From there, you can get an array of `Size` objects via a call to `getOutputSizes()`. Curiously, `getOutputSizes()` takes a Java class object, identifying the use case for the frames to be generated by the camera. So, passing `SurfaceTexture.class` would give you preview frame resolutions, but passing `ImageFormat.JPEG` would give you picture resolutions (at least, for images to be encoded in JPEG format).

So, you can get your roster of available picture sizes via:

```
CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map=
    cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
Size[] rawSizes=map.getOutputSizes(ImageFormat.JPEG);
```

From there, you will need to choose a size. This process can be a bit interesting; some notes about it appear [later in this chapter](#). But, for example, you might choose the size that is the highest resolution, as determined by the total area (width times height).

Next, you are going to need to set up an `ImageReader`. Typically this is done via the `newInstance()` factory method, which takes four parameters:

- The width and height of the desired resolution of the *picture* that you wish to later take with the camera

WORKING DIRECTLY WITH THE CAMERA

- The image format to use (e.g., `ImageFormat.JPEG`) for those pictures
- How many simultaneous frames will be needed (typical value: 2)

```
ImageReader reader=ImageReader.newInstance(pictureSize.getWidth(),  
    pictureSize.getHeight(), pictureFormat, 2);
```

Then, you need a `Surface` associated with your preview surface. For example, you can call `getSurfaceTexture()` on a `TextureView` to get a `SurfaceTexture`, then pass it to the `Surface` constructor to get the associated `Surface` object.

Next, you can call `createCaptureSession()` on the `CameraDevice` representing the opened camera. This takes three parameters:

- An `ArrayList` of `Surface` objects, for every places that the camera driver needs to route frames towards. Typically, you will have two elements in this list: the `Surface` for your preview surface and the `Surface` that you get from your `ImageReader` by calling `getSurface()` on it.
- A `CameraCaptureSession.StateCallback` instance, to be notified about state changes in the frame-capturing process
- The `Handler` tied to your `HandlerThread`

```
cameraDevice  
    .createCaptureSession(Arrays.asList(surface, reader.getSurface()),  
        new PreviewCaptureSession(), handler);
```

(where `PreviewCaptureSession` is some subclass of `CameraCaptureSession.StateCallback`)

That actually does not begin the previews. Instead, it configures the camera to indicate that it is possible to do previews.

To continue the work for getting the previews rolling, in the `onConfigured()` callback method on your `CameraCaptureSession.StateCallback`, you can create a `CaptureRequest.Builder` that you can use for configuring the camera to capture preview frames. You get one of those by calling `createCaptureRequest()` on the `CameraDevice`, passing in an `int` indicating the general type of request that you are creating, such as `TEMPLATE_PREVIEW` for preview frames:

```
CaptureRequest.Builder b=  
    cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);
```

WORKING DIRECTLY WITH THE CAMERA

You then call `setTarget()` on the `Builder`, supplying the `Surface` onto which the captured frames will be written. For previews, that target is the `Surface` associated with your preview surface.

You can also call `set()` on the `Builder` to configure various options that you would like for the camera, such as auto-focus modes, flash modes, and the like. The code snippet shown below demonstrates setting up “continuous picture” auto-focus mode and having the auto-exposure mode engage the flash as needed.

Eventually, you ask the `CaptureRequest.Builder` to `build()` you a `CaptureRequest`, and you pass that to `setRepeatingRequest()` on the `CameraCaptureSession` that is passed into `onConfigure()` of your `CameraCaptureSession.StateCallback`:

```
@Override
public void onConfigured(CameraCaptureSession session) {
    try {
        CaptureRequest.Builder b=
            cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);

        b.addTarget(surface);
        b.set(CaptureRequest.CONTROL_AF_MODE,
            CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
        b.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

        // other Builder configuration goes here

        CaptureRequest previewRequest=b.build();

        session.setRepeatingRequest(previewRequest, null, handler);
    }
    catch (CameraAccessException e) {
        // do something
    }
    catch (IllegalStateException e) {
        // do something
    }
}
```

`setRepeatingRequest()` takes three parameters:

- the `CaptureRequest` created by the `Builder`
- an optional `CameraCaptureSession.CaptureCallback` object to be notified about frame captures
- the `Handler` associated with your `HandlerThread`

Note that you will want to hold onto the `CaptureRequest.Builder` that you created here, as you will want it again when it comes time to take a picture.

When you go to `close()` the `CameraDevice`, before you do so, you must also close up the previews. You do this by calling `close()` on the `CameraCaptureSession` and `close()` on your `ImageReader`.

Taking a Picture

At some point, you will want to take a picture. Typically, this is based on user input, though it would not have to be. Taking a picture not only involves telling the camera to capture a picture (typically at a different resolution than the previews), but also to arrange to get that written out to disk somewhere as a JPEG file.

android.hardware.Camera

Taking a photo with a `Camera` is a matter of calling `takePicture()` on the `Camera` object. There are two flavors of `takePicture()`, for which three parameters are in common:

- a `Camera.ShutterCallback`, which will be called the moment the picture is taken, so that you can customize the “shutter” sound
- two `Camera.PictureCallback` objects, for raw (uncompressed) and JPEG photo data, where relatively few devices support raw images using the original camera API

The four-parameter version of `takePicture()` also takes a third `Camera.PictureCallback`, to be called when “a scaled, fully processed postview image is available”. This explanation probably means something to somebody, but the author of this book has no idea what it means.

You cannot call `takePicture()` until *after* `startPreview()` has been called to set up a preview pane. `takePicture()` will automatically stop the preview. At some point, if you want to be able to take another photo, you will need to call `startPreview()` again. Note, though, that you *cannot* call `startPreview()` until after the final compressed photo has been delivered to your `Camera.PictureCallback` object.

Before you call `takePicture()`, you are going to want to adjust the `Camera.Parameters` to configure how the photo should be taken. The primary setting to adjust is the size of the picture to take. Just as you ask `Camera.Parameters` for available preview sizes and choose one, you can call `getSupportedPictureSizes()`, which returns a `List` of `Camera.Size` objects. You can

WORKING DIRECTLY WITH THE CAMERA

then choose a size and pass its width and height to `setPictureSize()` on the `Camera.Parameters`. Other things to potentially adjust include:

- flash mode (`getSupportedFlashModes()` and `setFlashMode()`)
- focus mode (`getSupportedFocusModes()` and `setFocusMode()`)
- white balance (`getSupportedWhiteBalance()` and `setWhiteBalance()`)
- geo-tagging (`setGpsLatitude()`, `setGpsLongitude()`, `setGpsAltitude()`, etc.)
- JPEG image quality (`setJpegQuality()`)
- and so on

Note that calling `setParameters()` multiple times seems to lead to camera instability. Ideally, you collect all your desired settings from the user up front, then call `setParameters()` once when you set up your preview size. If you need to change parameters, you may wish to consider closing and re-opening the camera.

The `Camera.PictureCallback` will be called with `onPictureTaken()` and will be handed a byte array representing the picture. Typically, you will supply a `PictureCallback` for JPEG images, and so the byte array will represent the photo encoded in JPEG. At this point, you can hand that byte array off to a background thread to write it to disk, upload it to some server, or whatever else you planned to do with the picture.

Note that one thing you cannot readily do with the picture is hand it to another activity. There is a 1MB limit on the size of an Intent used with `startActivity()`, and usually the JPEG will be bigger than that. Hence, you cannot readily pass the picture via an Intent extra to another activity. If at all possible, use fragments or something else to keep all your relevant bits of UI together in a single activity, rather than try to get the images from activity to activity.

android.hardware.camera2

First, you should attach an `ImageReader.OnImageAvailableListener` instance to your `ImageReader`, using `setOnImageAvailableListener()`.

`ImageReader.OnImageAvailableListener` is an interface; you will be called with `onImageAvailable()` when a new image is delivered to the `ImageReader`. We will come back to that `onImageAvailable()` method after quite a bit of additional coding.

WORKING DIRECTLY WITH THE CAMERA

Next, given the `CaptureRequest.Builder` you created when you set up the previews, you need to adjust the builder to lock the auto-focus (assuming that auto-focus is enabled):

```
b.set(CaptureRequest.CONTROL_AF_TRIGGER,
      CameraMetadata.CONTROL_AF_TRIGGER_START);
```

At that point, you can `build()` a fresh `CaptureRequest` and call `setRepeatingRequest()` on the `CameraCaptureSession`, to change the previews to switch to a locked focus:

```
captureSession.setRepeatingRequest(b.build(),
    new RequestCaptureTransaction(),
    handler);
```

Here, `RequestCaptureTransaction` is a subclass of `CameraCaptureSession.CaptureCallback`, so you can be notified of how the auto-focus locking is proceeding. You wind up having to implement a fairly convoluted state machine to eventually find out it is time to take a picture... or possibly to ask for a “precapture trigger” to start on the auto-exposure system:

```
private class RequestCaptureTransaction extends CameraCaptureSession.CaptureCallback {
    private final Session s;
    boolean isWaitingForFocus=true;
    boolean isWaitingForPrecapture=false;
    boolean haveWeStartedCapture=false;

    RequestCaptureTransaction(CameraSession session) {
        this.s=(Session)session;
    }

    @Override
    public void onCaptureProgressed(CameraCaptureSession session,
        CaptureRequest request, CaptureResult partialResult) {
        capture(partialResult);
    }

    @Override
    public void onCaptureFailed(CameraCaptureSession session, CaptureRequest request, CaptureFailure
failure) {
        // TODO: raise event
    }

    @Override
    public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest request, TotalCaptureResult
result) {
        capture(result);
    }

    private void capture(CaptureResult result) {
        if (isWaitingForFocus) {
            isWaitingForFocus=false;
        }
    }
}
```

WORKING DIRECTLY WITH THE CAMERA

```
int autoFocusState=result.get(CaptureResult.CONTROL_AF_STATE);

if (CaptureResult.CONTROL_AF_STATE_FOCUSED_LOCKED == autoFocusState ||
    CaptureResult.CONTROL_AF_STATE_NOT_FOCUSED_LOCKED == autoFocusState) {
    Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

    if (state == null ||
        state == CaptureResult.CONTROL_AE_STATE_CONVERGED) {
        isWaitingForPrecapture=false;
        haveWeStartedCapture=true;
        capture(s);
    }
    else {
        isWaitingForPrecapture=true;
        precapture();
    }
}
}
else if (isWaitingForPrecapture) {
    Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

    if (state == null ||
        state == CaptureResult.CONTROL_AE_STATE_PRECAPTURE ||
        state == CaptureRequest.CONTROL_AE_STATE_FLASH_REQUIRED) {
        isWaitingForPrecapture=false;
    }
}
}
else if (!haveWeStartedCapture) {
    Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

    if (state == null ||
        state != CaptureResult.CONTROL_AE_STATE_PRECAPTURE) {
        haveWeStartedCapture=true;
        capture();
    }
}
}

private void precapture() {
    try {
        b.set(CaptureRequest.CONTROL_AE_PRECAPTURE_TRIGGER,
            CaptureRequest.CONTROL_AE_PRECAPTURE_TRIGGER_START);
        s.captureSession.capture(b.build(), this, handler);
    }
    catch (Exception e) {
        // do something
    }
}

private void capture() {
    try {
        CaptureRequest.Builder captureBuilder=
            cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_STILL_CAPTURE);

        captureBuilder.addTarget(reader.getSurface());
        captureBuilder.set(CaptureRequest.CONTROL_AF_MODE,
            CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
        captureBuilder.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);
    }
}
```

WORKING DIRECTLY WITH THE CAMERA

```
captureSession.stopRepeating();
captureSession.capture(captureBuilder.build(),
    new CapturePictureTransaction(), null);
}
catch (Exception e) {
    // do something
}
}
}
```

The author of this book wishes he understood what all this stuff is for.

