [the chapter on the action bar](#). Having them both be available, depending upon device version, is merely a matter of putting the resources into the proper directories.

For example, take a look at the [ActionBar/VersionedColor](#) sample project. This is a “mashup” of the `HoloColor` and `MaterialColor` sample projects, where the determination of which theme to use is based on API level.

In the `res/values/` directory, we have a `styles.xml` file that is the same as the one in the `HoloColor` example, just with the filename standardized to `styles.xml`. It uses a custom theme (`Theme.Apptheme`) generated by the Action Bar Style Generator.

There is also a `res/values-v21/` directory, indicating values resources to be used on API Level 21 and higher. It has the theme originally seen in the `MaterialColor` example, where the style resource is renamed to `Theme.Apptheme`, to match the one defined in `res/values/`.

Then, with `<application>` referencing `Theme.Apptheme`, we get the right action bar on the right device.

Here, having the style resources names be the same is important, as we are referencing the name in the `<application>` element in the manifest. To be able to pull in the right one, we need them both to have the same name. However, resources that are referred to by only one of those themes, such as color and drawable resources, could go in a versioned directory or not, as you see fit. They *have* to go in versioned directories and *have* to have the same names if you want multiple editions where the API level chooses which edition to use.

For example, the `Theme.Material`-based theme defined in `res/values-v21/styles.xml` references three color resources. The file for those resources happens to also be in `res/values-v21/ (colors.xml)`. However, since we are not looking to replace those colors based on API level, the `colors.xml` file could be placed in `res/values/` and work just as well. And, if we *did* want to have different colors by API level, we would need those colors defined in all relevant resource sets, such as both `res/values/` and `res/values-v21/`.

Default Change Behavior

When you call methods in the Android SDK that load a resource (e.g., the aforementioned `setContentView(R.layout.main)`), Android will walk through those resource sets, find the right resource for the given request, and use it.

But what happens if the configuration changes *after* we asked for the resource? For example, what if the user was holding their device in portrait mode, then rotates the screen to landscape? We would want a `-land` version of our layouts, if such versions exist. And, since we already requested the resources, Android has no good way of handing us revised resources on the fly... except by forcing us to re-request those resources.

So, this is what Android does, by default, to our foreground activity, when the configuration changes on the fly.

Destroy and Recreate the Activity

The biggest thing that Android does is destroy and recreate our activity. In other words:

- Android calls `onPause()`, `onStop()`, and `onDestroy()` on our original instance of the activity
- Android creates a brand new instance of the same activity class, using the same Intent that was used to create the original instance
- Android calls `onCreate()`, `onStart()`, and `onResume()` of the new activity instance
- The new activity appears on the screen

This may seem... invasive. You might not expect that Android would wipe out a perfectly good activity, just because the user flicked her wrist and rotated the screen

of her phone. However, this is the only way Android has that guarantees that we will re-request all our resources.

Rebuild the Fragments

If your activity is using fragments, the new instance of the activity will contain the same fragments that the old instance of the activity does. This includes both static and dynamic fragments.

By default, Android destroys and recreates the fragments, just as it destroys and recreates the activities. However, as we will see, we do have an option to tell Android to retain certain dynamic fragment instances — for those, it will have the new instance use the same fragment instances as were used by the old activity, instead of creating new instances from scratch.

Recreate the Views

Regardless of whether or not Android recreates all of the fragments, it will call `onCreateView()` of all of the fragments (plus call `onDestroyView()` on the original set of fragments). In other words, Android recreates all of the widgets and containers, to pour them into the new activity instance.

Retain Some Widget State

Android will hold onto the “instance state” of some of the widgets we have in our activity and fragments. Mostly, it holds onto obviously user mutable state, such as:

- What has been typed into an `EditText`
- Whether a `CompoundButton`, like a `CheckBox` or `RadioButton`, is checked or not
- Etc.

Android will collect this information from the widgets of the old activity instance, carry that data forward to the new activity instance, and update the new set of widgets to have that same state.

State Saving Scenarios

When the user rotates the screen, or puts the device in a car dock, or changes the language of the device, your process is not terminated. Your foreground activity will

be re-created by default — as will your widgets and fragments — but the process sticks around.

However, there are plenty of cases when your process will be terminated once you move into the background. That might be done automatically by Android or manually by the user.

Depending on *how* your process is terminated, there may be ways that the user can return to your app and expect that they will return to it just how they left it. For example, suppose the user is in your app, then presses HOME to move your app to the background. Hours pass, and Android terminates your process to free up memory for other apps. Sometime after that, the user brings up the recent-tasks list and taps on your app in that list. From the *user's* perspective, they should be returning to your app in the same state that they left it when they pressed HOME. However, if your process was terminated, by default you lost all that state.

Some of the techniques for dealing with a configuration change — those involving the “saved instance state Bundle” — will *also* help you handle the recent-tasks-list scenario. Some of the other techniques — such as retaining a fragment — only help with handling configuration changes and will do nothing for you in terms of the recent-tasks-list scenario. The general rule of thumb, therefore, is to use the Bundle where you can, and use other techniques (e.g., retained fragments) where the Bundle is inappropriate or inadequate. We will see those techniques in the next section.

However, bear in mind that all of this state is designed for transient data, data that the user will not mind if they never see again. For example, suppose the user is in your app, then presses HOME to move your app to the background. Hours pass, and due to the user having busily used their device, you “*fall off*” the recent-tasks list, as that list will not extend indefinitely. In this case, if the user starts up your app again (e.g., via the home screen launcher icon), you will *not* get any state information back for use. Data that the user filled into the old app instance, where that data *must be remembered* and reused in any future run of your app, will need to be persisted yourself, in a database or other type of file.

With all of that in mind, let's examine our options for dealing with the transient state, with an emphasis on configuration changes.

Your Options for Configuration Changes

As noted, a configuration change is fairly invasive on your activity, replacing it outright with all new content (albeit with perhaps some information from the old activity's widgets carried forward into the new activity's widgets).

Hence, you have several possible approaches for handling configuration changes in any given activity.

Do Nothing

The easiest thing to do, of course, is to do nothing at all. If all your state is bound up in stuff Android handles automatically, you do not need to do anything more than the defaults.

For example, the `ViewPager/Fragments` demo from [the preceding chapter](#) works correctly “out of the box”. All of our “state” is tied up in `EditText` widgets, which Android handles automatically. So, we can type in stuff in a bunch of those widgets, rotate the screen (e.g., via `<Ctrl>-<F11>` in the emulator on a Windows or Linux PC), and our entered text is retained.

Alas, there are plenty of cases where the built-in behavior is either incomplete or simply incorrect, and we will need to do more work to make sure that our configuration changes are handled properly.

Retain Your Fragments

One approach for handling these sorts of configuration changes is to have Android retain a dynamic fragment.

Here, “retain” means that Android will keep the same fragment instance across the configuration change, detaching it from the original hosting activity and attaching it to a new hosting activity. Since it is the same fragment instance, anything contained inside that instance is itself retained and, therefore, is not lost when the activity is destroyed and recreated.

To see this in action, take a look at the [ConfigChange/Fragments](#) sample project.

The business logic for this demo (and for all the other demos in this chapter) is that we want to allow the user to pick a contact out of the roster of contacts found on

RESOURCE SETS AND CONFIGURATIONS

their device or emulator. We will do that by having the user press a “Pick” button, at which time we will display an activity that will let the user pick the contact and return the result to us. Then, we will enable a “View” button, and let the user view the details of the selected contact. The key is that our selected contact needs to be retained across configuration changes — otherwise, the user will rotate the screen, and the activity will appear to forget about the chosen contact.

The activity itself just loads the dynamic fragment, following the recipe seen previously in this book:

```
package com.commonware.android.rotation.frag;

import android.app.Activity;
import android.os.Bundle;

public class RotationFragmentDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new RotationFragment()).commit();
        }
    }
}
```

The reason for checking for the fragment’s existence should now be clearer. Since Android will automatically recreate (or retain) our fragments across configuration changes, we do not want to create a *second* copy of the same fragment when we already have an existing copy.

The fragment is going to use an `R.layout.main` layout resource, with two implementations. One, in `res/layout-land/`, will be used in landscape:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/pick"
        android:enabled="true"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
```

RESOURCE SETS AND CONFIGURATIONS

```
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/view"
        android:enabled="false"
    />
</LinearLayout>
```

The portrait edition, in `res/layout/`, is identical save for the orientation of the `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/pick"
        android:enabled="true"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/view"
        android:enabled="false"
    />
</LinearLayout>
```

Here is the complete implementation of `RotationFragment`:

```
package com.commonware.android.rotation.frag;

import android.app.Activity;
import android.app.Fragment;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.provider.ContactsContract;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RotationFragment extends Fragment implements
    View.OnClickListener {
    static final int PICK_REQUEST=1337;
    Uri contact=null;

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        setRetainInstance(true);

        View result=inflater.inflate(R.layout.main, parent, false);
```

```
result.findViewById(R.id.pick).setOnClickListener(this);

View v=result.findViewById(R.id.view);

v.setOnClickListener(this);
v.setEnabled(contact != null);

return(result);
}

@Override
public void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (requestCode == PICK_REQUEST) {
        if (resultCode == Activity.RESULT_OK) {
            contact=data.getData();
            getView().findViewById(R.id.view).setEnabled(true);
        }
    }
}

@Override
public void onClick(View v) {
    if (v.getId() == R.id.pick) {
        pickContact(v);
    }
    else {
        viewContact(v);
    }
}

public void pickContact(View v) {
    Intent i=
        new Intent(Intent.ACTION_PICK,
            ContactsContract.Contacts.CONTENT_URI);

    startActivityForResult(i, PICK_REQUEST);
}

public void viewContact(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW, contact));
}
}
```

In `onClick()`, we hook up the “Pick” button to a `pickContact()` method. There, we call `startActivityForResult()` with an `ACTION_PICK` Intent, indicating that we want to pick something from the `ContactsContract.Contacts.CONTENT_URI` collection of contacts. We will discuss `ContactsContract` in greater detail [later in this book](#). For the moment, take it on faith that Android has such an `ACTION_PICK` activity, one that will display to the user the list of available contacts:

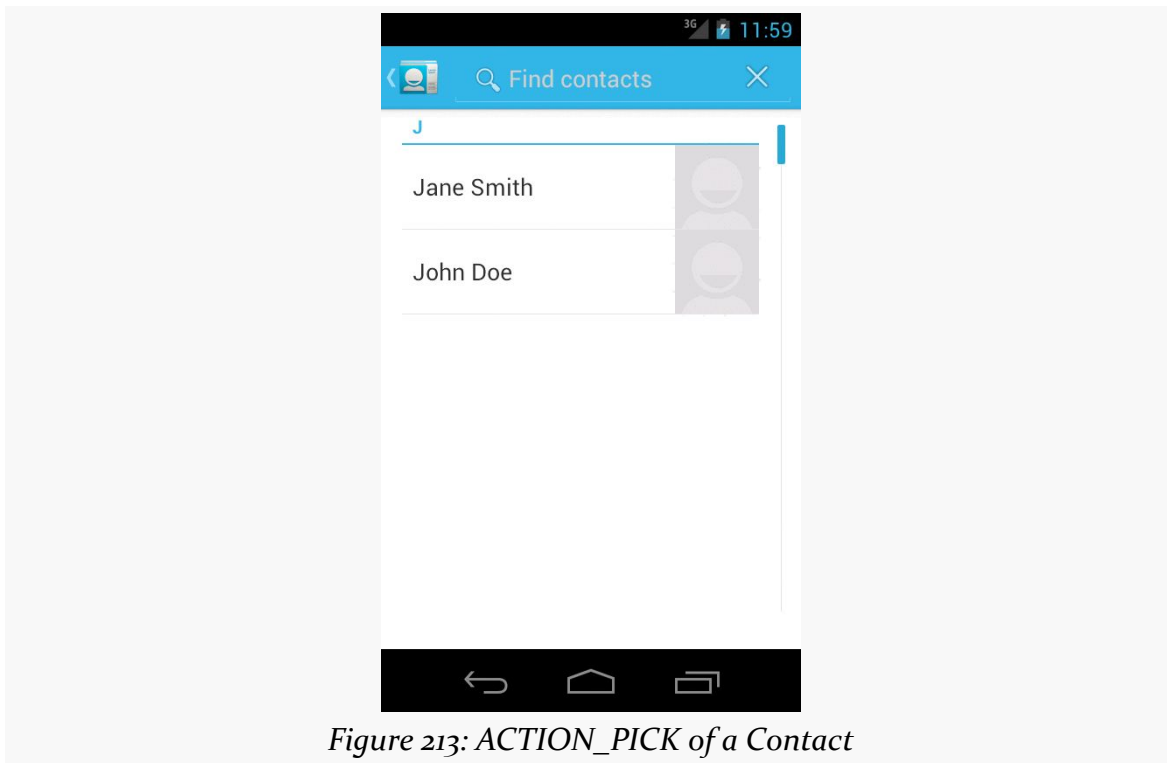

Figure 213: ACTION_PICK of a Contact

If the user picks a contact, control returns to our activity, with a call to `onActivityResult()`. `onActivityResult()` is passed:

- the unique ID we supplied to `startActivityForResult()`, to help identify this result from any others we might be receiving
- `RESULT_OK` if the user did pick a contact, or `RESULT_CANCELED` if the user abandoned the pick activity
- an `Intent` containing the result from the pick activity, which, in this case, will contain a `Uri` representing the selected contact, retrieved via `getData()`

We store that `Uri` in a data member, plus we enable the “View” button, which, when clicked, will bring up an `ACTION_VIEW` activity on the selected contact via its `Uri`:

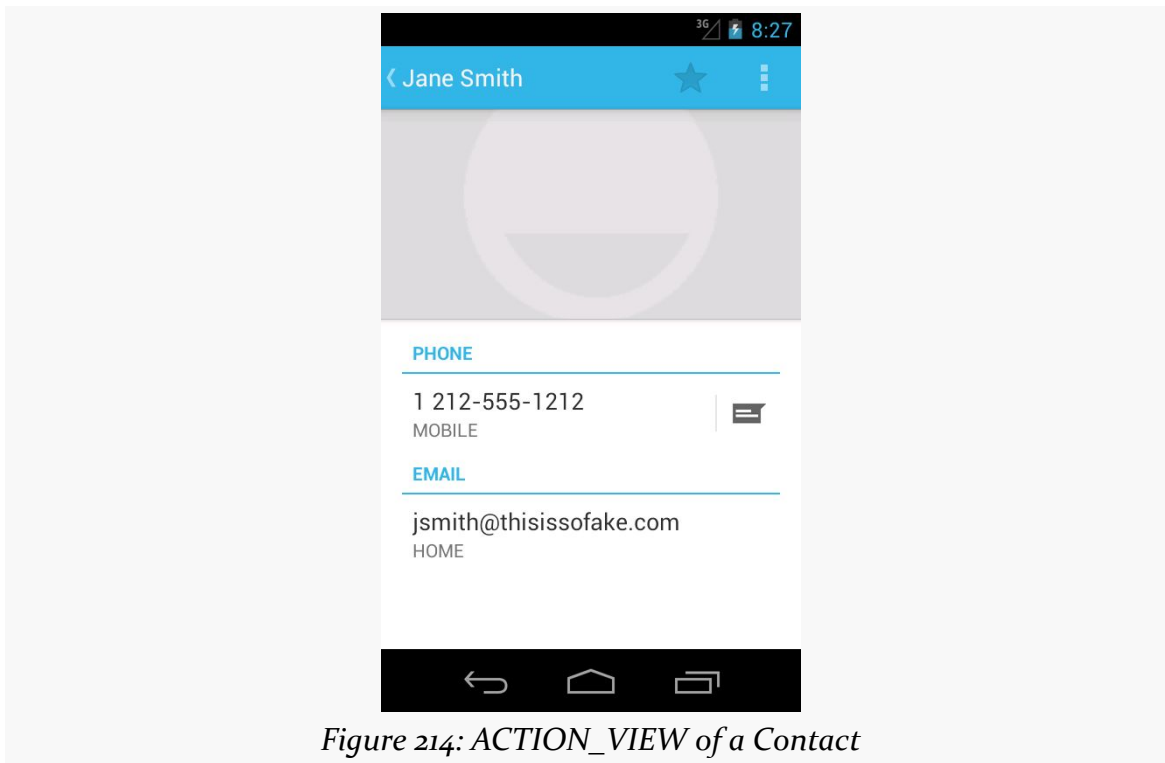

Figure 214: ACTION_VIEW of a Contact

Up in `onCreateView()`, we called `setRetainInstance(true)`. This tells Android to keep this fragment instance across configuration changes. Hence, we can pick a contact in portrait mode, then rotate the screen (e.g., `<Ctrl>-<F11>` in the emulator on Windows or Linux), and view the contact in landscape mode. Even though the activity and the buttons were replaced as a result of the rotation, the fragment was not, and the fragment held onto the `Uri` of the selected contact.

Note that `setRetainInstance()` only works with dynamic fragments, not static fragments. Static fragments are always recreated when the activity is itself destroyed and recreated.

The benefit of this technique, over others, is that you can retain any sort of data you want: any data type, any size, etc. However, this approach does not save state that will be given back to you after your process had been terminated, such as when the user goes back to your app via the recent-tasks list.

Model Fragment

A variation on this theme is the “model fragment”. While fragments normally are focused on supplying portions of the UI to a user, that is not really a requirement. A

model fragment is one that simply uses `setRetainInstance(true)` to ensure that it sticks around as configurations change. This fragment then holds onto any model data that its host activity needs, so as that activity gets destroyed and recreated, the model data sticks around in the model fragment.

This is particularly useful for data that might not otherwise have a fragment home. For example, imagine an activity whose UI consists entirely of a `ViewPager`, (like the tutorial app). Even though that `ViewPager` might hold fragments, there will be many pages in most pagers. It may be simpler to add a separate, UI-less model fragment and have it hold the activity's data model for the `ViewPager`. This allows the activity to still be destroyed and recreated, and even allows the `ViewPager` to be destroyed and recreated, while still retaining the already-loaded data.

Google recommends using a model fragment instead of using `setRetainInstance(true)` with a regular fragment. The less the retained fragment holds, the less likely it is that you will hold something that you should not be holding, such as a string that needs to be reloaded from a string resource due to a possible locale change. That being said, if you are careful and make sure that all your data members are accounted for properly, using `setRetainInstance(true)` from any fragment can be made safe.

Add to the Bundle

If you want state to be maintained not only for configuration changes, but also for process terminations, you will want to use `onSaveInstanceState()` and `onRestoreInstanceState()`.

You can override `onSaveInstanceState()` in your activity. It is passed a `Bundle`, into which you can store data that should be maintained across the configuration change. The catch is that while `Bundle` looks a bit like it is a `HashMap`, it actually cannot hold arbitrary data types, which limits the sort of information you can retain via `onSaveInstanceState()`. `onSaveInstanceState()` is called around the time of `onPause()` and `onStop()`.

The widget state maintained automatically by Android is via the built-in implementation of `onSaveInstanceState()`. If you override it yourself, typically you will want to chain to the superclass to get this inherited behavior, in addition to putting things into the `Bundle` yourself.

That `Bundle` is passed back to you in two places:

RESOURCE SETS AND CONFIGURATIONS

- onCreate()
- onRestoreInstanceState()

Since onCreate() is called in many cases other than due to a configuration change, frequently the passed-in Bundle is null. onRestoreInstanceState(), on the other hand, is only called when there is a Bundle to be used.

To see how this works, take a look at the [ConfigChange/Bundle](#) sample project.

Here, RotationBundleDemo is an activity with all the same core business logic as was in our fragment in the preceding demo. Since the activity will be destroyed and recreated on a configuration change, we override onSaveInstanceState() and onRestoreInstanceState() to retain our contact, if one was selected prior to the configuration change:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    if (contact != null) {
        outState.putParcelable("contact", contact);
    }
}

@Override
protected void onRestoreInstanceState(Bundle state) {
    super.onRestoreInstanceState(state);

    contact=state.getParcelable("contact");
    viewButton.setEnabled(contact != null);
}
```

Here, we use putParcelable() to put the Uri into the Bundle. Parcelable is an interface that you can implement on a Java class to allow an instance of it to be put into a Bundle. Uri happens to implement Parcelable. The full details of what Parcelable means and how you can make things implement Parcelable are provided [later in this book](#).

The downside of this approach is that not everything can go into a Bundle. A Bundle cannot hold arbitrary data types, so you cannot put a Socket into a Bundle, for example. Also, this Bundle needs to be fairly small, as it is passed across process boundaries, so you cannot put large objects (e.g., bitmaps) into the Bundle. For those cases, you will have to settle for the retained-fragment approach.

Fragments *and* a Bundle

Fragments also have an `onSaveInstanceState()` method that they can override. It works just like the Activity equivalent — you can store data in the supplied `Bundle` that will be supplied back to you later on. The biggest difference is that there is no `onRestoreInstanceState()` method — instead, you are handed the `Bundle` in other lifecycle methods:

- `onCreate()`
- `onCreateView()`
- `onViewCreated()`
- `onActivityCreated()`

We can see this in the [ConfigChange/FragmentBundle](#) sample project. This is effectively a mashup of the previous two samples: fragments, but using `onSaveInstanceState()` instead of `setRetainInstance(true)`.

Our `RotationFragment` now has an `onSaveInstanceState()` method that looks a lot like the one from the `ConfigChange/Bundle` sample's activity:

```
@Override
public void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    if (contact != null) {
        outState.putParcelable("contact", contact);
    }
}
```

Our `onCreateView()` method examines the passed-in `Bundle`, and if it is not null tries to obtain our contact from it:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
                        Bundle state) {
    View result=inflater.inflate(R.layout.main, parent, false);

    result.findViewById(R.id.pick).setOnClickListener(this);

    View v=result.findViewById(R.id.view);

    v.setOnClickListener(this);

    if (state != null) {
        contact=(Uri)state.getParcelable("contact");
    }

    v.setEnabled(contact != null);
}
```

```
return(result);  
}
```

This does not allow our fragment to hold onto arbitrary data, the way `setRetainInstance(true)` does. However, as with `onSaveInstanceState()` at the activity level, there are scenarios that `onSaveInstanceState()` handles that retained fragments will not, such as terminating your process due to low memory, yet the user later uses `BACK` to return to what should have been your activity (and its fragments).

DIY

In a few cases, even a retained fragment is insufficient, because transferring and re-applying the state would be too complex or too slow. Or, in some cases, the hardware will get in the way, such as when trying to use the Camera for taking pictures — a concept we will cover later in this book.

If you are completely desperate, you can tell Android to *not* destroy and recreate the activity on a configuration change... though this has its own set of consequences. To do this:

- Put an `android:configChanges` entry in your `AndroidManifest.xml` file, listing the configuration changes you want to handle yourself versus allowing Android to handle for you
- Implement `onConfigurationChanged()` in your Activity, which will be called when one of the configuration changes you listed in `android:configChanges` occurs

Now, for any configuration change you want, you can bypass the whole activity-destruction process and simply get a callback letting you know of the change.

For example, take a look at the [ConfigChange/DIY](#) sample project.

In `AndroidManifest.xml`, we add the `android:configChanges` attribute to the `<activity>` element, indicating that we want to handle several configuration changes ourselves:

```
<activity  
    android:name="RotationDIYDemo"  
    android:configChanges="keyboardHidden|orientation|screenSize"  
    android:label="@string/app_name">  
    <intent-filter>  
        <action android:name="android.intent.action.MAIN"/>  
    </intent-filter>  
</activity>
```

RESOURCE SETS AND CONFIGURATIONS

```
<category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
</activity>
```

Many recipes for this will have you handle orientation and keyboardHidden. However, nowadays, you need to also handle screenSize (and, in theory, smallestScreenSize), if you have your android:targetSdkVersion set to 13 or higher. Note that this will require your build target (e.g., compileSdkVersion in Android Studio) to be set to 13 or higher.

Hence, for those particular configuration changes, Android will not destroy and recreate the activity, but instead will call onConfigurationChanged(). In the RotationDIYDemo implementation, this simply toggles the orientation of the LinearLayout to match the orientation of the device:

```
@Override
public void onConfigurationChanged(Configuration newConfig) {
    super.onConfigurationChanged(newConfig);

    LinearLayout container=(LinearLayout)findViewById(R.id.container);

    if (newConfig.orientation == Configuration.ORIENTATION_LANDSCAPE) {
        container.setOrientation(LinearLayout.HORIZONTAL);
    }
    else {
        container.setOrientation(LinearLayout.VERTICAL);
    }
}
```

Since the activity is not destroyed during a configuration change, we do not need to worry at all about the Uri of the selected contact — it is not going anywhere.

The problem with this implementation is twofold:

1. We are not handling all possible configuration changes. If the user, say, puts the device into a car dock, Android will destroy and recreate our activity, and we will lose our selected contact.
2. We might forget some resource that needs to be changed due to a configuration change. For example, if we start translating the strings used by the layouts, and we include locale in android:configChanges, we not only need to update the LinearLayout but also the captions of the Button widgets, since Android will not do that for us automatically.

It is these two problems that are why Google does not recommend the use of this technique unless absolutely necessary.

Also, bear in mind that this approach does not help at all for retaining state when your process is terminated and the user returns to your app via the recent-tasks list.

Blocking Rotations

No doubt that you have seen some Android applications that simply ignore any attempt to rotate the screen. Many games work this way, operating purely in landscape mode, regardless of how the device is positioned.

To do this, add `android:screenOrientation="sensorLandscape"`, or possibly `android:screenOrientation="sensorPortrait"`, to your manifest. The “sensor” portions of those names indicate that your app can work in regular or “reverse” versions of the orientation (e.g., “regular” landscape is the device rotated 90 degrees counter-clockwise from portrait, while “reverse” landscape is the device rotated 90 degrees clockwise from portrait). On API Level 18+, you could use `userLandscape` or `userPortrait` instead, as those will honor the user’s system-level choice of whether to lock screen rotation or not, defaulting to the behavior of `sensorLandscape` or `sensorPortrait` if the user has not locked screen rotation.

Ideally, you choose landscape, as some devices (e.g., Android TV) can only *be* landscape.

Also note that Android *still* treats this as a configuration change, despite the fact that there is no visible change to the user. Hence, you still need to use one of the aforementioned techniques to handle this configuration change, along with any others (e.g., dock events, locale changes).

And Now, a Word From the Android Project View

Earlier in the book, when introducing Android Studio, we saw [the Android project view](#).

One of the reasons why the Android project view was created was to help you manage resources, particularly across various resource sets.

For example, here is a screenshot of the same Android project, but this time with the values resources expanded in the tree:

RESOURCE SETS AND CONFIGURATIONS

Figure 215: Android Project View, Showing Dimension Resources

The tree makes it appear as though there is just a `res/values/dimens.xml` file... but that the file somehow has children. One child has just the bare `dimens.xml` filename, while the other one has a “(w820dp)” appended.

This reflects the fact that there are two versions of `dimens.xml`: one in `res/values/` and one in `res/values-w820dp/`:

RESOURCE SETS AND CONFIGURATIONS

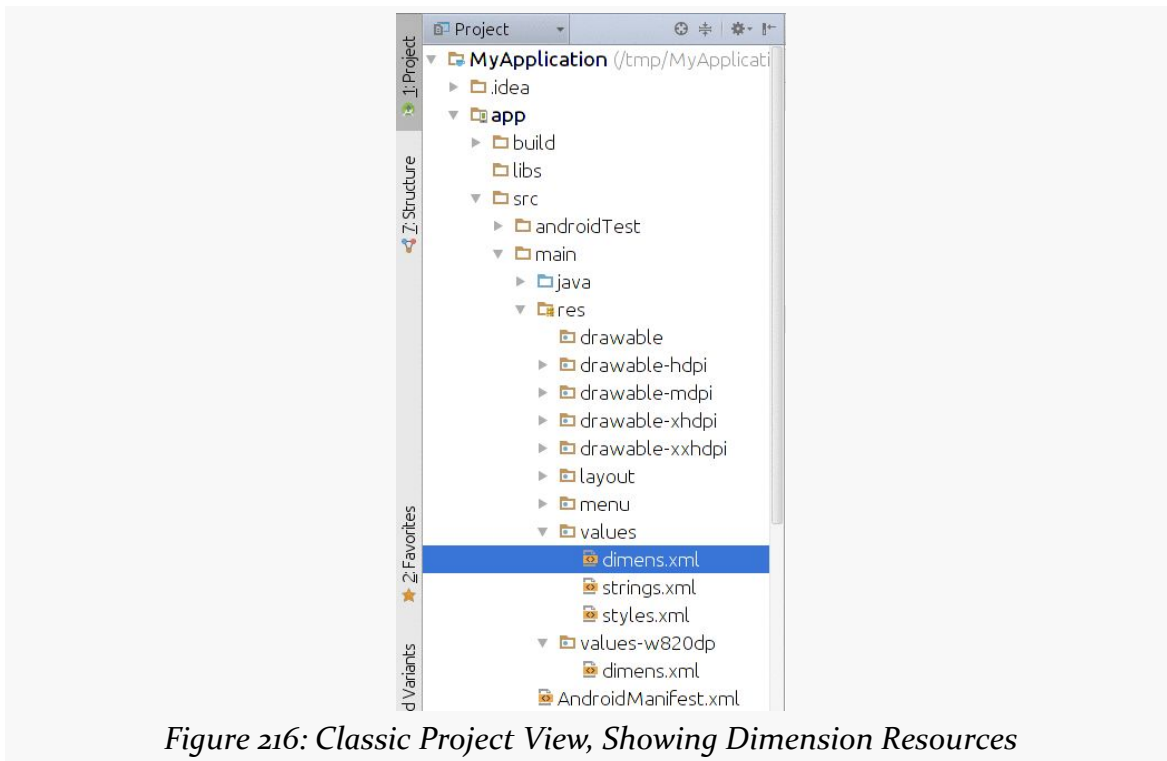

Figure 216: Classic Project View, Showing Dimension Resources

In the Android project view, resources are organized by resource, not by resource set. This can be useful for finding all files that need to be adjusted when you go to adjust one version of the resource, for example.

Material Design Basics

We have already been exposed to `Theme.Material` as part of this book, such as with the action bar.

Android 5.0+, combined with `Theme.Material`, gives you a lot of capabilities tied to Google's Material Design aesthetic. In this chapter, we will cover some basic Material Design capabilities that will affect your `Theme.Material` app on Android 5.0+, starting with color.

Your App, in Technicolor!

Some developers want to change the colors used by their app to match some specific color or color palette. In some cases, the colors in question are tied to the app's branding. In other cases, the developer simply wants something different than the stock colors you get from something like `Theme.Holo` or `Theme.Holo.Light`.

Creating custom themes to apply colors to `Theme.Holo` and kin was enough of a pain that a [separate theme generator](#) was created for it, independent of the generator for custom action bar colors.

Affecting color changes in your `Theme.Material`-based Android app is vastly simplified — both for the action bar and the widgets — courtesy of `Theme.Material`'s tinting options.

Basic Tinting Options

In the chapter on the action bar, we saw how to set up [a custom theme](#) based on `Theme.Material` that had custom color tinting rules that affected the action bar:

MATERIAL DESIGN BASICS

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

At that time, we focused on the effects that these tints had on the action bar itself. However, with `Theme.Material`, not only do the tints affect the action bar, but they affect the widgets themselves.

The [BasicMaterial](#) directory contains clones of some of the [basic widget samples](#) outlined earlier in this book, where each includes the custom theme demonstrated for the action bar.

In some cases, the custom tints are not normally visible, such as with a button:

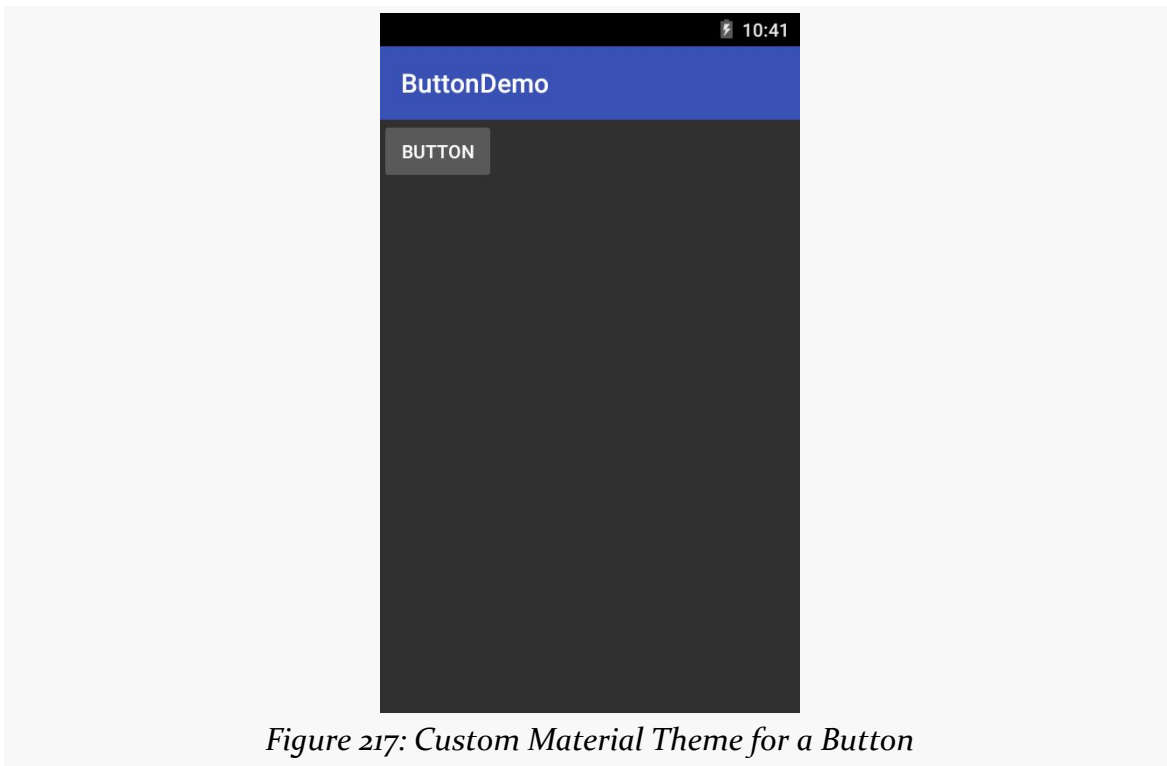

Figure 217: Custom Material Theme for a Button

However, when you tap the button, the animated “ripple” effect shown on the button will use your accent color.

In other cases, the accent color will show up in a more “steady state”, such as in a checked CheckBox:

Figure 218: Custom Material Theme for a CheckBox

Similarly, your accent color shows up in things like:

- the “underbar” and drag-cursor in an EditText:

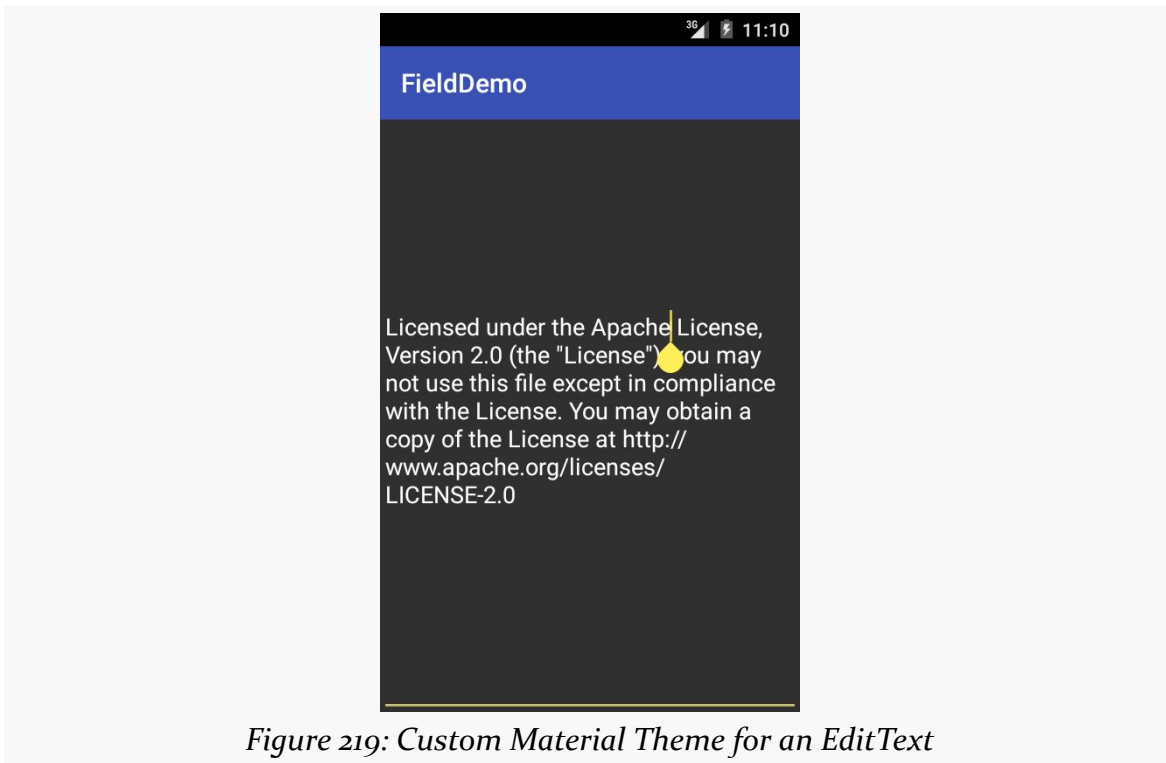

Figure 219: Custom Material Theme for an EditText

- the checked state (and ripple effect when toggling the state) of a `RadioButton`:

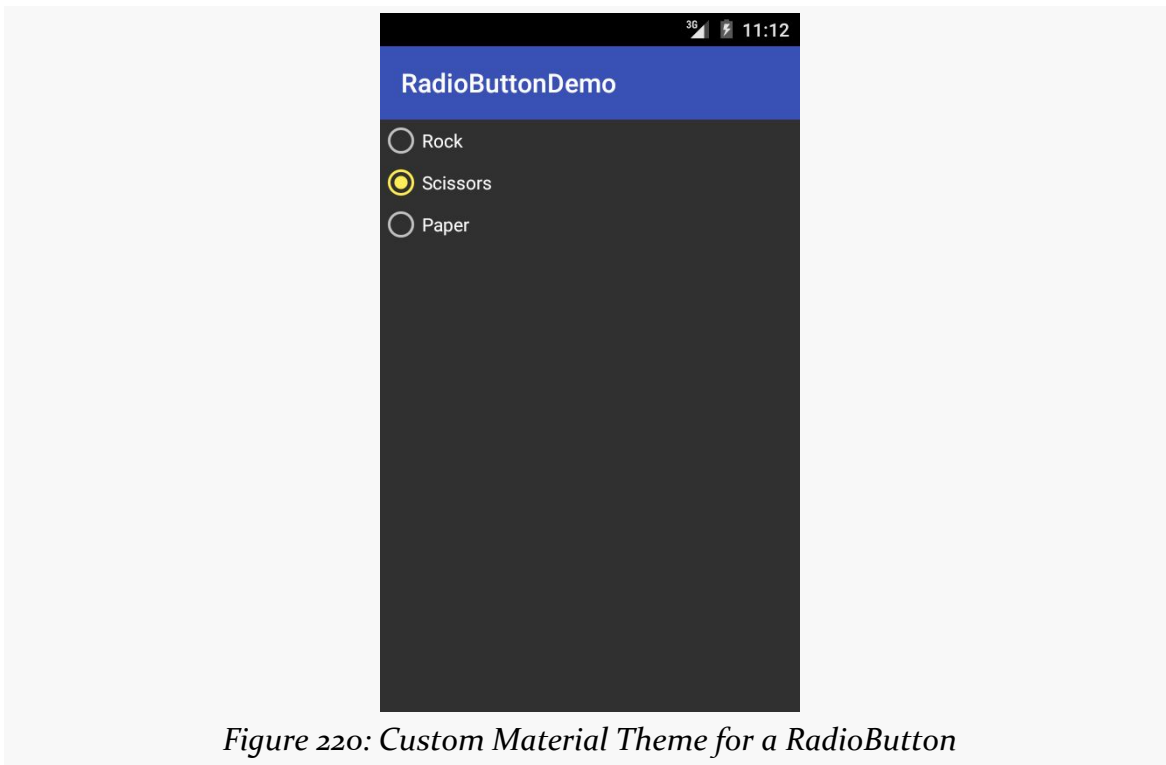

Figure 220: Custom Material Theme for a RadioButton

- the “checked” state of a Switch:

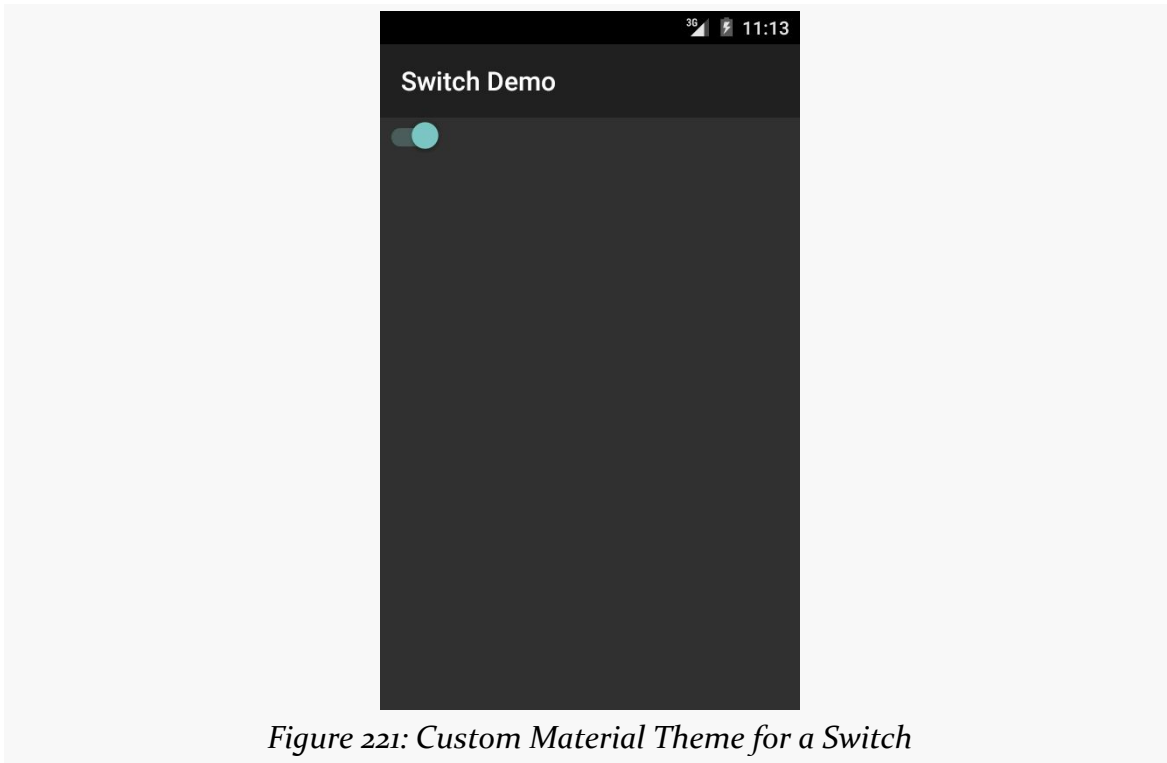

Figure 221: Custom Material Theme for a Switch

Similar effects can be seen in other widgets as well. Hence, your choice of tint values in your custom theme will affect the look of the widgets as well as of the action bar.

Official Google-Approved Colors

Of course, you are welcome to pick whatever colors you like for your theme.

Google has its opinion of what it thinks are good ideas.

As part of [the Material Design documentation](#), you will find [a “Color palette” page](#) that outlines possible colors to use.

[A Redditor](#) has also published [an Android color resource file](#) that contains all of the colors outlined in the Material Design guide.

There is also the [material palette site](#), which generates a color resource file based upon colors that you select from a large grid of color swatches.

Tinting the Status Bar

However, when our action bar is a color other than black, white, or shades in between, there can be a color clash with the black background of the status bar. To combat this, Android 5.0 allows you tint the status bar from your Java code. The general guidance is that if your action bar is using your primary color, the status bar should be tinted to the dark primary color.

To do this, as the first thing in your activity's `onCreate()` after chaining to `super.onCreate()` and before setting your content view, you will need to add a bit of code:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        Window window = getWindow();

        window.addFlags(WindowManager.LayoutParams.FLAG_DRAWS_SYSTEM_BAR_BACKGROUNDS);
        window.clearFlags(WindowManager.LayoutParams.FLAG_TRANSLUCENT_STATUS);
        window.setStatusBarColor(getResources().getColor(R.color.primary_dark));
    }

    initAdapter();
}
```

This code snippet assumes that your desired color is found in a color resource named `R.color.primary_dark`, which may need to be changed if you have the resource named differently. Or, if you really want to hard-code a hex color value here (e.g., `0x1a237e`), you can do that instead of looking up the color via a resource.

When run on hardware, you will see the tinted status bar:

MATERIAL DESIGN BASICS

The Android SDK emulators do not exhibit this behavior at the present time.

Dealing with Threads

Users like snappy applications. Users do not like applications that feel sluggish.

The way to help your application feel snappy is to use the standard threading capabilities built into Android. This chapter will go through the issues involved with thread management in Android and will walk you through some of the options for keeping the user interface crisp and responsive.

The Main Application Thread

When you call `setText()` on a `TextView`, you probably think that the screen is updated with the text you supply, right then and there.

You would be mistaken.

Rather, everything that modifies the widget-based UI goes through a message queue. Calls to `setText()` do not update the screen — they just place a message on a queue telling the operating system to update the screen. The operating system pops these messages off of this queue and does what the messages require.

The queue is processed by one thread, variously called the “main application thread” and the “UI thread”. So long as that thread can keep processing messages, the screen will update, user input will be handled, and so on.

However, the main application thread is also used for nearly all callbacks into your activity. Your `onCreate()`, `onClick()`, `onListItemClick()`, and similar methods are all called on the main application thread. While your code is executing in these methods, Android is not processing messages on the queue, and so the screen does not update, user input is not handled, and so on.

This, of course, is bad. So bad, that if you take more than a few seconds to do work on the main application thread, Android may display the dreaded “Application Not Responding” dialog (ANR for short), and your activity may be killed off.

Nowadays, though, the bigger concern is jank.

“Jank”, as used in Android, refers to sluggish UI updates, particularly when something is animating. For example, you may have encountered some apps that when you scroll a `ListView` in the app, the `ListView` does not scroll smoothly. Rather, it scrolls jerkily, interleaving periods of rapid movement with periods where the animation is frozen. Most of the time, this is caused by the app’s author doing too much work on the main application thread.

Android 4.1 introduced “Project Butter”, which, among other things, established a baseline for “doing too much work on the main application thread”. We will “drop frames” if we take more than ~16ms per frame (60 frames per second), and dropped frames are the source of jank. Since we may be called many times during a frame, each of our callbacks needs to be very cheap, ideally below 1ms. We will get much more into the issue of jank [later in the book](#), but it is important to understand now that any significant delay in the execution of our code on the main application thread can have visible effects to the user.

Hence, you want to make sure that all of your work on the main application thread happens quickly. This means that anything slow should be done in a background thread, so as not to tie up the main application thread. This includes things like:

1. Internet access, such as sending data to a Web service or downloading an image
2. Significant file operations, since flash storage can be remarkably slow at times
3. Any sort of complex calculations

Fortunately, Android supports threads using the standard `Thread` class from Java, plus all of the wrappers and control structures you would expect, such as the `java.util.concurrent` class package.

However, there is one big limitation: you cannot modify the UI from a background thread. You can only modify the UI from the main application thread. If you call `setText()` on a `TextView` from a background thread, your application will crash, with an exception indicating that you are trying to modify the UI from a “non-UI thread” (i.e., a thread other than the main application thread).

This is a pain.

Getting to the Background

Hence, you need to get long-running work moved into background threads, but those threads need to do something to arrange to update the UI using the main application thread.

There are various facilities in Android for helping with this.

Some are high-level frameworks for addressing this issue for major functional areas. One example of this is the Loader framework for retrieving information from databases, and we will examine this [in a later chapter](#).

Sometimes, there are asynchronous options built into other Android operations. For example, when we discuss SharedPreferences [in a later chapter](#), we will see that we can persist changes to those preferences synchronously or asynchronously.

And, there are a handful of low-level solutions for solving this problem, ones that you can apply for your own custom business logic.

Asyncing Feeling

One popular approach for handling this threading problem is to use AsyncTask. With AsyncTask, Android will handle all of the chores of coordinating separate work done on a background thread versus on the UI thread. Moreover, Android itself allocates and removes that background thread. And, it maintains a small work queue, further accentuating the “fire and forget” feel to AsyncTask.

The Theory

Theodore Levitt is quoted as saying, with respect to marketing: “People don’t want to buy a quarter-inch drill, they want a quarter-inch hole”. Hardware stores cannot sell holes, so they sell the next-best thing: devices (drills and drill bits) that make creating holes easy.

Similarly, many Android developers who have struggled with background thread management do not want background threads — they want work to be done off the UI thread, to avoid jank. And while Android cannot magically cause work to not

consume UI thread time, Android can offer things that make such background operations easier and more transparent. AsyncTask is one such example.

To use AsyncTask, you must:

1. Create a subclass of AsyncTask
2. Override one or more AsyncTask methods to accomplish the background work, plus whatever work associated with the task that needs to be done on the UI thread (e.g., update progress)
3. When needed, create an instance of the AsyncTask subclass and call `execute()` to have it begin doing its work

What you do *not* have to do is:

1. Create your own background thread
2. Terminate that background thread at an appropriate time
3. Call all sorts of methods to arrange for bits of processing to be done on the UI thread

AsyncTask, Generics, and Varargs

Creating a subclass of AsyncTask is not quite as easy as, say, implementing the Runnable interface. AsyncTask uses generics, and so you need to specify three data types:

1. The type of information that is needed to process the task (e.g., URLs to download)
2. The type of information that is passed within the task to indicate progress
3. The type of information that is passed when the task is completed to the post-task code

What makes this all the more confusing is that the first two data types are actually used as varargs, meaning that an array of these types is used within your AsyncTask subclass.

This should become clearer as we work our way towards an example.

The Stages of AsyncTask

There are four methods you can override in AsyncTask to accomplish your ends.

DEALING WITH THREADS

The one you must override, for the task class to be useful, is `doInBackground()`. This will be called by `AsyncTask` on a background thread. It can run as long as it needs to in order to accomplish whatever work needs to be done for this specific task. Note, though, that tasks are meant to be finite – using `AsyncTask` for an infinite loop is not recommended.

The `doInBackground()` method will receive, as parameters, a `varargs` array of the first of the three data types listed above — the data needed to process the task. So, if your task's mission is to download a collection of URLs, `doInBackground()` will receive those URLs to process.

The `doInBackground()` method must return a value of the third data type listed above — the result of the background work.

You may wish to override `onPreExecute()`. This method is called, from the UI thread, before the background thread executes `doInBackground()`. Here, you might initialize a `ProgressBar` or otherwise indicate that background work is commencing.

Also, you may wish to override `onPostExecute()`. This method is called, from the UI thread, after `doInBackground()` completes. It receives, as a parameter, the value returned by `doInBackground()` (e.g., success or failure flag). Here, you might dismiss the `ProgressBar` and make use of the work done in the background, such as updating the contents of a list.

In addition, you may wish to override `onProgressUpdate()`. If `doInBackground()` calls the task's `publishProgress()` method, the object(s) passed to that method are provided to `onProgressUpdate()`, but in the UI thread. That way, `onProgressUpdate()` can alert the user as to the progress that has been made on the background work. The `onProgressUpdate()` method will receive a `varargs` of the second data type from the above list — the data published by `doInBackground()` via `publishProgress()`.

A Sample Task

As mentioned earlier, implementing an `AsyncTask` is not quite as easy as implementing a `Runnable`. However, once you get past the generics and `varargs`, it is not too bad.

To see an `AsyncTask` in action, this section will examine the [Threads/AsyncTask](#) sample project.

The Fragment and its AsyncTask

We have a ListFragment, named AsyncDemoFragment:

```
package com.commonware.android.async;

import android.app.ListFragment;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.AdapterView;
import android.widget.Toast;
import java.util.ArrayList;

public class AsyncDemoFragment extends ListFragment {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private ArrayList<String> model=new ArrayList<String>();
    private ArrayAdapter<String> adapter=null;
    private AddStringTask task=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setRetainInstance(true);

        task=new AddStringTask();
        task.execute();

        adapter=
            new ArrayAdapter<String>(getActivity(),
                android.R.layout.simple_list_item_1,
                model);
    }

    @Override
    public void onViewCreated(View v, Bundle savedInstanceState) {
        super.onViewCreated(v, savedInstanceState);

        getListView().setScrollbarFadingEnabled(false);
        setListAdapter(adapter);
    }

    @Override
    public void onDestroy() {
        if (task != null) {
            task.cancel(false);
        }

        super.onDestroy();
    }

    class AddStringTask extends AsyncTask<Void, String, Void> {
```

```
@Override
protected Void doInBackground(Void... unused) {
    for (String item : items) {
        if (isCancelled())
            break;

        publishProgress(item);
        SystemClock.sleep(400);
    }

    return(null);
}

@Override
protected void onProgressUpdate(String... item) {
    if (!isCancelled()) {
        adapter.add(item[0]);
    }
}

@Override
protected void onPostExecute(Void unused) {
    Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
        .show();

    task=null;
}
}
```

This is another variation on the *lorem ipsum* list of words, used frequently throughout this book. This time, rather than simply hand the list of words to an ArrayAdapter, we simulate having to work to create these words in the background using AddStringTask, our AsyncTask implementation.

In onCreate(), we call setRetainInstance(true), so Android will retain this fragment across configuration changes, such as a screen rotation. Since our fragment is being newly created, we initialize our model to be an ArrayList of String values, plus kick off our AsyncTask (the AddStringTask inner class, described below), saving the AddStringTask in a task data member. Then, in onCreateView(), we set up the adapter and attach it to the ListView, also preventing the ListView scrollbars from fading away as is their norm.

In the declaration of AddStringTask, we use the generics to set up the specific types of data we are going to leverage. Specifically:

1. We do not need any configuration information in this case, so our first type is Void

DEALING WITH THREADS

2. We want to pass each string “generated” by our background task to `onProgressUpdate()`, so we can add it to our list, so our second type is `String`
3. We do not have any results, strictly speaking (beyond the updates), so our third type is `Void`

The `doInBackground()` method is invoked in a background thread. Hence, we can take as long as we like. In a production application, we would be, perhaps, iterating over a list of URLs and downloading each. Here, we iterate over our static list of *lorem ipsum* words, call `publishProgress()` for each, and then sleep 400 milliseconds to simulate real work being done. We also call `isCancelled()` on each pass, to see if our task has been cancelled, skipping the work if it has so we can clean up this background thread.

Since we elected to have no configuration information, we should not need parameters to `doInBackground()`. However, the contract with `AsyncTask` says we need to accept a varargs of the first data type, which is why our method parameter is `Void...`

Since we elected to have no results, we should not need to return anything. Again, though, the contract with `AsyncTask` says we have to return an object of the third data type. Since that data type is `Void`, our returned object is `null`.

The `onProgressUpdate()` method is called on the UI thread, and we want to do something to let the user know we are progressing on loading up these strings. In this case, we simply add the string to the `ArrayAdapter`, so it gets appended to the end of the list. However, we only do this if we have not already been canceled.

The `onProgressUpdate()` method receives a `String... varargs` because that is the second data type in our class declaration. Since we are only passing one string per call to `publishProgress()`, we only need to examine the first entry in the varargs array.

The `onPostExecute()` method is called on the UI thread, and we want to do something to indicate that the background work is complete. In a real system, there may be some `ProgressBar` to dismiss or some animation to stop. Here, we simply raise a `Toast` and set `task` to `null`. We do not need to worry about calling `isCancelled()`, because `onPostExecute()` will not be invoked if our task has been cancelled.

DEALING WITH THREADS

Since we elected to have no results, we should not need any parameters. The contract with `AsyncTask` says we have to accept a single value of the third data type. Since that data type is `Void`, our method parameter is `Void` unused.

To use `AddStringTask`, we simply create an instance and call `execute()` on it. That starts the chain of events eventually leading to the background thread doing its work.

If `AddStringTask` required configuration parameters, we would have not used `Void` as our first data type, and the constructor would accept zero or more parameters of the defined type. Those values would eventually be passed to `doInBackground()`.

Our fragment also has an `onDestroy()` method that calls `cancel()` on the `AsyncTask` if it is still outstanding (`task` is not `null`). This work of cancelling the task and checking to see if the task is cancelled exists for two reasons:

1. Efficiency, as we should skip any serious work that is not needed if our task itself is not needed
2. To avoid a crash if we attempt to raise a `Toast` on a destroyed activity, such as the user launching the activity, then pressing `BACK` before we complete the background work and display the `Toast`

The Activity and the Results

`AsyncDemo` is an `Activity` with the standard recipe for kicking off an instance of a dynamic fragment:

```
package com.commonware.android.async;

import android.app.Activity;
import android.os.Bundle;

public class AsyncDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new AsyncDemoFragment()).commit();
        }
    }
}
```

If you build, install, and run this project, you will see the list being populated in “real time” over a few seconds, followed by a Toast indicating completion.

Threads and Configuration Changes

One problem with the default destroy-and-create cycle that activities go through on a configuration change comes from background threads. If the activity has started some background work — through an `AsyncTask`, for example — and then the activity is destroyed and re-created, somehow the `AsyncTask` needs to know about this. Otherwise, the `AsyncTask` might well send updates and final results to the *old* activity, with the new activity none the wiser. In fact, the new activity might start up the background work *again*, wasting resources.

That is why, in the sample above, we are retaining the fragment instance. The fragment instance holds onto its data model (in this case, the `ArrayList` of Latin words) and knows not to kick off a new `AsyncTask` just because the configuration changed. Moreover, we retain that data model, so the new `ListView` created due to the configuration change can work with a new adapter backed by the old data model, so we do not lose our existing set of Latin words.

We also have to be very careful not to try referring to the activity (via `getActivity()` on the fragment) from our background thread (`doInBackground()`). Because, suppose that during the middle of the `doInBackground()` processing, the user rotates the screen. The activity we work with will change on the fly, on the main application thread, independently of the work being done in the background. The activity returned by `getActivity()` may not be in a useful state for us while this configuration change is going on.

However, it is safe for us to use `getActivity()` from `onPostExecute()`, and even from `onProgressUpdate()`. For those callbacks, either the configuration change has not yet happened, or it has been completed — we will not be in the middle of the change.

Where Not to Use `AsyncTask`

`AsyncTask`, particularly in conjunction with a dynamic fragment, is a wonderful solution for most needs for a background thread.

The key word in that sentence is “most”.

AsyncTask manages a thread pool, from which it pulls the threads to be used by task instances. Thread pools assume that they will get their threads back after a reasonable period of time. Hence, AsyncTask is a poor choice when you do not know how long you need the thread (e.g., thread listening on a socket for a chat client, where you need the thread until the user exits the client).

About the AsyncTask Thread Pool

Moreover, the thread pool that AsyncTask manages has varied in size.

In Android 1.5, it was a single thread.

In Android 1.6, it was expanded to support many parallel threads, probably more than you will ever need.

In Android 3.2, it has shrunk back to a single thread, if your `android:targetSdkVersion` is set to 13 or higher. This was to address concerns about:

- Forking too many threads and starving the CPU
- Developers thinking that there is an ordering dependency between forked tasks, when with the parallel execution there is none

If you wish, starting with API Level 11, you can supply your own Executor (from the `java.util.concurrent` package) that has whatever thread pool you wish, so you can manage this more yourself. In addition to the serialized, one-at-a-time Executor, there is a built-in Executor that implements the old thread pool, that you can use rather than rolling your own.

If your `minSdkVersion` is 11 or higher, use `executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR)` if you specifically want to opt into a multi-thread thread pool. If your `minSdkVersion` is below 11, you will still want to do that... but only on API Level 11+ devices, falling back to `execute()` on the older devices. This static utility method handles this for you:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)
static public <T> void executeAsyncTask(AsyncTask<T, ?, ?> task,
                                       T... params) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        task.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, params);
    }
    else {
        task.execute(params);
    }
}
```

```
}  
}
```

To use this, call `executeAsyncTask()`, passing in your `AsyncTask` instance and the parameters you would ordinarily have passed to `execute()`.

An explanation of what we are doing here, in terms of the `@TargetApi` annotation and such, will come [later in the book](#).

Also note that the number of threads in the multiple-thread thread pool has *also* changed over the years. Originally, that pool could climb to as many as 128 threads, which was far too many. As of Android 4.4, [the thread pool will only grow to “the number of CPU cores * 2 + 1”](#), so on a dual-core device, the thread pool will cap at 5 threads. Further tasks will be queued, up to a maximum of 128 queued tasks.

Alternatives to AsyncTask

There are other ways of handling background threads without using `AsyncTask`:

- You can employ a `Handler`, which has a `handleMessage()` method that will process `Message` objects, dispatched from a background thread, on the main application thread
- You can supply a `Runnable` to be executed on the main application thread to `post()` on any `View`, or to `runOnUiThread()` on `Activity`
- You can supply a `Runnable`, plus a delay period in milliseconds, to `postDelayed()` on any `View`, to run the `Runnable` on the main application thread after *at least* that number of millisecond has elapsed

Of these, the `Runnable` options are the easiest to use.

These can also be used to allow the main application thread to postpone work, to be done *later* on the main application thread. For example, you can use `postDelayed()` to set up a lightweight polling “loop” within an activity, without needing the overhead of an extra thread, such as the one created by `Timer` and `TimerTask`. To see how this works, let’s take a peek at the [Threads/PostDelayed](#) sample project.

This project contains a single activity, named `PostDelayedDemo`:

```
package com.commonware.android.post;  
  
import android.app.Activity;  
import android.os.Bundle;  
import android.view.View;
```

DEALING WITH THREADS

```
import android.widget.Toast;

public class PostDelayedDemo extends Activity implements Runnable {
    private static final int PERIOD=5000;
    private View root=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
        root=findViewById(android.R.id.content);
    }

    @Override
    public void onResume() {
        super.onResume();

        run();
    }

    @Override
    public void onPause() {
        root.removeCallbacks(this);

        super.onPause();
    }

    @Override
    public void run() {
        Toast.makeText(PostDelayedDemo.this, "Who-hoo!", Toast.LENGTH_SHORT)
            .show();
        root.postDelayed(this, PERIOD);
    }
}
```

We want to display a Toast every five seconds. To do this, in `onCreate()`, we get our hands on the container for an activity's UI, known as `android.R.id.content`, via `findViewById()`. Then, in `onResume()`, we call a `run()` method on our activity, which displays the Toast and calls `postDelayed()` to schedule *itself* (as an implementation of `Runnable`) to be run again in `PERIOD` milliseconds. While our activity is in the foreground, the Toast will appear every `PERIOD` milliseconds as a result. Once something else comes to the foreground — such as by the user pressing `BACK` — our `onPause()` method is called, where we call `removeCallbacks()` to “undo” the `postDelayed()` call.

And Now, The Caveats

Background threads, while eminently possible using `AsyncTask` and kin, are not all happiness and warm puppies. Background threads not only add complexity, but they have real-world costs in terms of available memory, CPU, and battery life.

To that end, there is a wide range of scenarios you need to account for with your background thread, including:

1. The possibility that users will interact with your activity's UI while the background thread is chugging along. If the work that the background thread is doing is altered or invalidated by the user input, you will need to communicate this to the background thread. Android includes many classes in the `java.util.concurrent` package that will help you communicate safely with your background thread.
2. The possibility that the process will be terminated while your work is still going on. This is why in many cases, rather than use an `AsyncTask` or a bare `Thread`, you will wind up using a `Service`, such as an `IntentService`. This will be explored in greater detail [later in this book](#).
3. The possibility that your user will get irritated if you chew up a lot of CPU time and battery life without giving any payback. Tactically, this means using `ProgressBar` or other means of letting the user know that something is happening. Strategically, this means you still need to be efficient at what you do — background threads are no panacea for sluggish or pointless code.
4. The possibility that you will encounter an error during background processing. For example, if you are gathering information off the Internet, the device might lose connectivity. Alerting the user of the problem via a `Notification` and shutting down the background thread may be your best option.

Event Buses

Event-driven programming has been around for nearly a quarter-century. Much of Android's UI model is event-driven, where we find out about these events via callbacks (e.g., `onCreate()` for the “start an activity” event) and registered listeners (e.g., `OnClickListener` for when the user taps on a widget).

However, originally, Android did not have a very fine-grained event or message bus implementation that we as developers could use. The `Intent` system works like a message bus, but it is aimed at inter-process communication (IPC) as much as in-process communication, and that comes with some costs.

However, over time, particularly starting in 2012, event buses started to pop up, and these are very useful for organizing communication within your Android application and across threads. Used properly, an event bus can eliminate the need for `AsyncTask` and the other solutions for communicating back to the main application

thread, while simultaneously helping you logically decouple independent pieces of your code.

What Is an Event Bus?

Whether you consider it an “event bus” (or “message bus”), the “publisher/subscriber” (or “pub/sub”) pattern, or a subset of the “observer” pattern, the programming model where components produce events that others consume is reasonably common in modern software development.

An event bus is designed to decouple the sources of events from the consumers of those events. Or, [as one event bus author put it](#):

I want an easy, centralized way to notify code that’s interested in specific types of events when those events occur without any direct coupling between the code the publishes an event and the code that receives it.

With the traditional Java listener or observer pattern implementation, the component producing an event needs direct access to consumers of that event. Sometimes, that list of consumers is limited to a single consumer, as with many event handlers associated with Android widgets (e.g., just one `OnClickListener`). But this source-holds-the-sinks coding pattern limits flexibility, as it requires explicit registration by consumers with producers of events, and it may not be that easy for the consumer to *reach* the producer. Furthermore, such direct connections are considered to be a relatively strong coupling between those components, and often times our objective is to have looser coupling.

An event bus provides a standard communications channel (or “bus”) that event producers and event consumers can hook into. Event producers merely need to hand the event to the bus; the bus will handle directing those events to relevant consumers. This reduces the coupling between the producers and consumers, sometimes even reducing the amount of code needed to source and sink these events.

OK, But Why Are We Bothering With This?

Later on, we are going to have components other than our activities. In particular, we will have [services](#), which are designed to run briefly in the background to perform some operation. Just as communications between activities tends to be loosely coupled, so too are communications between activities and services. An

event bus is a great way for the service to let other pieces of the app know that certain work was done (e.g., “the download is complete, so update the UI”).

In the short term, we will use an event bus to have a [model fragment](#) let the app know that some data was loaded. In the tutorials, “some data” will be the book contents; in the sample app illustrated in this chapter, “some data” will be some Latin words.

Introducing greenrobot’s EventBus

The event bus implementation that we will be using in the tutorials is [greenrobot’s EventBus](#), an open source implementation based on the Guava project’s event bus. With greenrobot’s EventBus, it is fairly easy to send a message from one part of your app to another disparate part of your app.

To illustrate its use, take a look at the [EventBus/AsyncDemo](#) sample project. This is a reworking of a previous example that used an AsyncTask to pretend to download our list of Latin words, populating a ListView with those words as they arrive. This sample replaces the AsyncTask with a model fragment that will keep track of the words and a background thread that will “download” the words. We will use events raised by the model fragment to let the UI fragment know words as they arrive.

Defining Events

With greenrobot’s EventBus, the “events” are objects of arbitrary classes that you define. Each different class represents a different type of event, and you can define as many different event classes as you wish. Those classes do not need to inherit from any special base class, or implement some special interface, or have any magic annotations. They are just classes.

You may wish to put data members, constructors, and accessor methods on the event classes, for any data you wish to pass around specific to the event itself. A SearchEvent, for example, might include the search query string as part of the event object.

In our case, we have a WordReadyEvent that contains the new word:

```
package com.commonware.android.eventbus;

class WordReadyEvent {
    private String word;
```

DEALING WITH THREADS

```
WordReadyEvent(String word) {
    this.word=word;
}

String getWord() {
    return(word);
}
}
```

Posting Events

To post an event, all you need to do is obtain an instance of an EventBus – typically via the `getDefault()` method on EventBus — and call `post()` on it, passing in the event to be delivered to any interested party within your app.

With that in mind, let's look at the `ModelFragment` that will be loading in our words:

```
package com.commonware.android.eventbus;

import android.app.Fragment;
import android.os.Bundle;
import android.os.SystemClock;
import java.util.ArrayList;
import java.util.Collections;
import java.util.List;
import de.greenrobot.event.EventBus;

public class ModelFragment extends Fragment {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private List<String> model=
        Collections.synchronizedList(new ArrayList<String>());
    private boolean isStarted=false;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setRetainInstance(true);

        if (!isStarted) {
            isStarted=true;
            new LoadWordsThread().start();
        }
    }

    public ArrayList<String> getModel() {
        return(new ArrayList<String>(model));
    }

    class LoadWordsThread extends Thread {
        @Override
```

```
public void run() {
    for (String item : items) {
        if (!isInterrupted()) {
            model.add(item);
            EventBus.getDefault().post(new WordReadyEvent(item));
            SystemClock.sleep(400);
        }
    }
}
```

This fragment has no UI — it exists solely to manage a data model on behalf of the rest of the hosting activity. Hence, there is no `onCreateView()` or any other UI logic directly in this fragment.

In `onCreate()`, we call `setRetainInstance(true)`, so that if the user rotates the screen or otherwise triggers a configuration change, our model fragment will survive the change and be attached to the new activity instance. Then, if we have not already started the `LoadWordsThread`, we do so. `LoadWordsThread` iterates over our list of words, sleeps for 400ms to simulate doing real work, adds each word to an `ArrayList` of words that it manages... and calls `post()` to raise a `WordReadyEvent` to let something else know that the model has changed.

Receiving Events

To receive posted events, you need to do three things:

1. Call `register()` on the `EventBus` to tell it that you have an object that wants to receive events
2. Call `unregister()` on the `EventBus` to tell it to stop delivering events to a previously-registered object
3. Implement `onEventMainThread()`, or other `onEvent()` method flavors, to indicate the type of event you want to receive (and to actually process those events)

This sample app has an `AsyncDemoFragment` that performs those three steps:

```
package com.commonware.android.eventbus;

import android.app.Activity;
import android.app.ListFragment;
import android.os.Bundle;
import android.view.View;
import android.widget.ArrayAdapter;
import java.util.ArrayList;
import de.greenrobot.event.EventBus;
```

DEALING WITH THREADS

```
public class AsyncDemoFragment extends ListFragment {
    private ArrayAdapter<String> adapter=null;
    private ArrayList<String> model=null;

    @Override
    public void onCreateView(View view, Bundle savedInstanceState) {
        adapter=
            new ArrayAdapter<String>(getActivity(),
                android.R.layout.simple_list_item_1,
                model);

        listView().setScrollbarFadingEnabled(false);
        setListAdapter(adapter);
    }

    @Override
    public void onAttach(Activity activity) {
        super.onAttach(activity);

        EventBus.getDefault().register(this);
    }

    @Override
    public void onDetach() {
        EventBus.getDefault().unregister(this);

        super.onDetach();
    }

    public void onEventMainThread(WordReadyEvent event) {
        adapter.add(event.getWord());
    }

    public void setModel(ArrayList<String> model) {
        this.model=model;
    }
}
```

The fragment starts by overriding `onViewCreated()`, where we create an `ArrayAdapter` and use that to populate the `ListView`.

The `onAttach()` and `onDetach()` methods are where we indicate to the `EventBus` that this fragment object wants to receive relevant posted events. `onAttach()` calls `register()`; `onDetach()` calls `unregister()`.

The `onEventMainThread()` method, via its parameter, indicates that we are interested in `WordReadyEvents` as they are raised. Our `onEventMainThread()` method will be called for each `WordReadyEvent` passed to `post()` on the `EventBus`. As the method name suggests, `onEventMainThread()` is called on the main application thread, so it is safe for us to update our UI. `greenrobot's EventBus` is responsible for getting this event to the main application thread — note that we are posting the event from the `LoadWordsThread`, which is a background thread.

DEALING WITH THREADS

In `onEventMainThread()`, we get the newly-added word, which we can add to our `ArrayAdapter`. `add()` on `ArrayAdapter` appends the word to the end of the list and informs the attached `ListView` that the data changed, so the `ListView` can redraw itself.

What is not obvious, though, from the code in this class is how we are getting the model that we are using in `onViewCreated()`. `AsyncDemoFragment` has its own `ArrayList` of words, set via the `setModel()` method. Our `ArrayAdapter` is wrapped around this model. But the master copy of the words is being held by the `ModelFragment`. If the `ModelFragment` has the model, and the `AsyncDemoFragment` needs the model, how are the two being connected?

The Activity

That is handled by our hosting activity, as it sets up these two fragments:

```
package com.commonware.android.eventbus;

import android.app.Activity;
import android.app.FragmentManager;
import android.app.FragmentTransaction;
import android.os.Bundle;

public class AsyncDemo extends Activity {
    private static final String MODEL_TAG="model";
    private ModelFragment mFrag=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        FragmentManager mgr=getFragmentManager();
        FragmentTransaction trans=mgr.beginTransaction();

        mFrag=(ModelFragment)mgr.findFragmentByTag(MODEL_TAG);

        if (mFrag == null) {
            mFrag=new ModelFragment();
            trans.add(mFrag, MODEL_TAG);
        }

        AsyncDemoFragment demo=
            (AsyncDemoFragment)mgr.findFragmentById(android.R.id.content);

        if (demo == null) {
            demo=new AsyncDemoFragment();
            trans.add(android.R.id.content, demo);
        }

        demo.setModel(mFrag.getModel());

        if (!trans.isEmpty()) {
```

```
        trans.commit();
    }
}
```

In `onCreate()`, we first see if we already have an instance of our model fragment, held by the `FragmentManager` under a `MODEL_TAG` tag. If not, we create an instance of the `ModelFragment` and add it to the `FragmentManager`, under that tag, via a `FragmentTransaction`.

We then see if we already have an instance of our `AsyncDemoFragment`. If not, we create one and add it to the `FragmentManager`, pouring its UI into `android.R.id.content`, via another `FragmentTransaction`.

Then, we connect the two, calling `getModel()` on the `ModelFragment` and handing the result to `setModel()` on the `AsyncDemoFragment`.

When our activity is newly launched, neither fragment exists. Both fragments are created, and the `AsyncDemoFragment` gets its model array from the `ModelFragment`. That array is initially empty. As the `ModelFragment` adds elements to the array, it posts the `WordReadyEvent`, which triggers the `AsyncDemoFragment` to tell the `ArrayAdapter` and `ListView` that the model data changed.

If we undergo a configuration change, the `ModelFragment` is retained, but the `AsyncDemoFragment` is not. Hence, the activity will always be creating an `AsyncDemoFragment`. But the model we give to the `AsyncDemoFragment` may already have words in it, and those words will appear immediately when the `ArrayAdapter` is wrapped around the model. If the `LoadWordsThread` is still running, the new `AsyncDemoFragment` will pick up any new `WordReadyEvents` that are raised, triggering it to update the `ListView` as before.

Visit the Trails!

We will cover much more about jank, and how to detect and diagnose it, [in a later chapter](#).

There are many more features in the greenrobot `EventBus` implementation. We will see some of those, plus other event bus implementations, in a later chapter on [event bus alternatives](#).

Requesting Permissions

In the late 1990's, a wave of viruses spread through the Internet, delivered via email, using contact information culled from Microsoft Outlook. A virus would simply email copies of itself to each of the Outlook contacts that had an email address. This was possible because, at the time, Outlook did not take any steps to protect data from programs using the Outlook API, since that API was designed for ordinary developers, not virus authors.

Nowadays, many applications that hold onto contact data secure that data by requiring that a user explicitly grant rights for other programs to access the contact information. Those rights could be granted on a case-by-case basis or all at once at install time.

Android is no different, in that it requires permissions for applications to read or write contact data. Android's permission system is useful well beyond contact data, and for content providers and services beyond those supplied by the Android framework.

You, as an Android developer, will frequently need to ensure your applications have the appropriate permissions to do what you want to do with other applications' data. This chapter covers this topic, both the classic approach used for all permissions prior to Android 6.0 and the new runtime permission system used for certain permissions in Android 6.0+.

You may also elect to require permissions for other applications to use your data or services, if you make those available to other Android components. This will be discussed [later in this book](#).

Frequently-Asked Questions About Permissions

Permissions are occasionally a confusing topic in Android app development, more so now that Android 6.0 has arrived and has changed the permission system a fair bit. Here are some common questions about permissions to help get us started.

What Is a Permission?

A permission is a way for Android (or, sometimes, a third-party app) to require an app developer to notify the user about something that the app will do that might raise concerns with the user. Only if an app holds a certain permission can the app do certain things that are defended by that permission.

Mechanically, permissions take the form of elements in the manifest. Right now, we are focusing on requesting and holding permissions, and so we will be working with the `<uses-permission>` element.

When Will I Need a Permission?

Most permissions that you will deal with come from Android itself. Usually, the documentation will tell you when you need to request and hold one of these permissions.

However, occasionally the documentation has gaps.

If you are trying out some code and you crash with a `SecurityException` the description of the exception may tell you that you need to hold a certain permission — that means you need to add the corresponding `<uses-permission>` element to your manifest.

Third-party code, including Google's own Play Services SDK, may define their own custom permissions. Once again, ideally, you find out that you need to request a permission through documentation, and otherwise you find out through crashing during testing.

What Are Some Common Permissions, and What Do They Defend?

There are dozens upon dozens of permissions in Android. Here are some of the permissions we will see in this book:

REQUESTING PERMISSIONS

- INTERNET, if your application wishes to access the Internet through any means from your own process, using anything from raw Java sockets through the WebView widget
- WRITE_EXTERNAL_STORAGE, for writing data to external storage
- ACCESS_COARSE_LOCATION and ACCESS_FINE_LOCATION, for determining where the device is
- READ_CONTACTS, to get at personally-identifying information of arbitrary contacts that the user has in their Contacts app

In this book and in casual conversation, we refer to the permissions using the unique portion of their name (e.g., INTERNET). Really, the full name of the permission will usually have `android.permission.` as a prefix (e.g., `android.permission.INTERNET`), for Android-defined permissions. Custom permissions from third-party apps should use a different prefix. You will need the full permission name, including the prefix, in your manifest entries.

How Do I Request a Permission?

Put a `<uses-permission>` element in your manifest, as a direct child of the root `<manifest>` element (i.e., as a peer element of `<application>`), with an `android:name` attribute identifying the permission that you are interested in.

For example, here is a sample manifest, with a request to hold the `WRITE_EXTERNAL_STORAGE` permission:

```
<?xml version="1.0"?>
<manifest package="com.commonware.android.fileseditor"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission
    android:name="android.permission.WRITE_EXTERNAL_STORAGE"
    android:maxSdkVersion="18"/>

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>

  <application
    android:icon="@drawable/ic_launcher"
    android:theme="@style/Theme.Apptheme"
    android:label="@string/app_name">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
```

REQUESTING PERMISSIONS

```
<intent-filter>
  <action android:name="android.intent.action.MAIN"/>

  <category android:name="android.intent.category.LAUNCHER"/>
</intent-filter>
</activity>
</application>
</manifest>
```

This is sufficient for most permissions and most devices. Permissions considered to be dangerous need special attention on Android 6.0+, and we will cover that in grand detail [later in this chapter](#).

Note that you are welcome to have zero, one, or several such `<uses-permission>` elements. Also note that some libraries that you elect to use might add their own `<uses-permission>` elements to your manifest, through a process called [“manifest merger”](#).

When Is the User Informed About These Permissions?

Well, that gets complicated. It depends on the permission, the version of Android the user is using, from where the user is installing the app, and the phase of the moon.

(well, OK, not really that last one)

Installing Through SDK Tools

Anyone who installs an app using Android Studio will not be prompted for permissions. The same holds true for anyone using anything else based on the Android SDK tools — while the app may request permissions, the user is not prompted for them, and the permissions are granted.

(Android 6.0+ and dangerous permissions change this up a bit – more on that [later in this chapter](#))

Installing from the Play Store, Android 5.1 and Older

If the user is running an Android 5.1 or older device, and the user goes to install your app from the Play Store, the user will be presented with a roster of permission groups that contain permissions that you are requesting and that are considered to be dangerous:

REQUESTING PERMISSIONS

Figure 223: Permission Confirmation Screen, on Play Store Web Site

We will discuss more about permission groups and this dangerous concept [later in this chapter](#).

Installing from the Play Store, Android 6.0+

On Android 6.0 and higher, when the user installs your app from the Play Store, what happens depends upon the value of `targetSdkVersion` for your app.

If your `targetSdkVersion` is 22 or lower, you get the same behavior as is described above, where the user sees the list of permission groups which contain permissions that you are requesting and that are considered to be dangerous.

If your `targetSdkVersion` is 23 or higher, the user is not prompted about permissions at install time. Instead these prompts will occur when the user runs your app and when you ask the user for the permissions, as we will see [later in this chapter](#).

Installing by Other Means, Android 5.1 and Older

If you install an app on Android 5.1 or older, by any means (e.g., downloading from a Web site), you will be prompted with a list of all requested permissions:

REQUESTING PERMISSIONS

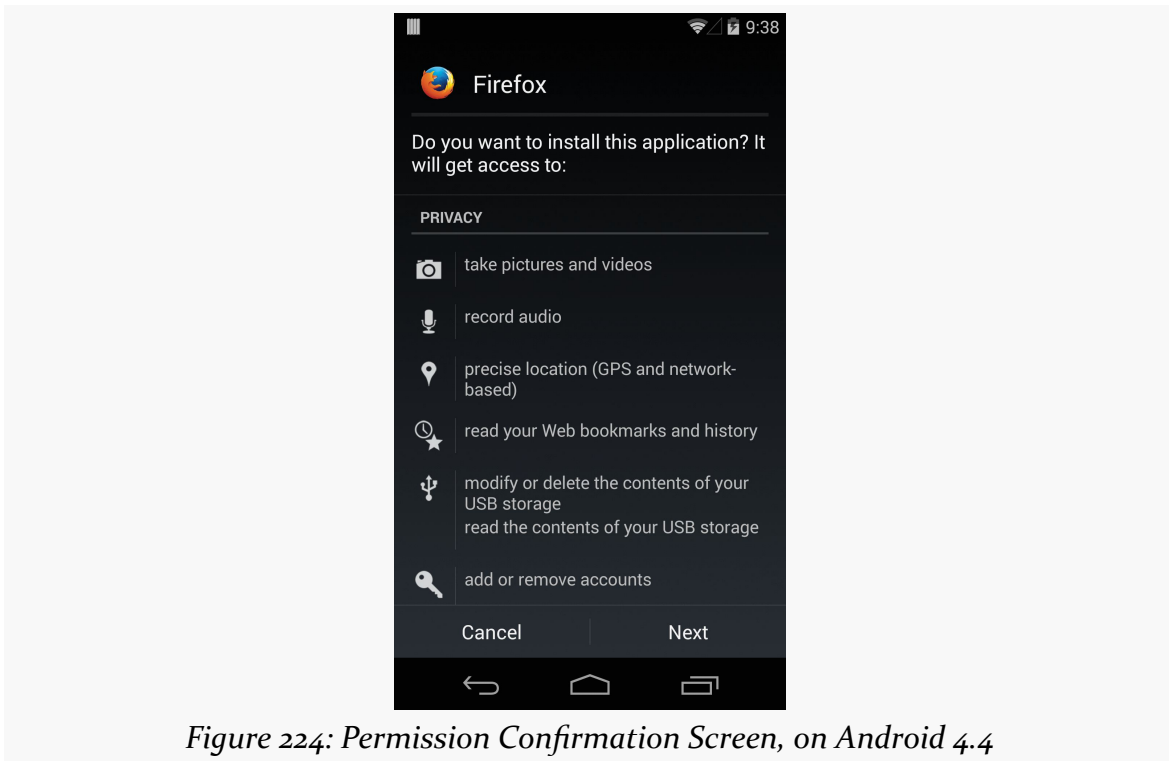

Figure 224: Permission Confirmation Screen, on Android 4.4

Note that this prompt will not appear until you actually have downloaded the app and have begun the installation process. Before then, the device cannot examine the manifest inside the APK file to find the permissions.

Installing by Other Means, Android 6.0+

If your app's `targetSdkVersion` is 23 or higher, and you install the app on an Android 6.0+ device by other means than the Play Store, you will not be prompted about any permissions at install time:

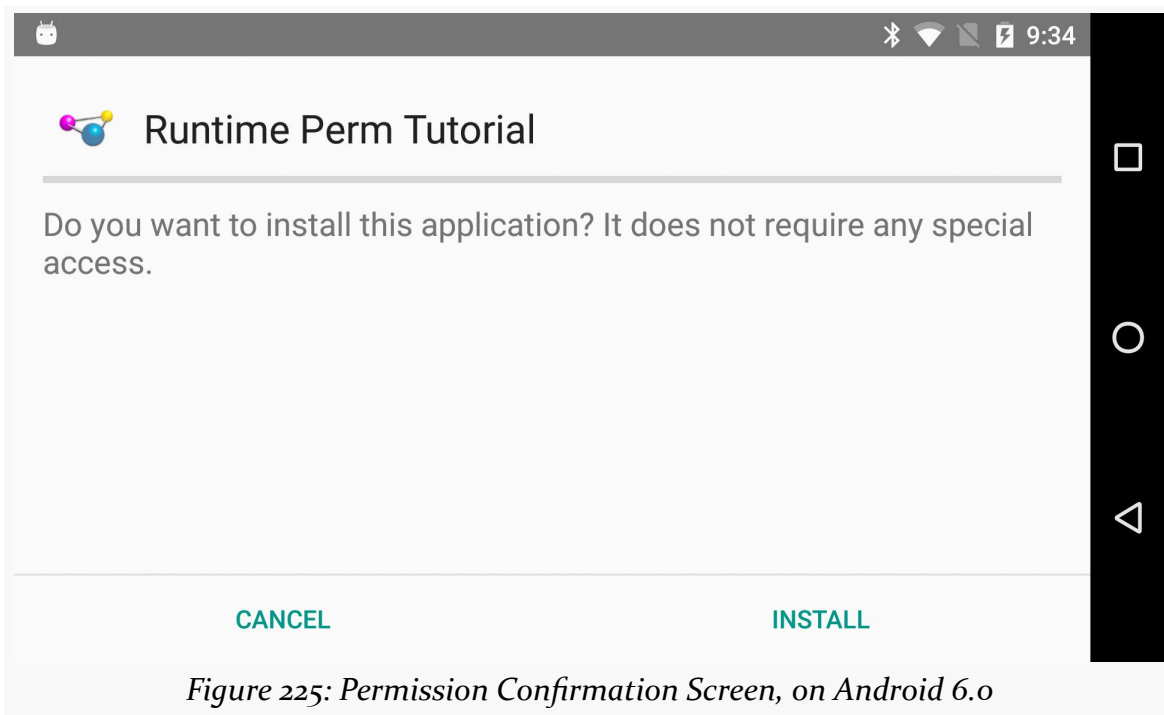

Figure 225: Permission Confirmation Screen, on Android 6.0

Characteristics of Permissions

Several bits of information make up a permission, and some of those affect app developers or users.

Name

We have already seen that permissions have names, and you use them in the `android:name` attribute of the `<uses-permission>` element to identify a permission that you would like your app to hold.

Android framework-defined permissions will begin with `android.permission`. Permissions from libraries or third-party apps will have some other prefix. Make sure that when you create your `<uses-permission>` element that you are using the *fully-qualified* permission name, including `android.permission` or any other prefix.

Also note that Android is case-sensitive, so make sure you use the case of the permission as documented (e.g., `android.permission.INTERNET`). Some versions of Android Studio had a bug where if you let the IDE auto-complete a `<uses-permission>` element for you, sometimes it would have the `android:name`

value appear IN ALL CAPS. This is a bug that has since been fixed, so hopefully it will not affect you in the future.

Protection Level

The definition of a permission, in the framework or in third-party code, will have a “protection level”. This describes how the permission itself should be validated. There are two protection levels that you will encounter most often are `normal` and `dangerous`.

Normal

A `normal` permission is something that the user *might* care about, but probably not. So, while we need to request the permission in the manifest via `<uses-permission>`, the user will not be bothered about this permission at install time.

The classic example is the `INTERNET` permission. Most Android apps wind up requesting this permission, either for functionality written by the developers or functionality pulled in from libraries (e.g., ad banners). `INTERNET` is considered `normal`, so while we need to request the `INTERNET` permission in the manifest, the user is not informed about this permission anymore at install time.

(the “anymore” note is because in the early days of Android, users were informed about all permissions, regardless of protection level)

Users can see `normal` permissions, though, in other places:

- the list of permissions shown on the Play Store when clicking on a “Permissions” link
- the list of permissions shown in Settings for an app
- third-party tools that help the user understand what capabilities are available to the apps that the user has installed

Dangerous

A `dangerous` permission is one that the definers of the permission (e.g., Google) wants to ensure that the user is aware of and has agreed to.

REQUESTING PERMISSIONS

Classically, this meant that the user would be prompted for this permission at install time. On old versions of Android and the Play Store, dangerous permissions would be listed before normal permissions.

With Android 6.0+, while dangerous permissions are not displayed at install time (for apps with a `targetSdkVersion` of 23 or higher), they will be displayed to the user while the app is running, before the app tries doing something that requires one of those permissions. This is a significant behavior change, so we will be covering it in depth [later in this chapter](#).

Permission Group

Permissions are collected into permission groups.

In the early days of Android, app developers were oblivious to this, as permission groups had no effect on app development, runtime behavior, or user experience.

In the past few years, the “permission” prompts at install time have really been prompting about permission groups. The user is told that the app is requesting permissions from certain groups. Moreover, the blessing that the user gives — by virtue of continuing to install the app — is by *group*, not by permission. If some future update to the app would ask for a new permission, but one from a group that the user agreed to previously, the user would not be informed about this new permission request.

With Android 6.0, permission groups also extend to the runtime permission UX, as while we developers will still request individual permissions, the user will be asked to grant rights with respect to permission groups.

Maximum SDK Version

`<uses-permission>` can have an `android:maxSdkVersion` attribute. This indicates the highest API level for which we need the permission. If the app is running on newer versions of Android, skip the permission.

This is for cases where Android relaxes restrictions over time. We will see an example of this, in the form of the `WRITE_EXTERNAL_STORAGE` permission, in [an upcoming chapter](#).

Minimum SDK Version

You might think that `<uses-permission>` would have an `android:minSdkVersion` attribute to serve as the counterpart to `android:maxSdkVersion`. The `minSdkVersion` would indicate the lowest API level for which to request a permission; older devices would skip the permission.

Alas, this is not available.

However, there is the awkwardly-named `<uses-permission-sdk23>` element.

This element functions identically to `<uses-permission>` on Android 6.0+ devices. On older devices, it is ignored.

This element illustrates a problem with the permission system in Android: you have to put all permissions that you want in the manifest. Prior to the runtime permission system in Android 6.0, this would mean that developers who need some controversial permission (e.g., `READ_CONTACTS`) for some fringe feature would need to request the permission from *everyone*, not just those who use the feature. As we will see, the runtime permission system lets us not bother the user until they try using the secured feature. `<uses-permission-sdk23>` would allow us to not bother with the permission at all on older devices, where its presence might scare away potential users.

New Permissions in Old Applications

Sometimes, Android introduces new permissions that govern behavior that formerly did not require permissions. `WRITE_EXTERNAL_STORAGE` is one example – originally, applications could write to external storage without any permission at all. Android 1.6 introduced `WRITE_EXTERNAL_STORAGE`, required before you can write to external storage. However, applications that were written before Android 1.6 could not possibly request that permission, since it did not exist at the time. Breaking those applications would seem to be a harsh price for progress.

What Android does is “grandfather” in certain permissions for applications supporting earlier SDK versions.

For example, if your `minSdkVersion` is 3 or lower, saying that you support Android 1.5, your application will automatically request `WRITE_EXTERNAL_STORAGE` and

REQUESTING PERMISSIONS

READ_PHONE_STATE, even if you do not explicitly request those permissions. People installing your application on an Android 1.5 device will see these requests.

Eventually, when you drop support for the older version (e.g., switch to `minSdkVersion` of 4 or higher), Android will no longer automatically request those permissions. Hence, if your code really *does* need those permissions, you will need to ask for them yourself.

Android 6.0+ Runtime Permission System

In Android 6.0 and higher devices, permissions that are considered to be dangerous not only have to be requested via `<uses-permission>` elements, but you *also* have to ask the user to grant you those permissions at runtime. What you gain, though, is that users are not bothered with these permissions at install time, and you can elect to delay asking for certain permissions until such time as the user actually does something that needs them.

This section will occasionally point out snippets of code from the [Permissions/PermissionMonger](#) sample project.

Let's explore the runtime permissions system via a new series of questions.

What Permissions Are Affected By This?

There are nine permission groups that Android 6.0 manages as user-controllable permissions:

Permission Group	Permission
CALENDAR	READ_CALENDAR, WRITE_CALENDAR
CAMERA	CAMERA
CONTACTS	GET_ACCOUNTS, READ_CONTACTS, WRITE_CONTACTS
LOCATION	ACCESS_COARSE_LOCATION, ACCESS_FINE_LOCATION
MICROPHONE	RECORD_AUDIO
PHONE	ADD_VOICEMAIL, CALL_PHONE, PROCESS_OUTGOING_CALLS, READ_CALL_LOG, READ_PHONE_STATE, USE_SIP, WRITE_CALL_LOG
SENSORS	BODY_SENSORS
SMS	READ_CELL_BROADCASTS, READ_SMS, RECEIVE_SMS, RECEIVE_MMS, RECEIVE_WAP_PUSH, SEND_SMS

REQUESTING PERMISSIONS

Permission Group	Permission
STORAGE	READ_EXTERNAL_STORAGE, WRITE_EXTERNAL_STORAGE

Users will be able to revoke permissions by group, through the Settings app. They can go into the page for your app, click on Permissions, and see a list of the permission groups for which you are requesting permissions:

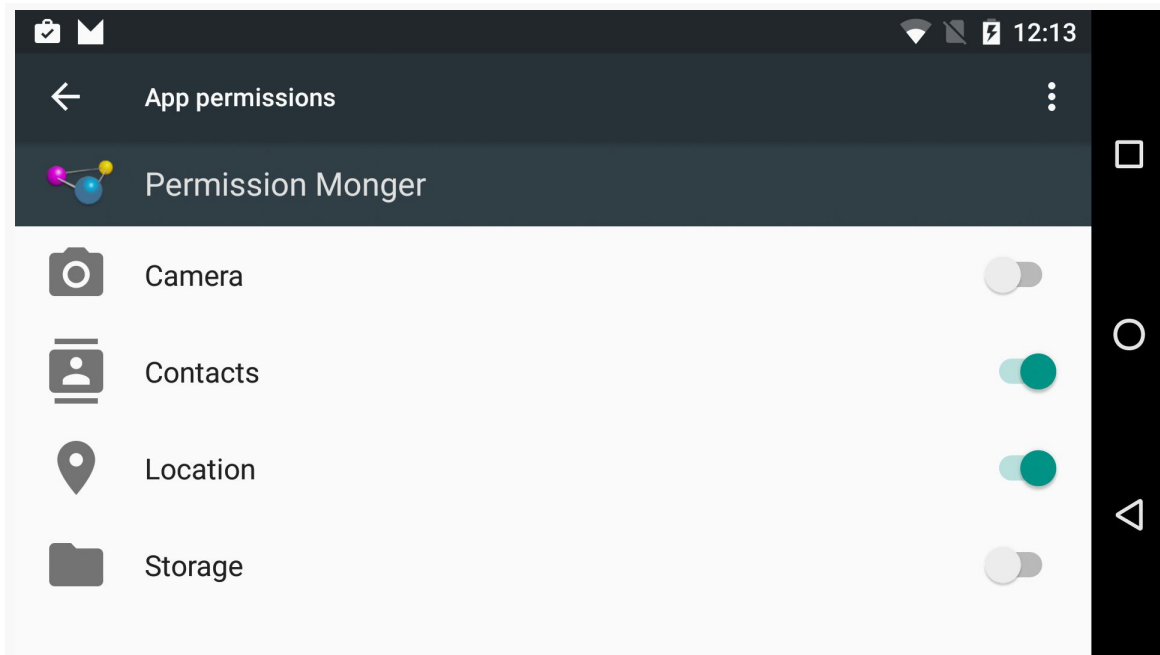

Figure 226: Settings Screen for Permission Monger, Showing Permissions

What Goes in the Manifest?

The same `<uses-permission>` elements as before. These declare the superset of all possible permissions that you can have. If you do not have a `<uses-permission>` element for a particular permission, you cannot ask for it at runtime, and the user cannot grant it to you.

How Do I Know If I Have Permission?

On Android 6.0+, you can call a `checkSelfPermission()` method, available on any `Context` (e.g., your `Activity`). This will return either `PERMISSION_GRANTED` or `PERMISSION_DENIED`, depending on whether or not the user granted you permission or you were automatically given permission (e.g., for normal permissions).

REQUESTING PERMISSIONS

For a simpler boolean check to see if you have the permission, you could have your own `hasPermission()` method:

```
private boolean hasPermission(String perm) {
    return(PackageManager.PERMISSION_GRANTED==checkSelfPermission(perm));
}
```

Then you can use that `hasPermission()` call where you need it.

For example, the `PermissionMonger` app requests five permissions in the manifest:

```
<uses-permission android:name="android.permission.ACCESS_FINE_LOCATION" />
<uses-permission android:name="android.permission.CAMERA" />
<uses-permission android:name="android.permission.INTERNET" />
<uses-permission android:name="android.permission.READ_CONTACTS" />
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```

The UI is then a table showing the current status of those five permissions:

```
private void updateTable() {
    location.setText(String.valueOf(canAccessLocation()));
    camera.setText(String.valueOf(canAccessCamera()));
    internet.setText(String.valueOf(hasPermission(Manifest.permission.INTERNET)));
    contacts.setText(String.valueOf(canAccessContacts()));
    storage.setText(String.valueOf(hasPermission(Manifest.permission.WRITE_EXTERNAL_STORAGE)));
}

private boolean canAccessLocation() {
    return(hasPermission(Manifest.permission.ACCESS_FINE_LOCATION));
}

private boolean canAccessCamera() {
    return(hasPermission(Manifest.permission.CAMERA));
}

private boolean canAccessContacts() {
    return(hasPermission(Manifest.permission.READ_CONTACTS));
}
```

At the outset, we only have the one “normal” permission: `INTERNET`:

REQUESTING PERMISSIONS

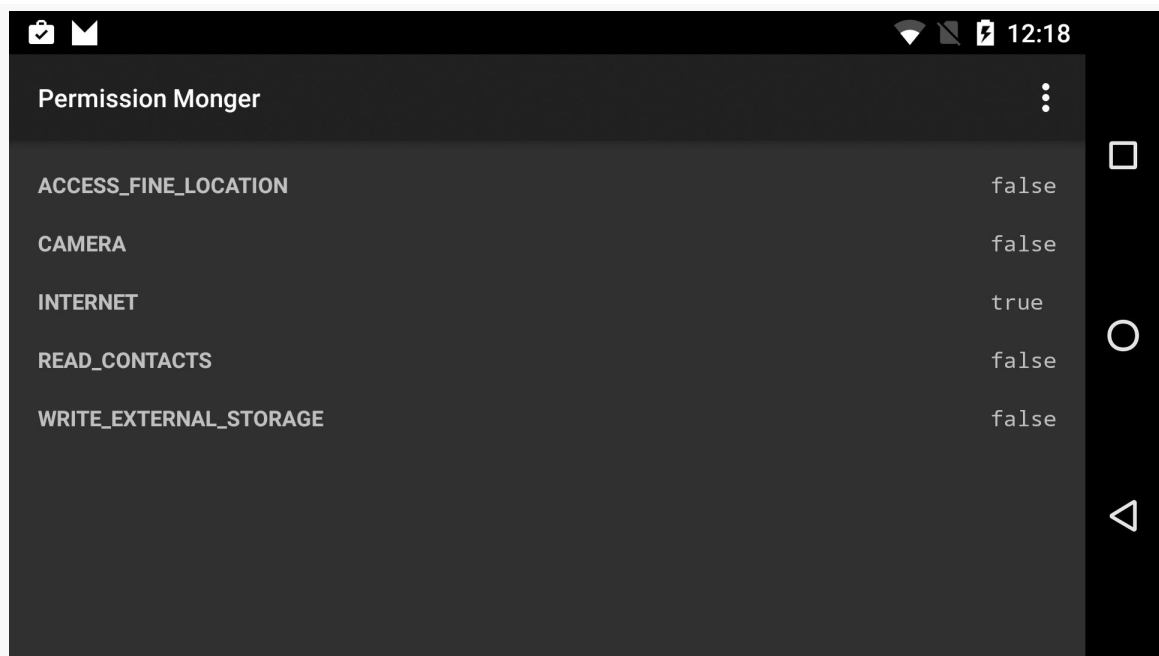

Figure 227: Permission Monger, Showing Initial Permissions

The `checkSelfPermission()` method on `Context` is only available on API Level 23. You can, if you wish, wrap your call to `checkSelfPermission()` in a check of the API level of the device you are running on:

```
if (Build.VERSION.SDK_INT > Build.VERSION_CODES.LOLLIPOP_MR2) {
    if (checkSelfPermission(Manifest.permission.WRITE_EXTERNAL_STORAGE) ==
        PackageManager.PERMISSION_GRANTED) {
        // do something cool
    }
}
```

A simpler approach is to use `ContextCompat`, from the `support-v4` library. This has a static implementation of `checkSelfPermission()` that takes a `Context` and your permission string as parameters. It returns the same value (e.g., `PackageManager.PERMISSION_GRANTED`) as does the `checkSelfPermission()` that ships with Android 6.0. But, if you are running on an older device, it checks the version for you and returns `PackageManager.PERMISSION_GRANTED` for older devices. So, the above code snippet turns into:

```
if (ContextCompat.checkSelfPermission(this,
    Manifest.permission.WRITE_EXTERNAL_STORAGE) ==
    PackageManager.PERMISSION_GRANTED) {
    // do something cool
}
```

(assuming that this is a subclass of Context, like Activity)

How Do I Know If the User Takes Permissions Away From Me?

If the user grants you access to some permission group, the only way the user can revoke that is via the Settings app. If the user *does* revoke access to a permission group, your process is terminated.

Hence, while your code is running, you will have all permissions that you started with, plus any new ones that the user grants on the fly based upon your request. There should be no circumstance where your process is running yet you lose a permission.

That being said, your app is not specifically notified about losing the permission. You should be calling `checkSelfPermission()` to determine what you can and cannot do, at least for every process invocation. And, since the call appears to be reasonably cheap, you should just call it whenever you need to know whether you can perform a particular operation.

How Do I Ask the User For Permission?

To ask the user for one of the runtime permissions, call `requestPermissions()` on your Activity. This takes a String array of the permissions that you are requesting and a locally-unique integer to identify this request from any other similar requests that you may be making.

For example, PermissionMonger will check in `onCreate()` to see if we can access locations or access contacts, and if not, it will request access to those two permissions:

```
if (!canAccessLocation() || !canAccessContacts()) {
    requestPermissions(INITIAL_PERMS, INITIAL_REQUEST);
}
```

INITIAL_PERMS and INITIAL_REQUEST are just static final data members:

```
private static final String[] INITIAL_PERMS={
    Manifest.permission.ACCESS_FINE_LOCATION,
    Manifest.permission.READ_CONTACTS
};
```

```
private static final int INITIAL_REQUEST=1337;
```

REQUESTING PERMISSIONS

When the app is first launched, dialogs will appear, one per permission that you requested, asking the user if they would be so kind as to allow your app to do the things that you requested:

Figure 228: Permission Monger, Requesting READ_CONTACTS Permission

REQUESTING PERMISSIONS

Figure 229: Permission Monger, Requesting ACCESS_FINE_LOCATION Permission

When the user has proceeded through the dialogs, you will be called with `onRequestPermissionsResult()`. You are passed three parameters:

- the locally-unique integer from your `requestPermissions()` call, to identify which `requestPermissions()` call this is the result for
- a `String` array of the requested permissions
- an `int` array of the corresponding results (`PERMISSION_GRANTED` or `PERMISSION_DENIED`)

Whether you use those latter two parameters or simply call `checkSelfPermission()` again is up to you. Regardless, at this point, you should determine what you got, so you know how to react, such as disabling things that the user cannot use given the lack of permission.

Just as `ContextCompat` offers a backwards-compatible implementation of `checkSelfPermission()`, `ActivityCompat` offers a backwards-compatible implementation of `requestPermissions()` that you can use. Otherwise, you will want to take other steps to ensure that you only call `requestPermissions()` on API Level 23+ devices.

When Do I Ask the User For Permission?

That depends a bit on the nature of the permission.

In an ideal world, your app can function without any of the revocable permissions granted to you, albeit perhaps in a limited fashion. In that case, you might ask for permission only when the user tries to do something (e.g., taps on an action bar item) for which you definitely need the permission.

However, sometimes you will need permission to be at all useful to the user. In that case, you will need to ask for permission when the app opens.

In either case, though, bear in mind that while the user will see the dialog asking for permission, the user may not understand *why* you are asking for this permission. You need to make sure that the user understands the cost/benefit trade-off in granting the permission — in other words, what does the user get out of the deal?

For permissions that you are requesting based on user input, you might pop your own dialog or other UI explaining what you want and why you want it, before calling `requestPermissions()`. For permissions that you would want to ask for when the app starts up, make sure that you clearly explain the need for the permissions and what the user gets in exchange as part of [a one-time introductory tutorial](#), one that might also be accessed via an overflow item or nav drawer entry as part of your app's help facility.

When Do I Not Ask the User For Permission?

One limitation with the `requestPermissions()` implementation is that it is oblivious to configuration changes.

For example, suppose that in `onCreate()` of your activity, you check to see if you have been granted a runtime permission (via `checkSelfPermission()`), and if you have not, you call `requestPermissions()` to request it from the user. This displays the dialog. Now the user rotates the screen. If the user denies the permission, by default, the user will immediately see the permission dialog again... because your activity will have been destroyed and recreated, and your `onCreate()` will see that you do not have the permission, and so you ask for it again.

In cases like this, you will need to track whether you are in the permission-request flow (e.g., via a `boolean` saved in the instance state `Bundle`) and skip requesting the

permission if you have been recreated in the middle of that flow. We will see this in action in [the upcoming runtime permissions tutorial](#).

What Do I Do If the User Says “No”?

If you were requesting permission as a direct response to some bit of user input (e.g., user tapped on an action bar item), and the user rejects the permission you need to do the work, obviously you cannot do the work. Depending on overall flow, showing a dialog or something to explain why you cannot do what the user asked for may be needed. In some cases, you may deem it to be obvious, by virtue of the fact that the user saw the permission-request dialog and said “deny”.

If you were requesting permission pre-emptively, such as when the activity starts, you will need to decide whether that decision needs to be reflected in the current UI (e.g., “no data available” messages, disabled action bar items).

One thing you can do to help here is to detect when this has occurred before you request permissions again. Before you call `requestPermissions()`, you can call `shouldShowRequestPermissionRationale()`, supplying the name of a permission. This will return `true` if the user had previously declined to grant you permission, in cases where Android thinks that the user might benefit from learning a bit more about *why* you need the permission. You can use this to determine whether you should show some explanatory UI of your own first, before continuing with the permission request, or if you should just go ahead and call `requestPermissions()`.

Note that `ActivityCompat` also has a backwards-compatible implementation of `shouldShowRequestPermissionRationale()`, so you can avoid your own API level checks.

What Do I Do If the User Says “No, And Please Stop Asking”?

The second time you ask a user for a particular runtime permission, the user will have a “Never ask again” checkbox:

REQUESTING PERMISSIONS

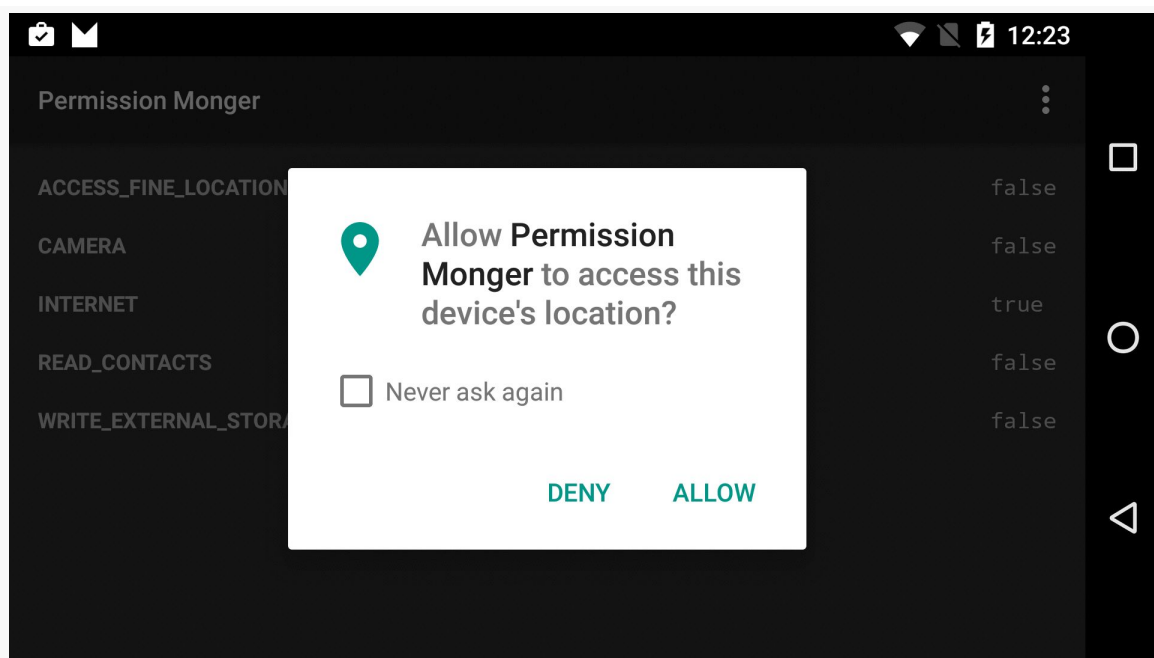

Figure 230: Permission Monger, Requesting ACCESS_FINE_LOCATION Permission (Again)

If the user checks that and clicks the Deny button, not only will you not get the runtime permission now, but all future requests will immediately call `onRequestPermissionsResult()` indicating that your request for permission was denied. The only way the user can now grant you this permission is via the Settings app.

You need to handle this situation with grace and aplomb.

Choices include:

- Disabling UI input (e.g., action bar items) that cannot be performed because you lack permission
- Display a dialog, explaining the situation, with a button that links the user over to your app's screen in Settings, so the user can grant you this permission
- Displaying inline messages about why you cannot show data (e.g., a list of contacts that you cannot show because the user did not grant you access), perhaps with a hyperlink that displays a screen with additional information about the situation

REQUESTING PERMISSIONS

For permissions that, when denied, leave your app in a completely useless state, you may wind up just displaying a screen on app startup that says “sorry, but this app is useless to you”, with options for the user to uninstall the app or grant you the desired permissions.

Note that `shouldShowRequestPermissionRationale()` returns `false` if the user declined the permission and checked the checkbox to ask you to stop pestering the user.

What Happens When I Ship This to an Older Device?

Older devices behave as they always have. Since you still list the permissions in the manifest, those permissions will be granted to you if the user installs the app, and the user will be notified about those permissions as part of the installation process. If you are checking the API level yourself, or you are using `ContextCompat` and `ActivityCompat` as described above, your code should just work.

What Happens When My App Has a Lower Target SDK Version?

Apps with a `targetSdkVersion` below 23, on the surface, behave on Android 6.0+ as they would on an older device: the user is prompted for all permissions, and the app is granted those permissions if the app is installed.

However, the user will *still* be able to go into Settings and revoke permissions from these apps, for any permissions the app requests that are in one of the runtime permission groups.

Generally, you will wind up ignoring the issue. All your calls to methods protected by permissions that the user revoke will still “work”, insofar as they will not throw a `SecurityException`. However, you just will not get any results back or have the intended effects. So, for example, if you try to `query()` the `ContactsContract` `ContentProvider`, and the user revoked your access to contact-related permissions, the `query()` will return an empty `Cursor`. This is a completely valid response, even ignoring the permission issue, as it is entirely possible that the user has no contacts. Your app should be handling these cases gracefully anyway. Hence, in theory, even if you do nothing special regarding the lost permissions, your app should survive, albeit with reduced functionality for the user. Dave Smith [outlines the expected results](#) for legacy apps calling methods sans permission.

However, all else being equal, you should set your `targetSdkVersion` to at least 23 and opt into the runtime permission system.

What Happens if the User Clears My App's Data?

If the user clears your app's data through the Settings app, the runtime permissions are cleared as well. Behavior at this point will be as if your app had been just installed — `checkSelfPermission()` will return `false`, and you will need to request the permissions.

How Can I Automate Permission Grants?

While the runtime permission system provides a reasonable user-facing UI, having to deal with that UI constantly as a developer can be a significant pain. For testing and debugging purposes, there are some [command-line options for granting and revoking permissions](#) that you can use.

Should I Be Using PermissionChecker?

`checkSelfPermission()` on `ContextCompat` always returns `PERMISSION_GRANTED` if either:

- Your app has a `targetSdkVersion` below 23, or
- Your app is running on a device older than Android 6.0

`PERMISSION_DENIED` will be returned only if you have opted into the new runtime permission system (`targetSdkVersion` of 23 or higher), you are running on Android 6.0 or higher, and the user either never granted the permission or revoked it through the Settings app.

The key is that even if you are running on Android 6.0, with an older `targetSdkVersion` (so all permissions are requested at install time and are granted to you automatically), `checkSelfPermission()` still returns `PERMISSION_GRANTED` even if the user revoked the permission in Settings.

The Android Support libraries — specifically `support-v4` — added a `PermissionChecker` class with a `checkPermission()` static method. If you are running on Android 6.0+ with an older `targetSdkVersion`, `checkPermission()` will return `PERMISSION_DENIED_APP_OP` if the user revoked the permission in Settings.

Hence, `PermissionChecker` is useful in cases where you have a really large code base, and you want to try to better handle cases where users revoke permissions, but you are not in position to do a complete implementation of the runtime

permissions system. However, it is merely a stopgap — your long-term plan should be to raise your `targetSdkVersion` to 23 or higher and implement the runtime permissions properly.

Where Can I See This In Action?

The book has [a standalone tutorial](#) demonstrating how to add the runtime permission checks to an existing app.

Tutorial: Runtime Permission Support

Android 6.0's runtime permissions sound simple on the surface: just call `checkSelfPermission()` to see if you have the permission, then call `requestPermissions()` if you do not.

In practice, even a fairly simple app that uses these permissions has to add a remarkable amount of code, to handle all of the combinations of states, plus deal with some idiosyncrasies in the API. And, of course, since not everybody will be running a new device, we also have backwards compatibility to consider.

This standalone tutorial — not part of the EmPubLite series of tutorials throughout the rest of the core chapters — focuses on how to add the runtime permission support to an existing Android application.

As with the other code snippets in this book, if you are trying to copy and paste from the PDF itself, you will tend to have the best luck if you use the official Adobe Acrobat reader app.

If you prefer, you can work with the tutorial code from GitHub, including:

- [the completed project](#)
- [the MainActivity for the completed project](#)

In particular, the latter link, being simple text, may be simpler to copy and paste from, for situations where we are modifying the code to directly match what will be in the completed project.

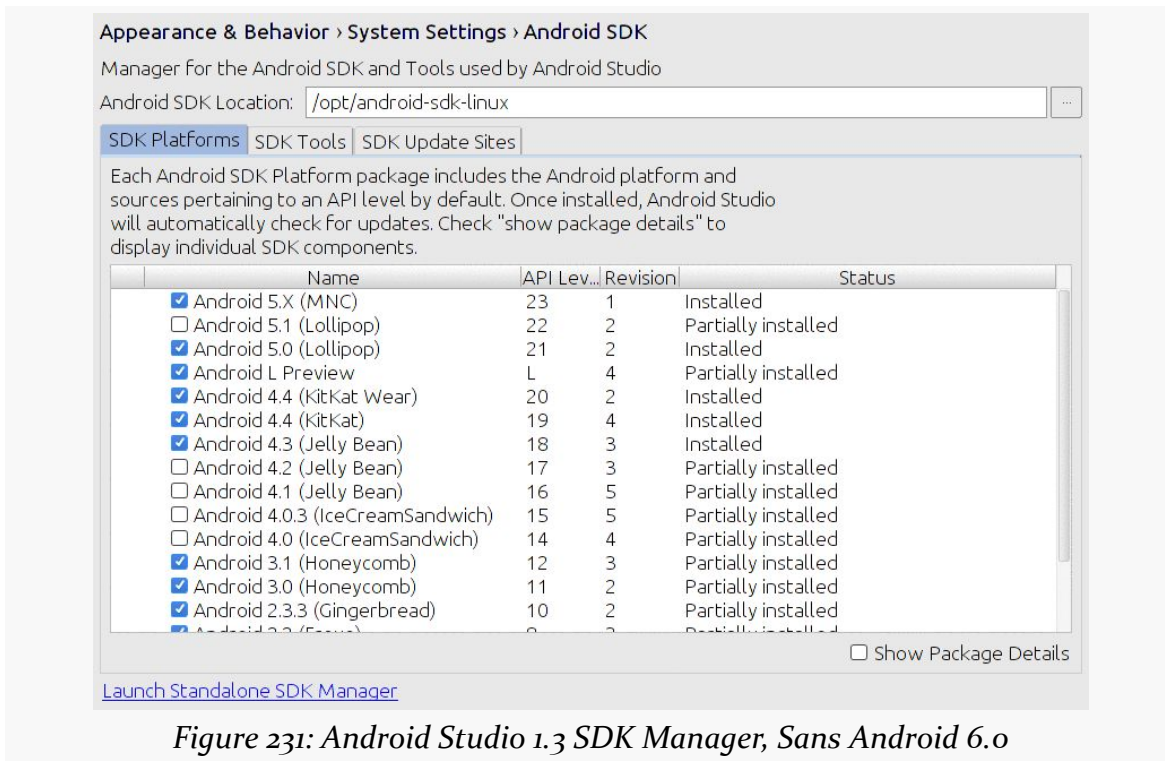

Also, as part of working on this tutorial, you will be adding many snippets of Java code. You will need to add `import` statements for the new classes introduced by those code snippets. Just click on the class name, highlighted in red, in Android

Studio and press <Alt>-<Enter> to invoke the quick-fix to add the required import statement.

Step #0: Install the Android 6.0 SDK

You are going to need the Android 6.0 (API 23) SDK Platform (or higher) in order to be able to implement runtime permission support. You may already have it, or you may need to install it.

If you open up Android Studio's SDK Manager, via Tools > Android > "SDK Manager", you may see Android 6.0 show up... or perhaps not:

You may need to click the "Launch Standalone SDK Manager" link to bring up the classic SDK Manager, where you should see Android 6.0:

TUTORIAL: RUNTIME PERMISSION SUPPORT

Figure 232: Classic SDK Manager, Showing Android 6.0

You will need the “SDK Platform” entry at minimum, and possibly an emulator “system image”.

If you have a device with Android 6.0+ on it, you are welcome to run the sample app, and it should allow you to take pictures and record videos. If you wish to run the sample app on an Android 6.0+ emulator, the permissions logic that we will be adding to the tutorial app will work, but it will not actually take pictures or record video. If your emulator image has 1+ cameras configured (see the “Advanced Settings” button when defining or editing your AVD), the activities to take a picture and record a video will come up but just show an indefinite progress indicator. If your emulator image has no cameras configured, those activities will just immediately finish and return control to our sample app’s main activity.

Step #1: Import and Review the Starter Project

Download [the starter project ZIP archive](#) and unzip it somewhere on your development machine.

TUTORIAL: RUNTIME PERMISSION SUPPORT

Then, use File > New > Import Project to import this project into Android Studio. Android Studio may prompt you for additional updates from the SDK Manager (e.g., build tools), depending upon what you have set up on your development machine.

If you run the project on an Android 4.0+ device or emulator, you will see our highly-sophisticated user interface, consisting of two big buttons:

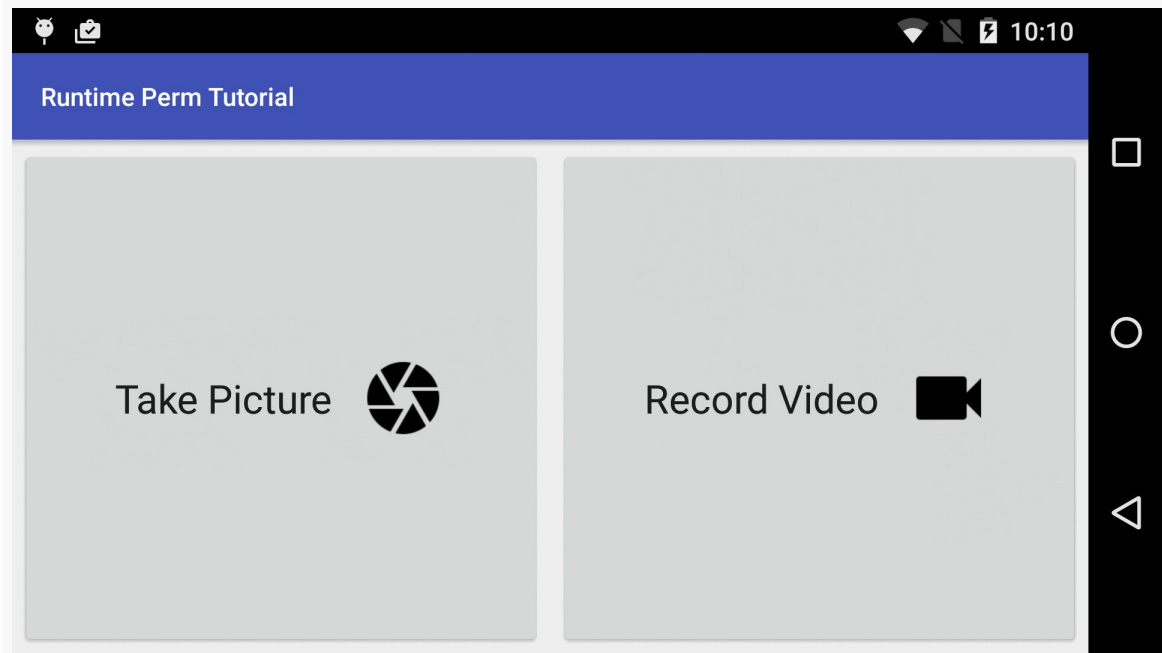

Figure 233: Runtime Permissions Tutorial App, As Initially Written and Launched

Tapping the “Take Picture” button will bring up a camera preview, with a floating action button (FAB) to take a picture:

Figure 234: Runtime Permissions Tutorial App, Showing Camera Preview

Tapping the FAB (and taking a picture) or pressing BACK will return you to the original two-button activity. There, tapping the “Record Video” button will bring up a similar activity, where you can press the green record FAB to start recording a video:

Figure 235: Runtime Permissions Tutorial App, Showing Video Preview

If you start recording, the FAB will change to a red stop button. Tapping that, or pressing BACK from either state, will return you to the initial two-button activity.

The application makes use of two third-party dependencies to pull all of this off:

- Philip Calvin's [IconButton](#)
- the author's [CWAC-Cam2](#), which implements the photo and video activities

```
dependencies {
    compile 'com.commonware.cwac:cam2:0.2.+
    compile 'com.githang:com-phillipcalvin-iconbutton:1.0.1@aar'
}
```

Our two layouts, `res/layout/main.xml` and `res/layout-land/main.xml`, have two `IconButton` widgets in a `LinearLayout`, with equal weights so the buttons each take up half of the screen:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
<com.phillipcalvin.iconbutton.IconButton
    android:id="@+id/take_picture"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_margin="4dp"
    android:layout_weight="1"
    android:drawableRight="@drawable/ic_camera_black_48dp"
    android:onClick="takePicture"
    android:text="Take Picture"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:iconPadding="16dp"/>

<com.phillipcalvin.iconbutton.IconButton
    android:id="@+id/record_video"
    android:layout_width="0dp"
    android:layout_height="match_parent"
    android:layout_margin="4dp"
    android:layout_weight="1"
    android:drawableRight="@drawable/ic_videocam_black_48dp"
    android:onClick="recordVideo"
    android:text="Record Video"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:iconPadding="16dp"/>
</LinearLayout>
```

MainActivity then uses CWAC-Cam2 to handle each of the button clicks:

```
package com.commonware.android.perm.tutorial;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.os.Environment;
import android.view.View;
import android.widget.Toast;
import com.commonware.cwac.cam2.CameraActivity;
import com.commonware.cwac.cam2.VideoRecorderActivity;
import java.io.File;

public class MainActivity extends Activity {
    private static final int RESULT_PICTURE_TAKEN=1337;
    private static final int RESULT_VIDEO_RECORDED=1338;
    private File rootDir;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        File downloads=Environment
            .getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

        rootDir=new File(downloads, "RuntimePermTutorial");
        rootDir.mkdirs();
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode,
        Intent data) {
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
Toast t=null;

if (resultCode==RESULT_OK) {
    if (requestCode==RESULT_PICTURE_TAKEN) {
        t=Toast.makeText(this, R.string.msg_pic_taken,
            Toast.LENGTH_LONG);
    }
    else if (requestCode==RESULT_VIDEO_RECORDED) {
        t=Toast.makeText(this, R.string.msg_vid_recorded,
            Toast.LENGTH_LONG);
    }
    t.show();
}

public void takePicture(View v) {
    takePictureForRealz();
}

public void recordVideo(View v) {
    recordVideoForRealz();
}

private void takePictureForRealz() {
    Intent i=new CameraActivity.IntentBuilder(MainActivity.this)
        .to(new File(rootDir, "test.jpg"))
        .updateMediaStore()
        .build();

    startActivityForResult(i, RESULT_PICTURE_TAKEN);
}

private void recordVideoForRealz() {
    Intent i=new VideoRecorderActivity.IntentBuilder(MainActivity.this)
        .quality(VideoRecorderActivity.Quality.HIGH)
        .sizeLimit(5000000)
        .to(new File(rootDir, "test.mp4"))
        .updateMediaStore()
        .forceClassic()
        .build();

    startActivityForResult(i, RESULT_VIDEO_RECORDED);
}
}
```

The details of how CWAC-Cam2 works are not particularly relevant for the tutorial, but you can learn more about that [later in the book](#) if you are interested.

Taking pictures and recording videos require three permissions:

- CAMERA
- WRITE_EXTERNAL_STORAGE (where the output is going)
- RECORD_AUDIO (for videos)

Our manifest asks for none of these permissions:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonware.android.perm.tutorial"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"
    android:xlargeScreens="true" />

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
</manifest>
```

The permissions come from the CWAC-Cam2 library, courtesy of a process known as [manifest merger](#).

You might wonder why we would bother doing this using a camera library in our own app. Most Android devices with camera hardware have a camera app, and most camera apps — particularly pre-installed camera apps — have activities that we could invoke to take pictures or record videos. However, these activities are infrequently tested, and many do not work properly. Since they are unreliable, you may be happier using something that is a library, packaged in your app.

Note that MainActivity has some seemingly superfluous bits of code:

- We find the two buttons in the inflated layout and assign them to `takePicture` and `recordVideo` fields... but then never use them
- We delegate the actual CWAC-Cam2 work to `takePictureForRealz()` and `recordVideoForRealz()`... instead of just doing that work in the `takePicture()` and `recordVideo()` methods invoked by the buttons

The reason for those apparent inefficiencies is to reduce the amount of work it will take you to add the runtime permissions, by handling a tiny bit of bookkeeping ahead of time.

Step #2: Update Gradle for Android 6.0

By default, if you run this app from your IDE on an Android 6.0 device, nothing appears to be different. The app runs as it did.

If you were to install it via a download, such as from a Web site, the installation process looks as it does on earlier Android versions, prompting the user for each of the permissions:

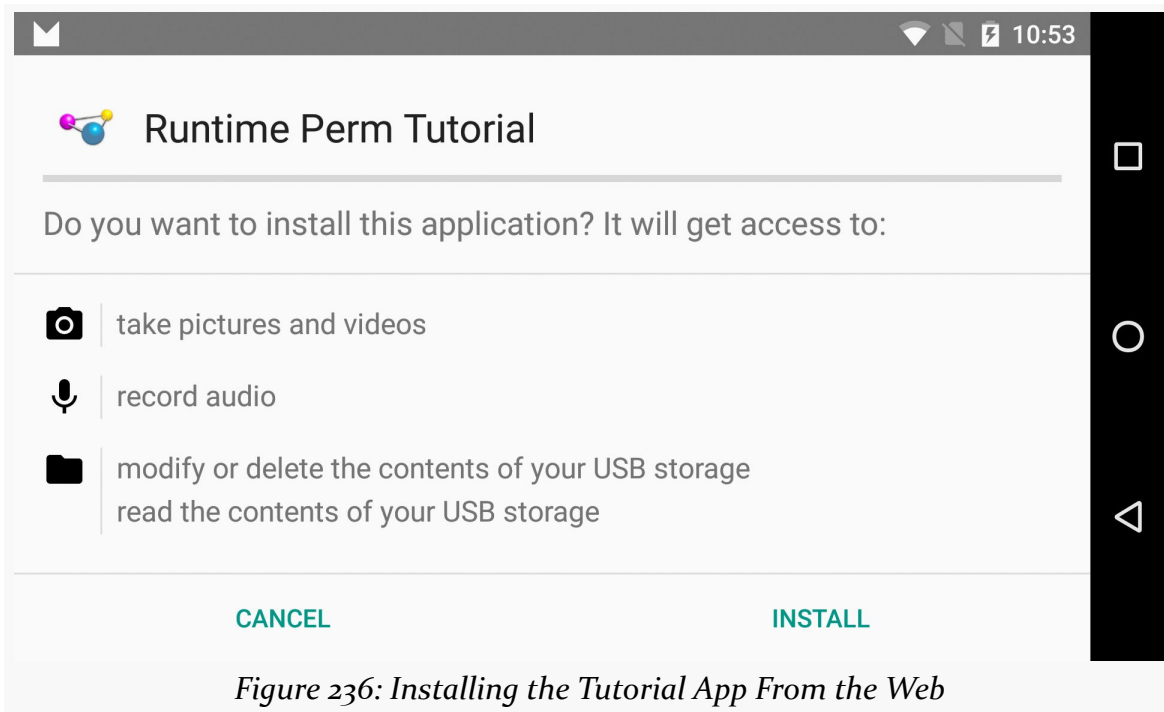

Figure 236: Installing the Tutorial App From the Web

However, the user can still go into Settings and elect to disable our access to those permissions:

Figure 237: Settings, On Android 6.0, Showing Tutorial App Permissions

In our case, not all those permissions are always needed, and it would be useful to know whether or not we hold a permission, and so adopting the new runtime permission model would seem to be a good idea.

The first step on the road to doing that is to adjust some values in our app/ module's `build.gradle` file:

- Change `compileSdkVersion` to 23, as we need to use methods from the latest SDK
- Change `buildToolsVersion` to 23.0.0, to keep it in sync with the `compileSdkVersion`, and
- Change `targetSdkVersion` to 23, to tell Android that our app was written with the runtime permission model in mind

This will give you an android closure like:

```
android {
    compileSdkVersion 23
    buildToolsVersion "23.0.0"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 23
    }
}
```

```
}  
}
```

Step #3: Review the Planned UX

So, our app is here to take pictures and record videos. Of the three permissions that our app is requesting in total, two are essential for the app to do anything meaningful: `CAMERA` and `WRITE_EXTERNAL_STORAGE`. `RECORD_AUDIO`, by contrast, is not needed if the user only wants to take pictures.

Part of the objective of the runtime permissions system is to allow you to lazy-request permissions that many users may not need. If there is some fringe feature in your app that, say, needs `READ_CONTACTS`, rather than force *everyone* to give you `READ_CONTACTS`, you can request it only of users who go down the path in your UI that leads to the feature that needs `READ_CONTACTS`-secured capabilities.

Hence, we will only ask for the `RECORD_AUDIO` permission if the user taps the “Record Video” button.

For the other two permissions, we could take the approach of asking for them only when the user taps either of the two buttons. However, those permissions are essential for app operation, and so another approach is to ask for those permissions on first run of the app, and only worry about them on button clicks if our original request was rejected. You might have some sort of “onboarding” welcome tutorial that explains a bit why we are going to ask for the permissions. Or, you could just ask for the permissions and hope that users will have seen those sorts of request dialogs before, as this app will do (for simplicity as much as anything else).

When the user clicks a button, we need to double-check to see if we have the permissions, and perhaps ask the user again for those permissions. Along the way, we may wish to show some “rationale” — an explanation, in our own UI, of why we need the permissions that we asked for previously and the user said “no”.

If, however, the user not only declines to grant us some permission, but also checks the checkbox indicating that we are not to keep asking, we may as well disable the affected button(s), as the user cannot use that functionality. Alternatively, we might keep the buttons clickable, but instead of doing the actual work (which we cannot do due to lack of permissions), show a message directing the user to the Settings app to flip the switches and grant the permissions to our app. The app in this tutorial will settle for just disabling the buttons.

So, for each of our permissions, we are in one of four states:

1. We have never asked for the permission before
2. We asked for the permission, and the user granted it
3. We asked for the permission, and either the user rejected our request, or perhaps granted it but then changed their mind and turned the permission back off in Settings
4. We asked for the permission, and not only did the user reject it, but the user also indicated (via a checkbox) that we are not to ask again

We are going to need to distinguish between these four states as part of our app logic, in order to present the proper behavior in each case.

Step #4: Detect the First Run

If we are going to ask for the CAMERA and WRITE_EXTERNAL_STORAGE permissions on the first run of our app, we need to know when the first run of our app has happened. To do this, we will take a typical approach, using a boolean value in SharedPreferences to determine if we have run before.

With that in mind, add the following constant declaration to MainActivity:

```
private static final String PREF_IS_FIRST_RUN="firstRun";
```

This will serve as the key to our boolean SharedPreferences value.

Then, add the following prefs data member to MainActivity:

```
private SharedPreferences prefs;
```

Next, initialize prefs in MainActivity, shortly after the setContentView() call:

```
prefs=PreferenceManager.getDefaultSharedPreferences(this);
```

Then, add the following method to MainActivity:

```
private boolean isFirstRun() {
    boolean result=prefs.getBoolean(PREF_IS_FIRST_RUN, true);

    if (result) {
        prefs.edit().putBoolean(PREF_IS_FIRST_RUN, false).apply();
    }
}
```

```
return(result);  
}
```

This retrieves the existing value, defaulting to true if there is no such value. If we get that default back, we then update the SharedPreferences to save false for future use.

Finally, at the bottom of onCreate() of MainActivity, add the following lines:

```
if (isFirstRun()) {  
    // TODO  
}
```

We will replace that comment shortly.

Step #5: On First Run, Ask For Permissions

As was covered back in [Step #3](#), we want to ask for the CAMERA and WRITE_EXTERNAL_STORAGE permissions on the first run of our app. To do that, we need to call requestPermissions() from within that if block we added in the previous step.

requestPermissions() takes two parameters:

1. A String array of the fully-qualified names of the permissions that we want
2. An int that will be returned to us in an onRequestPermissionsResult() callback method, so we can distinguish the results of one requestPermissions() call from another

You might wonder why, when adding this in 2015, the Android engineers did not use some sort of a callback object, rather than mess around with int values. Sometimes, the author of this book wonders too.

But, regardless, that is what we need, and we had best start implementing it.

First, to make our code a bit easier to read, add the following static import statements to MainActivity:

```
import static android.Manifest.permission.CAMERA;  
import static android.Manifest.permission.RECORD_AUDIO;  
import static android.Manifest.permission.WRITE_EXTERNAL_STORAGE;
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

If you have not seen this Java syntax before, a static import basically imports a static method or field from a class (in this case, from `Manifest.permission`). The result of the import is that we can refer to the imported items as if they were static items on our own class. So, we can just have a reference to `CAMERA`, for example, rather than having to spell out something like `Manifest.permission.CAMERA` every time.

Next, add the following static `String` array to `MainActivity`, one that uses some of our newly-added static imports:

```
private static final String[] PERMS_TAKE_PICTURE={
    CAMERA,
    WRITE_EXTERNAL_STORAGE
};
```

Also add the following `int` constant to `MainActivity`:

```
private static final int RESULT_PERMS_INITIAL=1339;
```

Now, we can request our permissions. However, if we call `requestPermissions()` on `Activity`, we have a problem: that method was only added in API Level 23. If our `minSdkVersion` were 23 or higher, that would not be a problem. However, our `minSdkVersion` is 15, and it would be nice to support Android 4.x and 5.x devices.

The recommended solution for this is to use an `ActivityCompat` class, supplied by the `support-v4` portion of the Android Support library. This class contains, among other things, a `requestPermissions()` static method that will confirm that we are on a device new enough to support `requestPermissions()`. On older devices, it gracefully degrades (in this case, doing nothing, as we already have our permissions).

So, with that in mind, edit the `build.gradle` file in the `app/` module to add in `support-v4`:

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:cam2:0.2.+
    compile 'com.githang:com-phillipcalvin-iconbutton:1.0.1@aar'
    compile 'com.android.support:support-v4:23.0.1'
}
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
android {
    compileSdkVersion 23
    buildToolsVersion "23.0.0"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 23
    }
}
```

Then, update the if block in onCreate() of MainActivity to look like:

```
if (isFirstRun()) {
    ActivityCompat.requestPermissions(this, PERMS_TAKE_PICTURE,
        RESULT_PERMS_INITIAL);
}
```

The corresponding callback for requestPermissions() is onRequestPermissionsResult(). So, add a stub implementation of this callback to MainActivity:

```
@Override
public void onRequestPermissionsResult(int requestCode,
    String[] permissions,
    int[] grantResults) {

    // TODO
}
```

As before, we will be replacing that // TODO a bit later in the tutorial.

At this point, run the app on your Android 6.0 environment. Immediately, you should be prompted for the permissions:

TUTORIAL: RUNTIME PERMISSION SUPPORT

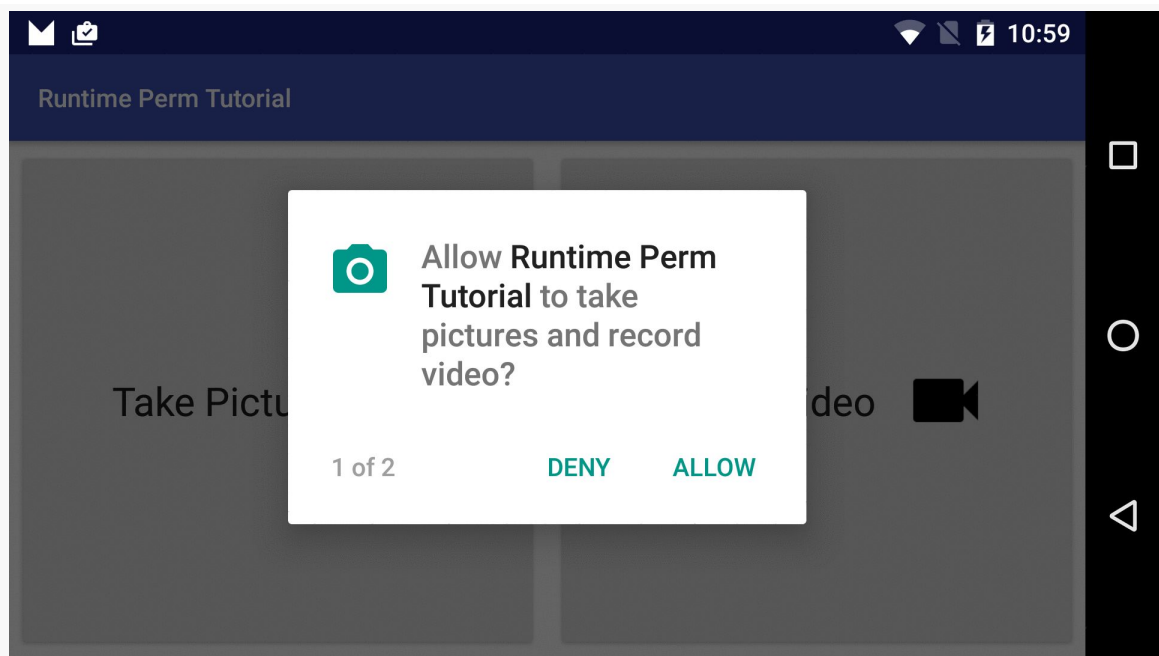

Figure 238: Tutorial App, Showing CAMERA Permission Request

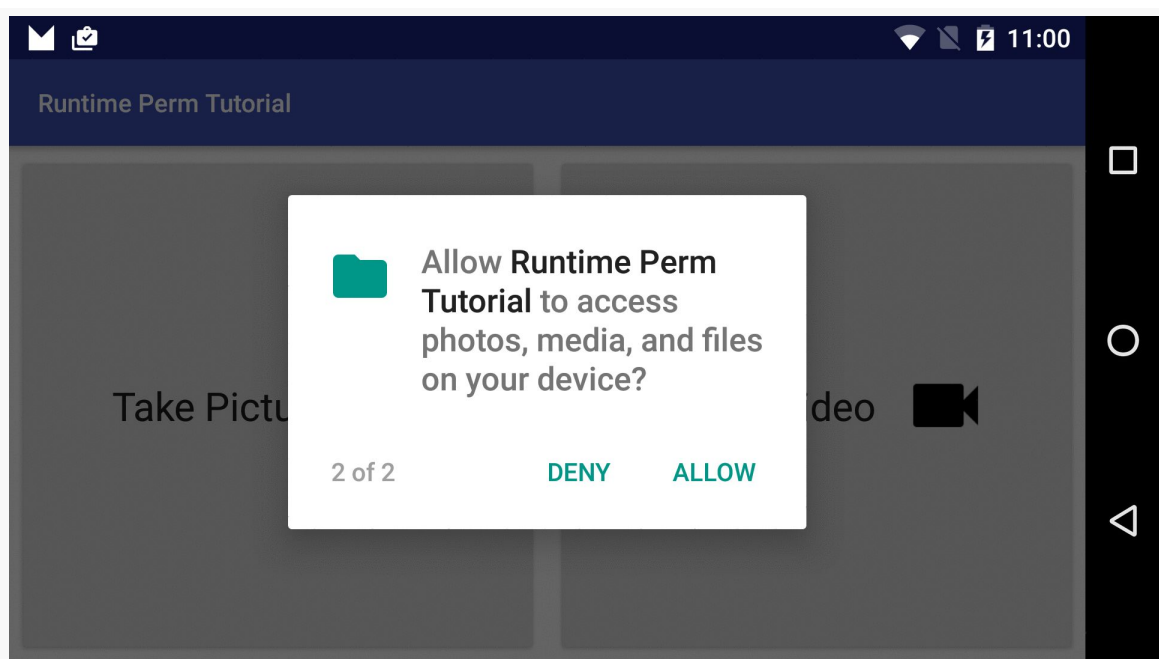

Figure 239: Tutorial App, Showing WRITE_EXTERNAL_STORAGE Permission Request

Then, uninstall the app. That way, no matter whether you accepted or declined those permissions, the next time you run the app, you are “starting from a clean slate”. An alternative to uninstalling would be to clear your app’s data from inside the Settings app, as that too will reset your permissions to their just-after-install state.

Step #6: Check for Permissions Before Taking a Picture

If we are lucky, our users will grant us the permissions that we requested. We will not always be lucky; some users will reject our request. Furthermore, some users might change these permissions for our app in Settings, granting or revoking them as those users see fit.

So, when the user taps the “Take Picture” button, we need to double-check to see if we actually have the permissions that we need. If we do not, we cannot go ahead and take the picture “for realz”, as we will crash with a `SecurityException`, because we lack the permission.

With that in mind, add the following method `hasPermission()` method to `MainActivity`:

```
private boolean hasPermission(String perm) {
    return(ContextCompat.checkSelfPermission(this, perm)==
        PackageManager.PERMISSION_GRANTED);
}
```

This is just a convenience method to reduce clutter elsewhere in the class when we try to determine whether or not we have a permission. This method uses `ContextCompat`, another compatibility class from `support-v4`, to see if we have the supplied permission. While we could call `checkSelfPermission()` directly on our `MainActivity`, we would run into the same problem that we did with `requestPermissions()` — `checkSelfPermission()` only exists on API Level 23+. The `ContextCompat` edition of the method gracefully degrades on older devices, returning `true`, since we already have the permission.

Next, add the following `canTakePicture()` method to `MainActivity`:

```
private boolean canTakePicture() {
    return(hasPermission(CAMERA) && hasPermission(WRITE_EXTERNAL_STORAGE));
}
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

Here, `canTakePicture()` simply checks to see if we can take a picture, by checking whether we have the `CAMERA` and `WRITE_EXTERNAL_STORAGE` permissions.

Then, modify the `takePicture()` method of `MainActivity` to look like this:

```
public void takePicture(View v) {  
    if (canTakePicture()) {  
        takePictureForRealz();  
    }  
}
```

Here, we only try taking the picture if we have the permissions.

Of course, if we do *not* have the permissions, right now we are ignoring the user clicks on our “Take Picture” button. We really should offer more feedback here, and we will be tackling that little problem in later steps of this tutorial.

Now, run the app on an Android 6.0 environment. When Android prompts you for the permissions, accept them. Then, tap the “Take Picture” button, and you should be able to take a picture.

Then, uninstall the app and run it again, this time rejecting the permissions when asked. Then, tap the “Take Picture” button, and you should get no response from the app.

Finally, uninstall the app.

Step #7: Detect If We Should Show Some Rationale

Having no response to tapping the “Take Picture” button, when we do not have the requisite permissions, is not a very good user experience. We should ask again for those permissions... if there is a chance that the user will actually grant them to us.

That chance will be improved if we explain to them, a bit more, why we keep asking for these permissions. Android 6.0 has a `shouldShowRequestPermissionRationale()` that we can use to decide whether we should show some UI (and then later ask for the permissions again) or whether the user has checked the “don’t ask again” checkbox and we should leave them alone.

With that in mind, add the following method to `MainActivity`:

```
private boolean shouldShowTakePictureRationale() {  
    return(ActivityResult.shouldShowRequestPermissionRationale(  

```

```
    this, CAMERA) ||  
    ActivityCompat.shouldShowRequestPermissionRationale(this,  
        WRITE_EXTERNAL_STORAGE));  
}
```

This `shouldShowTakePictureRationale()` simply checks to see if we need to show rationale for any of the permissions required to take a picture. It uses the `shouldShowRequestPermissionRationale()` method, which will return false if:

- You have never asked for the permission, or
- You already have the permission (in which case you probably should not be bothering to call this method), or
- You have asked for the permission a few times, and the last time out, the user not only denied the permission, but also checked the checkbox to prevent you from asking for permission again in the future

Otherwise, `shouldShowRequestPermissionRationale()` will return true.

As with the other runtime permission-specific methods used here in `MainActivity`, while there is one in the SDK for direct use (`shouldShowRequestPermissionRationale()` on `Activity`), it was added in API Level 23. The backport (`shouldShowRequestPermissionRationale()` on `ActivityCompat`) will handle cases where we are running on an older version of Android.

Then, modify the existing `takePicture()` method to look like this:

```
public void takePicture(View v) {  
    if (canTakePicture()) {  
        takePictureForRealz();  
    }  
    else if (shouldShowTakePictureRationale()) {  
        // TODO  
    }  
}
```

So, now we are checking to see if we should show the user an explanation for the permissions... though we are not doing that just yet. We will get to that in the next step.

Step #8: Add a Rationale UI and Re-Request Permissions

We need to do something to explain to the user why we need these permissions.

TUTORIAL: RUNTIME PERMISSION SUPPORT

A poor choice would be to display a Toast. Those are time-limited and so are not good for showing longer messages.

We might display a [dialog](#) or a [snackbar](#)... but we have not talked about how to do either of those just yet in this book.

We might display something from our help system, or go through the introductory tutorial again, or something like that... but this app does not have any of those things.

So, we will instead take a very crude UI approach: adding a hidden panel with our message that we will show when needed. Since this is not nearly as refined as a Toast, we will call this panel the breadcrust.

With that as background, let's add a TextView to our `res/layout/main.xml` file that is the breadcrust itself:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <TextView
        android:id="@+id/breadcrust"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="1"
        android:background="@color/accent"
        android:gravity="center"
        android:padding="8dp"
        android:textAppearance="?android:attr/textAppearanceLarge"
        android:visibility="gone"/>

    <com.phillipcalvin.iconbutton.IconButton
        android:id="@+id/take_picture"
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_margin="4dp"
        android:layout_weight="1"
        android:drawableRight="@drawable/ic_camera_black_48dp"
        android:onClick="takePicture"
        android:text="Take Picture"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:iconPadding="16dp"/>

    <com.phillipcalvin.iconbutton.IconButton
        android:id="@+id/record_video"
        android:layout_width="match_parent"
        android:layout_height="0dp">
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
    android:layout_margin="4dp"
    android:layout_weight="1"
    android:drawableRight="@drawable/ic_videocam_black_48dp"
    android:onClick="recordVideo"
    android:text="Record Video"
    android:textAppearance="?android:attr/textAppearanceLarge"
    app:iconPadding="16dp"/>
</LinearLayout>
```

Here, we are having it take up its share of the space, the same as the two buttons (`android:layout_weight="1"`) and giving it a yellow background (`android:background="@color/accent"`). The `android:textAppearance="?android:attr/textAppearanceLarge"` is Android's cumbersome way of saying "use the standard large-type font". Finally, `android:visibility="gone"` means that this `TextView` actually will not be seen, until we make it visible ourselves in Java code.

We need to add a similar `TextView` to the `res/layout-land/main.xml` file, simply inverting the axes for the width, height, and weight:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal">

    <TextView
        android:id="@+id/breadcrumb"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:background="@color/accent"
        android:gravity="center"
        android:padding="8dp"
        android:textAppearance="?android:attr/textAppearanceLarge"
        android:visibility="gone"/>

    <com.phillipcalvin.iconbutton.IconButton
        android:id="@+id/take_picture"
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_margin="4dp"
        android:layout_weight="1"
        android:drawableRight="@drawable/ic_camera_black_48dp"
        android:onClick="takePicture"
        android:text="Take Picture"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:iconPadding="16dp"/>

    <com.phillipcalvin.iconbutton.IconButton
        android:id="@+id/record_video"
        android:layout_width="0dp"
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
        android:layout_height="match_parent"
        android:layout_margin="4dp"
        android:layout_weight="1"
        android:drawableRight="@drawable/ic_videocam_black_48dp"
        android:onClick="recordVideo"
        android:text="Record Video"
        android:textAppearance="?android:attr/textAppearanceLarge"
        app:iconPadding="16dp"/>
</LinearLayout>
```

Next, add a data member for the broadcast to MainActivity:

```
private TextView broadcast;
```

Then, in onCreate() of MainActivity, add a call to findViewById() to look up the broadcast:

```
        broadcast=(TextView)findViewById(R.id.broadcast);
```

Next, in res/values/strings.xml, add in a string resource for the message we want to show in the broadcast when we are going to ask the user (again) for permission to take pictures:

```
<string name="msg_take_picture">You need to grant us permission! Tap the Take
Picture button again, and we will ask for permission.</string>
```

So, what we want to have happen when the user taps the “Take Picture” button is:

- If we have permission to take the picture, take the picture
- If we do not have permission, but the user can see the broadcast (and so can see our rationale for requesting the permission), request the permissions again
- If we do not have permission, and the broadcast is not visible, then we need to show the broadcast with our rationale message

To that end, modify takePicture() on MainActivity to look like this:

```
public void takePicture(View v) {
    if (canTakePicture()) {
        takePictureForRealz();
    }
    else if (broadcast.getVisibility()==View.GONE &&
        shouldShowTakePictureRationale()) {
        broadcast.setText(R.string.msg_take_picture);
        broadcast.setVisibility(View.VISIBLE);
    }
    else {
        broadcast.setVisibility(View.GONE);
        ActivityCompat.requestPermissions(this,
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
        netPermissions(PERMS_TAKE_PICTURE), RESULT_PERMS_TAKE_PICTURE);
    }
}
```

If breadcrust is visible, we make it GONE again and call `requestPermissions()`. If breadcrust is not visible, we make it VISIBLE and set its message to the string resource that we defined.

There are some things missing. The biggest one is the `netPermissions()` method:

```
private String[] netPermissions(String[] wanted) {
    ArrayList<String> result=new ArrayList<String>();

    for (String perm : wanted) {
        if (!hasPermission(perm)) {
            result.add(perm);
        }
    }

    return(result.toArray(new String[result.size()]));
}
```

This method iterates over our input string array of permissions and filters out those that we already hold. This is needed because a call to `requestPermissions()` requests *every* permission that we ask for... even permissions that the user has already granted. For example, suppose that on the initial run of our app, the user granted the `WRITE_EXTERNAL_STORAGE` permission but declined to grant the `CAMERA` permission. We only want to ask the user for the `CAMERA` permission. Ideally, `requestPermissions()` would look at our array and filter out those permissions that we were already granted, asking the user for the remainder. Unfortunately, `requestPermissions()` does not do that, so we have to do the filtering ourselves, as we are in `netPermissions()`.

`netPermissions()` just iterates over the array of permission names and uses a `hasPermission()` method to filter out ones that we already hold.

Also, your IDE should complain that `RESULT_PERMS_TAKE_PICTURE` is not defined, so add that as another constant on `MainActivity`:

```
private static final int RESULT_PERMS_TAKE_PICTURE=1340;
```

If we call `requestPermissions()` and the user grants the permissions, we should go ahead and take the picture. We also need to deal with the case where the user has denied the permission and checked the “stop asking” checkbox, as our `requestPermissions()` call will route straight to `onRequestPermissionsResult()` without prompting the user. So, we need to add some more logic to the

TUTORIAL: RUNTIME PERMISSION SUPPORT

onRequestPermissionsResult() callback method in MainActivity, so alter yours to look like this:

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                     String[] permissions,
                                     int[] grantResults) {

    boolean sadTrombone=false;

    if (requestCode==RESULT_PERMS_TAKE_PICTURE) {
        if (canTakePicture()) {
            takePictureForRealz();
        }
        else if (!shouldShowTakePictureRationale()) {
            sadTrombone=true;
        }
    }

    if (sadTrombone) {
        Toast.makeText(this, R.string.msg_no_perm,
                     Toast.LENGTH_LONG).show();
    }
}
```

Here, if the requestCode is the one we used in our call to requestPermissions() (RESULT_PERMS_TAKE_PICTURE), and if we have permission now to take a picture, we take the picture.

If, on the other hand, we are in onRequestPermissionsResult() (so we know we have asked for the permission) and shouldShowTakePictureRationale() returns false, we know that we cannot possibly get the permission anymore, other than by the user going into the Settings app and manually granting it to us. So, we show a Toast to inform the user about this.

Your IDE will complain that there is no R.string.msg_no_perm value, so add another string resource to your strings.xml file:

```
<string name="msg_no_perm">Sorry, you did not give us permission!</string>
```

Now, run the app on your Android 6.0 environment. When the app asks for permissions on the first run, reject at least one of them. Then, tap the “Take Picture” button, and you should see the breadcrust appear:

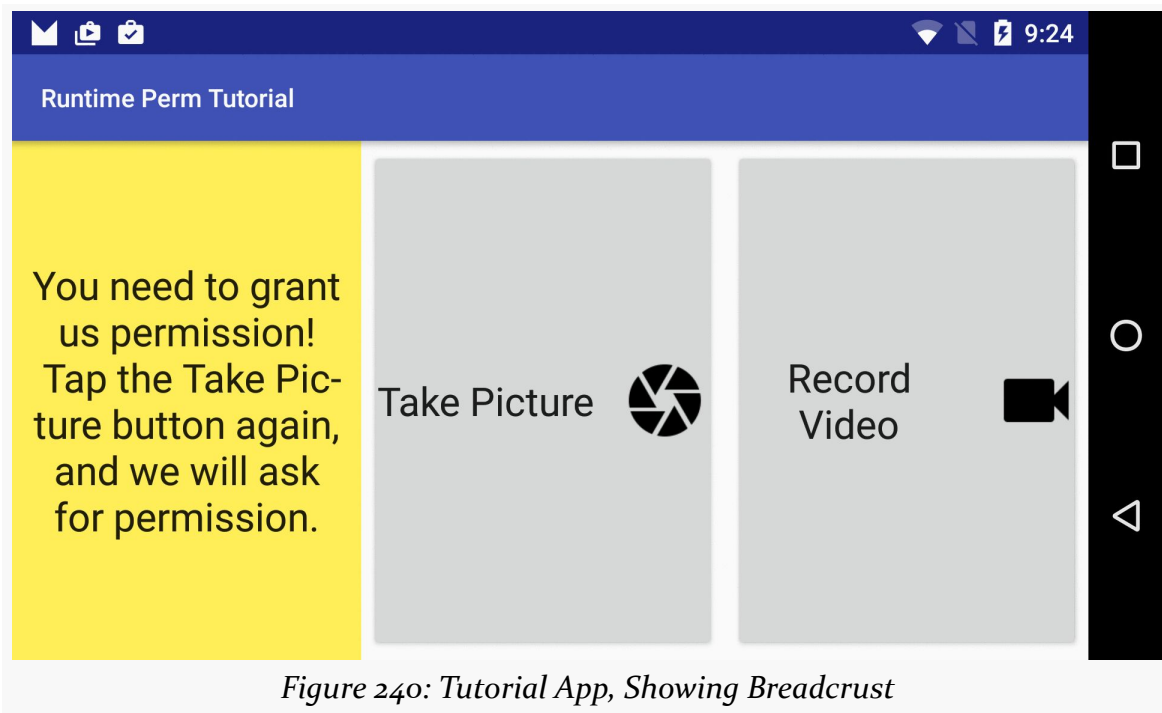

Figure 240: Tutorial App, Showing Breadcrumb

If you tap the “Take Picture” button again, the breadcrumb will go away, and you will be prompted for any permissions you did not grant previously. If you reject any permissions here, you are back where you were; if you accept all permissions, the app will allow you to take a picture. If, instead, you deny all permissions and check the “do not ask again” checkbox for at least one of them, you should see the Toast appear when you try tapping “Take Picture”.

Then, uninstall the app.

Step #9: Check for Permissions Before Recording a Video

So far, we have ignored the “Record Video” button, so let’s start wiring up support for it as well. The big difference with this button — besides recording a video instead of taking a picture — is that we are not asking for the `RECORD_AUDIO` permission up front.

However, that does not change some of the basics, like seeing if we have permission to record videos and only trying to record videos if we do.

First, add the following method to MainActivity:

```
private boolean canRecordVideo() {
    return(canTakePicture() && hasPermission(RECORD_AUDIO));
}
```

This `canRecordVideo()` method will return true if we can take a picture and have the `RECORD_AUDIO` permission. `canTakePicture()` already checks the `CAMERA` and `WRITE_EXTERNAL_STORAGE` permissions, so we are just chaining on the additional permission check.

Then, modify `recordVideo()` in MainActivity to use this:

```
public void recordVideo(View v) {
    if (canRecordVideo()) {
        recordVideoForRealz();
    }
}
```

If you run the sample app, and you tap the “Record Video” button, you should get no response, as we have never asked for the `RECORD_AUDIO` permission, so `canRecordVideo()` should return false. Then, uninstall the app.

Step #10: Detect If We Should Show Some Rationale (Again)

We also need to arrange to show the breadcrumb, with a video-related message, if we do not have permission to take a video but could get it.

So, add the following method to MainActivity:

```
private boolean shouldShowRecordVideoRationale() {
    return(shouldShowTakePictureRationale() ||
        ActivityCompat.shouldShowRequestPermissionRationale(this,
            RECORD_AUDIO));
}
```

Once again, we are checking to see if we need to show a rationale either because of camera-related permissions (`shouldShowTakePictureRationale()`) or because of the `RECORD_AUDIO` permission.

Then, add a couple of additional branches to the `recordVideo()` method:

```
public void recordVideo(View v) {
    if (canRecordVideo()) {
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
recordVideoForRealz();
}
else if (breadcrust.getVisibility()==View.GONE &&
shouldShowRecordVideoRationale()) {
breadcrust.setText(R.string.msg_record_video);
breadcrust.setVisibility(View.VISIBLE);
}
else {
breadcrust.setVisibility(View.GONE);
ActivityCompat.requestPermissions(this,
netPermissions(PERMS_ALL), RESULT_PERMS_RECORD_VIDEO);
}
}
```

Your IDE will complain that you are missing two constants. One is PERMS_ALL, the list of permissions needed to record a video, so add that to MainActivity:

```
private static final String[] PERMS_ALL={
CAMERA,
WRITE_EXTERNAL_STORAGE,
RECORD_AUDIO
};
```

Also, we need to add RESULT_PERMS_RECORD_VIDEO to MainActivity:

```
private static final int RESULT_PERMS_RECORD_VIDEO=1341;
```

You will also be missing the msg_record_video string resource, so add that:

```
<string name="msg_record_video">You need to grant us permission! Tap the Record Video
button again, and we will ask for permission.</string>
```

This is the same flow as we had with the takePicture() method:

- If we have permission to record the video, go ahead and do so
- If we do not, and we are not showing the breadcrust, but we should show some rationale, populate and show the breadcrust
- Otherwise, make sure the breadcrust is GONE and request our permissions

Finally, modify onRequestPermissionsResult() in MainActivity to record the video if we now have permission to do so, by adding the else if block:

```
@Override
public void onRequestPermissionsResult(int requestCode,
String[] permissions,
int[] grantResults) {

boolean sadTrombone=false;

if (requestCode==RESULT_PERMS_TAKE_PICTURE) {
if (canTakePicture()) {
takePictureForRealz();
```

```
    }
    else if (!shouldShowTakePictureRationale()) {
        sadTrombone=true;
    }
}
else if (requestCode==RESULT_PERMS_RECORD_VIDEO) {
    if (canRecordVideo()) {
        recordVideoForRealz();
    }
    else if (!shouldShowRecordVideoRationale()) {
        sadTrombone=true;
    }
}
}

if (sadTrombone) {
    Toast.makeText(this, R.string.msg_no_perm,
        Toast.LENGTH_LONG).show();
}
}
```

If you run the app and tap the “Record Video” button, you should be asked for all required permissions right away, as we have never asked you for RECORD_AUDIO. If you decline one or more of the permissions, and tap “Record Video” a second time, the breadcrumb should appear. If you tap “Record Video” a third time, the breadcrumb should vanish and you should be prompted for the permissions again. And, if you deny all permissions while checking the checkbox, you should see the Toast telling you that we cannot record a video. Then, uninstall the app.

Step #11: Support Configuration Changes

The final thing that we need to do is take configuration changes into account.

There are two things we need to track with regards to configuration changes:

1. We need to track whether the breadcrumb is visible, and if so, what message is displayed. That way, when our activity is destroyed and recreated on a configuration change, we can restore the breadcrumb to its last state as well.
2. We need to track if we requested permissions from onCreate() and are still waiting on the results, so that if the user rotates the screen or triggers some other configuration change, and the user denies one of the permissions, that we do not accidentally immediately display the request-permission dialog again right away.

That latter one might not make a lot of sense, but it will if you try the app in its current state:

TUTORIAL: RUNTIME PERMISSION SUPPORT

- Install and run the app
- When the request-permissions dialog appears on first run, rotate the screen, then deny both permissions
- Get irritated when you are asked again, right away, for those two permissions
- Uninstall the app in a pique of frustration

What is happening is that our activity is destroyed and recreated while the first dialog is in the foreground, because our activity is still visible in the background. That new activity instance goes through its `onCreate()`, which sees that we do not yet have our permissions... and it calls `requestPermissions()` again. Ideally, the permission system would detect that the dialog for those same permissions is in the foreground and ignore the duplicate request. Alas, it does not, so we have to handle this ourselves.

Add the following constants to `MainActivity`:

```
private static final String STATE_BREADCRUST=
    "com.commonware.android.perm.tutorial.breadcrumb";
private static final String STATE_IN_PERMISSION=
    "com.commonware.android.perm.tutorial.inPermission";
```

We will use `STATE_BREADCRUST` as the key to the `Bundle` value that we will store in the saved instance state. And, we will use `STATE_IN_PERMISSION` to track that we are in the middle of the permission-request flow from `onCreate()`.

Next, add the following field to `MainActivity`, used to track whether or not this current activity instance is in the permission-request flow:

```
private boolean isInPermission=false;
```

Then, add the following code to `onCreate()`, just after `setContentView()`, to populate the `isInPermission` flag based on our saved instance state (if we have any):

```
if (savedInstanceState!=null) {
    isInPermission=
        savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
}
```

Then, change the `if` check at the bottom of `onCreate()` to only go into the `if` block if we are not already in the permission-request flow, then flip that `isInPermission` flag to true before calling `requestPermissions()`:

```
if (isFirstRun() && !isInPermission) {
    isInPermission=true;
}
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
ActivityCompat.requestPermissions(this, PERMS_TAKE_PICTURE,  
    RESULT_PERMS_INITIAL);  
}
```

Next, add `onSaveInstanceState()` and `onRestoreInstanceState()` methods to `MainActivity`:

```
@Override  
protected void onSaveInstanceState(Bundle outState) {  
    super.onSaveInstanceState(outState);  
    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);  
  
    if (breadcrust.getVisibility() != View.VISIBLE) {  
        outState.putCharSequence(STATE_BREADCRUST,  
            breadcrust.getText());  
    }  
}  
  
@Override  
protected void onRestoreInstanceState(Bundle savedInstanceState) {  
    super.onRestoreInstanceState(savedInstanceState);  
  
    CharSequence cs = savedInstanceState.getCharSequence(STATE_BREADCRUST);  
  
    if (cs != null) {  
        breadcrust.setVisibility(View.VISIBLE);  
        breadcrust.setText(cs);  
    }  
}
```

If the `breadcrust` is visible, we save the message from the `breadcrust` in the `Bundle`. In `onRestoreInstanceState()`, we make the `breadcrust` be visible if we have a message, where we also put that message into the `breadcrust`.

NOTE: This is a sloppy approach that works only because this app only supports one language. Otherwise, in case of a locale change, we would be saving the message in the old language in the `Bundle` and reapplying it, while the rest of our UI is in the new language. A better implementation would track which of the two messages we need (e.g., via `int` string resource IDs) so we can reapply the resources, pulling in the proper translations. That requires a bit more bookkeeping, and this sample is already annoyingly long. However, just bear in mind that how we are saving the state here is crude and only effective for this limited scenario.

Finally, in `onRequestPermissionsResult()`, flip the `isInPermission` flag back to `false`:

```
@Override  
public void onRequestPermissionsResult(int requestCode,  
    String[] permissions,  
    int[] grantResults) {  
  
    boolean sadTrombone = false;
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
isInPermission=false;

if (requestCode==RESULT_PERMS_TAKE_PICTURE) {
    if (canTakePicture()) {
        takePictureForRealz();
    }
    else if (!shouldShowTakePictureRationale()) {
        sadTrombone=true;
    }
}
else if (requestCode==RESULT_PERMS_RECORD_VIDEO) {
    if (canRecordVideo()) {
        recordVideoForRealz();
    }
    else if (!shouldShowRecordVideoRationale()) {
        sadTrombone=true;
    }
}

if (sadTrombone) {
    Toast.makeText(this, R.string.msg_no_perm,
        Toast.LENGTH_LONG).show();
}
}
```

If you run the app one last time and get the breadcrumb to appear, rotating the device or otherwise triggering a configuration change will not lose the breadcrumb, even though our activity will be destroyed and recreated along the way.

Also, if you reproduce the test you (perhaps) tried at the outset of this step (install and run the app, rotate the device with the permission-request dialog up, then deny both permissions), you should not get a duplicate dialog.

At this point, your MainActivity should resemble the following:

```
package com.commonware.android.perm.tutorial;

import android.app.Activity;
import android.content.Intent;
import android.content.SharedPreferences;
import android.content.pm.PackageManager;
import android.os.Bundle;
import android.os.Environment;
import android.preference.PreferenceManager;
import android.support.v4.app.ActivityCompat;
import android.support.v4.content.ContextCompat;
import android.view.View;
import android.widget.TextView;
import android.widget.Toast;
import com.commonware.cwac.cam2.CameraActivity;
import com.commonware.cwac.cam2.VideoRecorderActivity;
import java.io.File;
import java.util.ArrayList;
import static android.Manifest.permission.CAMERA;
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
import static android.Manifest.permission.RECORD_AUDIO;
import static android.Manifest.permission.WRITE_EXTERNAL_STORAGE;

public class MainActivity extends Activity {

        .quality(VideoRecorderActivity.Quality.HIGH)
        .sizeLimit(5000000)
        .to(new File(rootDir, "test.mp4"))
        .updateMediaStore()
        .forceClassic()
        .build();

    startActivityForResult(i, RESULT_VIDEO_RECORDED);
}
```

TUTORIAL: RUNTIME PERMISSION SUPPORT

```
private boolean isFirstRun() {
    boolean result=prefs.getBoolean(PREF_IS_FIRST_RUN, true);

    if (result) {
        prefs.edit().putBoolean(PREF_IS_FIRST_RUN, false).apply();
    }

    return(result);
}

private boolean hasPermission(String perm) {
    return(ContextCompat.checkSelfPermission(this, perm)==
        PackageManager.PERMISSION_GRANTED);
}

private boolean canTakePicture() {
    return(hasPermission(CAMERA) && hasPermission(WRITE_EXTERNAL_STORAGE));
}

private boolean shouldShowTakePictureRationale() {
    return(ActivityCompat.shouldShowRequestPermissionRationale(
        this, CAMERA) ||
        ActivityCompat.shouldShowRequestPermissionRationale(this,
            WRITE_EXTERNAL_STORAGE));
}

private String[] netPermissions(String[] wanted) {
    ArrayList<String> result=new ArrayList<String>();

    for (String perm : wanted) {
        if (!hasPermission(perm)) {
            result.add(perm);
        }
    }

    return(result.toArray(new String[result.size()]));
}

private boolean canRecordVideo() {
    return(canTakePicture() && hasPermission(RECORD_AUDIO));
}

private boolean shouldShowRecordVideoRationale() {
    return(shouldShowTakePictureRationale() ||
        ActivityCompat.shouldShowRequestPermissionRationale(this,
            RECORD_AUDIO));
}
}
```

And your tutorial is now complete.

Assets, Files, and Data Parsing

Android offers a few structured ways to store data, notably [SharedPreferences](#) and [local SQLite databases](#). And, of course, you are welcome to store your data “in the cloud” by using an [Internet-based service](#). We will get to all of those topics shortly.

Beyond that, though, Android allows you to work with plain old ordinary files, either ones baked into your app (“assets”) or ones on so-called internal or external storage.

To make those files work — and to consume data off of the Internet — you will likely need to employ a parser. Android ships with several choices for XML and JSON parsing, in addition to [third-party libraries](#) you can attempt to use.

This chapter focuses on assets, files, and parsers.

Packaging Files with Your App

Let’s suppose you have some static data you want to ship with the application, such as a list of words for a spell-checker. Somehow, you need to bundle that data with the application, in a way you can get at it from Java code later on, or possibly in a way you can pass to another component (e.g., `WebView` for bundled HTML files).

There are three main options here: raw resources, XML resources, and assets.

Raw Resources

One way to deploy a file like a spell-check catalog is to put the file in the `res/raw` directory, so it gets put in the Android application `.apk` file as part of the packaging process as a raw resource.

To access this file, you need to get yourself a `Resources` object. From an activity, that is as simple as calling `getResources()`. A `Resources` object offers `openRawResource()` to get an `InputStream` on the file you specify. Rather than a path, `openRawResource()` expects an integer identifier for the file as packaged. This works just like accessing widgets via `findViewById()` – if you put a file named `words.xml` in `res/raw`, the identifier is accessible in Java as `R.raw.words`.

Since you can only get an `InputStream`, you have no means of modifying this file. Hence, it is really only useful for static reference data. Moreover, since it is unchanging until the user installs an updated version of your application package, either the reference data has to be valid for the foreseeable future, or you will need to provide some means of updating the data. The simplest way to handle that is to use the reference data to bootstrap some other modifiable form of storage (e.g., a database), but this makes for two copies of the data in storage. An alternative is to keep the reference data as-is but keep modifications in a file or database, and merge them together when you need a complete picture of the information. For example, if your application ships a file of URLs, you could have a second file that tracks URLs added by the user or reference URLs that were deleted by the user.

XML Resources

If, however, your file is in an XML format, you are better served not putting it in `res/raw/`, but rather in `res/xml/`. This is a directory for XML resources – resources known to be in XML format, but without any assumptions about what that XML represents.

To access that XML, you once again get a `Resources` object by calling `getResources()` on your Activity or other Context. Then, call `getXml()` on the `Resources` object, supplying the ID value of your XML resource (e.g., `R.xml.words`). This will return an `XmlResourceParser`, which implements the `XmlPullParser` interface. We will discuss how to use this parser, and the performance advantage of using XML resources, [later in this chapter](#).

As with raw resources, XML resources are read-only at runtime.

Assets

Your third option is to package the data in the form of an asset. You can create an `assets/` directory at the root of your project directory, then place whatever files you want in there. Those are accessible at runtime by calling `getAssets()` on your

Activity or other Context, then calling `open()` with the path to the file (e.g., `assets/foo/index.html` would be retrieved via `open("foo/index.html")`). As with raw resources, this returns an `InputStream` on the file's contents. And, as with all types of resources, assets are read-only at runtime.

One benefit of using assets over raw resources is the `file:///android_asset/Uri` prefix. You can use this to load an asset into a `WebView`. For example, for an asset located in `assets/foo/index.html` within your project, calling `loadUrl("file:///android_asset/foo/index.html")` will load that HTML into the `WebView`.

Note that assets are compressed when the APK is packaged. Unfortunately, on Android 1.x/2.x, this compression mechanism has a 1MB file size limit. If you wish to package an asset that is bigger than 1MB, you either need to give it a file extension that will not be compressed (e.g., `.mp3`) or actually store a ZIP file of the asset (to avoid the automatic compression) and decompress it yourself at runtime, using the standard `java.util.zip` classes. This restriction was lifted with Android 3.0, and so if your `minSdkVersion` is 11 or higher, this will not be an issue for you.

Files and Android

On the whole, Android just uses normal Java file I/O for local files. You will use the same `File` and `InputStream` and `OutputWriter` and other classes that you have used time and again in your prior Java development work.

What is distinctive in Android is *where* you read and write. Akin to writing a Java Web app, you do not have read and write access to arbitrary locations. Instead, there are only a handful of directories to which you have any access, particularly when running on production hardware.

Internal vs. External

Internal storage refers to your application's portion of the on-board, always-available flash storage. External storage refers to storage space that can be mounted by the user as a drive in Windows (or, possibly with some difficulty, as a volume in OS X or Linux).

Historically (i.e., Android 1.x/2.x), internal storage was very limited in space. That is far less of a problem on 3.0 and higher.

Similarly, external storage is not always available on Android 1.x and 2.x – if it is mounted as a drive or volume on a host desktop or notebook, your app will not have access to external storage. We will examine this limitation in a bit more detail [later in this chapter](#). This is not usually a problem on Android 3.0+.

Standard vs. Cache

On both internal and external storage, you have the option of saving files as a cache, or on a more permanent basis. Files located in a cache directory may be deleted by the OS or third-party apps to free up storage space for the user. Files located outside of cache will remain unless manually deleted.

Yours vs. Somebody Else's

Internal storage is on a per-application basis. Files you write to in your own internal storage cannot be read or written to by other applications... normally. Users who “root” their phones can run apps with superuser privileges and be able to access your internal storage. Most users do not root their phones, and so only your app will be able to access your internal storage files.

Files on external storage, though, are visible to all applications and the user. Anyone can read anything stored there, and any application that requests to can write or delete anything it wants.

Working with Internal Storage

You have a few options for manipulating the contents of your app's portion of internal storage.

One possibility is to use `openFileInput()` and `openFileOutput()` on your `Activity` or other `Context` to get an `InputStream` and `OutputStream`, respectively. However, these methods do not accept file paths (e.g., `path/to/file.txt`), just simple filenames.

If you want to have a bit more flexibility, `getFilesDir()` and `getCacheDir()` return a `File` object pointing to the roots of your files and cache locations on internal storage, respectively. Given the `File`, you can create files and subdirectories as you see fit.

To see how this works, take a peek at the [Files/FilesEditor](#) sample project.

ASSETS, FILES, AND DATA PARSING

This application implements a tabbed editor, using a ViewPager and [a third-party tab library](#). Each tab is an EditorFragment, implementing a large EditText widget, akin to what we saw as examples back in [the chapter on ViewPager](#).

However, those ViewPager samples had no persistence. Whatever you typed stayed in the fragments but was lost when the process was terminated. FileEditor instead will save what you enter into files, one file per tab.

The layout for the activity is reminiscent of the ViewPager samples, except that we are using an `io.karim.MaterialTabs` widget for the tabs, instead of something like a `PagerTabStrip`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <io.karim.MaterialTabs
        android:id="@+id/tabs"
        android:layout_width="match_parent"
        android:layout_height="48dp"
        app:mtIndicatorColor="@color/accent"
        app:mtSameWeightTabs="true"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>
</LinearLayout>
```

That library, `io.karim:materialtabs`, is one of our dependencies, along with the `support-v13` library for ViewPager itself:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'io.karim:materialtabs:2.0.2'
    compile 'com.android.support:support-v13:22.2.1'
}

android {
    compileSdkVersion 22
    buildToolsVersion "22.0.1"

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 18
    }
}
```

ASSETS, FILES, AND DATA PARSING

Other than some slight tweaks for using a `MaterialTabs` for the tabs, the `MainActivity` is not significantly different than the original `ViewPager` examples. It loads up the layout and populates the `ViewPager` and tabs:

```
package com.commonware.android.fileseditor;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.ViewPager;
import io.karim.MaterialTabs;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        pager.setAdapter(new SampleAdapter(this, getFragmentManager()));

        MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
        tabs.setViewPager(pager);
    }
}
```

Where things start to depart more significantly from the original samples comes in `SampleAdapter`. Rather than 10 pages, we limit the number of tabs to 3 in `getCount()`. Rather than delegate the page titles to the `EditorFragment`, `getPageTitle()` looks up a string resource value from an array, based on the position, and uses that for the title. And `getPage()`... becomes more complicated:

```
package com.commonware.android.fileseditor;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.os.Environment;
import android.support.v13.app.FragmentPagerAdapter;
import java.io.File;

public class SampleAdapter extends FragmentPagerAdapter {
    private static final int[] TITLES={R.string.internal,
        R.string.external, R.string.pub};
    private static final int TAB_INTERNAL=0;
    private static final int TAB_EXTERNAL=1;
    private static final String FILENAME="test.txt";
    private final Context ctxt;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);

        this.ctxt=ctxt;
    }
}
```

```
@Override
public int getCount() {
    return(3);
}

@Override
public Fragment getItem(int position) {
    File fileToEdit;

    switch(position) {
        case TAB_INTERNAL:
            fileToEdit=new File(ctxt.getFilesDir(), FILENAME);
            break;

        case TAB_EXTERNAL:
            fileToEdit=new File(ctxt.getExternalFilesDir(null), FILENAME);
            break;

        default:
            fileToEdit=
                new File(Environment.
                    getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS),
                    FILENAME);
            break;
    }

    return(EditorFragment.newInstance(fileToEdit));
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
}
}
```

Based on the supplied position, we create a File object representing where the data resides for our EditorFragment. Right now, let's focus on the TAB_INTERNAL case, where we use `getFilesDir()` to create a File object pointing to a `test.txt` file on our internal storage.

The `newInstance()` factory method on EditorFragment now takes the File object as input, instead of the position. A File is Serializable, and so we can put a File into the arguments Bundle:

```
static EditorFragment newInstance(File fileToEdit) {
    EditorFragment frag=new EditorFragment();
    Bundle args=new Bundle();

    args.putSerializable(KEY_FILE, fileToEdit);
    frag.setArguments(args);

    return(frag);
}
```

ASSETS, FILES, AND DATA PARSING

In `onCreateView()` of `EditorFragment`, we inflate a layout that contains our large `EditText` widget and retrieve that `EditText` widget:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);

    return(result);
}
```

In addition to an editor field for our `EditText`, `EditorFragment` has two other fields. One is a `LoadTextTask`, an `AsyncTask` subclass that we will use to load text from our file into our `EditText`. The other is `loaded`, a simple boolean to see if we have loaded our text yet:

```
private EditText editor;
private LoadTextTask loadTask=null;
private boolean loaded=false;
```

In `onViewCreated()`, if we have not yet loaded the text, we kick off a `LoadTextTask` to do just that, passing in the `File` that we put into the arguments `Bundle`:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    if (!loaded) {
        loadTask=new LoadTextTask();
        loadTask.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR,
            (File) getArguments().getSerializable(KEY_FILE));
    }
}
```

`LoadTextTask`, in `doInBackground()`, goes through a typical Java file I/O read-all-the-lines process to read in a text file, if it exists. The resulting string is poured into the `EditText`. In `onPostExecute()`, it updates the `EditText` with the read-in text, plus clears the `loadTask` field and sets `loaded` to true:

```
private class LoadTextTask extends AsyncTask<File, Void, String> {
    @Override
    protected String doInBackground(File... files) {
        String result=null;

        if (files[0].exists()) {
            BufferedReader br;

            try {
                br=new BufferedReader(new FileReader(files[0]));
            }
        }
    }
}
```

```
try {
    StringBuilder sb=new StringBuilder();
    String line=br.readLine();

    while (line!=null) {
        sb.append(line);
        sb.append("\n");
        line=br.readLine();
    }

    result=sb.toString();
}
finally {
    br.close();
}
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception reading file", e);
}
}

return(result);
}

@Override
protected void onPostExecute(String s) {
    editor.setText(s);
    loadTask=null;
    loaded=true;
}
}
```

However, since we are using an AsyncTask, we should retain this fragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
}
```

...and in onDestroy(), we should cancel() this task if it is still running, as we no longer need the results:

```
@Override
public void onDestroy() {
    if (loadTask!=null) {
        loadTask.cancel(false);
    }

    super.onDestroy();
}
```

Rather than have some dedicated “save” action bar item or similar UI element, we can just arrange to save the data when our fragment gets paused. This is a typical

approach in Android apps, as users do not necessarily get an opportunity to click some “save” UI element, if they get interrupted by a phone call or something. So, in `onPause()`, we kick off a `SaveThread` to write our `EditText` contents to the same `File`, once again pulled from the arguments `Bundle`:

```
@Override
public void onPause() {
    if (loaded) {
        new SaveThread(editor.getText().toString(),
            (File) getArguments().getSerializable(KEY_FILE)).start();
    }

    super.onPause();
}
```

However, note that we do not fork the `SaveThread` if `loaded` is still `false`. In that case, we know that we are still loading in the text, which means the text cannot possibly have been modified by the user, so there is nothing to save.

`SaveThread` ensures that the directory we want to write to exists (as it may or may not exist, particularly on emulators), then uses `Java Writer` objects to write out our text. Since there is nothing that we want to do with the UI here, a plain `Thread`, rather than an `AsyncTask`, is a better solution:

```
private static class SaveThread extends Thread {
    private final String text;
    private final File fileToEdit;

    SaveThread(String text, File fileToEdit) {
        this.text=text;
        this.fileToEdit=fileToEdit;
    }

    @Override
    public void run() {
        try {
            fileToEdit.getParentFile().mkdirs();

            FileOutputStream fos=new FileOutputStream(fileToEdit);

            Writer w=new BufferedWriter(new OutputStreamWriter(fos));

            try {
                w.write(text);
                w.flush();
                fos.getFD().sync();
            }
            finally {
                w.close();
            }
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception writing file", e);
        }
    }
}
```

```
}  
}  
}
```

The reason for using a `FileOutputStream`, and that mysterious `getFD().sync()` part, will be covered [later in this chapter](#).