But, eventually, it will be time to take the picture, represented by the `capture()` method in the above code dump. Here, we create a new `CaptureRequest.Builder`, this time using `TEMPLATE_STILL_CAPTURE` to indicate that we are trying to take a picture. We set up our target (via `addTarget()`) to be the `Surface` from the `ImageReader`. We re-establish our desired auto-focus and auto-exposure modes. Then, we stop the previews, by calling `stopRepeating()` on the `CameraCaptureSession`, undoing the prior `setRepeatingRequest()` call where we asked for previews. Then, we call `capture()` on the `CameraCaptureSession`, requesting a single-frame capture rather than a repeating request. This, like `setRepeatingRequest()`, takes our `CaptureRequest` from the `Builder`, a `CameraCaptureSession.CaptureCallback` to find out the results of the capture work, and our `Handler`.

The primary job of this `CameraCaptureSession.CaptureCallback` is to restart the previews, in `onCaptureCompleted()`. First, we use the preview edition of the `CaptureRequest.Builder` to undo some of the changes made during the camera capture process. Then, given the original preview `CaptureRequest`, we call `setRepeatingRequest()` again, to get the previews showing once more:

```
@Override
public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest request, TotalCaptureResult result) {
    try {
        b.set(CaptureRequest.CONTROL_AF_TRIGGER,
            CameraMetadata.CONTROL_AF_TRIGGER_CANCEL);
        b.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);
        s.captureSession.capture(b.build(), null, handler);
        s.captureSession.setRepeatingRequest(previewRequest, null, handler);
    }
    catch (CameraAccessException e) {
        // do something
    }
    catch (IllegalStateException e) {
        // do something
    }
}
```

WORKING DIRECTLY WITH THE CAMERA

As part of all of this work, your `onImageAvailable()` method on your `ImageReader.OnImageAvailableListener` will be called when the picture is ready. The recipe for getting your JPEG image looks like this:

```
@Override
public void onImageAvailable(ImageReader imageReader) {
    Image image=imageReader.acquireNextImage();
    ByteBuffer buffer=image.getPlanes()[0].getBuffer();
    byte[] bytes=new byte[buffer.remaining()];

    buffer.get(bytes);
    image.close();

    // do something with the byte[] of JPEG data
}
```

Here, you are subject to the same sorts of limitations as were described in the section on taking pictures with the original camera API. Notably, that byte array may be large, too large to put into an Intent extra and pass to another activity.

Recording a Video

Traditional Android video recording is handled via `MediaRecorder`. This means that we need to hand control over the camera from the regular camera API that we are using to `MediaRecorder`, record the video, and then return control back to the camera API (e.g., for previews).

`MediaRecorder` itself then has its own API for configuring the recorder, starting the recording, and stopping the recording.

`android.hardware.Camera`

To retain the camera access for your app, but allow `MediaRecorder` to take over the camera, call `stopPreview()`, then `unlock()`, on the `Camera` object:

```
camera.stopPreview();
camera.unlock();
```

When the recording is complete, you reverse the process, by calling `reconnect()` and `startPreview()`:

```
camera.reconnect();
camera.startPreview();
```

WORKING DIRECTLY WITH THE CAMERA

In between the `unlock()` and `reconnect()` calls is when you use the `MediaRecorder` API.

android.hardware.camera2

This particular combination (video recording with the Android 5.0+ camera API) will be covered in a future edition of this chapter.

Using MediaRecorder

Creating a `MediaRecorder` instance is simple enough: just use the zero-argument constructor.

You then need to tell it what camera to use. With the original camera API, that is a matter of calling `setCamera()` on the `MediaRecorder`, passing in your `Camera` object.

```
MediaRecorder recorder=new MediaRecorder();  
recorder.setCamera(camera);
```

Next, call `setAudioSource()` and `setVideoSource()` to indicate where the audio and video to be recorded are coming from. The typical value to use for the audio source is `CAMCORDER`. For the original camera API, you will need to use `CAMERA` as the video source:

```
recorder.setAudioSource(MediaRecorder.AudioSource.CAMCORDER);  
recorder.setVideoSource(MediaRecorder.VideoSource.CAMERA);
```

Next, you need to configure how the video should be recorded, in terms of things like resolution. The typical approach using the original camera API is to use `setProfile()`, passing in a `CamcorderProfile` to the `MediaRecorder`. You can find out what profiles are supported by calling methods like `hasProfile()` on `CamcorderProfile`. There are some fairly generic profiles, like `QUALITY_HIGH` and `QUALITY_LOW`, and some fairly specific profiles, like `QUALITY_2160P` for 2K video. Not all devices will support all profiles, based on Android version and camera driver capabilities. So, you will need to be responsive to varying cameras and gracefully degrade from the profile you want to a profile that you can get. For example, the following code snippet tries `QUALITY_HIGH`, falls back to `QUALITY_LOW` if `QUALITY_HIGH` is not available, and bails out if neither of those profiles exist:

```
boolean canGoHigh=CamcorderProfile.hasProfile(cameraId,  
    CamcorderProfile.QUALITY_HIGH);  
boolean canGoLow=CamcorderProfile.hasProfile(cameraId,
```

WORKING DIRECTLY WITH THE CAMERA

```
CamcorderProfile.QUALITY_LOW);

if (canGoHigh) {
    recorder.setProfile(CamcorderProfile.get(cameraId,
        CamcorderProfile.QUALITY_HIGH));
}
else if (canGoLow) {
    recorder.setProfile(CamcorderProfile.get(cameraId,
        CamcorderProfile.QUALITY_LOW));
}
else {
    throw new IllegalStateException(
        "cannot find valid CamcorderProfile");
}
```

Here, `cameraId` is the `int` identifying your open camera.

Then, you can configure:

- the file path to which the resulting video should be written
- the maximum file size you want, after which recording will automatically stop (optional)
- the maximum duration that you want, after which recording will automatically stop (optional)
- a hint for what orientation the video should be recorded in (optional)

```
recorder.
    setOutputFile(new File(getExternalFilesDir(null), FILENAME).getAbsolutePath());
recorder.setMaxFileSize(5000000); // ~5MB max
recorder.setMaxDuration(10000); // ~10 seconds max
recorder.setOrientationHint(90); // rotate output 90 degrees
```

Optionally, you can call `setInfoListener()` and `setErrorListener()`, supplying objects that will be invoked when certain events occur. Notably, if you use `setMaxFileSize()` or `setMaxDuration()`, the `OnInfoListener` object will be notified when recording automatically stops due to reaching one of those limits.

You then call `prepare()`, followed by `start()`, and your video recording will commence:

```
recorder.prepare();
recorder.start();
```

When it comes time to stop the recording manually (e.g., user taps a “stop” button), just call `stop()`, then `release()`, on the `MediaRecorder`.

Configuring the Still Camera

In general, when using the camera classes in Android, you get reasonable defaults for things like focus mode and flash mode. However, what might be reasonable defaults may not be what the user wants in any given circumstance. Other bits of configuration, like zoom, cannot really be defaulted (other than to “no zoom”).

For these, you will need to provide some sort of UI to allow the user to request settings, then apply them as part of your camera implementation. Here, we will focus on applying the configuration.

(and, yes, that was a pun)

Focus Mode

Frequently, a user will want simple autofocus behavior, where the camera attempts to focus on the content centered within the preview. However, in some situations, the user may want autofocus to be disabled, turning the camera into a fixed-focus camera. And there are some specialty focus modes that may be available to you as well, depending upon device and camera API.

Here is how you can set up the camera to use one of those focus modes, for each of the camera APIs.

android.hardware.Camera

The `Camera.Parameters` object has a `getSupportedFocusModes()` method. This returns a `List of String` objects, where each value corresponds to a focus mode that is available on this camera (front-facing, rear-facing) on this device. The possible strings are defined as constants on `Camera.Parameters`:

- `FOCUS_MODE_AUTO`
- `FOCUS_MODE_CONTINUOUS_PICTURE`
- `FOCUS_MODE_CONTINUOUS_VIDEO`
- `FOCUS_MODE_EDOF` (“extended depth of field”)
- `FOCUS_MODE_FIXED`
- `FOCUS_MODE_INFINITY`
- `FOCUS_MODE_MACRO`

WORKING DIRECTLY WITH THE CAMERA

In truth, few devices support all of these. However, every device will support at least one; `getSupportedFocusModes()` is guaranteed to not return `null` and not return an empty `List`.

To choose a focus mode, call `setFocusMode()` on the `Camera.Parameters`, supplying the string of the desired mode. And, of course, you will eventually need to call `setParameters()` on the `Camera`, supplying your modified `Camera.Parameters`.

android.hardware.camera2

Similarly, you can get a list of supported auto-focus modes by calling `get(CameraCharacteristics.CONTROL_AF_AVAILABLE_MODES)` on a `CameraCharacteristics` object tied to your chosen camera. This returns an array of `int` values, instead of a `List` of strings. The possible values are defined as constants on `CameraMetadata`:

- `CONTROL_AF_MODE_AUTO`
- `CONTROL_AF_MODE_CONTINUOUS_PICTURE`
- `CONTROL_AF_MODE_CONTINUOUS_VIDEO`
- `CONTROL_AF_MODE_EDOF` (“extended depth of field”)
- `CONTROL_AF_MODE_MACRO`
- `CONTROL_AF_MODE_OFF`

After the user chooses a value, you will need to call `set(CaptureRequest.CONTROL_AF_MODE, ...)` on your `CaptureRequest.Builder`, where `...` is the `int` of the desired focus mode. Note that you will need to do this both for the `CaptureRequest.Builder` for preview frames and for the `CaptureRequest.Builder` used when you take an actual picture. If the user is changing this value while you are already showing the preview, you will need to update the preview behavior, by calling `build()` on the `Builder` to create the `CameraRequest`, then calling `setRepeatingRequest()` to override your previous `CameraRequest` with the new one with the new focus mode. As a result, you tend to want to hang onto your `CameraRequest.Builder` for previews, so you can make these sorts of incremental changes in behavior, without having to create a fresh `Builder` from scratch with all of the desired settings.