The result is a set of tabbed editors, where the first one is our one for internal storage:

Figure 241: FilesEditor Sample, As Initially Launched

If you type something into the “Internal” tab, press BACK to exit the activity, and go back into the app again, whatever you typed in will be re-loaded from disk and will show up in the editor.

The files stored in internal storage are accessible only to your application, by default. Other applications on the device have no rights to read, let alone write, to this space. However, bear in mind that some users “root” their Android phones, gaining superuser access. These users will be able to read and write whatever files they wish. As a result, please consider application-local files to be secure against malware but not necessarily secure against interested users.

Working with External Storage

On most Android 1.x devices and some early Android 2.x devices, external storage came in the form of a micro SD card or the equivalent. On the remaining Android 2.x devices, external storage was part of the on-board flash, but housed in a separate partition from the internal storage. On most Android 3.0+ devices, external storage is now simply a special directory in the partition that holds internal storage.

Devices will have at least 1GB of external storage free when they ship to the user. That being said, many devices have much more than that, but the available size at any point could be smaller than 1GB, depending on how much data the user has stored.

Where to Write

If you have files that are tied to your application that are simply too big to risk putting in internal storage, or if the user should be able to download the files off their device at will, you can use `getExternalFilesDir()`, available on any activity or other Context. This will give you a File object pointing to an automatically-created directory on external storage, unique for your application. While not secure against other applications, it does have one big advantage: when your application is uninstalled, these files are automatically deleted, just like the ones in the application-local file area. This method was added in API Level 8. This method takes one parameter — typically `null` — that indicates a particular type of file you are trying to save (or, later, load).

In `SampleAdapter` of the sample app, if the user chooses the “External” tab, we use `getExternalFilesDir()` to create the File to be used by the `EditorFragment`:

```
case TAB_EXTERNAL:
    fileToEdit=new File(ctxt.getExternalFilesDir(null), FILENAME);
    break;
```

There is also `getExternalCacheDir()`, which returns a File pointing at a directory that contains files that you would like to have, but if Android or a third-party app clears the cache, your app will continue to function normally.

Android 4.4 (API Level 19) added two new methods, `getExternalCacheDirs()` and `getExternalFilesDirs()`, the plural versions of the classic methods. These return an array of File objects, representing one or more places where your app can work with external storage. The first element in the array will be the same File object

returned by the singular versions of the methods (e.g., `getExternalFilesDir()`). The other elements in the array, if any, will represent app-specific directories on alternative external storage locations, like removable cards. The Android Support package has a `ContextCompat` class containing static versions of `getExternalCacheDirs()` and `getExternalFilesDirs()`, so you can use the same code on API Level 4 and above, though the backport will only ever return one directory in the array.

If you have files that belong more to the user than to your app — pictures taken by the camera, downloaded MP3 files, etc. — a better solution is to use `getExternalStoragePublicDirectory()`, available on the `Environment` class. This will give you a `File` object pointing to a directory set aside for a certain type of file, based on the type you pass into `getExternalStoragePublicDirectory()`. For example, you can ask for `DIRECTORY_MOVIES`, `DIRECTORY_MUSIC`, or `DIRECTORY_PICTURES` for storing MP4, MP3, or JPEG files, respectively. These files will be left behind when your application is uninstalled. This method was also added in API Level 8.

In `SampleAdapter` of the sample app, if the user chooses the “Public” tab, we use `getExternalStoragePublicDirectory()` to create the `File` to be used by the `EditorFragment`, putting our file in the `DIRECTORY_DOCUMENTS` location:

```
default:
    fileToEdit=
        new File(Environment.
            getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS),
            FILENAME);
    break;
```

You will also find a `getExternalStorageDirectory()` method on `Environment`, pointing to the root of the external storage. This is no longer the preferred approach — the methods described above help keep the user’s files better organized. However, if you are supporting older Android devices, you may need to use `getExternalStorageDirectory()`, simply because the newer options may not be available to you.

Relevant Permissions

On all relevant Android versions prior to Android 4.4 (API Level 19), if you want to write to external storage, you need to hold the `WRITE_EXTERNAL_STORAGE` permission. And, on those versions, you do not need a permission to read from external storage.

On Android 4.4 and up, the rules are a bit different:

ASSETS, FILES, AND DATA PARSING

- To read or write in the directory trees rooted at `getExternalFilesDir()` and `getExternalCacheDir()`, you do not need a permission
- To write to anywhere else on external storage, you need `WRITE_EXTERNAL_STORAGE`
- To read from anywhere else on external storage, you need either `WRITE_EXTERNAL_STORAGE` (if you already have that) or `READ_EXTERNAL_STORAGE` (if not)

Hence, so long as your `android:minSdkVersion` is less than 19, you need to take the most conservative approach:

- If you are writing *anywhere* on external storage, request the `WRITE_EXTERNAL_STORAGE` permission
- If you are only reading, but from *anywhere* on external storage, request the `READ_EXTERNAL_STORAGE` permission

Note that you might get paths to external storage locations from third-party apps, typically in the form of a `Uri`. If you are handling `Uri` values from third-party apps, you should request `READ_EXTERNAL_STORAGE` or `WRITE_EXTERNAL_STORAGE`, in case the third-party app hands you a `Uri` pointing to external storage.

For example, here is the sample app's manifest, complete with the `<uses-permission>` element for `WRITE_EXTERNAL_STORAGE`:

```
<?xml version="1.0"?>
<manifest package="com.commonware.android.fileseditor"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission
        android:name="android.permission.WRITE_EXTERNAL_STORAGE"
        android:maxSdkVersion="18"/>

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:theme="@style/Theme.Apptheme"
        android:label="@string/app_name">
        <activity
            android:name=".MainActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
        <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
    </activity>
</application>

</manifest>
```

Note the use of `android:maxSdkVersion`. This tells Android to only request this permission up to the stated API level. After that, ignore the request. This sample uses `getExternalFilesDir()` and therefore does not need `WRITE_EXTERNAL_STORAGE` on API Level 19+ devices. Users who install this app on such devices will not be prompted for this permission, while users who install this app on older devices will.

When to Write

Also, external storage may be tied up by the user having mounted it as a USB storage device. You can use `getExternalStorageState()` (a static method on `Environment`) to determine if external storage is presently available or not. On Android 3.0 and higher, this should be much less of an issue, as they changed how the external storage is used by the host PC — originally, this used USB Mass Storage Mode (think thumb drives) and now uses the USB Media Transfer Protocol (think MP3 players). With MTP, both the Android device and the PC it is connected to can have access to the files simultaneously; Mass Storage Mode would only allow the host PC to have access to the files if external storage is mounted.

Nowadays, you can use `getStorageState()` on the `Environment` class (or `getStorageState()` on the `EnvironmentCompat` class from the Android Support package) to find out the state of external storage, for the particular `File` passed as a parameter.

Letting the User See Your Files

The switch to MTP has one side-effect for Android developers: files you write to external storage may not be automatically visible to the user. At the time of this writing, the only files that will show up on the user's PC will be ones that have been indexed by the `MediaStore`. While the `MediaStore` is typically thought of as only indexing “media” (images, audio files, video files, etc.), it was given the added role in Android 3.0 of maintaining an index of *all* files for the purposes of MTP.

Your file that you place on external storage will not be indexed automatically simply by creating it and writing to it. Eventually, it will be indexed, though it may be quite some time for an automatic indexing pass to take place.

ASSETS, FILES, AND DATA PARSING

To force Android to index your file, you can use `scanFile()` on `MediaScannerConnection`:

```
String[] paths={pathToYourNewFileOnExternalStorage};
MediaScannerConnection.scanFile(this, paths, null, null);
```

The third parameter to `scanFile()` is an array of MIME types, to line up with the array of paths in the second parameter. If your file is some form of media, and you know the MIME type, supplying that will ensure that your media will be visible as appropriate to the right apps (e.g., images in the Gallery app). Otherwise, Android will try to infer a MIME type from the file extension.

In the sample app, since the `EditorFragment` does not know whether the file is on external storage and therefore is reachable, it does not know whether or not this sort of indexing is appropriate. In a more conventional scenario, where the `EditorFragment` would consistently be writing to external storage, `SaveThread` could arrange to invoke `MediaScannerConnection` as part of its work. However, `scanFile()` needs a `Context`, and so the `SaveThread` would need one of those. You would wind up with something a bit like:

```
private static class SaveThread extends Thread {
    private final String text;
    private final File fileToEdit;
    private final Context ctxt;

    SaveThread(Context ctxt, String text, File fileToEdit) {
        this.ctxt=ctxt.getApplicationContext();
        this.text=text;
        this.fileToEdit=fileToEdit;
    }

    @Override
    public void run() {
        try {
            fileToEdit.getParentFile().mkdirs();

            FileOutputStream fos=new FileOutputStream(fileToEdit);

            Writer w=new BufferedWriter(new OutputStreamWriter(fos));

            try {
                w.write(text);
                w.flush();
                fos.getFD().sync();
            }
            finally {
                w.close();
                String[] paths={fileToEdit};
                MediaScannerConnection.scanFile(ctxt, paths, null, null);
            }
        }
        catch (IOException e) {
```

```
        Log.e(getClass().getSimpleName(), "Exception writing file", e);
    }
}
```

Here, we use `getApplicationContext()`, which returns to us a `Context` that is a process-wide singleton. That way, if our activity is destroyed while the thread is still running, we still have a valid `Context` to use.

Limits on External Storage Open Files

Many Android devices will have a per-process limit of 1024 open files, on any sort of storage. This is usually not a problem for developers.

On some devices — including probably all that are running Android 4.2 and higher — there is a *global* limit of 1024 open files on external storage. In other words, all running apps combined can only open 1024 files simultaneously on external storage.

This means that it is important for you to minimize how many open files on external storage you have at a time. Having a few open files is perfectly reasonable; having a few hundred open files is not.

Multiple User Accounts

On Android 4.1 and earlier, each Android device was assumed to be used by just one person.

On Android 4.2 and higher, though, it is possible for a tablet owner to set up multiple user accounts. Each user gets their own section of internal and external storage for files, databases, `SharedPreferences`, and so forth. From your standpoint, it is as if the users are really on different devices, even though in reality it is all the same hardware.

However, this means that paths to internal and external storage now may vary by user. Hence, it is *very important* for you to use the appropriate methods, outlined in this chapter, for finding locations on internal storage (e.g., `getFilesDir()`) and external storage (e.g., `getExternalFilesDir()`).

Some blog posts, Stack Overflow answers, and the like will show the use of hard-coded paths for these locations (e.g., `/sdcard` or `/mnt/sdcard` for the root of external

storage). Hard-coding such paths was never a good idea. And, as of Android 4.2, those paths are simply wrong and will not work.

On Android 4.2+, for the original user of the device, internal storage will wind up in the same location as before, but external storage will use a different path. For the second and subsequent users defined on the device, both internal and external storage will reside in different paths. The various methods, like `getFilesDir()`, will handle this transparently for you.

Note that, at the time of this writing, multiple accounts are not available on the emulators, only on actual tablets. Phones usually will not have multiple-account support, under the premise that tablets are more likely to be shared than are phones.

Linux Filesystems: You Sync, You Win

Android is built atop a Linux kernel and uses Linux filesystems for holding its files. Classically, Android used YAFFS (Yet Another Flash File System), optimized for use on low-power devices for storing data to flash memory.

YAFFS has one big problem: only one process can write to the filesystem at a time. For those of you into filesystems, rather than offering file-level locking, YAFFS has partition-level locking. This can become a bit of a bottleneck, particularly as Android devices grow in power and start wanting to do more things at the same time like their desktop and notebook brethren.

Android 3.0 switched to ext4, another Linux filesystem aimed more at desktops/notebooks. Your applications will not directly perceive the difference. However, ext4 does a fair bit of buffering, and it can cause problems for applications that do not take this buffering into account. Linux application developers ran headlong into this in 2008-2009, when ext4 started to become popular. Android developers will need to think about it now... for your own file storage.

If you are using SQLite or SharedPreferences, you do not need to worry about this problem. Android (and SQLite, in the case of SQLite) handle all the buffering issues for you. If, however, you write your own files, you may wish to contemplate an extra step as you flush your data to disk. Specifically, you need to trigger a Linux system call known as `fsync()`, which tells the filesystem to ensure all buffers are written to disk.

ASSETS, FILES, AND DATA PARSING

If you are using `java.io.RandomAccessFile` in a synchronous mode, this step is handled for you as well, so you will not need to worry about it. However, Java developers tend to use `FileOutputStream`, which does not trigger an `fsync()`, even when you call `close()` on the stream. Instead, you call `getFD().sync()` on the `FileOutputStream` to trigger the `fsync()`. Note that this may be time-consuming, and so disk writes should be done off the main application thread wherever practical, such as via an `AsyncTask`.

This is why, in `EditorFragment`, our `SaveThread` implementation looks like this:

```
private static class SaveThread extends Thread {
    private final String text;
    private final File fileToEdit;

    SaveThread(String text, File fileToEdit) {
        this.text=text;
        this.fileToEdit=fileToEdit;
    }

    @Override
    public void run() {
        try {
            fileToEdit.getParentFile().mkdirs();

            FileOutputStream fos=new FileOutputStream(fileToEdit);

            Writer w=new BufferedWriter(new OutputStreamWriter(fos));

            try {
                w.write(text);
                w.flush();
                fos.getFD().sync();
            }
            finally {
                w.close();
            }
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception writing file", e);
        }
    }
}
```

While we use a `Writer` to do the writing, it is wrapped around a `FileOutputStream`, so we can get access to the `FileDescriptor` (via `getFD()`) and call `sync()` on it.

StrictMode: Avoiding Janky Code

Users are more likely to like your application if, to them, it feels responsive. Here, by “responsive”, we mean that it reacts swiftly and accurately to user operations, like taps and swipes.

Conversely, users are less likely to be happy with you if they perceive that your UI is “janky” — sluggish to respond to their requests. For example, maybe your lists do not scroll as smoothly as they would like, or tapping a button does not yield the immediate results they seek.

While threads and `AsyncTask` and the like can help, it may not always be obvious where you should be applying them. A full-scale performance analysis, using [Traceview](#) or similar Android tools, is certainly possible. However, there are a few standard sorts of things that developers do, sometimes quite by accident, on the main application thread that will tend to cause sluggishness:

1. Flash I/O, both for internal and external storage
2. Network I/O

However, even here, it may not be obvious that you are performing these operations on the main application thread. This is particularly true when the operations are really being done by Android’s code that you are simply calling.

That is where `StrictMode` comes in. Its mission is to help you determine when you are doing things on the main application thread that might cause a janky user experience.

`StrictMode` works on a set of policies. There are presently two categories of policies: VM policies and thread policies. The former represent bad coding practices that pertain to your entire application, notably leaking `SQLite Cursor` objects and kin. The latter represent things that are bad when performed on the main application thread, notably flash I/O and network I/O.

Each policy dictates what `StrictMode` should watch for (e.g., flash reads are OK but flash writes are not) and how `StrictMode` should react when you violate the rules, such as:

1. Log a message to LogCat
2. Display a dialog

3. Crash your application (seriously!)

The simplest thing to do is call the static `enableDefaults()` method on `StrictMode` from `onCreate()` of your first activity. This will set up normal operation, reporting all violations by simply logging to LogCat. However, you can set your own custom policies via `Builder` objects if you so choose.

However, do not use `StrictMode` in production code. It is designed for use when you are building, testing, and debugging your application. It is not designed to be used in the field.

So, for example, you might have something like this in your launcher activity:

```
StrictMode.ThreadPolicy.Builder b=new StrictMode.ThreadPolicy.Builder();  
  
if (BuildConfig.DEBUG) {  
    b.detectAll().penaltyDeath();  
}  
else {  
    b.detectAll().penaltyLog();  
}  
  
StrictMode.setThreadPolicy(b.build());
```

`BuildConfig.DEBUG` will be true for debuggable builds, false otherwise. So, in the case of a debug build, we want to detect all mistakes and crash the app immediately when we encounter them, but in production, we want to just log information about the mistake to LogCat.

You will note that the sample app does not contain this code. That is because calling methods like `getFilesDir()` and `getExternalFilesDir()` really ought to be on background threads, as `StrictMode` will complain about them. Hence, this code would cause `SampleAdapter` to crash when it tries building the `File` object to use. This could be rectified by having `SampleAdapter` simply pass in a flag indicating the storage location and having `LoadThreadTask` and `SaveThread` deal with the `File` objects.

Note that `StrictMode` will also report leaked open files. For example, if you create a `FileOutputStream` on a `File` and fail to `close()` it later, when the `FileOutputStream` (and related objects) are garbage-collected, `StrictMode` will report to you the fact that you failed to close the stream. This is very useful to help you make sure that you are not leaking open files that may contribute to [exhausting the 1,024 open file limit on external storage](#).

Files, and Your Development Machine

All this reading and writing of data is nice, but for debugging and diagnostic purposes, it is often useful for you to be able to look at the files, other than through your app.

This is somewhat challenging, due to the lack of tools and due to security restrictions in production devices (as compared to emulators).

That being said, the following sections will outline some options that you have to access your app's files independently of your app.

Mounting as a Drive

If you have an actual Android device, when you plug it in via a USB cable, usually you will get external storage available as a drive letter (Windows) or a mounted volume (OS X and Linux). Depending upon the device, manufacturer, and configuration, you might also have access to removable storage this way as well.

In these cases, you can use your development machine's OS to poke around these file locations and look at your files (or anyone else's).

However, there are some wrinkles:

- On Android 6.0+, by default, a USB connection is only used for charging. You need to slide open the notification tray and tap on the Notification for the USB connection, to toggle it to share files using MTP.
- Some versions of OS X and Linux will require you to install additional software to view files over MTP.
- If you see a volume name labeled "Internal Storage", that is really external storage, because confusing people is fun, apparently.
- You cannot get to what the Android SDK refers to as internal storage by this means.

Push and Pull for External Storage

You can get at external storage (and possibly removable storage) of devices and emulators via the command-line `adb` tool. This program is in `platform-tools/` of your Android SDK installation, and it is a good idea to add that directory to your operating system's `PATH` environment variable, so you can run `adb` from anywhere.

ASSETS, FILES, AND DATA PARSING

`adb push` and `adb pull` allow you to upload and download files, respectively. Both take the local path and the remote (device/emulator) path as command-line arguments, although in varying order:

- `adb push localpath remotepath` will upload the file represented by `localpath` to the location represented by `remotepath`
- `adb pull remotepath localpath` will download the file represented by `remotepath` to the location represented by `localpath`

For external storage, the root directory name varies by Android OS version:

- Android 1.x/2.x: use `/sdcard/`
- Android 4.x/5.x: use `/mnt/shell/emulated/0/`
- Android 6.0+: use `/storage/emulated/0/`.

So, for example, the following command would push an `index.html` file to the `getExternalFilesDir()` location for the primary device account, for an app whose application is `your.package.name.here`:

```
adb push index.html /storage/emulated/0/Android/data/your.package.name.here/files
```

If you try to push a local directory, or pull a remote directory, the contents of those directories will be uploaded and downloaded, respectively. However, the *directory* itself is not, which can cause some confusion.

Suppose we have a directory on our development PC named `foo/`. It contains four PNG files, named `1.png`, `2.png`, `3.png`, and `parallelism-is-boring.png`. We then execute the following command on the command line:

```
adb push foo /storage/emulated/0/Android/data/your.package.name.here/files
```

You will wind up with:

- `/storage/emulated/0/Android/data/your.package.name.here/files/1.png`
- `/storage/emulated/0/Android/data/your.package.name.here/files/2.png`
- `/storage/emulated/0/Android/data/your.package.name.here/files/3.png`
- `/storage/emulated/0/Android/data/your.package.name.here/files/parallelism-is-boring.png`

Note, though, that the `foo` directory name is not included. In other words, the *contents* of `foo/` are transferred, but not `foo/` itself.

Run-As for Internal Storage

`adb push` and `adb pull` work directly for internal storage as well... on emulators.

On production hardware, though, you have some additional work to do. Specifically, you need to use external storage as an intermediary and use `adb run-as` to give yourself the temporary ability to work with internal storage.

For example, on an emulator, you could push `index.html` to the directory returned by `getFilesDir()`, for an app with an application ID of `your.package.name.here`, for the primary device account, via:

```
adb push index.html /data/data/your.package.name.here/files
```

If you try that on production hardware, it will fail. While the piece that `adb` communicates with on the emulator runs with superuser privileges, the equivalent piece on production hardware does not. The same security that prevents other apps from accessing your app's portion of internal storage prevents `adb` from doing so as well.

However, `adb` on production hardware *can* use the `run-as` command, to execute a Linux command as if it were being run by the Linux user associated with your app, the user that owns all your files and who has read/write access to those files.

So, the equivalent script to copy the file to internal storage on a production Android 4.x/5.x device would be:

```
adb push index.html /mnt/shell/emulated/0
adb shell run-as your.package.name.here cp /mnt/shell/emulated/0/index.html /data/data/
your.package.name.here/files
adb shell rm /mnt/shell/emulated/0/index.html
```

(note that the second command should appear all on one line, even though it may show up as word-wrapped here due to the length of the line and the available width of the book)

This will only work for debuggable apps, which is the normal state of apps that you run from your IDE. This script:

- Pushes the file to the root of external storage

- Uses `run-as` to run the Linux `cp` command to copy the file from external storage to the app's internal storage
- Runs the Linux `rm` command to remove the file that we placed on external storage

(if you are wondering why we do not use `mv` instead of `cp` and `rm`, `mv` generates errors related to attempting to change the ownership of the moved file)

XML Parsing Options

Android supports a fairly standard implementation of the Java DOM and SAX APIs. If you have existing experience with these, or if you have code that already leverages them, feel free to use them.

Android also bakes in the `XmlPullParser` from [the xmlpull.org site](http://the.xmlpull.org). Like SAX, the `XmlPullParser` is an event-driven interface, compared to the DOM that builds up a complete data structure and hands you that result. Unlike SAX, which relies on a listener and callback methods, the `XmlPullParser` has you pull events off a queue, ignoring those you do not need and dispatching the rest as you see fit to the rest of your code.

The primary reason the `XmlPullParser` was put into Android was for XML-encoded resources. While you write plain-text XML during development, what is packaged in your APK file is a so-called “binary XML” format, where angle brackets and quotation marks and such are replaced by bitfields. This helps compression a bit, but mostly this conversion is done to speed up parsing. Android's XML resource parser can parse this “binary XML” approximately ten times faster than it can parse the equivalent plain-text XML. Hence, anything you put in an XML resource (`res/xml/`) will be parsed similarly quickly.

For plain-text XML content, the `XmlPullParser` is roughly equivalent, speed-wise, to SAX. All else being equal, lean towards SAX, simply because more developers will be familiar with it from classic Java development. However, if you really like the `XmlPullParser` interface, feel free to use it.

You are welcome to try a third-party XML parser JAR, but bear in mind [that there may be issues when trying to get it working in Android](#).

JSON Parsing Options

Android has bundled the `org.json` classes into the SDK since the beginning, for use in parsing JSON. These classes have a DOM-style interface: you hand `JSONObject` a hunk of JSON, and it gives you an in-memory representation of the completely parsed result. This is handy but, like the DOM, a bit of a performance hog.

API Level 11 added `JSONReader`, based on Google's GSON parser, as a "streaming" parser alternative. `JSONReader` is much more reminiscent of the `XmlPullParser`, in that you pull events out of the "reader" and process them. This can have significant performance advantages, particularly in terms of memory consumption, if you do not need the entire JSON data structure. However, this is only available on API Level 11 and higher.

Because `JSONReader` is a bit "late to the party", there has been extensive work on getting other JSON parsers working on Android. [Google's GSON](#) is popular, as is [Jackson](#). Jackson offers a few APIs, and the streaming API reportedly works very nicely on Android with top-notch performance.

Visit the Trails!

In addition to this chapter, you can learn more about accessing multimedia files [via the MediaStore](#) and learn more about [the impacts of multiple user accounts on tablets](#).

Tutorial #11 - Adding Simple Content

Now that we have seen how to work with assets, we can start putting them to use, by defining some “help” and “about” HTML files and displaying them in their respective activities.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book’s GitHub repository.

Step #1: Adding Some Content

Your project may already have an `assets/` folder. If not, create one. In Android Studio, right-click over the main sourceset directory, choose `New > Directory` from the context menu, fill in the name `assets` in the dialog, and click `OK`. This should give you an `app/` module that looks like:

Figure 242: EmPubLite Project, Showing assets/ in main/ of app/

TUTORIAL #11 - ADDING SIMPLE CONTENT

In `assets/`, create a `misc/` sub-folder, by right-clicking over the `assets/` folder and choosing to add a new directory named `misc` (e.g., `New > Directory` from the Android Studio context menu), giving you something like:

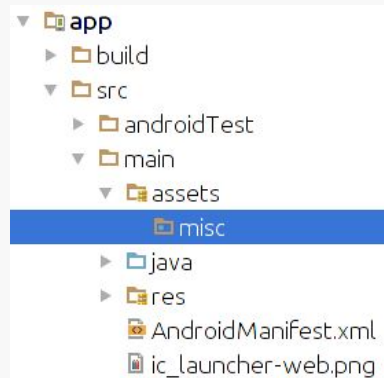

Figure 243: EmPubLite Project, Showing `assets/misc/` in `main/` of `app/`

In `assets/misc/`, create two files, about `.html` and `help.html`. In Android Studio, right-click over the `assets/misc/` folder in the project explorer, choose `New > File` from the context menu, fill in the desired filename in the dialog, and click OK.

The actual HTML content of these two files does not matter, so long as you can tell them apart when looking at them. If you prefer, you can download sample [about.html](#) and [help.html](#) files from the application's GitHub repository, via the links.

Step #2: Using SimpleContentFragment

Now, open up `SimpleContentActivity` and replace the stub implementation that we have now with the following Java:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class SimpleContentActivity extends Activity {
    public static final String EXTRA_FILE = "file";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
```

TUTORIAL #11 - ADDING SIMPLE CONTENT

```
String file = getIntent().getStringExtra(EXTRA_FILE);
Fragment f = SimpleContentFragment.newInstance(file);

getFragmentManager().beginTransaction()
    .add(android.R.id.content, f).commit();
}
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

In `onCreate()`, we follow the standard recipe for defining our fragment if (and only if) we were started new, rather than restarted after a configuration change, by seeing if the fragment already exists. If we do need to add the fragment, we retrieve a string extra from the Intent used to launch us (identified as `EXTRA_FILE`), create an instance of `SimpleContentFragment` using that value from the extra, and execute a `FragmentManager` transaction to add the `SimpleContentFragment` to our UI.

Step #3: Launching Our Activities, For Real This Time

Now, what remains is to actually supply that `EXTRA_FILE` value, which we are not doing presently when we start up `SimpleContentActivity` from `EmPubLiteActivity`.

Modify `onOptionsItemSelected()` of `EmPubLiteActivity` to look like this:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.about:
            Intent i = new Intent(this, SimpleContentActivity.class)
                .putExtra(SimpleContentActivity.EXTRA_FILE,
                    "file:///android_asset/misc/about.html");
            startActivity(i);

            return(true);

        case R.id.help:
            i = new Intent(this, SimpleContentActivity.class)
                .putExtra(SimpleContentActivity.EXTRA_FILE,
                    "file:///android_asset/misc/help.html");
            startActivity(i);

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

TUTORIAL #11 - ADDING SIMPLE CONTENT

You are adding the two `putExtra()` calls in the `R.id.about` and `R.id.help` branches of the switch statement. In both cases, we are using a quasi-URL with the prefix `file:///android_asset/`. This points to the root of our project's `assets/` folder. `WebView` knows how to interpret these URLs, to load files out of our assets directly.

Step #4: Getting a Bit More Material

Right now, our action bar on Android 5.0 devices is the one defined by `Theme.Holo.Light.DarkActionBar`. This certainly works. However, it looks a bit out of place, as most of the built-in apps will be using a material theme. So, let's make some minor adjustments to make our app blend in a bit better.

First, we need to add a `res/values-v21/` directory, representing resources that will be used solely on API Level 21+ devices. In Android Studio, right-click over the `res/` directory in your `main/` sourceset and choose `New > "Android resource directory"` from the context menu. Choose "values" as the "Resource type". Then, in the list of available qualifiers on the left, click on "Version", then click the ">>" button to the right of that list. This will give you a fairly messed-up dialog, at least in the current version of Android Studio:

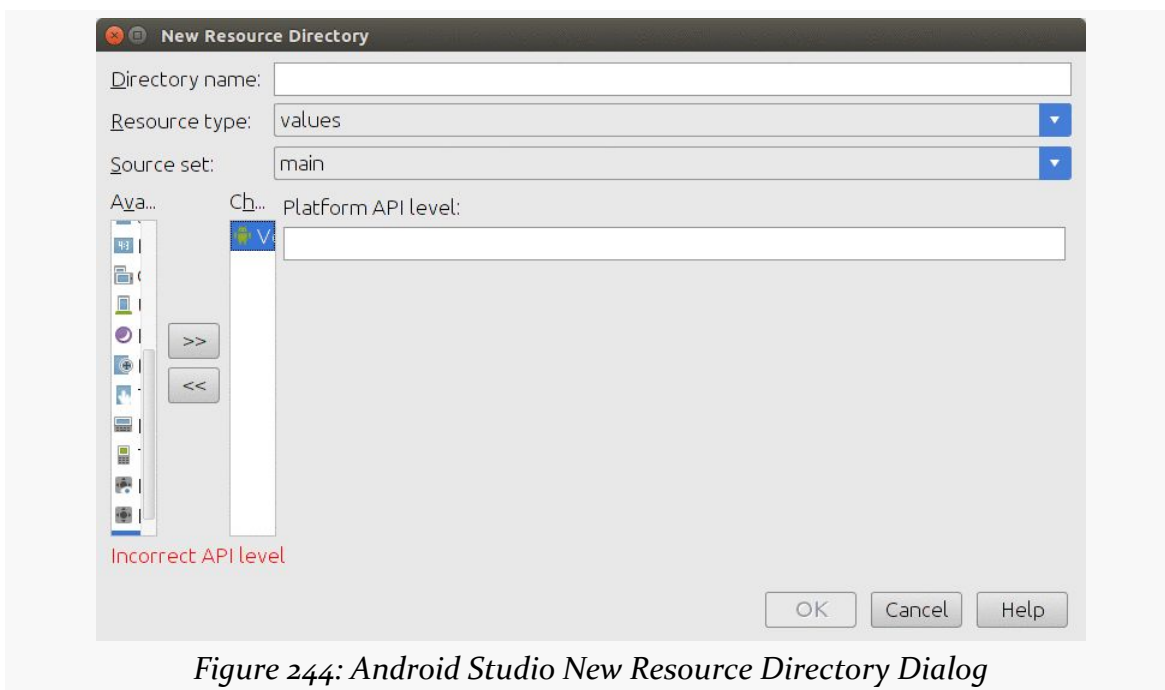

Figure 244: Android Studio New Resource Directory Dialog

TUTORIAL #11 - ADDING SIMPLE CONTENT

Fill in 21 in the “Platform API level” field, then click OK. This should give you an empty `res/values-v21/` directory, as desired.

Then, copy the `styles.xml` file from `res/values/` into `res/values-v21/`. Windows/Linux users can drag `styles.xml` from `res/values/` while holding down the Control key to make a copy. OS X users probably have a similar convention.

Open `res/values-v21/styles.xml` and change the parent attribute of our one style element to be `android:Theme.Material.Light.DarkActionBar`.

While this gives us a material theme, we will wind up with a bunch (though not fifty) shades of gray as our color scheme, which is a bit bland. However, `Theme.Material`-based themes let us tint the action bar fairly easily.

So, next, right-click over the `res/values-v21/` directory, choose `New > “Values resource file”` from the context menu, fill in `colors.xml` as the filename, and click OK. In that file, add three `<color>` elements:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <color name="primary">#3f51b5</color>
  <color name="primary_dark">#303f9f</color>
  <color name="accent">#ffc107</color>
</resources>
```

Then, back in `res/values-v21/styles.xml`, add three child elements to the `<style>` element:

```
<resources>
  <!-- Base application theme. -->
  <style name="AppTheme" parent="android:Theme.Material.Light.DarkActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

Step #5: Seeing the Results

Now, if you run the application and choose “Help” from the action bar overflow, you will see your help content on-screen:

TUTORIAL #11 - ADDING SIMPLE CONTENT

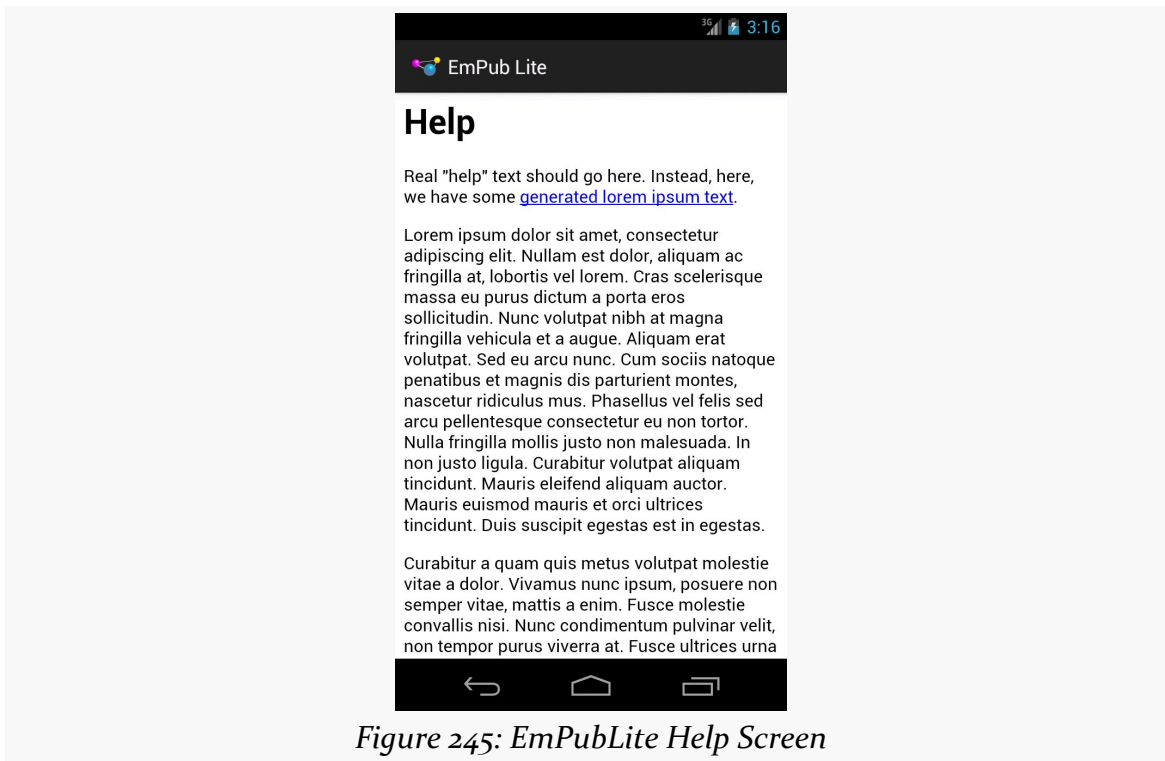

Figure 245: EmPubLite Help Screen

Pressing BACK and choosing "About" from the action bar overflow will bring up your about content:

TUTORIAL #11 - ADDING SIMPLE CONTENT

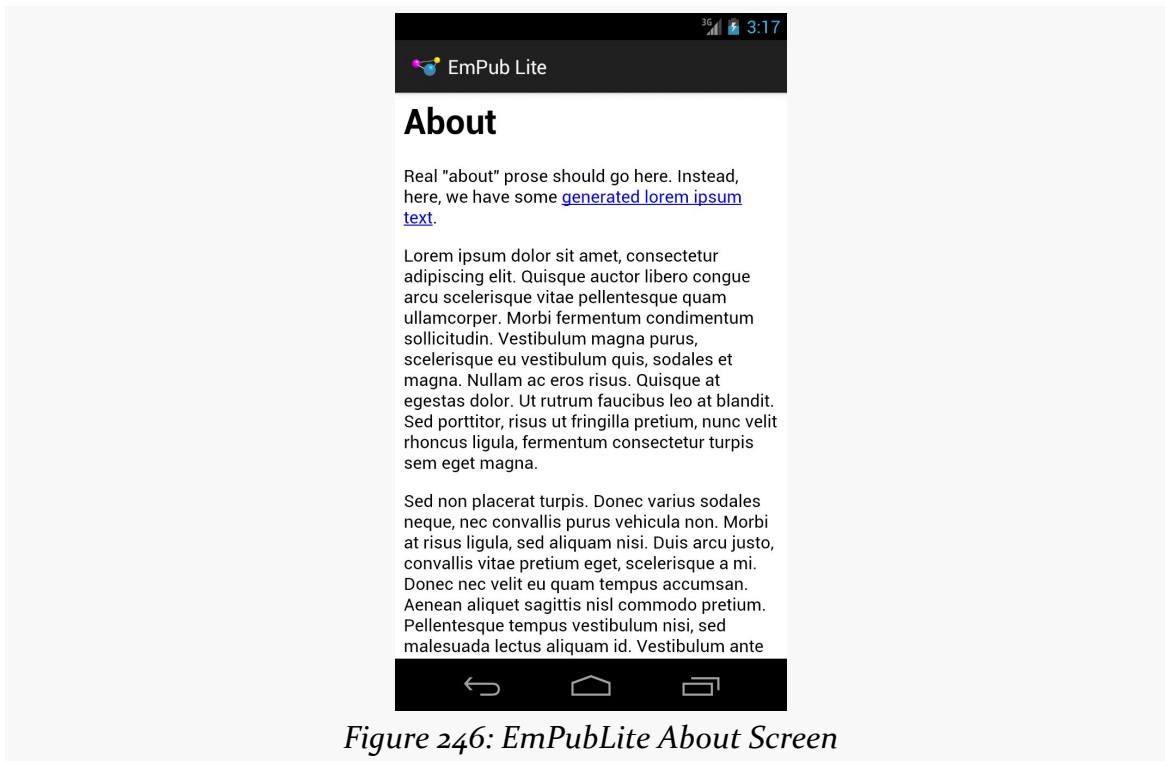

Figure 246: EmPubLite About Screen

However, on an Android 5.0 or higher device or emulator, our action bar will now sport our designated color scheme:

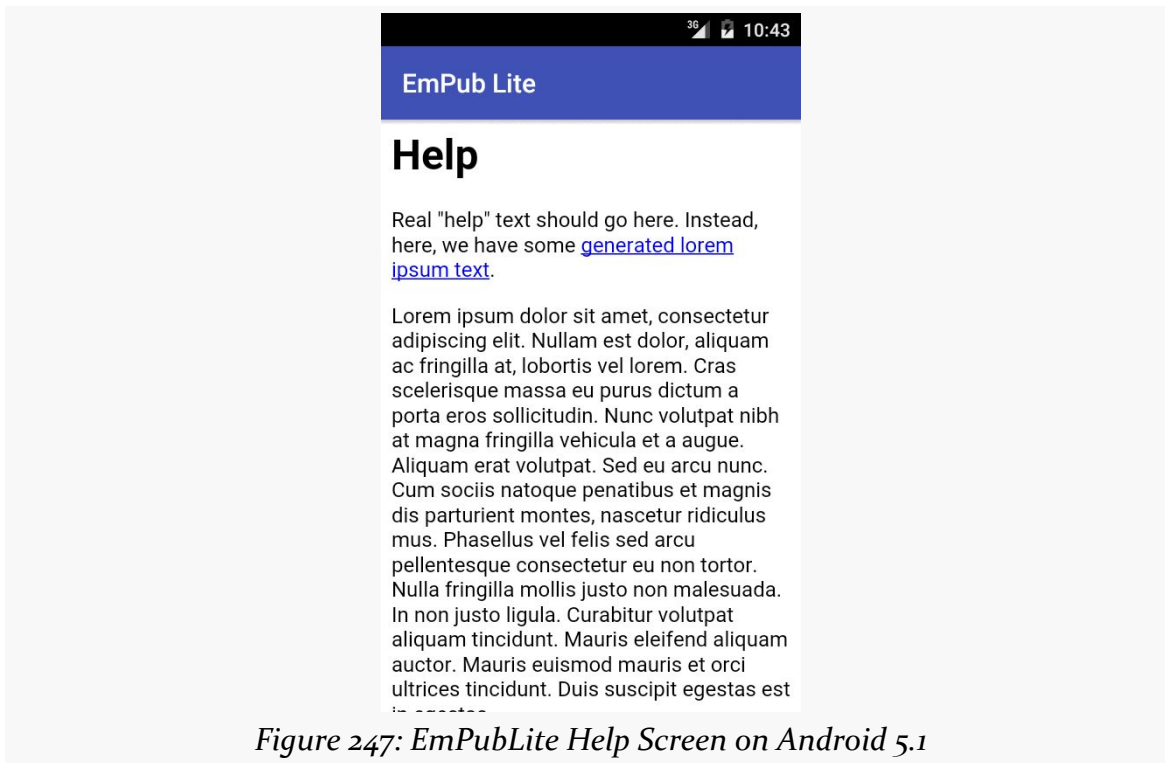

Figure 247: EmPubLite Help Screen on Android 5.1

In Our Next Episode...

... we will [display the actual content of our book](#) in our tutorial project.

Tutorial #12 - Displaying the Book

At this point, you are probably wondering when we are *ever* going to have our digital book reader let us read a digital book.

Now, in this tutorial, your patience will be rewarded.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository.

Note that starting in this tutorial, it is assumed that you know how to add `import` statements as needed as we refer to new classes in existing code, and so the required imports are not always going to be specified.

Step #1: Adding a Book

First, we need a book. Expecting you to write a book as part of this tutorial would seem to be a bit excessive. So, instead, we will use an already-written book: [The War of the Worlds](#), by H. G. Wells, as distributed by [Project Gutenberg](#).

EDITOR'S NOTE: We realize that this choice of book may be seen as offensive by Martians, as it depicts them as warlike invaders with limited immune systems. Please understand that this book is a classic of Western literature and reflects the attitude of the times. If you have any concerns about this material, please contact us at martians-so-do-not-exist@commonsware.com.

Download <http://misc.commonsware.com/WarOfTheWorlds.zip> and unpack its contents (a book/ directory of files) into your `assets/` folder of your project.

TUTORIAL #12 - DISPLAYING THE BOOK

Windows and Linux Android Studio users can drag this book/ directory into the project and drop it in assets/ to copy the files to the proper location. You should wind up with assets/book/ and files inside of there:

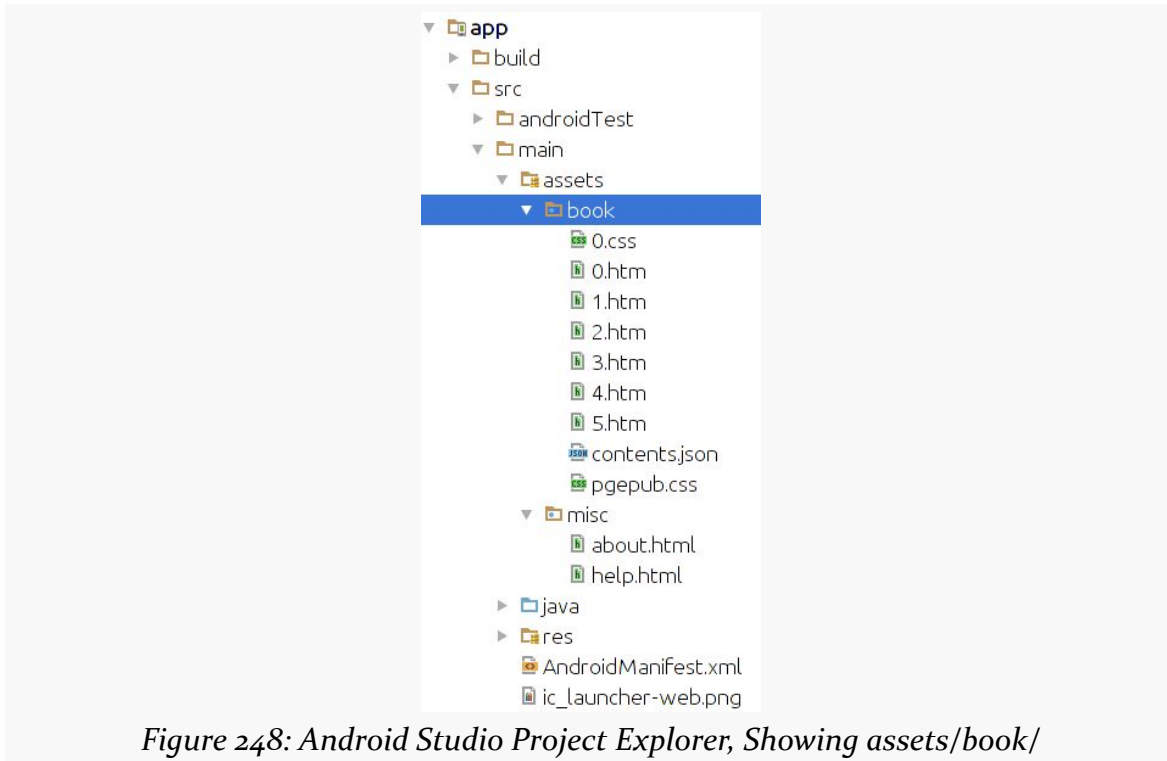

Figure 248: Android Studio Project Explorer, Showing assets/book/

In that directory, you will find some HTML and CSS files with the prose of the book, plus a `contents.json` file with metadata. We will examine this metadata in greater detail in the next section.

Step #2: Creating a ModelFragment

This sample project will use [the “model fragment” pattern](#) to hold onto the data about the book to be viewed. The “model fragment” pattern works well for cases where:

- the data is only needed by one activity, not several components, and
- we want to hold onto the data during a configuration change (e.g., screen rotation), so that we do not have to perform some work again to obtain the data

TUTORIAL #12 - DISPLAYING THE BOOK

Something has to load that BookContents, ideally in the background, since reading an asset and parsing the JSON will take time. Also, something has to hold onto that BookContents, so it can be used from EmPubLiteActivity and the various chapter fragments in the ViewPager.

To that end, we will create a new class, cunningly named ModelFragment.

Right-click over the com.commonware.empublite package in your java/ directory and choose New > Java Class from the context menu. Fill in ModelFragment as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;
import android.app.Fragment;
public class ModelFragment extends Fragment {
}
```

Step #3: Defining Our Model

That contents.json file contains a bit of metadata about the contents of the book: the book's title and a roster of its "chapters":

```
{
  "title": "The War of the Worlds",
  "chapters": [
    {
      "file": "0.htm",
      "title": "Book One: Chapters 1-9"
    },
    {
      "file": "1.htm",
      "title": "Book One: Chapters 10-14"
    },
    {
      "file": "2.htm",
      "title": "Book One: Chapters 14-17"
    },
    {
      "file": "3.htm",
      "title": "Book Two: Chapters 1-7"
    },
    {
      "file": "4.htm",
      "title": "Book Two: Chapters 7-10"
    },
    {

```

TUTORIAL #12 - DISPLAYING THE BOOK

```
"file": "5.htm",
"file": "5.htm",
"title": "Project Gutenberg"
}
]
}
```

In the case of this book from Project Gutenberg, the `assets/book/` directory contains six HTML files which `EmPubLite` will consider as “chapters”, even though each of those HTML files contains multiple chapters from the source material. You are welcome to reorganize that HTML if you wish, updating `contents.json` to match.

We need to load `contents.json` into memory, so `EmPubLite` knows how many chapters to display and where those chapters can be found. We will pour `contents.json` into a `BookContents` model object, leveraging the GSON library that we added to our project [in an earlier tutorial](#).

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookContents` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

import java.util.List;

public class BookContents {
    List<BookContents.Chapter> chapters;

    int getChapterCount() {
        return(chapters.size());
    }

    String getChapterFile(int position) {
        return(chapters.get(position).file);
    }

    static class Chapter {
        String file;
    }
}
```

If you prefer, you can view this file’s contents in your Web browser via [this GitHub link](#).

Step #4: Examining Our Model

`BookContents` is a GSON interpretation of the JSON structure of `contents.json`. `BookContents` holds onto the chapters, as a `List` of `BookContents.Chapter` objects, each of which holds onto its file.

`BookContents` also supplies two accessor methods:

- `getChapterCount()` to identify the number of chapters (i.e., the size of the `chapters` array in the JSON)
- `getChapterFile()`, to return the relative path within `assets/book/` that represents our “chapter” of HTML

Step #5: Defining Our Event

We will want to load the JSON and create the `BookContents` on a background thread, as we will be performing enough I/O and parsing that we might make our UI a bit sluggish if we do the work on the main application thread. However, we need to let the UI layer (`EmPubLiteActivity` and its `ViewPager`) know when the book is loaded, so it can be poured into the user interface.

We could use an `AsyncTask` for that, notifying the activity in `onPostExecute()`. However, we will need more flexible inter-component communication over time, things that cannot be handled by a simple `AsyncTask`. Hence, we will start using the event bus pattern here, employing greenrobot’s `EventBus` library that we added to our project [in a previous tutorial](#).

With `EventBus`, we create our own event classes. The one event that we have up front is one to indicate that our book metadata has been loaded and is ready for use, in the form of a `BookContents` object. Hence, in this step of the tutorial, we will define a `BookLoadedEvent` that will be posted when the book is loaded. And, we will have the event hold onto the `BookContents`, to lightly simplify populating the UI later on.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookLoadedEvent` as the name and click OK to create the empty class.

Then, replace the contents of that class with the following:

TUTORIAL #12 - DISPLAYING THE BOOK

```
package com.commonware.empublite;

public class BookLoadedEvent {
    private BookContents contents=null;

    public BookLoadedEvent(BookContents contents) {
        this.contents=contents;
    }

    public BookContents getBook() {
        return(contents);
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Step #6: Loading Our Model

Now, we need to actually arrange to load the book on a background thread and post our newly-created BookLoadedEvent. This is one of the key jobs of our ModelFragment: to manage the loading of our activity's model, using background threads.

With that in mind, replace our stub ModelFragment implementation with the following:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.os.Process;
import android.preference.PreferenceFragment;
import android.util.Log;
import com.google.gson.Gson;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import de.greenrobot.event.EventBus;

public class ModelFragment extends Fragment {
    private BookContents contents=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setRetainInstance(true);
    }

    @Override
```

TUTORIAL #12 - DISPLAYING THE BOOK

```
public void onAttach(Activity host) {
    super.onAttach(host);

    if (contents==null) {
        new LoadThread(host.getAssets()).start();
    }
}

synchronized public BookContents getBook() {
    return(contents);
}

private class LoadThread extends Thread {
    private AssetManager assets=null;

    LoadThread(AssetManager assets) {
        super();

        this.assets=assets;
    }

    @Override
    public void run() {
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
        Gson gson=new Gson();

        try {
            InputStream is=assets.open("book/contents.json");
            BufferedReader reader=
                new BufferedReader(new InputStreamReader(is));

            synchronized(this) {
                contents=gson.fromJson(reader, BookContents.class);
            }

            EventBus.getDefault().post(new BookLoadedEvent(contents));
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

In onCreate(), we call setRetainInstance(true), to tell the framework to keep this fragment despite a configuration change, just passing it to the new activity created as a result of that configuration change.

In onAttach(), if we do not already have our BookContents object, we fork a LoadThread to populate it, and we cannot readily get at an AssetManager until we

TUTORIAL #12 - DISPLAYING THE BOOK

are attached to the hosting activity. This is why we are not forking `LoadThread` in `onCreate()`.

`LoadThread` takes the `AssetManager` as a parameter, stashing it in a data member in the `LoadThread` constructor.

Then, in the `run()` method that is called on the background thread, we call `setThreadPriority()` to drop the thread's priority to that of a background thread. This reduces how much we compete with the main application thread for CPU time. Then, we read in the JSON using GSON to create the `BookContents` instance. GSON automatically de-serializes our JSON into the `BookContents` and `BookContents.Chapter` instances, given that we are telling the `fromJson()` method that it is to be loading an instance of a `BookContents` object. Finally, we `post()` a `BookLoadedEvent` to the default `EventBus`.

The `open()` method on `AssetManager` could throw an `IOException`. Normally, this indicates a development-time bug (e.g., we failed to actually set up the `book/contents.json` file), which is why we log the message to `LogCat`. A production-grade book reader should also `post()` an `EventBus` event to allow the UI layer to let the user know that we could not load the book. As it stands, the book reader will remain stuck on the `ProgressBar` forever in case of this sort of problem. Augmenting the tutorial in this way is left as an exercise for the reader.

Note that the `LoadThread` implementation has a pair of references to `Process`. In this case, this is `android.os.Process`, not `java.lang.Process`. Since `java.lang.Process` is automatically imported, if you fail to import `android.os.Process`, you will see errors about how `THREAD_PRIORITY_BACKGROUND` and `setThreadPriority()` are not defined. Since we are not using `java.lang.Process` in this class, having the import to `android.os.Process` (as shown in the code listing above) resolves this conflict.

Step #7: Registering for Events

Right now, our `BookLoadedEvent` will be posted... and ignored, as nothing in the application is set up to watch for such events. Our `EmPubLiteActivity` needs to know about these events, and the first step to accomplishing that is to have it register for events in general with the `EventBus`.

Add the following two methods to `EmPubLiteActivity`:

```
@Override
public void onResume() {
```

TUTORIAL #12 - DISPLAYING THE BOOK

```
super.onResume();
EventBus.getDefault().register(this);
}

@Override
public void onPause() {
    EventBus.getDefault().unregister(this);
    super.onPause();
}
```

These simply register the activity with the EventBus while it is in the foreground.

Step #8: Adapting the Content

Before we can use the BookContents, we need to update ContentsAdapter to display the prose on the screen.

First, add a BookContents data member to ContentsAdapter:

```
final BookContents contents;
```

Then, add the BookContents parameter to the constructor, assigning it to the new data member:

```
public ContentsAdapter(Activity ctxt, BookContents contents) {
    super(ctxt.getFragmentManager());

    this.contents=contents;
}
```

Next, update getCount() to use the getChapterCount() of our BookContents:

```
@Override
public int getCount() {
    return(contents.getChapterCount());
}
```

Finally, modify getItem() to retrieve the relative path for a given chapter from the BookContents and create a SimpleContentFragment on the complete file:///android_asset path to the file in question:

```
@Override
public Fragment getItem(int position) {
    String path=contents.getChapterFile(position);

    return(SimpleContentFragment.newInstance("file:///android_asset/book/"
        + path));
}
```

Note that you may need to change the parameter name in the `getItem()` declaration to be `position`, as it may be another value (e.g., `arg0`).

Step #9: Showing the Content When Loaded

Now, we can actually add the logic to display the book once it is loaded.

Create a `setupPager()` method on `EmPubLiteActivity` as follows:

```
private void setupPager(BookContents contents) {
    adapter=new ContentsAdapter(this, contents);
    pager.setAdapter(adapter);
    findViewById(R.id.progressBar1).setVisibility(View.GONE);
    pager.setVisibility(View.VISIBLE);
}
```

The contents of this method are almost identical to four lines in `onCreate()` – we have just moved them to a separate method. Remove those duplicate lines from `onCreate()`, so you have:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    pager=(ViewPager)findViewById(R.id.pager);
}
```

Then, add the following `onEventMainThread()` method to `EmPubLiteActivity`:

```
@SuppressWarnings("unused")
public void onEventMainThread(BookLoadedEvent event) {
    setupPager(event.getBook());
}
```

This tells `EventBus` that if a `BookLoadedEvent` is posted, we are interested in it, and it should be delivered to our `onEventMainThread()` method on the main application thread. This method looks like it is unused, because it will be called using reflection by the `EventBus`, and the IDE does not know that. The `@SuppressWarnings("unused")` annotation indicates that this method is used.

Step #10: Attaching our ModelFragment

We also need to add some code to set up the `ModelFragment` — it will not magically appear on its own. So, the first time we create an `EmPubLiteActivity`, we want to

TUTORIAL #12 - DISPLAYING THE BOOK

create our ModelFragment. To do that, define a static data member named MODEL in EmPubLiteActivity:

```
private static final String MODEL="model";
```

Then, update the onResume() method in EmPubLiteActivity to see if we already have the fragment before creating one:

```
@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);

    if (adapter==null) {
        ModelFragment mfrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag == null) {
            getFragmentManager().beginTransaction()
                .add(new ModelFragment(), MODEL).commit();
        }
    }
}
```

If you run the result in a device or emulator, you will see the book content appear:

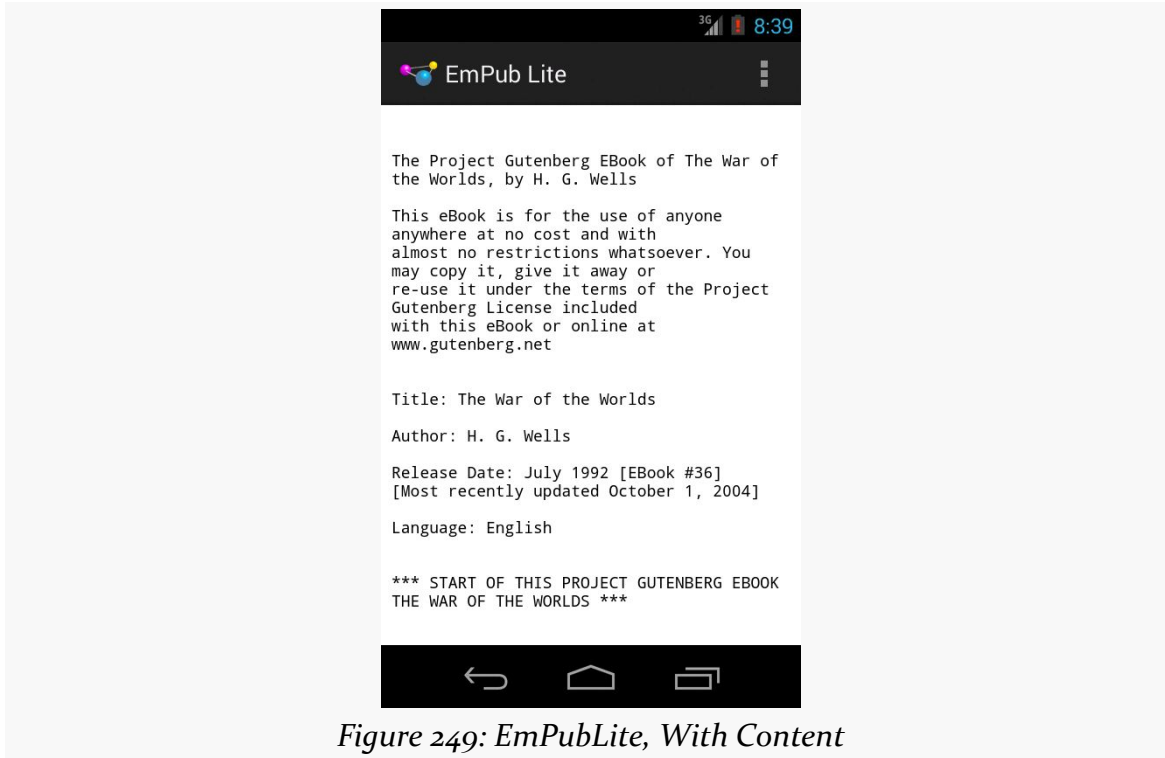

Figure 249: EmPubLite, With Content

Swiping left and right will take you to the other portions of the book.

Step #11: Showing the Content After a Configuration Change

While you can see the book contents now, if you try rotating the screen, the book contents will not appear. That is because the `ModelFragment` has already loaded the contents (so the `BookLoadedEvent` has passed), but we have no logic in `EmPubLiteActivity` to populate the book by other means.

To do that, simply add an `else if` clause to the `if` in `onResume()`, to get the book contents over to `setupPager()` if they are ready:

```
@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);

    if (adapter==null) {
        ModelFragment mfrag=
            (ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag==null) {
            mfrag=new ModelFragment();

            getFragmentManager()
                .beginTransaction()
                .add(mfrag, MODEL)
                .commit();
        }
        else if (mfrag.getBook()!=null) {
            setupPager(mfrag.getBook());
        }
    }
}
```

Now, if you run the sample and rotate the screen (e.g., `Ctrl-F11` on the Windows/Linux emulator), the book will appear in either case.

Step #12: Setting Up StrictMode

Since we are now starting to do disk I/O, particularly aiming to have it done on background threads, it would be a good idea to configure `StrictMode`, so it will complain if we fail in our quest and accidentally do this I/O on the main application thread.

Add the following method to `EmPubLiteActivity`:

```
private void setupStrictMode() {
    StrictMode.ThreadPolicy.Builder builder=
        new StrictMode.ThreadPolicy.Builder()
            .detectAll()
            .penaltyLog();

    if (BuildConfig.DEBUG) {
        builder.penaltyFlashScreen();
    }

    StrictMode.setThreadPolicy(builder.build());
}
```

Here, we create a `StrictMode.ThreadPolicy.Builder`, configured to detect all violations on the main application thread, logging them to LogCat. In addition, if we are in a DEBUG build, we will flash a red border around the screen.

Note, though, that this red border will appear even if we do not make any mistakes. Unfortunately, Google engineers do not check the framework code for these sorts of violations, leading to some bugs that we as app developers cannot resolve. Those will be reported as `StrictMode` violations, just as if we had made the mistakes ourselves.

Then, just after `super.onCreate()` in the `onCreate()` in `EmPubLiteActivity`, add in a call to the new `setupStrictMode()` method. This will give you an `onCreate()` method that looks like:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setupStrictMode();

    setContentView(R.layout.main);
    pager=(ViewPager)findViewById(R.id.pager);
}
```

In Our Next Episode...

... we will allow the user to [manipulate some preferences](#) in our tutorial project.

Using Preferences

Android has many different ways for you to store data for long-term use by your activity. The simplest ones to use are `SharedPreferences` and simple files.

Android allows activities and applications to keep preferences, in the form of key/value pairs (akin to a `Map`), that will hang around between invocations of an activity. As the name suggests, the primary purpose is for you to store user-specified configuration details, such as the last feed the user looked at in your feed reader, or what sort order to use by default on a list, or whatever. Of course, you can store in the preferences whatever you like, so long as it is keyed by a `String` and has a primitive value (`boolean`, `String`, etc.)

Preferences can either be for a single activity or shared among all activities in an application. Other components, such as services, also can work with shared preferences.

Getting What You Want

To get access to the preferences, you have three APIs to choose from:

- `getPreferences()` from within your `Activity`, to access activity-specific preferences
- `getSharedPreferences()` from within your `Activity` (or other application `Context`), to access application-level preferences
- `getDefaultSharedPreferences()`, on `PreferenceManager`, to get the shared preferences that work in concert with Android's overall preference framework

The first two take a security mode parameter. The right answer here is `MODE_PRIVATE`, so no other applications can access the file. The `getSharedPreferences()` method also takes a name of a set of preferences; `getPreferences()` effectively calls `getSharedPreferences()` with the activity's class name as the preference set name. The `getDefaultSharedPreferences()` method takes the `Context` for the preferences (e.g., your `Activity`).

All of those methods return an instance of `SharedPreferences`, which offers a series of getters to access named preferences, returning a suitably-typed result (e.g., `getBoolean()` to return a boolean preference). The getters also take a default value, which is returned if there is no preference set under the specified key.

Unless you have a good reason to do otherwise, you are best served using the third option above — `getDefaultSharedPreferences()` — as that will give you the `SharedPreferences` object that works with a `PreferenceActivity` by default, as will be described [later in this chapter](#).

Stating Your Preference

Given the appropriate `SharedPreferences` object, you can use `edit()` to get an “editor” for the preferences. This object has a set of setters that mirror the getters on the parent `SharedPreferences` object. It also has:

1. `remove()` to get rid of a single named preference
2. `clear()` to get rid of all preferences
3. `apply()` or `commit()` to persist your changes made via the editor

The last one is important — if you modify preferences via the editor and fail to save the changes, those changes will evaporate once the editor goes out of scope. `commit()` is a blocking call, while `apply()` works asynchronously. Ideally, use `apply()` where possible, though it was only added in Android 2.3, so it may not be available to you if you are aiming to support earlier versions of Android than that.

Conversely, since the preferences object supports live changes, if one part of your application (say, an activity) modifies shared preferences, another part of your application (say, a service) will have access to the changed value immediately.

Collecting Preferences with PreferenceFragment

Some “preferences” will be collected as part of the natural use of your user interface. For example, if you have a SeekBar to control a zoom level, you might elect to record the SeekBar position in SharedPreferences, so you can restore the user’s last zoom level later on.

However, in many cases, we have various settings that we would like the user to be able to configure but are not something that the user would configure elsewhere in our UI. You could roll your own UI to collect preferences in bulk from the user. On the whole, this is a bad idea. Instead, use preference XML resources and a PreferenceFragment.

Why?

One of the common complaints about Android developers is that they lack discipline, not following any standards or conventions inherent in the platform. For other operating systems, the device manufacturer might prevent you from distributing apps that violate their human interface guidelines. With Android, that is not the case — but this is not a blanket permission to do whatever you want. Where there is a standard or convention, please follow it unless you have a *clear* reason not to, so that users will feel more comfortable with your app and their device.

Using a PreferenceFragment for collecting preferences is one such convention.

The linchpin to the preferences framework and PreferenceFragment is yet another set of XML data structures. You can describe your application’s preferences in XML files stored in your project’s `res/xml/` directory. Given that, Android can present a UI for manipulating those preferences, one which matches what you see in the Settings app. The user’s choices are then stored in the SharedPreferences that you get back from `getDefaultSharedPreferences()`.

This can be seen in the [Prefs/Fragment](#) sample project.

Showing the Current Values

This project’s main activity hosts a `TableLayout`, into which we will load the values of five preferences:

USING PREFERENCES

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TableRow>

        <TextView
            style="@style/label"
            android:text="@string/checkbox"/>

        <TextView
            android:id="@+id/checkbox"
            style="@style/value"/>
    </TableRow>

    <TableRow>

        <TextView
            style="@style/label"
            android:text="@string/ringtone"/>

        <TextView
            android:id="@+id/ringtone"
            style="@style/value"/>
    </TableRow>

    <TableRow>

        <TextView
            style="@style/label"
            android:text="@string/checkbox2"/>

        <TextView
            android:id="@+id/checkbox2"
            style="@style/value"/>
    </TableRow>

    <TableRow>

        <TextView
            style="@style/label"
            android:text="@string/text"/>

        <TextView
            android:id="@+id/text"
            style="@style/value"/>
    </TableRow>

    <TableRow>

        <TextView
            style="@style/label"
            android:text="@string/list"/>

        <TextView
            android:id="@+id/list"
            style="@style/value"/>
    </TableRow>
</TableLayout>
```

USING PREFERENCES

```
</TableLayout>
```

The above layout is used by PreferenceContentsFragment, which populates the right-hand column of TextView widgets at runtime in onResume(), pulling the values from the default SharedPreferences for our application:

```
package com.commonware.android.preffrag;

import android.app.Fragment;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.TextView;

public class PreferenceContentsFragment extends Fragment {
    private TextView checkbox=null;
    private TextView ringtone=null;
    private TextView checkbox2=null;
    private TextView text=null;
    private TextView list=null;

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.content, parent, false);

        checkbox=(TextView)result.findViewById(R.id.checkbox);
        ringtone=(TextView)result.findViewById(R.id.ringtone);
        checkbox2=(TextView)result.findViewById(R.id.checkbox2);
        text=(TextView)result.findViewById(R.id.text);
        list=(TextView)result.findViewById(R.id.list);

        return(result);
    }

    @Override
    public void onResume() {
        super.onResume();

        SharedPreferences prefs=
            PreferenceManager.getDefaultSharedPreferences(getActivity());

        checkbox.setText(Boolean.valueOf(prefs.getBoolean("checkbox", false)).toString());
        ringtone.setText(prefs.getString("ringtone", "<unset>"));
        checkbox2.setText(Boolean.valueOf(prefs.getBoolean("checkbox2", false)).toString());
        text.setText(prefs.getString("text", "<unset>"));
        list.setText(prefs.getString("list", "<unset>"));
    }
}
```

USING PREFERENCES

The main activity, `FragmentsDemo`, simply loads `res/layout/main.xml`, which contains a `<fragment>` element pointing at `PreferenceContentsFragment`. It also defines an options menu, which we will examine later in this section.

The result is an activity showing the default values of the preferences when it is first run, since we have not set any values yet:

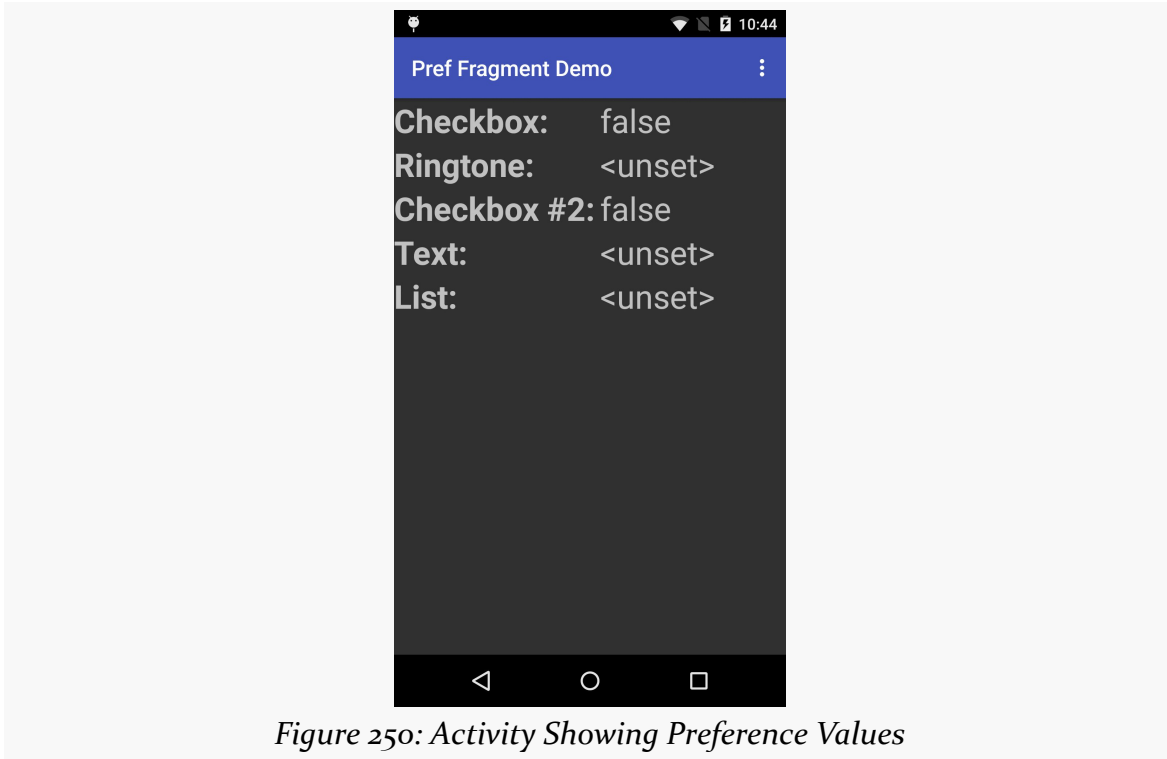

Figure 250: Activity Showing Preference Values

Defining Your Preferences

First, you need to tell Android what preferences you are trying to collect from the user.

To do this, you will need to add a `res/xml/` directory to your project, if one does not already exist. Then, for your `PreferenceFragment`, you will define one of these XML resource files. The root element of this XML file will be `<PreferenceScreen>`, and it will contain child elements, one per preference.

In the sample project, we have one such file, `res/xml/preferences.xml`:

```
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">
```

```
<CheckBoxPreference
    android:key="checkbox"
    android:summary="@string/pref1summary"
    android:title="@string/pref1title"/>

<RingtonePreference
    android:key="ringtone"
    android:showDefault="true"
    android:showSilent="true"
    android:summary="@string/pref2summary"
    android:title="@string/pref2title"/>

<EditTextPreference
    android:dialogTitle="@string/dialogtitle"
    android:key="text"
    android:summary="@string/pref3summary"
    android:title="@string/pref3title"/>

<ListPreference
    android:dialogTitle="@string/listdialogtitle"
    android:entries="@array/cities"
    android:entryValues="@array/airport_codes"
    android:key="list"
    android:summary="@string/pref4summary"
    android:title="@string/pref4title"/>

</PreferenceScreen>
```

Each preference element has two attributes at minimum:

1. `android:key`, which is the key you use to look up the value in the `SharedPreferences` object via methods like `getInt()`
2. `android:title`, which is a few words identifying this preference to the user

You may also wish to consider having `android:summary`, which is a short sentence explaining what the user is to supply for this preference.

There are lots of other attributes that are common to all preference elements, and there are more types of preference elements than the ones that we used in the preference XML shown above. We will examine more preference elements [later in this chapter](#).

Creating Your PreferenceFragment

Preference XML, on API Level 11 and higher, is loaded by an implementation of `PreferenceFragment`. The mission of `PreferenceFragment` is to call `addPreferencesFromResource()` in `onCreate()`, supplying the resource ID of the preference XML to load (e.g., `R.xml.preference2`). That fragment, in turn, can be loaded up by a simple `Activity`.

USING PREFERENCES

In fact, the fragment is so short, you could even make it be a static class inside the activity, as is done in the sample app. The activity that collects the preferences, `EditPreferences`, has a `Prefs` static subclass of `PreferenceFragment`:

```
package com.commonware.android.preffrag;

import android.app.Activity;
import android.os.Bundle;
import android.preference.PreferenceFragment;

public class EditPreferences extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new Prefs()).commit();
        }
    }

    public static class Prefs extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            addPreferencesFromResource(R.xml.preferences);
        }
    }
}
```

The only thing that `Prefs` does is call the inherited `addPreferencesFromResource()` in its `onCreate()` method, supplying the ID of the preference XML. All `EditPreferences` does is arrange to show the fragment, in this case using a `FragmentManager`.

The Results

An action bar item in `MainActivity` starts up the `EditPreferences` activity. If you click that from the overflow, you will get see the UI created from your XML by means of the `PreferenceFragment`:

USING PREFERENCES

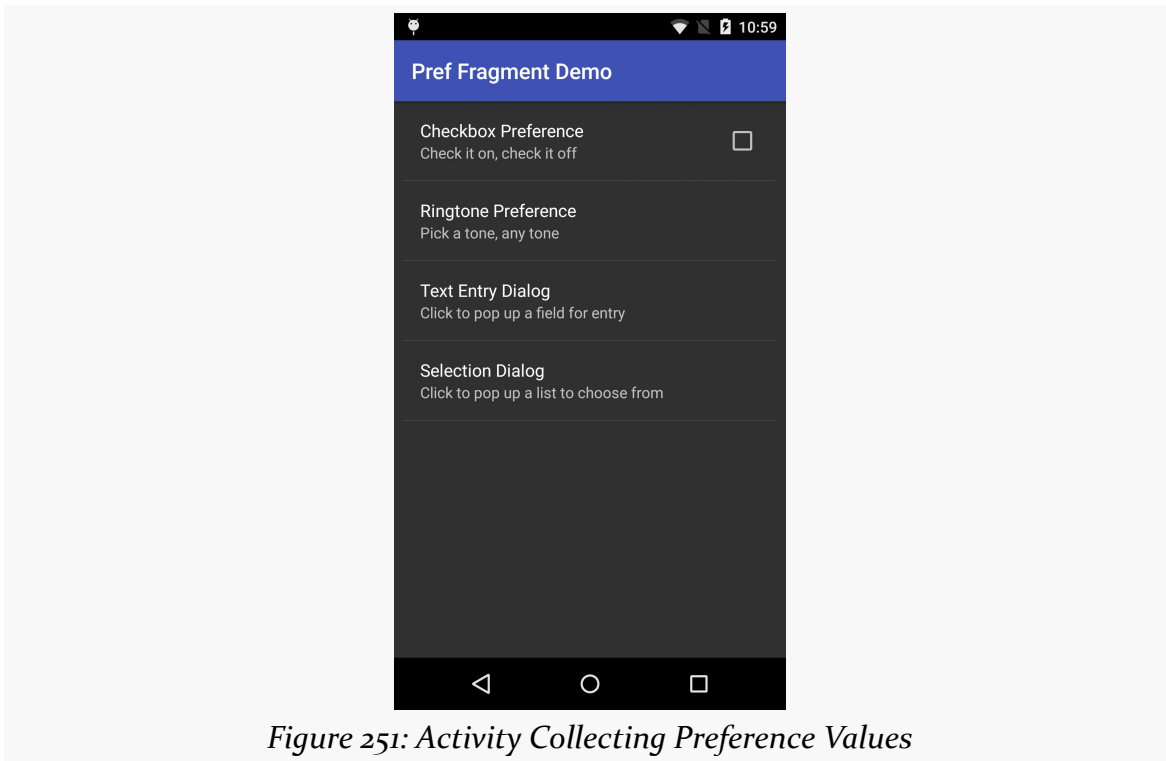

Figure 251: Activity Collecting Preference Values

If you make a change, such as tapping on the checkbox, and press BACK to return to the original activity, you will see the resulting change in the preference values themselves:

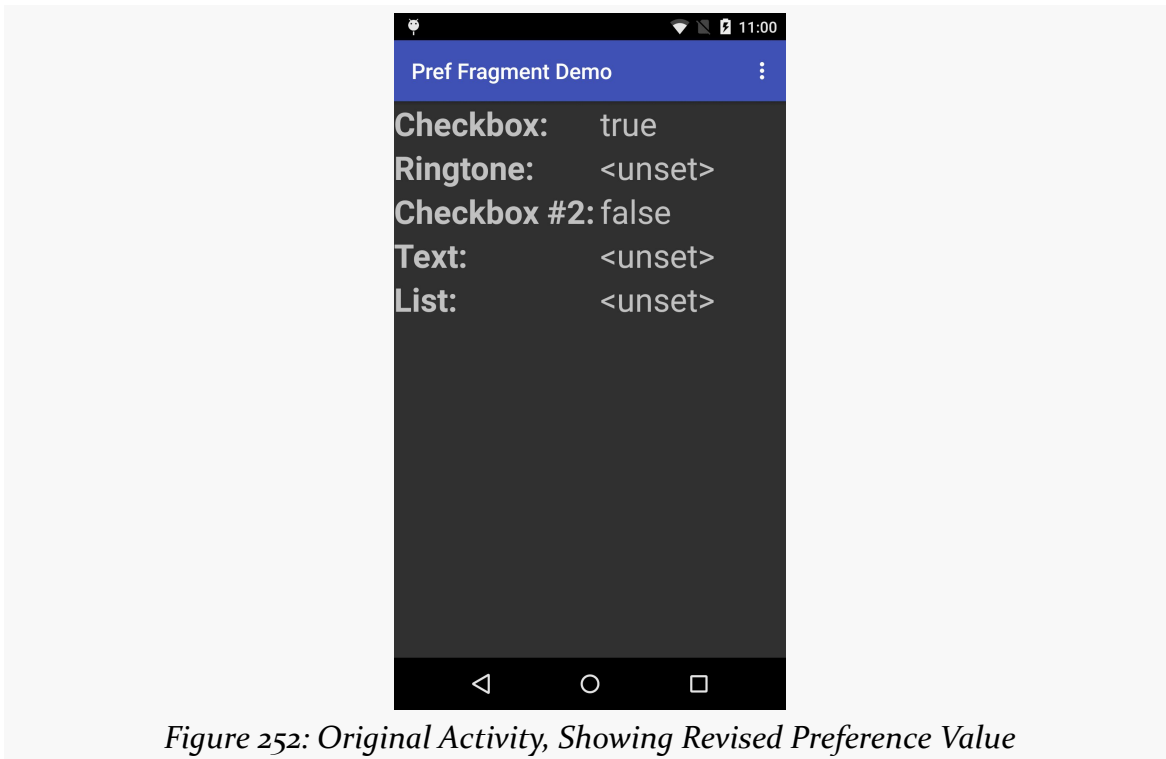

Figure 252: Original Activity, Showing Revised Preference Value

Types of Preferences

There are a variety of subclasses of Preference in the Android SDK for use with PreferenceActivity. This section will outline the major ones. [Later in the book](#) we will examine how to create your own custom Preference classes.

CheckBoxPreference and SwitchPreference

The sample application shown above has a pair of CheckBoxPreference elements, one per preference XML file. A CheckBoxPreference is an “inline” preference, in that the widget the user interacts with (in this case, a CheckBox) is part of the preference screen itself, rather than contained in a separate dialog.

SwitchPreference is functionally equivalent to CheckBoxPreference, insofar as both collect boolean values from the user. The difference is that SwitchPreference uses a Switch widget that the user slides left and right to toggle between “on” and “off” states. Also note that SwitchPreference was added in API Level 14 and therefore will not be available to older Android versions.

EditTextPreference

EditTextPreference, when tapped by the user, pops up a dialog that contains an EditText widget. You can configure this widget via attributes on the <EditTextPreference> element — in addition to standard preference attributes like android:key, you can include any attribute understood by EditText, such as android:inputType.

The value stored in the SharedPreferences is a string.

The sample app has an EditTextPreference:

```
<EditTextPreference
    android:dialogTitle="@string/dialogtitle"
    android:key="text"
    android:summary="@string/pref3summary"
    android:title="@string/pref3title" />
```

When the user taps on it in the PreferenceFragment, the user will see a dialog where they can fill in a value, or edit an existing value if they provided one previously:

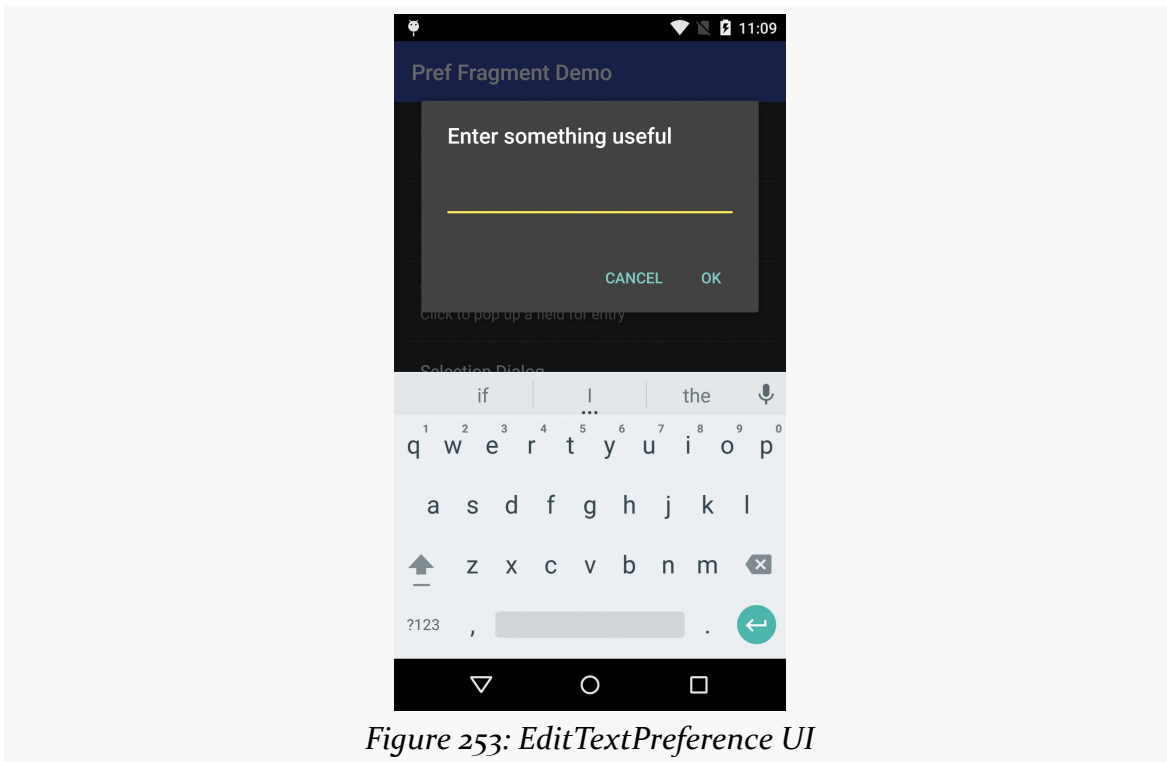

Figure 253: EditTextPreference UI

RingtonePreference

RingtonePreference pops up a dialog with a list of ringtones installed on the device or emulator. However, bear in mind that older emulator images may not have any pre-installed ringtones.

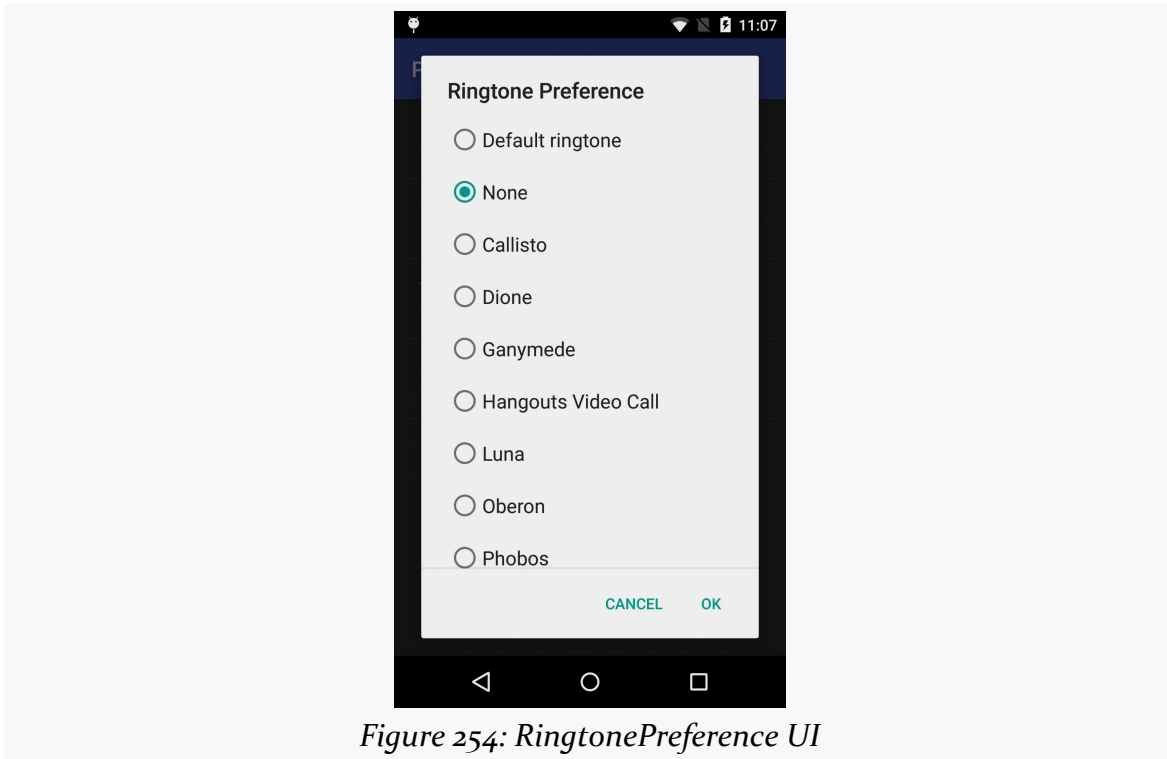

In addition to the standard preference attributes, you can include `android:showDefault`, indicating that the list should contain a “Default ringtone” option. If the user chooses this ringtone, they are effectively choosing the same ringtone that they have set up for incoming phone calls.

You can also use `android:showSilent`, which allows the user to choose a “Silence” pseudo-ringtone, to indicate not to play any ringtone.

The sample app has a RingtonePreference:

```
<RingtonePreference
    android:key="ringtone"
    android:showDefault="true"
    android:showSilent="true"
    android:summary="@string/pref2summary"
    android:title="@string/pref2title"/>
```

When the user taps on it in the PreferenceFragment, the user will see a roster of ringtones, along with “Default” and “None” options, since we opted into those:

The value stored in the `SharedPreferences` is a string, specifically the string representation of a `Uri` pointing to a `ContentProvider` that can serve up the ringtone for playback. The use of `ContentProvider` will be covered [in a later chapter](#), and playing back media like ringtones will be covered [in another later chapter](#).

ListPreference and MultiSelectListPreference

Visually, a `ListPreference` looks just like `RingtonePreference`, except that you control what goes into the list. You do this by specifying a pair of string-array resources in your preference XML.

String resources hold individual strings; string array resources hold a collection of strings. Typically, you will find string array resources in `res/values/arrays.xml` and related resource sets for translation. The `<string-array>` element has the `name` attribute to identify the resource, along with child `<item>` elements for the individual strings in the array.

So, our sample app has a pair of `<string-array>` resources in `res/values/arrays.xml`:

USING PREFERENCES

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <string-array name="cities">
    <item>Philadelphia</item>
    <item>Pittsburgh</item>
    <item>Allentown/Bethlehem</item>
    <item>Erie</item>
    <item>Reading</item>
    <item>Scranton</item>
    <item>Lancaster</item>
    <item>Altoona</item>
    <item>Harrisburg</item>
  </string-array>
  <string-array name="airport_codes">
    <item>PHL</item>
    <item>PIT</item>
    <item>ABE</item>
    <item>ERI</item>
    <item>RDG</item>
    <item>AVP</item>
    <item>LNS</item>
    <item>A00</item>
    <item>MDT</item>
  </string-array>
</resources>
```

Here, the actual strings are written in-line. They could just as easily be references to string resource (e.g., `<item>@string/philly</item>`). For user-facing strings, like those in the `cities` array, having them as string resources may make it easier for you to manage your translations.

The sample app then uses those arrays in a `ListPreference`:

```
<ListPreference
  android:dialogTitle="@string/listdialogtitle"
  android:entries="@array/cities"
  android:entryValues="@array/airport_codes"
  android:key="list"
  android:summary="@string/pref4summary"
  android:title="@string/pref4title"/>
```

This then allows the user to choose a city, when the user taps on this preference in the `PreferenceFragment`:

USING PREFERENCES

Figure 255: ListPreference UI

However, when the user chooses a city by name (e.g., Philadelphia), what is stored in the `SharedPreferences` is the *corresponding* airport code (e.g., PHL).

`MultiSelectListPreference` works much the same way, except:

- The list contains checkboxes, not radio buttons
- The user can check multiple items
- The result is stored in a “string set” in the `SharedPreferences`, retrieved via `getStringSet()`
- It is only available on API Level 11 and higher

Tutorial #13 - Using Some Preferences

Now that we have the core reading functionality working, we can start to add other features for the user.

One common thing in Android applications is to collect preferences from the user, tailoring the way the app behaves. In the case of EmPubLite, we will initially track two preferences:

- Whether the user wants to return to the book on the same chapter (page in the ViewPager) that they were on when they last were reading the book
- Whether the user wants us to keep the screen on, so they do not have to keep tapping the screen to prevent Android's automatic sleep mode from kicking in

In this tutorial, we will collect and use these two preferences.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Step #1: Defining the Preference XML Files

We need an XML resource file to define what preferences we wish to collect.

First, add four new `<string>` elements to `res/values/strings.xml`:

```
<string name="lastposition_title">Save Last Position</string>
<string name="lastposition_summary">Save the last chapter you were viewing and open up
on that chapter when re-opening the app</string>
```

TUTORIAL #13 - USING SOME PREFERENCES

```
<string name="keepscreenon_summary">Keep the screen powered on while the reader is in  
the foreground</string>  
<string name="keepscreenon_title">Keep Screen On</string>
```

Next, right click over `res/` in your project, and choose `New > "Android resource directory"` from the context menu. Change the "Resource type" drop-down to be "xml", then click OK to create the directory.

Then, right-click over your new `res/xml/` directory and choose `New > "XML resource file"` from the context menu. Fill in `pref_display.xml` in the "New XML Resource File" dialog, then click OK to create the file. It will open up into an XML editor, into which you can paste the following content:

```
<?xml version="1.0" encoding="utf-8"?>  
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">  
  <CheckBoxPreference  
    android:defaultValue="false"  
    android:key="saveLastPosition"  
    android:summary="@string/lastposition_summary"  
    android:title="@string/lastposition_title"/>  
  <CheckBoxPreference  
    android:defaultValue="false"  
    android:key="keepScreenOn"  
    android:summary="@string/keepscreenon_summary"  
    android:title="@string/keepscreenon_title"/>  
</PreferenceScreen>
```

If you prefer, you can [view that complete XML file in your browser](#).

Step #2: Creating Our Preference Activity

We will eventually load that preference XML into a PreferenceFragment. We could use a PreferenceActivity for that, but we do not have enough preferences to warrant a full master/detail setup. Instead, we can just display the PreferenceFragment in a regular Activity, named Preferences, using a static inner class implementation of a PreferenceFragment, named Display.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in Preferences as the name and click OK to create the empty class.

In the Preferences class that is created, replace the current implementation with the following:

```
package com.commonware.empublite;
```

TUTORIAL #13 - USING SOME PREFERENCES

```
import android.app.Activity;
import android.os.Bundle;
import android.preference.PreferenceFragment;

public class Preferences extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
            getFragmentManager()
                .beginTransaction()
                .add(android.R.id.content, new Display())
                .commit();
        }
    }

    public static class Display extends PreferenceFragment {
        @Override
        public void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);
            addPreferencesFromResource(R.xml.pref_display);
        }
    }
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Then, open up `AndroidManifest.xml` and add the following `<activity>` element inside the `<application>` element:

```
<activity android:name="Preferences"></activity>
```

Step #3: Adding To Our Action Bar

Of course, having this activity does us no good if we cannot start it up, so we need to add another hook to our action bar configuration for that.

Add the following XML element to `res/menu/options.xml` as the first child of the `<menu>` root element:

```
<item
    android:id="@+id/settings"
    android:icon="@drawable/ic_action_settings"
    android:showAsAction="never"
    android:title="@string/settings">
</item>
```

You will also need to add a settings string resource, with a value of `Settings`:

```
<string name="settings">Settings</string>
```

Step #4: Launching the Preference Activity

The only thing yet needed to allow the user to get to the preferences is to add another case to the `switch()` statement in `onOptionsItemSelected()` of `EmPubLiteActivity`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.about:
            Intent i = new Intent(this, SimpleContentActivity.class)
                .putExtra(SimpleContentActivity.EXTRA_FILE,
                    "file:///android_asset/misc/about.html");
            startActivity(i);

            return(true);

        case R.id.help:
            i = new Intent(this, SimpleContentActivity.class)
                .putExtra(SimpleContentActivity.EXTRA_FILE,
                    "file:///android_asset/misc/help.html");
            startActivity(i);

            return(true);

        case R.id.settings:
            startActivity(new Intent(this, Preferences.class));

            return(true);
    }
}
```

Now, if you run this in an emulator or device, you will see the new option in the action bar overflow:

TUTORIAL #13 - USING SOME PREFERENCES

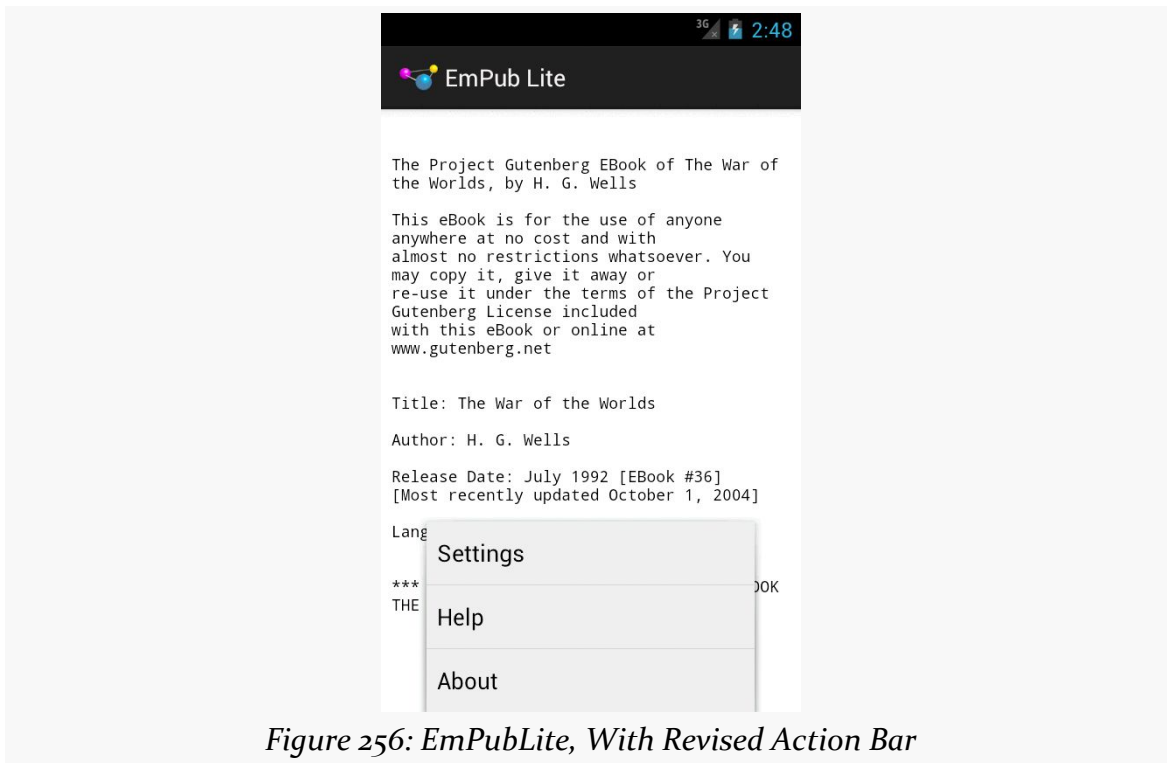

Figure 256: EmPubLite, With Revised Action Bar

Choosing the “Settings” option brings up our two preferences:

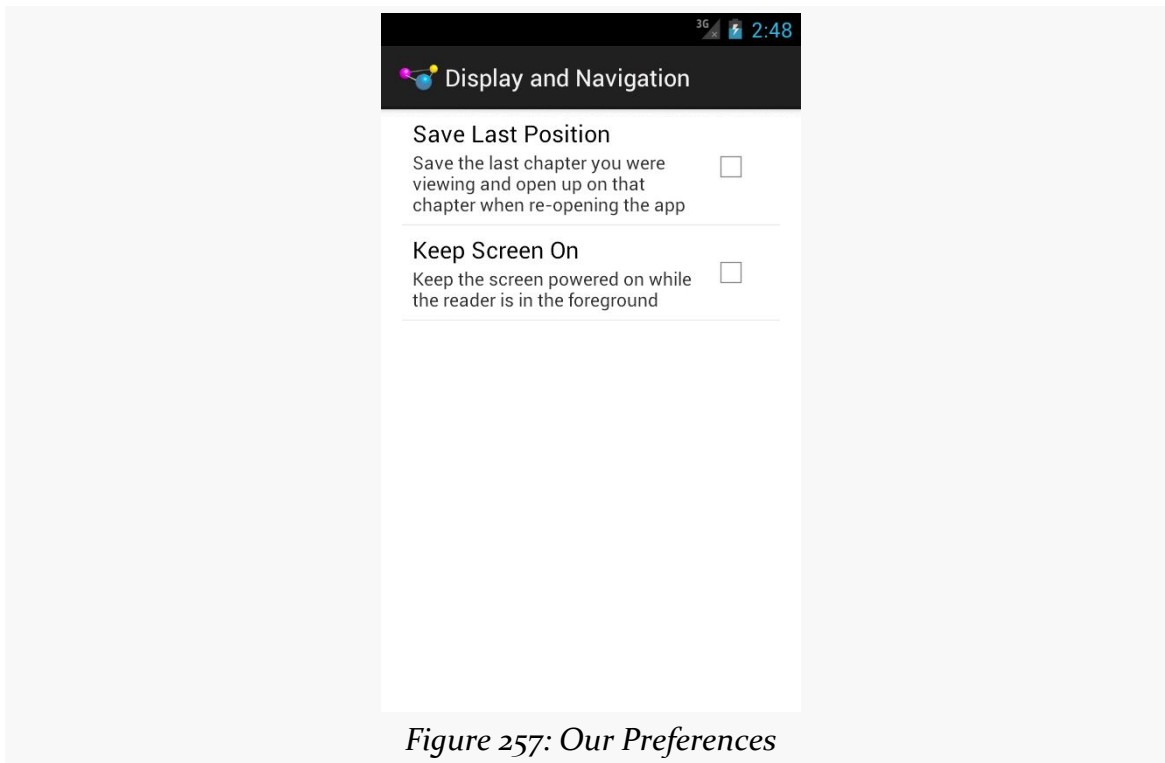

Figure 257: Our Preferences

Step #5: Loading the Preferences

Now, we need to actually arrange to load the preferences on a background thread. As noted, this will be handled by our `ModelFragment`, much as it handles the loading of the book contents.

First, add a private data member named `prefs`, of type `SharedPreferences`, to `ModelFragment`:

```
private SharedPreferences prefs=null;
```

Then, add a `getPrefs()` method to `ModelFragment` that returns the `prefs` value:

```
synchronized public SharedPreferences getPrefs() {  
    return(prefs);  
}
```

Next, revise `LoadThread` to:

- Replace the `assets` data member with a `ctxt` data member of type `Context`

TUTORIAL #13 - USING SOME PREFERENCES

- Take in a Context in the constructor, instead of an AssetManager (this way, even if for some strange reason our original activity is destroyed and recreated while we are loading the preferences, we will not be leaking the original activity)
- Save the application context (from getApplicationContext() on Context) in a data member, instead of an AssetManager
- Call getAssets() on that Context in run(), instead of using the former AssetManager
- Also retrieve the SharedPreferences in run()

```
private class LoadThread extends Thread {
    private Context ctxt=null;

    LoadThread(Context ctxt) {
        super();

        this.ctxt=ctxt(getApplicationContext());
    }

    @Override
    public void run() {
        synchronized(this) {
            prefs=PreferenceManager.getDefaultSharedPreferences(ctxt);
        }

        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
        Gson gson=new Gson();

        try {
            InputStream is=ctxt.getAssets().open("book/contents.json");
            BufferedReader reader=
                new BufferedReader(new InputStreamReader(is));

            synchronized(this) {
                contents=gson.fromJson(reader, BookContents.class);
            }

            EventBus.getDefault().post(new BookLoadedEvent(contents));
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
    }
}
```

This has our LoadThread load both the SharedPreferences and the BookContents, and do so in a known order (SharedPreferences first).

You will need to modify onAttach() to just pass in the Activity to the LoadThread constructor:

TUTORIAL #13 - USING SOME PREFERENCES

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    if (contents==null) {
        new LoadThread(host).start();
    }
}
```

The resulting ModelFragment should look like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.content.Context;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.os.Process;
import android.preference.PreferenceManager;
import android.util.Log;
import com.google.gson.Gson;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import de.greenrobot.event.EventBus;

public class ModelFragment extends Fragment {
    private BookContents contents=null;
    private SharedPreferences prefs=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setRetainInstance(true);
    }

    @Override
    public void onAttach(Activity host) {
        super.onAttach(host);

        if (contents==null) {
            new LoadThread(host).start();
        }
    }

    synchronized public BookContents getBook() {
        return(contents);
    }

    synchronized public SharedPreferences getPrefs() {
        return(prefs);
    }

    private class LoadThread extends Thread {
        private Context ctxt=null;

        LoadThread(Context ctxt) {
```

TUTORIAL #13 - USING SOME PREFERENCES

```
super();

this.ctxt=ctxt.getApplicationContext();
}

@Override
public void run() {
    synchronized(this) {
        prefs=PreferenceManager.getDefaultSharedPreferences(ctxt);
    }

    Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    Gson gson=new Gson();

    try {
        InputStream is=ctxt.getAssets().open("book/contents.json");
        BufferedReader reader=
            new BufferedReader(new InputStreamReader(is));

        synchronized(this) {
            contents=gson.fromJson(reader, BookContents.class);
        }

        EventBus.getDefault().post(new BookLoadedEvent(contents));
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }
}
}
```

Step #6: Saving the Last-Read Position

One preference is to restore our current page in the ViewPager when the user later re-opens the app. To make that work, we need to start saving the current page as the user leaves the app. And, we may as well use our freshly-minted SharedPreferences to store this value.

We need a key under which we will store this value in the SharedPreferences, so add a new static data member to EmPubLiteActivity:

```
private static final String PREF_LAST_POSITION="lastPosition";
```

We are also going to need access to our ModelFragment from outside of onCreate() in EmPubLiteActivity. Add a ModelFragment data member named mfrag:

```
private ModelFragment mfrag=null;
```

Then, modify onResume() to refer to the mfrag data member, replacing the former mfrag local variable:

TUTORIAL #13 - USING SOME PREFERENCES

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (adapter==null) {
        mfrag=
            (ModelFragment)getManager().findFragmentByTag(MODEL);

        if (mfrag == null) {
            mfrag=new ModelFragment();
            getFragmentManager().beginTransaction().add(mfrag, MODEL).commit();
        }
        else if (mfrag.getBook() != null) {
            setupPager(mfrag.getBook());
        }
    }
}
```

Next, update `onPause()` on `EmPubLiteActivity` to track the page of the `ViewPager` that the user is on at the point in time when `onPause()` is called:

```
@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    if (mfrag.getPrefs()!=null) {
        int position=pager.getCurrentItem();

        mfrag.getPrefs().edit().putInt(PREF_LAST_POSITION, position)
            .apply();
    }

    super.onPause();
}
```

Here, we check to see that we have the `SharedPreferences` loaded — odds are that we do, but we cannot be certain. If we do have access to the `SharedPreferences`, we find out the current position within the `ViewPager` via `getCurrentItem()` (e.g., 0 for the first page). We then obtain a `SharedPreferences.Editor` and use it to save this position value in the `SharedPreferences`, keyed as `PREF_LAST_POSITION`, using `apply()` to persist the changes.

Step #7: Restoring the Last-Read Position

Now that we are saving this position data, we can start to use it.

Our preference XML has our key to the “Save Last Position” preference, but we need it in Java code as well, so add another static data member to `EmPubLiteActivity`:

TUTORIAL #13 - USING SOME PREFERENCES

```
private static final String PREF_SAVE_LAST_POSITION="saveLastPosition";
```

Add the following lines to the end of `setupPager()` in `EmPubLiteActivity`:

```
SharedPreferences prefs=mfrag.getPrefs();

if (prefs != null) {
    if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
        pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
    }
}
```

Here, we check to see if the user has enabled having us restore the last-saved position (defaulting to `false`). If the user has, we retrieve the last-saved position (defaulting to 0, or the first page), and call `setCurrentItem()` on the `ViewPager` to shift to that particular page.

If you run this in a device or emulator, check the “Save Last Position” preference checkbox, flip ahead a couple of chapters, exit the app via the BACK button, and go back into the app, you will see that you are taken back to the chapter you were last reading.

Step #8: Keeping the Screen On

Our other preference is whether or not the screen should stay on, without user input, while we are reading the book. The bare-bones implementation of this requires just two lines of additional code.

First, we need to define another static data member on `EmPubLiteActivity`, this time with the key for our keep-screen-on preference:

```
private static final String PREF_KEEP_SCREEN_ON="keepScreenOn";
```

Then, add one more line to `setupPager()` in `EmPubLiteActivity`, inside of the `if` block:

```
pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
```

This will give you:

```
private void setupPager(BookContents contents) {
    adapter=new ContentsAdapter(this, contents);
    pager.setAdapter(adapter);
    findViewById(R.id.progressBar1).setVisibility(View.GONE);
    pager.setVisibility(View.VISIBLE);
}
```

TUTORIAL #13 - USING SOME PREFERENCES

```
SharedPreferences prefs=mfrag.getPrefs();

if (prefs!=null) {
    if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
        pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
    }

    pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
}
}
```

`setKeepScreenOn()`, called on any `View`, will keep the screen lit and active without continuous user input, so long as that `View` is on the screen.

This approach is somewhat limited, in that we are only setting this during the call to `setupPager()`. If the user changes the preference value, that change would only take effect when the activity was restarted (e.g., user rotates the screen, user exits the app via `BACK` and returns later).

The simplest way for us to have this take more immediate effect is to realize that `EmPubLiteActivity` will be paused and stopped when the Preferences activity is on the screen, and will be started and resumed when the user is done adjusting preferences. So, we can simply augment `onResume()` to also update the screen-on setting:

```
@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);

    if (adapter==null) {
        mfrag=(ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag==null) {
            mfrag=new ModelFragment();

            getFragmentManager()
                .beginTransaction()
                .add(mfrag, MODEL)
                .commit();
        }
        else if (mfrag.getBook()!=null) {
            setupPager(mfrag.getBook());
        }
    }

    if (mfrag.getPrefs()!=null) {
        pager.setKeepScreenOn(mfrag.getPrefs()
            .getBoolean(PREF_KEEP_SCREEN_ON, false));
    }
}
```

TUTORIAL #13 - USING SOME PREFERENCES

Of course, we may not *have* the `SharedPreferences` yet, when the app is first starting up, so we avoid making any changes in that case.

If you run this on a device (note: *not* an emulator), you can play with this preference and see the changes in the screen's behavior.

In Our Next Episode...

... we will allow the user to [write, save, and delete notes](#) for the currently-viewed chapter, using a database.

SQLite Databases

Besides SharedPreferences and your own file structures, the third primary means of persisting data locally on Android is via SQLite. For many applications, SQLite is the app's backbone, whether it is used directly or via some third-party wrapper.

This chapter will focus on how you can directly work with SQLite to store relational data.

Introducing SQLite

[SQLite](#) is a very popular embedded database, as it combines a clean SQL interface with a very small memory footprint and decent speed. Moreover, it is public domain, so everyone can use it. Lots of firms (Adobe, Apple, Google, Symbian) and open source projects (Mozilla, PHP, Python) all ship products with SQLite.

For Android, SQLite is “baked into” the Android runtime, so every Android application can create SQLite databases. Since SQLite uses a SQL interface, it is fairly straightforward to use for people with experience in other SQL-based databases. However, its native API is not JDBC, and JDBC might be too much overhead for a memory-limited device like a phone, anyway. Hence, Android programmers have a different API to learn — the good news being is that it is not that difficult.

This chapter will cover the basics of SQLite use in the context of working on Android. It by no means is a thorough coverage of SQLite as a whole. If you want to learn more about SQLite, the [SQLite Web site](#) may help.

Thinking About Schemas

SQLite is a typical relational database, containing tables (themselves consisting of rows and columns), indexes, and so on. Your application will need its own set of tables and so forth for holding whatever data you wish to hold. This structure is generally referred to as a “schema”.

It is likely that your schema will need to change over time. You might add new tables or columns in support of new features. Or, you might significantly reorganize your data structure and wind up dropping some tables while moving the data into new ones.

As a result, when you ship an update to your application to your users, not only will your Java code change, but the *expectations* of that Java code will change as well, with respect to what your database schema will look like. Version 1 of your app will use your original schema, but by the time you ship, say, version 5 of the app, you might need an adjusted schema.

Android has facilities to assist you with handling changing database schemas, mostly centered around the `SQLiteOpenHelper` class.

Start with a Helper

`SQLiteOpenHelper` is designed to consolidate your code related to two very common problems:

1. What happens the very first time when your app is run on a device after it is installed? At this point, we do not yet have a database, and so you will need to create your tables, indexes, starter data, and so on.
2. What happens the very first time when an upgraded version of your app is run on a device, where the upgraded version is expecting a newer database schema? Your database will still be on the old schema from the older edition of the app. You will need to have a chance to alter the database schema to match the needs of the rest of your app.

`SQLiteOpenHelper` wraps up the logic to create and upgrade a database, per your specifications, as needed by your application. You will need to create a custom subclass of `SQLiteOpenHelper`, implementing three methods at minimum:

SQLITE DATABASES

1. The constructor, chaining upward to the SQLiteOpenHelper constructor. This takes the Context (e.g., an Activity), the name of the database, an optional cursor factory (typically, just pass null), and an integer representing the version of the database schema you are using (typically start at 1 and increment from there).
2. onCreate(), called when there is no database and your app needs one, which passes you a SQLiteDatabase object, pointing at a newly-created database, that you use to populate with tables and initial data, as appropriate.
3. onUpgrade(), called when the schema version you are seeking does not match the schema version of the database, which passes you a SQLiteDatabase object and the old and new version numbers, so you can figure out how best to convert the database from the old schema to the new one.

To see how all this SQLite stuff works in practice, we will examine the [Database/ConstantsROWID](#) sample application. This application pulls a bunch of gravitational constants from the SensorManager class, puts them in a database table, displays them in a ListFragment, and allows the user to add new ones via the action bar.

First, we need a SQLiteOpenHelper subclass, here named DatabaseHelper.

The DatabaseHelper constructor chains to the superclass and supplies the name of the database (held in a DATABASE_NAME static data member) and the version number of our database schema (held in SCHEMA):

```
public class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="constants.db";
    private static final int SCHEMA=1;
    static final String TITLE="title";
    static final String VALUE="value";
    static final String TABLE="constants";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, SCHEMA);
    }
}
```

We also need an onCreate() method, which will be called and passed a SQLiteDatabase object when a database needs to be newly created. Below you will see the DatabaseHelper implementation of onCreate(), though we will get into how it is using the SQLiteDatabase object more later in this chapter:

```
@Override
public void onCreate(SQLiteDatabase db) {
    db.execSQL("CREATE TABLE constants (title TEXT, value REAL);");

    ContentValues cv=new ContentValues();
```

```
cv.put(TITLE, "Gravity, Death Star I");
cv.put(VALUE, SensorManager.GRAVITY_DEATH_STAR_I);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Earth");
cv.put(VALUE, SensorManager.GRAVITY_EARTH);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Jupiter");
cv.put(VALUE, SensorManager.GRAVITY_JUPITER);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Mars");
cv.put(VALUE, SensorManager.GRAVITY_MARS);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Mercury");
cv.put(VALUE, SensorManager.GRAVITY_MERCURY);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Moon");
cv.put(VALUE, SensorManager.GRAVITY_MOON);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Neptune");
cv.put(VALUE, SensorManager.GRAVITY_NEPTUNE);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Pluto");
cv.put(VALUE, SensorManager.GRAVITY_PLUTO);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Saturn");
cv.put(VALUE, SensorManager.GRAVITY_SATURN);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Sun");
cv.put(VALUE, SensorManager.GRAVITY_SUN);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, The Island");
cv.put(VALUE, SensorManager.GRAVITY_THE_ISLAND);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Uranus");
cv.put(VALUE, SensorManager.GRAVITY_URANUS);
db.insert(TABLE, TITLE, cv);

cv.put(TITLE, "Gravity, Venus");
cv.put(VALUE, SensorManager.GRAVITY_VENUS);
db.insert(TABLE, TITLE, cv);
}
```

Suffice it to say for the moment that it is creating a constants table and inserting several rows into it, all wrapped in a transaction.

We also need `onUpgrade()`... even though it should never be called right now:

SQLITE DATABASES

```
@Override
public void onUpgrade(SQLiteDatabase db, int oldVersion,
                      int newVersion) {
    throw new RuntimeException("How did we get here?");
}
```

After all, right now, we only have one version of our schema (1) and therefore will have no need to upgrade. If, in the future, we change SCHEMA to a higher value (e.g., 2), and we upgrade our app on a device that had previously been run with our earlier schema, *then* we will be called with `onUpgrade()`. We are passed the old and new schema versions, so we know what needs to be upgraded.

Bear in mind that users do not necessarily have to take on each of your application updates, and so you might find that a user skipped a schema version:

- You release an app on Monday, with schema version 1
- A user installs your app on Tuesday and runs it, creating a database via `onCreate()`
- You release an upgraded app on Wednesday, with schema version 2
- You release yet another upgrade on Thursday, with schema version 3
- The user installs your upgrade, now needing a schema version 3 database instead of the version 1 presently on the device, triggering a call to `onUpgrade()`

There are two other methods you can elect to override in your `SQLiteOpenHelper`, if you feel the need:

- You can override `onOpen()`, to get control when somebody opens this database. Usually, this is not required.
- Android 3.0 introduced `onDowngrade()`, which will be called if the code requests an older schema than what is in the database presently. This is the converse of `onUpgrade()` — if your version numbers differ, one of these two methods will be invoked. Since normally you are moving forward with updates, you can usually skip `onDowngrade()`.

Employing Your Helper

To use your `SQLiteOpenHelper` subclass, create and hold onto an instance of it. Then, when you need a `SQLiteDatabase` object to do queries or data modifications, ask your `SQLiteOpenHelper` to `getReadableDatabase()` or `getWritableDatabase()`, depending upon whether or not you will be changing its contents.

SQLITE DATABASES

For example, the ConstantsFragment from the sample app creates a DatabaseHelper instance in onCreateView() and holds onto it in a data member:

```
db=new DatabaseHelper(getActivity());
```

When you are done with the database (e.g., your activity is being closed), simply call close() on your SQLiteOpenHelper to release your connection, as ConstantsFragment does (among other things) in onDestroy():

```
@Override
public void onDestroy() {
    if (task != null) {
        task.cancel(false);
    }

    ((CursorAdapter)getListAdapter()).getCursor().close();
    db.close();

    super.onDestroy();
}
```

(we will explore those “other things” in a bit)

Where to Hold a Helper

For trivial apps, like the one profiled in this chapter, holding a SQLiteOpenHelper in a data member of your one-and-only activity is fine.

If, however, you have multiple components — such as multiple activities — all needing to use the database, you are much better served having a *singleton instance* of your SQLiteOpenHelper, compared to having each activity have its own instance.

The reason is threading.

You really should do your database I/O on background threads. Opening a database is cheap, but working with it (queries, inserts, etc.) is not. The SQLiteDatabase object managed by SQLiteOpenHelper is thread-safe... so long as all threads are using the same instance.

For singleton objects that depend upon a Context, like SQLiteOpenHelper, rather than create the object using a garden-variety Context like an Activity, you really should create it with an Application. There is a singleton instance of a Context, in the form of the Application subclass, created in your process moments after it is started. You can retrieve this singleton by calling getApplicationContext() on any other Context. The advantage of using Application is memory leaks: if you put a

SQLiteOpenHelper in a singleton, and use, say, an Activity to create it, then the Activity might not be able to be garbage-collected, because the SQLiteOpenHelper keeps a strong reference to it. Since Application is itself a singleton (and, hence, is “pre-leaked”, so to speak), the risks of a memory leak diminish significantly.

So, instead of:

```
db=new DatabaseHelper(getActivity());
```

in a fragment, with db as a data member, you might have:

```
db=new DatabaseHelper(getActivity().getApplicationContext());
```

with db as a static data member, shared by multiple activities or other components.

Getting Data Out

One popular thing to do with a database is to get data out of it. Android has a few ways you can execute a query on a SQLiteDatabase (from your SQLiteOpenHelper), along with some classes, like CursorAdapter, to help you use the results you get back.

Your Query Options

In most cases, your simplest option for executing a query is to call `rawQuery()` on the SQLiteDatabase. This takes two parameters:

- A SQL SELECT statement (or anything else that returns a result set), optionally with `?` characters in the WHERE clause (or ORDER BY or similar clauses) representing parameters to be bound at runtime
- An optional String array of the parameters to be used to replace the `?` characters in the query

If you do not use the `?` position parameter syntax in your query, you are welcome to pass `null` as the second parameter to `rawQuery()`.

The nice thing about `rawQuery()` is that any valid SQL syntax works, so long as it returns a result set. You are welcome to use joins, sub-selects, and so on without issue.

SQLITE DATABASES

There are two other query options — `query()` and `SQLiteQueryBuilder`. These both build up a SQL `SELECT` statement from its component parts (e.g., name of the table to query, `WHERE` clause and positional parameters). These are more cumbersome to use, particularly with complex `SELECT` statements. Mostly, they would be used in cases where, for one reason or another, you do not know the precise query at compile time and find it easier to use these facilities to construct the query from parts at runtime. Some developers will do this to avoid duplicating values, by defining constants for things like table names and column names.

For example, `ConstantsFragment` has a private inner class named `BaseTask` which has `doQuery()` method that uses `query()`:

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
    @Override
    public void onPostExecute(Cursor result) {
        ((CursorAdapter)getListAdapter()).changeCursor(result);
        task=null;
    }

    protected Cursor doQuery() {
        Cursor result=
            db
                .getReadableDatabase()
                .query(DatabaseHelper.TABLE,
                    new String[] {"ROWID AS _id",
                                    DatabaseHelper.TITLE,
                                    DatabaseHelper.VALUE},
                    null, null, null, null, DatabaseHelper.TITLE);

        result.getCount();

        return(result);
    }
}
```

Do not concatenate your own `WHERE` clause, though. Let the `?` positional parameters handle that for you, as the work they do to escape your apostrophes, quotation marks, and the like also helps to defend against SQL injection attacks. In this particular case, we do not have a `WHERE` clause.

If that `ROWID AS _id` piece looks a bit odd, we will see why that is in the query a bit later in this chapter.

What Is a Cursor?

All three of these give you a `Cursor` when you are done. In Android, a `Cursor` represents the entire result set of the query — all the rows and all the columns that

the query returned. In this respect, it is reminiscent of a “client-side cursor” from toolkits like ODBC, JDBC, etc.

(if the Cursor result set is over 1MB, it actually only holds a “window” on the data, and the story gets really really complicated...)

As such, a Cursor can be quite the memory hog. Please `close()` the Cursor when you are done with it, to free up the heap space it consumes and make that memory available to the rest of your application.

Using the Cursor Manually

With the Cursor, you can:

1. Find out how many rows are in the result set via `getCount()`
2. Iterate over the rows via `moveToFirst()`, `moveToNext()`, and `isAfterLast()`
3. Find out the names of the columns via `getColumnNames()`, convert those into column numbers via `getColumnIndex()`, and get values for the current row for a given column via methods like `getString()`, `getInt()`, etc.

For example, here we iterate over a fictitious `widgets` table’s rows:

```
Cursor result=
    db.rawQuery("SELECT _id, name, inventory FROM widgets", null);

while (result.moveToNext()) {
    int id=result.getInt(0);
    String name=result.getString(1);
    int inventory=result.getInt(2);

    // do something useful with these
}

result.close();
```

Introducing CursorAdapter

Another way to use a Cursor is to wrap it in a CursorAdapter. Just as ArrayAdapter adapts arrays, CursorAdapter adapts Cursor objects, making their data available to an AdapterView like a ListView.

The easiest way to set one of these up is to use SimpleCursorAdapter, which extends CursorAdapter and provides some boilerplate logic for taking values out of columns and putting them into row View objects for a ListView (or other AdapterView). The sample app does just that:

SQLITE DATABASES

```
SimpleCursorAdapter adapter=  
    new SimpleCursorAdapter(getActivity(), R.layout.row,  
        current, new String[] {  
            DatabaseHelper.TITLE,  
            DatabaseHelper.VALUE },  
        new int[] { R.id.title, R.id.value },  
        0);  
  
setListAdapter(adapter);
```

Here, we are telling `SimpleCursorAdapter` to take rows out of a `Cursor` named `current`, turning each into an inflated `R.layout.row` `ViewGroup`, in this case, a `RelativeLayout` holding a pair of `TextView` widgets:

```
<?xml version="1.0" encoding="utf-8"?>  
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="wrap_content">  
  
    <TextView  
        android:id="@+id/title"  
        android:layout_width="wrap_content"  
        android:layout_height="wrap_content"  
        android:layout_alignParentLeft="true"  
        android:textSize="20sp"  
        android:textStyle="bold" />  
  
    <TextView  
        android:id="@+id/value"  
        android:layout_width="wrap_content"  
        android:layout_height="wrap_content"  
        android:layout_alignParentRight="true"  
        android:textSize="20sp"  
        android:textStyle="bold" />  
  
</RelativeLayout>
```

For each row in the `Cursor`, the columns named `title` and `value` (represented by `TITLE` and `VALUE` constants on `DatabaseHelper`) are to be poured into their respective `TextView` widgets (`R.id.title` and `R.id.value`).

Note, though, that if you are going to use `CursorAdapter` or its subclasses (like `SimpleCursorAdapter`), your result set of your query *must* contain an integer column named `_id` that is unique for the result set. This “id” value is then supplied to methods like `onListItemClick()`, to identify what item the user clicked upon in the `AdapterView`. Note that this requirement is on the result set in the `Cursor`, so if you have a suitable column in a table that is not named `_id`, you can rename it in your query (e.g., `SELECT key AS _id, ...`).

However, if you want, you can use the built-in `ROWID`

Quoting [the SQLite documentation](#):

In SQLite, every row of every table has an 64-bit signed integer ROWID. The ROWID for each row is unique among all rows in the same table. You can access the ROWID of an SQLite table using one of the special column names ROWID, _ROWID_, or OID... If a table contains a column of type INTEGER PRIMARY KEY, then that column becomes an alias for the ROWID. You can then access the ROWID using any of four different names, the original three names described above or the name given to the INTEGER PRIMARY KEY column. All these names are aliases for one another and work equally well in any context.

With that in mind, if you want to query SQLite and use the results in a CursorAdapter, but you do not have your own INTEGER PRIMARY KEY column, you can just include ROWID in your query, renaming it to _id to satisfy CursorAdapter.

That is why we have the ROWID AS _id in the doQuery() method: to satisfy this _id requirement of CursorAdapter.

Also note that you cannot close() the Cursor used by a CursorAdapter until you no longer need the CursorAdapter. That is why we do not close the Cursor until onDestroy() of the fragment:

```
@Override
public void onDestroy() {
    if (task != null) {
        task.cancel(false);
    }

    ((CursorAdapter)getListAdapter()).getCursor().close();
    db.close();

    super.onDestroy();
}
```

We retrieve the Cursor from the CursorAdapter, which we get by calling getListAdapter() on the fragment.

Getting Data Out, Asynchronously

Ideally, queries are done on a background thread, as they may take some time.

One approach for doing that is to use an AsyncTask. In the sample application, ConstantsFragment kicks off a LoadCursorTask in onCreateView() (shown above).

SQLITE DATABASES

LoadCursorTask extends the BaseTask class mentioned previously, where the doQuery() method resides. LoadCursorTask is responsible for doing the query (via the doQuery() method shown above) and putting the results in the ListView inside the fragment (using the SimpleCursorAdapter shown above):

```
abstract private class BaseTask<T> extends AsyncTask<T, Void, Cursor> {
    @Override
    public void onPostExecute(Cursor result) {
        ((CursorAdapter)getListAdapter()).changeCursor(result);
        task=null;
    }

    protected Cursor doQuery() {
        Cursor result=
            db
                .getReadableDatabase()
                .query(DatabaseHelper.TABLE,
                    new String[] {"ROWID AS _id",
                        DatabaseHelper.TITLE,
                        DatabaseHelper.VALUE},
                    null, null, null, null, DatabaseHelper.TITLE);

        result.getCount();

        return(result);
    }
}

private class LoadCursorTask extends BaseTask<Void> {
    @Override
    protected Cursor doInBackground(Void... params) {
        return(doQuery());
    }
}
```

We execute the actual query in doInBackground() and call getCount() on the Cursor, to force it to actually perform the query — query() returns the Cursor, but the query is not actually executed until we do something that needs the result set. This also holds true for.rawQuery(), which is why we need to make sure to “touch” the Cursor while we are on the background thread.

onPostExecute() then uses changeCursor() to replace the Cursor in the SimpleCursorAdapter with the results. Since our SimpleCursorAdapter was created with a null Cursor, changeCursor() just slides in the new Cursor, telling the ListView that the data changed. This causes our ListView to be populated.

This way, the UI will not be frozen while the query is being executed, yet we only update the UI from the main application thread.

Note that the first time we try using the `SQLiteOpenHelper` is in our background thread. `SQLiteOpenHelper` will not try creating our database (e.g., for a new app install) until we call `getReadableDatabase()` or `getWritableDatabase()`. Hence, `onCreate()` (or, later, `onUpgrade()`) of our `SQLiteOpenHelper` will wind up being called on the background thread as well, meaning that the time spent creating (or upgrading) the database also does not freeze the UI.

Also note that in `onDestroy()`, as shown previously, we call `cancel()` on the `AsyncTask` if it is not `null`. If the task is still running, calling `cancel()` will prevent `onPostExecute()` from being invoked, and we will not have to worry about updating our UI after the fragment has been destroyed.

The Rest of the CRUD

To get data out of a database, it is generally useful to put data into it in the first place. The sample app starts by loading in data when the database is created (in `onCreate()` of `DatabaseHelper`), plus has an action bar item to allow the user to add other constants as needed.

In this section, we will examine in further detail how we manipulate the database, for both the write aspects of CRUD (create-read-update-delete) and for data definition language (DDL) operations (creating tables, creating indexes, etc.).

The Primary Option: `execSQL()`

For creating your tables and indexes, you will need to call `execSQL()` on your `SQLiteDatabase`, providing the DDL statement you wish to apply against the database. Barring a database error, this method returns nothing.

So, for example, you can call `execSQL()` to create the constants table, as shown in the `DatabaseHelper` `onCreate()` method:

```
db.execSQL("CREATE TABLE constants (title TEXT, value REAL);");
```

This will create a table, named `constants`, with two data columns: `title` (text) and `value` (a float, or “real” in SQLite terms).

Most likely, you will create tables and indexes when you first create the database, or possibly when the database needs upgrading to accommodate a new release of your application. If you do not change your table schemas, you might never drop your

tables or indexes, but if you do, just use `execSQL()` to invoke `DROP INDEX` and `DROP TABLE` statements as needed.

Alternative Options

For inserts, updates, and deletes of data, you have two choices. You can always use `execSQL()`, just like you did for creating the tables. The `execSQL()` method works for any SQL that does not return results, so it can handle `INSERT`, `UPDATE`, `DELETE`, etc. just fine.

Your alternative is to use the `insert()`, `update()`, and `delete()` methods on the `SQLiteDatabase` object, which eliminate much of the SQL syntax required to do basic operations.

For example, here we `insert()` a new row into our constants table, again from `onCreate()` of `DatabaseHelper`:

```
ContentValues cv=new ContentValues();  
  
cv.put(TITLE, "Gravity, Death Star I");  
cv.put(VALUE, SensorManager.GRAVITY_DEATH_STAR_I);  
db.insert(TABLE, TITLE, cv);
```

These methods make use of `ContentValues` objects, which implement a `Map`-esque interface, albeit one that has additional methods for working with `SQLite` types. For example, in addition to `get()` to retrieve a value by its key, you have `getAsInteger()`, `getAsString()`, and so forth.

The `insert()` method takes the name of the table, the name of one column as the “null column hack”, and a `ContentValues` with the initial values you want put into this row. The “null column hack” is for the case where the `ContentValues` instance is empty — the column named as the “null column hack” will be explicitly assigned the value `NULL` in the SQL `INSERT` statement generated by `insert()`. This is required due to a quirk in `SQLite`’s support for the SQL `INSERT` statement.

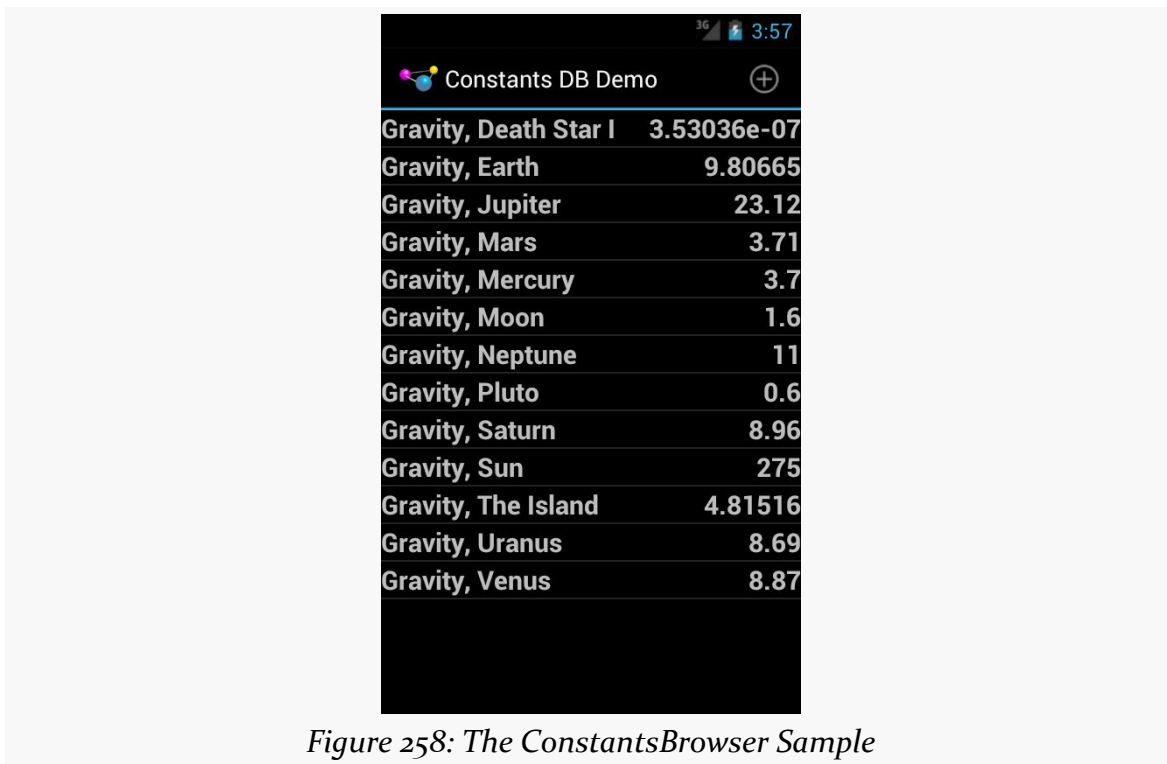

The `update()` method takes the name of the table, a `ContentValues` representing the columns and replacement values to use, an optional `WHERE` clause, and an optional list of parameters to fill into the `WHERE` clause, to replace any embedded question marks (?). Since `update()` only replaces columns with fixed values, versus ones computed based on other information, you may need to use `execSQL()` to accomplish some ends. The `WHERE` clause and parameter list works akin to the positional SQL parameters you may be used to from other SQL APIs.

The `delete()` method works akin to `update()`, taking the name of the table, the optional `WHERE` clause, and the corresponding parameters to fill into the `WHERE` clause.

Asynchronous CRUD and UI Updates

Just as querying a database should be done on a background thread, so should modifying a database. This is why it is important to make the first time you request a `SQLiteDatabase` from a `SQLiteOpenHelper` be on a background thread, in case `onCreate()` or `onUpgrade()` are needed.

The same thing holds true if you need to update the database during normal operation of your app. For example, the sample application has an “add” action bar item in the upper-right corner of the screen:

Clicking on that brings up a dialog — a technique we will discuss later in this book:

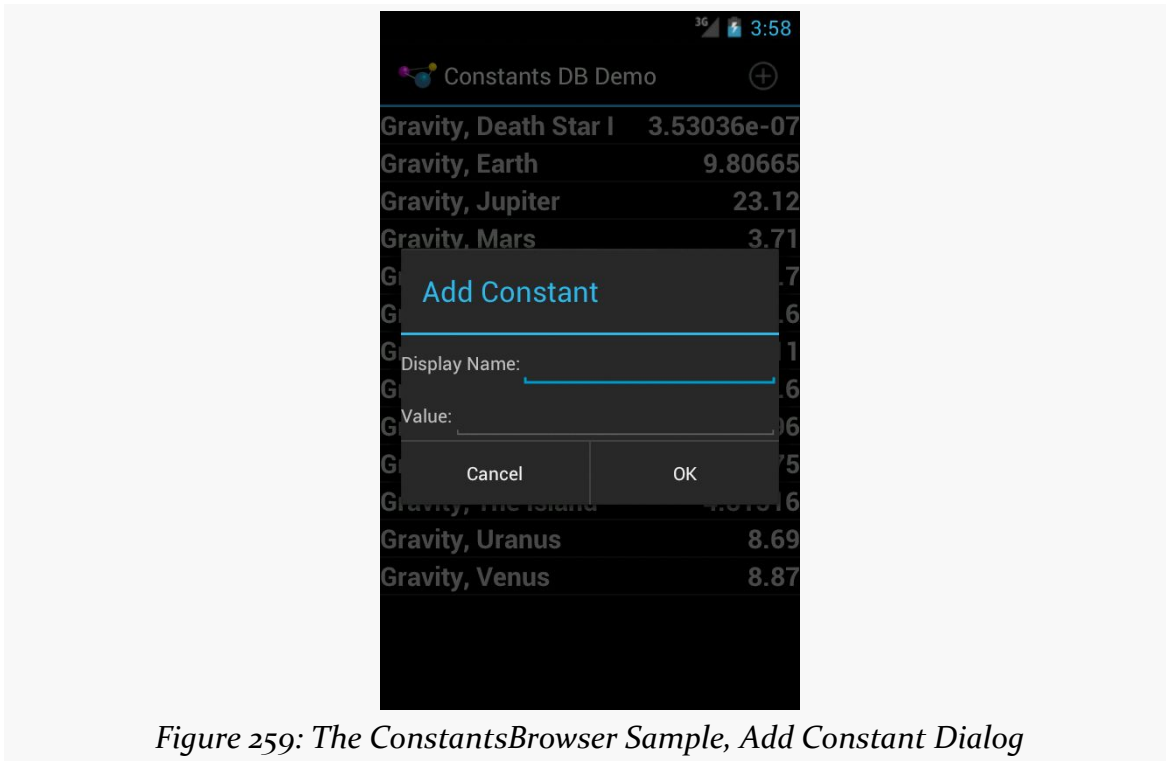

Figure 259: The ConstantsBrowser Sample, Add Constant Dialog

If the user fills in a constant and clicks the “OK” button, we need to insert a new record in the database. That is handled via an `InsertTask`:

```
private class InsertTask extends BaseTask<ContentValues> {  
    @Override  
    protected Cursor doInBackground(ContentValues... values) {  
        db.getWritableDatabase().insert(DatabaseHelper.TABLE,  
                                       DatabaseHelper.TITLE, values[0]);  
  
        return(doQuery());  
    }  
}
```

The `InsertTask` is supplied a `ContentValues` object with our title and value, just as we used in `onCreate()` of `DatabaseHelper`. In `doInBackground()`, we get a writable database from `DatabaseHelper` and perform the `insert()` call, so the database I/O does not tie up the main application thread.

However, in `doInBackground()`, we *also* call `doQuery()` again. This retrieves a fresh `Cursor` with the new roster of constants... including the one we just inserted. As with `LoadCursorTask`, we execute `doQuery()` in `doInBackground()` to keep the database I/O off the main application thread. This triggers the same `onPostExecute()` as

before, inherited from `BaseTask`, which uses `changeCursor()` to replace any existing results with the new results.

Setting Transaction Bounds

By default, each SQL statement executes in its own transaction — this is fairly typical behavior for a SQL database, and SQLite is no exception.

There are two reasons why you might want to have your own transaction bounds, larger than a single statement:

1. The classic “we have a series of operations that need to succeed or fail as a whole” rationale, for maintaining data integrity
2. Performance, as each database transaction involves disk I/O, and one large transaction will be much faster than lots of little transactions

The basic recipe for your own transactions is:

```
try {
    db.beginTransaction();

    // several SQL statements in here

    db.setTransactionSuccessful();
}
finally {
    db.endTransaction();
}
```

`beginTransaction()` marks the fact that you want a transaction. `setTransactionSuccessful()` indicates that you want the transaction to commit. However, the actual `COMMIT` or `ROLLBACK` does not occur until `endTransaction()`. In the normal case, `setTransactionSuccessful()` does get called, and `endTransaction()` performs a `COMMIT`. If, however, one of your SQL statements fails (e.g., violates a foreign key constraint), the `setTransactionSuccessful()` call is skipped, so `endTransaction()` will do a `ROLLBACK`.

You might wonder why we did not bother with a transaction in `onCreate()` method of `DatabaseHelper`, given the latter reason. That is because `onCreate()` is called within a transaction set up by `SQLiteOpenHelper` itself, so you do not need your own.

Hey, What About Hibernate?

Those of you with significant Java backgrounds outside of Android are probably pounding your head against your desk right about now. Outside of a few conveniences like `SQLiteOpenHelper` and `CursorAdapter`, Android's approach to database I/O feels a bit like classic JDBC. Java developers, having experienced the pain of raw JDBC, created various wrappers around it, the most prominent of which is an ORM (object-relational mapper) called Hibernate.

Alas, Hibernate is designed for servers, not mobile devices. It is a little bit heavyweight, and it is designed for use with JDBC, not Android's SQLite classes.

Android did not include any sort of ORM in the beginning for two main reasons:

1. To keep the firmware size as small as possible, as smaller firmware can lead to less-expensive devices
2. To eliminate the ORM overhead (e.g., reflection), which would have been too much for early Android versions on early Android devices

The Android ecosystem has come up with alternatives, such as [ORMLite](#) and [greenDAO](#). So, if you are used to using an ORM, you may want to investigate these sorts of solutions — they just are not built into Android itself.

Visit the Trails!

If you are interested in exposing your database contents to a third-party application, you may wish to read up on [ContentProvider](#).

The trails also have chapters on [encrypted databases using SQLCipher](#) and [shipping pre-packaged databases with your app](#).

Tutorial #14 - Saving Notes

It would be nice if the user could add some personal notes to the chapter that she is reading, whether that serves as commentary, points to be researched, complaints about the author's hair (or lack thereof), or whatever.

So, in this chapter, we will add a new fragment and new activity to allow the user to add notes per chapter, via a large `EditText` widget. Those notes will be stored in a SQLite database.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Step #1: Adding a DatabaseHelper

The first step for working with SQLite is to add an implementation of `SQLiteOpenHelper`, which we will do here, named `DatabaseHelper`.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `DatabaseHelper` as the name and click `OK` to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

import android.content.Context;
import android.database.sqlite.SQLiteDatabase;
import android.database.sqlite.SQLiteOpenHelper;
```

TUTORIAL #14 - SAVING NOTES

```
public class DatabaseHelper extends SQLiteOpenHelper {
    private static final String DATABASE_NAME="empublite.db";
    private static final int SCHEMA_VERSION=1;
    private static DatabaseHelper singleton=null;

    synchronized static DatabaseHelper getInstance(Context ctxt) {
        if (singleton == null) {
            singleton=new DatabaseHelper(ctxt.getApplicationContext());
        }

        return(singleton);
    }

    private DatabaseHelper(Context ctxt) {
        super(ctxt, DATABASE_NAME, null, SCHEMA_VERSION);
    }

    @Override
    public void onCreate(SQLiteDatabase db) {
        db.execSQL("CREATE TABLE notes (position INTEGER PRIMARY KEY, prose TEXT);");
    }

    @Override
    public void onUpgrade(SQLiteDatabase db, int oldVersion,
        int newVersion) {
        throw new RuntimeException("This should not be called");
    }
}
```

Step #2: Examining DatabaseHelper

Our initial version of DatabaseHelper has a few things:

- It has the constructor, supplying to the superclass the name of the database file (DATABASE_NAME) and the revision number of our schema (SCHEMA_VERSION). Note that the constructor is private, as we are using the singleton pattern, so only DatabaseHelper should be able to create DatabaseHelper instances.
- It has the onCreate() method, invoked the first time we run the app on a device or emulator, to let us populate the database. Here, we use execSQL() to define a notes with a position column (indicating our chapter) and a prose column (what the user types in as the note).
- It has the onUpgrade() method, needed because SQLiteOpenHelper is abstract, so our app will not compile without an implementation. Until we revise our schema, though, this method should never be called, so we raise a RuntimeException in the off chance that it is called unexpectedly.
- It has a static DatabaseHelper singleton instance and a getInstance() method to lazy-initialize it.

As noted in [the chapter on databases](#), it is important to ensure that all threads are accessing the same SQLiteDatabase object, for thread safety. That usually means you hold onto a single SQLiteOpenHelper object. And, in our case, we might want to get at this database from more than one activity. Hence, we go with the singleton approach, so everyone works with the same DatabaseHelper instance.

Step #3: Creating a NoteFragment

Having a database is nice and all, but we need to work on the UI to allow users to enter notes. To do that, we will start with a NoteFragment.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `NoteFragment` as the name and click OK to create the empty class.

Next, replace the contents of that class with the following:

```
package com.commonware.empublite;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class NoteFragment extends Fragment {
    private static final String KEY_POSITION="position";
    private EditText editor=null;

    static NoteFragment newInstance(int position) {
        NoteFragment frag=new NoteFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_POSITION, position);
        frag.setArguments(args);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.editor, container, false);

        editor=(EditText)result.findViewById(R.id.editor);

        return(result);
    }
}
```

TUTORIAL #14 - SAVING NOTES

```
private int getPosition() {  
    return getArguments().getInt(KEY_POSITION, -1);  
}
```

You will have a couple of warnings, for things in this code that we are setting up (editor and position) that are not yet used, but we will take care of that in later steps of the tutorial.

Then, right-click over the `res/` directory and choose `New > "Layout resource file"` from the context menu. This brings up the New Layout Resource File dialog:

Figure 260: Android Studio New Layout Resource File Dialog

Fill in `editor` as the “Layout File Name”, leave the rest of the dialog alone, and click the “Finish” button.

In the Design tab of the graphical layout editor for `res/layout/editor.xml`, drag a “Multiline Text” widget from the palette into the preview area. In the properties pane, change the `android:layout_width` and `android:layout_height` each to be `match_parent`, change the ID to `editor`, and change the gravity (*not* the layout gravity) to be both top and left:

TUTORIAL #14 - SAVING NOTES

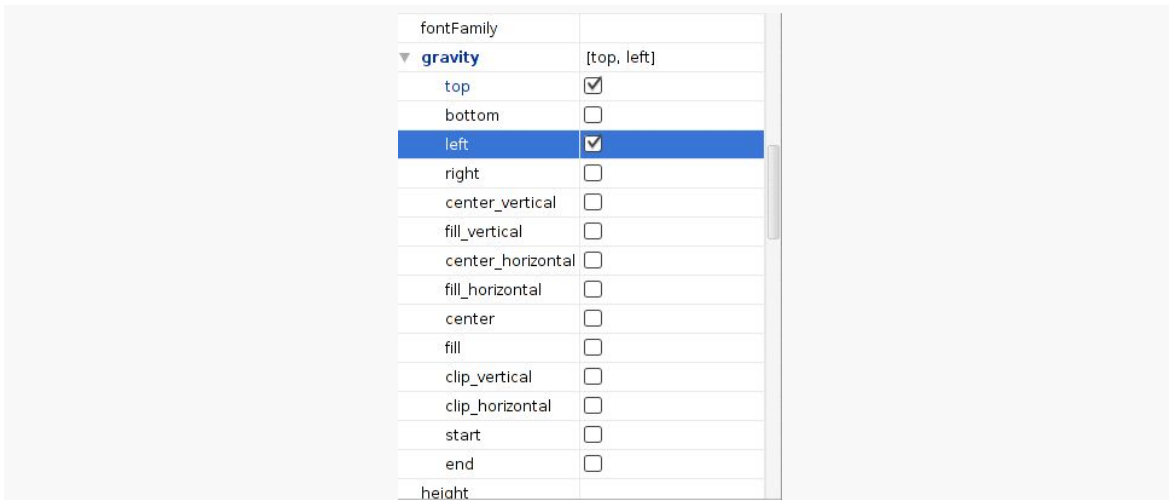

Figure 261: Android Studio Layout Editor Properties Pane, Showing Gravity Options

Next, in the properties pane, click on the “hint” entry, then click the “...” button to the right of it. This will open up a string resource picker dialog:

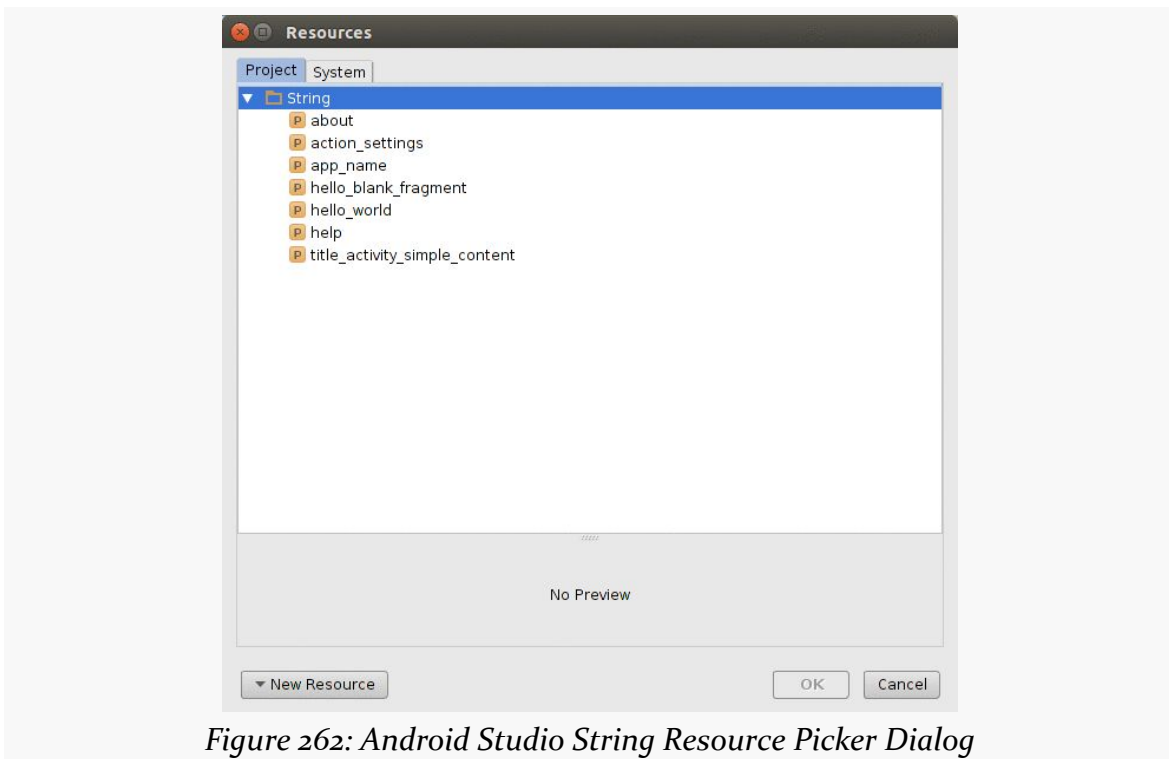

Figure 262: Android Studio String Resource Picker Dialog

TUTORIAL #14 - SAVING NOTES

Towards the bottom, click the “New Resource” drop-down and choose “New String Value...” from it, to bring up the string resource editor dialog:

Figure 263: Android Studio New String Resource Dialog

Fill in a resource name of `hint` and a value of `Enter notes here`. Leave the rest of the dialog alone, and click OK.

Step #4: Examining NoteFragment

Our `NoteFragment` is fairly straightforward and is reminiscent of the `SimpleContentFragment` we created in [Tutorial #11](#).

`NoteFragment` has a `newInstance()` static factory method. This method creates an instance of `NoteFragment`, takes a passed-in `int` (identifying the chapter for which we are creating a note), puts it in a `Bundle` identified as `KEY_POSITION`, hands the `Bundle` to the fragment as its arguments, and returns the newly-created `NoteFragment`.

In `onCreateView()`, we inflate the `R.layout.editor` resource that we defined and get our hands on our `EditText` widget for later use.

Step #5: Creating the NoteActivity

Having a fragment without displaying it is fairly pointless, so we need something to load a NoteFragment. Particularly for phones, the simplest answer is to create a NoteActivity for that, paralleling the relationship between SimpleContentFragment and SimpleContentActivity.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `NoteActivity` as the name and click `OK` to create the empty class.

In the `NoteActivity` class that is created, replace the current implementation with the following:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class NoteActivity extends Activity {
    public static final String EXTRA_POSITION="position";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            int position=getIntent().getIntExtra(EXTRA_POSITION, -1);

            if (position >= 0) {
                Fragment f=NoteFragment.newInstance(position);

                getFragmentManager().beginTransaction()
                    .add(android.R.id.content, f).commit();
            }
        }
    }
}
```

Then, open up `AndroidManifest.xml` and add the following `<activity>` element inside the `<application>` element:

```
<activity android:name="NoteActivity"></activity>
```

Step #6: Examining NoteActivity

As you can see, this is a fairly trivial activity. In `onCreate()`, if we are being created anew, we execute a `FragmentManager` to add a `NoteFragment` to our activity, pouring it into the full screen (`android.R.id.content`). Here, `android.R.id.content` identifies the container into which the results of `setContentView()` would go — it is a container supplied by Activity itself and serves as the top-most container for our content.

However, we expect that we will be passed an `Intent` extra with the position (`EXTRA_POSITION`), which we pass along to the `NoteFragment` factory method.

Step #7: Add Notes to the Action Bar

Of course, none of this is useful if we do not give the user a way to get to the `NoteActivity`. Specifically, we can add a notes entry to our `res/menu/options.xml` resource, to have a new toolbar button appear on our main activity's action bar.

Modify `res/menu/options.xml` to look like:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/notes"
        android:icon="@drawable/ic_action_edit"
        android:showAsAction="ifRoom|withText"
        android:title="@string/notes">
    </item>
    <item
        android:id="@+id/settings"
        android:icon="@drawable/ic_action_settings"
        android:showAsAction="never"
        android:title="@string/settings">
    </item>
    <item
        android:id="@+id/help"
        android:icon="@drawable/ic_action_help"
        android:title="@string/help">
    </item>
    <item
        android:id="@+id/about"
        android:icon="@drawable/ic_action_about"
        android:title="@string/about">
    </item>
</menu>
```

TUTORIAL #14 - SAVING NOTES

Either IDE can handle this via editing the XML. Eclipse users also can add this via the structured editor for `res/menu/options.xml`, following the instructions used for other action bar items.

Note that this menu definition requires a new string resource, named `notes`, with a value like `Notes`.

Then, in `EmPubLiteActivity`, add the following case to the switch statement in `onOptionsItemSelected()`:

```
case R.id.notes:
    i=new Intent(this, NoteActivity.class);
    i.putExtra(NoteActivity.EXTRA_POSITION, pager.getCurrentItem());
    startActivity(i);

return(true);
```

Note that depending on where you place this, you will need to remove one existing declaration of `Intent i` from one of the case blocks, whichever comes second.

Here, we get the currently-viewed position from the `ViewPager` and pass that as the `EXTRA_POSITION` extra to `NoteActivity`.

Step #8: Defining a NoteLoadedEvent

We will want to load notes from the database on a background thread. Hence, we can apply the same basic approach as we used with `ModelFragment`, posting an event on the greenrobot `EventBus` when the load is completed, to deliver the results to the `NoteFragment`. This step will create a `NoteLoadedEvent` to handle this case.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `NoteLoadedEvent` as the name and click `OK` to create the empty class.

Then, replace the contents of that class with the following:

```
package com.commonware.empublite;

class NoteLoadedEvent {
    int position;
    String prose;

    NoteLoadedEvent(int position, String prose) {
        this.position=position;
        this.prose=prose;
    }
}
```

```
int getPosition() {
    return(position);
}

String getProse() {
    return(prose);
}
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Step #9: Loading a Note from the Database

Next, we need to add code somewhere that will actually query the database (on a background thread) to load the note for a given ViewPager position. One common pattern is to put this sort of database-access logic on your SQLiteOpenHelper subclass, so all of your database-specific code resides in one place. That is the approach we will take here, adding a `loadNote()` method that will fork a thread, query the database, and post a `NoteLoadedEvent` as a result.

Edit your DatabaseHelper to add its own LoadThread inner class, reminiscent of the one from ModelFragment:

```
private class LoadThread extends Thread {
    private int position=-1;

    LoadThread(int position) {
        super();
        this.position=position;
    }

    @Override
    public void run() {
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);

        String[] args={String.valueOf(position)};
        Cursor c=
            getReadableDatabase().rawQuery("SELECT prose FROM notes WHERE position = ? ",
args);

        if (c.getCount() > 0) {
            c.moveToFirst();
            EventBus.getDefault().post(new NoteLoadedEvent(position,
                c.getString(0)));
        }

        c.close();
    }
}
```

TUTORIAL #14 - SAVING NOTES

Here, we use `rawQuery()` to retrieve the note based upon a supplied position. If there is no such note, our `Cursor` will have no rows, and we are done. If, however, we did get results back on the query, we then post a `NoteLoadedEvent` with the position and the prose (the text from the database).

You will need to add an import manually to `android.os.Process`, to be able to resolve the `setThreadPriority()` method and its parameter.

Also, add a `loadNote()` method to `DatabaseHelper` that forks this `LoadThread`:

```
void loadNote(int position) {
    new LoadThread(position).start();
}
```

Step #10: Loading the Note Into the Fragment

Now that we can query the database and get back a note (if any), we can tie that into the `NoteFragment` to load the note for the fragment's position when the fragment is opened. We will not only need to call `loadNote()` on the `DatabaseHelper`, but also be able to respond to the `NoteLoadedEvent` when it arrives.

Add the following `onResume()` method to `NoteFragment`:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (TextUtils.isEmpty(editor.getText())) {
        DatabaseHelper db=DatabaseHelper.getInstance(getActivity());
        db.loadNote(getPosition());
    }
}
```

Here, we register for the `EventBus`. Then, if we do not have any text in the `EditText` widget, we call `loadNote()` on our singleton instance of the `DatabaseHelper`, passing in the position that our fragment is managing. The reason for checking to see if the `EditText` is empty is to handle configuration changes. This fragment is not a retained fragment, and so it will be destroyed and re-created. The default `onSaveInstanceState()` logic of `EditText` will retain our note, though, so we do not want to re-load it from the database. This approach is not optimal, in that we will wind up calling `loadNote()` in cases where we could know that there is no note. That optimization is complex enough to not make it worthwhile for a set of book

TUTORIAL #14 - SAVING NOTES

tutorials, though it is something you might wish to explore in a commercial-grade application.

Next, add the corresponding `onPause()` to `NoteFragment`, to unregister from the `EventBus`:

```
@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

Finally, add an `onEventMainThread(NoteLoadedEvent)` method to `NoteFragment`, so we receive the `NoteLoadedEvent` on the main application thread:

```
@SuppressWarnings("unused")
public void onEventMainThread(NoteLoadedEvent event) {
    if (event.getPosition() == getPosition()) {
        editor.setText(event.getProse());
    }
}
```

Here, we confirm that the event is for our fragment's position, as it is conceivable that this event is for some other note, though that is rather unlikely given how the user would view notes. That being said, if the note is for our position, we populate the `EditText` with the note prose.

Step #11: Updating the Database

Of course, loading notes from a database is all fine and well... except that we do not have any notes *in* the database. We really should fix that.

Add an `UpdateThread` inner class to `DatabaseHelper`:

```
private class UpdateThread extends Thread {
    private int position=-1;
    private String prose=null;

    UpdateThread(int position, String prose) {
        super();
        this.position=position;
        this.prose=prose;
    }

    @Override
    public void run() {
        Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);
    }
}
```

TUTORIAL #14 - SAVING NOTES

```
String[] args={String.valueOf(position), prose};
getWritableDatabase().execSQL("INSERT OR REPLACE INTO notes (position, prose)
VALUES (?, ?)",
    args);
}
}
```

Here, we use `execSQL()` to execute an `INSERT OR REPLACE` SQL statement. As the name suggests, this will insert a new row if there is no match on our primary key (`position`). Otherwise, it will update the other columns if there is a match.

Note that we do not post an event here. We could, if there was something in the app that needed to know when a note was updated.

Also, add an `updateNote()` method to `DatabaseHelper` that forks this `UpdateThread`:

```
void updateNote(int position, String prose) {
    new UpdateThread(position, prose).start();
}
```

Step #12: Saving the Note

Somewhere, we need to call `updateNote()`. A classic “desktop” approach would be to have a “save” action bar item in the `NoteFragment`, which the user would need to click upon to save the note. However, this does not deal with the interrupt-driven nature of phones all that well. For example, the user might start typing in a note, then wind up taking a phone call. If our process is terminated, depending upon how the user tries getting back into our app, we might not have the note from our saved instance state.

A better approach, in many cases, is to save data in `onPause()` or `onStop()`, when the activity moves into the background. If there is a chance that the user might not want the partially-entered information, you could save it in a “side” area, such as a temporary file, and deal with it when the user returns to your app. Or, you could just update the real data store... which is what we will do here.

Edit the `onPause()` method in `NoteFragment` to look like the following:

```
@Override
public void onPause() {
    DatabaseHelper.getInstance(getActivity())
        .updateNote(getPosition(),
            editor.getText().toString());

    EventBus.getDefault().unregister(this);
}
```

TUTORIAL #14 - SAVING NOTES

```
super.onPause();  
}
```

Here, we update the note. This is a bit inefficient, as we update the database even if the user did not change the text of the note, or even if the note is empty. That represents another optimization that a production-grade app might wish to pursue but is skipped here in the interests of simplicity.

If you build and run the app on a device or emulator, you will see the new “notes” toolbar button in the action bar:

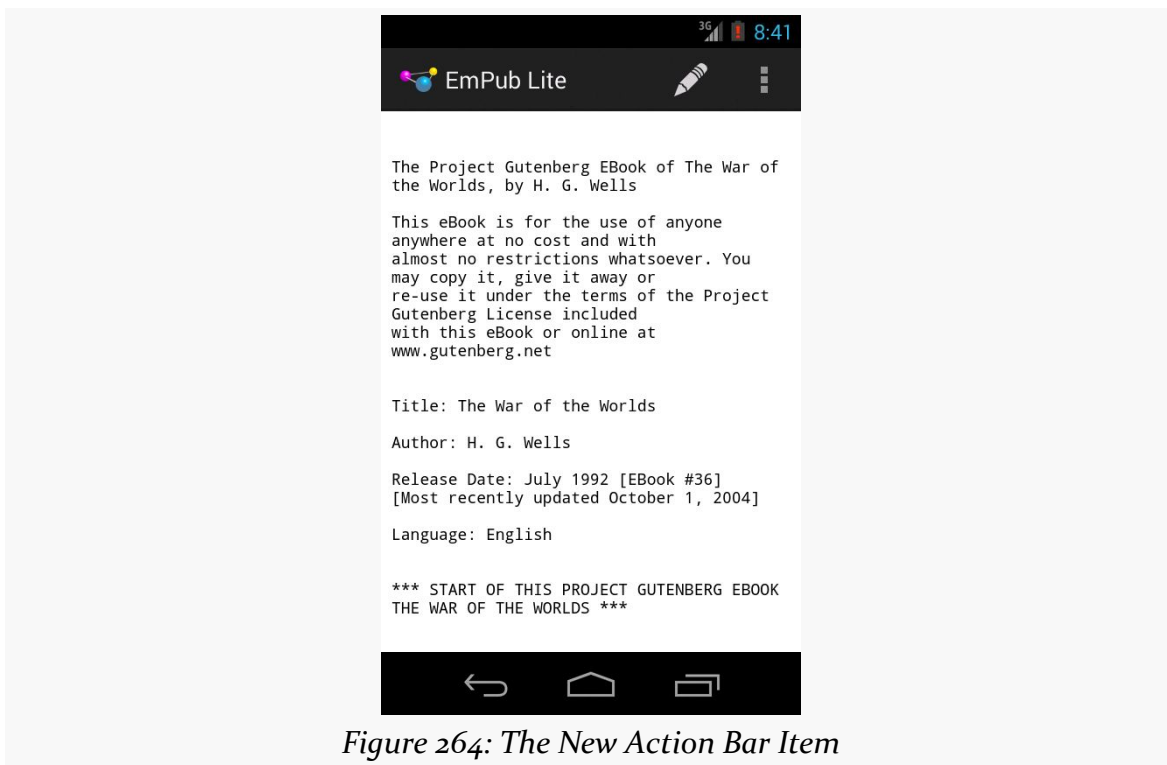

Figure 264: The New Action Bar Item

Tapping that will bring up the notes for whatever ViewPager position that you are on. Entering in some notes and pressing BACK to exit the activity will save those notes, which you will see again if you tap the action bar toolbar button again. If you change the notes, pressing BACK will save the changed notes in the database, to be viewed again later when you go back into the notes for that ViewPager position.

Step #13: Adding a Delete Action Bar Item

The only problem with this solution is that the notes never leave. While the user could manually delete everything in the `EditText`, it would be nice to make that perhaps a bit simpler. In this step, we will add an action bar item that will clear the `EditText` for the user.

Create a new resource, `res/menu/notes.xml`, to configure the action bar for the activity hosting our `NoteFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/delete"
    android:icon="@drawable/ic_action_discard"
    android:showAsAction="ifRoom|withText"
    android:title="@string/delete">
  </item>
</menu>
```

This simply defines a single action bar item, with an ID of `delete`.

To do this, Android Studio users can right-click over the `res/menu/` directory and choose `New > "Menu resource file"` from the context menu. Fill in `notes.xml` in the "New Menu Resource File" dialog and click OK. Paste in the XML shown above into that file.

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Note that you will also need to add a new string resource, named `delete`, with a value of `Delete`.

To let Android know that our `NoteFragment` wishes to participate in the action bar, we need to call `setHasOptionsMenu(true)` at some point. Add an `onCreate()` method to `NoteFragment` to handle this when the fragment is created:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setHasOptionsMenu(true);
}
```

TUTORIAL #14 - SAVING NOTES

That will trigger a call to `onOptionsItemSelected()`, which we will need to add to `NoteFragment`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.notes, menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

This just inflates our new resource for use in the options menu.

If the user taps on that toolbar button, `onOptionsItemSelected()` will be called, so we will need to add that as well to `NoteFragment`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.delete) {
        editor.setText(null);

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

Here, if the user tapped on our delete action bar item, we clear the `EditText` widget.

Step #14: Closing the NoteFragment When Deleted

However, tapping on that action bar item keeps the `NoteFragment` on the screen. It might be nice to automatically return to the book instead. However, the `NoteFragment` itself does not know how to do that, as something else (in this case, `NoteActivity`) put the `NoteFragment` on the screen. Hence, we need to pass the request to close the `NoteFragment` along to the proper party.

We could use another event object and our `EventBus`. In this case, we will demonstrate another approach: using the contract pattern to alert the hosting activity that the notes should be closed.

Define an *inner interface* in the `NoteFragment`, named `Contract`, as follows:

```
public interface Contract {
    void closeNotes();
}
```

TUTORIAL #14 - SAVING NOTES

You might put those lines immediately after the `public class NoteFragment...` line, before the declaration of any of the data members or methods, for example.

Then, add a private `getContract()` method, that casts the hosting Activity to the Contract interface:

```
private Contract getContract() {
    return((Contract) getActivity());
}
```

What we are doing here is enforcing that the activity that hosts our `NoteFragment` must implement the `NoteFragment.Contract` interface.

Then, add a call to `closeNotes()` on the Contract to our logic in `onOptionsItemSelected()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.delete) {
        editor.setText(null);
        getContract().closeNotes();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

Now, when the user clicks on the delete action bar item, we clear the `EditText` and ask the hosting activity to get rid of us. Along the way, our `onPause()` will be called, causing us to clear the content of the prose column in our database row as well.

At this point, `NoteFragment` should resemble:

```
package com.commonware.empublite;

import android.app.Fragment;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.LayoutInflater;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;
import de.greenrobot.event.EventBus;

public class NoteFragment extends Fragment {
    public interface Contract {
        void closeNotes();
    }
}
```

TUTORIAL #14 - SAVING NOTES

```
}

private static final String KEY_POSITION="position";
private EditText editor=null;

static NoteFragment newInstance(int position) {
    NoteFragment frag=new NoteFragment();
    Bundle args=new Bundle();

    args.putInt(KEY_POSITION, position);
    frag.setArguments(args);

    return(frag);
}

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setHasOptionsMenu(true);
}

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);

    return(result);
}

@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);

    if (TextUtils.isEmpty(editor.getText())) {
        DatabaseHelper db=DatabaseHelper.getInstance(getActivity());
        db.loadNote(getPosition());
    }
}

@Override
public void onPause() {
    DatabaseHelper.getInstance(getActivity())
        .updateNote(getPosition(),
            editor.getText().toString());

    EventBus.getDefault().unregister(this);

    super.onPause();
}

@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.notes, menu);
}
```

TUTORIAL #14 - SAVING NOTES

```
        super.onCreateOptionsMenu(menu, inflater);
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        if (item.getItemId() == R.id.delete) {
            editor.setText(null);
            getContract().closeNotes();

            return(true);
        }

        return(super.onOptionsItemSelected(item));
    }

    @SuppressWarnings("unused")
    public void onEventMainThread(NoteLoadedEvent event) {
        if (event.getPosition() == getPosition()) {
            editor.setText(event.getProse());
        }
    }

    private int getPosition() {
        return(getArguments().getInt(KEY_POSITION, -1));
    }

    private Contract getContract() {
        return((Contract) getActivity());
    }
}
```

NoteActivity now must implement NoteFragment.Contract and implement closeNotes(). Modify NoteActivity to look like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.Fragment;
import android.os.Bundle;

public class NoteActivity extends Activity implements NoteFragment.Contract {
    public static final String EXTRA_POSITION="position";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            int position=getIntent().getIntExtra(EXTRA_POSITION, -1);

            if (position >= 0) {
                Fragment f=NoteFragment.newInstance(position);

                getFragmentManager().beginTransaction()
                    .add(android.R.id.content, f).commit();
            }
        }
    }
}
```

TUTORIAL #14 - SAVING NOTES

```
@Override
public void closeNotes() {
    finish();
}
}
```

This adds the `implements` keyword and the `closeNotes()` implementation, which just finishes the `NoteActivity`, returning control to the `EmPubLiteActivity`.

If you run this in a device or emulator, and you go into the notes, you will see our delete toolbar button:

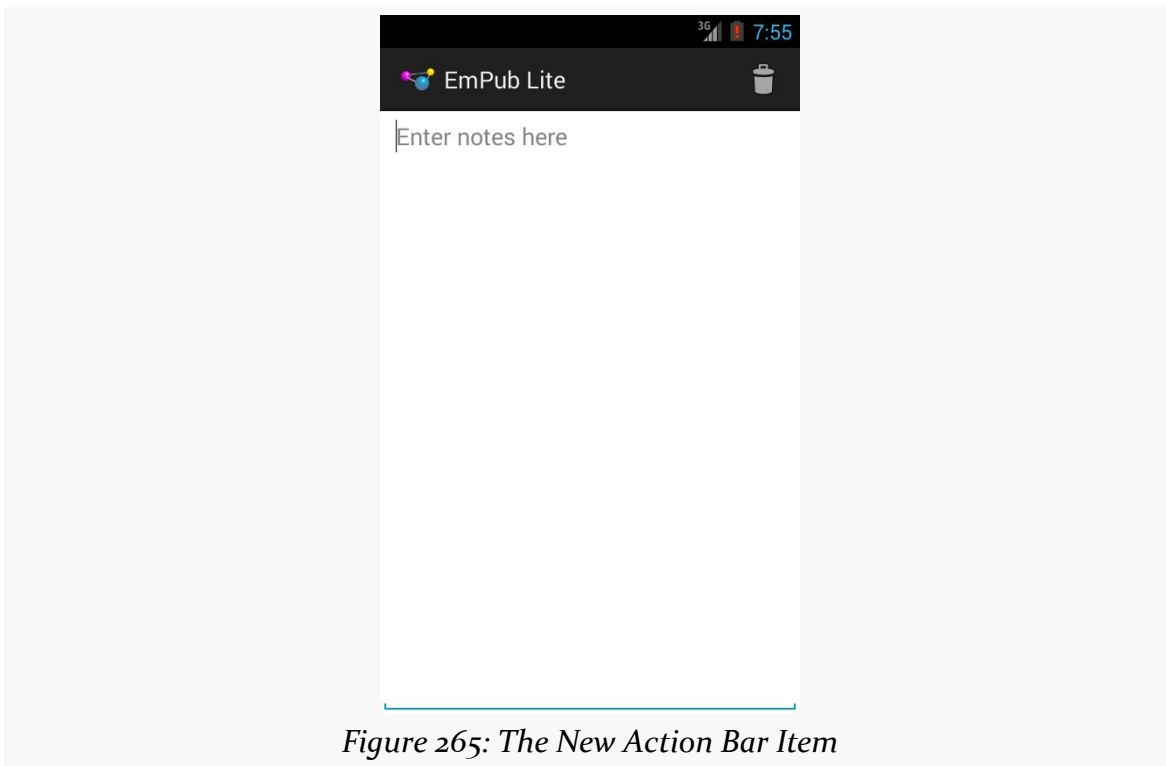

Figure 265: The New Action Bar Item

Tapping that toolbar button will clear the note and close the activity, returning you to the book.

In Our Next Episode...

... we will allow the user to [share a chapter's notes](#) with somebody else.

Internet Access

The expectation is that most, if not all, Android devices will have built-in Internet access. That could be WiFi, cellular data services (EDGE, 3G, etc.), or possibly something else entirely. Regardless, most people — or at least those with a data plan or WiFi access — will be able to get to the Internet from their Android phone.

Not surprisingly, the Android platform gives developers a wide range of ways to make use of this Internet access. Some offer high-level access, such as the integrated WebKit browser component (WebView) we saw in an [earlier chapter](#). If you want, you can drop all the way down to using raw sockets. Or, in between, you can leverage APIs — both on-device and from 3rd-party JARs — that give you access to specific protocols: HTTP, XMPP, SMTP, and so on.

The emphasis of this book is on the higher-level forms of access: the [WebKit component](#) and Internet-access APIs, as busy coders should be trying to reuse existing components versus rolling one's own on-the-wire protocol wherever possible.

DIY HTTP

In many cases, your only viable option for accessing some Web service or other HTTP-based resource is to do the request yourself. The Google-endorsed API for doing this nowadays in Android is to use the classic `java.net` classes for HTTP operation, centered around `URLConnection`. There is quite a bit of material on this already published, as these classes have been in Java for a long time. The focus here is in showing how this works in an Android context.

Note, however, that you may find it easier to use some HTTP client libraries that handle various aspects of the Internet access for you, as will be described [later in this chapter](#).

A Sample Usage of `URLConnection`

This chapter walks through several implementations of a Stack Overflow client application. The app has a single activity, with a single `ListFragment`. The app will load the latest block of Stack Overflow questions tagged with `android`, using the Stack Exchange public API. Those questions will be shown in the list, and tapping on a question will bring up the Web page for that question in the user's default Web browser.

All implementations of the app have the same core UI logic. What differs is in how each handles the Internet access. In this section, we will take a look at the [Internet/HURL](#) sample project, which uses `URLConnection` to retrieve the questions from the Stack Exchange Web service API.

Asking Permission

To do anything with the Internet (or a local network) from your app, you need to hold the `INTERNET` permission. This includes cases where you use things like `WebView` — if your *process* needs network access, you need the `INTERNET` permission.

Hence, the manifest for our sample project contains the requisite `<uses-permission>` declaration:

```
<uses-permission android:name="android.permission.INTERNET"/>
```

Creating Your Data Model

The Stack Exchange Web service API returns JSON in response to various queries. Hence, we need to create Java classes that mirror that JSON structure. In particular, many of the examples will be using Google's `Gson` to populate those data models automatically based upon its parsing of the JSON that we receive from the Web service.

In our case, we are going to use a specific endpoint of the Stack Exchange API, referred to as `/questions` after the distinguishing portion of the path. The documentation for this endpoint can be found in [the Stack Exchange API documentation](#).

We will examine the URL for the endpoint a bit later in this section.

The results we get for issuing a GET request for the URL is a JSON structure (here showing a single question, to keep the listing short):

```
{
  "items": [
    {
      "question_id": 17196927,
      "creation_date": 1371660594,
      "last_activity_date": 1371660594,
      "score": 0,
      "answer_count": 0,
      "title": "ksoap2 failing when in 3G",
      "tags": [
        "android",
        "ksoap2",
        "3g"
      ],
      "view_count": 2,
      "owner": {
        "user_id": 773259,
        "display_name": "Spark",
        "reputation": 513,
        "user_type": "registered",
        "profile_image": "http://www.gravatar.com/avatar/511b37f7c313984e624dd76e8cb9faa6?d=identicon&r=PG",
        "link": "http://stackoverflow.com/users/773259/spark"
      },
      "link": "http://stackoverflow.com/questions/17196927/ksoap2-failing-when-in-3g",
      "is_answered": false
    }
  ],
  "quota_remaining": 9991,
  "quota_max": 10000,
  "has_more": true
}
```

NOTE: Some of the longer URLs will word-wrap in the book, but they are on a single line in the actual JSON. Honest.

We get back a JSON object, where our questions are found under the name of `items`. `items` is a JSON array of JSON objects, where each JSON object represents a single question, with fields like `title` and `link`. The question JSON object has an embedded `owner` JSON object with additional information.

We do not necessarily need all of this information. In fact, for this first version of the sample, all we really need are the `title` and `link` of each entry in the `items` array.

The key is that, by default, the data members in our Java data model must *exactly* match the JSON keys for the JSON objects.

So, we have an `Item` class, representing the information from an individual entry in the `items` array:

```
package com.commonware.android.hurl;

public class Item {
    String title;
    String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

However, our Web service does not return the `items` array directly. `items` is the key in a JSON object that is the actual JSON returned by Stack Exchange. So, we need another Java class that contains the data members we need from that outer JSON object, here named `SOQuestions` (for lack of a better idea for a name...):

```
package com.commonware.android.hurl;

import java.util.List;

public class SOQuestions {
    List<Item> items;
}
```

Having an `items` data member that is a `List` of `Item` tells GSON that we are expecting the JSON object to be used for `SOQuestions` to have a JSON array, named `items`, where each element in that array should get mapped to `Item` objects.

A Thread for Loading

We need to do the network I/O on a background thread, so we do not tie up the main application thread. To that end, the sample app has a `LoadThread` that loads our questions:

```
package com.commonware.android.hurl;

import android.util.Log;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.net.HttpURLConnection;
import java.net.URL;
import com.google.gson.Gson;
import de.greenrobot.event.EventBus;

class LoadThread extends Thread {
```

INTERNET ACCESS

```
static final String SO_URL=
    "https://api.stackexchange.com/2.1/questions?"
    + "order=desc&sort=creation&site=stackoverflow&tagged=android";

@Override
public void run() {
    try {
        HttpURLConnection c=
            (HttpURLConnection)new URL(SO_URL).openConnection();

        try {
            InputStream in=c.getInputStream();
            BufferedReader reader=
                new BufferedReader(new InputStreamReader(in));
            SOQuestions questions=
                new Gson().fromJson(reader, SOQuestions.class);

            reader.close();

            EventBus.getDefault().post(new QuestionsLoadedEvent(questions));
        }
        catch (IOException e) {
            Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
        }
        finally {
            c.disconnect();
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }
}
}
```

LoadThread:

- Creates an `HttpURLConnection` by creating a URL for our Stack Exchange API endpoint and opening a connection
- Creates a `BufferedReader` wrapped around the `InputStream` from the HTTP connection
- Parses the JSON we get back from that HTTP request via a `Gson` instance, loading the data into an instance of our `SOQuestions`
- Close the `BufferedReader` (and the `InputStream` by extension)
- Post a `QuestionsLoadedEvent` to greenrobot's `EventBus`, to let somebody know that our questions exist
- Log messages to `LogCat` in case of errors

`QuestionsLoadedEvent` is a simple wrapper around an `SOQuestions` instance, serving as an event class for use with `EventBus`:

```
package com.commonware.android.hurl;
```

```
public class QuestionsLoadedEvent {
    final SOQuestions questions;

    QuestionsLoadedEvent(SOQuestions questions) {
        this.questions=questions;
    }
}
```

A Fragment for Questions

The sample app has a QuestionsFragment that should display these loaded questions:

```
package com.commonware.android.hurl;

import android.app.ListFragment;
import android.os.Bundle;
import android.text.Html;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.AdapterView.OnItemLongClickListener;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.AdapterView.OnItemLongClickListener;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.AdapterView.OnItemLongClickListener;
import java.util.List;
import de.greenrobot.event.EventBus;

public class QuestionsFragment extends ListFragment {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setRetainInstance(true);
        new LoadThread().start();
    }

    @Override
    public void onResume() {
        super.onResume();
        EventBus.getDefault().register(this);
    }

    @Override
    public void onPause() {
        EventBus.getDefault().unregister(this);
        super.onPause();
    }

    @Override
    public void onItemClick(AdapterView l, View v, int position, long id) {
        Item item=((ItemsAdapter)getListAdapter()).getItem(position);

        EventBus.getDefault().post(new QuestionClickedEvent(item));
    }

    public void onEventMainThread(QuestionsLoadedEvent event) {
        setListAdapter(new ItemsAdapter(event.questions.items));
    }
}
```

```
class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
        super(getActivity(), android.R.layout.simple_list_item_1, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        TextView title=(TextView)row.findViewById(android.R.id.text1);

        title.setText(Html.fromHtml(getItem(position).title));

        return(row);
    }
}
```

In `onCreate()`, we mark that this fragment should be retained and fork the `LoadThread`. Hence, once we have our questions, our retained fragment will hold onto that model data for us, and we avoid duplicating the `LoadThread` if a configuration change occurs sometime after our fragment was initially created.

In `onResume()` and `onPause()`, we register and unregister from the `EventBus`. Our `onEventMainThread()` method will be called when the `QuestionsLoadedEvent` is raised by `LoadThread`, and there we hold onto the loaded questions and populate the `ListView`. We use an `ItemsAdapter`, which knows how to render an `Item` as a simple `ListView` row showing the question title. The `ItemsAdapter` uses `Html.fromHtml()` to populate the `ListView` rows, not because Stack Overflow hands back titles with HTML tags, but because Stack Overflow hands back titles with HTML *entity references*, and `Html.fromHtml()` should handle many of those.

And, in `onListItemClick()`, we find the `Item` associated with the row that the user clicked upon, then raise a `QuestionClickedEvent` to let somebody know that the user clicked on that row. The `QuestionClickedEvent` class is a simple wrapper around an `Item` to serve as an event class for use with `EventBus`:

```
package com.commonware.android.hurl;

public class QuestionClickedEvent {
    final Item item;

    QuestionClickedEvent(Item item) {
        this.item=item;
    }
}
```

An Activity for Orchestration

MainActivity sets up the fragment in onCreate(), registers and unregisters for the event bus in onResume() and onPause(), and handles the click events in onEventMainThread():

```
package com.commonware.android.hurl;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import de.greenrobot.event.EventBus;

public class MainActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new QuestionsFragment()).commit();
        }
    }

    @Override
    public void onResume() {
        super.onResume();
        EventBus.getDefault().register(this);
    }

    @Override
    public void onPause() {
        EventBus.getDefault().unregister(this);
        super.onPause();
    }

    public void onEventMainThread(QuestionClickedEvent event) {
        startActivity(new Intent(Intent.ACTION_VIEW,
            Uri.parse(event.item.link)));
    }
}
```

Hence, MainActivity is serving in an orchestration role. QuestionsFragment is a local controller, handling direct events raised by its widgets (a ListView). MainActivity is responsible for handling events that transcend an individual fragment — in this case, it starts a browser to view the clicked-upon question.

The result is a simple ListView showing questions:

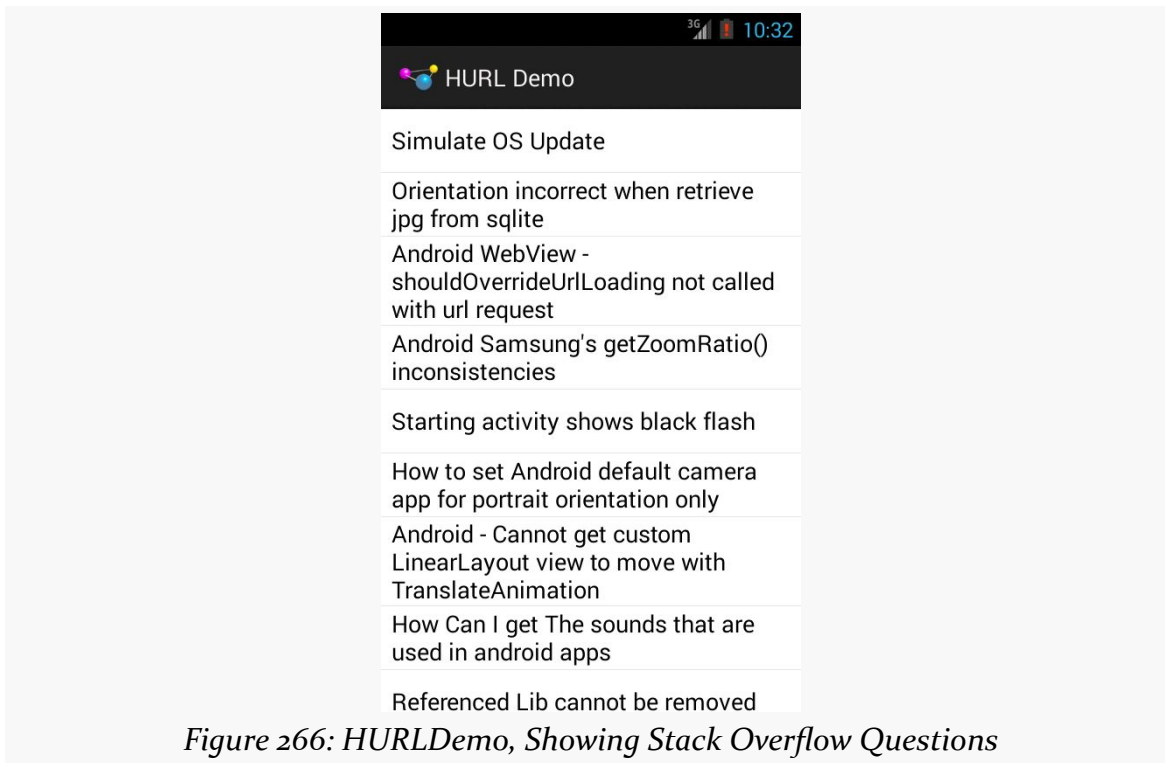

Figure 266: HURLDemo, Showing Stack Overflow Questions

What Android Brings to the Table

Google has augmented `URLConnection` to do more stuff to help developers. Notably:

- It automatically uses GZip compression on requests, adding the appropriate HTTP header and automatically decompressing any compressed responses (added in Android 2.3)
- It uses [Server Name Indication](#) to help work with several HTTPS hosts sharing a single IP address
- API Level 13 (Android 4.0) added an `HttpURLConnection` implementation of the `java.net.ResponseCache` base class, that can be installed to offer transparent caching of your HTTP requests.

Also, courtesy of some third-party code (`OkHttp`) that we will discuss shortly, `URLConnection` also supports [the SPDY protocol](#) for accelerating Web content distribution over SSL as of Android 4.4.

Testing with StrictMode

StrictMode, mentioned in [the chapter on files](#), can also report on performing network I/O on the main application thread. More importantly, on Android 3.0 and higher, by default, Android will crash your app with a `NetworkOnMainThreadException` if you try to perform network I/O on the main application thread.

Hence, it is generally a good idea to test your app, either using StrictMode yourself or using a suitable emulator, to make sure that you are not performing network I/O on the main application thread.

What About HttpClient?

Android also contains — or used to contain — a mostly-complete copy of version 4.0.2beta of the [Apache HttpClient library](#). Many developers use this, as they prefer the richer API offered by this library over the somewhat more clunky approach used by `java.net`. And, truth be told, this was the more stable option prior to Android 2.3.

There are a few reasons why this is no longer recommended, for Android 2.3 and beyond:

- The core Android team is better able to add capabilities to the `java.net` implementation while maintaining backwards compatibility, because its API is more narrow.
- The problems previously experienced on Android with the `java.net` implementation have largely been fixed.
- The Apache HttpClient project continuously evolves its API. This means that Android will continue to fall further and further behind the latest-and-greatest from Apache, as Android insists on maintaining the best possible backwards compatibility and therefore cannot take on newer-but-different HttpClient versions.
- Google officially deprecated this API in Android 5.1.
- Google officially removed this API in Android 6.0.

If you have legacy code that uses the HttpClient API, please consider using Apache's standalone edition of [HttpClient for Android](#).

And, if you cannot do any of that, and you are using Gradle for Android for your builds (e.g., you are using Android Studio's default settings), you can add

useLibrary 'org.apache.http.legacy' to the android closure to give you access to Android's stock HttpClient API:

```
android {  
    useLibrary 'org.apache.http.legacy'  
    // other settings go here  
}
```

HTTP via DownloadManager

If your objective is to download some large file, you may be better served by using the DownloadManager added to Android 2.3, as it handles a lot of low-level complexities for you. For example, if you start a download on WiFi, and the user leaves the building and the device fails over to some form of mobile data, you need to reconnect to the server and either start the download again or use some content negotiation to pick up from where you left off. DownloadManager handles that.

However, DownloadManager is dependent upon some broadcast Intent objects, a technique we have not discussed yet, so we will delay covering DownloadManager until [later in the book](#).

Using Third-Party JARs

To some extent, the best answer is to not write the code yourself, but rather use some existing JAR that handles both the Internet I/O and any required data parsing. This is commonplace when accessing public Web services — either because the firm behind the Web service has released a JAR, or because somebody in the community has released a JAR for that Web service.

Examples include:

- Using [JTwitter](#) to access Twitter's API
- Using [Amazon's JAR](#) to access various AWS APIs, including S3, SimpleDB, and SQS
- Using the [Dropbox SDK](#) for accessing DropBox folders and files

However, beyond the [classic potential JAR problems](#), you may encounter another when it comes to using JARs for accessing Internet services: versioning. For example:

- JTwitter bundles the `org.json` classes in its JAR, which will be superseded by Android's own copy, and if the JTwitter version of the classes have a different API, JTwitter could crash.
- Libraries dependent upon `HttpClient` might be dependent upon a version with a different API (e.g., 4.1.1) than is in Android (4.0.2 beta).

Try to find JARs that have been tested on Android and are clearly supported as such by their author. Lacking that, try to find JARs that are open source, so you can tweak their implementation if needed to add Android support.

[Later in this chapter](#), we will review another class of third-party JARs, ones that are more general-purpose than things like JTwitter, but still offer to simplify HTTP processing.

SSL

Of course, if you are thinking about HTTP, you really should be thinking about HTTPS — SSL-encrypted HTTP operations.

Normally, SSL “just works”, by using an `https://` URL. Hence, typically, there is little that you need to do to enable simple encryption.

However, there are other aspects of SSL to consider, including:

- What if the server is not using an SSL certificate that Android will honor, such as a self-signed certificate?
- What about man-in-the-middle attacks, hacked certificate authorities, and the like?

The trails contain [a chapter dedicated to SSL](#) that you are encouraged to read, so that this chapter does not get crazy-long.

Using HTTP Client Libraries

Often times, writing Internet access code is a pain in various body parts.

Not surprisingly, there are a variety of third-party libraries designed to assist with this. Some are designed to provide access to a specific API, such as the ones mentioned earlier in this chapter. However, others are more general-purpose, designed to make writing HTTP operations a bit easier, by handling things like:

- Retries (e.g., device failed over from WiFi to mobile data mid-transaction)
- Threading (e.g., handling doing the Internet work on a background thread for you)
- Data parsing and marshaling, for well-known formats (e.g., JSON)

In this section, we will look at three libraries that exemplify this approach: OkHttp, Retrofit, and Picasso. Later, we will see other libraries that you might wish to investigate, including Google’s own Volley HTTP client API.

OkHttp

[OkHttp](#) uses a modified clone of the standard `URLConnection` to offer many performance improvements. Most notable is its support for [SPDY](#), a Google sponsored enhanced version of HTTP, going beyond classic HTTP “keep-alive” support to allow for many requests and responses to be delivered over the same socket connection. Many Google APIs are served by SPDY-capable servers, and SPDY support is available for others to use as well.

Beyond that, OkHttp wraps up common HTTP performance-improvement patterns, such as GZIP compression, response caching, and connection pooling. It also is more aware of “real world” connection issues, like mis-configured proxy servers and the like.

Note that a version of OkHttp lies behind the standard implementation of `URLConnection` in Android 4.4 and higher — this is where Android’s SPDY support comes from.

The [Internet/OkHttp](#) sample project is a clone of the Stack Overflow sample shown earlier in this chapter. The original sample used `URLConnection` to download the Stack Exchange Web service data. This revised sample replaces that with OkHttp.

First, we need to add a dependency on OkHttp to our app/ module’s `build.gradle` file:

```
dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.google.code.gson:gson:2.3'
    compile 'com.squareup.okhttp:okhttp:2.4.0'
}
```

INTERNET ACCESS

OkHttp offers two basic flavors of HTTP API: synchronous and asynchronous. With a synchronous call, the call blocks until the HTTP I/O is completed (or, at least, the headers are downloaded). With an asynchronous call, that initial pulse of network I/O is handled on a background thread. The general rule of thumb is:

- If you can work with the raw HTTP response, and it's short, use the asynchronous API, as it saves you having to fuss with your own thread
- If the response may be long or requires significant post-retrieval work (e.g., parsing), use your own background thread and use the synchronous API

In our case, we need to parse the JSON using Gson, and so the second approach is the better answer. This has the side benefit of limiting our Java changes to only be in `LoadThread`:

```
package com.commonware.android.okhttp;

import android.util.Log;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.io.Reader;
import java.net.HttpURLConnection;
import java.net.URL;
import com.google.gson.Gson;
import com.squareup.okhttp.OkHttpClient;
import com.squareup.okhttp.Request;
import com.squareup.okhttp.Response;
import de.greenrobot.event.EventBus;

class LoadThread extends Thread {
    static final String SO_URL=
        "https://api.stackexchange.com/2.1/questions?"
        + "order=desc&sort=creation&site=stackoverflow&tagged=android";

    @Override
    public void run() {
        try {
            OkHttpClient client=new OkHttpClient();
            Request request=new Request.Builder().url(SO_URL).build();
            Response response=client.newCall(request).execute();

            if (response.isSuccessful()) {
                Reader in=response.body().charStream();
                BufferedReader reader=new BufferedReader(in);
                SOQuestions questions=
                    new Gson().fromJson(reader, SOQuestions.class);

                reader.close();

                EventBus.getDefault().post(new QuestionsLoadedEvent(questions));
            }
            else {
                Log.e(getClass().getSimpleName(), response.toString());
            }
        }
    }
}
```

```
    }  
  }  
  catch (Exception e) {  
    Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);  
  }  
}
```

Our revised `run()` method creates an instance of `OkHttpClient`. This is your gateway for performing HTTP requests.

An individual request, not surprisingly, is represented by a `Request` object, usually created using a `Request.Builder`. The `url()` method on the `Builder` is where you supply the URL to be retrieved via a GET request. There are other methods on `Builder`, such as `post()`, which supplies additional data for the request and converts it into a POST request. The [OkHttp recipes page](#) outlines a number of common scenarios.

To actually perform the synchronous request, call `newCall().execute()` on the `OkHttpClient`, passing in the `Request` to the `newCall()` method. This gives you a `Response` object, which should return `true` from `isSuccessful()`. `false` would indicate some sort of a problem, such as an HTTP 404 response code.

Given a successful `Response`, you can get at the body of the response via a `body()` method. This returns a `ResponseBody`, which offers three main ways to get at the response body itself:

- `string()` returns the entire response as a `String`, which is only really suitable for short text responses
- `byteStream()` returns an `InputStream` on the raw bytes of the response
- `charStream()`, despite its name, returns a `Reader` on the characters of the response, taking into account the response's character encoding (e.g., UTF-8)

Here, we use `charStream()` to get a `Reader`, which we then wrap in a `BufferedReader`. The rest of the `run()` method is pretty much the same as the original, asking `Gson` to parse the response and posting a `QuestionsLoadedEvent` to get the questions over to our fragment on the main application thread.

Retrofit

Many times, when working with HTTP requests, our needs are fairly simple: just retrieve some JSON (or other structured data, such as XML) from some Web service, or perhaps upload some JSON to that Web service.

[Retrofit](#) is designed to simplify this, by handling the data parsing and marshaling for us, along with the HTTP operations and (optionally) background threading. We are left with a fairly natural-looking Java API to send/receive Java objects to/from the Web service. Retrofit accomplishes this through the cunning use of annotations, reflection, and, where available, OkHttp itself.

To demonstrate Retrofit, let's review the [HTTP/Retrofit](#) sample project. This project is a clone of the preceding one, this time using Retrofit for retrieving and parsing our Stack Overflow questions.

Note that Stack Overflow happens to use JSON as its data format, which works nicely with Retrofit, as JSON is its default data format. However, you can supply your own conversion logic, to convert data to/from other formats, such as XML or [Protocol Buffers](#).

Downloading and Installing Retrofit

Retrofit is available as a small JAR from the aforementioned [Retrofit Web site](#). By default, it uses [Google's Gson](#) for its JSON parsing, so you will need to download that JAR as well. If you also have OkHttp in your project, Retrofit will automatically use it, falling back to standard Android HTTP APIs if OkHttp is unavailable.

The combination of these JARs totals around 600KB, mostly coming from Gson and OkHttp. For most apps, this will not be a major issue, but if APK size is important to you, you need to keep in mind the footprint that these JARs consume.

Creating Your Service Interface

The first thing we need is to tell Retrofit more about where our JSON is coming from. To do this, we need to create a Java interface with some specific Retrofit-supplied annotations, documenting:

- the HTTP operations that we wish to perform
- the path (and, if needed, query parameters) to apply an HTTP operation to
- the per-request data to configure the HTTP operation, such as the dynamic portions of the path for a REST-style API, or additional query parameters to attach to the URL
- what object should be used for pouring the HTTP response into

For example, let's take a look at `StackOverflowInterface`, our interface for making a query of Stack Exchange's API to get questions from Stack Overflow:

```
package com.commonware.android.retrofit;

import retrofit.Callback;
import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    void questions(@Query("tagged") String tags, Callback<SQQuestions> cb);
}
```

Each method in the interface should have an annotation identifying the HTTP operation to perform, such as `@GET` or `@POST`. The parameter to the annotation is the path for the request and any fixed query parameters. In our case, we are using the path documented by Stack Exchange for retrieving questions (`/2.1/questions`), plus some fixed query parameters:

- `order` for whether the results should be ascending (`asc`) or descending (`desc`)
- `sort` to indicate how the questions should be sorted, such as `creation` to sort by time when the question was posted
- `site` to indicate what Stack Exchange site we are querying (e.g., `stackoverflow`)

The method name can be whatever you want.

If you have additional query parameters that vary dynamically, you can use the `@Query` annotation on `String` parameters to have them be added to the end of the URL. In our case, the `tagged` query parameter will be added with whatever the `tags` parameter is to our `questions()` method.

Similarly, you can use `{name}` placeholders for path segments, and replace those at runtime via `@Path`-annotated parameters to the method.

To get results back, and indicate the data type for those results, you have two choices:

1. Have the method return the data type you wish, in which case when we eventually call this method, the HTTP operation will be performed synchronously, blocking our method call

2. Pass a `Callback` parameter, declared with the desired data type (e.g., `SOQuestions`), in which case when we eventually call this method, the HTTP operation will be performed on a background thread, with the results delivered to us asynchronously via a custom `Callback` implementation that we will supply

In this case, we are electing to let Retrofit handle the threading for us, so we supply a `Callback` and have the method return `void`.

Curiously, we will never create an implementation of the `StackOverflowInterface` ourselves. Instead, Retrofit generates one for us, with code that implements our requested behaviors.

Creating the `RestAdapter`

To use this generated `StackOverflowInterface`, and to actually perform these operations, we need to create an instance of a `RestAdapter`. Usually, you will do this via a `RestAdapter.Builder`, to configure what you want done.

The biggest thing you will provide to `RestAdapter.Builder` is the server tied to these HTTP operations. Calling `setEndpoint()` allows you to specify the scheme, host, and port to be attached to the rest of the URL, coming from your interface. For example, we need to make our requests of the `https://api.stackexchange.com` server, so we have:

```
RestAdapter restAdapter=  
    new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")  
        .build();
```

Other methods on `RestAdapter.Builder` include:

- `setConverter()`, if your payloads are not in JSON format, but something else
- `setExecutors()`, to provide `Executor` objects (e.g., instances of `ThreadPoolExecutor`) to be used for requests and callbacks
- `setLog()` and `setDebug()` for controlling log output

When you are done configuring the `RestAdapter.Builder`, call `build()` to get the resulting `RestAdapter`.

Making Requests

Given a configured `RestAdapter`, you can retrieve an implementation of your API interface by calling the `create()` method:

```
StackOverflowInterface so=  
    restAdapter.create(StackOverflowInterface.class);
```

You can then use the resulting interface-typed object no differently than you would any other Java object, despite the fact that you never wrote an implementation of that interface yourself.

In our case, we can call the `questions()` method, supplying the tag (or tags) from which we wish to receive recent questions:

```
so.questions("android", this);
```

The second parameter to `questions()` is an implementation of `Callback`, to receive asynchronous results from our HTTP GET request. `Callback` requires two methods, `success()` and `failure()`. `success()` takes two parameters: the data type you indicated in the interface (e.g., `SOQuestions`) representing the parsed results of the HTTP request, and a `Response` object containing other information from the HTTP response, such as headers:

```
@Override  
public void success(SOQuestions questions, Response response) {  
    setListAdapter(new ItemsAdapter(questions.items));  
}
```

Here, we update our `ListView` with an `ItemsAdapter` based upon the received questions.

`failure()` takes a single parameter, an instance of `RetrofitError`, which is an `Exception` providing details of something that went wrong in the HTTP request (e.g., authorization was denied). You can handle that no differently than you might other exceptions from elsewhere in your app, to let the user know that something went wrong. In this case, we take the crude-but-easy approach of showing a `Toast` and logging the details to `LogCat`:

```
@Override  
public void failure(RetrofitError exception) {  
    Toast.makeText(getActivity(), exception.getMessage(),  
        Toast.LENGTH_LONG).show();  
    Log.e(getClass().getSimpleName(),
```

```
        "Exception from Retrofit request to StackOverflow", exception);  
    }
```

Picasso

Sometimes, what you want to download is not JSON, or XML, or any sort of structured data.

Sometimes, it is an image.

For example, Stack Overflow users have avatars. In our sample app, it might be nice to display the avatar of the user who asked the question.

[Picasso](#) is a library from Square that is designed to help with asynchronously loading images, whether those images come from HTTP requests, local files, a ContentProvider, etc. In addition to doing the loading asynchronously, Picasso simplifies many operations on those images, such as:

- Caching the results in memory (or optionally on disk for HTTP requests)
- Displaying placeholder images while the real images are being loaded, and displaying error images if there was a problem in loading the image (e.g., invalid URL)
- Transforming the image, such as resizing or cropping it to fit a certain amount of space
- Loading the images directly into an `ImageView` of your choice, even handling cases where that `ImageView` is recycled (e.g., part of a row in a `ListView`, where the user scrolled while an image for that `ImageView` was still loading, and now *another* image is destined for that same `ImageView` when the row was recycled)

The [HTTP/Picasso](#) sample application extends the Retrofit one to download the avatar image of the person asking the question, displaying it in the `ListView` along with the question title.

Downloading and Installing Picasso

Picasso can be downloaded as a small JAR from [the aforementioned Web site](#). Android Studio users can just add a dependency for `com.squareup.picasso:picasso:...` for some version denoted by `...`, and it will pull down all other dependencies needed by Picasso.

Updating the Model

Our original data model did not include information about the owner. Hence, we need to augment our data model, so Retrofit pulls that information out of the Stack Exchange JSON and makes it available to us.

To that end, we now have an `Owner` class, holding onto the one piece of information we need about the owner: the URL to the avatar (a.k.a., “profile image”):

```
package com.commonware.android.picasso;

import com.google.gson.annotations.SerializedName;

public class Owner {
    @SerializedName("profile_image") String profileImage;
}
```

The JSON key for this in the Stack Exchange API is `profile_image`, and underscores are not the conventional way of separating words in a Java data member. Java samples usually use “camelCase” instead. The default behavior of Retrofit would require us to name our data member `profile_image` to match the JSON.

However, under the covers, Retrofit is using Google’s Gson to do the mapping from JSON to objects. Gson supports a `@SerializedName` annotation, to indicate the JSON key to use for this data member. This allows us to give the data member the more natural name of `profileImage`, by using `@SerializedName("profile_image")` to teach Gson how to populate it properly.

(The author would like to thank Alec Holmes for his assistance with the Gson support)

Our `Item` class now has an `Owner`, named `owner`, since the owner data is in the owner key of an item’s JSON object:

```
package com.commonware.android.picasso;

public class Item {
    String title;
    Owner owner;
    String link;

    @Override
    public String toString() {
        return(title);
    }
}
```

Those two changes are sufficient for Retrofit to give us our URL to be able to download the image.

Requesting the Images

Using Picasso is extremely simple, as it offers a fluent interface that allows us to set up a request in a single Java statement.

The statement begins with a call to the static `with()` method on the `Picasso` class, where we supply a `Context` (such as our activity) for Picasso to use. The statement *ends* with a call to `into()`, indicating the `ImageView` into which Picasso should load an image. In between those calls, we can chain other calls, as `with()` and most other methods on a `Picasso` object return the `Picasso` object itself.

So, we can do something like:

```
Picasso.with(getActivity()).load(item.owner.profileImage)
    .fit().centerCrop()
    .placeholder(R.drawable.owner_placeholder)
    .error(R.drawable.owner_error).into(icon);
```

Here, we:

- Indicate that we want to `load()` an image found at a certain URL, identified by the `profileImage` data member of the `Owner` inside an `Item` referred to as `item`
- Say that we want to `fit()` the image to our target `ImageView`
- Specify that the image should be resized using `centerCrop()` rules, to center the image within the desired size (if it is smaller on one or both axes) and to crop the image (if it is larger on one or both axes)
- Indicate that we want to put a certain drawable resource as the `placeholder()` image to show in the `ImageView` while the loading is going on in the background
- State that we want to show a certain drawable resource in the `ImageView` in case of an `error()` when the image was being loaded

And that's it. Picasso will go off, download the image, and pour it into the `ImageView` when it is ready (and resized).

The Rest of the Story

That bit of Picasso code is in a new `getView()` method on our `ItemsAdapter`:

INTERNET ACCESS

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    View row=super.getView(position, convertView, parent);
    Item item=getItem(position);
    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    Picasso.with(getActivity()).load(item.owner.profileImage)
        .fit().centerCrop()
        .placeholder(R.drawable.owner_placeholder)
        .error(R.drawable.owner_error).into(icon);

    TextView title=(TextView)row.findViewById(R.id.title);
    title.setText(Html.fromHtml(getItem(position).title));

    return(row);
}
```

We have created our own row layout (res/layout/row.xml), consisting of an ImageView and a TextView. We have ArrayAdapter inflate or recycle our row, retrieve the Item for this row, retrieve the ImageView out of the row, use Picasso to start loading the real image, fill in the HTML-entity-aware text into the TextView, and then return our updated row. By the time we return the row, Picasso will have already loaded the placeholder image, which is what the user will initially see, while we download the real image.

The result is that we now have icons next to each of our question titles:

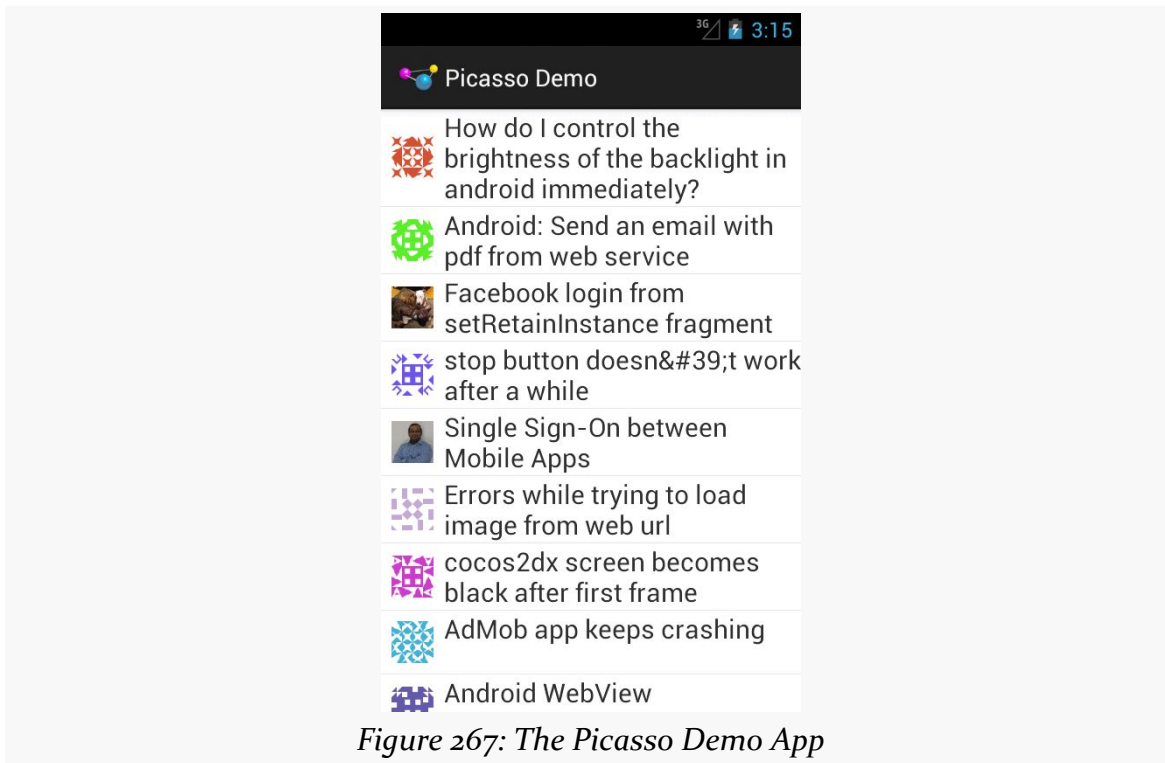

Figure 267: The Picasso Demo App

Volley

At the Google I/O 2013 conference, there was [a session](#) about Volley, an HTTP client library created by Google and used by internal apps, such as the Play Store. Volley can be thought of as a superset of Retrofit plus Picasso, minus Picasso's non-HTTP image loading facilities.

On the plus side, Volley is such a superset and therefore a single code base can be used to replace multiple libraries. Also, given Volley's use by Google, one imagines that this code has been applied to the widest range of possible devices.

However, Volley is distributed as just [a dump of source code](#). There is no packaging of the code into a JAR. There is no documentation beyond that I/O video and [a training module](#). There is no support mechanism, except perhaps via ad-hoc social media inquiries and general support sites (e.g., [Stack Overflow](#)).

All that being said, Volley is still rather popular, so let's see how one can use it in an Android project. Specifically, the [HTTP/Volley](#) sample application is based off of the Picasso sample, migrated over to use Volley instead of the combination of Picasso and Retrofit.

Getting Volley

Half the battle is just getting Volley in the first place.

One approach is to rely upon a third-party repackaging of Volley. The most popular of these appears to be [the mcxiaoke artifact](#), though others exist. Note, though, that this project does not precisely track Volley, sometimes adding bug fixes, sometimes falling behind what is on the Volley master branch. But, if you wish to use it, then adding Volley is not significantly different than adding any other library dependency:

```
dependencies {  
    compile 'com.mcxiaoke.volley:library:1.0.19'  
}
```

If you want to use Google's official copy of Volley, you will need to do a bit more work.

First, you will need to install `git`, if you have not done so already.

Next, you will need to clone the `git` repository for Volley to some temporary location on your development machine:

```
git clone https://android.googlesource.com/platform/frameworks/volley
```

Then, you can import this code as a module, via `File > New > Import Module from the Android Studio main menu`:

INTERNET ACCESS

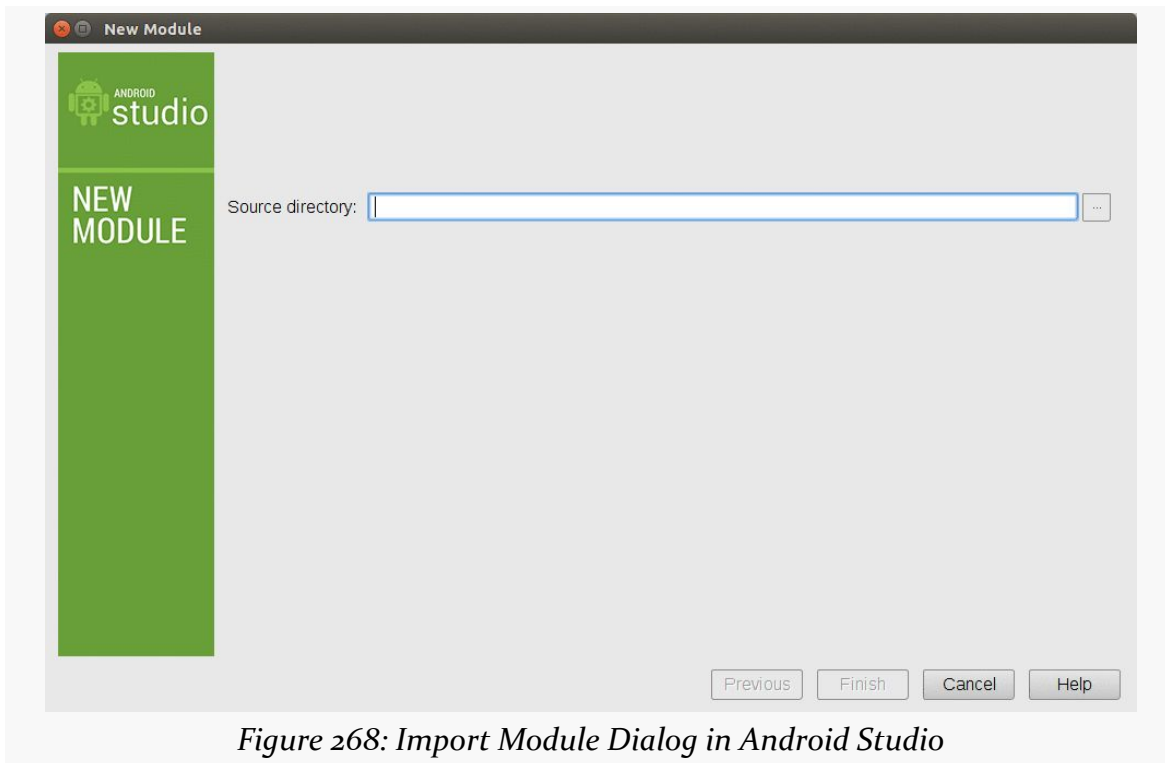

Figure 268: Import Module Dialog in Android Studio

Use the “...” button to browse for and find the directory containing your copy of Volley. This should then display volley as a suggested module name:

INTERNET ACCESS

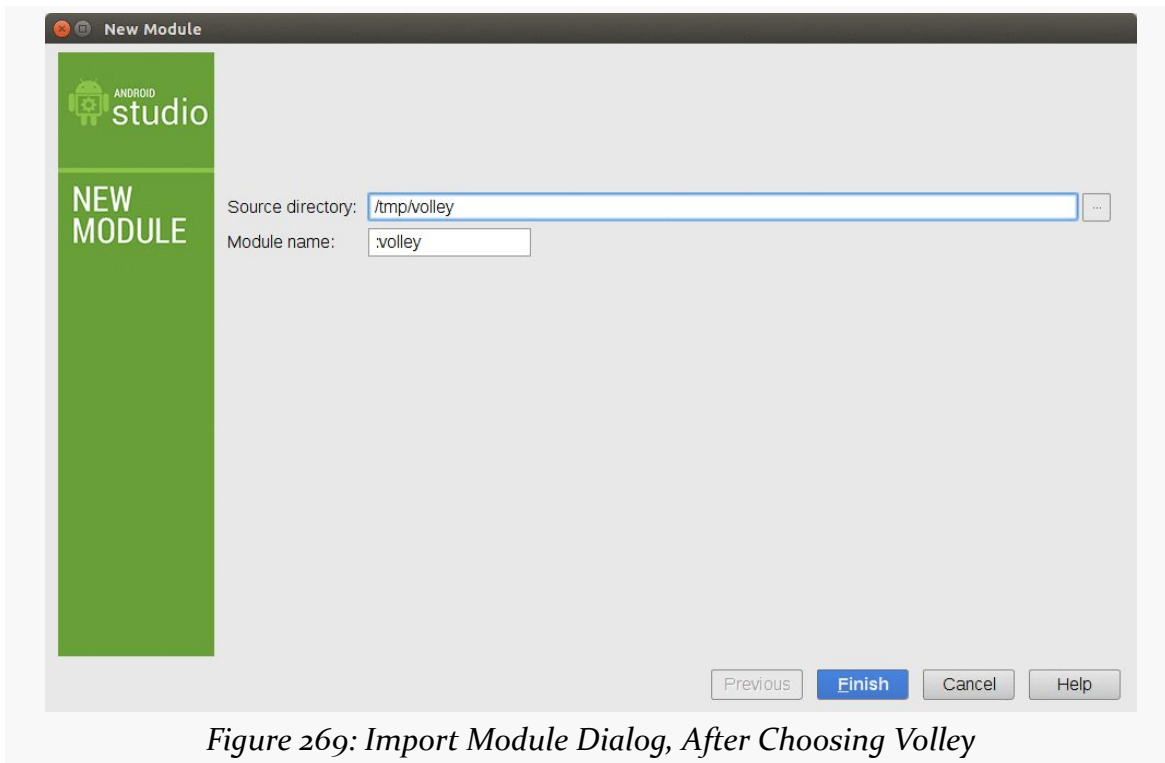

Figure 269: Import Module Dialog, After Choosing Volley

Click Finish, and wait a few moments for all the Gradle project synchronization to take place.

At that point, you can add a dependency on the module to your app:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile project(':volley')
    compile 'com.google.code.gson:gson:2.5'
    compile 'com.android.support:support-v4:23.1.1'
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

Other variations on this theme exist, such as using git submodules, but those are best left to advanced Android developers with substantial git experience (or a lot of patience).

The `build.gradle` file shown above is from the `app/` module of the sample project. You will notice that it also includes dependencies for Google's Gson, along with `support-v4`. We used to get those from having Retrofit as a dependency; with Retrofit gone, we needed to add those dependencies ourselves.

Requests and Queues

Volley's primary API is via a class called `RequestQueue`. As the name suggests, it queues requests, whether those requests are for images, strings, JSON structures, or whatever. A request – in the form of a `Request` instance – embodies the URL to be retrieved, any additional information (e.g., extra HTTP headers), and the rules for interpreting the response received from the server.

Under the covers, `RequestQueue` maintains a thread pool for processing those requests. You can optionally configure this thread pool, indicating how many threads it should have and so on. You can also optionally configure how responses should be cached and the actual HTTP stack to be used for doing the network I/O. By default, on modern versions of Android, Volley delegates to `URLConnection`.

Making a Manager

Retrofit and Picasso manage application-level thread pools and caches for you, via supplied singletons. Alas, Volley does not. While this provides flexibility, it does mean that you need your own singleton wrapper around a `RequestQueue`. In the sample project, we have `VolleyManager` for that:

```
package com.commonware.android.volley;

import android.content.Context;
import android.widget.ImageView;
import com.android.volley.Request;
import com.android.volley.RequestQueue;
import com.android.volley.toolbox.ImageLoader;
import com.android.volley.toolbox.Volley;

public class VolleyManager {
    private static volatile VolleyManager INSTANCE;
    private final RequestQueue queue;
    private final ImageLoader imageLoader;

    synchronized static VolleyManager get(Context ctxt) {
        if (INSTANCE==null) {
            INSTANCE=new VolleyManager(ctxt.getApplicationContext());
        }

        return(INSTANCE);
    }
}
```

```
private VolleyManager(Context ctxt) {
    queue=Volley.newRequestQueue(ctxt);
    imageLoader=new ImageLoader(queue, new LruBitmapCache(ctxt));
}

void enqueue(Request<?> request) {
    queue.add(request);
}

void loadImage(String url, ImageView iv,
               int placeholderDrawable, int errorDrawable) {
    imageLoader.get(url,
        ImageLoader.getImageListener(iv, placeholderDrawable,
            errorDrawable));
}
}
```

VolleyManager holds the singleton instance in a static field named `INSTANCE`. That is lazy-initialized via the `get()` method to retrieve the instance, as we need a `Context` for a bit of our work.

The private constructor creates a new `RequestQueue` via the static `newRequestQueue()` helper method on the `Volley` class. If you prefer to have more control (e.g., supply your own response cache), you can also create a `RequestQueue` via a constructor, then call `start()` on the `RequestQueue` to kick off the thread pool.

We will discuss the rest of `VolleyManager`, including the mysterious `ImageLoader` we are creating in the constructor, a bit later in our examination of the sample app.

Requesting JSON

Volley has built-in support for retrieving strings and images from a Web service. If the Web service serves JSON, Volley also has built-in support for parsing that JSON. However, it uses the legacy `org.json` classes from the Android SDK, which work, but are slow and clunky.

Retrofit has built-in support for retrieving a JSON payload from a Web service via an HTTP request, using `Gson` to parse that payload into your desired POJOs. Alas, Volley does not offer `Gson` support out of the box.

The author of Volley, Ficus Kirkpatrick, wrote a `GsonRequest` class that handles this and published it via [a GitHub gist](#). This has since been replicated in the Android documentation. Since this more closely matches what we had in Retrofit, the sample project uses this `GsonRequest`:

INTERNET ACCESS

```
// from https://gist.github.com/ficusk/5474673

package com.commonware.android.volley;

import com.google.gson.Gson;
import com.google.gson.JsonSyntaxException;

import com.android.volley.AuthFailureError;
import com.android.volley.NetworkResponse;
import com.android.volley.ParseError;
import com.android.volley.Request;
import com.android.volley.Response;
import com.android.volley.Response.ErrorListener;
import com.android.volley.Response.Listener;
import com.android.volley.toolbox.HttpHeaderParser;

import java.io.UnsupportedEncodingException;
import java.util.Map;

/**
 * Volley adapter for JSON requests that will be parsed into Java objects by Gson.
 */
public class GsonRequest<T> extends Request<T> {
    private final Gson gson = new Gson();
    private final Class<T> clazz;
    private final Map<String, String> headers;
    private final Listener<T> listener;

    /**
     * Make a GET request and return a parsed object from JSON.
     *
     * @param url URL of the request to make
     * @param clazz Relevant class object, for Gson's reflection
     * @param headers Map of request headers
     */
    public GsonRequest(String url, Class<T> clazz, Map<String, String> headers,
        Listener<T> listener, ErrorListener errorListener) {
        super(Method.GET, url, errorListener);
        this.clazz = clazz;
        this.headers = headers;
        this.listener = listener;
    }

    @Override
    public Map<String, String> getHeaders() throws AuthFailureError {
        return headers != null ? headers : super.getHeaders();
    }

    @Override
    protected void deliverResponse(T response) {
        listener.onResponse(response);
    }

    @Override
    protected Response<T> parseNetworkResponse(NetworkResponse response) {
        try {
            String json = new String(
                response.data, HttpHeaderParser.parseCharset(response.headers));
            return Response.success(
                gson.fromJson(json, clazz), HttpHeaderParser.parseCacheHeaders(response));
        }
    }
}
```

INTERNET ACCESS

```
} catch (UnsupportedEncodingException e) {  
    return Response.error(new ParseError(e));  
}  
} catch (JsonSyntaxException e) {  
    return Response.error(new ParseError(e));  
}  
}  
}
```

A custom Request implementation like this needs four things:

1. To supply the HTTP method, URL, and a `Response.ErrorListener` to the superclass constructor
2. To override `getHeaders()`, returning a `Map` of HTTP headers to inject into the request, or `null` if there are none
3. To override `parseNetworkResponse()`, taking the raw data from the server and turning into a `Response` wrapped around the actual data to be returned to the app (in this case, the custom POJO parsed by Gson)
4. To override `deliverResponse()`, which may be just a matter of calling `onResponse()` on a `Response.Listener`

However, many developers can get away with using just one of the built-in Request implementations, or perhaps other pre-built implementations, like this `GsonRequest`.

Our `QuestionsFragment` can now create a `GsonRequest` for retrieving our Stack Overflow questions and turning them into an `S0Questions` object. In this version of the sample, the work to populate the `ListView` has been moved from `onCreateView()` to `onViewCreated()`:

```
@Override  
public void onViewCreated(View view,  
                           Bundle savedInstanceState) {  
    super.onViewCreated(view, savedInstanceState);  
  
    GsonRequest<S0Questions> request=  
        new GsonRequest<S0Questions>(getString(R.string.url),  
                                     S0Questions.class, null, this, this);  
  
    VolleyManager.get(getActivity()).enqueue(request);  
}
```

The `R.string.url` value points to a string resource containing the full URL, as it is a bit long for a Java code listing, or even to reproduce easily here in this book. However, note two things about it:

1. In the Retrofit-powered examples, we added the tagged query parameter via a `@Query` annotated parameter on our `StackOverflowInterface`. That

was mostly to demonstrate using such parameters, as we were always requesting the android questions. Since we do not have Retrofit's URL construction anymore, the URL in the string resource contains the `tagged=android` query parameter.

2. Because values resource files are XML files, all the `&` characters in the URL need to be escaped as `&`, to satisfy XML parsing rules.

The rest of the `GsonRequest` parameters are the class for the response (`SOQuestions.class`), our extra HTTP headers (`null`), and our implementations of `Listener` and `ErrorListener` (both the fragment itself).

We then retrieve our `VolleyManager` singleton and call `enqueue()` on it, which in turn calls `add()` on the `RequestQueue`, to cause one of Volley's threads to go do the HTTP work and process the result.

`ErrorListener` requires an `onErrorResponse()` method, which works much like its Retrofit counterpart:

```
@Override
public void onErrorResponse(VolleyError error) {
    Toast.makeText(getActivity(), error.getMessage(),
        Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(),
        "Exception from Volley request to StackOverflow", error);
}
```

`Listener` requires an `onResponse()` method, which takes the type of data we are trying to load as a parameter (`SOQuestions`). Once again, this works like its Retrofit counterpart:

```
@Override
public void onResponse(SOQuestions questions) {
    setListAdapter(new ItemsAdapter(questions.items));
}
```

Requesting Images

Volley has an `ImageRequest`, one that works like `GsonRequest`, except that it gives you a `Bitmap` back. You are welcome to use this, particularly for occasional one-off requests for images.

However, if you are going to be fetching a lot of images — particularly in something like a `ListView`, as the sample app does — you need some more smarts than that. Picasso supplies those smarts to you automatically. With Volley, you use an

INTERNET ACCESS

ImageLoader. An ImageLoader coordinates loading many images, dealing with things like:

- canceling requests when views get recycled
- having a memory cache for images, to supplement the disk cache that Volley uses for responses
- trying to minimize redraws of the UI when multiple images are decoded roughly simultaneously
- and so on

Now, for reasons that are not entirely clear, while ImageLoader needs a memory cache to work properly, it does not have one. Nor does Volley itself. Instead, you have to make your own implementation of ImageLoader. ImageCache.

The Android documentation supplies an LruBitmapCache that does this, on the back of Android's LruCache:

```
// from http://developer.android.com/training/volley/request.html
package com.commonware.android.volley;

import android.content.Context;
import android.graphics.Bitmap;
import android.support.v4.util.LruCache;
import android.util.DisplayMetrics;
import com.android.volley.toolbox.ImageLoader.ImageCache;

public class LruBitmapCache extends LruCache<String, Bitmap>
    implements ImageCache {

    public LruBitmapCache(int maxSize) {
        super(maxSize);
    }

    public LruBitmapCache(Context ctx) {
        this(getCacheSize(ctx));
    }

    @Override
    protected int sizeOf(String key, Bitmap value) {
        return value.getRowBytes() * value.getHeight();
    }

    @Override
    public Bitmap getBitmap(String url) {
        return get(url);
    }

    @Override
    public void putBitmap(String url, Bitmap bitmap) {
        put(url, bitmap);
    }
}
```

INTERNET ACCESS

```
// Returns a cache size equal to approximately three screens worth of images.
public static int getCacheSize(Context ctx) {
    final DisplayMetrics displayMetrics = ctx.getResources().
        getDisplayMetrics();
    final int screenWidth = displayMetrics.widthPixels;
    final int screenHeight = displayMetrics.heightPixels;
    // 4 bytes per pixel
    final int screenBytes = screenWidth * screenHeight * 4;

    return screenBytes * 3;
}
}
```

The key for any cache, particularly a memory cache, is its maximum size. LruBitmapCache lets you specify that directly if you wish. Alternatively, you can provide it with a Context, and it will size the cache to be the size of three full-screen images. This is not a great cache sizing algorithm — it is better to tie the size to the maximum heap size of your app — but it is what Google used.

VolleyManager creates an ImageLoader in its constructor, providing it with an LruBitmapCache. VolleyManager also has a loadImage() method that works a bit like the builder methods on Picasso. It takes four parameters:

- The URL of the image to load
- The ImageView into which to load the image
- A drawable resource ID for an image placeholder
- A drawable resource ID for an image to show if there is an error retrieving the real image (e.g., 404 from the Web server when requesting the URL)

loadImage() in turn passes those on to the ImageLoader, which will handle retrieving the image, caching it, and putting it in the supplied ImageView.

The getView() method on ItemsAdapter can then replace its Picasso code with a call to loadImage():

```
class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
        super(getActivity(), R.layout.row, R.id.title, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        Item item=getItem(position);
        ImageView icon=(ImageView)row.findViewById(R.id.icon);

        VolleyManager
            .get(getActivity())
            .loadImage(item.owner.profileImage, icon,
```

```
        R.drawable.owner_placeholder,  
        R.drawable.owner_error);  
  
        TextView title=(TextView)row.findViewById(R.id.title);  
  
        title.setText(Html.fromHtml(getItem(position).title));  
  
        return(row);  
    }  
}
```

Comparison with Retrofit + Picasso

Volley's big claim to fame is that it is used in the Play Store app and elsewhere in Google's proprietary apps, supposedly.

However, its lack of official packaging and support makes it a bit more difficult for the average developer to use. It also lacks some of the "creature comforts" of Retrofit and Picasso, requiring a few extra classes to do what Square's libraries provide directly.

Other Candidate Libraries

There are plenty of other libraries that similarly try to help simplify Android HTTP operations, including:

- [AndroidAsync](#)
- [android-json-rpc](#)
- [Universal Image Loader \(UIL\)](#), which will be used in some samples later in this book

If you happen to be using support-v4 or support-v13 from the Android Support package in your app, you might also consider [Ion](#).

The Android Arsenal has categories for [general HTTP clients/networking libraries](#) for [REST client libraries](#), and for [image loading libraries](#).

Visit the Trails

As noted earlier, there is a [chapter on SSL](#) that you should read, if you run into trouble using SSL in Android or want to improve your security further than you get with just stock SSL handling.

INTERNET ACCESS

There is also a [chapter on miscellaneous network capabilities](#) – the coverage of DownloadManager can be found there.

Intents, Intent Filters

We have seen Intent objects briefly, in our discussion of [having multiple activities in our application](#). However, we really did not dive into too much of the details about those Intent objects, and they can be used in other ways besides starting up an activity. In this chapter, we will examine Intent and their filters.

What's Your Intent?

When Sir Tim Berners-Lee cooked up the Hypertext Transfer Protocol — HTTP — he set up a system of verbs plus addresses in the form of URLs. The address indicated a resource, such as a Web page, graphic, or server-side program. The verb indicated what should be done: GET to retrieve it, POST to send form data to it for processing, etc.

An Intent is similar, in that it represents an action plus context. There are more actions and more components to the context with Intent than there are with HTTP verbs and resources, but the concept is still the same.

Just as a Web browser knows how to process a verb+URL pair, Android knows how to find activities or other application logic that will handle a given Intent.

Pieces of Intents

The two most important pieces of an Intent are the action and what Android refers to as the “data”. These are almost exactly analogous to HTTP verbs and URLs — the action is the verb, and the “data” is a `Uri`, such as `https://commonsware.com` representing an HTTP URL to some balding guy's Web site. Actions are constants, such as `ACTION_VIEW` (to bring up a viewer for the resource) or `ACTION_EDIT` (to edit the resource).

INTENTS, INTENT FILTERS

If you were to create an Intent combining ACTION_VIEW with a content Uri of `https://commonsware.com`, and pass that Intent to Android via `startActivity()`, Android would know to find and open an activity capable of viewing that resource.

There are other criteria you can place inside an Intent, besides the action and “data” Uri, such as:

1. Categories. Your “main” activity will be in the LAUNCHER category, indicating it should show up on the launcher menu. Other activities will probably be in the DEFAULT category, though other categories exist and are used on occasion.
2. A MIME type, indicating the type of resource you want to operate on.
3. A component, which is to say, the class of the activity that is supposed to receive this Intent.
4. “Extras”, which is a Bundle of other information you want to pass along to the receiver with the Intent, that the recipient might want to take advantage of. What pieces of information a given recipient can use is up to the recipient and (hopefully) is well-documented.

You will find rosters of the standard actions, categories, and extras in the Android SDK documentation for the Intent class.

Intent Routing

As noted above, if you specify the target component in your Intent, Android has no doubt where the Intent is supposed to be routed to — it will launch the named activity. This might be OK if the target recipient (e.g., the activity to be started) is in your application. It definitely is not recommended for invoking functionality in other applications. Component names, by and large, are considered private to the application and are subject to change. Actions, Uri templates, and MIME types are the preferred ways of identifying capabilities you wish third-party code to supply.

If you do not specify the target component, then Android has to figure out what recipients are eligible to receive the Intent. For example, Android will take the Intent you supply to `startActivity()` and find the activities that might support it. Note the use of the plural “activities”, as a broadly-written intent might well resolve to several activities. That is the... ummm... intent (pardon the pun), as you will see [later in this chapter](#). This routing approach is referred to as implicit routing.

Basically, there are three rules, all of which must be true for a given activity to be eligible for a given Intent:

- The activity must support the specified action
- The activity must support the stated MIME type (if supplied)
- The activity must support all of the categories named in the Intent

The upshot is that you want to make your Intent specific enough to find the right recipient, and no more specific than that.

This will become clearer as we work through some examples throughout this chapter.

Stating Your Intent(ions)

All Android components that wish to be started via an Intent must declare Intent filters, so Android knows which intents should go to that component. A common approach for this is to add one or more `<intent-filter>` elements to your `AndroidManifest.xml` file, inside the element for the component that should respond to the Intent.

For example, all of the sample projects in this book have an `<intent-filter>` on an `<activity>` that looks like this:

```
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
```

Here, we declare that this activity:

1. Is the main activity for this application
2. It is in the LAUNCHER category, meaning it gets an icon in anything that thinks of itself as a “launcher”, such as the home screen

You are welcome to have more than one action or more than one category in your Intent filters. That indicates that the associated component (e.g., activity) handles multiple different sorts of Intent patterns.

Responding to Implicit Intents

We saw in the chapter on multiple activities how one activity can start another via an explicit Intent, identifying the particular activity to be started:

INTENTS, INTENT FILTERS

```
startActivity(new Intent(this, OtherActivity.class));
```

In that case, `OtherActivity` does not need an `<intent-filter>` in the manifest. It will automatically respond when somebody explicitly identifies it as the desired activity.

However, what if you want to respond to an implicit Intent, one that focuses on an action string and other values? Then you *will* need an `<intent-filter>` in the manifest.

For example, take a look at the [Intents/FauxSender](#) sample project.

Here, we have an activity, `FauxSender`, set up to respond to an `ACTION_SEND` Intent, specifically for content that has the MIME type of `text/plain`:

```
<activity
  android:name="FauxSender"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.NoDisplay">
  <intent-filter android:label="@string/app_name">
    <action android:name="android.intent.action.SEND"/>

    <data android:mimeType="text/plain"/>

    <category android:name="android.intent.category.DEFAULT"/>
  </intent-filter>
</activity>
```

The call to `startActivity()` will always add the `DEFAULT` category if no other category is specified, which is why our `<intent-filter>` also filters on that category.

Hence, if somebody on the system calls `startActivity()` on an `ACTION_SEND` Intent with a MIME type of `text/plain`, our `FauxSender` activity might get control. We will explain the use of the term “might” in the next section.

The [documentation for ACTION_SEND](#) indicates that a standard extra on the Intent is `EXTRA_TEXT`, representing the text to be sent. There might also be an `EXTRA_SUBJECT`, representing a subject line, if the “send” operation might have such a concept, such as an email client.

`FauxSender` can retrieve those extras and make use of them:

```
package com.commonware.android.fsender;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
```

INTENTS, INTENT FILTERS

```
import android.text.TextUtils;
import android.widget.Toast;

public class FauxSender extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        String msg=getIntent().getStringExtra(Intent.EXTRA_TEXT);

        if (TextUtils.isEmpty(msg)) {
            msg=getIntent().getStringExtra(Intent.EXTRA_SUBJECT);
        }

        if (TextUtils.isEmpty(msg)) {
            Toast.makeText(this, R.string.no_message_supplied,
                Toast.LENGTH_LONG).show();
        }
        else {
            Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
        }

        finish();
    }
}
```

Here, we use `TextUtils.isEmpty()` to detect if an extra is either null or has an empty string as its value. If `EXTRA_TEXT` is supplied, we show it in a Toast. Otherwise, we use `EXTRA_SUBJECT` if it is supplied, and if that is also missing, we show a stock message from a string resource.

The activity then immediately calls `finish()` from `onCreate()` to get rid of itself. That, coupled with `android:theme="@android:style/Theme.NoDisplay"` in the `<activity>` element, means that [the activity will have no user interface](#), beyond the Toast. If run from the launcher, you will still see the launcher behind the Toast:

Requesting Implicit Intents

To send something via `ACTION_SEND`, you first set up the Intent, containing whatever information you want to send in `EXTRA_TEXT`, such as this code from the `FauxSenderTest` activity:

```
Intent i=new Intent(Intent.ACTION_SEND);  
  
i.setType("text/plain");  
i.putExtra(Intent.EXTRA_SUBJECT, R.string.share_subject);  
i.putExtra(Intent.EXTRA_TEXT, theMessage);
```

(where `theMessage` is a passed-in parameter to the method containing this code fragment)

If we call `startActivity()` on this Intent directly, there are three possible outcomes, described in the following sections.

Zero Matches

It is possible, though unlikely, that there are no activities at all on the device that will be able to handle this Intent. In that case, we crash with an `ActivityNotFoundException`. This is a `RuntimeException`, which is why we do not have to keep wrapping all our `startActivity()` calls in `try/catch` blocks. However, if we might start something that does not exist, we really should catch that exception... or avoid the call in the first place. Detecting up front whether there will be any matches for our activity is a topic that will be discussed later in this book.

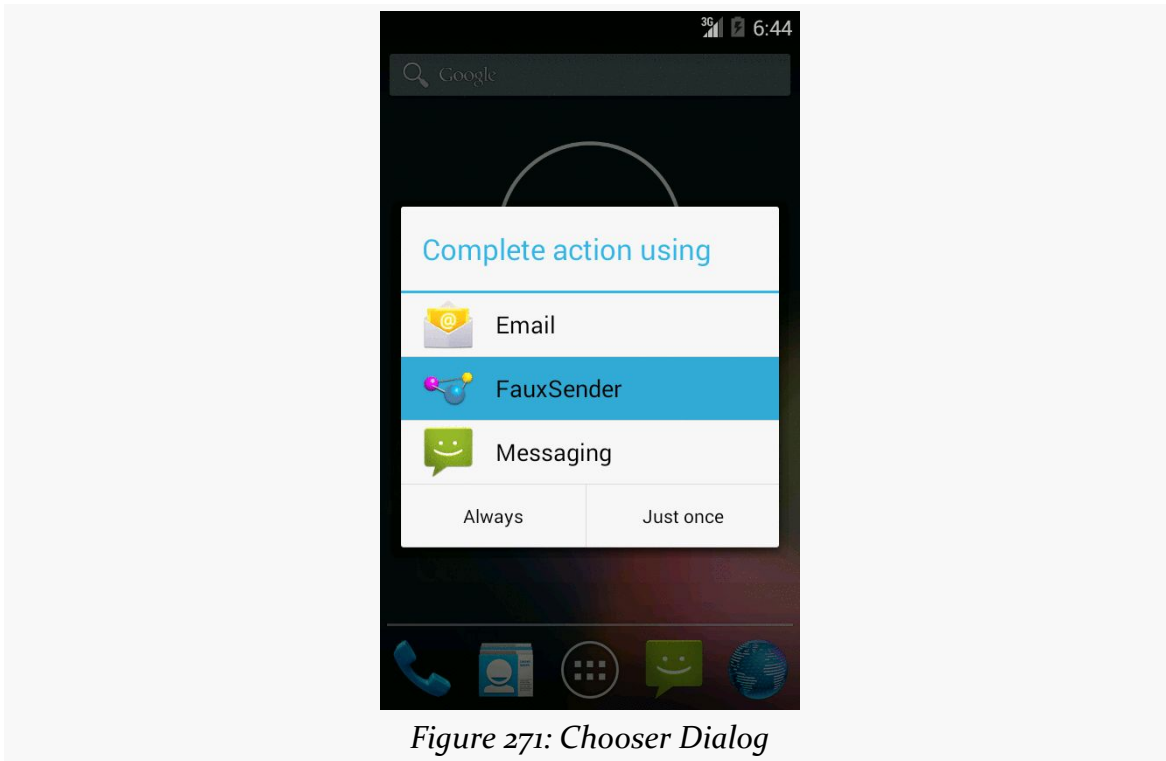

Note that the odds of an `ActivityNotFoundException` climb substantially on Android 4.3+ tablets, when a restricted profile is in use, as will be discussed [later in this book](#).

One Match

It is possible that there will be exactly one matching activity. In that case, the activity in question starts up and takes over the foreground. This is what we see with the explicit Intent.

Many Matches, Default Behavior

It is possible that there will be more than one matching activity. In that case, by default, the user will be presented with a so-called “chooser” dialog box:

The user can tap on any item in the list to have that particular activity be the one to process this event. And, if the user clicks on “Always”, and we invoke the same basic Intent again (same action, same MIME type, same categories, same Uri scheme), whatever the user chooses *now* will be used again automatically, bypassing the chooser. The “Always” button in the chooser dialog sets the default activity for handling the particular Intent structure that triggered the chooser.

The Chooser Override

For many Intent patterns, the notion of the user choosing a default makes perfect sense. For example, if the user installs another Web browser, until they set a default activity, every time they go to view a Web page, they will be presented with a chooser, to choose among the installed browsers. This can get annoying quickly.

However, ACTION_SEND is one of those cases where a default activity is usually inappropriate. Just because the user on Monday chose to send something via Bluetooth and accidentally clicked “Always” does not mean that every day thereafter, they *always* want *every* ACTION_SEND to go via Bluetooth, instead of Gmail or Email or Facebook or Twitter or any other ACTION_SEND-capable apps they may have installed.

INTENTS, INTENT FILTERS

You can elect to force a chooser to display, regardless of whether the user has set a default activity or not. To do this, instead of calling `startActivity()` on the Intent directly, you wrap the Intent in another Intent returned by the `createChooser()` static method on Intent itself:

```
void sendIt(String theMessage) {
    Intent i=new Intent(Intent.ACTION_SEND);

    i.setType("text/plain");
    i.putExtra(Intent.EXTRA_SUBJECT, R.string.share_subject);
    i.putExtra(Intent.EXTRA_TEXT, theMessage);

    startActivity(Intent.createChooser(i,
                                     getString(R.string.share_title)));
}
```

The second parameter to `createChooser()` is a message to appear at the top of the dialog box:

Figure 272: Your Tailored Chooser Dialog

Notice the lack of the “Always” button — not only must the user make a choice now, but also they cannot make a default choice for the future, either.

Direct Share Targets

On Android 6.0, it is possible for an app to not only have an activity appear in the chooser, but also to provide “direct share targets”. These items in the chooser are supplied by the app offering an ACTION_SEND implementation, but rather than representing a simple activity, they can also have additional data in the extras Bundle in the Intent used to start that activity. The idea is that the app could offer a few icons to allow sharing to some fine-grained destination, such as a particular contact or a particular folder or something.

Direct share targets are covered [later in this book](#).

ShareActionProvider

Above, we saw how you can bring up a chooser when using startActivity() on an implicit Intent action, such as ACTION_SEND.

There is another option, if you are using the action bar: ShareActionProvider. Designed for use with ACTION_SEND, ShareActionProvider supplies a drop-down menu in the action bar to let the user invoke some implementation of an Intent that you configure and supply.

To see how you can add a ShareActionProvider to your activity or fragment, let us take a look at the [ActionBar/ShareNative](#) sample project.

Our activity — MainActivity — will utilize the action bar. Its action bar items are contained in a res/menu/actions.xml file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/share"
    android:actionProviderClass="android.widget.ShareActionProvider"
    android:showAsAction="ifRoom"/>

</menu>
```

In addition to specifying an ID and indicating that the item should be shown in the action bar if there is room, we also include the android:actionProviderClass attribute. This points to a concrete implementation of the ActionProvider abstract base class, which is responsible for rendering the action bar item. In our case, we are using ShareActionProvider.

INTENTS, INTENT FILTERS

Our activity UI is simply a large EditText widget:

```
<EditText xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/editor"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="left|top"
    android:inputType="textMultiLine"/>
```

We load that layout in onCreate() of MainActivity, along with initializing an Intent to be used when we employ the ShareActionProvider:

```
package com.commonware.android.sap;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.Editable;
import android.text.TextWatcher;
import android.view.Menu;
import android.widget.EditText;
import android.widget.ShareActionProvider;
import android.widget.Toast;

public class MainActivity extends Activity implements
    ShareActionProvider.OnShareTargetSelectedListener, TextWatcher {
    private ShareActionProvider share=null;
    private Intent shareIntent=new Intent(Intent.ACTION_SEND);
    private EditText editor=null;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.activity_main);

        shareIntent.setType("text/plain");
        editor=(EditText)findViewById(R.id.editor);
        editor.addTextChangedListener(this);
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        share=
            (ShareActionProvider)menu.findItem(R.id.share)
                .getActionProvider();
        share.setOnShareTargetSelectedListener(this);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onShareTargetSelected(ShareActionProvider source,
        Intent intent) {
        Toast.makeText(this, intent.getComponent().toString(),
            Toast.LENGTH_LONG).show();
    }
}
```

```
        return(false);
    }

    @Override
    public void afterTextChanged(Editable s) {
        shareIntent.putExtra(Intent.EXTRA_TEXT, s.toString());
        share.setShareIntent(shareIntent);
    }

    @Override
    public void beforeTextChanged(CharSequence s, int start, int count,
        int after) {
        // ignored
    }

    @Override
    public void onTextChanged(CharSequence s, int start, int before,
        int count) {
        // ignored
    }
}
```

We also register the activity itself to be a `TextWatcher`, to find out when the user types something into the `EditText` widget.

`onCreateOptionsMenu()` is where we configure the `ShareActionProvider`, which we obtain by calling `findItem()` on our `Menu` to get the item associated with the provider, then calling `getActionProvider()` on the supplied `MenuItem`. Specifically:

- We supply an `Intent` — configured with the action, MIME type, etc. that we wish to invoke — to `setShareIntent()`
- We supply `MainActivity` itself, as an implementation of `OnShareTargetSelectedListener`, via `setOnShareTargetSelectedListener()`

In the `afterTextChanged()` method needed by the `TextWatcher` interface, we update the `EXTRA_TEXT` extra in the `Intent` to be the current contents of the `EditText`. This way, as the user types, we keep the `Intent` “fresh” with respect to what should be shared. Many consumers of a `ShareActionProvider` will have less dynamic contents, in which case you can just set up the `Intent` up front before you register it with the `ShareActionProvider`.

If the user chooses an item from the `ShareActionProvider`, we are notified via a call to our `onShareTargetSelected()` method. Registering as the `OnShareTargetSelectedListener` is optional — Android will automatically start the selected activity without our involvement. `onShareTargetSelected()` is there if you

INTENTS, INTENT FILTERS

wish to know the means of sharing that the user chose. In our case, we just flash a Toast to indicate that the callback worked.

Broadcasts and Broadcast Receivers

One channel of the Intent message bus is used to start activities. A second channel of the Intent message bus is used to send broadcasts. As the name suggests, a broadcast Intent is one that — by default — is published to any and all applications on the device that wish to tune in.

Sending a Simple Broadcast

The simplest way to send a broadcast Intent is to create the Intent you want, then call `sendBroadcast()`.

That's it.

At that point, Android will scan through everything set up to tune into a broadcast matching your Intent, typically filtering just on the action string. Anyone set up to receive this broadcast will, indeed, receive it, using a `BroadcastReceiver`.

Receiving a Broadcast: In an Activity

To receive such a broadcast in an activity (or a fragment), you will need to do four things.

First, you will need to create an instance of your own subclass of `BroadcastReceiver`. The only method you need to (or should) implement is `onReceive()`, which will be passed the Intent that was broadcast, along with a `Context` object that, in this case, you will typically ignore.

BROADCASTS AND BROADCAST RECEIVERS

Second, you will need to create an instance of an `IntentFilter` object, describing the sorts of broadcasts you want to receive. Most of these filters are set up to watch for a single broadcast `Intent` action, in which case the simple constructor suffices:

```
new IntentFilter(Intent.ACTION_CAMERA_BUTTON)
```

Third, you will need to call `registerReceiver()`, typically from `onResume()` of your activity or fragment, supplying your `BroadcastReceiver` and your `IntentFilter`.

Fourth, you will need to call `unregisterReceiver()`, typically from `onPause()` of your activity or fragment, supplying the same `BroadcastReceiver` instance you provided to `registerReceiver()`.

In between the calls to `registerReceiver()` and `unregisterReceiver()`, you will receive any broadcasts matching the `IntentFilter`.

The biggest downside to this approach is that some activity has to register the receiver. Sometimes, you want to receive broadcasts even when there is no activity around. To do that, you will need to use a different technique: registering the receiver in the manifest.

Receiving a Broadcast: Via the Manifest

You can also tell Android about broadcasts you wish to receive by adding a `<receiver>` element to your manifest, identifying the class that implements your `BroadcastReceiver` (via the `android:name` attribute), plus an `<intent-filter>` that describes the broadcast(s) you wish to receive:

```
<receiver android:name=".OnBootReceiver">
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED"/>
  </intent-filter>
</receiver>
```

The good news is that this `BroadcastReceiver` will be available for broadcasts occurring at any time. There is no assumption that you have an activity already running that called `registerReceiver()`.

The bad news is that the instance of the `BroadcastReceiver` used by Android to process a broadcast will live for only so long as it takes to execute the `onReceive()` method. At that point, the `BroadcastReceiver` is discarded. Hence, it is not safe for a manifest-registered `BroadcastReceiver` to do anything that needs to run after `onReceive()` itself completes, such as forking a thread. After all, Android may well

terminate the process within milliseconds, if there is no other running component in the process.

More bad news: `onReceive()` is called on the main application thread — the same main application thread that handles the UI of all of your activities. And, you are subject to the same limitations as are your activity lifecycle methods and anything else called on the main application thread:

- Any time spent in `onReceive()` will freeze your UI, if you happen to have a foreground activity
- If you spend too long in `onReceive()`, Android will terminate your `BroadcastReceiver` without waiting for `onReceive()` to complete

This makes using a manifest-registered `BroadcastReceiver` a bit tricky. If the work to be done is very quick, just implement it in `onReceive()`. Otherwise, you will probably need to pair this `BroadcastReceiver` with a component known as an `IntentService`, which we will examine [in the next chapter](#).

The Stopped State

On Android 3.1 and higher, when your app is first installed on the device, it is in a “stopped” state. This has nothing to do with `onStop()` of any activity. While in the stopped state, your manifest-registered `BroadcastReceivers` will not receive any broadcasts.

Getting Out of the Stopped State

To get out of the stopped state, something on the device, such as another app (that itself is not in the stopped state), must use an explicit `Intent` to invoke one of your components.

The most common way this happens is for the user to tap on a launcher icon associated with your launcher activity. Under the covers, the home screen’s launcher will create an explicit `Intent`, identifying your activity, and use that with `startActivity()`. This moves you out of the stopped state.

Getting Into the Stopped State

As noted above, you start off in the stopped state. Once you are moved out of the stopped state, via the explicit Intent, you will remain out of the stopped state until one of two things happens:

1. The user uninstalls your app
2. The user “force-stops” your app

The latter normally occurs when the user clicks the “Force Stop” button on your app’s screen in the Settings app (Settings > Apps). There is some evidence that some device manufacturers have tied their own device’s task manager to do a “force stop” when the user removes a task — this was not a particularly wise choice on the part of those manufacturers.

Note that a reboot does *not* move you back into the stopped state. You remain in the normal state through a reboot.

Example System Broadcasts

There are many, many broadcasts sent out by Android itself, which you can tune into if you see fit. Many, but not all, of these are documented on the Intent class. The values in the “Constants” table that have “Broadcast Action” leading off their description are action strings used for system broadcasts. There are other such broadcast actions scattered around the SDK, though, so do not assume that they are all documented on Intent.

The following sections will examine two of these broadcasts, to see how the BroadcastReceiver works in action.

At Boot Time

A popular request is to have code get control when the device is powered on. This is doable but somewhat dangerous, in that too many on-boot requests slow down the device startup and may make things sluggish for the user.

In order to be notified when the device has completed its system boot process, you will need to request the RECEIVE_BOOT_COMPLETED permission. Without this, even if you arrange to receive the boot broadcast Intent, it will not be dispatched to your receiver.

BROADCASTS AND BROADCAST RECEIVERS

As the Android documentation describes it:

Though holding this permission does not have any security implications, it can have a negative impact on the user experience by increasing the amount of time it takes the system to start and allowing applications to have themselves running without the user being aware of them. As such, you must explicitly declare your use of this facility to make that visible to the user.

We also need to register our `BroadcastReceiver` in the manifest — by the time an activity would call `registerReceiver()`, the boot will have long since occurred.

For example, let us examine the [Intents/OnBoot](#) sample project.

In our manifest, we request the needed permission and register our `BroadcastReceiver`, along with an activity:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sysevents.boot"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="false"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <receiver android:name=".OnBootReceiver">
            <intent-filter>
                <action android:name="android.intent.action.BOOT_COMPLETED"/>
            </intent-filter>
        </receiver>

        <activity
            android:name="BootstrapActivity"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

```
</application>
</manifest>
```

OnBootReceiver simply logs a message to LogCat:

```
package com.commonware.android.sysevents.boot;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.util.Log;

public class OnBootReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Log.d(getClass().getSimpleName(), "Hi, Mom!");
    }
}
```

To test this on Android 3.0 and earlier, simply install the application and reboot the device — you will see the message appear in LogCat.

However, on Android 3.1 and higher, the user must first manually launch some activity before any manifest-registered BroadcastReceiver objects will be used, as noted above in [the section covering the stopped state](#). Hence, if you were to just install the application and reboot the device, nothing would happen. The little BootstrapActivity is merely there for the user to launch, so that the ACTION_BOOT_COMPLETED BroadcastReceiver will start working.

On Battery State Changes

One theme with system events is to use them to help make your users happier by reducing your impacts on the device while the device is not in a great state. Most applications are impacted by battery life. Dead batteries run no apps. Hence, knowing the battery level may be important for your app.

There is an ACTION_BATTERY_CHANGED Intent that gets broadcast as the battery status changes, both in terms of charge (e.g., 80% charged) and charging (e.g., the device is now plugged into AC power). You simply need to register to receive this Intent when it is broadcast, then take appropriate steps.

One of the limitations of ACTION_BATTERY_CHANGED is that you have to use registerReceiver() to set up a BroadcastReceiver to get this Intent when broadcast. You cannot use a manifest-declared receiver. There are separate ACTION_BATTERY_LOW and ACTION_BATTERY_OK broadcasts that you *can* receive from a

BROADCASTS AND BROADCAST RECEIVERS

manifest-registered receiver, but they are broadcast far less frequently, only when the battery level falls below or rises above some undocumented “low” threshold.

To demonstrate ACTION_BATTERY_CHANGED, take a peek at the [Intents/OnBattery](#) sample project.

In there, you will find a `res/layout/batt.xml` resource containing a `ProgressBar`, a `TextView`, and an `ImageView`, to serve as a battery monitor:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <ProgressBar
        android:id="@+id/bar"
        style="?android:attr/progressBarStyleHorizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content" />

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <TextView
            android:id="@+id/level"
            android:layout_width="0px"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:textSize="36sp" />

        <ImageView
            android:id="@+id/status"
            android:layout_width="0px"
            android:layout_height="wrap_content"
            android:layout_weight="1" />
    </LinearLayout>
</LinearLayout>
```

This layout is used by a `BatteryFragment`, which registers to receive the `ACTION_BATTERY_CHANGED` Intent in `onResume()` and unregisters in `onPause()`:

```
package com.commonware.android.battmon;

import android.app.Fragment;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.content.IntentFilter;
import android.os.BatteryManager;
import android.os.Bundle;
```

BROADCASTS AND BROADCAST RECEIVERS

```
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import android.widget.ProgressBar;
import android.widget.TextView;

public class BatteryFragment extends Fragment {
    private ProgressBar bar=null;
    private ImageView status=null;
    private TextView level=null;

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.batt, parent, false);

        bar=(ProgressBar)result.findViewById(R.id.bar);
        status=(ImageView)result.findViewById(R.id.status);
        level=(TextView)result.findViewById(R.id.level);

        return(result);
    }

    @Override
    public void onResume() {
        super.onResume();

        IntentFilter f=new IntentFilter(Intent.ACTION_BATTERY_CHANGED);

        getActivity().registerReceiver(onBattery, f);
    }

    @Override
    public void onPause() {
        getActivity().unregisterReceiver(onBattery);

        super.onPause();
    }

    BroadcastReceiver onBattery=new BroadcastReceiver() {
        public void onReceive(Context context, Intent intent) {
            int pct=
                100 * intent.getIntExtra(BatteryManager.EXTRA_LEVEL, 1)
                / intent.getIntExtra(BatteryManager.EXTRA_SCALE, 1);

            bar.setProgress(pct);
            level.setText(String.valueOf(pct));

            switch (intent.getIntExtra(BatteryManager.EXTRA_STATUS, -1)) {
                case BatteryManager.BATTERY_STATUS_CHARGING:
                    status.setImageResource(R.drawable.charging);
                    break;

                case BatteryManager.BATTERY_STATUS_FULL:
                    int plugged=
                        intent.getIntExtra(BatteryManager.EXTRA_PLUGGED, -1);

                    if (plugged == BatteryManager.BATTERY_PLUGGED_AC
                        || plugged == BatteryManager.BATTERY_PLUGGED_USB) {
```

BROADCASTS AND BROADCAST RECEIVERS

```
        status.setImageResource(R.drawable.full);
    }
    else {
        status.setImageResource(R.drawable.unplugged);
    }
    break;

default:
    status.setImageResource(R.drawable.unplugged);
    break;
}
}
};
}
```

The key to ACTION_BATTERY_CHANGED is in the “extras”. Many extras are packaged in the Intent, to describe the current state of the battery, such as the following constants defined on the BatteryManager class:

- EXTRA_HEALTH, which should generally be BATTERY_HEALTH_GOOD
- EXTRA_LEVEL, which is the proportion of battery life remaining as an integer, specified on the scale described by the EXTRA_SCALE value
- EXTRA_PLUGGED, which will indicate if the device is plugged into AC power (BATTERY_PLUGGED_AC) or USB power (BATTERY_PLUGGED_USB)
- EXTRA_SCALE, which indicates the maximum possible value of level (e.g., 100, indicating that level is a percentage of charge remaining)
- EXTRA_STATUS, which will tell you if the battery is charging (BATTERY_STATUS_CHARGING), full (BATTERY_STATUS_FULL), or discharging (BATTERY_STATUS_DISCHARGING)
- EXTRA_TECHNOLOGY, which indicates what sort of battery is installed (e.g., "Li-Ion")
- EXTRA_TEMPERATURE, which tells you how warm the battery is, in tenths of a degree Celsius (e.g., 213 is 21.3 degrees Celsius)
- EXTRA_VOLTAGE, indicating the current voltage being delivered by the battery, in millivolts

In the case of BatteryFragment, when we receive an ACTION_BATTERY_CHANGED Intent, we do three things:

1. We compute the percentage of battery life remaining, by dividing the level by the scale
2. We update the ProgressBar and TextView to display the battery life as a percentage
3. We display an icon, with the icon selection depending on whether we are charging (status is BATTERY_STATUS_CHARGING), full but on the charger

BROADCASTS AND BROADCAST RECEIVERS

(status is `BATTERY_STATUS_FULL` and plugged is `BATTERY_PLUGGED_AC` or `BATTERY_PLUGGED_USB`), or are not plugged in

If you plug this into a device, it will show you the device's charge level:

Figure 273: The Battery Monitor

Sticky Broadcasts and the Battery

NOTE: Sticky broadcasts are deprecated in Android 5.0, and the documentation hints that they may be abandoned entirely in the future.

Android has a notion of “sticky broadcast Intents”. Normally, a broadcast Intent will be delivered to interested parties and then discarded. A sticky broadcast Intent is delivered to interested parties and retained until the next matching Intent is broadcast. Applications can call `registerReceiver()` with an `IntentFilter` that matches the sticky broadcast, but with a null `BroadcastReceiver`, and get the sticky Intent back as a result of the `registerReceiver()` call.

This may sound confusing. Let's look at this in the context of the battery.

BROADCASTS AND BROADCAST RECEIVERS

Earlier in this section, you saw how to register for `ACTION_BATTERY_CHANGED` to get information about the battery delivered to you. You can also, though, get the latest battery information without registering a receiver. Just create an `IntentFilter` to match `ACTION_BATTERY_CHANGED` (as shown above) and call `registerReceiver()` with that filter and a null `BroadcastReceiver`. The `Intent` you get back from `registerReceiver()` is the last `ACTION_BATTERY_CHANGED` `Intent` that was broadcast, with the same extras. Hence, you can use this to get the current (or near-current) battery status, rather than having to bother registering an actual `BroadcastReceiver`.

This is why the sample app shows its results immediately — it was given the last-broadcast edition of the `ACTION_BATTERY_CHANGED` broadcast once we called `registerReceiver()`.

Battery and the Emulator

Your emulator does not really have a battery. If you run this sample application on an emulator, you will see, by default, that your device has 50% fake charge remaining and that it is being charged. However, it is charged infinitely slowly, as it will not climb past 50%... at least, not without help.

NOTE: At the time of this writing, the Linux emulator does not properly emulate the battery for AVDs created from certain device profiles (e.g., Nexus S), showing 0% battery charge and not responding to the `telnet` commands described below. As is noted in [this issue](#), if you encounter this, go into the `config.ini` file for your AVD (found in `~/.android/avd/...`, where `~/` is your home directory and `...` is the name of the AVD) and add `hw.battery=yes` as a property. If that property exists but is set to no, change it to yes.

While the emulator will only show fixed battery characteristics, you can change what those values are, through the highly advanced user interface known as `telnet`.

You may have noticed that your emulator title bar consists of the name of your AVD plus a number, frequently 5554. That number is not merely some engineer's favorite number. It is also an open port, on your emulator, to which you can `telnet` into, on `localhost` (127.0.0.1) on your development machine.

There are many commands you can issue to the emulator by means of `telnet`. To change the battery level, use `power capacity NN`, where `NN` is the percentage of battery life remaining that you wish the emulator to return. If you do that while you

have an `ACTION_BATTERY_CHANGED` `BroadcastReceiver` registered, the receiver will receive a broadcast `Intent`, informing you of the change.

You can also experiment with some of the other power subcommands (e.g., `power ac on` or `power ac off`), or other commands (e.g., `geo`, to send simulated GPS fixes, just as you can do from DDMS).

Battery Data on Android 5.0+

As noted earlier, Android 5.0 deprecates sticky broadcasts. The existing broadcasts still work, though. And, even if someday Android gets rid of sticky broadcasts entirely, broadcasts like `ACTION_BATTERY_CHANGED` most likely will *still* work, albeit just as a regular broadcast.

To get current battery information on Android 5.0 and higher, `BatteryManager` offers `getIntProperty()` and `getLongProperty()`, where the keys for the “properties” are `BATTERY_PROPERTY_*` constants defined on `BatteryManager`, such as `BATTERY_PROPERTY_CAPACITY` to determine the percentage of remaining battery capacity.

The Order of Things

Another variation on the broadcast `Intent` is the ordered broadcast.

Normally, if you broadcast an `Intent`, and there are 10 registered `BroadcastReceivers` that match that `Intent`, all 10 will receive the broadcast, in indeterminate order, and possibly in parallel (particularly on multi-core devices).

With an ordered broadcast, the behavior shifts a bit:

- Only one `BroadcastReceiver` at a time will receive the broadcast
- The order in which the `BroadcastReceivers` receive the broadcast is (somewhat) controlled by their developers
- A `BroadcastReceiver` can “abort” the broadcast, preventing other receivers in the chain from receiving it

Sending an ordered broadcast is merely a matter of calling `sendOrderedBroadcast()`.

Receiving an ordered broadcast, at its core, is identical to receiving a regular broadcast: you write a `BroadcastReceiver` and register it via the manifest or `registerReceiver()`. However, you have two additional options when registering that `BroadcastReceiver`.

First, you can specify a priority, either via `setPriority()` on the `IntentFilter` or `android:priority` on the `<intent-filter>` element. The priority is a positive integer, with higher numbers indicating higher priority. Higher-priority receivers will get the broadcast sooner than will lower-priority receivers.

Second, your `BroadcastReceiver` can call `abortBroadcast()` to consume the event, preventing any lower-priority receivers from even seeing the broadcast.

Keeping It Local

A broadcast `Intent`, by default and nearly by definition, is broadcast. Anything on the device could have a receiver “tuned in” to listen for such broadcasts. While you can use `setPackage()` on `Intent` to restrict the distribution, the broadcast still goes through the standard broadcast mechanism, which involves transferring the `Intent` to an OS process, which then does the actual broadcasting. Hence, a broadcast `Intent` has some overhead.

Yet, there are times when using broadcasts within an app is handy, but it would be nice to avoid the overhead. To help with this the core Android team added `LocalBroadcastManager` to the Android Support package, to provide an in-process way of doing broadcasts with the standard `Intent`, `IntentFilter`, and `BroadcastReceiver` classes, yet with less overhead.

`LocalBroadcastManager` is supplied by both the `android-support-v4.jar` and `android-support-v13.jar` libraries. Generally speaking, if your `android:minSdkVersion` is less than 13, you probably should choose `android-support-v4.jar`.

The only real difference, from a coding standpoint, in using `LocalBroadcastManager` is that you call `registerReceiver()`, `unregisterReceiver()`, and `sendBroadcast()` on an instance of `LocalBroadcastManager`, instead of on an instance of `Context`. You get the `LocalBroadcastManager` singleton for your process via a static `getInstance()` method on `LocalBroadcastManager` itself.

We will see LocalBroadcastManager in use in one of the samples in [the services chapter](#).

Visit the Trails!

We examine LocalBroadcastManager in more detail, along with other event bus alternatives, [later in the book](#).

Tutorial #15 - Sharing Your Notes

Perhaps you would like to get your notes off of our book reader app and into someplace else, or perhaps you would like to share them with somebody else. Either way, we can do that using an `ACTION_SEND` operation, to allow the user to choose how to “send” the notes, such as sending them by email or uploading them to some third-party note service.

To make this work, we will add a `ShareActionProvider` to our action bar on the `NoteFragment`.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book’s GitHub repository:

Step #1: Adding a `ShareActionProvider`

First, we need to allow the user to indicate that they want to “share” the note displayed in the current `NoteFragment`. By putting an action bar item on the activity where the `NoteFragment` is displayed, we do not need to worry about letting the user choose which note to send — we simply send whichever note they happen to be viewing or editing.

By using a `ShareActionProvider`, the action item will handle most of the work for allowing the user to choose where to send the note to. We only need to provide an `Intent` that identifies what is to be shared.

Modify `res/menu/notes.xml` to add in the new share toolbar button:

TUTORIAL #15 - SHARING YOUR NOTES

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/share"
    android:actionProviderClass="android.widget.ShareActionProvider"
    android:showAsAction="ifRoom"
    android:title="@string/share"/>
  <item
    android:id="@+id/delete"
    android:icon="@drawable/ic_action_discard"
    android:showAsAction="ifRoom|withText"
    android:title="@string/delete">
  </item>
</menu>
```

Note that this menu definition requires a new string resource, named share, with a value like Share.

Step #2: Sharing the Note

Now, we need to configure the ShareActionProvider, in particular supplying it with a continuously-updated Intent, based upon what the user has typed into the EditText.

Add a ShareActionProvider data member to NoteFragment, named share, along with an Intent data member named shareIntent configured to use ACTION_SEND of a MIME type of text/plain:

```
private ShareActionProvider share=null;
private Intent shareIntent=
    new Intent(Intent.ACTION_SEND).setType("text/plain");
```

Then, in onCreateView(), tell the EditText to let us know when the user changes the text, via addTextChangedListener():

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);
    editor.addTextChangedListener(this);

    return(result);
}
```

TUTORIAL #15 - SHARING YOUR NOTES

This will fail to compile, as our NoteFragment is not implementing the TextWatcher interface. So, modify the NoteFragment class declaration to include the TextWatcher interface:

```
public class NoteFragment extends Fragment implements TextWatcher {
```

That, in turn, will require us to implement three methods:

1. afterTextChanged()
2. beforeTextChanged()
3. onTextChanged()

In our case, we care about afterTextChanged(). So, add the following three methods to NoteFragment:

```
@Override
public void afterTextChanged(Editable s) {
    shareIntent.putExtra(Intent.EXTRA_TEXT, s.toString());
}

@Override
public void beforeTextChanged(CharSequence s, int start, int count,
                               int after) {
    // ignored
}

@Override
public void onTextChanged(CharSequence s, int start, int before,
                           int count) {
    // ignored
}
```

Here, we update the shareIntent with the latest text to be shared, storing it in EXTRA_TEXT, per the instructions in the Android developer documentation for working with ACTION_SEND.

However, we have not initialized share yet. We can do that in onCreateOptionsMenu(), adding a call to findItem() to find our R.id.share menu item, then calling getActionProvider() to get the ShareActionProvider out of the menu item:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.notes, menu);

    share=
        (ShareActionProvider)menu.findItem(R.id.share)
            .getActionProvider();
    share.setShareIntent(shareIntent);
}
```

TUTORIAL #15 - SHARING YOUR NOTES

```
super.onCreateOptionsMenu(menu, inflater);  
}
```

Here, we also attach the `shareIntent` to the `ShareActionProvider`, so when it comes time to share the text, the `ShareActionProvider` knows how to do that.

Step #3: Testing the Result

If you run this on a device and navigate to a filled-in note, you will see the new action bar item:

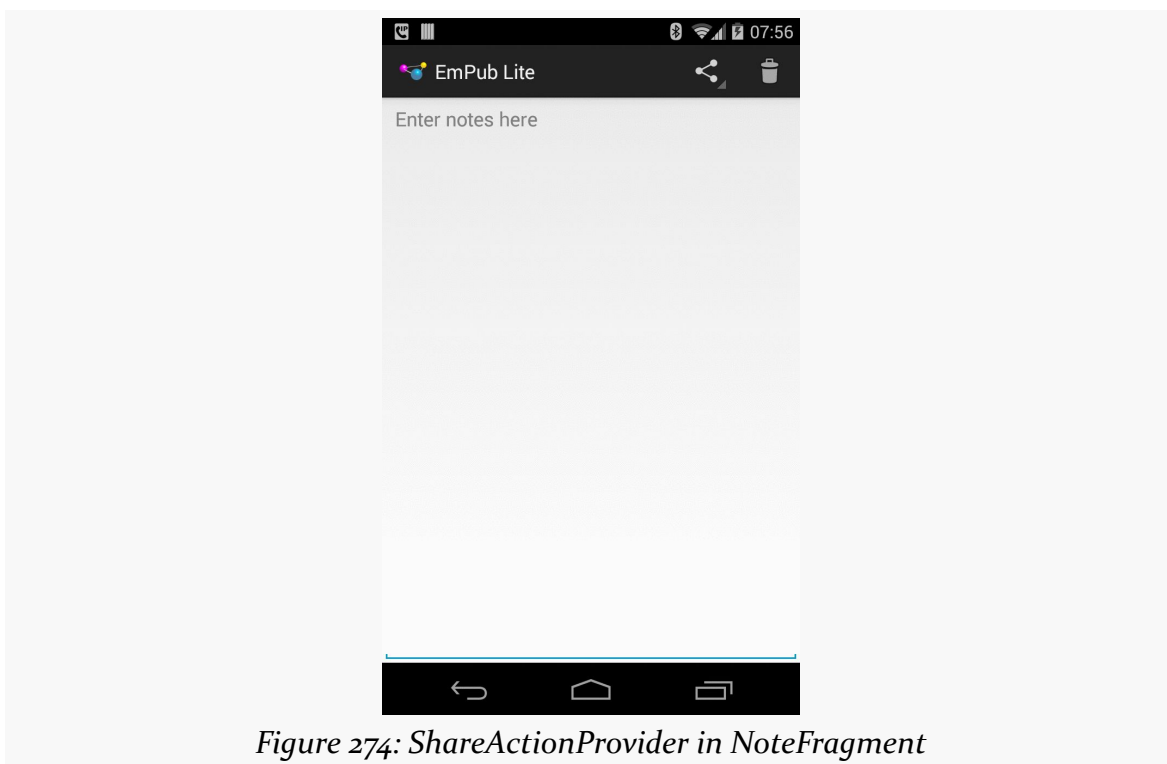

Figure 274: ShareActionProvider in NoteFragment

If you tap on it, you will get a roster of possible ways to share the text:

TUTORIAL #15 - SHARING YOUR NOTES

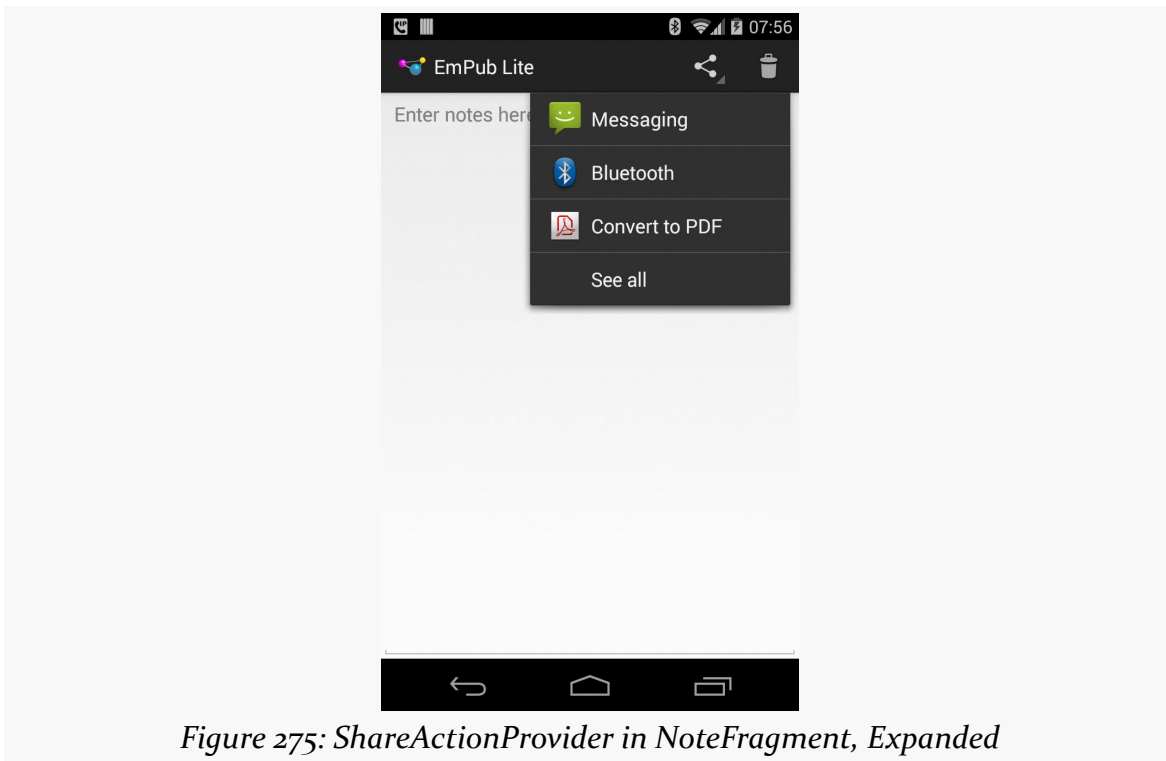

Figure 275: ShareActionProvider in NoteFragment, Expanded

The exact options you see will vary based on your device or emulator, and what apps are installed on it that know how to share plain text. If you only have one choice (e.g., Messenger), it will appear next to the share icon, and you will only be able to tap on that one choice.

Unfortunately, your emulator may have nothing that can handle this Intent. If that is the case, you will crash with an `ActivityNotFoundException`. To get past this, if you enter `http://goo.gl/w113e` in your emulator's browser, that should allow you to download and install a copy of the APK from the [Intents/FauxSender](#) sample project that we covered [earlier in this book](#). When the download is complete (which should be very quick), open up the notification drawer and tap on the "download complete" notification. This should begin the installation process. Depending on your Android version, you may also need to "allow installation of non-Market apps" — after fixing this, you can use the Downloads app on the emulator to try installing the APK again. Once FauxSender is installed, it will respond to your attempts to share a note.

In Our Next Episode...

... we will allow the user to [update the book's contents](#) over the Internet.

Services and the Command Pattern

As noted previously, Android services are for long-running processes that may need to keep running even when decoupled from any activity. Examples include playing music even if the “player” activity is destroyed, polling the Internet for RSS/Atom feed updates, and maintaining an online chat connection even if the chat client loses focus due to an incoming phone call.

Services are created when manually started (via an API call) or when some activity tries connecting to the service via inter-process communication (IPC). Services will live until specifically shut down or until Android is desperate for RAM and terminates the process. Running for a long time has its costs, though, so services need to be careful not to use too much CPU or keep radios active too much of the time, lest the service cause the device’s battery to get used up too quickly.

This chapter outlines the basic theory behind creating and consuming services, including a look at the “command pattern” for services.

Why Services?

Services are a “Swiss Army knife” for a wide range of functions that do not require direct access to an activity’s user interface, such as:

1. Performing operations that need to continue even if the user leaves the application’s activities, like a long download (as seen with the Play Store) or playing music (as seen with Android music apps)
2. Performing operations that need to exist regardless of activities coming and going, such as maintaining a chat connection in support of a chat application

3. Providing a local API to remote APIs, such as might be provided by a Web service
4. Performing periodic work without user intervention, akin to cron jobs or Windows scheduled tasks

Even things like home screen app widgets often involve a service to assist with long-running work.

The primary role of a service is as a flag to the operating system, letting it know that your process is still doing work, despite the fact that it is in the background. This makes it *somewhat* less likely that Android will terminate your process due to low memory conditions.

Many applications will not need any services. Very few applications will need more than one. However, the service is a powerful tool for an Android developer's toolbox and is a subject with which any qualified Android developer should be familiar.

Setting Up a Service

Creating a service implementation shares many characteristics with building an activity. You inherit from an Android-supplied base class, override some lifecycle methods, and hook the service into the system via the manifest.

The Service Class

Just as an activity in your application extends either `Activity` or an Android-supplied `Activity` subclass, a service in your application extends either `Service` or an Android-supplied `Service` subclass. The most common `Service` subclass is `IntentService`, used primarily for the command pattern, described [later in this chapter](#). That being said, many services simply extend `Service`.

Lifecycle Methods

Just as activities have `onCreate()`, `onResume()`, `onPause()` and kin, `Service` implementations have their own lifecycle methods, such as:

- `onCreate()`, which, as with activities, is called when the service is created, by any means
- `onStartCommand()`, which is called each time the service is sent a command via `startService()`

- `onBind()`, which is called whenever a client binds to the service via `bindService()`
- `onDestroy()` which is called as the service is being shut down

As with activities, services initialize whatever they need in `onCreate()` and clean up those items in `onDestroy()`. And, as with activities, the `onDestroy()` method of a service might not be called, if Android terminates the entire application process, such as for emergency RAM reclamation.

The `onStartCommand()` and `onBind()` lifecycle methods will be implemented based on your choice of communicating to the client, as will be explained [later in this chapter](#).

Note that `Service` is an abstract class and `onBind()` is an abstract method, so even if you are not using `bindService()`, you will need to implement `onBind()` in order to successfully compile. A common approach here is to have `onBind()` simply return `null`.

Manifest Entry

Finally, you need to add the service to your `AndroidManifest.xml` file, for it to be recognized as an available service for use. That is simply a matter of adding a `<service>` element as a child of the application element, providing `android:name` to reference your service class.

Since the service class is in the same Java namespace as everything else in this application, we can use the shorthand (e.g., "PlayerService") to reference our class.

For example, here is a manifest showing the `<service>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.fakeplayer"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

</manifest>
```

```
<application
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
  <activity
    android:name="FakePlayer"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>

  <service android:name="PlayerService"/>
</application>
</manifest>
```

Communicating To Services

Clients of services — frequently activities, though not necessarily — have two main ways to send requests or information to a service. One approach is to send a command, which creates no lasting connection to the service. The other approach is to bind to the service, establishing a communications channel that lasts as long as the client needs it.

Sending Commands with `startService()`

The simplest way to work with a service is to call `startService()`. The `startService()` method takes an `Intent` parameter, much like `startActivity()` does. In fact, the `Intent` supplied to `startService()` has the same two-part role as it does with `startActivity()`:

1. Identify the service to communicate with
2. Supply parameters, in the form of `Intent` extras, to tell the service what it is supposed to do

For a local service — the focus of this chapter — the simplest form of `Intent` is one that identifies the class that implements the `Service` (e.g., `new Intent(this, MyService.class);`).

The call to `startService()` is asynchronous, so the client will not block. The service will be created if it is not already running, and it will receive the `Intent` via a call to the `onStartCommand()` lifecycle method. The service can do whatever it needs to in `onStartCommand()`, but since `onStartCommand()` is called on the main application

thread, it should do its work very quickly. Anything that might take more than a handful of milliseconds should be delegated to a background thread.

The `onStartCommand()` method can return one of several values, mostly to indicate to Android what should happen if the service's process should be killed while it is running. The most likely return values are:

1. `START_STICKY`, meaning that the service should be moved back into the started state (as if `onStartCommand()` had been called), but do not re-deliver the Intent to `onStartCommand()`
2. `START_REDELIVER_INTENT`, meaning that the service should be restarted via a call to `onStartCommand()`, supplying the same Intent as was delivered this time
3. `START_NOT_STICKY`, meaning that the service should remain stopped until explicitly started by application code

By default, calling `startService()` not only sends the command, but tells Android to keep the service running until something tells it to stop. One way to stop a service is to call `stopService()`, supplying the same Intent used with `startService()`, or at least one that is equivalent (e.g., identifies the same class). At that point, the service will stop and will be destroyed. Note that `stopService()` does not employ any sort of reference counting, so three calls to `startService()` will result in a single service running, which will be stopped by a call to `stopService()`.

Another possibility for stopping a service is to have the service call `stopSelf()` on itself. You might do this if you use `startService()` to have a service begin running and doing some work on a background thread, then having the service stop itself when that background work is completed.

Binding to Services

Another approach to communicating with a service is to use the binding pattern. Here, instead of packaging commands to be sent via an Intent, you can obtain an actual API from the service, with whatever data types, return values, and so on that you wish. You then invoke that API no different than you would on some local object.

The benefit is the richer API. The cost is that binding is more complex to set up and more complex to maintain, particularly across configuration changes.

We will discuss the binding pattern [later in this book](#).

Scenario: The Music Player

Most audio player applications in Android — for music, audiobooks, or whatever — do not require the user to remain in the player application itself. Rather, the user can go on and do other things with their device, with the audio playing in the background.

The sample project reviewed in this section is [Service/FakePlayer](#).

The Design

We will use `startService()`, since we want the service to run even when the activity starting it has been destroyed. However, we will use a regular `Service`, rather than an `IntentService`. An `IntentService` is designed to do work and stop itself, whereas in this case, we want the user to be able to stop the music playback when the user wants to.

Since music playback is outside the scope of this chapter, the service will simply stub out those particular operations.

The Service Implementation

Here is the implementation of this `Service`, named `PlayerService`:

```
package com.commonware.android.fakeplayer;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.util.Log;

public class PlayerService extends Service {
    public static final String EXTRA_PLAYLIST="EXTRA_PLAYLIST";
    public static final String EXTRA_SHUFFLE="EXTRA_SHUFFLE";
    private boolean isPlaying=false;

    @Override
    public int onStartCommand(Intent intent, int flags, int startId) {
        String playlist=intent.getStringExtra(EXTRA_PLAYLIST);
        boolean useShuffle=intent.getBooleanExtra(EXTRA_SHUFFLE, false);

        play(playlist, useShuffle);

        return(START_NOT_STICKY);
    }

    @Override
    public void onDestroy() {
```

```
    stop();
}

@Override
public IBinder onBind(Intent intent) {
    return(null);
}

private void play(String playlist, boolean useShuffle) {
    if (!isPlaying) {
        Log.w(getClass().getName(), "Got to play!");
        isPlaying=true;
    }
}

private void stop() {
    if (isPlaying) {
        Log.w(getClass().getName(), "Got to stop!");
        isPlaying=false;
    }
}
}
```

In this case, we really do not need anything for `onCreate()`, so that lifecycle method is skipped. On the other hand, we have to implement `onBind()`, because that is an abstract method on `Service`.

When the client calls `startService()`, `onStartCommand()` is called in `PlayerService`. Here, we get the `Intent` and pick out some extras to tell us what to play back (`EXTRA_PLAYLIST`) and other configuration details (e.g., `EXTRA_SHUFFLE`). `onStartCommand()` calls `play()`, which simply flags that we are playing and logs a message to `LogCat` — a real music player would use `MediaPlayer` to start playing the first song in the playlist. `onStartCommand()` returns `START_NOT_STICKY`, indicating that if Android terminates the process (e.g., low memory), it should not restart it once conditions improve.

`onDestroy()` stops the music from playing — theoretically, anyway — by calling a `stop()` method. Once again, this just logs a message to `LogCat`, plus updates our internal are-we-playing flag.

In [the upcoming chapter on notifications](#), we will revisit this sample and discuss the use of `startForeground()` to make it easier for the user to get back to the music player, plus let Android know that the service is delivering part of the foreground experience and therefore should not be shut down.

Using the Service

The PlayerFragment demonstrating the use of PlayerService has a very elaborate UI, consisting of two large buttons:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/start"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/start_the_player"/>

    <Button
        android:id="@+id/stop"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="@string/stop_the_player"/>

</LinearLayout>
```

The fragment itself is not much more complex:

```
package com.commonware.android.fakeplayer;

import android.app.Fragment;
import android.content.Intent;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class PlayerFragment extends Fragment implements
    View.OnClickListener {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup parent,
        Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.main, parent, false);

        result.findViewById(R.id.start).setOnClickListener(this);
        result.findViewById(R.id.stop).setOnClickListener(this);

        return(result);
    }

    @Override
    public void onClick(View v) {
        Intent i=new Intent(getActivity(), PlayerService.class);

        if (v.getId() == R.id.start) {
```

```
i.putExtra(PlayerService.EXTRA_PLAYLIST, "main");
i.putExtra(PlayerService.EXTRA_SHUFFLE, true);

getActivity().startService(i);
}
else {
    getActivity().stopService(i);
}
}
```

The `onCreateView()` method merely loads the UI. The `onClick()` method constructs an `Intent` with fake values for `EXTRA_PLAYLIST` and `EXTRA_SHUFFLE`, then calls `startService()`. After you press the “Start” button, you will see the corresponding message in LogCat. Similarly, `stopPlayer()` calls `stopService()`, triggering the second LogCat message. Notably, you do not need to keep the activity running in between those button clicks — you can exit the activity via `BACK` and come back later to stop the service.

Communicating *From* Services

Sending commands to a service, by default, is a one-way street. Frequently, though, we need to get results from our service back to our activity. There are a few approaches for how to accomplish this.

Broadcast Intents

One approach, first mentioned in the chapter on [Intent filters](#), is to have the service send a broadcast `Intent` that can be picked up by the activity... assuming the activity is still around and is not paused. The service can call `sendBroadcast()`, supplying an `Intent` that identifies the broadcast, designed to be picked up by a `BroadcastReceiver`. This could be a component-specific broadcast (e.g., `new Intent(this, MyReceiver.class)`), if the `BroadcastReceiver` is registered in the manifest. Or, it can be based on some action string, perhaps one even documented and designed for third-party applications to listen for.

The activity, in turn, can register a `BroadcastReceiver` via `registerReceiver()`, though this approach will only work for `Intent` objects specifying some action, not ones identifying a particular component. But, when the activity’s `BroadcastReceiver` receives the broadcast, it can do what it wants to inform the user or otherwise update itself.

However, for local services, this is not a good choice. System broadcasts like this are intrinsically system-wide; for a local service, you should be using a communications channel that is private to your process.

Pending Results

Your activity can call `createPendingResult()`. This returns a `PendingIntent` – an object that represents an `Intent` and the corresponding action to be performed upon that `Intent` (e.g., use it to start an activity). In this case, the `PendingIntent` will cause a result to be delivered to your activity's implementation of `onActivityResult()`, just as if another activity had been called with `startActivityForResult()` and, in turn, called `setResult()` to send back a result.

Since a `PendingIntent` is [Parcelable](#), and can therefore be put into an `Intent` extra, your activity can pass this `PendingIntent` to the service. The service, in turn, can call one of several flavors of the `send()` method on the `PendingIntent`, to notify the activity (via `onActivityResult()`) of an event, possibly even supplying data (in the form of an `Intent`) representing that event.

We will be seeing `PendingIntent` used many places later in this book, such as with notifications and `AlarmManager`.

Event Buses

Event bus implementations — like `LocalBroadcastManager` or `greenrobot's EventBus` — are a great solution for having a service communicate with objects elsewhere within your process. You can have the service raise events (e.g., `NewEmailEvent`, `UploadCompletedEvent`, `MartiansHaveLandedEvent`), which activities or fragments can listen for and respond to.

Messenger

Yet another possibility is to use a `Messenger` object. A `Messenger` sends messages to an activity's `Handler`. Within a single activity, a `Handler` can be used to send messages to itself, as was mentioned briefly in the [chapter on threads](#). However, between components — such as between an activity and a service — you will need a `Messenger` to serve as the bridge.

As with a `PendingIntent`, a `Messenger` is `Parcelable`, and so can be put into an `Intent` extra. The activity calling `startService()` or `bindService()` would attach a

Messenger as an extra on the Intent. The service would obtain that Messenger from the Intent. When it is time to alert the activity of some event, the service would:

1. Call `Message.obtain()` to get an empty `Message` object
2. Populate that `Message` object as needed, with whatever data the service wishes to pass to the activity
3. Call `send()` on the `Messenger`, supplying the `Message` as a parameter

The `Handler` will then receive the message via `handleMessage()`, on the main application thread, and so can update the UI or whatever is necessary.

Notifications

Another approach is for the service to let the user know directly about the work that was completed. To do that, a service can raise a `Notification` — putting an icon in the status bar and optionally shaking or beeping or something. This technique is covered in [an upcoming chapter](#).

We can also combine these techniques, such as using an event bus event and detecting when nothing in the UI layer receives the event, so we know that we need to display a `Notification`. We will be examining this pattern later in the book as well.

Scenario: The Downloader

If you elect to download something from the Play Store, you are welcome to back out of the Play Store application entirely. This does not cancel the download – the download and installation run to completion, despite no Play Store activity being on-screen.

You may have similar circumstances in your application, from downloading a purchased e-book to downloading a map for a game to downloading a file from some sort of “drop box” file-sharing service. And, perhaps `DownloadManager` is not going to be a great choice, for any number of reasons (e.g., you want to download the file to internal storage).

The sample project reviewed in this section is [Service/Downloader](#), which implements such a downloading service.

The Design

This sort of situation is a perfect use for the command pattern and an `IntentService`. The `IntentService` has a background thread, so downloads can take as long as needed. An `IntentService` will automatically shut down when the work is done, so the service will not linger and you do not need to worry about shutting it down yourself. Your activity can simply send a command via `startService()` to the `IntentService` to tell it to go do the work.

Admittedly, things get a bit trickier when you want to have the activity find out when the download is complete. This example will show the use of `LocalBroadcastManager` for this.

Using the Service

The `DownloadFragment` demonstrating the use of `Downloader` has a trivial UI, consisting of one large button:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/button"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/do_the_download"
/>
```

That UI is initialized in `onCreateView()`, as usual:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, parent, false);

    b=(Button)result.findViewById(R.id.button);
    b.setOnClickListener(this);

    return(result);
}
```

When the user clicks the button, `onClick()` is called to disable the button (to prevent accidental duplicate downloads) and call `startService()` to send over a command:

```
@Override
public void onClick(View v) {
    b.setEnabled(false);

    Intent i=new Intent(getActivity(), Downloader.class);
```

```
i.setData(Uri.parse("https://commonsware.com/Android/excerpt.pdf"));
getActivity().startService(i);
}
```

Here, the Intent we pass over has the URL of the file to download (in this case, a URL pointing to a PDF).

The Service Implementation

Here is the implementation of this IntentService, named Downloader:

```
package com.commonsware.android.downloader;

import android.app.IntentService;
import android.content.Intent;
import android.os.Environment;
import android.support.v4.content.LocalBroadcastManager;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class Downloader extends IntentService {
    public static final String ACTION_COMPLETE=
        "com.commonsware.android.downloader.action.COMPLETE";

    public Downloader() {
        super("Downloader");
    }

    @Override
    public void onHandleIntent(Intent i) {
        try {
            File root=
                Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

            root.mkdirs();

            File output=new File(root, i.getData().getLastPathSegment());

            if (output.exists()) {
                output.delete();
            }

            URL url=new URL(i.getData().toString());
            HttpURLConnection c=(HttpURLConnection)url.openConnection();

            FileOutputStream fos=new FileOutputStream(output.getPath());
            BufferedOutputStream out=new BufferedOutputStream(fos);
```

```
try {
    InputStream in=c.getInputStream();
    byte[] buffer=new byte[8192];
    int len=0;

    while ((len=in.read(buffer)) >= 0) {
        out.write(buffer, 0, len);
    }

    out.flush();
}
finally {
    fos.getFD().sync();
    out.close();
    c.disconnect();
}

LocalBroadcastManager.getInstance(this)
    .sendBroadcast(new Intent(ACTION_COMPLETE));
}
catch (IOException e2) {
    Log.e(getClass().getName(), "Exception in download", e2);
}
}
```

Our business logic is in `onHandleIntent()`, which is called on an Android-supplied background thread, so we can take whatever time we need. Also, when `onHandleIntent()` ends, the `IntentService` will stop itself automatically... assuming no other requests for downloads occurred while `onHandleIntent()` was running. In that case, `onHandleIntent()` is called again for the next download, and so on.

In `onHandleIntent()`, we first set up a `File` object pointing to where we want to download the file. We use `getExternalStoragePublicDirectory()` to find the public folder for downloads. Since this directory may not exist, we need to create it using `makedirs()`. We then use the `getLastPathSegment()` convenience method on `Uri`, which returns to us the filename portion of a path-style `Uri`. The result is that our output `File` object points to a file, named the same as the file we are downloading, in a public folder.

We then go through a typical `URLConnection` process to connect to the URL supplied via the `Uri` in the `Intent`, streaming the results from the connection (8KB at a time) out to our designated file. Then, we follow the requested recipe to ensure our file is saved:

- `flush()` the stream
- `sync()` the `FileDescriptor` (from `getFD()`)
- `close()` the stream

This recipe was explained back in [the chapter on file I/O](#).

Finally, it would be nice to let somebody know that the download has completed. So, we send a local broadcast Intent, with our own custom action (ACTION_COMPLETE), using LocalBroadcastManager.

Receiving the Broadcast

Our DownloadFragment is set up to listen for that local broadcast Intent, by registering a local BroadcastReceiver in onResume() and unregistering it in onPause():

```
@Override
public void onResume() {
    super.onResume();

    IntentFilter f=new IntentFilter(Downloader.ACTION_COMPLETE);

    LocalBroadcastManager.getInstance(getActivity())
        .registerReceiver(onEvent, f);
}

@Override
public void onPause() {
    LocalBroadcastManager.getInstance(getActivity())
        .unregisterReceiver(onEvent);

    super.onPause();
}
```

The BroadcastReceiver itself re-enables our button, plus displays a Toast indicating that the download is complete:

```
private BroadcastReceiver onEvent=new BroadcastReceiver() {
    public void onReceive(Context ctxt, Intent i) {
        b.setEnabled(true);

        Toast.makeText(getActivity(), R.string.download_complete,
            Toast.LENGTH_LONG).show();
    }
};
```

Note that if the user leaves the activity (e.g., BACK, HOME), the broadcast will not be received by the activity. There are other ways of addressing this, particularly combining an ordered broadcast with a Notification, which we will examine [later in this book](#).

Services and Configuration Changes

Services are not directly affected by configuration changes the way that activities are. While activities will be destroyed and recreated by default, services continue running if they were created.

Usually, services do not really care about configuration changes. However, if you have a service that *does* care, you can override `onConfigurationChanged()` in the service.

This means that you have two choices for dealing with configuration changes: override `onConfigurationChanged()` or simply re-read in the configuration information as needed. For example, suppose that you need to know the user's chosen locale, to include as information in a Web service call. If you are checking the locale on each Web service call, your service does not need to know about configuration changes. If, on the other hand, you prefer to cache the locale data, reading it in from the `Locale` class when the service is created, you will want to override `onConfigurationChanged()` and update that cache, in case the configuration change was a locale change.

Tutorial #16 - Updating the Book

The app is designed to ship a copy of the book's chapters as assets, so a user can just download one thing and get everything they need: book and reader.

However, sometimes books get updated. This is a bit less likely with the material being used in this tutorial, as it is rather unlikely that H. G. Wells will rise from the grave to amend *The War of the Worlds*. However, other books, such as Android developer guides written by balding guys, might be updated more frequently.

Most likely, the way you would get those updates is by updating the entire app, so you get improvements to the reader as well. However, another approach would be to be able to download an update to the book as a separate ZIP file. The reader would use the contents of that ZIP file if one has been downloaded, otherwise it will “fall back” to the copy in assets. That is the approach that we will take in this tutorial, to experiment a bit with Internet access and services. Along the way, we will use [Retrofit](#) to call a Web service (of sorts) to find out if an update is available.

This is a continuation of the work we did in [the previous tutorial](#).

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book's GitHub repository:

Step #1: Adding a Stub DownloadCheckService

There are a few pieces to our download-the-book-update puzzle:

- We need to determine if there is an update available and, if so, where we can find the ZIP file that is the update
- We need to download the update's ZIP file, which could be a fairly large file

TUTORIAL #16 - UPDATING THE BOOK

- We need to unpack that ZIP file into internal or external storage, so that it is more easily used by the rest of our code and performs more quickly than would dynamically reading the contents out of the ZIP on the fly
- All of that needs to happen in the background from a threading standpoint
- Ideally, all of that could happen either in the foreground or the background from a UI standpoint (i.e., user manually requests an update check, or an update check is performed automatically on a scheduled basis)

To address the first puzzle piece — determining if there is an update available — we can use an `IntentService`. That makes it easy for us to do the work not only in the background from a threading standpoint, but also be able to use it either from the UI or from some sort of background-work scheduler. So, let's add a `DownloadCheckService` to our project.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Service > "Service (IntentService)"` from the context menu. Fill in `DownloadCheckService` as the class name and uncheck the "helper methods" checkbox. Click `Finish` to generate the `DownloadCheckService` class and add an entry for you to the manifest.

Then, replace the generated implementation of `DownloadCheckService` with:

```
package com.commonware.empublite;

import android.app.IntentService;
import android.content.Intent;

public class DownloadCheckService extends IntentService {
    public DownloadCheckService() {
        super("DownloadCheckService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
    }
}
```

Also, add the corresponding `<service>` element to the manifest:

```
<service android:name="DownloadCheckService"></service>
```

Step #2: Tying the Service Into the Action Bar

To allow the user to manually request that we update the book (if an update is available), we should add a new action bar item to `EmPubLiteActivity`.

Modify the `res/menu/options.xml` file to include the following `<item>` element:

```
<item
  android:id="@+id/update"
  android:icon="@drawable/ic_action_refresh"
  android:showAsAction="ifRoom|withText"
  android:title="@string/download_update">
</item>
```

Note that this menu definition requires a new string resource, named `download_update`, with a value like `Download Update`.

That allows us to add a new case to the switch statement in `onOptionsItemSelected()` in `EmPubLiteActivity`:

```
case R.id.update:
    startService(new Intent(this, DownloadCheckService.class));

return(true);
```

All we do here is send a command to our `DownloadCheckService` to see if a download is available.

Step #3: Defining Our Event

Our `IntentService` will do the work of updating the book in the background. However, we will want to let the rest of the app know when the book is updated. In particular, the `ModelFragment`, if it exists, needs to know that there is a new set of book contents to display. To accomplish this, we can use another event on our `EventBus`, a `BookUpdatedEvent` in this case.

Right-click over the `com.commonware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookUpdatedEvent` as the name and click `OK` to create the empty class.

Step #4: Defining Our JSON

Under the covers, `Retrofit` uses `GSON` for parsing the JSON it retrieves from the Web service (or other URL). Hence, just as we needed to define a Java class that models our JSON for the book contents, we need a Java class that models the data we will get from our server as to whether or not a book update is available.

That JSON looks like:

TUTORIAL #16 - UPDATING THE BOOK

```
{
  "updatedOn": "20120512",
  "updateUrl": "http://misc.commonsware.com/WarOfTheWorlds-Update.zip"
}
```

We can create a `BookUpdateInfo` class that mimics this structure.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookUpdateInfo` as the name and click OK to create the empty class.

Then, with `BookUpdateInfo` open in the editor, paste in the following class definition:

```
package com.commonsware.empublite;

public class BookUpdateInfo {
    String updatedOn;
    String updateUrl;
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Step #5: Defining Our Retrofit Interface

Retrofit then needs a Java *interface* that provides most of the details for how to fetch our JSON and convert it into a Java object. In our case, we will be using an HTTP GET operation to retrieve the JSON, and so we will use the Retrofit `@GET` annotation to point to a path on a server pointing to that JSON.

Right-click over the `com.commonsware.empublite` package in your `java/` directory and choose `New > Java Class` from the context menu. Fill in `BookUpdateInterface` as the name, switch the “Kind” to be “Interface”, and click OK to create the empty interface.

Then, with `BookUpdateInterface` open in the editor, paste in the following interface definition:

```
package com.commonsware.empublite;

import retrofit.http.GET;

public interface BookUpdateInterface {
    @GET("/misc/empublite-update.json")
}
```

```
BookUpdateInfo update();  
}
```

If you prefer, you can view this file's contents in your Web browser via [this GitHub link](#).

Here, we define our interface as having an `update()` method, returning an instance of our `BookUpdateInfo` structure, with the `@GET` annotation pointing to a path where the corresponding JSON can be found on a server to be designated later.

Step #6: Retrieving Our JSON Via Retrofit

Now, we can actually use Retrofit to retrieve our `BookUpdateInfo` and see if we have a book update.

First, we need to add the `INTERNET` permission to our app, as we are going to be downloading materials from the `INTERNET`.

Android Studio users can add the following `<uses-permission>` element as children of the root `<manifest>` element in `AndroidManifest.xml`:

```
<uses-permission android:name="android.permission.INTERNET" />
```

Next, in `DownloadCheckService`, add an `OUR_BOOK_DATE` static data member, representing the edit date of the book baked into our APK, in `YYYYMMDD` format:

```
private static final String OUR_BOOK_DATE="20120418";
```

Then, add a `getUpdateUrl()` method to `DownloadCheckService`:

```
private String getUpdateUrl() {  
    RestAdapter restAdapter=  
        new RestAdapter.Builder().setEndpoint("https://commonsware.com")  
            .build();  
    BookUpdateInterface updateInterface=  
        restAdapter.create(BookUpdateInterface.class);  
    BookUpdateInfo info=updateInterface.update();  
  
    if (info.updatedOn.compareTo(OUR_BOOK_DATE) > 0) {  
        return(info.updateUrl);  
    }  
  
    return(null);  
}
```

TUTORIAL #16 - UPDATING THE BOOK

Here, we create a Retrofit RestAdapter, pointing to the server that is our “Web service” (really a static JSON file, but that does not matter from the standpoint of the client code). We then use the RestAdapter to create an instance of a BookUpdateInterface implementation, code-generated by Retrofit. We then call update() on that object to get our BookUpdateInfo. If the date in the updatedOn field of our BookUpdateInfo is newer than OUR_BOOK_DATE, we return the updateUrl field of the BookUpdateInfo, which will be a URL pointing to a ZIP archive containing the updated book. If the updatedOn value is older than OUR_BOOK_DATE, we return null to signify that no updates are available.

This is not a particularly well-optimized approach. In particular, we never take into account that, once we have downloaded an update, we are only interested in updates newer than the one we downloaded. As it stands, we always compare the updatedOn value to OUR_BOOK_DATE, not the last updatedOn value that we used. A production-grade app would aim to handle this, such as by saving the last-used updatedOn value in a SharedPreferences and comparing against it, where available.

Finally, update onHandleIntent() to call getUpdateUrl():

```
@Override
protected void onHandleIntent(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            // do something really cool here
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception downloading update", e);
    }
}
```

Step #7: Downloading the Update

While the above code gets us the URL of the ZIP archive, it does not actually download it. We need more code to accomplish that.

Add a private static final String data member named UPDATE_FILENAME to DownloadCheckService, representing the name of the file to be stored locally representing the downloaded ZIP file:

```
private static final String UPDATE_FILENAME="book.zip";
```

TUTORIAL #16 - UPDATING THE BOOK

Then, in `DownloadCheckService`, add the following `download()` method:

```
private File download(String url) throws IOException {
    File output=new File(getFilesDir(), UPDATE_FILENAME);

    if (output.exists()) {
        output.delete();
    }

    OkHttpClient client=new OkHttpClient();
    Request request=new Request.Builder().url(url).build();
    Response response=client.newCall(request).execute();
    BufferedSink sink=Okio.buffer(Okio.sink(output));

    sink.writeAll(response.body().source());
    sink.close();

    return(output);
}
```

This method deletes the existing output file if it exists, then uses `OkHttp` (and its `Okio` transitive dependency) to download the book, writing the results to the designated output file.

Then, update `onHandleIntent()` in `DownloadCheckService` to call `download()` when we have something to download:

```
@Override
protected void onHandleIntent(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            File book=download(url);

            // do something almost as cool here

            book.delete();
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception downloading update", e);
    }
}
```

Here, we delete the file after downloading it, so we do not clutter up our internal storage with the downloaded ZIP. This would appear to defeat the purpose of downloading the ZIP file in the first place, but we will add some code to use the ZIP file in the next step of the tutorial.

Step #8: Unpacking the Update

The last step in the book-download process is to unpack the ZIP archive onto internal storage, so we can start using the downloaded contents.

Add a public static final String data member named UPDATE_BASEDIR to DownloadCheckService:

```
public static final String UPDATE_BASEDIR="updates";
```

This will point to the directory on internal storage where the latest book update will reside.

Then, update onHandleIntent() on DownloadCheckService once again, this time to add in a call to ZipUtils.unzip() and some other necessary changes:

```
@Override
protected void onHandleIntent(Intent intent) {
    try {
        String url=getUpdateUrl();

        if (url != null) {
            File book=download(url);
            File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);

            updateDir.mkdirs();
            ZipUtils.unzip(book, updateDir);
            book.delete();
            EventBus.getDefault().post(new BookUpdatedEvent());
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception downloading update", e);
    }
}
```

Here, we:

- Create the UPDATE_BASEDIR directory if it does not already exist
- Call ZipUtils.unzip() to unZIP the ZIP file into that directory
- Post a BookUpdatedEvent to signify that a book update is ready

ZipUtils is a class from the CWAC-Security library that we added to our project back in tutorial #6. Its unzip() method handles a variety of possible flaws in the ZIP archive that might be injected by an attacker who is intercepting our communications with the book update server.

TUTORIAL #16 - UPDATING THE BOOK

Despite that, this update logic is a bit sloppy. It is possible that different book updates will have different files, and our UPDATE_BASEDIR will have some extra files as a result. Ideally, we should clean out UPDATE_BASEDIR before unpacking the ZIP archive. Adding in some recursive delete-all-the-files-in-a-directory logic is left as an exercise for the reader.

At this point, DownloadCheckService should resemble:

```
package com.commonware.empublite;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;
import com.commonware.cwac.security.ZipUtils;
import com.squareup.okhttp.OkHttpClient;
import com.squareup.okhttp.Request;
import com.squareup.okhttp.Response;
import java.io.File;
import java.io.IOException;
import de.greenrobot.event.EventBus;
import okio.BufferedSink;
import okio.Okio;
import retrofit.RestAdapter;

public class DownloadCheckService extends IntentService {
    private static final String OUR_BOOK_DATE="20120418";
    private static final String UPDATE_FILENAME="book.zip";
    private static final String UPDATE_BASEDIR="updates";

    public DownloadCheckService() {
        super("DownloadCheckService");
    }

    @Override
    protected void onHandleIntent(Intent intent) {
        try {
            String url=getUpdateUrl();

            if (url != null) {
                File book=download(url);
                File updateDir=new File(getFilesDir(), UPDATE_BASEDIR);

                updateDir.mkdirs();
                ZipUtils.unzip(book, updateDir);
                book.delete();
                EventBus.getDefault().post(new BookUpdatedEvent());
            }
        } catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception downloading update", e);
        }
    }

    private String getUpdateUrl() {
        RestAdapter restAdapter=
```

TUTORIAL #16 - UPDATING THE BOOK

```
        new RestAdapter.Builder().setEndpoint("https://commonsware.com")
            .build();
        BookUpdateInterface updateInterface=
            restAdapter.create(BookUpdateInterface.class);
        BookUpdateInfo info=updateInterface.update();

        if (info.updatedOn.compareTo(OUR_BOOK_DATE) > 0) {
            return(info.updateUrl);
        }

        return(null);
    }

    private File download(String url) throws IOException {
        File output=new File(getFilesDir(), UPDATE_FILENAME);

        if (output.exists()) {
            output.delete();
        }

        OkHttpClient client=new OkHttpClient();
        Request request=new Request.Builder().url(url).build();
        Response response=client.newCall(request).execute();
        BufferedSink sink=Okio.buffer(Okio.sink(output));

        sink.writeAll(response.body().source());
        sink.close();

        return(output);
    }
}
```

Step #9: Using the Update

All this work is nice. However, nothing else in the app knows about this UPDATE_BASEDIR copy of the book to actually display it.

In fact, we have two scenarios to consider:

- The user taps the update action bar item, and we download the update and want to show the updated book to the user right now
- Later on, when the user opens the book, we need to realize that we already have an update and use it, rather than using the copy baked into the APK

That will require some changes to our data model, how we populate it from ModelFragment, and how we use the results in our ContentsAdapter.

First, add a File baseDir data member to BookContents, along with an accompanying setter method:

TUTORIAL #16 - UPDATING THE BOOK

```
File baseDir=null;

void setBaseDir(File baseDir) {
    this.baseDir=baseDir;
}
```

Then, add a `getChapterPath()` method to `BookContents` that uses `getChapterFile()` for getting the relative path from the book's JSON, then uses that in conjunction with `baseDir` or the `android_asset` path to come up with a full `WebView`-friendly path to the file, whether it is in assets or a local file:

```
String getChapterPath(int position) {
    String file=getChapterFile(position);

    if (baseDir == null) {
        return("file:///android_asset/book/" + file);
    }

    return(Uri.fromFile(new File(baseDir, file)).toString());
}
```

Next, change the `getItem()` method on `ContentsAdapter` to use this new `getChapterPath()` method on `BookContents`:

```
@Override
public Fragment getItem(int position) {
    return(SimpleContentFragment.newInstance(contents.getChapterPath(position)));
}
```

Then, modify the `run()` method of the `LoadThread` in `ModelFragment` to try to use the update:

```
@Override
public void run() {
    Process.setThreadPriority(Process.THREAD_PRIORITY_BACKGROUND);

    synchronized(this) {
        prefs=PreferenceManager.getDefaultSharedPreferences(ctxt);
    }

    Gson gson=new Gson();
    File baseDir=
        new File(ctxt.getFilesDir(),
            DownloadCheckService.UPDATE_BASEDIR);

    try {
        InputStream is;

        if (baseDir.exists()) {
            is=new FileInputStream(new File(baseDir, "contents.json"));
        }
        else {
            is=ctxt.getAssets().open("book/contents.json");
        }
    }
```

TUTORIAL #16 - UPDATING THE BOOK

```
BufferedReader reader=
    new BufferedReader(new InputStreamReader(is));

synchronized(this) {
    contents=gson.fromJson(reader, BookContents.class);
}

is.close();

if (baseDir.exists()) {
    contents.setBaseDir(baseDir);
}

EventBus.getDefault().post(new BookLoadedEvent(contents));
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
}
}
```

Here, we do the following, in addition to our original logic:

- See if the UPDATE_BASEDIR directory exists or not
- If it does, we use the contents.json in it; otherwise, we fall back to the one in assets/ as before
- Update the BookContents with the update directory if we used that for loading the contents

This will handle the case where an update exists when we fire up the app and go to view the book. However, we still need some code that responds to the BookUpdatedEvent and arranges to use the updated contents at that point.

With that in mind, augment onAttach() on ModelFragment to register with the EventBus:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    EventBus.getDefault().register(this);

    if (contents==null) {
        new LoadThread(host).start();
    }
}
```

We also now need a corresponding onDetach() method on ModelFragment to unregister from the EventBus:

TUTORIAL #16 - UPDATING THE BOOK

```
@Override
public void onDetach() {
    EventBus.getDefault().unregister(this);

    super.onDetach();
}
```

Finally, we can respond to the `BookUpdatedEvent`, via a new `onEventBackgroundThread()` method on `ModelFragment`:

```
@SuppressWarnings("unused")
public void onEventBackgroundThread(BookUpdatedEvent event) {
    if (getActivity() != null) {
        new LoadThread(getActivity()).start();
    }
}
```

The name `onEventBackgroundThread()` signals to the `EventBus` that we want to receive this event on a background thread. In our case, the event is posted on a background thread (the one from the `IntentService`). Hence, our `onEventBackgroundThread()` method is called on that thread. If, however, we were to post a `BookUpdatedEvent` from the main application thread, `EventBus` would deliver our `BookUpdatedEvent` to `onEventBackgroundThread()` on an `EventBus-supplied` background thread, to ensure that we do not tie up the main application thread.

Here, we just kick off a fresh `LoadThread` to reload the `BookContents`, assuming that the user has not just pressed `BACK` or otherwise destroyed our activity. The new `LoadThread` will see that the update is available and use it, posting its own event to have our UI layer apply the update to the screen.

At this point, if you build and run the app, you will see the update action bar item:

TUTORIAL #16 - UPDATING THE BOOK

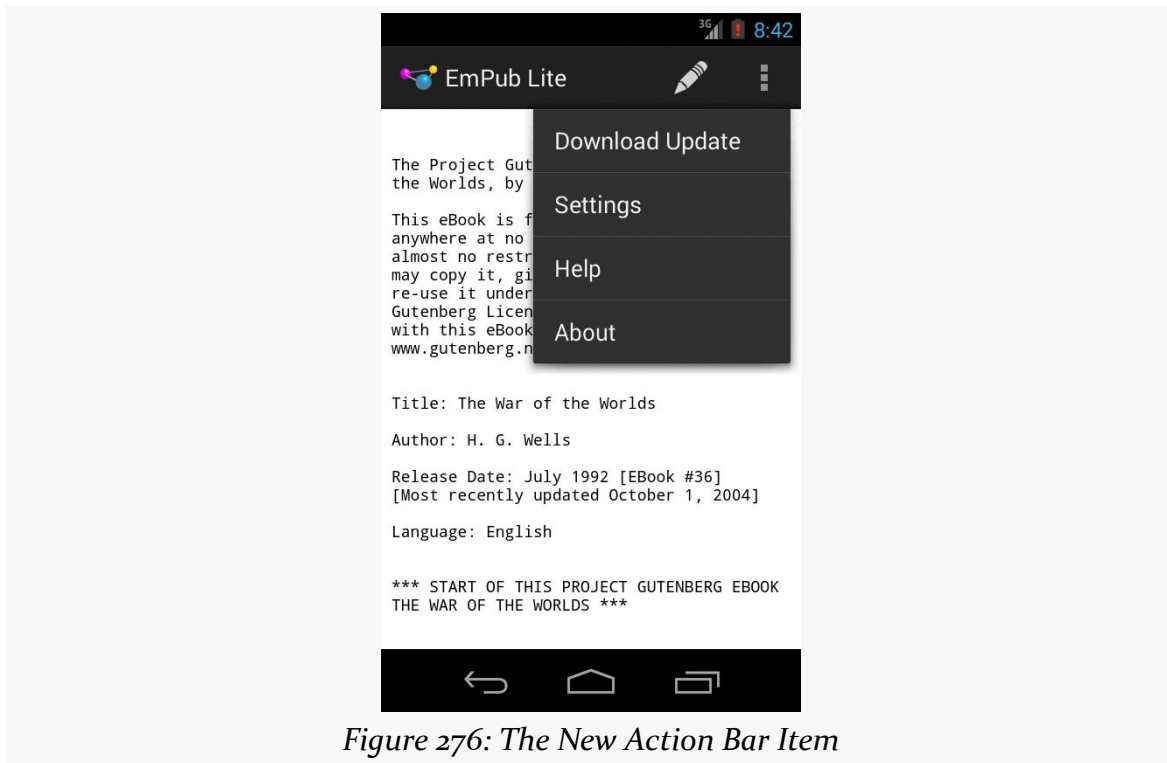

Figure 276: The New Action Bar Item

Swiping back to the first page in the ViewPager, tapping that action bar item, and waiting a few moments, should cause your book to be updated with new contents downloaded from the Internet:

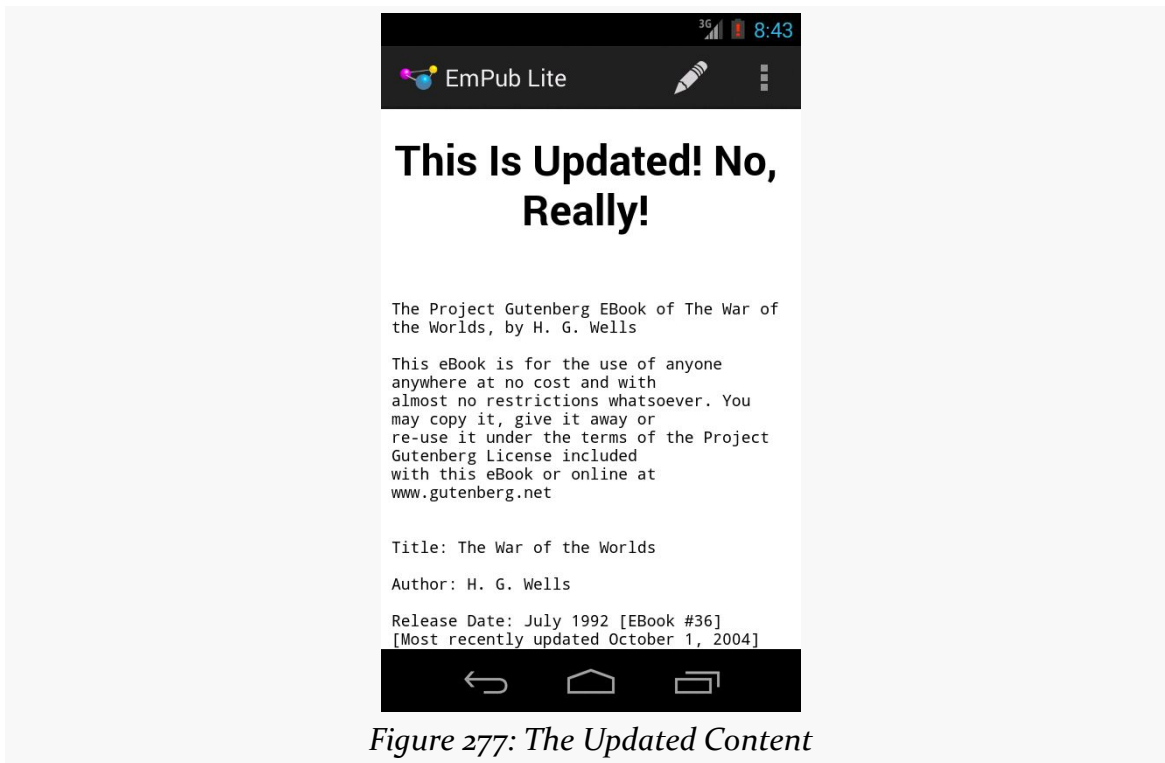

Figure 277: The Updated Content

In Our Next Episode...

... we will [move some fragments into a sidebar](#) on large-screen devices, like tablets.

Large-Screen Strategies and Tactics

So far, we have been generally ignoring screen size. With the vast majority of Android devices being in a fairly narrow range of sizes (3" to just under 5"), ignoring size while learning is not a bad approach. However, when it comes time to create a production app, you are going to want to strongly consider how you are going to handle other sizes, mostly larger ones (e.g., tablets).

Objective: Maximum Gain, Minimum Pain

What you want is to be able to provide a high-quality user experience without breaking your development budget — time *and* money — in the process.

An app designed around a phone, by default, may look fairly lousy on a tablet. That is because Android is simply going to try to stretch your layouts and such to fill the available space. While that will work, technically, the results may be unpleasant, or at least ineffective. If we have the additional room, it would be nice to allow the user to do something with that room.

At the same time, though, you do not have an infinite amount of time to be dealing with all of this. After all, there are a variety of tablet sizes. While ~7" and ~10" screens are the most common, there are certainly others that are reasonably popular (e.g., Amazon's Kindle Fire HD 8.9").

The Fragment Strategy

Some apps will use the additional space of a large screen directly. For example, a painting app would use that space mostly to provide a larger drawing canvas upon which the user can attempt to become the next Rembrandt, Picasso, or Pollock. The

LARGE-SCREEN STRATEGIES AND TACTICS

app might elect to make more tools available directly on the screen as well, versus requiring some sort of pop-up to appear to allow the user to change brush styles, choose a different color, and so forth.

However, this can be a lot of work.

Some apps can make a simplifying assumption: the tablet UI is really a bunch of phone-sized layouts, stitched together. For example, if you take a 10" tablet in landscape, it is about the same size as two or three phones side-by-side. Hence, one could imagine taking the smarts out of a few activities and having them be adjacent to one another on a tablet, versus having to be visible only one at a time as they are on phones.

For example, consider the original edition of the Gmail app for Android.

On a phone, you would see conversations in a particular label on one screen:

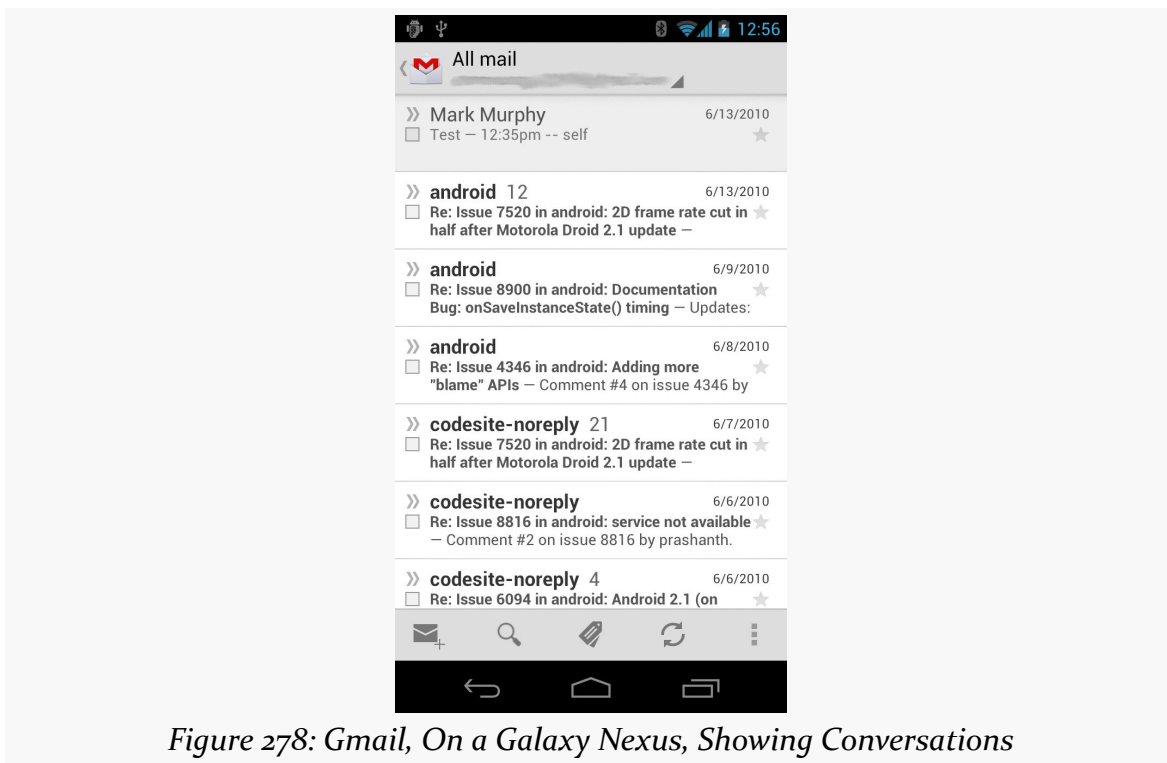

Figure 278: Gmail, On a Galaxy Nexus, Showing Conversations

... and the list of labels on another screen:

LARGE-SCREEN STRATEGIES AND TACTICS

Figure 279: Gmail, On a Galaxy Nexus, Showing Labels

... and the list of messages in some selected conversation in a third screen:

LARGE-SCREEN STRATEGIES AND TACTICS

Figure 280: Gmail, On a Galaxy Nexus, Showing Messages

Whereas on a 7" tablet, you would see the list of labels and the conversations in a selected label at the same time:

LARGE-SCREEN STRATEGIES AND TACTICS

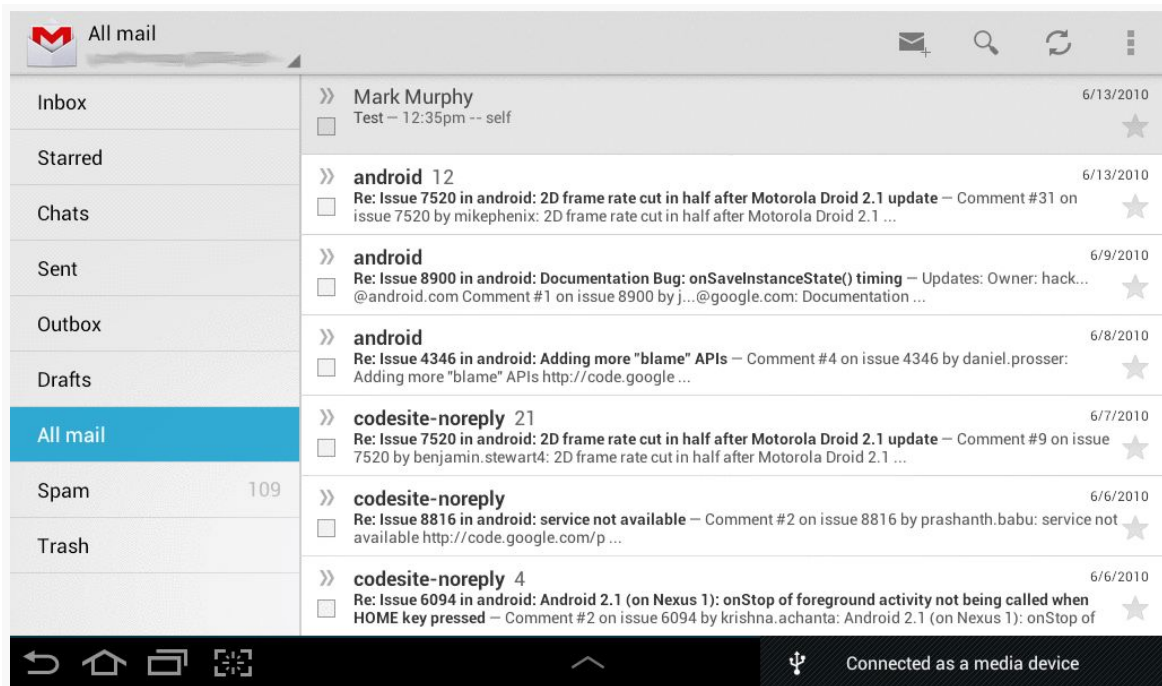

Figure 281: Gmail, On a Galaxy Tab 2, Showing Labels and Conversations

On that 7" tablet, tapping on a specific conversation brings up the list of messages for that conversation in a new screen. But, on a 10" tablet, tapping on a specific conversation showed that conversation, plus the list of conversations, side-by-side:

LARGE-SCREEN STRATEGIES AND TACTICS

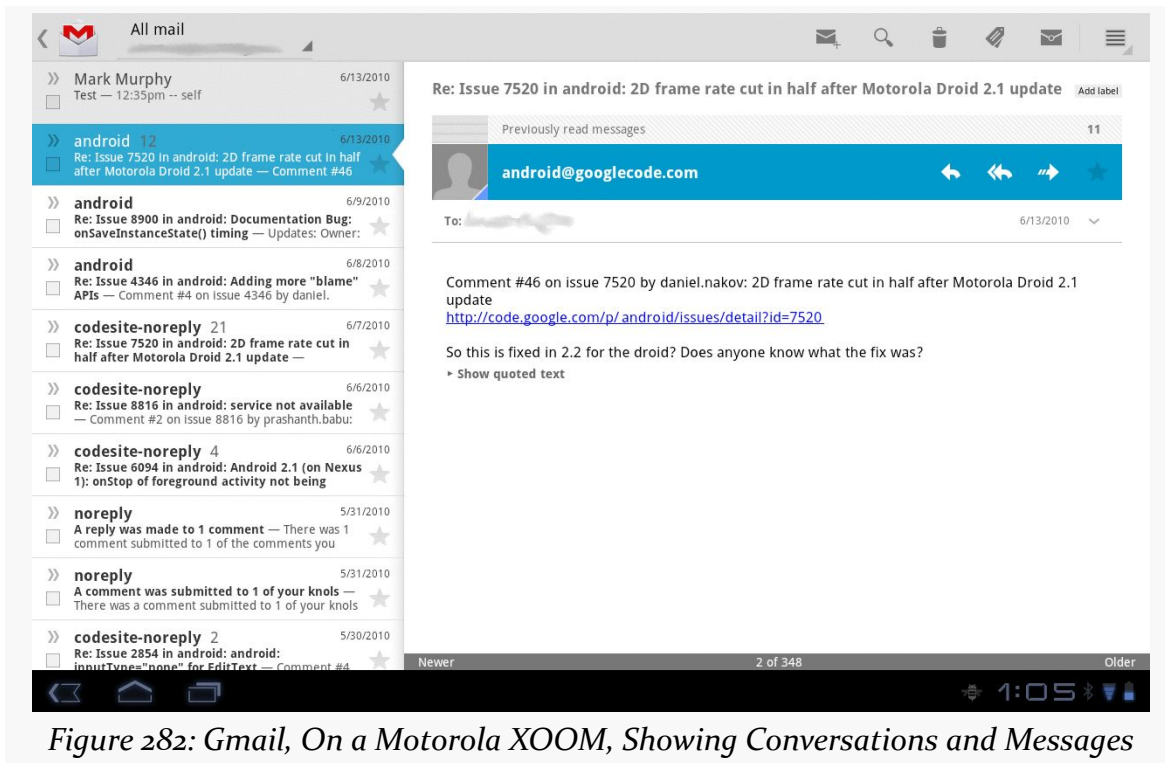

Figure 282: Gmail, On a Motorola XOOM, Showing Conversations and Messages

Yet all of that was done with one app with very little redundant logic, by means of fragments.

The list-of-labels, list-of-conversations, and list-of-messages bits of the UI were implemented as fragments. On a smaller screen (e.g., a phone), each one is displayed by an individual activity. Yet, on a larger screen (e.g., a tablet), more than one fragment is displayed by a single activity. In fact — though it will not be apparent from the static screenshots — on the 10” tablet, the activity showed *all three fragments*, using animated effects to slide the list of labels off-screen and the list of conversations over to the left slot when the user taps on a conversation to show the messages.

The vision, therefore, is to organize your UI into fragments, then choose which fragments to show in which circumstances based on available screen space:

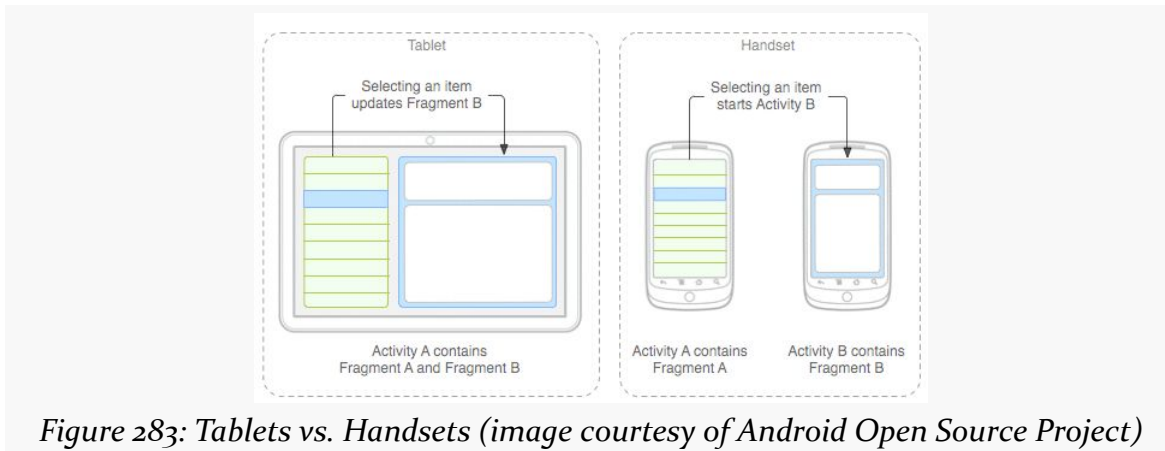

Figure 283: Tablets vs. Handsets (image courtesy of Android Open Source Project)

Changing Layout

One solution is to say that you have the same fragments for all devices and all configurations, but that the sizing and positioning of those fragments varies. This is accomplished by using different layouts for the activity, ones that provide the sizing and positioning rules for the fragments.

So far, most of our fragment examples have been focused on activities with a single fragment, like you might use on smaller screens (e.g., phones). However, activities can most certainly have more than one fragment, though you will need to provide the “slots” into which to plug those fragments.

For example, you could have the following in `res/layout-w720dp/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="horizontal"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <FrameLayout
    android:id="@+id/countries"
    android:layout_weight="30"
    android:layout_width="0px"
    android:layout_height="match_parent"
  />
  <FrameLayout
    android:id="@+id/details"
    android:layout_weight="70"
    android:layout_width="0px"
    android:layout_height="match_parent"
  />
</LinearLayout>
```

LARGE-SCREEN STRATEGIES AND TACTICS

Here we have a horizontal `LinearLayout` holding a pair of `FrameLayout` containers. Each of those `FrameLayout` containers will be a slot to load in a fragment, using code like:

```
getSupportFragmentManager().beginTransaction()  
    .add(R.id.countries, someFragmentHere)  
    .commit();
```

In principle, you could also have a `res/layout-h720dp/main.xml` that holds both of the same `FrameLayout` containers, but just in a vertical `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    android:orientation="vertical"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent">  
    <FrameLayout  
        android:id="@+id/countries"  
        android:layout_weight="30"  
        android:layout_width="0px"  
        android:layout_height="match_parent"  
    />  
    <FrameLayout  
        android:id="@+id/details"  
        android:layout_weight="70"  
        android:layout_width="0px"  
        android:layout_height="match_parent"  
    />  
</LinearLayout>
```

As the user rotates the device, the fragments will go in their appropriate slots.

Changing Fragment Mix

However, for larger changes in screen size, you will probably need to have larger changes in your fragments. The most common pattern is to have fewer fragments on-screen for an activity on a smaller-screen device (e.g., one fragment at a time on a phone) and more fragments on-screen for an activity on a larger-screen device (e.g., two fragments at a time on a tablet).

So, for example, as the counterpart to the `res/layout-w720dp/main.xml` shown in the previous section, you might have a `res/layout/main.xml` that looks like this:

```
<?xml version="1.0" encoding="utf-8"?>  
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    android:id="@+id/countries"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
>  
</FrameLayout>
```

This provides a single slot, `R.id.countries`, for a fragment, one that fills the screen. For a larger-screen device, held in landscape, you would use the two-fragment layout; for anything else (e.g., tablet in portrait, or phone in any orientation), you would use the one-fragment layout.

Of course, the content that belongs in the second fragment would have to show up *somewhere*.

Sometimes, when you add another fragment for a large screen, you only want it to be there some of the time. For example, a digital book reader (like the one we are building in the tutorials) might normally take up the full screen with the reading fragment, but might display a sidebar fragment based upon an action bar item click or the like. If you would like the BACK button to reverse your `FragmentManager` that added the second fragment — so pressing BACK removes that fragment and returns you to the single-fragment setup — you can add `addToBackStack()` as part of your `FragmentManager` construction:

```
getSupportFragmentManager().beginTransaction()  
    .addToBackStack(null)  
    .replace(R.id.sidebar, f)  
    .commit();
```

We will see this in [the next tutorial](#).

The Role of the Activity

So, what is the activity doing?

First, the activity is the one loading the overall layout, the one indicating which fragments should be loaded (e.g., the samples shown above). The activity is responsible for populating those “slots” with the appropriate fragments. It can determine which fragments to create based on which slots exist, so it would only try to create a fragment to go in `R.id.details` if there actually is an `R.id.details` slot to use.

Next, the activity is responsible for handling any events that are triggered by UI work in a fragment (e.g., user clicking on a `ListView` item), whose results should impact other fragments (e.g., displaying details of the clicked-upon `ListView` item). The activity knows which fragments exist at the present time. So, the activity can either call some method on the second fragment if it exists, or it can call `startActivity()` to pass control to another activity that will be responsible for the second fragment if it does not exist in the current activity.

Finally, the activity is generally responsible for any model data that spans multiple fragments. Whether that model data is held in a “model fragment” (as outlined [in the chapter on fragments](#)) or somewhere else is up to you.

Fragment Example: The List-and-Detail Pattern

This will make a bit more sense as we work through another example, this time focused on a common pattern: a list of something, where clicking on the list brings up details on the item that was clicked upon. On a larger-screen device, in landscape, both pieces are typically displayed at the same time, side-by-side. On smaller-screen devices, and sometimes even on larger-screen devices in portrait, only the list is initially visible — tapping on a list item brings up some other activity to display the details.

Describing the App

The sample app for this section is [LargeScreen/EU4You](#). This app has a list of member nations of the European Union (EU). Tapping on a member nation will display the mobile Wikipedia page for that nation in a WebView widget.

The data model — such as it is and what there is of it — consists of a Country class which holds onto the country name (as a string resource ID), flag (as a drawable resource ID), and mobile Wikipedia URL (as another string resource ID):

```
Country(int name, int flag, int url) {  
    this.name=name;  
    this.flag=flag;  
    this.url=url;  
}
```

The Country class has a static ArrayList of Country objects representing the whole of the EU, initialized in a static initialization block:

```
static {  
    EU.add(new Country(R.string.austria, R.drawable.austria,  
        R.string.austria_url));  
    EU.add(new Country(R.string.belgium, R.drawable.belgium,  
        R.string.belgium_url));  
    EU.add(new Country(R.string.bulgaria, R.drawable.bulgaria,  
        R.string.bulgaria_url));  
    EU.add(new Country(R.string.cyprus, R.drawable.cyprus,  
        R.string.cyprus_url));  
    EU.add(new Country(R.string.czech_republic,  
        R.drawable.czech_republic,  
        R.string.czech_republic_url));  
    EU.add(new Country(R.string.denmark, R.drawable.denmark,
```

```
        R.string.denmark_url));
EU.add(new Country(R.string.estonia, R.drawable.estonia,
    R.string.estonia_url));
EU.add(new Country(R.string.finland, R.drawable.finland,
    R.string.finland_url));
EU.add(new Country(R.string.france, R.drawable.france,
    R.string.france_url));
EU.add(new Country(R.string.germany, R.drawable.germany,
    R.string.germany_url));
EU.add(new Country(R.string.greece, R.drawable.greece,
    R.string.greece_url));
EU.add(new Country(R.string.hungary, R.drawable.hungary,
    R.string.hungary_url));
EU.add(new Country(R.string.ireland, R.drawable.ireland,
    R.string.ireland_url));
EU.add(new Country(R.string.italy, R.drawable.italy,
    R.string.italy_url));
EU.add(new Country(R.string.latvia, R.drawable.latvia,
    R.string.latvia_url));
EU.add(new Country(R.string.lithuania, R.drawable.lithuania,
    R.string.lithuania_url));
EU.add(new Country(R.string.luxembourg, R.drawable.luxembourg,
    R.string.luxembourg_url));
EU.add(new Country(R.string.malta, R.drawable.malta,
    R.string.malta_url));
EU.add(new Country(R.string.netherlands, R.drawable.netherlands,
    R.string.netherlands_url));
EU.add(new Country(R.string.poland, R.drawable.poland,
    R.string.poland_url));
EU.add(new Country(R.string.portugal, R.drawable.portugal,
    R.string.portugal_url));
EU.add(new Country(R.string.romania, R.drawable.romania,
    R.string.romania_url));
EU.add(new Country(R.string.slovakia, R.drawable.slovakia,
    R.string.slovakia_url));
EU.add(new Country(R.string.slovenia, R.drawable.slovenia,
    R.string.slovenia_url));
EU.add(new Country(R.string.spain, R.drawable.spain,
    R.string.spain_url));
EU.add(new Country(R.string.sweden, R.drawable.sweden,
    R.string.sweden_url));
EU.add(new Country(R.string.united_kingdom,
    R.drawable.united_kingdom,
    R.string.united_kingdom_url));
}
```

CountriesFragment

The fragment responsible for rendering the list of EU nations is `CountriesFragment`. It is a `ListFragment`, using a `CountryAdapter` to populate the list:

```
class CountryAdapter extends ArrayAdapter<Country> {
    CountryAdapter() {
        super(getActivity(), R.layout.row, R.id.name, Country.EU);
    }

    @Override
```

LARGE-SCREEN STRATEGIES AND TACTICS

```
public View getView(int position, View convertView, ViewGroup parent) {
    CountryViewHolder wrapper=null;

    if (convertView == null) {
        convertView=
            LayoutInflater.from(getActivity()).inflate(R.layout.row,
                                                    parent, false);

        wrapper=new CountryViewHolder(convertView);
        convertView.setTag(wrapper);
    }
    else {
        wrapper=(CountryViewHolder)convertView.getTag();
    }

    wrapper.populateFrom(getItem(position));

    return(convertView);
}
```

This adapter is somewhat more complex than the ones we showed in the [chapter on selection widgets](#). We will get into what CountryAdapter is doing, and the CountryViewHolder it references, in [a later chapter of this book](#). Suffice it to say for now that the rows in the list contain both the country name and its flag.

When the user taps on a row in our ListView, something needs to happen – specifically, the details of that country need to be displayed. However, displaying those details is not the responsibility of CountriesFragment, as it simply displays the list of countries and nothing else. Hence, we need to pass the event up to the hosting activity to handle.

We could accomplish this using an event bus, as seen in other examples earlier in the book. The EU4You series of samples, though, use a different approach, referred to as the contract pattern. In this pattern, the fragment defines an interface, which is the “contract” that all hosting activities of that fragment must implement. This requirement is enforced by the superclass, ContractListFragment:

```

```
// derived from https://gist.github.com/Jakewharton/2621173

package com.commonware.android.eu4you;

import android.app.Activity;
import android.app.ListFragment;

public class ContractListFragment<T> extends ListFragment {
    private T contract;

    @SuppressWarnings("unchecked")
    @Override
    public void onAttach(Activity activity) {
        super.onAttach(activity);

        try {
            contract=(T)activity;
        }
        catch (ClassCastException e) {
            throw new IllegalStateException(activity.getClass()
                .getSimpleName()
                + " does not implement contract interface for "
                + getClass().getSimpleName(), e);
        }
    }

    @Override
    public void onDetach() {
        super.onDetach();

        contract=null;
    }

    public final T getContract() {
        return(contract);
    }
}
```

`onAttach()` is called when the fragment has been attached to an activity, whether that is from when the activity was initially created, after a configuration change, or whenever. In those cases, we cast the activity to be the contract interface (provided via the data type in the declaration), raising an exception if the cast fails. Subclasses can then access the contract object via the `getContract()` method.

`CountriesFragment` inherits from `ContractListFragment` and defines its contract. Hence, any activity that hosts a `CountriesFragment` is responsible for implementing this contract interface, so we can call `onCountrySelected()` when the user clicks on a row in the list:

```
@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    if (getContract().isPersistentSelection()) {
        getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    }
}
```

```
        l.setItemChecked(position, true);
    }
    else {
        listView().setChoiceMode(ListView.CHOICE_MODE_NONE);
    }

    getContract().onCountrySelected(Country.EU.get(position));
}
```

CountriesFragment also has quite a bit of code dealing with clicked-upon rows being in an “activated” state. This provides visual context to the user and is often used in the list-and-details pattern. For example, in the tablet renditions of Gmail shown earlier in this chapter, you will notice that the list on the left (e.g., list of labels) has one row highlighted with a blue background. This is the “activated” row, and it indicates the context for the material in the adjacent fragment (e.g., list of conversations in the label). Managing this “activated” state is a bit beyond the scope of this section, however, so we will delay discussion of that topic to [a later chapter in this book](#).

DetailsFragment

The details to be displayed come in the form of a URL to a mobile Wikipedia page for a country, designed to be displayed in a WebView. The EU4You sample app makes use of the same WebViewFragment that we saw earlier in this book, such as in the tutorials. DetailsFragment itself, therefore, simply needs to expose some method to allow a hosting activity to tell it what URL to display:

```
package com.commonware.android.eu4you;

import android.os.Bundle;
import android.view.View;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import android.webkit.WebViewFragment;

public class DetailsFragment extends WebViewFragment {
    @Override
    public void onViewCreated(View view, Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);

        getWebView().setWebViewClient(new URLHandler());
    }

    public void loadUrl(String url) {
        getWebView().loadUrl(url);
    }

    private static class URLHandler extends WebViewClient {
        @Override
        public boolean shouldOverrideUrlLoading(WebView view, String url) {
            view.loadUrl(url);
        }
    }
}
```

```
        return(true);
    }
}
```

You will notice that this fragment is not retained via `setRetainInstance()`. That is because, as you will see, we will not always be displaying this fragment. Fragments that are displayed in some configurations (e.g., landscape) but not in others (e.g., portrait), where a device might change between those configurations at runtime, cannot be retained without causing crashes.

You will also notice that this fragment uses `setWebViewClient()` to associate a `URLHandler` with the `WebView`. This `URLHandler` class simply forces all URLs back into the `WebView`, as opposed to launching a browser. Wikipedia now uses HTTPS for many pages, and it uses HTTP Strict Transport Security (HSTS) to redirect HTTP requests to their HTTPS counterparts as appropriate. The mobile Wikipedia URLs used in the app all have the `https` scheme, and so in theory there should be no server-side redirects. But, just in case, the `URLHandler` ensures that such redirects will stay within the `WebView`.

The Activities

Our launcher activity is also named `EU4You`. It uses two of the layouts shown above. Both are `main.xml`, but one is in `res/layout-w720dp/`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <FrameLayout
        android:id="@+id/countries"
        android:layout_weight="30"
        android:layout_width="0px"
        android:layout_height="match_parent"
    />
    <FrameLayout
        android:id="@+id/details"
        android:layout_weight="70"
        android:layout_width="0px"
        android:layout_height="match_parent"
    />
</LinearLayout>
```

The other is in `res/layout/`:

LARGE-SCREEN STRATEGIES AND TACTICS

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/countries"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

Both have a `FrameLayout` for the `CountriesFragment` (`R.id.countries`), but only the `res/layout-w720dp/` edition has a `FrameLayout` for the `DetailsFragment` (`R.id.details`).

Here is the complete implementation of the `EU4You` activity:

```
package com.commonware.android.eu4you;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class EU4You extends Activity implements
    CountriesFragment.Contract {
    private CountriesFragment countries=null;
    private DetailsFragment details=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        countries=
            (CountriesFragment)getFragmentManager().findFragmentById(R.id.countries);

        if (countries == null) {
            countries=new CountriesFragment();
            getFragmentManager().beginTransaction()
                .add(R.id.countries, countries)
                .commit();
        }

        details=
            (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

        if (details == null && findViewById(R.id.details) != null) {
            details=new DetailsFragment();
            getFragmentManager().beginTransaction()
                .add(R.id.details, details).commit();
        }
    }

    @Override
    public void onCountrySelected(Country c) {
        String url=getString(c.url);

        if (details != null && details.isVisible()) {
            details.loadUrl(url);
        }
        else {
```

LARGE-SCREEN STRATEGIES AND TACTICS

```
Intent i=new Intent(this, DetailsActivity.class);

i.putExtra(DetailsActivity.EXTRA_URL, url);
startActivity(i);
}
}

@Override
public boolean isPersistentSelection() {
    return(details != null && details.isVisible());
}
}
```

The job of onCreate() is to set up the UI. So, we:

- See if we already have an instance of CountriesFragment, by asking our FragmentManager to give us the fragment in the R.id.countries slot — this might occur if we underwent a configuration change, as CountriesFragment would be recreated in that case
- If we do not have a CountriesFragment instance, create one and execute a FragmentTransaction to load it into R.id.countries of our layout
- Find the DetailsFragment (which, since DetailsFragment is not retained, should always return null, but, as they say, “better safe than sorry”)
- If we do not have a DetailsFragment *and* the layout has an R.id.details slot, create a DetailsFragment and execute the FragmentTransaction to put it in that slot... but otherwise do nothing

The net result is that EU4You can correctly handle either situation, where we have both fragments or just one.

Similarly, the onCountrySelected() method (required by the Contract interface) will see if we have our DetailsFragment or not (and whether it is visible, or is hidden because we created it but it is not visible in the current screen orientation). If we do, we just call loadUrl() on it, to populate the WebView. If we do not have a visible DetailsFragment, we need to do something to display one. In principle, we could elect to execute a FragmentTransaction to replace the CountriesFragment with the DetailsFragment, but this can get complicated. Here, we start up a separate DetailsActivity, passing the URL for the chosen Country in an Intent extra.

DetailsActivity is similar:

```
package com.commonware.android.eu4you;

import android.app.Activity;
import android.os.Bundle;

public class DetailsActivity extends Activity {
```

LARGE-SCREEN STRATEGIES AND TACTICS

```
public static final String EXTRA_URL=
    "com.commonware.android.eu4you.EXTRA_URL";
private String url=null;
private DetailsFragment details=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    details=(DetailsFragment)getFragmentManager()
        .findFragmentById(android.R.id.content);

    if (details == null) {
        details=new DetailsFragment();

        getFragmentManager().beginTransaction()
            .add(android.R.id.content, details)
            .commit();
    }

    url=getIntent().getStringExtra(EXTRA_URL);
}

@Override
public void onResume() {
    super.onResume();

    details.loadUrl(url);
}
}
```

We create the `DetailsFragment` and load it into the layout, capture the URL from the Intent extra, and call `loadUrl()` on the `DetailsFragment`. However, since we are executing a `FragmentManager.beginTransaction()`, the actual UI for the `DetailsFragment` is not created immediately, so we cannot call `loadUrl()` right away (otherwise, `DetailsFragment` will try to pass it to a non-existent `WebView`, and we crash). So, we delay calling `loadUrl()` to `onResume()`, at which point the `WebView` should exist.

The Results

On a larger-screen device, in landscape, we have both fragments, though there is nothing initially loaded into the `DetailsFragment`:

LARGE-SCREEN STRATEGIES AND TACTICS

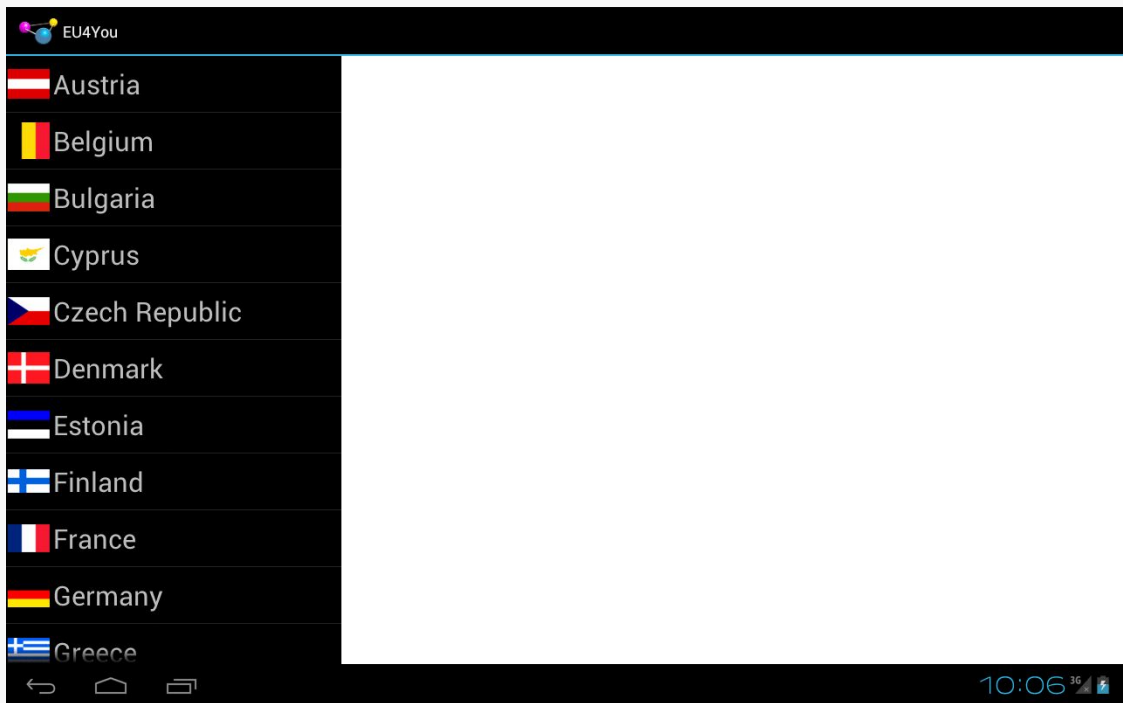

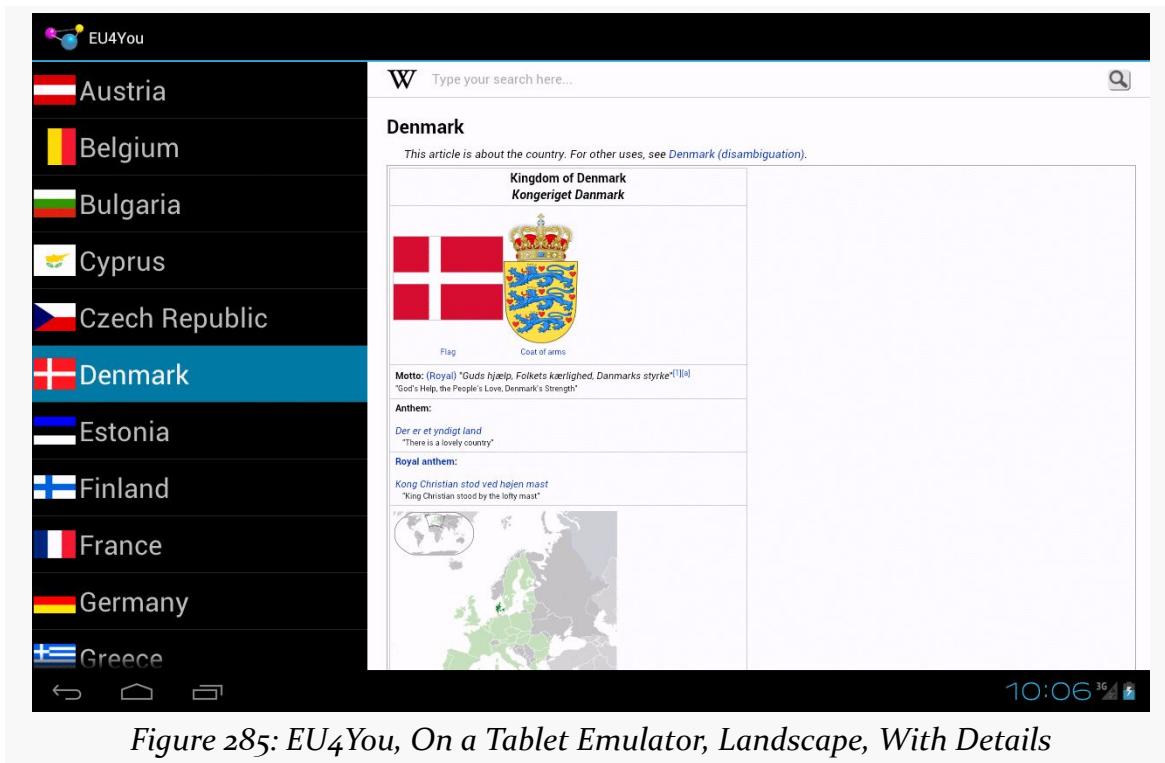

Figure 284: EU4You, On a Tablet Emulator, Landscape

Tapping on a country brings up the details on the right:

LARGE-SCREEN STRATEGIES AND TACTICS

In any other configuration, such as a smaller-screen device, we only see the CountriesFragment at the outset:

Figure 286: EU4You, On a Phone Emulator

Tapping on a country brings up the DetailsFragment full-screen in the DetailsActivity:

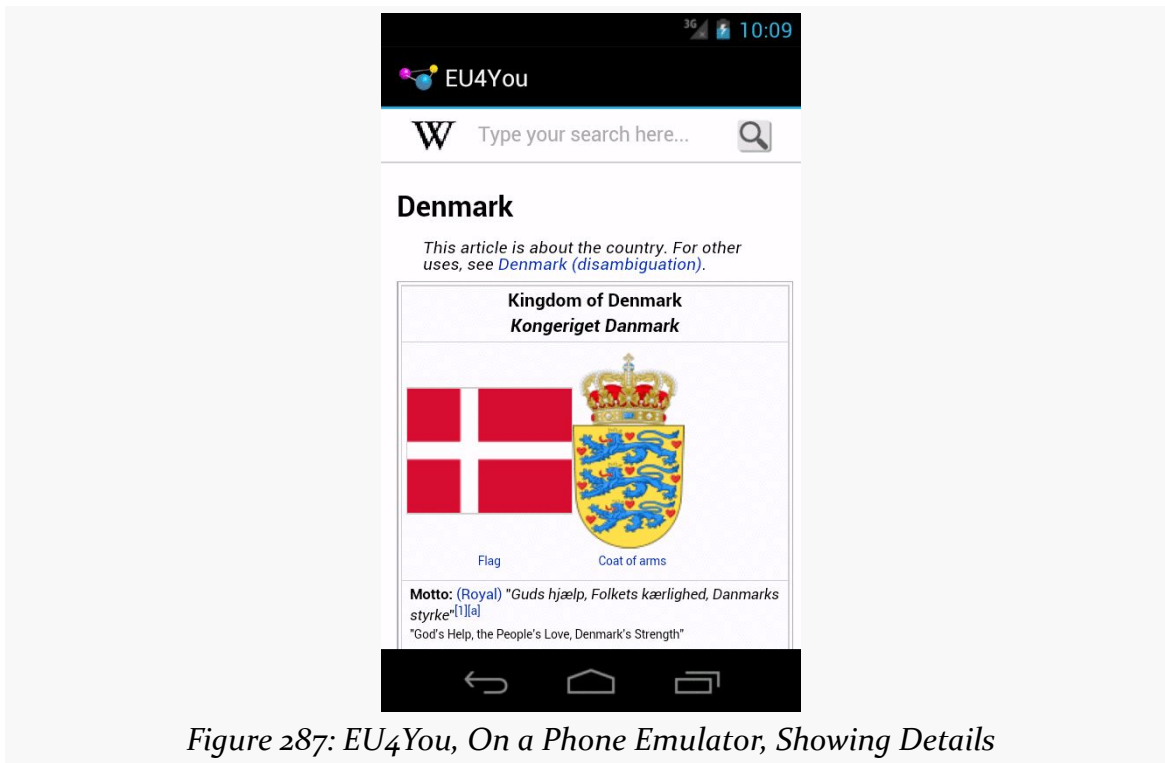

Figure 287: EU4You, On a Phone Emulator, Showing Details

Other Master-Detail Strategies

The EU4You sample from above is one way of approaching this master-detail pattern. It is not the only one. In this section, we will review other implementations of EU4You that use other techniques for implementing the master-detail pattern.

Static CountriesFragment

In the original EU4You activity, both fragments were dynamic, each added via a `FragmentManager`. `DetailsFragment` has to be dynamic, as whether or not it is visible depends upon screen size and orientation. However, there is no particular need for our `CountriesFragment` to be dynamic, as you will see in the [LargeScreen/EU4YouStaticCountries](#) sample project.

Here, our single-pane layout uses a `<fragment>` element to wire in the `CountriesFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/countries"
```

LARGE-SCREEN STRATEGIES AND TACTICS

```
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.eu4you3.CountriesFragment"
/>
```

Similarly, our dual-pane layout uses a `<fragment>` element for the `CountriesFragment`, alongside the `FrameLayout` for the details:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:baselineAligned="false"
    android:orientation="horizontal">

    <fragment
        android:id="@+id/countries"
        android:name="com.commonware.android.eu4you3.CountriesFragment"
        android:layout_width="0px"
        android:layout_height="match_parent"
        android:layout_weight="30"/>

    <FrameLayout
        android:id="@+id/details"
        android:layout_width="0px"
        android:layout_height="match_parent"
        android:layout_weight="70"/>

</LinearLayout>
```

Our `onCreate()` for `EU4You` is simpler, in that we do not need to mess with the `CountriesFragment` at all:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    details=
        (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);

    if (details == null && findViewById(R.id.details) != null) {
        details=new DetailsFragment();
        getFragmentManager().beginTransaction()
            .add(R.id.details, details).commit();
    }
}
```

Neither `CountriesFragment` or anything involving the details necessarily needs to change.

Going With One Activity

You might wonder why we need to bother with `DetailsActivity`. After all, the `EU4You` activity is perfectly capable of showing the `DetailsFragment` in a second pane — why not have it display the `DetailsFragment` in the first pane as well, in single-pane scenarios? Surely, this will be much simpler, as we can dispense with the activity and its entry in the manifest!

Yes, this is possible. No, it is not simpler.

The reason for the complexity is now managing all of our possible mix of fragments. We already had to deal with the following possibilities:

- Single-pane, showing the countries
- Single-pane, showing the countries, but on a large screen in portrait mode, after the activity had been launched in landscape, so the `DetailsFragment` exists in the `FragmentManager`, but is not visible
- Dual-pane, showing both fragments

If we get rid of `DetailsActivity` and dump all the responsibility onto `EU4You`, we have more scenarios:

- Single-pane, showing the details, having replaced the countries via a `FragmentTransaction`
- Single-pane, showing the countries, after having shown the details and the user then pressing `BACK`

Basically, what we must do now is `replace()` the `CountriesFragment` with the `DetailsFragment`, when we are in single-pane mode, when the user taps on a country in the list. This requires a fairly extensive number of changes, as you will see in the [LargeScreen/EU4YouSingleActivity](#) sample project.

The Revised Layouts

In our single-pane mode, our one pane will either hold the `CountriesFragment` or the `DetailsFragment`, depending upon what the user has done. Right now, our `FrameLayout` is named `R.id.countries`, which was fine before, but now seems like an inappropriate name. So, the new project's layouts change this to `R.id.mainfrag`, without changing anything else:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/mainfrag"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
/>
```

The New onCountrySelected()

The “simple” part of the changes comes in the revised onCountrySelected() method in EU4You:

```
@Override
public void onCountrySelected(Country c) {
    String url=getString(c.url);

    details.loadUrl(url);

    if (details.getId() != R.id.details) {
        getFragmentManager().beginTransaction()
            .replace(R.id.mainfrag, details,
                TAG_DETAILS)
            .addToBackStack(null).commit();
    }
}
```

In our revised scenario, we will *always* have a DetailsFragment. The question is merely whether it is presently visible. Hence, we can call loadUrl() on details directly.

However, there are two possible scenarios for the status of our DetailsFragment at the point in time of onCountrySelected() being called:

1. It exists in the details FrameLayout of our dual-pane layout resource
2. It exists, perhaps due to a configuration change, but is not presently in a container

You might think that there would be a third scenario, where it is the visible fragment in the mainfrag FrameLayout. Indeed, sometimes DetailsFragment will be in that container... just not now. The only time that onCountrySelected() will be called is if the user tapped on an item in our CountriesFragment, which means that CountriesFragment must be in mainfrag.

The ID of a fragment, from getId(), is the ID of its container, when used with dynamic fragments. So, we check to see whether our DetailsFragment is in the details FrameLayout by comparing ID values. If they differ, then we commit() a replace() FragmentTransaction to put DetailsFragment into mainfrag. Note,

though, that we use `addToBackStack()`, so if the user presses the BACK button, we will roll back this transaction and return to the `CountriesFragment`.

The New `onCreate()`

If you thought that was messy, you will not like the changes required to `onCreate()` of `EU4You` much more:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    countries=
        (CountriesFragment)getFragmentManager().findFragmentByTag(TAG_COUNTRIES);
    details=
        (DetailsFragment)getFragmentManager().findFragmentByTag(TAG_DETAILS);

    if (countries == null) {
        countries=new CountriesFragment();
        getFragmentManager().beginTransaction()
            .add(R.id.mainfrag, countries,
                TAG_COUNTRIES).commit();
    }

    if (details == null) {
        details=new DetailsFragment();

        if (findViewById(R.id.details) != null) {
            getFragmentManager().beginTransaction()
                .add(R.id.details, details,
                    TAG_DETAILS).commit();
        }
    }
    else {
        if (details.getId() == R.id.mainfrag) {
            if (findViewById(R.id.details) != null) {
                getFragmentManager().popBackStackImmediate();
            }
        }
        else {
            getFragmentManager().beginTransaction().remove(details)
                .commit();
        }
    }

    if (findViewById(R.id.details) != null) {
        getFragmentManager().beginTransaction()
            .add(R.id.details, details,
                TAG_DETAILS).commit();
    }
}
}
```

LARGE-SCREEN STRATEGIES AND TACTICS

This sample is derived from the original EU4You sample, and so we are still using a `FragmentManager` to set up the `CountriesFragment` in `mainfrag`, if we did not create `CountriesFragment` earlier.

Dealing with `DetailsFragment`, though, is decidedly more complicated. The flow that we want is if we were in dual-pane mode and switch to single-pane mode, that we show the `CountriesFragment` in that single pane. If we switch from single-pane mode to dual-pane mode, both fragments will be shown, of course.

First, we have the case where our `DetailsFragment` does not yet exist. This is much like the original sample: we need to create the fragment and put it into the `details` `FrameLayout`, if the `details` `FrameLayout` exists.

If the `DetailsFragment` exists, we need to make sure that it winds up in the `details` `FrameLayout`, if one exists.

To do that, we first check its ID to see if it is presently located in `mainfrag`. If it is, and if we have a `details` `FrameLayout`, we have switched to dual-pane mode and need to pop our back stack, in preparation for moving the `DetailsFragment` to the `details` `FrameLayout`.

If the `DetailsFragment` exists but is not in `mainfrag`, we `remove()` it entirely.

Then, if the `DetailsFragment` exists, regardless of where it was before, we `add()` it to the `details` `FrameLayout`.