Flash Mode

Typically, users want flash when they need flash, due to insufficient ambient lighting. However, once again, they may want specific flash modes instead (definitely flash, definitely *not* flash, etc.).

As with focus modes, you can ask the camera APIs what flash modes are available for a given camera. In this case, though, there is no guarantee of any flash mode configurability, since not all cameras have flash (and Android considers “off” and “flash does not exist” to be different things). And, once the user has chosen a flash mode, you can configure the camera APIs to use that particular mode.

Of course, the details vary by camera API.

android.hardware.Camera

`Camera.Parameters` has `getSupportedFlashModes()`, which returns a `List` of strings representing the supported flash modes, or `null` if flash modes cannot be configured for this camera. The string values map to constants defined on `Camera.Parameters`:

- `FLASH_MODE_AUTO`
- `FLASH_MODE_OFF`
- `FLASH_MODE_ON`
- `FLASH_MODE_RED_EYE` (“red-eye reduction mode”)

There is an additional flash mode, `FLASH_MODE_TORCH`, that will keep the flash during the preview as well as flashing it during the actual act of taking the picture. In truth, this setting is more often used for flashlight apps.

Once the user has chosen a flash mode, you can call `setFlashMode()` on the `Camera.Parameters`, then eventually call `setParameters()` on the `Camera`.

android.hardware.camera2

To find out what flash modes are available for a `camera2` camera, you can call `get(CameraCharacteristics.CONTROL_AE_AVAILABLE_MODES)` on the `CameraCharacteristics` for the camera in question. This returns an array of `int` values, mapping to constants defined on `CameraCharacteristics`:

- `CONTROL_AE_MODE_ON` (which really means “off”)

WORKING DIRECTLY WITH THE CAMERA

- `CONTROL_AE_MODE_ON_ALWAYS_FLASH`
- `CONTROL_AE_MODE_ON_AUTO_FLASH`
- `CONTROL_AE_MODE_ON_AUTO_FLASH_REDEYE`

Here, AE is short for “auto-exposure”. `CONTROL_AE_MODE_ON` says that auto-exposure is enabled, just without any flash. There is a separate `CONTROL_AE_MODE_OFF` which totally disables the auto-exposure capability. However, that will screw up auto-focus and auto-white balance, and so rarely will camera apps want to use `CONTROL_AE_MODE_OFF`.

Once the user chooses the desired flash mode, you can call `set(CaptureRequest.CONTROL_AE_MODE, ...)` on your `CaptureRequest.Builder` object, where `...` is the desired flash mode int. You will need to do this both for the preview `Builder` and the `Builder` used when actually taking the picture. If the user is changing this value on the fly, you will need to update the preview behavior, by calling `build()` on the `Builder` to create the `CameraRequest`, then calling `setRepeatingRequest()` to override your previous `CameraRequest` with the new flash-enabled one.

Zoom

Flash and focus modes might be the sort of thing that the user could choose before you start up your camera preview, let alone take a picture. Zoom, on the other hand, is the sort of thing that the user will want to adjust on the fly, based on what they see in the preview.

Hence, your first challenge with implementing a zoom feature is deciding how you want users to indicate that they want to zoom in or out, given that probably most of your screen space is taken up by the preview itself. Options include:

- Float a `SeekBar` over the preview along an edge, where the user can slide the thumb or tap on the bar to move the thumb to indicate an increase or decrease in the zoom
- Use a pinch-zoom gesture, via `ScaleGestureDetector`
- Use some other gesture, such as a vertical swipe, using a `GestureDetector`
- Have a pair of buttons to increase or decrease the zoom

Both Android camera APIs have the notion of a numeric zoom level. The bottom end of the zoom range is either 0 (for the classic camera API) or 1 (for the camera2 API). The top end is found by from the camera APIs. Your job will be to convert

WORKING DIRECTLY WITH THE CAMERA

whatever input signals you get from the user into a zoom level, then update the camera settings to zoom to that setting.

The code segments shown in this section assume that your input is giving you a zoom level in the 0-100 range, such as via a SeekBar with the default maximum value.

android.hardware.Camera

`Camera.Parameters` offers several methods related to zoom.

The big one is `isZoomSupported()`. `false` means that the camera does not offer any sort of zoom (digital or optical). You might use that to disable your zoom input option, so as not to offer something to the user that will not work. Few devices will return `false`, though.

Assuming `isZoomSupported()` is true, then `getMaxZoom()` will tell you the highest possible zoom value. Your overall range of zoom values will be from 0 to this maximum.

If you are using some form of user input that only indicates incremental changes in zoom (e.g., buttons for zoom in and zoom out), you can use `getZoom()` to find out the current zoom value. You can then increment or decrement that value and check your new value against the ends of the range (0 and `getMaxZoom()`) to ensure that it is valid.

Given a new zoom value, you have two choices for applying it:

- `setZoom()` on `CameraParameters` does a “smash cut”, jumping to the new zoom value immediately upon applying those parameters to the camera via `setParameters()`.
- `startSmoothZoom()` on `Camera` will “animate” the zoom change from the current to the new value over a period of a second or two. However, not all devices support this. Call `isSmoothZoomSupported()` on the `Camera.Parameters` to see if smooth zoom is available to you.

The following code snippet takes a zoom level from 0 to 100 and zooms the camera, assuming zoom is supported:

```
@Override
public boolean zoomTo(Camera camera, int zoomLevel) {
    Camera camera=descriptor.getCamera();
```

WORKING DIRECTLY WITH THE CAMERA

```
Camera.Parameters params=camera.getParameters();
int zoom=zoomLevel*params.getMaxZoom()/100;
boolean result=false;

if (params.isSmoothZoomSupported()) {
    camera.setZoomChangeListener(this);
    camera.startSmoothZoom(zoom);
    result=true;
}
else if (params.isZoomSupported()) {
    params.setZoom(zoom);
    camera.setParameters(params);
}

return(result);
}
```

You will notice that if `isSmoothZoomSupported()` returns true, we not only call `startSmoothZoom()`, but we also call `setZoomChangeListener()`. This registers a listener to find out about how the smooth zoom is progressing. In particular, you should disable further changes to the zoom until the smooth zoom process completes. Your `OnZoomChangeListener` will be called with `onZoomChange()` for each incremental change in the zoom from start to finish, with `stopped` set to true when we are done with the smooth zoom operation:

```
@Override
public void onZoomChange(int zoomValue, boolean stopped,
    Camera camera) {
    if (stopped) {
        // do something
    }
}
```

If you need to stop the smooth zoom before completion, there is a `stopSmoothZoom()` method on `Camera` that you can call. For example, instead of disabling zoom controls, you might stop the current smooth zoom operation if the user chooses a new zoom level, then start a fresh smooth zoom operation to the newly-requested level.

android.hardware.camera2

(the author would like to thank Daniel Albert for [helping](#) with this section)

On the surface, the camera2 API works much the same: you find out the maximum zoom value, translate your user input into the valid zoom value range (this time, from 1.0f to the maximum), and then update the camera for that zoom value.

However, that last step is substantially different than before.

WORKING DIRECTLY WITH THE CAMERA

For digital zoom, rather than saying “zoom in to this value”, we say “crop the camera inputs to this rectangle, and expand that rectangle to fill the preview or the picture”. This is rather more complex, albeit with potentially more power.

To find out the maximum digital zoom value, call `get(CameraCharacteristics.SCALER_AVAILABLE_MAX_DIGITAL_ZOOM)` on the `CameraCharacteristics` for the camera in question. That will be a float value. `1.0f` would indicate that the camera cannot perform digital zoom. The range of possible digital zoom values is from `1.0f` to whatever the maximum is.

So, the first part of this edition of `zoomTo()` normalizes a 0-100 integer into a float representing the zoom value:

```
@Override
public boolean zoomTo(String cameraId,
    CaptureRequest.Builder previewRequestBuilder,
    CameraCaptureSession captureSession,
    int zoomLevel) {
    try {
        final CameraCharacteristics cc=
            mgr.getCameraCharacteristics(cameraId);
        final float maxZoom=
            cc.get(
                CameraCharacteristics.SCALER_AVAILABLE_MAX_DIGITAL_ZOOM);

        // if <=1, zoom not possible, so eat the event
        if (maxZoom>1.0f) {
            float zoomTo=1.0f+((float)zoomLevel*(maxZoom-1.0f)/100.0f);

            zoomRect=cropRegionForZoom(cc, zoomTo);

            previewRequestBuilder
                .set(CaptureRequest.SCALER_CROP_REGION, zoomRect);
            previewRequest=previewRequestBuilder.build();
            captureSession.setRepeatingRequest(previewRequest,
                null, handler);
        }
    }
    catch (CameraAccessException e) {
        // ummm... do something
    }

    return(false);
}
```

Given a zoom value, we need to determine the Rect that represents the subset of the field of vision that we want to zoom into. The following algorithm zooms into the center of the field:

```
private static Rect cropRegionForZoom(CameraCharacteristics cc,
    float zoomTo) {
    Rect sensor=
```

WORKING DIRECTLY WITH THE CAMERA

```
cc.get(CameraCharacteristics.SENSOR_INFO_ACTIVE_ARRAY_SIZE);
int sensorCenterX=sensor.width()/2;
int sensorCenterY=sensor.height()/2;
int deltaX=(int)(0.5f*sensor.width()/zoomTo);
int deltaY=(int)(0.5f*sensor.height()/zoomTo);

return(new Rect(
    sensorCenterX-deltaX,
    sensorCenterY-deltaY,
    sensorCenterX+deltaX,
    sensorCenterY+deltaY));
}
```

That Rect then gets used:

- Immediately, via a call to `set()` on the `CaptureRequest.Builder`, to set the `SCALER_CROP_REGION`. That Builder then is used to re-establish the preview repeating capture request.
- At the point in time when the user requests to take a picture. We will need to call `set()` on *that* `CaptureRequest.Builder`, to reproduce the same zoom.
- Later, if we have to set up the preview capture request again and we still want this zoom value taken into account.

Note that this does not cover optical zoom. On Android 5.0, that is handled as available focal lengths. You can get the list of available focal lengths by requesting `LENS_INFO_AVAILABLE_FOCAL_LENGTHS` from the `CameraCharacteristics`. Setting `LENS_FOCAL_LENGTH` on a `CaptureRequest.Builder` will shift the camera's focal length as requested. This may take a moment, as optical zoom usually requires mechanical changes in the camera configuration. The `LENS_STATE` (on `CaptureResult`) will be reported as `MOVING` while the focal length is changing, or `STATIONARY` once the focal length has reached the requested value.