The “OMG! Our Fragments Have No Views!” Changes

In testing, there are now scenarios in which `CountriesFragment` is called with `onSaveInstanceState()`, but without its views having been created (i.e., `onCreateView()` was not called). This would cause us to fail when trying to use `getListView()`, as that method would return `null`, since the `ListView` did not exist. So, we modify `onSaveInstanceState()` to be a bit more robust:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    if (getView() != null) {
        state.putInt(STATE_CHECKED,
            getListView().getCheckedItemPosition());
    }
}
```

LARGE-SCREEN STRATEGIES AND TACTICS

We also need to beef up DetailsFragment a bit. Before, we relied on the fact that, on a configuration change, our extras on our Intent for DetailsActivity would still be available. Now, though, there is no DetailsActivity, which means that DetailsFragment has to maintain its state, so that we do not lose the URL we were viewing when the user rotates the screen or causes another configuration change. And, to top it off, we have the same potential issue as with CountriesFragment, where the fragment might exist but not have onCreateView() called (e.g., we were in dual-pane mode and switched to single-pane mode, and DetailsFragment has not yet been displayed), so we cannot assume that getWebView() will always return a non-null value.

To that end, DetailsFragment gets complicated:

```
package com.commonware.android.eu4you2;

import android.os.Bundle;
import android.view.View;
import android.webkit.WebView;
import android.webkit.WebViewClient;
import android.webkit.WebViewFragment;

public class DetailsFragment extends WebViewFragment {
    private static final String STATE_URL="url";
    private String url=null;
    @Override
    public void onCreateView(View view, Bundle savedInstanceState) {
        super.onCreateView(view, savedInstanceState);

        getWebView().setWebViewClient(new URLHandler());
    }

    @Override
    public void onActivityCreated(Bundle savedInstanceState) {
        super.onActivityCreated(savedInstanceState);

        if (url == null && savedInstanceState != null) {
            url=savedInstanceState.getString(STATE_URL);
        }

        if (url != null) {
            loadUrl(url);
            url=null;
        }
    }

    @Override
    public void onSaveInstanceState(Bundle outState) {
        super.onSaveInstanceState(outState);

        if (url == null) {
            outState.putString(STATE_URL, getWebView().getUrl());
        }
        else {
            outState.putString(STATE_URL, url);
        }
    }
}
```

```
    }  
  }  
  
  void loadUrl(String url) {  
    if (getView() == null) {  
      this.url=url;  
    }  
    else {  
      getWebView().loadUrl(url);  
    }  
  }  
}  
  
private static class URLHandler extends WebViewClient {  
  @Override  
  public boolean shouldOverrideUrlLoading(WebView view, String url) {  
    view.loadUrl(url);  
  
    return(true);  
  }  
}
```

The `url` data member will temporarily hold the URL of the page we should be viewing, particularly when we have no `WebView` to work with. So, our `loadUrl()` method now puts the URL into `url` if we have no `WebView` or loads it into the `WebView` if the `WebView` exists. `onSaveInstanceState()` will put the URL — whether from `url` or from the `WebView` — into the state `Bundle`. `onActivityCreated()` will attempt to populate `url` from the `Bundle` (if we do not already have a URL), then use that to populate the `WebView` (which should exist if `onActivityCreated()` is called). `url` is set to `null` to indicate that the `WebView` holds our URL, once that is completed.

The Results

From a user experience standpoint, things have not significantly changed. The user still sees the list, still sees the details when tapping on an entry in the list, and still gets the dual-pane experience on larger screens.

However, the transition between the list and the details in single-pane mode is a bit faster, as a `FragmentTransaction` takes less time than does starting up another activity. However, by default, our `FragmentTransaction` does not apply any transition effects, and so the fragment changes “just happen” without any fades, zooms, or the like. It is certainly possible to specify fragment transition effects, if desired, though this is outside the scope of this chapter.

The Mashup Possibilities

It should be possible to combine the two revised versions of EU4You, having a single activity manage all the fragments, with CountriesFragment set up as a static fragment. The proof that this is possible is left to the reader.

The SlidingPaneLayout Variant

The R13 update to the Android Support package introduced SlidingPaneLayout, another way of handling this sort of master-detail pattern. SlidingPaneLayout significantly reduces the level of effort for setting up master-detail, as it handles all of the “dirty work” of showing the different fragments in different scenarios (normal screen, large screen, etc.).

The Role of SlidingPaneLayout

In the master-detail pattern, we are showing both the master and the detail fragment, side-by-side, on larger screens, while showing only one at a time on smaller screens. In the preceding examples, we had to manage all of that ourselves, in terms of deciding how many fragments to show and for switching between those fragments as needed.

SlidingPaneLayout encapsulates that logic.

SlidingPaneLayout will detect the screen size. If the screen size is big enough, SlidingPaneLayout will display its two children side-by-side. If the screen size is not big enough, SlidingPaneLayout will display one child at a time. However, by default, when the “master” child is visible, a thin strip on the right will allow the user to return to the “detail” child. Similarly, a swiping gesture can switch from the “detail” back to the “master” child. These are in addition to any changes in context you might introduce based on UI operations (e.g., tapping on an element in a master ListView automatically switching to the detail child).

Converting to SlidingPaneLayout

The [LargeScreen/EU4YouSlidingPane](#) sample project represents a rework of the EU4You core sample, this time using SlidingPaneLayout for handling the master-detail pattern.

LARGE-SCREEN STRATEGIES AND TACTICS

Since `SlidingPaneLayout` encapsulates the master-detail logic, we can drop a lot of stuff that we used before but no longer need, including:

- `DetailsActivity` (as `SlidingPaneLayout` works akin to our single-activity implementation)
- the dedicated large-screen layout (as `SlidingPaneLayout` “bakes in” the logic for handling different screen sizes)
- dynamic fragments (as `SlidingPaneLayout` will work better with static fragments, anyway)
- `isPersistentSelection()` (as we will always want to use activated rows, on API Level 11+, as the user can more readily switch back and forth between master and detail on smaller screens, and we want to indicate in the master what the context is that is displayed in the detail)

However, we did have to add a bit of pane management, plus move around some list-related behaviors in our `CountriesFragment`.

For starters, our `res/layout/main.xml` file now contains a `SlidingPaneLayout`, along with our two fragments, each set up as static `<fragment>` elements:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/
apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <fragment
        android:id="@+id/countries"
        android:name="com.commonware.android.eu4you4.CountriesFragment"
        android:layout_width="300sp"
        android:layout_height="match_parent"/>

    <fragment
        android:id="@+id/details"
        android:name="com.commonware.android.eu4you4.DetailsFragment"
        android:layout_width="400dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>

</android.support.v4.widget.SlidingPaneLayout>
```

By putting an `android:layout_weight` on our details fragment, we indicate that we want that one to take up all remaining room when the two fragments are shown side-by-side. You might think that we should then set the width of the details fragment to `0dp`; however, for some reason, this does not work.

LARGE-SCREEN STRATEGIES AND TACTICS

The size of the countries (master) fragment will be honored on larger screens. On smaller screens, the size of the master fragment will be dictated by the width of the screen, minus a strip to allow the user to see a portion of the detail fragment and swipe that to display the detail fragment *in toto*.

Our CountriesFragment now always sets up the ListView to be single-choice mode, in `onActivityCreated()`. It also calls `onCountrySelected()` on our CountriesFragment.Contract, to ensure that the master is highlighting the last selection — this is needed to make sure that everything is displayed properly after a configuration change:

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    setListAdapter(new CountryAdapter());
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);

    if (state != null) {
        int position=state.getInt(STATE_CHECKED, -1);

        if (position > -1) {
            getListView().setItemChecked(position, true);
            getContract().onCountrySelected(Country.EU.get(position));
        }
    }
}
```

`onListItemClick()` of CountriesFragment becomes a bit simpler:

```
@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    l.setItemChecked(position, true);
    getContract().onCountrySelected(Country.EU.get(position));
}
```

The EU4You activity overall becomes *substantially* simpler:

```
package com.commonware.android.eu4you4;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.widget.SlidingPaneLayout;

public class EU4You extends Activity implements
    CountriesFragment.Contract {
    private DetailsFragment details=null;
    private SlidingPaneLayout panes=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
```

```
setContentView(R.layout.main);

details=
    (DetailsFragment)getFragmentManager().findFragmentById(R.id.details);
panes=(SlidingPaneLayout)findViewById(R.id.panes);
panes.openPane();
}

@Override
public void onBackPressed() {
    if (panes.isOpen()) {
        super.onBackPressed();
    }
    else {
        panes.openPane();
    }
}

@Override
public void onCountrySelected(Country c) {
    details.loadUrl(getString(c.url));
    panes.closePane();
}
}
```

In `SlidingPaneLayout` terminology, the pane is “open” if the *master* is shown on smaller screens, and the pane is “closed” if the *detail* is shown on smaller screens. If this feels a bit counter-intuitive to you, you are not alone in that regard.

By default, the `SlidingPaneLayout` is closed. So, if we want to start (on smaller screens) with the master pane shown, we need to call `openPane()`, as we do in `onCreate()`. Similarly:

- If we want to show the details when the user clicks on a country in the `CountriesFragment`, we need to call `closePane()` in `onCountrySelected()`
- If we want to show the master pane if the user presses BACK while viewing the detail pane, we need to override `onBackPressed()` and consume that event (calling `openPane()`), instead of performing the normal superclass behavior

What `SlidingPaneLayout` Looks Like

On a larger screen, the `SlidingPaneLayout` edition of the EU4You activity looks the same as the prior examples.

However, on a smaller screen, things look slightly different. Specifically:

- Our master perspective has a thin strip on the right, showing a peek of the detail fragment

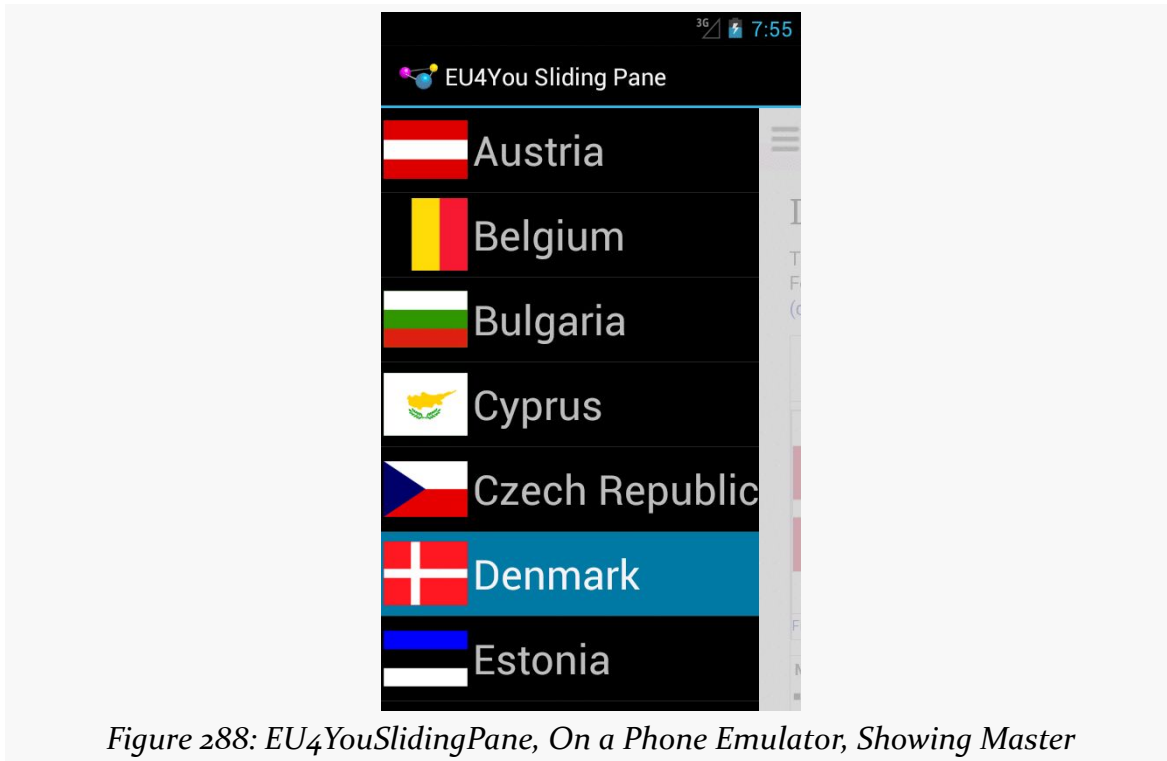

Figure 288: *EU4YouSlidingPane*, On a Phone Emulator, Showing Master

- The user can switch to the detail pane either by swiping open the detail pane or clicking on a country
- The user can switch back to the master pane either by swiping the detail pane back closed or by pressing the BACK button

Showing More Pages

`ViewPager` is a popular container in Android, as horizontal swiping is an increasingly popular navigational model, to move between peer pieces of content (e.g., swiping between contacts, swiping between book chapters). In some cases, when the `ViewPager` is on a larger screen, we simply want larger pages — a digital book reader, for example, would simply have a larger page in a bigger font for easier reading.

Sometimes, though, we might not be able to take advantage of the full space offered by the large screen, particularly when our `ViewPager` takes up the whole screen. In cases like this, it might be useful to allow `ViewPager`, in some cases, to show more

LARGE-SCREEN STRATEGIES AND TACTICS

than one page at a time. Each “page” is then designed to be roughly phone-sized, and we choose whether to show one, two, or perhaps more pages at a time based upon the available screen space.

Mechanically, allowing ViewPager to show more than one page is fairly easy, involving overriding one more method in our PagerAdapter: getPageWidth(). To see this in action, take a look at the [ViewPager/MultiView1](#) sample project.

Each page in this sample is simply a TextView widget, using the activity’s style’s “large appearance”, centered inside a LinearLayout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="center"
    android:orientation="vertical">

    <TextView
        android:id="@+id/text"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textAppearance="?android:attr/textAppearanceLarge"/>

</LinearLayout>
```

The activity, in onCreate(), gets our ViewPager from the res/layout/activity_main.xml resource, and sets its adapter to be a SampleAdapter:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    pager.setAdapter(new SampleAdapter());
    pager.setOffscreenPageLimit(6);
}
```

In this case, SampleAdapter is not a FragmentPagerAdapter, nor a FragmentStatePagerAdapter. Instead, it is its own implementation of the PagerAdapter interface:

```
/*
 * Inspired by
 * https://gist.github.com/8cbe094bb7a783e37ad1
 */
private class SampleAdapter extends PagerAdapter {
    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        View page=
            getLayoutInflater().inflate(R.layout.page, container, false);
```

```
TextView tv=(TextView)page.findViewById(R.id.text);
int blue=position * 25;

final String msg=
    String.format(getString(R.string.item), position + 1);

tv.setText(msg);
tv.setOnClickListener(new OnClickListener() {
    @Override
    public void onClick(View v) {
        Toast.makeText(MainActivity.this, msg, Toast.LENGTH_LONG)
            .show();
    }
});

page.setBackgroundColor(Color.argb(255, 0, 0, blue));
container.addView(page);

return(page);
}

@Override
public void destroyItem(ViewGroup container, int position,
    Object object) {
    container.removeView((View)object);
}

@Override
public int getCount() {
    return(9);
}

@Override
public float getPageWidth(int position) {
    return(0.5f);
}

@Override
public boolean isViewFromObject(View view, Object object) {
    return(view == object);
}
}
```

To create your own PagerAdapter, the big methods that you need to implement are:

- `instantiateItem()`, where you create the page itself and add it to the supplied container. In this case, we inflate the page, set the text of the `TextView` based on the supplied position, set the background color of the page itself to be a different shade of blue based on the position, set up a click listener to show a `Toast` when the `TextView` is tapped, and use that for our page. We return some object that identifies this page; in this case, we return the inflated `View` itself. A fragment-based `PagerAdapter` would probably return the fragment.

LARGE-SCREEN STRATEGIES AND TACTICS

- `destroyItem()`, where we need to clean up a page that is being removed from the pager, where the page is identified by the `Object` that we had previously returned from `instantiateItem()`. In our case, we just remove it from the supplied container.
- `isViewFromObject()`, where we confirm whether some specific page in the pager (represented by a `View`) is indeed tied to a specific `Object` returned from `instantiateItem()`. In our case, since we return the `View` from `instantiateItem()`, we merely need to confirm that the two objects are indeed one and the same.
- `getCount()`, as with the built-in `PagerAdapter` implementations, to return how many total pages there are.

In our case, we also override `getPageWidth()`. This indicates, for a given position, how much horizontal space in the `ViewPager` should be given to this particular page. In principle, each page could have its own unique size. The return value is a float, from `0.0f` to `1.0f`, indicating what fraction of the pager's width goes to this page. In our case, we return `0.5f`, to have each page take up half the pager.

The result is that we have two pages visible at a time:

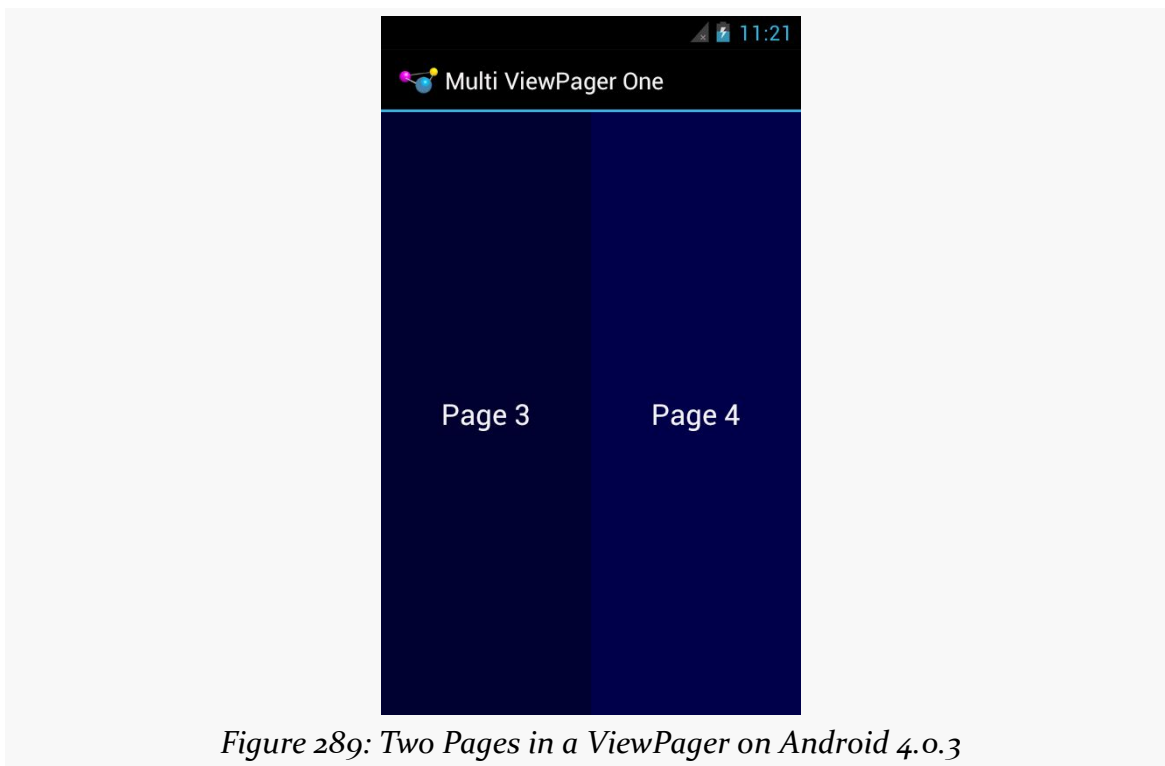

Figure 289: Two Pages in a ViewPager on Android 4.0.3

It is probably also a good idea to call `setOffscreenPageLimit()` on the `ViewPager`, as we did in `onCreate()`. By default (and at minimum), `ViewPager` will cache three pages: the one presently visible, and one on either side. However, if you are showing more than one at a time, you should bump the limit to be 3 times the number of simultaneous pages. For a page width of 0.5f — meaning two pages at a time — you would want to call `setOffscreenPageLimit(6)`, to make sure that you had enough pages cached for both the current visible contents and one full swipe to either side.

`ViewPager` even handles “partial swipes” — a careful swipe can slide the right-hand page into the left-hand position and slide in a new right-hand page. And `ViewPager` stops when you run out of pages, so the last page will always be on the right, no matter how many pages at a time and how many total pages you happen to have.

The biggest downside to this approach is that it will not work well with the current crop of indicators. `PagerTitleStrip` and `PagerTabStrip` assume that there is a single selected page. While the indicator will adjust properly, the visual representation shows that the left-hand page is the one selected (e.g., the tab with the highlight), even though two or more pages are visible. You can probably overcome this with a custom indicator (e.g., highlight the selected tab and the one to its right).

Also note that this approach collides a bit with `setPageMargin()` on `ViewPager`. `setPageMargin()` indicates an amount of whitespace that should go in a gutter between pages. In principle, this would work great with showing multiple simultaneous pages in a `ViewPager`. However, `ViewPager` does not take the gutter into account when interpreting the `getPageWidth()` value. For example, suppose `getPageWidth()` returns 0.5f and we `setPageMargin(20)`. On a 480-pixel-wide `ViewPager`, we will actually use 500 pixels: 240 for the left page, 240 for the right page, and 20 for the gutter. As a result, 20 pixels of our right-hand page are off the edge of the pager. Ideally, `ViewPager` would subtract out the page margin *before* applying the page width. One workaround is for you to derive the right `getPageWidth()` value based upon the `ViewPager` size and gutter yourself, rather than hard-coding a value. Or, build in your gutter into your page contents (e.g., using `android:layout_marginLeft` and `android:layout_marginRight`) and skip `setPageMargin()` entirely.

Columns or Pages

Another pattern — using pages for smaller screens and having the “pages” side-by-side in columns for larger screens — will be explored [later in the book](#).

The Grid Pattern

Yet another approach for taking advantage of larger screen sizes is to always show a full-size master and a full-size detail — perhaps using different activities — but to use a grid rather than a list for the master. This works well when the data being shown in the grid can be represented as “cards”, often dominated by some photo or other image.

The basic approach is to use fewer grid columns (e.g., 1 or 2) on smaller screen sizes and more grid columns (e.g., 3 or 4) on larger screen sizes. This way, the application flow is identical across screen sizes, yet the screen usage on larger screens is more effective. This is particularly true if you use one of the “staggered” grid widgets available from third parties, like [Etsy’s AndroidStaggeredGrid](#) or [Maurycy Wojtowicz’s StaggeredGridView](#):

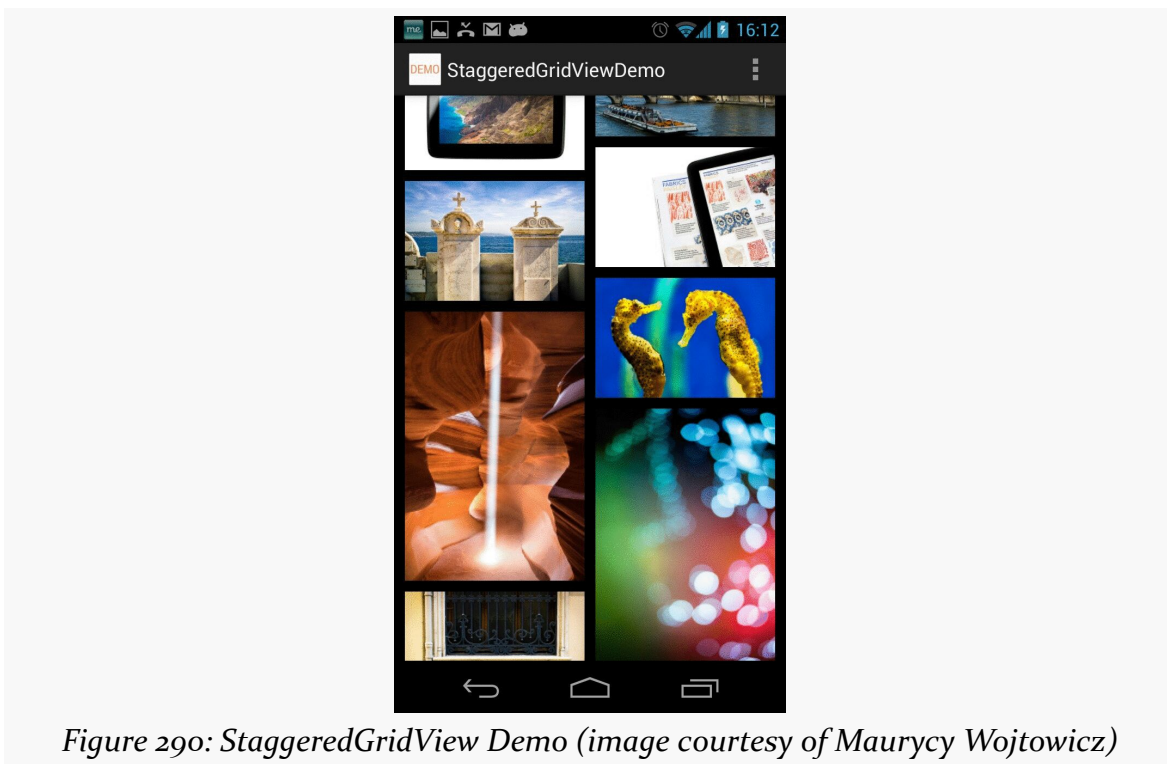

Figure 290: StaggeredGridView Demo (image courtesy of Maurycy Wojtowicz)

Fragment FAQs

Here are some other common questions about the use of fragments in support of large screen sizes:

Does *Everything* Have To Be In a Fragment?

In a word, no.

UI constructs that do not change based on screen size, configurations, and the like could simply be defined in the activity itself. For example, the activity can add items to the action bar that should be there regardless of what fragments are shown.

What If Fragments Are Not Right For Me?

While fragments are useful, they do not solve all problems. Few games will use fragments for the core of game play, for example. Applications with other forms of specialized user interfaces — painting apps, photo editors, etc. — may also be better served by eschewing fragments *for those specific activities* and doing something else.

That “something else” might start with custom layouts for the different sizes and orientations. At runtime, you can determine what you need either by inspecting what you got from the layout, or by using `Configuration` and `DisplayMetrics` objects to determine what the device capabilities are (e.g., screen size). The activity would then need to have its own code for handling whatever you want to do differently based on screen size (e.g., offering a larger painting canvas plus more on-screen tool palettes).

Do Fragments Work on TVs?

Much of the focus on “larger-screen devices” has been on tablets, because, as of the time of this writing, they are the most popular “larger-screen devices” in use. However, there are plenty of scenarios involving Android on TV to consider. A TV or other external display will present itself as a `-large` (720p) or `-xlarge` (1080p) screen. Fragments can certainly help with displaying a UI for a TV, but there are other design considerations to take into account, based upon the fact that the user sits much further from a TV than they do from a phone or tablet (so-called “10-foot user experience”). This is covered in greater detail [later in the book](#).

Screen Size and Density Tactics

Even if we take the “tablet = several phones” design approach, the size of the “phone” will vary, depending on the size of the tablet. Plus, there are real actual *phones*, and those too vary in size. Hence, our fragments (or activities hosting their

own UI directly) need to take into account micro fluctuations in size, as well as the macro ones.

Screen density is also something that affects us tactically. It is rare that an application will make wholesale UI changes based upon whether the screen is 160dpi or 240dpi or 320dpi or something else. However, changes in density can certainly impact the sizes of things, like images, that are intrinsically tied to pixel sizes. So, we need to take density into account as we are crafting our fragments to work well in a small range of sizes.

Dimensions and Units

As a unit of measure, the pixel (px) is a poor choice, because its size varies by density. Two phones might have very similar screen sizes but radically different densities. Anything specified in terms of pixels will be smaller on the higher-density device, and typically you would want them to be about the same size. For example, a Button should not magically shrink for a ~4" phone just because the phone happens to have a much higher screen density than some other phone.

The best answer is to avoid specifying concrete sizes where possible. This is why you tend to see containers, and some widgets, use `match_parent` and `wrap_content` for their size — those automatically adjust based upon device characteristics.

Some places, though, you have to specify a more concrete size, such as with padding or margins. For these, you have two major groups of units of measure to work with:

- Those based upon pixels, but taking device characteristics into account. These include density-independent pixels (dp or dip), which try to size each dp to be about 1/160 of an inch. These also include scaled pixels (sp), which scales the size based upon the default font size on the device — sp is often used with `TextView` (and subclasses) for `android:textSize` attributes.
- Those based purely on physical units of measure: mm (millimeters), in (inches), and pt (points = 1/72 of an inch).

Any of those tends to be better than px. Which you choose will depend on which you and your graphics designer are more comfortable with.

If you find that there are cases where the dimensions you want to use vary more widely than the automatic calculations from these density-aware units of measure, you can use dimension resources. Create a `dimens.xml` file in `res/values/` and related resource sets, and put in there `<dimen>` elements that give a dimension a

name and a size. In addition to perhaps making things a bit more DRY (“don’t repeat yourself”), you can perhaps create different values of those dimensions for different screen sizes, densities, or other cases as needed.

Layouts and Stretching

Web designers need to deal with the fact that the user might resize their browser window. The approaches to deal with this are called “fluid” designs.

Similarly, Android developers need to create “fluid” layouts for fragments, rows in a `ListView`, and so on, to deal with similar minor fluctuations in size.

Each of “The Big Three” container classes has its approach for dealing with this:

- Use `android:layout_weight` with `LinearLayout` to allocate extra space
- Use `android:stretchColumns` and `android:shrinkColumns` with `TableLayout` to determine which columns should absorb extra space and which columns should be forcibly “shrunk” to yield space for other columns if we lack sufficient horizontal room
- Use appropriate rules on `RelativeLayout` to anchor widgets as needed to other widgets or the boundaries of the container, such that extra room flows naturally wherever the rules call for

Drawables That Resize

Images, particularly those used as backgrounds, will need to be resized to take everything into account:

- screen size and density
- size of the widget, and its contents, for which it serves as the background (e.g., amount of prose in a `TextView`)

Android supports what is known as the “nine-patch” PNG format, where resizing information is held in the PNG itself. This is typically used for things like rounded rectangles, to tell Android to stretch the straight portions of the rectangle but to not stretch the corners. Nine-patch PNG files will be examined in greater detail in [a later chapter of this book](#).

The `ShapeDrawable` XML drawable resource uses an ever-so-tiny subset of SVG (Scalable Vector Graphics) to create a vector art definition of an image. Once again, this tends to be used for rectangles and rounded rectangles, particularly those with a

gradient fill. Since Android interprets the vector art definition at runtime, it can create a smooth gradient, interpolating all intervening colors from start to finish. Stretching a PNG file — even a nine-patch PNG file — tends to result in “banding effects” on the gradients. `ShapeDrawable` is also covered later in this book.

Third-party libraries can also help. The [svg-android](#) project supplies a JAR that handles more SVG capabilities than does `ShapeDrawable`, though it too does not cover the entire SVG specification. Also, `WebView` has some ability to view SVG files on Android 3.0+.

Drawables By Density

Sometimes, though, there is no substitute for your traditional bitmap image. Icons and related artwork are not necessarily going to be stretched at runtime, but they are still dependent upon screen density. A 80x80 pixel image may look great on a Samsung Galaxy Nexus or other -xhdpi device, coming in at around a quarter-inch on a side. However, when viewed on a -mdpi device, that same icon will be a half-inch on a side, which may be entirely too large.

The best answer is to create multiple renditions of the icon at different densities, putting each icon in the appropriate drawable resource directory (e.g., `res/drawable-mdpi`, `res/drawable-hdpi`). This is what Android Asset Studio did for us in the tutorials, creating launcher icons from some supplied artwork for all four densities. Even better is to create icons tailored for each density — rather than just reducing the pixel count, take steps to draw an icon that will still make sense to the user at the lower pixel count, exaggerating key design features and dropping other stuff off. Google’s Kiril Grouchnikov has [an excellent blog post on this aspect](#)

However, Android will let you cheat.

If you supply only some densities, but your app runs on a device with a different density, Android will automatically resample your icons to try to generate one with the right density, to keep things the same size. On the plus side, this saves you work — perhaps you only ship an -xhdpi icon and let Android do the rest. And it can reduce your APK size by a bit. However, there are costs:

- This is a bit slower at runtime and consumes a bit more battery
- Android’s resampling algorithm may not be as sophisticated as that of your preferred image editor (e.g., Photoshop)
- You cannot finesse the icon to look better than a simple resampling (e.g., drop off design elements that become unidentifiable)

Other Considerations

There are other things you should consider when designing your app to work on multiple screen sizes, beyond what is covered above.

Small-Screen Devices

It is easy to think of screen size issues as being “phones versus tablets”. However, not only do tablets come in varying sizes (5” Samsung Galaxy Note to a bunch of 10.1” tablets), but phones come in varying sizes. Those that have less than a 3” diagonal screen size will be categorized as -small screen devices, and you can have different layouts for those.

Getting things to work on small screens is sometimes more difficult than moving from normal to larger screens, simply because you lack sufficient room. You can only shrink widgets so far before they become unreadable or “untappable”. You may need to more aggressively use `ScrollView` to allow your widgets to have more room, but requiring the user to pan through your whole fragment’s worth of UI. Or, you may need to divide your app into more fragments than you originally anticipated, and use more activities or other tricks to allow the user to navigate the fragments individually on small-screen devices, while stitching them together into larger blocks for larger phones.

Avoid Full-Screen Backgrounds

Android runs in lots of different resolutions.

Lots and lots of different resolutions.

Trying to create artwork for each and every resolution in use today will be tedious and fragile, the latter because new resolutions pop up every so often, ones you may not be aware of.

Hence, try to design your app to avoid some sort of full-screen background, where you are expecting the artwork to perfectly fit the screen. Either:

- Do not use a background, or
- Use a background, but one that is designed to be cropped to fit and will look good in its cropped state, or

LARGE-SCREEN STRATEGIES AND TACTICS

- Use a background, but one that can naturally bleed into some solid fill to the edges (e.g., a starfield that simply lacks stars towards the edges), so you can “fill in” space around your background with that solid color to fill the screen, or
- Dynamically draw the background (e.g., a starfield where you place the stars yourself at runtime using 2D graphics APIs)

For most conventional apps, just using the background from your stock theme will typically suffice. This problem is much bigger for 2D games, which tend to rely upon backgrounds as a game surface.

Manifest Elements for Screen Sizes

There are two elements you can add to your manifest that impact how your application will behave with respect to screen sizes.

`<compatible-screens>` serves as an advertisement of your capabilities, to the Google Play Store and similar “markets”. You can have a `<compatible-screens>` element with one or more child `<screen>` elements — each `<screen>` enumerates a combination of screen size and screen density that you support:

```
<compatible-screens>
  <!-- all possible normal size screens -->
  <screen android:screenSize="normal" android:screenDensity="ldpi" />
  <screen android:screenSize="normal" android:screenDensity="mdpi" />
  <screen android:screenSize="normal" android:screenDensity="hdpi" />
  <screen android:screenSize="normal" android:screenDensity="xhdpi" />
  <!-- all possible large size screens -->
  <screen android:screenSize="large" android:screenDensity="ldpi" />
  <screen android:screenSize="large" android:screenDensity="mdpi" />
  <screen android:screenSize="large" android:screenDensity="hdpi" />
  <screen android:screenSize="large" android:screenDensity="xhdpi" />
</compatible-screens>
```

The Google Play Store will filter your app, so it will not show up on devices that have screens that do not meet one of your `<screen>` elements. However, new densities show up every year or so, and devices running those densities will *not* be supported by your `<compatible-screens>` element unless you add the appropriate `<screen>` element for that density. For example, the above `<compatible-screens>` element does not cover `tvdpi` or `xxhdpi` devices. As a result, Google discourages the use of `<compatible-screens>`.

There is also a `<supports-screens>` element, as we saw when we set up our initial project in the tutorials. Here, you indicate what screen sizes you support, akin to `<compatible-screens>` (minus any density declarations). And, the Google Play Store

will filter your app, so it will not show up on devices that have screens *smaller than what you support*.

So, for example, suppose that you have a `<supports-screens>` element like this:

```
<supports-screens android:smallScreens="false"
                  android:normalScreens="true"
                  android:largeScreens="true"
                  android:xlargeScreens="false"
/>
```

You will not show up in the Google Play Store for any `-small` screen devices. However, you *will* show up in the Google Play Store for any `-xlarge` screen devices — Android will merely apply some runtime logic to try to help your app run well on such screens. So, while `<compatible-screens>` is purely a filter, `<supports-screens>` is a filter for smaller-than-supported screens, and a runtime “give me a hand!” flag for larger-than-supported screens.

Considering Newer Densities

`-tvdpi` — around 213dpi — was added for Android TV, and is the density used for 720p Android TV devices. However, Google *also* elected to use `-tvdpi` for the Nexus 7 tablet. However, not even Google bothered to create many `-tvdpi`-specific resources, allowing the OS to downsample from the `-hdpi` edition.

`-xxhdpi` was added in late 2012 and is for devices with a screen density around 480dpi. While Android can up-sample an `-xhdpi` image for `-xxhdpi`, the results may not be as crisp as you would like. Hence, you may wish to consider creating `-xxhdpi` as your “top tier” density, so other devices can downsample if needed. At the time of this writing, about 15% of Play Store-equipped Android devices are `-xxhdpi`.

`-xxxhdpi` is for devices with screens around 640dpi. At the time of this writing `-xxxhdpi` is not in significant use.

Tutorial #17 - Supporting Large Screens

So far, we have created a variety of fragments that are being used one at a time in a hosting activity: notes, help, and about. And, on smaller-screen devices, like phones, that is probably the best solution. But on devices like 10” tablets, it might be nice to be able to have some of those fragments take over a part of the main activity’s space. For example, the user could be reading the chapter and reading the online help.

Hence, in this tutorial, we will arrange for the help and about fragments to be loaded into `EmPubLiteActivity` directly on tablets, while retaining our existing functionality for other devices.

This is a continuation of the work we did in [the previous tutorial](#).

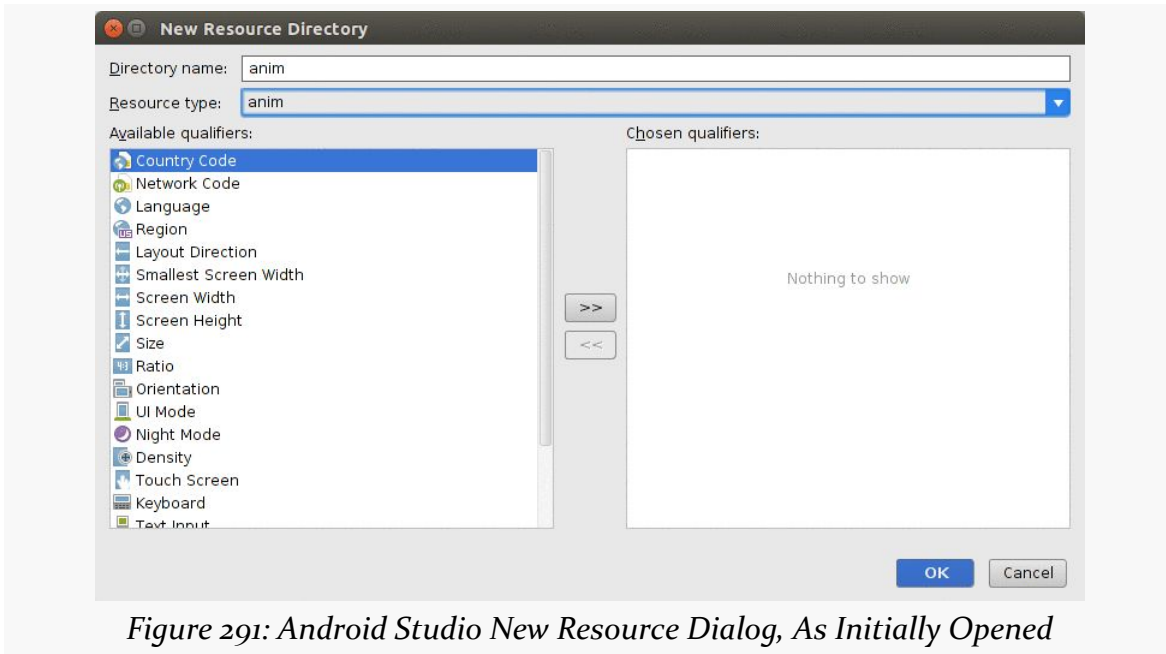

You can find the results of the [previous tutorial](#) and the results of [this tutorial](#) in the book’s GitHub repository:

Step #1: Creating Our Layouts

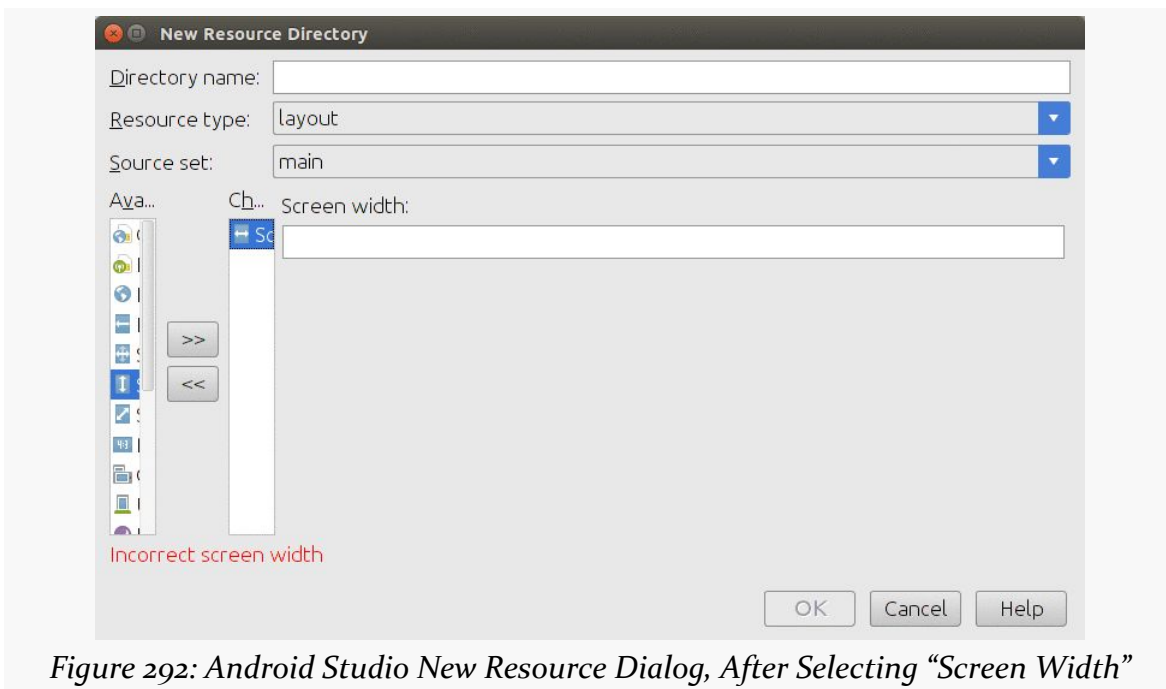

The simplest way to both add a place for these other fragments and to determine when we should be using these other fragments in the main activity is to create new layout resource sets for larger-screen devices, with customized versions of `main.xml` to be used by `EmPubLiteActivity`.

Right-click over the `res/` directory in your app, then choose `New > “Android Resource Directory”` from the context menu. As before, this brings up the new resource directory dialog:

TUTORIAL #17 - SUPPORTING LARGE SCREENS

Choose “layout” from the “Resource type” drop-down. Then, click on “Screen Width” in the list of qualifiers on the left, and click the “>>” button to add that to the list on the right:

TUTORIAL #17 - SUPPORTING LARGE SCREENS

In the “Screen width” field, fill in 880:

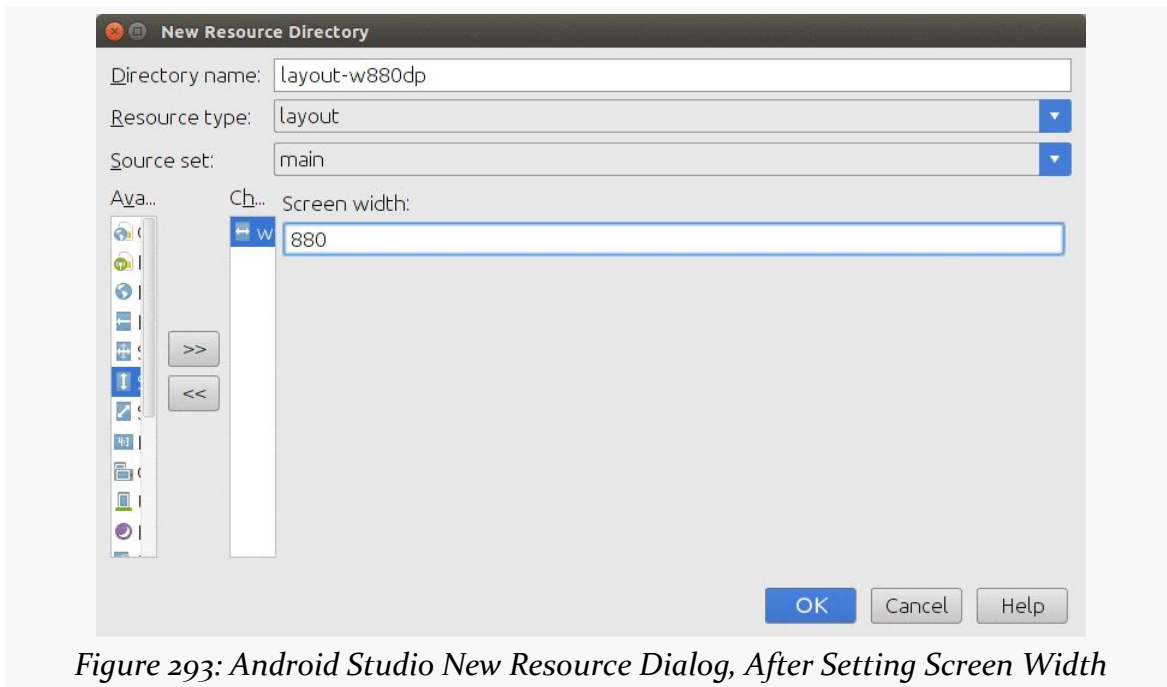

Figure 293: Android Studio New Resource Dialog, After Setting Screen Width

Click OK to create the directory. Repeat that process to create a `res/layout-h880dp/` directory, this time choosing “Screen Height” rather than “Screen Width”.

Then, right-click over the `res/layout/main.xml` file and choose “Copy” from the context menu. After that, right-click over the new `res/layout-w880dp/` directory and choose “Paste” from the context menu. This brings up the copy dialog:

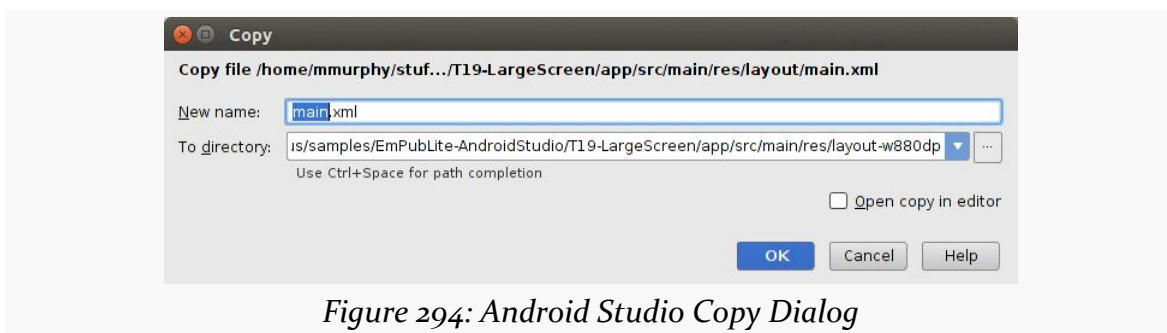

Figure 294: Android Studio Copy Dialog

Check the “Open copy in editor” checkbox and click OK. This will bring up the graphical layout editor on this copy of the main layout.

TUTORIAL #17 - SUPPORTING LARGE SCREENS

Unfortunately, what we want to do is not readily supported by Android Studio's edition of the drag-and-drop GUI builder. So, switch over to the XML for this layout, and replace it with:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/something"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <RelativeLayout
        android:layout_width="0dp"
        android:layout_height="match_parent"
        android:layout_weight="7"
        tools:context=".EmPubLiteActivity">
        <ProgressBar
            android:id="@+id/progressBar1"
            style="?android:attr/progressBarStyleLarge"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_centerHorizontal="true"
            android:layout_centerVertical="true"/>
        <android.support.v4.view.ViewPager
            android:id="@+id/pager"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:visibility="gone"/>
    </RelativeLayout>
    <View
        android:id="@+id/divider"
        android:layout_width="2dp"
        android:layout_height="match_parent"
        android:background="#AA000000"
        android:visibility="gone"/>
    <FrameLayout
        android:id="@+id/sidebar"
        android:layout_width="0dp"
        android:layout_height="match_parent">
    </FrameLayout>
</LinearLayout>
```

Repeat the same process, copying `res/layout/main.xml` into the `res/layout-h880dp/` directory, and replacing the copy's contents with:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/something"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">
    <RelativeLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="7"
        tools:context=".EmPubLiteActivity">
        <ProgressBar
            android:id="@+id/progressBar1"
```

```
        style="?android:attr/progressBarStyleLarge"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_centerHorizontal="true"
        android:layout_centerVertical="true"/>
<android.support.v4.view.ViewPager
    android:id="@+id/pager"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:visibility="gone"/>
</RelativeLayout>
<View
    android:id="@+id/divider"
    android:layout_width="match_parent"
    android:layout_height="2dp"
    android:background="#AA000000"
    android:visibility="gone"/>
<FrameLayout
    android:id="@+id/sidebar"
    android:layout_width="match_parent"
    android:layout_height="0dp">
</FrameLayout>
</LinearLayout>
```

Step #2: Loading Our Sidebar Widgets

Now that we added the divider widget and sidebar container to (some of) our layouts, we need to access those widgets at runtime.

So, in `EmPubLiteActivity`, add data members for them:

```
private View sidebar=null;
private View divider=null;
```

Then, in `onCreate()` of `EmPubLiteActivity`, initialize those data members, sometime after the call to `setContentView()`:

```
sidebar=findViewById(R.id.sidebar);
divider=findViewById(R.id.divider);
```

Step #3: Opening the Sidebar

A real production-grade app would use animated effects to hide and show our sidebar. However, we have not yet covered animations in this book, so we will simply:

- Cause the divider to become visible

TUTORIAL #17 - SUPPORTING LARGE SCREENS

- Adjust the `android:layout_weight` of our sidebar to be 3 instead of 0, giving it ~30% of the screen (with the original `RelativeLayout` getting 70%, courtesy of its `android:layout_weight="7"`)

With that in mind, add the following implementation of an `openSidebar()` method to `EmPubLiteActivity`:

```
private void openSidebar() {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)sidebar.getLayoutParams();
    if (p.weight == 0) {
        p.weight=3;
        sidebar.setLayoutParams(p);
    }

    divider.setVisibility(View.VISIBLE);
}
```

Here, we:

- Get the existing `LinearLayout.LayoutParams` from the sidebar
- If it is still 0 (meaning the sidebar has not been opened), assign it a weight of 3, update the layout via `setLayoutParams()`, and toggle the visibility of the divider

Step #4: Loading Content Into the Sidebar

Now that we can get our sidebar to appear, we need to load content into it... but only if we have the sidebar. If `EmPubLiteActivity` loads a layout that does not have the sidebar, we need to stick with our existing logic that starts up an activity to display the content.

With that in mind, add data members to `EmPubLiteActivity` to hold onto our help and about fragments:

```
private SimpleContentFragment help=null;
private SimpleContentFragment about=null;
```

Also add a pair of static data members that will be used as tags for identifying these fragments in our `FragmentManager`:

```
private static final String HELP="help";
private static final String ABOUT="about";
```

TUTORIAL #17 - SUPPORTING LARGE SCREENS

Also add a pair of static data members that will hold the paths to our help and about assets, since we will be referring to them from more than one place when we are done:

```
private static final String FILE_HELP=
    "file:///android_asset/misc/help.html";
private static final String FILE_ABOUT=
    "file:///android_asset/misc/about.html";
```

In `onCreate()` of `EmPubLiteActivity`, initialize the fragments from the `FragmentManager`:

```
help=
    (SimpleContentFragment)getFragmentManager().findFragmentByTag(HELP);
about=
    (SimpleContentFragment)getFragmentManager().findFragmentByTag(ABOUT);
```

The net result is that *if* we are returning from a configuration change, we will have our fragments, otherwise we will not at this point.

Next, add the following methods to `EmPubLiteActivity`:

```
private void showAbout() {
    if (sidebar!=null) {
        openSidebar();

        if (about==null) {
            about=SimpleContentFragment.newInstance(FILE_ABOUT);
        }

        getFragmentManager().beginTransaction().addToBackStack(null)
            .replace(R.id.sidebar, about, ABOUT).commit();
    }
    else {
        Intent i=new Intent(this, SimpleContentActivity.class);

        i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_ABOUT);
        startActivity(i);
    }
}

private void showHelp() {
    if (sidebar!=null) {
        openSidebar();

        if (help==null) {
            help=SimpleContentFragment.newInstance(FILE_HELP);
        }

        getFragmentManager().beginTransaction().addToBackStack(null)
            .replace(R.id.sidebar, help, HELP).commit();
    }
    else {
        Intent i=new Intent(this, SimpleContentActivity.class);
```

TUTORIAL #17 - SUPPORTING LARGE SCREENS

```
i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_HELP);
startActivity(i);
}
}
```

Both of these methods follows the same basic recipe:

- Check to see if sidebar is null, to see if we have a sidebar or not
- If we have a sidebar, call `openSidebar()` to ensure the user can see the sidebar, create our Fragment if we do not already have it, and use a `FragmentManager` to replace whatever was in the sidebar with the new Fragment
- If we do not have the sidebar, launch an activity with an appropriately-configured Intent

Note a couple of things with our `FragmentManager` objects:

- We use `addToBackStack(null)`, so if the user presses BACK, Android will reverse this transaction
- We use `replace()` instead of `add()`, as there may already be a fragment in the sidebar (`replace()` will behave the same as `add()` for an empty sidebar)

Then, in the `onOptionsItemSelected()` of `EmPubLiteActivity`, replace the about, and help case blocks to use the newly-added methods, replacing their existing implementations:

```
case R.id.about:
    showAbout();

    return(true);

case R.id.help:
    showHelp();

    return(true);
```

Step #5: Removing Content From the Sidebar

While `addToBackStack(null)` will allow Android to automatically remove fragments as the user presses BACK, that will not cause our sidebar to magically close. Rather, we need to do that ourselves.

The easiest way to track this is to track the state of the “back stack”. So, add implements `FragmentManager.OnBackStackChangeListener` to the declaration of

TUTORIAL #17 - SUPPORTING LARGE SCREENS

EmPubLiteActivity, and in onCreate() of EmPubLiteActivity, add the following line, sometime after you initialized the sidebar and divider data members:

```
getFragmentManager().addOnBackStackChangeListener(this);
```

The first statement registers our activity as receiving events related to changes in the state of the back stack.

To make this compile, we need to implement onBackPressed() in EmPubLiteActivity:

```
@Override
public void onBackPressed() {
    if (getFragmentManager().getBackStackEntryCount() == 0) {
        LinearLayout.LayoutParams p=
            (LinearLayout.LayoutParams)sidebar.getLayoutParams();
        if (p.weight > 0) {
            p.weight=0;
            sidebar.setLayoutParams(p);
            divider.setVisibility(View.GONE);
        }
    }
}
```

Here, if our back stack is empty, we reverse the steps from openSidebar() and close it back up again, hiding the divider and setting the sidebar's weight to 0.

The complete revised EmPubLiteActivity should now look something like:

```
package com.commonware.empublite;

import android.app.Activity;
import android.app.FragmentManager;
import android.content.Intent;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.os.StrictMode;
import android.support.v4.view.ViewPager;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.LinearLayout;
import de.greenrobot.event.EventBus;

public class EmPubLiteActivity extends Activity
    implements FragmentManager.OnBackStackChangeListener {
    private static final String MODEL="model";
    private static final String PREF_LAST_POSITION="lastPosition";
    private static final String PREF_SAVE_LAST_POSITION="saveLastPosition";
    private static final String PREF_KEEP_SCREEN_ON="keepScreenOn";
    private static final String HELP="help";
    private static final String ABOUT="about";
    private static final String FILE_HELP=
```

TUTORIAL #17 - SUPPORTING LARGE SCREENS

```
        "file:///android_asset/misc/help.html";
private static final String FILE_ABOUT=
        "file:///android_asset/misc/about.html";
private ViewPager pager=null;
private ContentsAdapter adapter=null;
private ModelFragment mfrag=null;
private View sidebar=null;
private View divider=null;
private SimpleContentFragment help=null;
private SimpleContentFragment about=null;

@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setupStrictMode();

    setContentView(R.layout.main);
    pager=(ViewPager)findViewById(R.id.pager);
    sidebar=findViewById(R.id.sidebar);
    divider=findViewById(R.id.divider);

    getFragmentManager().addOnBackStackChangeListener(this);

    help=
        (SimpleContentFragment)getFragmentManager().findFragmentByTag(HELP);
    about=
        (SimpleContentFragment)getFragmentManager().findFragmentByTag(ABOUT);
}

@Override
public void onResume() {
    super.onResume();
    EventBus.getDefault().register(this);

    if (adapter==null) {
        mfrag=(ModelFragment)getFragmentManager().findFragmentByTag(MODEL);

        if (mfrag==null) {
            mfrag=new ModelFragment();

            getFragmentManager()
                .beginTransaction()
                .add(mfrag, MODEL)
                .commit();
        }
        else if (mfrag.getBook()!=null) {
            setupPager(mfrag.getBook());
        }
    }

    if (mfrag.getPrefs()!=null) {
        pager.setKeepScreenOn(mfrag.getPrefs()
            .getBoolean(PREF_KEEP_SCREEN_ON, false));
    }
}

        case R.id.about:
            showAbout();

            return(true);

        case R.id.help:
            showHelp();

            return(true);

        case R.id.settings:
            startActivity(new Intent(this, Preferences.class));

            return(true);

        case R.id.notes:
            Intent i=new Intent(this, NoteActivity.class);

            i.putExtra(NoteActivity.EXTRA_POSITION, pager.getCurrentItem());
            startActivity(i);

            return(true);

        case R.id.update:
            startService(new Intent(this, DownloadCheckService.class));

            return(true);
    }

    return(super.onOptionsItemSelected(item));
}

@Override
public void onBackPressed() {
    if (getFragmentManager().getBackStackEntryCount() == 0) {
        LinearLayout.LayoutParams p=
            (LinearLayout.LayoutParams)sidebar.getLayoutParams();
        if (p.weight > 0) {
            p.weight=0;
        }
    }
}
```

TUTORIAL #17 - SUPPORTING LARGE SCREENS

```
        sidebar.setLayoutParams(p);
        divider.setVisibility(View.GONE);
    }
}

@SuppressWarnings("unused")
public void onEventMainThread(BookLoadedEvent event) {
    setupPager(event.getBook());
}

private void setupPager(BookContents contents) {
    adapter=new ContentsAdapter(this, contents);
    pager.setAdapter(adapter);
    findViewById(R.id.progressBar1).setVisibility(View.GONE);
    pager.setVisibility(View.VISIBLE);

    SharedPreferences prefs=mfrag.getPrefs();

    if (prefs!=null) {
        if (prefs.getBoolean(PREF_SAVE_LAST_POSITION, false)) {
            pager.setCurrentItem(prefs.getInt(PREF_LAST_POSITION, 0));
        }
    }

    pager.setKeepScreenOn(prefs.getBoolean(PREF_KEEP_SCREEN_ON, false));
}

private void openSidebar() {
    LinearLayout.LayoutParams p=
        (LinearLayout.LayoutParams)sidebar.getLayoutParams();
    if (p.weight == 0) {
        p.weight=3;
        sidebar.setLayoutParams(p);
    }

    divider.setVisibility(View.VISIBLE);
}

private void showAbout() {
    if (sidebar!=null) {
        openSidebar();

        if (about==null) {
            about=SimpleContentFragment.newInstance(FILE_ABOUT);
        }

        getFragmentManager().beginTransaction().addToBackStack(null)
            .replace(R.id.sidebar, about, ABOUT).commit();
    }
    else {
        Intent i=new Intent(this, SimpleContentActivity.class);

        i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_ABOUT);
        startActivity(i);
    }
}

private void showHelp() {
    if (sidebar!=null) {
```

TUTORIAL #17 - SUPPORTING LARGE SCREENS

```
openSidebar();

if (help==null) {
    help=SimpleContentFragment.newInstance(FILE_HELP);
}

getFragmentManager().beginTransaction().addToBackStack(null)
    .replace(R.id.sidebar, help, HELP).commit();
}
else {
    Intent i=new Intent(this, SimpleContentActivity.class);

    i.putExtra(SimpleContentActivity.EXTRA_FILE, FILE_HELP);
    startActivity(i);
}
}

private void setupStrictMode() {
    StrictMode.ThreadPolicy.Builder builder=
        new StrictMode.ThreadPolicy.Builder()
            .detectAll()
            .penaltyLog();

    if (BuildConfig.DEBUG) {
        builder.penaltyFlashScreen();
    }

    StrictMode.setThreadPolicy(builder.build());
}
}
```

At this point, if you build the project and run it on a -large or -xlarge device or emulator, and you choose to view the help or about pages, you will see the sidebar appear, whether in portrait or landscape.

TUTORIAL #17 - SUPPORTING LARGE SCREENS

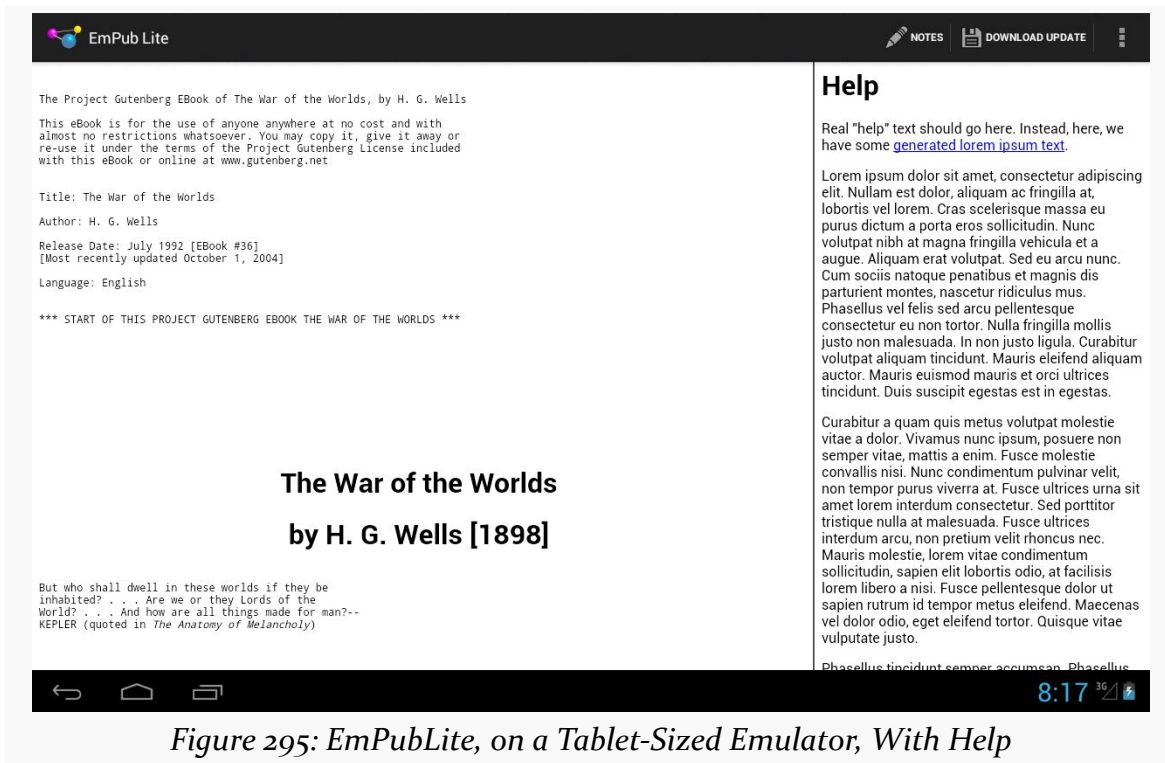

Figure 295: EmPubLite, on a Tablet-Sized Emulator, With Help

Note that a tablet emulator usually will only run acceptably fast if you are using the x86 emulator images.

Backwards Compatibility Strategies and Tactics

Android is an ever-moving target, averaging about 2.5 API level increments per year. The Android Developer site maintains a chart and table showing the most recent [breakdown of OS versions](#) making requests of the Play Store.

Most devices tend to be clustered around 1-3 minor releases. However, these are never the most recent release, which takes time to percolate through the device manufacturers and carriers and onto devices, whether those are new sales or upgrades to existing devices.

Some developers panic when they realize this.

Panic is understandable, if not necessary. This is a well-understood problem, that occurs frequently within software development — ask any Windows developer who had to simultaneously support everything from Windows 98 to Windows XP, or Windows XP through Windows 8.1. Moreover, there are many things in Android designed to make this problem as small as possible. What you need are the strategies and tactics to make it all work out.

Think Forwards, Not Backwards

Android itself tries very hard to maintain backwards compatibility. While each new Android release adds many classes and methods, relatively few are marked as deprecated, and almost none are outright eliminated. And, in Android, “deprecated” means “there’s probably a better solution for what you are trying to accomplish, though we will maintain this option for you as long as we can”.

Despite this, many developers aim purely for the lowest common denominator. Aiming to support older releases is noble. Ignoring what has happened since those releases is stupid, if you are trying to distribute your app to the public via the Play Store or similar mass-distribution means.

Why? You want your app to be distinctive, not decomposing.

For example, as we saw in the chapter on the action bar, adding one line to the manifest (`android:targetSdkVersion="11"`) gives you the action bar, the holographic widget set (e.g., `Theme.Holo`), the new style of options menu, and so on. Those dead-set on avoiding things newer than Android 2.1 would not use this attribute. As a result, on Android 3.0+ devices, their apps will tend to look old. Some will not, due to other techniques they are employing (e.g., running games in a full-screen mode), but many will.

You might think that this would not matter. After all, how many people in 2011 were even using Android 3.x? 5%?

However, those in position to trumpet your application — Android enthusiast bloggers chief among them — will tend to run newer equipment. Their opinion matters, if you are trying to have their opinion sway others relative to your app. Hence, if you look out-of-touch to them, they may be less inclined to provide glowing recommendations of your app to their readers.

Besides, not everything added to newer versions of Android is pure “eye candy”. It is entirely possible that features in the newer Android releases might help make your app stand out from the competition, whether it is making greater use of NFC or offering tighter integration to the stock Calendar application or whatever. By taking an “old features only” approach, you leave off these areas for improvement.

And, to top it off, the world moves faster than you think. It takes about a year for a release to go from release to majority status (or be already on the downslope towards oblivion, passed over by something newer still). You need to be careful that the decisions you make today do not doom you tomorrow. If you focus on “old features only”, how much rework will it take you to catch up in six months, or a year?

Hence, this book advocates an approach that differs from that taken by many: aim high. Decide what features you want to use, whether those features are from older releases or the latest-and-greatest release. Then, write your app using those features, and take steps to ensure that everything still works reasonably well (if not as full-featured) on older devices. This too is a well-trodden path, used by Web developers

for ages (e.g., support sexy stuff in Firefox and Safari, while still gracefully degrading for IE6). And the techniques that those Web developers use have their analogous techniques within the Android world.

Aim Where You Are Going

One thing to bear in mind is that the OS distribution chart and table shown above is based on devices contacting the Play Store. Hence, this is only directly relevant if you are actually distributing through the Play Store.

If you are distributing through the Amazon AppStore, or to device-specific outlets (e.g., BlackBerry World), you will need to take into account what sorts of devices are using those means of distribution.

If you are specifically targeting certain non-Play Store devices, like the Kindle Fire, you will need to take into account what versions of Android they run.

If you are building an app to be distributed by a device manufacturer on a specific device, you need to know what Android version will (initially) be on that device and focus on it.

If you are distributing your app to employees of a firm, members of an organization, or the like, you need to determine if there is some specific subset of devices that they use, and aim accordingly. For example, some enterprises might distribute Android devices to their employees, in which case apps for that enterprise should run on those devices, not necessarily others.

A Target-Rich Environment

There are a few places in your application where you will need to specify Android API levels of relevance to your code.

The most important one is the `android:minSdkVersion` attribute, as discussed early in this book. You need to set this to the oldest version of Android you are willing to support, so you will not be installed on devices older than that.

There is also `android:targetSdkVersion`, mentioned in passing earlier in this chapter. In the abstract, this attribute tells Android “this is the version of Android I was thinking of when I wrote the code”. Android can use this information to help both backwards and forwards compatibility. Historically, this was under-utilized.

However, with API Level 11 and API Level 14, `android:targetSdkVersion` took on greater importance. Specifying 11 or higher gives you the action bar and all the rest of the look-and-feel introduced in the Honeycomb release. Specifying 14 or higher will give you some new features added in Ice Cream Sandwich, such as automatic whitespace between your app widgets and other things on the user's home screen. In general, use a particular `android:targetSdkVersion` when instructions tell you to.

The third place — and perhaps the one that confuses developers the most — is the build target. This shows up as `compileSdkVersion` in `build.gradle` for Android Studio users, or in Project > Properties > Android for Eclipse users.

Part of the confusion is the multiple uses of the term “target”. The build target has nothing to do with `android:targetSdkVersion`. Nor is it strictly tied to what devices you are targeting.

Rather, it is a very literal term: it is the target **of the build**. It indicates:

- What version of the Android class library you wish to compile against, dictating what classes and methods you will be able to refer to directly
- What rules to apply when interpreting resources and the manifest, to complain about things that are not recognized

The net is that you set your build target to be the lowest API level that has everything you are using directly.

Lint: It's Not Just For Belly Buttons

In the old days, the only way to find out that you were using a newer class or method than what was in your `minSdkVersion` would be to set your build target to be the same as your `minSdkVersion`. That way, any attempt to use something newer than your minimum would be greeted with compile errors. This works, but at a high cost: it makes *intentionally* using newer capabilities very painful, forcing you to use reflection to access them.

Nowadays, this is no longer needed, thanks to Lint.

Lint is part of the standard build process, adding new errors and warnings for things that are syntactically valid but probably not the right answer. In particular, Lint will tell you if you are using classes or methods that are newer than your `minSdkVersion`, *even if they are valid for your build target*.

Hence, the targeting strategy nowadays is:

- Set your `minSdkVersion` to be the oldest version that you are willing to support
- Set your build target to be the version of Android that has all of the classes and methods you intend to use, allowing Lint to point out places where you need to pay attention to what sort of device you are running on ([more on this later](#))
- Set your `targetSdkVersion` to be something relatively recent, unless you have specific reasons to use some specific version

A Little Help From Your Friends

The simplest way to use a feature yet support devices that lack the feature is to use a compatibility library that enables the feature for more devices. The Android Support package is one such compatibility library, though it also offers other classes as well.

With a compatibility library, the API for using the library is nearly identical to using the native Android capability, mostly involving slightly different package names (e.g., `android.support.v4.app.Fragment` instead of `android.app.Fragment`).

So, if there is something new that you want to use on older devices, and the new feature is not obviously tied to hardware, see if there is a “backport” of the feature available to you. Examples include backports of:

- `CalendarView` (<https://github.com/SimonVT/android-calendarview>)
- `Switch` (<https://github.com/BoD/android-switch-backport>)
- `DatePicker` (<https://github.com/SimonVT/android-datepicker>)
- `NumberPicker` (<https://github.com/SimonVT/android-numberpicker>)
- `TimePicker` (<https://github.com/SimonVT/android-timepicker>)

Avoid the New on the Old

If the goal is to support new capabilities on new devices, while not losing support for older devices, that implies we have the ability to determine what devices are newer and what devices are older. There are a few techniques for doing this, involving Java and resources.

Java

If you wish to conditionally execute some lines of code based on what version of Android the device is running, you can check the value of `Build.VERSION`, referring to the `android.os.Build` class. For example:

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {  
    // do something only on API Level 9 and higher  
}
```

Any device running an older version of Android will skip the statements inside this version guard and therefore will not execute.

That technique is sufficient for Android 2.0 and higher devices. If you are still supporting Android 1.x devices, the story gets a bit more complicated, and that will be discussed later in the book.

If you decide that you want your build target to match your `minSdkVersion` level — as some developers elect to do — your approach will differ. Rather than *blocking* some statements from being executed on *old* devices, you will *enable* some statements to be executed on *new* devices, where those statements use Java reflection (e.g., `Class.forName()`) to reference things that are newer than what your build target supports. Since using reflection is extremely tedious in Java, it is usually simpler to have your build target reflect the classes and methods you are actually using.

@TargetAPI

One problem with this technique is that Eclipse will grumble at you, saying that you are using classes and methods not available on the API level you set for your `minSdkVersion`. To quiet down these Lint messages, you can use the `@TargetAPI` annotation.

For example, earlier in the book, we saw code like this:

```
@TargetApi(Build.VERSION_CODES.HONEYCOMB)  
static public <T> void executeAsyncTask(AsyncTask<T, ?, ?> task, T... params) {  
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {  
        task.executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, params);  
    }  
    else {  
        task.execute(params);  
    }  
}
```

This utility method executes an `AsyncTask` using a multi-threaded thread pool. That is the default behavior of `execute()` on API Level 10 and below. On higher versions of Android, we can explicitly opt into the multi-threaded thread pool by using `executeOnExecutor()`, but that method does not exist prior to API Level 11. Hence, we check our API level at runtime via `Build.VERSION.SDK_INT`, see if we are on HONEYCOMB or higher, and branch accordingly. However, for a project with a `minSdkVersion` of 10 or below, Lint will still complain — Lint is just not sophisticated enough to realize that we are correctly handling newer API levels. The `@TargetApi(Build.VERSION_CODES.HONEYCOMB)` annotation tells Lint that we have indeed confirmed that we are “doing the right thing”, at least through API Level 11.

However, by using `@TargetApi(Build.VERSION_CODES.HONEYCOMB)`, we are implicitly saying that we have *not* checked to see if we are doing things properly for higher versions of Android. So long as all the classes, methods, and such that we reference in this `executeAsyncTask()` method are available in API Level 11, we are fine. If we change the implementation to reference something from, say, API Level 14, now Lint will start complaining again. **This is what we want**, so we are alerted to the problem and can fix it. Hence, *only* set the `@TargetApi()` annotation to the API level that are you explicitly handling. Do not just set it to some arbitrarily high level (or, worse, use `@SuppressWarnings` to try to get Lint to shut up entirely).

Resources

The aforementioned version guards only work for Java code. Sometimes, you will want to have different resources for different versions of Android. For example, you might want to make a custom style that inherits from `Theme.Holo` for Android 3.0 and higher. Since `Theme.Holo` does not exist on earlier versions of Android, trying to use a style that inherits from it will fail miserably on, say, an Android 2.2 device.

To handle this scenario, use the `-vNN` suffix to have two resource sets. One (e.g., `res/values-v11/`) would be restricted to certain Android versions and higher (e.g., API Level 11 and higher). The default resource set (e.g., `res/values/`) would be valid for any device. However, since Android chooses more specific matches first, an Ice Cream Sandwich phone would go with the resources containing the `-v11` suffix. So, in the `-v11` resource directories, you put the resources you want used on API Level 11 and higher, and put the backwards-compatible ones in the set without the suffix. This works for Android 2.0 and higher. You can also use `-v3` for resources that *only* will be used on Android 1.5 (and no higher) or `-v4` for resources that *only* will be used on Android 1.6.

Components

One variation on the above trick allows you to conditionally enable or disable components, based on API level.

Every `<activity>`, `<receiver>`, or `<service>` in the manifest can support an `android:enabled` attribute. A disabled component (`android:enabled="false"`) cannot be started by anyone, including you.

We have already seen string resources be used in the manifest, for things like `android:label` attributes. Boolean values can also be created as resources. By convention, they are stored in a `bools.xml` file in `res/values/` or related resource sets. Just as `<string>` elements provide the definition of a string resource, `<bool>` elements provide the definition of a boolean resource. Just give the boolean resource a name and a value:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <bool name="on_honeycomb">false</bool>
</resources>
```

The above example has a boolean resource, named `on_honeycomb`, with a value of `false`. That would typically reside in `res/values/bools.xml`. However, you might also have a `res/values-v11/bools.xml` file, where you set `on_honeycomb` to `true`.

Now, you can use `@bool/on_honeycomb` in `android:enabled` to conditionally enable a component for API Level 11 or higher, leaving it disabled for older devices.

This can be a useful trick in cases where you might need multiple separate implementations of a component, based on API level. For example, later in the book we will examine app widgets — those interactive elements users can add to their home screens. App widgets have limited user interfaces, but API Level 11 added a few new capabilities that previously were unavailable, such as the ability to use `ListView`. However, the code for a `ListView`-backed app widget may be substantially different than for a replacement app widget that works on older devices. And, if you leave the `ListView` app widget enabled in the manifest, the user might try choosing it and crashing. So, you would only enable the `ListView` app widget on API Level 11 or higher, using the boolean resource trick.

Testing

Of course, you will want to make sure your app really does work on older devices as well as newer ones.

At build time, one trick to use periodically is to change your build target to match your `minSdkVersion`, then see where the compiler complains (or, in Eclipse, where you get all the red squiggles). If everything is known (e.g., resource attributes that will be ignored on older versions) or protected (e.g., Java statements inside a version guard `if` statement), then you are OK. If, however, you see complaints about something you forgot was only in newer Android releases, you can take steps to fix things.

You will also want to think about Android versions when it comes to testing, a topic that will be covered later in this book.

Keeping Track of Changes

Each Android SDK release is accompanied by API release notes, such as [this set for Android 4.4/API Level 19](#).

Similarly, each Android SDK release is accompanied by its “API Differences Report”, a roster of each added, removed, or modified class or method. For example, this [API Differences Report](#) points out the changes between API Level 18 and API Level 19.

Other changes are called out in [the JavaDocs for `Build.VERSION_CODES`](#), with particular emphasis on what happens when you set a specific API level as your `android:targetSdkVersion`. Note that this roster is not complete, but may mention some things not mentioned in the other locations.

Each class, method, and field in the JavaDocs has a notation as to what API level that particular item was added. Class API levels appear towards the top of the page; method and field API levels appear on the right side of the gray bar containing the method signature or field declaration. Also, in the JavaDocs “Android APIs” column on the left, there is a drop-down that allows you to filter the contents based upon API level.

System Services

One of the problems that we have in Android app development is the overloading of terms. We have already seen how “layouts” sometimes refer to layout resources and sometimes refer to container classes like `LinearLayout`.

Another example comes in the name “service”. This was already used in a few places in Java (e.g., `ExecutorService`). Android then used it for [one of our four app components](#). Android *also* uses “service” as part of the term “system service”... where system services have little to do with Java services or Android services.

What is a System Service?

System services are “manager”-type classes that you get by calling `getSystemService()` on some `Context`, such as an `Activity` or `Service`. Usually, system services are tied to lower-level device functionality, like telephony. However, not all low-level device functionality is exposed by means of system services; some have separate APIs implemented by other sorts of “manager” classes.

There are two flavors of `getSystemService()`. The one that you are likely to use is the one that takes a `String` parameter that is the name of the system service that you want. You get back a generic `Object`, which you then have to downcast to the specific type of system service that you are trying to use:

```
AlarmManager mgr=(AlarmManager)someContext.getSystemService(Context.ALARM_SERVICE);
```

API Level 23 finally added a type-safe version of `getSystemService()`. You pass in the Java class object for the system service and get an instance of that class back:

```
AlarmManager mgr=someContext.getSystemService(AlarmManager.class);
```

However, until your `minSdkVersion` rises to 23 or higher, you will not be able to use that version of `getSystemService()` on `Context` on older devices.

Alas, [there is no backport](#) of `getSystemService()` on `ContextCompat` from the Android Support library.

What System Services Are There?

There are many system services, with new ones coming every Android version release or two. Here are the major ones as of Android 6.0, with links to chapters that focus on them (where available):

- `AccessibilityManager`, for being notified of key system events (e.g., activities starting) that might be relayed to users via haptic feedback, audio prompts, or other non-visual cues
- `AccountManager`, for working with Android's system of user accounts and synchronization
- `ActivityManager`, for getting more information about what processes and components are presently running on the device
- `AlarmManager`, for scheduled tasks (a.k.a., “cron jobs”), covered [elsewhere in this book](#)
- `AppOpsManager`, for “tracking application operations on the device”
- `AppWidgetManager`, for creating or hosting [app widgets](#)
- `AudioManager`, for managing audio stream volumes, audio ducking, and other system-wide audio affordances
- `BatteryManager`, for finding out about the state of the battery
- `BluetoothManager`, for exposing or connecting to Bluetooth services
- `ClipboardManager`, for working with the device clipboard, covered [elsewhere in this book](#)
- `ConnectivityManager`, for a high-level look as to what sort of network the device is connected to for data (e.g., WiFi, 3G)
- `ConsumerIrManager`, for creating “IR blaster” or other IR-sending apps, on hardware that has an IR transmitter
- `DevicePolicyManager`, for accessing [device administration](#) capabilities, such as wiping the device
- `DisplayManager`, for working with external displays, covered [elsewhere in this book](#)
- `DownloadManager`, for downloading large files on behalf of the user, covered in [elsewhere in the book](#)

SYSTEM SERVICES

- DropBoxManager, for maintaining your own ring buffers of logging information akin to LogCat
- FingerprintManager, for working with fingerprint readers on Android 6.0+ devices
- InputMethodManager, for working with input method editors
- InputManager, for identifying external sources of input, such as keyboards and trackpads
- JobScheduler, for scheduling periodic background work, covered [elsewhere in the book](#)
- KeyguardManager, for locking and unlocking the keyguard, where possible
- LauncherApps, for identifying launchable apps on the device (e.g., for home screen launchers), taking into account device policies
- LayoutInflater, for inflating layout XML files into Views, as you saw earlier in the book
- LocationManager, for determining the device's location (e.g., GPS), covered in [the chapter on location tracking](#)
- MediaProjectionManager, for [capturing screenshots and screencasts](#)
- MediaRouter, for [working with external speakers and displays](#)
- MediaSessionManager, for teaching Android about media that you are playing back
- MidiManager, for playing MIDI audio
- NetworkStatsManager, “for querying network usage stats”
- NfcManager, for [reading NFC tags or pushing NFC content](#)
- NotificationManager, for putting icons in the status bar and otherwise alerting users to things that have occurred asynchronously, covered in [the chapter on Notification](#)
- NsdManager, for network service discovery operations
- PowerManager, for obtaining WakeLock objects and such, covered [elsewhere in this book](#)
- PrintManager, for [printing from Android](#)
- RestrictionsManager, for identifying and working with restricted operations
- SearchManager, for interacting with the global search system
- SensorManager, for accessing data about sensors, such as the accelerometer, covered [elsewhere in this book](#)
- StorageManager, for working with expanded payloads (OBBs) delivered as part of your app's installation from the Play Store
- SubscriptionManager, for dealing with data roaming and other telephony subscription rules
- TelecomManager, for dealing with incoming and outgoing phone calls

SYSTEM SERVICES

- TelephonyManager, for finding out about the state of the phone and related data (e.g., SIM card details)
- TextServicesManager, for working with spelling checkers and other “text services”
- TvInputManager, for Android-powered televisions, to find out about TV inputs
- UiModeManager, for dealing with different “UI modes”, such as being docked in a car or desk dock
- UsageStatsManager, “for querying device usage stats”
- UsbManager, for working directly with accessories and hosts over USB
- UserManager, for working with multiple user accounts on a compatible device (Android 4.2+ tablets, Android 5.0+ phones)
- Vibrator, for shaking the phone (e.g., haptic feedback)
- WallpaperService, for working with the device wallpaper
- WifiManager, for getting more details about the active or available WiFi networks
- WifiP2pManager, for setting up and communicating over WiFi peer-to-peer (P2P) networks
- WindowManager, mostly for accessing details about the default display for the device

Google Play Services

A term that you will encounter a fair bit as an Android developer is “Google Play Services”, or “Play Services” for short. This is your gateway into a series of proprietary capabilities that Google has layered on top of Android. Many of these capabilities are tied to Google’s servers and services, such as ads and Google Drive.

However, these capabilities, while usually free from monetary cost to the developer, are not free from problems or controversy.

What Is Google Play Services?

Google Play Services is a “kitchen sink” term, encompassing a wide range of things from the standpoint of developers and users alike.

...From the Standpoint of Developers?

The Play Services SDK allows you to integrate your Android app with a number of Google proprietary services, from leaderboard management for games to interacting with Chromecast devices. Many, but not all, of these services are tied to Google servers. Many, but not all, of these services will require some sort of API key as a result.

The SDK comes in the form of an Android library project that you link into your app, giving you access to classes and methods that let you add maps, or payment options, or push message receipt into your Android apps.

Note that while the name “Play Services” contains the word “services”, Play Services is merely an API, one that does not directly have anything to do with [services](#) or [system services](#).

...From the Standpoint of Users of Google Play Devices?

In Western countries, the common perception is that all Android devices are part of the Google Play world. These devices will have the Play Services Framework pre-installed from the device manufacturer and silently updated over the air by Google. Apps that use the Play Services SDK in theory can use all of the SDK's available APIs on all devices equipped with the Play Services Framework.

In practice, older devices (particularly Android 2.x) will have some number of limitations related to Play Services, not the least of which being the lack of automatic over-the-air updates. As many developers are now setting their `minSdkVersion` to be something newer (e.g., 15), this particular class of problems will tend to fall by the wayside.

...From the Standpoint of the Android Ecosystem?

Google's continued expansion of the Play Services SDK, sometimes at the expense of Android itself, has not proven to be universally popular:

- Developers who depend on the Play Services SDK will not be able to run on devices that lack the Play Services Framework. And while many people think that the only devices that matter have the Play Services Framework, some estimates indicate that over half of Android devices in use today are from manufacturers that are not part of the Google Play ecosystem.
- The Play Services SDK is closed-source, and as such it makes debugging certain classes of problem more difficult.
- The terms and conditions for using different aspects of the Play Services SDK may cause problems for some developers, ranging from interfering with their planned business model to interfering with their planned software license (e.g., GPL).

What Is In the Play Services SDK?

As mentioned earlier, the Play Services SDK is *vast*. The following sub-sections outline some of the major pieces of the Play Services SDK, what Gradle dependency pulls them in, and what independent alternatives exist (if any).

Android Pay / Google Wallet

Google has tried a couple of times to get into the mobile payments market, starting with Google Wallet, which has now morphed into Android Pay. If you want to allow users to purchase goods and services through your app, and you want to allow those users to pay via Android Pay, you can use this portion of the Play Services SDK.

The Gradle compile statement for your dependencies, to pull in the Android Pay APIs, is:

```
compile "com.google.android.gms:play-services-wallet:8.1.0"
```

Android Wear

To communicate from a device running an open source operating system (Android, on a phone or tablet) to a device running an open source operating system (Android, on an Android Wear device), you have to use a proprietary, closed-source library.

It is possible to show a Notification on a Wear device straight from the Android SDK. It is also possible to create a Wear app that exists standalone straight from the Android SDK. But if you want to send data to the Wear device from the phone or tablet, or vice versa, that requires the Wear portion of the Play Services SDK.

This library provides a few discrete APIs for communication:

- A shared data API, where both sides can read and write from a key-value store that is synchronized between the two environments
- A message API, for a classic point-to-point communications pattern
- An asset transfer API, designed for larger data sets (e.g., large images)

The Gradle compile statement for your dependencies, to pull in the Wear APIs, is:

```
compile "com.google.android.gms:play-services-wearable:8.1.0"
```

Google+

The documentation and business proposition for the Google+ API is a bit limited at this time. However, it appears that you can:

- add a +1 button to your app, if that sounds interesting

- have richer options for sharing content to a user's Google+ account, beyond simple ACTION_SEND
- examine the user's Google+ profile and some of the user's friends on Google+

The Gradle `compile` statement for your dependencies, to pull in the Google+ APIs, is:

```
compile "com.google.android.gms:play-services-plus:8.1.0"
```

Google Account Login / Sign In with Google

Rather than maintain your own account system, your app could ask the users to sign into their Google account as part of using your app.

The Gradle `compile` statement for your dependencies, to pull in the “Sign In with Google” APIs, is:

```
compile "com.google.android.gms:play-services-identity:8.1.0"
```

In addition, you will need the aforementioned Google+ APIs (`play-services-plus`).

Google Analytics

“Analytics” refers to tracking usage. Web analytics uses a mix of Web server logs, tracking cookies, and the like to determine popular Web pages, navigation flows, time spent in certain areas of a site, and so forth. Mobile analytics tracks usage within an app: certain activities, certain operations, etc.

Google Analytics is very popular for Web sites, and Google extended this to a mobile API designed for tracking app usage.

The Gradle `compile` statement for your dependencies, to pull in the in-app Google Analytics API, is:

```
compile "com.google.android.gms:play-services-analytics:8.1.0"
```

There are countless analytics services with Android APIs (e.g., Flurry) beyond Google's. While there appear to be few self-hosted or open source solutions, analytics data collection is not especially difficult to implement on your own, if you would prefer to keep this information more private. Data analysis is where the challenges with home-grown solutions arise. Or, you could simply not collect this sort of information.

Google App Indexing

Google App Indexing, among other things, allows for “deep links” into an Android app, surfaced from Google search results. That, on its own, does not require any particular proprietary APIs. However, to allow Google to discover these “deep links”, it appears that you need to use a custom app-indexing API.

The Gradle `compile` statement for your dependencies, to pull in the “Sign In with Google” APIs, is:

```
compile "com.google.android.gms:play-services-appindexing:8.1.0"
```

Google App Invites

Google’s App Invites service allows your users to annoy their contacts, bugging them to install your app.

The Gradle `compile` statement for your dependencies, to pull in the App Invite APIs, is:

```
compile "com.google.android.gms:play-services-appinvite:8.1.0"
```

A simpler, albeit less slick, solution is to allow the user to send messages from your app with a link back to your app from its distribution channel (e.g., Play Store), such as via an `ACTION_SEND` Intent.

Google Cast

Google Cast can be thought of as a control protocol for Google Cast-enabled receivers. Through a Google-supplied SDK (or other means), Google Cast client apps (“senders”) can direct a Google Cast-enabled receiver to play, pause, rewind, fast-forward, etc. a stream. Android TV devices and Chromecast devices are the primary Cast-enabled receivers.

Google Cast does assume that, in general, the media receiver runs its own OS and is capable of playing streaming media without ongoing assistance from the Google Cast client. Hence, the client is not “locked into” having to keep feeding content to the Google Cast client, allowing the user to go off and do other things with that client while playback is going on.

Chromecast offers up remote playback media routes and works with `RemotePlaybackClient`, as is discussed in [the chapter on `MediaRouter`](#). The sample app for `RemotePlaybackClient` was tested on a Chromecast.

If you want greater control than is offered via `RemotePlaybackClient`, though, you can use [the Cast SDK](#). However, using the Cast SDK will tie you to Google Cast — and some of its restrictions, both technical and legal — but will give you greater developer control over the behavior of both the Google Cast device and your app.

The Gradle `compile` statement for your dependencies, to pull in the Cast SDK, is:

```
compile "com.google.android.gms:play-services-cast:8.1.0"
```

As noted above, `RemotePlaybackClient`, along with [the Presentation API](#), offer a significant subset of what the Cast SDK offers.

Google Cloud Messaging

[Google Cloud Messaging](#) – GCM for short — is Google’s current framework for asynchronously delivering notifications from the Internet (“cloud”) to Android devices. Rather than the device waking up and polling on a regular basis at the behest of your app, your app can register for notifications and then wait for them to arrive. GCM is engineered with efficiency in mind:

- Apps do not have to be constantly running, maintaining their own socket connections to some XMPP or MQTT server (let alone several such apps)
- Apps can share a single managed connection to a Google server, one that is carefully tuned to minimize power draw while also keeping the connection alive
- Apps can avoid frequent wakeup events for polling, letting some server do the “heavy lifting” and just tap the app on the virtual shoulder to inform it of some data of interest

The proper use of GCM means better battery life for your users. It can also reduce the amount of time your code runs, which helps you stay out of sight of users looking to pounce on background tasks and eradicate them with task killers.

GCM has gone through three revisions of its API, the latest coming in 2015. Be sure to use up-to-date references and examples when adding GCM to your apps.

The Gradle `compile` statement for your dependencies, to pull in GCM, is:

```
compile "com.google.android.gms:play-services-gcm:8.1.0"
```

You may also encounter references to “C2DM”, GCM’s precursor. C2DM debuted in 2010 and quickly became popular, for everything from triggering near-real-time data synchronization (e.g., Remember the Milk to-do list updates) to lightweight coordination between multiple players in a game. However, C2DM was a Google Labs product and in perpetual beta form. When Google Labs was shut down, C2DM was in limbo: not canceled, but not converted into an actual product. In 2012, GCM formally replaced C2DM, and in 2015, C2DM was shut down entirely. Hence, while high-level concepts about push messaging from the C2DM era might still be relevant to you, any actual C2DM-related code will be useless.

Other devices from outside the Google Play ecosystem may offer their own counterparts to GCM. Independent push implementations can range from XMPP and MQTT to simple WebSockets, though these have limitations when compared to GCM.

Google Drive

Google Drive is Google’s hosted file-storage service. Via Drive APIs in the Play Services SDK, you can work indirectly with the user’s Google Drive-hosted content, including creating and deleting files, plus searching through files for ones that meet particular search criteria.

The Gradle `compile` statement for your dependencies, to pull in the Android Drive API, is:

```
compile "com.google.android.gms:play-services-drive:8.1.0"
```

Note that some of this functionality is available via the [Storage Access Framework](#) in Android 4.4+, with the advantage that it works across multiple content sources, not just Google Drive.

Other services (e.g., Dropbox) have their own APIs as well.

Google Fit

Google Fit is Google’s wearable sensor initiative, for “smartbands” and related gadgets. Through the Fit APIs, you can detect Fit gadgets associated with a user’s device, read data from those gadgets’ sensors (e.g., heart rate), and so forth.

The Gradle `compile` statement for your dependencies, to pull in the Fit API, is:

```
compile "com.google.android.gms:play-services-fitness:8.1.0"
```

Other manufacturers in this space (e.g., Fitbit) have their own SDKs as well.

Google Location Services

This portion of the Play Services SDK offers the “fused location provider”. This combines GPS and network sources of location data, plus sensor information, to try to offer better location information with less power draw. For example, if the sensors suggest that the device is not moving, the fused location provider can scale back how aggressively it uses the location sources, since the location probably is not changing.

This library also offers a “geofencing” implementation, where you ask the Play Services SDK to keep track of certain locations and let you know if the device gets within a certain distance of those locations.

The Gradle `compile` statement for your dependencies, to pull in the fused location provider and geofencing, is:

```
compile "com.google.android.gms:play-services-location:8.1.0"
```

This book has a chapter on [the fused location provider](#).

Google Maps

Android has offered integrated Google Maps to developers since the outset. With the introduction of Maps V2 in 2012, this capability was folded into the Play Services SDK. Through Maps V2, you can embed a map powered by Google Maps into your application, complete with markers and popups, lines and shaded areas, and so on.

The Gradle `compile` statement for your dependencies, to pull in Maps V2, is:

```
compile "com.google.android.gms:play-services-maps:8.1.0"
```

This book has a chapter on [Maps V2](#).

Due to the popularity of embedded maps, other manufacturers (e.g., Amazon, Blackberry) have offered their own map engines, often with APIs that attempt to

mimic that of Maps V₂ (or perhaps its predecessor, now known as Maps V₁). Beyond that, there is [the OpenStreetMap project](#), for which Android libraries are available.

Google Mobile Ads / AdMob

Google is an advertising company. They offer the [Google Mobile Ads SDK \(a.k.a., AdMob for Android\)](#) as part of the Play Services SDK, for you to be able to add banners, interstitials, and other forms of advertising to your app.

The Gradle `compile` statement for your dependencies, to pull in the Google Mobile Ads SDK, is:

```
compile "com.google.android.gms:play-services-ads:8.1.0"
```

There are other competing mobile ad networks that you could consider, though you may be better served focusing on coming up with a better business model.

Google Mobile Vision

Google has a variety of APIs, grouped under the “Mobile Vision” banner, designed for detecting specific sorts of objects or other information in still photos and videos. These include:

- detection of faces, and the state of those faces (e.g., expressions)
- detection and decoding of barcodes

The Gradle `compile` statement for your dependencies, to pull in these APIs, is:

```
compile "com.google.android.gms:play-services-vision:8.1.0"
```

Android’s native camera API has some amount of face recognition, though not to the level of the Face API in the Mobile Vision SDK.

There are a variety of barcode scanning apps (e.g., the legendary ZXing Barcode Scanner) and libraries (e.g., ZBar) that one can use independently of the Play Services SDK.

Google Nearby

Google Nearby offers a pair of APIs for communication between nearby devices.

The Nearby Messages API offers a publish-and-subscribe messaging framework, designed for sending small blocks of data between Internet-connected Android and iOS devices. This is largely frictionless for the user (beyond the network connection), as the Messages API uses a mix of radios (Bluetooth, Bluetooth LE, WiFi) and ultrasonic signaling to handle the pairing and interaction.

The Nearby Connections API offers connection-based group messaging between devices on the same WiFi network. While you can pass more data this way, since everybody has to be on WiFi, it reduces the number of potential communications partners.

The Gradle `compile` statement for your dependencies, to pull in these APIs, is:

```
compile "com.google.android.gms:play-services-nearby:8.1.0"
```

While some aspects of Google Nearby (e.g., ultrasound) are unusual, there have been many projects offering server-less group communications, from ZeroMQ to AllJoyn.

SafetyNet

The SafetyNet APIs lets your app know “whether the device where it is running matches the profile of a device that has passed Android compatibility testing”. Presumably, this is designed to help you detect custom ROMs or copies of your app installed from pirate sites onto incompatible hardware.

The Gradle `compile` statement for your dependencies, to pull in the SafetyNet API, is:

```
compile "com.google.android.gms:play-services-safetynet:8.1.0"
```

Adding Play Services to Your Project

On the surface, using Play Services should be simple: add the aforementioned `compile` statement(s), then start calling some methods from the supplied Play Services SDK libraries.

Unfortunately, it is not that simple. There are a number of other things that you will need to deal with in order to integrate Play Services into your app.

The Metadata

You will see plenty of examples that show having a `<meta-data>` element, inside your `<application>` element, with an `android:name` of `com.google.android.gms.version` and a value pulling in an integer resource (`@integer/google_play_services_version`) from the Play Services SDK:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
  <activity android:name=".WeatherDemo">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
  <activity android:name=".LegalNoticesActivity"/>

  <meta-data
    android:name="com.google.android.gms.version"
    android:value="@integer/google_play_services_version"/>
</application>
```

This is no longer required, if you are using version 8.1.0 or higher of the Play Services SDK. This element will be added to your manifest automatically via [the manifest merger process](#).

The License

The terms and conditions for using the Play Services SDK state that you must show some license terms from Play Services in your app. Exactly where and how you do this is largely up to you, though bear in mind that Google might check your app for compliance, and so you should not try to cheat and not show the licenses. If you have your own license (e.g., in an About screen), you might show the Play Services licenses along with your own.

In the case of this book's sample apps that use the Play Services SDK, there is a dedicated activity (`LegalNoticesActivity`) that is responsible for displaying the licenses:

```
package com.commonware.android.weather2;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;
```

GOOGLE PLAY SERVICES

```
import com.google.android.gms.common.GoogleApiAvailability;

public class LegalNoticesActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.legal);

        TextView legal=(TextView)findViewById(R.id.legal);

        legal.setText(
            GoogleApiAvailability
                .getInstance()
                .getOpenSourceSoftwareLicenseInfo(this));
    }
}
```

To get the license text, call `getOpenSourceSoftwareLicenseInfo()` on an instance of `GoogleApiAvailability`. You can then display this somewhere (e.g., in a `TextView`). Note that this method returns a `String`, not a `CharSequence`, and so the text will not be formatted.

Then, it is merely a matter of allowing the user to see this activity, such as having a menu resource for it:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/legal"
        android:orderInCategory="100"
        android:showAsAction="never"
        android:title="@string/legal"/>

</menu>
```

...and using that resource in some other activity

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater()
        .inflate(R.menu.abstract_google_api_client_activity, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.legal) {
        startActivity(new Intent(this, LegalNoticesActivity.class));

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

Dealing with Runtime Permissions

Android 6.0's runtime permission system affects some of the Play Services APIs. For example, if you are trying to get the location via the [fused location provider](#), you will need ACCESS_COARSE_LOCATION or ACCESS_FINE_LOCATION. Both of those are dangerous permissions, so apps with a targetSdkVersion of 23 or higher will need to request those permissions at runtime.

The [Location/FusedNew](#) sample application contains an AbstractGoogleApiClientActivity that, among other things, helps us deal with runtime permissions in our Play Services SDK-using apps.

Detecting If We Have Permission

The idea behind AbstractGoogleApiClientActivity is that apps using the Play Services SDK will have activities that inherit from AbstractGoogleApiClientActivity, overriding a few methods to configure how AbstractGoogleApiClientActivity handles things like runtime permissions. For example, AbstractGoogleApiClientActivity has an abstract method named getDesiredPermissions() that subclasses must override, providing a String array of permissions that the activity needs. AbstractGoogleApiClientActivity then uses hasAllPermissions() and hasPermission() private methods to determine whether all of the requested permissions are currently held:

```
private boolean hasAllPermissions(String[] perms) {
    for (String perm : perms) {
        if (!hasPermission(perm)) {
            return(false);
        }
    }

    return(true);
}

private boolean hasPermission(String perm) {
    return(ContextCompat.checkSelfPermission(this, perm)==
        PackageManager.PERMISSION_GRANTED);
}
```

In onCreate() of AbstractGoogleApiClientActivity, among other things, we call hasAllPermissions() to see if we have all of our required permissions — if yes, we can go ahead and call an initPlayServices() method to start the process of initializing our access to the Play Services SDK:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
```

```
super.onCreate(savedInstanceState);

if (savedInstanceState!=null) {
    isInPermission=
        savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
    isResolvingPlayServicesError=
        savedInstanceState.getBoolean(STATE_IN_RESOLUTION, false);
}

if (hasAllPermissions(getDesiredPermissions())) {
    initPlayServices();
}
else if (!isInPermission) {
    isInPermission=true;

    ActivityCompat
        .requestPermissions(this,
            netPermissions(getDesiredPermissions()),
            REQUEST_PERMISSION);
}
```

Requesting Permissions

If we do not have all of the permissions, `onCreate()` will call `requestPermissions()` on `ActivityCompat` to ask the user for them. However, it also leverages `netPermissions()` to filter out the permissions that the user previously granted, so we only bother the user with permissions that either the user has not seen before or has previously denied:

```
private String[] netPermissions(String[] wanted) {
    ArrayList<String> result=new ArrayList<String>();

    for (String perm : wanted) {
        if (!hasPermission(perm)) {
            result.add(perm);
        }
    }

    return(result.toArray(new String[result.size()]));
}
```

Note that this code is not making use of `shouldShowRequestPermissionRationale()`, to detect previous permission denials and perhaps show some UI to educate the user on what the impacts are of this rejection.

Handling the Result

The call to `requestPermissions()` will eventually trigger a callback to `onRequestPermissionsResult()`. Here, if we now have all of the permissions, we call

`initPlayServices()` (more on this in a bit) and then `connect()` to the Play Services SDK (also, more on this in a bit):

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                       String[] permissions,
                                       int[] grantResults) {

    isInPermission=false;

    if (requestCode==REQUEST_PERMISSION) {
        if (hasAllPermissions(getDesiredPermissions())) {
            initPlayServices();
            playServices.connect();
        }
        else {
            handlePermissionDenied();
        }
    }
}
```

If, however, we do not have all of the requested permissions, another abstract method on this class is `handlePermissionDenied()`, where the subclass can do what it wants to. That could range from explaining to the user what can and cannot be done to simply calling `finish()` and going away.

Dealing with Configuration Changes

There is a possibility that the user will rotate the screen or otherwise trigger a configuration change while we are in the request-permission process. Even though our activity is not in the foreground from an input standpoint, it *is* visible, and so it will undergo the configuration change while the request-permission dialog is still in the foreground. We do not want to pop up the dialog *again* (and confuse the user). So, the `isInPermission` field is tracking whether the request-permission dialog is outstanding, so we do not attempt to show the dialog again in `onCreate()`.

Since the activity could be destroyed and recreated as part of the configuration change, we hang onto the `isInPermission` value in the saved instance state `Bundle`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
    outState.putBoolean(STATE_IN_RESOLUTION,
                       isResolvingPlayServicesError);
}
```

(the `STATE_IN_RESOLUTION` bit will be explained shortly)

And, in `onCreate()`, we re-initialize `isInPermission` if we got the saved instance state `Bundle` passed in.

Checking for Play Services

While you typically think of Android devices as having Play Services, that is not always the case. Sometimes, they do not, yet wind up having a copy of your app anyway, perhaps through less-than-legal measures. Or, the device has Play Services, but it is not the latest version — perhaps the user missed a recent Play Services update due to international travel, taking up temporary residence in a Faraday cage, or other technical issues.

Hence, another thing that `AbstractGoogleApiClientActivity` does is confirm that the device has Play Services and can connect to the Play Services process for whatever particular API(s) we wish to use.

Initializing the GoogleApiClient

For many, though not all, Play Services APIs, you use a `GoogleApiClient` as your entry point for talking to Play Services. Some APIs, like [Maps V2](#), do not use `GoogleApiClient` for some reason. But, more often than not, you will find yourself needing `GoogleApiClient`.

To create a `GoogleApiClient` instance, use a `GoogleApiClient.Builder`. As the class name suggests, `GoogleApiClient` is used as a client connection to many (but not all) Google Play Services APIs, and `GoogleApiClient.Builder` is a builder for building such a connection. In particular:

- We pass our `Activity` as our `Context`
- We call `addConnectionCallbacks()` to indicate what should be notified when our connection to the Play Services process is ready
- We call `addOnConnectionFailedListener()` to indicate what should be notified if we have a problem connecting to the Play Services process
- We call `build()` on the `Builder` to actually build the `GoogleApiClient`

This is handled by `initPlayServices()` on `AbstractGoogleApiClientActivity`, which we call once we have our permissions set up:

```
protected void initPlayServices() {
    playServices=
        configureApiClientBuilder(new GoogleApiClient.Builder(this))
            .addConnectionCallbacks(this)
}
```

```
.addOnConnectionFailedListener(this)
    .build();
}
```

This includes calling out to the subclass' implementation of `configureApiClientBuilder()`, where the subclass can use methods like `addApi()` to indicate specifically what parts of the Play Services family of APIs the activity wants to use.

Given that we have a `GoogleApiClient`, we need to `connect()` to it to be able to start requesting location data, then `disconnect()` from it when we no longer need that location data.

Disconnecting is easy: we do that in `onStop()` of `AbstractGoogleApiClientActivity`:

```
@Override
protected void onStop() {
    if (playServices!=null) {
        playServices.disconnect();
    }

    super.onStop();
}
```

There are two places where we possibly call `connect()`. One is if we needed to ask for permissions, and the user granted them. In `onRequestPermissionsResult()`, after confirming that we do indeed have all necessary permissions, we call `initPlayServices()` and then immediately call `connect()` on the `GoogleApiClient`:

```
@Override
public void onRequestPermissionsResult(int requestCode,
                                       String[] permissions,
                                       int[] grantResults) {

    isInPermission=false;

    if (requestCode==REQUEST_PERMISSION) {
        if (hasAllPermissions(getDesiredPermissions())) {
            initPlayServices();
            playServices.connect();
        }
        else {
            handlePermissionDenied();
        }
    }
}
```

If we did *not* need to request permissions, we call `connect()` in `onStart()`, mirroring the `onStop()` where we are disconnecting:

```
@Override
protected void onStart() {
    super.onStart();

    if (!isResolvingPlayServicesError && playServices!=null) {
        playServices.connect();
    }
}
```

The `isResolvingPlayServicesError` boolean value will be discussed a bit later in this chapter.

Connecting and Disconnecting

The call to `connect()`, in turn, will trigger calls to our `onConnected()` and `onDisconnected()` methods of the `GoogleApiClient.ConnectionCallbacks` interface, assuming all goes well. `AbstractGoogleApiClientActivity` does not provide those implementations; they are considered part of the abstract API and therefore need to be implemented by subclasses.

However, apparently it is possible for this connection attempt to fail. Exactly how and why it might fail is not well documented. If it fails, the `onConnectionFailed()` method from our `GoogleApiClient.OnConnectionFailedListener` implementation will be called. `onConnectionFailed()` is passed a `ConnectionResult` indicating what specifically went wrong.

It turns out that this `ConnectionResult` may contain a `PendingIntent` that can be used to try to help the user recover from whatever the problem was. The recipe that [we have been given](#) to try to use this is to call `hasResolution()` (to see if the `PendingIntent` exists) and to use `startResolutionForResult()` (to invoke the activity pointed to by the `PendingIntent`). Of course, `hasResolution()` may return false, and apparently the `PendingIntent` might be broken, so we have to handle those scenarios as well:

```
@Override
public void onConnectionFailed(ConnectionResult result) {
    if (!isResolvingPlayServicesError) {
        if (result.hasResolution()) {
            try {
                isResolvingPlayServicesError=true;
                result.startResolutionForResult(this, REQUEST_RESOLUTION);
            }
            catch (IntentSender.SendIntentException e) {
                playServices.connect();
            }
        }
        else {
            AlertDialogFragment.newInstance(result.getErrorCode())
        }
    }
}
```

```
        .show(getFragmentManager(),
            TAG_ERROR_DIALOG_FRAGMENT);
        isResolvingPlayServicesError=true;
    }
}
```

If we have a resolution and successfully start up the resolution activity, our activity will be stopped and later started, at which point we will wind up trying to connect() again naturally.

If there is no PendingIntent to try to resolve the problem, we can still attempt to display a dialog with information about what is going wrong. The Play Services SDK provides this dialog, though we are responsible for wrapping it in a DialogFragment ourselves. That comes in the form of ErrorDialogFragment:

```
public static class ErrorDialogFragment extends
    DialogFragment {
    static final String ARG_ERROR_CODE="errorCode";

    static ErrorDialogFragment newInstance(int errorCode) {
        Bundle args=new Bundle();
        ErrorDialogFragment result=new ErrorDialogFragment();

        args.putInt(ARG_ERROR_CODE, errorCode);
        result.setArguments(args);

        return(result);
    }

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        return(GoogleApiAvailability
            .getInstance()
            .getErrorDialog(
                getActivity(),
                getArguments().getInt(ARG_ERROR_CODE),
                REQUEST_RESOLUTION));
    }

    @Override
    public void onCancel(DialogInterface dlg) {
        if (getActivity()!=null) {
            getActivity().finish();
        }

        super.onCancel(dlg);
    }

    @Override
    public void onDismiss(DialogInterface dlg) {
        if (getActivity()!=null) {
            ((AbstractGoogleApiClientActivity)getActivity())
                .isResolvingPlayServicesError=false;
        }
    }
}
```

```
        super.onDismiss(dlg);  
    }  
}
```

`onCreateDialog()` uses the `GoogleApiAvailability` singleton to show the error dialog, given the error code that came from our previous attempt to connect. We pass that error code over to the `ErrorDialogFragment` via the arguments `Bundle`, so that it can survive a configuration change.

However, we also have to take into account that the device might undergo a configuration change while either the resolution activity started by `startActivityForResult()` or the `ErrorFragmentDialog` is in the foreground. What we do not want to do is immediately try connecting to Play Services again in `onStart()`, while we are in the process of trying to fix whatever problem prevented us from connecting to it previously.

So, we have to track a boolean state, `isResolvingPlayServicesError`, as a field in our activity. That is initially set to `false`, but we flip it to `true` if we show the resolution activity or the `ErrorFragmentDialog`. We flip it back to `false` when either the started activity returns control to us in `onActivityResult()` or when the `ErrorDialogFragment` is dismissed. While that flag is `true`, we skip attempting to connect to Play Services in `onStart()`. And this flag is part of our saved instance state, so we can handle configuration changes.

Getting Help

Obviously, this book does not cover everything. And while your #1 resource (besides the book) is going to be the Android SDK documentation, you are likely to need information beyond what's covered in either of those places.

Searching online for “android” and a class name is a good way to turn up tutorials that reference a given Android class. However, be sure to check the age of the blog post or whatever that you are reading. The older it is, the more likely that it is out of date, based upon changes in Android or just better solutions that have evolved over time.

Beyond randomly hunting around for tutorials, though, this chapter outlines some other resources to keep in mind.

Questions. Sometimes, With Answers.

The “official” places to get assistance with Android are the Android Google Groups. With respect to the SDK, there are three to consider following:

1. Stack Overflow's [android](#) tag
2. [android-developers](#), for SDK questions and answers
3. [adt-dev](#), for questions and answers about the official Android development tools

The author of this book also maintains [the AndGlobe site](#), a list of Android developer support sites, with an emphasis on ones operating in languages other than English.

It is important, particularly for Stack Overflow and the Google Groups, to write well-written questions:

1. Include relevant portions of the source code (e.g., the method in which you are getting an exception) and the stack trace from LogCat, if the problem is an unhandled exception.
2. On Stack Overflow, make sure your source code and stack trace are formatted as source code; on Google Groups, consider posting long listings on gist.github.com or a similar sort of code-paste site.
3. Explain thoroughly what you are trying to do, how you are trying to do it, and why you are doing it this way (if you think your goal or approach may be a little offbeat).
4. On Stack Overflow, respond to answers and comments with your own comments, addressing the person using the @ syntax (e.g., @CommonsWare), to maximize the odds you will get a reply. However, only use that for people who are already involved in your question.
5. On the Google Groups, do not “ping” or reply to your own message to try to elicit a response until a reasonable amount of time has gone by (e.g., 24 hours).

Heading to the Source

The source code to Android is now available. Mostly this is for people looking to enhance, improve, or otherwise fuss with the insides of the Android operating system. But, it is possible that you will find the answers you seek in that code, particularly if you want to see how some built-in Android component “does its thing”.

The source code and related resources can be found at <http://source.android.com>. Here, you can:

1. [Download](#) the source code
2. File [bug reports](#) against the operating system itself
3. [Submit patches](#) and learn about the process for how such patches get evaluated and approved
4. Join a separate set of [Google Groups](#) for Android platform development

Getting Your News Fix

Ed Burnette, a nice guy who happened to write his own Android book, is also the manager of [Planet Android](#), a feed aggregator for a number of Android-related blogs. Subscribing to the planet's feed will let you monitor quite a bit of Android-related blog posts, though not exclusively related to programming.

Trail: Code Organization and Gradle

Working with Library Projects

Android library projects are the primary unit of Android source reuse, particularly where that source involves more than just Java source code, such as Android resources.

In this chapter, we will explore the basics of setting up and using an Android library project.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Creating a Library Project

An Android library project, in many respects, looks like a regular Android project. It has source code and resources. It has a manifest.

What it does not do, though, is build an APK file. Instead, it represents a basket of programming assets that the Android build tools know how to blend in with regular Android projects.

How you set up an Android library project depends upon your IDE.

Android Studio

Making a project be an Android library project is simply a matter of choosing the right Android Plugin for Gradle.

WORKING WITH LIBRARY PROJECTS

Rather than have:

```
apply plugin: 'com.android.application'
```

use:

```
apply plugin: 'com.android.library'
```

That's it — the `com.android.library` plugin now knows that it is creating a library, not an app.

The real question is, *where* are you making this library? In many cases, you will do so as a module in a project, where there is another module that is an app. This covers both:

- A library designed to be standalone, but with a sample app demonstrating its use
- A library designed to be used by the app, and perhaps other app modules in this project

Adding new modules to an Android Studio project is handled most simply via the new-module wizard, which you can bring up via `File > New Module...` from the main menu. This brings up the first page of the new-module wizard:

WORKING WITH LIBRARY PROJECTS

Figure 296: Android Studio New-Module Wizard, First Page

To add a library project as a module to an existing project, choose “Android Library” in the list of module types, then click Next to proceed to the second page of the wizard:

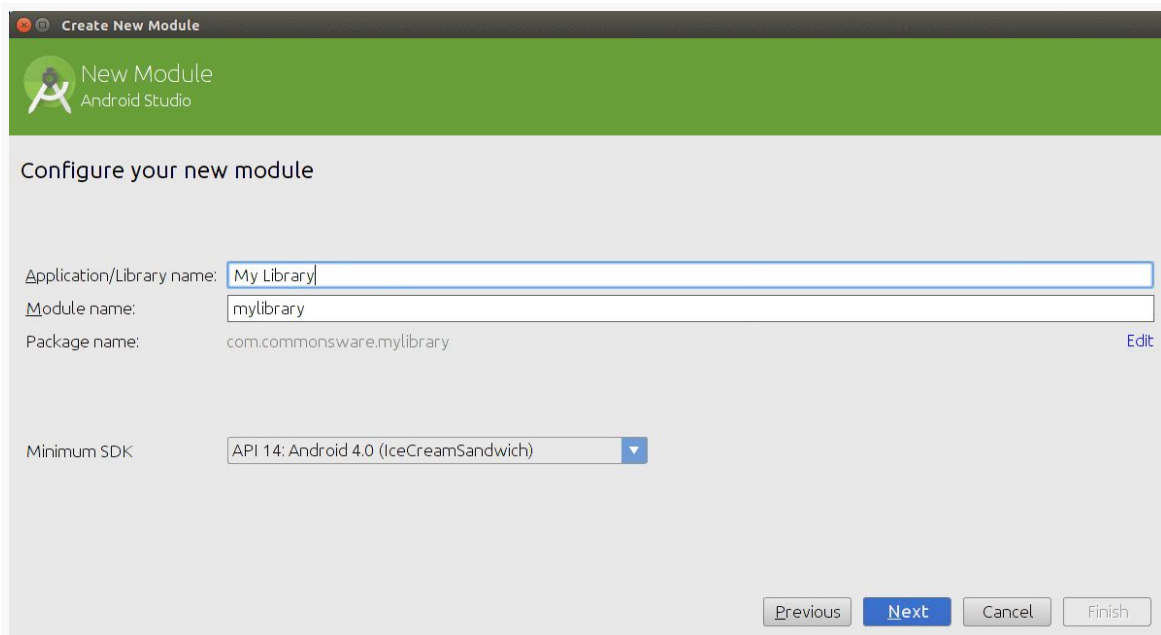

Figure 297: Android Studio New-Module Wizard, Second Page

This collects some bits of information, including:

- the “application name”, whose use in this case is unclear
- the “module name”, which will be the directory in this project into which this library will be created
- the “package name”, which will go into the manifest of the generated library
- your `minSdkVersion`

At this point, clicking Next will take you to the same new-activity flow that you saw when creating a new project. If you want an activity to be generated for you in this library, proceed by selecting the activity template and providing the activity template configuration data. If you do not want an activity, choose “Add No Activity” in the grid of templates, then click “Finish” to create the module.

In the end, the new-module wizard will set up the new module for you, in your designated subdirectory of the project, including modifying `settings.gradle` to list this subdirectory as being a module within the project. At this point, you will be able to start using the library within the project itself.

Eclipse

To create a library project in Eclipse, start by creating a normal Android project. Then, in the project properties window (e.g., right-click on the project and choose Properties), in the Android area, check the “Is Library” checkbox. Click “Apply”, and you are done.

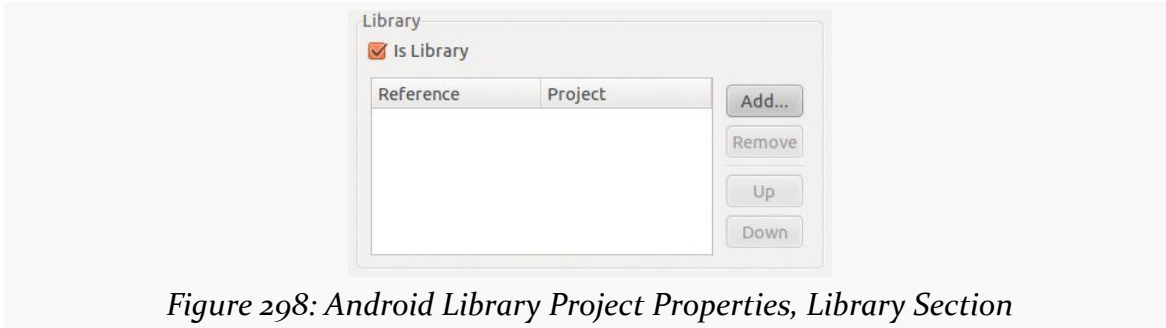

Figure 298: Android Library Project Properties, Library Section

Using a Library Project, Part II

Once you have a library project, you can attach it to a regular Android project, so the regular Android project has access to everything in the library. We covered simple scenarios for this [earlier in the book](#). With Android Studio, you have two other major possibilities, besides what was covered previously.

If the library exists in support of a couple of your own applications, you could organize all of that into a single project with several modules (e.g., `app/` and `app2/` for the apps, with `myCoolLibrary/` for the library). How to set up this structure will be covered in [the chapter on Gradle dependencies](#).

If the library exists in support of applications that you are not writing, such as one for another development team in your organization, or one for public distribution — you will probably wind up publishing an AAR file compiled from the library. This too is covered in [the chapter on Gradle dependencies](#).

Library Projects and the Manifest

Library projects can publish their own `AndroidManifest.xml` file, which contributes to the overall manifest used by apps that incorporate the library. Hence, a library can:

- request permissions that perhaps are not in the app's own manifest
- publish activities or other components, without the app developer having to add entries to the app's own manifest
- stipulate a minimum SDK version required by the library code, which might be higher than the minimum SDK version required by the app itself

However, merging these manifests is a rather complex topic, and as such will be covered [much later in the book](#).

Limitations of Library Projects

While library projects are useful for code organization and reuse, they do have their limits, such as:

- As noted above, if more than one project (main plus libraries) defines the same resource, the higher-priority project's copy gets used. Generally, that is a good thing, as it means that the main project can replace resources defined by a library (e.g., change icons). However, it does mean that two libraries might collide. It is important to keep your resource names distinct to minimize the odds of this occurrence.
- Since you are using the source code of the other project, you are subject to the limitations of its code. For example, if the third-party project is using `@Override` annotations on its implementations of interface methods, you will need to ensure that, in Eclipse, you have the compiler compliance level set to 1.6 or 1.7 — sometimes, this is set to 1.5, which complains about such annotations.

Gradle and Eclipse Projects

Projects fall into two main categories: those using the new Gradle-specific directory structure, and those that use the legacy structure that everyone used from 2008 through 2013 (and, to some extent, beyond) — mostly, projects created using Eclipse.

However, Gradle is capable of building projects in either directory layout. This chapter will review how to add Gradle support to an Eclipse Android project, without having to change your directory structure.

Prerequisites and Warnings

Understanding this chapter requires that you have read the chapter that [introduces Gradle](#).

“Legacy”?

Here, “legacy directory structure” means a project tree that looks a bit like this:

Figure 299: Legacy Directory Structure

It is dominated by a traditional Java `src/` tree, plus the Android-specific items like `res/`, `AndroidManifest.xml`, and so forth.

This directory structure will work perfectly fine with Gradle, and you may need to keep this structure for a while in order to maintain compatibility with other tools, like Eclipse.

Creating Your Gradle Build File

You need a `build.gradle` file to be able to build your project with Gradle.

As noted in [the introductory chapter on Gradle](#), Gradle is the native build system for Android Studio. Hence, if you are using that IDE, you should get a `build.gradle` file automatically. Also, if you are moving from Eclipse to Android Studio, use the Android Studio import wizard, as it is better than your alternatives and will also help reorganize your code into the sourceset-based project structure that Android Studio (and Gradle for Android) use natively.

If you are not using Android Studio, though, there are two main ways of getting a `build.gradle` file today: export one from an Eclipse project, or create one by hand. In theory, exporting from Eclipse would be the best bet. But with Eclipse being unsupported, you may wind up having to create it fully by hand. After all, as you will see, what you get from the Eclipse export process is out of date.

Exporting from Eclipse

If you have an existing Eclipse project, the easiest way to get a `build.gradle` file for that project is to let the ADT plugin export one for you.

Performing the Export

To export `build.gradle`, either choose `File > Export` from the Eclipse main menu, or choose “Export...” from the context menu in the Package Explorer. Either of those should bring up a wizard-style dialog where you can choose what you want to export:

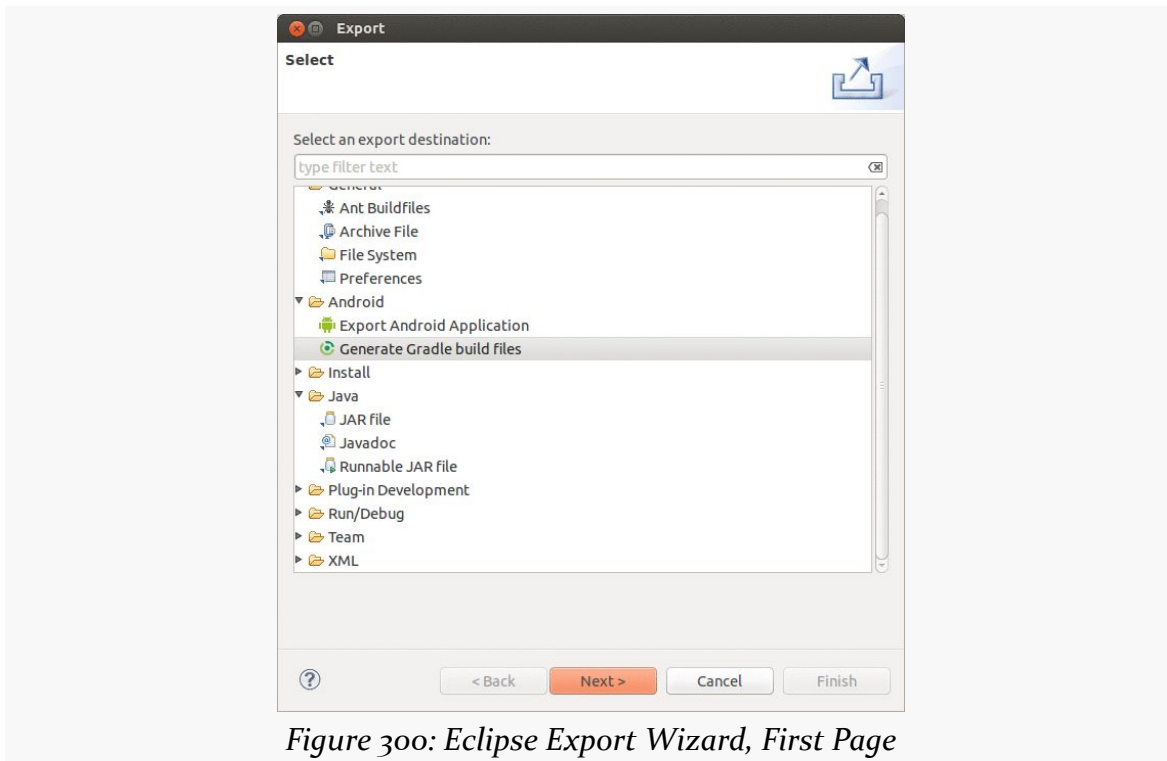

Figure 300: Eclipse Export Wizard, First Page

GRADLE AND ECLIPSE PROJECTS

Here, choose “Generate Gradle build files”. If that is not an option, you may be on an older version of the ADT plugin and would need to upgrade.

Clicking Next will then bring up a list of all installed projects, where you will need to check the project that you wish to export:

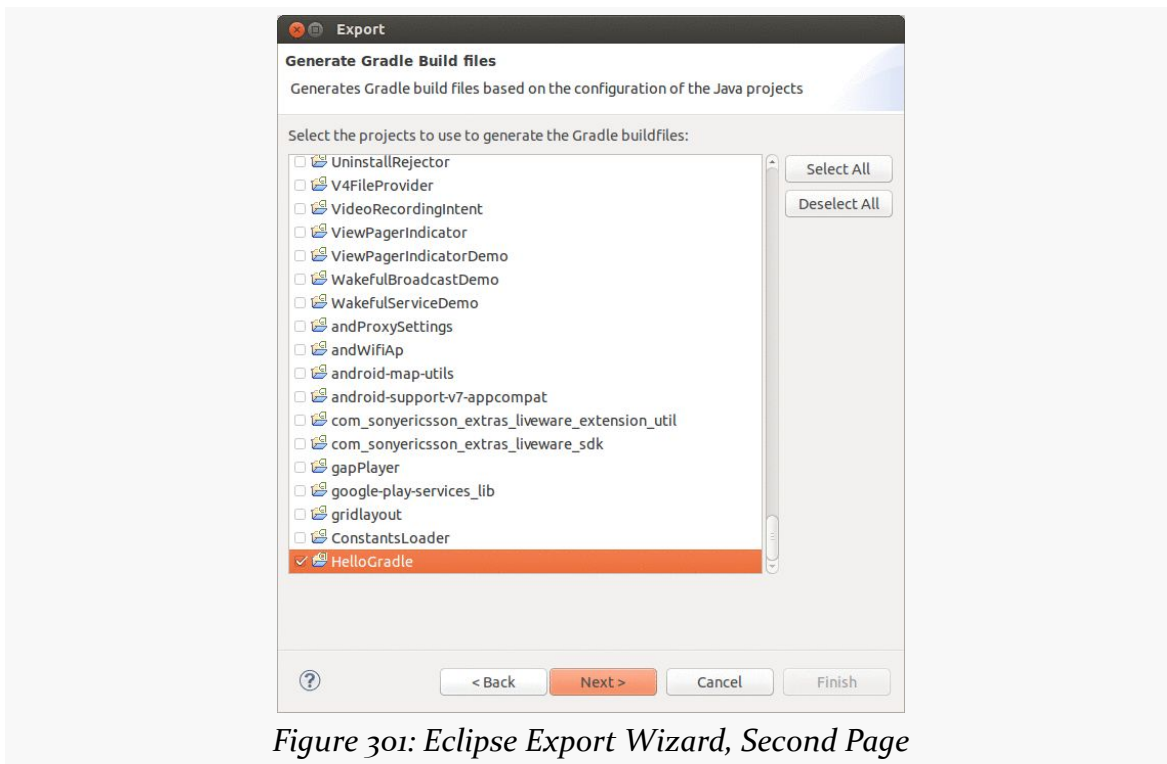

Figure 301: Eclipse Export Wizard, Second Page

Note that your project may not already be checked, due to a bug in the wizard.

Once you have checked the project, the Next button should be enabled. Clicking that will bring up a confirmation wizard page:

GRADLE AND ECLIPSE PROJECTS

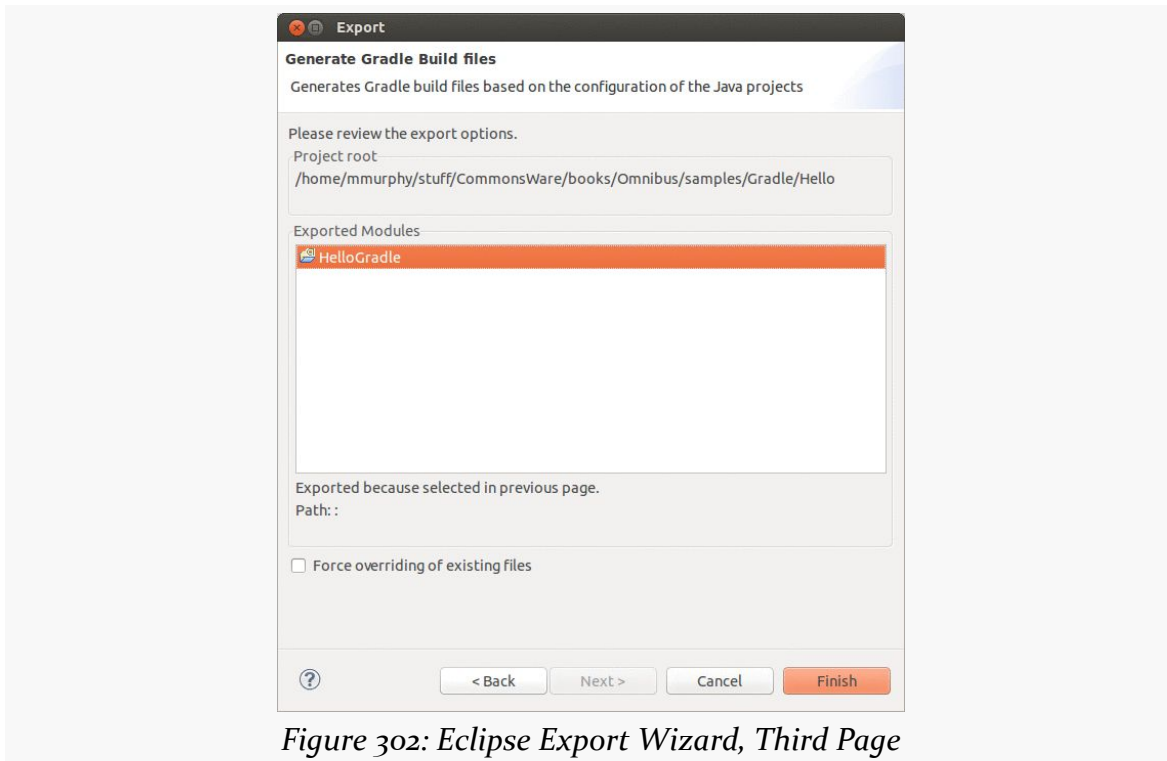

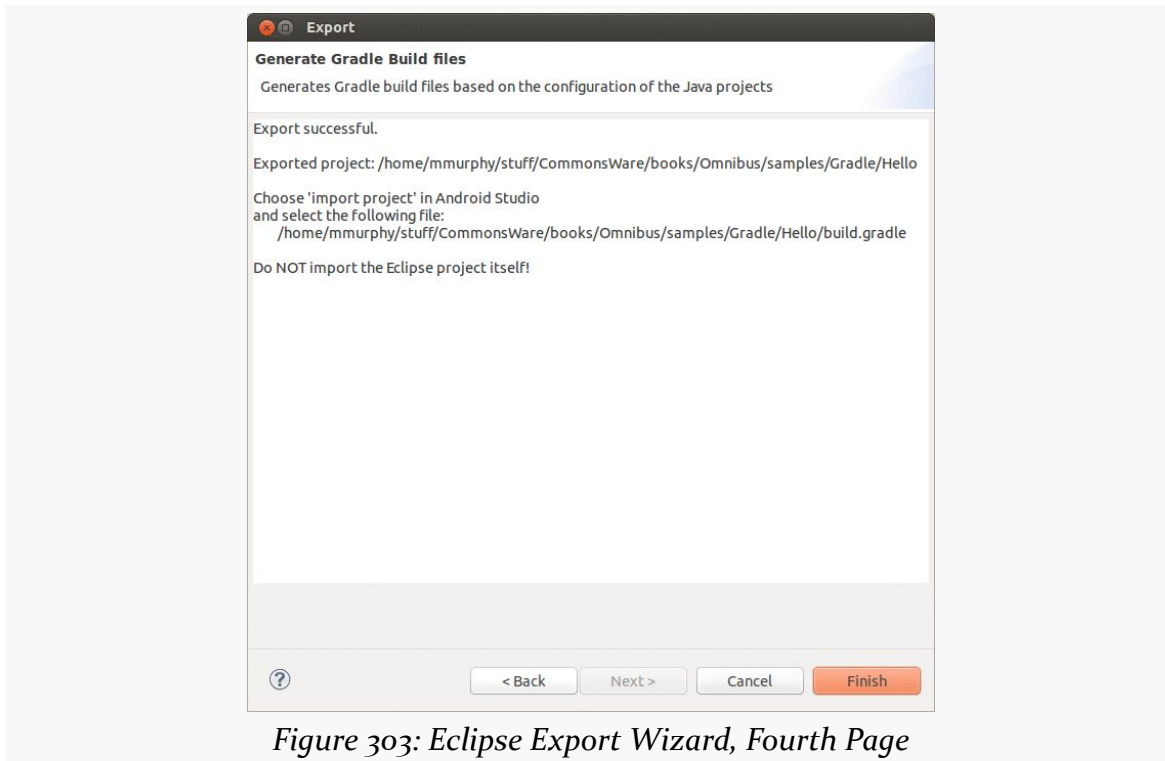

Figure 302: Eclipse Export Wizard, Third Page

It should show the project you checked in the wizard. There is a “Force overriding of existing files” checkbox — use that if you had previously exported the Gradle files and wish to replace them with a freshly-exported copy.

Clicking the Finish button will do the export and bring up a report page:

After carefully reviewing the notes here (or possibly just ignoring them), click Finish to close the wizard.

What Gets Generated

What you get for your troubles is:

- A build.gradle file.
- A Gradle wrapper, in the form of a gradlew and/or gradlew.bat file and a gradle/ subdirectory, as was discussed [in the previous chapter](#). If you will not be using the wrapper, feel free to delete these files, except for the gradle-wrapper.properties file.
- A .gradle/ hidden subdirectory, containing cached data used by the Gradle build process, such as a parsed copy of your build.gradle file, for faster execution if you run Gradle without having modified build.gradle since your last Gradle run.

What Needs Fixing

To have the resulting project work well with Android Studio, change:

- the version of the Android Plugin for Gradle to 1.0.0 or higher (classpath 'com.android.tools.build:gradle:0.12.+') to classpath 'com.android.tools.build:gradle:1.0.0')
- the apply plugin: 'android' statement to apply plugin: 'com.android.application'
- the distributionUrl in the gradle/wrapper/gradle-wrapper.properties file to <https://services.gradle.org/distributions/gradle-2.2.1-all.zip>

Examining the Gradle File

The book's sample code contains a [Gradle/Hello](#) sample project. This is just a stock "Hello, world" app, as created by the Eclipse new-project wizard.

However, it also contains a build.gradle, exported by Eclipse:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}
apply plugin: 'com.android.application'

dependencies {
    compile fileTree(dir: 'libs', include: '*.jar')
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        // Move the tests to tests/java, tests/res, etc...
```

GRADLE AND ECLIPSE PROJECTS

```
instrumentTest.setRoot('tests')

// Move the build types to build-types/<type>
// For instance, build-types/debug/java, build-types/debug/AndroidManifest.xml,
...
// This moves them out of their default location under src/<type>/... which would
// conflict with src/ being used by the main source set.
// Adding new build types or product flavors should be accompanied
// by a similar customization.
debug.setRoot('build-types/debug')
release.setRoot('build-types/release')
}
```

Most of the contents of this file is covered in [the introductory chapter on Gradle](#). The one bit that is not — the `sourcesets` closure — is covered in [an upcoming chapter](#).

Gradle and Tasks

A `build.gradle` file teaches Gradle how to execute tasks, such as how to compile an Android project. Outside of a Gradle-aware IDE like Android Studio, you use Gradle itself to run these tasks. If you have installed your own copy of Gradle, you would use the `gradle` command; if you are relying upon a trusted copy of the Gradle Wrapper, you would use the `./gradlew` script in your project root.

For the purposes of this book, the `gradle` command will be shown – just substitute `./gradlew` where you see `gradle` if you are using the Gradle Wrapper script.

Key Build-Related Tasks

To find out what tasks are available to you, you can run `gradle tasks` from the project directory. That will result in output akin to:

```
:tasks
-----
All tasks runnable from root project
-----

Android tasks
-----
androidDependencies - Displays the Android dependencies of the project
signingReport - Displays the signing info for each variant

Build tasks
-----
assemble - Assembles all variants of all applications and secondary packages.
assembleDebug - Assembles all Debug builds
assembleDebugTest - Assembles the Test build for the Debug build
assembleRelease - Assembles all Release builds
build - Assembles and tests this project.
buildDependents - Assembles and tests this project and all projects that depend on it.
buildNeeded - Assembles and tests this project and all projects it depends on.
clean - Deletes the build directory.
```

GRADLE AND TASKS

Build Setup tasks

init - Initializes a new Gradle build. [incubating]
wrapper - Generates Gradle wrapper files. [incubating]

Help tasks

components - Displays the components produced by root project 'Decktastic'. [incubating]
dependencies - Displays all dependencies declared in root project 'Decktastic'.
dependencyInsight - Displays the insight into a specific dependency in root project 'Decktastic'.
help - Displays a help message.
projects - Displays the sub-projects of root project 'Decktastic'.
properties - Displays the properties of root project 'Decktastic'.
tasks - Displays the tasks runnable from root project 'Decktastic'.

Install tasks

installDebug - Installs the Debug build
installDebugTest - Installs the Test build for the Debug build
uninstallAll - Uninstall all applications.
uninstallDebug - Uninstalls the Debug build
uninstallDebugTest - Uninstalls the Test build for the Debug build
uninstallRelease - Uninstalls the Release build

Verification tasks

check - Runs all checks.
connectedAndroidTest - Installs and runs the tests for Build 'debug' on connected devices.
connectedCheck - Runs all device checks on currently connected devices.
deviceCheck - Runs all device checks using Device Providers and Test Servers.
lint - Runs lint on all variants.
lintDebug - Runs lint on the Debug build
lintRelease - Runs lint on the Release build

Other tasks

compileDebugSources
compileDebugTestSources
compileReleaseSources

Rules

Pattern: clean<TaskName>: Cleans the output files of a task.
Pattern: build<ConfigurationName>: Assembles the artifacts of a configuration.
Pattern: upload<ConfigurationName>: Assembles and uploads the artifacts belonging to a configuration.

To see all tasks and more detail, run with --all.

BUILD SUCCESSFUL

Total time: 9.669 secs

This list is dynamically generated based on the contents of build.gradle, notably including tasks defined by the com.android.application plugin.

In principle, you are supposed to specify the entire task name when running that task. However, you can use shorthand, so long as it uniquely identifies the task.

Probably the most common task that a developer will use, at least in the short term, is `installDebug` (or `iD` for short). This will build a debug version of the app and install it on an available device or emulator. This roughly corresponds to `ant install debug` for those familiar with legacy Ant-based command-line builds.

Just as there is `installDebug`, there can also be `installRelease`. The Debug and Release portions of the task are not hard-coded, but rather are derived from the “build types” defined in the `build.gradle` file. The concept, role, and usage of build types will be covered in [the next chapter](#). However, `installRelease` is not available by default, because installing an app requires that the APK be signed, and Gradle for Android does not know how to sign it. We will address this in [the next chapter](#) as well.

If you just want to build the app, without installing it, `assembleDebug` (`aD`) or `assembleRelease` (`aR`) will accomplish that aim. If you want to uninstall the app from a device or emulator, `uninstallDebug` (`uD`) and `uninstallRelease` (`uR`) should work.

Discussion of other tasks, such as the “check” tasks, will be covered in later chapters.

Results

With Eclipse, the build output went in a `bin/` directory, and generated source code (e.g., `R.java`) went in a `gen/` directory. With Gradle, all build output goes into a `build/` directory.

Specifically, your APKs will go into `build/outputs/apk`, with different APK editions based upon whether you did a debug or release build.

Gradle has a `clean` task that wipes out the `build/` directory. However, note that Eclipse does not use the `build/` directory, so a Gradle `clean` will not “clean” the pre-compiled classes and such that Eclipse uses.

Gradle and the New Project Structure

A [previous chapter](#) showed how you can use Gradle, and the Android Plugin for Gradle, to do command-line builds of projects that can also work with Eclipse, IntelliJ IDEA, Ant, etc.

However, while the legacy project directory structure works, it does not let you leverage the full power of the Android Plugin for Gradle. To take advantage of the build flexibility of the new build system, you will need to organize your source, resources, assets, and related files somewhat differently.

This chapter will outline this “new project structure” and show you how Gradle for Android’s concepts of build types and product flavors will make it easier for you to have multiple different forms of output from a single, albeit reorganized, project tree. This project structure is native to Android Studio, so Android Studio projects are already set up to be able to support these sorts of advanced capabilities.

NOTE: The projects demonstrated in this chapter are *not* set up to be used by Eclipse, as Eclipse does not support Gradle as of the time of this writing.

Prerequisites and Warnings

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, in the context of [covering the use of Gradle with the legacy project structure](#).

Objectives of the New Project Structure

In the beginning, Android apps tended to be pretty simple, as we only had a handful of devices, a smattering of users, one primary distribution channel (the then-Android Market) and few major investors in the Android ecosystem.

Times have changed.

Now, Android apps for public consumption can be terribly complex, let alone apps for internal enterprise use (which seem to be complex as a side effect of being developed by an enterprise). We have multiple distribution channels, such as the Amazon AppStore for Android and Yandex.Store. We have a billion devices and nearly a billion users. Brands large and small are flocking to Android, bringing with them their own challenges.

The new build system is designed to simplify creating complex Android applications, while, ideally, not making simple Android applications a lot harder. It is designed for scenarios like:

- Supporting multiple distribution channels, which may require multiple in-app purchasing engines
- Supporting one app that is customized for individual clients, such as for use by different enterprises
- Supporting an app that really needs to have different APKs for different types of devices, despite all efforts to support all devices from a single APK
- Supporting an app that is part of a much larger integrated system and needing to be built as part and parcel of that larger system
- Supporting a fleet of apps that depend upon common code, resources, third-party libraries, and the like
- And so on

The new project structure, coupled with the Android Plugin for Gradle and Gradle itself, makes all of this possible... albeit with a bit of a learning curve.

Terminology

To understand what the new project structure entails, we need to define a few terms, from Gradle and the Android Plugin for Gradle.

Sourcesets

To quote [the Gradle documentation](#): “A sourceset is simply a group of source files which are compiled and executed together.” Here, “source” means all the inputs that you are creating for the app, such as Java source code, Android resources and manifest files, and the like. This is in contrast to *dependencies*, which are inputs that you are (usually) obtaining from other developers, such as reusable libraries.

Sourcesets, on their own, have no particular semantic meaning. You can elect to have your project use a single sourceset, or several sourcesets, for organizing your code. You might have different sourcesets for:

- Production code versus test code, replacing the separate test project that we historically used in Android development
- Interface code versus implementation code
- Different major functional areas within the app, particularly if they are maintained by separate teams or developer pairs
- And so on

As we will see, the new project structure assumes the existence of at least one sourceset, typically named `main`, but other features of the new build system will involve additional sourcesets.

Build Types

A build type is one axis of possible alternative outcomes from the build process.

By default, the Android Plugin for Gradle assumes that you want two build types: release and debug. These may go through somewhat different build steps, such as applying ProGuard to the release build but skipping it for the debug build.

With Eclipse, those two build types were “baked in” — you had them, you had *only* them, and you had limited ability to configure anything different beyond what the build tools would do differently automatically.

The Android Plugin for Gradle though allows build types to have slightly different configurations, such as adding a `.debug` suffix to the APK’s package name, so that you can have a release build and a debug build of your app on the same device at the same time. You also can create new build types for handling different scenarios. The new build system documentation, for example, suggests a separate “jnidebug” build

type, where you can indicate that the Linux `.so` files for a project should be compiled in debug mode.

As we will see, creating a new build type involves modifications to the `build.gradle` file and adding a matching `sourceset`.

Product Flavors

A build type is one axis for varying your output. A product flavor is another, independent axis for varying your output.

Product flavors are designed for scenarios where you want different release output for different cases. For example, you may want to have one version of your app built to use Google's in-app purchasing APIs (for distribution through the Play Store) and another version of your app built to use Amazon's in-app purchasing APIs (for distribution through the Amazon AppStore for Android). In this case, both versions of the app will be available in release form, and you may wish to have separate debug builds as well. And *most* of the code for the two versions of the app will be the same. However, you will have different code for the different distribution channels — not only does the right code have to run for the right channel, but there is no particular value in distributing the code for one channel through the other channel.

Another example would be an app that is branded and configured for different enterprise customers. You see this a lot with Web apps — the vendor sells a branded-and-configured version of the Web app to the customer, whether that app runs on vendor-supplied hardware or customer-supplied hardware. Similarly, the maker of an Android app for collecting employee timesheets might want to offer to its customers for *their* version of the timesheet app to sport the customer's logo, tie into the customer's specific accounting server, enable or disable features based upon how the customer uses timesheets, and so on. However, *most* of the code is shared between all customers, and so when the app is updated to add features or fix bugs, new builds are needed for *all* of the customers. In this case, each customer can be set up as an independent product flavor, sharing much of the code, but with slightly different code, resources (e.g., logo), and configuration based upon that customer's needs.

Product flavors are optional. If you do not describe any product flavors in your `build.gradle` file, it is assumed that you have a single product flavor, referred to internally as `default`. Many apps will not need product flavors; this is a feature that you will opt into as needed.

As we will see, creating a new product flavor involves modifications to the `build.gradle` file and adding a matching sourceset.

Build Variants

The term “build variant” is used for the cross product of the build types and the product flavors. So, a project with debug and release build types and google and amazon product flavors will result in a total of four build variants by default:

1. debug + google
2. debug + amazon
3. release + google
4. release + amazon

Flavor Dimensions

Sometimes, even this is insufficient flexibility, such as the google and amazon scenario described earlier in this section. Or, you might need separate free versus paid editions, if you want to have an up-front fee for accessing a premium version of your app.

By default, product flavors are considered to be part of a single “flavor dimension”. However, you can organize your flavors into your own separate flavor dimensions (e.g., one for free versus paid, one for distribution channel).

These then add another factor into the cross-product that determines your build variants. Suppose we have a `dist` flavor dimension, consisting of free and paid product flavors, and we have a `channel` flavor dimension, consisting of google and amazon flavors. Now, we have a total of 8 possible build variants, when we factor in the build types:

1. debug + google + free
2. debug + amazon + free
3. release + google + free
4. release + amazon + free
5. debug + google + paid
6. debug + amazon + paid
7. release + google + paid
8. release + amazon + paid

Creating a Project in the New Structure

As of the time of this writing, there are two major ways of getting a project into the new project structure: use Android Studio, or do it by hand.

As noted in the book's earliest chapters, Android Studio's native build system is Gradle with the Android Plugin for Gradle. When you create a new project through that IDE, it will automatically be set up with the new project structure.

Unfortunately, at the time of this writing, there is no way to get a project organized into the new structure out of Eclipse, simply because Eclipse does not support the new structure. Similarly, there is no command-line tool, akin to `android create project` that will create a Gradle project.

Hence, in the short term, if you are not using Android Studio, and you want a project in the new structure, you will need to craft the directory tree and `build.gradle` file yourself. That could be a matter of creating them from scratch, or it could be a matter of copying a project structure from an existing source. Martin Liersch (a.k.a., "Goddchen") has published [a GitHub repository with a variety of sample projects](#) that you can use as a source of inspiration, along with the samples presented over the rest of this chapter.

What the New Project Structure Looks Like

With all that as background, let's take a look at the [Gradle/HelloNew](#) sample project. This project started as an Eclipse project, then had a `build.gradle` file added to it via the Eclipse export wizard. Later, though, it was reorganized to fit the new project structure.

The Directory Tree

The pre-reorganization directory tree for the project is fairly conventional, just with some added Gradle-specific files:

```
Hello
|— AndroidManifest.xml
|— assets/
|— build.gradle
|— libs/
|   |— android-support-v4.jar
|— local.properties
```

```
|— proguard-project.txt
|— project.properties
|— res/
|   |— drawable-hdpi/
|   |   |— ic_launcher.png
|   |— drawable-ldpi/
|   |— drawable-mdpi/
|   |   |— ic_launcher.png
|   |— drawable-xhdpi/
|   |   |— ic_launcher.png
|   |— layout/
|   |   |— activity_main.xml
|   |— menu/
|   |   |— main.xml
|   |— values/
|   |   |— dims.xml
|   |   |— strings.xml
|   |   |— styles.xml
|   |— values-sw600dp/
|   |   |— dims.xml
|   |— values-sw720dp-land/
|   |   |— dims.xml
|   |— values-v11/
|   |   |— styles.xml
|   |— values-v14/
|   |   |— styles.xml
|— src/
|   |— com/
|   |   |— commonsware/
|   |   |   |— android/
|   |   |   |   |— gradle/
|   |   |   |   |   |— hello/
|   |   |   |   |   |   |— MainActivity.java
```

(note: above listing includes only files of relevance for the current discussion)

The new project structure, though, is a bit different:

```
HelloNew
|— build.gradle
|— libs/
|   |— android-support-v4.jar
|— local.properties
|— proguard-project.txt
|— project.properties
|— src/
|   |— main/
|   |   |— AndroidManifest.xml
```

```
|— assets/
|— java/
|   |— com/
|       |— commonsware/
|           |— android/
|               |— gradle/
|                   |— hello/
|                       |— MainActivity.java
|— res/
|   |— drawable-hdpi/
|       |— ic_launcher.png
|   |— drawable-ldpi/
|   |— drawable-mdpi/
|       |— ic_launcher.png
|   |— drawable-xhdpi/
|       |— ic_launcher.png
|   |— layout/
|       |— activity_main.xml
|   |— menu/
|       |— main.xml
|   |— values/
|       |— dims.xml
|       |— strings.xml
|       |— styles.xml
|   |— values-sw600dp/
|       |— dims.xml
|   |— values-sw720dp-land/
|       |— dims.xml
|   |— values-v11/
|       |— styles.xml
|   |— values-v14/
|       |— styles.xml
```

While the `libs/` directory is in its original spot, along with `build.gradle` and related build files, the rest has shifted.

With the new project structure, `src/` is the root of the source *sets*, not just where the source *code* goes. There is one sourceset, named `main`, in the `src/main/` directory. In there is where the `assets/` and `res/` directories go, along with the `AndroidManifest.xml` file. And, there is a `java/` directory that contains the Java source tree (what had been in the original `src/` directory).

The `build.gradle` File

The `build.gradle` file is much like what we profiled back in [the introductory chapter on Gradle](#):

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

We have the `buildscript` closure to describe what we need for our build tools, the `com.android.application` plugin, and details for what version of Android we are compiling against and what version of the build tools we are using.

And, as a result, we have [the standard tasks](#), including `installDebug`.

Configuring the Stock Build Types

The debug and release build types are ready “out of the box” for your use, with a reasonable set of defaults. However, you can change those defaults and make other adjustments to how those build types work, in addition to [defining your own build types](#). Here, we will look at the options for changing the behavior of any build type, focusing on the stock debug and release build types.

Specifically, we will examine the [Gradle/HelloConfig](#) sample project, which builds upon the previous sample, modifying the behavior of both debug and release.

Sourceset

Each build type can have its own associated sourceset. If you skip the directory for it, that means that the build type is not contributing changes to the main sourceset.

So, in the [Gradle/HelloConfig](#) sample project, we have a replacement version of the `strings.xml` resource, in a debug sourceset:

```
HelloConfig
|— build.gradle
```

```
|— HelloConfig.keystore
|— libs/
|   |— android-support-v4.jar
|— local.properties
|— proguard-project.txt
|— project.properties
|— src/
|   |— debug/
|       |— res/
|           |— values/
|               |— strings.xml
|   |— main/
|       |— AndroidManifest.xml
|       |— assets/
|       |— java/
|           |— com/
|               |— commonsware/
|                   |— android/
|                       |— gradle/
|                           |— hello/
|                               |— MainActivity.java
|   |— res/
|       |— drawable-hdpi/
|           |— ic_launcher.png
|       |— drawable-ldpi/
|       |— drawable-mdpi/
|           |— ic_launcher.png
|       |— drawable-xhdpi/
|           |— ic_launcher.png
|       |— layout/
|           |— activity_main.xml
|       |— menu/
|           |— main.xml
|       |— values/
|           |— dims.xml
|           |— strings.xml
|           |— styles.xml
|       |— values-sw600dp/
|           |— dims.xml
|       |— values-sw720dp-land/
|           |— dims.xml
|       |— values-v11/
|           |— styles.xml
|       |— values-v14/
|           |— styles.xml
```

That `strings.xml` contains a revised version of the `app_name`, to help make it more obvious that we are running the debug version of the app:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <string name="app_name">HelloGradle DEBUG</string>

</resources>
```

As we will see, resources in build types' sourcesets *replace* their counterparts in the main. Or, a build type could add a new resource that is missing from main, if desired.

build.gradle Settings

We can also use the `buildTypes` closure in `build.gradle` to configure the behavior of the debug and/or release build types. In this sample project, we alter both, plus make some other changes:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }

    signingConfigs {
        release {
            storeFile file('HelloConfig.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        debug {
            applicationIdSuffix ".d"
            versionNameSuffix "-debug"
        }
    }
}
```

```
        release {
            signingConfig signingConfigs.release
        }
    }
}
```

As was noted back in [the introduction to Gradle for Android](#), the `defaultConfig` closure allows us to change aspects of what is found in the `AndroidManifest.xml` file, replacing anything found in the actual file from the main sourceset.

The `buildTypes` closure is where we configure the behavior of the build types. Each build type to be configured gets its own closure inside of `buildTypes`, and in there we can override various properties.

Notable properties that we can specify for a build type include:

- `debuggable` (to override `android:debuggable` from the `<application>` element in the manifest, to indicate that the app should be considered debuggable)
- `applicationIdSuffix` (to append to the package name specified by the manifest or the `defaultConfig` `applicationId` property)
- `versionNameSuffix` (to append to the version name specified by the manifest or the `defaultConfig` `versionName` property)

(NOTE: `applicationIdSuffix` was formerly known as `packageNameSuffix` prior to the Gradle for Android 0.11 release)

Our debug build type adds suffixes to the version name and the application ID role for the package name. Note that altering the application ID *only* affects the package name as seen by Android when the app is installed and when the app is run. It does *not* affect the directory in which the R class is built, which uses the package name from the `AndroidManifest.xml` file. It also does not affect any of the Java packages for our own classes, which are whatever we used when we wrote them. Hence, much of our code will be oblivious to the package name change. However, if you want to reference the *real* package name, such as for looking things up in `PackageManager` or for use with constructing a `ComponentName`, use `getPackageName()` on any `Context` (like an `Activity`), rather than some hard-coded string, as `getPackageName()` returns what the runtime environment thinks the package is, which will include any suffixes added during the build process. Or, use `BuildConfig.APPLICATION_ID`, in cases where you do not have a `Context` handy on which to call `getPackageName()`.

We can also have a `signingConfig` property, for configuring how our APK files are digitally signed. This will be covered [in a later chapter](#).

Order of Precedence

Properties defined for a build type, and the properties defined for the `defaultConfig` will override their equivalents in the `AndroidManifest.xml` file. However, a build type's sourceset can *also* have its own `AndroidManifest.xml` file. The overall order of precedence is:

- What is in `build.gradle` takes precedence over...
- ...what is in a build type's `AndroidManifest.xml` file, which takes precedence over...
- ...what is in the main `AndroidManifest.xml` file

However, merging manifests in general is a complex topic, with [a separate chapter](#) later in this book.

Resources from the build type's sourceset are merged into the resources from the main sourceset, and if there are collisions, the build type's resource takes precedence. The same is true for assets.

However, the behavior of Java source is slightly different. The build type's source set is still merged with the main sourceset, but if there is a collision, the result is a build error. Either the build type or the main sourceset can define any given source file, not both. So, while debug could have one version of your `/package/name/Foo.java` and release could have a different version of your `/package/name/Foo.java`, main could not *also* have your `/package/name/Foo.java`. Hence, if you define a class in a build type, you may need to define that class in *all* build types, so that any references from main to that class are satisfied for all build types.

One case where this would not be required would be for debug-only activities. Suppose that you wanted an activity in your app to provide diagnostic information to developers of that app regarding the state of caches and other in-memory constructs. While you could get at that stuff via a debugger, that is sometimes annoying, and just tapping on a launcher icon can be easier. But you do not want, let alone need, this diagnostic activity in your release builds. To make this work, you would put the activity's Java class only in the debug sourceset, along with its resources and manifest entry (complete with `MAIN/LAUNCHER <intent-filter>`). Since the main sourceset does not refer to your diagnostic activity, there is no requirement for the release build type to have an implementation of that Java class.

Adding Build Types

Many developers will fare just fine with the debug and release build types, perhaps with some adjustments as shown above. A few developers, though, will have other scenarios that warrant new build types. Fortunately, adding a new build type is rather easy, as seen in the [Gradle/HelloBuildType](#) sample project, which builds upon the previous sample, adding a new build type.

As with the built-in build types, your new build types can have their own sourcesets, by adding the appropriately-named directories underneath `src/`. And, as with the built-in build types, you can configure the new build types in the `buildTypes` closure in `build.gradle`:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }

    signingConfigs {
        release {
            storeFile file('HelloConfig.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        debug {
            applicationIdSuffix ".d"
            versionNameSuffix "-debug"
        }
    }
}
```

```
release {
    signingConfig signingConfigs.release
}

mezzanine.initWith(buildTypes.release)

mezzanine {
    applicationIdSuffix ".mezz"
    debuggable true
}
}
```

In this project, we want a third build type, named `mezzanine`, representing a “middle ground” between a regular debug build and the release build.

To tell Android about the new build type, we need to initialize one. That is handled by the `mezzanine.initWith(buildTypes.release)` statement, which initializes the new `mezzanine` build type configuration based upon the already-defined `release` build type. From there, the subsequent `mezzanine` closure can amend the properties of that build type. In this case we:

- Put a `.mezz` suffix on the package name
- Flag the project as `debuggable`
- Sign with the release signing key

Since the `mezzanine` build type started with the `release` build configuration, the net effect is that we have a build that is equivalent to the `release` build, just with the `debuggable` flag set (and a unique package name).

Now, we gain Gradle tasks with `Mezzanine` in the name, like `installMezzanine`, to go along with their `Debug` and `Release` counterparts.

Adding Product Flavors and Getting Build Variants

Many apps will not need product flavors, but some will. Adding a product flavor is similar, in many respects, to adding a build type, as we will see in the [Gradle/HelloProductFlavors](#) sample project, which builds upon the previous sample, adding a pair of product flavors: `vanilla` and `chocolate`.

(note: product flavors do not have to be named after actual flavors)

GRADLE AND THE NEW PROJECT STRUCTURE

Each product flavor, as with each build type, can have its own sourceset. In this sample, we have `src/vanilla/` and `src/chocolate/` directories representing a source set for each product flavor:

```
HelloProductFlavors
|— build.gradle
|— HelloConfig.keystore
|— libs/
|   |— android-support-v4.jar
|— local.properties
|— proguard-project.txt
|— project.properties
|— src/
|   |— chocolate/
|   |   |— java/
|   |   |   |— com/
|   |   |   |   |— commonsware/
|   |   |   |   |   |— android/
|   |   |   |   |   |   |— gradle/
|   |   |   |   |   |   |   |— hello/
|   |   |   |   |   |   |   |— MainActivityOptionsStrategy.java
|   |— debug/
|   |   |— res/
|   |   |   |— values/
|   |   |   |   |— strings.xml
|   |— main/
|   |   |— AndroidManifest.xml
|   |   |— assets/
|   |   |— java/
|   |   |   |— com/
|   |   |   |   |— commonsware/
|   |   |   |   |   |— android/
|   |   |   |   |   |   |— gradle/
|   |   |   |   |   |   |   |— hello/
|   |   |   |   |   |   |   |— MainActivity.java
|   |   |— res/
|   |   |   |— drawable-hdpi/
|   |   |   |   |— ic_launcher.png
|   |   |   |— drawable-ldpi/
|   |   |   |— drawable-mdpi/
|   |   |   |   |— ic_launcher.png
|   |   |   |— drawable-xhdpi/
|   |   |   |   |— ic_launcher.png
|   |   |   |— layout/
|   |   |   |   |— activity_main.xml
|   |   |   |— menu/
|   |   |   |   |— main.xml
|   |   |   |— values/
```

```
|
|
|   |— dims.xml
|   |— strings.xml
|   |— styles.xml
|— values-sw600dp/
|   |— dims.xml
|— values-sw720dp-land/
|   |— dims.xml
|— values-v11/
|   |— styles.xml
|— values-v14/
|   |— styles.xml
|— vanilla/
|   |— java/
|       |— com/
|           |— commonsware/
|               |— android/
|                   |— gradle/
|                       |— hello/
|                           |— MainActivityOptionsStrategy.java
```

In the sourcesets, we have a `MainActivityOptionsStrategy` class, one implementation per product flavor. This class is referenced by a new implementation of the `MainActivity` class in the main sourceset, to delegate the handling of `onOptionsItemSelected()`:

```
package com.commonsware.android.gradle.hello;

import android.os.Bundle;
import android.app.Activity;
import android.view.Menu;
import android.view.MenuItem;

public class MainActivity extends Activity {

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        // Inflate the menu; this adds items to the action bar
        // if it is present.
        getMenuInflater().inflate(R.menu.main, menu);
        return true;
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        return(MainActivityOptionsStrategy.onOptionsItemSelected(item));
    }
}
```

GRADLE AND THE NEW PROJECT STRUCTURE

Since we do not have anything much to do in the menu option, each product flavor's implementation of `MainActivityOptionsStrategy` simply logs a flavor-specific message to LogCat, such as the one shown here for vanilla:

```
package com.commonware.android.gradle.hello;

import android.util.Log;
import android.view.MenuItem;

public class MainActivityOptionsStrategy {
    public static boolean onOptionsItemSelected(MenuItem item) {
        Log.d("HelloProductFlavors", "vanilla!");

        return(false);
    }
}
```

To tell Gradle for Android about our product flavors, and to configure their behavior, we have a new `productFlavors` closure in the `build.gradle` file:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }

    signingConfigs {
        release {
            storeFile file('HelloConfig.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        debug {

```

```
        applicationIdSuffix ".d"
        versionNameSuffix "-debug"
    }

    release {
        signingConfig signingConfigs.release
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
        signingConfig signingConfigs.release
    }
}

productFlavors {
    vanilla {
        applicationId "com.commonware.android.gradle.hello.vanilla"
    }

    chocolate {
        applicationId "com.commonware.android.gradle.hello.chocolate"
    }
}
}
```

The `defaultConfig` is implemented using the same object type as is used for product flavors. Hence, we can configure the same things on a product flavor that we can on the `defaultConfig`, such as `applicationId`, as is done in this `build.gradle` file.

In terms of order of precedence:

- Product flavors override the main `sourceset` and the `defaultConfig`
- Build types override the product flavors

So, a debug build of the `vanilla` product flavor will result in a package name of `com.commonware.android.gradle.hello.vanilla.d`.

Our task names get more numerous and more complicated, to reflect the cross product of the product flavors and build types. Now, rather than `installDebug`, `installMezzanine`, and `installRelease`, we have:

- `installChocolateDebug`
- `installChocolateMezzanine`
- `installChocolateRelease`
- `installVanillaDebug`
- `installVanillaMezzanine`

- `installVanillaRelease`

Doing the Splits

Gradle for Android 0.13 introduced splits as a lightweight canned replacement for product flavors for two scenarios:

- Having different APK files with different NDK binaries for ARM vs. x86 (vs. anything else)
- Having different APK files with resources for a specific screen density, important for those apps that have so many graphics that they are bumping up against distribution channel limits (e.g., 100MB on the Play Store, up from an earlier 50MB limit)

All you as a developer do is request that a particular split be enabled, with limited configuration. Notably, you do not have separate Gradle configuration (e.g., `applicationId`) nor sourcesets for splits. That allows splits to be processed more quickly at build time, as the build tools can make some simplifying assumptions and avoid a lot of recompiling.

Scoping Your Splits

A split, by default, will generate one APK per *possible* type of output. For example, splitting on density will give you one APK for `ldpi`, `mdpi`, `tvdpi`, `hdpi`, `xhdpi`, `xxhdpi`, and `xxxhdpi`. Plus, in the case of density, you also get one “universal” APK containing support for all densities by default.

That’s nice... but what if you do not need separate APKs for all of those densities? For example, if you do not ship `tvdpi` resources, there is little reason to set up an APK for it separate from, say, the `hdpi` APK.

There are two basic patterns to controlling the scope of what gets built:

1. Use an `exclude` statement to start with the defaults and remove some options
2. Use a `reset()` method to wipe out the defaults, then use an `include` statement to list what you want

In other words, `exclude` implements a blacklist, and the `reset()/include` combination implements a whitelist. All else being equal, a whitelist is probably a better choice, so you can explicitly line it up with what you have written in your app.

Requesting NDK Splits

In your android closure, you can add a `splits` closure, containing an `abi` closure, which in turn sets up the APK splits by CPU architecture:

```
splits {
  abi {
    enable true
    reset()
    include 'armeabi-v7a', 'x86'
    universalApk true
  }
}
```

Here, we:

- Enable the split (`enable true`)
- Remove the default ABIs to be included (`reset()`)
- List the ABIs that we want to be included (`include 'armeabi-v7a', 'x86'`)
- Request that a “universal APK” also be created, containing all ABIs (`universalApk true`)

The latter would be useful for distribution channels that do not allow you to upload multiple APK files for different CPU architectures. This way, you can at least distribute your app there, even if it takes up more disk space than you like. By default, for the CPU architectures, you do not get a “universal APK”.

Requesting Density Splits

The same basic pattern can be implemented for densities:

```
splits {
  density {
    enable true
    reset()
    include 'hdpi', 'xhdpi', 'xxhdpi'
  }
}
```

Once again, we enable the split, reset the defaults, then opt into the densities that we want.

Note, though, that a “universal APK” is always generated for densities. We do not need to have `universalApk true`, and it would appear that `universalApk false` is not an option at the present time.

Revisiting the Legacy Gradle File

Given all of this, let’s revisit the `build.gradle` file exported from Eclipse:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}
apply plugin: 'com.android.application'

dependencies {
    compile fileTree(dir: 'libs', include: '*.jar')
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        // Move the tests to tests/java, tests/res, etc...
        instrumentTest.setRoot('tests')

        // Move the build types to build-types/<type>
        // For instance, build-types/debug/java, build-types/debug/AndroidManifest.xml,
        ...
        // This moves them out of their default location under src/<type>/... which would
        // conflict with src/ being used by the main source set.
        // Adding new build types or product flavors should be accompanied
        // by a similar customization.
        debug.setRoot('build-types/debug')
        release.setRoot('build-types/release')
    }
}
```

The bulk of the android-specific configuration in the exported `build.gradle` file comes in the `sourceSets` closure inside the `android` closure. Here, we specify what should be compiled.

Gradle allows for separate locations for items presently all dumped into `src/`: Java source, AIDL interface definitions, RenderScript source files, and Java-style resources (not to be confused with Android resources). Since this build file is for a classic directory structure, though, each of those types of input files will still be found in `src/`, so the main `sourceSet` points Android to `src/` for each of them. In addition, `main` indicates the name of the manifest file and the location of the `res/` and `assets/` trees.

The `main` closure in the `sourceSets` closure overrides the default locations of files that comprise the `sourceSet`. For example, in the new project structure, the Java source code goes in `java/` within the `sourceSet`, but in the old project structure, it goes in a `src/` directory in the project root.

The `setRoot()` calls on the stock `debug` and `release` build types indicate that their `sourceSets`, if they exist, should be in a separate `build-types/` directory, as the normal `src/` location is being used for Java source code.

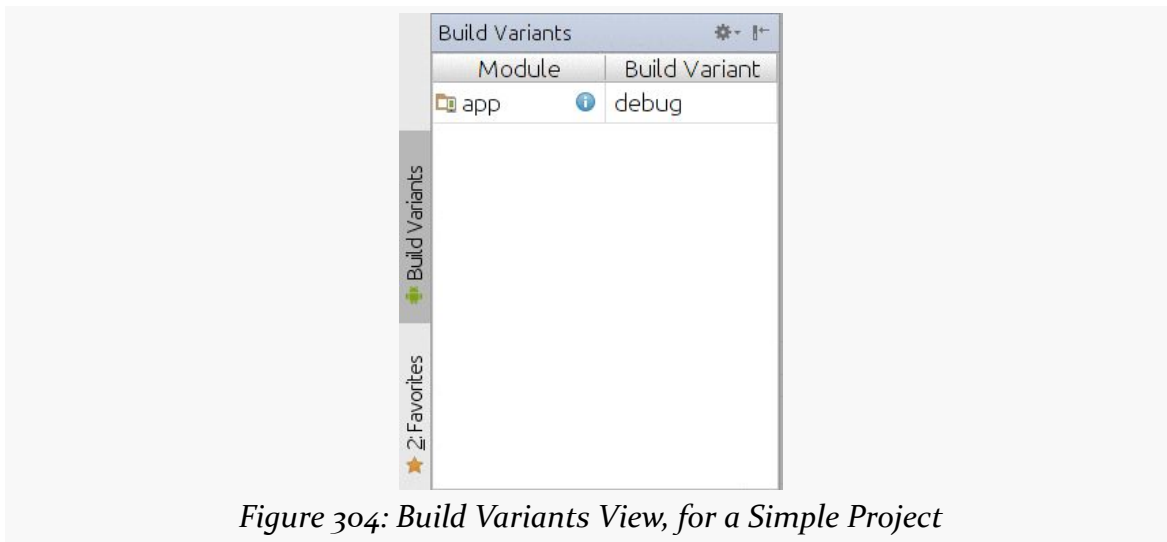

Working with the New Project Structure in Android Studio

Not surprisingly, Android Studio has a few features designed to help you work with the various `sourceSets` that you elect to create and use.

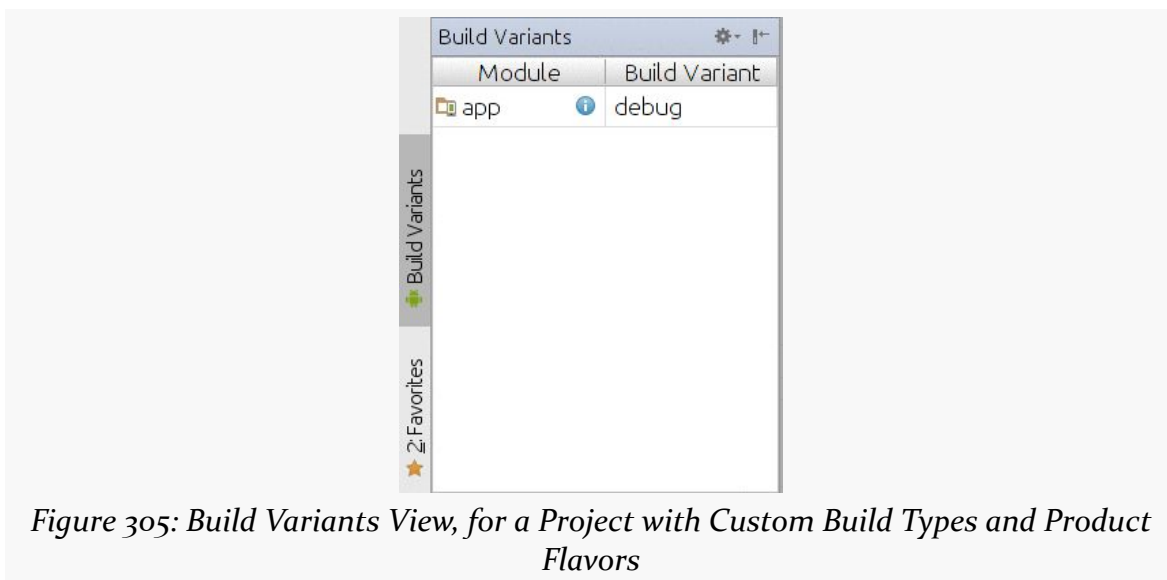

The Build Variants View

When we run our project, Android Studio does not prompt us for a build type or a product flavor. It just runs the project. This begs the question of how Android Studio is determining which build variant is the one to run.

This is handled by the Build Variants view, usually docked on the left side of the Android Studio IDE window:

Each of your app's modules is shown, along with the current build variant that will be used if you run that module. Tapping on the build variant will allow you to choose an alternative build variant:

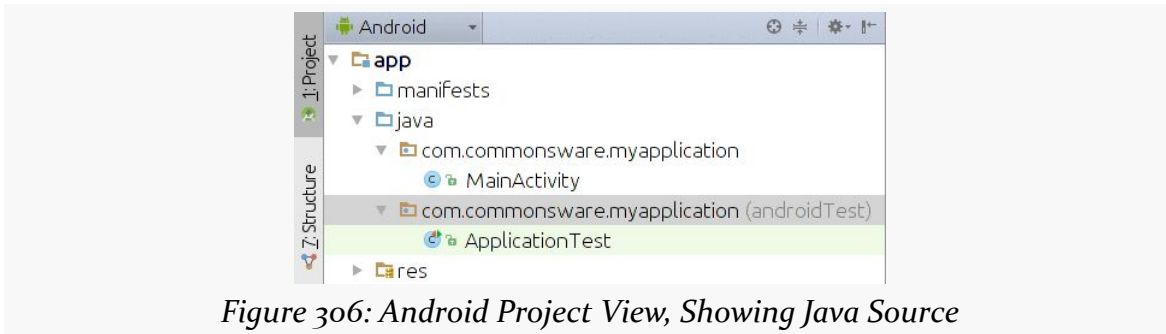

The Android Project View

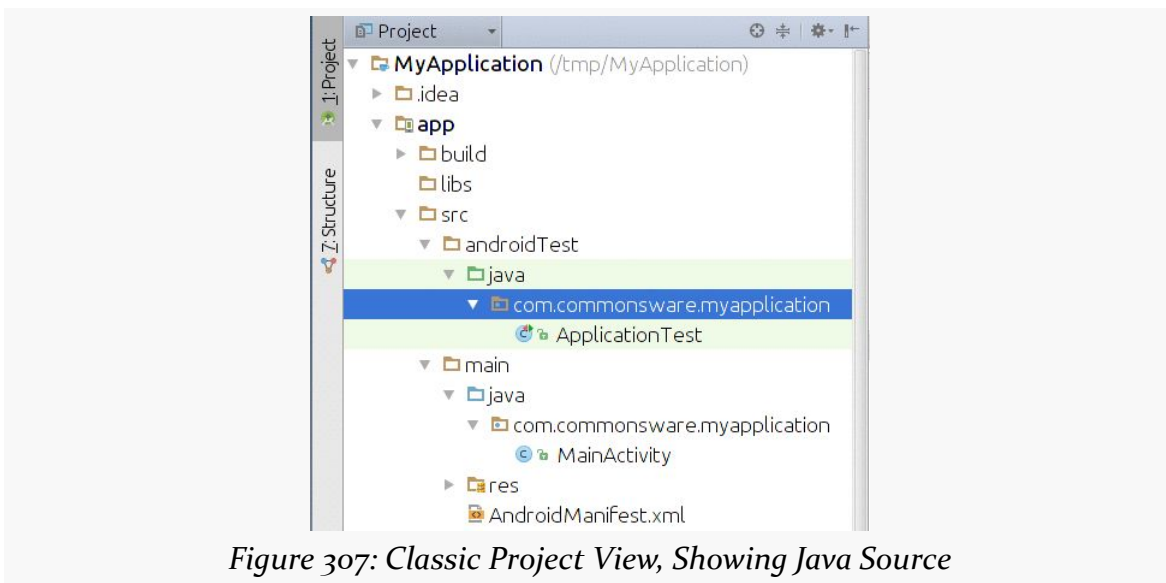

Earlier in the book, when introducing Android Studio, we saw [the Android project view](#). Elsewhere, we saw how the Android project view can help you manage resources across multiple resource sets.

GRADLE AND THE NEW PROJECT STRUCTURE

Just as the Android project view “collapses” resource set, it also collapses sourcesets:

Here, we have two editions of the `com.commonware.myapplication` package. One is just the package name, while the other has “(androidTest)” appended to it. That, as you might imagine, reflects the main and androidTest sourceset, respectively:

This may be a bit useful between main and androidTest. It is likely to be far more useful if you employ product flavors, as your classes for the flavors will appear side-by-side... at least for the currently-selected flavor in the Build Variants view. [At the present time](#), Android Studio only treats the active variant’s sourcesets (plus main and androidTest) as “source”, with other build variant sourcesets being considered just plain files.

Flavors, Build Types, and the Project Structure Dialog

You are welcome to use the Build Types and Product Flavors tabs in [the project structure dialog](#) to maintain these portions of your `build.gradle` file, at least for simpler scenarios.

Gradle and Dependencies

John Donne wrote “no man is an island”. Nowadays, few apps are islands, either. It is the rare app that can avoid using all third-party code bases. Most apps will need a backport or other class (e.g., `ViewPager`) from the Android Support package, or will rely upon the Play Services SDK, or will use any number of third party JARs and Android library projects.

The good news is that Gradle adds a lot of power for referencing these third-party code bases when you build your app. While it increases the complexity a bit for “reuse in the small” (e.g., a simple JAR), it can greatly simplify “reuse in the large” (e.g., several Android library projects).

This chapter will outline what sorts of “dependencies” your app can have and how you can configure Gradle to support them.

NOTE: The projects demonstrated in this chapter are *not* set up to be used by Eclipse, as Eclipse does not support Gradle as of the time of this writing.

Prerequisites and Warnings

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, including both [the legacy project structure](#) and [the new project structure](#).

“Dependencies”?

In case the term is new to you, in this chapter, and in the Gradle documentation, “dependencies” means “code external to your project that your project depends upon”.

In the case of Gradle-built Android apps, this includes:

- local JARs
- NDK-built local Linux `.so` files
- local Android library projects
- other types of “sub-projects”
- “artifacts” obtained from “repositories”, like Maven Central

Each of these will be covered in turn in this chapter.

A Tale of Two Dependencies Closures

A `build.gradle` file — or the pair of `build.gradle` files in a classic Android Studio project — will have two dependencies closures.

One will be inside the `buildscript` closure, and this set of dependencies are dependencies for the build process itself. Here, we will list dependencies such as the Android build tools, the ones that define the android options we can configure.

The dependencies closure that is a peer of `buildscript` and `android` lists the dependencies for the project that is being built by this particular `build.gradle` file.

In other words, the `buildscript` dependencies are tooling dependencies, while the regular dependencies are compile-time sources of third-party code.

Depending Upon a JAR

Since early 2012, Ant and Eclipse shared a common rule for third-party JARs: put them in your project’s `libs/` directory, and both build environments would take it from there. Specifically, they would:

- Add those JARs to the compile-time classpath, so your code that references those JARs’ public APIs would compile, and

- Add the contents of those JARs to your APK, so at runtime, your references to those JARs' classes can be resolved

And it worked.

The new Gradle-based build system does not automatically use the contents of your `libs/` directory in the same way. That is why our `build.gradle` files that use simple local JARs will wind up with a `dependencies` closure that looks like this:

```
dependencies {
    compile fileTree(dir: 'libs', include: '*.jar')
}
```

The `fileTree()` will walk the directory tree rooted in the `dir` property (here, `libs`) and look for files matching the `include` wildcard pattern (here, `*.jar`). This will return all JAR files in `libs/`, which are then added to the `compile` process.

And, while we do not explicitly say to include those JARs in the resulting APK file, that is actually handled for us as part of android processing.

Note that this is configurable. So, if for some reason, you would prefer to have your JARs be in a directory other than `libs/`, such as `jars/` or `localDependencies/` or `wheeMakingLongDirectoryNameIsFun/`, you are welcome to do so.

...And Why Some Do Not Like This

However, using simple JARs this way is frowned upon, at least in the absence of better options.

One reason is that a JAR file does not necessarily contain any information about the *version* of that JAR file. JARs are frequently updated, and unless the author of the JAR is “mangling in” the version information into the filename, you cannot tell by looking at a JAR whether it is old or new.

For example, the classic Android Support package's JAR is `android-support-v4.jar`. Some developers see the `-v4` part and assume that this means that this specific JAR is version 4 of the library. In reality, `-v4` means that it contains primarily the classes from `android.support.v4` and is designed for use with apps looking to support back to API Level 4. However, this JAR is updated every couple of months with new classes and bug fixes. Hence, two files named `android-support-v4.jar` may have radically different contents, if one is from 2011 and one is from 2013, for example.

This is what causes the Ant/Eclipse build process to hiccup when it encounters multiple copies of the same JAR file (e.g., one in your project and one with the same name in an Android library project). Name alone cannot distinguish whether they are the same. The build tools wound up using MD5 hashes to try to determine if the contents were indeed identical, which works but is not an ideal solution.

Another reason why people frown upon bare JARs is that there is nothing to manage the dependencies of the JAR itself. Many times a JAR depends upon other JARs, but the JAR has no way of expressing that. Instead, developers are supposed to take care of that on their own, perhaps through reading documentation and following those instructions. And, since developers do not always read documentation or follow those instructions, manual dependency management is fraught with peril.

In classic Java development, “artifacts” and “repositories” were introduced to help provide some wrapper metadata around a JAR, to help developers find the right version and determine when updates are needed. Using artifacts and repositories is recommended with Gradle, and Gradle makes it comparatively easy to use these structures, as we will see [later in this chapter](#).

Depending Upon NDK Binaries

It is possible to use the NDK with Gradle for Android. However, this is complicated enough that it is relegated to [the chapter on advanced Gradle for Android techniques](#).

Depending Upon an Android Library Project

[Android library projects](#) have become popular ways of sharing code between projects, as they encompass resources in addition to Java code. Some developers will use Android library projects purely internally, for reusable code between projects. Some developers will depend upon third-party library projects, such as widget libraries or Google’s `appcompat-v7` backport of the action bar pattern. Some developers will publish their own libraries for third-party use.

At their core, Android library projects do not change a lot when built with Gradle as opposed to being built with Ant or Eclipse. However, the way you tell Android that a project is a library project, and how you consume such library projects, has changed substantially.

Creating a Library Project

As noted in [the chapter on the Android library project](#), the primary difference between a regular Android project and an Android library project, in terms of Gradle configuration, is which plugin you use. Regular application projects will use the `com.android.application` plugin, while Android library projects use the `com.android.library` plugin:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.library'

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

Source sets will behave the same as they do for regular apps, and otherwise your code is no different than it would be for a regular app. However, as always, an Android library project is not designed to create an APK file, but rather to serve as a library.

However, Android library projects *can* have associated test code, which is covered in the chapter on [unit testing](#).

Depending Upon the Library Project

You have two major choices for depending upon a library project:

1. If the library project is yours, and particularly if it is only really to serve one app, you could set up the library project as a module or sub-project of the project containing that app, as we will see in [the next section](#).
2. You can [publish the library project to some repository as an AAR artifact](#), such as [a local repository](#), then [reference that AAR as a dependency](#). Coverage of artifacts and repositories appears [later in this chapter](#).

These are not mutually exclusive. The CWAC libraries published by the author of this book, for example, use *both* techniques. These projects are published as an

Android library project plus one (or more) demo app(s) demonstrating the use of the library. In debug builds, the demo app(s) depend upon the library as a sub-project. In release builds, though, the demo app(s) depend upon a published AAR of the library, to better model what other developers would see. We will see how to have dependencies vary by build type [later in this chapter](#).

Depending Upon Sub-Projects

In classic Eclipse projects, we did not have the concept of a sub-project. However, Gradle and Android Studio both support a structure of a top-level directory (sometimes referred to as a “module”) containing a series of projects.

For example, the [Gradle/HelloMultiProject](#) directory contains:

- a `HelloLibraryConsumer` project
- a `libraries/` subdirectory containing a `HelloLibrary` project

In this case, `HelloLibrary` is an Android library project, the one from which we saw the `build.gradle` file earlier in this chapter. `HelloLibraryConsumer` is a regular app that uses code found in the `HelloLibrary` Android library project.

If your library project is solely for use with one app, you might elect to structure your code using this approach.

The top-level directory must have a `settings.gradle` file, listing the Gradle projects found in the directory (and any of its subdirectories):

```
include ':HelloLibraryConsumer', ':libraries:HelloLibrary'
```

The leading `:` refers to the overall root directory, so `:HelloLibraryConsumer` is a reference to the `HelloLibraryConsumer/` directory under the root. Other `:` values represent levels in the hierarchy, so `:libraries:HelloLibrary` refers to the `libraries/HelloLibrary/` subdirectory. `:` is used instead of `/` as `/` is used by Gradle for other purposes.

Hence, the `include` statement tells Gradle that this aggregate project is made up of the two sub-projects.

To indicate that `HelloLibraryConsumer` wishes to consume code from the `HelloLibrary` library, another line is added to the `dependencies` closure, referencing the sub-project:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
    compile project(':libraries:HelloLibrary')
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

Whereas `fileTree()` is finding the JARs in the `libs/` directory, `project(':libraries:HelloLibrary')` is identifying the sub-project, and we are telling Gradle to compile that sub-project into our project.

From the overall root directory (the one with the `settings.gradle` file), you can run `gradle` tasks for the overall app. This also works from the main app's directory (in this case, `HelloLibraryConsumer/`).

While this approach is fine for some applications, this structure will not work well if the library has multiple possible consuming apps, particularly if those apps might be by other authors. In that case, the library will need to be published as an artifact to a repository, which is covered in the next section.

Depending Upon Artifacts

While JARs and sub-projects are certainly possible using Gradle for Android, the predominant approach for specifying dependencies is by referencing artifacts hosted in repositories.

What Is an Artifact?

In the context of Java-based programming, an artifact usually refers to a JAR (or other compiled output, like a Java EE WAR), accompanied by metadata that provides version information, a roster of the artifact's own dependencies, and related information.

What Is a Repository?

A repository is a collection of artifacts, stored in some location, that can be referred to in order to find and resolve requests for dependencies.

Such repositories tend to be sub-divided into “local” and “remote”. A local repository is one that resides on your own development machine; a remote repository is one that resides on some server. That server could be *relatively* local (e.g., a repository in support of a corporate development team), or it could be somewhere else. Perhaps the best-known “somewhere else” is Maven Central, a repository used by many open source projects for distributing their artifacts.

Types of Artifacts and Repositories

There are two types of repositories, and associated artifact structures, supported by Gradle: Maven and Ivy. Each has their own format for the metadata and their own structure for how the files are stored.

Maven

[Apache Maven](#) is a full-fledged build system. Part of that build system is a system of artifacts and repositories. While Gradle does not use Maven’s build system — rather, it largely replaces it — Gradle can consume artifacts published in a Maven-structured repository. Maven Central, as one might expect, is one such repository, but it is eminently possible to set up your own, and some organizations have done that.

As Maven seems to be the more popular of the two, this book will focus on Maven-structured repositories and Maven-style artifacts.

Ivy

[Apache Ivy](#) is an off-shoot of the Apache Ant project that gave us the Ant build system. Ivy is simply a way of declaring dependencies between components, including handling “transitive dependencies” (i.e., App A depends upon Library B, which in turn depends upon Libraries C and D).

General Artifact Dependency Setup

To depend upon artifacts, you need to teach Gradle two things:

1. Where can artifacts be found?
2. What artifact(s) do you need?

The former comes from a `repositories` closure in your `build.gradle` file, to specify the repositories that you wish to search for artifacts.

The latter comes from other variations on the `compile` statement in your `dependencies` closure. Rather than using `compile` with something like a `fileTree()`, you will specify the artifacts that you wish to use.

Artifacts are identified by three pieces of data:

1. A group
2. An artifact ID
3. A version number

These are separated by colons, so `compile 'com.commonware.cwac:colormixer:0.5.0'` would indicate that you are seeking the artifact that:

- ...is in the `com.commonware.cwac` group...
- ...has the `colormixer` artifact ID, and...
- ...is version `0.5.0`

Depending Upon Maven Central or JCenter Artifacts

The single most common place to get artifacts is [Maven Central](#). This is roughly analogous to the RubyGems repository for Ruby developers, or CPAN for Perl developers. Maven Central is a warehouse of many, many artifacts, only a subset of which will be relevant for Android, as Maven Central has been used for many other Java environments (e.g., Java Web containers).

Bintray — a firm in the artifact repository business — has JCenter. JCenter is a mirror of Maven Central, and developers can publish artifacts directly to JCenter as well.

If you wish to use artifacts from one of these repositories, your `build.gradle` file will need a `repositories` closure, at the top level (i.e., distinct from the one inside the `buildscript` closure), that requests either `mavenCentral()` or `jcenter()`:

```
repositories {  
    mavenCentral()  
}
```

Then, you can have `compile` statements in your dependencies closure that list artifacts that can be found on Maven Central or JCenter. One way to find out what you can include is to visit the [“Gradle, please” Web site](#), where you can type in the name of a popular library (e.g., `otto`) and get the corresponding dependencies closure:

```
dependencies {  
    compile 'com.squareup:otto:1.3.4'  
}
```

If you have several dependencies, list them in the one dependencies closure, one after the next. So, for example, to depend both upon Otto and local JARs, you would have:

```
dependencies {  
    compile 'com.squareup:otto:1.3.4'  
    compile fileTree(dir: 'libs', include: '*.jar')  
}
```

You may recall that an Android Studio project’s top-level `build.gradle` file contains something like:

```
allprojects {  
    repositories {  
        jcenter()  
    }  
}
```

The `allprojects` closure represents configuration that should be applied to all modules (sub-projects) in the project. Hence, the repositories defined here will be defined for all modules, above and beyond any repositories closure in the module’s own `build.gradle` file.

Depending Upon Googly Artifacts

However, not all artifacts are stored at Maven Central or JCenter.

One important set of artifacts stored elsewhere are Google’s. Rather than have you depend upon Maven Central, they offer their own repositories, ones that you can download to your development machine via the SDK Manager. They are called “Android repository” and “Google repository”, where the former is the home for

things like the Android Support package, and the latter is the home for things like the Play Services SDK.

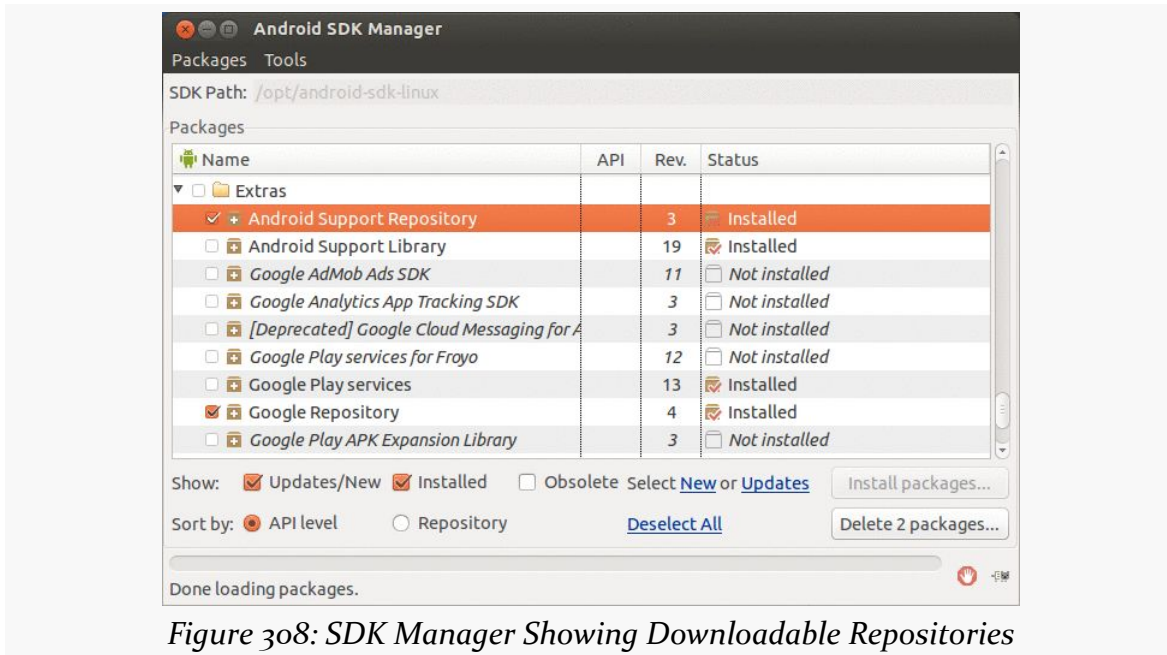

Figure 308: SDK Manager Showing Downloadable Repositories

These repositories, if found, are automatically added to your Gradle environment. So, unlike with Maven Central, you do not need to add them manually to a repositories closure.

If you read through the core chapters of this book, you learned about the support-v4 and support-v13 artifacts, providing classes like ViewPager and NotificationCompat. There are dozens of others combined between the Android Repository and Google Repository, many of which are covered elsewhere in this book.

By referencing these artifacts, you no longer need to mess around with copying JARs or attaching Android library projects to your own projects.

Depending Upon Other Artifact Repositories

Gradle supports custom artifact repositories, in Maven or Ivy style, for retrieval of artifacts. For example, your development team might have a common artifact repository for your projects, shared among the developers and a continuous integration server. Or, you may elect to publish your reusable components in your own repository, eschewing Maven Central.

The [Gradle documentation](#) covers the various possibilities, such as how to include authentication credentials for secured repositories. Typically, though, you will use a simple URL:

```
repositories {
    maven {
        url "http://repo.commonsware.com"
    }
}
```

This repositories closure adds a Maven-style repository, located at `http://repo.commonsware.com`.

```
repositories {
    maven {
        url "https://repo.commonsware.com.s3.amazonaws.com"
    }
}
```

This is an equivalent repositories closure, but specifies `https` as the scheme, for secure downloads of the artifacts. Since this particular repository happens to be hosted at Amazon S3, the SSL certificate requires that we use the full Amazon S3 domain name (`repo.commonsware.com.s3.amazonaws.com`) rather than the CNAME shorthand (`repo.commonsware.com`).

From there, you can then request to compile against whatever artifacts the publisher of that repository makes available.

Your Very Own Repository

You may want to have your own local repository, just on your own development machine. For example, if you are writing an Android library project, and using sub-projects to reference it is inappropriate (e.g., the library is being used by several disparate apps), you can publish your AAR artifact to your local repository, then have your other apps depend upon that artifact as found in that repository.

Consuming artifacts from your local repository is just a matter of having a `mavenLocal()` entry in your repositories closure:

```
repositories {
    mavenLocal()
}
```

The precise location of this repository will be platform-dependent. On Linux, for example, it is in `~/m2/`. However, it will be on your local machine.

NOTE: On some versions of Gradle, `mavenLocal()` does not work. The workaround is:

```
repositories {
    maven { url "${System.env.HOME}/.m2/repository" } // mavenLocal()
}
```

You can have your own hosted repository, if you wish. For example, the author of this book is slowly converting his CWAC projects over to be available as JAR and AAR artifacts from the `repo.commonsware.com` repository mentioned above. From Gradle's (and Maven's) standpoint, there is no real difference between a repository hosted on a nearby file server or some remote Web server. A discussion of how to get your artifacts to such a repository is outside the scope of this book.

Publishing Libraries as Artifacts

Of course, having a local (or remote) repository is only as good as is your ability to put things into that repository. And, right now, that is a place where the current Gradle for Android plugin falls down. The documentation mentions the AAR format but offers no instructions related to publishing it, and changes in the plugin have broken many cobbled-together solutions from 2013.

The current simplest solution comes in the form of the maven plugin, which, as the name suggests, is a plugin for Gradle that adds support for the publishing of Maven artifacts from Gradle builds.

As this is a standard Gradle plugin, all you need to do is have `apply plugin: 'maven'` in your `build.gradle` file to use it.

Then, you can configure where and how the Maven plugin should publish your AAR, via an `uploadArchives` closure, as a top-level closure (i.e., a peer of your `android` closure):

```
apply plugin: 'maven'

uploadArchives {
    repositories.mavenDeployer {
        pom.groupId = 'com.commonsware.cwac'
        pom.artifactId = 'everything-is-awesome'
        pom.version = '0.0.1'

        repository(url: 'file:///home/somebody/put/a/real/path/in/here/kthxbye')
    }
}
```

The `groupId` and `artifactId` form the basis of the name of your artifact (in this case, a fictitious `com.commonware.cwac:everything-is-awesome` library). The `version`, of course, is the version of the artifact. The `url` parameter on the repository call indicates where the artifact should be uploaded to, and this can point to a public repository (e.g., Maven Central), a private enterprise hosted repository, a local repository (as is the case here), etc.

At this point, the `gradle uploadArchives` command will build your AAR and deploy it to your designated Maven repository.

Publishing Legacy-Structured Libraries as Artifacts

Note that there is no particular requirement that your AARs be created from Android projects that use the new build system's preferred directory structure. Your AARs can come from a project that retains the legacy directory structure. This is key for the next few years, while AAR support slowly becomes dominant, so that you can support your Android library project being used in traditional source form as well.

We will see examples of using legacy structures for AAR-creating library projects [later in this chapter](#).

About Artifact Updates

The version of the artifact that you get is determined by the version qualified in your stated dependency. There does not appear to be anything in Gradle itself to tell you about cases where there are artifacts with upgraded versions available to you. Ben Manes has published [a Gradle plugin](#) that adds a `dependencyUpdates` task that generates a report of what the status is of all of your dependencies.

Creating Android JARs from Gradle

Gradle has a long history of being used in Java development, and the standard `java` plugin for Gradle knows how to create JAR files.

However, we are not using the `java` plugin. Instead, we are using the `android` or `android-library` plugin. In the latter case, you could argue that it should support JAR-creation tasks, for libraries that do not actually use resources and so forth. Unfortunately, it does not, at least as of the time of this writing. Hence, there is no JAR-creation task available from `android` or `android-library` projects.

As is common in these cases, Jake Wharton has come to the rescue.

Jake posted [an answer on a Stack Overflow question](#) providing a quick-and-dirty bit of Gradle code to add JAR-creation tasks to an android-library project:

```
android.libraryVariants.all { variant ->
    def name = variant.buildType.name
    if (name.equals(com.android.builder.core.BuilderConstants.DEBUG)) {
        return; // Skip debug builds.
    }
    def task = project.tasks.create "jar${name.capitalize()}", Jar
    task.dependsOn variant.javaCompile
    task.from variant.javaCompile.destinationDir
}
```

The Gradle DSL in Groovy primarily involves building up data structures. Hence, all of our build variants wind up in a collection of objects available at `android.libraryVariants`. Jake's snippet iterates over those, tosses out those that are for debug builds, and *dynamically defines a new task*. That new task will be named `jar...`, where the `...` is the name of the build type. His snippet then configures that task to create a JAR file, after the Java code has been compiled, putting the result in the destination directory for Java compilation.

The net result is that including this snippet at the bottom of your `build.gradle` file will add tasks like `jarRelease` that will create a JAR in `build/libs/` of your project. Note that the `jarRelease` task does not appear when you run `gradle tasks`, though it will appear if you run `gradle tasks --all` to get the complete list.

This does not create a full artifact around the JAR, so if your plan was to submit this JAR to an artifact repository, you would have additional work to do. However, for the simple case of creating a JAR for manual distribution (e.g., through the “releases” area of a GitHub repository), it should work fine.

A Property of Transitive (Dependencies)

One thing to watch out for when specifying dependencies is where your dependencies' dependencies come from. Short of examining configuration files for those dependencies (e.g., their Maven POM file), you have no good way to know what your dependencies' dependencies are, let alone where they are supposed to come from.

Despite that, [according to Gradleware](#):

Only the repository declarations for the project whose configuration is currently resolved are taken into account, even when transitive dependencies are involved.

So, for example, suppose App A depends upon Library B, which in turn depends upon Library C. Library B is in your team's own Maven repository, while Library C comes from Maven Central. App A will need to have *both* your own Maven repository *and* Maven Central defined in the `repositories` closure, in order for Gradle to be able to obtain both libraries.

Dependencies By Build Type

A build type can have its own dependencies.

The `compile` statement in a `dependencies` closure defines dependencies for all build types. However, each build type has its own version of the `compile` statement, like `debugCompile`, that will add a dependency for use solely by that build type.

If you create your own custom build types, note that you will need to have your `dependencies` closure *after* you define the build type in the `build.gradle` file. Only after Gradle has defined your build type will your custom `compile` statement be available.

There is also `androidTestCompile`, which defines dependencies solely for use with testing. This is covered in greater detail [in the chapter on unit testing](#).

Dependencies By Flavor

Similarly, if you define product flavors, you can have dependencies that are tied only to a particular flavor.

For example, suppose you were writing an app for various wearables, and you set up three product flavors:

```
productFlavors {
    standard {
        applicationId "com.commonware.android.wearable.qr"
    }

    imwatch {
        applicationId "com.commonware.android.wearable.qr.imwatch"
    }
}
```

```
sony {
    applicationId "com.commonware.android.wearable.qr.sony"
}
}
```

A dependencies closure *after* the android closure containing the above productFlavors configuration could have a mix of per-flavor dependencies and flavor-specific dependencies, such as:

```
dependencies {
    compile 'com.android.support:support-v4:19.0.1'
    compile 'com.google.code.gson:gson:2.2.4'
    compile 'com.squareup.okhttp:okhttp:1.3.0'
    compile 'com.squareup.retrofit:retrofit:1.4.0'
    compile 'com.squareup.picasso:picasso:2.2.0'
    sonyCompile 'com.sonyericsson.extras.liveware.aef:SmartExtensionUtils:2.1.0'
}
```

Here, the last dependency uses `sonyCompile`, rather than `compile`, indicating that it is a dependency to be used only for the sony product flavor.

Note that the artifact listed for the `sonyCompile` directive does not actually exist, at least as of the time of this writing. It is possible to convert SONY's code samples into local artifacts, for reference via `mavenLocal()`, until such time as SONY starts hosting them on Maven Central or their own artifact repository.

Examining Some CWAC Builds

The author of this book publishes several open source libraries, known as the CommonsWare Android Components (CWAC). These pose an interesting challenge for conversion to Gradle, insofar as the libraries have many existing users, some of whom are still using Eclipse, Ant, or other tools based on the legacy project structure. Hence, these projects need to be able to be built sans Gradle, yet still be able to publish artifacts that can be used by Gradle.

In this section, we will examine a few of these projects, to see how the Gradle support was implemented, with a particular eye on dependencies.

A Simple CWAC Project: `cwac-layouts`

Most of the CWAC projects are fairly simple. Beyond having relatively few classes, most CWAC projects have no dependencies beyond Android itself. These are fairly straightforward to support with Gradle, both for building the library itself and for publishing a Gradle-compatible artifact.

GRADLE AND DEPENDENCIES

For example, [the CWAC-Layouts project](#) is discussed in [the chapter on custom Views](#), as it offers a few such views, particularly the mirroring classes.

The CWAC-Layouts repository has two projects: layouts and demo. The layouts project is the one for the library itself, while demo demonstrates the use of the library.

When built using Eclipse, Ant, or related tools, layouts is an Android library project, which demo depends upon via its `project.properties` file:

```
# This file is automatically generated by Android Tools.
# Do not modify this file -- YOUR CHANGES WILL BE ERASED!
#
# This file must be checked in Version Control Systems.
#
# To customize properties used by the Ant build system edit
# "ant.properties", and override values to adapt the script to your
# project structure.
#
# To enable ProGuard to shrink and obfuscate your code, uncomment this (available
properties: sdk.dir, user.home):
#proguard.config=${sdk.dir}/tools/proguard/proguard-android.txt:proguard-project.txt

# Project target.
target=android-17
android.library.reference.1=../layouts
```

For the Gradle build, demo and layouts turn into modules, courtesy of `settings.gradle` in the project root directory:

```
include ':layouts', ':demo'
```

The demo module depends upon the layouts module, as it does with Eclipse/Ant builds. However, it does so in one of two ways:

- if this is a debug build, it depends on the layouts module, so the demo app can use the under-development version of that module
- if this is a release build, it depends upon the AAR artifact in the CommonsWare artifact repository

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    debugCompile project(':layouts')
```

GRADLE AND DEPENDENCIES

```
        releaseCompile 'com.commonware.cwac:layouts:0.4.+'  
    }  
  
    android {  
        compileSdkVersion 17  
        buildToolsVersion "19.1.0"  
  
        sourceSets {  
            main {  
                manifest.srcFile 'AndroidManifest.xml'  
                java.srcDirs = ['src']  
                resources.srcDirs = ['src']  
                aidl.srcDirs = ['src']  
                renderscript.srcDirs = ['src']  
                res.srcDirs = ['res']  
                assets.srcDirs = ['assets']  
            }  
  
            debug.setRoot('build-types/debug')  
            release.setRoot('build-types/release')  
        }  
    }  
}
```

In all other respects, the demo project's `build.gradle` file is a conventional “please use the legacy project structure” implementation.

The library's `build.gradle` file is a bit more involved:

```
apply plugin: 'com.android.library'  
  
android {  
    compileSdkVersion 17  
    buildToolsVersion "19.1.0"  
  
    sourceSets {  
        main {  
            manifest.srcFile 'AndroidManifest.xml'  
            java.srcDirs = ['src']  
            resources.srcDirs = ['src']  
            aidl.srcDirs = ['src']  
            renderscript.srcDirs = ['src']  
            res.srcDirs = ['res']  
            assets.srcDirs = ['assets']  
        }  
  
        debug.setRoot('build-types/debug')  
        release.setRoot('build-types/release')  
    }  
}  
  
if (project.hasProperty('PUBLISH_GROUP_ID')) {  
    // from http://stackoverflow.com/a/19484146/115145  
  
    android.libraryVariants.all { variant ->  
        def name = variant.buildType.name  
        if (name.equals(com.android.builder.core.BuilderConstants.DEBUG)) {  
            return; // Skip debug builds.  
        }  
    }  
}
```

```
    }
    def task = project.tasks.create "jar${name.capitalize()}", Jar
    task.dependsOn variant.javaCompile
    task.from variant.javaCompile.destinationDir
    task.baseName = "cwac-${PUBLISH_ARTIFACT_ID}"
    task.version = PUBLISH_VERSION
    task.exclude('com/commonsware/cwac/**/BuildConfig.**')
}

apply plugin: 'maven'

uploadArchives {
    repositories.mavenDeployer {
        pom.groupId = PUBLISH_GROUP_ID
        pom.artifactId = PUBLISH_ARTIFACT_ID
        pom.version = PUBLISH_VERSION

        repository(url: LOCAL_REPO)
    }
}
}
```

It uses the maven plugin to enable the uploadArchives task, as mentioned [earlier in this chapter](#). That will compile the library project into an AAR and publish it to the development machine's local CWAC Maven repository. Separately, the author has a script that will push the necessary files to the Amazon S3-hosted CommonsWare Maven repository.

The constants referred to in the repositories.mavenDeployer closure come from a gradle.properties file, which will be covered [in an upcoming chapter](#).

The library's build.gradle file also contains the custom Gradle code that adds a jarRelease task, as described [earlier in this chapter](#). This task also uses values like PUBLISH_VERSION and PUBLISH_ARTIFACT_ID from the gradle.properties file. Hence, when the author wishes to push a new version of the library, the steps are:

1. Modify the PUBLISH_VERSION in the gradle.properties file
2. Run `gradle uploadArchives` to generate the AAR and publish it locally
3. Use an external mechanism to publish the AAR to the CommonsWare repo
4. Run `gradle jarRelease` to generate the JAR version of the project
5. Publish that JAR via the GitHub "releases" portion of the GitHub repository

CWAC-Upon-CWAC: cwac-presentation

One CWAC project that has a dependency is [the CWAC-Presentation project](#). This is discussed in [the chapter on Presentation and external display support](#), offering the

PresentationHelper and related classes to ease the creation of apps that support external displays.

Some of those related classes use the CWAC-Layouts mirroring classes. For example, MirrorPresentationFragment is designed to display a mirror of a part of the primary display on an external display, such as mirroring only the slides, with the primary display also having controls for the slide presenter. Hence, CWAC-Presentation depends upon CWAC-Layouts, and that needs to be taken into account in the project build files.

As with CWAC-Layouts, the CWAC-Presentation repository has the library (presentation) and a demo project (demo). It also has a separate demoService project, which is set up to demonstrate another portion of the library. And, as before, for the purposes of an Ant/Eclipse build, the demo and demoService projects each have a project.properties file that adds a dependency upon the presentation library project:

```
# This file is automatically generated by Android Tools.
# Do not modify this file -- YOUR CHANGES WILL BE ERASED!
#
# This file must be checked in Version Control Systems.
#
# To customize properties used by the Ant build system edit
# "ant.properties", and override values to adapt the script to your
# project structure.
#
# To enable ProGuard to shrink and obfuscate your code, uncomment this (available
properties: sdk.dir, user.home):
#proguard.config=${sdk.dir}/tools/proguard/proguard-android.txt:proguard-project.txt

# Project target.
target=android-17
android.library.reference.1=../presentation
```

And, other than switching the dependency to be on presentation rather than layouts, the build.gradle file of the demo and demoService projects are the same as the one for the CWAC-Layouts:

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    debugCompile project(':presentation')
    releaseCompile 'com.commonsware.cwac:presentation:0.4.+'
```

```
android {
    compileSdkVersion 17
    buildToolsVersion "19.1.0"

    sourceSets {
        main {
            manifest.srcFile 'AndroidManifest.xml'
            java.srcDirs = ['src']
            resources.srcDirs = ['src']
            aidl.srcDirs = ['src']
            renderscript.srcDirs = ['src']
            res.srcDirs = ['res']
            assets.srcDirs = ['assets']
        }

        debug.setRoot('build-types/debug')
        release.setRoot('build-types/release')
    }
}
```

The library's `build.gradle` file is the same as the one for the CWAC-Layouts library, with two exceptions:

1. It contains a `repositories` closure, supplying the URL to the CommonsWare Maven repository
2. It adds a dependency on the CWAC-Layouts library in its `dependencies` closure

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:layouts:0.4.+'
```

The resulting AAR will have, in its Maven POM metadata file, a dependency upon CWAC-Layouts. Hence, when we build the demo project, it will download both the presentation AAR and the layouts AAR, to fulfill all its dependencies.

Dependencies and the Project Structure Dialog

You are welcome to use the Dependencies tab in [the project structure dialog](#) to maintain your dependencies, at least for simpler scenarios.

Manifest Merger Rules

When Android library projects were added as an option for app development, one problem became apparent: while libraries could contribute code and resources, they could not contribute manifest entries. Developers using libraries would sometimes have to add elements to their app manifest at the request of library authors, to add permissions, define components, and the like.

Eclipse gained some limited amount of ability to merge things from a library's manifest into a hosting app's manifest somewhere along the line, but it was all undocumented.

Gradle for Android, as of 0.10, has a much more robust and well-defined set of rules for “manifest merger”. While the term “manifest merger” is still used, in reality, Gradle for Android synthesizes a manifest for your app from a variety of sources, including apps, libraries, and `build.gradle` files, also varying based upon build types and product flavors.

This chapter will help to explain a bit more about what is possible what the rules are for the manifest merger process.

Prerequisites

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, including [the new project structure](#) and [Gradle dependencies](#).

Manifest Scenarios

You might be wondering “why do we need all of this?” That is a fair question. Certainly, we were able to get by for quite a while without this sort of flexibility and accompanying confusion.

Here are some scenarios which help explain what you will get out of the manifest merger capabilities.

Library Manifest and App Manifest

A library — whether one of yours or one obtained via an AAR artifact from some repository — may need to augment the app’s manifest. For example:

- a library for an ad network might require the `INTERNET` permission, so that apps that do not directly use the Internet still wind up requesting that permission
- a library providing a canned “about” activity might want to inject the `<activity>` element that you can use without requiring the developer to add it manually
- a library needs to be able to specify the `minSdkVersion` that it requires, which might supersede the value specified by the app, so the combined whole uses the most conservative value

App Manifest and Build Types

You may have particular needs for your main application that vary based upon build type that affect the manifest versus other things (e.g., ProGuard configuration).

For example, it may be that in debug builds, you want to have an activity that you can bring up, perhaps through `adb shell am`, that will give you diagnostic information about the app itself, or starts some diagnostic service that you can then access through your development machine’s Web browser. In this case, that activity and that service would only be desired in debug builds, not release builds. And while the activity and the service code would simply be in the debug sourceset, you also need to merge in the manifest `<activity>` and `<service>` elements, plus perhaps other things (e.g., extra `<uses-permission>` elements that those diagnostic components need but the rest of the app does not).

App Manifest and Product Flavors

Product flavors can override values from the `defaultConfig`, such as defining distinct `applicationId` values, and that needs to be taken into account in the combined app.

Also, product flavors might need their own manifest entries to accommodate distribution channel-specific APIs, such as swapping between Play Services and Amazon equivalents for in-app purchasing or maps.

Combo Platters

And, of course, you may have some mix of all of the above.

Pieces of Manifest Generation

When you build your app, the build tools will combine information from all of the aforementioned sources to synthesize “one true manifest” that is used for the build.

However, there may be overlaps in what the sources provide, such as both a library and the app specifying a `minSdkVersion`. Hence, there are some basic rules and control structures that you have to manage the generation process, at least somewhat.

Merger Rules

Generally speaking:

- the manifests and Gradle configurations for product flavors and build types will override...
- the app’s `main/` manifest, which will override...
- the manifest of any libraries

Libraries will be considered in the order of declaration — in other words, the order that they appear in the `dependencies` closure. This includes transitive dependencies, where one dependency requires another dependency, though the exact rules here are presently unclear.

For any given element or attribute, there are specific rules for how conflicts are resolved. We will explore those later in this chapter.

Note that values in `build.gradle`, such as the `defaultConfig` closure and its `minSdkVersion` and such, trump everything that result from the merger of disparate manifests from different sources.

Markers and Selectors

Through `tools:` attributes in the manifests that you control (i.e., not manifests from third-party libraries), you will be able to override the default rules for conflict resolution.

For example, a library might declare a particular theme to use for an activity that it publishes. That might be a reasonable default theme, but you may wish to override that theme in your app. A `tools:replace` attribute, in your `<activity>` element, will be able to teach the build tools that your `android:theme` value should replace the one from the library, whereas normally a conflict on an attribute like this would result in a build error.

You can also use “selectors” to help control in which scenarios a particular marker is applied, such as applying a marker only for a conflict arising from a specific library.

These markers and selectors will be explored in greater detail later in this chapter.

Placeholders

Sometimes, the “merger” we want to do involves something more involved.

For example, the `applicationId` and `applicationIdSuffix` properties that we set in various places in `build.gradle` can be used to allow for different variants of our builds to be installed at the same time on the same device. However, that is only true some of the time. If an app publishes a `ContentProvider`, not only does the application ID have to be unique, but so does the authority (or authorities) supported by that `ContentProvider`. This is not handled automatically, and so even though you might have the application ID distinct for different build variants, they still would conflict at install time because their provider authorities were the same.

The manifest generation process supports the notion of placeholders, where for string values in the manifest — like the `android:authorities` attribute on a `<provider>` — you can “splice in” dynamic values. One dynamic value that you can use “out of the box” is your build variant’s `applicationId`, so you can have something like:

```
android:authorities="${applicationId}.provider"
```

to have the authority for the provider match the build variant's application, but with a `.provider` suffix.

We will explore the rules around these placeholders later in this chapter.

Examining the Merger Results

The generated manifest, combining the contents of all the manifests from the app, build types, product flavors, and libraries, will wind up in the `build/intermediates/manifests/` directory of your module (e.g., `app/`). Inside that directory will be subdirectories associated with each build variant, and in those subdirectories reside the generated manifest for that build variant.

The [Manifest/Merger](#) sample application is designed to illustrate how these merger rules work. Note that the application does not run — it exists merely to show the results of building the APK and, along the way, generating the manifests.

This project contains an app module (`app/`) and a library module (`lib/`), with the app depending upon the library. The app module has sourcesets for both `main/` and `debug/`, the latter for debug builds. The app module also defines two product flavors, `chocolate` and `vanilla`, with a sourceset for `vanilla/`. All three sourcesets (`main/`, `debug/`, `vanilla/`) have their own `AndroidManifest.xml` files. Adding in the manifest from the library, and you have four manifests in total that may be used to create the manifest for the app. In particular, for a `vanilla debug` build, all four manifests will be relevant and merged together.

If you build the project, particularly via the `gradle` command, you will get manifests based on what builds you create. For example, `gradle assembleVanillaDebug` will create a generated manifest in `build/intermediates/manifests/vanilla/debug/`.

As you are trying to determine how manifest merging is working in your project, you may find it useful to peek at these generated manifests from time to time... as we will here in this chapter.

Merging Elements and Attributes

Different sources of manifest data can contribute elements to the generated combined manifest. In many cases, these elements do not conflict, such as a library contributing a `<uses-permission>` element to an app. However, sometimes, what one source of manifest data wants is different than what another source of manifest data wants, and for that, we need to settle out what the generated manifest will contain.

Basic Merger Rules

Many element names can appear several times in a manifest, such as multiple `<uses-permission>` elements. Many of those have an identifier, usually `android:name`, that distinguishes one from the next. In general, if two manifest sources both contribute the same element (i.e., same element name, same `android:name` value), those two elements are themselves merged, which means:

- Any attributes that are in one, but not the other, are added to the combined element
- Any attributes that are in both, and are not identical in value, result in a merge conflict compile error, unless the resolution is specified via a [marker](#)
- All child elements (e.g., `<intent-filter>` inside of an `<activity>`) are merged, applying the same rules

Of course, if one manifest supplies a specific element instance, and others do not, then the specific element instance is simply included without worrying about any other merge logic.

Singleton elements — ones that could only ever appear once in the manifest — are treated as matching if they exist in more than one manifest. So, for example, the `android:versionCode` and `android:versionName` attributes of the `<manifest>` element are merged, as are attributes of `<support-screens>`, each of which can only exist once.

Example #1: Manifest Attributes

The main/ version of the manifest defines an `android:versionName` attribute:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.merger"
  android:versionName="1.0 Main">
```

MANIFEST MERGER RULES

```
// other stuff here  
</manifest>
```

None of the other manifest versions do. Hence, the main/ version of the manifest “wins”, and its `android:versionName` is used (only to perhaps be overridden by `build.gradle` values):

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"  
  package="com.commonware.android.merger.vanilla"  
  android:versionCode="1"  
  android:versionName="1.0 Main" >  
  
  // other stuff here  
</manifest>
```

Here, we are showing the results of building the vanilla debug version of the app, so the package name reflects the `applicationId` defined in `build.gradle` for the vanilla product flavor:

```
productFlavors {  
  vanilla {  
    applicationId "com.commonware.android.merger.vanilla"  
  }  
  
  chocolate {  
    applicationId "com.commonware.android.merger.chocolate"  
  }  
}
```

Similarly, the `versionCode` shows up because it is defined in `build.gradle`:

```
defaultConfig {  
  applicationId "com.commonware.android.merger"  
  minSdkVersion 15  
  targetSdkVersion 19  
  versionCode 1  
}
```

However, since `build.gradle` did not specify `versionName`, the version name comes from the manifests.

If another manifest also defined `android:versionName`, its value would need to match that of the one in `main/`, or you will get a build error from Gradle for Android... unless you use a marker, described later in this chapter.

MANIFEST MERGER RULES

Example #2: Additional Permissions

The debug/ version of the manifest has a `<uses-permission>` element:

```
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />
```

So does the vanilla/ version, though its has `android:maxSdkVersion` set to 18:

```
<uses-permission
  android:name="android.permission.WRITE_EXTERNAL_STORAGE"
  android:maxSdkVersion="18" />
```

The manifest you get from a vanilla debug build has the `android:maxSdkVersion` attribute:

```
<uses-permission
  android:name="android.permission.WRITE_EXTERNAL_STORAGE"
  android:maxSdkVersion="18" />
```

Example #3: Additional Components

The lib/ version of the manifest has an `<activity>`:

```
<activity android:name="ThisActivityDoesNotExist">
  <intent-filter>
    <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

This is contributed by the library (or would be, if there actually was source code for the activity...). Neither the main/ nor the debug/ sourceset defines it, and so it is included verbatim in the result for chocolate builds:

```
<activity android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist" >
  <intent-filter>
    <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Note that since the `android:name` attribute had a bare class name, the generated manifest expands that to include the *library's* package name (`com.commonware.android.merger.lib`). Note that this is the package name defined in `AndroidManifest.xml` — you cannot have an `applicationId` in `build.gradle` for a library project.

Example #4: Intent Filter

However, the vanilla/ manifest also defines the same activity, this time with another `<intent-filter>`:

```
<activity android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist">
  <intent-filter>
    <action android:name="com.commonware.android.merger.SOMETHING_VANILLA" />
    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

Note that here, we need to have the fully-qualified class name, as we are trying to affect the library-supplied activity.

In a vanilla build, *both* `<intent-filter>` elements will be included by default:

```
<activity android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist" >
  <intent-filter>
    <action android:name="com.commonware.android.merger.SOMETHING_VANILLA" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

This allows an app developer to add new ways of accessing an activity (or other component) exposed by a library.

Some Unusual Scenarios

Not everything fits the neat-and-tidy rules from the above sections and require special explanation.

uses-sdk

The `android:minSdkVersion` and `android:targetSdkVersion` from the highest-priority manifest will be used. If, however, a library's manifest specifies higher values for `minSdkVersion`, you will get a build error.

Hence, it is incumbent upon library authors to correctly assess how old a version of Android they are able to support, setting `android:minSdkVersion` as low as possible.

MANIFEST MERGER RULES

Conversely, library authors should aim to support either old or new behavior that is controlled by `android:targetSdkVersion`. For example, a library that uses `AsyncTask` should not assume that the `android:targetSdkVersion` is below 13 and therefore `execute()` will result in multi-threaded behavior on Android 3.2+. Instead, the library should use `executeOnExecutor()` on API Level 11+ devices, to specifically opt into the multi-thread thread pool, as this avoids any behavior changes based upon `android:targetSdkVersion`.

uses-feature and uses-library

The `android:required` attribute is logically OR'd among all contributors of a `<uses-feature>` element for a specific `android:name` value. In other words, if any contributor says that the feature is required, it is required. Otherwise, if one or more contributors ask for the `<uses-feature>` element but say that it is not required, it is put in the combined manifest with `android:required="false"`.

The under-utilized `<uses-library>` uses the same rule for handling the merger of its `android:required` attribute.

Markers and Selectors

Sometimes, the default merger rules will not work to your satisfaction. In particular, when there are conflicts, the build will fail, and probably that is not a desired outcome.

To declare who wins in the case of conflicts, you can use `tools:*` attributes in the manifest elements. Specifically:

- `tools:node` indicates how to resolve a conflict between two editions of this particular XML element (e.g., an `<activity>` for the same `android:name`)
- `tools:replace` indicates that certain attributes from a lower-priority edition of the manifest should be overwritten by their replacement values from a higher-priority edition of the manifest
- `tools:remove` indicates that certain attributes from a lower-priority edition of the manifest should be removed entirely

Each of these, being in the `tools` namespace, will require you to have `xmlns:tools="http://schemas.android.com/tools"` on the root `<manifest>` element, if it is not there already. These attributes only affect the build tools and

MANIFEST MERGER RULES

have no runtime implications, other than in terms of how the build tools build your app based on the tools attributes.

For example, the main manifest has `android:supportsRtl="true"` on the `<application>` element:

```
<application android:allowBackup="true"
  android:label="@string/app_name"
  android:icon="@drawable/ic_launcher"
  android:theme="@style/AppTheme"
  android:supportsRtl="true">

  // other stuff here
</application>
```

For a project with a `targetSdkVersion` of 17 or higher, `android:supportsRtl="true"` enables automatic mirroring support for your layouts for right-to-left (RTL) languages.

The vanilla manifest wants to override this, replacing the value with `false`, as perhaps the code in that flavor is not yet ready for automatic mirroring. However, if the vanilla manifest just had `android:supportsRtl="false"` in its `<application>` element, the build would fail, as that value conflicts with the one in the main manifest. Hence, the vanilla manifest also needs to indicate that its `android:supportsRtl` value should replace the original one, via a `tools:replace` attribute:

```
<application android:allowBackup="true"
  android:label="@string/app_name"
  android:icon="@drawable/ic_launcher"
  android:theme="@style/AppTheme"
  android:supportsRtl="false"
  tools:replace="android:supportsRtl">

  // other stuff here
</application>
```

In the output, `android:supportsRtl="false"` wins:

```
<application
  android:allowBackup="true"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/AppTheme"
  android:supportsRtl="false" >

  // other stuff here
```

```
</application>
```

Both `tools:replace` and `tools:remove` take a comma-delimited list of attributes that should be affected by that rule.

The `tools:node` attribute affects the entire XML element in which it resides. There are five primary values for `tools:node`:

1. `merge`, which is the default behavior described by the merger rules earlier in this chapter
2. `replace` says that the lower-priority manifest's version of this element should be replaced in its entirety with the higher-priority manifest's version of this element
3. `merge-only-attributes` says that the lower-priority manifest's version of this element should have its attributes replaced by the ones from the higher-priority manifest's version of this element, but child elements (e.g., an `<intent-filter>` underneath the annotated `<activity>` element) are left alone
4. `remove` says that the lower-priority manifest's version of this element should be removed without any replacement
5. `removeAll` says that all elements of this name (e.g., `<uses-permission>`) from lower-priority manifests should be removed, regardless of scopes like `android:name`

There is also a `strict` value that indicates that any duplication, even if it could be successfully merged, should result in a build failure. Most likely, this would be used sparingly.

By default, these `tools` attributes affect all manifests. However, it could be that you only want to affect a specific manifest, such as one coming from a certain library. In that case, `tools:selector`, in the same XML element as the other `tools:*` attributes, provides the package name of the library that the other `tools:*` attributes affect.

Employing Placeholders

The [Google Cloud Messaging](#) (GCM) system has some unusual requirements for the manifest of apps that use GCM:

MANIFEST MERGER RULES

- The app needs to define a custom permission, based on the application ID, via a `<permission>`
- The app needs to hold that custom permission, via a `<uses-permission>` element
- The app needs to have a `BroadcastReceiver` whose `<intent-filter>` has a `<category>` whose name is the application ID

Hence, in a GCM client app's manifest, there are three places where the application ID needs to appear. This needs to be the app's actual application ID, as may be defined either via manifests or via `applicationId` or `applicationIdSuffix` statements in a `build.gradle` file. Since the application ID can be overridden by those Gradle statements, we cannot just hard-code the application ID into the spots in the manifest.

Fortunately, part of what we get with manifest generation are placeholders.

Placeholders allow us to inject values from `build.gradle` into the manifest, particularly in XML attribute values. An `applicationId` placeholder is available automatically, and we can define custom ones via a `manifestPlaceholders` map.

For example, the main manifest for the sample project uses the `applicationId` placeholder in the requisite locations:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.merger"
    android:versionName="1.0 Main">

    <permission android:name="${applicationId}.C2D_MESSAGE"
        android:protectionLevel="signature" />
    <uses-permission android:name="${applicationId}.C2D_MESSAGE" />

    <application android:allowBackup="true"
        android:label="@string/app_name"
        android:icon="@drawable/ic_launcher"
        android:theme="@style/AppTheme"
        android:supportsRtl="true">
        <receiver
            android:name=".GcmBroadcastReceiver"
            android:permission="com.google.android.c2dm.permission.SEND" >
            <intent-filter>
                <action android:name="com.google.android.c2dm.intent.RECEIVE" />
                <category android:name="${applicationId}" />
            </intent-filter>
        </receiver>
    </application>

</manifest>
```

MANIFEST MERGER RULES

The vanilla debug version of the generated manifest replaces those `{applicationId}` placeholders with the actual `applicationId`, such as the following for a vanilla build:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.merger.vanilla"
  android:versionCode="1"
  android:versionName="1.0 Main" >

  <uses-sdk
    android:minSdkVersion="15"
    android:targetSdkVersion="19" />

  <uses-permission
    android:name="android.permission.WRITE_EXTERNAL_STORAGE"
    android:maxSdkVersion="18" />

  <permission
    android:name="com.commonware.android.merger.vanilla.C2D_MESSAGE"
    android:protectionLevel="signature" />

  <uses-permission android:name="com.commonware.android.merger.vanilla.C2D_MESSAGE" />

  <application
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme"
    android:supportsRtl="false" >
    <activity android:name="com.commonware.android.merger.lib.ThisActivityDoesNotExist"
    >
      <intent-filter>
        <action android:name="com.commonware.android.merger.SOMETHING_VANILLA" />

        <category android:name="android.intent.category.DEFAULT" />
      </intent-filter>
      <intent-filter>
        <action android:name="com.commonware.android.merger.lib.SOMETHING_COOL" />

        <category android:name="android.intent.category.DEFAULT" />
      </intent-filter>
    </activity>

    <receiver
      android:name="com.commonware.android.merger.GcmBroadcastReceiver"
      android:permission="com.google.android.c2dm.permission.SEND" >
      <intent-filter>
        <action android:name="com.google.android.c2dm.intent.RECEIVE" />

        <category android:name="com.commonware.android.merger.vanilla" />
      </intent-filter>
    </receiver>
  </application>
</manifest>
```

MANIFEST MERGER RULES

Note that the entire XML attribute value does not have to be a placeholder. For example, the `android:name` values for the `<permission>` and `<uses-permission>` elements blend the `applicationId` in with a fixed string:

```
android:name="${applicationId}.C2D_MESSAGE".
```

If you want additional placeholders, you can define a `manifestPlaceholders` map in `defaultConfig` or in a product flavor:

```
android {
    defaultConfig {
        manifestPlaceholders = [ foo: "bar" ]
    }

    productFlavors {
        vanilla {
        }

        chocolate {
            manifestPlaceholders = [ foo: "baz" ]
        }
    }
}
```

Then, you can refer to any of your custom placeholders via the same `${}` syntax (e.g., `${foo}`), with the proper value being applied during manifest generation.

Signing Your App

Perhaps the most important step in preparing your application for production distribution is signing it with a production signing key. While mistakes here may not be immediately apparent, they can have significant long-term impacts, particularly when it comes time for you to distribute an update.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Role of Code Signing

There are many reasons why Android wants you to sign your application with a production key. Here are perhaps the top three:

- It will help distinguish your production applications from debug versions of the same applications
- Multiple applications signed with the same key can access each other's private files, if they are set up to use a shared user ID in their manifests
- You can only update an application if it has a signature from the same digital certificate

The latter one is the most important for you, if you plan on offering updates of your application. If you sign version 1.0 of your application with one key, and you sign version 2.0 of your application with another key, version 2.0 will not install over the top of version 1.0 — it will fail with a certificate-match error.

What Happens In Debug Mode

Of course, you may be wondering how you got this far in life without worrying about keys and certificates and signatures (unless you are using Google Maps, in which case you experienced a bit of this when you got your API key).

The Android build process creates a debug key for you automatically. That key is automatically applied when you create a debug version of your application (e.g., running the app in your IDE). This all happens behind the scenes, so it is very possible for you to go through weeks and months of development and not encounter this problem.

In fact, the most likely place where you might encounter this problem is in a distributed development environment, such as an open source project. There, you might have encountered the third bullet above, where a debug application compiled by one team member cannot install over the debug application from another team member, since they do not share a common debug key. You may have run into similar problems just on your own if you use multiple development machines (e.g., a desktop in the home office and a notebook for when you are on the road delivering Android developer training).

Finding Your Debug Keystore

The debug keystore is a `debug.keystore` file in your Android SDK data directory. This directory is not where your SDK is installed, but rather is where the tools store data unique to your account on your developer machine, such as your emulator AVDs.

This directory can be found at:

- `~/.android/` on OS X and Linux
- `C:\Documents and Settings\...\android\` on Windows XP
- `C:\Users\...\android\` on Windows environments newer than XP

(where `...` is your Windows username)

Synchronizing Your Debug Signing Key

If you have a development team that, for better coordination, should all use the same `debug.keystore`, just pick one and copy it to all team members' development

machines, replacing their generated ones. The `debug.keystore` file is a binary file and should be transferrable between operating systems (e.g., from Linux to Windows).

Production Signing Keys

Beyond the debug keystore, though, you will need one for production use. Distribution channels like the Play Store do not accept apps signed with the debug signing key. So, you will need to create a key that *is* acceptable to those channels, plus arrange to use that key when creating your production apps.

How long your production signing key is valid for is important. Once your key expires, you can no longer use it for signing new applications, which means once the key expires, you cannot update existing Android applications. Also, the Play Store requires your key to be valid beyond October 22, 2033. When you create your key, you will indicate how long it should be valid for.

Note that both the debug signing key and its production counterpart are self-signed certificates — you do not have to purchase a certificate from Verisign or anyone. These keys are for creating immutable identity, but are not for creating confirmed identity. In other words, these certificates do not prove you are such-and-so person, but can prove that the same key signed two different APKs.

Creating a Production Signing Key

The mechanics of creating a production signing key depend on whether you will use an IDE (and, if so, which one) or will create one outside of any IDE.

Android Studio

Android Studio has support to create a production signing key as part of its overall process for creating a production-signed APK, which is covered [later in this chapter](#).

Eclipse

Eclipse also has support to create a production signing key as part of its overall process for creating a production-signed APK, which is covered [later in this chapter](#).

Manually

To manually create a production signing key, you will need to use `keytool`. This comes with the Java SDK, and so it should be available to you already.

The `keytool` utility manages the contents of a “keystore”, which can contain one or more keys. Each “keystore” has a password for the store itself, and keys can also have their own individual passwords. You will need to supply these passwords later on when signing an application with the key.

Here is an example of running `keytool`:

```
keytool -genkey -v -keystore cw-release.keystore -alias cw-release -keyalg RSA -validity 10000 -keysize 2048
```

The parameters used here are:

1. `-genkey`, to indicate we want to create a new key
2. `-v`, to be verbose about the key creation process
3. `-keystore`, to indicate what keystore we are manipulating (`cw-release.keystore`), which will be created if it does not already exist
4. `-alias`, to indicate what human-readable name we want to give the key (`cw-release`)
5. `-keyalg`, to indicate what public-key encryption algorithm to be using for this key (RSA)
6. `-validity`, to indicate how long this key should be valid, where 10,000 days or more is recommended
7. `-keysize`, for indicating the length of the signing key (2,048 bits recommended, or go higher if you prefer)

If you run the above command, you will be prompted for a number of pieces of information. If you have ever created an SSL certificate, the prompts will be familiar:

```
$ keytool -genkey -v -keystore cw-release.keystore -alias cw-release -keyalg RSA -validity 10000 -keysize 2048
Enter keystore password:
Re-enter new password:
What is your first and last name?
  [Unknown]: Mark Murphy
What is the name of your organizational unit?
  [Unknown]:
What is the name of your organization?
  [Unknown]: CommonsWare, LLC
What is the name of your City or Locality?
  [Unknown]:
What is the name of your State or Province?
```

SIGNING YOUR APP

```
[Unknown]: PA
What is the two-letter country code for this unit?
[Unknown]: US
Is CN=Mark Murphy, OU=Unknown, O="CommonsWare, LLC", L=Unknown, ST=PA, C=US correct?
[no]: yes

Generating 2,048 bit RSA key pair and self-signed certificate (SHA256withRSA) with a
validity of 10,000 days
  for: CN=Mark Murphy, OU=Unknown, O="CommonsWare, LLC", L=Unknown, ST=PA, C=US
Enter key password for <cw-release>
(RETURN if same as keystore password):
[Storing cw-release.keystore]
```

Signing with the Production Key

How you will apply this production signing key to sign your production app again varies by your tool chain.

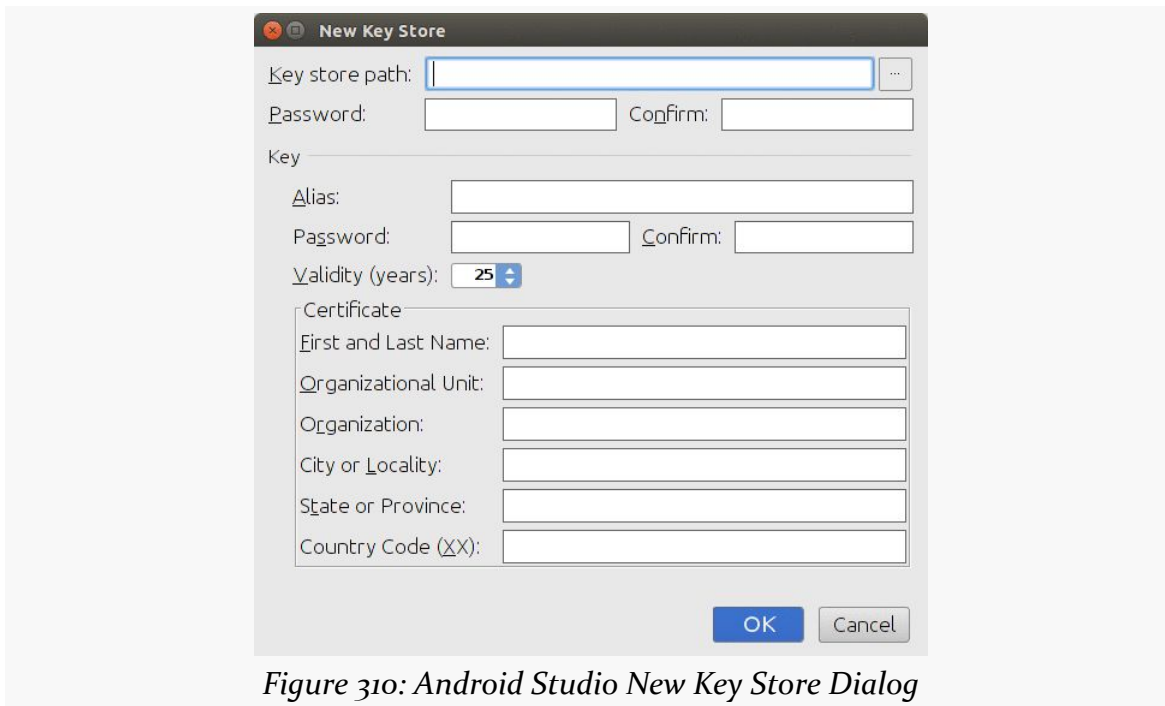

Android Studio

Start by opening up your project and going to Build > Generate Signed APK from the main menu. This brings up the first page of a signing wizard:

If this is the first time you are going to sign a production app, you will need to create your production signing key, which you can do by clicking the “Create new...” button in the wizard. This brings up a separate dialog for describing the new signing key:

SIGNING YOUR APP

You will need to provide a path to the keystore, manually or via the “...” button to pick a location via a dialog. You will also need to provide a password (twice) for the keystore.

You can then supply information for the signing key within the keystore, including:

- “Alias” to indicate what human-readable name we want to give the key
- “Password” and “Confirm”, to specify a password for this specific key in the keystore (independent of the keystore’s own password)
- “Validity”, to indicate how long this key should be valid, where 25 years or more is recommended
- Details about you and your organization, asking for the standard information used in generating SSL-style keys

Clicking “OK” will generate the keystore and save it where you specified. **Be sure to back up this keystore** and record the passwords that you used.

If you already have a keystore, though, back on the first page of the “Generate Signed APK” wizard, you can click “Choose existing” to bring up a file-open dialog where you can choose your keystore. Then, fill in the keystore password, the key alias, and the key password in the dialog.

SIGNING YOUR APP

Clicking Next in the wizard brings up a page allowing you to determine what will be generated:

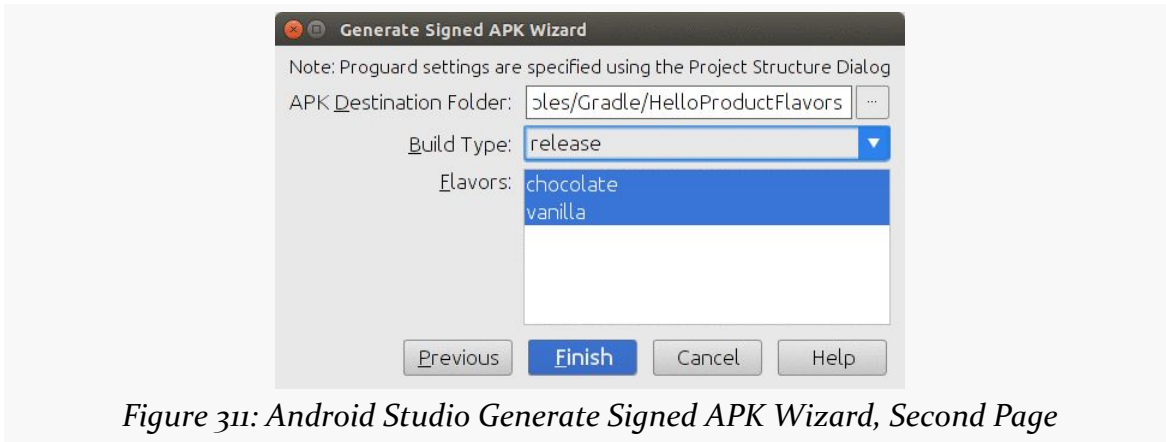

Figure 311: Android Studio Generate Signed APK Wizard, Second Page

You can indicate where the APK file should be written, what build type to use (release being the default), and which product flavors to use (where you can select one or several).

Clicking “Finish” will have Android Studio begin generating the APK files. This may take some time. When it is done, a dialog will appear indicating that the work is completed. In the directory that you specified, you will get one APK file per product flavor you chose, plus manifest merger reports for those APK files. And, of course, the APK files will be signed with your chosen keystore and signing key.

Gradle for Android

Gradle for Android can also be used to sign a production app. Curiously, this is completely independent of the mechanism that Android Studio uses to sign a production app. Filling in the dialogs in Android Studio does not affect your `build.gradle` file, and Android Studio’s “Generate Signed APK” completely ignores any manual signing configuration that you may set up in `build.gradle` (and is discussed in this section). What is covered in this section focuses on automating the signing process, to be done via a build server or just running a Gradle task from the command line.

To be able to use Gradle for Android to sign your production app, you need to provide a signing configuration to the release build type:

```
buildscript {  
    repositories {
```

SIGNING YOUR APP

```
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

apply plugin: 'com.android.application'

dependencies {
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"

    defaultConfig {
        versionCode 2
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }

    signingConfigs {
        release {
            storeFile file('HelloConfig.keystore')
            keyAlias 'HelloConfig'
            storePassword 'laser.yams.heady.testy'
            keyPassword 'fw.stabs.steady.wool'
        }
    }

    buildTypes {
        debug {
            applicationIdSuffix ".d"
            versionNameSuffix "-debug"
        }

        release {
            signingConfig signingConfigs.release
        }
    }
}
```

Here, our release build type has a `signingConfig` property, referencing the name of a signing configuration specified in the `signingConfigs` closure. This is used to provide rules for how to sign the APK that is assembled by Gradle. In this project's `build.gradle` file, we have a release closure in `signingConfigs`, supplying the requisite information about the keystore:

- The `storeFile` path, specified as a `file()` pointing to a keystore in the project's root directory
- The `keyAlias` given to the signing key inside the keystore
- The `storePassword` and `keyPassword` used to access the keystore

SIGNING YOUR APP

The `signingConfig` property in the `release` closure in `buildTypes` references the signing configuration we want as `signingConfigs.release`. All of these Groovy closures of properties in the `build.gradle` file are effectively building up a data structure, which we can access. So, `signingConfigs.release` says to find the release definition in the `signingConfigs` closure.

This sample bakes in the keystore data into the `build.gradle` file, including the passwords, and has the keystore in the root of the project. That is for demonstration simplicity and will not be suitable for all projects. In particular, keystores and their credentials should *not* be stored in a publicly accessible repository, as that would allow others to sign *their* apps with *your* signing key, which is not good. There are a variety of strategies for handling this, from using environment variables to requesting the data be entered on the command line, as are discussed in [the chapter on advanced Gradle techniques](#).

Adding a `signingConfig` property in our `release` build type enables the `installRelease` task. Running `gradle` tasks will show `installRelease` as an available option, because now Gradle for Android knows how to sign the APK. Of course, there could be flaws in the signing configuration (e.g., mis-entered key alias), and that will result in build errors when you try to `installRelease` the project.

Eclipse

To create a production signed version of your app, right-click over the app in the Package Explorer and choose `Export` from the context menu. In the list of things to export, choose “Export Android Application”:

SIGNING YOUR APP

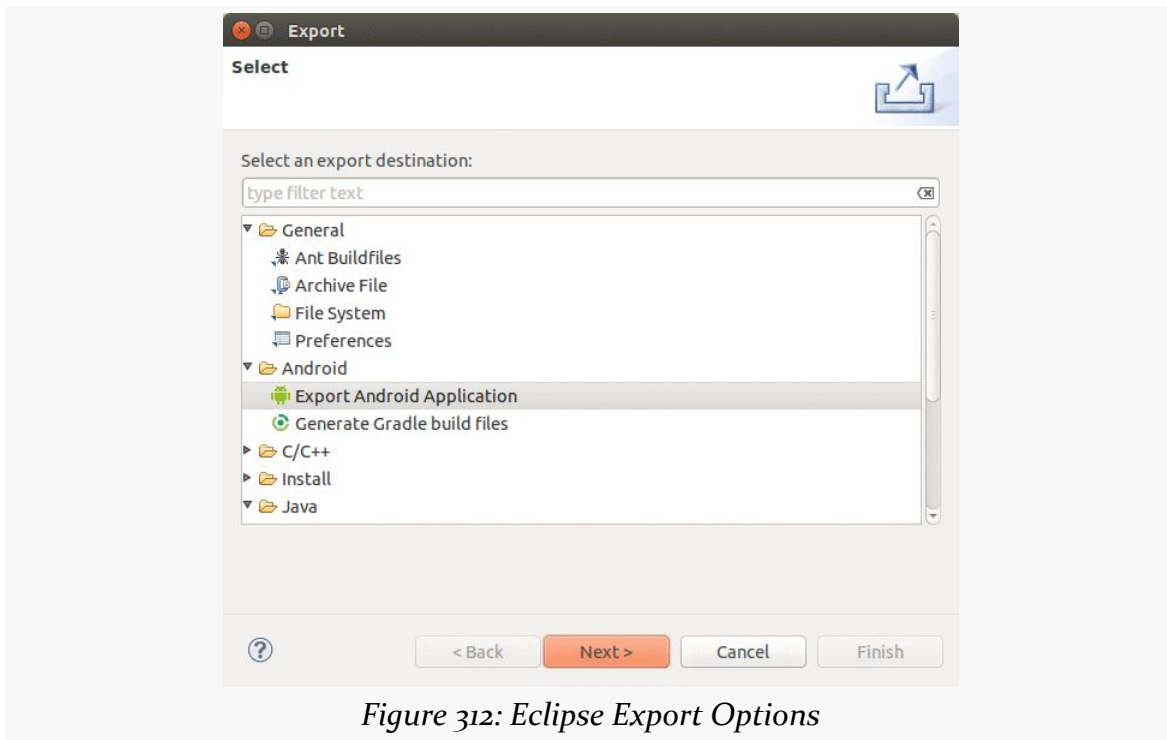

Figure 312: Eclipse Export Options

This kicks off a wizard where you can create the production-signed app. The first page of this wizard just confirms what you wish to export and whether or not there are any problems that would prevent the export, such as compile errors:

SIGNING YOUR APP

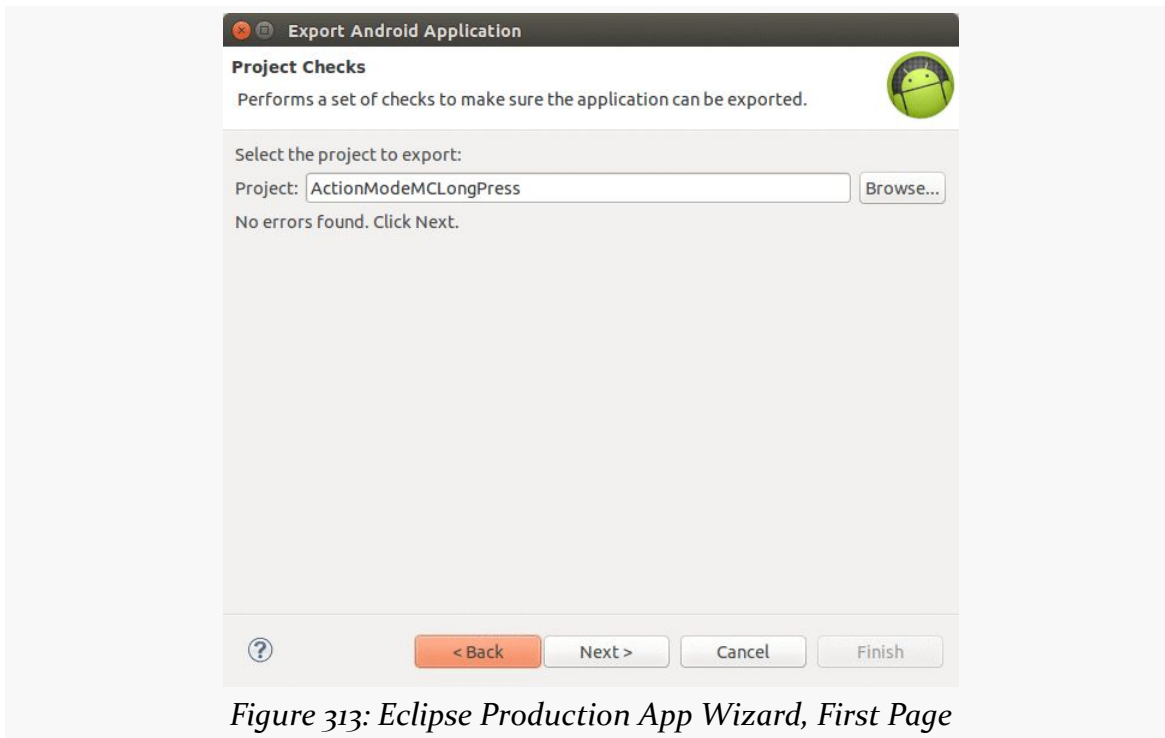

Figure 313: Eclipse Production App Wizard, First Page

Clicking the Next button brings up the second wizard page, focusing on the production keystore:

SIGNING YOUR APP

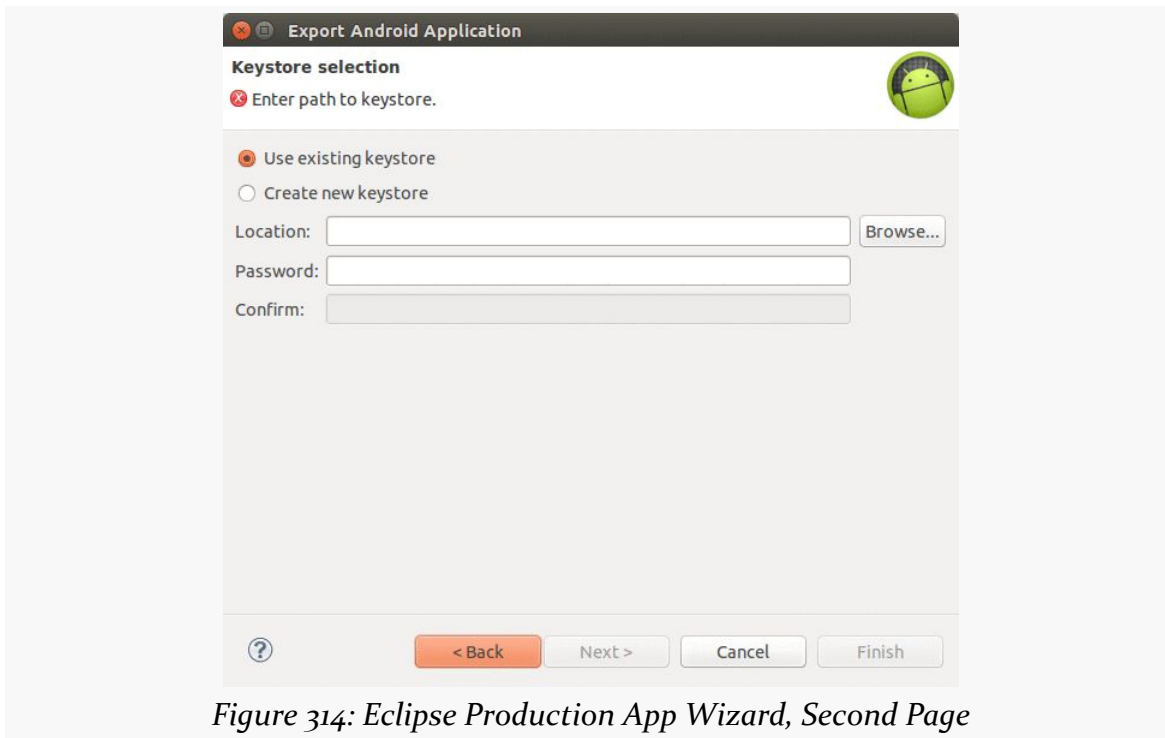

Figure 314: Eclipse Production App Wizard, Second Page

If you used this wizard previously, and you already have a production keystore, choose it via the “Browse...” button and fill in your keystore’s password. If you need to create a new keystore, choose the “Create new keystore” radio button, choose where to store the keystore via the “Browse...” button, and fill in your desired keystore password.

SIGNING YOUR APP

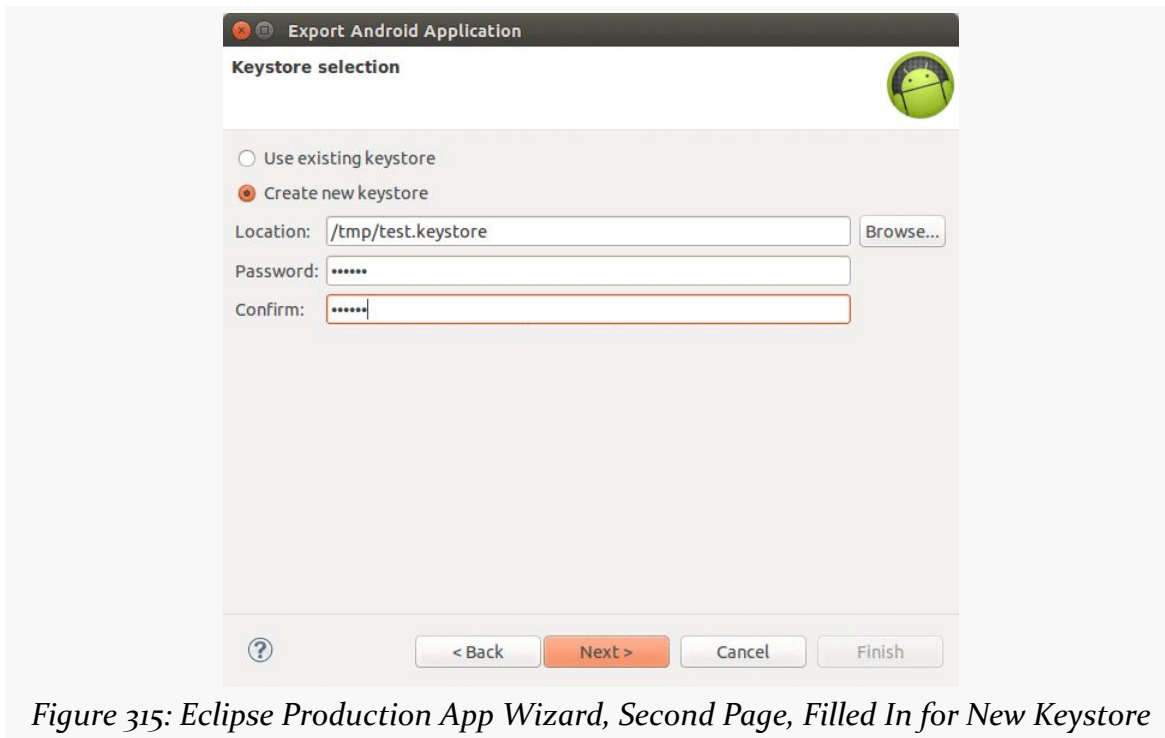

Figure 315: Eclipse Production App Wizard, Second Page, Filled In for New Keystore

If you chose to create a new keystore, the Next button brings up a dialog where you can fill in details of the production signing key:

SIGNING YOUR APP

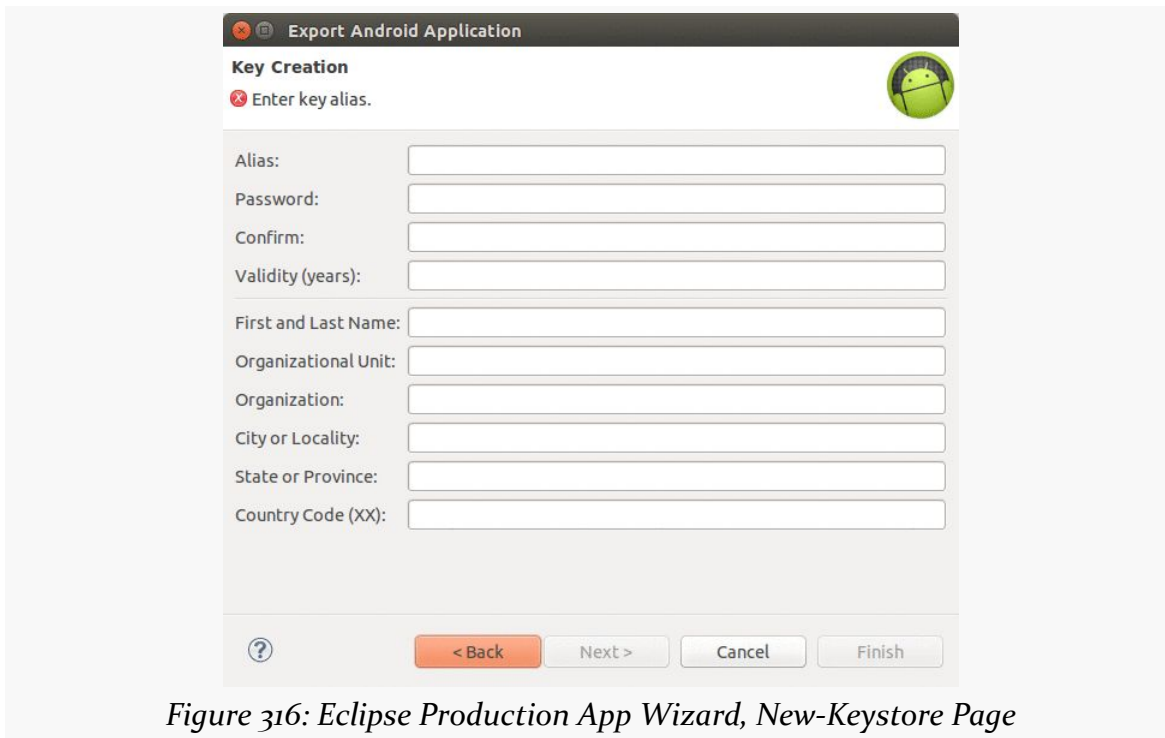

Figure 316: Eclipse Production App Wizard, New-Keystore Page

This includes:

- “Alias” to indicate what human-readable name we want to give the key
- “Password” and “Confirm”, to specify a password for this specific key in the keystore (independent of the keystore’s own password)
- “Validity”, to indicate how long this key should be valid, where 25 years or more is recommended
- Details about you and your organization, asking for the standard information used in generating SSL-style keys

If, instead, you chose to open an existing keystore, the Next button would take you to a wizard page to choose your desired signing key and provide *its* password, or to create a new signing key within the keystore:

SIGNING YOUR APP

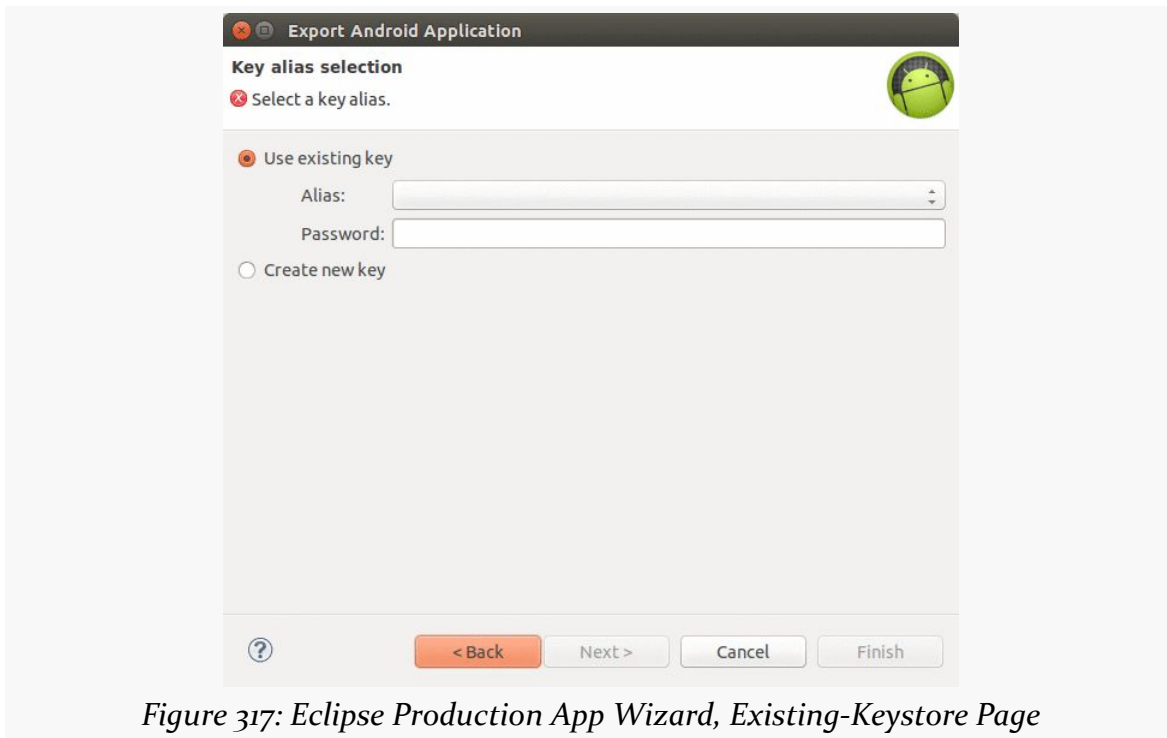

Figure 317: Eclipse Production App Wizard, Existing-Keystore Page

Once your keystore and key are set up or chosen, the last page of the wizard is where you indicate where the signed APK should be stored:

SIGNING YOUR APP

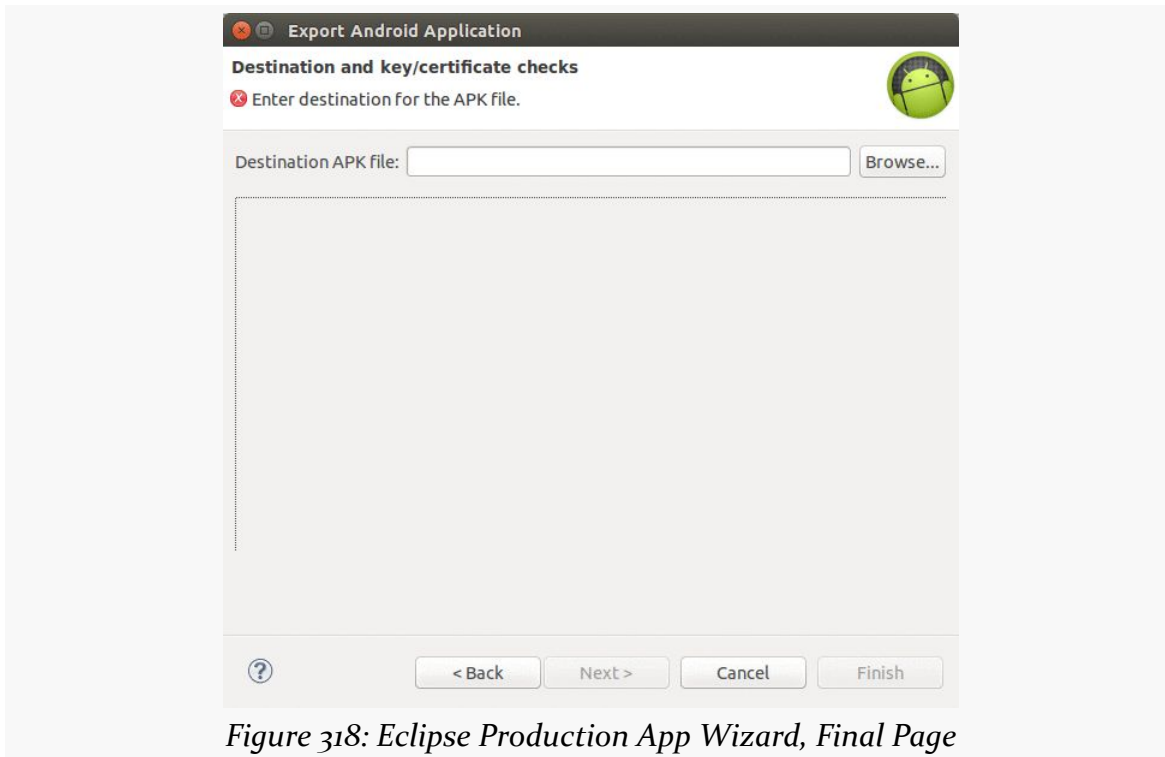

Figure 318: Eclipse Production App Wizard, Final Page

Providing a path and clicking Finish will export the signed production APK file.

Two Types of Key Security

There are two facets to securing your production key that you need to think about:

- You need to make sure nobody steals your production keystore and its password. If somebody does, they could publish replacement versions of your applications — since they are signed with the same key, Android will assume the replacements are legitimate.
- You need to make sure you do not lose your production keystore and its password. Otherwise, even you will be unable to publish replacement versions of your applications.

For solo developers, the latter scenario is more probable. There already have been **many** cases where developers had to rebuild their development machine and wound up with new keys, locking themselves out from updating their own applications. As with everything involving computers, having a solid backup regimen is highly recommended. In particular, consider a secure off-site backup, such as having your production keystore on a thumb drive in a bank safe deposit box.

SIGNING YOUR APP

For teams, the former scenario may be more likely. If more than one person needs to be able to sign the application, the production keystore will need to be shared, possibly even stored in the revision control system for the project. The more people who have access to the keystore, the more likely it is somebody will wind up doing something evil with it. This is particularly true for projects with public revision control systems, such as open source projects — developers might not think of the implications of putting the production keystore out for people to access.

Distribution

It is entirely possible that the user base for your app consists solely of yourself.

However, in most cases, you are going to be giving your app to others, free or for some sort of fee.

This chapter outlines things you will need to think about when distributing your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly the chapter on [signing your app](#).

Get Ready To Go To Market

While being able to sign your application reliably with a production key is necessary for publishing a production application, it is not sufficient. Particularly for the Play Store, there are other things you must do, or should do, as part of getting ready to release your application.

Versioning

You need to supply `versionCode` and `versionName` values in your `build.gradle` file (or in your `<manifest>` element in your `AndroidManifest.xml` file for Eclipse users). The value of `versionName` is what users and prospective users will see in terms of the label associated with your application version (e.g., “1.0.1”, “System V”, “Loquacious Llama”). More important, though, is the value of `versionCode`, which needs to be an

integer increasing with each release — that is how Android tells whether some edition of your APK is an upgrade over what the user currently has.

Application ID

You also need to make sure that your application ID is going to be unique. If somebody tries downloading your application onto their device, and some other application is already installed with that same package name, your application will fail to install.

Your application ID defaults to be the value of your package attribute in your `<manifest>` element in the manifest. You can override the application ID using `applicationId` properties in `defaultConfig` or a product flavor in `build.gradle`. You can also append an `applicationIdSuffix` tied to a build type in Gradle as well.

Since the manifest's package also provides the base Java package for your project, and since you hopefully named your Java packages with something based on a domain name you own or something else demonstrably unique, this should not cause a huge problem.

Also, bear in mind that your application ID must be unique across all applications on the Play Store, should you choose to distribute that way.

Icon and Label

Your `<application>` element needs to specify `android:icon` and `android:name` attributes, to supply the name and icon that will be associated with the application in the My Applications list on the device and related screens. Your activities will inherit the icon if they do not specify icons of their own.

If you have graphic design skills, the Android developer site has [guidelines](#) for creating icons that will match other icons in the system.

Logging

In production, try to minimize unnecessary logging, particularly at low logging levels (e.g., debug). Remember that even if Android does not actually log the information, whatever processing is involved in making the `Log.d()` call will still be done, unless you arrange to skip the processing somehow. You could outright delete the extraneous logging calls, or wrap them in an `if()` test:

```
if (BuildConfig.DEBUG) {  
    Log.d(TAG, "This is what happened");  
}
```

Here, `BuildConfig.DEBUG` is a public static final boolean value, supplied by Android, that indicates whether you are building for debug or production. Whether you adjust the definition by hand or by automating the build process is up to you. But, when `BuildConfig.DEBUG` is false, any work that would have been done to build up the actual Log invocation will be skipped, saving CPU cycles and battery life.

Conversely, error logs become even more important in production. Sometimes, you have difficulty reproducing bugs “in the lab” and only encounter them on customer devices. Being able to get stack traces from those devices could make a major difference in your ability to get the bug fixed rapidly.

First, in addition to your regular exception handlers, consider catching everything those handlers miss, notably runtime exceptions:

```
Thread.setDefaultUncaughtExceptionHandler(onBlooeey);
```

This will route all uncaught exceptions to an `onBlooeey` handler:

```
private Thread.UncaughtExceptionHandler onBlooeey=  
    new Thread.UncaughtExceptionHandler() {  
        public void uncaughtException(Thread thread, Throwable ex) {  
            Log.e(TAG, "Uncaught exception", ex);  
        }  
    };
```

There, you can log it, raise a dialog if appropriate, etc.

Then, offer some means to get your logs off the device and to you, via email or a Web service. Some Android analytics firms, like [Flurry](#), offer exception stack trace collection as part of their service. There are also open source projects that support this feature, such as [ACRA](#).

Testing

As always, testing, particularly acceptance testing, is important.

Bear in mind that the act of creating the production signed version of your application could introduce errors, such as having the wrong Google Maps V2 API key. Hence, it is important to do user-level testing of your application after you sign,

DISTRIBUTION

not just before you sign, in case the act of signing messed things up. After all, what you are shipping to those users is the production signed edition — you do not want your users tripping over obvious flaws.

As you head towards production, also consider testing in as many distinct environments as possible, such as:

1. Trying more than one device, particularly if you can get devices with different display sizes
2. If you rely on the Internet, try your application with WiFi, with 3G, with EDGE/2G, and with the Internet unavailable
3. If you rely on GPS, try your application with GPS disabled, GPS enabled and working, and GPS enabled but not available (e.g., underground)

EULA

End-user license agreements — EULAs — are those long bits of legal prose you are supposed to read and accept before using an application, Web site, or other protected item. Whether EULAs are enforceable in your jurisdiction is between you and your qualified legal counsel to determine.

In fact, many developers, particularly of free or open source applications, specifically elect not to put a EULA in their applications, considering them annoying, pointless, or otherwise bad.

However, the Play Store developer distribution agreement has one particular clause that might steer you towards having a EULA:

You agree that if you use the Store to distribute Products, you will protect the privacy and legal rights of users. If the users provide you with, or your Product accesses or uses, user names, passwords, or other login information or personal information, you must make the users aware that the information will be available to your Product, and you must provide legally adequate privacy notice and protection for those users. Further, your Product may only use that information for the limited purposes for which the user has given you permission to do so. If your Product stores personal or sensitive information provided by users, it must do so securely and only for as long as it is needed. But if the user has opted into a separate agreement with you that allows you or your Product to store or use personal or sensitive information directly related to your Product (not including other products or applications) then the terms of that separate agreement

DISTRIBUTION

will govern your use of such information. If the user provides your Product with Google Account information, your Product may only use that information to access the user's Google Account when, and for the limited purposes for which, the user has given you permission to do so.

Hence, if you are concerned about being bound by what Google thinks appropriate privacy is, you may wish to consider a EULA just to replace their terms with your own.

Unfortunately, having a EULA on a mobile device is particularly annoying to users, because EULAs tend to be long and screens tend to be short.

Again, please seek professional legal assistance on issues regarding EULAs.

Advanced Gradle for Android Tips

There are *lots* of things you can do given a full scripting language as the basis for your build system. This chapter represents a collection of tips for things that you can do that go beyond stock capabilities provided by the Android Plugin for Gradle.

NOTE: The projects demonstrated in this chapter are *not* set up to be used by Eclipse, as Eclipse does not support Gradle as of the time of this writing.

Prerequisites

Understanding this chapter requires that you have read the chapters that [introduce Gradle](#) and cover basic Gradle/Android integration, including both [the legacy project structure](#) and [the new project structure](#). Having read [the chapter on Gradle dependencies](#) would also be a pretty good idea.

Gradle, DRY

Ideally, your build scripts do not repeat themselves any more than is logically necessary. For example, a project and sub-projects probably should use the same version of the build tools, yet by default, we define them in each `build.gradle` file. This section outlines some ways to consolidate this sort of configuration.

It's build.gradle All The Way Down

If you have sub-projects, you can have `build.gradle` files at each level of your project hierarchy. Your top-level `build.gradle` file is also applied to the sub-projects when they are built.

ADVANCED GRADLE FOR ANDROID TIPS

In particular, you can “pass data” from the top-level `build.gradle` file to sub-projects [by configuring the ext object via a closure](#). In the top-level `build.gradle` file, you would put common values to be used:

```
ext {
    compileSdkVersion=19
}
```

(note the use of the = sign here)

Sub-projects can then reference `rootProject.ext` to retrieve those values:

```
android {
    compileSdkVersion rootProject.ext.compileSdkVersion
}
```

By this means, you can ensure that whatever needs to be synchronized at build time is synchronized, by defining it once.

Another way that a top-level `build.gradle` file can configure subprojects is via the `subprojects` closure. This contains bits of configuration that will be applied to each of the subprojects as a part of their builds.

The HelloAIDL sample project demonstrates this. The `build.gradle` in the overall project root (outside the `Client/` and `Service/` sub-projects) has a `subprojects` closure to define the code-signing rules for these two applications and common values for the two sub-projects:

```
buildscript {
    repositories {
        mavenCentral()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.0.0'
    }
}

subprojects {
    buildscript {
        repositories {
            mavenCentral()
        }
        dependencies {
            classpath 'com.android.tools.build:gradle:1.0.0'
        }
    }

    apply plugin: 'com.android.application'

    android {
```

```
compileSdkVersion 19
buildToolsVersion "21.1.2"

signingConfigs {
    release {
        storeFile file('HelloAIDL.keystore')
        keyAlias 'HelloConfig'
        storePassword 'laser.yams.heady.testy'
        keyPassword 'fw.stabs.steady.wool'
    }
}

buildTypes {
    release {
        signingConfig signingConfigs.release
    }
}
}
```

The subprojects closure contains its own reference to the android plugin for Gradle, in addition to android closure for configuring the signingConfigs and buildTypes. Because this code is written in the root project's build.gradle file, file() references refer to the root project's directory, which is why file('HelloAIDL.keystore') will find the keystore in the root project's directory.

Note that subprojects applies to *all* sub-projects, which limits its utility. For example, a top-level project with one sub-project for an app and another sub-project for a library used by that app cannot readily use subprojects. That is because the library sub-project needs to configure the com.android.library plugin, while the application sub-project needs to configure the com.android.application plugin. The subprojects closure is only good for common configuration to apply to all sub-projects regardless of project type.

gradle.properties

Another approach would be to add a gradle.properties file to your project root directory. Those properties are automatically read in and would be available up and down your project hierarchy.

Per-developer properties can go in a gradle.properties file in the user's Gradle home directory (e.g., ~/.gradle on Linux), where they will not be accidentally checked into version control.

So, to achieve the synchronized compileSdkVersion value, you could have a gradle.properties file with:

```
COMPILE_SDK_VERSION=19
```

Then, your projects' `build.gradle` files could use:

```
android {  
    compileSdkVersion COMPILE_SDK_VERSION  
}
```

The [Gradle/HelloProperties](#) sample project illustrates this. It is a clone of the HelloAIDL sample application from earlier in this chapter, but one where we have a `gradle.properties` file in the root project's directory:

```
BUILD_TOOLS_VERSION=21.1.2
```

Here, we are defining a build tools version for use with the `buildToolsVersion` property in the `android` closure. The sub-projects use the `BUILD_TOOLS_VERSION` property that we defined in `gradle.properties` in their own `build.gradle` files, courtesy of a `subprojects` closure defined in the top-level `build.gradle` file:

```
buildToolsVersion BUILD_TOOLS_VERSION
```

Custom Properties Files

You are also welcome to use your own custom properties files. For example, perhaps you want to use `gradle.properties` for properties that you are willing to put in version control (e.g., `BUILD_TOOLS_VERSION`), but you would *also* like to use a properties file to keep your code-signing details outside of your `build.gradle` file and out of version control.

Loading in custom properties files is slightly clunky, as it does not appear to be built into Gradle itself. However, you can take advantage of the fact that Gradle is backed by Groovy and use some ordinary Groovy code to load the properties.

This can also be seen in the `HelloProperties` sample project, where the `build.gradle` in the root project's directory uses a `signing.properties` file to isolate sensitive data:

```
buildscript {  
    repositories {  
        mavenCentral()  
    }  
    dependencies {  
        classpath 'com.android.tools.build:gradle:1.0.0'  
    }  
}
```

ADVANCED GRADLE FOR ANDROID TIPS

```
subprojects {
    buildscript {
        repositories {
            mavenCentral()
        }
        dependencies {
            classpath 'com.android.tools.build:gradle:1.0.0'
        }
    }

    apply plugin: 'com.android.application'

    android {
        compileSdkVersion 19
        buildToolsVersion BUILD_TOOLS_VERSION

        def signingPropFile = rootProject.file('signing.properties')

        if (signingPropFile.canRead()) {
            def Properties signingProps = new Properties()

            signingProps.load(new FileInputStream(signingPropFile))

            signingConfigs {
                release {
                    storeFile rootProject.file('HelloAIDL.keystore')
                    keyAlias signingProps['KEY_ALIAS']
                    storePassword signingProps['STORE_PASSWORD']
                    keyPassword signingProps['KEY_PASSWORD']
                }
            }

            buildTypes {
                release {
                    signingConfig signingConfigs.release
                }
            }
        }
    }
}
```

Let's look at the key lines, one at a time:

```
def signingPropFile = rootProject.file('signing.properties')
```

This statement grabs the `signing.properties` file from the root project and assigns it to the `signingPropFile` variable. Groovy, by default, is a dynamic language and does not use data types for its variables. Under the covers, `signingPropFile` is a `java.io.File` object, just like you are used to in ordinary Java/Android development.

```
if (signingPropFile.canRead()) {
}
```

Since `signingPropFile` is a `File`, we can call a `canRead()` method to confirm that the file exists and is readable.

```
def Properties signingProps = new Properties()
```

This creates an empty instance of a `java.util.Properties` object and assigns it to the `signingProps` variable.

```
signingProps.load(new FileInputStream(signingPropFile))
```

This creates a standard `java.io.FileInputStream` for the properties file, then passes it to the `load()` method on the `Properties` object, to read in the properties file.

```
keyAlias signingProps['KEY_ALIAS']  
storePassword signingProps['STORE_PASSWORD']  
keyPassword signingProps['KEY_PASSWORD']
```

These statements access properties from the `Properties` object, where Groovy has augmented `Properties` to support square-bracket syntax to access individual properties.

The author would like to thank Gabriele Mariotti for [his blog post](#) that, among other things, depicted this technique.

Environment Variables

Any environment variables with a prefix of `ORG_GRADLE_PROJECT_` will show up as global variables in your Gradle script. So, for example, you can access an environment variable named `ORG_GRADLE_PROJECT_foo` by accessing a `foo` variable in `build.gradle`.

If you would prefer to use environment variables without that prefix, you can call `System.getenv()`, passing in the name of the environment variable, to retrieve its value.

Note, however, that you may or may not have access to the environment variables that you think you should. Android Studio, for example, does not expose environment variables to Gradle for its builds, and so an environment variable that you can access perfectly well from the command line may not be available in the same `build.gradle` script when run from Android Studio.

Automating APK Version Information

Once Gradle for Android started catching on, one of the first things many developers raced to do was automate the `android:versionCode` and `android:versionName` properties from the manifest. Since those can be defined in a Gradle file (overriding values from any `AndroidManifest.xml` files), and since Gradle is backed by Groovy, it is possible to programmatically assign values to those properties.

This section outlines a few approaches to that problem.

Auto-Incrementing the `versionCode`

Since the `android:versionCode` is a monotonically increasing integer, one approach for automating it is to simply increment it on each build. While this may seem wasteful, two billion builds is a *lot* of builds, so a solo developer is unlikely to run out. Synchronizing such `versionCode` values across a team will get a bit more complex, but for an individual case (developer, build server, etc.), it is eminently doable using Groovy.

The [Gradle/HelloVersioning](#) sample project uses a `version.properties` file as the backing store for the version information:

```
if (versionPropsFile.canRead()) {
    def Properties versionProps = new Properties()

    versionProps.load(new FileInputStream(versionPropsFile))

    def code = versionProps['VERSION_CODE'].toInteger() + 1

    versionProps['VERSION_CODE']=code.toString()
    versionProps.store(versionPropsFile.newWriter(), null)

    defaultConfig {
        versionCode code
        versionName "1.1"
        minSdkVersion 14
        targetSdkVersion 18
    }
}
else {
    throw new GradleException("Could not read version.properties!")
}
```

First, we try to open a `version.properties` file and fail if it does not exist, requiring the developer to create a starter file manually:

```
VERSION_CODE=1
```

Of course, a more robust implementation of this script would handle this case and supply a starter value for the developer.

The script then uses the read-the-custom-properties logic illustrated in [the preceding section](#) to read the existing value... but it increments the old value by 1 to get the new code to use. The revised code is then written back to the properties file before it is applied in the defaultConfig closure.

In this case, the script throws a `GradleException` to halt the build if the `version.properties` file could not be found or otherwise could not be read.

Synchronizing the `versionName...` with the `versionCode`

If you do not want to automatically increment the `android:versionCode` value, you could use it to also create a matching `android:versionName` value. Jake Wharton illustrated this in [a Google+ post](#), showing how you can build the `versionCode` up from parts representing the major, minor, and patch-level numbers, then use those same numbers to generate a standard dot-notation `versionName`.

Synchronizing the `versionName...` with the APK File Name

You can also use the `android:versionCode` and `android:versionName` elsewhere in your Gradle build file, to apply to other aspects of your build. For example, Kevin Coppock posted [a snippet of code](#) showing how to embed your `versionName` into your compile APK's filename. The `HelloVersioning` sample uses a modified version of this same approach as part of its `buildTypes` closure:

```
buildTypes {
    debug {
        applicationIdSuffix ".d"
        versionNameSuffix "-debug"
    }

    release {
        signingConfig signingConfigs.release
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
        signingConfig signingConfigs.release
    }
}
```

```
    }  
  
    // from http://stackoverflow.com/a/27068573/115145  
  
    applicationVariants.all { variant ->  
        variant.outputs.each { output ->  
            output.outputFile = new File(  
                output.outputFile.parent,  
                output.outputFile.name.replace(".apk",  
                "-${variant.versionName}.apk"))  
        }  
    }  
}
```

When defining the build types, we iterate over all application variants (build type/product flavor combinations), over each of the possible variant outputs (courtesy of splits), and modify the `outputFile` property of the variant to embed the `variant.versionName` value.

Adding to BuildConfig

The Android development tools have been code-generating the `BuildConfig` class for some time now. Historically, the sole element of that class was the `DEBUG` flag, which is true for a debug build and false otherwise. This is useful for doing runtime changes based upon build type, such as only configuring `StrictMode` in debug builds.

Nowadays, the Android Plugin for Gradle also defines:

- `BUILD_TYPE`, which is the build type used to build this APK.
- `FLAVOR`, which is the product flavor used to build this APK.
- `PACKAGE_NAME`, which is the name that serves as the application ID (i.e., it includes build type suffixes and product flavor overrides). This is useful for cases where you cannot just call `getPackageName()` on a `Context` because you do not have a handy `Context`.
- `VERSION_CODE`, which is the version code derived from your manifest in conjunction with any overrides coming from your `build.gradle` file.
- `VERSION_NAME`, which is the version name derived from your manifest in conjunction with any overrides coming from your `build.gradle` file.

However, you can add your own data members to `BuildConfig`, by including a `buildConfigField` statement in the `defaultConfig` closure of your `android` closure:

```
android {  
    defaultConfig {
```

ADVANCED GRADLE FOR ANDROID TIPS

```
    buildConfigField "int", "FOO", '5'
  }
}
```

You can use this to embed any sort of information you want into BuildConfig, so long as it is knowable at compile time.

Moreover, you can also have `buildConfigField` statements in build types. This would be useful if you have custom build types, beyond just debug and release, and you need runtime configuration for those. For example, you could put server URLs in `buildConfigField`, so your debug server is different from your integration test server, which in turn is different than your production server.

You can see this approach used in the [Gradle/HelloBuildConfig](#) sample project. Its `buildTypes` closure defines three different variations of a `SERVER_URL` field on the BuildConfig object:

```
buildTypes {
    debug {
        applicationIdSuffix ".d"
        versionNameSuffix "-debug"
        buildConfigField "String", "SERVER_URL", "http://test.this-is-so-fake.com"
    }

    release {
        signingConfig signingConfigs.release
        buildConfigField "String", "SERVER_URL", "http://prod.this-is-so-fake.com"
    }

    mezzanine.initWith(buildTypes.release)

    mezzanine {
        applicationIdSuffix ".mezz"
        debuggable true
        buildConfigField "String", "SERVER_URL", "http://stage.this-is-so-fake.com"
    }
}
```

The Java code can refer to `BuildConfig.SERVER_URL` to retrieve this value. Since it is defined for all current build types, there will always be a value at compile time. Note, though, that if you add a build type, you need to ensure that it will have a `SERVER_URL` defined.

As of version 0.8 of the Android Plugin for Gradle, if you redefine the same `buildConfigField` name, it replaces the previous value. So, in the `build.gradle` segment shown above, we define the `SERVER_URL` on the `release` build type *before* using `release` as the basis for the `mezzanine` build type. Right after the `mezzanine.initWith(buildTypes.release)` statement, the `mezzanine` build type

has the same `buildConfigField` value for `SERVER_URL` as did `release`. But, we then replace that value in the `mezzanine` closure, to have a different server URL for `mezzanine` builds than we use for `release` or `debug` builds.

Down and Dirty with the DSL

What `build.gradle` does is build up an object model that describes a build process, in the form of defining tasks. Many times you can define the object model in a declarative fashion, with closures like `android` and `buildTypes` and `signingConfigs` and so on. However, as seen in this chapter, sometimes you need to get into Groovy scripting, and sometimes that scripting involves working with the Gradle for Android object model directly.

To help you understand what that object model looks like, the [“Android Plug-in for Gradle”](#) page contains link for “Android Plugin DSL”. This is documentation for the domain-specific language (DSL) published by the Android Plugin for Gradle, including:

- all of the “configuration blocks”, such as the `defaultConfig` closure
- all of the “DSL types”, or the objects that are built up by those “configuration blocks”, such as `BuildType` and `ProductFlavor`

Trail: Testing

JUnit and Android

Presumably, you will want to test your code, beyond just playing around with it yourself by hand. Android offers several means of testing your app, covered in this next series of chapters.

The first Android SDK testing solution we will examine is the JUnit test framework. This is a standard Java unit testing framework. The Android SDK ships a version of JUnit, along with special test classes that will help you build test cases that exercise Android components, like activities and services.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

This chapter also assumes you have some familiarity with JUnit, though you certainly do not need to be an expert. You can learn more about JUnit at the [JUnit site](#), from various books, and from the [JUnit Yahoo forum](#).

Android Studio and Gradle for Android users may also wish to read [the chapter on Gradle dependencies](#).

JUnit Basics

As a quick terminology refresher, for those who have not used JUnit much or have not used it recently:

- A **test case** is a Java class, inheriting (directly or indirectly) from `junit.framework.TestCase`, that represents a set of tests to run
- A **test method** is a method, in a test case, that begins with the keyword `test`, and contains code that tests something in some production code base
- A **test suite** is a collection of test cases

So, a test **suite** enumerates test **cases**, which in turn implement test **methods**.

A test case can also have `setUp()` and `tearDown()` methods, in addition to test methods. `setUp()` is called before each test method invocation, while `tearDown()` is called after each test method invocation. So, for a test case with `testOne()` and `testTwo()` methods, along with `setUp()` and `tearDown()` methods, the following series of method invocations will occur when that test case is run:

- `setUp()`
- `testOne()`
- `tearDown()`
- `setUp()`
- `testTwo()`
- `tearDown()`

Note that while the above list shows `testOne()` being called before `testTwo()`, developers should not rely upon the exact order in which test methods are invoked. Instead, the `setUp()` and `tearDown()` methods are specifically there to establish the environment for each test method run.

Pondering Gradle for Android

Android Studio uses Gradle for Android for building the APK. It *also* uses Gradle for Android for running JUnit tests.

Testing is one aspect of software development that is often automated. You could use a full-blown continuous integration server like [Jenkins](#). Or, you could use something more casual like a Windows Scheduled Task to run tests daily in the early morning hours. Regardless, there is an above-average chance that you will want to run your tests both inside of and outside of Android Studio.

Hence, the instructions in this chapter will not only explain how to run tests from the IDE (both Android Studio and Eclipse), but also how to run tests from the command line using Gradle.

Where Your Test Code Lives

One common problem with testing is determining where the test code should reside, relative to the production code being tested. Ideally, these are not intermingled, as that would increase the odds that you might accidentally ship the testing code as part of your production app — at best, this increases your APK size; at worst, it could open up security flaws.

The approach that you take with JUnit and Android development depends on the environment in which your tests will run.

Android Studio and Gradle for Android

With Gradle-based projects, including those created for Android Studio, we have a dedicated *sourceset* for our instrumentation tests, named `androidTest`, where the code for those tests would reside.

NOTE: The name `androidTest` is for version 0.9.0 or higher of the Gradle for Android plugin. Older versions used `instrumentTest`.

As with any *sourceset*, `androidTest` can have Java code, resources, etc. It does not need an `AndroidManifest.xml` file, though, as that will be auto-generated.

The [Testing/JUnit-Gradle](#) sample project contains such an `androidTest` *sourceset*, and we will be looking at the Java code in there [later in this chapter](#).

Your Android Studio projects should already start with an empty `androidTest` directory, into which you can add a `java/` subdirectory with your test code.

Your `build.gradle` file needs a couple of additional lines in its `defaultConfig` closure:

```
defaultConfig {
    testApplicationId "com.commonware.android.gradle.hello.test"
    testInstrumentationRunner "android.test.InstrumentationTestRunner"
}
```

Here, we define:

- `testApplicationId` (formerly known as `testPackageName`), which is the name of the package to be used for the instrument test APK. For testing

apps, this needs to be a separate package name from the package name of the app. We will discuss testing Android library projects [later in this chapter](#).

- `testInstrumentationRunner`, is the name of the Java class that implements the JUnit test runner to use for executing your tests. Usually, you will use `android.test.InstrumentationTestRunner`, though third-party libraries may offer alternative test runners.

Eclipse

Eclipse takes a different approach, where your test code resides in a completely separate Android test project.

An Android test project is a complete set of Android project artifacts: manifest, source directories, resources, etc. Much of its structure is identical to a regular project. In fact, the generated test project is all ready to go, other than not having any tests. For example, the [Testing/JUnit](#) project has a `tests/` subdirectory containing a test project.

To create a test project, from the standard Eclipse new-project dialog (File > New > Project), choose “Android Test Project”.

The first page of the wizard will ask for your Eclipse settings, such as the project name:

JUNIT AND ANDROID

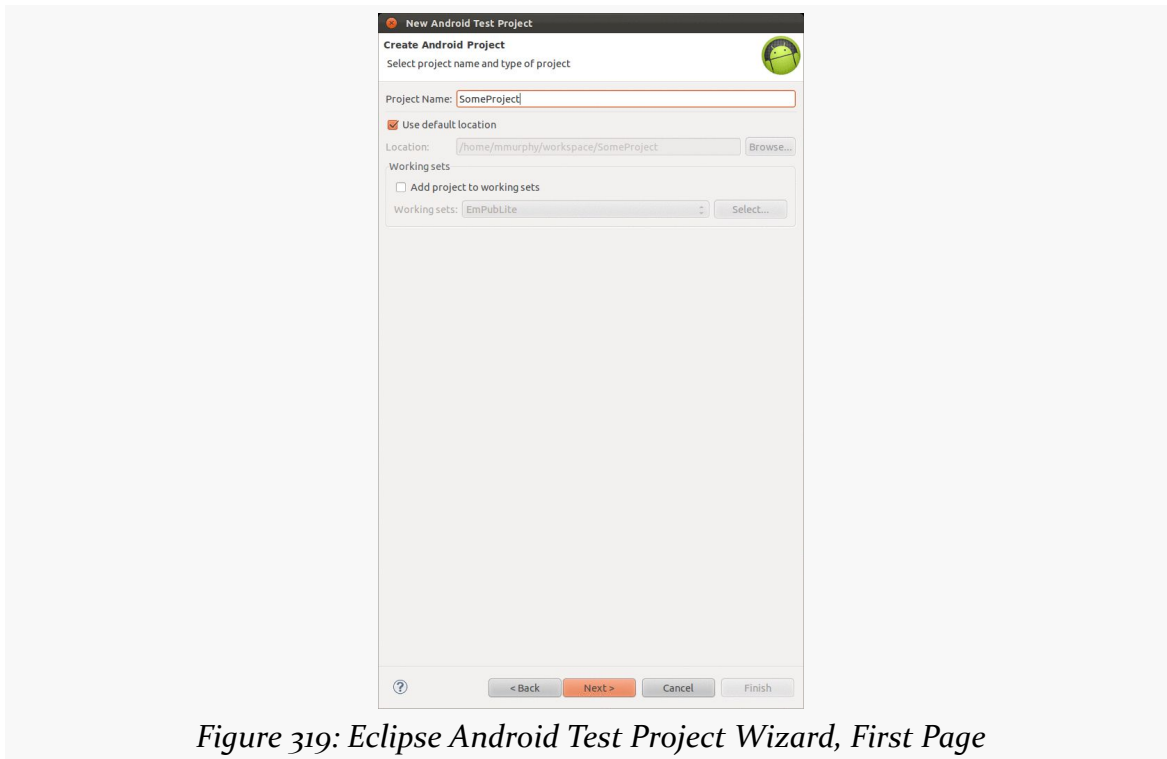

Figure 319: Eclipse Android Test Project Wizard, First Page

The second page of the wizard has you pick from one of your Android projects the one that you wish to test:

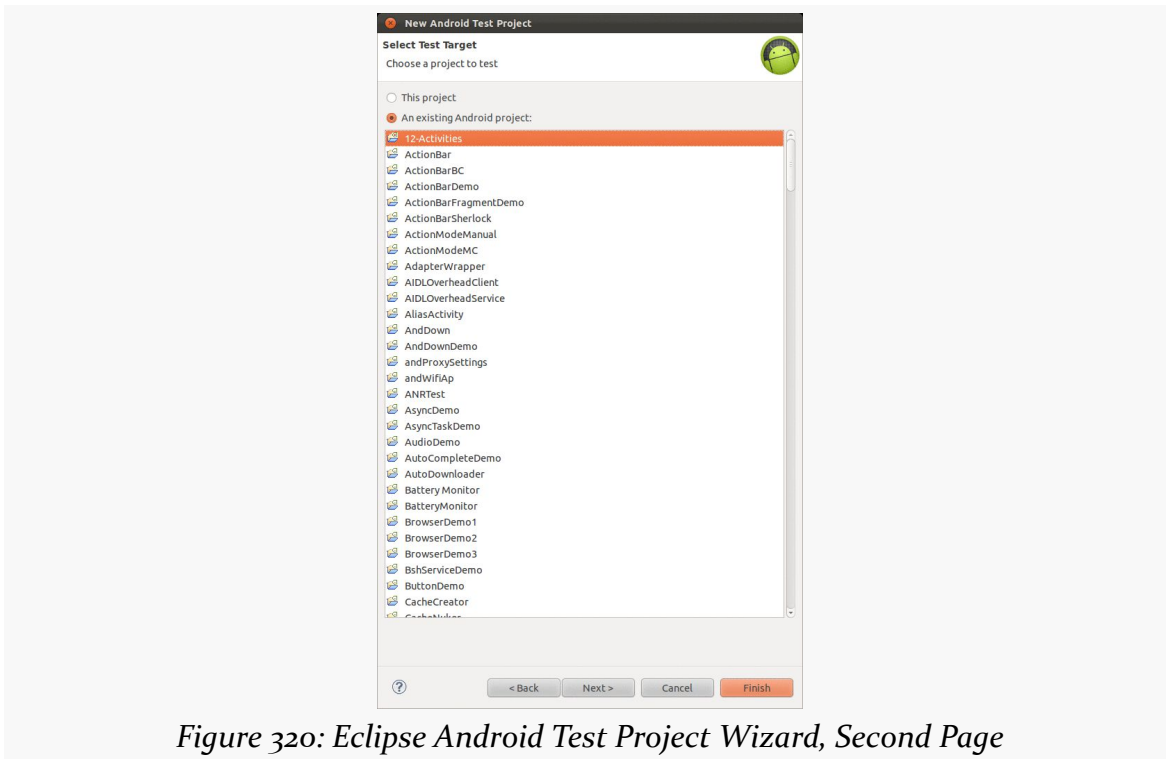

Figure 320: Eclipse Android Test Project Wizard, Second Page

The last page of the wizard lets you specify the build target, which will be based on the build target of the project you specified in the second page:

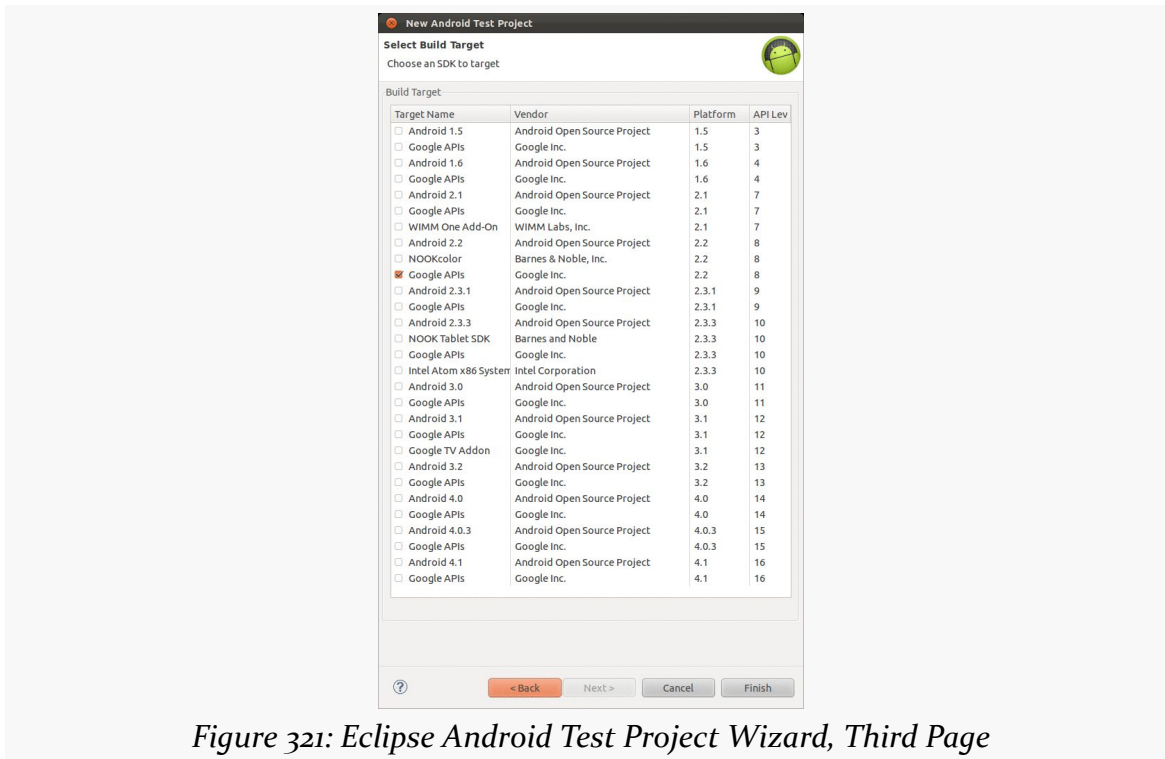

Figure 321: Eclipse Android Test Project Wizard, Third Page

Where Your Test Code Runs

Ordinarily, each code base (e.g., project) is packaged in its own APK and is executed in its own process.

In the case of so-called “instrumentation tests”, like these JUnit tests, your test code and your production code are combined into a single process in a single copy of the virtual machine.

This will allow your JUnit test methods to access objects from your production code, such as your activities and their widgets.

However, this does limit instrumentation testing to be run from a developer’s computer. You cannot package JUnit tests to be initiated from the device itself, except perhaps on rooted devices.

Writing Your Test Cases

A JUnit test project is made up of one (or potentially more) test suites, each comprising one (or usually more) test cases. A test case is a class, containing a series of test methods, designed to test some specific functionality. When a test case is run, JUnit:

- Creates an instance of the test case class
- Calls `setUp()`, where you can do any preparatory work
- Calls one of your test methods
- Calls `tearDown()` for post-test cleanup work
- Repeats the above steps for each test method

Hence, you need to write a series of test cases with test methods, and optionally `setUp()` and `tearDown()` as you see fit.

POJTCs (Plain Old JUnit Test Cases)

For tests that have nothing much to do with Android, you can use the standard JUnit `TestCase` base class. This works the same as JUnit would outside of Android, and is useful for testing business logic on POJOs (plain old Java objects) and the like.

For example, here is a test case that is, well, silly:

```
package com.commonware.android.abf.test;

import junit.framework.TestCase;

public class SillyTest extends TestCase {
    protected void setUp() throws Exception {
        super.setUp();

        // do initialization here, run on every test method
    }

    protected void tearDown() throws Exception {
        // do termination here, run on every test method

        super.tearDown();
    }

    public void testNonsense() {
        assertEquals(1, 1);
    }
}
```

All we have is a single test method — `testNonsense()` that validates that `1` really does equal `1`. Fortunately, this test usually succeeds. Our `TestCase` subclass (`SillyTest`) also implements `setUp()` and `tearDown()` for illustration purposes, as there is little preparation needed for our rigorous and demanding test method.

ActivityInstrumentationTestCase2

While ordinary JUnit tests are certainly helpful, they are still fairly limited, since much of your application logic may be tied up in activities, services, and the like.

To that end, Android has a series of `TestCase` subclasses that you can extend designed specifically to assist in testing these sorts of components.

The one most people focus on is `ActivityInstrumentationTestCase2`. As the name suggests, this class will run your activity for you, giving you access to the `Activity` object itself. You can then:

1. Access your widgets
2. Invoke public and package-private methods (more on this below)
3. Simulate key and touch events

Here are the steps to making use of `ActivityInstrumentationTestCase2`:

- Extend the class to create your own implementation. Since `ActivityInstrumentationTestCase2` is a generic, you need to supply the name of the activity being tested:

```
ActivityInstrumentationTestCase2<ActionBarFragmentActivity>
```

- In the constructor, when you chain to the superclass, supply the activity class itself.
- In `setUp()`, use `getActivity()` to get your hands on your `Activity` object, already typecast to the proper type (e.g., `ActionBarFragmentActivity`) courtesy of our generic. You can also at this time access any widgets, since the activity is up and running by this point.
- If needed, clean up stuff in `tearDown()`, no different than with any other JUnit test case.
- Implement test methods to exercise your activity.

For example, here is a short test case that exercises `ActionBarFragmentActivity`:

```
package com.commonware.android.abf.test;

import android.test.ActivityInstrumentationTestCase2;
import android.test.TouchUtils;
import android.widget.ListView;
import com.commonware.android.abf.ActionBarFragmentActivity;

public class DemoActivityTest extends
    ActivityInstrumentationTestCase2<ActionBarFragmentActivity> {
    private ListView list=null;

    public DemoActivityTest() {
        super(ActionBarFragmentActivity.class);
    }

    @Override
    protected void setUp() throws Exception {
        super.setUp();

        setActivityInitialTouchMode(false);

        ActionBarFragmentActivity activity=getActivity();

        list=(ListView)activity.findViewById(android.R.id.list);
    }

    public void testListCount() {
        assertEquals(25, list.getAdapter().getCount());
    }

    public void testKeyEvents() {
        sendKeys("4*DPAD_DOWN");
        assertEquals(4, list.getSelectedItemPosition());
    }

    public void testTouchEvent() {
        TouchUtils.scrollToBottom(this, getActivity(), list);
        getInstrumentation().waitForIdleSync();
        assertEquals(24, list.getLastVisiblePosition());
    }
}
```

In `setUp()`, we get access to the `ListView` that makes up the bulk of our UI, so we have access to that widget in any test method. We also have three test methods:

- `testListCount()`, where we check our `ListAdapter` in the `ListView` to make sure we have all 25 of our Latin words at the outset
- `testKeyEvents()`, where we simulate pressing the down arrow of a physical keyboard four times, then confirm that the selected row is the proper one
- `testTouchEvent()`, where we use `TouchUtils` and its `scrollToBottom()` method to scroll the `ListView` to the bottom, then confirm that we are actually at the bottom (the last visible row is the 25th row)

The `sendKeys()` method takes both individual key events via their `KeyEvent` constants (e.g., `KeyEvent.KEYCODE_BACK`) or a string containing space-delimited events, where the `KeyEvent.KEYCODE_` prefix is dropped for convenience. Also, a key event can be prefixed by a number and `*` to indicate that the key should be pressed that number of times. So, the `testKeyEvents()` call to `sendKeys("4*DPAD_DOWN")` will simulate four down arrow/D-pad presses in succession.

The `TouchUtils` class has a bunch of low-level methods for performing basic touch events — `scrollToBottom()` is about as sophisticated as they get. In the case of `scrollToBottom()`, the method takes the test case instance, the activity being tested, and the `ViewGroup` to be scrolled. Note that we call `getInstrumentation().waitForIdleSync()` after `scrollToBottom()`, to make sure that our test code blocks waiting for the work to be completed. This was not necessary for `sendKeys()`, as that is documented to have that behavior already.

If you are looking at your emulator or device while this test is running, you will actually see the activity launched on-screen. `ActivityInstrumentationTestCase2` creates a true running copy of the activity. This means you get access to everything you need; on the other hand, it does mean that the test case runs slowly, since the activity needs to be created and destroyed for each test method in the test case. If your activity does a lot on startup and/or shutdown, this may make running your tests a bit sluggish.

Note that our `ActivityInstrumentationTestCase2` resides in a different package than the Activity it is testing. This restricts us to pure black-box testing. If, however, we elected to put the test case in the same package as the activity, we could also call any package-private methods, for a test that is closer to white-box in style.

AndroidTestCase

For tests that only need access to your application resources, you can skip some of the overhead of `ActivityInstrumentationTestCase2` and use `AndroidTestCase`. In `AndroidTestCase`, you are given a `Context` and not much more, so anything you can reach from a `Context` is testable, but individual activities or services are not.

While this may seem somewhat useless, bear in mind that a lot of the static testing of your activities will come in the form of testing the layout: are the widgets identified properly, are they positioned properly, does the focus work, etc. As it turns out, none of that actually needs an Activity object — so long as you can get the inflated `View` hierarchy, you can perform those sorts of tests.

Similarly, if you need to test business objects, but because they come from a database you need a Context for use with SQLiteOpenHelper, you could test those with an AndroidTestCase.

Here is a sample AndroidTestCase:

```
package com.commonware.android.abf.test;

import android.test.AndroidTestCase;
import android.view.LayoutInflater;
import android.view.View;
import com.commonware.android.abf.R;

public class DemoContextTest extends AndroidTestCase {
    private View field=null;
    private View root=null;

    @Override
    protected void setUp() throws Exception {
        super.setUp();

        LayoutInflater inflater=LayoutInflater.from(getContext());

        root=inflater.inflate(R.layout.add, null);
        root.measure(800, 480);
        root.layout(0, 0, 800, 480);

        field=root.findViewById(R.id.title);
    }

    public void testExists() {
        assertNotNull(field);
    }

    public void testPosition() {
        assertEquals(0, field.getTop());
        assertEquals(0, field.getLeft());
    }
}
```

Here, we manually inflate the contents of the res/layout/add.xml resource, and lay them out as if they were really in an activity, via calls to measure() and layout() to simulate a WVGA800 display. At that point, we can start testing the widgets inside of that layout, from simple assertions to confirm that they exist, to testing their size and position.

Other Test Cases

Android also offers various other test case base classes designed to assist in testing Android components, such as:

1. `ServiceTestCase`, used for testing services, as you might expect given the name
2. `ActivityUnitTestCase`, a `TestCase` that creates the `Activity` (like `ActivityInstrumentationTestCase`), but does not fully connect it to the environment, so you can supply a mock `Context`, a mock `Application`, and other mock objects to test out various scenarios
3. `ApplicationTestCase`, for testing custom `Application` subclasses

Your Test Suite

You will want to organize your test cases into one or more test suites. Many test projects have a single suite. However, elaborate test projects may have different suites for different situations, each representing some subset of the total roster of test cases defined in the project.

The simplest way to set up a test suite is to use Android's built-in `TestSuiteBuilder` class, that pulls in a series of test cases based upon package name, such as the `FullSuite` class in our sample test project:

```
package com.commonware.android.abf.test;

import android.test.suitebuilder.TestSuiteBuilder;
import junit.framework.Test;
import junit.framework.TestSuite;

public class FullSuite extends TestSuite {
    public static Test suite() {
        return(new TestSuiteBuilder(FullSuite.class)
            .includeAllPackagesUnderHere()
            .build());
    }
}
```

Here, we are telling Android to find everything in this package (and sub-packages, if there were any) that implements `TestCase` and include it in the suite. Hence, organizing multiple suites would be a matter of organizing their test cases into separate packages and creating `TestSuite` classes per package.

Running Your Tests

Writing tests is nice. Running tests is nicer. Hence, it would be useful if we could run our JUnit tests. The exact procedure for doing this varies by environment.

Android Studio

At the moment, running tests from Android Studio is a bit of a pain.

First, you must define a new run configuration. To do that, choose Run > “Edit Configurations” from the main menu. That will bring up a dialog showing your current run configurations:

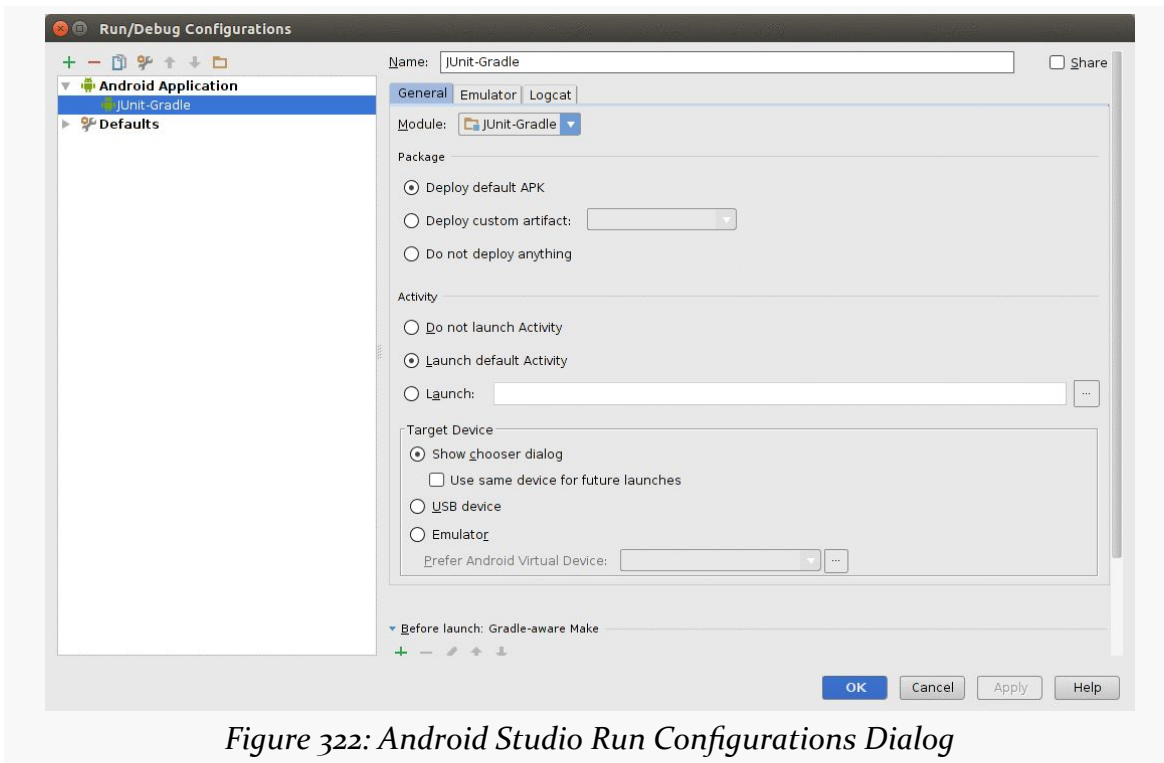

Figure 322: Android Studio Run Configurations Dialog

Towards the upper-left corner of the dialog, you will see a green plus sign. Tapping that will drop down a list of configuration types to choose from:

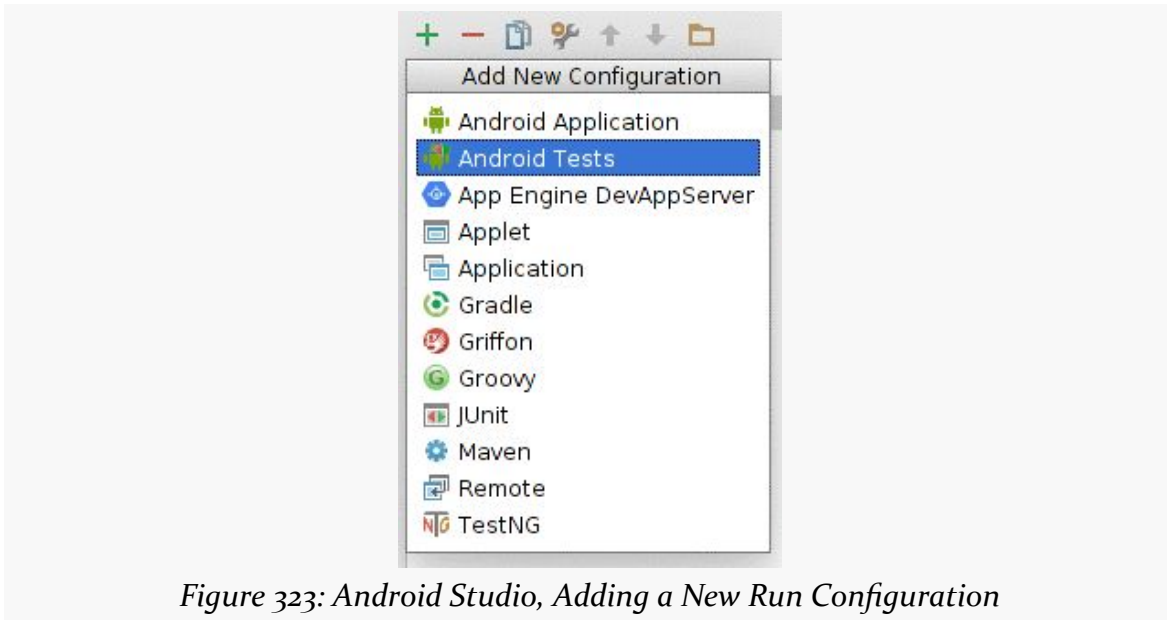

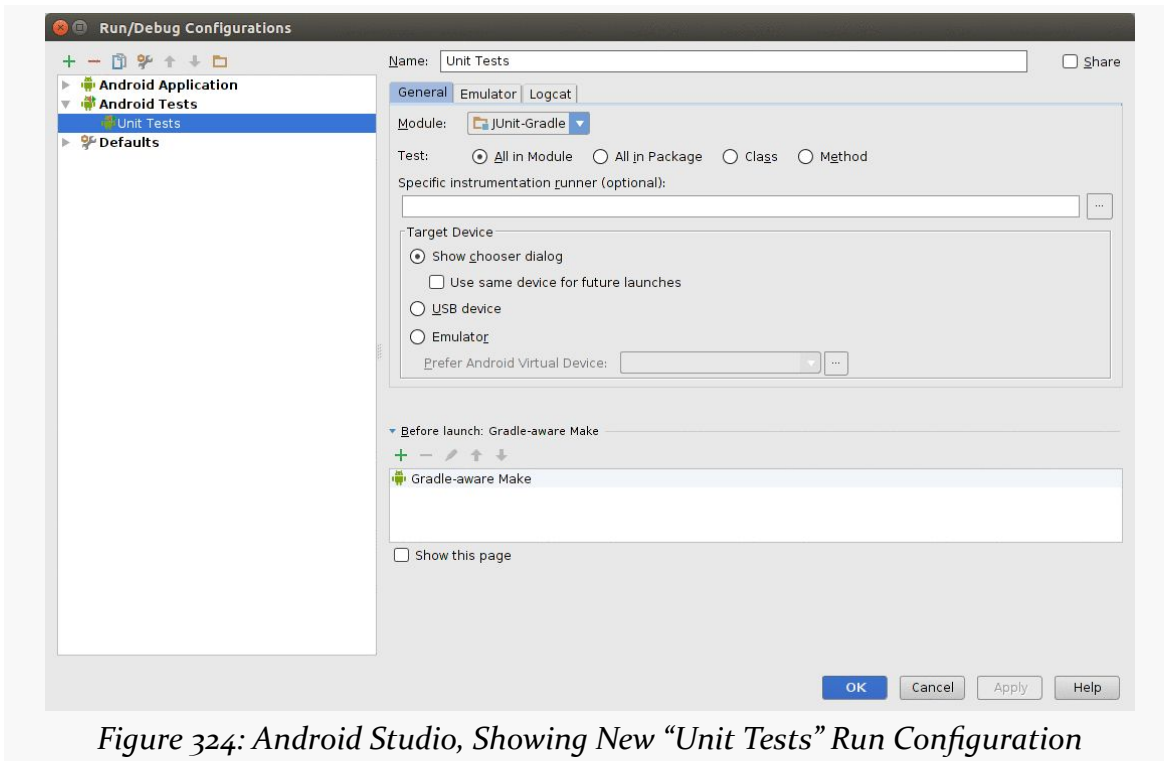

Figure 323: Android Studio, Adding a New Run Configuration

Choose “Android Tests”, and a new empty configuration will be set up for you. You can name it whatever you want via the “Name” field (e.g., “Unit Tests”). Choose your project’s module that you wish to test in the “Module” drop-down (e.g., app). You can also choose the scope of the testing (e.g., “All in Module”), where to run the tests (e.g., “Show chooser dialog”), plus other settings.

JUNIT AND ANDROID

At that point, you can choose your run configuration from the drop-down to the left of the “play” button in the toolbar:

Running that configuration will run your tests. The output will be shown in the Run view, normally docked in the bottom of your IDE window:

JUNIT AND ANDROID

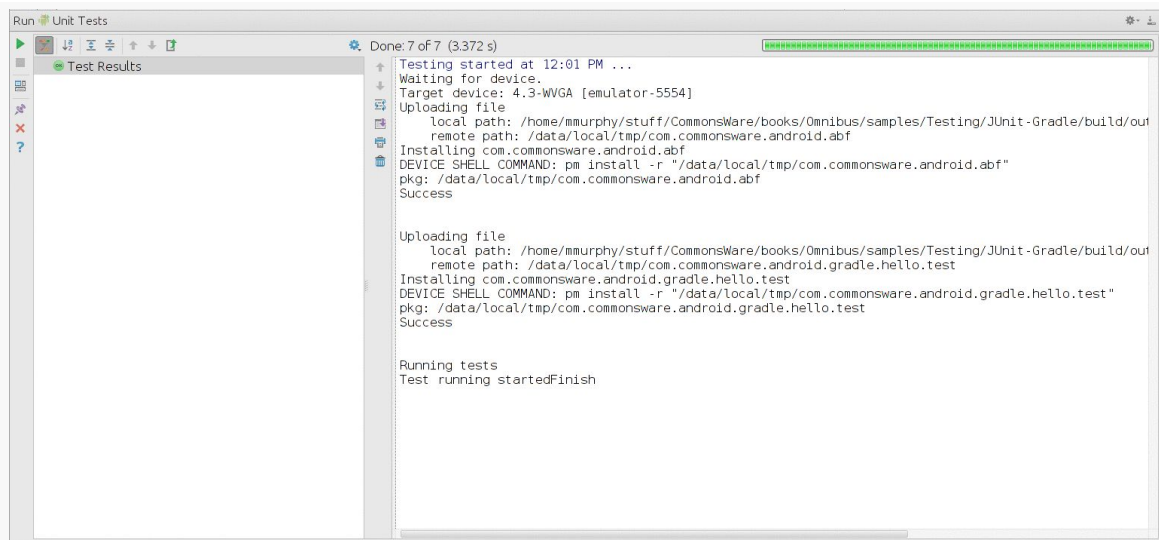

Figure 326: Android Studio, Showing Run Unit Tests Results

If a test fails an assertion or crashes, the test results will show the test case and test method that failed, along with the associated stack trace:

Figure 327: Android Studio, Showing Run Unit Tests Results With a Failure

Gradle for Android

The primary Gradle task that you will use related to testing is `connectedCheck`. This task will build the main app, then, build the test app (using a generated manifest to go along with the code from your `androidTest` sourceset).

At that point, the task will iterate over *all* compatible connected devices and running emulator instances. For each such Android environment, the task will install both apps, run the tests, and uninstall both apps.

Raw test results, in XML format, will be written to `build/outputs/androidTest-results/connected`. These will primarily be of interest to toolsmiths, such as those adding support for Android Gradle-based builds to continuous integration (CI) servers.

For others, the HTML reports will be of greater use. These will be written to `build/outputs/reports/androidTests/connected`, with an `index.html` file serving as your entry point. These will show the results of all of your tests, with hyperlinked pages to be able to “drill down” into the details, such as to investigate failed tests.

Eclipse

You run a test project in Android the same way that you run a regular project. However, when you get the “Run As” dialog, choose “Android JUnit Test”. By default, it will run all of your tests.

However, if you have a single `TestCase` class selected in your Package Explorer, Android can run just that single test case, rather than the full thing — again, choose “Android JUnit Test” in the “Run As” dialog:

JUNIT AND ANDROID

Figure 328: Eclipse “Run As” Dialog for JUnit Test

The results will be displayed in a JUnit view added to your Eclipse workspace, showing the successful and failed tests:

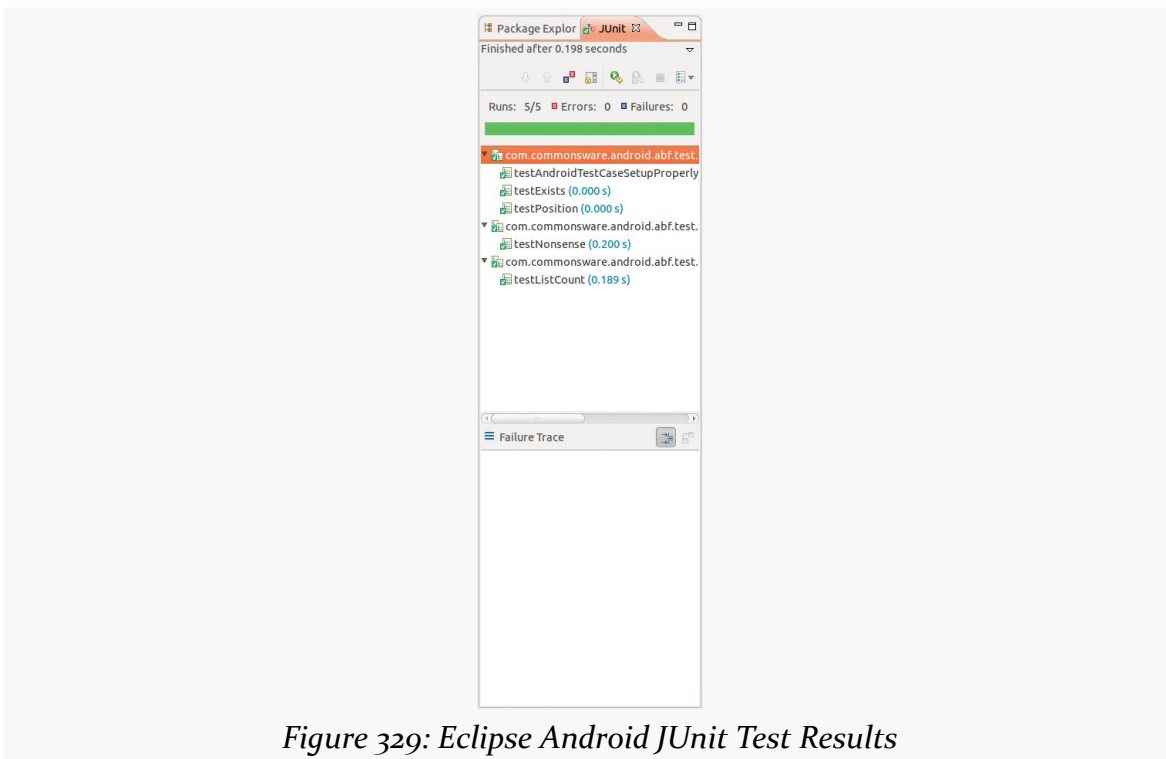

Figure 329: Eclipse Android JUnit Test Results

Testing Android Library Projects

The above procedures are aimed at testing Android application projects. If you are creating an Android library project, you can also use JUnit for testing. However, there will be slight variations in the procedure, once again depending upon environment.

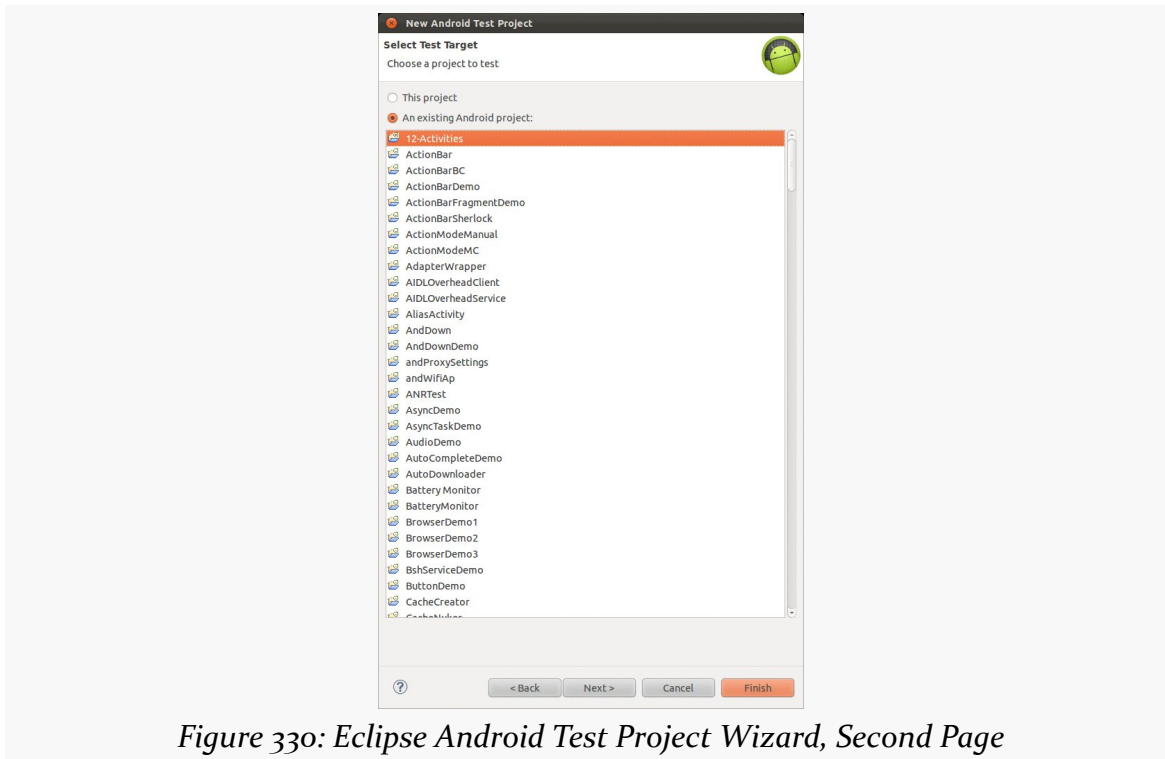

Android Studio and Gradle for Android

A Gradle-built Android library project can have an `androidTest` sourceset, just like a regular app. And, a Gradle-built Android library project can be tested via the `connectedCheck` task. However, that task will create and install a single APK, consisting of the code from the `androidTest` sourceset combined with the library project's own code.

From the standpoint of what you do as a developer, though, it works just like testing an app: add your test cases to the `androidTest` source set and use `connectedCheck` to run the tests.

Eclipse

In Eclipse, to test an Android library project, you create a separate test project and set it up to “this project” (i.e., the package being tested was the test project's own package). This is an option shown on the second page of the new test project wizard:

Toggle the radio button at the top to “This project” to set up a test project that tests itself. You then add the Android library project to the test project and write test cases to exercise the library.

Test Dependencies

Sometimes, your test code will have no dependencies, other than the app (or library) being tested.

Sometimes, your test code will have its own dependencies, such as on libraries like [Robotium](#). You need those dependencies for your test code, but you do not want those dependencies to be part of the production app.

To handle this, Gradle for Android (and Android Studio by extension) supports an `androidTestCompile` statement in the dependencies closure. Where `compile` states dependencies for the entire project; `androidTestCompile` states dependencies only for the instrumentation testing:

```
dependencies {  
    // regular dependencies
```

```
compile 'com.android.support:support-v4:19.0.0'  
// ...  
  
// test dependencies  
androidTestCompile 'com.jayway.android.robotium:robotium-solo:4.3.+'  
// ...  
}
```

This works similarly to [specifying dependencies for a particular build type](#).

The equivalent in Eclipse would be to add the dependencies to the test project, such as copying a JAR into the test project's `libs/` directory.

Testing Legacy Project Structures with Gradle for Android

Suppose that you have a project that you still need to be buildable using Eclipse, yet you want to start using Gradle. For ordinary projects, using an Eclipse-exported `build.gradle` file will have a setup that supports this. However, your test project will be a standalone Android project, not merely some sourceset, as Eclipse does not know what a “sourceset” even is.

However, just as you can teach the main sourceset where it can find its files, you can do the same thing with the `androidTest` sourceset.

For example, suppose that you have an Android project, one that has a test project located in `tests/`. Both projects follow the legacy project structure. The `android` closure of your `build.gradle` file could look like this:

```
android {  
    sourceSets {  
        main {  
            manifest.srcFile 'AndroidManifest.xml'  
            java.srcDirs = ['src']  
            resources.srcDirs = ['src']  
            aidl.srcDirs = ['src']  
            renderscript.srcDirs = ['src']  
            res.srcDirs = ['res']  
            assets.srcDirs = ['assets']  
        }  
  
        androidTest {  
            java.srcDirs = ['tests/src']  
            resources.srcDirs = ['tests/src']  
            aidl.srcDirs = ['tests/src']  
            renderscript.srcDirs = ['tests/src']  
            res.srcDirs = ['tests/res']  
            assets.srcDirs = ['tests/assets']  
        }  
    }  
}
```

JUNIT AND ANDROID

```
}  
  }  
}
```

(from [Xavier Ducrohet's answer on Stack Overflow](#))

Here, we teach both the main and the androidTest sourcesets where their respective files are. In the case of the androidTest sourceset, we point it to files in the tests/ subdirectory.

Given this, Gradle can run the tests, just as IDEs can.

Testing with JUnit4

Since the beginning of Android app development, we had unit testing capability via the `AndroidTestRunner`. However, this was based on JUnit3, which nowadays is a bit old.

In late 2014, the `AndroidJUnitRunner` (supporting JUnit4) was added to the Android Support package. This was initially developed outside of the Android tools team, by a separate group in Google devoted to test automation.

In this chapter, we will review how to apply the `AndroidJUnitRunner` to run JUnit4 tests for our Android apps.

Prerequisites

Understanding this chapter requires that you have read [the chapter on JUnit](#) and [the chapter on Gradle dependencies](#).

The AndroidJUnitRunner

JUnit uses test runners to execute our tests. Historically, most developers used `AndroidTestRunner`, as that was what was in the Android SDK and what was officially supported. However, in principle, JUnit test runners do not need to be part of the firmware. `AndroidJUnitRunner` is a great example of this, as it comes as part of the Android Support package, not as part of Android itself.

The primary reason to use `AndroidJUnitRunner` is to be able to use JUnit4 and Espresso tests. That being said, and subject to a few caveats, it is entirely possible for `AndroidJUnitRunner` to run existing JUnit3 tests. This is very useful, given that

rewriting an entire test suite to move *en masse* to JUnit4 may be very time-consuming.

The [Testing/AndroidJUnitRunner](#) sample project is a modified fork of the [Testing/JUnit-Gradle](#) sample project seen in [the chapter on JUnit](#), with the minimum changes needed to get the tests to run successfully with AndroidJUnitRunner.

Note that this sample app only supports Android Studio. There does not appear to be an official recipe for using AndroidJUnitRunner on Eclipse.

Gradle Changes

To use AndroidJUnitRunner, you will need to make a few adjustments to your module's `build.gradle` file.

First, you need to add a test dependency — a dependency that will only be used as part of instrumentation testing. That can be accomplished via an `androidTestCompile` statement in the `dependencies` closure, instead of a `compile` statement, to limit the scope of the dependency to the case where the `androidTest` sourceset is in use.

Specifically, AndroidJUnitRunner resides in the `com.android.support.test:rules` artifact in the Android Support Repository, which by now you probably have installed via the SDK Manager. So, you can add that as a dependency:

```
dependencies {  
    androidTestCompile 'com.android.support.test:rules:0.3'  
}
```

As of the time of this writing, the latest version of this artifact is 0.3. Note that you *used* to get AndroidJUnitRunner from a `testing-support-lib` dependency; that has since been deprecated.

However, the `rules` artifact also depends upon some other artifacts available in public repositories, like Maven Central or Bintray's JCenter. If you have one of those set up already — and a typical Android Studio project will via the top-level `build.gradle` file — then Gradle will be able to search those repositories for the dependencies. If you do not already have such a repository set up, you will need to do so via the `repositories` closure, such as is the case in the sample app:

```
repositories {  
    mavenCentral() // this or jcenter() required for testing-support-lib dependencies  
}
```

Switching Test Runners

Then, every place where we specify a test runner, we can use `AndroidJUnitRunner` instead of `AndroidTestRunner`. This includes the `testInstrumentationRunner` defined in the `defaultConfig` closure, shown above.

When running tests within Android Studio, the run configuration can specify the instrumentation runner to use:

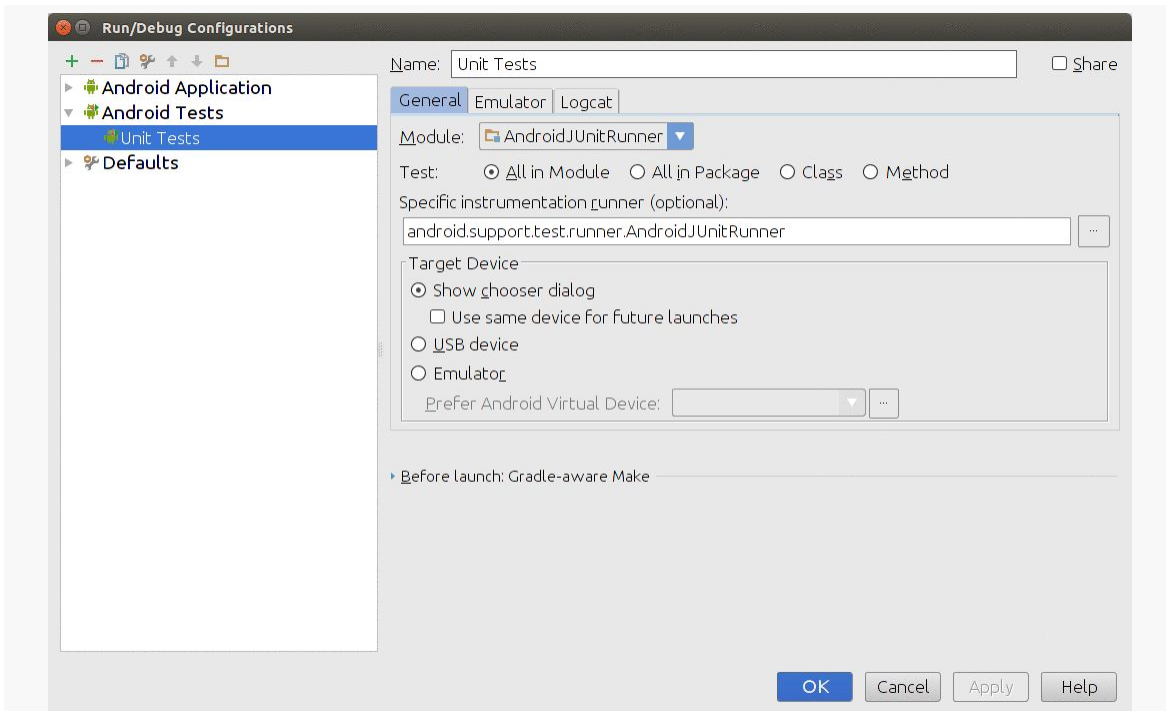

Figure 331: Android Studio Run Configuration Dialog, Showing `AndroidJUnitRunner`

Removing Your Suites

The JUnit-Gradle sample app from [the chapter on JUnit](#) had a `FullSuite` implementation of JUnit3's `TestSuite`. [This does not appear to be supported by `AndroidJUnitRunner` at present.](#)

Results

The results of running the `AndroidJUnitRunner` tests — other than the aforementioned suite limitation — should be identical to what you would have with using the classic `AndroidTestRunner`.

JUnit4

JUnit4, introduced in 2006, is a substantial revision to JUnit3, offering greater flexibility in how you set up your test code. JUnit4 is the current basis for JUnit, and so with `AndroidJUnitRunner`, Android developers are more up to date with respect to which version of JUnit they can use.

This book does not attempt to cover all aspects of JUnit4. For that, you are encouraged to read [the JUnit documentation](#) or other books on Java testing. This chapter will cover some of the basics of using JUnit4 tests, plus some of the issues with using JUnit4 tests in Android.

The Basics of 4

JUnit4 has the same spirit of testing as does JUnit3, but the actual mechanics are significantly different.

The Class

In JUnit3, we had to inherit from a magic `TestCase` class, supplied by JUnit.

In JUnit4, that is no longer the case (pun lightly intended).

Any Java class can serve as a test case, so long as it has a zero-argument public constructor and is known to the test runner that it contains tests to be run. In the case of `AndroidJUnitRunner`, that comes via a `@RunWith(AndroidJUnit4.class)` annotation on the class, to signal that this class contains tests:

```
@RunWith(AndroidJUnit4.class)
public class ICanHazTests {
    // test code goes here
}
```

Identifying Test Methods

In JUnit3, test methods were literally methods whose names began with test. That, coupled with the reliance upon TestCase as a base class, allowed JUnit3 to use reflection to find the subclasses of TestCase, then find all of the test methods within those test cases.

In JUnit4, a test method is any public method that is annotated with the @Test annotation:

```
@RunWith(AndroidJUnit4.class)
public class ICanHazTests {
    @Test
    public void kThxBye() {
        // do some testing
    }
}
```

While there is nothing stopping you from prefixing the method name with test, it is superfluous and usually skipped.

Asserting Results

Since we no longer have access to inherited assertion methods from TestCase, JUnit4 supplies an Assert class with static assertion methods that we can employ:

```
@RunWith(AndroidJUnit4.class)
public class SillyTest {
    @Test
    public void thisIsReallySilly() {
        Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
    }
}
```

assertEquals() takes either two parameters of the same type for comparison (e.g., two int values), or three parameters, where the first is a custom assertion failure message.

There are countless other methods on Assert (e.g., assertNotNull()) for testing objects, collections, etc.

Setup and Teardown

In JUnit3, we could have methods with the magic names of setUp() and tearDown(). These would be called before (setUp()) and after (tearDown()) each test method

TESTING WITH JUNIT4

invocation, to set up test “fixtures” (i.e., starter data to be available to all test methods).

In JUnit4, you can name the methods whatever you want, but you need to annotate them with `@Before` (replacing `setUp()`) and `@After` (replacing `tearDown()`). JUnit4 also adds static `@BeforeClass` and `@AfterClass` methods, which are invoked once for the entire test case, designed for setting up immutable starter data for test methods and avoiding the overhead of doing that work on each test method invocation.

The [Testing/JUnit4](#) sample project is a reworking of the `Testing/AndroidJUnitRunner` sample project, this time with all of the test cases set up for JUnit4. Here, `SillyTest` has more flexibility — showing off the implementation of `@BeforeClass` and `@AfterClass`, for example — but is still equally silly:

```
package com.commonware.android.abf.test;

import android.support.test.runner.AndroidJUnit4;
import junit.framework.Assert;
import org.junit.After;
import org.junit.AfterClass;
import org.junit.Before;
import org.junit.BeforeClass;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class SillyTest {
    @BeforeClass
    static public void doThisFirstOnlyOnce() {
        // do initialization here, run once for all SillyTest tests
    }

    @Before
    public void doThisFirst() {
        // do initialization here, run on every test method
    }

    @After
    public void doThisLast() {
        // do termination here, run on every test method
    }

    @AfterClass
    static public void doThisLastOnlyOnce() {
        // do termination here, run once for all SillyTest tests
    }

    @Test
    public void thisIsReallySilly() {
        Assert.assertEquals("bit got flipped by cosmic rays", 1, 1);
    }
}
```

The Rules

In JUnit3, if you wanted to reuse test-related logic, you would use Java inheritance, putting the common logic in a base class that your test cases would inherit from.

In JUnit4, while that is still possible, they also have the notion of adding rules to a test case. This approach — favoring composition over inheritance — makes it easier to reuse test logic. A rule can encapsulate functionality that gets applied to each of the tests that are run.

Requirements and Backwards Compatibility

One major limitation with `AndroidJUnitRunner`, with respect to JUnit4, is that while your overall suite of test code can be a mix of JUnit3 and JUnit4, you cannot have a single test *class* mix the approaches. Either the class should extend `TestCase` and follow JUnit3 rules (e.g., test methods prefixed by `test`) or use the JUnit4 annotations, but not both.

Reworking Android-Specific Test Cases

Standard JUnit4 stuff works fine for testing POJOs or other functionality that is not tied to Android constructs like a `Context`.

The `testing-support-lib` artifact does not contain equivalents for classes like `ActivityInstrumentationTestCase2` (or other classes that inherit from `InstrumentationTestCase`) or `AndroidTestCase`. If you wish, you are welcome to stick with JUnit3 syntax for those. If, however, you would prefer to use JUnit4 syntax, you can certainly try.

`ActivityInstrumentationTestCase2`

The [documentation for AndroidJUnitRunner](#) contains instructions — albeit incomplete ones — for using `ActivityInstrumentationTestCase2` with JUnit4 syntax. The same basic approach may work for other subclasses of `InstrumentationTestCase`. This is illustrated in the revised version of `DemoActivityTest` in the sample app.

First, as with any JUnit4 test class, you have to add the `@RunWith(AndroidJUnit4.class)` annotation to the class itself:

TESTING WITH JUNIT4

```
@RunWith(AndroidJUnit4.class)
public class DemoActivityTest extends
    ActivityInstrumentationTestCase2<ActionBarFragmentActivity> {
```

If you did not have a `setUp()` method, you need to add one. If you did have a `setUp()` method, you will need to change it. Specifically:

- It now needs to be `public`
- It now needs the `@Before` annotation, as JUnit4 does not pay any attention to the `setUp()` method name
- It needs to have the `injectInstrumentation(InstrumentationRegistry.getInstrumentation())` statement added, shortly after `super.setUp()`, to hook in the instrumentation offered via `AndroidJUnitRunner`

```
@Before
@Override
public void setUp() throws Exception {
    super.setUp();

    injectInstrumentation(InstrumentationRegistry.getInstrumentation());
    setActivityInitialTouchMode(false);

    ActionBarFragmentActivity activity=getActivity();

    list=(ListView)activity.findViewById(android.R.id.list);
}
```

If you did not have a `tearDown()` method, you need to add one. If you did have a `tearDown()` method, you will need to change it, with the same basic steps as the first two we did for `setUp()`:

- It now needs to be `public`
- It now needs the `@After` annotation, as JUnit4 does not pay any attention to the `tearDown()` method name

The required `setUp()` and `tearDown()` is because we can no longer rely upon JUnit4 magically calling those methods, and `ActivityInstrumentationTestCase2` expects them to be called.

You also need to add the `@Test` annotation to any test method, as with any other JUnit4 test class. Plus, you will need to switch to the `Assert` class' assertions, rather than any inherited ones.

So, the revised `DemoActivityTest` looks like:

TESTING WITH JUNIT4

```
package com.commonware.android.abf.test;

import android.support.test.InstrumentationRegistry;
import android.support.test.runner.AndroidJUnit4;
import android.test.ActivityInstrumentationTestCase2;
import android.test.TouchUtils;
import android.widget.ListView;
import com.commonware.android.abf.ActionBarFragmentActivity;
import junit.framework.Assert;
import org.junit.After;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoActivityTest extends
    ActivityInstrumentationTestCase2<ActionBarFragmentActivity> {
    private ListView list=null;

    public DemoActivityTest() {
        super(ActionBarFragmentActivity.class);
    }

    @Before
    @Override
    public void setUp() throws Exception {
        super.setUp();

        injectInstrumentation(InstrumentationRegistry.getInstrumentation());
        setActivityInitialTouchMode(false);

        ActionBarFragmentActivity activity=getActivity();

        list=(ListView)activity.findViewById(android.R.id.list);
    }

    @After
    public void tearDown() throws Exception {
        super.tearDown();
    }

    @Test
    public void listCount() {
        Assert.assertEquals(25, list.getAdapter().getCount());
    }

    @Test
    public void keyEvents() {
        sendKeys("4*DPAD_DOWN");
        Assert.assertEquals(4, list.getSelectedItemPosition());
    }

    @Test
    public void touchEvents() {
        TouchUtils.scrollToBottom(this, getActivity(), list);
        getInstrumentation().waitForIdleSync();
        Assert.assertEquals(24, list.getLastVisiblePosition());
    }
}
```

Note that you will get warnings on each of your @Test methods, complaining about how you are using that annotation on a class that inherits from JUnit3's TestCase. This is intentional behavior on our part. However, [there is no obvious way to suppress this warning](#).

The ActivityTestRule Alternative

However, nowadays, this is not your only option. The 0.3 edition of the rules artifact added ActivityTestRule, in an attempt to abstract out some of the logic from ActivityInstrumentationTestCase2 into a JUnit4 rule.

This does simplify testing for some cases. For example, DemoActivityRuleTest in the sample app supports the listCount() test from the earlier DemoActivityTest, but by using an ActivityTestRule instead of inheriting from ActivityInstrumentationTestCase2:

```
package com.commonware.android.abf.test;

import android.support.test.rule.ActivityTestRule;
import android.support.test.runner.AndroidJUnit4;
import android.widget.ListView;
import com.commonware.android.abf.ActionBarFragmentActivity;
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Rule;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoActivityRuleTest {
    private ListView list=null;
    @Rule public final ActivityTestRule<ActionBarFragmentActivity> main
        =new ActivityTestRule(ActionBarFragmentActivity.class, true);

    @Before
    public void init() {
        list=(ListView)main.getActivity().findViewById(android.R.id.list);
    }

    @Test
    public void listCount() {
        Assert.assertEquals(25, list.getAdapter().getCount());
    }
}
```

The @Rule annotation tells JUnit4 that this data member represents a JUnit4 rule that should be applied to the tests in this test case. ActivityRuleTest takes over the work of creating and destroying an instance of our ActionBarFragmentActivity as

part of standard @Before and @After processing. The true in the ActivityTestRule constructor simply indicates that we want the activity to start off in touch mode.

From there, our init() and listCount() methods work as before. However:

- The keyEvents() test method from DemoActivityTest relies upon sendKeys() from ActivityInstrumentationTestCase2, which ActivityTestRule does not provide. We would have to directly work with the Instrumentation object, and methods like sendStringSync(), to achieve the same end.
- The touchEvents() test method from DemoActivityTest relies upon TouchUtils, which in turn relies upon the magic JUnit3 test case classes like InstrumentationTestCase.

AndroidTestCase

AndroidTestCase and its subclasses are simpler to retrofit. These can be converted into ordinary JUnit4 test classes. Anywhere you used to call getContext() in an AndroidTestCase can be replaced with a call to InstrumentationRegistry.getTargetContext(), which will give you a Context in the app being tested.

The DemoContextTest, therefore, turns into:

```
package com.commonware.android.abf.test;

import android.support.test.InstrumentationRegistry;
import android.support.test.runner.AndroidJUnit4;
import android.test.AndroidTestCase;
import android.test.UiThreadTest;
import android.view.LayoutInflater;
import android.view.View;
import com.commonware.android.abf.R;
import junit.framework.Assert;
import org.junit.Before;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class DemoContextTest {
    private View field=null;
    private View root=null;

    @Before
    public void init() {
        InstrumentationRegistry.getInstrumentation().runOnMainSync(new Runnable() {
            @Override
            public void run() {
                LayoutInflater inflater=LayoutInflater
```

```
        .from(InstrumentationRegistry.getTargetContext());

        root=inflater.inflate(R.layout.add, null);
    }
});

root.measure(800, 480);
root.layout(0, 0, 800, 480);

field=root.findViewById(R.id.title);
}

@Test
public void exists() {
    Assert.assertNotNull(field);
}

@Test
public void position() {
    Assert.assertEquals(0, field.getTop());
    Assert.assertEquals(0, field.getLeft());
}
}
```

The `InstrumentationRegistry` also has `getInstrumentation()` (which returns the `Instrumentation` object that we are using for testing) and `getContext()` (which returns the `Context` for our test code's package).

Note that the act of inflating the layout is performed inside a `Runnable`, which itself is passed to `runOnUiThread()` on an `Instrumentation`. `runOnUiThread()` says "run this code on the main application thread, then block the current thread until that code has completed". On some versions of Android, layout inflation needs to happen on the main application thread, and therefore the test is more reliable if we do that inflation via `runOnUiThread()`.

MonkeyRunner and the Test Monkey

Many GUI environments have some means or another of “fuzz” or “bash” testing, where some test driver executes a bunch of random input, in hopes of catching errors (e.g., missing validation logic). Android offers the Test Monkey for this.

Many GUI environments have some means or another of scripting GUI events from outside the application itself, to simulate button clicks or touch events. Android offers MonkeyRunner for this.

As the names suggest, there is a bit of commonality in their implementation. And, as you might expect, there is a bit of commonality in their coverage in this book — we will examine both MonkeyRunner and the Test Monkey in this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

MonkeyRunner

MonkeyRunner is a means of creating test suites for Android applications based on scripted UI input. Rather than write a series of JUnit test cases or the like, you create Jython (JVM implementation of Python) scripts that run commands to install apps, execute GUI events, and take screenshots of results.

Writing a MonkeyRunner Script

The primary object you will work with in a MonkeyRunner script is a `MonkeyDevice`, which represents your connection to the device or emulator that you are testing. You obtain a `MonkeyDevice` by calling `waitForConnection()` on `MonkeyRunner`; this will return once it has established a connection.

From there, `MonkeyDevice` lets you send events to the device or emulator:

- `installPackage()` allows you to install an APK from your development machine, and `removePackage()` allows you to get rid of it
- `startActivity()` and `broadcastIntent()` allow you to start up components of your app
- `press()` to simulate key events, including QWERTY keys, standard device keys like BACK, D-pad/trackball events, and anything else represented by a standard Android `KeyEvent`
- `type()` to simulate entering a whole string, as a simplification over calling `press()` once per letter
- `touch()` and `drag()` let you simulate touch events
- and so on

The biggest limitation is in getting data out of the device, to determine if your test worked successfully. Your options are:

- `takeSnapshot()`, which will capture a screenshot that you can save to disk, compare with other screenshots, etc.
- `shell()` executes `adb shell` commands, returning any results
- ...and that's about it

Unlike [JUnit-based testing](#), you have no visibility into the activity beyond what appears on the screen — you cannot inspect widgets, call methods, or the like.

For example, here is a script that installs an app, runs an activity from it, and presses the down button on the D-pad three times:

```
from com.android.monkeyrunner import MonkeyRunner, MonkeyDevice

device = MonkeyRunner.waitForConnection()
device.installPackage('bin/JUnitDemo.apk')
device.startActivity(component='com.commonware.android.abf/
com.commonware.android.abf.ActionBarFragmentActivity')
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
device.press('KEYCODE_DPAD_DOWN', MonkeyDevice.DOWN_AND_UP)
```

```
# result = device.takeSnapshot()  
# result.writeToFile('tests/monkey_sample_shots/test1.png', 'png')
```

Executing MonkeyRunner

To execute your MonkeyRunner script, have your device or emulator set up at a likely starting point (e.g., home screen), then execute the `monkeyrunner` command, passing it the path to your script (e.g., `monkeyrunner monkey_sample.py`). You will see the script executing on the screen of your device or emulator, and your console will contain whatever output you might emit from your test script itself. For example, you might take screenshots, compare them against a master copy (using methods on `MonkeyImage` to help with this), and emit warnings if they differ unexpectedly.

Monkeying Around

Independent from the JUnit system and MonkeyRunner is the Test Monkey (referred to here as “the Monkey” for short).

The Monkey is a test program that simulates random user input. It is designed for “bash testing”, confirming that no matter what the user does, the application will not crash. The application may have odd results — random input entered into a Twitter client may, indeed, post that random input to Twitter. The Monkey does not test to make sure that results of random input make sense; it only tests to make sure random input does not blow up the program.

You can run the Monkey by setting up your initial starting point (e.g., the main activity in your application) on your device or emulator, then running a command like this:

```
adb shell monkey -p your.package.here -v --throttle 100 600
```

(substituting the application ID of a project on your device or emulator for `your.package.here`)

Working from right to left, we are asking for 600 simulated events, throttled to add 100 millisecond delays. We want to see a list of the invoked events (`-v`) and we want to throw out any event that might cause the Monkey to leave our application, as determined by the application ID (`-p your.package.here`).

Note that this truly is the application ID, not the package name. In simple apps — such as most of this book’s samples — the package name *is* the application ID. But if you have modified the application ID in your `build.gradle` file (e.g., replaced the application ID for a product flavor), you will need to use the actual application ID here, not the package name. In general, despite any legacy documentation to the contrary, “package name” only affects code-generated classes like `R` and `BuildConfig`. Any other use of the term “package name” really is referring to the application ID.

The Monkey will simulate keypresses (both QWERTY and specialized hardware keys, like the volume controls), D-pad/trackball moves, and sliding the keyboard open or closed. Note that the latter may cause your emulator some confusion, as the emulator itself does not itself actually rotate, so you may end up with your screen appearing in landscape while the emulator is still, itself, portrait. Just rotate the emulator a couple of times (e.g., `<Ctrl>-<F12>`) to clear up the problem.

Also note that the throttle time is only used in between batches of related events. So, a batch of several touch events, or a pair of up/down events for a hardware key, will not be throttled. You can see this if you pass `-v -v -v` for “ultimate verbose mode” and look at the output, such as this snippet:

```
:Sending Key (ACTION_DOWN): 134 // KEYCODE_F4
:Sending Key (ACTION_UP): 134 // KEYCODE_F4
Sleeping for 100 milliseconds
:Sending Touch (ACTION_DOWN): 0:(1302.0,842.0)
:Sending Touch (ACTION_MOVE): 0:(1295.3395,838.0863)
:Sending Touch (ACTION_MOVE): 0:(1290.1539,827.0493)
:Sending Touch (ACTION_MOVE): 0:(1280.0454,826.9068)
:Sending Touch (ACTION_MOVE): 0:(1272.0161,816.8062)
:Sending Touch (ACTION_MOVE): 0:(1260.7244,810.8302)
:Sending Touch (ACTION_UP): 0:(1250.5455,801.67444)
Sleeping for 100 milliseconds
:Sending Key (ACTION_DOWN): 19 // KEYCODE_DPAD_UP
:Sending Key (ACTION_UP): 19 // KEYCODE_DPAD_UP
Sleeping for 100 milliseconds
:Sending Key (ACTION_DOWN): 68 // KEYCODE_GRAVE
:Sending Key (ACTION_UP): 68 // KEYCODE_GRAVE
Sleeping for 100 milliseconds
```

Here, we see actual messages where the throttling is applied (“Sleeping for 100 milliseconds”). Hence, the time it takes the Test Monkey to run a test will be at most the number of events times the throttle time, but due to event batching, it is usually substantially less than that. 25-30% of the maximum time seems typical.

For playing with a Monkey, the above command works fine. However, if you want to regularly test your application this way, you may need some measure of repeatability.

MONKEYRUNNER AND THE TEST MONKEY

After all, the particular set of input events that trigger your crash may not come up all that often, and without that repeatable scenario, it will be difficult to repair the bug, let alone test that the repair worked.

To deal with this, the Monkey offers the `-s` switch, where you provide a seed for the random number generator. By default, the Monkey creates its own seed, giving totally random results. If you supply the seed, while the sequence of events is random, it is random for that seed — repeatedly using the same seed will give you the same events. If you can arrange to detect a crash and know what seed was used to create that crash, you may well be able to reproduce the crash.

There are many more Monkey options, to control the mix of event types, to generate profiling reports as tests are run, and so on. The [Monkey documentation](#) in the SDK's Developer's Guide covers all of that and more.

Testing with UI Automator

Yet another approach for testing Android applications is UI Automator. This is designed for integration testing, both how your app components integrate with one another (e.g., activities starting activities) and how your app components integrate with the rest of a device.

In early 2015, Google released version 2.0 of the UI Automator framework. This update ties UI Automator into the same instrumentation testing engine that is used for JUnit/JUnit4 testing. This also makes it possible to run UI Automator tests through Android Studio and Gradle for Android, which previously had been difficult.

Prerequisites

This chapter assumes that you have read [the chapter on JUnit-based testing](#) and [the chapter on JUnit4](#). Having read [the chapter on monkeyrunner and the Test Monkey](#) is also a good idea, again for comparison purposes.

What Is UI Automator?

UI Automator, as the name suggests, automates UIs. It simulates user input, in the form of tapping on items and the like. It does so without modifying your process' contents, and so in that respect it behaves like the Test Monkey.

However, unlike the Test Monkey, tests run by UI Automator are implemented in JUnit, and those tests have limited access to the widgets inside of a UI. Such access not only allows for directing simulated user input (e.g., “click the OK button”), but

also for asserting that various test conditions are true (e.g., “does the list have five rows?”). In this respect, UI Automator behaves like traditional Android JUnit testing.

Why Choose UI Automator Over Alternatives?

In some respects, UI Automator represents the worst of both worlds. You have to use JUnit, making test authoring a challenge for those not skilled with Java. Yet you only have fairly generic access to an activity’s widgets, versus the complete white-box capability of normal instrumentation-based JUnit testing.

Hence, why would anyone bother?

The big thing that UI Automator offers over classic JUnit testing is greater ability to test an *application* versus testing *individual components*. The classic JUnit test cases are organized around testing some specific component, such as using `ActivityInstrumentationTestCase2` to exercise some specific activity. Testing the flow of work between activities is difficult from classic JUnit, but is relatively easy with UI Automator. You can also use this for integration testing, as you can exercise and analyze applications other than your own, such as to confirm that you are starting a third-party app correctly.

Similarly, classic JUnit testing cooks up activity instances “out of thin air”. Instead, UI Automator executes normal UI operations to create the activities, such as tapping on your app’s icon in the home screen launcher. This more accurately simulates what a user will do — users are far more likely to tap on a launcher than to hack into your Dalvik VM and manually instantiate an activity.

You can see a set of UI Automator tests in a suitable project in the [Testing/UIAutomator](#) directory. Note, though, that the UI Automator tests will only work successfully on Android 4.x emulators, and perhaps a few other environments. The tests are testing the integration of the home screen to the app, along with the app’s functionality, and the particular code used to navigate the home screen will only work with the stock Android home screen, not necessarily any manufacturer’s home screen or third-party home screen.

Gradle and Android Studio Settings

Your project needs to be set up to use the `AndroidJUnitRunner` as is outlined in [the chapter on JUnit4](#). That includes the `androidTestCompile` dependency on the `testing-support-lib` artifact.

TESTING WITH UI AUTOMATOR

For UI Automator, you additionally need to have an `androidTestCompile` dependency on the `uiautomator-v18` artifact:

```
dependencies {
    androidTestCompile 'com.android.support.test:rules:0.3'
    androidTestCompile 'com.android.support.test.uiautomator:uiautomator-v18:2.1.0'
}
```

Here the `-v18` suffix, as with the regular Android Support package libraries, means that this only works on API Level 18 and higher.

If you wish to run the tests from Android Studio, you will also need to set up a run configuration, as outlined in [the chapter on JUnit4](#).

Creating a Test Case

Your test case classes do not need to inherit from any particular base class, just like regular JUnit4 tests. They do need to be annotated with the `@RunWith(AndroidJUnit4.class)` annotation:

```
@RunWith(AndroidJUnit4.class)
public class ListTests {
```

Your test case is welcome to have `@Before`, `@After`, and other setup/teardown methods, in addition to `@Test` methods, just like a regular JUnit4 test case. In fact, from Android's standpoint, UI Automator tests *are* just regular JUnit4 test cases — you are welcome to have UI Automator test cases and regular instrumentation testing JUnit4 test cases in the same `androidTest` sourceset.

Performing Device-Level Actions

The root of most of our work with UI Automator is a `UiDevice` object. This allows us to perform device-level actions, such as pressing `BACK` or `HOME`.

To get a `UiDevice`, call the static `getInstance()` method on `UiDevice`, passing in the `Instrumentation` that you get from `InstrumentationRegistry.getInstrumentation()`:

```
@Before
public void setUp() throws UiObjectNotFoundException {
    device=UiDevice.getInstance(InstrumentationRegistry.getInstrumentation());
    openActivity();
}
```

Here, we get the `UiDevice` and stash it in a data member for the life of this `ListTests` instance.

`UiDevice` has many methods that allow you to perform device-level actions, such as calling `pressHome()` to press the HOME button (and thereby bring up the home screen). Similarly, you can call:

- `pressBack()` and `pressMenu()` for the BACK and MENU buttons
- `pressDPadUp()`, `pressDPadLeft()`, etc. for D-pad events
- `pressRecentApps()` to bring up the recent tasks list
- `pressKeyCode()` to press an arbitrary key based on the keycode from `KeyEvent`

...and so on.

Inspecting and Interacting with the UI

Of course, pressing some buttons is not especially useful on its own, only as a means to an end, such as launching your activity. To do more than this, you will need to get your hands on widgets and containers, to perform operations related to them.

The key is that you can “get your hands on widgets and containers” *from whatever activity is in the foreground*. This is not limited to your own app, but rather works for *any* app, including the home screen itself.

The following sections will work through some common UI Automator operations, in the context of the `openActivity()` from the `ListTests` class in the sample project. This method, called from `setUp()`, consolidates the work to bring an instance of our production activity to the foreground, by means of interacting with the home screen:

```
private void openActivity() throws UiObjectNotFoundException {
    device.pressHome();

    UiObject allAppsButton=
        device.findObject(new UiSelector().description("Apps"));

    allAppsButton.clickAndWaitForNewWindow();

    UiObject appsTab=device.findObject(new UiSelector().text("Apps"));

    appsTab.click();

    UiScrollable appViews=
        new UiScrollable(new UiSelector().scrollable(true));
}
```

```
appViews.setAsHorizontalList();

UiObject ourApp=
    appViews.getChildByText(new UiSelector().className("android.widget.TextView"),
        "Action Bar Fragment Demo");

ourApp.clickAndWaitForNewWindow();

UiObject appValidation=
    device.findObject(new UiSelector().packageName("com.commonware.android.abf"));

Assert.assertTrue("Could not open test app", appValidation.exists());
}
```

Finding and Interacting with Widgets

`openActivity()` starts by calling `pressHome()` on the `UiDevice`, to ensure that the home screen is in the foreground:

```
device.pressHome();
```

Next, we want to bring up the home screen's launcher, showing the available launchable activities, so that we can find our app and launch it. What a user would do, on a stock Android environment like an emulator, would be to click on the appropriate button to bring up the launcher. We need to do the same thing, except from our test code. This implies:

- Finding that widget
- Simulating a click of that widget

Web developers are used to finding DOM nodes by CSS queries. Developers using XML are used to using XPath queries to find particular elements. Along the same lines, UI Automator gives us a flexible system to find widgets in the foreground activity, by means of a `UiSelector` object, typically created using the public zero-argument constructor (i.e., `new UiSelector()`).

In CSS, a “selector” can identify DOM nodes by class, id, or ones with particular properties. A `UiSelector` can do much the same thing. So, the first `UiSelector` created in `openActivity()` will find a widget in the foreground activity whose “description” is Apps (`new UiSelector().description("Apps")`). Here, “description” will mean either the text of a `TextView` or the `android:contentDescription` of other types of widgets.

How do we know that this particular button has a “description” of Apps? In this case, we found out using `uiautomatorviewer`, which will be discussed in a future update to this chapter.

By passing our `UiSelector` to `findObject()` on the `UiDevice`, we get a `UiObject` that, hopefully, knows how to interact with this particular button of the home screen. In particular, we call `clickAndWaitForNewWindow()` on it, which taps the button and blocks until something else (e.g., a new activity) has taken over the foreground:

```
UiObject allAppsButton=
    device.findObject(new UiSelector().description("Apps"));

allAppsButton.clickAndWaitForNewWindow();
```

The stock Android launcher has two tabs, one for apps and one for (app) widgets. We need to ensure that the apps tab is selected. So, once again, we create a `UiSelector` and use it to create a `UiObject` to represent the apps tab. This time, we use `text()` instead of `description()`. `text()` will find a widget based solely on its display text (e.g., `android:text` of a `TextView`). In truth, we could have used `description()` here as well, with the same results.

Then, we call `click()` on the `UiObject`, to simulate a tap on this tab, to ensure that is the selected tab.