And Now, The Problems

Of course, taking pictures is not nearly this simple. The preceding sections glossed over all sorts of problems that you will run into in practice when trying to implement these APIs. The following sections outline a few of those problems, particularly ones that will affect both camera APIs.

Choosing a Preview Size

Camera drivers are capable of delivering preview images to your preview surface in one of several resolutions. You have to sift through a roster of resolutions and choose one.

Your gut instinct might be to choose the highest-available resolution. After all, that should result in the highest-quality previews. However, this can be wasteful, if the preview images are significantly bigger than your preview surface. Plus, the larger the preview frames, the slower the camera driver will be to deliver them, reducing your possible frames-per-second (fps) for the previews. You might instead elect to choose the largest preview that is smaller than the surface, or some algorithm like that.

Previews and Aspect Ratios

Compounding the problem of choosing preview sizes is that the resolutions of available preview sizes bear no relationship at all to the size of your preview surface. After all, you might have a `TextureView` that fills the screen, or you might have a `TextureView` that is rather tiny. That is up to you from a UI design standpoint; the camera driver is oblivious to such considerations.

In particular, the aspect ratios (width divided by height) of the preview frames do not necessarily have to match the aspect ratio of your preview surface. For example, few camera drivers support square previews, yet for aesthetic reasons you might be aiming for a square preview surface.

You have two main approaches for dealing with this: letterboxing and cropping.

Letterboxing is where your preview frames retain their aspect ratio, but do not fill up all the available space in the preview surface. Instead, part of the preview surface is unused. For example, if your preview surface is square, and your preview frames have a landscape aspect ratio (width is greater than the height), letterboxing would show the landscape aspect ratio within the square box of the preview surface, with black bars for the unused portion of the square's height. Typically, using gravity, you try to have the preview frames be centered and the unused portion of the surface be split to either side of the frames.

If you want to fill the preview surface, then letterboxing is not a viable option. However, if you just take the preview frames and try to put them into the surface, the surface will stretch the frames to fit the surface. If the aspect ratio of the frames is significantly different than is the aspect ratio of the surface, the subject matter in the preview will seem significantly stretched, either vertically or horizontally.

The trick to deal with this, on API Level 14+ (with graphics acceleration enabled, as is the default), is to have the surface be *bigger* than what you really want, but then to have something overlapping the surface and causing it to be visually cropped. You

have your new, larger surface match the aspect ratio of the preview frames, so there is no stretching. However, now what the user sees in your preview surface may differ substantially from what winds up in the picture or video, as you are cropping off portions that do not fit your preview surface, where those cropped areas might well show up in final output.

Choosing a Picture or Video Size

Choosing a picture or video size is reminiscent of choosing a preview size. While many cases will call for as high of a resolution as you can muster, some use cases will lead you towards choosing a lower resolution. For example, situations requiring a rapid upload of the resulting media might select a lower resolution, as that will reduce the file size and make the upload process that much faster.

Also, bear in mind that the aspect ratio of the available picture or video sizes do not necessarily match the aspect ratio of *either* the preview frames *or* your preview surface. Emphasize to your users that the preview surface is for *aiming* the camera; what actually gets recorded may be somewhat different in scope but should be centered on the same spot.

Picture Orientation

Your app may wish to take pictures in both landscape and portrait modes. However, the camera drivers are designed around taking pictures in landscape, particularly for rear-facing cameras.

You can hint to the camera driver what orientation you think the resulting picture should have, such as via `setRotation()` on the `Camera.Parameters` in the original camera API. However, as the documentation for that method states:

The camera driver may set orientation in the EXIF header without rotating the picture. Or the driver may rotate the picture and the EXIF thumbnail. If the Jpeg picture is rotated, the orientation in the EXIF header will be missing or 1 (row #0 is top and column #0 is left side).

Many camera drivers take the approach of leaving the image alone and setting the Orientation EXIF header. That header tells image viewers to rotate the image. Unfortunately, not all image viewers or image decoding libraries pay attention to this. Notably, *Android* usually does not pay attention to this, as `BitmapFactory` ignores this EXIF header. As a result, when you go to load in your own picture that you took, your result may come out mis-oriented.

You have two major choices:

1. Put more smarts in any logic that you are using to display images that you take with the camera, where you read the EXIF headers yourself and you arrange to rotate the image as needed, perhaps by rotating the `ImageView` you are using to show the image.
2. As part of post-processing the image before saving it, you rotate the image based upon what is in the EXIF header, and save the image with the proper rotation and no EXIF header. This has the advantage of making the image “correct” for all image viewers. However, rotating full-resolution photos is rather memory-intensive and slow. Using NDK code, such as [this library](#), may be able to help.

Storage Considerations

Bear in mind that if you wish to save pictures or videos in common locations on external storage, such as the standard location for digital camera output (`Environment.DIRECTORY_DCIM`), you will need the `WRITE_EXTERNAL_STORAGE` permission on all relevant API levels. As of Android M, this is a dangerous permission handled via the runtime permission system, so you will need to have the `<uses-permission>` element in the manifest *and* ask the user for that permission at runtime.

Also, files written out to external storage will not be picked up immediately by `MediaStore`, and so “gallery” and related apps that rely upon the `MediaStore` will not see your pictures or videos. You can use `MediaScannerConnection` to proactively have the `MediaStore` add your newly-created files to the index, as was covered [earlier in the book](#).

Configuration Changes

Opening and closing a camera each takes a fair amount of time. As a result, if your app wants to support taking pictures and videos in either portrait or landscape, this is a case where you will want to strongly consider using a retained fragment to hold onto your `Camera` (or combination of `CameraManager` and `CameraDevice`) across a configuration change. That way, Android will not destroy and recreate the fragment, and you can keep the camera open during the change.

Camera Peeking Attacks

(NOTE: this section is based upon [a blog post](#) from the author)

A [research paper](#) points out an interesting Android attack vector, resulting in a possible leak of private information. The paper's authors refer to it as the "camera peeking" attack.

An Android camera driver can only be used by one app at a time. The attack is simple:

- monitor for when an app that might use the camera for something important comes to the foreground
- at that point, start watching for the camera to become unavailable
- once the camera is unavailable, then available again, grab the camera and take a picture, in hopes that the camera is still pointing at the private information

The example cited by the paper's authors is to watch for a banking app taking a photo of a check, to try to take another photo of the check to send to those who might use the information for various types of fraud.

Polling for camera availability is slow, simply because the primary way to see if the camera is available is to open it, and that takes hundreds of milliseconds. The paper's specific technique helped to minimize the polling, by knowing when the right activity was in the foreground and therefore the camera was probably already in use. Then, it would be a matter of polling until the camera is available again and taking a picture. Even without the paper's specific attack techniques, this general attack is possible, and there may be more efficient ways to see if the camera is in use.

On the other hand, the defense is simple: if your app is taking pictures, and those pictures may be of sensitive documents, ask the user to point the camera somewhere else before you release the camera. So long as you have exclusive control over the camera, nothing else can use it, including any attackers.

A sophisticated implementation of this might use image-recognition techniques to see, based upon preview frames plus the taken picture, if the camera is pointing somewhere else. For example, a banking app offering check-scanning might determine if the dominant color in the camera field significantly changes, as that would suggest that the camera is no longer pointed at a check, since checks are typically fairly monochromatic.

WORKING DIRECTLY WITH THE CAMERA

Or, just ask the user to point the camera somewhere else, then close the camera after some random number of seconds.

General-purpose camera apps might offer an “enhanced security” mode that does this sort of thing, but having that on by default might annoy the user trying to take pictures at the zoo, or at a sporting event. However, document-scanning apps might want to have this mode on by default, and check-scanning apps might simply always use this mode.

Media Routes

Android can send audio and video to a variety of places, such as:

- Bluetooth headsets or headphones
- External displays, like a TV or monitor
- External devices that themselves play back media, such as a Chromecast

There is a common API for determining which of these “places” are available and allowing the user to choose which of these “places” should be used for a given bit of media. This common API centers around a `MediaRouter`, which is the focus of this chapter.

Prerequisites

Understanding this chapter requires that you have read the core chapters of the book. In addition, you should read the chapters on [advanced action bar techniques](#) and [the AppCompatActivity backport](#).

Terminology

First, we need to establish some common ground in terms of..., well, terms.

Media

In this chapter, “media” refers to audio or video. This includes both media that may be stored on the device as well as media that may be streamed from some other source, frequently over the Internet.

Route

A route indicates where media should be played. There are three categories of routes that concern us:

- Where should we be playing live audio, in terms of speakers or headphones or other things connected to the device?
- Where should we be playing live video: on the device's own screen or on some other screen connected via a cable?
- Is there any sort of “remote playback” device available, such as a Chromecast, that can play back media on its own under our direction, rather than requiring our own app to play back the media itself

MediaRouter

MediaRouter is the name of a class (actually, two classes) that know what routes are possible given the current environment and what routes are selected for the different categories (by default or by user choice).

A Tale of Two MediaRouters

MediaRouter and its related classes represent a curious API. There are two versions of the MediaRouter class related support classes that will concern you as a developer.

android.media

MediaRouter debuted in Android in API Level 16, through classes added to the `android.media` package. This version of MediaRouter can work with live audio and live video routes, but not the Chromecast-style remote playback routes.

`android.media` also contains other classes that pertain to routes, such as `MediaRouteActionProvider`, a way to allow the user to choose media routes via an action bar item. The version of these classes in `android.media` work with native API Level 11 versions of the action bar and fragments.

android.support.v7.media

In 2013, an update to the Android Support package was released that contained another version of MediaRouter and kin, in `android.support.v7` packages. These are contained in a dedicated Android library project that you can add to your app, found

MEDIA ROUTES

in the `extras/android/support/v7/mediarouter` directory of your Android SDK installation, if you have a current Android Support package installed.

While the native version of `MediaRouter` is a system service — obtained via `getSystemService()` — the v7 version of `MediaRouter` is a singleton, obtained from a static `getInstance()` method on the `MediaRouter` class.

The good news is that this updated version of `MediaRouter` can work with all three categories of routes, including the Chromecast-style remote playback routes.

However, the bad news is that the v7 version of `MediaRouter`'s support classes only support the Android Support backports of fragments and the action bar. This requires you to inherit from `ActionBarActivity` and use the v4 version of `Fragment` and kin. This is a rather annoying limitation, considering that many developers have specifically started dropping support for older API levels to be able to *avoid* using this backport.

Attaching to MediaRouter

To be able to take advantage of all that `MediaRouter` has to offer, we need to obtain an instance of it and connect to that instance, via method calls and registering callbacks.

Getting a MediaRouter Instance

To get an instance of the `android.support.v7.media.MediaRouter` flavor of `MediaRouter`, call `getInstance()` on `MediaRouter`.

This is in contrast to the `android.media.MediaRouter` variant, which is a system service, obtained by calling `getSystemService()`.