```
UiObject appsTab=device.findObject(new UiSelector().text("Apps"));

appsTab.click();
```

Dealing with Collections

Finding widgets by text or description is fairly easy when there is only one possible widget that has that text or description. Things get more complicated when you are dealing with a collection of widgets, such as an `AdapterView`.

For example, the Apps tab of the standard Android launcher uses a `GridView` to show up to 20 launchable activities. Then, you need to swipe horizontally, courtesy of a `ViewPager`, to uncover additional `GridView` collections of launchable activities.

A `UiCollection` helps deal with this, in terms of allowing you to inspect a collection of widgets, including performing the necessary swipe operations to access all of the contents.

A `UiSelector` called with `scrollable(true)` will return a widget that is scrollable. Creating a `UiCollection` with that `UiSelector` will create a `UiCollection` around the first scrollable widget. In the case of the Apps tab, that will be the `ViewPager-and-GridView` combination.

In our case, to get to other elements in the collection, you need to swipe horizontally. To configure the `UiCollection` that way, we have to call `setAsHorizontalList()` on the `UiCollection`:

```
UiScrollable appViews=  
    new UiScrollable(new UiSelector().scrollable(true));  
  
appViews.setAsHorizontalList();  
  
UiObject ourApp=  
    appViews.getChildByText(new UiSelector().className("android.widget.TextView"),  
        "Action Bar Fragment Demo");
```

Finding Widgets By Type

In that collection, we want to find the item that contains our app's caption. This test project is designed to test the same sample app that was tested in [the JUnit chapter](#), a slightly modified version of an early action bar sample. Our launcher entry's name will be "Action Bar Fragment Demo", as that is what we set up in the production project's manifest and string resources. So, we need to find the entry in the `ViewPager-of-GridViews` that has that title.

To do that, we will create yet another `UiSelector`. This time, though, we will find widgets by type, specifying `className("android.widget.TextView")` to only work with `TextView` widgets.

That `UiSelector` is passed into the `getChildByText()` method of `UiCollection`, which will iterate over the children to find the first one that matches the `UiSelector` and where the selected widget contains the supplied text:

```
UiObject ourApp=  
    appViews.getChildByText(new UiSelector().className("android.widget.TextView"),  
        "Action Bar Fragment Demo");
```

Then, we again call `clickAndWaitForNewWindow()`, to tap on our launcher entry, triggering our app's activity to come to the foreground:

```
ourApp.clickAndWaitForNewWindow();
```

Asserting Conditions

`UiSelector` and `UiObject` can also be used for some operations that do not fit the normal widgets-and-containers pattern shown above.

For example, now that we have opened a window from our app to be tested, it would be nice to confirm that, indeed, this is our app, and that our `openActivity()` method did not open some other app by mistake.

To do this, we can create a `UiSelector` and apply `packageName()`, to constrain the selection to widgets coming from an app with our desired package name:

```
UiObject appValidation=  
    device.findObject(new UiSelector().packageName("com.commonware.android.abf"));
```

The `UiObject` we create always exists (i.e., is not null), as we are creating it via the constructor. However, it is entirely possible that our `UiSelector` cannot match any widget, such as would be the case if we accidentally opened the wrong app and tried to find a widget stemming from our package. The `exists()` method on a `UiObject` returns true if the `UiObject` is pointing at an actual widget, false otherwise. Hence, we can assert that we indeed have a widget coming from our package:

```
Assert.assertTrue("Could not open test app", appValidation.exists());
```

The net result is that we open our main activity and confirm that, indeed, that is what we opened.

And Now... The Real Test Methods

All of that was just to get the activity for testing onto the screen.

Now the *real* testing begins.

The `ListTests` class has two test methods, `testContents()` and `testAdd()`, designed to (lightly) exercise the UI.

testContents()

The objective of the `testContents()` method is to confirm that the 25 words all appear in the `ListView`.

To do that, we:

TESTING WITH UI AUTOMATOR

- Create a `UiScrollable` for a `UiSelector` that finds the `ListView` in our activity
- Mark that `UiScrollable` as being a vertical list, where swipes up and down will expose the various children
- Iterate over the array of words, finding the `TextView` for each word and confirming that this widget does indeed exist

```
@Test
public void testContents() throws UiObjectNotFoundException {
    UiScrollable words=
        new UiScrollable(
            new UiSelector().className("android.widget.ListView"));

    words.setAsVerticalList();

    for (String s : items) {
        Assert.assertNotNull("Could not find " + s,
            words.getChildByText(new UiSelector().className("android.widget.TextView"),
                s));
    }
}
```

testAdd()

The objective of the `testAdd()` method is to add a new word to the list, via the `EditText` widget in our action bar, then confirm that the new word was actually added to the list.

To do that, we:

- Retrieve the `EditText` by finding the widget whose text is “Word” (the hint of our `EditText`)
- Call `setText()` to fill in `snicklefritz` into the `EditText` widget, which `UiObject` accomplishes by actually typing in the value
- Call `pressEnter()` on the `UiDevice` to simulate pressing the Enter key of a keyboard, which will trigger our action listener in the test activity and will add the word to the list
- Create a `UiScrollable` for a `UiSelector` that finds the `ListView` in our activity
- Mark that `UiScrollable` as being a vertical list, where swipes up and down will expose the various children
- Try to find a `TextView` whose text is `snicklefritz` and assert that it was found

```
@Test
public void testAdd() throws UiObjectNotFoundException {
```

TESTING WITH UI AUTOMATOR

```
UiObject add=device.findObject(new UiSelector().text("Word"));

add.setText("snicklefritz");
device.pressEnter();

UiScrollable words=
    new UiScrollable(
        new UiSelector().className("android.widget.ListView"));

words.setAsVerticalList();

Assert.assertNotNull("Could not find snicklefritz",
    words.getChildByText(new UiSelector().className("android.widget.TextView"),
        "snicklefritz"));
}
```

Cleaning Up

Our `ListTests` class also has a `tearDown()` method, invoked by JUnit after each test method courtesy of the `@After` annotation. Here, we press BACK twice, to return us to the main home screen from our activity, setting things back up for the next test method:

```
@After
public void tearDown() {
    device.pressBack();
    device.pressBack();
}
```

Running Your Tests

You run your UI Automator tests as you would any other instrumentation test:

- By running the run configuration that you set up for your tests in Android Studio
- By running commands like `gradle connectedCheck` at the command line
- Through integrations into your continuous integration server or similar build infrastructure

Finding Your Widgets

The key to finding your desired widgets stems in large part from the `text()` or `description()` methods on `UiSelector`. Of those two, the latter is more flexible, as it will use the `android:contentDescription` from any widget, while `text()` is limited to `TextView` and its subclasses.

However, this implies that your widgets have `android:contentDescription` defined. This is also important for [accessibility](#), and therefore is a good idea regardless of its use with UI Automator.

For testing your own code, you can also find widgets via their resource IDs. `UiSelector` has `resourceId()` and `resourceIdMatches()` methods to configure the resource ID you want. As the `resourceIdMatches()` method name suggests, the resource ID here is a *string representation* of the resource name. It will be of the form `your.app.package:id/resource` (e.g., `com.commonsware.android.hotkey:id/editor`). However:

- Note that this requires API Level 18 or higher versions of the two JARs (`UIAutomator.jar` and `android.jar`)
- Note that this requires running the tests on an API Level 18+ device or emulator
- Bear in mind that third party apps are welcome to rename their widgets when they wish, so your integration tests may break when third parties do so

Using the UI Automator Viewer

Identifying widgets can be a bit tricky with UI Automator. Identifying widgets *in other apps*, for your integration tests, would in theory be next to impossible. After all, while Hierarchy View can give you widget IDs, that only works on an emulator, and you would not stoop to the level of making an unauthorized copy of an app onto an emulator, right?

Fortunately, you do not need to ponder acts like that, as we have the UI Automator Viewer. This tool basically walks the view hierarchy of whatever activity is in the foreground of a device (or emulator) and gives us access to whatever information is exposed by the accessibility APIs. Nowadays, this includes widget IDs, in addition to more traditional accessibility data like the text in a `TextView`, the `contentDescription` of an `ImageView`, and so on.

At the present time, the UI Automator Viewer is not integrated into Android Studio, Eclipse, or the Android Device Monitor GUIs. Instead, you will have to launch it the old-fashioned way, by running the `uiautomatorviewer` command from the command line. This will map to a batch file or shell script in the `tools/` directory of your Android SDK installation.

When initially launched, the UI Automator Viewer does not look like much:

TESTING WITH UI AUTOMATOR

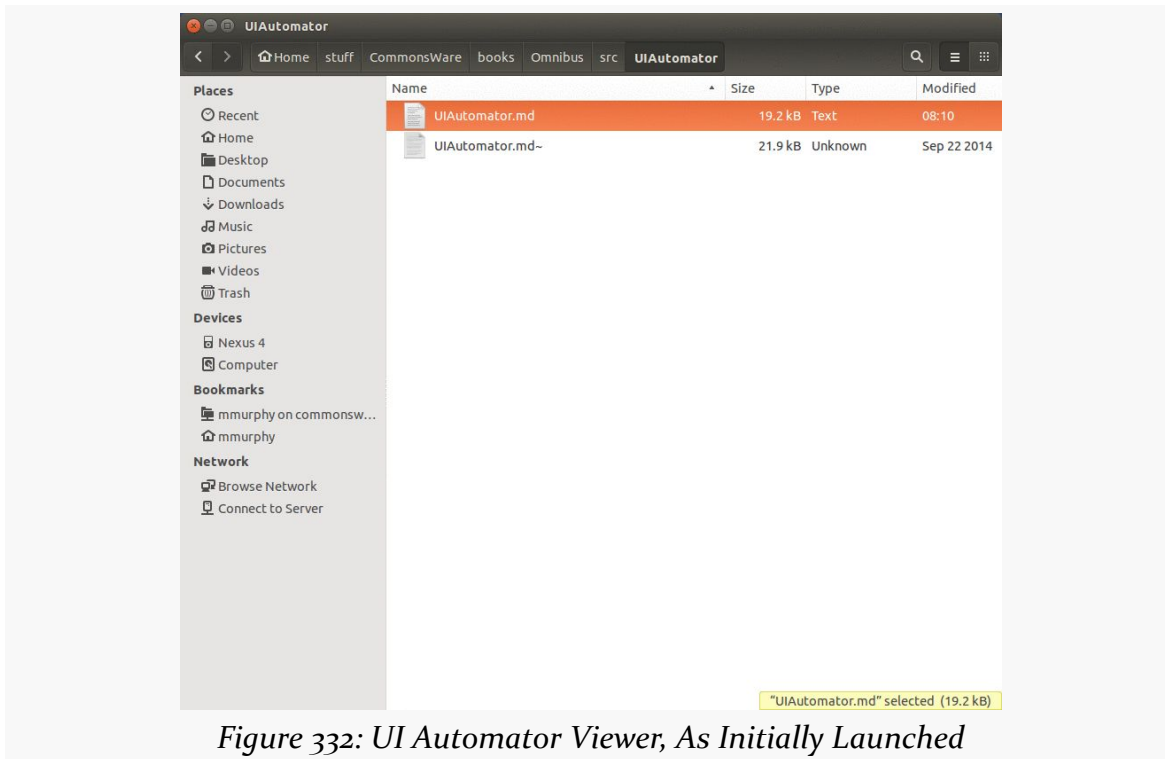

Figure 332: UI Automator Viewer, As Initially Launched

Given that you have a device or emulator ready, you can click the second icon from the left in the toolbar, to capture the view hierarchy of the foreground activity. This will give you:

- A screenshot of the foreground activity in the main area of the UI Automator Viewer screen
- The view hierarchy of that activity, in the upper-right corner of the UI Automator Viewer screen
- Properties of a node from the selected view, in the lower-right corner of the UI Automator Viewer screen

TESTING WITH UI AUTOMATOR

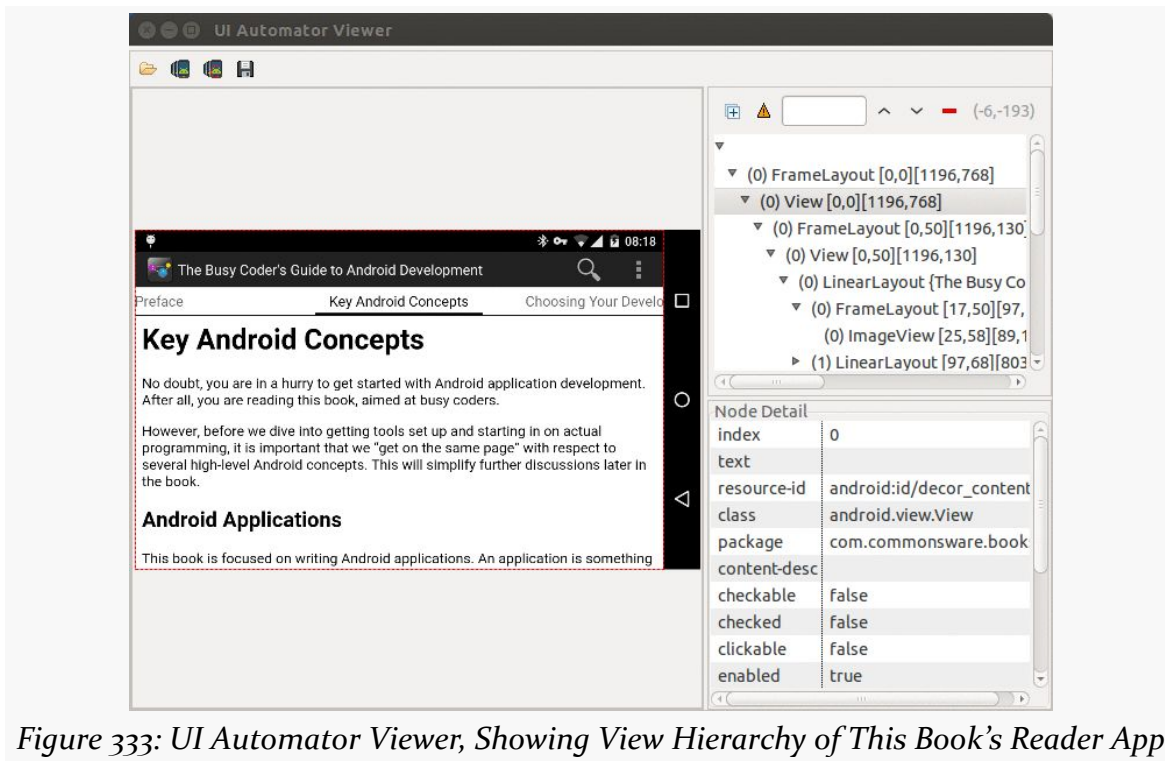

Figure 333: UI Automator Viewer, Showing View Hierarchy of This Book's Reader App

Clicking either on the preview or on the view hierarchy will change the selected view, which shows up with a red dashed outline on the preview. The properties ("Node Detail") pane will then update to show the properties of whatever is newly selected.

Trail: Advanced UI

Notifications

Pop-up messages. Tray icons and their associated “bubble” messages. Bouncing dock icons. You are no doubt used to programs trying to get your attention, sometimes for good reason.

Your phone also probably chirps at you for more than just incoming calls: low battery, alarm clocks, appointment notifications, incoming text message or email, etc.

Not surprisingly, Android has a whole framework for dealing with these sorts of things, collectively called “notifications”.

What’s a Notification?

A service, running in the background, needs a way to let users know something of interest has occurred, such as when email has been received. Moreover, the service may need some way to steer the user to an activity where they can act upon the event — reading a received message, for example. For this, Android supplies status bar icons, flashing lights, and other indicators collectively known as “notifications”.

Your current phone may well have such icons, to indicate battery life, signal strength, whether Bluetooth is enabled, and the like. With Android, applications can add their own status bar icons, with an eye towards having them appear only when needed (e.g., a message has arrived).

Notifications will appear in one of two places. On most devices, they will appear in the status bar, on the top of the screen, left-aligned:

NOTIFICATIONS

On a pre-Android 4.2 tablet (and occasionally on other tablets newer than that), they will appear in the system bar, on the bottom of the screen, towards the lower-right corner:

In either case, you can expand the “notification drawer” to get more details about the active notifications, either by sliding down the status bar:

NOTIFICATIONS

Figure 336: Notification Drawer, on a Galaxy Nexus

or by tapping on the clock on the system bar on some tablets:

Figure 337: Notification Drawer, on a Galaxy Tab 2

Some notifications will be complex, showing real-time information, such as the progress of a long download. More often, notifications are fairly simple, providing just a couple of lines of information, plus an identifying icon. Tapping on the notification drawer entry will typically trigger some action, such as starting an activity — an email app letting the user know that “you’ve got mail” can have its notification bring up the inbox activity when tapped.

Showing a Simple Notification

Suppose we want to download a file. That may take some time, depending on the size of the file. It would be nice to let the user know when the download has been completed. Ideally, we would let the user know by some means other than popping up a Toast. If we are having a service download the file — which is a good idea for longer downloads — there is the possibility that our UI is no longer in the foreground at the time the download is done, so we cannot necessarily update the UI to let the user know the file is ready for use.

An alternative would be for the background service doing the download to raise a Notification when the download is complete. That would work even if the activity was no longer around (e.g., user pressed BACK to exit it). This can be seen in the [Notifications/DownloadNotify](#) sample project. This is a slightly modified clone of the download-a-PDF-file sample from [the chapter on services](#).

Our DownloadFragment for triggering the download dispenses with the BroadcastReceiver and logic related to it, including disabling and enabling the Button. Otherwise, it is the same as before.

The download logic in the `onHandleIntent()` method of `Downloader` is nearly identical as well, with two changes.

One change is that we pull out the MIME type of the response from its response header:

```
URL url=new URL(i.getData().toString());
URLConnection c=(URLConnection)url.openConnection();
FileOutputStream fos=new FileOutputStream(output.getPath());
BufferedOutputStream out=new BufferedOutputStream(fos);
String mimeType=c.getHeaderField("Content-type");
```

The other difference is that at the end, rather than sending a broadcast Intent, we call a private `raiseNotification()` method. We also call this method if there is an exception during the download. The `raiseNotification()` method takes the MIME

NOTIFICATIONS

type that we collected earlier, the File object representing the downloaded results (if we succeeded), and the Exception that was raised (if we crashed). As one might guess given the method's name, raiseNotification() will raise a Notification:

```
private void raiseNotification(String mimeType, File output,
                               Exception e) {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true).setDefaults(Notification.DEFAULT_ALL);

    if (e == null) {
        b.setTitle(getString(R.string.download_complete))
        .setContentText(getString(R.string.fun))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setTicker(getString(R.string.download_complete));

        Intent outbound=new Intent(Intent.ACTION_VIEW);

        outbound.setDataAndType(Uri.fromFile(output), mimeType);

        b.setContentIntent(PendingIntent.getActivity(this, 0, outbound, 0));
    }
    else {
        b.setTitle(getString(R.string.exception))
        .setContentText(e.getMessage())
        .setSmallIcon(android.R.drawable.stat_notify_error)
        .setTicker(getString(R.string.exception));
    }

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());
}
```

The first thing we do in raiseNotification() is create a Builder object to help construct the Notification. On API Level 11 and higher, there is a Notification.Builder class that you can use.

However, the notification system in Android has been changing frequently over the past few OS updates, and there are signs that this will continue. Hence, you may prefer to use NotificationCompat.Builder. First, this will work back to API Level 4, in case you are supporting notifications on older devices. More importantly, NotificationCompat.Builder is updated to reflect the latest Notification.Builder API, offering a backwards-compatible implementation of that API. Some newer features are not supported on older devices, but the NotificationCompat.Builder API lets you code to the new API, and it quietly ignores things that cannot be done on older devices.

NOTIFICATIONS

We can call methods on the `Builder` to configure the `Notification` that we want to display. Whether our download succeeded or failed, we use various methods on `Builder`:

- `setAutoCancel(true)` means that when the user slides open the notification drawer and taps on our entry, the `Notification` is automatically canceled and goes away
- `setDefaults(Notification.DEFAULT_ALL)` means that we want the device's standard notification tone, LED light flash, and vibration to occur when the `Notification` is displayed

If we succeeded (the passed-in `Exception` is `null`), we further configure our `Notification` via more calls to the `Builder`:

- `setContentTitle()` and `setContentText()` supply the prose to display in the two lines of the notification drawer entry for our `Notification`
- `setSmallIcon()` indicates the icon to display in the status bar or system bar when the `Notification` is active (in this case, specifying one supplied by Android itself)
- `setTicker()` supplies some text to be displayed in the status bar or system bar for a few seconds right when the `Notification` is displayed, so users who happen to be looking at their device at that time will get more information at a glance about what just happened that is demanding their attention

In addition, `setContentIntent()` supplies a `PendingIntent` to be invoked when the notification drawer entry for our `Notification` is tapped. In our case, we create an `ACTION_VIEW` `Intent` for our `File` (using `Uri.fromFile()` to get a `Uri` pointing to our file on external storage) with the `MIME` type supplied by the Web server. Hence, if the user taps on our notification drawer entry, we will attempt to bring up a PDF viewer on the downloaded PDF file – whether this will succeed or not will depend upon whether there is a PDF viewer installed on the device.

If, instead, we did have an `Exception`, we use the same methods on `Builder` (minus `setContentIntent()`) to configure the `Notification`, but using different text and icons.

To actually display the `Notification`, we need to get a `NotificationManager`, which is another system service. Calling `getSystemService()` and asking for the `NOTIFICATION_SERVICE` will give us our `NotificationManager`, albeit after a cast. Then, we can call `notify()` on the `NotificationManager`, supplying our `Notification` (from `build()` on the `Builder`) and a locally-unique integer

NOTIFICATIONS

(NOTIFY_ID, defined as a static data member on the service). That integer can later be used with a `cancel()` method to remove the Notification from the screen, even if the user has not canceled it themselves (e.g., via tapping on it with `setAutoCancel(true)`).

NOTE: You may see some samples using `getNotification()` with `NotificationBuilder` instead of `build()`. `getNotification()` was the original method, but it has since been deprecated in favor of `build()`.

Also, because we are using `setDefaults(Notification.DEFAULT_ALL)`, and since the default behavior for a Notification may involve vibrating the phone, we need to hold the VIBRATE permission in the manifest:

```
<uses-permission android:name="android.permission.VIBRATE"/>
```

Note that as of Android 4.4, you no longer need the VIBRATE permission, if you are using `DEFAULT_ALL` or `DEFAULT_VIBRATE` for `setDefaults()`. If you specify a custom vibration pattern, via `setVibrate()`, you still need the VIBRATE permission.

Running this in a device or emulator will display the Notification upon completion of the download:

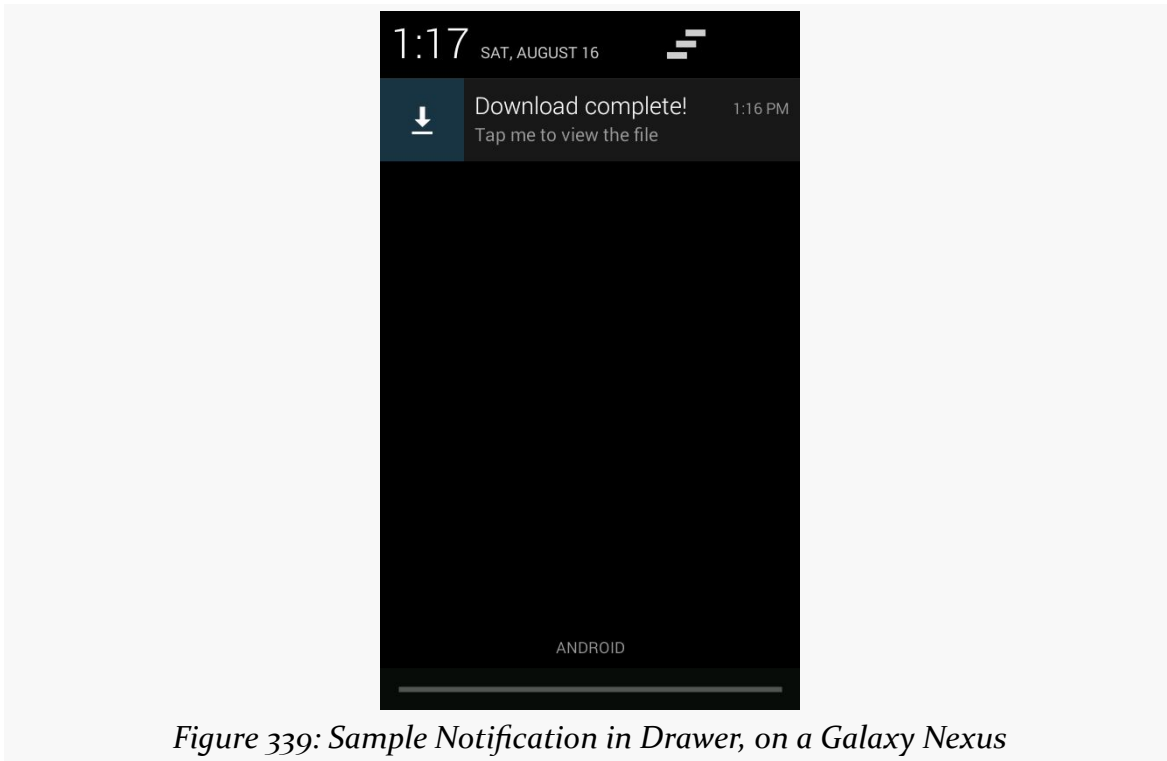

Figure 338: Sample Notification, on Android 4.4

Opening the notification drawer displays our Notification details:

Tapping on the drawer entry will try to start a PDF viewer, perhaps bringing up a chooser if there are multiple such viewers on the device. Also, tapping on the drawer entry will cancel the Notification and remove it from the screen.

The Activity-Or-Notification Scenario

Let us suppose that you are writing an email app. In addition to an “inbox” activity, you have an `IntentService`, scheduled via `AlarmManager`, to go check for new email messages every so often. This means, when your service discovers and downloads new messages, there are two possibilities:

- The user has your inbox activity in the foreground, and that activity should update to reflect the fact that there are new messages
- The user does *not* have your inbox activity in the foreground, so you want to display a Notification to alert the user of the new messages and lead them back to the inbox

However, ideally, the service neither knows nor cares whether the inbox activity is in the foreground, exists in the process but is not in the foreground, or does not exist

in the process (e.g., Android started a new process to handle this middle-of-the-night check for new email messages).

One way to handle this is via an event bus.

The recipe for the Activity-or-Notification pattern is:

1. Define an event (e.g., event class for greenrobot's EventBus, custom action string for LocalBroadcastManager)
2. Have your activity or fragment register to respond to these events while in the foreground (e.g., in `onResume()`) and unregister when leaving the foreground (e.g., `onPause()`). The activity or fragment can then update the UI in response to the event.
3. The service raises the event bus event at appropriate times.
4. By some means appropriate to the event bus implementation, the service needs to know whether an activity or fragment responded to the event, so it can raise a Notification if the event has not already been handled.

We will see three implementations of this pattern [in the chapter on event bus alternatives](#).

Big (and Rich) Notifications

Android 4.1 introduced new Notification styles that automatically expand into a “big” area when they are the top Notification in the drawer. These expanded Notifications can display more text (or a larger thumbnail of an image), plus add some action buttons to allow the user to directly perform more actions straight from the Notification itself.

And while these new Notification styles are only available on API Level 16 and higher, a familiar face has created a compatibility layer so our code can request the larger styles and still work on older devices.

The Styles

There are three main styles supplied for expanded Notifications. There is the BigText style:

NOTIFICATIONS

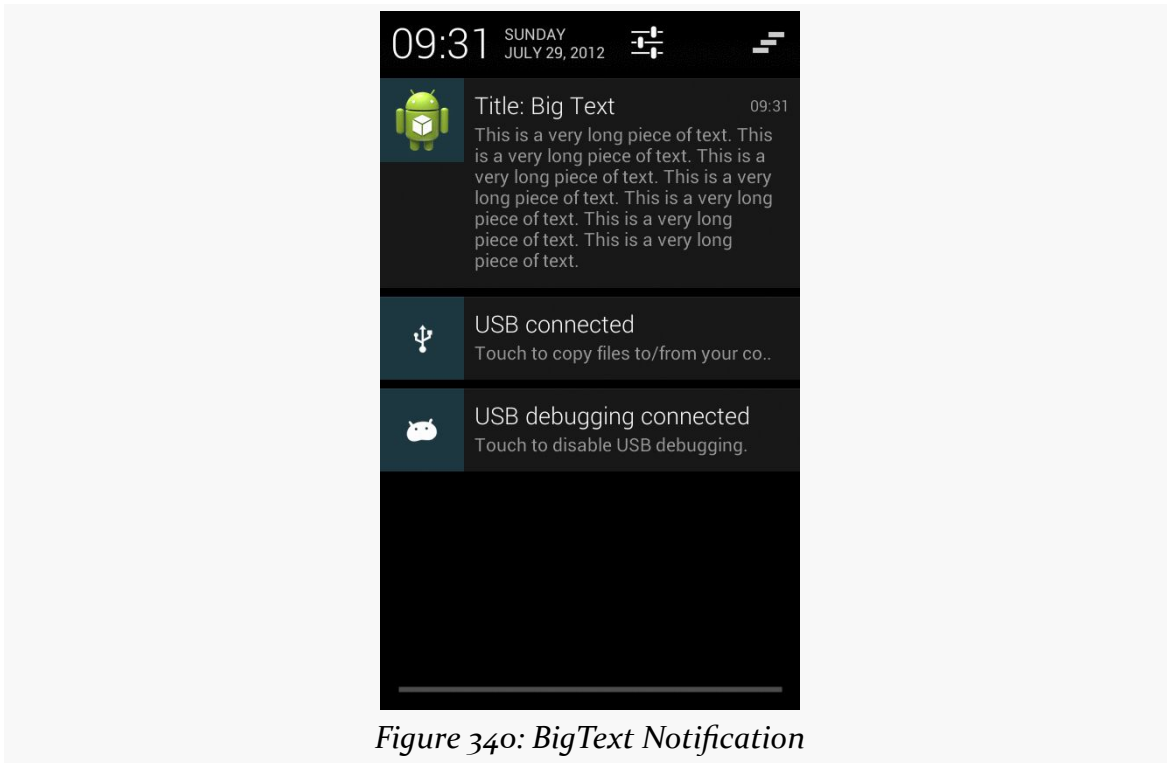

Figure 340: BigText Notification

We also have the Inbox style, which is the same basic concept but designed, for several discrete lines of text:

NOTIFICATIONS

And, we have the BigPicture style, ideal for a photo, album cover, or the like:

NOTIFICATIONS

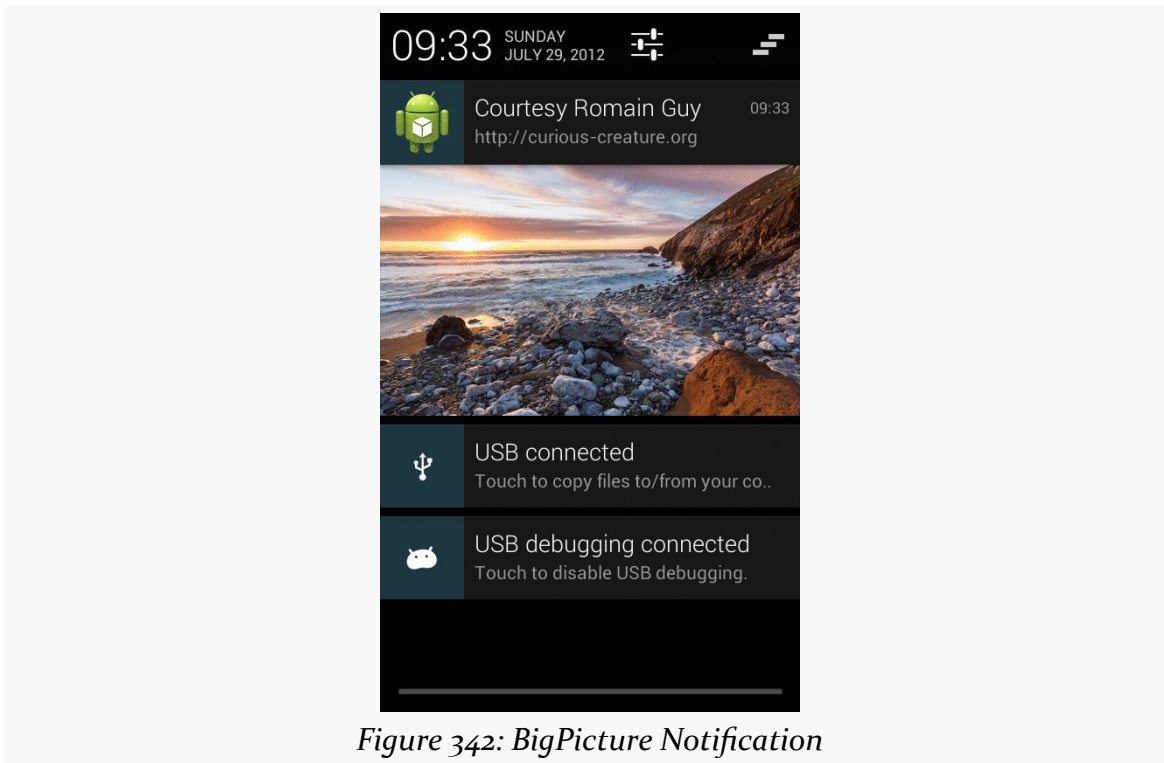

Figure 342: BigPicture Notification

(as noted in the screenshot, the photo is courtesy of Romain Guy, a former engineer on the core Android team and photography buff)

The Builders

`Notification.Builder` and `NotificationCompat.Builder` have been enhanced to support these new styles. Specifically:

- There is an `addAction()` method on the `Builder` class to define the action buttons, in terms of icon, caption, and `PendingIntent` that should be executed when the button is clicked
- There are style-specific builders, such as `Notification.InboxStyle`, that take a `Notification.Builder` and define the alternative expanded definition to be used when the `Notification` is at the top

The Sample

To see expanded notifications, take a peek at the [Notifications/BigNotify](#) sample application. This application consists of a single activity (`MainActivity`) that will raise a `Notification` and `finish()`, using `@style/Theme.NoDisplay` to suppress the

NOTIFICATIONS

activity's own UI. Hence, the result of running the app is to display the Notification and do nothing else. While silly, it minimizes the amount of ancillary code involved in the project.

The process of displaying an expanded Notification is to first create the basic Notification, containing what you want to display for any non-expanded circumstance:

- Older devices that cannot display expanded Notifications, or
- Newer devices where the Notification is not the top-most entry in the notification drawer, and therefore appears in the classic non-expanded form

Hence, in `onCreate()`, after getting our hands on a `NotificationManager`, we use `NotificationCompat.Builder` to create a regular Notification, wrapped in a private `buildNormal()` method:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setTitle(getString(R.string.download_complete))
      .setText(getString(R.string.fun))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setPriority(Notification.PRIORITY_HIGH)
      .addAction(android.R.drawable.ic_media_play,
                 getString(R.string.play),
                 buildPendingIntent(Settings.ACTION_SETTINGS));

    return(b);
}
```

Most of what `buildNormal()` does is the same sort of stuff we saw with `NotificationCompat.Builder` earlier in this chapter. There are two things, though, that are new:

1. We call `setPriority()` to set the priority of the Notification to `PRIORITY_HIGH`. This means that this Notification *may* be displayed higher in the notification drawer than it might ordinarily appear.
2. We call `addAction()` to add an action button to the Notification, to be shown in the expanded form. We are able to supply an icon, caption, and `PendingIntent`, the latter created by a `buildPendingIntent()` method that wraps our desired Intent action string (here, `Settings.ACTION_SETTINGS`) in an Intent:

NOTIFICATIONS

```
private PendingIntent buildPendingIntent(String action) {
    Intent i=new Intent(action);

    return(PendingIntent.getActivity(this, 0, i, 0));
}
```

Ordinarily, we might use this Builder directly, to raise the Notification we described. And, if we just wanted the action button to appear and nothing else new in the expanded form, we could do just that. But in our case, we also want to change the look of the expanded widget to a new style, `InboxStyle`. To do that, we need to wrap our Builder in a `NotificationCompat.InboxStyle` builder:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle(normal);

    mgr.notify(NOTIFY_ID,
        big.setSummaryText(getString(R.string.summary))
            .addLine(getString(R.string.entry))
            .addLine(getString(R.string.another_entry))
            .addLine(getString(R.string.third_entry))
            .addLine(getString(R.string.yet_another_entry))
            .addLine(getString(R.string.low)).build());

    finish();
}
```

Each of these “big” builders has a set of methods that are unique to that type of builder to configure the look beyond what a standard Notification might have. Specifically, in this case, we call:

- `setSummaryText()`, to provide “the first line of text after the detail section in the big form of the template”, in the words of the JavaDocs, though this does not necessarily mean what you think it does
- `addLine()`, to append several lines of text to appear in the Notification

It is the Notification created by our `NotificationCompat.InboxStyle` builder that we use with the call to `notify()` on `NotificationManager`.

The Results

If we run our app, we get this:

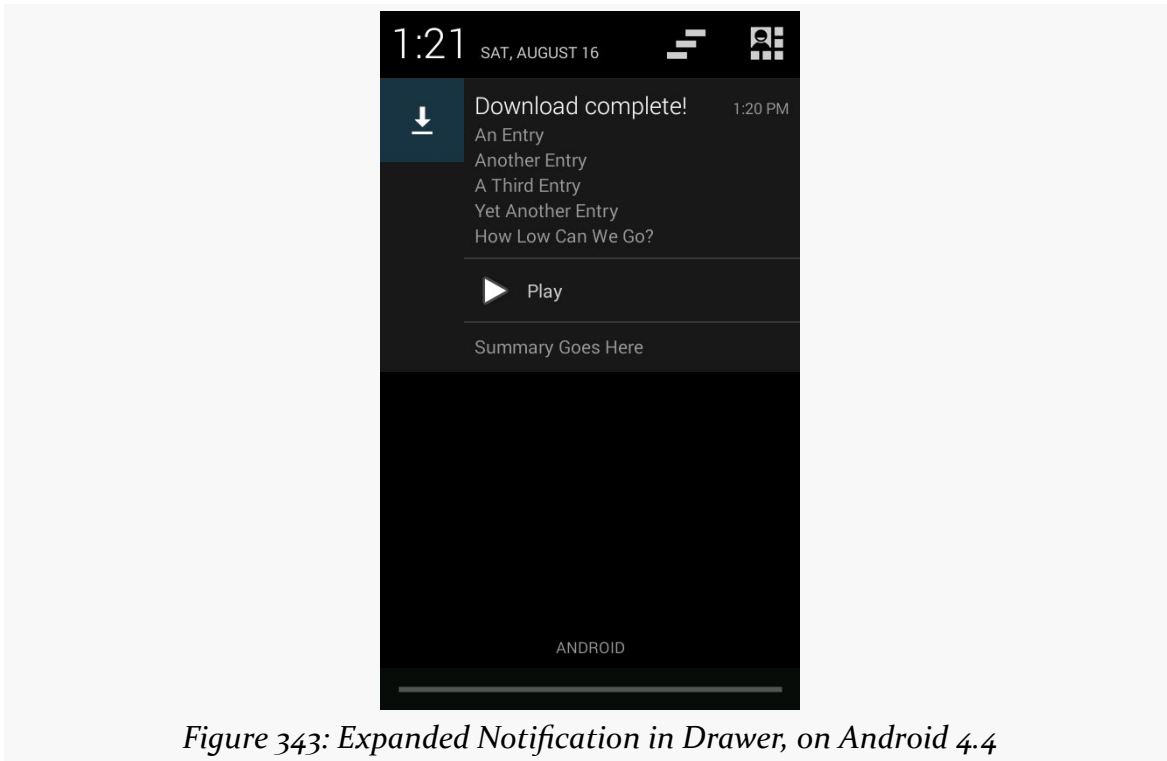

Figure 343: Expanded Notification in Drawer, on Android 4.4

From top to bottom, we have:

- Our content text
- Our appended lines of text
- Our action button
- Our summary text

Note that this is the appearance when we are in expanded mode, at the top of the notification drawer. If our Notification is not at the top, or if it is displayed on a pre-4.1 device, the appearance is the normal style, as defined by our `buildNormal()` method, though on Android 4.1+ devices the user can use a two-finger downward swipe gesture to expand the un-expanded Notification.

The Target Requirement

Note that to use action buttons successfully, you need to have your `android:targetSdkVersion` set to 11 or higher. Technically, they will work with lower values, but the contents of the button will be rendered incorrectly, with a gray-on-gray color scheme that makes the buttons all but unreadable. Using 11 or higher will cause the buttons to be rendered with an appropriate color scheme.

Foreground Services

If you have a service that will run for a substantial period of time, there is a risk that your process will still be terminated. That could be triggered by the user, or it could be the OS's own decision, based on the age of your process.

Generally speaking, this is a good thing for the user, because too many developers “leak” services, causing them to run unnecessarily, without adding value to the user, and tying up system RAM as a result.

But, what about services that *are* delivering value to the user for a long period? For example, what about a music player, where, in theory, the service is delivering value until the user presses some sort of “stop” button somewhere to turn off the music?

For those sorts of situations, you can flag a service as being a “foreground service”.

Isn't “Foreground Service” an Oxymoron?

You might be forgiven for thinking that “foreground” and “service” are not designed to go together.

Partly, that is because we have overloaded the term “foreground”.

A foreground service is *not* one that somehow takes over the screen. A foreground service *is* one that runs with foreground priority. That means:

- It will be treated similarly to the app that is in the UI foreground, from the standpoint of determining processes eligible for termination
- It will be classified as foreground from a CPU standpoint, rather than being relegated to the standard background process group

The former is what many developers want: a service (and process) that will not go away.

The latter is what many users fear: a service (and process) that is capable of stealing chunks of CPU time away from the game, video, or whatever else is truly in the foreground from a UI standpoint.

Services themselves, while useful, are best when used *sparingly*, only running when they are actively delivering value to the user. “This goes double” for foreground services.

Putting Your Service in the Foreground

Putting a service into the foreground is a matter of calling `startForeground()`. This method takes two parameters, the same two parameters that you would pass to `notify()` of `NotificationManager`:

- A prepared `Notification`
- A unique ID for that `Notification`

Android will then display the `Notification`. So long as the `Notification` is visible, your app’s process will be given foreground priority.

You undo this by calling `stopForeground()`. `stopForeground()` takes a boolean parameter, indicating if the `Notification` should be removed (`true`) or not (`false`). Typically, you will pass `true`, so the `Notification` only clutters up the screen while you need it.

The [Notifications/Foreground](#) sample project is a clone of the `Notifications/DownloadNotify` sample that opened this chapter, adding in the use of `startForeground()` and `stopForeground()`.

Towards the top of `onHandleIntent()`, we call `startForeground()`, to *really* ensure that our process will remain intact long enough to complete the requested download:

```
startForeground(FOREGROUND_ID,
               buildForegroundNotification(filename));
```

This, in turn, uses a `buildForegroundNotification()` method to build the `Notification` that will be displayed while the service is categorized as being in the foreground:

```
private Notification buildForegroundNotification(String filename) {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setOngoing(true);

    b.setContentTitle(getString(R.string.downloading))
      .setContentText(filename)
      .setSmallIcon(android.R.drawable.stat_sys_download)
```

NOTIFICATIONS

```
.setTicker(getString(R.string.downloading));  
return(b.build());  
}
```

Note that we use `setOngoing(true)`, to indicate that this is an “ongoing” operation. This precludes the user from removing the `Notification` manually, as doing that would drop our process out of foreground priority.

Towards the end of `onHandleIntent()`, we call `stopForeground()`, before calling `raiseNotification()`:

```
stopForeground(true);  
raiseNotification(i, output, null);
```

There is a similar `stopForeground()` call in the catch block that raises the failure `Notification` in case of an I/O error.

In both cases, we pass `true` to `stopForeground()` to remove the `Notification`. From the user’s perspective, we could just as easily have passed `false`, as the `Notification` used with `startForeground()` will also be removed once our service is destroyed, which will happen shortly after `onHandleIntent()` ends.

If you want to update the foreground `Notification`, you can either:

- Call `notify()` again with the same notification ID and a fresh `Notification`, as you would use to update any `Notification`, or
- Simply call `startForeground()` again, with the same notification ID and a fresh `Notification`

We will see this particular practice in use later in the book, where we use a foreground service’s `Notification` to control [recording a screencast of an Android device](#).

The Malformed Notification

Of course, some developers do not play nicely with the other kids.

A technique that had been around for a while was for an app to pass an intentionally-flawed `Notification` to `startForeground()`. While Android would blow up silently somewhere internally actually trying to display the `Notification`, the foreground status was still granted. This resulted in behavior reminiscent of the long-since-deprecated `setForeground()` method.

NOTIFICATIONS

`setForeground()` allowed a service to get foreground priority with no repercussions. Not surprisingly, lots of developers used it, as they decided that their app was more important than any other apps on the device. `setForeground()` was replaced by `startForeground()`, adding in the `Notification` requirement, to put a “cost” on foreground status. The malformed-`Notification` trick allowed developers to avoid that cost.

In Android 4.3, if you pass a malformed `Notification` to `startForeground()`, Android will create one for you, featuring your app’s launcher icon, and use it instead. Hence, on Android 4.3 and higher, you cannot hide your foreground status from the user.

Needless to say, when this behavior was mentioned in [a Google+ post by Dianne Hackborn](#), a number of developers complained.

That being said, if you were using this hack, you will really need to consider alternative strategies, as users do get irritated with everlasting services when they are made aware of them:

- If you were using a foreground service to fix some bug in your app caused by your process being terminated and later restarted (e.g., `START_STICKY`), fix the bug.
- Consider making foreground behavior optional. Since the decision of marking a service as a foreground service is made in Java, not the manifest, it is relatively easy for you to add a checkbox to your app settings to allow the user to indicate whether the benefits of foreground-ness are worth the cost of having the `Notification` around.
- Consider making the service optional, if the foreground status is needed for the service to be useful, but the features enabled by the service itself are not absolutely essential.
- There is no need to have more than one simultaneous foreground service. One service can have multiple threads to do disparate operations.

Disabled Notifications

Because apps have the ability to display larger-than-normal `Notifications`, plus force them towards the top of the list via priority levels, Android has given users the ability to disable `Notifications` on a per-app basis. The degree of control, and the way the user sets up that control, depends upon Android version.

Android 4.x

Users visiting an app's page in Settings will see a "Show notifications" checkbox:

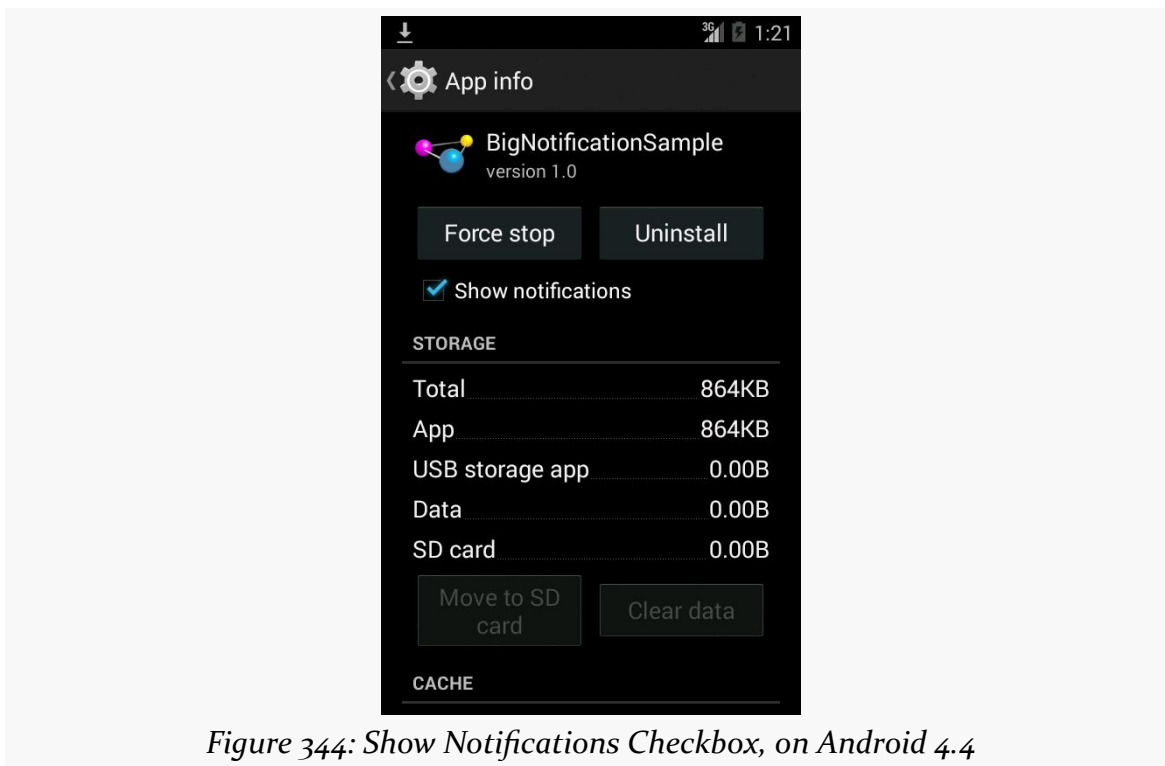

Figure 344: Show Notifications Checkbox, on Android 4.4

If the user unchecks the checkbox and agrees on the resulting confirmation dialog, your requests to raise a Notification will be largely ignored. An error message will appear in LogCat ("Suppressing notification from package ... by user request"), but no exception will be raised. Further, there does not appear to be an API for you to determine if the notification will actually be displayed.

Also note that, on Android 4.2+, if the user blocks notifications, it also blocks Toast requests from your app.

And, also note that this setting survives an uninstall of your app. If the user unchecks this checkbox, uninstalls your app, then reinstalls your app, the checkbox is still unchecked, meaning that notifications will still be blocked.

The one notable exception to this blocking, as of Android 4.3, is that the Notification associated with a foreground service will not be blocked. It will always appear, even if the user unchecked "Show notifications" for your app in Settings.

Android 5.0+

In the “Sound & notification” area of Settings, the user can tap on an “App notifications” option, and from there choose an app. This brings up a screen where the user can “block” (i.e., disable) notifications:

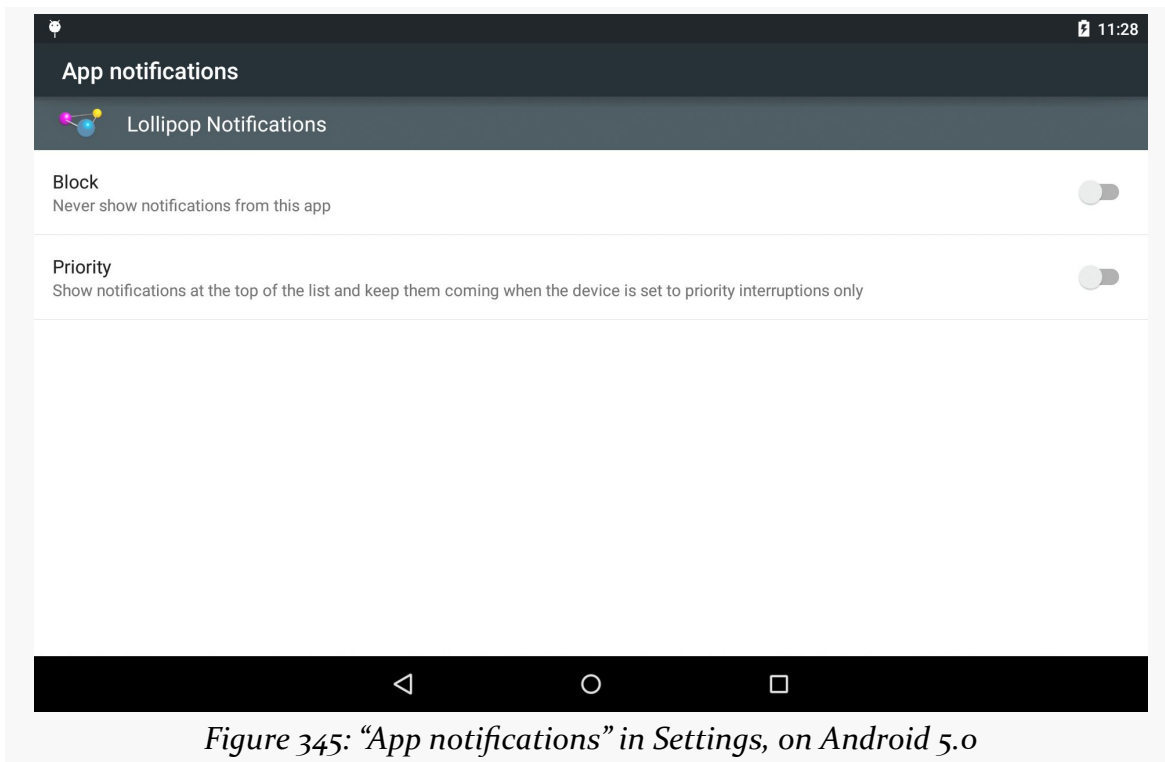

Figure 345: “App notifications” in Settings, on Android 5.0

The top “Block” SwitchPreference, if toggled on, will prevent app notifications from being displayed.

The bottom “Priority” SwitchPreference, if toggled on, marks this app’s notifications as being “priority”. Then, in the main “Sound & notification” area of Settings, the user can tap on an “Interruptions” option:

NOTIFICATIONS

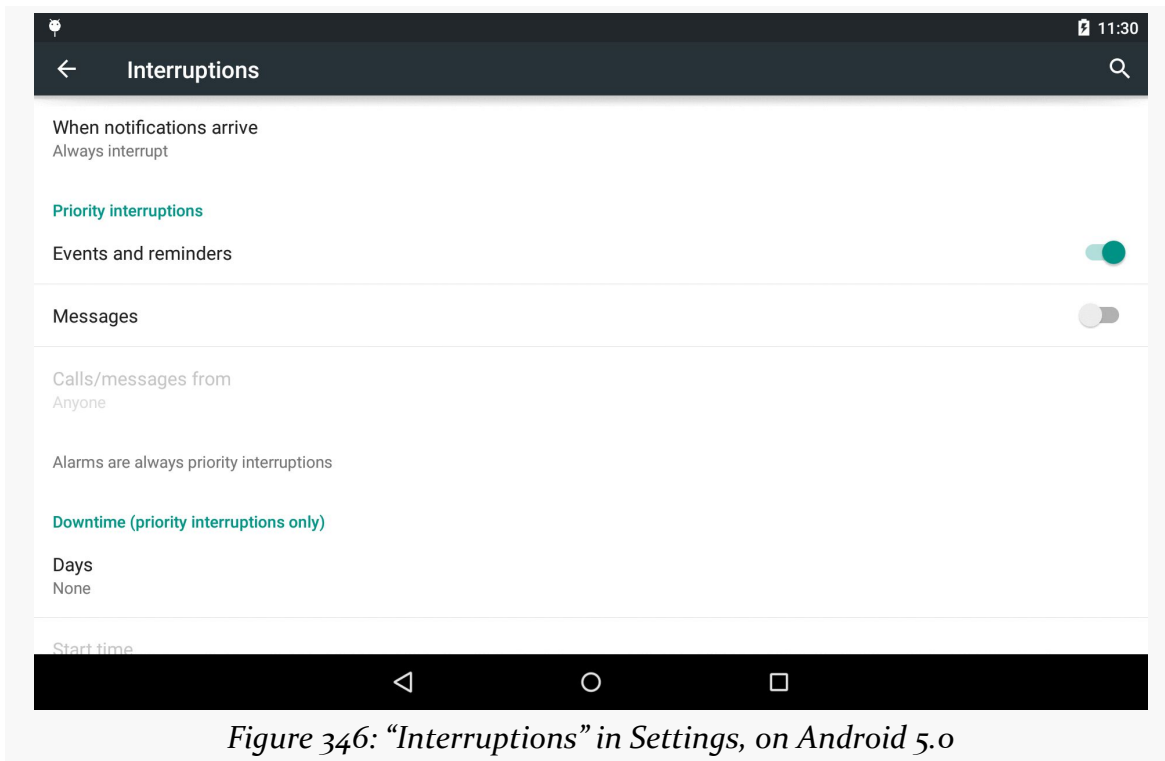

Figure 346: “Interruptions” in Settings, on Android 5.0

If the user toggles the “When notifications arrive” option to “Allow only priority interruptions”, then those apps that the user configures as “Priority” in “App notifications” will behave normally. Other apps’ notifications will appear, but will not play a ringtone or vibrate the device.

If the user toggles the “When notifications arrive” option to “Don’t interrupt”, all notifications — even those marked as “Priority” — will have their ringtones and vibrations suppressed.

Advanced Notifications

Notifications are those icons that appear in the status bar (or system bar on tablets), typically to alert the user of something that is going on in the background or has completed in the background. Many apps use them, to let the user know of new email messages, calendar reminders, and so on. Foreground services, such as music players, also use notifications, to tell the OS that they are part of the foreground user experience and to let the user rapidly return to the apps to turn the music off.

There are other tricks available with the Notification object beyond those originally discussed [in an earlier chapter](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on basic notifications](#) and [the section on RemoteViews](#) in [the chapter on basic app widgets](#).

Being a Good Citizen

Users have a love/hate relationship with apps that use notifications:

- They love apps that raise notifications for events that the user cares about...
- ...but they hate apps that raise notifications for events that the user does not care about (e.g., Evernote’s “please confirm your email” notifications)
- They love apps that provide control over when and how notifications appear...
- ...but they hate apps that display notifications solely because the developer wanted them (e.g., ads in notifications)

ADVANCED NOTIFICATIONS

- They love apps that use notifications to let the user control some background operation, like media playback...
- ...but they hate apps that have ongoing notifications for no obvious reason (e.g., developers trying to use a foreground service to keep their process around, rather than using `AlarmManager`, `JobScheduler`, or other means of doing work periodically)
- They love apps that set up notifications for use in different scenarios, such as supporting Android Wear devices...
- ...but they hate apps that wind up flooding their wrist (or eyes, or other wearable locations) with notifications that have to be individually dismissed

And so on.

Users' discomfort with how apps handle notifications is why Android allows users to [disable notifications](#).

Some of the items in this chapter, particularly those surrounding Android Wear, can help you improve user satisfaction with your notification strategy and tactics. Yet, at the same time, misuse of notifications is magnified by Wear, as Wear takes extra steps to get the user to pay attention to the notifications, with possibly disastrous results for your Play Store reviews.

In short, your objective with notifications is to be a good citizen:

- Have a reasonable default mode for your notifications
- Allow users to tailor that mode to better suit their needs, where practical

Wear? There!

The humble `Notification` has been steadily advancing over the past few years, with “big” styles and the like adding new capabilities for newer devices.

Android Wear takes notifications to a new level, by having the notification not only appear on the user's device, but also on wearables connected to that device.

The good news is that this works “out of the box”. There is nothing you absolutely need to do in your app to get your notifications to appear on a Wear device.

ADVANCED NOTIFICATIONS

The bad news is that the “out of the box” experience may be poor, as a Notification approach that is fine for devices that reside in pockets and backpacks might be inappropriate for wrists and eyes.

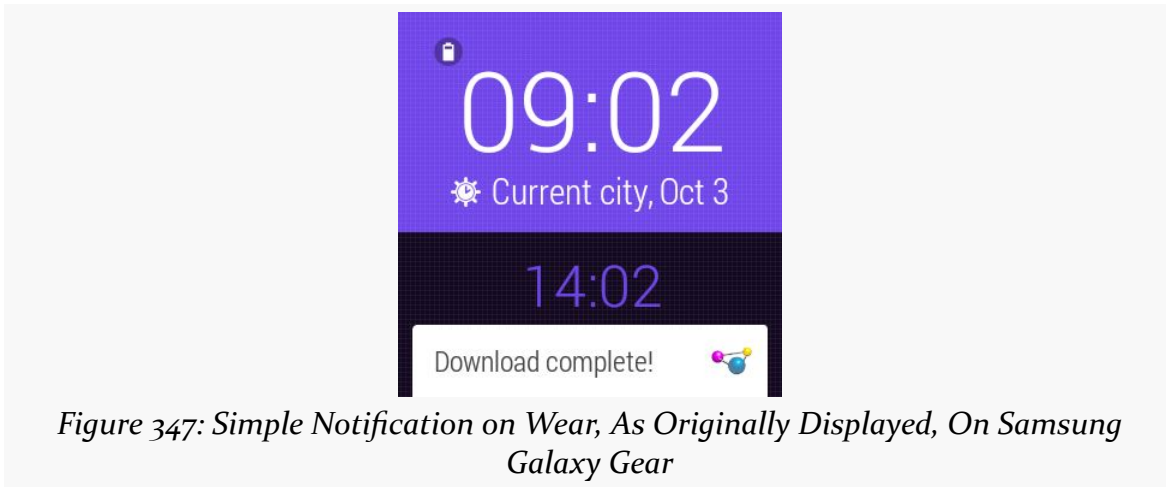

With that in mind, let’s see what some notification samples from earlier in the book behave like when they are run on a phone connected to a Wear device.

NOTE: For this section, and the rest of this chapter, “primary device” will refer to the user’s phone or tablet that the “Wear device” will be connected to.

Simple Notification

The [Notifications/DownloadNotify](#) sample project allows the user to download a PDF file, raising a Notification when that download is complete.

With a Wear device paired with the phone, the Notification also appears on the device, first as a “mini card”:

Swiping up on that will bring up the full card:

Swiping to the right will bring up the action associated with `setContentIntent()` on the `NotificationCompat.Builder`:

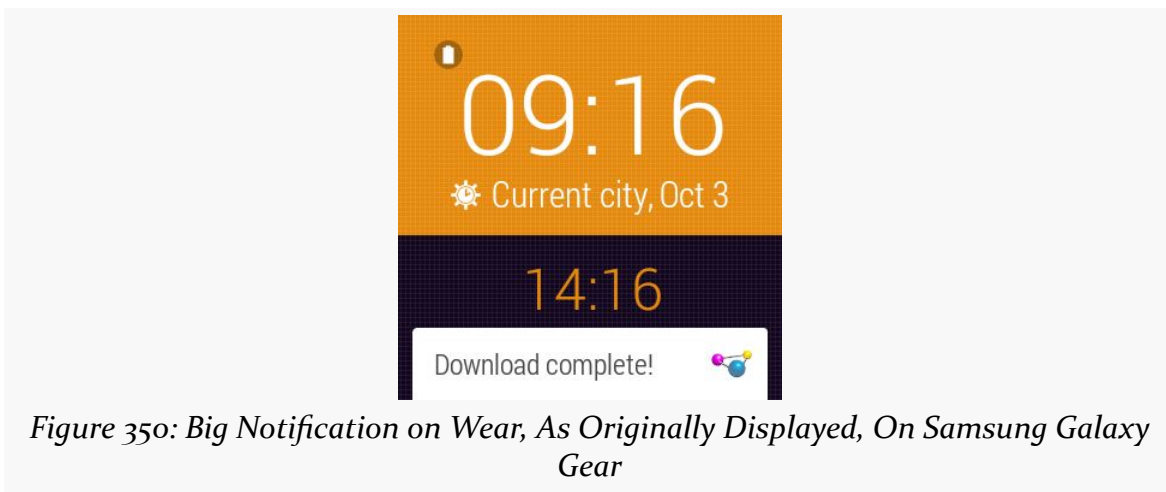

Tapping on that dismisses the Notification on the Wear device and the primary device, plus it invokes the `PendingIntent` on the phone itself (in this case, opening up the PDF file).

This is a fine example of a Notification that perhaps should *not* appear on the Wear device. The fact that the download completed is interesting but not all that important. Furthermore, the user cannot do anything about this download other than to pull out the primary device to see the PDF. Low-priority primary-device-centric notifications generally should be shown on the primary device alone, not on the Wear device. We will see how to do that [later in this chapter](#).

“Big” Style and Action Button

The [Notifications/BigNotify](#) sample application wrapped a regular Notification in a NotificationCompat.InboxStyle “big” Notification, one with both a regular action and a separate “Play” action button.

As before, with a Wear device paired with the phone, the Notification also appears on the device, first as a “mini card”:

However, this time, when the user swipes up to show the full card, it is the InboxStyle version that appears, albeit without the summary text:

Swiping to the right shows our actions, starting with the custom “Play” action:

...followed by the default action:

Tapping on either action will cause the primary device to invoke its `PendingIntent`, but only the default action dismisses the `Notification` from both devices. The custom “Play” action does not.

Foreground Service

The [Notifications/Foreground](#) sample project is another version of the download-the-file sample, but this time uses a `Notification` and `startForeground()` to mark the service as a foreground service while it is downloading things.

This particular sample does not spend much time in the foreground state, so for testing purposes, you may want to add a `SystemClock.sleep()` call to the service,

between the `startForeground()` and `stopForeground()` calls, to better examine the behavior while the foreground service `Notification` is around.

However, in truth, that modification is probably not necessary... as the foreground service `Notification` is not displayed on the Wear device, only on the primary device. This is by design. The expectation is that you would use a Wear app to control your service from the Wear device, not some un-dismissable card.

Stacking Notifications

If you are writing an email client, and you want to use a `Notification` to let the user know about new email messages, you do *not* want to raise a separate `Notification` for each email. Users will come to your home with pitchforks and torches... and not to help you with farming.

Instead, the vision is that you update an existing `Notification` with new content. For example, you might start with a regular `Notification` for the first received email. Then, when the second one comes in, you replace that `Notification` with one that has a simple summary (“2 messages are in your inbox!”), plus perhaps an `InboxStyle` “big” `Notification` variant that could show the subject lines for both of those messages.

Android Wear devices, however, add an interesting wrinkle: you want the `Notification` to be informative about the event itself. You want the user to be able to make an informed decision about whether they should pull out their primary device to read the new messages, and that decision is only partly based on how many messages there are. Users will want to know more about the outstanding messages (sender and/or subject line) to help them make that decision... at least to a point. If there are 57 unread messages, users may get frustrated dealing with all of those as individual items on the wearable itself.

The pattern here, then, takes advantage of some “group” capabilities added to `NotificationCompat`:

- Raise one “summary” `Notification`, that will only be shown on the primary device, with the same sort of “2 messages are in your inbox!” information that you would have used without considering Wear
- Raise individual notifications for individual messages that will appear on the Wear device

ADVANCED NOTIFICATIONS

- Collect all of those in a “group”, so the primary device shows only the summary and the Wear device shows only the individual ones

This can be seen in action in the [Notifications/Stacked](#) sample project.

The setup is reminiscent of the “big” style one from [the original chapter on Notification](#). However, this time, there are a total of three Notification objects created: two for individual events for the Wear device, and one summary one for the primary device.

However, to make this work, we need a new version of the support-v13 library from the Android Support package: 20.0.0 (or higher), as it is where the extra compatibility smarts were added to support this whole group-and-summary construct. Hence, in build.gradle, we have compile 'com.android.support:support-v13:20.0.0', and for Eclipse, we have the corresponding JAR in libs/.

Similarly, while we will still use NotificationCompat for creating the Notification objects, we will *not* use NotificationManager for displaying them. Instead, we need to use NotificationManagerCompat from the Android Support package. While the NotificationManager API has not changed to support the group-and-summary pattern, the *implementation* has, and NotificationManagerCompat gives us a version of that implementation that can work on compatible devices and gracefully degrade on older ones. However, since the API did not change, it is easy to miss this requirement, use NotificationManager, and not quite get the desired results. Notably, the primary device will wind up showing all three notifications, not just the summary as we want.

Hence, our MainActivity will hold onto a NotificationManagerCompat as a data member, initialized in onCreate():

```
private NotificationManagerCompat mgr=null;

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    mgr=NotificationManagerCompat.from(this);

    showWearOne();
    showWearTwo();
    showSummary();

    finish();
}
```

ADVANCED NOTIFICATIONS

The three `show...()` methods are each responsible for raising one Notification: `showWearOne()` and `showWearTwo()` are ones that will wind up on the Wear device, and `showSummary()` will show the summary Notification for use on the primary device.

Beyond using `NotificationManagerCompat` instead of `NotificationManager`, the only substantial difference is the use of `setGroup()` and `setGroupSummary()` methods on the `NotificationCompat.Builder`.

`setGroup()` associates the Notification with a group, identified by a String key. On a Wear device, notifications that are part of a group will be shown stacked as part of a single card by default. So, the two `showWear...()` methods call `setGroup()` as part of building the Notification:

```
private void showWearOne() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentType(getString(R.string.entry))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setGroup(GROUP_SAMPLE);

    mgr.notify(NOTIFY_ID2, b.build());
}

private void showWearTwo() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentType(getString(R.string.another_entry))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setGroup(GROUP_SAMPLE);

    mgr.notify(NOTIFY_ID3, b.build());
}

private PendingIntent buildPendingIntent(String action) {
    Intent i=new Intent(action);

    return(PendingIntent.getActivity(this, 0, i, 0));
}
```

`setGroupSummary()` indicates a particular Notification that should serve as the summary for its group. This Notification will not be passed to the Wear device, and it replaces all other notifications for this group on the primary device. Hence,

ADVANCED NOTIFICATIONS

showSummary() (or, more accurately, the buildNormal() method that creates the base Notification for the summary) uses setGroupSummary():

```
private void showSummary() {
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle();

    big.setSummaryText(getString(R.string.summary))
        .addLine(getString(R.string.entry))
        .addLine(getString(R.string.another_entry));

    mgr.notify(NOTIFY_ID, normal.setStyle(big).build());
}

private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL)
        .setContentTitle(getString(R.string.download_complete))
        .setContentText(getString(R.string.fun))
        .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setTicker(getString(R.string.download_complete))
        .setGroup(GROUP_SAMPLE)
        .setGroupSummary(true);

    return(b);
}
```

Note that you need to use setGroupSummary() on a NotificationCompat.Builder on which you have also called setGroup(), to identify the group for which this Notification is a summary.

When you run this, the primary device shows the summary Notification:

ADVANCED NOTIFICATIONS

Figure 354: Stacked Notifications, Summary on Primary Device

On the Wear device, you will see the two original notifications as part of a single card at the outset:

Figure 355: Stacked Notifications, Stacked on Wear Device

Tapping on the stack brings up separate mini cards for each individual Notification:

...And the Passage of Time

Of course, this sample is artificially simple, like most of the samples in this book.

In the sample, we are raising all three notifications all at once. That is certainly conceivable, but it is not especially likely. A more likely scenario is that the mix of notifications needs to change over time, based upon continuing events, such as a trickle of new unread email messages for an email client.

This adds a few complexities to what you need to implement all of this properly.

The big thing is that your persistent data model (e.g., database) needs to have enough information for you to know how to notify the user about the next event, when that event occurs. Using the email client as an example:

- We start off in the “steady state” of no unread email messages and, therefore, no notifications from our app.
- A new email message arrives. At this point, we want to show a regular Notification on both the Wear device and the primary device, with the sender and subject line of the unread message.
- A second new email message arrives later. At this point, we want to show another regular Notification (requiring a separate notification ID) for the Wear device, but also show a summary Notification for the primary device. For all that to work, we need to know this *is* a second unread message, and that the user has not read the first message in between the two incoming messages. And, we need to know enough details about the unread messages to format the summary properly.

This gets even more complex when events “stack themselves” (e.g., one poll of the mail server results in two unread messages), in addition to having to deal with user input (e.g., user clears the notification stack from either device, yet does not read the messages).

Among other things, you cannot rely upon static data members as being the sole source of your Notification-related data, as your process may be terminated in between events. You are welcome to use it as a cache, in case your process does happen to survive long enough to process more than one event, but you will need to also save this data to a persistent store, so that you can properly handle new events requiring Notification changes with your process having been terminated since the last Notification-related event.

Avoiding Wear

Sometimes, you will want to raise a Notification that does not make sense to show on a Wear device, only on the primary device. In the case of the group summary for the stacked notifications, this primary-only behavior happens automatically. In other cases, though, you will need to call `setLocalOnly()` on the `NotificationCompat.Builder` to tell the framework that this Notification should only be displayed on the current device.

The [Notifications/BigLocal](#) sample project demonstrates this, through a clone of the `Notifications/BigNotify` sample that has just two changes:

1. It switches to the 20.0.0 version of the `support-v13` library, to get a version of `NotificationCompat.Builder` that offers `setLocalOnly()`
2. It calls `setLocalOnly(true)` as part of configuring the Notification:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL)
      .setContentTitle(getString(R.string.download_complete))
      .setContentText(getString(R.string.fun))
      .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
      .setSmallIcon(android.R.drawable.stat_sys_download_done)
      .setTicker(getString(R.string.download_complete))
      .setPriority(Notification.PRIORITY_HIGH)
      .setLocalOnly(true)
      .addAction(android.R.drawable.ic_media_play,
        getString(R.string.play),
        buildPendingIntent(Settings.ACTION_SETTINGS));
}
```

```
return(b);  
}
```

Note that we do not need to use `NotificationManagerCompat` for local-only behavior — simply calling `setLocalOnly(true)` on an up-to-date `NotificationCompat.Builder` will suffice.

Running this sample provides the same behavior as `Notifications/BigNotify`, except that the `Notification` only appears on the primary device, not the Wear device.

Other Wear-Specific Notification Options

Configuring stacked notifications, and opting into local-only behavior when needed, should give you Wear behavior that is acceptable. Right now, Android Wear is fairly nascent, and therefore it may not behoove you to do much more than this, as you decide how to prioritize your engineering time.

However, there are other things that you can do to further tailor your notifications on Wear that can improve user satisfaction, if you wish for Wear to be a key part of your marketing message.

Pages

On the primary device, the amount of information you can provide in a `Notification` is intentionally capped. This prevents a `Notification` from drowning out its peers. The cap is not a big problem, simply because the whole UI for the app raising the `Notification` is usually just a tap away.

With a Wear device, though, the whole UI for the app raising the `Notification` involves pulling out the primary device.

Hence, it might be nice to provide some additional information to the Wear user, so that perhaps they can make a more informed decision as to whether it is worthwhile to open up their primary device. In Wear terms, this involves adding more “pages” to a `Notification`.

To do this, you must:

- Create the second (and additional) pages as their own separate `Notification` objects, probably via a `NotificationCompat.Builder`

ADVANCED NOTIFICATIONS

- Use a `NotificationCompat.WearableExtender` to teach the primary Notification about the additional pages
- Raise the primary Notification using a `NotificationManagerCompat` variant of the system service

We can see this in action in the [Notifications/Pages](#) sample project. This is a clone of `Notifications/BigNotify`, where we make the “big” content be on a second page.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManagerCompat mgr=
        NotificationManagerCompat.from(this);
    NotificationCompat.Builder normal=buildNormal();
    NotificationCompat.InboxStyle big=
        new NotificationCompat.InboxStyle();

    big.setSummaryText(getString(R.string.summary))
        .addLine(getString(R.string.entry))
        .addLine(getString(R.string.another_entry))
        .addLine(getString(R.string.third_entry))
        .addLine(getString(R.string.yet_another_entry))
        .addLine(getString(R.string.low));

    NotificationCompat.Builder bigPage=
        new NotificationCompat.Builder(this)
            .setStyle(big);
    NotificationCompat.Builder twoPages=
        new NotificationCompat.WearableExtender()
            .addPage(bigPage.build())
            .extend(normal);

    mgr.notify(NOTIFY_ID, twoPages.build());

    finish();
}
```

Here, we:

- Create a `NotificationManagerCompat` instance
- Create the primary (“normal”) Notification, using the same process as before
- Create the `InboxStyle` structure with our expanded content
- Wrap that “big” style in another Notification via a `NotificationCompat.Builder`, using the `setStyle()` method to associate the “big” style with the Notification
- Create a `NotificationCompat.WearableExtender`, tell it to add the second page using `addPage()`, and tell it to apply that second page to the primary Notification via the `extend()` method

ADVANCED NOTIFICATIONS

- Use `notify()` as normal to raise the Notification, using the already-created `NotificationManagerCompat` instance

On the primary device, we just see the primary Notification content:

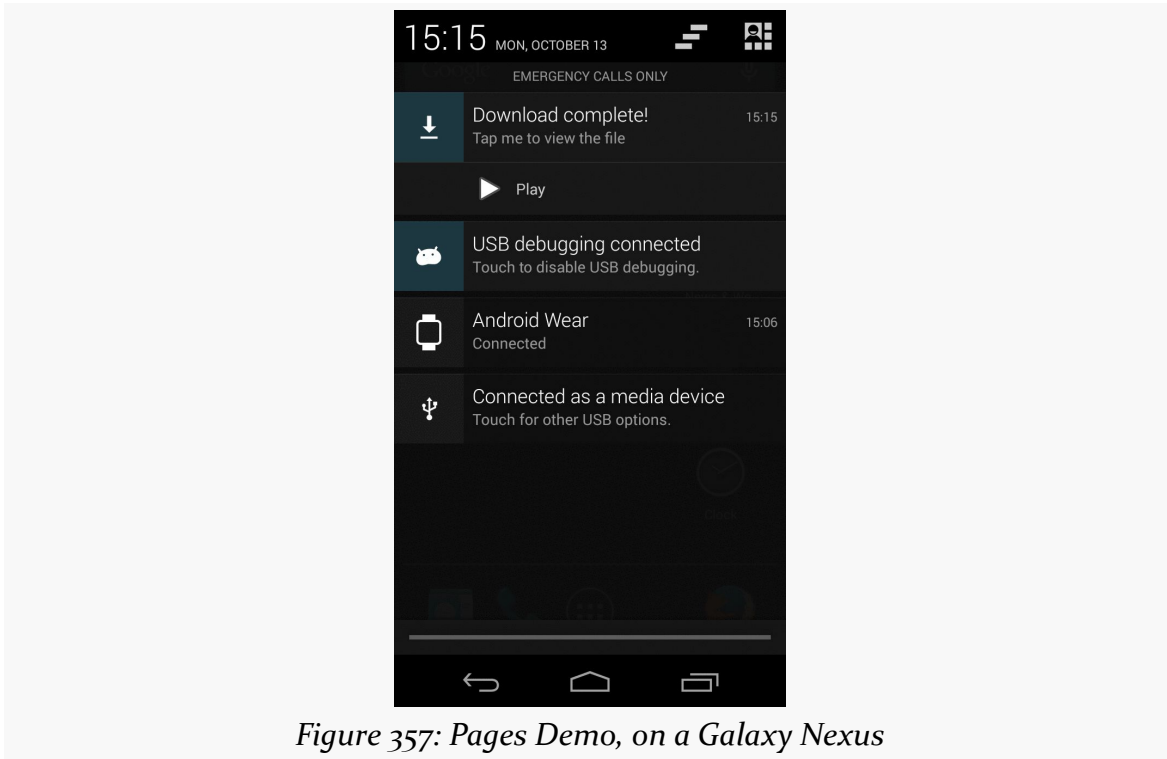

Figure 357: Pages Demo, on a Galaxy Nexus

On the Wear device, we see the main Notification and the second page as separate pages on the wearable:

Figure 358: Pages Demo, on a Samsung Galaxy Wear, Showing Initial Notification

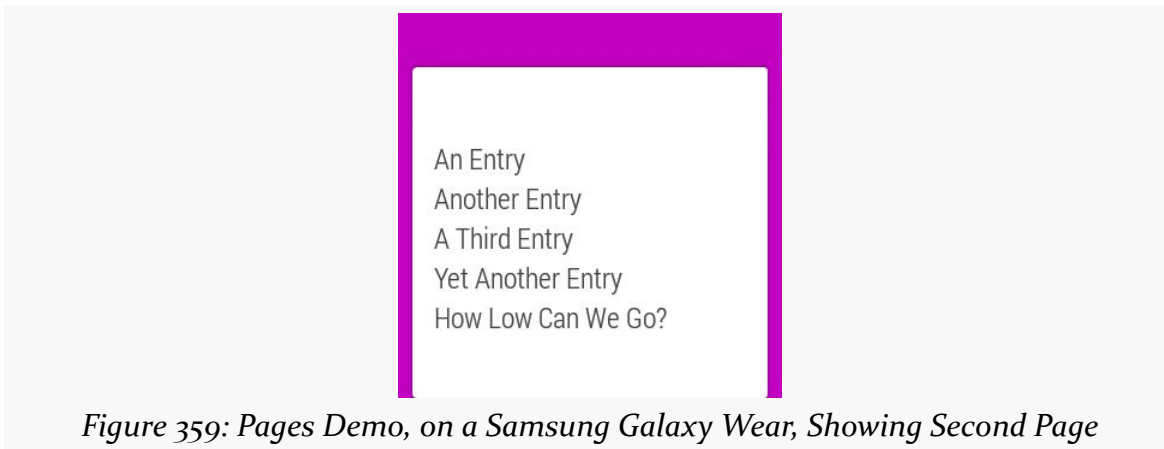

Figure 359: Pages Demo, on a Samsung Galaxy Wear, Showing Second Page

Note that you cannot use `addAction()` to define a custom action on the extra pages added to the primary Notification. Instead, use `addAction()` and `setContentAction()` on the `WearableExtender` to define actions associated with those extra pages. We will see this in use in the next section.

Wear-Only Actions

Sometimes, you may want certain actions to only be available on the Wear device, and not on the primary device. We will see a specific example of this coming up in [the next section](#), when we cover voice input actions.

Sometimes, you may want a different mix of actions on the primary device versus the Wear device — some in common, some only on the primary device, some only on the Wear device.

To set up Wear-only actions, use `addAction()` on `WearableExtender`, as opposed to (or in addition to) `addAction()` on `NotificationCompat.Builder`. This takes an action as a parameter, which you create using `NotificationCompat.Action.Builder`, a custom builder for building Notification actions.

This is illustrated in the [Notifications/WearActions](#) sample project, yet another variation on the “launch an activity, show a Notification” samples that we have been using. This time, though, we will apply an action to the Wear device:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    NotificationManagerCompat mgr=
        NotificationManagerCompat.from(this);
```

ADVANCED NOTIFICATIONS

```
NotificationCompat.Builder normal=buildNormal();
NotificationCompat.Action.Builder wearActionBuilder=
    new NotificationCompat.Action.Builder(android.R.drawable.ic_media_pause,
        getString(R.string.pause),
buildPendingIntent(Settings.ACTION_DATE_SETTINGS));

NotificationCompat.Builder extended=
    new NotificationCompat.WearableExtender()
        .addAction(wearActionBuilder.build())
        .extend(normal);

mgr.notify(NOTIFY_ID, extended.build());

finish();
}
```

Here, we:

- Create a NotificationManagerCompat instance
- Create the primary (“normal”) Notification, using the same process as before
- Create an instance of NotificationCompat.Action.Builder, providing it the icon, label, and PendingIntent to be invoked for this action
- Create an instance of NotificationCompat.WearableExtender, adding the newly-defined action to it, and using the WearableExtender to extend() the primary Notification
- Show that extended Notification using the NotificationManagerCompat instance

However, note that we have also defined an action on the primary Notification:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL)
        .setContentTitle(getString(R.string.download_complete))
        .setContentText(getString(R.string.fun))
        .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
        .setSmallIcon(android.R.drawable.stat_sys_download_done)
        .setTicker(getString(R.string.download_complete))
        .addAction(android.R.drawable.ic_media_play,
            getString(R.string.play),
            buildPendingIntent(Settings.ACTION_SETTINGS));

    return(b);
}
```

ADVANCED NOTIFICATIONS

`addAction()` on `WearableExtender` *replaces*, for the Wear device, any actions defined on the `Notification` itself using `addAction()`, but not the action defined via `setContentIntent()`.

On the primary device, we do not see the wear-only action:

Figure 360: WearActions Demo, on a Galaxy Nexus

On a Wear device, though, we see both the wear-only and the main content action, but not the device-only action added via `addAction()` on the `NotificationCompat.Builder`:

ADVANCED NOTIFICATIONS

Figure 361: WearActions Demo, on a Samsung Galaxy Wear, Showing Notification

Figure 362: WearActions Demo, on a Samsung Galaxy Wear, Showing Wear-Only Action

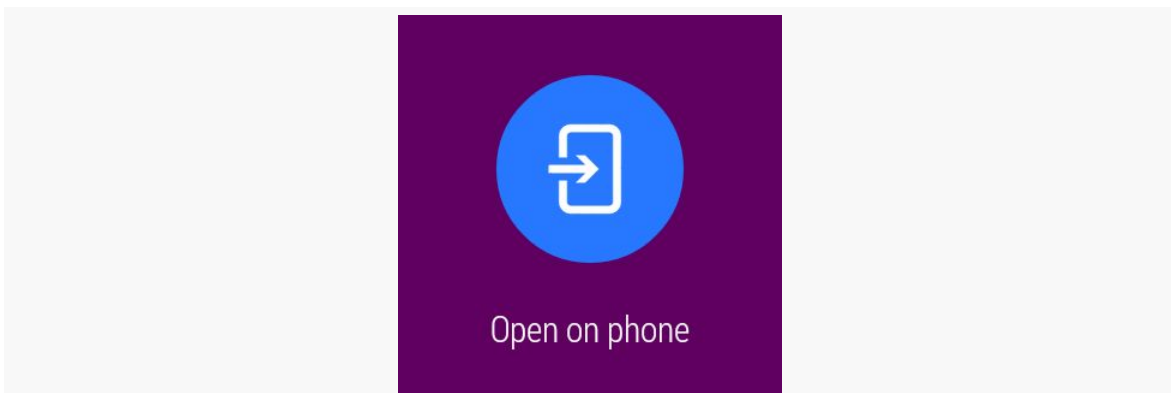

Figure 363: WearActions Demo, on a Samsung Galaxy Wear, Showing Main Content Action

Hence:

ADVANCED NOTIFICATIONS

- If you want actions only on the primary device, define those before applying a `WearableExtender` and its `addAction()`
- If you want actions only on the Wear device, define those using a `WearableExtender` and its `addAction()`
- If you want the same actions on both devices, define those using both flavors of `addAction()` (on `NotificationCompat.Builder` for the primary device and on `WearableExtender` for the Wear device)

Voice Input

In the spirit of [Dick Tracy's](#) two-way wrist radio, Android Wear allows you to talk to your wrist and not seem like you are completely insane.

In particular, your `Notification`, when presented on the Wear, can request that the user provide you with a response, via voice input or via canned responses. This can be very handy:

- Responding to a text message without pulling out one's phone
- Directing your app to file an incoming email message into a particular folder or label
- Responding to a police alert, requesting your assistance, by indicating that you will be on your way as soon as you can find your bright yellow trenchcoat
- And so on

In many cases, with a regular `Notification`, the result of the user choosing an action is for us to display an activity. Sometimes, though, that's not what we want, such as a music player's `Notification` handling "pause" and similar events via its background service. Similarly, actions from a `Notification` seen on a Wear device will sometimes need to perform operations in the background, as the user may not be in position to look at your UI. This is especially true with voice input — usually, if we are bothering to dictate words to our wrist, that should happen instead of opening up the primary device. As a result, our flow for responding to the action is a little bit different, as is illustrated in the [Notifications/VoiceInput](#) sample project.

The Activity and Notification

Let's walk through the `MainActivity` that sets up our `Notification`:

```
package com.commonware.android.wearvoice;
```

ADVANCED NOTIFICATIONS

```
import android.app.Activity;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;

public class MainActivity extends Activity {
    private static final int NOTIFY_ID=1337;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Intent i=new Intent(this, VoiceReceiver.class);
        PendingIntent pi=
            PendingIntent.getBroadcast(this, 0, i,
                PendingIntent.FLAG_UPDATE_CURRENT);

        RemoteInput remoteInput=
            new RemoteInput.Builder(VoiceReceiver.EXTRA_SPEECH)
                .setLabel(getString(R.string.talk))
                .setChoices(getResources().getStringArray(R.array.replies))
                .build();

        NotificationCompat.Action wearAction=
            new NotificationCompat.Action.Builder(
                android.R.drawable.ic_btn_speak_now,
                getString(R.string.talk),
                pi).addRemoteInput(remoteInput).build();

        NotificationCompat.WearableExtender wearExtender=
            new NotificationCompat.WearableExtender()
                .addAction(wearAction);

        NotificationCompat.Builder builder=
            new NotificationCompat.Builder(this)
                .setSmallIcon(android.R.drawable.stat_sys_download_done)
                .setContentTitle(getString(R.string.title))
                .setContentText(getString(R.string.talk))
                .extend(wearExtender);

        NotificationManagerCompat
            .from(this)
            .notify(NOTIFY_ID, builder.build());

        finish();
    }
}
```

We start by creating a broadcast `PendingIntent`, pointing to a `VoiceReceiver` that will respond to the voice input. We will examine this `VoiceReceiver` later in this example.

ADVANCED NOTIFICATIONS

We then set up a `RemoteInput.Builder`. This is a builder-style API for defining a `RemoteInput` configuration to attach to a Wear-only action. Here, we configure it with:

- the key for retrieving the response in our `VoiceReceiver` (`VoiceReceiver.EXTRA_SPEECH`)
- the label to prompt the user for what we are looking for them to provide (an `R.string.talk` string resource)
- a `String` array of canned responses that the user can choose from rather than dictate their own answer and go through speech-to-text conversion (pulled from an `R.array.replies <string-array>` resource)

That `RemoteInput` is then applied to a `NotificationCompat.Action`, via its `NotificationCompat.Action.Builder` and the `addRemoteInput()` method. That `Action`, in turn, is wrapped in a `NotificationCompat.WearableExtender`, which is used to `extend()` a `NotificationCompat.Builder`.

Finally, the resulting `Notification` is raised using a `NotificationManagerCompat` instance.

The Receiver

Our `VoiceReceiver`, registered in the manifest, is set up to respond to the voice action:

```
package com.commonware.android.wearvoice;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.RemoteInput;
import android.util.Log;
import android.widget.TextView;

public class VoiceReceiver extends BroadcastReceiver {
    static final String EXTRA_SPEECH="speech";

    @Override
    public void onReceive(Context ctxt, Intent i) {
        Bundle input=RemoteInput.getResultsFromIntent(i);

        if (input!=null) {
            CharSequence speech=input.getCharSequence(EXTRA_SPEECH);

            if (speech!=null) {
                Log.d(getClass().getSimpleName(), speech.toString());
            }
        }
    }
}
```

ADVANCED NOTIFICATIONS

```
else {
    Log.e(getClass().getSimpleName(), "No voice response speech");
}
}
else {
    Log.e(getClass().getSimpleName(), "No voice response Bundle");
}
}
}
```

It uses `RemoteInput.getResultsFromIntent(i)` to pick out the response we got from the user for this action. There are three major possibilities:

1. We did not get any response (should not happen)
2. We got a response, but for whatever reason, the decoded `Bundle` is missing our `VoiceReceiver.EXTRA_SPEECH` key (also should not happen)
3. The `CharSequence` from the `VoiceReceiver.EXTRA_SPEECH` key in the decoded `Bundle` is the user's response, whether from speech recognition or from choosing one of our canned responses

In this case, we just log the message to LogCat, but in principle you could do whatever you wanted. Just bear in mind that your UI may not be in the foreground, and that the device screen may be off entirely. It is also possible that your process will have been terminated between the time you raised the `Notification` and the user got around to responding to it from the Wear device. Hence, you should be making few assumptions about the environment at the point when you get the voice response.

The Results

The Wear device starts off with a typical action:

ADVANCED NOTIFICATIONS

Tapping it brings up a voice input screen, where the user can dictate some text:

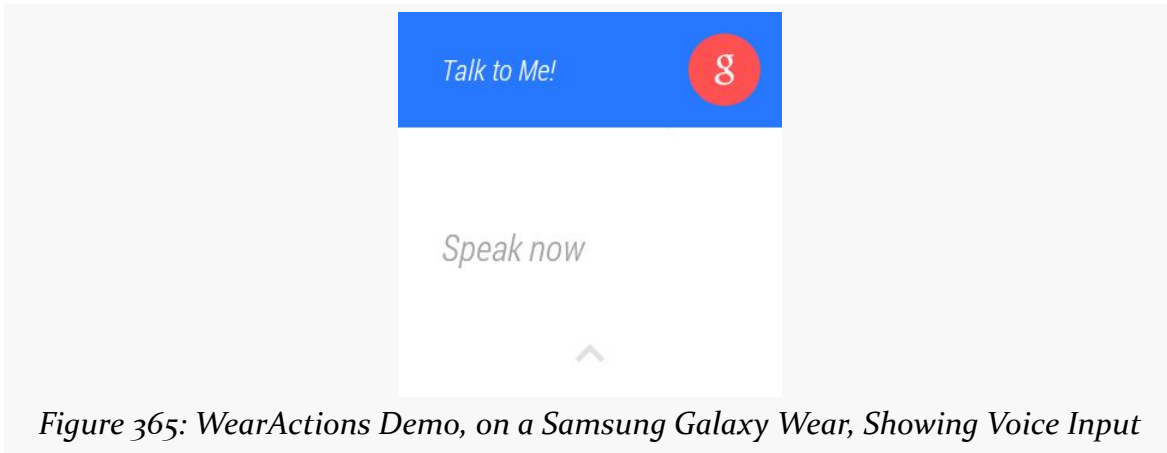

Figure 365: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input

If the user delays too long without saying anything recognizable, or if the user swipes up the screen, they are taken to our list of canned responses:

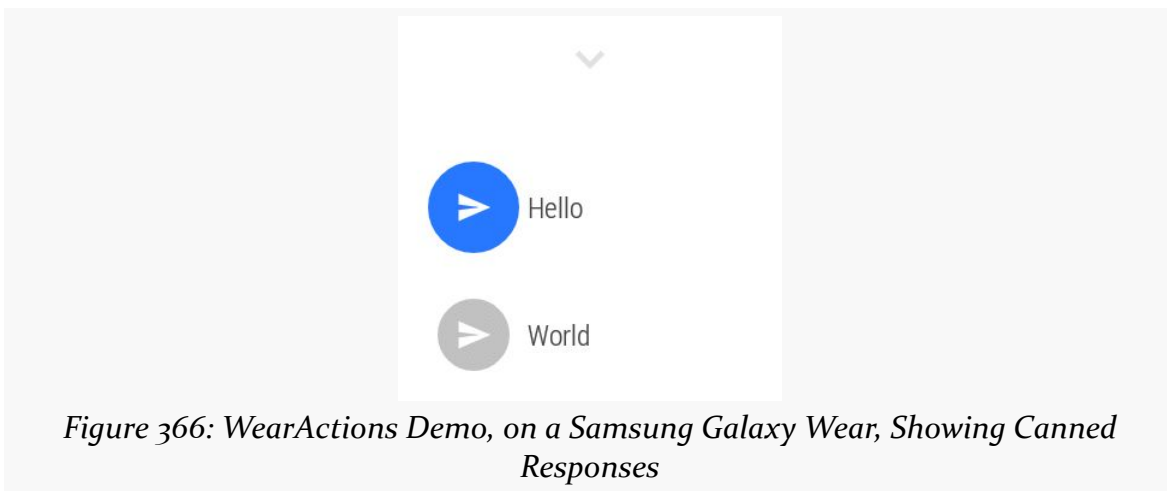

Figure 366: WearActions Demo, on a Samsung Galaxy Wear, Showing Canned Responses

If the user instead does dictate some text, initially they are shown just the interpreted text:

ADVANCED NOTIFICATIONS

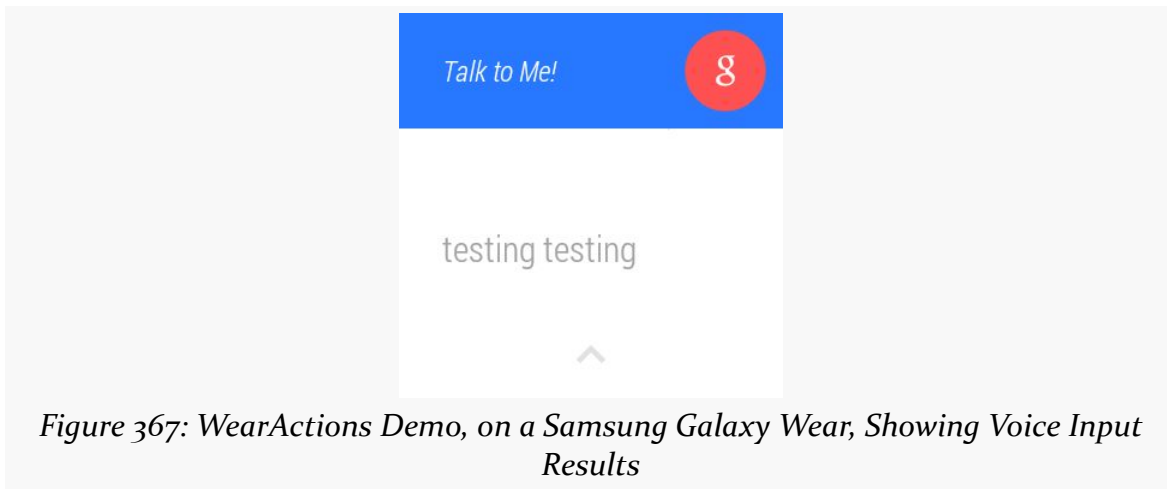

Figure 367: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input Results

Then a cancel button with a progress indicator around the edge appears:

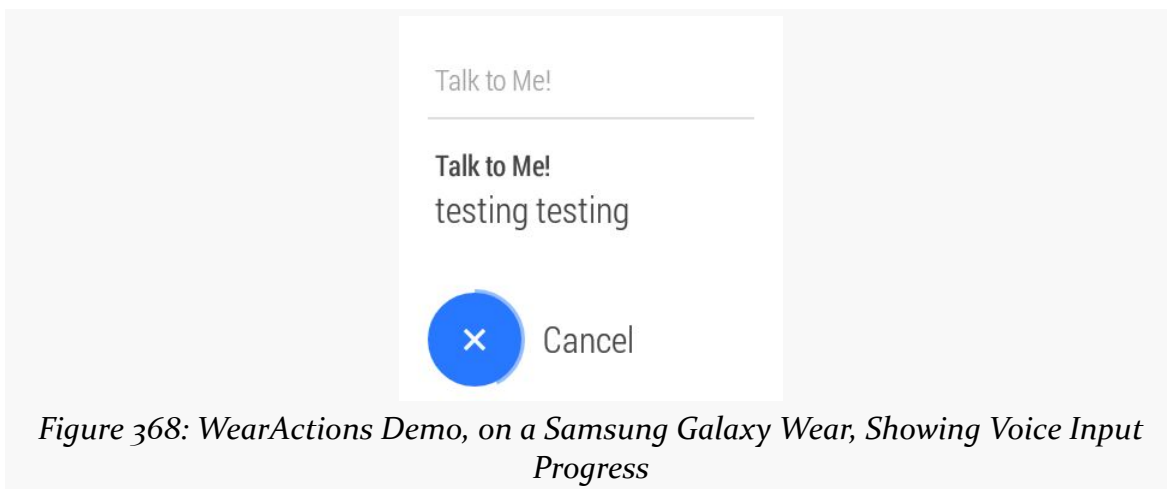

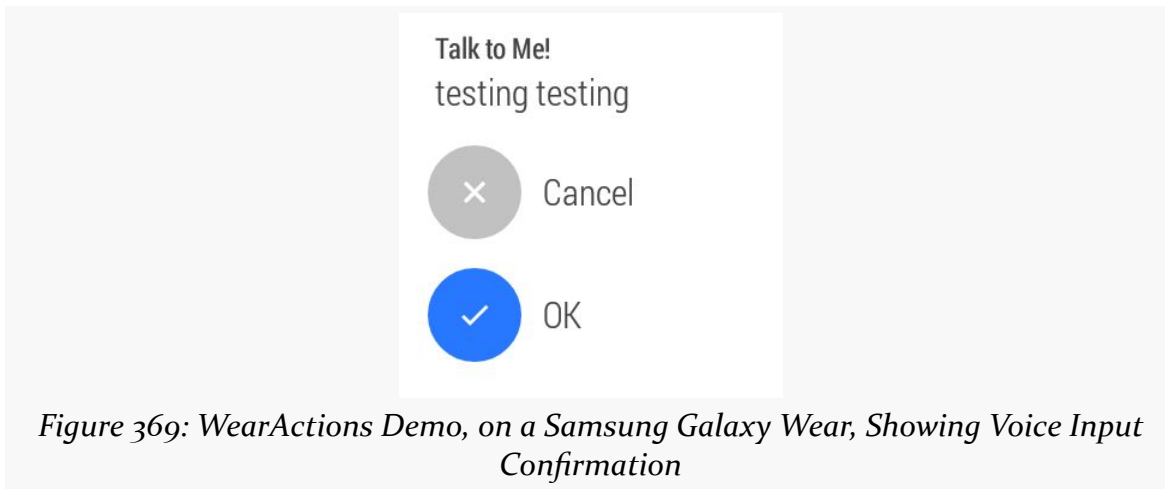

Figure 368: WearActions Demo, on a Samsung Galaxy Wear, Showing Voice Input Progress

If the user taps the cancel button before the progress indicator elapses, they are prompted to confirm or reject the input:

Lockscreen Notifications

Historically, notification icons would be visible on the user's lockscreen, but that was it. This would give the user an indication of what apps need attention, but no additional context.

Android 5.0 added notifications to the lockscreen, to help provide that missing context. Now users can have more details about the notifications, to determine whether it is necessary to unlock the device right now to deal with them.

However, this also raises privacy concerns, as now notification text can be seen by anyone with access to the phone. As such, Android 5.0 introduced the concept of *visibility* to notifications, so developers can help control what is shown on the lockscreen versus what is shown only past the lockscreen.

However, these visibility options are only useful if:

- The device has a pattern, PIN, or password set, so it is not merely some swipe-to-unlock approach
- The user has indicated that the system should “hide sensitive notification content”, either when they set up the pattern/PIN/password:

ADVANCED NOTIFICATIONS

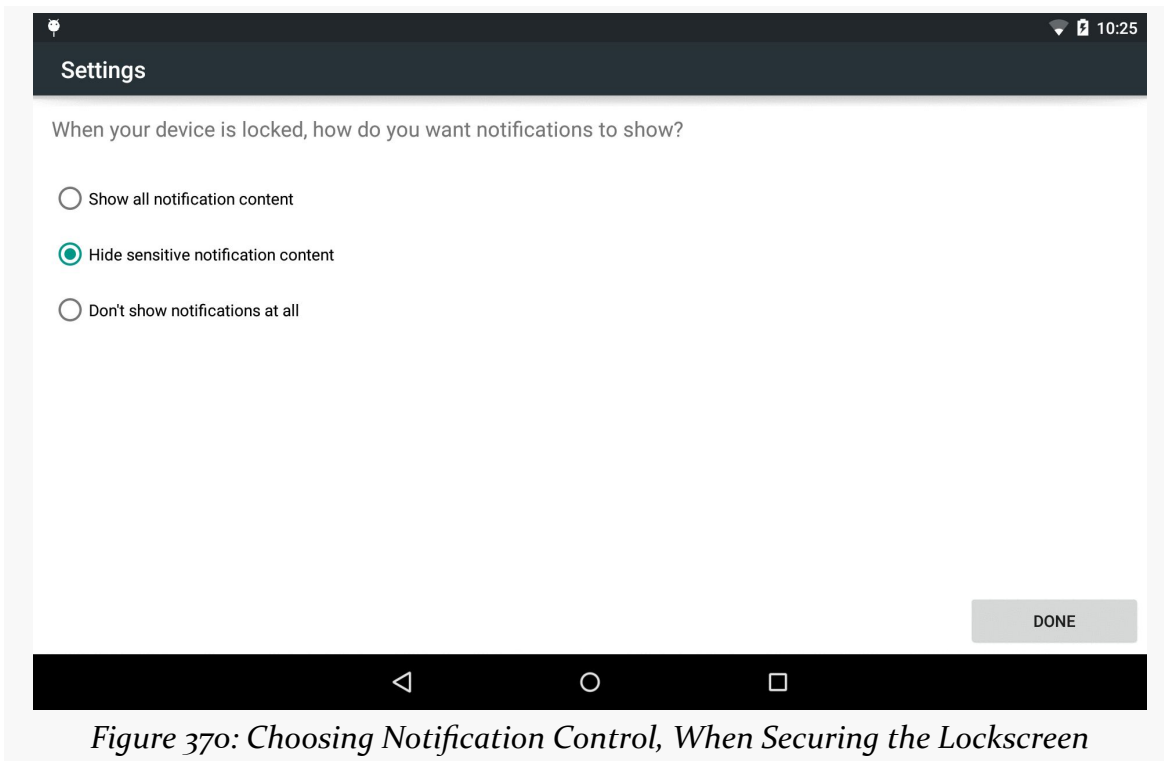

Figure 370: Choosing Notification Control, When Securing the Lockscreen

or in the “Sound & notification” portion of the Settings app:

ADVANCED NOTIFICATIONS

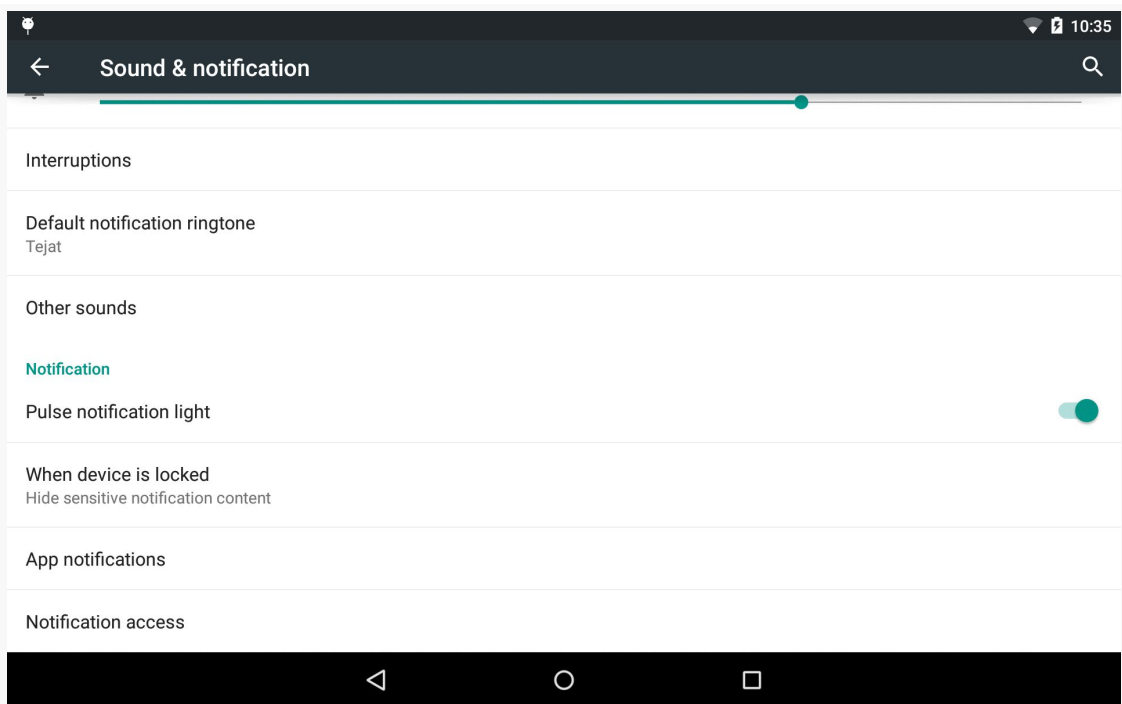

Figure 371: "Sound & notification" Settings

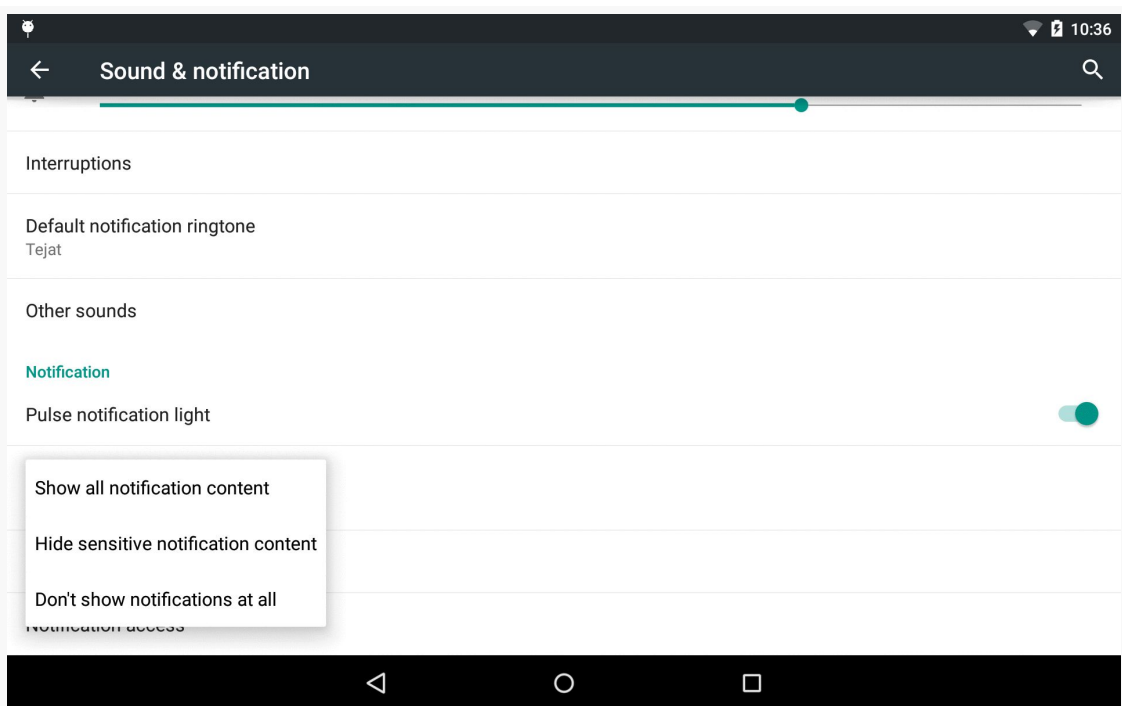

Figure 372: Notification Control Options in "Sound & notification" in Settings

ADVANCED NOTIFICATIONS

Given that the user has enabled “hide sensitive notification content” mode, you as a developer can choose a visibility to apply to your notifications. There are three such visibility options — private, public, and secret — covered in the following sections.

Private Notifications

The default behavior is a “private” Notification. Basic information appears on the lockscreen, but not the whole Notification. However, you as a developer can also provide a *separate* Notification that *will* be shown on the lockscreen, so you can choose what information appears publicly and what information does not.

The sample app for this section has a “public” edition of the Notification that shows up on the lockscreen:

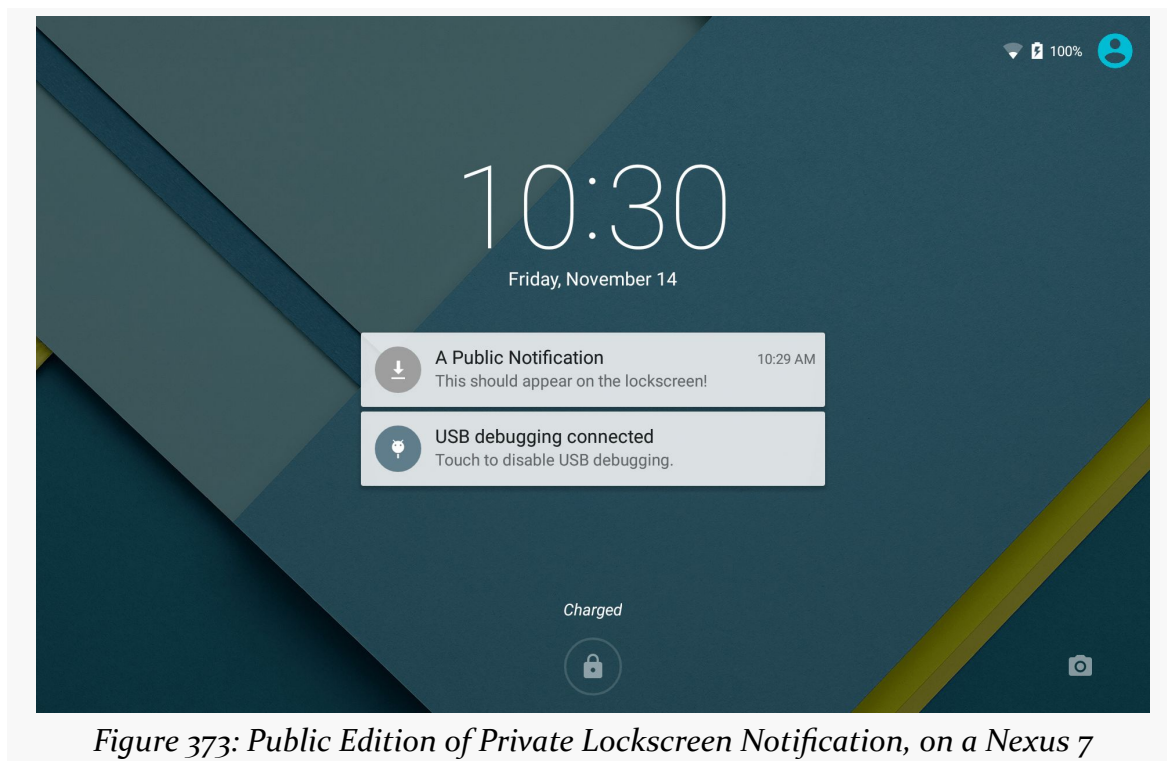

Figure 373: Public Edition of Private Lockscreen Notification, on a Nexus 7

Public Notifications

Instead of creating a separate Notification for public visibility on the lockscreen, you could flag your main Notification as having public visibility. This is suitable for notifications where there is little to no privacy implications for having the information appear on the lockscreen.

Secret Notifications

A Notification with visibility set to “secret” will not show up on the lockscreen at all. The ringtone, etc. will occur, as requested (and based on device settings, like it being muted), but otherwise there is no visible indication on the lockscreen that your Notification exists. Only when the user gets past the lockscreen will your Notification appear, in the status bar.

A Visibility Sample

The [Notifications/Lollipop](#) sample project demonstrates the use of these visibility values. It also demonstrates heads-up notifications, covered [later in this chapter](#).

The user interface consists of a Spinner of possible Notification variants, a SeekBar to allow the user to specify a delay period in seconds before showing the Notification, and a Button to trigger showing the Notification:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp"
    android:stretchColumns="1">
    <TableRow>
        <TextView
            android:text="@string/type_label"/>
        <Spinner
            android:id="@+id/type"/>
    </TableRow>
    <TableRow>
        <TextView
            android:text="@string/delay_label"/>
        <SeekBar
            android:id="@+id/delay"
            android:progress="5"
            android:max="30"/>
    </TableRow>
    <Button
        android:text="@string/notify_button"
        android:id="@+id/download"
        android:onClick="notifyMe"/>
</TableLayout>
```

ADVANCED NOTIFICATIONS

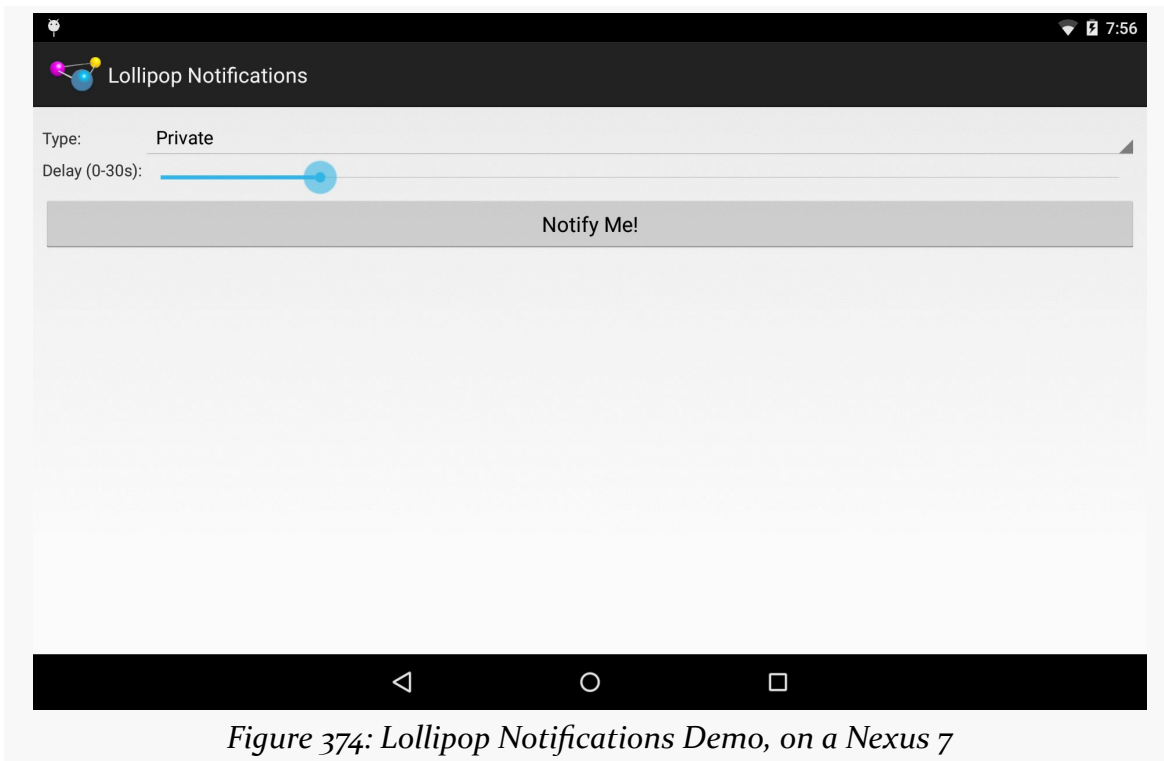

Figure 374: Lollipop Notifications Demo, on a Nexus 7

The `onCreate()` method of our launcher activity (`MainActivity`) initializes the UI:

```
package com.commonware.android.lollipopnotify;

import android.app.Activity;
import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.SeekBar;
import android.widget.SeekBar.OnSeekBarChangeListener;
import android.widget.Spinner;

public class MainActivity extends Activity {
    private Spinner type=null;
    private SeekBar delay=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        type=(Spinner)findViewById(R.id.type);

        ArrayAdapter<String> types=
            new ArrayAdapter<String>(this,
```

ADVANCED NOTIFICATIONS

```
        android.R.layout.simple_spinner_item,
        getResources().getStringArray(R.array.types));

    types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    type.setAdapter(types);

    delay=(SeekBar)findViewById(R.id.delay);
}

public void notifyMe(View v) {
    Intent i=new Intent(this, AlarmReceiver.class)
        .putExtra(AlarmReceiver.EXTRA_TYPE, type.getSelectedItemPosition());
    PendingIntent pi=PendingIntent.getBroadcast(this, 0, i,
        PendingIntent.FLAG_UPDATE_CURRENT);
    AlarmManager mgr=(AlarmManager) getSystemService(ALARM_SERVICE);

    mgr.set(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+(1000*delay.getProgress()),
        pi);
}
}
```

In particular, onCreate() populates the Spinner based on a <string-array> resource:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <string-array name="types">
        <item>Private</item>
        <item>Public</item>
        <item>Secret</item>
        <item>Heads-Up</item>
    </string-array>
</resources>
```

When the button is clicked, the notifyMe() method on MainActivity is called. Here, we:

- Create an Intent pointing at an AlarmReceiver
- Package an extra on the Intent that contains the selected position of the Spinner
- Wrap the Intent in a getBroadcast() PendingIntent
- Use set() on AlarmManager to invoke the PendingIntent after the delay period specified via the SeekBar

Since the targetSdkVersion of this project is below 19, the set() method will behave in an exact fashion, triggering our AlarmReceiver at the designated time.

AlarmReceiver, in turn, uses a switch statement to call out to different private methods based upon which Spinner item was selected:

        Intent i=new Intent(action);

        return(PendingIntent.getActivity(ctxt, 0, i, 0));
    }
}
```

If the user chooses the “Private” option in the Spinner, we call `notifyPrivate()`. That method builds two Notification objects: the regular one and a separate public edition. We attach the public edition to the regular Notification via a call to `setPublicVersion()` on the `NotificationCompat.Builder`. Then, we raise the regular Notification. This will show the public edition if the lockscreen is locked; otherwise, it will show the regular edition.

If the user chooses the “Public” option, we call `notifyPublic()`. That, in turn, calls `setVisibility(NotificationCompat.VISIBILITY_PUBLIC)` on the

`NotificationCompat.Builder`, causing our `Notification` to appear normally both on the lockscreen and past the lockscreen.

If the user chooses the “Secret” option, we call `notifySecret()`. That uses `setVisibility(NotificationCompat.VISIBILITY_SECRET)` to configure the `Notification` to only appear once the user has gotten past the lockscreen.

The “Heads-Up” option — fourth in the Spinner — is covered in the next section.

Priority, and Heads-Up Notifications

Notifications can have a priority associated with them. Normally, notifications with higher priority will appear higher in the list of notifications in the notification tray than will notifications with lower priority.

Android 5.0 took this a step further, showing high-priority notifications in a “heads-up” style, popping up a small dialog-like window over the main screen, with the same basic content as would appear for the `Notification` in its tile in the notification tray:

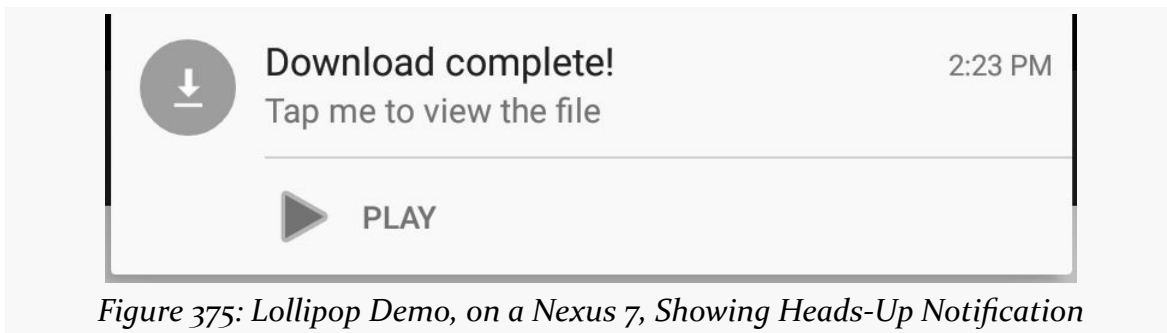

Figure 375: Lollipop Demo, on a Nexus 7, Showing Heads-Up Notification

Users can interact with the heads-up `Notification` or ignore it; in the latter case, the `Notification` will move into the status bar and the “heads-up” display will disappear from the screen.

Note that the “priority” concept being described here seems to be independent of the notion of “priority notifications” in the user’s interruption configuration in Settings. There, “priority notifications” is tied to the app, not tied to any sort of configuration of the `Notification` itself.

Specifying the Priority

`NotificationCompat.Builder` has a `setPriority()` method that allows you to specify your requested priority. There are five priority values accepted as a parameter, all defined as constants out on the `NotificationCompat` class:

- `PRIORITY_MAX`
- `PRIORITY_HIGH`
- `PRIORITY_DEFAULT`
- `PRIORITY_LOW`
- `PRIORITY_MIN`

The actual priority applied to the `Notification` will depend upon other factors, and so you should not assume that your requested value will be accepted and applied as-is.

Results on Android 5.x Devices

The heads-up Notification appears as shown in the above screenshot. The pop-up itself is centered across the top of the screen, as shown below:

After a few seconds of inactivity, the pop-up vanishes, and the Notification goes into the status bar.

Results on Older Devices

The concept of priority was introduced in API Level 16 (Android 4.1). On Android 4.1 through 4.4, the only effect of priority was to help influence the sort order of notifications in the notification tray, with higher-priority items drifting towards the top.

While `NotificationCompat.Builder` will allow you to specify a priority even on devices running older versions of Android than 4.1, the requested priority will be ignored, simply because priority did not exist back then. Hence, while your code will still work, it will have no effect on such old devices.

Full-Screen Notifications

Before Android 5.0 added heads-up notifications, while priority would influence things like sort order, it would have no real impact on how the user would be informed about whatever event triggered the Notification. The user would still just get an icon in the status bar, and perhaps a ringtone and other hardware output.

However, sometimes we need to be somewhat more “in the user’s face”, such as for a calendar event reminder, or for an incoming phone call from our VOIP app.

It is tempting to launch an activity in these cases. In fact, that is what the user tends to perceive as happening, on Android 4.4 and older devices. And some apps no doubt actually do launch an activity.

A “middle ground” between showing a Notification and launching an activity is to use a full-screen Notification. Here, we provide a `PendingIntent` that should be invoked if the user is actively using the device at the time of the Notification. Typically, that `PendingIntent` will display an activity. However, on Android 5.0+, the behavior has changed, where a full-screen Notification actually just triggers a heads-up notification, as would a high-priority Notification.

Requesting Full-Screen Output

All you need to do to set up a Notification to be full-screen is to call `setFullScreenIntent()` on your `NotificationCompat.Builder`, supplying two values:

1. A `PendingIntent` to be invoked when the notification is added to the screen
2. A boolean, where `true` indicates that even if the user has blocked notifications, you want this one to appear

For example, in the [Notifications/FullScreen](#) sample project, `MainActivity` shows a Notification constructed via the `buildNormal()` method:

```
private NotificationCompat.Builder buildNormal() {
    NotificationCompat.Builder b=new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
    .setDefaults(Notification.DEFAULT_ALL)
    .setTitle(getString(R.string.download_complete))
    .setText(getString(R.string.fun))
    .setContentIntent(buildPendingIntent(Settings.ACTION_SECURITY_SETTINGS))
    .setSmallIcon(android.R.drawable.stat_sys_download_done)
    .setTicker(getString(R.string.download_complete))
    .setFullScreenIntent(buildPendingIntent(Settings.ACTION_DATE_SETTINGS), true)
    .addAction(android.R.drawable.ic_media_play,
        getString(R.string.play),
        buildPendingIntent(Settings.ACTION_SETTINGS));

    return(b);
}
```

Here, the `PendingIntent` is created using the same `buildPendingIntent()` method as before, this time opening up a distinct screen from the Settings app.

Results on Android 5.x Devices

On Android 5.0, the “full screen” Notification appears as a heads-up Notification:

Note that there is no obvious way to actually invoke the `PendingIntent` associated with the `setFullScreenIntent()` method. Hence, you need to make sure that the `Notification` has some other means of getting the user to the right place in your UI, such as via `setContentIntent()` or an action.

Results on Android 3.0-4.4 Devices

On API Levels 11 through 19 (Android 3.0 through 4.4), the effect of a full-screen `PendingIntent` is to invoke the `PendingIntent` when the `Notification` is added to the screen. This will happen regardless of whether the user is using the device or not, though if the device is asleep, the activity triggered by the `PendingIntent` will only be visible once the user gets past their lockscreen.

Note that the `Notification` is *also* shown, along with whatever the `PendingIntent` does. That `Notification` is not automatically cleared when the user exits out of that activity via `BACK`, `HOME`, etc. Hence, it is up to you to clear that `Notification` if and when it is no longer relevant. The primary value of the `Notification` is to have the icon appear in the status bar on the lockscreen — even though the user cannot interact with your `Notification` then, the user may recognize your icon and therefore elect to unlock their device to see what all the fuss is about.

Results on Older Devices

Full-screen notifications were not supported prior to Android 3.0. While `NotificationCompat.Builder` will allow you to call `setFullScreenIntent()`, the value will be ignored prior to API Level 11.

In theory, there is nothing stopping `NotificationCompat` from launching an activity itself, in addition to displaying the `Notification`. However, at least at this time, it is not doing so, and it is fairly likely that Google will not add this in at this point.

Hence, the only way to do a “full-screen notification” is for your app to launch the desired activity, in addition to (or instead of) showing the Notification.

Custom Views

Some applications have specific tasks that take a chunk of time. The most common situation for these is a download — while downloading a file should not take forever, it may take several seconds or minutes, depending on the size of the file and the possible download speed.

You may have noticed that some applications, such as the Android Market, have a Notification for a download that shows the progress of the download itself. Visually, it’s obvious how they accomplish this: they use a `ProgressBar`. But normally you create `Notification` objects with just a title and description as text. How do they get the `ProgressBar` in there? And, perhaps more importantly, how are they continuously updating it?

This section will explain how that works, along with a related construct added in Android 3.0: the custom ticker.

Custom Content

When you specify a title and a description for a `Notification`, you are implicitly telling Android to use a stock layout for the structure of the `Notification` object’s entry in the notification drawer. However, instead, you can provide Android with the layout to use and the contents of all the widget, by means of a `RemoteViews`. In other words, by using the same techniques that you use to create [app widgets](#), you can create tailored notification drawer content. Just create the `RemoteViews` and put it in the `contentView` data member of the `Notification`.

To update the notification drawer content — such as updating a `ProgressBar` to show download progress — you update your `RemoteViews` in your `Notification` and re-raise the `Notification` via a call to `notify()`. Android will apply your revised `RemoteViews` to the notification drawer content, and the user will see the changed widgets. However, you will also want to remove requested features from the `Notification` that you do not want to occur every time you update the `RemoteViews`. For example, if you keep the `tickerText` in place, every time you update the `RemoteViews`, the ticker text will be re-displayed, which can get annoying.

We will see an example of this in action [later in this chapter](#).

Custom Tickers

Traditionally, the “ticker” is a piece of text that is placed in the status bar when the Notification is raised, so that if the user happens to be looking at the phone at that moment (or glances at it quickly, cued by a vibration or ringtone), they get a bit more contextual information about the Notification and why it is there.

On API Level 11+ tablets, you also have the option of creating a custom ticker, once again using a RemoteViews. Create the RemoteViews to be what you want to show as the ticker, and assign it to the tickerView data member of the Notification. On devices with room (e.g., tablets), your RemoteViews will be displayed instead of the contents of the tickerText data member. However, it is a good idea to also fill in the tickerText value, for devices that elect to show that instead of your custom view.

Also, tickers in general were removed in Android 5.0, so investing too much in custom tickers now is probably a waste of effort.

Seeing It In Action

To see custom tickers and custom content in a complete project, take a peek at the [Notifications/HCNotifyDemo](#) sample project. This is perhaps the smallest possible project that uses all of these features, so do not expect much elaborate business logic.

The Activity

The launcher icon for this application is tied to an activity named HCNotifyDemoActivity. All it does is spawn a background service named SillyService, that will simulate doing real work in the background and maintaining a Notification along the way:

```
package com.commonware.android.hcnotify;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import com.commonware.android.hcnotify.R;

public class HCNotifyDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

```
startService(new Intent(this, SillyService.class));  
finish();  
}  
}
```

The IntentService

SillyService is an IntentService, to take advantage of the two key features of an IntentService: the supplied background thread, and automatically being destroyed when the work being done in the background is finished.

Since SillyService is an IntentService, and IntentService requires a constructor, supplying a display name for the service, we oblige:

```
public SillyService() {  
    super("SillyService");  
}
```

All of the rest of the business logic is in onHandleIntent(), which will be described in pieces below.

The Builder

In theory, SillyService is going to do some real long-running work, updating a ProgressBar in a Notification along the way. To keep the example simple — and not to violate “truth in advertising” laws given the service’s name — SillyService will emulate doing real work by sleeping.

Hence, the first thing SillyService does in onHandleIntent() is get a NotificationManager and a NotificationCompat.Builder, then configure the builder to get the base Notification to use:

```
NotificationManager mgr=(NotificationManager)getSystemService(NOTIFICATION_SERVICE);  
NotificationCompat.Builder builder=new NotificationCompat.Builder(this);  
  
builder  
    .setContent(buildContent(0))  
    .setTicker(getText(R.string.ticker), buildTicker())  
    .setContentIntent(buildContentIntent())  
    .setLargeIcon(buildLargeIcon())  
    .setSmallIcon(R.drawable.ic_stat_notif_small_icon)  
    .setOngoing(true);  
  
Notification notif=builder.build();
```

Configuring the builder, in this case, involves calling the following setters:

ADVANCED NOTIFICATIONS

1. `setContent()`, to provide the `RemoteViews` for the notification drawer entry, here delegated to a `buildContent()` method we will examine in a bit
2. `setTicker()`, to provide the material to be displayed as the ticker, in this case using a `setTicker()` variant that takes a `CharSequence` (e.g., a `String`, or the result of `getText()` on a string resource ID) and a `RemoteViews` to use in cases where the device supports custom tickers (delegated here to `buildTicker()`)
3. `setContentIntent()`, to provide the `PendingIntent` to be invoked if the user taps on our custom content `RemoteViews`, here delegated to `buildContentIntent()`
4. `setLargeIcon()`, used on some devices for a larger representation of our notification icon for use in tickers and non-custom notification drawer contents, here delegated to `buildLargeIcon()`
5. `setSmallIcon()`, use for the status bar/system bar icon and, on some devices, for non-custom notification drawer contents
6. `setOngoing()`, which sets `FLAG_ONGOING_EVENT`, preventing this Notification from being deleted by the user

Finally, we call `build()` to retrieve the `Notification` object as configured by the builder. Note that previous versions of `NotificationBuilder` used `getNotification()` instead of `build()`, but `getNotification()` is now officially deprecated.

The ProgressBar

Our `buildContent()` method just returns a `RemoteViews` object:

```
private RemoteViews buildContent(int progress) {
    RemoteViews content=new RemoteViews(this.getPackageName(),
                                       R.layout.content);

    return(content);
}
```

The `RemoteViews` object, in turn, is based on a trivial layout (`res/layout/content.xml`) containing a `ProgressBar`:

```
<ProgressBar xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@android:id/progress"
    style="?android:attr/progressBarStyleHorizontal"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:indeterminate="false">
</ProgressBar>
```

ADVANCED NOTIFICATIONS

The simplest way to update a `ProgressBar` in a `Notification` is to simply hold onto the `Notification` object and update the `ProgressBar` in the `RemoteViews` as needed.

`SillyService` takes this approach, looping 20 times for 1000-millisecond naps, updating the `ProgressBar` on each pass of the loop:

```
for (int i=0;i<20;i++) {
    notif.contentView.setProgressbar(android.R.id.progress,
                                     100, i*5, false);
    mgr.notify(NOTIFICATION_ID, notif);

    if (i==0) {
        notif.tickerText=null;
        notif.tickerView=null;
    }

    SystemClock.sleep(1000);
}
```

You update the progress of a `ProgressBar` by calling `setProgressbar()` on the `RemoteViews`, and you get your content `RemoteViews` from the `contentView` data member of the configured `Notification`. `SillyService` has the `ProgressBar` run from 0 to 100 and sets the progress to be 5 times our loop counter. Each time we update the `RemoteViews`, we call `notify()` to raise or update the `Notification`.

The key is that the first time we do this, we want to display our ticker, but not every time the `ProgressBar` updates, as that would really aggravate the user. So, after we raise the `Notification` in the first pass of our loop, we set the `tickerText` and `tickerView` data members of the `Notification` to `null`, to suppress further tickers from being displayed.

When the loop is finished, we just `cancel()` the `Notification`, to remove it from the screen.

The Rest of the Story

The `buildTicker()` method also returns a `RemoteViews`:

```
private RemoteViews buildTicker() {
    RemoteViews ticker=new RemoteViews(this.getPackageName(),
                                     R.layout.ticker);

    ticker.setTextViewText(R.id.ticker_text,
                          getString(R.string.ticker));

    return(ticker);
}
```

ADVANCED NOTIFICATIONS

It, in turn, is based on a `res/layout/ticker.xml` resource:

```
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/ticker_text"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="TextView">
</TextView>
```

There is nothing requiring the ticker (or the content, for that matter) to be completely static. You might well customize `TextView` or other widgets at runtime with details about the work being done. Here, `buildTicker()` does that via `setTextViewText()`, albeit just pulling in a string resource.

The `buildContentIntent()` method returns a `PendingIntent` to be invoked when the user taps on our `ProgressBar`-laden notification drawer entry. Here, lacking any better ideas and being generally lazy, we return a `PendingIntent` designed to bring up the Settings application:

```
private PendingIntent buildContentIntent() {
    Intent i=new Intent(Settings.ACTION_SETTINGS);

    return(PendingIntent.getActivity(this, 0, i, 0));
}
```

While small icons in a `Notification` must be resources, large icons are bitmaps. Presumably, that is to support the large icon holding contact photos, chat avatars, album art for music players, and whatnot. Hence, `buildLargeIcon()` needs to return a `Bitmap` object. In our case, it is simply a drawable resource, so we use `BitmapFactory` and `decodeResource()` to get a `Bitmap` from the PNG:

```
private Bitmap buildLargeIcon() {
    Bitmap raw=BitmapFactory.decodeResource(getResources(),
                                         R.drawable.icon);

    return(raw);
}
```

The Results

When we launch `HCNotifyDemoActivity`, which in turns starts up `SillyService`, we initially get our custom ticker on a tablet:

ADVANCED NOTIFICATIONS

Figure 378: The custom ticker in our Notification, as seen on a Honeycomb tablet

Eventually, the ticker vanishes, leaving us with the traditional system bar icon:

Figure 379: The system bar icon for our Notification, as seen on a Honeycomb tablet

Tapping on the icon brings up the notification drawer, with our custom content, including our ProgressBar:

Figure 380: Notification ProgressBar, on Android 3.x Tablet

On an Android 4.0 phone, the status bar and ticker are no different than their Android 1.x/2.x counterparts, though we still get our custom content:

Figure 381: Notification ProgressBar, on Android 4.x Phone

Progress Notifications

While it is entirely possible to have a Notification with a ProgressBar using RemoteViews, there is a far simpler solution: use `setProgress()` on the `Notification.Builder` (or `NotificationCompat.Builder`). This is illustrated in the [Notifications/Progress](#) sample project, which is simplified clone of the `HCNotifyDemo` project.

The `SillyService` `onHandleIntent()` method now eschews the `RemoteViews` in favor of `setProgress()`:

```
@Override
protected void onHandleIntent(Intent intent) {
    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);
    NotificationCompat.Builder builder=
        new NotificationCompat.Builder(this);

    builder.setTicker(getText(R.string.ticker))
        .setContentTitle(getString(R.string.progress_notification))
        .setContentText(getString(R.string.busy))
        .setContentIntent(buildContentIntent())
        .setSmallIcon(R.drawable.ic_stat_notif_small_icon)
        .setOngoing(true);

    for (int i=0; i < 20; i++) {
        builder.setProgress(20, i, false);
        mgr.notify(NOTIFICATION_ID, builder.build());

        SystemClock.sleep(1000);
    }

    builder.setContentText(getString(R.string.done))
        .setProgress(0, 0, false).setOngoing(false);

    mgr.notify(NOTIFICATION_ID, builder.build());
}
```

After initializing the stock data for the `NotificationCompat.Builder`, we enter the same sort of loop-20-times-sleeping-a-second loop as was seen in the previous demo. This time, though, we call `setProgress()` on the `Builder` to set the current progress, then have it `build()` a `Notification` object to use with the `NotificationManager`.

`setProgress()` takes three parameters:

- the maximum value of the `ProgressBar`, which eventually routes to `setMax()` on the `ProgressBar` itself

ADVANCED NOTIFICATIONS

- the current progress of the ProgressBar, which eventually routes to `setProgress()` on the ProgressBar itself
- true if the progress is indeterminate, false otherwise

In this case, we set the maximum to be 20 and the progress to be the value of our loop counter `i`.

When the loop is finished, we update the Builder to:

- Provide an alternative piece of text to show below the ProgressBar
- Remove the ProgressBar via `setProgress(0, 0, false)`
- Use `setOngoing(false)` to allow the user to get rid of the Notification

When we run this sample, we see our ProgressBar-based Notification at the outset:

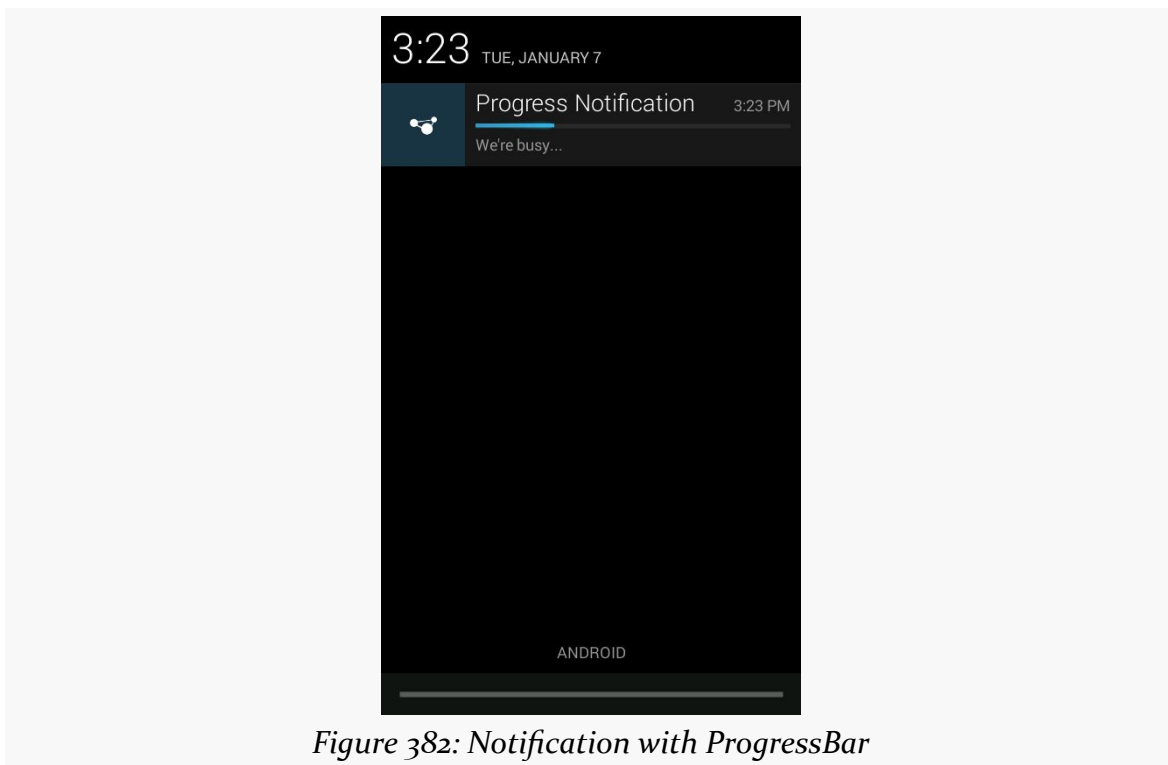

Figure 382: Notification with ProgressBar

When the loop is finished, we see the Notification as updated for its final state:

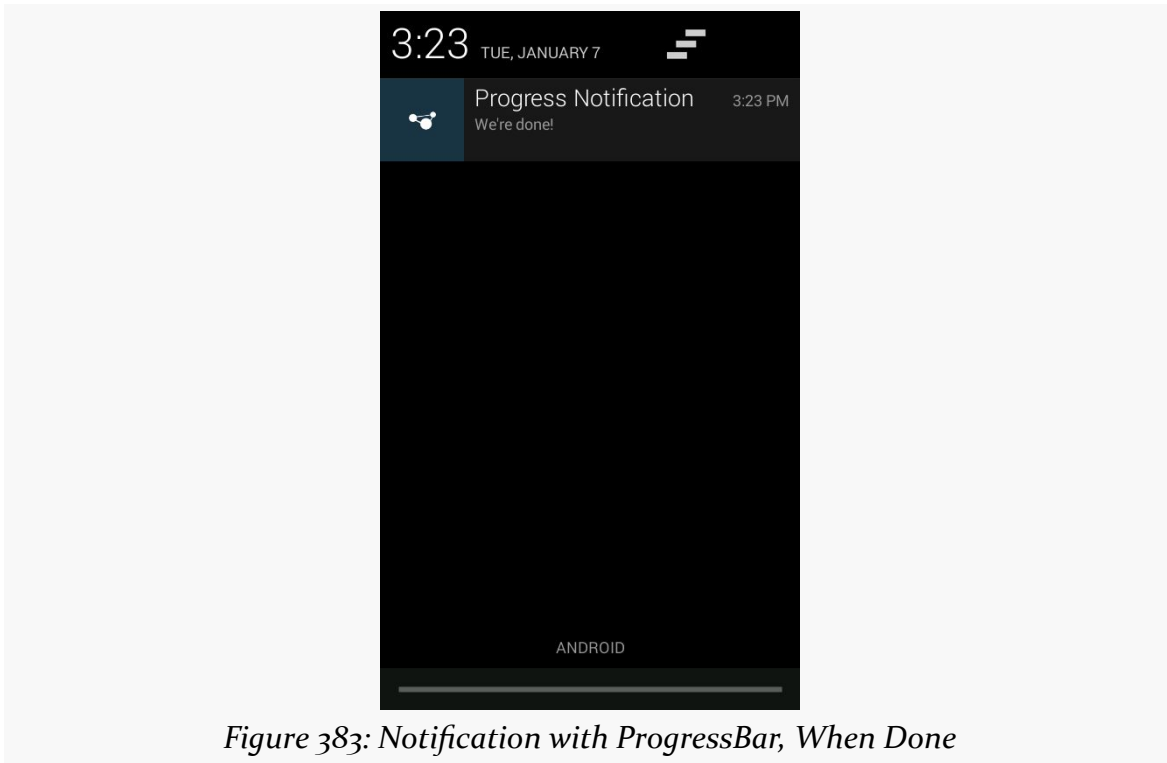

Figure 383: Notification with ProgressBar, When Done

Life After Delete

Most of the time, you do not care about your Notification being dismissed by the user from the notification drawer (e.g., pressing the Clear button on Android 1.x/2.x devices). If you do care about the Notification being deleted this way, you can supply a `PendingIntent` in the `deleteIntent` data member of the Notification — this will be executed when the user gets rid of your Notification. Usually, this will be a `getService()` or `getBroadcast()` `PendingIntent`, to have you do something in the background related to the dismissal. Users are likely to get rather irritated with you if you pop up an activity because they got rid of your Notification.

Note that this only works for Notification objects that can be cleared. If you have `FLAG_ONGOING_EVENT` set on the Notification, it will remain on-screen until you get rid of it.

The Mysterious Case of the Missing Number

The `Notification` class has a `number` data member. On Android 1.x and 2.x, setting that data member would cause a number to be super-imposed on top of your icon in the status bar. That data member no longer works as of Android 3.0.

However, `Notification.Builder` has a `setNumber()` method which *does* work on API Level 11 and higher, though with slightly different behavior. Instead of putting the number on top of your status bar icon, the number will appear in your notification drawer entry. This only works if you do not use `setContent()` with `Notification.Builder` to define your own notification drawer entry layout — in that case, you could put your own number in wherever you would like.

Changes in API Level 23

Historically, while we could supply a “large bitmap” (e.g., photo or avatar) to a `Notification` for use in the tile in the notification tray as a `Bitmap`, the “small icon” used for the status bar always had to be a resource in our app. This was aggravating for developers that wanted to tailor the small icon, such as a weather app showing the current temperature. Now, we can supply an `Icon` object, which can wrap a drawable resource, a `Uri` to a `ContentProvider`, a byte array of encoded bitmap data, a `Bitmap`, or a path to a local PNG or JPEG file. Any of those can be used for the small icon, offering greater flexibility. That being said, please do bear in mind that the small icon is small (i.e., tiny changes may not be noticeable) and that ideally it should adhere to the platform aesthetic for notification icons (i.e., do not use a photo).

The user can now disable our heads-up notifications, if the user finds them irritating. We can get an idea of what the user’s chosen notification policies are via `getCurrentInterruptionFilter()` and `getNotificationPolicy()`, so we have some general sense of what the user is and is not expecting to see in terms of notifications.

And, at long last, we can find out all of our active notifications, via a `getActiveNotifications()` method. This will include any notification that is visible to the user (i.e., the user has not dismissed it and we have not gotten rid of it via `cancel()`).

Introducing GridLayout

In 2011, Google added `GridLayout` to our roster of available container classes (a.k.a., layout managers). `GridLayout` is an attempt to make setting up complex Android layouts a bit easier, particularly with an eye towards working well with IDE graphical layout editors. In this chapter, we will examine why `GridLayout` was added and how we can use it in our projects.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Issues with the Classic Containers

Most layouts are implemented using a combination of `LinearLayout`, `RelativeLayout`, and `TableLayout`. Almost everything you would want to be able to create can be accomplished using one, or sometimes more than one, of those containers.

However, there are issues with the classic containers. The two most prominent might be the over-reliance upon nested containers and issues with drag-and-drop GUI building capability.

Nested Containers

`LinearLayout` and `TableLayout` suffer from a tendency to put too many containers inside of other containers. For example, implementing some sort of 2x2 grid would involve:

INTRODUCING GRIDLAYOUT

- A vertical `LinearLayout` holding onto a pair of horizontal `LinearLayout`s, or
- A `TableLayout` holding onto a pair of `TableRows`

On the surface, this does not seem that bad. And, in many cases, it is not that bad.

However, views and containers are relatively heavyweight items. They consume a fair bit of heap space, and when it comes time to lay them out on the screen, they consume a fair bit of processing power. In particular, the fact that a container can hold onto *any* type of widget or container means that it is difficult to optimize common scenarios (e.g., a 2x2 grid) for faster processing. Instead, a container treats its children more or less as “black boxes”, requiring lots of method invocations up and down the call stack to calculate sizes and complete the layout process.

Moreover, the call stack itself can be an issue. The stack size of the main application thread has historically been rather small (8KB was the last reported value). If you have a complex UI, with more than ~15 nested containers, you are likely to run into a `StackOverflowError`. Android itself will contribute some of these containers, exacerbating this problem.

`RelativeLayout`, by comparison, can implement some UI patterns without any nested containers, simply by positioning widgets relative to the container’s bounds and relative to each other.

Drag-and-Drop

Where `RelativeLayout` falls down is with the drag-and-drop capability of the graphical layout editor in IDEs like Eclipse and Android Studio.

When you release the mouse button when dropping a widget into the preview area, the tools need to determine what that really means in terms of layout rules.

`LinearLayout` works fairly well: it will either insert your widget in between two other widgets or add it to the end of the row or column you dropped into. `TableLayout` behaves similarly.

`RelativeLayout`, though, has a more difficult time guessing what particular combination of rules you really mean by this particular drop target. Are you trying to attach the widget to another widget? If so, which one? Are you trying to attach the widget to the bounds of the `RelativeLayout`? While sometimes it will guess properly, sometimes it will not, with potentially confusing results. It is reasonably

likely that you will need to tweak the layout rules manually, either via the Properties pane or via the raw XML.

The New Contender: GridLayout

GridLayout tries to cull the best of the capabilities of the classic containers and drop as many of their limitations as possible.

GridLayout works a bit like `TableLayout`, insofar as it sets things up in a grid, with rows and columns, where the row and column sizes are computed based upon what is placed into those rows and columns. However, unlike `TableLayout`, which relies upon a separate `TableRow` container to manage the rows, `GridLayout` takes the `RelativeLayout` approach of putting rules on the individual widgets (or containers) in the grid, where those rules steer the layout processing. For example, with `GridLayout`, widgets can declare specifically which row and column they should slot into.

`GridLayout` also goes a bit beyond what `TableLayout` offers in terms of capabilities. Notably, it supports row spans as well as column spans, whereas `TableRow` only supports a column span. This gives you greater flexibility when designing your layout to fit the grid-style positioning rules. You can also:

- Explicitly state how many columns there are, rather than having that value be inferred by row contents
- Allow Android to determine where to place a widget without specifying any row or column, with it finding the next available set of grid cells capable of holding the widget, based upon its requested row span and column span values
- Have control over orientation: whereas `TableLayout` always was a column of rows, you could have a `GridLayout` be a row of columns, if that makes implementing the design easier
- And so on

GridLayout and the Android Support Package

`GridLayout` was natively added to the Android SDK in API Level 14 (Android 4.0). Fortunately, the Android Support package has a backport of `GridLayout`. However, the backport is not in one of the JAR files, such as `support-v4`, as `GridLayout` requires some resources. Hence, it is in an Android library project that you must add to your project, known as `gridlayout-v7`.

INTRODUCING GRIDLAYOUT

Android Studio users can simply add a compile 'com.android.support:gridlayout-v7:...' statement to their top-level dependencies closure, for some version identified by So long as those users have the Android Repository set up in the SDK Manager, Gradle will be able to find and incorporate the artifact.

Eclipse users can copy the library project from \$SDK/extras/android/support/v7/gridlayout (where \$SDK is wherever you installed your copy of the Android SDK) to some other spot on their development machine. Then, they can import the library project and attach it to their app project, as was described in the [chapter on library projects](#).

When using the backported GridLayout, you will need to declare another XML namespace in your layout XML resources. That namespace will be http://schemas.android.com/apk/res-auto. If you use an IDE to add the GridLayout to the layout resource, it will automatically add this namespace, under the prefix of app, such as:

```
<android.support.v7.widget.GridLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2">
</android.support.v7.widget.GridLayout>
```

That namespace is required for GridLayout-specific attributes. For example, we can have a columnCount attribute, indicating how many columns the GridLayout should contain. For the native API Level 14 GridLayout, that attribute would be android:columnCount. For the backport, it will be app:columnCount, assuming that you gave the namespace the prefix of app.

When citing GridLayout-specific attributes, the rest of this chapter will use the app prefix, to clarify which attributes need that prefix for the backport. If you are using the native API Level 14 implementation of GridLayout, and you are manually working with the XML, just remember to use android as a prefix instead of app.

The sample app shows *both* the native and the backport implementations of GridLayout: on API Level 14+ devices/emulators it will use native implementations from res/layout-v14/, and it will use the backport on older environments.

Eclipse and GridLayout

You will find `GridLayout` in the “Layouts” portion of the palette of available widgets and containers. As with anything else, you can drag it from the palette into the preview area, then use the Outline and Properties views to configure it.

However, this is the native API Level 14 version of `GridLayout`, not the backport. If you wish to use the backport, you will need to go into the XML and manually adjust the element name, to be `android.support.v7.widget.GridLayout` instead of `GridLayout`. This may, in turn, require restarting Eclipse to make it happy, if you get errors in the preview area when trying to view the resulting `GridLayout`.

Trying to Have Some Rhythm

One of the things that the Android design guidelines try to emphasize is having everything work in 48dp-high blocks, to give you a reasonable set of touch targets for fingers, while maintaining some uniformity of sizing.

Figure 384: 48dp Rhythm, Depicted (image courtesy of Android Open Source Project)

When working with `GridLayout` in the Eclipse graphical layout editor, you will be prompted to try to put your widgets in 48dp-based positions. There is even a “snap to grid” toolbar toggle button that, when pressed, will force everything you drag into the `GridLayout` to reside on a 16dp-based grid.

To accomplish this, it adds a series of `Space` widgets to your layout (or, if you are working with the backport of `GridLayout`, you get `android.support.v7.widget.Space` widgets). These will consume the space that gets your widgets to line up in what Eclipse thinks is the proper positioning. We will see examples of that as we examine our sample application.

Our Test App

To look at a series of GridLayout-based layouts, let's turn our attention to the [GridLayout/Sampler](#) sample project. This has the same ViewPager and PagerTabStrip as did the second sample app from [the chapter on ViewPager](#). However, rather than use a list of 10 EditText widgets managed by fragments, in this case, our fragments will manage layouts containing GridLayout. Each page of our pager will contain a TrivialFragment, whose contents are based on a Sample class that is a simple pair of a layout resource ID and a string resource ID for the fragment's title:

```
package com.commonware.android.gridlayout;

class Sample {
    int layoutId;
    int titleId;

    Sample(int layoutId, int titleId) {
        this.layoutId=layoutId;
        this.titleId=titleId;
    }
}
```

Our revised SampleAdapter maintains a static ArrayList of these Sample objects, one per layout we wish to examine, and uses those values to populate our ViewPager title:

```
package com.commonware.android.gridlayout;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;
import java.util.ArrayList;

public class SampleAdapter extends FragmentPagerAdapter {
    static ArrayList<Sample> SAMPLES=new ArrayList<Sample>();
    private Context ctxt=null;

    static {
        SAMPLES.add(new Sample(R.layout.row, R.string.row));
        SAMPLES.add(new Sample(R.layout.column, R.string.column));
        SAMPLES.add(new Sample(R.layout.table, R.string.table));
        SAMPLES.add(new Sample(R.layout.table_flex, R.string.flexible_table));
        SAMPLES.add(new Sample(R.layout.implicit, R.string.implicit));
        SAMPLES.add(new Sample(R.layout.spans, R.string.spans));
    }

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }
}
```

INTRODUCING GRIDLAYOUT

```
@Override
public int getCount() {
    return(SAMPLES.size());
}

@Override
public Fragment getItem(int position) {
    return(TrivialFragment.newInstance(getSample(position).layoutId));
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(getSample(position).titleId));
}

private Sample getSample(int position) {
    return(SAMPLES.get(position));
}
}
```

TrivialFragment just inflates our desired layout, having received the layout resource ID as a parameter to its factory method:

```
package com.commonware.android.gridlayout;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class TrivialFragment extends Fragment {
    private static final String KEY_LAYOUT_ID="layoutId";

    static TrivialFragment newInstance(int layoutId) {
        TrivialFragment frag=new TrivialFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_LAYOUT_ID, layoutId);
        frag.setArguments(args);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        return(inflater.inflate(getArguments().getInt(KEY_LAYOUT_ID, -1),
                                container, false));
    }
}
```

Note that if you load this project from the GitHub repository, you will need to update it for your copy of the GridLayout library project.

Replacing the Classics

Let's first examine the behavior of `GridLayout` by seeing how it can replace some of the classic layouts we would get from `LinearLayout` and `TableLayout`. Each of the following sub-sections will examine one `GridLayout`-based layout XML resource, how it can be constructed, and what the result looks like when viewed in the sample project.

Horizontal `LinearLayout`

The classic way to create a row of widgets is to use a horizontal `LinearLayout`. The `LinearLayout` will put each of its children, one after the next, within the row.

The `GridLayout` equivalent is to specify one that has an `app:columnCount` equal to the number of widgets in the row. Then, each widget will have `app:layout_column` set to its specific column index (starting at 0) and `app:layout_row` set to 0, as seen in `res/layout/row.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/
android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="2">

    <Button
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/button"/>

    <Button
        app:layout_column="1"
        app:layout_row="0"
        android:text="@string/button"/>

</android.support.v7.widget.GridLayout>
```

Unlike `LinearLayout`, though, we do not specify sizes of the children, in terms of `android:layout_width` and `android:layout_height`. `GridLayout` works a bit like `TableLayout` in this regard, supplying default values for these attributes. In the case of `GridLayout`, the defaults are `wrap_content`, and this cannot be overridden (akin to the behavior of immediate children of a `TableRow`). Instead, you will control size via row and column spans, as will be illustrated later in this chapter.

Given the above layout, we get:

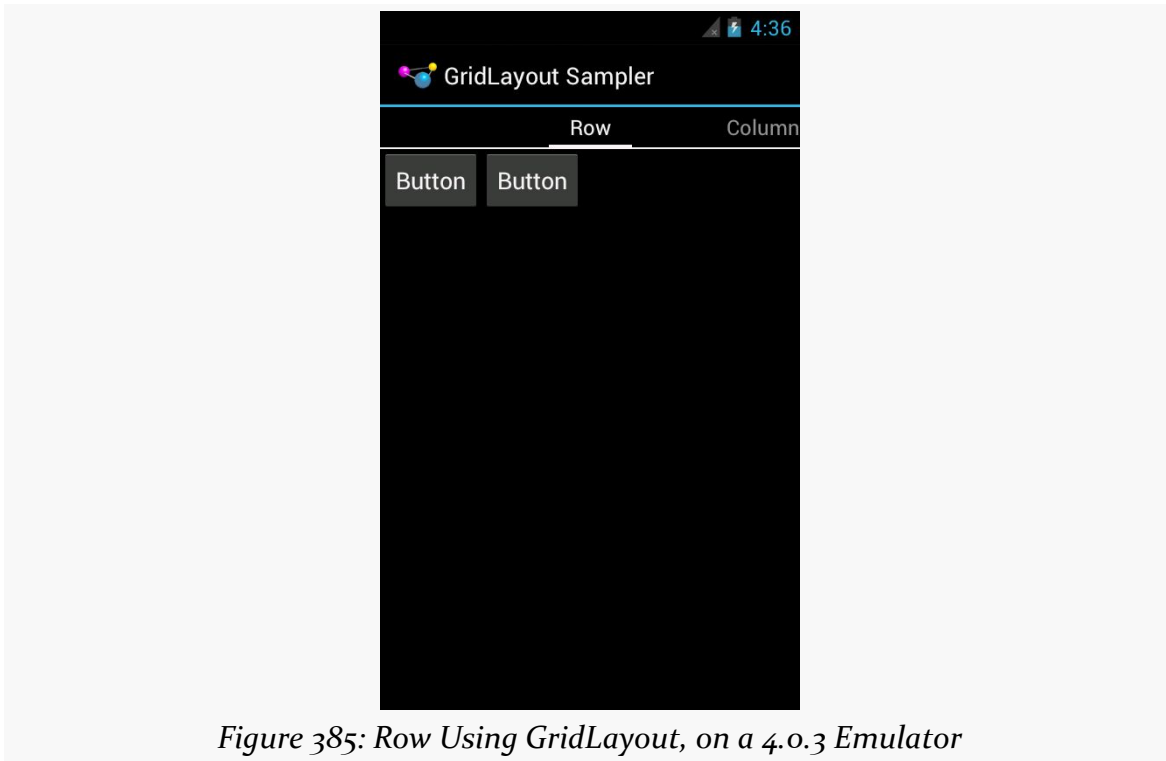

Figure 385: Row Using GridLayout, on a 4.0.3 Emulator

Vertical LinearLayout

Similarly, the conventional way you would specify a column is to use a vertical LinearLayout, which would position its children one after the next. The GridLayout equivalent would be to have `app:columnCount` set to 1, and to place the widgets in each required row via `app:layout_row` attributes, as seen in `res/layout/column.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/
android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="1">
    <Button
        app:layout_column="0"
        app:layout_row="0"
        android:text="@string/button"/>
    <Button
        app:layout_column="0"
        app:layout_row="1"
        android:text="@string/button"/>
</android.support.v7.widget.GridLayout>
```

```
</android.support.v7.widget.GridLayout>
```

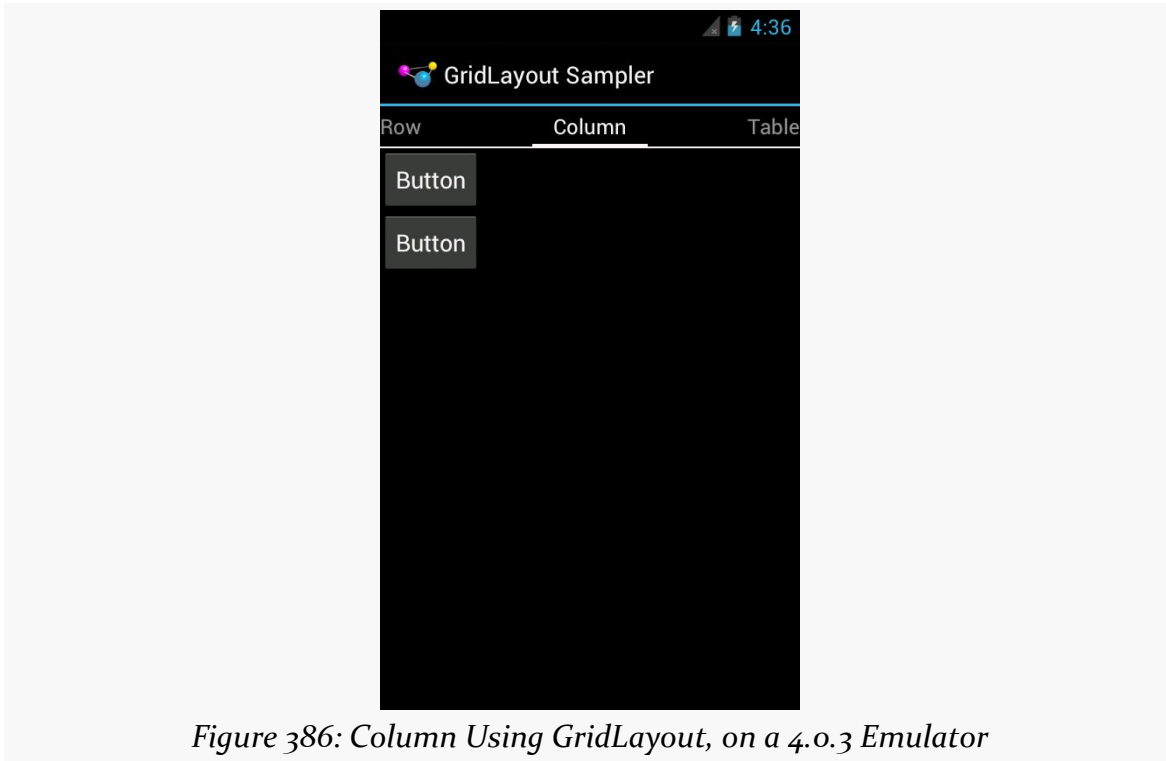

Figure 386: Column Using GridLayout, on a 4.0.3 Emulator

All that being said, it is still probably better to use `LinearLayout` in these cases, rather than mess with `GridLayout`.

TableLayout

The big key to a `TableLayout` is column width, where columns expand to fill their contents, assuming there is sufficient room in the table. `GridLayout` also expands its columns to address the sizes of its contents.

For example, here is a simple 2x2 table, with `TextView` widgets in the left column and `EditText` widgets in the right column, as seen in `res/layout/table.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/
android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2">
  <TextView
```

INTRODUCING GRIDLAYOUT

```
app:layout_column="0"  
app:layout_row="0"  
android:text="@string/name"  
android:textAppearance="?android:attr/textAppearanceLarge"/>  
  
<EditText  
app:layout_column="1"  
app:layout_row="0"  
android:inputType="textPersonName">  
  
    <requestFocus/>  
</EditText>  
  
<TextView  
app:layout_column="0"  
app:layout_row="1"  
android:text="@string/address"  
android:textAppearance="?android:attr/textAppearanceLarge"/>  
  
<EditText  
app:layout_column="1"  
app:layout_row="1"  
android:inputType="textPostalAddress"/>  
</android.support.v7.widget.GridLayout>
```

One feature of the Eclipse graphical layout editor is that we can toggle on a series of lines showing the sizing of the rows and columns, by clicking the “Show Structure” toolbar button:

This helps illustrate that our right column actually takes up all remaining room on the screen, by showing green gridlines denoting the transitions between rows and columns:

However, our EditText widgets are small, because nothing is causing them to fill the available space. To do that, we can use `android:layout_gravity`, to ask the GridLayout to let the widgets fill the available horizontal space, as seen in `res/layout/table_flex.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2">

  <TextView
    app:layout_column="0"
    app:layout_row="0"
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_column="1"
    app:layout_row="0"
    app:layout_gravity="fill_horizontal"
    android:inputType="textPersonName">

    <requestFocus/>
  </EditText>

  <TextView
    app:layout_column="0"
    app:layout_row="1"
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_column="1"
    app:layout_row="1"
    app:layout_gravity="fill_horizontal"
    android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

This allows the EditText widgets to fill the width of the column:

INTRODUCING GRIDLAYOUT

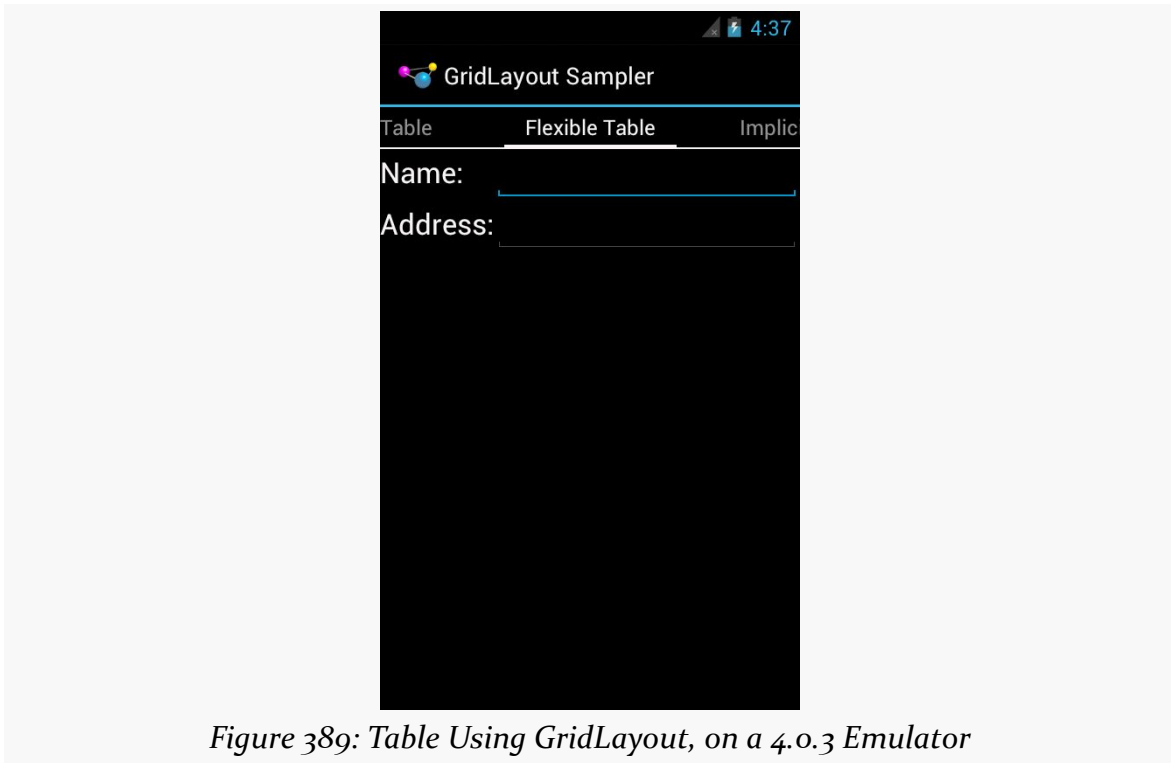

Figure 389: Table Using GridLayout, on a 4.0.3 Emulator

That holds true regardless of how wide that column is:

Figure 390: Table Using GridLayout, in Landscape, on a 4.0.3 Emulator

Implicit Rows and Columns

While all the previous samples showed the row and column of each widget being defined explicitly via `app:layout_row` and `app:layout_column` attributes, that is not your only option.

If you have `app:columnCount` on the `GridLayout` element itself, you can allow `GridLayout` to assign rows and columns. In this respect, `GridLayout` behaves a bit like a “flow layout”: it assigns widgets to cells in the first row, starting from the first column and working its way across, wrapping to the next row when it runs out of room. This makes for a more terse layout file, at the cost of perhaps introducing a bit of confusion when you add or remove a widget and everything after it in the layout file shifts location.

For example, `res/layout/implicit.xml` is the same as `res/layout/table_flex.xml`, except that it skips the `app:layout_row` and `app:layout_column` attributes, allowing `GridLayout` to assign the positions:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/
android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  app:columnCount="2"
  app:orientation="horizontal">

  <TextView
    android:text="@string/name"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPersonName">

    <requestFocus/>
  </EditText>

  <TextView
    android:text="@string/address"
    android:textAppearance="?android:attr/textAppearanceLarge"/>

  <EditText
    app:layout_gravity="fill_horizontal"
    android:inputType="textPostalAddress"/>

</android.support.v7.widget.GridLayout>
```

Visually, this sample is identical to the last one:

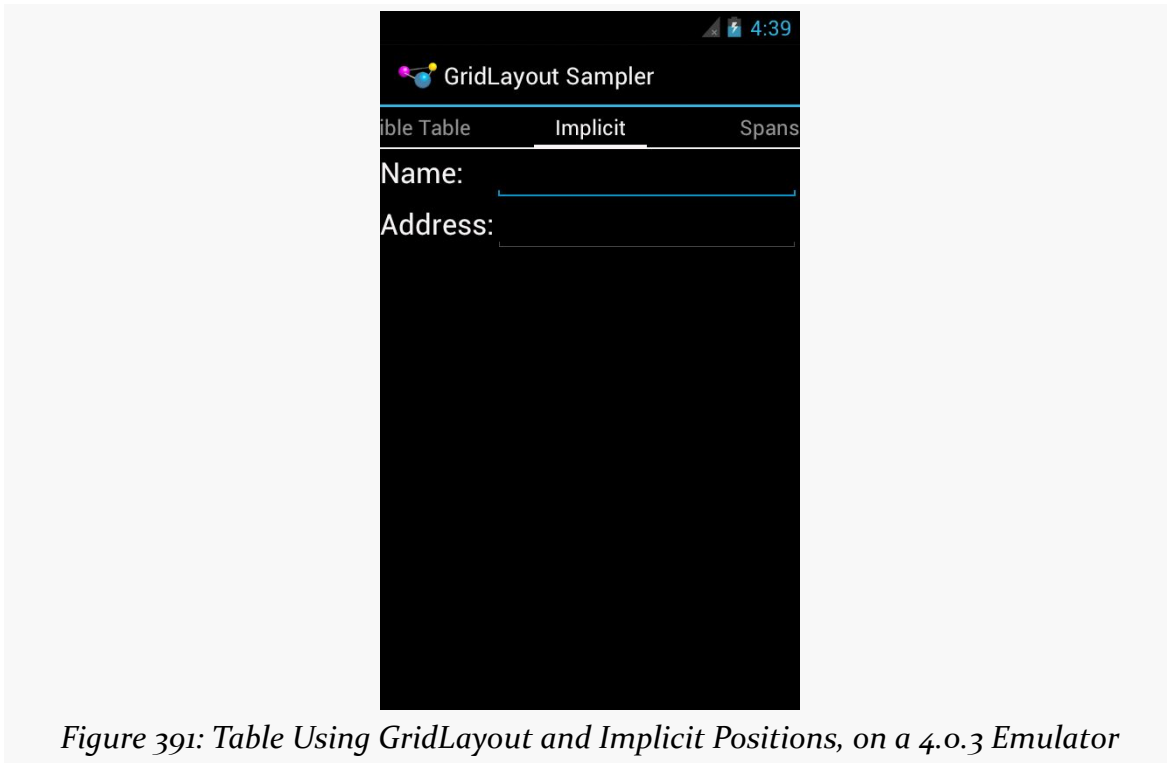

Figure 391: Table Using GridLayout and Implicit Positions, on a 4.0.3 Emulator

The “across columns, then down rows” model holds for GridLayout in the default orientation: horizontal. You can add an `app:orientation` attribute to the GridLayout, setting it to vertical. Then, based on an `app:rowCount` value, GridLayout will automatically assign positions, working down the first column, then across to the next column when it runs out of rows.

Row and Column Spans

Like `TableLayout`, `GridLayout` supports the notion of column spans. You can use `app:layout_columnSpan` to indicate how many columns a particular widget should span in the resulting grid.

However, `GridLayout` also supports row spans, in the form of `app:layout_rowSpan` attributes. A widget can span rows, columns, or both, as needed.

If you are using implicit positions, per the previous section, `GridLayout` will seek the next available space that has sufficient rows and columns for a widget’s set of spans.

INTRODUCING GRIDLAYOUT

For example, the following diagram depicts five buttons placed in a GridLayout with various spans, and an attempt to add a sixth button that should span two columns:

Assuming the first five buttons were added in sequence and with implicit positioning, GridLayout ordinarily would drop the sixth button into the fourth column of the third row. However, there is only a one-column-wide space available there, given that the third button intrudes into the third row. Hence, GridLayout will skip over the smaller space and put the sixth button into the sixth column in the third row.

A GridLayout-based layout that implements the above diagram can be found in `res/layout/spans.xml`:

```
<android.support.v7.widget.GridLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:columnCount="9"
    app:orientation="horizontal"
    app:rowCount="5">

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="2"
        android:text="@string/string_1"/>

    <Button
        app:layout_gravity="fill_horizontal"
        app:layout_columnSpan="2"
        android:text="@string/string_2"/>

    <Button
        app:layout_gravity="fill_vertical"
        app:layout_rowSpan="4"
        android:text="@string/string_3"/>

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="2"
        android:text="@string/string_4"/>

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="1"
        android:text="@string/string_5"/>

    <Button
        app:layout_gravity="fill"
        app:layout_columnSpan="2"
        app:layout_rowSpan="1"
        android:text="@string/string_6"/>

</android.support.v7.widget.GridLayout>
```

INTRODUCING GRIDLAYOUT

```
    android:text="@string/string_3"/>

<Button
    app:layout_gravity="fill"
    app:layout_columnSpan="3"
    app:layout_rowSpan="2"
    android:text="@string/string_4"/>

<Button
    app:layout_gravity="fill_horizontal"
    app:layout_columnSpan="3"
    android:text="@string/string_5"/>

<Button
    app:layout_gravity="fill_horizontal"
    app:layout_columnSpan="2"
    android:text="@string/string_6"/>

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="0"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="1"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="2"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="3"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="4"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="5"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="6"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_width="36dp"
    app:layout_column="7"
    app:layout_row="4" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
```

INTRODUCING GRIDLAYOUT

```
app:layout_column="8"
app:layout_row="0" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="1" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="2" />

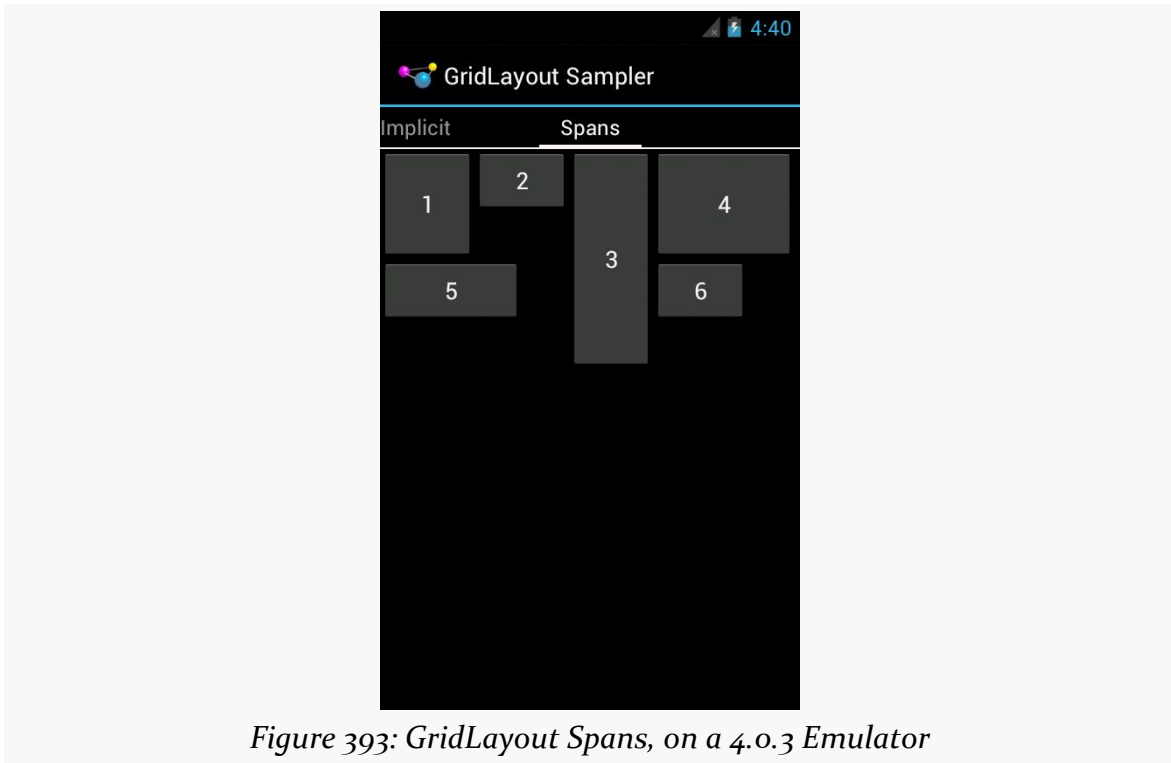

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="3" />

<android.support.v7.widget.Space
    android:layout_height="36dp"
    app:layout_column="8"
    app:layout_row="4" />

</android.support.v7.widget.GridLayout>
```

This layout shows one of the limitations of `GridLayout`: its columns and rows will have a size of 0 by default. Hence, to ensure that each row and column has a minimum size, this layout uses `Space` elements (in an eighth column and fifth row) to establish those minimums. This makes the layout file fairly verbose, but it gives the desired results:

INTRODUCING GRIDLAYOUT

However, the fixed-sized Space elements break the fluidity of the layout:

INTRODUCING GRIDLAYOUT

Perhaps someday someone will create a PercentSpace widget, occupying a percentage of the parent's size, that could be used instead.

The author would like to give thanks to [those on Stack Overflow who assisted in getting the span layout to work](#).

The Percent Support Library

The classic general-purpose Android containers — `LinearLayout`, `RelativeLayout`, and `TableLayout` — have been available since the dawn of Android. The only other general-purpose Android container added to the core SDK has been [GridLayout](#), and it has not proven popular.

In 2015, as part of the suite of Android Support libraries, Google released the Percent Support Library (`percent`). This gives developers two new general-purpose containers, in the form of `PercentFrameLayout` and `PercentRelativeLayout`. These add incremental functionality to the `FrameLayout` and `RelativeLayout` from the regular Android SDK, specifically to be able to specify child sizes and margins based on a percentage of the parent's size.

Handling percentage-based sizing has always been possible through the use of `LinearLayout` and its `layout_weight` attribute. That approach has limitations, notably that everything has to be in a row or column. The percent classes offer that same percentage-based sizing, but with far more flexible placement of children.

One other touted benefit is performance gains, due to lingering concerns about the performance of `layout_weight`. As this chapter will demonstrate, it is unclear if the percent classes necessarily help a lot with performance.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

What Percent Gives Us

Directly, `PercentFrameLayout` and `PercentRelativeLayout` give us all the features of their ancestor classes (`FrameLayout` and `RelativeLayout`), plus additional layout attributes to express widget sizes and margins based on a percentage of the size of the parent.

Indirectly, these classes give us greater ability to get our code to match what the designers are asking for.

In cases where the person developing the graphic design for an app is not the person who is implementing the design, there tends to be a communications gap between the two parties. Android's layout system is not the same as systems that the designers might have prior experience in (e.g., CSS for Web development). Some designers have no experience with implementations at all, settling for drawing in Photoshop and leaving it up to others to implement the vision.

Many designs will use percentages, as that is one way of doing responsive design in other areas (e.g., the Web). Prior to the percent support library, you had three major options for implementing percentage-based layouts:

1. Use `LinearLayout`... if everything requiring the percentage-based sizing happens to be in rows or columns
2. Use something else (e.g., `FrameLayout`, `RelativeLayout`) and implement the percentage-based solution yourself in code, dynamically generating the sizes and margins to put in the `LayoutParams` structures
3. Create your own custom `ViewGroup` from scratch

The first solution is easy but inflexible. The other two are more flexible but are far from easy. The percent support library gives you ease and flexibility, at the cost of a small library.

In addition to constraining size and margins based on parent size, the percent classes also allow you to constrain the aspect ratio of a widget. For example, your app involves showing images that you download from your own server. You know that those images have a consistent aspect ratio (e.g., 16:9, 4:3). If the `ImageView` that will display the image is a child of a `PercentFrameLayout` or `PercentRelativeLayout`, you can arrange to keep the `ImageView` in the right aspect ratio, while allowing the *size* of the `ImageView` to vary, whether using percentage-based sizes or more traditional `match_parent/wrap_content` sizes.

Using Percent

On the whole, using the percent classes is very simple, stemming in part because they extend existing framework classes that you are already used to.

The [Percent/Comparison](#) sample project is yet another ViewPager-with-material-tabs demo app. This one is being used to compare using the percent classes with achieving similar structures using LinearLayout and weights.

Adding the Dependency

The percent library is part of the Android Support set of libraries, and so you add percent the same way as you add libraries like support-v4, via a compile statement in your dependencies closure of your module:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'io.karim:materialtabs:2.0.2'
    compile 'com.android.support:support-v13:23.1.1'
    compile 'com.android.support:percent:23.1.1'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.2"

    defaultConfig {
        minSdkVersion 17
        targetSdkVersion 18
    }
}
```

Here, we are pulling in percent:23.1.1; you will want to use the latest version at the time you are adding the dependency.

Using PercentFrameLayout

Back in Android 1.0, AbsoluteLayout was available, allowing developers to create layout resources based on pixel locations. This was deprecated many years ago, as it does not give you a very responsive design.

Still, there are developers who insist in that sort of mid-1990's GUI design approach. Their workaround — short of using the deprecated AbsoluteLayout or rolling a

THE PERCENT SUPPORT LIBRARY

custom ViewGroup — was to use `FrameLayout`, using margins to set the positions of the widgets.

`PercentFrameLayout` gives these developers the additional ability to set those margins, and sizes, on a percentage basis, making this technique somewhat less troublesome for dealing with varying screen sizes.

Three of the five tabs in the sample app all show the same output: a `ListView` in which each row shows three colored blocks. The three blocks take up 30%, 20%, and 30% of the row, and each block is surrounded by 5% worth of margin:

Figure 395: Percent Comparison Demo, Showing PercentFrameLayout Rows

To accomplish this with a `PercentFrameLayout`, you just need to use `android.support.percent.PercentFrameLayout` as the row container, put your three blocks in as children, set their widths and margins based upon those percentages (and their position in the row)... and deal with a minor annoyance with your IDE:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.percent.PercentFrameLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
```

```
<!--suppress AndroidDomInspection -->
<TextView
    android:id="@+id/start"
    android:layout_height="wrap_content"
    android:background="#FF00FFFF"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"
    app:layout_marginLeftPercent="5%"
    app:layout_widthPercent="30%" />

<!--suppress AndroidDomInspection -->
<TextView
    android:id="@+id/center"
    android:layout_height="wrap_content"
    android:background="#FFFFFF00"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"
    app:layout_marginLeftPercent="40%"
    app:layout_widthPercent="20%" />

<!--suppress AndroidDomInspection -->
<TextView
    android:id="@+id/end"
    android:layout_height="wrap_content"
    android:background="#FFFFFF00"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"
    app:layout_marginLeftPercent="65%"
    app:layout_widthPercent="30%" />
</android.support.percent.PercentFrameLayout>
```

Since `PercentFrameLayout` comes from a library and resides in a library-specific Java package, we have to fully-qualify the element name as `android.support.percent.PercentFrameLayout`.

Each block is represented as a `TextView`. The heights are conventional, using `wrap_content`. However, the widths are not handled by `android:layout_width`, but instead by `app:layout_widthPercent`. The `app:` prefix is because this attribute comes from a library. `layout_widthPercent` takes a percentage as a value (e.g., "30%") and will assign a width based on that percentage of the total available width.

Since we are assigning a width based upon the percentage, we do not need `android:layout_width` as an attribute. Android Studio is oblivious to this and will show errors because you are missing that attribute. The `<!--suppress AndroidDomInspection -->` comment is the XML layout equivalent of an annotation to tell the IDE to ignore this sort of error for this element.

THE PERCENT SUPPORT LIBRARY

The other library-supplied attribute used by the blocks is `app:layout_marginLeftPercent`. This indicates how much margin should be applied on the left side, expressed as a percentage of the total available width. In the case of `PercentFrameLayout`, as with `android:layout_marginLeft` in `FrameLayout`, this does not control spacing between widgets, but instead controls the horizontal positioning of the widget. Hence, while the first block has a “normal” sort of margin (5%), the other two blocks need to take into account their overall position from the left edge of the `PercentFrameLayout`, and so they use 40% (5% + 30% + 5%) and 65% (40% + 20% + 5%), respectively.

That may seem clunky, and in truth, it is. `PercentRelativeLayout` would be a better choice here, as will be seen in the next section.

Either, though, are better than our `LinearLayout` equivalent. That is because there is no way to express margins on a percentage basis with a `LinearLayout`. Expressing widget sizes on a percentage basis could be handled with `layout_weight` attributes, but margins do not participate in the weights. As a result, we have to use transparent widgets as “struts” to implement the percentage-based margins. In this case, we use the `Space` widget, added in API Level 14 for this sort of scenario:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="horizontal">

  <Space
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="5"/>

  <TextView
    android:id="@+id/start"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="30"
    android:background="#FF00FFFF"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"/>

  <Space
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="5"/>

  <TextView
    android:id="@+id/center"
    android:layout_width="0dp"
    android:layout_height="wrap_content">
```

THE PERCENT SUPPORT LIBRARY

```
        android:layout_weight="20"
        android:background="#FFFF00FF"
        android:gravity="center"
        android:padding="8dp"
        android:textColor="@android:color/black"/>

<Space
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="5"/>

<TextView
    android:id="@+id/end"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="30"
    android:background="#FFFFFF00"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"/>

<Space
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="5"/>
</LinearLayout>
```

But, as you can see, this results in a very verbose layout file.

Using PercentRelativeLayout

PercentRelativeLayout works similarly to PercentFrameLayout. However, because PercentRelativeLayout is based on RelativeLayout, it is easier for us to express layouts like the row-of-three-boxes shown above. Rather than having to position each box relative to the left edge, we can position each box relative to the preceding box:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.percent.PercentRelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <!--suppress AndroidDomInspection -->
    <TextView
        android:id="@+id/start"
        android:layout_height="wrap_content"
        android:layout_alignParentStart="true"
        android:background="#FF00FFFF"
        android:gravity="center"
        android:padding="8dp"
        android:textColor="@android:color/black"
        app:layout_marginLeftPercent="5%"
        app:layout_widthPercent="30%" />
```

```
<!--suppress AndroidDomInspection -->
<TextView
    android:id="@+id/center"
    android:layout_height="wrap_content"
    android:layout_toEndOf="@id/start"
    android:background="#FFFF00FF"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"
    app:layout_marginLeftPercent="5%"
    app:layout_widthPercent="20%" />

<!--suppress AndroidDomInspection -->
<TextView
    android:id="@+id/end"
    android:layout_height="wrap_content"
    android:layout_toEndOf="@id/center"
    android:background="#FFFFFF00"
    android:gravity="center"
    android:padding="8dp"
    android:textColor="@android:color/black"
    app:layout_marginLeftPercent="5%"
    app:layout_widthPercent="30%" />
</android.support.percent.PercentRelativeLayout>
```

However, in the end, we get the same visual results as we do with the first two layouts. As Perl developers like to say, “there’s more than one way to do it”.

About Those Performance Gains

Part of the argument for the percent classes is concerns about the performance of `layout_weight` with `LinearLayout`.

The sample project takes some steps to attempt to prove or disprove the percent performance theory.

Testing the Three Row Types

Each of those three row layouts are used in a `ListView` managed by a subclass of `SampleListFragment`:

```
package com.commonware.android.percent.comparison;

import android.app.ListFragment;
import android.os.AsyncTask;
import android.os.Bundle;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.view.View;
```

```
abstract public class SampleListFragment extends ListFragment {
    abstract int getLayoutId();

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setHasOptionsMenu(true);
    }

    @Override
    public void onViewCreated(View view,
                              Bundle savedInstanceState) {
        super.onViewCreated(view, savedInstanceState);

        StuffAdapter adapter=
            new StuffAdapter(getActivity().getLayoutInflater(),
                             getLayoutId());

        setListAdapter(adapter);
    }

    @Override
    public void onCreateOptionsMenu(Menu menu,
                                    MenuInflater inflater) {
        inflater.inflate(R.menu.actions, menu);
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        if (item.getItemId()==R.id.perftest) {
            View test=
                getActivity()
                    .getLayoutInflater()
                    .inflate(getLayoutId(), null);

            new TestTask(getActivity())
                .executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, test);
        }

        return(super.onOptionsItemSelected(item));
    }
}
```

This class is abstract, and there is one concrete subclass for each of the three row layouts. The subclasses override `getLayoutId()` and return the layout ID to use for that particular fragment. For example, here is the `PercentListFragment` that uses the layout resource that employs the `PercentFrameLayout`:

```
package com.commonware.android.percent.comparison;

public class PercentListFragment extends SampleListFragment {
    @Override
    int getLayoutId() {
        return(R.layout.percent);
    }
}
```

THE PERCENT SUPPORT LIBRARY

```
}  
}
```

SampleListFragment uses that layout ID in two places. The big one is `onViewCreated()`, where it passes the layout ID to a `StuffAdapter`. `StuffAdapter` is responsible for filling the `ListView` with, um, stuff:

```
package com.commonware.android.percent.comparison;  
  
import android.view.LayoutInflater;  
import android.view.View;  
import android.view.ViewGroup;  
import android.widget.BaseAdapter;  
import android.widget.TextView;  
  
public class StuffAdapter extends BaseAdapter {  
    private final LayoutInflater inflater;  
    private final int layoutId;  
  
    StuffAdapter(LayoutInflater inflater, int layoutId) {  
        this.inflater=inflater;  
        this.layoutId=layoutId;  
    }  
  
    @Override  
    public int getCount() {  
        return(25);  
    }  
  
    @Override  
    public Object getItem(int position) {  
        return(Integer.valueOf(position));  
    }  
  
    @Override  
    public long getItemId(int position) {  
        return(position);  
    }  
  
    @Override  
    public View getView(int position, View convertView,  
                        ViewGroup parent) {  
        if (convertView==null) {  
            convertView=inflater.inflate(layoutId, parent, false);  
        }  
  
        String prefix=Integer.toString(position+1);  
        TextView tv=(TextView)convertView.findViewById(R.id.start);  
  
        tv.setText(prefix+"A");  
        tv=(TextView)convertView.findViewById(R.id.center);  
        tv.setText(prefix+"B");  
        tv=(TextView)convertView.findViewById(R.id.end);  
        tv.setText(prefix+"C");  
  
        return(convertView);  
    }  
}
```

THE PERCENT SUPPORT LIBRARY

This is a simple BaseAdapter that fills in each of the three TextView widgets in the row with a string based on the row and column (e.g., 1A for the first column of the first row, 2C for the third column of the second row). Mostly, we are using StuffAdapter to demonstrate that the rows look identical to the user, even though we are using three different approaches for creating them.

However, SampleListFragment also defines an overflow item that, when tapped, will inflate that layout resource and pass it to TestTask via executeOnExecutor(). TestTask is designed to see how quickly the layout responds to being rendered, specifically via calls to measure() and layout():

```
package com.commonware.android.percent.comparison;

import android.content.Context;
import android.os.AsyncTask;
import android.os.SystemClock;
import android.util.Log;
import android.view.View;
import android.widget.Toast;

class TestTask extends
    AsyncTask<View, Void, Void> {
    private static final int PASSES=10000000;
    private final Context ctxt;

    public TestTask(Context ctxt) {
        super();

        this.ctxt=ctxt.getApplicationContext();
    }

    @SuppressWarnings("ResourceType")
    @Override
    protected Void doInBackground(View... params) {
        View test=params[0];

        test.measure(480, 800);

        long start=SystemClock.uptimeMillis();

        for (int i=0; i<PASSES; i++) {
            test.layout(0, 0, 480, 800);
        }

        long split=SystemClock.uptimeMillis();

        Log.d("PerfTest",
            String.format("%d layout passes in %d ms", PASSES,
                split-start));

        for (int i=0; i<PASSES; i++) {
            test.measure(480, 800);
            test.layout(0, 0, 480, 800);
        }
    }
}
```

```
Log.d("PerfTest",
    String.format("%d measure & layout passes in %d ms",
        PASSES,
        SystemClock.uptimeMillis()-split));

return (null);
}

@Override
protected void onPostExecute(Void aVoid) {
    Toast
        .makeText(ctxt, "Test complete", Toast.LENGTH_LONG)
        .show();
}
}
```

In `doInBackground()`, `TestTask` runs two separate tests:

1. 10,000,000 passes of `layout()` on an already-measured layout, and
2. 10,000,000 passes of both `measure()` and `layout()`

`measure()` and `layout()` are two key methods in the work being done to render a `View` or `ViewGroup`. If there is a massive performance difference, you should see massive differences in the times reported in `LogCat`.

And, at least when tested on a Nexus 5 running Android 6.0, the performance of all three are roughly equivalent.

Wait! What About Nested Weights?

The `LinearLayout` used for the `ListView` rows uses weights for allocating space on a percentage basis. However, it consists of a single row, which is not especially complex. In particular, it does not use *nested* weights, where a weight-based `LinearLayout` holds weight-based `LinearLayout` children. Some of the performance concerns with `LinearLayout` and weights are specific to nested weights.

So, this sample app has two other tabs. Rather than showing `ListView` widgets with rows, instead, they show a basic grid of boxes:

THE PERCENT SUPPORT LIBRARY

Figure 396: Percent Comparison Demo, Showing PercentFrameLayout Grid

Two editions of that grid are included. One uses PercentFrameLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.percent.PercentFrameLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <!--suppress AndroidDomInspection -->
  <TextView
    android:background="#FF00FFFF"
    android:gravity="center"
    android:padding="8dp"
    android:text="Top Left"
    android:textColor="@android:color/black"
    app:layout_heightPercent="24%"
    app:layout_marginLeftPercent="7%"
    app:layout_marginTopPercent="7%"
    app:layout_widthPercent="24%" />

  <!--suppress AndroidDomInspection -->
  <TextView
    android:background="#FF00FFFF"
    android:gravity="center"
    android:padding="8dp"
    android:text="Center Left"
    android:textColor="@android:color/black"
    app:layout_heightPercent="24%"
    app:layout_marginLeftPercent="7%"
```

THE PERCENT SUPPORT LIBRARY

```
    app:layout_marginTopPercent="38%"
    app:layout_widthPercent="24%" />

<!--suppress AndroidDomInspection -->
<TextView
    android:background="#FF00FFFF"
    android:gravity="center"
    android:padding="8dp"
    android:text="Bottom Left"
    android:textColor="@android:color/black"
    app:layout_heightPercent="24%"
    app:layout_marginLeftPercent="7%"
    app:layout_marginTopPercent="69%"
    app:layout_widthPercent="24%" />

<!--suppress AndroidDomInspection -->
<TextView
    android:background="#FFFF00FF"
    android:gravity="center"
    android:padding="8dp"
    android:text="Top Center"
    android:textColor="@android:color/black"
    app:layout_heightPercent="24%"

    app:layout_marginLeftPercent="69%"
    app:layout_marginTopPercent="69%"
    app:layout_widthPercent="24%" />
</android.support.percent.PercentFrameLayout>
```

The other replicates the same layout using nested `LinearLayout` widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Space
        android:layout_width="wrap_content"
        android:layout_height="0dp"
        android:layout_weight="7"/>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="0dp"
        android:layout_weight="24"
        android:orientation="horizontal">

        <Space
            android:layout_width="0dp"
            android:layout_height="wrap_content"
            android:layout_weight="7"/>

        <TextView
            android:layout_width="0dp"
            android:layout_height="match_parent"
            android:layout_weight="24"
            android:background="#FF00FFFF"
            android:gravity="center"
```

```
    android:padding="8dp"
    android:text="Top Left"
    android:textColor="@android:color/black"/>

<Space
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="7"/>

    android:padding="8dp"
    android:text="Bottom Right"
    android:textColor="@android:color/black"/>

<Space
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:layout_weight="7"/>
</LinearLayout>

<Space
    android:layout_width="wrap_content"
    android:layout_height="0dp"
    android:layout_weight="7"/>
</LinearLayout>
```

As before, the PercentFrameLayout is simpler. In addition, it may take up less heap space (fewer View objects overall) and will use less stack space (one less level in the view hierarchy).

The SampleFragment (and subclasses) responsible for showing these layouts follow the same basic pattern as did SampleListFragment. Subclasses of SampleFragment

override a `getLayoutId()`, where `SampleFragment` arranges to show the desired layout (this time, just a single instance) and run a `TestTask` to test the layout's `measure()` and `layout()` performance.

Once again, when tested on a Nexus 5 running Android 6.0, there is no significant difference in terms of performance between the two implementations.

Hence, while flexibility and conciseness of layouts are fine reasons to consider the percent classes, do not use them with the expectation that they will solve performance issues magically.

Maintaining Aspect Ratio

The percent classes also support an `aspectRatio` attribute. You would use this if you wanted to keep a widget in a particular aspect ratio, while letting the overall size float. For example, you could use `layout_widthPercent` to set the width to a percentage of the parent, then use `aspectRatio` to have the height be calculated based upon the width:

```
<!--suppress AndroidDomInspection -->
<ImageView
  app:layout_widthPercent="60%"
  app:aspectRatio="1.333"/> <!-- for 4:3 -->
```

This is useful in cases where you are sure that you want a particular aspect ratio. One example would be `ImageView` widgets where you know that the images will be coming from some source in a particular aspect ratio.

Other Problems

[The documentation](#) suggests that instead of just using `layout_widthPercent` and `layout_heightPercent`, you could also use `layout_width` and `layout_height` as well:

It is not necessary to specify `layout_width/height` if you specify `layout_widthPercent`. However, if you want the view to be able to take up more space than what percentage value permits, you can add `layout_width/height="wrap_content"`. In that case if the percentage size is too small for the View's content, it will be resized using `wrap_content` rule.

That does not seem to work as advertised, as Mark Allison points out in [a blog post](#).

Dialogs and DialogFragments

Generally speaking, modal dialogs are considered to offer poor UX, particularly on mobile devices. You want to give the user more choices, not fewer, and so locking them into “deal with this dialog right now, or else” is not especially friendly. That being said, from time to time, there will be cases where that sort of modal interface is necessary, and to help with that, Android does have a dialog framework that you can use.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

DatePickerDialog and TimePickerDialog

Android has a pair of built-in dialogs that handle the common operations of allowing the user to select a date (`DatePickerDialog`) or a time (`TimePickerDialog`). These are simply dialog wrappers around the [DatePicker](#) and [TimePicker](#) widgets, as are described in this book’s Widget Catalog.

The `DatePickerDialog` allows you to set the starting date for the selection, in the form of a year, month, and day of month value. Note that the month runs from 0 for January through 11 for December. Most importantly, both let you provide a callback object (`OnDateChangeListener` or `OnDateSetListener`) where you are informed of a new date selected by the user. It is up to you to store that date someplace, particularly if you are using the dialog, since there is no other way for you to get at the chosen date later on.

Similarly, `TimePickerDialog` lets you:

- Set the initial time the user can adjust, in the form of an hour (0 through 23) and a minute (0 through 59)
- Indicate if the selection should be in 12-hour mode with an AM/PM toggle, or in 24-hour mode (what in the US is thought of as “military time” and what in much of the rest of the world is thought of as “the way times are supposed to be”)
- Provide a callback object (`OnTimeChangeListener` or `OnTimeSetListener`) to be notified of when the user has chosen a new time, which is supplied to you in the form of an hour and minute

For example, from the [Dialogs/Chrono](#) sample project, here’s a trivial layout containing a label and two buttons — the buttons will pop up the dialog flavors of the date and time pickers:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <TextView android:id="@+id/dateAndTime"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    />
  <Button android:id="@+id/dateBtn"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="Set the Date"
    android:onClick="chooseDate"
    />
  <Button android:id="@+id/timeBtn"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="Set the Time"
    android:onClick="chooseTime"
    />
</LinearLayout>
```

The more interesting stuff comes in the Java source:

```
package com.commonware.android.chrono;

import android.app.Activity;
import android.app.DatePickerDialog;
import android.app.TimePickerDialog;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.view.View;
```

DIALOGS AND DIALOGFRAGMENTS

```
import android.widget.DatePicker;
import android.widget.TextView;
import android.widget.TimePicker;
import java.util.Calendar;

public class ChronoDemo extends Activity {
    TextView dateAndTimeLabel;
    Calendar dateAndTime=Calendar.getInstance();

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        dateAndTimeLabel=(TextView)findViewById(R.id.dateAndTime);

        updateLabel();
    }

    public void chooseDate(View v) {
        new DatePickerDialog(this, d,
            dateAndTime.get(Calendar.YEAR),
            dateAndTime.get(Calendar.MONTH),
            dateAndTime.get(Calendar.DAY_OF_MONTH))
            .show();
    }

    public void chooseTime(View v) {
        new TimePickerDialog(this, t,
            dateAndTime.get(Calendar.HOUR_OF_DAY),
            dateAndTime.get(Calendar.MINUTE),
            true)
            .show();
    }

    private void updateLabel() {
        dateAndTimeLabel
            .setText(DateUtils
                .formatDateTime(this,
                    dateAndTime.getTimeInMillis(),
                    DateUtils.FORMAT_SHOW_DATE|DateUtils.FORMAT_SHOW_TIME));
    }

    DatePickerDialog.OnDateSetListener d=new DatePickerDialog.OnDateSetListener() {
        public void onDateSet(DatePicker view, int year, int monthOfYear,
            int dayOfMonth) {
            dateAndTime.set(Calendar.YEAR, year);
            dateAndTime.set(Calendar.MONTH, monthOfYear);
            dateAndTime.set(Calendar.DAY_OF_MONTH, dayOfMonth);
            updateLabel();
        }
    };

    TimePickerDialog.OnTimeSetListener t=new TimePickerDialog.OnTimeSetListener() {
        public void onTimeSet(TimePicker view, int hourOfDay,
            int minute) {
            dateAndTime.set(Calendar.HOUR_OF_DAY, hourOfDay);
            dateAndTime.set(Calendar.MINUTE, minute);
            updateLabel();
        }
    }
}
```

DIALOGS AND DIALOGFRAGMENTS

```
};  
}
```

The “model” for this activity is just a `Calendar` instance, initially set to be the current date and time. In the `updateLabel()` method, we take the current `Calendar`, format it using `DateUtils` and `formatDateTime()`, and put it in the `TextView`. The nice thing about using Android’s `DateUtils` class is that it will format dates and times using the user’s choice of date formatting, determined through the `Settings` application.

Each button has a corresponding method that will get control when the user clicks it (`chooseDate()` and `chooseTime()`). When the button is clicked, either a `DatePickerDialog` or a `TimePickerDialog` is shown. In the case of the `DatePickerDialog`, we give it an `OnDateSetListener` callback that updates the `Calendar` with the new date (year, month, day of month). We also give the dialog the last-selected date, getting the values out of the `Calendar`. In the case of the `TimePickerDialog`, it gets an `OnTimeSetListener` callback to update the time portion of the `Calendar`, the last-selected time, and a `true` indicating we want 24-hour mode on the time selector

With all this wired together, the resulting activity looks like this:

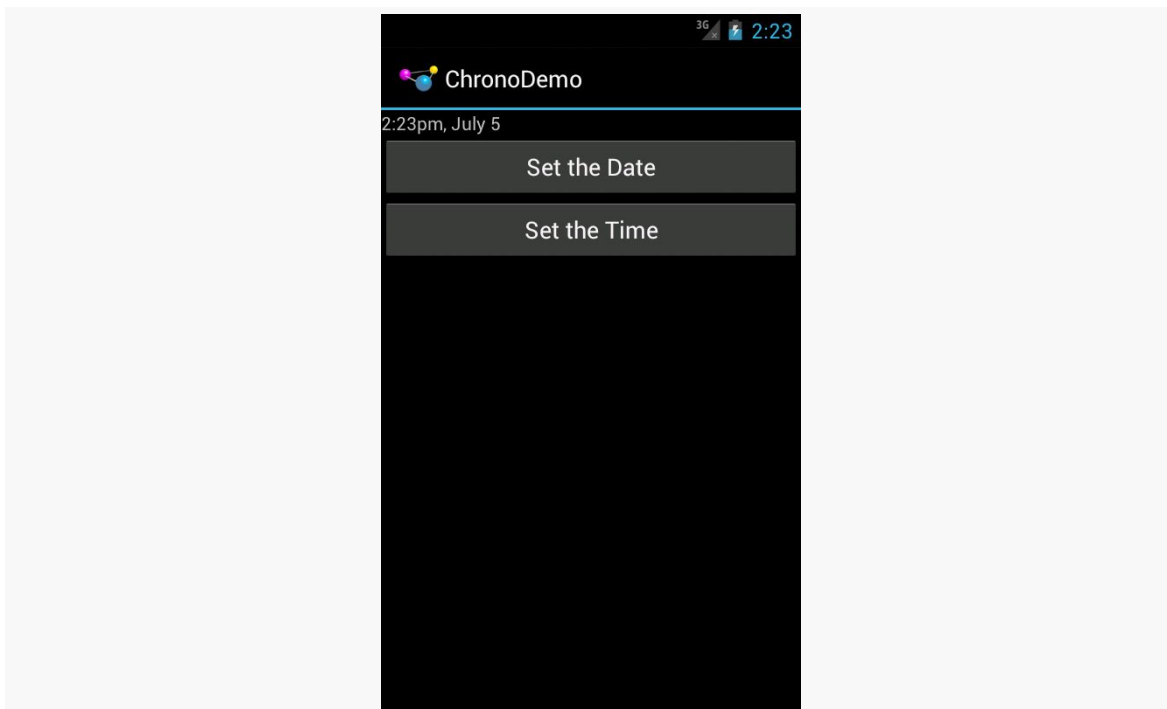

Figure 397: ChronoDemo, As Initially Launched, on Android 4.0.3

Figure 398: ChronoDemo, Showing DatePickerDialog

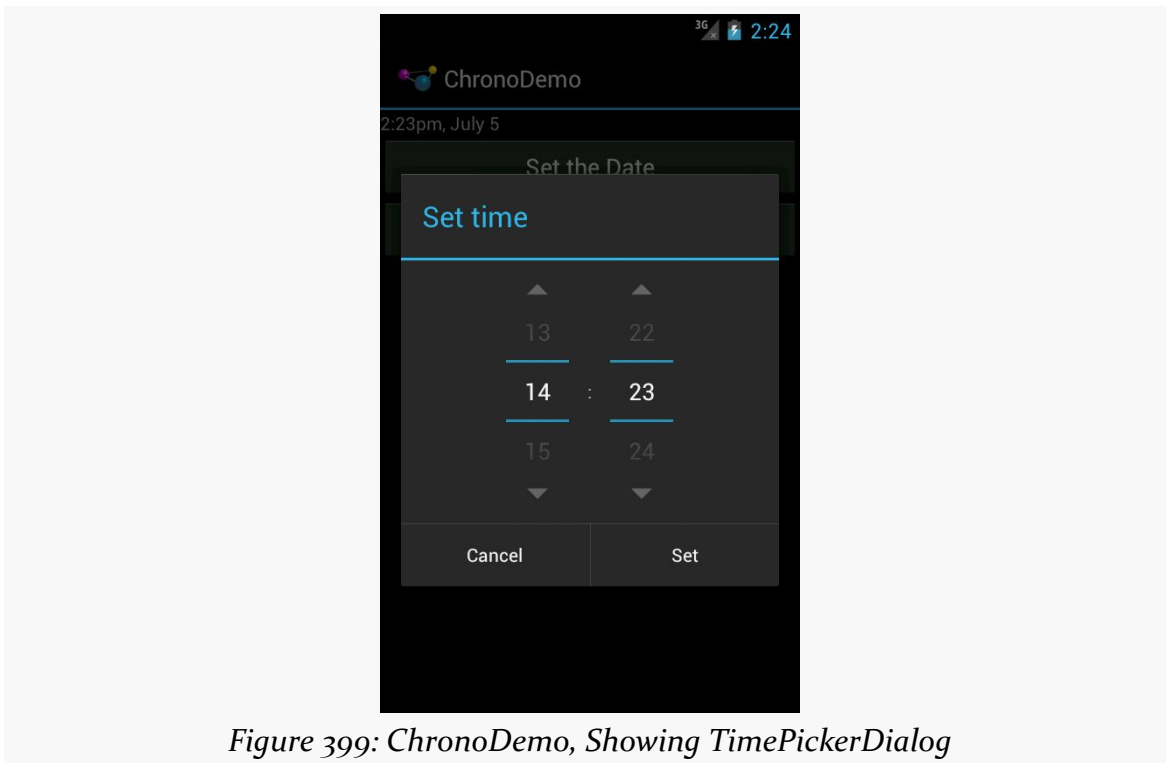

Figure 399: ChronoDemo, Showing TimePickerDialog

Changes and Bugs

Android 4.1 through 4.4 have some changes in behavior from what came before and what came after.

First, the “Cancel” button was removed, unless you specifically add a negative button listener to the underlying DatePicker or TimePicker widget:

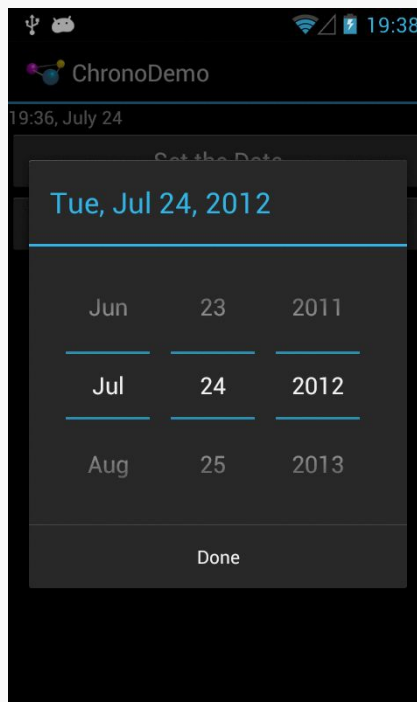

Figure 400: ChronoDemo, Showing DatePickerDialog, on Android 4.1

The user can press BACK to exit the dialog, so all functionality is still there, but you may need to craft your documentation to accommodate this difference. And, on Android 5.0+, the Cancel button returned.

Second, your OnDateSetListener or OnTimeSetListener will be called an extra time. If the user presses BACK to leave the dialog, your onDateSet() or onTimeSet() will be called. If the user clicks the positive button of the dialog, you are called *twice*. There is a workaround [documented on Stack Overflow](#), and [the bug report can be found on the Android issue tracker](#). This too was repaired in Android 5.0.

AlertDialog

For your own custom dialogs, you could extend the `Dialog` base class, as do `DatePickerDialog` and `TimePickerDialog`. More commonly, though, developers create custom dialogs via `AlertDialog`, in large part due to the existence of `AlertDialog.Builder`. This builder class allows you to construct a custom dialog using a single (albeit long) Java statement, rather than having to create your own custom subclass. `Builder` offers a series of methods to configure an `AlertDialog`, each method returning the `Builder` for easy chaining.

Commonly-used configuration methods on `Builder` include:

- `setMessage()` if you want the “body” of the dialog to be a simple textual message, from either a supplied `String` or a supplied string resource ID.
- `setTitle()` and `setIcon()`, to configure the text and/or icon to appear in the title bar of the dialog box.
- `setPositiveButton()`, `setNeutralButton()`, and `setNegativeButton()`, to indicate which button(s) should appear across the bottom of the dialog, where they should be positioned (left, center, or right, respectively), what their captions should be, and what logic should be invoked when the button is clicked (besides dismissing the dialog).

Calling `create()` on the `Builder` will give you the `AlertDialog`, built according to your specifications. You can use additional methods on `AlertDialog` itself to perhaps configure things beyond what `Builder` happens to support.

Note, though, that calling `create()` does not actually display the dialog. The modern way to display the dialog is to tie it to a `DialogFragment`, as will be discussed in the next section.

DialogFragments

One challenge with dialogs comes with configuration changes, notably screen rotations. If they pivot the device from portrait to landscape (or vice versa), presumably the dialog should remain on the screen after the change. However, since Android wants to destroy and recreate the activity, that would have dire impacts on your dialog.

DIALOGS AND DIALOGFRAGMENTS

Pre-fragments, Android had a “managed dialog” facility that would attempt to help with this. However, with the introduction of fragments came the `DialogFragment`, which handles the configuration change process.

You have two ways of supplying the dialog to the `DialogFragment`:

1. You can override `onCreateDialog()` and return a `Dialog`, such as `AlertDialog` created via an `AlertDialog.Builder`
2. You can override `onCreateView()`, as you would with an ordinary fragment, and the `View` that you return will be placed inside of a dialog

The [Dialogs/DialogFragment](#) sample project demonstrates the use of a `DialogFragment` in conjunction with an `AlertDialog` in this fashion.

Here is our `DialogFragment`, named `SampleDialogFragment`:

```
package com.commonware.android.dlgfrag;

import android.app.AlertDialog;
import android.app.Dialog;
import android.app.DialogFragment;
import android.content.DialogInterface;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.EditText;
import android.widget.Toast;

public class SampleDialogFragment extends DialogFragment implements
    DialogInterface.OnClickListener {
    private View form=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        form=
            getActivity().getLayoutInflater()
                .inflate(R.layout.dialog, null);

        AlertDialog.Builder builder=new AlertDialog.Builder(getActivity());

        return(builder.setTitle(R.string.dlg_title).setView(form)
            .setPositiveButton(android.R.string.ok, this)
            .setNegativeButton(android.R.string.cancel, null).create());
    }

    @Override
    public void onClick(DialogInterface dialog, int which) {
        String template=getActivity().getString(R.string.toast);
        EditText name=(EditText)form.findViewById(R.id.title);
        EditText value=(EditText)form.findViewById(R.id.value);
        String msg=
            String.format(template, name.getText().toString(),
                value.getText().toString());
    }
}
```

DIALOGS AND DIALOGFRAGMENTS

```
    Toast.makeText(getActivity(), msg, Toast.LENGTH_LONG).show();
}

@Override
public void onDismiss(DialogInterface unused) {
    super.onDismiss(unused);

    Log.d(getClass().getSimpleName(), "Goodbye!");
}

@Override
public void onCancel(DialogInterface unused) {
    super.onCancel(unused);

    Toast.makeText(getActivity(), R.string.back, Toast.LENGTH_LONG).show();
}
}
```

In `onCreateDialog()`, we inflate a custom layout (`R.layout.dialog`) that consists of some `TextView` labels and `EditText` fields:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/display_name"/>

        <EditText
            android:id="@+id/title"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:inputType="text"/>
    </LinearLayout>

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="4dp"
        android:orientation="horizontal">

        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="@string/value"/>

        <EditText
```

DIALOGS AND DIALOGFRAGMENTS

```
        android:id="@+id/value"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:inputType="number"/>
    </LinearLayout>
</LinearLayout>
```

We then create an instance of `AlertDialog.Builder`, then start configuring the dialog by calling a series of methods on the Builder:

- `setTitle()` to supply the text to appear in the title bar of the dialog
- `setView()` to define the contents of the dialog, in the form of our inflated View
- `setPositiveButton()` to define the caption of one button (set here to the Android-supplied “OK” string resource) and to arrange to get control when that button is clicked (via this as the second parameter and our activity implementing `DialogInterface.OnClickListener`)
- `setNegativeButton()` to define the caption of the other button (set here to the Android-supplied “Cancel” resource)

We do not supply a listener to `setNegativeButton()`, because we do not need one in this case. Whenever the user clicks on *any* of the buttons, the dialog will be dismissed automatically. Hence, you only need a listener if you intend to do something special beyond dismissing the dialog when a button is clicked.

At that point, we call `create()` to construct the actual `AlertDialog` instance and hand that back to Android.

If the user taps our positive button, we are called with `onClick()` and can collect information from our form and do something with it, in this case displaying a Toast.

We also override:

- `onCancel()`, which is called if the user presses the BACK button to exit the dialog
- `onDismiss()`, which is called whenever the dialog goes away for any reason (BACK or a button click)

Our activity (`MainActivity`), has a big button tied to a `showMe()` method, which calls `show()` on a newly-created instance of our `SampleDialogFragment`:

DIALOGS AND DIALOGFRAGMENTS

```
public void showMe(View v) {  
    new SampleDialogFragment().show(getFragmentManager(), "sample");  
}
```

The second parameter to `show()` is a tag that can be used to retrieve this fragment again later from the `FragmentManager` via `findFragmentByTag()`.

When you click the big button in the activity, our dialog is displayed:

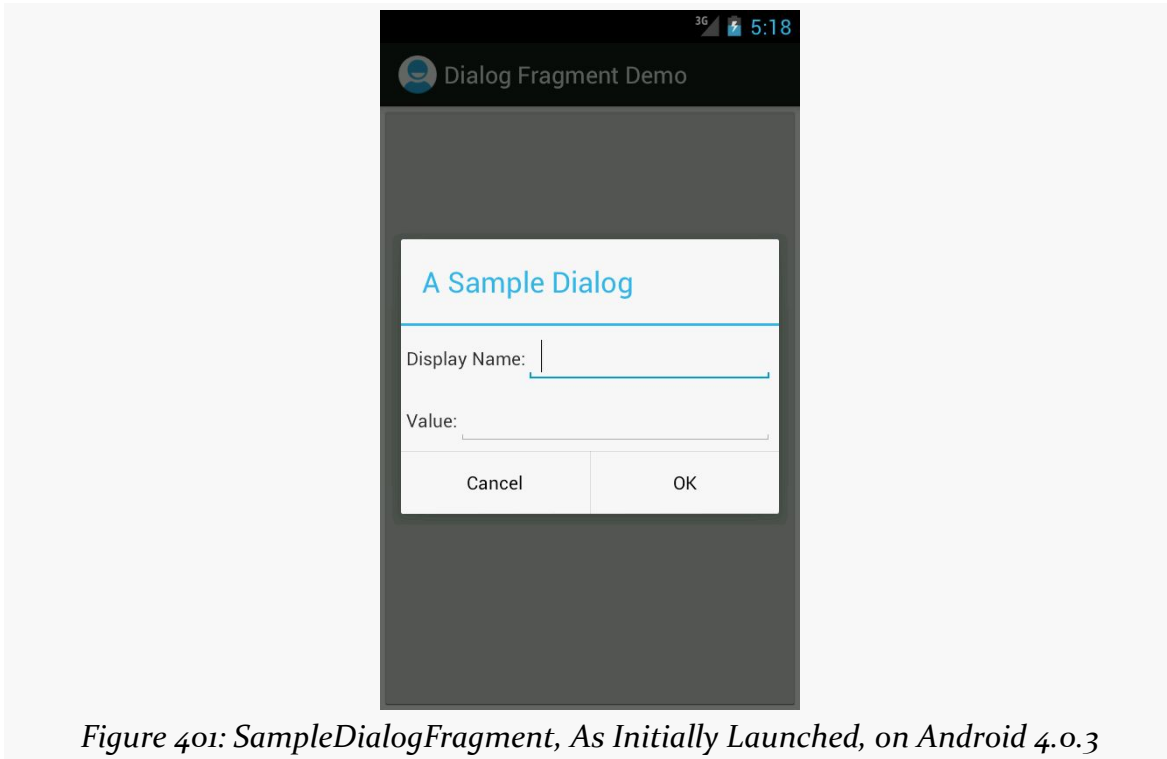

Figure 401: SampleDialogFragment, As Initially Launched, on Android 4.0.3

Android will handle the configuration change, and so long as our dialog uses typical widgets like `EditText`, the standard configuration change logic will carry our data forward from the old activity's dialog to the new activity's dialog.

DialogFragment: The Other Flavor

If you do not override `onCreateDialog()`, Android will assume that you want the `View` returned by `onCreateView()` to be poured into an ordinary `Dialog`, which `DialogFragment` will create for you automatically.

One advantage of this approach is that you can selectively show the fragment as a dialog *or* show it as a regular fragment as part of your main UI.

To show the fragment as a dialog, use the same `show()` technique as was outlined in the previous section. To display the fragment as part of the main UI, use a `FragmentManager` to `add()` it, the way you would for any other dynamic fragment.

This is one alternative to the normal fragment approach of having dedicated activities for each fragment on smaller screen sizes.

We will also see this approach used when we try to apply fragments to display content on a secondary screen using Android 4.2's `Presentation` class, covered [elsewhere in this book](#).

Dialogs: Modal, Not Blocking

Dialogs in Android are modal in terms of UI. The user cannot proceed in your activity until they complete or dismiss the dialog.

Dialogs in Android are not blocking in terms of the programming model. When you call `show()` to display a dialog — either directly or by means of adding a `DialogFragment` to the screen — this is not a blocking call. The dialog will be displayed sometime after the call to `show()`, asynchronously. You use callbacks, such as the button event listeners, to find out about events going on with respect to the dialog that you care about.

This runs counter to a couple of GUI toolkits, where displaying the dialog blocks the thread that does the displaying. In those toolkits, the call to `show()` would not return until the dialog had been displayed and dealt with by the user. That being said, most modern GUI toolkits take the approach Android does and have dialogs be non-blocking. Some developers try to figure out some way of hacking a blocking approach on top of Android's non-blocking dialogs — their time would be far better spent learning modern event-driven programming.

Advanced ListViews

The humble `ListView` is the backbone of many an Android application. On phone-sized screens, the screen may be dominated by a single `ListView`, to allow the user to choose something to examine in more detail (e.g., pick a contact). On larger screens, the `ListView` may be shown side-by-side with the details of the selected item, to minimize the “pogo stick” effect seen on phones as users bounce back and forth between the list and the details.

While we have covered the basics of `ListView` in the core chapters of this book, there is a lot more that you can do if you so choose, to make your lists that much more interesting — this chapter will cover some of these techniques.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on Adapter and AdapterView](#).

Multiple Row Types, and Self Inflation

When we originally looked at `ListView`, we had all of our rows come from a common layout. Hence, while the data in each row would vary, the row structure itself would be consistent for all rows. This is very easy to set up, but it is not always what you want. Sometimes, you want a mix of row structures, such as header rows versus detail rows, or detail rows that vary a bit in structure based on the data:

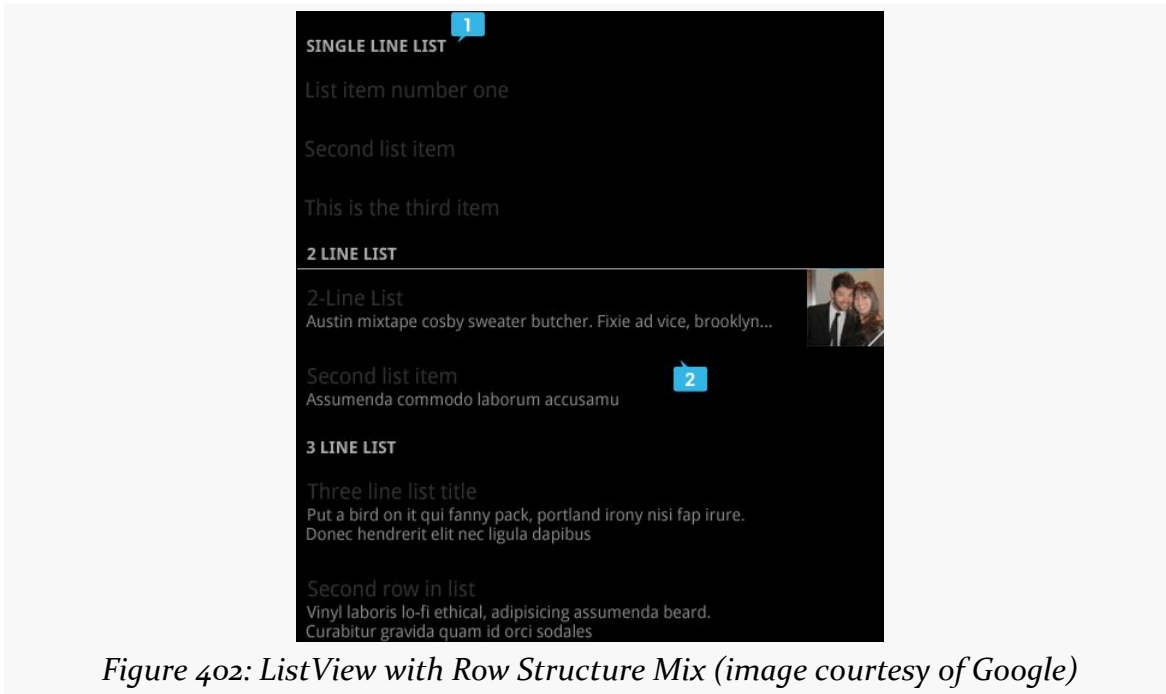

Figure 402: ListView with Row Structure Mix (image courtesy of Google)

Here, we see some header rows (e.g., “SINGLE LINE LIST”) along with detail rows. While the detail rows visually vary a bit, they might still be all inflated from the same layout, simply making some pieces (second line of text, thumbnail, etc.) visible or invisible as needed. However, the header rows are sufficiently visually distinct that they really ought to come from separate layouts.

The good news is that Android supports multiple row types. However, this comes at a cost: you will need to handle the row creation yourself, rather than chaining to the superclass.

Our sample project, [Selection/HeaderDetailList](#) will demonstrate this, along with showing how you can create your own custom adapter straight from BaseAdapter, for data models that do not quite line up with what Android supports natively.

Our Data Model and Planned UI

The HeaderDetailList project is based on the ViewHolderDemo project from [the chapter on ListView](#). However, this time, we have our list of 25 Latin words broken down into five groups of five, as seen in the HeaderDetailList activity:

```
private static final String[][] items= {
    { "lorem", "ipsum", "dolor", "sit", "amet" },
    { "consectetuer", "adipiscing", "elit", "morbi", "vel" },
```

ADVANCED LISTVIEWS

```
{ "ligula", "vitae", "arcu", "aliquet", "mollis" },  
{ "etiam", "vel", "erat", "placemat", "ante" },  
{ "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

We want to display a header row for each batch:

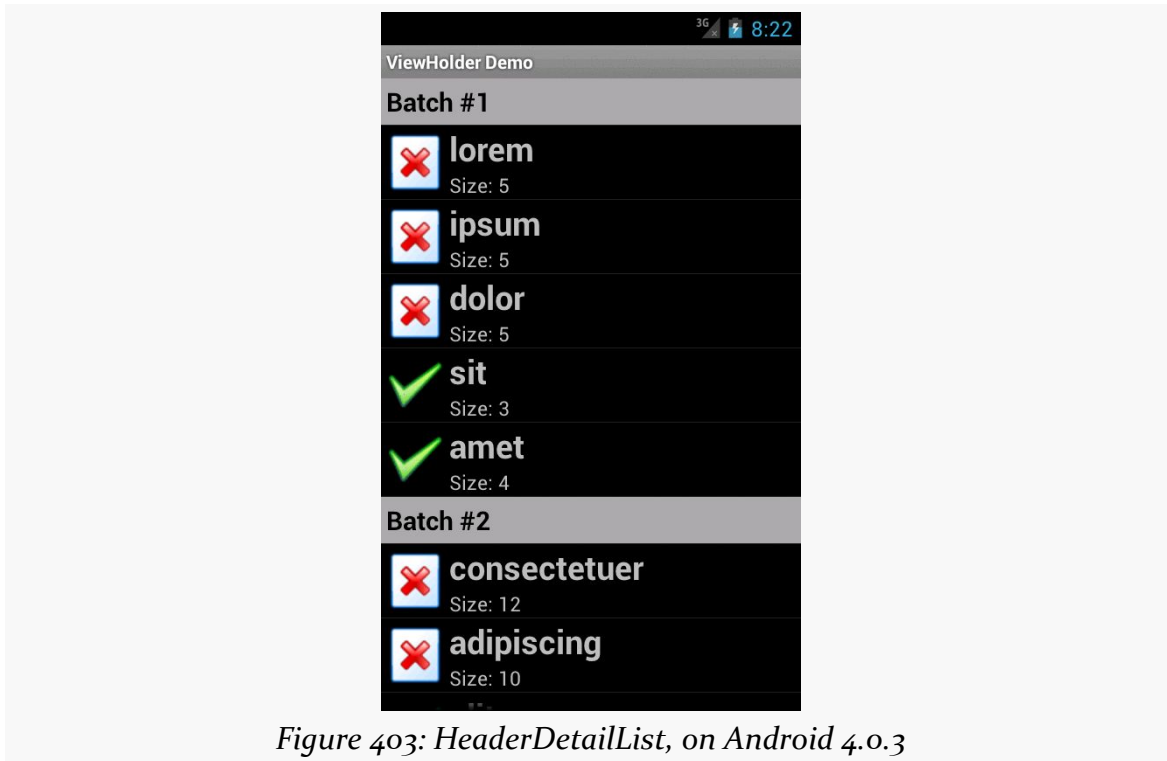

Figure 403: HeaderDetailList, on Android 4.0.3

The Basic BaseAdapter

Once again, we have a custom ListAdapter named IconicAdapter. However, this time, instead of inheriting from ArrayAdapter, or even CursorAdapter, we are inheriting from BaseAdapter. As the name suggests, BaseAdapter is a basic implementation of the ListAdapter interface, with stock implementations of many of the ListAdapter methods. However, BaseAdapter is abstract, and so there are a few methods that we need to implement:

- getCount() returns the total number of rows that would be in the list. In our case, we total up the sizes of each of the batches, plus add one for each batch for our header rows:

```
@Override  
public int getCount() {  
    int count=0;
```

ADVANCED LISTVIEWS

```
for (String[] batch : items) {
    count+=1 + batch.length;
}

return(count);
}
```

- `getItem()` needs to return the data model for a given position, passed in as the typical `int` index. An `ArrayAdapter` would return the value out of the array at that index; a `CursorAdapter` would return the `Cursor` positioned at that row. In our case, we will return one of two objects: either the `String` for rows that are to display a Latin word, or an `Integer` containing our batch's index for rows that are to be a header:

```
@Override
public Object getItem(int position) {
    int offset=position;
    int batchIndex=0;

    for (String[] batch : items) {
        if (offset == 0) {
            return(Integer.valueOf(batchIndex));
        }

        offset--;

        if (offset < batch.length) {
            return(batch[offset]);
        }

        offset-=batch.length;
        batchIndex++;
    }

    throw new IllegalArgumentException("Invalid position: "
        + String.valueOf(position));
}
```

- `getItemId()` needs to return a unique `long` value for a given position. A `CursorAdapter` would find the `_id` value in the `Cursor` for that position and return it. In our case, lacking anything else, we simply return the position itself:

```
@Override
public long getItemId(int position) {
    return(position);
}
```

- `getView()`, which returns the `View` to use for a given row. This is the method that we overrode on our `IconicAdapter` in some previous incarnations to tailor the way the rows were populated. Our `getView()` implementation will

be a bit more complex in this case, due to our multiple-row-type requirement, so we will examine it a bit later in this section.

Requesting Multiple Row Types

The methods listed above are the abstract ones that you have no choice but to implement yourself. Anything else on the `ListAdapter` interface that you wish to override you can, to replace the stub implementation supplied by `BaseAdapter`.

If you wish to have more than one type of row, there are two such methods that you will wish to override:

- `getViewTypeCount()` needs to return the number of distinct row types you will use. In our case, there are just two:

```
@Override
public int getViewTypeCount() {
    return(2);
}
```

- `getItemViewType()` needs to return a value from 0 to `getViewTypeCount()-1`, indicating the index of the particular row type to use for a particular row position. In our case, we need to return different values for headers (0) and detail rows (1). To determine which is which, we use `getItem()` — if we get an `Integer` back, we need to use a header row for that position:

```
@Override
public int getItemViewType(int position) {
    if (getItem(position) instanceof Integer) {
        return(0);
    }

    return(1);
}
```

The reason for supplying this information is for row recycling. The `View` that is passed into `getView()` is either `null` or a row that we had previously created that has scrolled off the screen. By passing us this now-unused `View`, Android is asking us to reuse it if possible. By specifying the row type for each position, Android will ensure that it hands us the right type of row for recycling — we will not be passed in a header row to recycle when we need to be returning a detail row, for example.

Creating and Recycling the Rows

Our `getView()` implementation, then, needs to have two key enhancements over previous versions:

1. We need to create the rows ourselves, particularly using the appropriate layout for the required row type (header or detail)
2. We need to recycle the rows when they are provided, as this has a **major** impact on the scrolling speed of our `ListView`

To help simplify the logic, we will have `getView()` focus on the detail rows, with a separate `getHeaderView()` to create/recycle and populate the header rows. Our `getView()` determines up front whether the row required is a header and, if so, delegates the work to `getHeaderView()`:

```
@Override
public View getView(int position, View convertView, ViewGroup parent) {
    if (getItemViewType(position) == 0) {
        return(getHeaderView(position, convertView, parent));
    }

    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.row, parent, false);
    }

    ViewHolder holder=(ViewHolder)row.getTag();

    if (holder == null) {
        holder=new ViewHolder(row);
        row.setTag(holder);
    }

    String word=(String)getItem(position);

    if (word.length() > 4) {
        holder.icon.setImageResource(R.drawable.delete);
    }
    else {
        holder.icon.setImageResource(R.drawable.ok);
    }

    holder.label.setText(word);
    holder.size.setText(String.format(getString(R.string.size_template),
        word.length()));

    return(row);
}
```

Assuming that we are to create a detail row, we then check to see if we were passed in a non-null `View`. If we were passed in `null`, we cannot recycle that row, so we

ADVANCED LISTVIEWS

have to inflate a new one via a call to `inflate()` on a `LayoutInflater` we get via `getLayoutInflater()`. But, if we were passed in an actual `View` to recycle, we can skip this step.

From here, the `getView()` implementation is largely the way it was before, including dealing with the `ViewHolder`. The only change of significance is that we have to manage the label `TextView` ourselves — before, we chained to the superclass and let `ArrayAdapter` handle that. So our `ViewHolder` now has a label data member with our label `TextView`, and we fill it in along with the size and icon. Also, we use `getItem()` to retrieve our Latin word, so it can find the right word for the given position out of our various word batches.

Our `getHeaderView()` does much the same thing, except it uses `getItem()` to retrieve our batch index, and we use that for constructing our header:

```
private View getHeaderView(int position, View convertView,
                          ViewGroup parent) {
    View row=convertView;

    if (row == null) {
        row=getLayoutInflater().inflate(R.layout.header, parent, false);
    }

    Integer batchIndex=(Integer)getItem(position);
    TextView label=(TextView)row.findViewById(R.id.label);

    label.setText(String.format(getString(R.string.batch),
                                1 + batchIndex.intValue()));

    return(row);
}
```

Choice Modes and the Activated Style

In [the chapter on large-screen strategies](#), we saw the EU4You sample application, and we mentioned that the `ListView` formatted its rows as “activated” to represent the current selection, when the `ListView` was side-by-side with the details.

In [the chapter on styles](#), we saw an example of an “activated” style that referred to a device-specific color to use for an activated background. It just so happens that this is the same style that we used in EU4You.

Hence, the recipe for using activated notation for a `ListView` adjacent to details on the last-clicked-upon `ListView` row is:

ADVANCED LISTVIEWS

- Use `CHOICE_MODE_SINGLE` (or `android:choiceMode="singleChoice"`) on the `ListView`.
- Have a style resource, in `res/values-v11/`, that references the device-specific activated background:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated" parent="android:Theme.Holo">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>
</resources>
```

- Have the same style resource also defined in `res/values` if you are supporting pre-Honeycomb devices, where you skip the parent and the background color override, as neither of those specific values existed before API Level 11:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="activated">
  </style>
</resources>
```

- Use that style as the background of your `ListView` row (e.g., `style="@style/activated"`)

Android will automatically color the row background based upon the last row clicked, instead of checking a `RadioButton` as you might ordinarily see with `CHOICE_MODE_SINGLE` lists.

Custom Mutable Row Contents

Lists with pretty icons next to them are all fine and well. But, can we create `ListView` widgets whose rows contain interactive child widgets instead of just passive widgets like `TextView` and `ImageView`? For example, there is a `RatingBar` widget that allows users to assign a rating by clicking on a set of star icons. Could we combine the `RatingBar` with text in order to allow people to scroll a list of, say, songs and rate them right inside the list?

There is good news and bad news.

The good news is that interactive widgets in rows work just fine. The bad news is that it is a little tricky, specifically when it comes to taking action when the interactive widget's state changes (e.g., a value is typed into a field). We need to store that state somewhere, since our `RatingBar` widget will be recycled when the

ADVANCED LISTVIEWS

ListView is scrolled. We need to be able to set the RatingBar state based upon the actual word we are viewing as the RatingBar is recycled, and we need to save the state when it changes so it can be restored when this particular row is scrolled back into view.

What makes this interesting is that, by default, the RatingBar has absolutely no idea what item in the ArrayAdapter it represents. After all, the RatingBar is just a widget, used in a row of a ListView. We need to teach the rows which item in the ArrayAdapter they are currently displaying, so when their RatingBar is checked, they know which item's state to modify.

So, let's see how this is done, using the activity in the [Selection/RateList](#) sample project. We will use the same basic classes as in most of our ListView samples, where we are showing a list of Latin words. In this case, you can rate the words on a three-star rating. Words given a top rating are put in all caps:

```
package com.commonware.android.ratelist;

import android.app.ListActivity;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.LinearLayout;
import android.widget.RatingBar;
import android.widget.TextView;
import java.util.ArrayList;

public class RateListDemo extends ListActivity {
    private static final String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel",
        "ligula", "vitae", "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat", "placemat", "ante",
        "porttitor", "sodales", "pellentesque", "augue", "purus"};

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        ArrayList<RowModel> list=new ArrayList<RowModel>();

        for (String s : items) {
            list.add(new RowModel(s));
        }

        setListAdapter(new RatingAdapter(list));
    }

    private RowModel getModel(int position) {
        return(((RatingAdapter)getListAdapter()).getItem(position));
    }
}
```

ADVANCED LISTVIEWS

```
class RatingAdapter extends ArrayAdapter<RowModel> {
    RatingAdapter(ArrayList<RowModel> list) {
        super(RateListDemo.this, R.layout.row, R.id.label, list);
    }

    public View getView(int position, View convertView,
        ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        RatingBar bar=(RatingBar)row.getTag();

        if (bar==null) {
            bar=(RatingBar)row.findViewById(R.id.rate);
            row.setTag(bar);

            RatingBar.OnRatingBarChangeListener l=
                new RatingBar.OnRatingBarChangeListener() {
                    public void onRatingChanged(RatingBar ratingBar,
                        float rating,
                        boolean fromTouch) {
                        Integer myPosition=(Integer)ratingBar.getTag();
                        RowModel model=getModel(myPosition);

                        model.rating=rating;

                        LinearLayout parent=(LinearLayout)ratingBar.getParent();
                        TextView label=(TextView)parent.findViewById(R.id.label);

                        label.setText(model.toString());
                    }
                };

            bar.setOnRatingBarChangeListener(l);
        }

        RowModel model=getModel(position);

        bar.setTag(Integer.valueOf(position));
        bar.setRating(model.rating);

        return(row);
    }
}

class RowModel {
    String label;
    float rating=2.0f;

    RowModel(String label) {
        this.label=label;
    }

    public String toString() {
        if (rating>=3.0) {
            return(label.toUpperCase());
        }

        return(label);
    }
}
```

ADVANCED LISTVIEWS

Here is what is different in this activity and `getView()` implementation than in earlier, simpler samples:

1. While we are still using `String` array items as the list of Latin words, rather than pour that `String` array straight into an `ArrayAdapter`, we turn it into a list of `RowModel` objects. `RowModel` is the mutable model: it holds the Latin word plus the current rating. In a real system, these might be objects populated from a database, and the properties would have more business meaning.
2. Utility methods like `onItemClickListener()` had to be updated to reflect the change from a pure-`String` model to use a `RowModel`.
3. The `ArrayAdapter` subclass (`RatingAdapter`), in `getView()`, lets `ArrayAdapter` inflate and recycle the row, then checks to see if we have a `ViewHolder` in the row's tag. If not, we create a new `ViewHolder` and associate it with the row. For the row's `RatingBar`, we add an anonymous `onRatingChanged()` listener that looks at the row's tag (`getTag()`) and converts that into an `Integer`, representing the position within the `ArrayAdapter` that this row is displaying. Using that, the rating bar can get the actual `RowModel` for the row and update the model based upon the new state of the rating bar. It also updates the text adjacent to the `RatingBar` when checked to match the rating bar state.
4. We always make sure that the `RatingBar` has the proper contents and has a tag (via `setTag()`) pointing to the position in the adapter the row is displaying.

The row layout is very simple: just a `RatingBar` and a `TextView` inside a `LinearLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    >
    <RatingBar
        android:id="@+id/rate"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:numStars="3"
        android:stepSize="1"
        android:rating="2" />
    <TextView
        android:id="@+id/label"
        android:padding="2dip"
        android:textSize="18sp"
        android:layout_gravity="left|center_vertical"
        android:layout_width="match_parent"
```

ADVANCED LISTVIEWS

```
android:layout_height="wrap_content"/>  
</LinearLayout>
```

And the result is what you would expect, visually:

Figure 404: RateList, As Initially Shown

This includes the toggled rating bars turning their words into all caps:

Figure 405: RateList, With a Three-Star Word

From Head To Toe

Perhaps you do not need section headers scattered throughout your list. If you only need extra “fake rows” at the beginning or end of your list, you can use header and footer views.

ListView supports `addHeaderView()` and `addFooterView()` methods that allow you to add View objects to the beginning and end of the list, respectively. These View objects otherwise behave like regular rows, in that they are part of the scrolled area and will scroll off the screen if the list is long enough. If you want fixed headers or footers, rather than put them in the ListView itself, put them outside the ListView, perhaps using a `LinearLayout`.

To demonstrate header and footer views, take a peek at the [Selection/HeaderFooter](#) sample project, particularly the `HeaderFooterDemo` class:

```
package com.commonware.android.header;

import java.util.Arrays;
import java.util.Collections;
import java.util.List;
import android.app.ListActivity;
import android.os.Bundle;
import android.os.SystemClock;
import android.view.View;
import android.widget.AdapterView;
import android.widget.Button;
import android.widget.TextView;

public class HeaderFooterDemo extends ListActivity {
    private static String[] items={"lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer",
        "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae",
        "arcu", "aliquet", "mollis",
        "etiam", "vel", "erat",
        "placerat", "ante",
        "porttitor", "sodales",
        "pellentesque", "augue",
        "purus"};

    private long startTime=SystemClock.uptimeMillis();
    private boolean areWeDeadYet=false;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
        getListView().addHeaderView(buildHeader());
        getListView().addFooterView(buildFooter());
        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1,
            items));
    }
}
```

ADVANCED LISTVIEWS

```
}

@Override
public void onDestroy() {
    super.onDestroy();

    areWeDeadYet=true;
}

private View buildHeader() {
    Button btn=new Button(this);

    btn.setText("Randomize!");
    btn.setOnClickListener(new View.OnClickListener() {
        public void onClick(View v) {
            List<String> list=Arrays.asList(items);

            Collections.shuffle(list);

            setListAdapter(new ArrayAdapter<String>(HeaderFooterDemo.this,
                android.R.layout.simple_list_item_1,
                list));
        }
    });

    return(btn);
}

private View buildFooter() {
    TextView txt=new TextView(this);

    updateFooter(txt);

    return(txt);
}

private void updateFooter(final TextView txt) {
    long runtime=(SystemClock.uptimeMillis()-startTime)/1000;

    txt.setText(String.valueOf(runtime)+" seconds since activity launched");

    if (!areWeDeadYet) {
        getListView().postDelayed(new Runnable() {
            public void run() {
                updateFooter(txt);
            }
        }, 1000);
    }
}
}
```

Here, we add a header View built via `buildHeader()`, returning a `Button` that, when clicked, will shuffle the contents of the list. We also add a footer View built via `buildFooter()`, returning a `TextView` that shows how long the activity has been running, updated every second. The list itself is the ever-popular list of *lorem ipsum* words.

ADVANCED LISTVIEWS

When initially displayed, the header is visible but the footer is not, because the list is too long:

Figure 406: A ListView with a header view shown

If you scroll downward, the header will slide off the top, and eventually the footer will scroll into view:

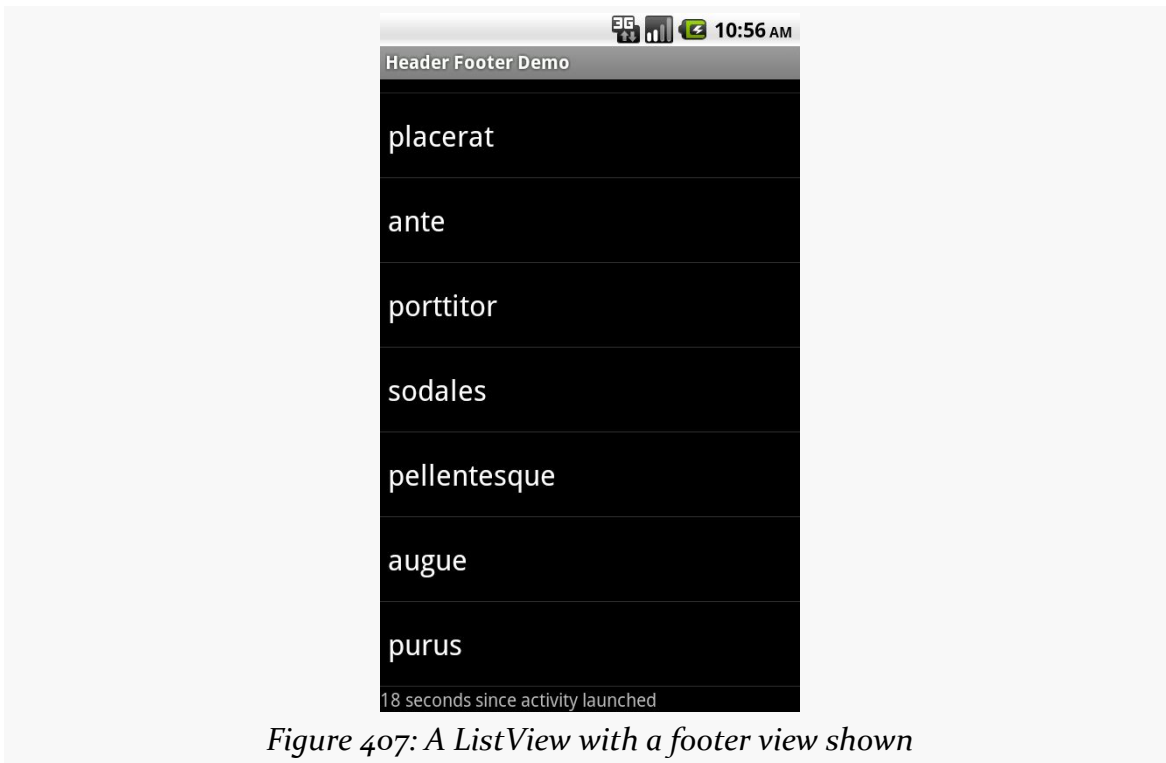

Figure 407: A ListView with a footer view shown

Enter RecyclerView

RecyclerView is a more powerful (and more complex) replacement for ListView and GridView. You can read more about [what it does and how you can use it](#).

Action Bar Navigation

Beyond the app icon (a.k.a., icon on the left), action bar toolbar items, and the overflow menu, the action bar also supports a navigation area. This resides to the right of the app icon and to the left of the toolbar items/overflow menu. You can:

- Put tabs in here, to allow users to switch between portions of your app
- Use “list navigation”, which effectively puts a Spinner in here, also to allow users to switch from place to place
- Put in some other custom form of navigation, such as a search field

This chapter will review how to do these things, and how they tie into other constructs in Android, notably the `ViewPager`.

NOTE: The tab and list navigation forms outlined in this chapter have been marked as deprecated in Android 5.0. Developers are encouraged to use other techniques for in-activity navigation.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

List Navigation

Android’s action bar supports a “list navigation” option. Despite the name, the “list” is really a `Spinner`, hosted in the action bar. You get to populate the `Spinner` via your own `SpinnerAdapter`, and you get control when the user changes the selected item, so that you can update your UI as you see fit.

To set this up:

1. Call `setNavigationMode(ActionBar.NAVIGATION_MODE_LIST)` on the `ActionBar` to enable the list navigation mode, which you get via `getActionBar()`
2. Call `setListNavigationCallbacks()` on the `ActionBar`, simultaneously supplying the `SpinnerAdapter` to use to populate the `Spinner` and an `ActionBar.OnNavigationListener` object to be notified when there is a selection change in the `Spinner`

The [ActionBar/ListNavNative](#) sample project demonstrates this, using a variation on the “whole lot of editors” UI first seen in [the ViewPager chapter](#).

We want to display a full-screen `EditText` widget whose contents will be driven by the list navigation selection. The fragment for this — `EditorFragment` — is a slightly revised version of the same class from the `ViewPager` samples. Here, though, state management will be handled completely by the activity, so we simply expose getters and setters as needed for working with the text in the editor, along with its hint:

```
package com.commonware.android.listnav;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class EditorFragment extends Fragment {
    private EditText editor=null;

    @Override
    public View onCreateView(LayoutInflater inflater,
                            ViewGroup container,
                            Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.editor, container, false);

        editor=(EditText)result.findViewById(R.id.editor);

        return(result);
    }

    CharSequence getText() {
        return(editor.getText());
    }

    void setText(CharSequence text) {
        editor.setText(text);
    }

    void setHint(CharSequence hint) {
```

ACTION BAR NAVIGATION

```
    editor.setHint(hint);
}
}
```

Setting up the list navigation mode is part of the work we do in `onCreate()`:

```
ArrayAdapter<String> nav=null;
ActionBar bar=getActionBar();

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.ICE_CREAM_SANDWICH) {
    nav=
        new ArrayAdapter<String>(
            bar.getThemedContext(),
            android.R.layout.simple_spinner_item,
            labels);
}
else {
    nav=
        new ArrayAdapter<String>(
            this,
            android.R.layout.simple_spinner_item,
            labels);
}

nav.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
bar.setNavigationMode(ActionBar.NAVIGATION_MODE_LIST);
bar.setListNavigationCallbacks(nav, this);
```

Android 4.0 added a `getThemedContext()` method on `ActionBar`. Use the `Context` returned by this method when working with resources that relate to the `ActionBar`. In this case, we use it when creating our `ArrayAdapter` to use with the `Spinner`. However, since this is only available on API Level 14 and higher, you need to check for that and fall back to using the `Activity` as your `Context` for earlier versions of Android.

We then use `setNavigationMode()` to indicate that we want list navigation, then use `setListNavigationCallbacks()` to supply our `ArrayAdapter`, plus our implementation of `OnNavigationItemSelectedListener` — in this case, we are implementing this interface on the activity itself.

Because we are implementing `OnNavigationItemSelectedListener`, we need to override the `onNavigationItemSelectedListener` method. This will get called when the `Spinner` selection changes (including when it is initially set), and it is up to us to affect our UI. That requires a bit of additional preparation work:

- We set up our `EditorFragment` in `onCreate()`, if it does not already exist:

```
frag=
    (EditorFragment)getFragmentManager().findFragmentById(android.R.id.content);
```

ACTION BAR NAVIGATION

```
if (frag==null) {
    frag=new EditorFragment();
    getFragmentManager().beginTransaction()
        .add(android.R.id.content, frag)
        .commit();
}
```

- We track the last known position of the Spinner selection, by means of a lastPosition data member
- We store our data model (the text held by the editor) in a models CharSequence array

Our objective is to have 10 total “editors”, accessible via the list navigation. Our labels array in our ArrayAdapter has 10 entries, and models is a 10-item array to match.

That allows us to implement onNavigationItemSelected():

```
@Override
public boolean onNavigationItemSelected(int itemPosition, long itemId) {
    if (lastPosition > -1) {
        models[lastPosition]=frag.getText();
    }

    lastPosition=itemPosition;
    frag.setText(models[itemPosition]);
    frag.setHint(labels[itemPosition]);

    return(true);
}
```

In the ViewPager sample, we actually had 10 instances of EditorFragment. Here, we have just one. We will use it for all 10 positions. Hence, all we do is grab the current contents of the editor and save them in models (except when we are first starting and have no prior position). Then, we populate the editor with the next model and a suitable hint.

Now, we *could* have 10 instances of EditorFragment and swap between them with FragmentTransactions. Or, we could have a variety of distinct fragment instances, from different classes, and swap between them using FragmentTransactions. What you do to update your UI based upon the list navigation change is up to you.

One limitation of list navigation, compared to ViewPager, is state management on configuration changes. ViewPager handled keeping track of what page we were on, and if we retained all our fragments, our model data (the editors’ contents) were retained as well. With list navigation and a single non-retained fragment, we have to do all of that ourselves.

ACTION BAR NAVIGATION

So, we implement `onSaveInstanceState()` to persist both the `models` array and our current position:

```
@Override
public void onSaveInstanceState(Bundle state) {
    if (lastPosition > -1) {
        models[lastPosition]=frag.getText();
    }

    state.putCharSequenceArray(KEY_MODELS, models);
    state.putInt(KEY_POSITION,
        getActionBar().getSelectedNavigationIndex());
}
```

In `onCreate()`, we restore our `models` array:

```
if (state != null) {
    models=state.getCharSequenceArray(KEY_MODELS);
}
```

And, later in `onCreate()`, we tell the action bar which position to select:

```
if (state != null) {
    bar.setSelectedNavigationItem(state.getInt(KEY_POSITION));
}
```

The result is a Spinner in the action bar, allowing the user to choose which of the 10 “editors” to work with:

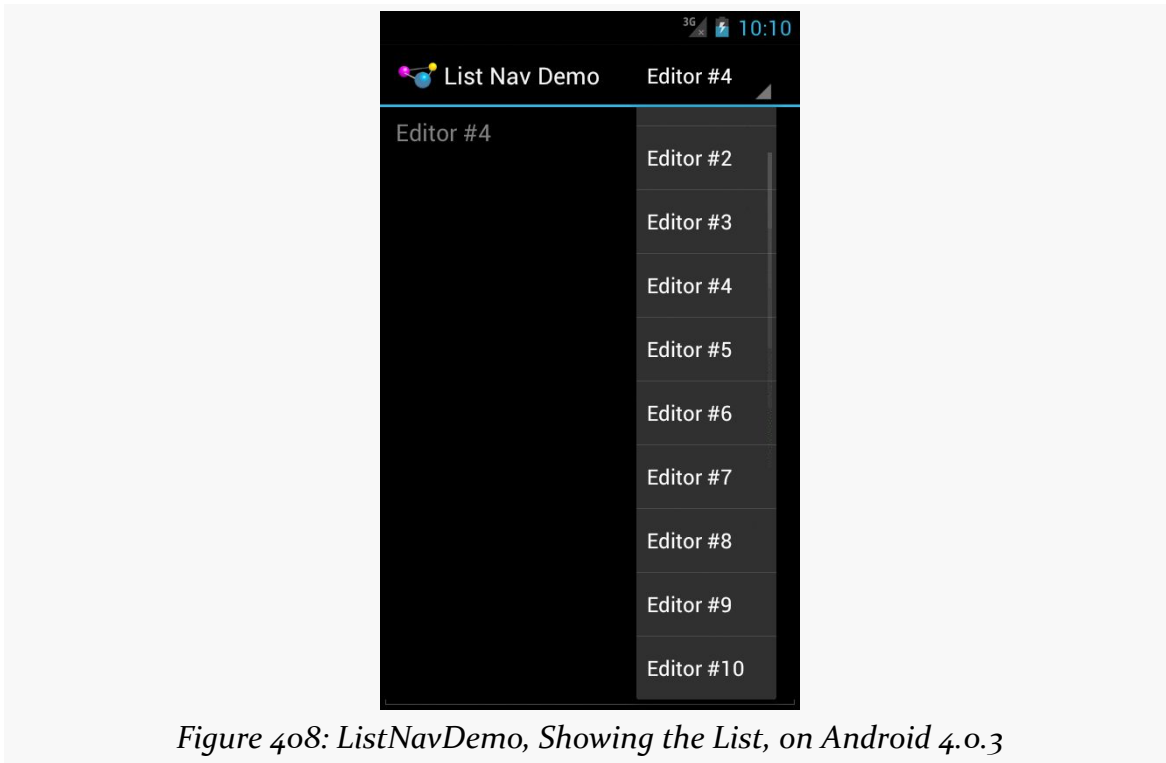

Figure 408: ListNavDemo, Showing the List, on Android 4.0.3

Tabs (And Sometimes List) Navigation

Similarly, you can set up tab navigation, where you present a roster of tabs the user can tap on.

Maybe.

(We'll get to the explanation of "maybe" in a bit)

Setting up tabs is fairly straightforward, once you know the recipe:

1. Call `setNavigationMode(ActionBar.NAVIGATION_MODE_TABS)` on the `ActionBar`, which you get via `getActionBar()`
2. Call `addTab()` on `ActionBar` for each tab you want, supplying at minimum the text caption of the tab and a `TabListener` implementation that will be notified of state changes in that tab

The [ActionBar/TabFragmentDemoNative](#) sample project is very similar to the one for list navigation described above, except that it uses tabs instead of list navigation. We

ACTION BAR NAVIGATION

have the same 10 editors, the same data model (models), and the same basic logic for saving and restoring our instance state. What differs is in how we set up the UI.

As with list navigation, you can do whatever you want when tabs are selected or unselected. You could:

- Add and remove fragments
- Attach and detach fragments (which remove them from the UI but keep them in the `FragmentManager` for later reuse)
- Flip pages of a `ViewPager`
- Update a simple UI in place (akin to what we did in the list navigation sample above)

In our case, we will take the “caveman” approach of replacing our entire fragment on each tab click.

Our `EditorFragment` is a bit closer to the original from the `ViewPager` samples, except that this time we pass in the initial text to display, along with the position, in the factory method:

```
package com.commonware.android.tabfrag;

import android.app.Fragment;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.EditText;

public class EditorFragment extends Fragment {
    private static final String KEY_POSITION="position";
    private static final String KEY_TEXT="text";
    private EditText editor=null;

    static EditorFragment newInstance(int position,
                                     CharSequence text) {
        EditorFragment frag=new EditorFragment();
        Bundle args=new Bundle();

        args.putInt(KEY_POSITION, position);
        args.putCharSequence(KEY_TEXT, text);
        frag.setArguments(args);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=inflater.inflate(R.layout.editor, container, false);
```

ACTION BAR NAVIGATION

```
editor=(EditText)result.findViewById(R.id.editor);

int position=getArguments().getInt(KEY_POSITION, -1);

editor.setHint(String.format(getString(R.string.hint), position + 1));
editor.setText(getArguments().getCharSequence(KEY_TEXT));

return(result);
}

CharSequence getText() {
    return(editor.getText());
}
}
```

In `onCreate()`, we tell the `ActionBar` that we want tab navigation, then we add 10 tabs to the bar:

```
ActionBar bar=getActionBar();
bar.setNavigationMode(ActionBar.NAVIGATION_MODE_TABS);

for (int i=0; i < 10; i++) {
    bar.addTab(bar.newTab().setText("Tab #" + String.valueOf(i + 1))
        .setTabListener(this).setTag(i));
}
```

Calling `newTab()` on the `ActionBar` gives us an `ActionBar.Tab` object, which we can use builder-style to configure the tab. In our case, we are setting the caption (`setText()`), the listener (`setTabListener()`), and a tag to use to identify this tab (`setTag()`). The tag is akin to the tags on `Views` — it can be any object you want. In our case, we just use the index of the tab.

Our activity needs to implement the `TabListener` interface, since we are passing it into the `setTabListener()` method. There are three methods you must implement on that interface:

1. `onTabSelected()` is called when the tab is selected by the user
2. `onTabUnselected()` is called when some other tab is selected by the user
3. `onTabReselected()` is called, presumably, when the user taps on an already-selected tab (e.g., to refresh the tab's contents)

Our implementation ignores the latter and focuses on the first two:

```
@Override
public void onTabSelected(Tab tab, FragmentTransaction ft) {
    int i=((Integer)tab.getTag()).intValue();

    ft.replace(android.R.id.content,
        EditorFragment.newInstance(i, models[i]));
}
```

ACTION BAR NAVIGATION

```
}  
  
@Override  
public void onTabUnselected(Tab tab, FragmentTransaction ft) {  
    int i=((Integer)tab.getTag()).intValue();  
    EditorFragment frag=  
        (EditorFragment)getFragmentManager().findFragmentById(android.R.id.content);  
  
    if (frag != null) {  
        models[i]=frag.getText();  
    }  
}  
  
@Override  
public void onTabReselected(Tab tab, FragmentTransaction ft) {  
    // unused  
}
```

In `onTabSelected()`, we get our tab's position via its tag, then call `replace()` on the supplied `FragmentTransaction` to replace the current contents of the activity with a new `EditorFragment`, set up with the proper position and model data.

In `onTabUnselected()`, we get our tab's position and the `EditorFragment`, then save the updated text (if any) from the editor in `models` for later reuse.

Running this on a phone-sized screen gives you your tabs, in a row beneath the main action bar itself:

ACTION BAR NAVIGATION

Those tabs are “swipey”, meaning that the user can fling the row of tabs to get to all 10 of them.

This UI makes perfect sense for something described as “tab navigation”. Where things get a bit odd is in any configuration, such as a normal-sized screen in landscape:

ACTION BAR NAVIGATION

Figure 410: TabFragmentDemo, on Android 4.0.3, Phone-Sized Screen in Landscape

or on a large-sized screen in portrait:

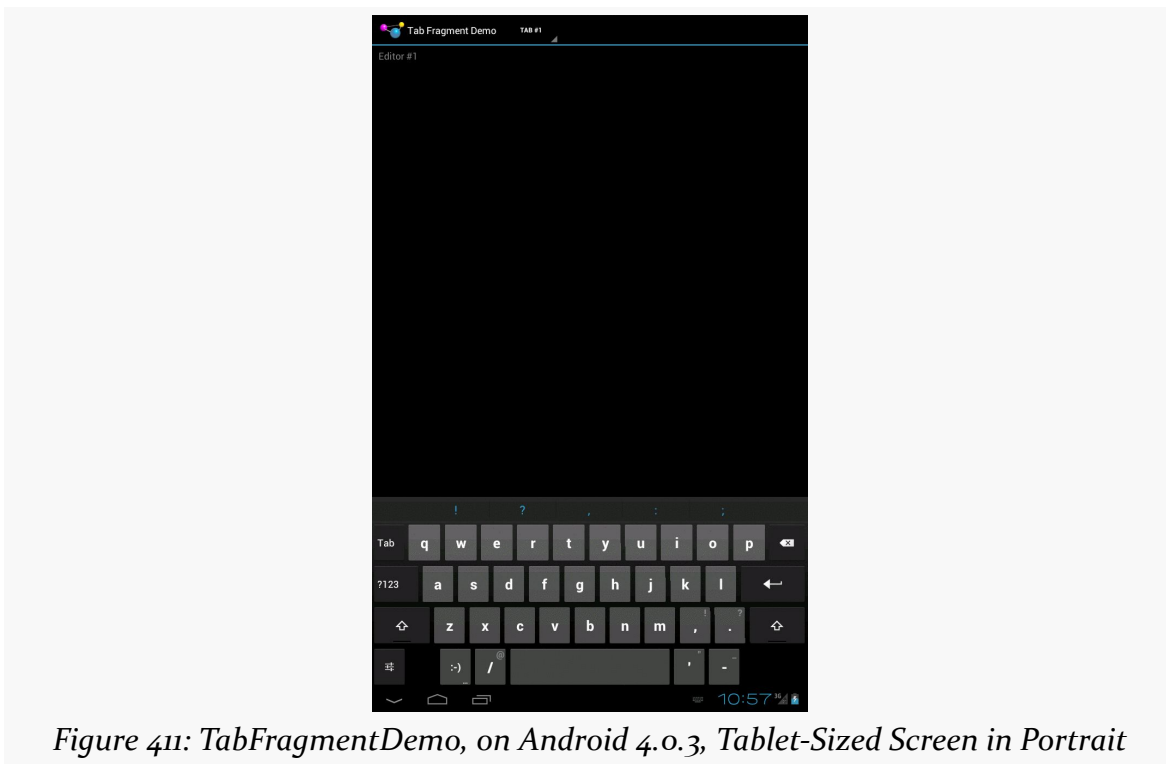

Figure 411: TabFragmentDemo, on Android 4.0.3, Tablet-Sized Screen in Portrait

Android will automatically convert your tab navigation to list navigation if and when it wishes to. You do not have control over this behavior, and it will vary by Android release:

The system will apply the correct UX policy for the device. As the exact policy of presentation may change on different devices or in future releases, it is intentionally not specified in documentation.

(from [the issue filed by the author of this book over this behavior](#))

Custom Navigation

You could also elect to use one of the various flavors of `setCustomView()` on `ActionBar`. These allow you to completely control what goes in the navigation area of the bar, by supplying either a `View` or a layout resource ID that should get inflated into the bar. Particularly in the latter case, you would call `getCustomView()` later on to retrieve the inflated layout, so you can access the widgets, configure listeners, and so forth.

While Google definitely steers you in the direction of using the tabs or list navigation, plenty of apps will use a custom navigation option, for things like:

- a search field
- an `AutoCompleteTextView` (e.g., a browser's address bar)
- etc.

Action Modes

If you have spent much time on an Android 3.0+ device, then you probably have run into a curious phenomenon. Sometimes, when you select an item in a list or other widget, the action bar magically transforms from its normal look:

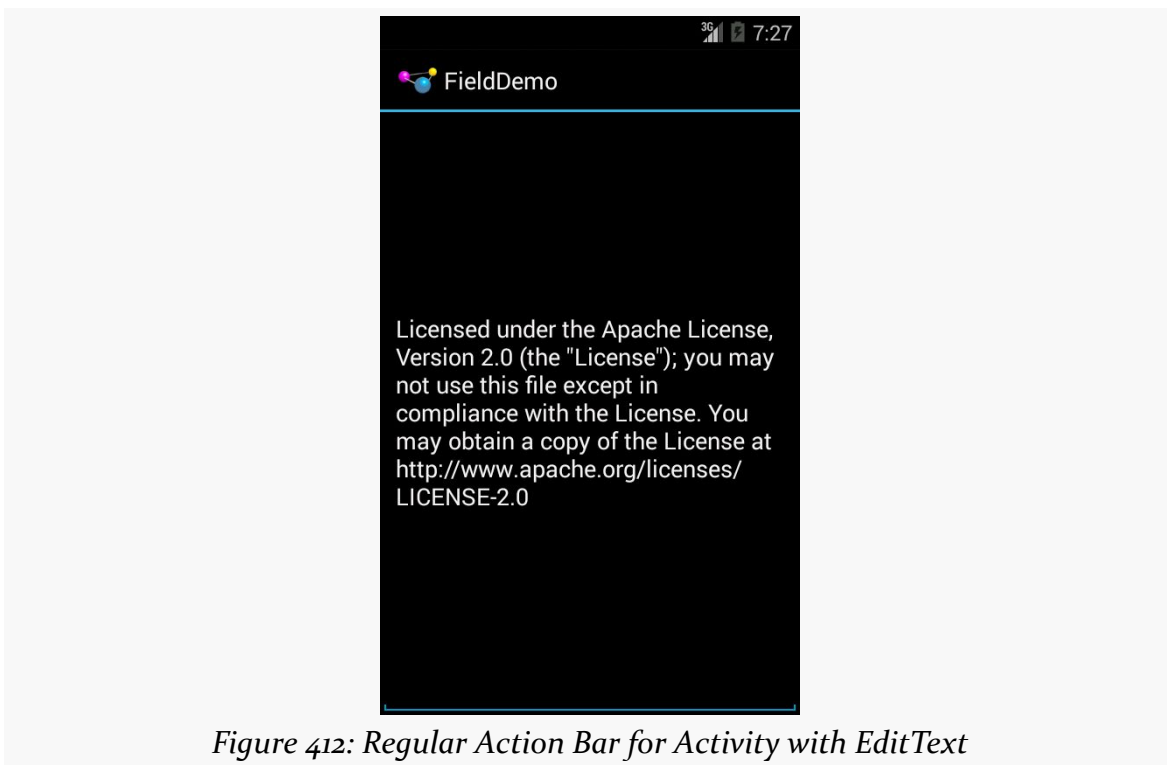

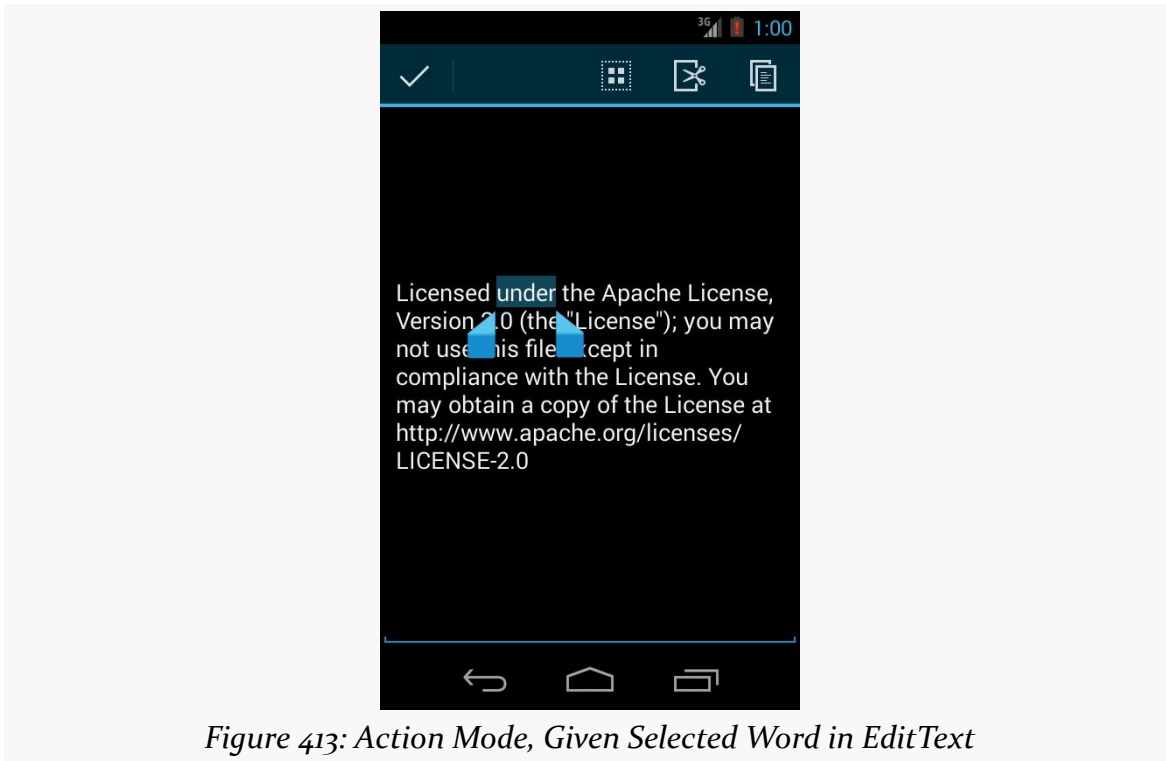

Figure 412: Regular Action Bar for Activity with EditText

to one designed to perform operations on what you have selected:

The good news is that this is not some sort of magic limited only to built-in widgets like `EditText`. You too can have this effect in your application, by triggering an “action mode”.

In this chapter, we will explore how you can set up and respond to action modes.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

A Matter of Context

Most desktop operating systems have had the notion of a “context menu” for some time, typically triggered by a click of the right mouse button. In particular, a right-click over some selected item might bring up a context menu of operations to perform on that item:

- Selecting text in a text editor, then right-clicking, might bring up a context menu for cut/copy/paste of the text
- Right-clicking over a file in some sort of file explorer might bring up a context menu for cut/copy/paste of the file
- Etc.

Android supports context menus, driven by a long-tap on a widget rather than a right-click. You will find a few applications that offer such menus, particularly on lists of things. However, context menus are a very old UI design pattern in Android, and modern apps rarely use them.

Instead, contextual operations are raised via an action mode, so when the user specifies a context (e.g., selects a word in an `EditText`), the action bar changes to show operations relevant for the selection.

Manual Action Modes

A common pattern will be to activate an action mode when the user checks off something in a multiple-choice `ListView`. If you want to go that route, there is some built-in scaffolding to make that work, described [later in this chapter](#).

You can, if you wish, move the action bar into an action mode whenever you want. This would be particularly important if your UI is not based on a `ListView`. For example, tapping on an image in a `GridView` might activate it and move you into an action mode for operations upon that particular image.

In this section, we will examine the [ActionMode/ManualNative](#) sample project. This is another variation on the “show a list of Latin words in a list” sample used elsewhere in this book.

Choosing Your Trigger

As mentioned above, selecting a word or passage in an `EditText` (e.g., via a long-tap) brings up an action mode for cut/copy/paste operations. Other apps might bring up an action mode when you check an item in a checklist. Yet others might bring up an action mode when you long-tap on an item in a regular list. And so on.

You will need to choose, for your own UI, what trigger mechanism will bring up an action mode. It should be some trigger that makes it obvious to the user what the action mode will be acting upon. For example:

ACTION MODES

- If the user long-taps on an item in a `GridView`, bring up an action mode, and treat future taps on `GridView` items as adding or removing items from the “selection” while that action mode is visible
- If the user “rubber-bands” some figures in your vector art drawing `View`, bring up an action mode for operations on those figures (e.g., rotate, resize)
- And so on

In the case of the sample project, we stick with the classic long-tap on a `ListView` row to bring up an action mode:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    initAdapter();
    getListView().setLongClickable(true);
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    getListView().setOnItemLongClickListener(new ActionModeHelper(
                                                                    this,
                                                                    getListView()));
}
```

Starting the Action Mode

Starting an action mode is trivially easy: just call `startActionMode()` on your `Activity`, passing in an implementation of `ActionMode.Callback`, which will be called with various lifecycle methods for the action mode itself.

In the case of the `ActionMode` sample project, `ActionModeHelper` – our `OnItemLongClickListener` from the preceding section – also is our `ActionMode.Callback` implementation. Hence, when the user long-clicks on an item in the `ListView`, the `ActionModeHelper` establishes itself as the action mode:

```
@Override
public boolean onItemLongClick(AdapterView<?> view, View row,
                               int position, long id) {
    modeView.clearChoices();
    modeView.setItemChecked(position, true);

    if (activeMode == null) {
        activeMode=host.startActionMode(this);
    }

    return true;
}
```

Note that `startActionMode()` returns an `ActionMode` object, which we can use later on to configure the mode’s behavior, by stashing it in an `actionMode` data member.

Also, we make the long-clicked-upon item be “checked”, to show which item the action mode will act upon. Our row layout will make a checked row show up with the “activated” style, courtesy of Android’s `simple_list_item_activated_1` stock layout.

Also note that we only start the action mode if it is not already started.

Implementing the Action Mode

The real logic behind the action mode lies in your `ActionMode.Callback` implementation. It is in these four lifecycle methods where you define what the action mode should look like and what should happen when choices are made in it.

`onCreateActionMode()`

The `onCreateActionMode()` method will be called shortly after you call `startActionMode()`. Here, you get to define what goes in the action mode. You get the `ActionMode` object itself (in case you do not already have a reference to it). More importantly, you are passed a `Menu` object, just as you get in `onCreateOptionsMenu()`. And, just like with `onCreateOptionsMenu()`, you can inflate a menu resource into the `Menu` object to define the contents of the action mode:

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=host.getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);

    return(true);
}
```

In addition to inflating our menu resource into the action mode’s menu, we also set the title of the `ActionMode`, which shows up to the right of the Done button:

Figure 414: The ManualNative Sample App, Showing an Action Mode

onPrepareActionMode()

If you determine that you need to change the contents of your action mode, you can call `invalidate()` on the `ActionMode` object. That, in turn, will trigger a call to `onPrepareActionMode()`, where you once again have an opportunity to configure the `Menu` object. If you do make changes, return `true` — otherwise, return `false`. In the case of `ActionModeHelper`, we take the latter approach:

```
@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}
```

onActionItemClicked()

Just as `onCreateActionMode()` is the action mode analogue to `onCreateOptionsMenu()`, `onActionItemClicked()` is the action mode analogue to `onOptionsItemSelected()`. This will be called if the user clicks on something related to your action mode. You are passed in the corresponding `MenuItem` object (plus the `ActionMode` itself), and you can take whatever steps are necessary to do whatever the work is.

On the `ActionModeDemo` class, we have the business logic for handling the data-change operations in a `performAction()` method:

ACTION MODES

```
public boolean performAction(int itemId, int position) {
    switch (itemId) {
        case R.id.cap:
            String word=words.get(position);

            word=word.toUpperCase();

            adapter.remove(words.get(position));
            adapter.insert(word, position);

            return(true);

        case R.id.remove:
            adapter.remove(words.get(position));

            return(true);
    }

    return(false);
}
```

And, the `onActionItemClicked()` method calls `performAction()`:

```
@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    boolean result=
        host.performAction(item.getItemId(),
            modeView.getCheckedItemPosition());

    if (item.getItemId() == R.id.remove) {
        activeMode.finish();
    }

    return(result);
}
```

`onActionItemClicked()` also dismisses the action mode if the user chose the “remove” item, since the action mode is no longer needed. You get rid of an active action mode by calling `finish()` on it.

onDestroyActionMode()

The `onDestroyActionMode()` callback will be invoked when the action mode goes away, for any reason, such as:

1. The user clicks the Done button on the left
2. The user clicks the BACK button
3. You call `finish()` on the `ActionMode`

Here, you can do any necessary cleanup. `ActionModeHelper` tries to clean things up, notably the “checked” state of the last item long-tapped-upon:

ACTION MODES

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    activeMode=null;
    modeView.clearChoices();
    modeView.requestLayout();
}
```

However, for reasons that are not yet clear, `clearChoices()` does not update the UI when called from `onDestroyActionMode()` unless you also call `requestLayout()`.

Multiple-Choice-Modal Action Modes

For many cases, the best user experience will be for you to have a multiple-choice `ListView`, where checking items in that list enables an action mode for performing operations on the checked items. For this scenario, API Level 11+ has a built-in `ListView` choice mode, `CHOICE_MODE_MULTIPLE_MODAL`, that automatically sets up an `ActionMode` for you as the user checks and unchecks items.

To see how this works, let's examine the [ActionMode/ActionModeMC](#) sample project. This is the same project as in the preceding section, but altered to have a multiple-choice `ListView`, utilizing an action mode on API Level 11+.

Once again, in `onCreate()`, we need to set up the smarts for our `ListView`. This time, though, we will use `CHOICE_MODE_MULTIPLE_MODAL`:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    initAdapter();

    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
    getListView().setMultiChoiceModeListener(new HCMultiChoiceModeListener(
        this, getListView()));
}
```

We enable `CHOICE_MODE_MULTIPLE_MODAL` for the `ListView`, and register an instance of an `HCMultiChoiceModeListener` object via `setMultiChoiceModeListener()`. This object is an implementation of the `MultiChoiceModeListener` interface that we will examine shortly.

Since we now may have multiple checked items, our `performAction()` method must take this into account, capitalizing or removing all checked words:

```
public boolean performActions(MenuItem item) {
    SparseBooleanArray checked=getListView().getCheckedItemPositions();
```

ACTION MODES

```
switch (item.getItemId()) {
    case R.id.cap:
        for (int i=0; i < checked.size(); i++) {
            if (checked.valueAt(i)) {
                int position=checked.keyAt(i);
                String word=words.get(position);

                word=word.toUpperCase(Locale.ENGLISH);

                adapter.remove(words.get(position));
                adapter.insert(word, position);
            }
        }

        return(true);

    case R.id.remove:
        ArrayList<Integer> positions=new ArrayList<Integer>();

        for (int i=0; i < checked.size(); i++) {
            if (checked.valueAt(i)) {
                positions.add(checked.keyAt(i));
            }
        }

        Collections.sort(positions, Collections.reverseOrder());

        for (int position : positions) {
            adapter.remove(words.get(position));
        }

        getListView().clearChoices();

        return(true);
}

return(false);
}
```

MultiChoiceModeListener extends the ActionMode.Callback interface we used with our manual action mode earlier in this book. Hence, we need to implement all the standard ActionMode.Callback methods, plus a new onItemCheckedStateChanged() method introduced by MultiChoiceModeListener:

```
package com.commonware.android.actionmodemc;

import android.annotation.TargetApi;
import android.os.Build;
import android.view.ActionMode;
import android.view.Menu;
import android.view.MenuInflater;
import android.view.MenuItem;
import android.widget.AbsListView;
import android.widget.ListView;

@TargetApi(Build.VERSION_CODES.HONEYCOMB)
```

ACTION MODES

```
public class HCMultiChoiceModeListener implements
    AbsListView.MultiChoiceModeListener {
    ActionModeDemo host;
    ActionMode activeMode;
    ListView lv;

    HCMultiChoiceModeListener(ActionModeDemo host, ListView lv) {
        this.host=host;
        this.lv=lv;
    }

    @Override
    public boolean onCreateActionMode(ActionMode mode, Menu menu) {
        MenuInflater inflater=host.getMenuInflater();

        inflater.inflate(R.menu.context, menu);
        mode.setTitle(R.string.context_title);
        mode.setSubtitle("(1)");
        activeMode=mode;

        return(true);
    }

    @Override
    public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
        return(false);
    }

    @Override
    public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
        boolean result=host.performActions(item);

        updateSubtitle(activeMode);

        return(result);
    }

    @Override
    public void onDestroyActionMode(ActionMode mode) {
        activeMode=null;
    }

    @Override
    public void onItemCheckedStateChanged(ActionMode mode, int position,
        long id, boolean checked) {
        updateSubtitle(mode);
    }

    private void updateSubtitle(ActionMode mode) {
        mode.setSubtitle("(" + lv.getCheckedItemCount() + ")");
    }
}
```

Android will automatically start our action mode for us when the user checks the first item in the list, using our `MultiChoiceModeListener` as the callback. Android will also automatically finish the action mode if the user unchecks all previously-checked items.

ACTION MODES

In `onCreateActionMode()`, we populate the menu, plus set up a title and subtitle on the `ActionMode`. The subtitle appears below the title, as you might expect. In this case, we are indicating how many words are checked and therefore will be affected by the actions the user chooses in the action mode:

Figure 415: The ActionModeMC Sample App, Showing the Action Mode

Then, in `onActionItemClicked()`, we both call `performActions()` to affect the desired changes, plus update the subtitle in case the user removed words (which means they are no longer checked).

The new `onItemCheckedStateChanged()` will be called whenever the user checks or unchecks an item, up until the last item is unchecked. `HCMultiChoiceModelListener` simply updates the subtitle to reflect the new count of checked items.

On the whole, using `CHOICE_MODE_MULTIPLE_MODAL` is simpler than setting up your own trigger mechanism and managing the action mode yourself. That being said, both are completely valid options, which is particularly important for situations where a multiple-choice `ListView` is not the desired user interface.

Long-Click To Initiate an Action Mode

However, rather than having checkboxes or the like always in the `ListView`, a more modern approach is to move into multiple-selection mode based on a long-click.

Before then, clicks on rows behave like with any other `ListView`, but after a long-click, the action mode appears and the user can tap on rows to select which of them to operate upon.

The [ActionMode/LongPress](#) sample project is a variation on the preceding project, with some slight simplifications, and adopting the long-click as the means to enter the action mode.

Setting Up the Listeners

In `onCreate()`, we set up listeners for both a long click (via `setOnItemLongClickListener()`) and for multiple-choice mode (via `setMultiChoiceModeListener()`). Both times, we supply the activity as the listener, as it implements the appropriate interfaces:

```
getListView().setOnItemLongClickListener(this);
getListView().setMultiChoiceModeListener(this);
```

Handling the Long Click

By default, the `ListView` is in no-choice mode, where clicks on rows simply trigger `onListItemClick()` or the equivalent. However, if the user long-clicks on a row, our `onItemLongClick()` method will be called, and we can both switch into multiple-choice mode and mark the long-clicked row as being checked:

```
@Override
public boolean onItemLongClick(AdapterView<?> parent, View view,
                                int position, long id) {
    getListView().setChoiceMode(ListView.CHOICE_MODE_MULTIPLE_MODAL);
    getListView().setItemChecked(position, true);

    return true;
}
```

At this point, the action mode will also start up, courtesy of having called `setMultiChoiceModeListener()`.

Addressing Configuration Changes

If we undergo a configuration change, we want:

1. To keep the current set of words, including any that were added
2. To keep the action mode going, if the user had long-clicked to enter the action mode

ACTION MODES

3. To keep our checked item states, if the action mode is active

Keeping the checked item states will be handled for us by the built-in instance-state management of `ListView` and `ListActivity`. However, the rest we need to handle ourselves. So, we have an `onSaveInstanceState()` implementation in the activity, which saves the current choice mode, plus the current word list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);
    state.putInt(STATE_CHOICE_MODE, getListView().getChoiceMode());
    state.putStringArrayList(STATE_MODEL, words);
}
```

Plus, in `onCreate()`, after setting up the listeners, we set up the choice mode of the `ListView` based upon the passed in instance state `Bundle`, if there is one:

```
@Override
public void onCreate(Bundle state) {
    super.onCreate(state);

    if (state == null) {
        initAdapter(null);
    }
    else {
        initAdapter(state.getStringArrayList(STATE_MODEL));
    }

    getListView().setOnItemLongClickListener(this);
    getListView().setMultiChoiceModeListener(this);

    int choiceMode=
        (state == null ? ListView.CHOICE_MODE_NONE
         : state.getInt(STATE_CHOICE_MODE));

    getListView().setChoiceMode(choiceMode);
}
```

Once we call `setChoiceMode()` with the previous activity instance's choice mode, if that was `CHOICE_MODE_MULTIPLE_MODAL`, Android will automatically open up the action mode again and restore our checked items.

Resetting the Choice Mode

Where things get a bit interesting is when the user dismisses the action mode, at which point we need to move back to no-choice mode.

ACTION MODES

You might think that this would merely be a matter of calling `setChoiceMode()` on the `ListView`, asking for `CHOICE_MODE_NONE`. Indeed, that is part of the solution. However, there are two problems:

1. If you call that in `onDestroyActionMode()` directly, you wind up with infinite recursion and a `StackOverflowError`, as changing the choice mode while the action mode is still technically active will cause it to destroy the action mode again.
2. Switching the choice mode back to “none” enables some optimizations within `ListView` that ignore the checked state of our rows. However, those rows still already checked will show up as activated, even after calling `setChoiceMode()` to return to the normal “none” mode. `clearChoices()` also does not have a worthwhile effect, for whatever reason.

Hence, in `onDestroyActionMode()`, not only do we need to call `setChoiceMode()`, but we need to “smack around” the `ListView` enough to get it to clear our checked rows, and the easiest way to do that is to call `setAdapter()` on it, passing in its existing adapter:

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        getListView().setChoiceMode(ListView.CHOICE_MODE_NONE);
        getListView().setAdapter(getListView().getAdapter());
    }
}
```

And, we only do that while our action mode is active (i.e., `activeMode` is not `null`), to avoid the infinite recursion.

This is a bit clunky, but it works.

The Results

When initially launched, the activity looks like a simple `ListActivity`:

ACTION MODES

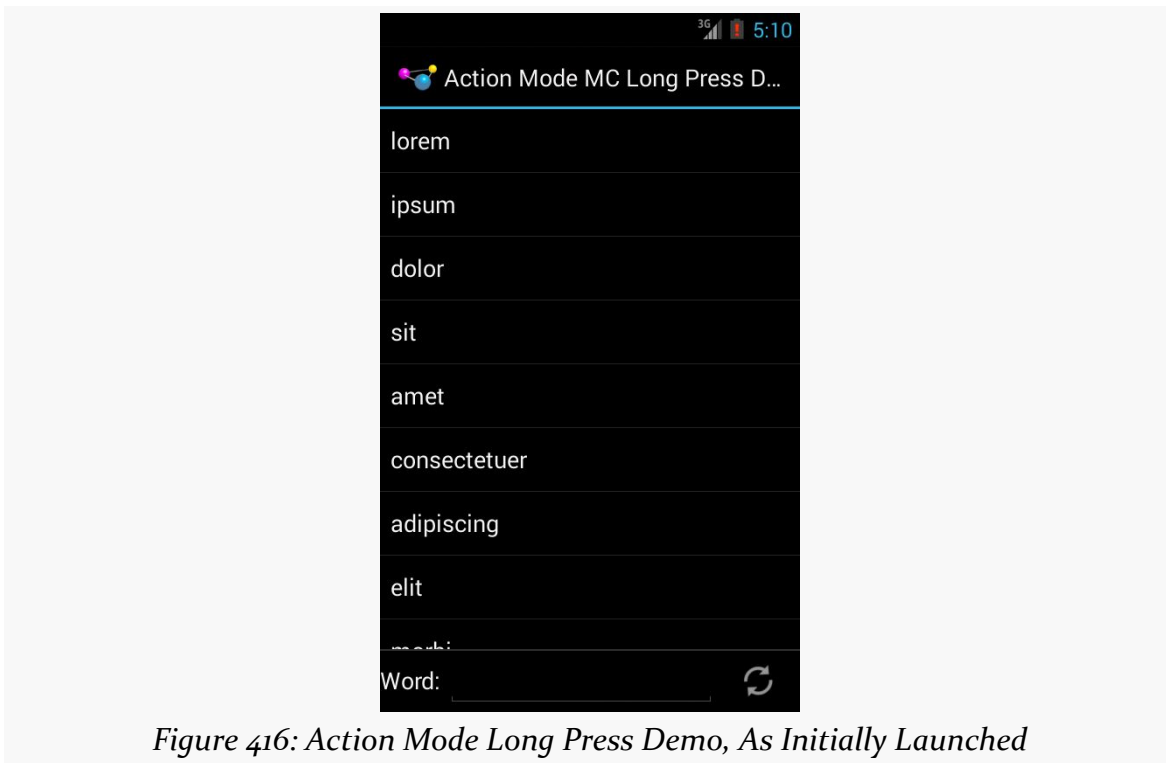

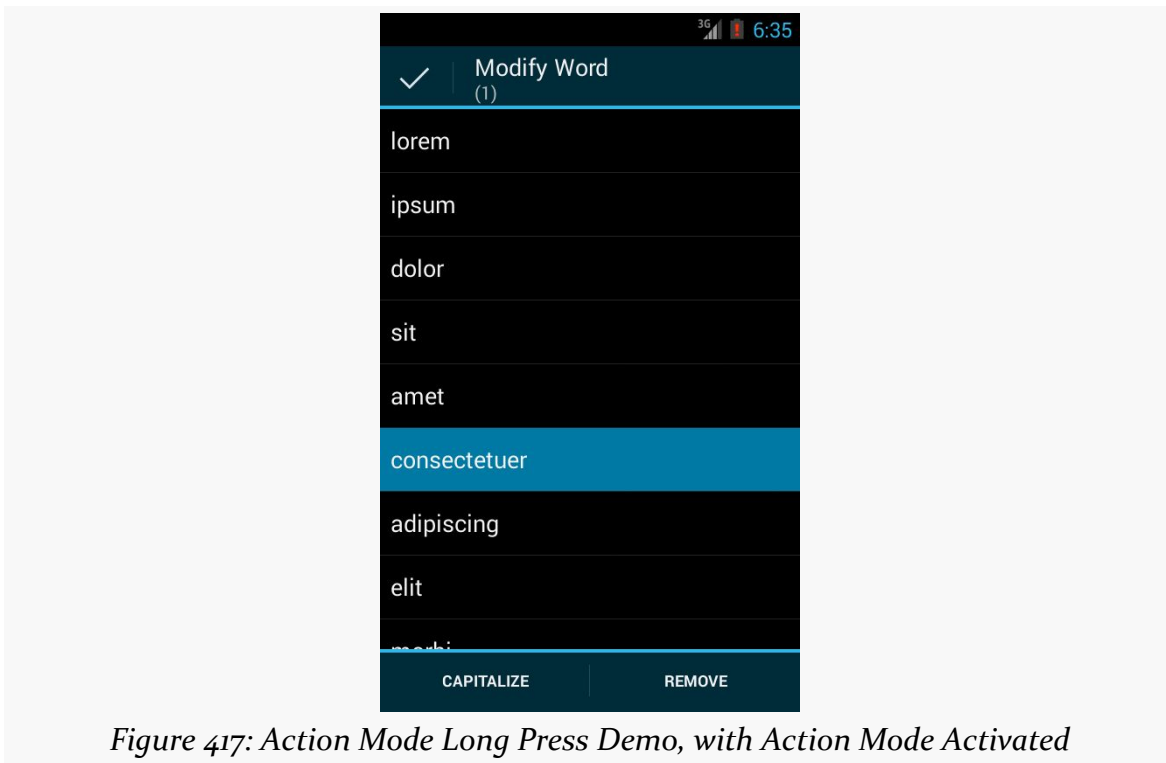

Figure 416: Action Mode Long Press Demo, As Initially Launched

Tapping on a row provides the normal momentary highlight.

However, if the user long-clicks a row, we move into the action mode and a multiple-choice `ListView`:

ACTION MODES

ACTION MODES

Dismissing the action mode returns the `ListView` to normal operation.

Other Advanced Action Bar Techniques

The action bar offers a number of other features that developers can take advantage of, ones that do not necessarily fit into the other chapters. Hence, this chapter is a “catch all” for other things you may wish to do with your action bar. Note that this chapter is focused on the native action bar, not the [ActionBarSherlock](#) or [AppCompat](#) backports.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Action Layouts

What happens if you want something other than a button to appear as an action bar item? Suppose you want a field instead?

Fortunately, this is supported. Otherwise, this would be a completely pointless section of the book.

You can specify `android:actionLayout` on an `<item>` element in a menu resource. This will point to a reference to a layout XML resource that you want to have inflated into the action bar instead of a toolbar button. Then, in `onCreateOptionsMenu()`, you can call `findMenuItem()` on the `Menu` to retrieve the `MenuItem` associated with this `<item>` element, then call `getActionView()` to retrieve the root of your inflated

layout. At that point, you can hook up event listeners to the widgets in that layout, as needed.

Obviously, since the action bar is only so big, you will need to be judicious about your use of space.

Action Views and Action Providers

If all you need is a single widget to replace the toolbar button, rather than a whole layout resource, you can use `android:actionViewClass` instead of `android:actionLayout`. In `android:actionViewClass`, you provide the fully-qualified class name of the widget that you wish to use to replace the toolbar button. You still use `getActionView()` to retrieve a reference to this at runtime.

If the widget you use implements the `CollapsibleActionView` interface, then it has an additional behavior: the ability to collapse into a standard toolbar button or expand into its normal mode. The only example of this in the current Android SDK is `SearchView`, which can expand into a field for searching or collapse into a simple search icon (magnifying glass) as needed. We will see more about `SearchView`, and how it behaves as a `CollapsibleActionView`, [later in this chapter](#).

Yet another possible toolbar button replacement is an action provider. Whereas an action view or action layout provide the UI, and your code provides the handling of touch events, an action provider is an “all-in-one” solution. It is designed to be configured, then used by the user without any required additional intervention by the developer. That being said, an action provider can have its own listener interfaces to let developers know about various events that have occurred. The two primary implementations of the `ActionProvider` base class are:

- `MediaRouteActionProvider`, covered [later elsewhere in the book](#), is used to allow users to control the destination for media, such as routing audio to Bluetooth headphones instead of the device speaker or playing content back on a Chromecast
- `ShareActionProvider` can simplify sharing content via `ACTION_SEND`, as is covered [elsewhere in the book](#)

To use an `ActionProvider`, you add the `android:actionProviderClass` attribute to an `<item>` in the `<menu>` resource, providing the fully-qualified class name of the `ActionProvider` implementation. You can call `getActionProvider()` on the `MenuItem` to retrieve the `ActionProvider` instance, for configuration at runtime.

Searching with SearchView

Many apps employ a SearchView in their action bar. The user typically sees the search icon as a regular toolbar button:

Figure 419: SearchView Demo, Showing Collapsed Action View

Tapping that opens a search field, taking over more of the action bar:

Figure 420: SearchView Demo, Showing Expanded Action View

Typing something in initiates some sort of search, as defined by the activity that is using the SearchView. BACK or the app icon in the action bar will “collapse” the SearchView back into its iconified state.

The [ActionBar/SearchView](#) sample project, profiled in this section, shows how you can use SearchView within your app. This sample is a clone of one of the previous action bar samples, where we have the list of 25 words, hosted in a ListFragment, with action bar items to add a word and reset the word list. In this section, we will augment the sample with a SearchView and a filtered ListView.

SearchView... in the Menu Resource

The project’s menu resource (res/menu/actions.xml) contains a regular action item (reset), an action item employing an action layout (add), and an action item containing our SearchView (search):

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/search"
        android:actionViewClass="android.widget.SearchView"
        android:icon="@drawable/ic_action_search"
        android:showAsAction="ifRoom|collapseActionView"
        android:title="@string/filter">
    </item>
```

```
</menu>
```

Note that the search item not only has `android:actionViewClass="android.widget.SearchView"` to tie in our action view, but it also has `android:showAsAction="ifRoom|collapseActionView"`, to indicate that this action view should support collapsing and expanding.

SearchView... in the Action Bar Configuration

In `onCreateOptionsMenu()` of our `ActionBarFragment`, in addition to inflating the menu resource and calling a `configureActionItem()` method to configure the add action layout, we now also call a `configureSearchView()` method to configure the `SearchView`:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.actions, menu);

    configureSearchView(menu);

    super.onCreateOptionsMenu(menu, inflater);
}
```

In `configureSearchView()`, surprisingly enough, we configure the `SearchView`:

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

Specifically, we:

- Register our fragment as the `QueryTextListener` and the `OnCloseListener`, which will be covered in greater detail [later in this chapter](#)
- Disable the submit button, as we will be using the `SearchView` for filtering rather than querying

OTHER ADVANCED ACTION BAR TECHNIQUES

- Indicate that the SearchView should be collapsed (“iconified”) as the default state

Also, our fragment has an `initialQuery` data member, and if that is not null, we expand the SearchView and fill in `initialQuery` as the query to be shown in the SearchView, also submitting it.

`initialQuery` comes from our configuration change logic, as if the user fills in something in the SearchView in one configuration (e.g., portrait), we do not want to lose it on a configuration change (e.g., to landscape). In our `onSaveInstanceState()` method, we save both the query from the SearchView and the words currently in our list:

```
@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    if (!sv.isIconified()) {
        state.putCharSequence(STATE_QUERY, sv.getQuery());
    }

    state.putStringArrayList(STATE_MODEL, words);
}
```

In `onActivityCreated()`, we use the saved `InstanceState` Bundle to populate the adapter with the previous set of words, plus store the old SearchView’s query in `initialQuery`:

```
@Override
public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    if (savedInstanceState == null) {
        initAdapter(null);
    }
    else {
        initAdapter(savedInstanceState.getStringArrayList(STATE_MODEL));
        initialQuery=savedInstanceState.getCharSequence(STATE_QUERY);
    }

    setHasOptionsMenu(true);
}
```

Hence, on a configuration change, by the time `configureSearchView()` is called, we will have our `initialQuery`, if there is one, and we can set up the UI to be the same as it was in the old configuration.

SearchView... And Filtering a ListView

The `ActionBarFragment` implements the `SearchView.OnQueryTextListener` and `SearchView.OnCloseListener` interfaces, which is why we can pass this to `setOnQueryTextListener()` and `setOnCloseListener()` in `configureSearchView()`.

Those two interfaces require a total of three methods, described below.

`onQueryTextChange()`

The `onQueryTextChange()` method — required by `SearchView.OnQueryTextListener` — will be called whenever the user has changed the contents of the expanded `SearchView`, such as by typing a character. This is used when you want to employ the `SearchView` for filtering, updating the filter as the user types, rather than for searching, in which case you would wait until the user “submits” the search request.

Our implementation takes advantage of `ArrayAdapter`'s built-in filtering capability:

```
@Override
public boolean onQueryTextChange(String newText) {
    if (TextUtils.isEmpty(newText)) {
        adapter.getFilter().filter("");
    }
    else {
        adapter.getFilter().filter(newText.toString());
    }

    return true;
}
```

Adapters that implement the `Filterable` interface can be filtered, automatically restricting the displayed items to ones that match the filter. Calling `getFilter()` on a `Filterable` returns a `Filter`. The default implementation of a `Filter` filters on the leading characters of `toString()` of `getItem()` from the `Adapter`. Hence, filtering an `ArrayAdapter` on our roster of 25 words, where the filter string is 'm', would show `morbi` and `mollis` but skip `amet`, let alone other words not beginning with `m`.

So, our `onQueryTextChange()` method simply updates the `Filter` with whatever the user has typed into the `SearchView`, setting the filter to the empty string if the `SearchView` is either empty or has null contents.

onQueryTextSubmit()

The `onQueryTextSubmit()` method — required by `SearchView.OnQueryTextListener` — would be called if the user tapped on the submit button within the expanded `SearchView`, to ask us to perform the search. In this sample, we have disabled that button, as we are filtering our list on the fly, rather than performing a query once the `SearchView` is filled out. Hence, `ActionBarFragment` has a do-nothing implementation of `onQueryTextSubmit()`, simply returning `false` to indicate that we have not consumed the event:

```
@Override
public boolean onQueryTextSubmit(String query) {
    return(false);
}
```

The chapter on advanced database techniques has [a section on full-text indexing](#), and the sample app in that chapter demonstrates the use of the submit button in a `SearchView` and `onQueryTextSubmit()`.

onClose()

The `onClose()` method — required by `SearchView.OnCloseListener` — in theory will be called when the `SearchView` is collapsed. Here, we simply clear out the filter that we are using to limit the contents of the `ListView`, plus return `true` to say that we have handled the event:

```
@Override
public boolean onClose() {
    adapter.getFilter().filter("");

    return(true);
}
```

According to the `SearchView` source code, it will only be called if:

- The query text is empty, and
- The `SearchView` is iconified by default (`setIconifiedByDefault(true)`)

In practice, [not even that works](#).

Hence, if you really need to find out when the `SearchView` is collapsed, you will probably need to use the more generic `OnActionExpandListener` interface, attached to the `SearchView` via `setOnActionExpandListener().onMenuItemActionCollapse()`

should be called when the `SearchView` is collapsed. This also works for other types of collapsible action views, not just `SearchView`.

SearchView... From the User's Perspective

If the user taps on the search icon, then starts typing into the `SearchView`'s editing area, the `ListView` is filtered based upon the typed-in prefix:

Figure 421: SearchView Demo, Showing Filtered Results

Floating Action Bars

By default, your action bar will be separate from the main content area of your activity. Normally, that is what you want.

But, sometimes, you may want to have the action bar(s) float over the top of your activity, as can be seen in Google Maps:

OTHER ADVANCED ACTION BAR TECHNIQUES

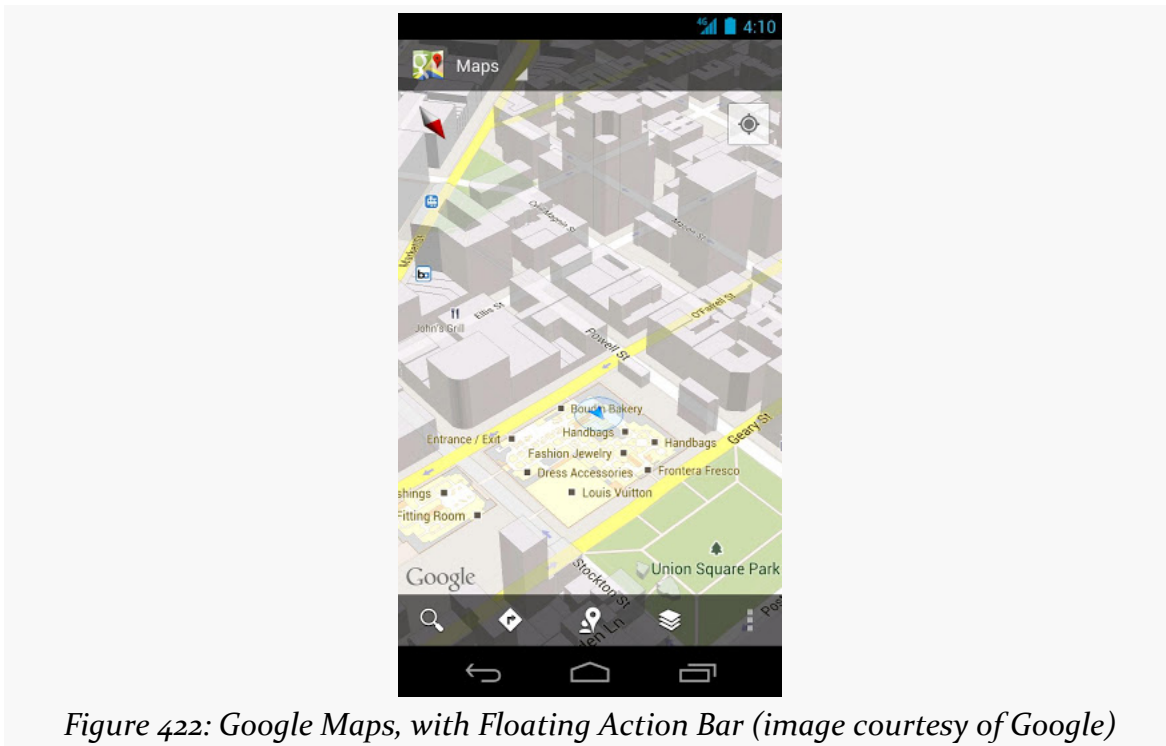

Figure 422: Google Maps, with Floating Action Bar (image courtesy of Google)

To accomplish this, you can use `FEATURE_ACTION_BAR_OVERLAY`, as is illustrated in the [ActionBar/OverlayNative](#) sample project.

This is nearly identical to the `ActionBar/ActionBarDemoNative` sample project, with just a few changes, mostly in the `onCreate()` method of our activity:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    getWindow().requestFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getActionBar().setBackgroundDrawable(d);
}
```

In addition to the original logic, we:

- Call `requestFeature()` on our `Window` (obtained via a call to `getWindow()`), asking for `FEATURE_ACTION_BAR_OVERLAY`

OTHER ADVANCED ACTION BAR TECHNIQUES

- Call `setBackgroundDrawable()` on our `ActionBar` (obtained via a call to `getSupportActionBar()`), since we are using `ActionBarSherlock`, supplying a reference to a drawable resource to use for the background of the floating action bar

The drawable resource is a `ShapeDrawable`, defined in XML:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <solid android:color="#AAFFFFFF" />
</shape>
```

We will discuss `ShapeDrawable` in much greater detail [later in this book](#) . For the moment, take it on faith that our resource is defining a rectangle, with a translucent white fill. The alpha channel (AA) for our translucence is important, so the user can see a bit of our activity underneath the floating action bar.

The result is that our action bars float over the top of the list:

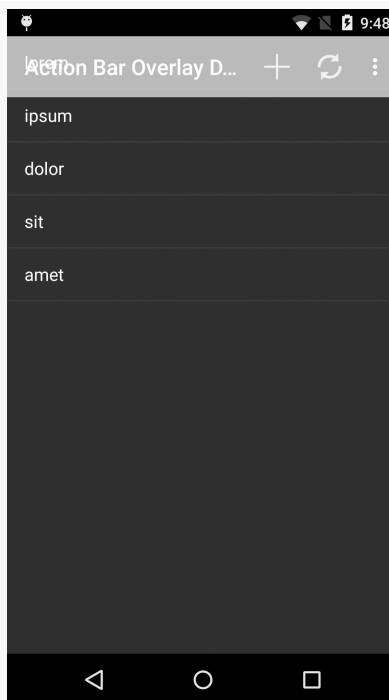

Figure 423: Floating Action Bar

OTHER ADVANCED ACTION BAR TECHNIQUES

In this case, the effect is not very good, as the words will blend in too strongly with the overlaid action bars. However, that is a question of organizing the screen content and using this overlay feature only in cases where you will see good results, such as in the Google Maps example shown above.

Toolbar

Android 5.0 introduced a `Toolbar` widget, offering functionality akin to the action bar, but in the form of a `ViewGroup` that can be positioned where you need it. You can even use a `Toolbar` as an outright replacement for the action bar, for cases where you need a bit more control over the action bar implementation than you get by default.

In this chapter, we will explore the use of `Toolbar`. Note that [an upcoming chapter](#) will cover the use of [a backport of `Toolbar`](#) that works back to API Level 7... albeit with some issues.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Note that the examples in this chapter are clones of a couple from the core chapters. This chapter's prose was written assuming that you were familiar with those samples, so you may need to go back and review them as needed.

One of the samples relies upon using a custom `Parcelable` class, which is covered [in another chapter](#).

Basic `Toolbar` Mechanics

As noted earlier, a `Toolbar` is an ordinary `ViewGroup`. While it does not support placing arbitrary children in it the way a `LinearLayout` might, it otherwise can be used like any other `ViewGroup`. In particular, you can put it in a layout resource and

position it wherever it makes sense, such as in a lower quadrant of a tablet-sized screen, tied to some specific part of your UI.

However, the `Toolbar` is not the action bar... at least, not by default. As such, you will use somewhat different methods for interacting with it, particularly for dealing with menu items:

- You will call `inflateMenu()` when you want to pour action items into the menu, as a counterpart to the work you do in `onOptionsItemSelected()` for the action bar
- You will call `setOnMenuItemClickListener()` to set a listener to be invoked when the user taps on a menu item in the `Toolbar`, as a counterpart to the work you do in `onOptionsItemSelected()`

A `Toolbar` does not automatically adopt much in the way of styling from your activity's theme. In particular, it does not set the background color to be the primary color of a `Theme.Material` theme, the way the action bar does. However, whether via a style resource, XML attributes in a layout file, or Java code, you can affect these same sorts of capabilities.

Use Case #1: Split Action Bar

In Android 4.x, and in the original implementation of [the `appcompat-v7` action bar backport](#), we had the notion of the “split action bar”. On phone-sized screens in portrait orientation, the action bar could easily get too crowded. We could opt into having a split action bar in these cases, where action items and the overflow would go into a bar at the bottom of the screen, leaving the top for the app's title, icon, and navigation items.

However, `Theme.Material` and modern editions of `appcompat-v7` have dropped support for the split action bar. To achieve the same basic effect, you can use a `Toolbar` that you position yourself at the bottom of the screen.

The [Toolbar/SplitActionBar](#) sample project demonstrates both the original Android 4.x way of getting a split action bar and using `Toolbar` to get the same basic visual effect on Android 5.0+. This is a clone of the `ActionBar/VersionedColor` sample app from [a previous chapter](#), supporting a tinted action bar on Android 4.x (via a custom theme based off of `Theme.Holo`) and Android 5.0+ (via a custom theme based off of `Theme.Material`).

Enabling Stock Android 4.x Behavior

Getting a split action bar on Android 4.x was easy: just add `android:uiOptions="splitActionBarWhenNarrow"` to the `<activity>` or `<application>` in the manifest. Putting it on `<application>` will affect the default for all activities; putting it on a single `<activity>` affects only that activity.

The sample app's manifest uses `android:uiOptions="splitActionBarWhenNarrow"` on the one-and-only activity:

```
<activity
  android:name="ActionBarDemoActivity"
  android:label="@string/app_name"
  android:uiOptions="splitActionBarWhenNarrow">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
```

The result is, as the name suggests, a split action bar:

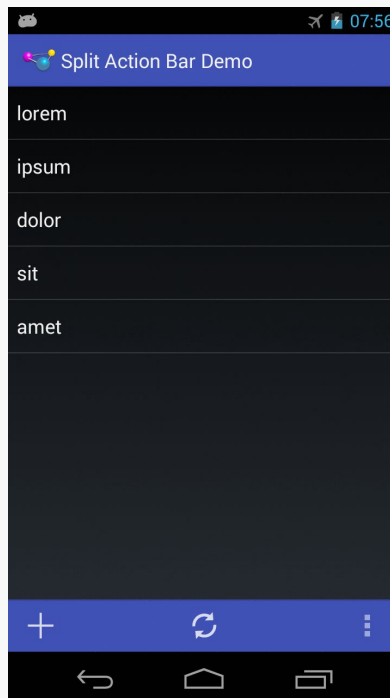

Figure 424: Split Action Bar on Android 4.3

TOOLBAR

Note that the bottom bar retains the tinting rules applied via our theme, created via [the Action Bar Style Generator](#).

Adding the Toolbar

Since Toolbar is an ordinary ViewGroup, we can put one in a layout resource, such as `res/layout-v21/main.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ListView
    android:id="@android:id/list"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="1"/>

  <Toolbar
    android:id="@+id/toolbar"
    style="@style/SplitActionBar"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

</LinearLayout>
```

Here, we allocate `wrap_content` height for the Toolbar and give all remaining space to the ListView (by means of `android:layout_weight="1"` and no weight on the Toolbar).

The style attribute on the Toolbar points to a custom style resource, in `res/values-v21/styles.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="SplitActionBar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

This sets the background color of the Toolbar to be the same background color that we are using for the `colorPrimary` tint for our `Theme.Material`-based custom theme.

TOOLBAR

By default, Toolbar has a black background, despite setting `colorPrimary` on the theme.

Using the Layout

In `onCreate()` of the activity, we load up the layout file if we are on Android 5.0 or higher:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        setContentView(R.layout.main);
    }

    initAdapter();
}
```

Note that we could have had a separate `res/layout/main.xml` resource, containing just the `ListView`. Then, we could call `setContentView()` regardless of API level, with the resource system pulling in the right one based on the device's API level. In this case, since we are using `ListActivity`, we do not need a layout for Android 4.x. Having two lines of Java versus a separate layout resource is a tradeoff that could be made either way.

This gives us a `Toolbar`, but by default it will be empty, making it less than useful.

Populating and Using the Toolbar

On Android 4.x, we can just implement `onCreateOptionsMenu()` and `onOptionsItemSelected()`, and the items will work, whether we chose a split action bar or not. On Android 5.0+, we need to explicitly put the action bar items into the `Toolbar` and explicitly register a listener to find out when those items are tapped.

We handle all of that in `onCreateOptionsMenu()` itself, using different behavior based on API level:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        Toolbar tb = (Toolbar) findViewById(R.id.toolbar);

        tb.inflateMenu(R.menu.actions);
        tb.setOnMenuItemClickListener(new Toolbar.OnMenuItemClickListener() {
            @Override
            public boolean onOptionsItemSelected(MenuItem item) {
```

TOOLBAR

```
        return(onOptionsItemSelected(item));
    }
});
}
else {
    getMenuInflater().inflate(R.menu.actions, menu);
}

return(super.onCreateOptionsMenu(menu));
}
```

If we are on an Android 4.x device, we just `inflate()` a menu resource into the supplied Menu for the action bar. If we are on an Android 5.0+ device, we:

- Retrieve the Toolbar from the inflated layout
- Inflate our menu resource into the Toolbar via `inflateMenu()`
- Register an `OnMenuItemClickListener` with the Toolbar, routing the menu item click over to our `onOptionsItemSelected()` method, so we can have one common implementation of logic for handling action items that are either in the action bar or the Toolbar

Results and Changes

Running this sample on Android 5.0+ gives us a split “action bar” implemented as a Toolbar:

TOOLBAR

One significant visual difference is the horizontal placement of the action items. In a true split action bar, they are evenly spaced across the bar. In a Toolbar, they are flush right (or, more accurately, flush “end”, to handle right-to-left languages). There is nothing built into Toolbar to spread the items out. While there are [hacks to make this happen](#), they rely on internal implementation of Toolbar and may prove unreliable over time.

Use Case #2: Contextual Actions

Sometimes, the reason to consider a Toolbar is that you want the user to have an easier time performing actions that pertain to a part of the UI, instead of the whole UI. This is particularly the case on tablet-sized screens, where the visual gap between parts of your UI and the top action bar may be substantial.

As an example, the [Toolbar/EU4YouToolbar](#) sample project is based on the EU4You samples from [the chapter on large-screen strategies](#). There, we had a master/detail pattern with a list of member nations of the EU as the master and the mobile Wikipedia page as the detail.

TOOLBAR

EU4YouToolbar makes a few changes:

- On tablets, it splits the detail area, to show a larger rendition of the country's flag, to go along with the mobile Wikipedia page.
- It adds navigational controls, so as the user browses the Web through the WebView in our UI, the user can go forward and backwards in their browsing history, plus reload the current page. On smaller screens, where the WebView fills the screen, these controls are in the action bar:

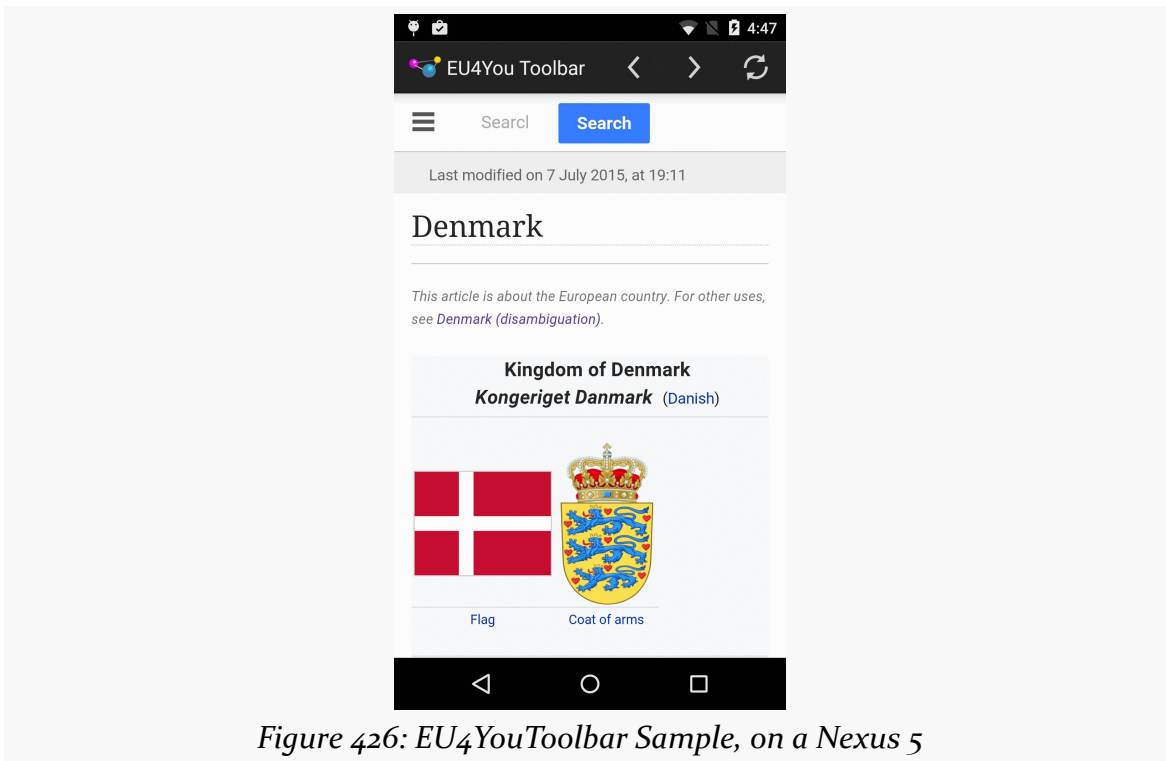

Figure 426: EU4YouToolbar Sample, on a Nexus 5

On larger screens, these controls are in a Toolbar placed immediately above the WebView:

TOOLBAR

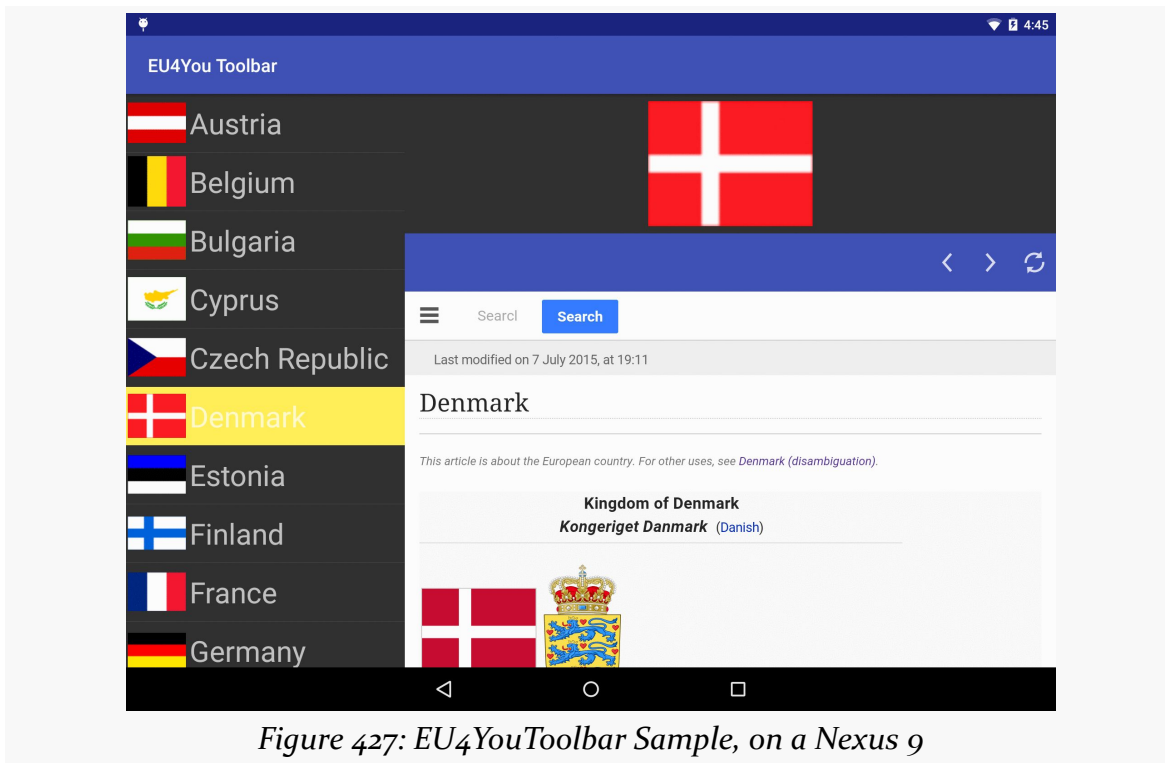

Figure 427: EU4YouToolbar Sample, on a Nexus 9

To keep things a bit simpler, this project has a `minSdkVersion` of 21, so we do not need to fuss with backwards compatibility. In truth, this would not be too difficult, requiring a different large-screen detail layout (that lacks the `Toolbar`) and falling back to having the navigational controls in the action bar if we cannot find a `Toolbar`.

The original sample used a `WebViewFragment` subclass (`DetailFragment`) to display the detail, and it supplied its own `WebView`. Now, we may want to show a flag (`ImageView`) and `Toolbar` as well, so we need our own layouts. Normally, we still only show a `WebView`:

```
<?xml version="1.0" encoding="utf-8"?>
<WebView
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:id="@+id/webview"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
</WebView>
```

However, on 720dp or larger screens, we add in an `ImageView` for the flag and a `Toolbar` for the navigational controls:

TOOLBAR

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:orientation="vertical">

  <ImageView
    android:id="@+id/flag"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_margin="8dp"
    android:layout_weight="1"
    android:scaleType="fitCenter"/>

  <Toolbar
    android:id="@+id/toolbar"
    style="@style/Toolbar"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"/>

  <WebView
    android:id="@+id/webview"
    android:layout_width="match_parent"
    android:layout_height="0dp"
    android:layout_weight="3"/>

</LinearLayout>
```

That layout gives the Toolbar a style of `@style/Toolbar`, which sets the background color of the Toolbar to be the primary color used by our overall theme:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="Toolbar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

Originally, our `DetailFragment` only needed the mobile Wikipedia URL as a data model. Now, though, we also need to know the image resource to use for the flag. While we could handle this as two separate bits of data (e.g., two extras to use with `DetailActivity`), another approach would be to pass the `Country` as the data model. However, that requires `Country` [to be Parcelable](#), so we need to add some code to `Country` to fulfill the `Parcelable` contract:

```
protected Country(Parcel in) {
    name = in.readInt();
    flag = in.readInt();
    url = in.readInt();
}
```

TOOLBAR

```
}

@Override
public int describeContents() {
    return 0;
}

@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeInt(name);
    dest.writeInt(flag);
    dest.writeInt(url);
}

@SuppressWarnings("unused")
public static final Parcelable.Creator<Country> CREATOR = new
Parcelable.Creator<Country>() {
    @Override
    public Country createFromParcel(Parcel in) {
        return new Country(in);
    }

    @Override
    public Country[] newArray(int size) {
        return new Country[size];
    }
};
```

The `onCountrySelected()` method of the `EU4You` activity — which is called when the user taps on a country in the “master” list — now passes the `Country` itself over to the `DetailFragment`, whether directly or by means of starting the `DetailsActivity`:

```
@Override
public void onCountrySelected(Country c) {
    if (details != null && details.isVisible()) {
        details.showCountry(c);
    }
    else {
        Intent i=new Intent(this, DetailsActivity.class);

        i.putExtra(DetailsActivity.EXTRA_COUNTRY, c);
        startActivity(i);
    }
}
```

`DetailsActivity` just turns around and invokes the same `showCountry()` method on `DetailFragment` that `EU4You` uses when the `DetailFragment` is hosted directly in `EU4You`:

```
package com.commonware.android.eu4youtb;

import android.app.Activity;
import android.os.Bundle;
```

TOOLBAR

```
public class DetailsActivity extends Activity {
    public static final String EXTRA_COUNTRY=
        "com.commonware.android.eu4you.EXTRA_COUNTRY";
    private Country c=null;
    private DetailsFragment details=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        details=(DetailsFragment)getFragmentManager()
            .findFragmentById(android.R.id.content);

        if (details == null) {
            details=new DetailsFragment();

            getFragmentManager().beginTransaction()
                .add(android.R.id.content, details)
                .commit();
        }

        c=getIntent().getParcelableExtra(EXTRA_COUNTRY);
    }

    @Override
    public void onResume() {
        super.onResume();

        details.showCountry(c);
    }
}
```

For the navigation controls, we need a menu resource. So, we define a webview menu resource that contains action bar items to go back in the browsing history, go forward in the browsing history, or reload the current page:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/back"
        android:title="@string/menu_back"
        android:icon="@drawable/ic_action_back"
        android:showAsAction="ifRoom"/>
    <item
        android:id="@+id/fwd"
        android:title="@string/menu_fwd"
        android:icon="@drawable/ic_action_fwd"
        android:showAsAction="ifRoom"/>
    <item
        android:id="@+id/reload"
        android:title="@string/menu_reload"
        android:icon="@drawable/ic_action_reload"
        android:showAsAction="ifRoom"/>
</menu>
```

TOOLBAR

Most of the changes, not surprisingly, reside in `DetailsFragment`, which now must manage the flag's `ImageView`, the `Toolbar` (when it exists), the action bar items (when the `Toolbar` does not exist), and the behaviors to be invoked when any of those toolbar/action bar items are invoked.

`DetailsFragment` is no longer a `WebViewFragment`, as we need our own layout. While `ListFragment` supports subclasses inflating a layout (so long as the layout has a `ListView` named `@android:id/list`), `WebViewFragment` does not. So, we inherit from the stock `Fragment` class instead and have an `onCreateView()` method that inflates our desired layout:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container, Bundle
savedInstanceState) {
    View result=inflater.inflate(R.layout.details, container, false);

    webView=(WebView)result.findViewById(R.id.webview);
    flag=(ImageView)result.findViewById(R.id.flag);
    toolbar=(Toolbar)result.findViewById(R.id.toolbar);

    if (toolbar==null) {
        setHasOptionsMenu(true);
    }
    else {
        toolbar.inflateMenu(R.menu.webview);
        getNavItems(toolbar.getMenu());
        toolbar.setOnMenuItemClickListener(this);
    }

    return(result);
}
```

Here, we inflate that `details` layout resource and retrieve our three main widgets (`webView`, `flag`, and `toolbar`). However, there are two versions of that layout resource, one for larger screens and one for smaller screens. Only the larger screen has a `Toolbar`; the plan is for smaller screens to use the action bar instead. Hence, `toolbar` may be null.

If `toolbar` is null, we call `setHasOptionsMenu(true)`, to opt into this fragment participating in the action bar. If the `toolbar` is not null, we have it inflate a menu resource via `inflateMenu()`, and we set the fragment itself up to be the listener for click events via `setOnMenuItemClickListener()`.

In between those two steps, we call `getNavItems()`, passing the `Menu` object that the `Toolbar` is using:

```
private void getNavItems(Menu menu) {
    navBack=menu.findItem(R.id.back);
}
```

TOOLBAR

```
navForward=menu.findItem(R.id.fwd);
navReload=menu.findItem(R.id.reload);

updateNav();
}
```

Here, we retrieve our three toolbar items, stashing them as fields in the fragment class. We also call `updateNav()`:

```
private void updateNav() {
    navBack.setEnabled(webView.canGoBack());
    navForward.setEnabled(webView.canGoForward());
    navReload.setEnabled(webView.getUrl()!=null);
}
```

`updateNav()` updates the enabled state for each of those three toolbar items, based upon the state of the `WebView`. If we can navigate back (`canGoBack()` returns `true`), we enable the back toolbar item, and so on. There is no `canReload()` method, so we substitute a check to see if the URL in the `WebView` (via `getUrl()`) is `null`.

Since we called `setOnMenuItemClickListener()` on the `Toolbar`, indicating that the fragment itself is the listener, the fragment needs to implement the `Toolbar.OnMenuItemClickListener` interface. That requires an implementation of a `onMenuItemClick()` method. In our case, as with the previous example, we delegate that to `onOptionsItemSelected()`:

```
@Override
public boolean onMenuItemClick(MenuItem item) {
    return(onOptionsItemSelected(item));
}
```

`onOptionsItemSelected()`, along with `onCreateOptionsMenu()`, will also be used if toolbar was `null` and we called `setHasOptionsMenu(true)` to use the action bar. So, we have a mostly-typical implementation of those methods, where `onOptionsItemSelected()` happens to be used both for the action bar and the `Toolbar` scenarios:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    inflater.inflate(R.menu.webview, menu);
    getNavItems(menu);

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch(item.getItemId()) {
        case R.id.back:
            if (webView.canGoBack()) {
```

TOOLBAR

```
        webView.goBack();
    }
    break;

    case R.id.fwd:
        if (webView.canGoForward()) {
            webView.goForward();
        }
        break;

    case R.id.reload:
        webView.reload();
        break;

    default:
        return(super.onOptionsItemSelected(item));
    }

    return(true);
}
```

Note that in `onCreateOptionsMenu()`, we call `getNavItems()`, passing in the `Menu` supplied to `onCreateOptionsMenu()`. Hence, no matter whether we are using the action bar or a `Toolbar` to host the navigation items, we have those `MenuItem` objects as fields.

The `onOptionsItemSelected()` implementation just calls appropriate methods on `WebView` tied to the particular `MenuItem`, such as `canGoBack()` and `goBack()` if the user taps the “back” `MenuItem`.

This gives us the visual result that we want. However, with the code as shown so far, the toolbar items would not change state as the user browses in the `WebView`. Their enabled states are only set when the fragment is set up. We also need to update those states as the user browses.

To handle this, we attach a `URLHandler` subclass of `WebViewClient` to the `WebView` in the `onViewCreated()` method:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    webView.setWebViewClient(new URLHandler());
}
```

(note: this work could have been done in `onCreateView()`, but some of this code was ported from a sample app that used `WebViewFragment`, where we would not have an `onCreateView()` method)

TOOLBAR

Partly, `URLHandler` is responsible for ensuring that all clicks on links keep the user within the `WebView`, via a `shouldOverrideUrlLoading()` implementation. Partly, `URLHandler` is responsible for calling `updateNav()` when it appears that the navigation state of the `WebView` has changed. Unfortunately, there is no canonical place to update those navigation items, so we hook into three methods and hope for the best: `onPageStarted()`, `onPageFinished()`, and `doUpdateVisitedHistory()`:

```
private class URLHandler extends WebViewClient {
    @Override
    public void onPageStarted(WebView view, String url, Bitmap favicon) {
        super.onPageStarted(view, url, favicon);

        updateNav();
    }

    @Override
    public void onPageFinished(WebView view, String url) {
        super.onPageFinished(view, url);

        updateNav();
    }

    @Override
    public void doUpdateVisitedHistory(WebView view, String url, boolean isReload) {
        super.doUpdateVisitedHistory(view, url, isReload);

        updateNav();
    }
}
```

Now, assuming that those two hooks are sufficient, our back, forward, and reload navigation items will be enabled or disabled as appropriate as the user navigates within our app and the `WebView`.

Use Case #3: Replacement Action Bar

Another thing that you can do with a `Toolbar` is make it serve as your action bar. The net effect is that you can position your activity's action bar wherever you like, rather than have it be anchored at the top of the screen. Also, you can control the `Toolbar` more than you can the original action bar, for things like animations. For example, if you have seen apps where the action bar slides out of the way while you are scrolling down a list, only to return when you scroll back up the list, that could be accomplished via a `Toolbar` as your action bar.

The basic mechanics of making a `Toolbar` serve as the action bar are not especially difficult. Primarily, you need to inherit from `Theme.Material.NoActionBar` (to suppress the regular action bar) and call `setActionBar()` to attach your `Toolbar` to the activity to serve as the activity's action bar. As with all `Toolbar`-specific code,

TOOLBAR

this will only work on API Level 21+, though the `appcompat-v7` backport offers similar capabilities.

The [Toolbar/SplitActionBar2](#) sample project is a clone of the `SplitActionBar` project from earlier in this chapter, except that the `Toolbar` is set up to serve as the activity's action bar.

Our activity's theme (`Theme.Apptheme`) now inherits from `Theme.Material.NoActionBar`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material.NoActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
  <style name="SplitActionBar">
    <item name="android:background">@color/primary</item>
  </style>
</resources>
```

The `build.gradle` file sets the `minSdkVersion` to 21, so we dispense with the backwards-compatibility checks. So, in `onCreate()`, rather than conditionally using `main.xml` as our layout, we always use it, followed by a call to `setSupportActionBar()`:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    setContentView(R.layout.main);
    setSupportActionBar((Toolbar)findViewById(R.id.toolbar));

    initAdapter();
}
```

Our `onCreateOptionsMenu()` can also dispense with the conditional check to see if we are on API Level 21+. However, since we are using the `Toolbar` as our action bar, we can simply populate the action bar normally, and it will affect the `Toolbar`:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}
```

TOOLBAR

The result is that we have a regular action bar, with its normal contents (e.g., title), but positioned where we put the Toolbar, at the bottom of the screen, where it used to serve as the bottom half of the split action bar:

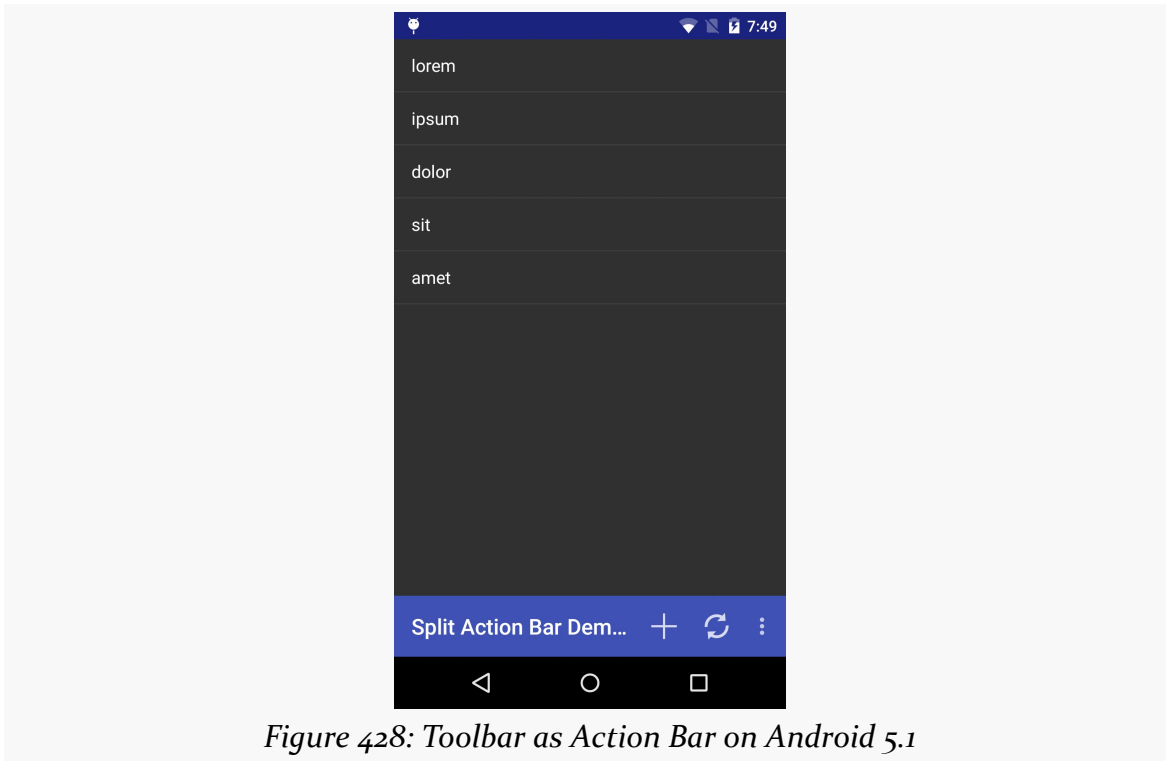

Figure 428: Toolbar as Action Bar on Android 5.1

AppCompat: The Official Action Bar Backport

Approximately 30 months after Google added the action bar to Android 3.0, Google released a backport for previous devices. Referred to here as AppCompat or, `appcompat-v7` (after its library name), this fills much the same niche as does [ActionBarSherlock](#), adding action bar support to Android apps, going all the way back to API Level 7.

The `appcompat-v7` Android Support Package artifact houses AppCompat. Version 21 and higher of this artifact change the way that AppCompat looks, to try to not only backport the action bar, but to backport a bit of the Material Design aesthetic.

This chapter will outline why you might want to use AppCompat and how to employ it in your Android applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Ummmm... Why?

You might wonder why we would bother with any of it. AppCompat is not required, and apps can work fine without it. And, in truth, most apps will be just fine using the native action bar implementation.

That being said, you may find some pressures nudging you towards using an action bar backport, and AppCompatActivity specifically.

Why an Action Bar Backport?

If your `minSdkVersion` is 11 or higher, you have an action bar on all Android versions that your app supports.

If, however, your `minSdkVersion` is below 11, by default you will get the old-style options menu on Android 1.x/2.x devices. That is not a crime. However, the action bar design pattern had been used in various Android apps prior to Android 3.0's formalization of the pattern. Many apps that users will see on older devices will have an action bar, courtesy of one of the backports. By adopting a backport, you will gain a measure of consistency in your UX across Android versions that you would otherwise miss by falling back to the options menu.

You might also adopt a backport because something else is steering you to use AppCompatActivity, and therefore you elect to use it for those reasons.

Why AppCompatActivity?

AppCompatActivity is a somewhat controversial library nowadays. It did not start that way when it was released in the Summer of 2013, other than being the target of “why didn't Google just endorse [ActionBarSherlock](#)?” inquiries. But Google has been rather aggressive about trying to get developers to use AppCompatActivity, and that aggressiveness has had its downsides.

Supported

The #1 reason for using AppCompatActivity is because you decided, for other reasons, that you wanted an action bar backport, and AppCompatActivity right now is the primary supported option. [ActionBarSherlock](#) is officially deprecated by its author (Jake Wharton), who is steering you towards the native action bar or AppCompatActivity as alternatives. While this does not prevent you from using ActionBarSherlock, it is probably not a great choice today given that Google is supporting AppCompatActivity.

Materialistic

The current version of AppCompatActivity does not only give you an action bar. It gives you an action bar that looks like the one that you get from `Theme.Material`. It also will

attempt to apply your accent color to select widgets, the way Android 5.0 and Theme.Material do, to make your app abide a bit more by the Material Design aesthetic.

[Whether or not this is a good thing is up to you.](#)

Consistent

One hidden advantage of using AppCompatActivity, particularly in concert with the fragments backport, is consistency across Android versions. By using the native action bar and fragments, you are at some risk of inconsistent behavior based upon:

- Android OS version, due to bug fixes, deprecations, and the like
- Manufacturer or ROM modder tweaks to the native implementations, which you do not control

Having your action bar and fragments be in a library in your app isolates you from those changes. In particular, while ActionBarSherlock will defer to the native action bar implementation on API Level 14+ devices, AppCompatActivity always uses its own implementation, so any changes in the native implementation will not affect your app.

This comes at a cost of additional complexity and APK size.

Forced

Some things in the Android development ecosystem, like official support for the `MediaRouteActionProvider`, only work with the AppCompatActivity action bar, as Google has either not shipped or has deprecated their native alternatives.

You may find some “cross-ports” of those things that work with the native action bar, but those are unlikely to be as well-supported as Google’s own editions.

Also, new projects created via Android Studio basically shove `appcompat-v7` down your throat. This is why this book’s tutorials have you start by importing an existing project, so you do not have to rip `appcompat-v7` and its references out by the roots to start a new project.

While it is theoretically possible that Google itself will eventually offer native action bar implementations of those things, it is unlikely. Hence, if you determine that you

need one of those, you may be more inclined to use AppCompatActivity, even if you do not need it for any other reason.

The Basics of Using AppCompatActivity

The recipe for using the AppCompatActivity action bar requires no new skills beyond what you have learned so far in this book. However, there are some subtle and not-so-subtle differences in the approaches AppCompatActivity takes when compared to the native action bar, let alone other backports like ActionBarSherlock.

To see the basic differences, we will take a look at the [AppCompatActivity/ActionBar](#) sample project. This is a port of the fragments-and-action-bar sample from [earlier in the book](#), where we have replaced the native action bar with AppCompatActivity.

The Library Project

AppCompatActivity is provided by the appcompat-v7 Android library project, part of the Android Support Package. How you get that depends upon your build environment.

Android Studio and Gradle for Android

Just add the compile 'com.android.support:appcompat-v7:...' line to your dependencies closure, replacing ... with a suitable version number of the library. That will take care of downloading the library and adding it to your project.

To get the material effects described in this chapter, you will want to use version 21 or higher of appcompat-v7 (e.g., com.android.support:appcompat-v7:22.2.0). And, due to a particular name change that we will examine shortly, using version 22 or higher is probably a good idea.

But, more importantly, you *really* want version 23 or higher. There are [changes to ART](#) – the Android runtime used on Android 5.0+ — that apparently will break the older versions of appcompat-v7 when running on Android 6.0+ devices.

Eclipse

Your SDK's copy of the AppCompatActivity library project can be found in your Android SDK installation, inside the extras/android/support/v7/appcompat/ directory.

You will want to import that project into your workspace. Ideally, you should make a copy of the project, so that way when the project gets updated by Google (and you install the update via the SDK Manager), your existing copy is not immediately affected. This will allow you to decide when to upgrade to the new AppCompat version.

Your Build Settings

If you are using version 22 or higher of AppCompat, your build target must be API Level 22 or higher. Basically, for the Android Support libraries, your `compileSdkVersion` should match the major version of the library.

In Android Studio and Gradle for Android, this would be the `compileSdkVersion` found in your `build.gradle` file. In Eclipse, this would be the API level chosen in Project > Properties > Android.

Your Theme

Rather than using `Theme.Holo` or `Theme.Material`, when using AppCompat you will use `Theme.AppCompat`, whether you use that theme directly or create your own custom theme inheriting from it. There is also `Theme.AppCompat.Light` and `Theme.AppCompat.Light.DarkActionBar`, mirroring their native counterparts.

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/Theme.AppCompat">
```

Your Menu Resources

Where things start to get a bit strange with AppCompat comes with our menu resources. AppCompat forces you to use a *different namespace* for any action bar-related attributes, those added in API Level 11 or higher.

So, we started with:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

  <item
    android:id="@+id/add"
    android:icon="@drawable/ic_action_new"
    android:showAsAction="always"
    android:title="@string/add"/>
```

```
<item
  android:id="@+id/reset"
  android:icon="@drawable/ic_action_refresh"
  android:showAsAction="always|withText"
  android:title="@string/reset"/>
</menu>
```

and we had to change it to:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/add"
    android:icon="@drawable/ic_action_new"
    app:showAsAction="always"
    android:title="@string/add"/>
  <item
    android:id="@+id/reset"
    android:icon="@drawable/ic_action_refresh"
    app:showAsAction="always|withText"
    android:title="@string/reset"/>
  <item
    android:id="@+id/about"
    android:icon="@drawable/ic_action_about"
    app:showAsAction="never"
    android:title="@string/about">
  </item>
</menu>
```

Note that we have a new `xmlns:app="http://schemas.android.com/apk/res-auto"` namespace declaration in the root `<menu>` element, and that namespace is used for the `app:showAsAction` attribute. The actual prefix name, here shown as `app`, can be whatever you want. It just has to be unique within the document and a valid XML namespace prefix (e.g., no whitespace).

Your Activity and Fragments

We have to inherit from an `AppCompatActivity` class to use `AppCompat`. `AppCompatActivity` itself inherits from `FragmentActivity`, and so we can use the Android Support Package's backport of fragments without issue, so you have access to backported versions of `Fragment`, `ListFragment`, etc.

NOTE: Prior to version 22 of `appcompat-v7`, you would inherit from an `ActionBarActivity` class. That class is still available for backwards compatibility, but you are recommended to inherit from `AppCompatActivity` instead.

However, note that there are no other analogues of AppCompatActivity for other scenarios, such as ListActivity. In principle, you should be able to make your own mash-ups of AppCompatActivity and other base activity classes, though the proof of this is left as an exercise for the reader. The sample app just uses AppCompatActivity directly for showing a ListView:

```
package com.commonware.android.inflation;

import android.os.Bundle;
import android.support.v7.app.AppCompatActivity;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.ArrayAdapter;
import android.widget.ListAdapter;
import android.widget.ListView;
import android.widget.Toast;
import java.util.ArrayList;

public class ActionBarDemoActivity extends AppCompatActivity {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };
    private ArrayList<String> words=null;
    private ArrayAdapter<String> adapter=null;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        setContentView(R.layout.list_content_simple);
        initAdapter();
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        switch(item.getItemId()) {
            case R.id.add:
                addWord();

                return(true);

            case R.id.reset:
                initAdapter();

                return(true);

            case R.id.about:
                Toast.makeText(this, R.string.about_toast, Toast.LENGTH_LONG)

```

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

```
        .show();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}

private void initAdapter() {
    words=new ArrayList<String>();

    for (int i=0;i<5;i++) {
        words.add(items[i]);
    }

    adapter=
        new ArrayAdapter<String>(this,
                                android.R.layout.simple_list_item_1,
                                words);

    setListAdapter(adapter);
}

private void addWord() {
    if (adapter.getCount()<items.length) {
        adapter.add(items[adapter.getCount()]);
    }
}

private void setListAdapter(ListAdapter la) {
    ((ListView)findViewById(android.R.id.list)).setAdapter(la);
}
}
```

The layout, `res/layout/list_content_simple.xml`, is cloned from the one used by `ListActivity` itself:

```
<?xml version="1.0" encoding="utf-8"?>
<!--

*/
-->
<ListView xmlns:android="http://schemas.android.com/apk/res/android"
android:id="@android:id/list"
```

```
android:layout_width="match_parent"  
android:layout_height="match_parent"  
android:drawSelectorOnTop="false"  
</>
```

Your Callback Methods

In many cases, your `onOptionsItemSelected()` and `onOptionsItemSelected()` methods will be the same for `AppCompatActivity` as they would be for a regular Android app.

However, if you do need to manipulate action bar-specific attributes of your inflated menu resources, you will be unable to do so directly. The workaround is to use `MenuItemCompat` and `MenuCompat`, from the Android Support package, to give you access to newer `MenuItem` and `Menu` features in a backwards-compatible fashion.

Your Results

Visually, the results are very similar to what we get from `Theme.Material`, whether we run on Android 5.0 itself:

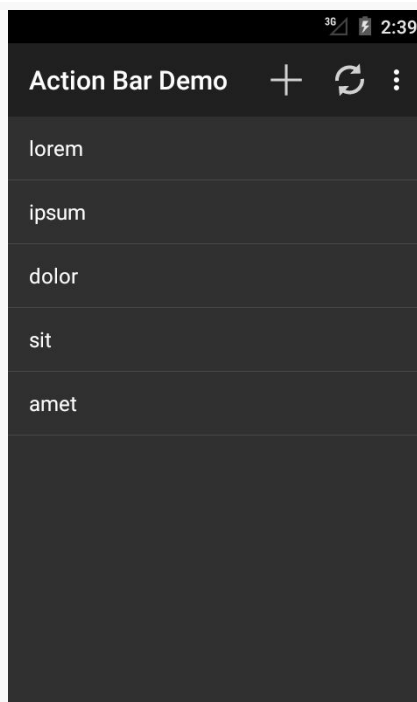

Figure 429: AppCompatActivity, on Android 5.0 Emulator

...or on something older, like an Android 4.1 emulator:

Figure 430: AppCompat, on Android 4.1 Emulator

Other AppCompat Effects

While the above recipe will give you the basics, you can go a lot further with AppCompat, just as you can with the native action bar. Generally speaking, AppCompat's backport includes all of the capabilities of the native action bar.

The biggest key is that when working with `AppCompatActivity`, if you need to access your `ActionBar` instance, call `getSupportActionBar()`, not `getActionBar()`. The latter will compile, but it will return `null` at runtime, as you are disabling the native action bar and using AppCompat's instead.

Tinting

The same basic tinting rules that apply for `Theme.Material` apply for `Theme.AppCompat` and `AppCompatActivity`, with two noteworthy differences.

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

First, the theme attributes do not have the android prefix, but instead are just the bare names (e.g., colorPrimary). So, in the [AppCompat/ActionBarColor](#) sample project, the style resource becomes:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="Theme.AppCompat">
    <item name="colorPrimary">@color/primary</item>
    <item name="colorPrimaryDark">@color/primary_dark</item>
    <item name="colorAccent">@color/accent</item>
  </style>
</resources>
```

Second, not all widgets will have their colors affected by the theme. As of version 22 of appcompat-v7, the roster is limited to:

- AutoCompleteTextView
- Button
- CheckBox
- CheckedTextView
- EditText
- MultiAutoCompleteTextView
- RadioButton
- RatingBar
- Spinner
- TextView

Also, Switch adopts the colors, if you use the SwitchCompat backport discussed in the next section.

In the [AppCompat/Basic](#) directory you will find projects mirroring those from the BasicMaterial directory. In BasicMaterial, we saw how widgets were tinted based on a Theme.Material-based theme; in AppCompat/Basic, you will see how widgets are tinted based upon a Theme.AppCompat-based theme.

Note that AppCompat does not affect the status bar. You can use [the Android 5.0 APIs for changing the status bar color](#) on such devices from an AppCompatActivity. However, you cannot tint the status bar on older devices, despite using AppCompat.

Switch Backport

As mentioned above, there is an official backport of the Switch widget, known as SwitchCompat, added to the appcompat-v7 library. This works back to API Level 7, as

does everything in `appcompat-v7`. And, for better or worse, it provides a backport of the Material Design implementation of a Switch. So, rather than the `Theme.Holo.ON/OFF` toggle, we get the unlabeled “looks like a really tiny SeekBar” widget:

Figure 431: SwitchCompat, on an Android 4.3 Emulator

The above screenshot comes from the [AppCompat/Basic/Switch](#) sample project, which uses a layout specifying the `SwitchCompat` widget:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.SwitchCompat
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/toggle"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content" />
```

Also note that `SwitchCompat` only works inside an `AppCompatActivity`. It is not a general backport of `Switch` that can be used in any activity.

Overlay

`AppCompat` supports the same basic sort of [floating action bar](#) that is supported by the native action bar implementation. There are two slight changes in the recipe:

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

- Use `supportRequestWindowFeature()`, rather than `requestWindowFeature()`, to request `Window.FEATURE_ACTION_BAR_OVERLAY`
- Use `getSupportActionBar()`, rather than `getActionBar()`, to set the background

This is illustrated in `onCreate()` of the `ActionBarDemoActivity` version found in the [AppCompat/Overlay](#) sample project:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    supportRequestWindowFeature(Window.FEATURE_ACTION_BAR_OVERLAY);

    setContentView(R.layout.list_content_simple);

    initAdapter();

    Drawable d=
        getResources().getDrawable(R.drawable.action_bar_background);

    getSupportActionBar().setBackgroundDrawable(d);
    getSupportActionBar().setSplitBackgroundDrawable(d);
}
```

And, you get the same basic results as with the native action bar:

Figure 432: AppCompatActivity with `FEATURE_ACTION_BAR_OVERLAY` on an Android 4.3 Emulator

SearchView

AppCompatActivity has its own implementation of `SearchView`, as `android.support.v7.widget.SearchView`. To use it, switch to that class in your menu resource, then use `MenuItemCompat.getActionView()` to retrieve the instance after your menu resource has been inflated.

For example, the [AppCompatActivity/SearchView](#) sample project uses the AppCompatActivity implementation of `SearchView` in its `res/menu/actions.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<menu
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/search"
    app:actionViewClass="android.support.v7.widget.SearchView"
    android:icon="@drawable/ic_action_search"
    app:showAsAction="ifRoom|collapseActionView"
    android:title="@string/filter">
  </item>
```

```
</menu>
```

Then, in `onCreateOptionsMenu()`, `ActionBarFragment` calls out to a private `configureSearchView()` method that retrieves the `SearchView` and sets it up, much as you saw with the native implementation of `SearchView` from [earlier in this book](#):

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    sv=(SearchView)MenuItemCompat.getActionView(search);
    sv.setOnQueryTextListener(this);
    sv.setOnCloseListener(this);
    sv.setSubmitButtonEnabled(false);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

The resulting `SearchView` is tied into `AppCompatActivity` and offers a Material Design-esque look, applying your tints when opened:

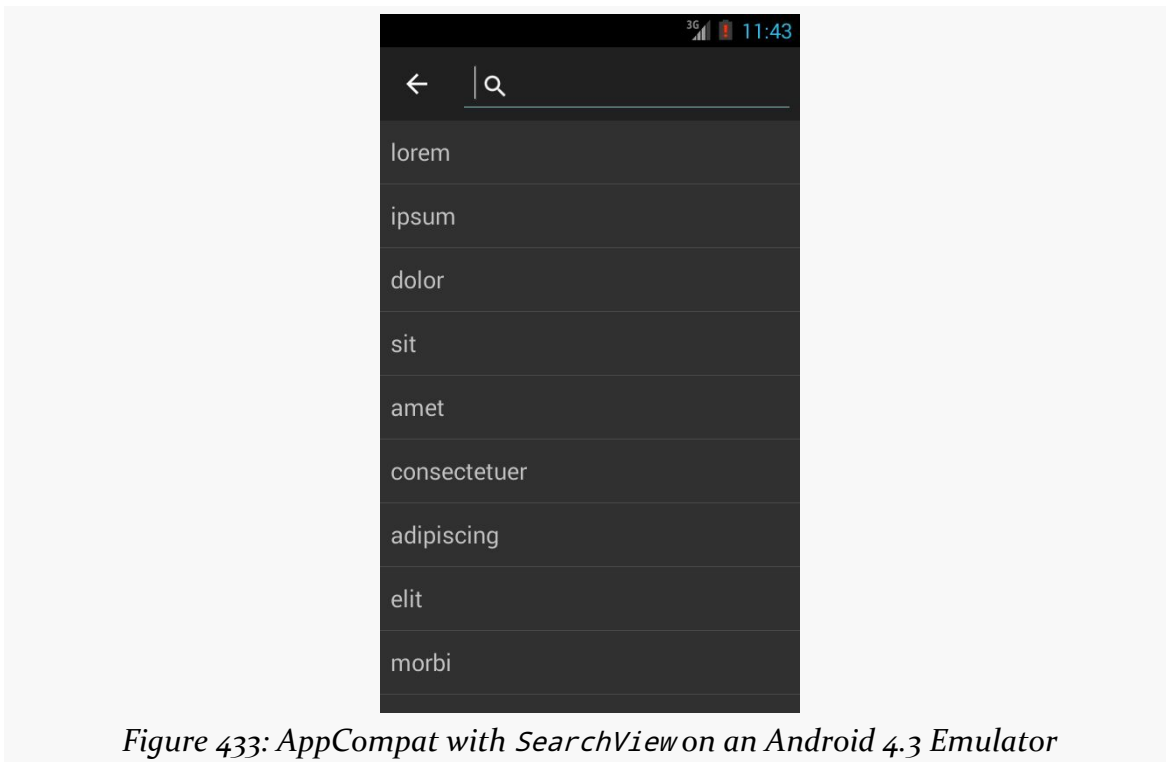

Figure 433: AppCompatActivity with SearchView on an Android 4.3 Emulator

ShareActionProvider

Similarly, AppCompatActivity has its own implementation of ShareActionProvider, as `android.support.v7.widget.ShareActionProvider`. The recipe for using it resembles that of using `SearchView`:

- Refer to the AppCompatActivity edition of the class in your menu resource
- Use `MenuItemCompat.getActionProvider()` to retrieve your `ShareActionProvider` instance after inflating the menu resource, to configure and use it

The [AppCompatActivity/Share](#) sample project is a clone of the `ShareActionProvider` project described [elsewhere in the book](#), converted to use AppCompatActivity and its edition of `ShareActionProvider`.

Toolbar and AppCompatActivity

AppCompatActivity has its own backport of [the Toolbar widget](#). By and large, you use it in much the same way as you use the native `Toolbar`. On the plus side, the backported `Toolbar` works back to API Level 7, allowing you to take advantage of this on much older devices. However, it requires you to be using `AppCompatActivity` — you cannot use the backported `Toolbar` with a regular activity.

The [Toolbar/SplitActionBarCompat](#) sample project is a clone of the `Toolbar/SplitActionBar` sample. That sample uses the native `Toolbar` to replicate [the “split action bar” pattern](#), where there is a second “action bar” at the bottom of the screen, for actions that would not fit in the regular action bar. This clone uses the AppCompatActivity backport of `Toolbar`, and that requires some changes.

First, we now depend upon `appcompat-v7` in the `app/` module’s `build.gradle` file:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'com.android.support:appcompat-v7:22.2.1'
}

android {
    compileSdkVersion 22
    buildToolsVersion "22.0.1"

    defaultConfig {
        minSdkVersion 14
        targetSdkVersion 22
    }
}
```

```
}  
}
```

Our styles and themes change to use `Theme.AppCompat` as a base:

```
<?xml version="1.0" encoding="utf-8"?>  
<resources>  
  
  <style name="Theme.Apptheme" parent="Theme.AppCompat">  
    <item name="colorPrimary">@color/primary</item>  
    <item name="colorPrimaryDark">@color/primary_dark</item>  
    <item name="colorAccent">@color/accent</item>  
  </style>  
  
  <style name="SplitActionBar">  
    <item name="background">@color/primary</item>  
  </style>  
</resources>
```

Note that the `SplitActionBar` style, like `Theme.Apptheme`, drops the `android:` from the name attributes. That is because our `Toolbar` now comes from a library, and so we are no longer using system-defined attributes, but rather library-defined attributes.

The layout resource simply fully-qualifies the class name for the `Toolbar` widget to refer to the one from `AppCompat`:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout  
  xmlns:android="http://schemas.android.com/apk/res/android"  
  android:layout_width="match_parent"  
  android:layout_height="match_parent"  
  android:orientation="vertical">  
  
  <ListView  
    android:id="@android:id/list"  
    android:layout_width="match_parent"  
    android:layout_height="0dp"  
    android:layout_weight="1"/>  
  
  <android.support.v7.widget.Toolbar  
    android:id="@+id/toolbar"  
    style="@style/SplitActionBar"  
    android:layout_width="match_parent"  
    android:layout_height="wrap_content"/>  
</LinearLayout>
```

`ActionBarDemoActivity` now needs to inherit from `AppCompatActivity`, rather than `ListActivity`. That means we no longer have any scenario in which we will get a `ListView` “for free” — we always have to inflate our layout resource:

APPCOMPAT: THE OFFICIAL ACTION BAR BACKPORT

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);
    initAdapter();
}
```

This also means we need our own `setListAdapter()` method, since we are no longer inheriting one:

```
private void setListAdapter(ListAdapter adapter) {
    ListView lv=(ListView)findViewById(R.id.list);

    lv.setAdapter(adapter);
}
```

The only other change is to the `Toolbar` import statement, to pull in the backport:

```
import android.support.v7.widget.Toolbar;
```

The result is visually very similar to what we would have had on Android 5.0+, but it works back to API Level 7:

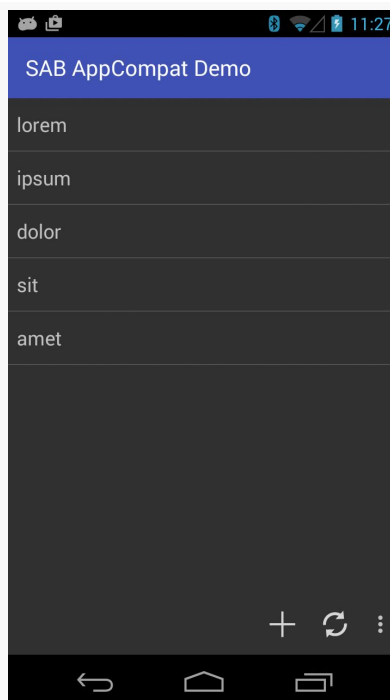

Figure 434: AppCompatActivity Toolbar Backport, as a Split Action Bar

To Material, or Not to Material

(the following is adapted from [one of the author's blog posts](#))

There has been a lot of discussion regarding the adoption of Material Design aesthetics in Android apps. Newcomers to Android might conclude that Material Design must be The Most Important Thing in Android Development and therefore should be pursued immediately at all costs.

[Not everybody shares this opinion](#)

With that in mind, here are the author's recommendations on what to consider with Material Design:

DO start considering the effects of Material Design upon your Android app. Theme.Material is the dominant theme on Android 5.0 devices, and it should remain the dominant theme on future Android versions, at least for a while. There will be hundreds of millions of these devices in use, eventually, and you will want your app to look like "it belongs" on those devices. On those devices, not only will Google's apps be employing Theme.Material, but manufacturer-supplied apps should do so as well. While not everything on the device may necessarily adopt this theme, more than enough will that your app may stand out somewhat if your app does not and the user thinks that it should.

DON'T worry about this right away. Android 4.4 reached 30% of the Android device ecosystem after one year, and we have not seen that rate of adoption since Android 1.0. Odds are that it will be mid-2015 before Android 5.0 crosses the 10% threshold. As such, there just are not that many Android 5.0 devices out there, so worrying about those devices over the next several weeks is serious overkill.

DO plan on including Material Design impacts in your next UI refresh, and you should probably try to budget time for that refresh by the end of 2015 (by which time Android 5.0 might be 20-30% of the ecosystem).

DON'T blindly assume that you should be using a Material-ish look on all versions of Android. Your objective should be having an app that looks like it belongs on the device. Material-themed apps are highly unlikely to achieve majority status, let alone dominance, on pre-Android 5.0 releases. After all, device manufacturers are not going to be shipping Material-themed updates to built-in apps *en masse*, and there are plenty of apps out there that are still using pre-Holo themes. This is all on top of

app that have no identifiable Android theme (e.g., most games). Certainly, there will be Material-themed apps running on Android 4.x devices, courtesy of Google and some other developers. But there will be enough Holo-themed apps that your app will not look out of place on Android 4.x any time soon, if ever. Hence, you have your choice of adopting Material Design across the board or not — user pressure is unlikely to be a major criterion any time soon.

DON'T fall victim to the “our app must look the same across all devices” mindset. Again, your app should look like it belongs on the device, which is why trying to ape an iOS look-and-feel on Android is rarely a good move. Most people do not have two Android devices, and only a small subset of those will have an Android 5.x device and an Android 4.x (or older) device. Hence, most of the people who will care about your app appearing identical on those devices will be in your meeting room discussing the issue. Few of your users will notice — they want an app that works, does what the user wants, and looks like it belongs on their device.

DO consider whether adopting Material Design across the board may offer *engineering* benefits. For example, if you have been heavily customizing widget colors in a Ho1o-based theme, the tinting options provided by `appcompat-v7` may simplify your app a fair bit, reducing APK size, maintenance costs after the Material conversion, etc. Since your users are unlikely to be terribly concerned one way or the other, engineering considerations may help to “tip the scales” in one direction or another.