Note that the `android.support.v7.media.MediaRouter` flavor is global for your process, but weakly held from a garbage collection standpoint. You need to ensure that you hold onto your instance of `MediaRouter` as long as you need it. Once your application code lets go of the `MediaRouter` instance, it becomes eligible for garbage collection, disposing of any registered callbacks and such along the way.

Working with Routes

`MediaRouter` has a `getSelectedRoute()` method that returns the media route chosen by the user, or the overall default if the user has not yet had a chance in your app to choose a route. This method returns a `MediaRouter.RouteInfo` object, containing details about the route. In particular, you can call `supportsControlCategory()` to determine if the route is a live audio route, a live video route, or a remote playback route, so you can take advantage of it accordingly.

There is also `getDefaultRoute()`, which, as the name suggests, returns the `MediaRouter.RouteInfo` instance that is the overall default for your app.

You can call `getRoutes()` to obtain a list of all routes known at the present time. You might use this to allow the user to choose a route, though `MediaRouteActionProvider` is generally a better choice, as will be seen [later in this chapter](#).

Given that you have a `MediaRouter.RouteInfo` instance from somewhere, you can call `selectRoute()` to make this route the active one, replacing whatever the previously-selected route was.

Registering a Callback

You can also call `addCallback()` to provide a `MediaRouter.Callback` instance that will be invoked at various points in time based on the changes in media routes. `addCallback()` also takes a `MediaRouteSelector`, which describes what sorts of routes you are interested in. We will examine `MediaRouteSelector` in greater detail in the coverage of `MediaRouteActionProvider` [later in this chapter](#).

There are two flavors of `addCallback()`. Both take the `MediaRouteSelector` and the `MediaRouter.Callback`, but one also takes an `int` supplying flags to control the behavior of `addCallback()`. One flag of particular importance is `CALLBACK_FLAG_REQUEST_DISCOVERY`. This tells `MediaRouter` to not only set up the callback, but to attempt to find new routes previously unknown to it. Mostly, this is for remote callback routes, which require network I/O to find and are not necessarily known if not specifically scanned for.

`MediaRouter.Callback` is a class, not an interface. You create your own subclass of `MediaRouter.Callback` and override the callback methods that interest you. Some noteworthy callback methods include:

MEDIA ROUTES

- `onRouteAdded()` and `onRouteRemoved()`, which are called when routes are newly detected or have been lost, such as when a user plugs in or unplugs an HDMI cable from the device
- `onRouteSelected()` is called when a new route is selected, either by the user (e.g., via `MediaRouteActionProvider`) or by you (e.g., via `selectRoute()`)
- `onRouteUnselected()` is also called when a new route is selected, but in this case, you are notified about the *old* route being unselected

When you are done with the callback, call `removeCallback()` on the `MediaRouter`, passing in the same `MediaRouter.Callback` instance you supplied to `addCallback()`.

We will see examples of using `MediaRouter.Callback` [in the next section](#).

User Route Selection with `MediaRouteActionProvider`

To give the user some measure of control over where media is played, you can add a `MediaRouteActionProvider` to your action bar. This will add a button that, when tapped, will allow the user to choose routes of relevance to your app (live audio, live video, remote playback).

However, this does not really work the way you (or the user) might expect, simply because some routes are automatically applied by the OS. Depending upon what the Android device is connected to will determine what routes are automatically applied and which ones the user can choose via `MediaRouteActionProvider`. For example, while Android will route live video to an HDMI-connected external display automatically, the user must opt into connecting to a Chromecast for remote playback capability.

This section outlines how to use `MediaRouteActionProvider` — both the Google and CWAC versions — and what the user will see for various circumstances. Most of the sections will be focusing on the [MediaRouter/ActionProvider](#) sample project, which uses the Google version of `MediaRouteActionProvider`.

The Basic Project and Dependencies

The project has dependency on the `mediarouter` Android library project. Projects that need `mediarouter` will need to have access to the Android Support library from the SDK Manager and follow [the instructions to add it to your project](#). Since `mediarouter` depends upon `appcompat`, you will need both library projects.

MEDIA ROUTES

The AppCompatActivity backport of the action bar requires that your activities use a theme extending from Theme.AppCompat. Hence, we have a res/values/styles.xml resource that defines AppTheme in the context of Theme.AppCompat.Light.DarkActionBar:

```
<resources>

  <style name="AppBaseTheme" parent="@style/Theme.AppCompat.Light.DarkActionBar"></style>

  <style name="AppTheme" parent="AppBaseTheme">
    <!-- All customizations that are NOT specific to a particular API-level can go here. -->
  </style>

</resources>
```

(from [MediaRouter/ActionProvider/app/src/main/res/values/styles.xml](#))

And our <activity> in the manifest, pointing to MainActivity, refers to that theme:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.mrap"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="7"
    android:targetSdkVersion="18"/>

  <application
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name="com.commonware.android.mrap.MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

(from [MediaRouter/ActionProvider/app/src/main/AndroidManifest.xml](#))

The Menu Resource

Since MediaRouteActionProvider is an action provider, we can add it to our action bar via an actionProviderClass attribute in a menu resource. And, since the Google implementation of MediaRouteActionProvider works with the AppCompatActivity action

MEDIA ROUTES

bar backport, we specifically need to use the AppCompatActivity approach to adding `actionProviderClass`, putting it in our app's custom XML namespace:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android"
      xmlns:app="http://schemas.android.com/apk/res-auto">

    <item
        android:id="@+id/route_provider"
        android:title="@string/route_provider_title"
        app:actionProviderClass="android.support.v7.app.MediaRouteActionProvider"
        app:showAsAction="always"/>

</menu>
```

(from [MediaRouter/ActionProvider/app/src/main/res/menu/main.xml](#))

Initializing the MediaRouter and Selector

Our activity (`MainActivity`) is an `ActionBarActivity` subclass, following the rules for using the AppCompatActivity action bar backport:

```
package com.commonware.android.mrap;

import android.os.Bundle;
import android.support.v4.view.MenuItemCompat;
import android.support.v7.app.ActionBarActivity;
import android.support.v7.app.MediaRouteActionProvider;
import android.support.v7.media.MediaControlIntent;
import android.support.v7.media.MediaRouteSelector;
import android.support.v7.media.MediaRouter;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.TextView;

public class MainActivity extends ActionBarActivity {
    private MediaRouteSelector selector=null;
    private MediaRouter router=null;
    private TextView selectedRoute=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
        selectedRoute=(TextView)findViewById(R.id.selected_route);

        router=MediaRouter.getInstance(this);
        selector=
            new MediaRouteSelector.Builder().addControlCategory(MediaControlIntent.CATEGORY_LIVE_AUDIO)
                .addControlCategory(MediaControlIntent.CATEGORY_LIVE_VIDEO)
                .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
                .build();
    }

    @Override
    public void onStart() {
```

MEDIA ROUTES

```
super.onStart();

router.addCallback(selector, cb,
    MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
}

@Override
public void onStop() {
    router.removeCallback(cb);

    super.onStop();
}

@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.main, menu);

    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

    provider.setRouteSelector(selector);