DON'T blindly assume that `appcompat-v7` will result in a simpler app, or that it should be the basis for all new apps. While the original `appcompat-v7` has now been around for 16 months or so, the new Material `appcompat-v7` is very young, and hence it has bugs. Not all of those bugs are Google's fault (e.g., the Samsung device issue was really caused by a screwy decision on Samsung's part), but that comes as cold comfort to developers trying to distribute `appcompat-v7` apps. And, if you are comfortable with using themes based on `Theme.Ho1o` for pre-Android 5.0 devices, `appcompat-v7` may be much more of an impediment than an advance. `appcompat-v7` is a tool, not a religion — use it where it clearly adds value *to you and your app*.

DO start planning for Google's next major theme overhaul. Google, of course, is portraying Material Design as being The One True UI Design. Google will probably get irritated when people point out that `Theme.Material` is the third major theme in the six-year production history of Android, and so assuming that `Theme.Material` is “the be-all and end-all” of themes is unrealistic. Whether the next-generation theme is a refinement on Material Design or a larger overhaul remains to be seen. But you should be taking into account that we may well wind up going through this same

APPCompat: THE OFFICIAL ACTION BAR BACKPORT

process in, say, early 2018. The more you can isolate the theme-related changes from the rest of your app, the more likely it is that you will be able to accommodate future theme changes with less work.

ActionBarSherlock

As noted in [the chapter on AppCompat](#), there was a ~2.5 year gap where older devices had no official backport of the action bar. Various third-party projects implemented action bars to try to fill this gap, and none did that nearly as well as did [ActionBarSherlock](#).

ActionBarSherlock, in effect, extends the support-v4 library, adding a backported action bar for apps running on devices prior to API Level 14. While native action bars became available with API Level 11, there were enough differences that ActionBarSherlock uses its own implementation from API Level 13 on down to API Level 7 (Android 2.1).

Today, ActionBarSherlock is considered to be deprecated, with Jake Wharton (the author of ActionBarSherlock) steering developers towards the native action bar or AppCompat. That being said, many existing projects still use ActionBarSherlock successfully today.

To use ActionBarSherlock, you need to do a few things, above and beyond what you would ordinarily need to do to use the native action bar implementation. This chapter reviews what is required and how to use this library.

NOTE: This chapter is scheduled to be removed from this book in one of the 2015 updates.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the one on the action bar](#).

Installation

Android Studio users can add a dependency for `com.actionbarsherlock:actionbarsherlock:4.4.0@aar` to their dependencies closure. The `@aar` suffix is to help distinguish the AAR artifact from others for this group ID/artifact ID combination.

Eclipse users will need to download ActionBarSherlock, such as by downloading a ZIP file or by cloning [the project's GitHub repository](#). Inside of the ActionBarSherlock distribution is an `actionbarsherlock/` directory, containing an Android library project that you will need to add to your application's project as described [in a previous chapter](#).

Code Changes

There are some changes to your code needed to use ActionBarSherlock, compared with the code you might use with the native API Level 11+ action bar. These changes are fairly minor in scope, to make it easy for you to move back to the native action bar implementation at some time in the future.

Base Activity Class

You will need to adjust your activities to inherit from `SherlockActivity` or one of its kin (e.g., `SherlockListActivity`). This is mostly a matter of adding the Sherlock prefix and adjusting your imports to refer to the `com.actionbarsherlock.app` package instead of `android.app`.

This, in turn, will require some changes to the code in the activities themselves:

- References to `Menu` and `MenuItem` need to be changed from the `android.view` package to the `com.actionbarsherlock.view` package
- Calls to `getActionBar()` need to be replaced with `getSupportActionBar()`
- Calls to `getMenuInflater()` need to be replaced with `getSupportMenuInflater()`

Similarly, if you are using fragments, they need to inherit from `SherlockFragment` or some other Sherlock-flavored class (e.g., `SherlockListFragment`). This too will require the aforementioned changes to imports and methods. Also, bear in mind that ActionBarSherlock is using the fragments backport from the Android Support package, and so calls to `getFragmentManager()` need to be replaced by calls to

`getSupportFragmentManager()`, references to classes like `FragmentManager` need to be replaced with their Android Support backport equivalents, etc.

Theme

You will also need to apply an `ActionBarSherlock`-flavored theme to your activities, either on a per-activity basis, or for the application as a whole. The Sherlock theme that most closely resembles the default theme is `Theme.Sherlock`.

The [ActionBar/ActionBarDemo](#) sample project applies `Theme.Sherlock` to the whole application, via an `android:theme` attribute on the `<application>` element:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.inflation"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:anyDensity="true"
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="true"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="14"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@style/Theme.Sherlock"
        android:uiOptions="splitActionBarWhenNarrow">
        <activity
            android:name=".ActionBarDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

NOTE: If you use this sample app, or any other one that uses `ActionBarSherlock`, on Eclipse, you will need to update its configuration to point to your own copy of `ActionBarSherlock`'s Android library project.

Menu Resources

Your menu resources for use with ActionBarSherlock are largely identical to their native action bar counterparts. In fact, most menu resources will not need to change at all.

The only significant difference is if you are using `ShareActionProvider`. You will need to use a backport of `ShareActionProvider` supplied by the ActionBarSherlock library, `com.actionbarsherlock.widget.ShareActionProvider`. You will need to reference this class in the menu resource, plus use this class in your Java code when you configure the `ShareActionProvider`. By and large, though, the API exposed by the ActionBarSherlock edition of `ShareActionProvider` is the same as the API exposed by the native `ShareActionProvider`.

RecyclerView

Visually representing collections of items is an important aspect of many mobile apps. The classic Android implementation of this was the `AdapterView` family of widgets: `ListView`, `GridView`, `Spinner`, and so on. However, they had their limitations, particularly with respect to advanced capabilities like animating changes in the list contents.

In 2014, Google released `RecyclerView`, via the Android Support package. Developers can add the `recyclerview-v7` to their projects and use `RecyclerView` as a replacement for most of the `AdapterView` family. `RecyclerView` was written from the ground up to be a more flexible container, with lots of hooks and delegation to allow behaviors to be plugged in.

This had two major impacts:

1. `RecyclerView` is indeed much more powerful than its `AdapterView` counterparts
2. `RecyclerView`, out of the box, is nearly useless, and wiring together enough stuff to even replicate basic `ListView/GridView` functionality takes quite a bit of code

In this chapter, we will review `RecyclerView` from the ground up, starting with basic operation. Many of the `ListView` samples from elsewhere in the book will be replicated here, to see how to pull off the same things with `RecyclerView`. And, we will explore some of the additional capabilities that make `RecyclerView` perhaps worth the effort on high-end Android applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the one on [AdapterView and adapters](#).

One section involves the use of [custom XML drawables](#). Another section demonstrates using content pulled from [the MediaStore ContentProvider](#).

This chapter also covers things like [action modes](#) and other [advanced ListView techniques](#).

AdapterView and its Discontents

AdapterView, and particularly its ListView and GridView subclasses, serve important roles in Android application development. And, for basic scenarios, they work reasonably well.

However, there are issues.

Perhaps the biggest tactical issue is that updating an AdapterView tends to be an all-or-nothing affair. If there is a change to the model data — new rows added, existing rows removed, or data changes that might affect the AdapterView presentation — the only well-supported solution is to call `notifyDataSetChanged()` and have the AdapterView rebuild itself. This is slow and can have impacts on things like choice states. And, if you wanted to get really elaborate about your changes, and use animated effects to show where rows got added or removed, that was halfway to impossible.

Strategically, AdapterView, AbsListView (the immediate parent of ListView and GridView), and ListView are large piles of code that resemble [pasta](#) to many outsiders. There are so many responsibilities piled into these classes that maintainability was a challenge for Google and extensibility was a dream more than a reality.

Enter RecyclerView

RecyclerView is designed to correct those sorts of flaws.

RecyclerView, on its own, does very little other than help manage view recycling (e.g., row recycling of a vertical list). It delegates almost everything else to other classes, such as:

- a layout manager, responsible for organizing the views into various structures (vertical list, grid, staggered grid, etc.)
- an item decorator, responsible for applying effects and light positioning to the views, such as adding divider lines between rows in a vertical list
- an item animator, responsible for animated effects as the model data changes

This is on top of the adapters and view holders that were the hallmarks of conventional AdapterView usage.

Because things like layout managers are handled via abstract classes and replaceable concrete implementations, third-party developers can contribute options for developers to use, just as Google does. [Later in this chapter](#), we will explore some of these contributions.

On the flip side, though, RecyclerView does *much* less “out of the box” than does ListView or GridView. Not everything that is missing is supplied anywhere in the `recyclerview-v7` library, requiring that you either roll a bunch of code yourself or rely upon those third-party libraries to get anything much done.

A Trivial List

Back in the original chapter on [AdapterView and adapters](#), we had the Selection/Dynamic sample app. This app would display a list of 25 Latin words, each with the word’s length and an accompanying icon (different for short and long words):

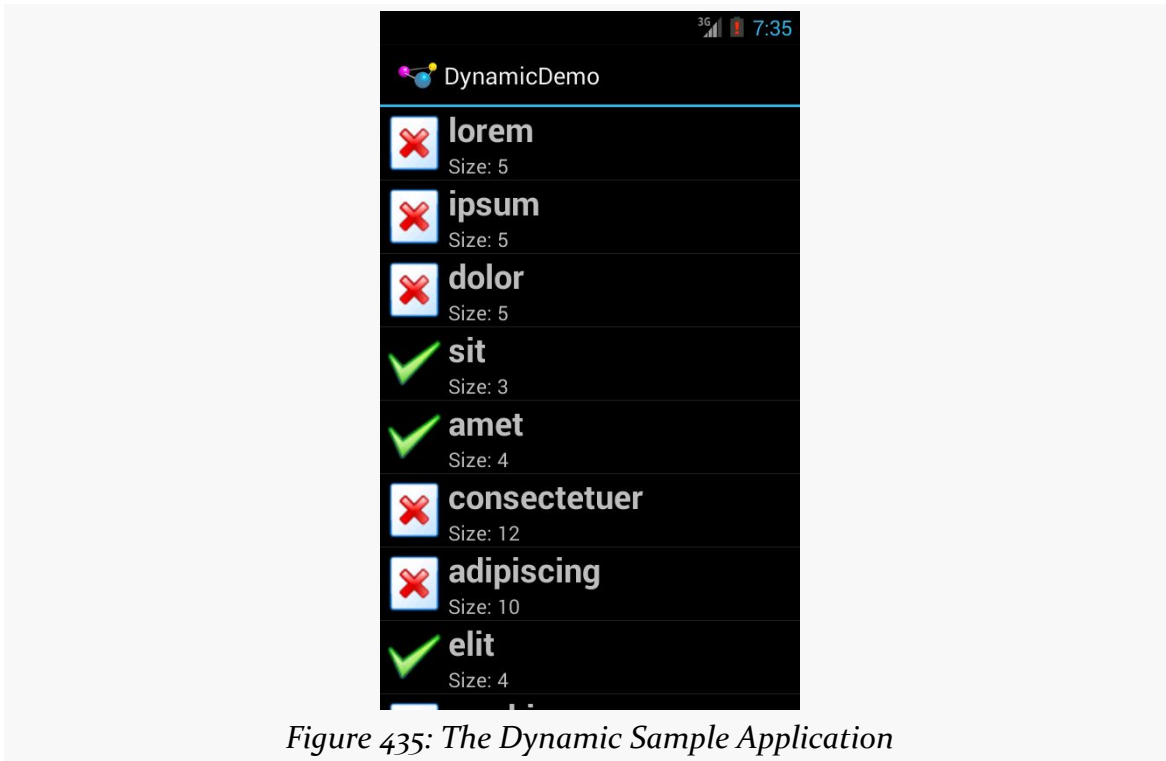

Figure 435: The Dynamic Sample Application

Here, we will review the [RecyclerView/SimpleList](#) sample project, which is a first pass at porting the Selection/Dynamic demo over to use RecyclerView.

The Dependency

Any project that wishes to use RecyclerView needs to have access to the `recyclerview-v7` library from the Android Support package. Android Studio users can simply have a reference to it in the top-level dependencies closure:

However, if you are using `recyclerview-v7`, you want to use version 23 or higher of that library. There are [changes to ART](#) – the Android runtime used on Android 5.0+ — that apparently will break the older versions of `recyclerview-v7` when running on Android 6.0+ devices.

Eclipse users will need to copy the library project from the Android SDK to another location, import that copy into their Eclipse workspace, then add it as a library to whatever app needs RecyclerView. This process is covered [earlier in the book](#).

A RecyclerViewActivity

With `ListView`, we could use `ListActivity`, to isolate some of the `ListView`-management code. There is no `RecyclerViewActivity` in the `recyclerview-v7` library... but we can create one:

```
package com.commonware.android.recyclerview.simplelist;

import android.app.Activity;
import android.support.v7.widget.RecyclerView;

public class RecyclerViewActivity extends Activity {
    private RecyclerView rv=null;

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        return(getRecyclerView().getAdapter());
    }

    public void setLayoutManager(RecyclerView.LayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        if (rv==null) {
            rv=new RecyclerView(this);
            rv.setHasFixedSize(true);
            setContentView(rv);
        }

        return(rv);
    }
}
```

The important part is the `getRecyclerView()` method. Here, if we have not already initialized the `RecyclerView`, we create an instance of it and set it as the activity's content view via `setContentView()`. Along the way, we call `setHasFixedSize(true)` on the `RecyclerView`, to tell it that its size should not be changing based upon the contents of the adapter. This knowledge can help `RecyclerView` operate more efficiently.

The `RecyclerViewActivity` also has `getAdapter()` and `setAdapter()` analogues for their `ListActivity` counterparts. We will explore the differences in the adapter classes [later in this section](#). We also have a `setLayoutManager()` convenience method, that just calls `setLayoutManager()` on the underlying `RecyclerView` — we will see what a layout manager is in the context of `RecyclerView` [in the next section](#).

There are other features of `ListActivity` that are not mirrored here in `RecyclerViewActivity`, just to keep `RecyclerViewActivity` short. Notably, `ListActivity` supports either inflating a custom layout that contains the `ListView` or creating its own. `RecyclerViewActivity` does not support this, though it could with some minor extensions.

The `LayoutManager`

The “real” activity of the project is `MainActivity`, which consists of a single method: `onCreate()`

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(new RecyclerViewLayout(this));
    setAdapter(new IconicAdapter());
}
```

After chaining to the superclass, the first thing we do is call `setLayoutManager()`, which will associate a `RecyclerView.LayoutManager` with our `RecyclerView`. Specifically, we are using a `LinearLayoutManager`.

`ListView` has the notion of a vertically-scrolling list of rows “baked into” its implementation. Similarly, `GridView` has the notion of a two-dimensional vertically-scrolling grid “baked into” its implementation. `RecyclerView`, on the other hand, knows absolutely nothing about how to lay out its children. That work is delegated to a `RecyclerView.LayoutManager`, so that different approaches can be plugged in as needed.

There are three concrete subclasses of the abstract `RecyclerView.LayoutManager` base class that ship with `recyclerview-v7`:

- `LinearLayoutManager`, which implements a vertically-scrolling list, akin to `ListView`
- `GridLayoutManager`, which implements a two-dimensional vertically-scrolling list, akin to `GridView`
- `StaggeredGridLayoutManager`, which implements a “staggered grid”, which has columns of cells like a `GridView`, but where the cells do not have to all have the same size

In addition, it is eminently possible to create your own `RecyclerView.LayoutManager`, or use ones from third-party libraries.

In this example, though, we stick with a simple `LinearLayoutManager`, as we are attempting to replicate the functionality of a `ListView`.

The Adapter

Our `onCreate()` method also calls `setAdapter()`, to associate an `RecyclerView.Adapter` with our `RecyclerView` (specifically, a revised version of our `IconicAdapter` from the original `Selection/Dynamic` sample app). As with the `AdapterView` family, `RecyclerView` uses an adapter to help convert our model data into visual representations. However, the implementation of a `RecyclerView.Adapter` is substantially different from a classic `ListAdapter` for use with `ListView` or `GridView`.

Reminiscent of `ArrayAdapter`, a `RecyclerView.Adapter` uses generics, and we declare what sort of stuff we are adapting. However, `ArrayAdapter` uses the generic to describe the model data. `RecyclerView.Adapter` instead uses the generic to identify a `ViewHolder` that will be responsible for doing the work to actually tie model data to row widgets:

```
class IconicAdapter extends RecyclerView.Adapter<ViewHolder> {
    @Override
    public ViewHolder onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new ViewHolder(getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(ViewHolder holder, int position) {
        holder.bindModel(items[position]);
    }

    @Override
    public int getItemCount() {
        return(items.length);
    }
}
```

In our case, `IconicAdapter` is using a `ViewHolder` class that we will examine in [the next section](#).

A `RecyclerView.Adapter` has three abstract methods that need to be implemented.

One is `getItemCount()`, which fills the same role as does `getCount()` with a `ListAdapter`, indicating how many items there will be in the `RecyclerView`. In the case of `IconicAdapter`, this is based on the length of the `items` static array of

RECYCLERVIEW

String objects, same as it was with IconicAdapter in the Selection/Dynamic sample app:

```
private static final String[] items={"lorem", "ipsum", "dolor",
    "sit", "amet",
    "consectetuer", "adipiscing", "elit", "morbi", "vel",
    "ligula", "vitae", "arcu", "aliquet", "mollis",
    "etiam", "vel", "erat", "placerat", "ante",
    "porttitor", "sodales", "pellentesque", "augue", "purus"};
```

The other two methods are `onCreateViewHolder()` and `onBindViewHolder()`. These are a bit reminiscent of the `newView()` and `BindView()` methods that are used by a `CursorAdapter`. However, rather than working directly with views, `onCreateViewHolder()` and `onBindViewHolder()` work with `ViewHolder` objects, as a formalization of the view holder pattern seen originally in [the chapter on selection widgets](#).

`onCreateViewHolder()`, as the name suggests, needs to create, configure, and return a `ViewHolder` for a particular row of our list. It is passed two parameters:

- a `ViewGroup` that will hold the views managed by the holder, mostly for use with layout inflation, and
- an `int` that is the particular view type we are using, for cases where we have [multiple view types](#)

The `IconicAdapter` implementation inflates our row view (`R.layout.row`) and passes it to the `RowHolder` constructor, returning the resulting `RowHolder`.

`onBindViewHolder()` is responsible for updating a `ViewHolder` based upon the model data for a certain position. `IconicAdapter` handles this by passing the model into a private `bindModel()` method implemented on `RowHolder`.

There are many other methods you could override on `RecyclerView.Adapter`, and we will see a few of those later in this chapter. But, for a simple list, these three will suffice.

The ViewHolder

The `RecyclerView.ViewHolder` is responsible for binding data as needed from our model into the widgets for a row in our list:

```
static class RowHolder extends RecyclerView.ViewHolder {
    TextView label=null;
    TextView size=null;
```

RECYCLERVIEW

```
ImageView icon=null;
String template=null;

ViewHolder(View row) {
    super(row);

    label=(TextView)row.findViewById(R.id.label);
    size=(TextView)row.findViewById(R.id.size);
    icon=(ImageView)row.findViewById(R.id.icon);

    template=size.getContext().getString(R.string.size_template);
}

void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }
}
}
```

However, other than needing to use the base class of `RecyclerView.ViewHolder`, there is no other particular protocol that is mandated between the adapter and the view holder. You can invent your own API. Here, we use the `ViewHolder` constructor to pass in the row `View`, where the constructor retrieves the individual widgets and sets up our string resource template. Then, a private `bindModel()` method takes our model object (a `String`) and binds it to the row's widgets, applying our business rules along the way.

The Results

As the project name suggests, this gives us a simple list:

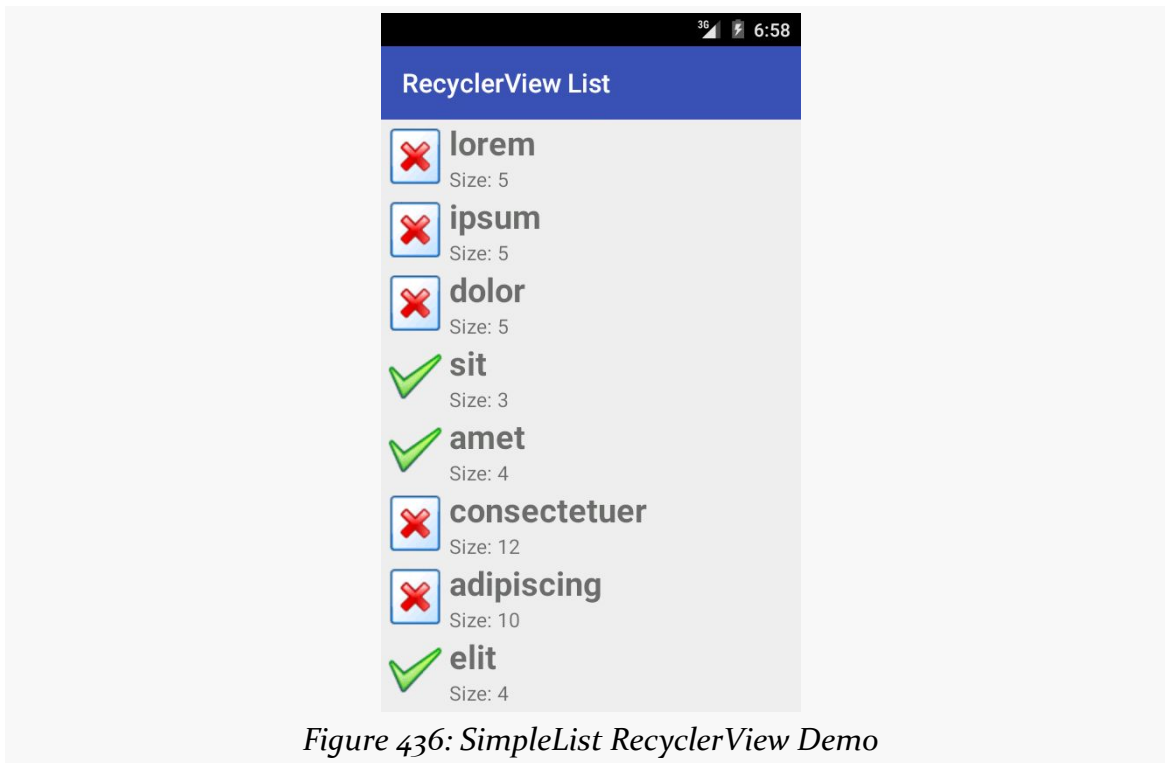

Figure 436: SimpleList RecyclerView Demo

As with `ListView`, `RecyclerView` (along with the `RecyclerView.LayoutManager`) handles the vertical scrolling through our available rows.

What's Missing?

However, we are lacking two things that we had in the Selection/Dynamic edition of this sample that used a `ListView`.

First, there are no dividers between the rows. That may not be a huge issue for this particular row layout, but other layouts may need more assistance in visually separating one row from the next. We will explore ways of accomplishing this [in the next section](#).

Second, we are missing click events. The user can tap on rows as much as she wants. Not only will the user not get any visual feedback from those taps, but we have no `setOnClickListener()` to find out about those taps. We will explore how to fill in this gap [later in the chapter](#).

`RecyclerView` also lacks a variety of other things that we could get from a `ListView`, that we happen to not be using in this sample, such as:

- choice modes, for checklists and such
- header and footer views
- any concept of a “selected” row
- filter support
- and so on

We will explore some of those and how to address them in this chapter.

Divider Options

There are two main approaches for visually separating items in a `RecyclerView`:

1. Ensure that this is handled via the layout itself, such as using a `CardView`
2. Use a `RecyclerView.ItemDecorator` to apply a common divider between items

Both of these techniques will be covered in this chapter.

CardView

Cards are a popular visual metaphor in mobile development. Dividing content collections (or aspects of a larger piece of content) into cards makes it clearer how you can reorganize that content to fit various screen sizes and orientations. In some cases, you might have a single column of cards, while in other cases, you have cards arranged more laterally.

In 2014, Google released `cardview-v7`, another library in the Android Support package, that offers a `CardView`. `CardView` is a simple subclass of `FrameLayout`, designed to provide a card UI, consisting of a rounded rectangle and a drop shadow. In particular, `CardView` will use Android 5.0’s default drop shadows based on widget elevation, while offering emulated drop shadows on earlier Android releases. This way, you can get a reasonably consistent look going back to API Level 7.

To use this, you will have to add the `cardview-v7` library to your app project. Android Studio users can just add a dependency on the `cardview-v7` artifact in the Android Support repository, as seen in the [RecyclerView/CardViewList](#) sample project:

```
dependencies {  
    compile 'com.android.support:recyclerview-v7:22.2.0'
```

RECYCLERVIEW

```
    compile 'com.android.support:cardview-v7:22.2.0'  
}
```

Eclipse users would have to use the same approach used to attach `recyclerview-v7` to their project, repeated for `cardview-v7`.

Then, you can wrap your row layout in a `CardView` (or, more accurately, in an `android.support.v7.widget.CardView`):

```
<?xml version="1.0" encoding="utf-8"?>  
<android.support.v7.widget.CardView  
    xmlns:android="http://schemas.android.com/apk/res/android"  
    xmlns:cardview="http://schemas.android.com/apk/res-auto"  
    android:layout_width="match_parent"  
    android:layout_height="wrap_content"  
    android:layout_margin="4dp"  
    cardview:cardCornerRadius="4dp">  
  
    <LinearLayout  
        android:layout_width="match_parent"  
        android:layout_height="wrap_content"  
        android:orientation="horizontal">  
  
        <ImageView  
            android:id="@+id/icon"  
            android:layout_width="wrap_content"  
            android:layout_height="wrap_content"  
            android:layout_gravity="center_vertical"  
            android:padding="2dip"  
            android:src="@drawable/ok"  
            android:contentDescription="@string/icon"/>  
  
        <LinearLayout  
            android:layout_width="match_parent"  
            android:layout_height="wrap_content"  
            android:orientation="vertical">  
  
            <TextView  
                android:id="@+id/label"  
                android:layout_width="wrap_content"  
                android:layout_height="wrap_content"  
                android:textSize="25sp"  
                android:textStyle="bold"/>  
  
            <TextView  
                android:id="@+id/size"  
                android:layout_width="wrap_content"  
                android:layout_height="wrap_content"  
                android:textSize="15sp"/>  
        </LinearLayout>  
    </LinearLayout>  
</android.support.v7.widget.CardView>
```

With no other code changes from the original RecyclerView/SimpleList sample, we get this:

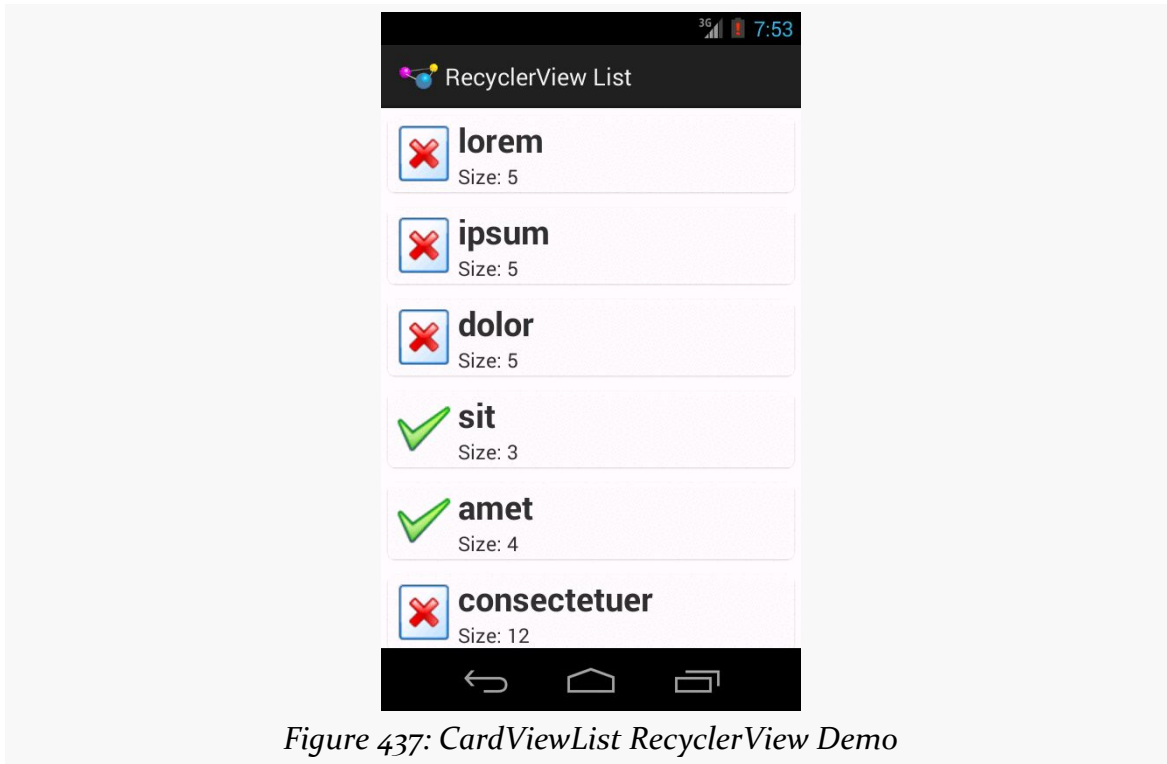

Figure 437: CardViewList RecyclerView Demo

Note that drop shadows from CardView may not show up on Android 5.0+ emulators, particularly if you have Host GPU mode disabled in the emulator AVD. The CardView itself will work fine, just without the drop shadow effect.

Manual

A CardView may not be an appropriate visual approach for your list. Perhaps you want a regular divider, like we had with ListView. While that is possible, it is not especially straightforward.

RecyclerView considers things like dividers to be “item decorations”. There is a `RecyclerView.ItemDecoration` abstract class that you can extend to handle item decoration, and you can attach such a decoration to a RecyclerView via `addItemDecoration()`. As the name suggests, you can have more than one decorator if needed.

RECYCLERVIEW

However, Google did not bother to provide any concrete implementation of such a decoration.

A few enterprising developers experimented with this, leading to solutions like [this one, published as a GitHub gist](#). The [RecyclerView/ManualDividerList](#) sample project demonstrates the use of such a decoration.

First, we will need a drawable resource for the divider itself:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">

    <size
        android:width="1dp"
        android:height="1dp" />

    <solid android:color="@color/divider" />
</shape>
```

This is a ShapeDrawable, as is covered in [the chapter on drawables](#). The big thing is the solid fill, here pointing to a color resource for the color to use for that fill:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <color name="divider">#ffaafaaa</color>
</resources>
```

The ShapeDrawable is given a size of 1dp square. In reality, it will be resized on the fly by the decorator to fill the width of the RecyclerView.

Note that there is nothing especially magic about using this particular drawable. You could have a gradient fill to have the divider taper off towards the ends and be solid in the middle. Or, you could use a nine-patch PNG file, a VectorDrawable on Android 5.0+, or anything else that will resize well.

Next, we need a RecyclerView.ItemDecoration implementation, such as the sample project's HorizontalDividerItemDecoration:

```
package com.commonware.android.recyclerview.manualdivider;

import android.graphics.Canvas;
import android.graphics.drawable.Drawable;
import android.support.v7.widget.RecyclerView;
import android.view.View;

// inspired by https://gist.github.com/polbins/e37206fbc444207c0e92
```

RECYCLERVIEW

```
public class HorizontalDividerItemDecoration extends RecyclerView.ItemDecoration {
    private Drawable divider;

    public HorizontalDividerItemDecoration(Drawable divider) {
        this.divider=divider.mutate();
    }

    @Override
    public void onDrawOver(Canvas c, RecyclerView parent, RecyclerView.State state) {
        int left=parent.getPaddingLeft();
        int right=parent.getWidth()-parent.getPaddingRight();

        int childCount=parent.getChildCount();

        for (int i=0; i<childCount-1; i++) {
            View child=parent.getChildAt(i);
            RecyclerView.LayoutParams params=
                (RecyclerView.LayoutParams)child.getLayoutParams();

            int top=child.getBottom()+params.bottomMargin;
            int bottom=top+divider.getIntrinsicHeight();

            divider.setBounds(left, top, right, bottom);
            divider.draw(c);
        }
    }
}
```

This class takes the Drawable that is the divider as input, so it can be used for different dividers as needed. HorizontalDividerItemDecoration calls mutate() on the Drawable to get a Drawable that can be changed independently of any original instance of the Drawable. This is important when using Drawable resources, as the Drawable instances get reused for other references to the same resource, so changing the core Drawable itself (e.g., via a setBounds() call) is unsafe.

The main logic of HorizontalDividerItemDecoration resides in the onDrawOver() method. This will be called to let us draw over top of the items in the RecyclerView. Here we:

- Determine the left and right extents to draw, relative to the left and right edges of the RecyclerView, but subtracting the padding, so that we only draw inside of that padding
- Iterate over the child views of the RecyclerView, find the vertical location for that divider, resize the divider to fit the desired space, and then draw the divider on the supplied Canvas, skipping the last child so we do not draw a divider at the bottom of the list

RECYCLERVIEW

Using that bit of magic, then, is merely a matter of attaching our `HorizontalDividerItemDecoration` to our `RecyclerView`, done here in `onCreate()` of `MainActivity`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(new LinearLayoutManager(this));

    Drawable divider=getResources().getDrawable(R.drawable.item_divider);

    getRecyclerView().addItemDecoration(new HorizontalDividerItemDecoration(divider));
    setAdapter(new IconicAdapter());
}
```

The rest of the sample project is a clone of the original `SimpleList` sample project from the beginning of this chapter.

The result is that we have a divider drawn between the children:

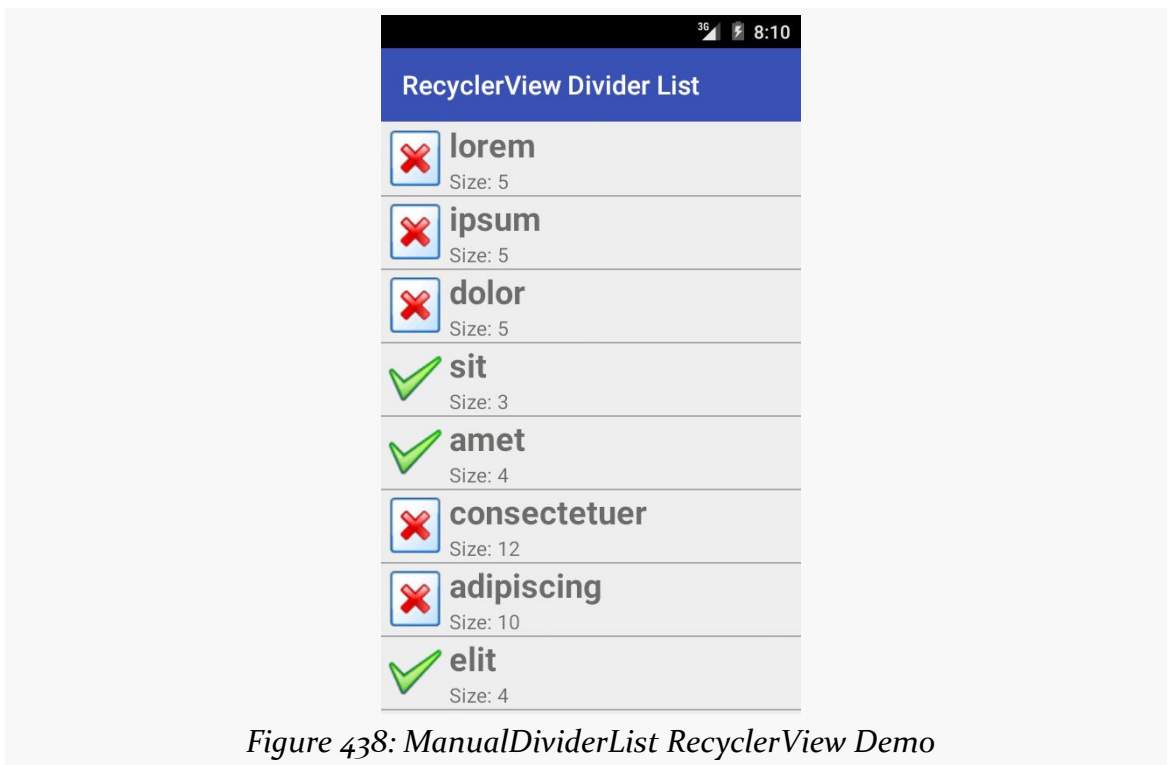

Figure 438: `ManualDividerList` `RecyclerView` Demo

If the idea of having to do all of this yourself irritates you, there are third-party libraries that offer item decorations that you can use “out of the box”. We will examine one such library [later in this chapter](#).

Handling Click Events

However, having nice dividers does not address the larger problem: responding to input.

The RecyclerView vision, overall, is that RecyclerView itself has nothing much to do with input, other than scrolling. Anything having to do with users clicking things and triggering some sort of response is the responsibility of the views inside the RecyclerView, such as the rows in a list-style RecyclerView.

This has its benefits. Clickable widgets, like a RatingBar, in a ListView row had long been in conflict with click events on rows themselves. Getting rows that can be clicked, with row contents that can also be clicked, gets a bit tricky at times. With RecyclerView, you are in more explicit control over how this sort of thing gets handled... because you are the one setting up all of the on-click handling logic.

Of course, that does not help the users much. Users do not care what bit of code is responsible for input. Users simply want to provide the input. If you present them with a vertically-scrolling list-style UI, they will attempt to click on rows in the list and will expect some sort of outcome.

The RecyclerView approach, though, means that you are largely on your own for handling that input. This requires yet more code that, in an ideal world, would be offered as an “out of the box” option by RecyclerView.

Responding to Clicks

At its core, responding to clicks is a matter of setting an OnClickListener on the appropriate Views.

So, for example, the [RecyclerView/CardClickList](#) sample project is a clone of the CardViewList sample, where we call `setOnClickListener()` on the row View in the RecyclerView.ViewHolder, now renamed RowController:

```
package com.commonware.android.recyclerview.cardclicklist;
import android.support.v7.widget.RecyclerView;
```

RECYCLERVIEW

```
import android.view.View;
import android.widget.ImageView;
import android.widget.TextView;
import android.widget.Toast;

class RowController extends RecyclerView.ViewHolder
    implements View.OnClickListener {
    TextView label=null;
    TextView size=null;
    ImageView icon=null;
    String template=null;

    RowController(View row) {
        super(row);

        label=(TextView)row.findViewById(R.id.label);
        size=(TextView)row.findViewById(R.id.size);
        icon=(ImageView)row.findViewById(R.id.icon);

        template=size.getContext().getString(R.string.size_template);

        row.setOnClickListener(this);
    }

    @Override
    public void onClick(View v) {
        Toast.makeText(v.getContext(),
            String.format("Clicked on position %d", getAdapterPosition()),
            Toast.LENGTH_SHORT).show();
    }

    void bindModel(String item) {
        label.setText(item);
        size.setText(String.format(template, item.length()));

        if (item.length()>4) {
            icon.setImageResource(R.drawable.delete);
        }
        else {
            icon.setImageResource(R.drawable.ok);
        }
    }
}
```

In this sample, all the `onClick()` method does is show a Toast. However, you could:

- Raise an event on an event bus, or
- Call a method on some supplied interface (e.g., passed into the `RowController` constructor) to delegate the event to a higher-order controller, or
- Whatever else might be needed

In this case, since none of the widgets in the row are interactive and might consume click events themselves, the user can tap anywhere on the row, and the Toast will

appear. If you have more complex scenarios — such as a checklist where you have a `CheckBox` in the rows — you can decide for yourself how to handle click events on different parts of the row. We will see checklists in action [later in this chapter](#).

Visual Impact of Clicks

However, if you run the `CardClickList` sample, you will notice one major remaining flaw: there is no visual feedback to the user about the click event. Yes, the `Toast` appears, but users are used to seeing some sort of transient state change in the row itself on a click, such as a flash of color. Once again, we have the ability to control this as we see fit... by having the responsibility to make it happen at all.

There are a few approaches to this problem, such as the ones outlined in this section.

Option #1: Translucent Selector on Top

An approach that Mark Allison suggested in [his Styling Android blog](#) mimics the `drawSelectorOnTop` approach available to `ListView`. Using something like a `FrameLayout`, you layer a translucent selector atop the rows, where the selector implements the click feedback.

The [RecyclerView/CardRippleList](#) sample project is a clone of `CardClickList` that takes Mr. Allison's approach. The revised `row.xml` takes advantage of the fact that `CardView` is a subclass of `FrameLayout`, so it layers a plain `View` atop the `LinearLayout` that is the core content of the row:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"/>
```

RECYCLERVIEW

```
        android:src="@drawable/ok"
        android:contentDescription="@string/icon"/>

<LinearLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/size"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"/>
</LinearLayout>

</LinearLayout>

<View
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="?android:attr/selectableItemBackground" />

</android.support.v7.widget.CardView>
```

The background of that View is the `selectableItemBackground` from the current theme. On apps using `Theme`, this will give you an orange flash. On apps using `Theme.Holo`, this will give you a blue flash. On apps using `Theme.Material`, this will give you a ripple animation. And, of course, you can supply your own override value for `selectableItemBackground` to use your own `StateListDrawable` instead.

The downside of this approach is that the View is higher on the Z axis than is the rest of the row content. In this case, since the rest of the row content is non-interactive, this is not a problem. However, if we elect to put interactive widgets in the rows — such as `CheckBox` widgets to implement a checklist — now our View will prevent the user from interacting with those widgets.

Option #2: Background Selector

Another approach would be to apply the `selectableItemBackground` to our existing row content, rather than to some separate selector widget that overlays the row content. This is the approach taken in the [RecyclerView/CardRippleList2](#) sample project. Here, the `selectableItemBackground` is applied to the `LinearLayout` inside of the `CardView`:

RECYCLERVIEW

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal"
        android:background="?android:attr/selectableItemBackground">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"
            android:src="@drawable/ok"
            android:contentDescription="@string/icon"/>

        <LinearLayout
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:orientation="vertical">

            <TextView
                android:id="@+id/label"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="25sp"
                android:textStyle="bold"/>

            <TextView
                android:id="@+id/size"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="15sp"/>
        </LinearLayout>
    </LinearLayout>
</android.support.v7.widget.CardView>
```

For non-interactive widgets, like our TextViews and ImageView, touch events will get propagated to the LinearLayout, which will trigger the changes in the state of the StateListDrawable that is the LinearLayout background. Yet, if we change the rows to have interactive widgets, those widgets will still be able to process their own touch events, as we will see [later in this chapter](#).

However, particularly for this sample app, the visual effect is largely the same as with `CardRippleList`: the user will get click feedback based upon the `selectableItemBackground` in use given the activity's theme.

Option #3: Controlled Ripple Emanation Point

There is one problem with both click event implementations, though: the ripples on Android 5.0+ start in the center of each row.

According to the Material Design rules, the ripples should start where the touch event occurs, so they seem to flow outward from the finger.

To do this, you need to use the `setHotspot()` method, added to `Drawable` in API Level 21. `setHotspot()` provides to the drawable a "hot spot", and `RippleDrawable` apparently uses this as the emanation point for the ripple effect. `setHotspot()` takes a pair of float values, presumably with an eye towards using `setHotspot()` inside of an `OnTouchListener`, as the `MotionEvent` reports X/Y positions of the touch event with float values.

The [RecyclerView/CardRippleList3](#) sample project is a clone of `CardRipple2` that adds this feature.

The row layout is the same as before. However, in `RowController`, when setting up the row, we register an `OnTouchListener`, to find out the low-level `MotionEvent` of when the user touches our row:

```
RowController(View row) {
    super(row);

    label=(TextView)row.findViewById(R.id.label);
    size=(TextView)row.findViewById(R.id.size);
    icon=(ImageView)row.findViewById(R.id.icon);

    template=size.getContext().getString(R.string.size_template);

    row.setOnClickListener(this);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
        row.setOnTouchListener(new View.OnTouchListener() {
            @TargetApi(Build.VERSION_CODES.LOLLIPOP)
            @Override
            public boolean onTouch(View v, MotionEvent event) {
                v
                .findViewById(R.id.row_content)
                .getBackground()
                .setHotspot(event.getX(), event.getY());

                return false;
            }
        });
    }
}
```

```
    }  
    });  
  }  
}
```

We only bother registering this listener on API Level 21+, as there is no `setHotspot()` method on prior versions of Android and therefore no need for the listener. However, *if* we are on an Android 5.0+ device, we intercept the touch event, pass it along to `setHotspot()` on the background `Drawable`, and return `false` to ensure that regular touch event processing proceeds.

The effect is subtle and may be difficult for you to discern. But, if you look at the touch events in slow motion (e.g., screen record a session, then examine the resulting video frame-by-frame), you will see that the ripple effect appears to emanate from the touch point, rather than from the row's center as before. And, since this logic is only used on API Level 21+, older devices are unaffected.

What About Cursors?

So far, our model data has been a simple static array. Often times, though, we need to be working with model data culled from a database or `ContentProvider`. It may be that, for other reasons, we want to convert the `Cursor` we get back from queries into an array of ordinary Java objects. However, there is nothing stopping us from using a `Cursor` more directly as the model for a `RecyclerView`.

The `RecyclerView.Adapter` is responsible for teaching the `RecyclerView.ViewHolder` the model data to bind against. The `RecyclerView.Adapter` base class is oblivious to how that model data is organized: array, `ArrayList`, `Cursor`, `JSONArray`, etc. And the actual bind-the-data logic for the `RecyclerView.ViewHolder` is our responsibility — again, the base class is oblivious to where the data is coming from. Hence, we can create our own protocol for passing the model data for the needed position from the `RecyclerView.Adapter` to the `RecyclerView.ViewHolder`. If we want to use a `Cursor` as the vehicle for doing this, we are welcome to do so.

This is illustrated in the [RecyclerView/VideoList](#) sample project, which is a clone of the `VideoList` project introduced in [the chapter on the MediaStore ContentProvider](#). In the original sample, the list was a `ListView`; in this sample, the list is a `RecyclerView`.

RECYCLERVIEW

The core “plumbing” of the app is akin to the previous RecyclerView samples, such as using RecyclerViewActivity for handling getting the RecyclerView on the screen. However, our row layout is now based on the original VideoList row:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="64dp"
        android:layout_height="64dp"
        android:contentDescription="@string/thumbnail"/>

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>

</LinearLayout>
```

Similarly, onCreate() of MainActivity now handles the Universal Image Loader (UIL) setup (ImageLoader) and kicking off a loader of videos from the MediaStore (initLoader()). In addition, onCreate() specifies a LinearLayoutManager for a vertically-scrolling list-style RecyclerView, and indicates that the contents will come from a VideoAdapter:

```
public class MainActivity extends RecyclerViewActivity implements
    LoaderManager.LoaderCallbacks<Cursor> {
    private ImageLoader imageLoader;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        ImageLoaderConfiguration ilConfig=
            new ImageLoaderConfiguration.Builder(this).build();

        imageLoader=ImageLoader.getInstance();
        imageLoader.init(ilConfig);

        getLoaderManager().initLoader(0, null, this);

        setLayoutManager(new LinearLayoutManager(this));
        setAdapter(new VideoAdapter());
    }
}
```

RECYCLERVIEW

The CursorLoader logic, for getting details about videos from the MediaStore, is pretty much the same as before, other than providing the Cursor to the VideoAdapter when it is ready:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(this,
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}

@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    ((VideoAdapter)getAdapter()).setVideos(c);
}

@Override
public void onLoaderReset(Loader<Cursor> loader) {
    ((VideoAdapter)getAdapter()).setVideos(null);
}
```

VideoAdapter is another subclass of RecyclerView.Adapter, this time with smarts for dealing with a Cursor as the source of model data:

```
class VideoAdapter extends RecyclerView.Adapter<RowController> {
    Cursor videos=null;

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(getLayoutInflater()
            .inflate(R.layout.row, parent, false),
            imageLoader));
    }

    void setVideos(Cursor videos) {
        this.videos=videos;
        notifyDataSetChanged();
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        videos.moveToPosition(position);
        holder.bindModel(videos);
    }

    @Override
    public int getItemCount() {
        if (videos==null) {
            return(0);
        }

        return(videos.getCount());
    }
}
```

RECYCLERVIEW

Specifically:

- `getItemCount()` returns the count of videos from the Cursor, or 0 if the Cursor is null (mimicking the behavior of CursorAdapter, which also treats a null Cursor as merely being one that has no rows)
- `onCreateViewHolder()` passes the ImageLoader to the RowController, so that all rows share a common ImageLoader instance
- `onBindViewHolder()` moves the Cursor to the desired position, then passes the Cursor over to the RowController

Also note that we have a `setVideos()` method that is used to associate our Cursor of video information with the adapter. This also triggers a call to `notifyDataSetChanged()`, to ensure that the RecyclerView knows that our model has changed and it should re-render its contents.

The RowController constructor stashes that ImageLoader in a data member (`imageLoader`), in addition to retrieving the necessary widgets from the row and setting up an OnClickListener:

```
RowController(View row, ImageLoader imageLoader) {
    super(row);
    this.imageLoader=imageLoader;

    title=(TextView)row.findViewById(android.R.id.text1);
    thumbnail=(ImageView)row.findViewById(R.id.thumbnail);

    row.setOnClickListener(this);
}
```

The `bindModel()` method invoked by `onBindViewHolder()` on VideoAdapter uses the same basic logic from the original VideoList sample to populate the row widgets, plus holds onto the Uri and MIME type of the video in data members for the current row:

```
void bindModel(Cursor row) {
    title.setText(row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    Uri video=
        ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
    DisplayImageOptions opts=new DisplayImageOptions.Builder()
        .showImageOnLoading(R.drawable.ic_media_video_poster)
        .build();

    imageLoader.displayImage(video.toString(), thumbnail, opts);

    int uriColumn=row.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
```

RECYCLERVIEW

```
videoUri=row.getString(uriColumn);
videoMimeType=row.getString(mimeTypeColumn);
}
```

The `onClick()` method uses those saved `Uri` and `MIME` type values for starting up the activity to play the selected video:

```
@Override
public void onClick(View v) {
    Uri video=Uri.fromFile(new File(videoUri));
    Intent i=new Intent(Intent.ACTION_VIEW);

    i.setDataAndType(video, videoMimeType);
    title.getContext().startActivity(i);
}
```

Other than the lack of dividers, the UI is very similar to the original `VideoList`.

Grids

So far, we have focused on one visual representation of our collection of model data: a vertically-scrolling list. In the `AdapterView` family, a given `AdapterView` subclass has a specific visual representation (`ListView` for a vertically-scrolling list, `GridView` for a two-dimensional grid, etc.). With `RecyclerView`, the choice of layout manager determines most of the visual representation, and so switching from a list to a grid can be as simple as a single-line change to our code.

The key, though, is the word *can* in the previous sentence. Depending upon what you want to do, a grid-styled `RecyclerView` can be more complicated, simply because you now have two dimensions' worth of power and configuration to play with.

A Simple Grid

Making a `RecyclerView` use a grid is a matter of swapping out `LinearLayoutManager` for `GridLayoutManager`. In the [RecyclerView/Grid](#) sample project, you will see a clone of the `CardRippleList3` sample app, where we are now using `GridLayoutManager` in `onCreate()` of `MainActivity`:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    setLayoutManager(new GridLayoutManager(this, 2));
}
```

RECYCLERVIEW

```
setAdapter(new IconicAdapter());  
}
```

GridLayoutManager takes a number of “spans”, as well as a Context, as constructor parameters. In the simple case, as is with this app, “spans” will equate to “columns”: each item returned by the RecyclerView.Adapter will go into a single-row, single-span cell.

In our case, we requested two spans, and so our result resides in two columns:

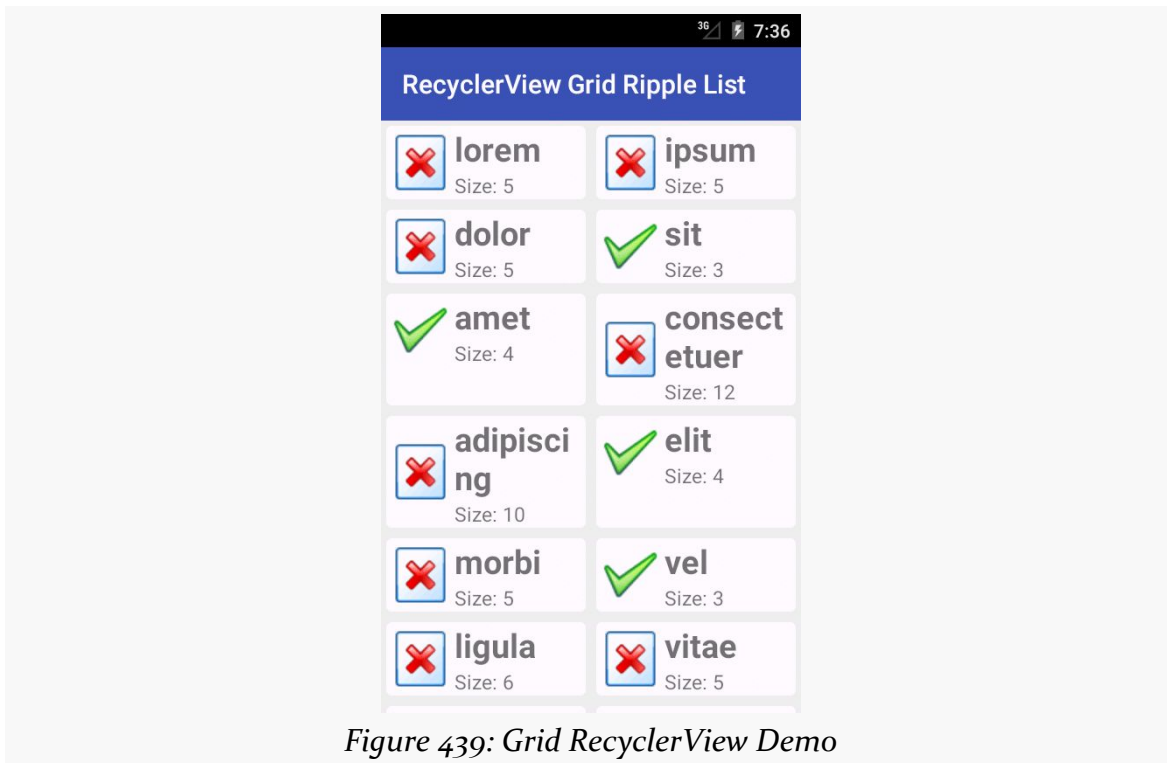

Figure 439: Grid RecyclerView Demo

In this case, this is a “true” grid, with rows and columns of cells. Hence, the height of a row is determined by the tallest cell in that row. The “amet” cell in the left column of the third row is taller than required because of the word-wrap of the “consectetuer” cell in the right column of the same row, for example. [Later in this chapter](#), we will examine yet another option, StaggeredGridLayoutManager, where cells do not necessarily line up neatly in rows.

Choosing the Number of Columns

If we rotate the screen for the above sample, you will see that the cells fit a bit better, since they are really repurposed list-style rows:

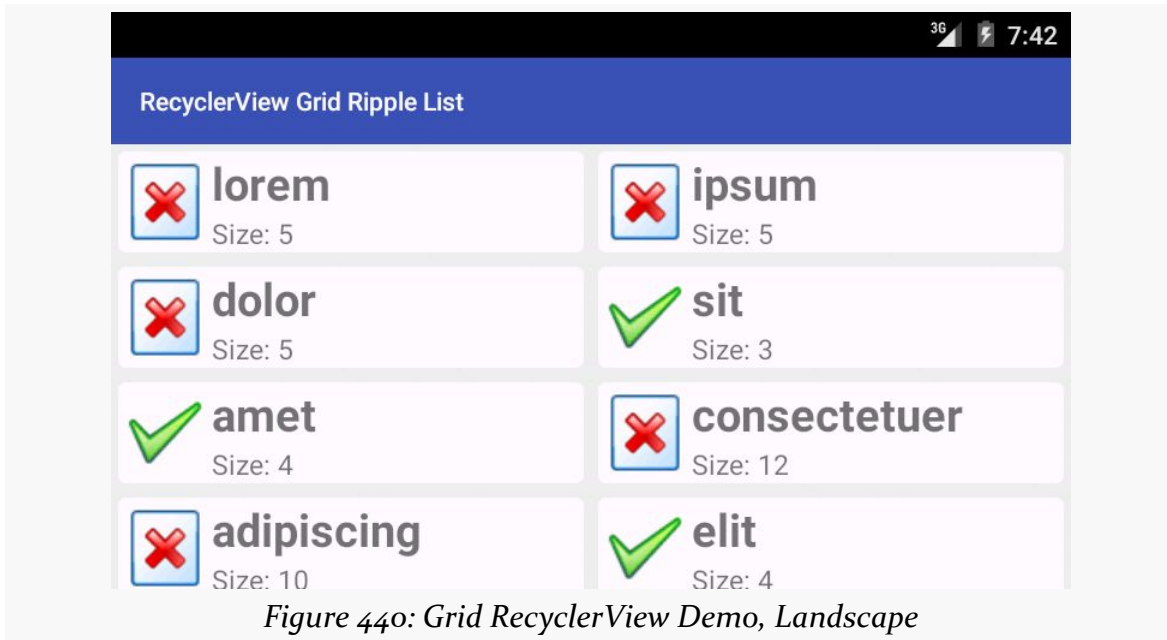

Figure 440: Grid RecyclerView Demo, Landscape

However, some apps may have smaller per-cell content. Plus, we have tablets to consider, and perhaps even televisions. It may be that you want to determine how many spans to use based on screen size and orientation.

One approach for doing that would be to use integer resources. You could have a `res/values/ints.xml` file with `<integer>` elements, giving the integer a name (name attribute) and value (text of the `<integer>` node). You could also have `res/values-w600dp/ints.xml` or other variations of the resource, where you provide different values to use for different screen sizes. Then, at runtime, call `getResources().getInteger()` to retrieve the correct value of the resource to use for the current device, and use that in your `GridLayoutManager` constructor. Now, you are in control over how many columns there are, by controlling how many spans are supplied to the constructor.

Another approach, [suggested by Chiu-Ki Chan](#), is to create a subclass of `RecyclerView`, on which you provide a custom attribute for a desired approximate column width. Then, in your subclass' `onMeasure()` method, you can *calculate* the number of spans to use to give you the desired column width.

Of course, another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The `GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item's position, how many spans it should take up in the grid. We will examine how this works [later in this chapter](#).

Varying the Items

So far, all of the items in the `RecyclerView` have had the same basic structure, just with varying content in the widgets in those items. But, it is entirely possible that we will want to have some items be more substantively different, based on different layouts. `ListView` and kin handle this via `getViewTypeCount()` and `getItemViewType()` in the `ListAdapter`. `RecyclerView` and `RecyclerView.Adapter` offer a similar mechanism, including their own variant of the `getItemViewType()` method. In this section, we will examine how this works, both with lists and grids.

A List with Headers

There are many cases where we want to have a list with some sort of section headers. The look of the headers usually is substantially different than the look of the rest of the rows, and therefore the best way to handle this is to teach the adapter about multiple row types.

This can be seen in the [RecyclerView/HeaderList](#) sample project. This is a clone of a similar project for `ListView`, where we want to put the 25 Latin words into 5 groups of 5 words each, with each group getting its own header.

Hence, our model data is now a two-dimensional `String` array:

```
private static final String[][] items= {
    { "lorem", "ipsum", "dolor", "sit", "amet" },
    { "consectetur", "adipiscing", "elit", "morbi", "vel" },
    { "ligula", "vitae", "arcu", "aliquet", "mollis" },
    { "etiam", "vel", "erat", "placerat", "ante" },
    { "porttitor", "sodales", "pellentesque", "augue", "purus" } };
```

Our `getItemCount()` method now needs to take into account the headers, as well as the regular rows. There is one header row per batch of items, and so `getItemCount()` sums up the sizes of the batches with the extra header rows:

RECYCLERVIEW

```
@Override
public int getItemCount() {
    int count=0;

    for (String[] batch : items) {
        count+=1 + batch.length;
    }

    return(count);
}
```

In order to teach RecyclerView about our different rows, we need to implement `getItemViewType()`. Unlike its counterpart on `ListAdapter`, `getItemViewType()` can return *any* int value, so long as it is unique for the row type. In fact, the recommendation is to use dedicated ID resources to ensure that uniqueness.

To that end, we define two ID resources, in a `res/values/ids.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <item type="id" name="header"/>
    <item type="id" name="detail"/>
</resources>
```

Then, `getItemViewType()` can return `R.id.header` or `R.id.detail` to identify the two row types, and specifically which row type corresponds to the supplied position:

```
@Override
public int getItemViewType(int position) {
    if (getItem(position) instanceof Integer) {
        return(R.id.header);
    }

    return(R.id.detail);
}

private Object getItem(int position) {
    int offset=position;
    int batchSize=0;

    for (String[] batch : items) {
        if (offset == 0) {
            return(Integer.valueOf(batchIndex));
        }

        offset--;

        if (offset < batch.length) {
            return(batch[offset]);
        }

        offset-=batch.length;
        batchSize++;
    }
}
```

RECYCLERVIEW

```
    }  
  
    throw new IllegalArgumentException("Invalid position: "  
        + String.valueOf(position));  
}
```

This leverages a copy of the `getItem()` method from the original `ListView` version of this sample, which returns an `Integer` for a header item (identifying which header it is) and a `String` for detail item (identifying what Latin word to use). Note that `getItem()` is not part of the `RecyclerView.Adapter` protocol, but you are certainly welcome to have one if you want it.

In `onCreateViewHolder()`, we can now start paying attention to the second parameter, which we have been studiously ignoring until now. That value, `viewType`, will be a value that we returned from `getItemViewType()`, and it indicates what sort of `RecyclerView.ViewHolder` we should return. In our case, there are only two possibilities, and so we just inflate the appropriate layout and use a dedicated controller class (`HeaderController` for headers, `RowController` for detail):

```
@Override  
public RecyclerView.ViewHolder onCreateViewHolder(ViewGroup parent, int viewType) {  
    if (viewType==R.id.detail) {  
        return(new RowController(getLayoutInflater()  
            .inflate(R.layout.row, parent, false)));  
    }  
  
    return(new HeaderController(getLayoutInflater()  
        .inflate(R.layout.header, parent, false)));  
}
```

Similarly, our binding logic in `onBindViewHolder()` needs to route the right sort of model information to the proper controller:

```
@Override  
public void onBindViewHolder(RecyclerView.ViewHolder holder, int position) {  
    if (holder instanceof RowController) {  
        ((RowController)holder).bindModel((String)getItem(position));  
    }  
    else {  
        ((HeaderController)holder).bindModel((Integer)getItem(position));  
    }  
}
```

`RowController` is the same sort of setup as we have had in past examples. `HeaderController` is too, though it is far simpler, as we have only one widget needing to be updated (a `TextView` named `label`) and we do not care about click events:

RECYCLERVIEW

```
package com.commonware.android.recyclerview.headerlist;

import android.support.v7.widget.RecyclerView;
import android.view.View;
import android.widget.TextView;

class HeaderController extends RecyclerView.ViewHolder {
    TextView label=null;
    String template=null;

    HeaderController(View row) {
        super(row);

        label=(TextView)row.findViewById(R.id.label);

        template=label.getContext().getString(R.string.header_template);
    }

    void bindModel(Integer headerIndex) {
        label.setText(String.format(template, headerIndex.intValue()+1));
    }
}
```

The results are header rows with one look-and-feel, and detail rows with a different look-and-feel:

Figure 441: HeaderList RecyclerView Demo

A Grid-Style Table

In the discussion of RecyclerView grids, we saw that one way to take advantage of larger screens is to have more cells, in part by having more spans across the screen.

Another way to take advantage of screen space is to grow the cells. By default, they will grow evenly, as each cell takes up one span, and the spans are evenly sized. However, you can change that behavior, by attaching a `GridLayoutManager.SpanSizeLookup` to the `GridLayoutManager`. The `GridLayoutManager.SpanSizeLookup` is responsible for indicating, for a given item's position, how many spans it should take up in the grid.

One way of employing a `GridLayoutManager.SpanSizeLookup` is to make a table. If you want a table, but the user should only be able to select rows, that would be a matter of using a `LinearLayoutManager` and setting up the rows with “cells” that are of consistent size per row. For example, each row could be a horizontal `LinearLayout`, where the “column” widths are determined using `android:layout_weight`. But sometimes you want a table where individual cells can be clicked upon (or selected via a five-way navigation option, like a trackball). In this case, `GridLayoutManager.SpanSizeLookup` will let you indicate, for a “column” of your output, how many spans the cell should take up. By using a consistent number of spans for each column, you can get the same sort of weighted column width that you might get with `LinearLayout`-based rows in a `LinearLayoutManager`-powered RecyclerView.

And that will make a lot more sense (hopefully) when you see an example.

The [RecyclerView/VideoTable](#) sample project is a clone of the `VideoList` sample project from earlier in the chapter, with a few changes:

- We are going to use a `GridLayoutManager`, yet still organize our output into logical rows, by having three cells per row (title, thumbnail, and video duration)
- We are going to use `GridLayoutManager.SpanSizeLookup` to control the widths of each column in our grid
- Because our cells have varying content (`ImageView` in one, `TextView` in others), we will use different controllers for those cells, each optimized for handling that cell's sort of content

The two columns that will hold text (title and video duration) will use the following layout:

RECYCLERVIEW

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <TextView
        android:id="@android:id/text1"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginLeft="8dp"
        android:layout_gravity="center_vertical"
        android:textSize="24sp"/>
</LinearLayout>
```

The `LinearLayout` root element may seem superfluous, but we are using it for the `selectableItemBackground`, to provide a response when the cell is clicked upon.

Similarly, we have a layout dedicated to the thumbnail:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal"
    android:padding="8dp"
    android:background="?android:attr/selectableItemBackground">

    <ImageView
        android:id="@+id/thumbnail"
        android:layout_width="96dp"
        android:layout_height="72dp"
        android:contentDescription="@string/thumbnail"/>
</LinearLayout>
```

`onCreate()` of `MainActivity` is largely the same as before. This time, though, we are creating an instance of a `ColumnWeightSpanSizeLookup` class and using it for two things:

1. Calling its `getTotalSpans()` to tell the `GridLayoutManager` how many spans to use
2. Using it as a `GridLayoutManager.SpanSizeLookup`, attaching it to the `GridLayoutManager` via `setSpanSizeLookup()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    ImageLoaderConfiguration ilConfig=
        new ImageLoaderConfiguration.Builder(this).build();

    imageLoader=ImageLoader.getInstance();
```

RECYCLERVIEW

```
imageLoader.init(ilConfig);

getLayoutManager().initLoader(0, null, this);

ColumnWeightSpanSizeLookup spanSizer=new ColumnWeightSpanSizeLookup(COLUMN_WEIGHTS);
GridLayoutManager mgr=new GridLayoutManager(this, spanSizer.getTotalSpans());

mgr.setSpanSizeLookup(spanSizer);
setLayoutManager(mgr);
setAdapter(new VideoAdapter());
}
```

The latter point means that `ColumnWeightSpanSizeLookup` is a subclass of the abstract `GridLayoutManager.SpanSizeLookup` base class. The one method that you need to override in a `GridLayoutManager.SpanSizeLookup` subclass is `getSpanSize()`. Given an item's position, `getSpanSize()` returns the number of spans that the item's cell should... um... span.

(we overload the word “span” a lot in Android...)

`ColumnWeightSpanSizeLookup` handles this via a set of column weights, which it gets as an `int` array in the constructor. `onCreate()` referenced a `COLUMN_WEIGHTS` static data member for the weights:

```
private static final int[] COLUMN_WEIGHTS={1, 4, 1};
```

This `int` array tells us both how many columns there are and how wide each column should be, in terms of spans.

Converting the position to a column index is a matter of applying the modulo (%) operator, so the implementation of `getSpanSize()` on `ColumnWeightSpanSizeLookup` just returns the `columnWeights` value for the desired column:

```
package com.commonware.android.recyclerview.videotable;

import android.support.v7.widget.GridLayoutManager;

class ColumnWeightSpanSizeLookup extends GridLayoutManager.SpanSizeLookup {
    private final int[] columnWeights;

    ColumnWeightSpanSizeLookup(int[] columnWeights) {
        this.columnWeights=columnWeights;
    }

    @Override
    public int getSpanSize(int position) {
        return(columnWeights[position % columnWeights.length]);
    }

    int getTotalSpans() {
        int sum=0;
    }
}
```

RECYCLERVIEW

```
for (int weight : columnWeights) {
    sum+=weight;
}

return(sum);
}
```

`getTotalSpans()` is a convenience method, to sum all of the column weights. That is how many spans the `GridLayoutManager` will use overall, with each column getting its specific number of spans based upon the `int` array. Note that while we hard-coded the `int` array values in this case, there is nothing stopping us from using `<integer-array>` resources to pull these values out of the Java code, and perhaps even vary them by screen size or other configuration variations.

All of that will set up our grid with the correct number of spans and the right number of spans to use per column of the output. The combination will give us the row structure, as each row's worth of columns uses all of the spans for that row, forcing `GridLayoutManager` to put subsequent items on the next row.

The rest of the project is focused on having different widgets for those different cells, using `getItemViewType()` and so on.

The `VideoAdapter` implementation of `getItemViewType()` simply returns the position modulo 3, to return a unique value (in this case, 0, 1, or 2):

```
@Override
public int getItemViewType(int position) {
    return(position % 3);
}
```

`getItemCount()` takes into account that there are three cells per video, and so the number of items being managed by this adapter is triple the number of videos:

```
@Override
public int getItemCount() {
    if (videos==null) {
        return(0);
    }

    return(videos.getCount()*3);
}
```

The `onCreateViewHolder()` and `onBindViewHolder()` methods take into account those three item types, using a `VideoThumbnailController` or a `VideoTextController` depending on the item type. Both of those classes will inherit

RECYCLERVIEW

from a BaseVideoController, which defines a bindModel() method that onBindViewHolder() can use:

```
@Override
public BaseVideoController onCreateViewHolder(ViewGroup parent, int viewType) {
    BaseVideoController result=null;

    switch(viewType) {
        case 0:
            result=new VideoThumbnailController(getLayoutInflater()
                .inflate(R.layout.thumbnail,
                    parent, false),
                imageLoader);

            break;

        case 1:
            int
            cursorColumn=videos.getColumnIndex(MediaStore.Video.VideoColumns.DISPLAY_NAME);

            result=new VideoTextController(getLayoutInflater()
                .inflate(R.layout.label,
                    parent, false),
                android.R.id.text1,
                cursorColumn);

            break;

        case 2:
            cursorColumn=videos.getColumnIndex(MediaStore.Video.VideoColumns.DURATION);

            result=new VideoTextController(getLayoutInflater()
                .inflate(R.layout.label,
                    parent, false),
                android.R.id.text1,
                cursorColumn);

            break;
    }

    return(result);
}

void setVideos(Cursor videos) {
    this.videos=videos;
    notifyDataSetChanged();
}

@Override
public void onBindViewHolder(BaseVideoController holder, int position) {
    videos.moveToPosition(position/3);
    holder.bindModel(videos);
}
```

BaseVideoController handles click events on the cell, along with collecting the Uri and MIME type of the video to use on click events:

```
package com.commonware.android.recyclerview.videotable;

import android.content.Intent;
```

RECYCLERVIEW

```
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.support.v7.widget.RecyclerView;
import android.view.View;
import com.nostra13.universalimageloader.core.ImageLoader;
import java.io.File;

abstract class BaseVideoController extends RecyclerView.ViewHolder
    implements View.OnClickListener {
    private String videoUri=null;
    private String videoMimeType=null;

    BaseVideoController(View cell) {
        super(cell);

        cell.setOnClickListener(this);
    }

    @Override
    public void onClick(View v) {
        Uri video=Uri.fromFile(new File(videoUri));
        Intent i=new Intent(Intent.ACTION_VIEW);

        i.setDataAndType(video, videoMimeType);
        itemView.getContext().startActivity(i);
    }

    void bindModel(Cursor row) {
        int uriColumn=row.getColumnIndex(MediaStore.Video.Media.DATA);
        int mimeTypeColumn=
            row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);

        videoUri=row.getString(uriColumn);
        videoMimeType=row.getString(mimeTypeColumn);
    }
}
```

VideoTextController extends BaseVideoController and handles binding some column from the MediaStore Cursor to a TextView with some ID:

```
package com.commonware.android.recyclerview.videotable;

import android.database.Cursor;
import android.view.View;
import android.widget.TextView;

class VideoTextController extends BaseVideoController {
    private TextView label=null;
    private int cursorColumn;

    VideoTextController(View cell, int labelId, int cursorColumn) {
        super(cell);
        this.cursorColumn=cursorColumn;

        label=(TextView)cell.findViewById(labelId);
    }
}
```

RECYCLERVIEW

```
@Override
void bindModel(Cursor row) {
    super.bindModel(row);

    label.setText(row.getString(cursorColumn));
}
}
```

VideoThumbnailController handles using UIL to get the video thumbnail asynchronously and binding it to an ImageView in the inflated cell View:

```
package com.commonware.android.recyclerview.videotable;

import android.content.ContentUri;
import android.database.Cursor;
import android.net.Uri;
import android.provider.MediaStore;
import android.view.View;
import android.widget.ImageView;
import com.nostra13.universalimageloader.core.DisplayImageOptions;
import com.nostra13.universalimageloader.core.ImageLoader;

class VideoThumbnailController extends BaseVideoController {
    private ImageView thumbnail=null;
    private ImageLoader imageLoader=null;

    VideoThumbnailController(View cell, ImageLoader imageLoader) {
        super(cell);
        this.imageLoader=imageLoader;

        thumbnail=(ImageView)cell.findViewById(R.id.thumbnail);
    }

    @Override
    void bindModel(Cursor row) {
        super.bindModel(row);

        Uri video=
            ContentUri.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID)));
        DisplayImageOptions opts=new DisplayImageOptions.Builder()
            .showImageOnLoading(R.drawable.ic_media_video_poster)
            .build();

        imageLoader.displayImage(video.toString(), thumbnail, opts);
    }
}
```

The result is the same information as was in the original VideoList demo, but organized into a table, where each cell is clickable:

RECYCLERVIEW

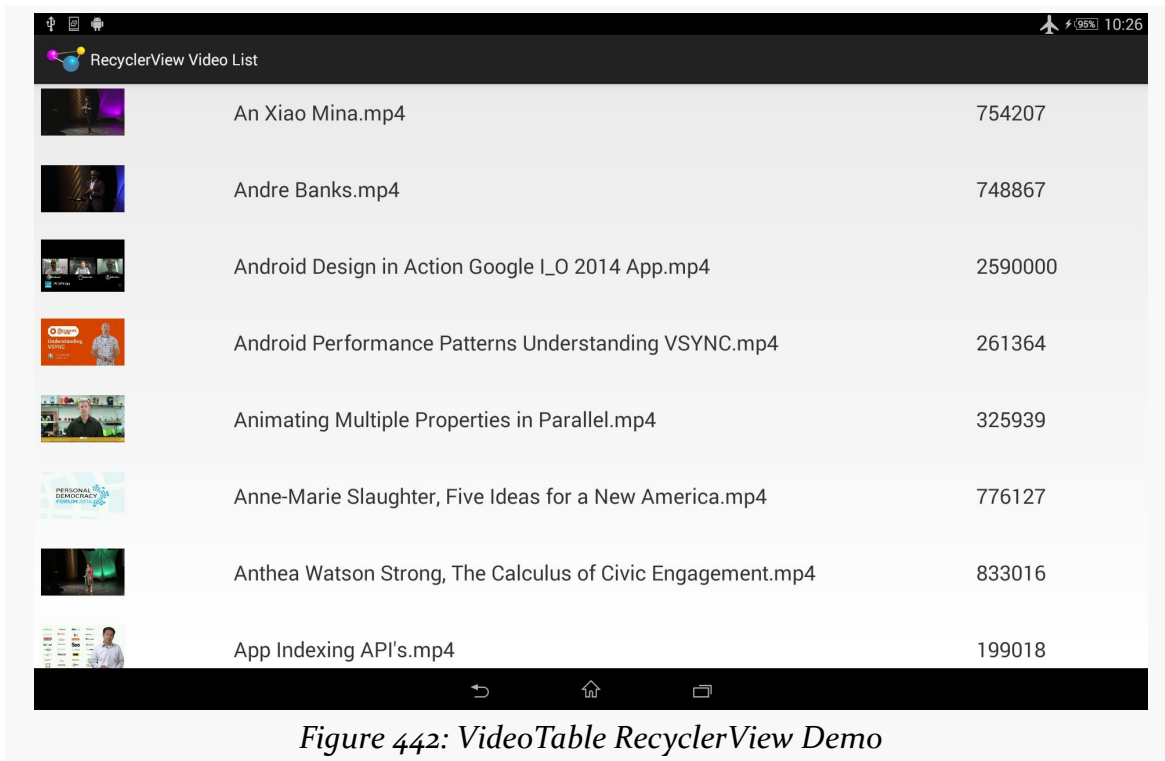

Figure 442: VideoTable RecyclerView Demo

The duration is returned by `MediaStore` in milliseconds, which is not a great choice to present directly to the user. An improved version of this app might use a dedicated `RecyclerView.ViewHolder` that would convert the millisecond count into a duration measured in hours, minutes, and seconds (e.g., shown as `HH:MM:SS` to the user).

Also note that the cell sizes are purely driven by their weights, which will not necessarily handle all content in all configurations very well. The chosen weights barely work on a 10" tablet in portrait, for example:

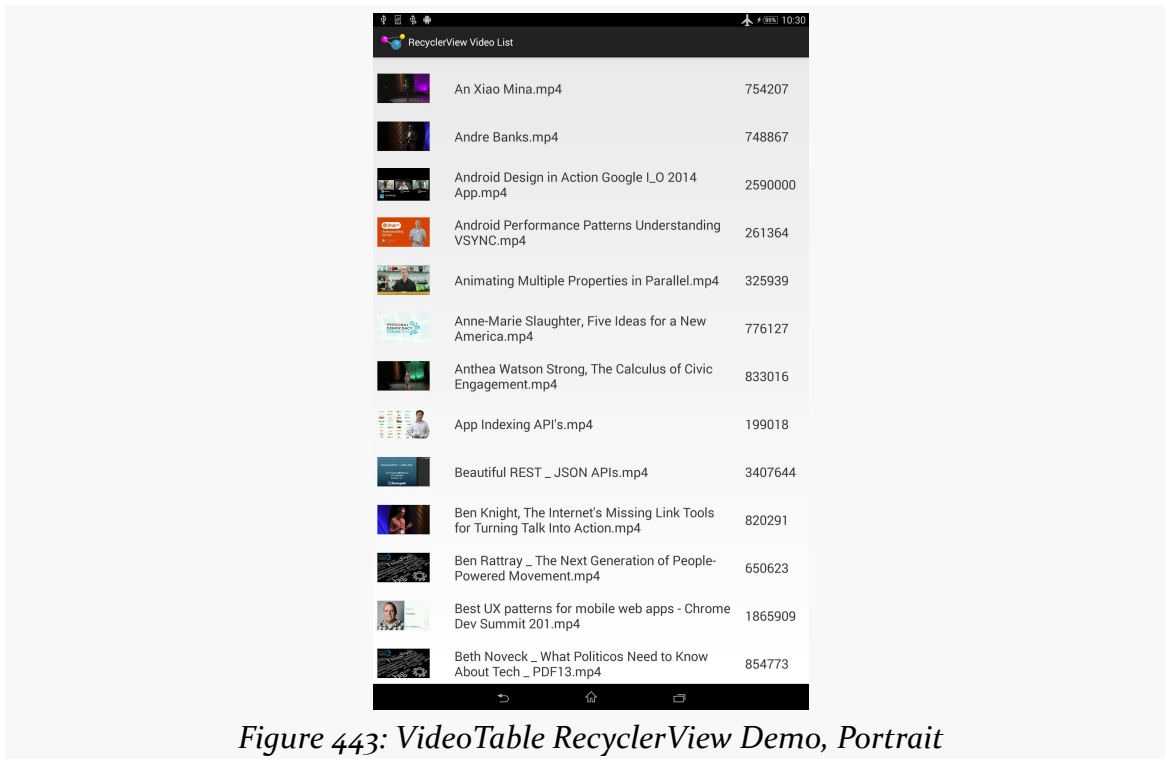

Figure 443: VideoTable RecyclerView Demo, Portrait

Mutable Row Contents

So far, all of the items we have used have been display-only. At most, they might respond to click events, along the lines of clicking a `ListView` row or `GridView` cell.

But, what about choice modes?

`ListView` and `GridView` — by way of their common `AbsListView` ancestor — have the concept of choice modes, where the user can “check” and “uncheck” items, and the list or grid will keep track of those states.

Well, as with lots of other things involving `RecyclerView`, `RecyclerView` does not offer choice modes... though you can implement that yourself. The [RecyclerView/ChoiceList](#) sample project turns our list-style `RecyclerView` into a checklist, with `CheckBox` widgets in each row, where the `RecyclerView.Adapter` will keep track of the `CheckBox` checked states for us.

First, we need to add a `CheckBox` to the row:

RECYCLERVIEW

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v7.widget.CardView
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:cardview="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_margin="4dp"
    cardview:cardCornerRadius="4dp">

    <LinearLayout
        android:id="@+id/row_content"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="horizontal"
        android:background="?android:attr/selectableItemBackground">

        <ImageView
            android:id="@+id/icon"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:layout_gravity="center_vertical"
            android:padding="2dip"
            android:src="@drawable/ok"
            android:contentDescription="@string/icon"/>

        <LinearLayout
            android:layout_width="0dip"
            android:layout_height="wrap_content"
            android:layout_weight="1"
            android:orientation="vertical">

            <TextView
                android:id="@+id/label"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="25sp"
                android:textStyle="bold"/>

            <TextView
                android:id="@+id/size"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:textSize="15sp"/>
        </LinearLayout>

        <CheckBox
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:id="@+id/cb"
            android:layout_gravity="center_vertical"/>
    </LinearLayout>
</android.support.v7.widget.CardView>
```

Our IconicAdapter is only slightly different than before:

- it inherits from a ChoiceCapableAdapter that we will examine shortly, and

RECYCLERVIEW

- it supplies a `MultiChoiceMode` instance to `ChoiceCapableAdapter` as part of chaining to the `ChoiceCapableAdapter` constructor

```
class IconicAdapter extends ChoiceCapableAdapter<RowController> {
    IconicAdapter() {
        super(new MultiChoiceMode());
    }

    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(this, getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(items[position]);
    }

    @Override
    public int getItemCount() {
        return(items.length);
    }
}
```

`ChoiceCapableAdapter` is simply a `RecyclerView.Adapter` that knows how to handle choice modes, as implemented via the `ChoiceMode` interface:

```
package com.commonware.android.recyclerview.choicelist;

import android.os.Bundle;

public interface ChoiceMode {
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
}
```

A `ChoiceMode` is effectively a strategy class, responsible for tracking the checked states, not only for the current `ChoiceCapableAdapter` instance, but for future ones created as part of a configuration change. It requires four methods:

- `setChecked()` and `isChecked()` are getters and setters for whether or not a given position is checked
- `onSaveInstanceState()` and `onRestoreInstanceState()` manage storing and restoring those check states from the saved instance state `Bundle` of an activity or fragment

This project uses a `MultiChoiceMode` implementation of `ChoiceMode`:

RECYCLERVIEW

```
package com.commonware.android.recyclerview.choicelist;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES="checkStates";
    private ParcelableSparseBooleanArray checkStates=new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        checkStates.put(position, isChecked);
    }

    @Override
    public boolean isChecked(int position) {
        return(checkStates.get(position, false));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates=state.getParcelable(STATE_CHECK_STATES);
    }
}
```

MultiChoiceMode, in turn, is mostly handled by a ParcelableSparseBooleanArray. SparseBooleanArray is a class, supplied in the Android SDK, that is a space-efficient mapping of int values to boolean values, as opposed to using a HashMap and having to convert those primitives to Integer and Boolean objects. However, for inexplicable reasons, SparseBooleanArray was not [implemented to be Parcelable](#), and therefore it cannot be stored in a Bundle. ParcelableSparseBooleanArray is a subclass of SparseBooleanArray that handles the Parcelable aspects:

```
package com.commonware.android.recyclerview.choicelist;

import android.os.Parcel;
import android.os.Parcelable;
import android.util.SparseBooleanArray;

public class ParcelableSparseBooleanArray extends SparseBooleanArray
    implements Parcelable {
    public static Parcelable.Creator<ParcelableSparseBooleanArray> CREATOR
    =new Parcelable.Creator<ParcelableSparseBooleanArray>() {
        @Override
        public ParcelableSparseBooleanArray createFromParcel(Parcel source) {
            return(new ParcelableSparseBooleanArray(source));
        }

        @Override
        public ParcelableSparseBooleanArray[] newArray(int size) {
            return(new ParcelableSparseBooleanArray[size]);
        }
    }
}
```

RECYCLERVIEW

```
};

public ParcelableSparseBooleanArray() {
    super();
}

private ParcelableSparseBooleanArray(Parcel source) {
    int size=source.readInt();

    for (int i=0; i < size; i++) {
        put(source.readInt(), (Boolean)source.readValue(null));
    }
}

@Override
public int describeContents() {
    return(0);
}

@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeInt(size());

    for (int i=0;i<size();i++) {
        dest.writeInt(keyAt(i));
        dest.writeValue(valueAt(i));
    }
}
}
```

The net effect is that `MultiChoiceMode`, by means of `ParcelableSparseBooleanArray`, can track the checked/unchecked states of particular item position values.

`ChoiceCapableAdapter`, then, is a `RecyclerView.ViewHolder` that surfaces a `ChoiceMode` implementation:

```
package com.commonware.android.recyclerview.choicelist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;

    public ChoiceCapableAdapter(ChoiceMode choiceMode) {
        super();
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        choiceMode.setChecked(position, isChecked);
    }
}
```

RECYCLERVIEW

```
boolean isChecked(int position) {
    return(choiceMode.isChecked(position));
}

void onSaveInstanceState(Bundle state) {
    choiceMode.onSaveInstanceState(state);
}

void onRestoreInstanceState(Bundle state) {
    choiceMode.onRestoreInstanceState(state);
}
}
```

The methods exposed by ChoiceCapableAdapter can then be used by outside parties. Specifically, MainActivity delegates onSaveInstanceState() and onRestoreInstanceState() to ChoiceCapableAdapter, so checked states can span configuration changes and the like. Plus, RowController can hook up on OnCheckedChangeListener and to update ChoiceCapableAdapter based on the state of checkbox changes:

```
package com.commonware.android.recyclerview.choicelist;

import android.annotation.TargetApi;
import android.os.Build;
import android.support.v7.widget.RecyclerView;
import android.view.MotionEvent;
import android.view.View;
import android.widget.CheckBox;
import android.widget.CompoundButton;
import android.widget.ImageView;
import android.widget.TextView;
import android.widget.Toast;

class RowController extends RecyclerView.ViewHolder
    implements View.OnClickListener, CompoundButton.OnCheckedChangeListener {
    private ChoiceCapableAdapter adapter;
    private TextView label=null;
    private TextView size=null;
    private ImageView icon=null;
    private String template=null;
    private CheckBox cb=null;

    RowController(ChoiceCapableAdapter adapter, View row) {
        super(row);

        this.adapter=adapter;
        label=(TextView)row.findViewById(R.id.label);
        size=(TextView)row.findViewById(R.id.size);
        icon=(ImageView)row.findViewById(R.id.icon);
        cb=(CheckBox)row.findViewById(R.id.cb);

        template=size.getContext().getString(R.string.size_template);

        row.setOnClickListener(this);

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.LOLLIPOP) {
```

RECYCLERVIEW

```
row.setOnTouchListener(new View.OnTouchListener() {
    @TargetApi(Build.VERSION_CODES.LOLLIPOP)
    @Override
    public boolean onTouch(View v, MotionEvent event) {
        v
            .findViewById(R.id.row_content)
            .getBackground()
            .setHotspot(event.getX(), event.getY());

        return(false);
    }
});

cb.setOnCheckedChangeListener(this);
}

@Override
public void onClick(View v) {
    Toast.makeText(v.getContext(),
        String.format("Clicked on position %d", getAdapterPosition()),
        Toast.LENGTH_SHORT).show();
}

@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    adapter.onChecked(getAdapterPosition(), isChecked);
}

void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }
}

cb.setChecked(adapter.isChecked(getAdapterPosition()));
}
}
```

Here, `bindModel()` updates the `CheckBox` based upon the `ChoiceCapableAdapter` `isChecked()` value for the `RecyclerView.ViewHolder` position (obtained via `getPosition()`). And, `onCheckedChanged()` updates the `ChoiceCapableAdapter` to keep track of whether this position is checked or unchecked, to handle row recycling, configuration changes, etc.

The result is much as you would expect: a version of our same sort of UI as before, except that if the user clicks the `CheckBox`, instead of the rest of the row, the `CheckBox` toggles its checked state, and that state survives row recycling, configuration changes, and so on:

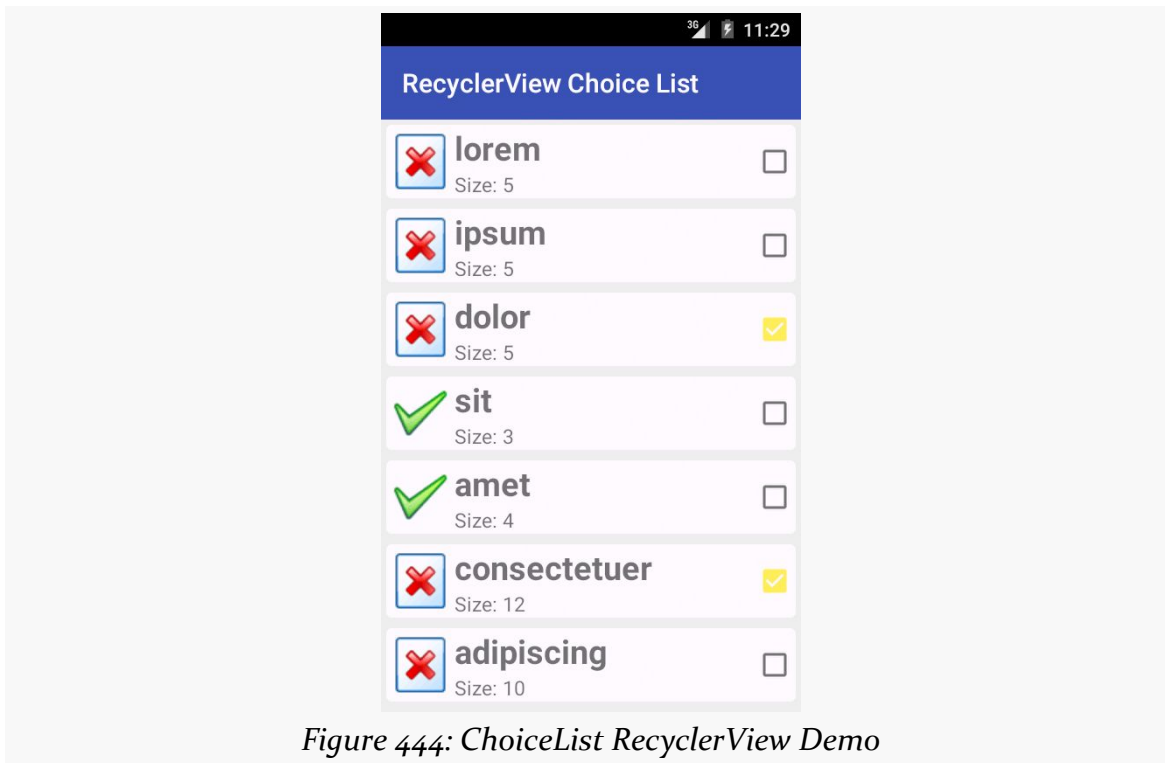

Figure 444: ChoiceList RecyclerView Demo

Note that since this sample is using `Theme.Material` on Android 5.0+ devices, and since the screenshot is from an Android 5.0 emulator, the `CheckBox` styling is based on the accent color, here shown as bright yellow.

Switching to the Activated Style

Also note that `ChoiceCapableAdapter`, `MultiChoiceMode`, and `kin` are oblivious to *how* the user is informed about what is checked and unchecked. `RowController` in the previous sample happens to use a `CheckBox`. `RowController` could use some other widget, like a `Switch`.

Another approach is to use the activated state. Once again, this is the sort of thing that is automatically handled for us by `ListView` and its choice modes, but with some minor tweaks, we can get our `RowController` to use this approach. This is shown in the [RecyclerView/ActivatedList](#) sample project.

First, we need to give our row a background that has a `StateListDrawable` that supports the activated state. The simplest approach — and the one traditionally used with `ListView` — is to set up an activated style with the stock theme-supplied background drawable, then apply that style to the row.

RECYCLERVIEW

So, this sample app defines activated in res/values/styles.xml:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <style name="Theme.Apptheme" parent="@android:style/Theme.Holo.Light.DarkActionBar">
  </style>

  <style name="activated" parent="Theme.Apptheme">
    <item name="android:background">?android:attr/activatedBackgroundIndicator</item>
  </style>

</resources>
```

Note that activated inherits from Theme.Apptheme. This means that we will get the Theme.Holo-flavored background normally, but on API Level 21+, we will get the Theme.Material-flavored background, courtesy of a res/values-v21/styles.xml override of Theme.Apptheme:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="Theme.Apptheme" parent="android:Theme.Material.Light.DarkActionBar">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>
</resources>
```

Our row layout now dumps the CardView (whose own background may conflict with the activated one) and applies the activated style to the root LinearLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:orientation="horizontal"
  style="@style/activated">

  <ImageView
    android:id="@+id/icon"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center_vertical"
    android:padding="2dip"
    android:src="@drawable/ok"
    android:contentDescription="@string/icon"/>

  <LinearLayout
    android:layout_width="0dip"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:orientation="vertical">

    <TextView
```

RECYCLERVIEW

```
        android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="25sp"
        android:textStyle="bold"/>

        <TextView
            android:id="@+id/size"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:textSize="15sp"/>
    </LinearLayout>
</LinearLayout>
```

The row also no longer has the `CheckBox`, as it is no longer needed.

`RowController` now uses the `OnClickListener` interface to respond to clicks and use that to toggle the activated state for that row:

```
@Override
public void onClick(View v) {
    boolean isCheckedNow=adapter.isChecked(getAdapterPosition());

    adapter.onChecked(getAdapterPosition(), !isCheckedNow);
    row.setActivated(!isCheckedNow);
}
```

`setActivated()`, applied to a `View`, indicates that it is (or is not) activated, affecting anything in that `View` that depends upon that state, such as the background.

Similarly, `bindModel()` uses `setActivated()` to update the activated state when binding our data:

```
void bindModel(String item) {
    label.setText(item);
    size.setText(String.format(template, item.length()));

    if (item.length()>4) {
        icon.setImageResource(R.drawable.delete);
    }
    else {
        icon.setImageResource(R.drawable.ok);
    }

    row.setActivated(adapter.isChecked(getAdapterPosition()));
}
```

Everything else is the same as the original `CheckBox` version of the sample. But now, the “checked” state is indicated by the activated highlight:

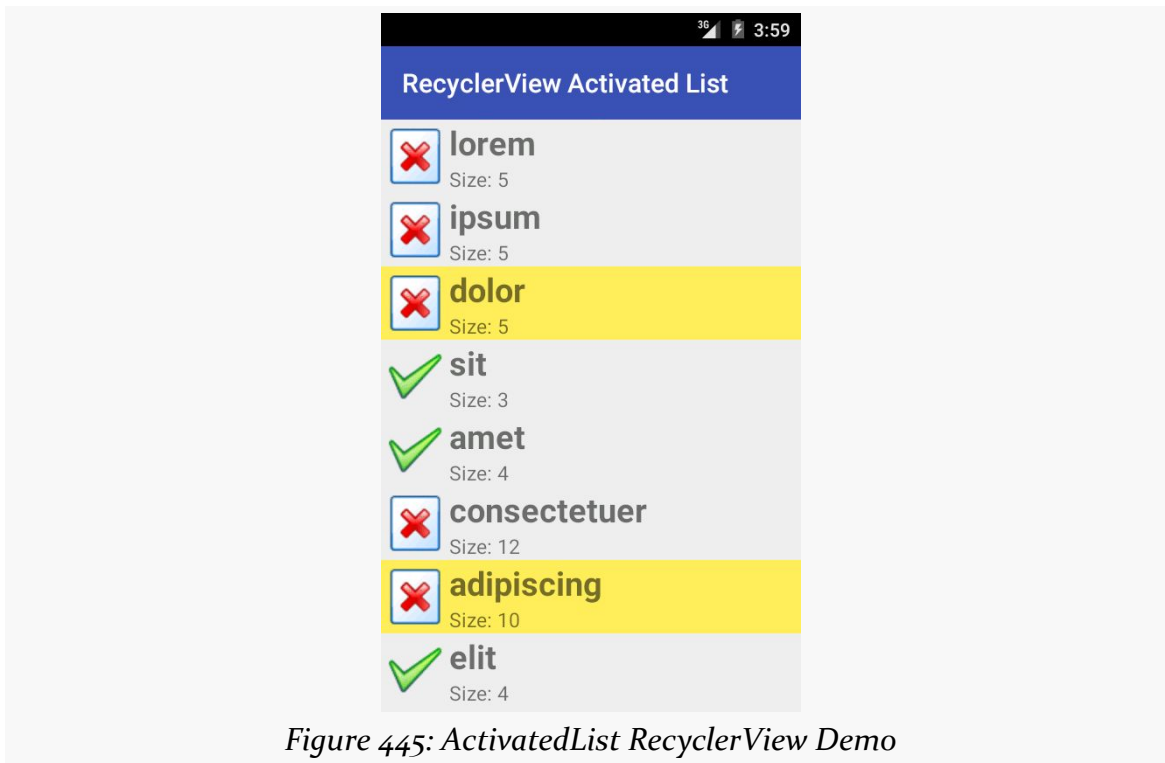

Figure 445: ActivatedList RecyclerView Demo

And, since this demo is running on Android 5.0, the activated highlight color is the accent color, which in this case is set to be yellow.

But, What About Single-Choice?

Both of the preceding examples illustrate multiple-choice behavior. Sometimes, though, single-choice behavior is the better option. For example, in a master-detail structure, in dual-pane mode (e.g., tablets, where the master and the detail are both visible), you probably normally want single-choice mode.

That is certainly possible, though, once again, RecyclerView does not offer it. It also adds a wrinkle: how do we arrange to uncheck a previously-checked item, when the user checks another item? Like `RadioButton` widgets in a `RadioGroup`, we need to ensure that only one item at a time is checked, and that will require us to update the UI of the formerly-checked-but-now-unchecked item.

With some tweaks, the last sample project, where we used the activated state for a multiple-choice list, can be revised to limit the user to a single choice. Those tweaks are illustrated in the [RecyclerView/SingleActivatedList](#) sample project.

The ChoiceMode interface now has two new methods:

1. `isSingleChoice()` will return true for a single-choice ChoiceMode strategy, false otherwise
2. `getCheckedPosition()` will return the position of whatever the currently-checked item is

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public interface ChoiceMode {
    boolean isSingleChoice();
    int getCheckedPosition();
    void setChecked(int position, boolean isChecked);
    boolean isChecked(int position);
    void onSaveInstanceState(Bundle state);
    void onRestoreInstanceState(Bundle state);
}
```

SingleChoiceMode is now our implementation of ChoiceMode:

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;

public class SingleChoiceMode implements ChoiceMode {
    private static final String STATE_CHECKED="checkedPosition";
    private int checkedPosition=-1;

    @Override
    public boolean isSingleChoice() {
        return(true);
    }

    @Override
    public int getCheckedPosition() {
        return(checkedPosition);
    }

    @Override
    public void setChecked(int position, boolean isChecked) {
        if (isChecked) {
            checkedPosition=position;
        }
        else if (isChecked(position)) {
            checkedPosition=-1;
        }
    }

    @Override
    public boolean isChecked(int position) {
        return(checkedPosition==position);
    }
}
```

RECYCLERVIEW

```
@Override
public void onSaveInstanceState(Bundle state) {
    state.putInt(STATE_CHECKED, checkedPosition);
}

@Override
public void onRestoreInstanceState(Bundle state) {
    checkedPosition=state.getInt(STATE_CHECKED, -1);
}
}
```

SingleChoiceMode tracks the currently-checked position, using -1 to indicate no position is checked. Of note, if a position was checked, then `setChecked()` unchecks it, SingleChoiceMode goes back to -1 and indicates that there is no currently-checked position.

ChoiceCapableAdapter also has a couple of modifications. First, it now accepts the RecyclerView itself as a constructor parameter, holding onto it in an `rv` data member. And, `onChecked()` needs to be modified to take care of removing the activated state from whatever item had been previously checked when some new item is checked:

```
package com.commonware.android.recyclerview.singleactivatedlist;

import android.os.Bundle;
import android.support.v7.widget.RecyclerView;

abstract public class
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>
    extends RecyclerView.Adapter<T> {
    private final ChoiceMode choiceMode;
    private final RecyclerView rv;

    public ChoiceCapableAdapter(RecyclerView rv,
        ChoiceMode choiceMode) {
        super();
        this.rv=rv;
        this.choiceMode=choiceMode;
    }

    void onChecked(int position, boolean isChecked) {
        if (choiceMode.isSingleChoice()) {
            int checked=choiceMode.getCheckedPosition();

            if (checked>=0) {
                RowController row=
                    (RowController)rv.findViewByIdForAdapterPosition(checked);

                if (row!=null) {
                    row.setChecked(false);
                }
            }
        }
    }
}
```

RECYCLERVIEW

```
        choiceMode.setChecked(position, isChecked);
    }

    boolean isChecked(int position) {
        return choiceMode.isChecked(position);
    }

    void onSaveInstanceState(Bundle state) {
        choiceMode.onSaveInstanceState(state);
    }

    void onRestoreInstanceState(Bundle state) {
        choiceMode.onRestoreInstanceState(state);
    }

    @Override
    public void onViewAttachedToWindow(T holder) {
        super.onViewAttachedToWindow(holder);

        if (holder.getAdapterPosition() != choiceMode.getCheckedPosition()) {
            ((RowController)holder).setChecked(false);
        }
    }
}
```

To do that, `onChecked()` asks the `ChoiceMode` if it is single choice. If yes, it gets the last checked position. If that position is plausible (0 or higher), it gets the `RecyclerView.ViewHolder` for that position via `findViewHolderForAdapterPosition()`, called on the `RecyclerView`. If this returns something other than null, then it must be a `RowController`, and so `onChecked()` calls `setChecked(false)` on that row to remove the activated state.

`findViewHolderForAdapterPosition()` and `findViewHolderForLayoutPosition()` replace the now-deprecated `findViewHolderForPosition()` method. All three methods do the same basic thing: given a position, return the `ViewHolder` for that position, if any. `findViewHolderForPosition()` and `findViewHolderForLayoutPosition()` have the same implementation, at least at the present time. The primary thing that `findViewHolderForAdapterPosition()` does differently is it always returns null if the data has been changed (e.g., `notifyDataSetChanged()` was called on the adapter) but those changes have not yet been laid out. In this sample app, that difference is academic, but `findViewHolderForAdapterPosition()` probably is a safer choice for most use cases.

However, these `find...()` methods have a wrinkle: they only return a `ViewHolder` if the row is *visible*. If the `ViewHolder` is cached, but not visible, `find...()` will still not return it. This causes a problem where we need to de-select a row that is not visible (and so `find...()` does not work) but will not be re-bound using `onBindViewHolder()` (as the `ViewHolder` is already set up). This requires us to

RECYCLERVIEW

implement `onViewAttachedToWindow()` — called whenever a `ViewHolder` contents are actually attached as children to the `RelativeLayout` — and update the checked state there, as a fallback.

(and many thanks to Mahmoud Abou-Eita for [reporting that problem](#))

`setChecked()` did not exist in the previous sample, as the activated state was handled purely internally to `RowController`. So, now `RowController` has a `setChecked()` method to toggle the activated state:

```
void setChecked(boolean isChecked) {
    row.setActivated(isChecked);
}
```

`MainActivity` now must supply the `RecyclerView` to the `IconicAdapter` in `onCreate()`:

```
@Override
public void onCreate(Bundle icle) {
    super.onCreate(icle);

    setLayoutManager(new LinearLayoutManager(this));
    adapter=new IconicAdapter(getRecyclerView());
    setAdapter(adapter);
}
```

...so that `IconicAdapter()` can supply it to the `ChoiceCapableAdapter` superclass constructor:

```
IconicAdapter(RecyclerView rv) {
    super(rv, new SingleChoiceMode());
}
```

Visually, the results are identical to the previous example, except that at most only one item can be checked at a time. The key is the phrase “at most” — this implementation allows the user to tap on a checked item to uncheck it. This may be fine, as your app may simply hide the detail in this scenario, still allowing the user to interact with action bar items (e.g., a “create new model” item). If you wanted to prevent that, have `SingleChoiceMode` *not* set `checkedPosition` to `-1` when the user taps on a previously-checked item, to leave the currently-checked position intact.

Action Modes

Another thing that `ListView` gave us was support for action modes. In particular, the “multiple-choice modal” setting would automatically start and finish an action mode for us.

And, once again, `RecyclerView` has no hooks for action modes, though you can do it yourself if desired. We have to manually start and destroy the action mode, in addition to responding to the user’s interaction with the action mode (tapping on items, or dismissing the action mode manually).

Where things get interesting is in the connection between checked items and the action mode. There are two UX rules:

1. When there are no checked items, there should be no action mode
2. When there is no action mode, there should be no checked items

You might think that those two rules are the same, and to some extent they are. They are phrased this way to emphasize the state changes that are involved:

- When the user checks an item, an action mode should appear
- When the user unchecks the last checked item, and therefore there are no more checked items, the action mode should disappear
- When the user dismisses the action mode (e.g., presses BACK), all checked items should become unchecked

Handling these transitions takes a bit of work, demonstrated in the [RecyclerView/ActionModeList](#) sample project. This is a clone of the `ChoiceList` sample from earlier, augmented with an action mode when 1+ items are checked. The action mode logic is largely cloned from one of the book’s action mode samples, where we want to allow the user to capitalize or remove the checked items.

Once again, we have some tweaks to `ChoiceMode`, adding two methods:

1. `getCheckedCount()`, to return the number of checked items, which we will use for the subtitle of the action mode
2. `clearChecks()`, to uncheck all checked items

```
package com.commonware.android.recyclerview.actionmodelist;
import android.os.Bundle;
public interface ChoiceMode {
```

RECYCLERVIEW

```
void setChecked(int position, boolean isChecked);
boolean isChecked(int position);
void onSaveInstanceState(Bundle state);
void onRestoreInstanceState(Bundle state);
int getCheckedCount();
void clearChecks();
}
```

MultiChoiceMode implements those, plus adds a subtle change to `setChecked()`. Previous editions of `MultiChoiceMode` would simply put the checked state `boolean` into the `ParcelableSparseBooleanArray`, with `false` as a default value for any position not in the array. Now, we specifically *remove* items that are unchecked, so the only items in the `ParcelableSparseBooleanArray` are those that are checked. This makes `getCheckedCount()` and `clearChecks()` very simple to implement:

```
package com.commonware.android.recyclerview.actionmodelist;

import android.os.Bundle;

public class MultiChoiceMode implements ChoiceMode {
    private static final String STATE_CHECK_STATES="checkStates";
    private ParcelableSparseBooleanArray checkStates=new ParcelableSparseBooleanArray();

    @Override
    public void setChecked(int position, boolean isChecked) {
        if (isChecked) {
            checkStates.put(position, isChecked);
        }
        else {
            checkStates.delete(position);
        }
    }

    @Override
    public boolean isChecked(int position) {
        return(checkStates.get(position, false));
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
        state.putParcelable(STATE_CHECK_STATES, checkStates);
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
        checkStates=state.getParcelable(STATE_CHECK_STATES);
    }

    @Override
    public int getCheckedCount() {
        return(checkStates.size());
    }

    @Override
    public void clearChecks() {
        checkStates.clear();
    }
}
```

RECYCLERVIEW

```
}  
}
```

ChoiceCapableAdapter exposes the two new ChoiceMode capabilities to its subclasses:

```
package com.commonware.android.recyclerview.actionmodelist;  
  
import android.os.Bundle;  
import android.support.v7.widget.RecyclerView;  
  
abstract public class  
    ChoiceCapableAdapter<T extends RecyclerView.ViewHolder>  
        extends RecyclerView.Adapter<T> {  
    private final ChoiceMode choiceMode;  
  
    public ChoiceCapableAdapter(ChoiceMode choiceMode) {  
        super();  
        this.choiceMode=choiceMode;  
    }  
  
    void onChecked(int position, boolean isChecked) {  
        choiceMode.setChecked(position, isChecked);  
    }  
  
    boolean isChecked(int position) {  
        return(choiceMode.isChecked(position));  
    }  
  
    void onSaveInstanceState(Bundle state) {  
        choiceMode.onSaveInstanceState(state);  
    }  
  
    void onRestoreInstanceState(Bundle state) {  
        choiceMode.onRestoreInstanceState(state);  
    }  
  
    int getCheckedCount() {  
        return(choiceMode.getCheckedCount());  
    }  
  
    void clearChecks() {  
        choiceMode.clearChecks();  
    }  
}
```

IconicAdapter now not only extends ChoiceCapableAdapter, but it implements the ActionMode.Callback interface, and therefore will be responsible for managing the action mode:

```
class IconicAdapter extends ChoiceCapableAdapter<RowController>  
    implements ActionMode.Callback {
```

RECYCLERVIEW

IconicAdapter now overrides `onChecked()`, normally just handled by `ChoiceCapableAdapter`. In addition to chaining to the superclass for standard behavior, `IconicAdapter` manages the action mode:

- If we are checking an item (`isChecked` is true), and if we do not already have an action mode going (tracked by an `activeMode` data member), start the action mode using `startActionMode()`
- If we have checked items, and we do have an action mode, then just update the subtitle, as our number of checked items should have just changed
- If we do not have any checked items, and we have an active action mode, `finish()` that action mode, as the user has unchecked the last checked item and the action mode is no longer needed

```
@Override
void onChecked(int position, boolean isChecked) {
    super.onChecked(position, isChecked);

    if (isChecked) {
        if (activeMode==null) {
            activeMode=startActionMode(this);
        }
        else {
            updateSubtitle(activeMode);
        }
    }
    else if (getCheckedCount()==0 && activeMode!=null) {
        activeMode.finish();
    }
}
```

Because `IconicAdapter` implements `ActionMode.Callback`, it needs to implement the methods required by that interface. This includes:

- `onCreateActionMode()`, to set up the action mode
- `onPrepareActionMode()`, just because it is required by the interface
- `onActionItemClicked()`, where we should do some real work, but for the moment just have a TODO comment
- `onDestroyActionMode()`, where we make sure that all checked items are unchecked (`clearChecks()`) and tell the `RecyclerView.Adapter` that the data set changed, to force a repaint of all the visible rows, so they will now reflect the fact that they are no longer checked

```
@Override
public boolean onCreateActionMode(ActionMode mode, Menu menu) {
    MenuInflater inflater=getMenuInflater();

    inflater.inflate(R.menu.context, menu);
    mode.setTitle(R.string.context_title);
}
```

RECYCLERVIEW

```
    activeMode=mode;
    updateSubtitle(activeMode);

    return(true);
}

@Override
public boolean onPrepareActionMode(ActionMode mode, Menu menu) {
    return(false);
}

@Override
public boolean onActionItemClicked(ActionMode mode, MenuItem item) {
    // TODO: do something based on the action

    updateSubtitle(activeMode);

    return(true);
}

@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        clearChecks();
        notifyDataSetChanged();
    }
}
```

The `updateSubtitle()` method, referred to by some of the previous methods, just updates the subtitle of the action mode to reflect the current count of checked items:

```
private void updateSubtitle(ActionMode mode) {
    mode.setSubtitle("(" + getCheckedCount() + ")");
}
```

The resulting app looks a lot like the original `ChoiceList` sample, until we check one or more items, at which point the action mode appears:

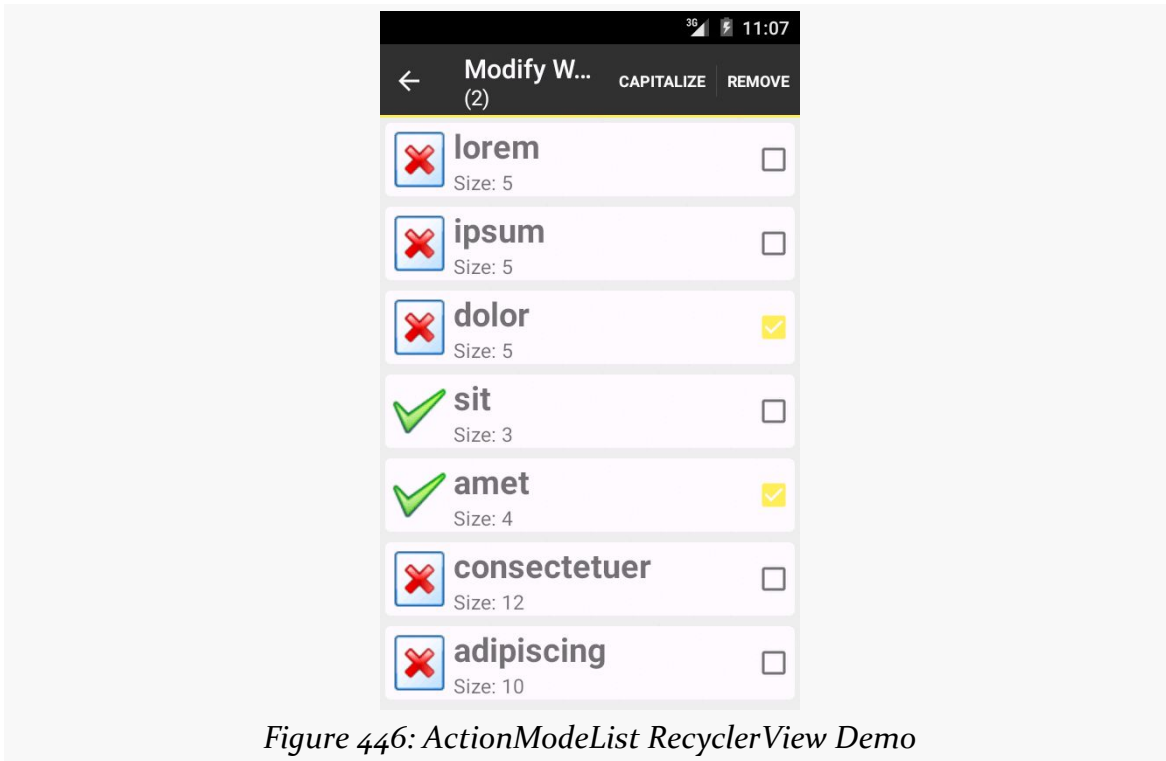

Figure 446: ActionModeList RecyclerView Demo

Changing the Contents

The obvious problem with the preceding sample is that we are not actually doing anything in response to user clicks on action mode items. We really should be capitalizing and/or removing words. However, this involves modifying the model data and how that model data is being visually displayed by the RecyclerView.

The less-obvious problem is that we are calling `notifyDataSetChanged()` when the action mode is dismissed, to force a full repaint of the RecyclerView contents. While this works, it is overkill, as probably only a subset of the visible items are checked. Ideally, we would only update the specific positions that were checked and now, with the action mode finished, are unchecked. We could find the affected `ViewHolder` instances, using `findViewHolderByPosition()` on RecyclerView, as we did in the single-choice list sample. But, really, updating the checked state is just another manifestation of the same problem that capitalizing or removing words causes: we need to ensure that the RecyclerView depicts the current model state, ideally with minimum work.

So, let's see how this is accomplished, by looking at the [RecyclerView/ActionModeList2](#) sample project. As the name suggests, this is a clone of the `ActionModeList` shown in the preceding section. This time, we will fully implement `onActionItemClicked()` and allow our model data to be mutable.

Updating Existing Contents

With `AdapterView` and `Adapter` classes based on `BaseAdapter`, the only way we had to tell the `AdapterView` about model data changes was `notifyDataSetChanged()`. This would trigger a rebuild of the entire `AdapterView`, which is slow and expensive.

While `RecyclerView.Adapter` has its own `notifyDataSetChanged()`, that is really for total reloads of the model data, such as having gotten a fresh `Cursor` from a database and not knowing exactly what the changes are. If you are driving the changes yourself from the UI — and particularly if your model data is something like an `ArrayList` of model objects — you can use methods on `RecyclerView.Adapter` that are more fine-grained than is `notifyDataSetChanged()`.

If an item was updated in place — such as a word now being capitalized — you can use `notifyItemChanged()` on `RecyclerView.Adapter` to point out the specific position that changed. Alternatives include:

- `notifyItemMoved()`, to indicate that an item is still in the model data but now is in a new position
- `notifyItemRangeChanged()`, to indicate a range of positions that were modified, instead of having to repeatedly call `notifyItemChanged()`

`ActionModeList2` uses `notifyItemChanged()` when the user capitalizes words, to get those items repainted, if needed. It may not be needed immediately, if one or more of those items are not presently visible within the `RecyclerView`.

However, so far, our model data has been a static `String` array, and now we need a mutable model. So, we take the same approach as the `ListView` action mode samples use, converting our model to be an `ArrayList` that happens to be populated by a static `String` array.

The `items` data member of `MainActivity` is now an `ArrayList` of `String`, with the static `String` array being converted into `ORIGINAL_ITEMS`:

```
private static final String[] ORIGINAL_ITEMS={"lorem", "ipsum", "dolor",  
    "sit", "amet",  
    "consectetuer", "adipiscing", "elit", "morbi", "vel",
```

RECYCLERVIEW

```
        "ligula", "vitae", "arcu", "aliquet", "mollis",  
        "etiam", "vel", "erat", "placemat", "ante",  
        "porttitor", "sodales", "pellentesque", "augue", "purus"};  
private ArrayList<String> items;
```

Places that used to refer to items now use a private `getItems()` method, which lazy-instantiates the list if needed:

```
private ArrayList<String> getItems() {  
    if (items==null) {  
        items=new ArrayList<String>();  
  
        for (String s : ORIGINAL_ITEMS) {  
            items.add(s);  
        }  
    }  
  
    return(items);  
}
```

We also need to ensure that we hold onto the items across configuration changes, since those items could be changed by the user. So, our `onSaveInstanceState()` and `onRestoreInstanceState()` methods on `MainActivity` now handle that chore, in addition to their original behavior of having the `ChoiceCapableAdapter` persist checked states:

```
@Override  
public void onSaveInstanceState(Bundle state) {  
    adapter.onSaveInstanceState(state);  
    state.putStringArrayList(STATE_ITEMS, items);  
}  
  
@Override  
public void onRestoreInstanceState(Bundle state) {  
    adapter.onRestoreInstanceState(state);  
    items=state.getStringArrayList(STATE_ITEMS);  
}
```

(here, `STATE_ITEMS` is a static data member, serving as the constant key for the `Bundle` entry)

In order to be able to capitalize or remove the checked words from the list, we need to know which ones are checked. Rather than expose that data directly, `ChoiceMode` now has a `visitChecks()` method, where we can supply a `Visitor` to be invoked for every checked position:

```
package com.commonware.android.recyclerview.actionmodelist2;  
  
import android.os.Bundle;  
  
public interface ChoiceMode {
```

RECYCLERVIEW

```
void setChecked(int position, boolean isChecked);
boolean isChecked(int position);
void onSaveInstanceState(Bundle state);
void onRestoreInstanceState(Bundle state);
int getCheckedCount();
void clearChecks();
void visitChecks(Visitor v);

public interface Visitor {
    void onCheckedPosition(int position);
}
}
```

MultiChoiceMode implements `visitChecks()` by iterating over a *copy* of the `checkStates` `ParcelableSparseBooleanArray`. That way, if the visitor modifies `checkStates` (e.g., unchecks a position), our loop is unaffected.

```
@Override
public void visitChecks(Visitor v) {
    SparseBooleanArray copy=checkStates.clone();

    for (int i=0;i<copy.size();i++) {
        v.onCheckedPosition(copy.keyAt(i));
    }
}
```

`visitChecks()` is also exposed by `ChoiceCapableAdapter`, as are all the other methods on `ChoiceMode`.

Now, `IconicAdapter` can capitalize the words, by using `visitChecks()`:

```
case R.id.cap:
    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            String word=getItems().get(position);

            word=word.toUpperCase(Locale.ENGLISH);
            getItems().set(position, word);
            notifyItemChanged(position);
        }
    });
    break;
```

Here, for each checked item, we capitalize the word, replace the original word with its capitalized equivalent, and call `notifyItemChanged()` to let the `RecyclerView` know that this position had its model data changed and therefore should be repainted, if needed.

We also use `visitChecks()` now in `onDestroyActionMode()`, to avoid the `notifyDataSetChanged()` call:

RECYCLERVIEW

```
@Override
public void onDestroyActionMode(ActionMode mode) {
    if (activeMode != null) {
        activeMode=null;
        visitChecks(new ChoiceMode.Visitor() {
            @Override
            public void onCheckedPosition(int position) {
                onChecked(position, false);
                notifyItemChanged(position);
            }
        });
    }
}
```

Each item that was checked is unchecked, and we use `notifyItemChanged()` to ensure that the item is repainted if needed.

Now, checking some items and choosing “CAPITALIZE” from the action mode will capitalize those words:

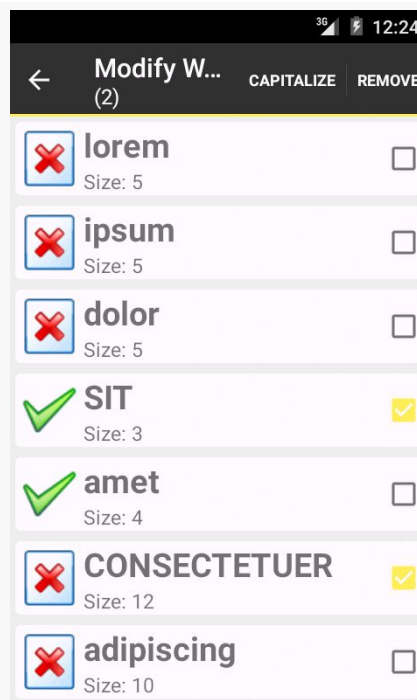

Figure 447: *ActionModeList2 RecyclerView Demo, with Capitalized Words*

Adding and Removing Items

There are also methods on `RecyclerView.Adapter` to specifically call out when you are adding or removing items from the adapter. Not only does this cause the

RECYCLERVIEW

RecyclerView to update itself, but it will animate the changes, if the relevant position(s) are visible.

Specifically, you can call:

- `notifyItemInserted()`, to indicate that a new item was inserted at a specified position, with everything else moving one position later in the roster
- `notifyItemRangeInserted()`, to insert several items in a block
- `notifyItemRemoved()`, to indicate a position that had an item removed from the roster, with later items moving up to take over earlier positions
- `notifyItemRangeRemoved()`, to remove several items in a block

The `ActionModeList2` sample uses `notifyItemRemoved()` as part of its handling of the remove action mode item:

```
case R.id.remove:
    final ArrayList<Integer> positions=new ArrayList<Integer>();

    visitChecks(new ChoiceMode.Visitor() {
        @Override
        public void onCheckedPosition(int position) {
            positions.add(position);
        }
    });

    Collections.sort(positions, Collections.reverseOrder());

    for (int position : positions) {
        getItems().remove(position);
        notifyItemRemoved(position);
    }

    clearChecks();
    activeMode.finish();
    break;
```

Because items slide up to take over vacated positions, when removing items, it is important to remove the lowest items first and work your way up the roster. That is why this code:

- Aggregates the list of positions that are checked
- Sorts the checked items in reverse order
- Iterates over the checked items, removing each from the `ArrayList` and calling `notifyItemRemoved()` to inform the adapter that the old item at this position is now gone

- Clears all of the checks from the ChoiceMode (as all checked items are now removed) and finishes the action mode (as there are no more checked items)

The result is that when the user removes items, they rapidly fade out, then later items in the list slide up to occupy the now-vacated space. If you would prefer to use other animations, you can do so, by creating your own subclass of `RecyclerView.ItemAnimator` and attaching it to the `RecyclerView` with `setItemAnimator()`.

The Order of Things

Version 22+ of `recyclerview-v7` offers `SortedList`. On the surface, the class appears to be a regular `List` that offers sorting. However, it also has a callback interface designed to be tied into `RecyclerView`, so that changes made to the `SortedList` can be reflected in the `RecyclerView` itself, complete with animations, optional batched processing, and so on.

This is illustrated in the [RecyclerView/SortedList](#) sample project. Along the way, we will also see how to use `RecyclerView` in a fragment and how to populate `RecyclerView` from the background thread.

The Gradle Change

This project requires version 22 or higher of `recyclerview-v7`, as the original v21 release of `recyclerview-v7` did not have `SortedList`. So, the Gradle build file requests something appropriate:

```
compile 'com.android.support:recyclerview-v7:22.2.0'  
compile 'com.android.support:cardview-v7:22.2.0'
```

Note that it pulls in the same version of `cardview-v7`. In general, it is best to try to keep Android Support package libraries in sync, at least in terms of major versions. Similarly, it is best to have the `compileSdkVersion` match the major library version, as the library may be conditionally using APIs made available in that version of Android. Hence, the project also has `compileSdkVersion` (and `buildTools`) set to pull from v22:

```
compileSdkVersion 22  
buildToolsVersion "22.0.1"
```

The RecyclerViewFragment

Prior samples in this chapter used a RecyclerViewActivity for basic RecyclerView setup. However, in this sample, we want to use a retained fragment for managing the AsyncTask, which suggests putting the RecyclerView in a fragment, rather than having it be managed directly by the activity.

So, this project has a reworking of RecyclerViewActivity into RecyclerViewFragment:

```
package com.commonware.android.recyclerview.sorted;

import android.app.Fragment;
import android.os.Bundle;
import android.support.v7.widget.RecyclerView;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class RecyclerViewFragment extends Fragment {
    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container,
        Bundle savedInstanceState) {
        RecyclerView rv=new RecyclerView(getActivity());

        rv.setHasFixedSize(true);

        return(rv);
    }

    public void setAdapter(RecyclerView.Adapter adapter) {
        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        return(getRecyclerView().getAdapter());
    }

    public void setLayoutManager(RecyclerView.LayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        return((RecyclerView)getView());
    }
}
```

Basically, what had been in onCreate() mostly moves into onCreateView(), where we set up the RecyclerView. The rest of the core API is unchanged.

The project has SortedFragment, which extends RecyclerViewFragment and handles loading of the data — we will examine more of it later in this chapter.

RECYCLERVIEW

The revised MainActivity then just loads up SortedFragment via a FragmentTransaction:

```
package com.commonware.android.recyclerview.sorted;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new SortedFragment()).commit();
        }
    }
}
```

The SortedFragment

Most of SortedFragment is reminiscent of the original AsyncTask demo from [the chapter on threads](#), mashed up with one of the CardView/RecyclerView samples from earlier in this chapter. However, the SortedList gets weaved throughout.

The SortedList

The model in the original AsyncTask demo was a simple ArrayList. Now it is a SortedList, initialized in onCreate() of the SortedFragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    model=new SortedList<String>(String.class, sortCallback);

    task=new AddStringTask();
    task.execute();
}
```

The SortedList constructor takes two parameters:

- the Java class object for the models inside the list (in this case, String.class)

RECYCLERVIEW

- a `SortedList.Callback` object that will be invoked when the model changes based on List APIs (e.g., `add()`, `insert()`, `remove()`)

There is an optional third parameter for the capacity, unused in this sample.

We will take a peek at the `SortedList.Callback` implementation, named `sortCallback`, shortly.

The IconicAdapter

The `IconicAdapter` from earlier `RecyclerView` samples worked directly off of the static array of `String` values. Now, we want it to work off of the model `SortedList`. Hence, `onBindViewHolder()` and `getItemCount()` need to be modified to refer to appropriate methods on the model:

```
class IconicAdapter extends RecyclerView.Adapter<RowController> {
    @Override
    public RowController onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowController(getActivity().getLayoutInflater()
            .inflate(R.layout.row, parent, false)));
    }

    @Override
    public void onBindViewHolder(RowController holder, int position) {
        holder.bindModel(model.get(position));
    }

    @Override
    public int getItemCount() {
        return(model.size());
    }
}
```

Also note that when we create the adapter in `onViewCreated()`, that we hold onto it in an adapter data member of the fragment:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setLayoutManager(new LinearLayoutManager(getActivity()));
    adapter=new IconicAdapter();
    setAdapter(adapter);
}
```

The SortedList.Callback

The job of the `SortedList.Callback` is to serve as the bridge between the `SortedList` and the `RecyclerView.Adapter`.

`SortedList`, as the name suggests, sorts its contents. That means that any change to the `SortedList` contents can have different impacts on the `RecyclerView`. For example, while an `add()` to an `ArrayList` would just add a new row to the end of the `RecyclerView`, an `add()` on `SortedList` might need to insert a row in the middle of the `RecyclerView`, to maintain the sorted order.

Hence, your `SortedList.Callback` is responsible for two things:

- Helping with the sorting itself, by comparing elements
- Passing information about how the sorting is done out to the `RecyclerView.Adapter`, so the appropriate moves can be made there, complete with animations

With that in mind, here is the `sortedCB` implementation of `SortedList.Callback`:

```
private SortedList.Callback<String> sortCallback=new SortedList.Callback<String>() {
    @Override
    public int compare(String o1, String o2) {
        return o1.compareTo(o2);
    }

    @Override
    public boolean areContentsTheSame(String oldItem, String newItem) {
        return(areItemsTheSame(oldItem, newItem));
    }

    @Override
    public boolean areItemsTheSame(String oldItem, String newItem) {
        return(compare(oldItem, newItem)==0);
    }

    @Override
    public void onInserted(int position, int count) {
        adapter.notifyItemRangeInserted(position, count);
    }

    @Override
    public void onRemoved(int position, int count) {
        adapter.notifyItemRangeRemoved(position, count);
    }

    @Override
    public void onMoved(int fromPosition, int toPosition) {
        adapter.notifyItemMoved(fromPosition, toPosition);
    }
}
```

```
@Override
public void onChanged(int position, int count) {
    adapter.notifyItemRangeChanged(position, count);
}
};
```

The first method is your standard sort of `compare()` comparison method, as you might implement on a `Comparator`. It should return zero if the two model objects are the same from a sorting standpoint, a negative number if the first parameter sorts before the second parameter, or a positive number if the first parameter sorts after the second parameter.

Then there are two similarly-named methods that serve as more-or-less replacements for the `equals()` that you might have on a `Comparator`: `areContentsTheSame()` and `areItemsTheSame()`.

`areItemsTheSame()` should return `true` if the two passed-in values represent the same actual logical item. In the case of `SortedFragment`, that is simply whether or not the strings are equal. But, with a more complex data model, you might be comparing primary keys or some other form of immutable identifier.

`areContentsTheSame()` should return `true` if the visual representation of the items look the same, as this will be used to optimize the changes made to the `RecyclerView`.

For example, suppose a shopping cart fragment wanted to use `SortedList`. Further suppose that if you added three boxes of laundry detergent to the cart, rather than having one row in the list with “Quantity: 3”, you were representing them as three rows in the `RecyclerView`. In this case:

- `compare()` returns a value to indicate the sorting rules of those shopping cart items, perhaps based on the title of the item
- `areItemsTheSame()` might return `false` for any combination of these three items, as they are logically distinct rows within the `RecyclerView`
- `areContentsTheSame()` might return `true` for any combination of these three items, as while they are three separate line items, each is visually identical in terms of what the `RecyclerView` rows look like

In many cases, `areContentsTheSame()` can simply invoke `areItemsTheSame()`, under the premise that different items *probably* have different visual representations. That is what is done in this sample, where `areItemsTheSame()` in turn uses `compare()` to see whether or not the items are the same.

RECYCLERVIEW

Finally, there are four `on...()` methods that are simply forwarded along to their `RecyclerView.Adapter` counterparts, so changes to the `SortedList` make the corresponding changes to the `RecyclerView` contents.

Note that there is a `SortedListAdapterCallback` that takes a `RecyclerView.Adapter` as a constructor parameter and handles the `on...()` methods for you. However, since we want to retain the `SortedList` across configuration changes, and since `SortedList` does not allow us to change the `SortedList.Callback` object, we cannot readily switch the `SortedList` to the new fragment and new adapter after a configuration change.

The AsyncTask

The `AddStringTask` is the same as with the original `AsyncTask` sample, except that now it adds the words to the `SortedList`, which (via its `Callback`) will update the `RecyclerView`:

```
private class AddStringTask extends AsyncTask<Void, String, Void> {
    @Override
    protected Void doInBackground(Void... unused) {
        for (String item : items) {
            if (isCancelled())
                break;

            publishProgress(item);
            SystemClock.sleep(400);
        }

        return(null);
    }

    @Override
    protected void onProgressUpdate(String... item) {
        if (!isCancelled()) {
            model.add(item[0]);
        }
    }

    @Override
    protected void onPostExecute(Void unused) {
        Toast.makeText(getActivity(), R.string.done, Toast.LENGTH_SHORT)
            .show();

        task=null;
    }
}
```

The Results

If you run this sample, you will see the words be added to the list, every 400ms. However, in the original `ListView`-based sample, new rows were appended to the end, and so you would not see new rows appear after the `ListView` space was filled. In this sample, the Latin words are sorted by `SortedList`, and you will see them animate into position at the appropriate spots as they are added. In the end, you get the same look as in earlier `CardView`-based `RecyclerView` implementations, except that the words are sorted:

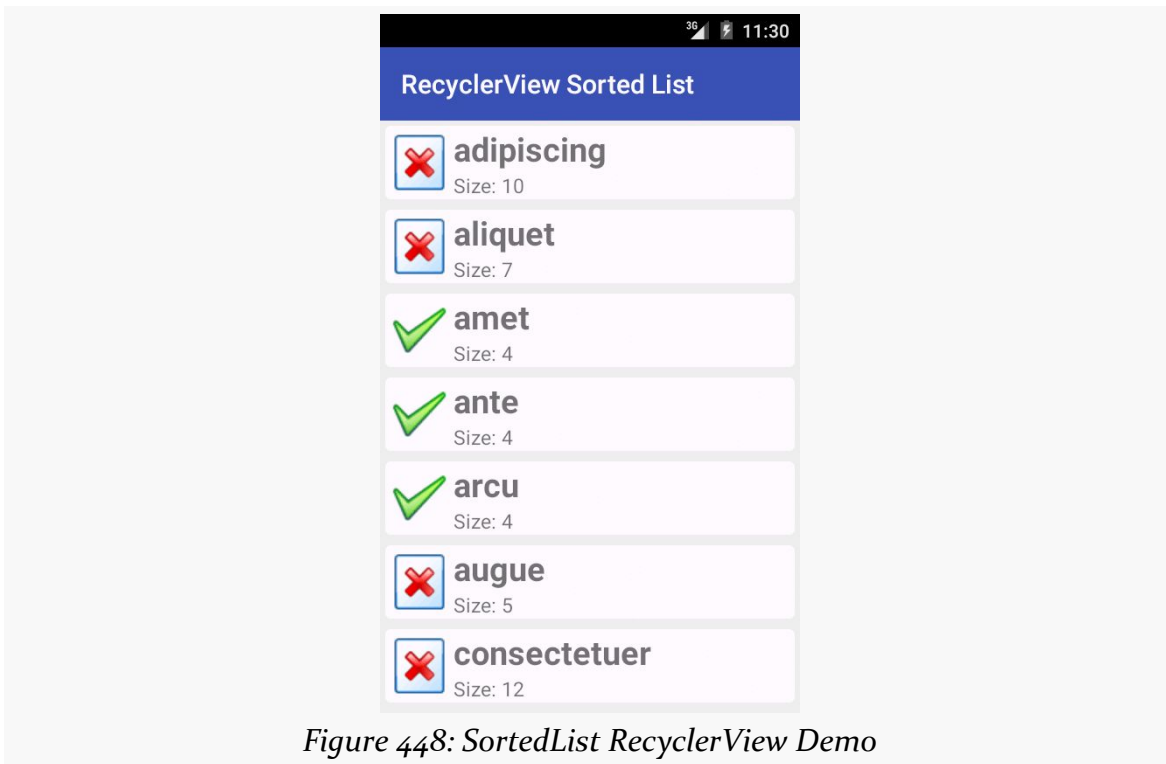

Figure 448: SortedList RecyclerView Demo

Other Bits of Goodness

To quote the infamous American infomercial line: “But wait! There’s more!”

In addition to `LinearLayoutManager` and `GridLayoutManager`, there is `StaggeredGridLayoutManager`. With a vertically-scrolling `GridLayoutManager`, rows are all a consistent height, but the cell widths might vary. With a vertically-scrolling `StaggeredGridLayoutManager`, the columns are all the same width, but the cell heights might vary.

All three of the standard layout managers support horizontal operation as well, through a boolean on a constructor. In these cases, the content will scroll horizontally, rather than vertically. This eliminates the need for third-party horizontal `ListView` implementations and the like.

And, of course, you can implement your own `RecyclerView.LayoutManager`, eschewing any of the built-in ones.

The March of the Libraries

By this point in time, you may be wailing in anguish and rending your garments over how much is involved in getting `RecyclerView` going.

(pro tip: do not rend your garments in public, to avoid running afoul of indecency laws)

There is little doubt that `RecyclerView` is the epitome of “some assembly required”. However, other developers have come to the forefront with libraries that can help fill in these gaps without you having to roll all the code yourself.

Note that the author has not tried many of these libraries, and listing them here neither is an endorsement of these libraries nor a knock on any libraries not listed here.

DynamicRecyclerView

The [DynamicRecyclerView library](#) offers:

- Drag and drop reordering of items, via a simple custom `OnItemTouchListener` implementation
- An implementation of the horizontal “swipe-to-dismiss” UI pattern, also via a custom `OnItemTouchListener` implementation
- An implementation of choice modes, akin to those shown in this chapter
- An implementation of click-style events, by handling them as touch events using yet another custom `OnItemTouchListener` implementation

Advanced RecyclerView

The [Advanced RecyclerView library](#) offers its own drag-and-drop and swipe-to-dismiss implementations. Rather than using `OnItemTouchListener`

implementations, you implement certain interfaces on your `RecyclerView.Adapter` and `RecyclerView.ViewHolder` classes to support drag-and-drop and/or swipe-to-dismiss, plus work with “manager” classes to tie the support together.

It also supports an expandable item, where clicking on the item expands or collapses a set of views vertically beneath the item, offering an approach for using `RecyclerView` to replace `ExpandableListView`. And, it has a few item decorators, including a basic divider implementation.

SuperRecyclerView

The [SuperRecyclerView library](#) has its own swipe-to-dismiss implementation. It also supports the “swipe layout” pattern, where a horizontal swipe gesture slides out the main view and uncovers a set of contextual operations on the item.

It also offers:

- scrollbars (which are not enabled on `RecyclerView`)
- progress bars and/or empty views to handle the asynchronous loading of data
- an “endless” or “infinite scrolling” implementation, where when the user scrolls to the bottom of the data, you get a chance to go load more data
- sticky headers, where as the user scrolls, the top-most header remains pinned to the top of the `RecyclerView`, until replaced by a new header that scrolls to the top

However, this library requires that you inherit from a custom `RecyclerView` subclass.

FlexibleDivider

The [FlexibleDivider library](#) does just one thing: provides dividers. However, it offers *deep* support for dividers, where you can easily control all sorts of aspects, from color and width to margins and path effects (e.g., dashed lines versus solid lines).

The [RecyclerView/FlexDividerList](#) sample project is a clone of the `ManualDividerList` sample from earlier in the chapter, where the dividers are now provided by the `FlexibleDivider` library, which is loaded via the `build.gradle` file:

```
dependencies {  
    compile 'com.android.support:recyclerview-v7:22.2.0'  
    compile 'com.yqritc:recyclerview-flexibledivider:1.0.1'  
}
```

RECYCLERVIEW

Then, we use the library's `HorizontalDividerItemDecoration` to set up our dividers:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(new LinearLayoutManager(this));

    RecyclerView.ItemDecoration decor =
        new HorizontalDividerItemDecoration.Builder(this)
            .color(getResources().getColor(R.color.primary))
            .build();

    getRecyclerView().addItemDecoration(decor);
    setAdapter(new IconicAdapter());
}
```

The results are a solid blue divider:

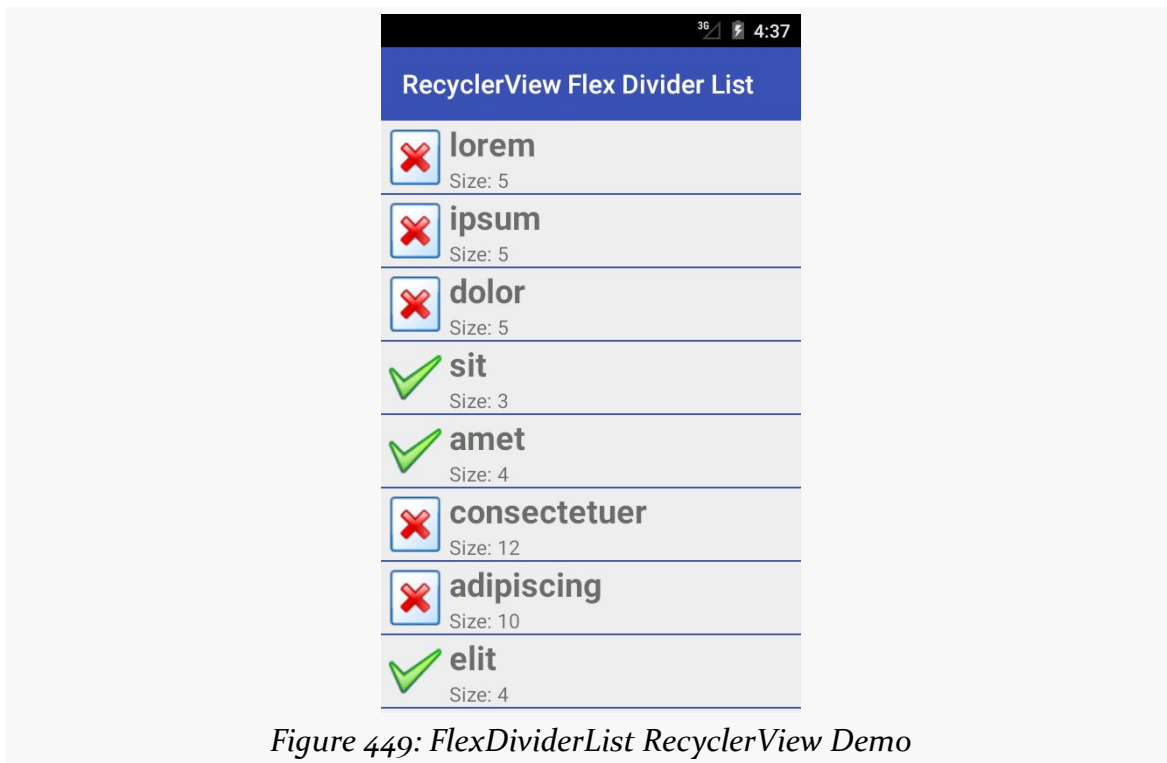

Figure 449: *FlexDividerList RecyclerView Demo*

Of course, through the library, you can change a lot more about the divider than just its color, through its builder-style API.

Implementing a Navigation Drawer

Each year brings a new design pattern in Android that takes the development community by storm. In 2011, it was the [action bar](#). In 2012, it was [ViewPager](#). In 2013, it was the navigation drawer.

This chapter covers that navigation drawer pattern: what it is, where you use it, and how you implement it, using a `DrawerLayout` class supplied by the Android Support package.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, one section ties into [the chapter on action modes](#).

What is a Navigation Drawer?

Complex apps often require complex navigation, to get to all of the different areas of the app. And, in many cases, that navigation is tied to nouns, reflecting different types of content, more so than verbs, reflecting operations to be performed against a particular piece of content. Verbs are actions, and can usually go in the action bar as action bar items (e.g., toolbar-style buttons). Nouns *could* be put in the action bar as well as items, though having a mixed bunch of nouns and verbs makes the action bar item roster inconsistent.

Back before the action bar, the “go-to” design pattern for navigation was the so-called “dashboard”:

IMPLEMENTING A NAVIGATION DRAWER

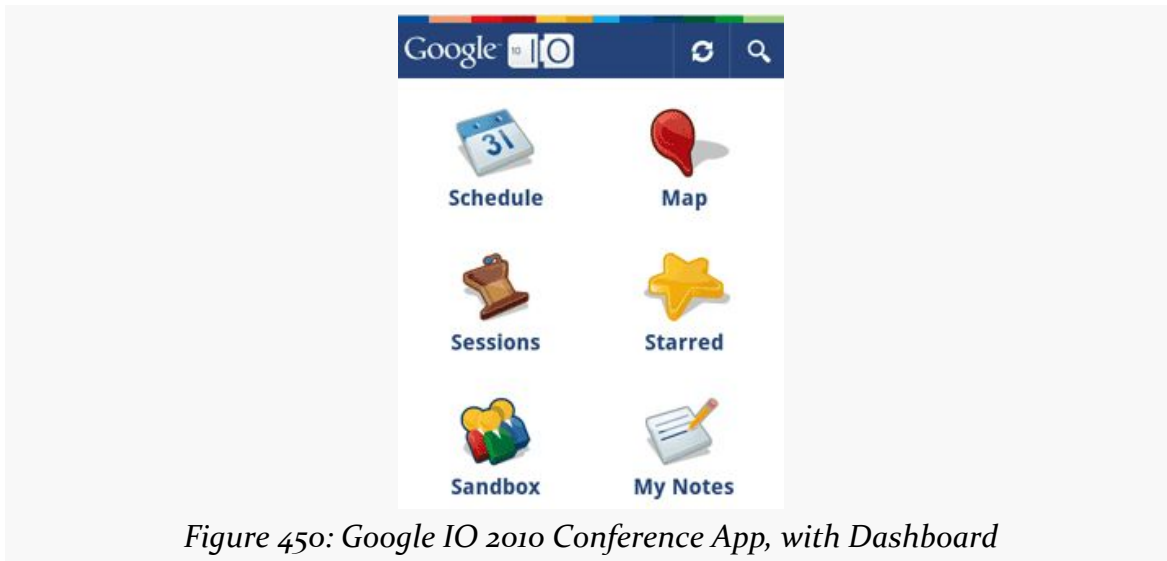

Figure 450: Google IO 2010 Conference App, with Dashboard

But this took up the whole screen and was therefore only available as the “home” activity of an app.

The navigation drawer, or “sliding menu”, pattern has the same sort of content navigation options available in a drawer that slides out from the side of the screen:

IMPLEMENTING A NAVIGATION DRAWER

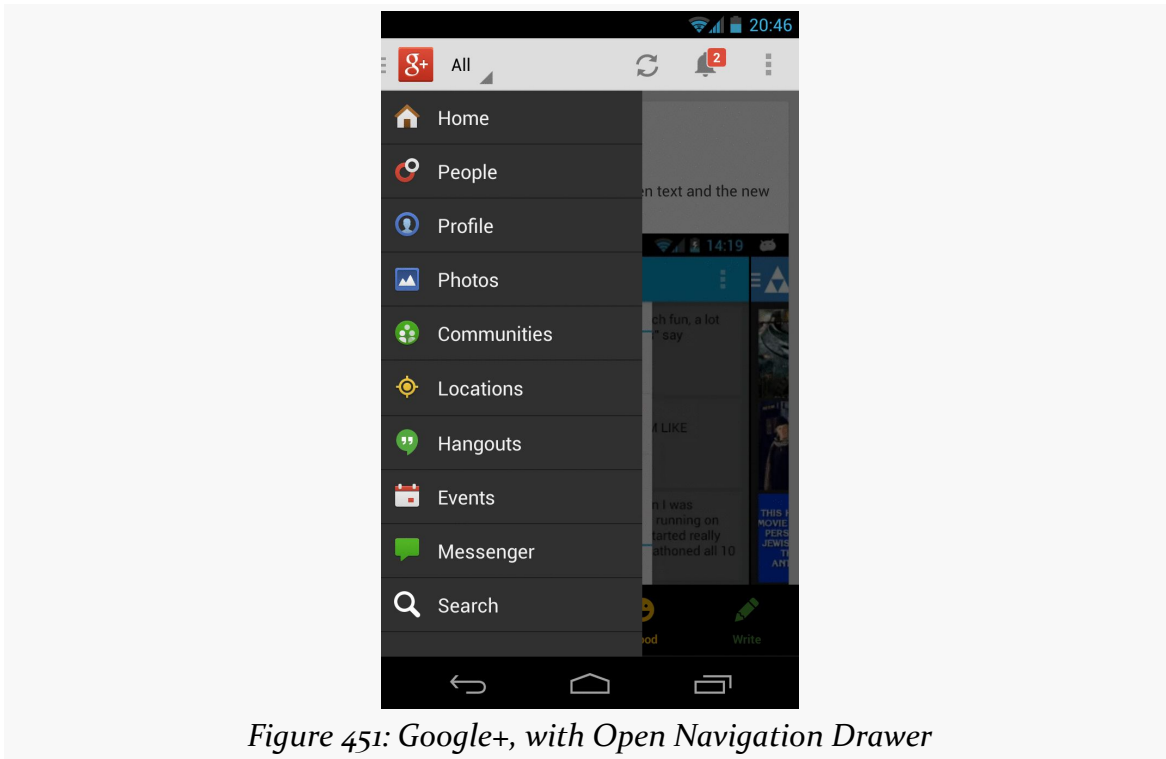

Figure 451: Google+, with Open Navigation Drawer

The drawer can be accessed from many, if not all, activities in the app, to allow the user to get wherever they need to from wherever they happen to be.

A Simple Navigation Drawer

The good news is that Google released an implementation of the navigation drawer pattern, called `DrawerLayout`, in the Android Support package (`support-v4` and `support-v13`).

The bad news is that it still takes a bit of work to get this integrated with your app.

This section will review the [NavDrawer/Simple](#) sample project, that shows a fairly simplistic integration of a `DrawerLayout` into an activity.

The Activity Layout

The root element of your activity layout, for an activity using `DrawerLayout`, is `DrawerLayout` itself:

IMPLEMENTING A NAVIGATION DRAWER

```
<android.support.v4.widget.DrawerLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/drawer_layout"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <FrameLayout
        android:id="@+id/content"
        android:layout_width="match_parent"
        android:layout_height="match_parent"/>

    <ListView
        android:id="@+id/drawer"
        android:layout_width="240dp"
        android:layout_height="match_parent"
        android:layout_gravity="start"
        android:background="#111"
        android:choiceMode="singleChoice"
        android:divider="@android:color/transparent"
        android:dividerHeight="0dp"/>

</android.support.v4.widget.DrawerLayout>
```

DrawerLayout itself is rather unremarkable in the layout resource: you size and position it, usually to fill the screen. It needs to have precisely two child elements:

1. The first child represents the “real” activity content
2. The second child represents the contents of the drawer that can be opened and closed

If you are adapting an existing activity to use the DrawerLayout, that first child could well be an `<include>` element pointing to your existing activity layout resource, so that you can leave it undisturbed and just point your activity to start with this new DrawerLayout resource.

There are a couple of attributes in the children that are important for proper DrawerLayout operation:

- The second child — often a `ListView` — needs to have its `android:layout_gravity` set to indicate what side of the screen the drawer will slide out from. Typically this will be `left` (or `start` if you are on API Level 17+ and are taking advantage of the RTL layout support).
- The second child also specifies its `android:layout_width` to indicate the size of the drawer when opened. This should *not* be the full width of the screen, and the [Android design guidelines](#) suggest a width between 240dp and 320dp.

The ActionBarDrawerToggle

The `onCreate()` method of `MainActivity` is responsible for setting up the drawer, as well as the activity's main content:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
        showLorem();
    }

    ListView drawer=(ListView)findViewById(R.id.drawer);

    drawer.setAdapter(new ArrayAdapter<String>(
        this,
        R.layout.drawer_row,
        getResources().getStringArray(R.array.drawer_rows)));
    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
            R.drawable.ic_drawer,
            R.string.drawer_open,
            R.string.drawer_close);
    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);
}
```

In terms of the content, if the `FrameLayout` placed in the layout resource is empty, we call `showLorem()` to lazy-create a `LoremFragment` (a `ListFragment` with 25 Latin words) and run a `FragmentManager` to display it:

```
private void showLorem() {
    if (lorem == null) {
        lorem=new LoremFragment();
    }

    if (!lorem.isVisible()) {
        getFragmentManager().beginTransaction()
            .replace(R.id.content, lorem).commit();
    }
}
```

`onCreate()` then retrieves the `ListView`, sets the contents of the list to be a `<string-array>` resource named `drawer_rows`, and sets up the activity itself to respond to clicks on the list.

IMPLEMENTING A NAVIGATION DRAWER

`onCreate()` then sets up an `ActionBarDrawerToggle`. This allows the app icon on the left of the action bar to open and close the navigation drawer. The `ActionBarDrawerToggle` constructor takes five parameters:

- The Activity as a Context
- The `DrawerLayout` widget to be managed by this toggle
- The icon to superimpose on the app icon to indicate that there is a toggle
- String resources for the open and close operations, for accessibility

The sample app uses icons from Google’s discontinued “Action Bar Icon Pack” for the third parameter. In addition, the [Android Asset Studio](#) offers a way for you to customize the navigation drawer indicator artwork for other themes.

In addition to creating the toggle instance, we need to:

- Associate it with the `DrawerLayout`, by calling `setDrawerListener()` on it
- Enable the app icon via `setHomeButtonEnabled()` and enable it for “up” navigation via `setDisplayHomeAsUpEnabled()`
- Forward the `onPostCreate()`, `onConfigurationChanged()`, and `onOptionsItemSelected()` activity callback methods on to the toggle:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    toggle.syncState();
}

@Override
public void onConfigurationChanged(Configuration newConfig) {
    super.onConfigurationChanged(newConfig);

    toggle.onConfigurationChanged(newConfig);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (toggle.onOptionsItemSelected(item)) {
        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

Without any additional work, launching the app will show the “mini hamburger” navigation drawer icon in the action bar:

IMPLEMENTING A NAVIGATION DRAWER

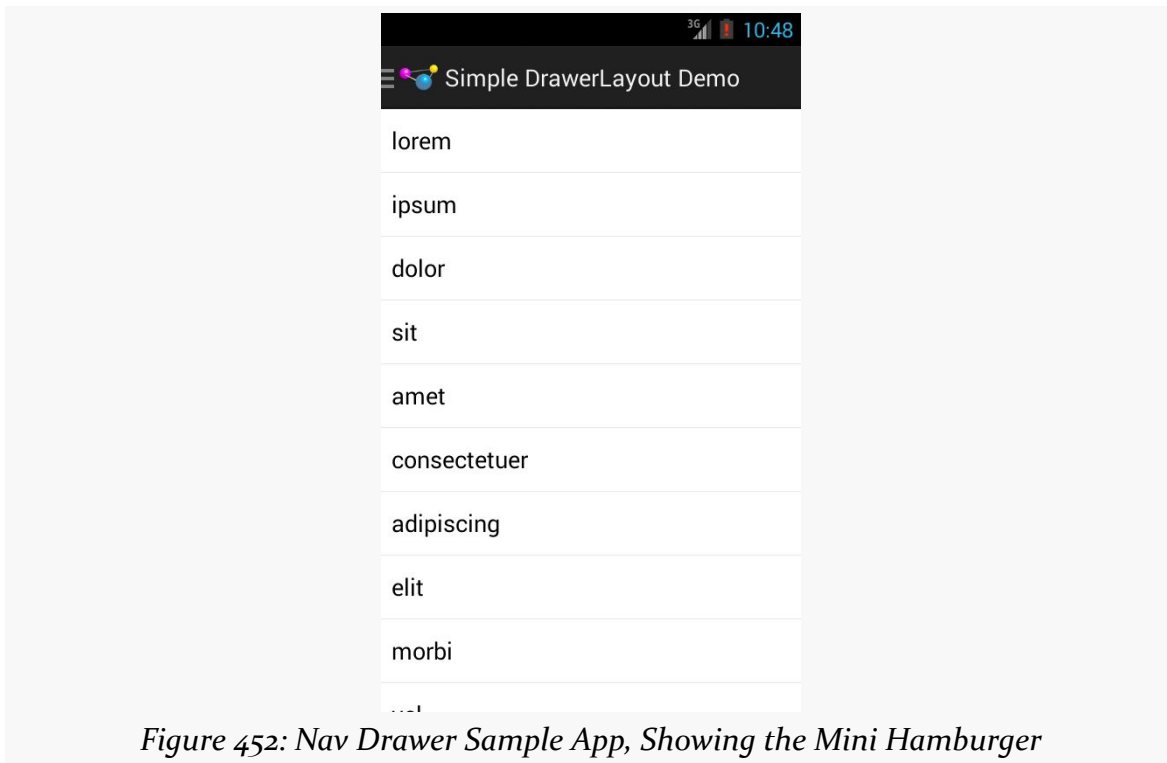

Figure 452: Nav Drawer Sample App, Showing the Mini Hamburger

Tapping the app icon will open the drawer:

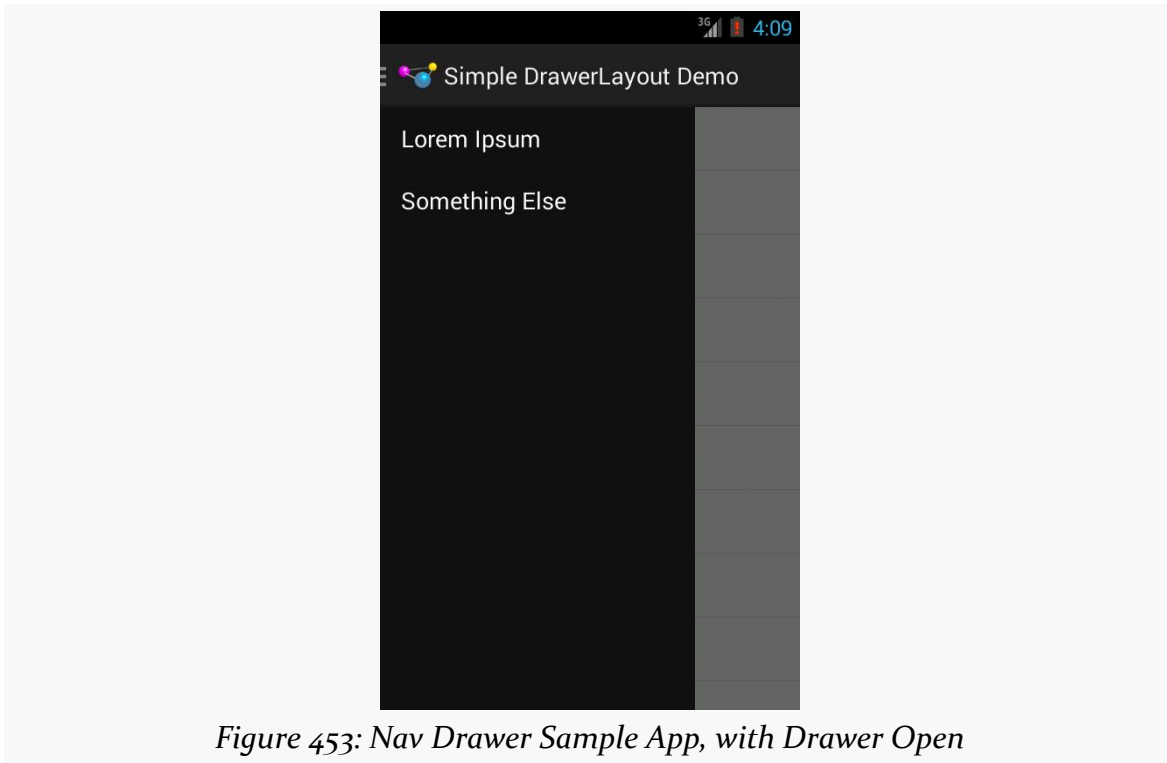

Figure 453: Nav Drawer Sample App, with Drawer Open

The drawer slides over the content, rather than pushing the content away, which is why we do not see the words peeking out on the right side of the screen.

Tapping the app icon again will close the drawer.

The user can also open the drawer via gestures. A bezel swipe from the left side will open the drawer, and swiping the open drawer right to left will close it. In addition, tapping and holding on the left edge of the content will cause the drawer to “peek” open by a handful of pixels, to hint to the user that there may be something that they can access by swiping from the left.

NOTE: This implementation of `ActionBarDrawerToggle` is officially deprecated as of the 21.0.0 version of the Android Support library. However, it is still necessary, at this time, for using `DrawerLayout` with the native action bar.

The Actions on Navigation Clicks

Of course, a navigation drawer is useless unless we do something when the user interacts with it, clicking on list rows in this case.

IMPLEMENTING A NAVIGATION DRAWER

Our list is very simple, with just two elements. The app simply toggles between two fragments based upon the list item click:

```
@Override
public void onItemClick(AdapterView<?> listView, View row,
                        int position, long id) {
    if (position == 0) {
        showLorem();
    }
    else {
        showContent();
    }

    drawerLayout.closeDrawers();
}
```

We also close the drawer, using `closeDrawers()`, as otherwise the `DrawerLayout` is unaware that the user chose something and that we should return to the content.

Alternative Row Layouts

The rows in the sample app's `ListView` were fairly conventional. Rows in a nav drawer should be fairly simple, as you are merely trying to lead the users to pieces of content, not present content itself.

That being said, the navigation options can have a bit more to them than what the sample app showed. The [Android design guidelines](#) will steer you in the direction of how best to style:

- Rows with leading icons
- Rows with trailing badges (e.g., unread message counts)
- Expandable sections (e.g., less-important items but still worth having in the drawer)
- Dividers, to help organize groups of related rows

IMPLEMENTING A NAVIGATION DRAWER

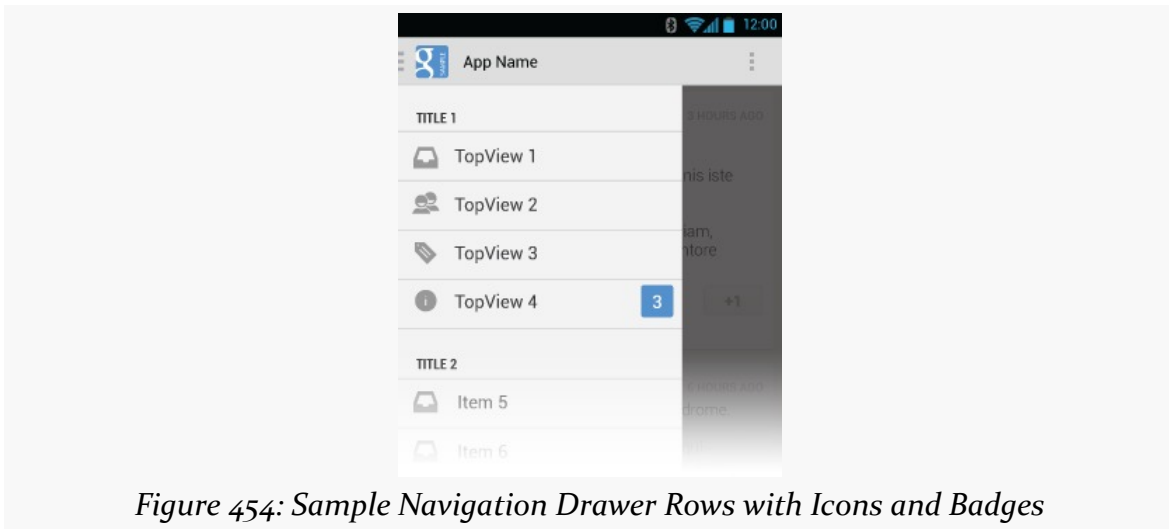

Figure 454: Sample Navigation Drawer Rows with Icons and Badges

You will see other apps experiment with other capabilities. For example, Gmail used to use RadioButton widgets for the accounts:

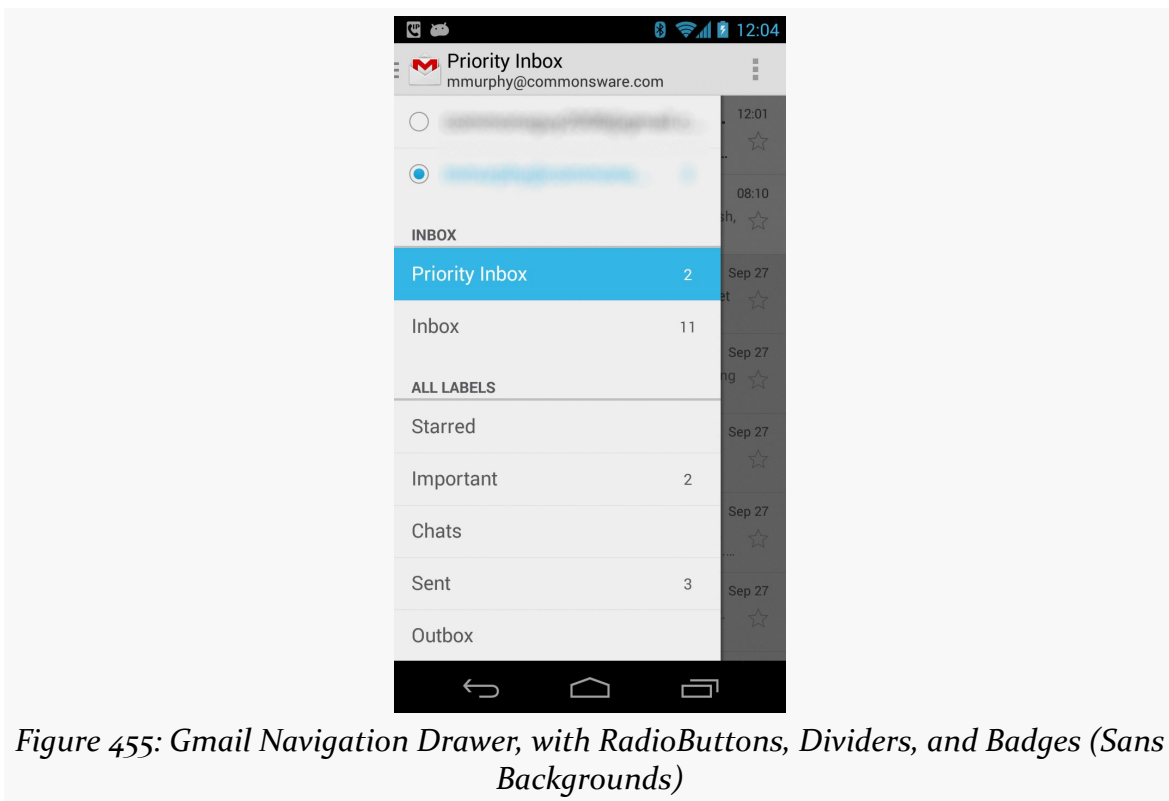

Figure 455: Gmail Navigation Drawer, with RadioButtons, Dividers, and Badges (Sans Backgrounds)

That being said, the closer you can stick with the official design guidelines, the better off you will tend to be, in terms of meeting user expectations and not encountering rendering or click event oddities with `DrawerLayout`.

Additional Considerations

Beyond putting the right things into the navigation drawer, there are some other things that you will need to take into account, particularly as your navigation drawer interacts with the rest of the activity and overall application.

Highlighting the Current Location

If the user opens the navigation drawer, and they are already at one of the navigation destinations shown in the drawer, that destination should show up with the activated state, to indicate to the user that she is already there. Conversely, if the user has drilled down into some part of your application that does *not* have a corresponding entry in the navigation drawer, the navigation drawer should show no activated entry.

One way to handle this is to keep the `ListView` updated as the user navigates (whether through the navigation drawer or by other means), selecting and de-selecting items as needed.

The row layout used in the original sample, culled from [Google's DrawerLayout sample code](#), already has the activated background:

```
<android.support.v4.widget.DrawerLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/drawer_layout"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <FrameLayout
        android:id="@+id/content"
        android:layout_width="match_parent"
        android:layout_height="match_parent"/>

    <ListView
        android:id="@+id/drawer"
        android:layout_width="240dp"
        android:layout_height="match_parent"
        android:layout_gravity="start"
        android:background="#111"
        android:choiceMode="singleChoice"
        android:divider="@android:color/transparent"
        android:dividerHeight="0dp"/>
```

IMPLEMENTING A NAVIGATION DRAWER

```
</android.support.v4.widget.DrawerLayout>
```

However, we were not using it in that sample, so the drawer `ListView` did not give the user any indication that they had already navigated to a navigable destination. But, we have the [NavDrawer/Activated](#) sample project, a clone of the original sample, that adds this activation capability, and demonstrates the headaches it causes.

First, as part of our `onCreate()` work in `MainActivity`, we need to configure the `ListView` to work in single-choice mode (the `ListView` engine behind the activated state), along with the rest of the `ListView` setup:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    drawer=(ListView)findViewById(R.id.drawer);
    drawer.setChoiceMode(ListView.CHOICE_MODE_SINGLE);

    String[] rows=getResources().getStringArray(R.array.drawer_rows);

    drawer.setAdapter(new ArrayAdapter<String>(this,
                                                R.layout.drawer_row,
                                                rows));

    drawer.setOnItemClickListener(this);

    drawerLayout=(DrawerLayout)findViewById(R.id.drawer_layout);
    toggle=
        new ActionBarDrawerToggle(this, drawerLayout,
                                   R.drawable.ic_drawer,
                                   R.string.drawer_open,
                                   R.string.drawer_close);

    drawerLayout.setDrawerListener(toggle);
    getActionBar().setDisplayHomeAsUpEnabled(true);
    getActionBar().setHomeButtonEnabled(true);

    getFragmentManager().addOnBackStackChangeListener(this);

    if (getFragmentManager().findFragmentById(R.id.content) == null) {
        showLorem();
    }
}
```

Our `showLorem()` method now will `post()` a `Runnable`, named `onNavChange`, after it calls `commit()` on its `FragmentManager`:

```
private void showLorem() {
    if (lorem == null) {
        lorem=new LoremFragment();
    }
}
```

IMPLEMENTING A NAVIGATION DRAWER

```
if (!lorem.isVisible()) {
    getFragmentManager().popBackStack();
    getFragmentManager().beginTransaction()
        .replace(R.id.content, lorem).commit();
    drawer.post(onNavChange);
}
}
```

That magic `onNavChange` Runnable simply sees what fragment is presently visible and updates the checked item in the nav drawer's `ListView` to match:

```
private Runnable onNavChange=new Runnable() {
    @Override
    public void run() {
        if (lorem != null && lorem.isVisible()) {
            drawer.setItemChecked(0, true);
        }
        else if (content != null && content.isVisible()) {
            drawer.setItemChecked(1, true);
        }
        else {
            int toClear=drawer.getCheckedItemPosition();

            if (toClear >= 0) {
                drawer.setItemChecked(toClear, false);
            }
        }
    }
};
```

By using `post()`, we schedule the Runnable to be executed after the fragment change has occurred. Ideally, we would somehow more explicitly attach the Runnable to the `FragmentManager`, but [that does not appear to be an option](#).

Since we call `showLorem()` in `onCreate()`, this causes our navigation drawer to show that we are in `LoremFragment` when the activity first starts up:

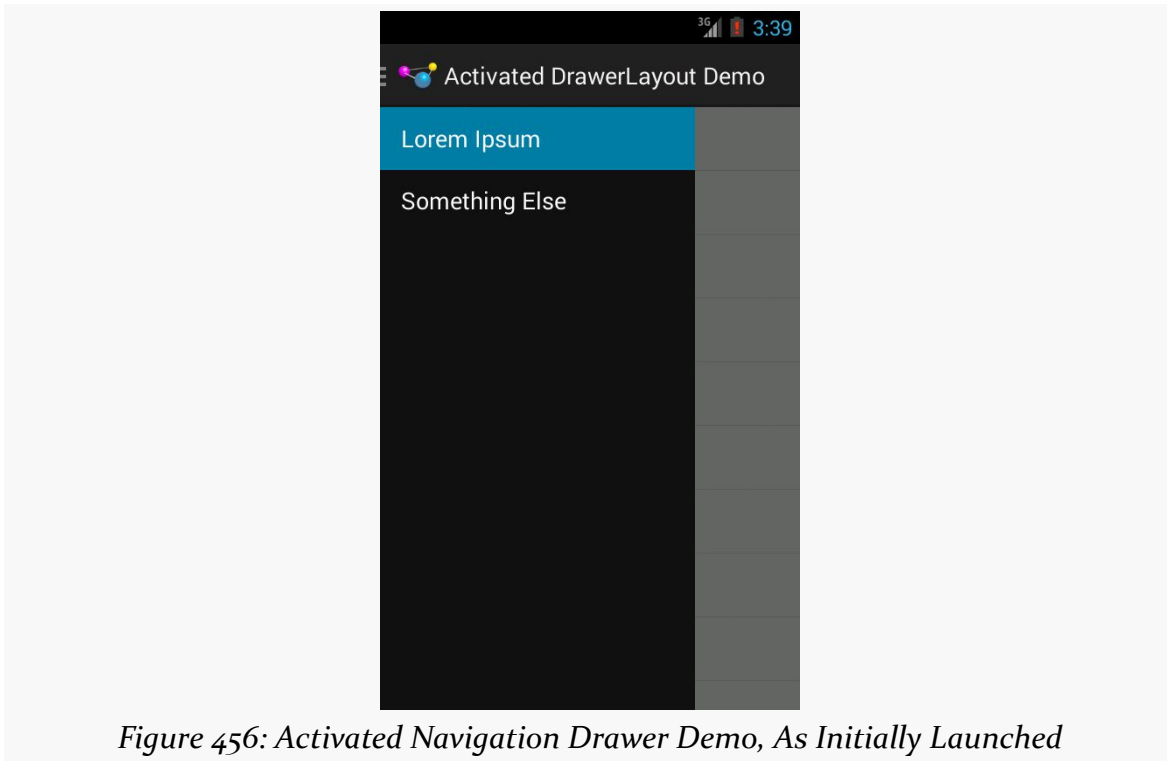

Figure 456: Activated Navigation Drawer Demo, As Initially Launched

The natural behavior of a single-choice `ListView` will check the row that we tap upon, and so when the user taps on an entry in the navigation drawer, it automatically becomes activated. This means we do not have to do our own work for that.

If *everything* in your app is represented by an entry in the navigation drawer, your work is done. However, most likely, there are parts of your app that do not directly map to entries in the navigation drawer... and that is where things get a wee bit complex.

To demonstrate this, we need a bit more to our UI. So, we make `LoremFragment` use the contract pattern, seen elsewhere in the book. We override `onListItemClick()` to call a `wordClicked()` method on the contract, to let the hosting activity know about that UI operation:

```
package com.commonware.android.drawer.activated;

import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ListView;
```

IMPLEMENTING A NAVIGATION DRAWER

```
public class LoremFragment extends ContractListFragment<LoremFragment.Contract> {
    private static final String[] items= { "lorem", "ipsum", "dolor",
        "sit", "amet", "consectetuer", "adipiscing", "elit", "morbi",
        "vel", "ligula", "vitae", "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante", "porttitor", "sodales",
        "pellentesque", "augue", "purus" };

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setListAdapter(new ArrayAdapter<String>(
            getActivity(),
            android.R.layout.simple_list_item_1,
            items));
    }

    @Override
    public void onItemClick(ListView l, View v, int position, long id) {
        getContract().wordClicked();
    }

    interface Contract {
        void wordClicked();
    }
}
```

We also create a StuffFragment that displays a simple message:

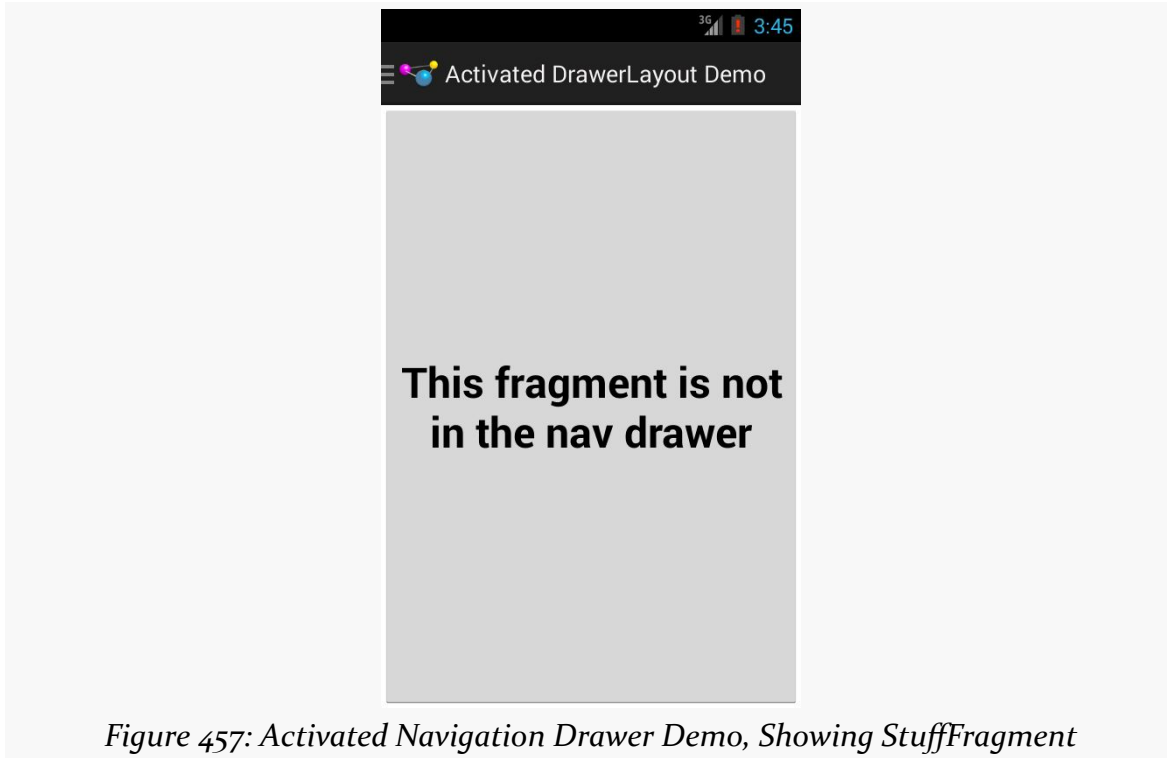

Figure 457: Activated Navigation Drawer Demo, Showing StuffFragment

IMPLEMENTING A NAVIGATION DRAWER

The idea is that clicking on a word in the LoremFragment should bring up the StuffFragment, as if this were a master/detail implementation.

The implementation of wordClicked() in MainActivity does indeed show a StuffFragment (while also adding it to the back stack), but it also needs to make the drawer ListView have no checked items, reflecting the fact that the UI state does not reflect one of the navigation destinations:

```
@Override
public void wordClicked() {
    if (stuff == null) {
        stuff=new StuffFragment();
    }

    getFragmentManager().beginTransaction()
        .replace(R.id.content, stuff)
        .addToBackStack(null).commit();
    drawer.post(onNavChange);
}
```

Note that we also post() the onNavChange Runnable here as well.

The result is that when we do tap on a word in the list, the StuffFragment appears, but the navigation drawer shows no activated row:

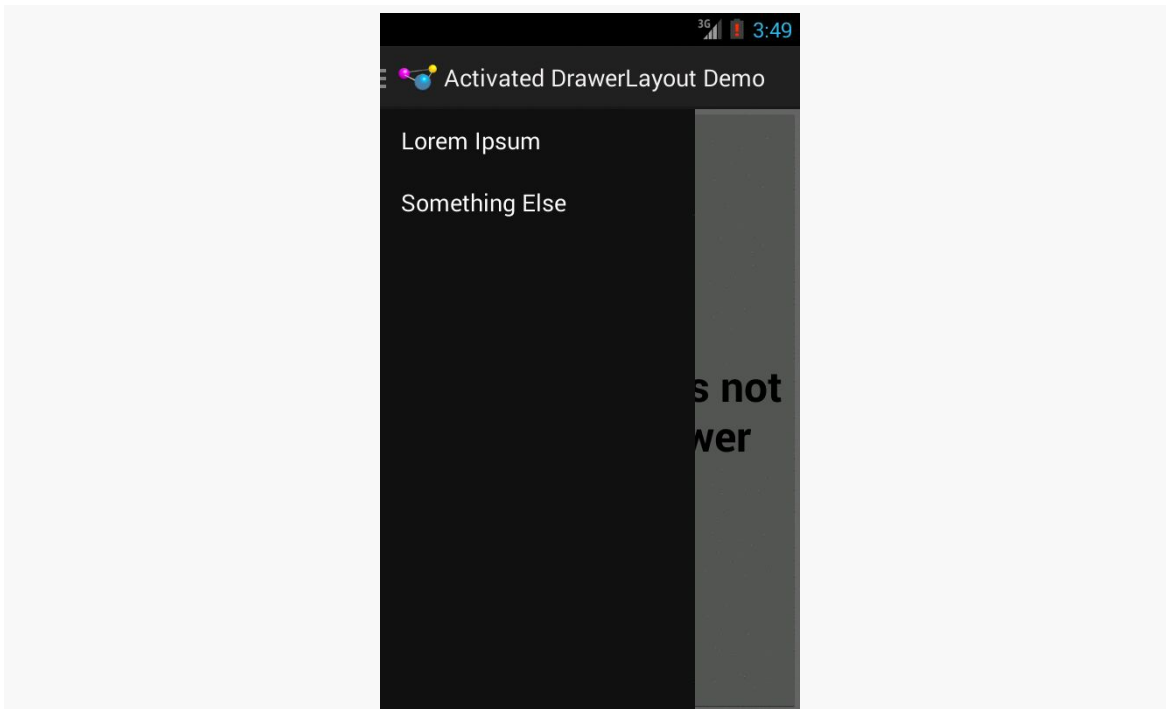

Figure 458: Activated Navigation Drawer Demo, Showing StuffFragment and Navigation Drawer

However, since we manually cleared the checked state, we now need to re-check a row if the user navigates back to one of the other fragments. There are two ways the user could return to one of those other fragments: via the navigation drawer, or via the BACK button (popping our transaction off the back stack).

If they navigate to one of the other fragments via the navigation drawer, the appropriate row will be activated automatically by the user's click event. However, we need to consider what to do about that transaction hanging around the back stack from before. One option is to remove it, so the other fragments behave as they do normally, where BACK exits the activity. That is a matter of calling `popBackStack()` on the `FragmentManager` as part of showing one of the fragments, such as the `showContent()` method that shows the `ContentFragment`:

```
private void showContent() {
    if (content == null) {
        content=new ContentFragment();
    }

    if (!content.isVisible()) {
        getFragmentManager().popBackStack();
        getFragmentManager().beginTransaction()
            .replace(R.id.content, content).commit();
    }
}
```

```
        drawer.post(onNavChange);  
    }  
}
```

If the user presses the BACK button, having the earlier fragment reappear happens automatically. However, we need to fix up the navigation drawer to show the proper row as being activated. To do that, we implement `OnBackStackChangeListener` on `MainActivity` and call `addOnBackStackChangeListener()` on the `FragmentManager` in the `onCreate()` initialization work. That way, `onBackStackChanged()` will be called when there is a change in the state of the back stack. Then, it is merely a matter of calling `post()` for `onNavChanged` again, to update the nav drawer:

```
@Override  
public void onBackStackChanged() {  
    drawer.post(onNavChange);  
}
```

Hiding Context-Specific Action Bar Items

Another Google design guideline that makes sense, but adds complexity, is to only show action bar items that pertain to the entire application while the navigation drawer is visible. So, for example, a “Help” action bar item should remain visible, to allow users to switch over to that. But an “Edit” action bar item, to edit something in the main activity, should be hidden while the navigation drawer is visible.

The navigation drawer is effectively an application-level construct, even if we wind up implementing it on a per-activity basis due to the way Android user interfaces are constructed. Hence, the action bar items with the drawer open should pertain to the same scope that the drawer itself does: the application, not a particular activity or fragment inside of it.