    return(true);
}

private MediaRouter.Callback cb=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
        MediaRouter.RouteInfo route) {
        selectedRoute.setText(route.toString());
    }
};
}
```

(from [MediaRouter/ActionProvider/app/src/main/java/com/commonsware/android/mrap/MainActivity.java](#))

In `onCreate()` we obtain an instance of `MediaRouter`. More specifically, we obtain an instance of `android.support.v7.media.MediaRouter`.

We also will need a `MediaRouteSelector` instance. `MediaRouteSelector` expresses rules for what sorts of media routes we are interested in. The simplest way to set up a `MediaRouteSelector` is to use the `MediaRouteSelector.Builder` inner class, which follows the fluent API style of other Android Builder classes (e.g., `Notification.Builder`, `AlertDialog.Builder`). Here, we call `addControlCategory()` three times, indicating three categories of routes that we are interested in:

- `MediaControlIntent.CATEGORY_LIVE_AUDIO`
- `MediaControlIntent.CATEGORY_LIVE_VIDEO`
- `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK`

Calling `build()` on the resulting `Builder` gives us our `MediaRouteSelector`, which we will use elsewhere in the activity.

Configuring the ActionProvider

In `onCreateOptionsMenu()` of `MainActivity`, we inflate our menu resource and pull out the `MediaRouteActionProvider`. To obtain an action provider from the `AppBar` action bar, the simplest solution is to use the `MenuItemCompat` helper class from the `Android Support` package, calling its static `getActionProvider()` method. This will work both with the `AppBar` backport of the action bar *and* with the native API Level 11+ action bar, though you do not need to use `MenuItemCompat` for the latter if you do not want.

We then call the `setRouteSelector()` method on our `MediaRouteActionProvider` instance, passing in the `MediaRouteSelector` we configured back in `onCreate()`. This tells the action provider what routes the user should be able to configure. In our case, that is all three major categories of routes (live audio, live video, and remote playback).

Registering for Route Changes

Interestingly enough, that is insufficient to make the `MediaRouteActionProvider` work. We *also* need to register a `MediaRouter.Callback` with the `MediaRouter`, to be informed about events related to media routes. Our `cb` private data member is an instance of an anonymous inner class extending `MediaRouter.Callback`, overriding the `onRouteSelected()` method. This method will be called whenever a new route is selected, telling us the `MediaRouter.RouteInfo` of the newly-selected route. In our case, we just update a `TextView` that is our activity's UI with the details of that route, courtesy of calling `toString()` on the `RouteInfo` object.

To inform `MediaRouter` about our desire for such callbacks, we need to call `addCallback()` on the `MediaRouter`, and later on call `removeCallback()` when we no longer need to know about such events. In `MainActivity`, these steps are done in `onStart()` and `onStop()`, respectively.

Note that we provide the `CALLBACK_FLAG_REQUEST_DISCOVERY` flag in the `addCallback()` method, to trigger a search for any Chromecast or other remote playback-capable devices that can serve as media routes.

The Results

Running this on an emulator is largely pointless, as emulators do not emulate media routes.

Running this on a device will give varying results, depending upon what other media-related accessories are available to that device. If there are no user-selectable media routes available, the `MediaRouteActionProvider` is marked as invisible, so the user does not see the icon and perhaps get confused by why tapping on it has no effect.

However, our `TextView` will show some initial route that was chosen by the device:

Figure 686: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route

Live Audio Routes

If you launch the demo with some form of external headset or speakers attached, such as via Bluetooth, you will see the route for that is automatically selected:

MEDIA ROUTES

Figure 687: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Audio Route

The `MediaRouteActionProvider` appears, with a blue highlight, indicating an active selected route. More importantly, the blue highlight indicates that the route is configurable by tapping on it to bring up a dialog:

MEDIA ROUTES

Figure 688: MediaRouter ActionProvider Demo, on a Nexus 4, Live Audio Route Configuration

Here, we can adjust the volume, plus disconnect from the route. Disconnecting shows our MediaRouteActionProvider with the default white highlight:

MEDIA ROUTES

Figure 689: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route and Provider

The white highlight means that there are possible routes, though none in use. Tapping the icon brings up a connection dialog:

MEDIA ROUTES

Figure 690: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Routes

Live Video Routes

If you launch the demo with some form of external display attached — HDMI, MHL, SlimPort, etc. — you still will not see the `MediaRouteActionProvider`, as live video routes are automatically selected, at least if there is only one such route.

However, `onRouteSelected()` will still be called as part of starting up the activity, so the `TextView` will reflect the live video route:

MEDIA ROUTES

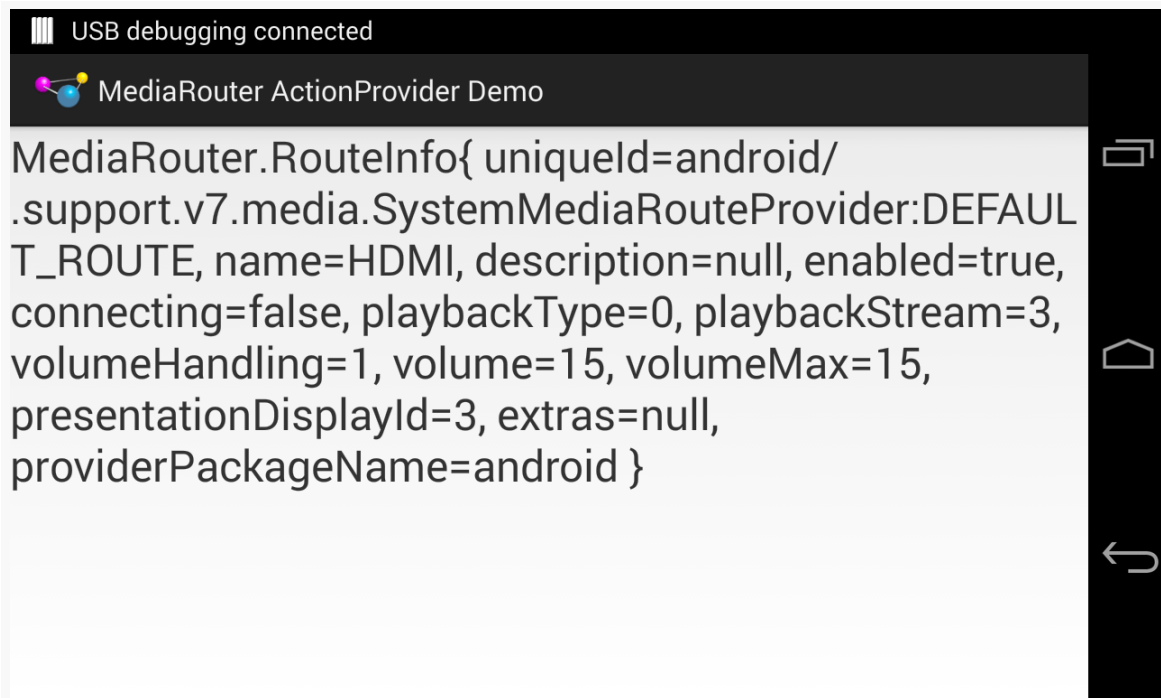

Figure 691: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Video Route

Remote Playback Routes

Since the user has to opt into remote playback media routes, the `MediaRouteActionProvider` *will* appear if you configure it to show such routes and a route is available:

MEDIA ROUTES

Figure 692: MediaRouter ActionProvider Demo, on a Nexus 4, Showing ActionProvider

The `MediaRouteActionProvider`, when tapped, will pop up a dialog of available routes that the user can select:

MEDIA ROUTES

Figure 693: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Chromecast Route

Note that if the device has both a Bluetooth audio connection *and* access to a remote playback route (like a Chromecast), and you requested both live audio and remote playback routes, then the route selection dialog could have multiple choices:

MEDIA ROUTES

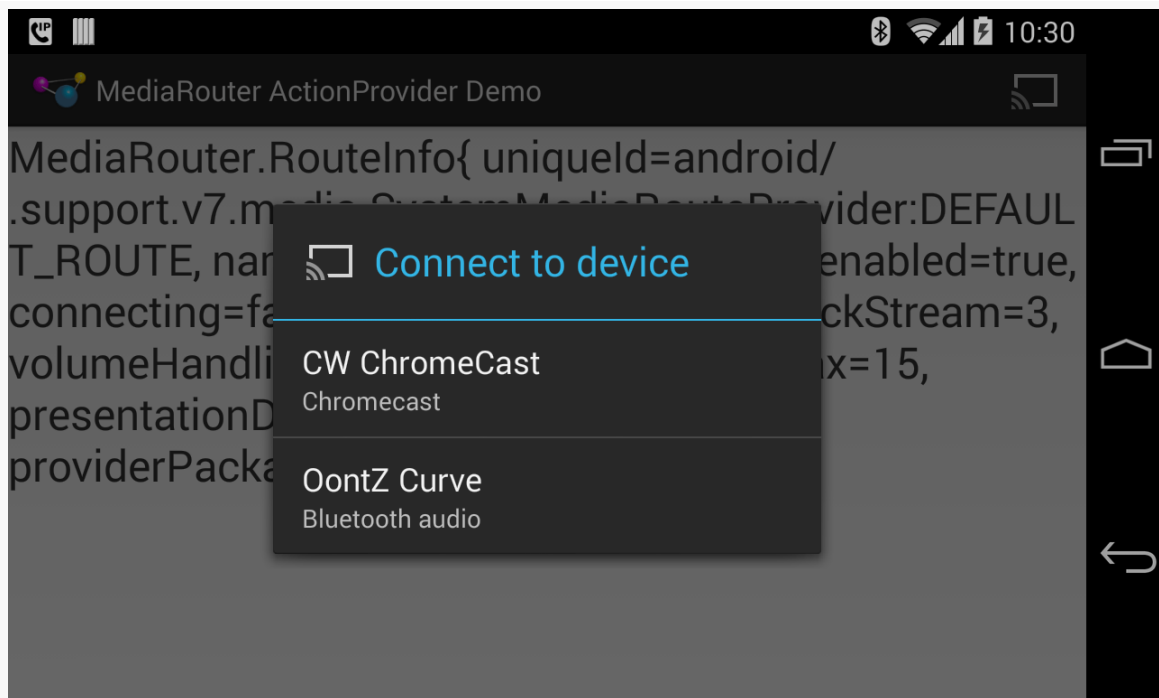

Figure 694: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Multiple Available Routes

If the user chooses a route from the dialog, our `onRouteSelected()` method will be called to reflect the new selection:

MEDIA ROUTES

Figure 695: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Selected Chromecast Route

Also note that the `MediaRouteActionProvider` color changes from white to blue, indicating an altered route.

Tapping the action provider again pops up a dialog to control the volume of the route, plus a “Disconnect” button:

Figure 696: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Route Dialog

Tapping that “Disconnect” button returns everything to its original state.

Using Live Video Routes

A live video route is designed to be used with `Presentation`, a class that enables you to render your own content on the external display, much like how you would render your own content in a `Dialog`.

The use of `Presentation` is covered [in an upcoming chapter](#).

Using Remote Playback Routes

In principle, `RemotePlaybackClient` allows you to work with remote playback routes, to specify `Uri` values to play back.

In practice, not even Google’s own sample code for `RemotePlaybackClient` works reliably, let alone as documented.

That being said, let's take a look at the [MediaRouter/RemotePlayback](#) sample project, to see how RemotePlaybackClient works and where the current problems lie.

Setting Up MediaRouteActionProvider

Much of the basic setup of this application mirrors the MediaRouteActionProvider sample shown [earlier in this chapter](#). One difference is that the UI is now encapsulated in a PlaybackFragment, with MainActivity simply setting up that fragment when needed:

```
package com.commonware.android.remoteplayback;

import android.os.Bundle;
import android.support.v7.app.ActionBarActivity;

public class MainActivity extends ActionBarActivity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new PlaybackFragment()).commit();
        }
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonware/android/remoteplayback/MainActivity.java](#))

PlaybackFragment, when it is created, opts into being retained on configuration changes, tells Android that it wishes to add items to the action bar, and sets up a MediaRouteSelector for CATEGORY_REMOTE_PLAYBACK routes:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    setHasOptionsMenu(true);
    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK).build();
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonware/android/remoteplayback/PlaybackFragment.java](#))

Then, in onAttach() — called when the PlaybackFragment is attached to the hosting activity — we obtain a MediaRouter instance:

```
@Override
public void onAttach(Activity host) {
```

MEDIA ROUTES

```
super.onAttach(host);

router=MediaRouter.getInstance(host);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

In `onStart()`, we hook a `cb` data member — an instance of `MediaRouter.Callback` up to the `MediaRouter`, also requesting that the `MediaRouter` initiate discovery of available routes. We remove our callback in `onStop()`:

```
@Override
public void onStart() {
    super.onStart();

    router.addCallback(selector, cb,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
}

@Override
public void onStop() {
    router.removeCallback(cb);

    super.onStop();
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

We will examine `cb`'s declaration later in this section.

Later on, as part of our `onCreateOptionsMenu()` processing, we configure the `MediaRouteActionProvider` as before:

```
MenuItem item=menu.findItem(R.id.route_provider);
MediaRouteActionProvider provider=
    (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

provider.setRouteSelector(selector);
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

All of this is very similar to the earlier examples. From here, though, we will actually use the route once the user selects it, to play back some media.

The Rest of the User Interface

The UI of the `PlaybackFragment` — other than the action bar — consists of a “transcript”. This is a `TextView` inside of a `ScrollView`:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
```

MEDIA ROUTES

```
android:layout_height="match_parent">

<TextView
    android:id="@+id/transcript"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:textSize="20sp"/>

</ScrollView>
```

(from [MediaRouter/RemotePlayback/app/src/main/res/layout/activity_main.xml](#))

As with most fragments, we inflate this layout in `onCreateView()`, holding onto the `TextView` and `ScrollView` widgets:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    scroll=
        (ScrollView)inflater.inflate(R.layout.activity_main, container,
                                    false);

    transcript=(TextView)scroll.findViewById(R.id.transcript);

    logToTranscript("Started");

    return(scroll);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `logToTranscript()` method will append a `String` to the `TextView` contents on a new line, plus scroll to the bottom to ensure that the new text is visible:

```
private void logToTranscript(String msg) {
    if (client != null) {
        String sessionId=client.getSessionId();

        if (sessionId != null) {
            msg="(" + sessionId + ") " + msg;
        }
    }

    transcript.setText(transcript.getText().toString() + msg + "\n");
    scroll.fullScroll(View.FOCUS_DOWN);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `client` data member referred to in `logToTranscript()` is our `RemotePlaybackClient` instance, which will be covered in the next section.

MEDIA ROUTES

What the user sees when first running the sample is the action bar (with our `MediaRouteActionProvider`) and the transcript, with a simple “Started” message:

Figure 697: RemotePlaybackClient Demo, on a Nexus 4, As Initially Launched

As before, tapping on the “cast” action bar item pops up our dialog of available routes:

Figure 698: RemotePlaybackClient Demo, on a Nexus 4, Showing Available Routes

Connecting and Session Management

When the user selects a route, our `MediaRouter.Callback (cb)` is called with `onRouteSelected()`. Similarly, if the user elects to disconnect via the `MediaRouteActionProvider`, our `Callback` is called with `onRouteUnselected()`. In the `MediaRouter.Callback` implementation inside `PlaybackFragment`, those events route to `connect()` and `disconnect()` methods, respectively, after logging a message to the transcript:

```
private MediaRouter.Callback cb=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
                               MediaRouter.RouteInfo route) {
        logToTranscript(getActivity().getString(R.string.route_selected));
        connect(route);
    }

    @Override
    public void onRouteUnselected(MediaRouter router,
                                  MediaRouter.RouteInfo route) {
        logToTranscript(getActivity().getString(R.string.route_unselected));
        disconnect();
    }
};
```

MEDIA ROUTES

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `connect()` method handles connecting to the remote playback device and starting a session:

```
private void connect(MediaRouter.RouteInfo route) {
    client=
        new RemotePlaybackClient(getActivity().getApplication(), route);

    if (client.isRemotePlaybackSupported()) {
        logToTranscript(getActivity().getString(R.string.connected));

        if (client.isSessionManagementSupported()) {
            client.startSession(null, new SessionActionCallback() {
                @Override
                public void onResult(Bundle data, String sessionId,
                                     MediaSessionStatus sessionStatus) {
                    logToTranscript(getActivity().getString(R.string.session_started));
                    updateMenu();
                }

                @Override
                public void onError(String error, int code, Bundle data) {
                    logToTranscript(getActivity().getString(R.string.session_failed));
                }
            });
        }
        else {
            getActivity().supportInvalidateOptionsMenu();
        }
    }
    else {
        logToTranscript(getActivity().getString(R.string.remote_playback_not_supported));
        client=null;
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

All of that, though, requires a bit more explanation.

What's a Session?

The objective of the `connect()` method is to establish a “session” with the `RemotePlaybackClient`. In Android’s terms, a “session” is the state associated with an application’s interactions with the remote playback client. In principle, the session could be shared among several instances of the app, such as several people contributing tracks to a dynamic playlist for audio playback at a party. Here, though, we are simply focused on having this one application instance have a session.

In principle, not all remote playback clients may support session management. In those cases, everybody is considered to be part of the same session. The test device for this sample (Chromecast) does support session management, however.

Connecting the Client

Connecting to the remote playback device is simply a matter of creating an instance of `RemotePlaybackClient`, specifying the route to connect to:

```
client=  
    new RemotePlaybackClient(getActivity().getApplication(), route);
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

Here, we use `getActivity().getApplication()` in the `RemotePlaybackClient` constructor. That is because we want to hold onto this `RemotePlaybackClient` instance across configuration changes, so we can easily maintain our session. Since we do not know what `RemotePlaybackClient` may hold onto given the supplied `Context`, and since we do not want to leak our activity by retaining a reference to it, we use the global `Application` instance, for a “leak-resistant” `Context`.

We also call `isRemotePlaybackSupported()` to confirm that, indeed, the `RemotePlaybackClient` is connected to something that supports remote playback. This should always return true in this case, as we are only interested in remote playback routes. But, a little defensive programming never hurts.

Assuming that is all OK, we log a “connected” message to the transcript and continue on to start our session.

Starting a Session

`isSessionManagementSupported()` on `RemotePlaybackClient` will indicate if the device supports explicit session management or not. If not, we will use the default implicit session and just continue on.

Otherwise, we call `startSession()` to explicitly start a session. This takes an optional `Bundle` of additional information to send in the start-session request to the device (or null if unused), plus a `SessionActionCallback`. The `SessionActionCallback` is supposed to be called when the session is ready for use. Surprisingly enough, this actually works... for `startSession()`.

MEDIA ROUTES

The `SessionActionCallback` will be called with `onResult()` for success and `onError()` for failure. In either case, we log a message to the transcript indicating the status.

In addition, if we have a session — either explicitly created via `startSession()` or implicitly created for devices without explicit session management — we call an `updateMenu()` method to update the action bar items.

About the Action Bar

The fragment maintains two boolean values representing key states in the operation of the playback:

1. `isPlaying` indicates if playback was started and not yet stopped
2. `isPaused` indicates if playback was paused and not yet resumed

The aforementioned `updateMenu()` implementation uses those, plus the existence of a non-null `client`, to configure the action bar items:

```
private void updateMenu() {
    if (menu != null) {
        menu.findItem(R.id.stop).setVisible(client != null && isPlaying);
        menu.findItem(R.id.pause).setVisible(client != null && isPlaying
            && !isPaused);
        menu.findItem(R.id.play)
            .setVisible(client != null && (!isPlaying || isPaused));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

Specifically:

- When we are not playing, the play item is visible; when we *are* playing, the stop item is visible
- When we are not paused, the pause item is visible (play serves “double duty”, handling starting playback from a stopped state and resuming playback from a paused state)

This is based on a cached copy of the `Menu` object, saved in `onCreateOptionsMenu()` as part of setting up the action bar:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    this.menu=menu;
    inflater.inflate(R.menu.main, menu);
}
```

MEDIA ROUTES

```
updateMenu();

MenuItem item=menu.findItem(R.id.route_provider);
MediaRouteActionProvider provider=
    (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

provider.setRouteSelector(selector);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

This is also where the logic shown previously for configuring the `MediaRouteActionProvider` resides.

Session IDs

A session has a `String` identifier. In principle, this can be shared with other instances of your application, to allow for shared management of the session.

In the case of this sample, the session ID is merely logged to the transcript for all messages that are tied to an active session.

Hence, when the user chooses a remote playback route from the `MediaRouteActionProvider`, the resulting UI should resemble:

Figure 699: RemotePlaybackClient Demo, on a Nexus 4, Showing an Active Session

We see that we have connected to the client and started our session, and the play action bar item is now available to start playback of some media.

Playing

The play action bar item is tied to a play() method via onOptionsItemSelected(), if we are not paused:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.play:
            if (isPlaying && isPaused) {
                resume();
            }
            else {
                play();
            }
        case R.id.stop:
            stop();
            return(true);
        case R.id.pause:
```

MEDIA ROUTES

```
    pause();
    return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

`play()`, in turn, uses the `play()` method on `RemotePlaybackClient` to play back a copy of “[Elephants Dream](#)”, a Creative Commons-licensed video, hosted on CommonsWare’s corner of the Amazon S₃ service:

```
private void play() {
    logToTranscript(getActivity().getString(R.string.play_requested));

    ItemActionCallback playCB=new ItemActionCallback() {
        @Override
        public void onResult(Bundle data, String sessionId,
            MediaSessionStatus sessionStatus,
            String itemId, MediaItemStatus itemStatus) {
            logToTranscript(getActivity().getString(R.string.playing));
            isPlaying=true;
            updateMenu();
        }

        @Override
        public void onError(String error, int code, Bundle data) {
            logToTranscript(getActivity().getString(R.string.play_error)
                + error);
        }
    };

    client.play(Uri.parse("http://misc.commonsware.com/ed_hd_512kb.mp4"),
        "video/mp4", null, 0, null, playCB);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `play()` method on `RemotePlaybackClient` takes a few parameters:

- The `Uri` of the media to be played back
- The MIME type of that media (or `null` if you do not know the MIME type)
- An optional `Bundle` of metadata about the media to be played, where the `Bundle` keys come from `MediaItemMetadata` class (or `null` if none)
- The starting offset in the media to begin playback from (use 0 to start from the beginning)
- An optional `Bundle` of additional data to pass to the device
- An instance of `ItemActionCallback` to be notified when playback has started or has failed

MEDIA ROUTES

`ItemActionCallback` is reminiscent of `SessionActionCallback`, in that `onResult()` will be called when playback begins and `onError()` will return when playback ends. The method signature of `onResult()` is slightly different, offering an ID and status of this particular media item.

In our case, we log a message to the transcript before requesting playback, then again on success or failure. On success, we also update `isPlaying` to be true and refresh the action bar.

Hence, once the user begins playback by tapping the play action bar item, the UI will look like this:

Figure 700: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Started

And, of course, the movie should be showing up on your remote playback device.

Stopping, and a Bug

The `stop()` action bar item is tied to a `stop()` method in `PlaybackFragment`. You would think that this would be very similar to starting playback — call some `stop()` method on `RemotePlaybackClient` and update the UI after playback has stopped.

MEDIA ROUTES

And, indeed, that is what we do... except that we have to deal with a bug:

```
private void stop() {
    logToTranscript(getActivity().getString(R.string.stop_requested));

    StopCallback stopCB=new StopCallback();

    client.stop(null, stopCB);
    transcript.postDelayed(stopCB, 1000);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The stop() Call, and the Bug

stop() on RemotePlaybackClient takes an optional Bundle (here, null) and a SessionActionCallback. The SessionActionCallback is supposed to be called when playback has stopped (onResult()) or if there was some error in processing the request (onError()).

In practice, [neither happen when testing this on a Chromecast](#). This same behavior can be seen with [Google's own sample code](#), so it would not appear to be a problem with the author's own sample.

What actually happens is that playback is indeed stopped, but the SessionActionCallback is not called with onResult() or onError().

The Workaround: RunnableSessionActionCallback

Since we cannot rely upon onResult() to be called for us, if we have work that we need to do in that case, we have to have some sort of fallback mechanism. One crude fallback is to assume that the request succeeded if we have not received a specific response after a period of time (say, 1000 milliseconds).

To that end, this sample has RunnableSessionActionCallback, a SessionActionCallback that implements Runnable:

```
abstract class RunnableSessionActionCallback extends
    SessionActionCallback implements Runnable {
    abstract protected void doWork();

    private boolean hasRun=false;

    @Override
    public void onResult(Bundle data, String sessionId,
        MediaSessionStatus sessionStatus) {
        transcript.removeCallbacks(this);
    }
}
```

MEDIA ROUTES

```
run();
}

@Override
public void run() {
    if (!hasRun) {
        hasRun=true;
        doWork();
    }
}
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `run()` method sees whether or not the callback has already been run from a previous `run()` call. If not, it does the work specified by the abstract `doWork()` method, to be implemented in subclasses.

`StopCallback`, as seen in the `stop()` method above, extends `RunnableSessionActionCallback` and overrides `doWork()`:

```
private class StopCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPlaying=false;
        isPaused=false;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.stopped));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

`stop()` then not only passes the `StopCallback` to the `stop()` implementation on `RemotePlaybackClient`, but also schedules it as a `Runnable` to be invoked in 1000 milliseconds, via a call to `postDelayed()` on the `TextView` portion of the transcript. The `onResult()` implementation in `RunnableSessionActionCallback` calls `removeCallbacks()`, so we do not bother invoking the posted `Runnable` if that is not needed.

The `doWork()` implementation in `StopCallback` updates our flags, refreshes the action bar, and logs a message to the transcript. The result will look like:

Figure 701: *RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Stopped*

This sample also does not handle the case where the media completes playback on its own, insofar as this event is not detected, to update the action bar. This will be added in a future version of this sample, if further bugs allow such support to actually work.

Pausing and Resuming

Similarly, the pause action bar item forwards to a `pause()` method that calls `pause()` on the `RemotePlaybackClient`:

```
private void pause() {
    logToTranscript(getActivity().getString(R.string.pause_requested));

    PauseCallback pauseCB=new PauseCallback();

    client.pause(null, pauseCB);
    transcript.postDelayed(pauseCB, 1000);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

That, in turn, uses `PauseCallback`:

MEDIA ROUTES

```
private class PauseCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPaused=true;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.paused));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

This updates the action bar and logs messages to the transcript, similar to the `stop()` behavior. It also should successfully pause playback on the remote device.

The play action bar item routes to `resume()` if playback is paused:

```
private void resume() {
    logToTranscript(getActivity().getString(R.string.resume_requested));

    ResumeCallback resumeCB=new ResumeCallback();

    client.resume(null, resumeCB);
    transcript.postDelayed(resumeCB, 1000);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

That, in turn, uses `ResumeCallback`:

```
private class ResumeCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPaused=false;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.resumed));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

This too updates the action bar and logs messages to the transcript, in addition to resuming playback on the remote device.

Disconnecting

A call to `disconnect()` on `PlaybackFragment` is triggered from two locations:

- `onRouteUnselected()` in our `MediaRouter.Callback`, such as when the user uses the `MediaRouteActionProvider` to disconnect from the route
- `onDestroy()`, as part of general cleanup of the fragment

MEDIA ROUTES

`disconnect()` should reverse the work done in `connect()`, ending our session and releasing the client:

```
private void disconnect() {
    isPlaying=false;
    isPaused=false;

    if (client != null) {
        logToTranscript(getActivity().getString(R.string.session_ending));
        EndSessionCallback endCB=new EndSessionCallback();

        if (client.isSessionManagementSupported()) {
            client.endSession(null, endCB);
        }

        transcript.postDelayed(endCB, 1000);
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

This simply calls the `endSession()` method on the `RemotePlaybackClient`, supplying an `EndSessionCallback` to be notified (theoretically) of when the session has been torn down. But it only calls `endSession()` if session management is supported; otherwise, we would get a runtime error.

To be sure we complete the disconnection, though, we schedule the `EndSessionCallback` as seen in the `stop()`, `pause()`, and `resume()` methods. `EndSessionCallback` calls `release()` on the `RemotePlaybackClient`, to indicate that we are done with it, before setting `client` to `null`, refreshing the action bar, and logging something to the transcript:

```
private class EndSessionCallback extends
    RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        client.release();
        client=null;

        if (getActivity() != null) {
            updateMenu();
            logToTranscript(getActivity().getString(R.string.session_ended));
        }
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

Other Remote Playback Features

There are other things that `RemotePlaybackClient` offers that are not shown in this sample:

- `enqueue()` allows you to build up a queue of media to be played back in the current session. This could be used by an individual or, in principle, by several people using the same app with a shared session ID. `remove()` allows you to remove specific items from the playback queue. These methods only work if `isQueueingSupported()` returns true.
- `getStatus()` will return information about the currently-playing piece of media, while `getSessionStatus()` will return information about the overall session. You can also find out about these changes on the fly by registering with `setStatusCallback()`.
- `seek()` allows you to move the playback to a new offset within the media, for “rewind” and “fast-forward” functionality. The status APIs (above) can tell you where you are in the playback, so you can determine the appropriate offset to seek to.

Supporting External Displays

Android 4.2 inaugurated support for applications to control what appears on an external or “secondary” display (e.g., TV connected via HDMI), replacing the default screen mirroring. This is largely handled through a `Presentation` object, where you declare the UI that goes onto the external display, in parallel with whatever your activity might be displaying on the primary screen.

In this chapter, we will review how Android supports these external displays, how you can find out if an external display is attached, and how you can use `Presentation` objects to control what is shown on that external display.

The author would like to thank Mark Allison, whose “Multiple Screens” blog post series helped to blaze the trail for everyone in this space.

Prerequisites

In addition to the core chapters, you should read [the chapter on dialogs](#) and [the chapter on `MediaRouter`](#) before reading this chapter.

A History of External Displays

In this chapter, “external displays” refers to a screen that is temporarily associated with an Android device, in contrast with a “primary screen” that is where the Android device normally presents its user interface. So, most Android devices connected to a television via HDMI would consider the television to be a “external display”, with the touchscreen of the device itself as the “primary screen”. However, a [Android TV](#) box or a [Fire TV](#) connected to a television via HDMI would consider the television to be the “primary screen”, simply because there is no other screen. Some

devices themselves may have multiple screens, such as the [Sony Tablet P](#) — what those devices do with those screens will be up to the device.

Historically, support for external displays was manufacturer-dependent. Early Android devices had no ability to be displayed on an external display except through so-called “software projectors” like Jens Riboe’s [Droid@Screen](#). Some Android 2.x devices had ports that allowed for HDMI or composite connections to a television or projector. However, control for what would be displayed resided purely in the hands of the manufacturer. Some manufacturers would display whatever was on the touchscreen (a.k.a., “mirroring”). Some manufacturers would do that, but only for select apps, like a built-in video player.

Android 3.0 marked the beginning of Android’s formal support for external displays, as the Motorola XOOM supported mirroring of the LCD’s display via an micro-HDMI port. This mirroring was supplied by the core OS, not via device-dependent means. Any Android 3.0+ device with some sort of HDMI connection (e.g., micro-HDMI port) should support this same sort of mirroring capability.

However, mirroring was all that was possible. There was no means for an application to have something on the external display (e.g., a video) and something *else* on the primary screen (e.g., playback controls plus IMDB content about the movie being watched).

Android 4.2 changed that, with the introduction of Presentation.

What is a Presentation?

A Presentation is a container for displaying a UI, in the form of a View hierarchy (like that of an activity), on an external display.

You can think of a Presentation as being a bit like a Dialog in that regard. Just as a Dialog shows its UI separate from its associated activity, so does a Presentation. In fact, as it turns out, Presentation *inherits from* Dialog.

The biggest difference between a Presentation and an ordinary Dialog, of course, is where the UI is displayed. A Presentation displays on an external display; a Dialog displays on the primary screen, overlaying the activity. However, this difference has a profound implication: the *characteristics* of the external display, in terms of size and density, are likely to be different than those of a primary screen.

Hence, the resources used by the UI on an external display may be different than the resources used by the primary screen. As a result, **the Context of the Presentation is not the Activity**. Rather, it is a separate Context, one whose Resources object will use the proper resources based upon the external display characteristics.

This seemingly minor bit of bookkeeping has some rippling effects on setting up your Presentation, as we will see as this chapter unfolds.

Playing with External Displays

To write an app that uses an external display via a Presentation, you will need Android 4.2 or higher.

Beyond that, though, you will also need an external display of some form. Presently, you have three major options: emulate it, use a screen connected via some sort of cable, or use Miracast for wireless external displays.

Emulated

Even without an actual external display, you can lightly test your Presentation-enabled app via the Developer Options area of Settings on your Android 4.2 device. There, in the Drawing category, you will see the “Simulate secondary displays” preference:

SUPPORTING EXTERNAL DISPLAYS

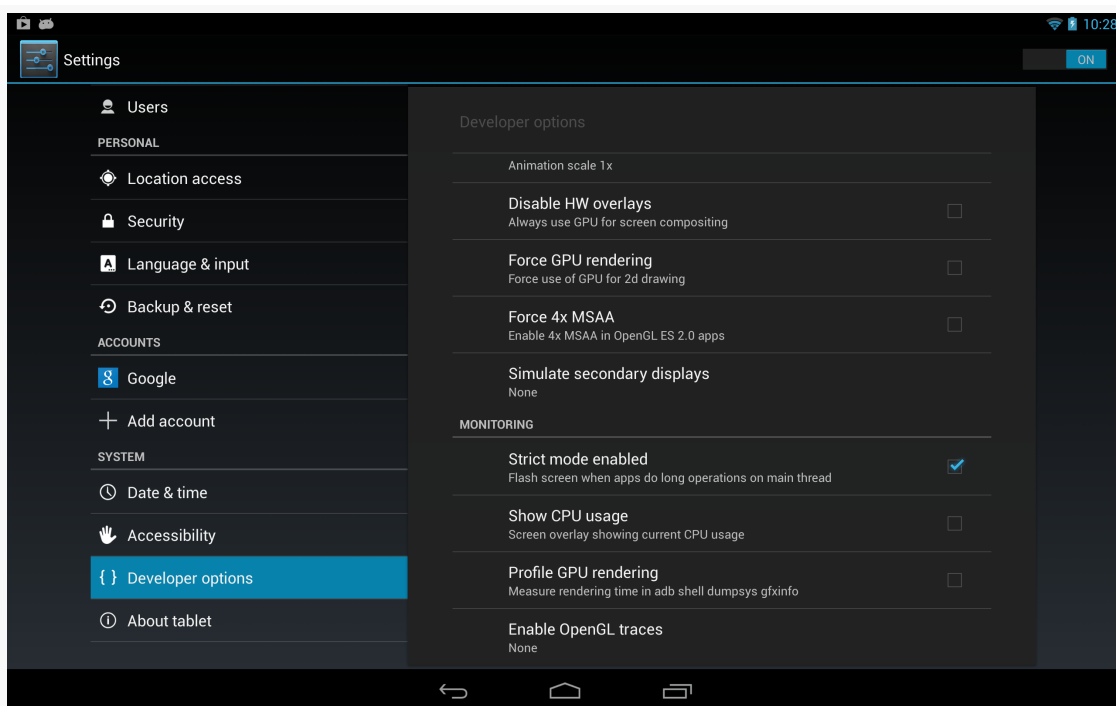

Figure 702: Nexus 10 “Simulate secondary displays” Preference

Tapping that will give you various options for what secondary display to emulate:

SUPPORTING EXTERNAL DISPLAYS

Figure 703: Nexus 10 “Simulate secondary displays” Options

Tapping one of those will give you a small window in the upper-left corner, showing the contents of the external display, overlaid on top of your regular screen:

SUPPORTING EXTERNAL DISPLAYS

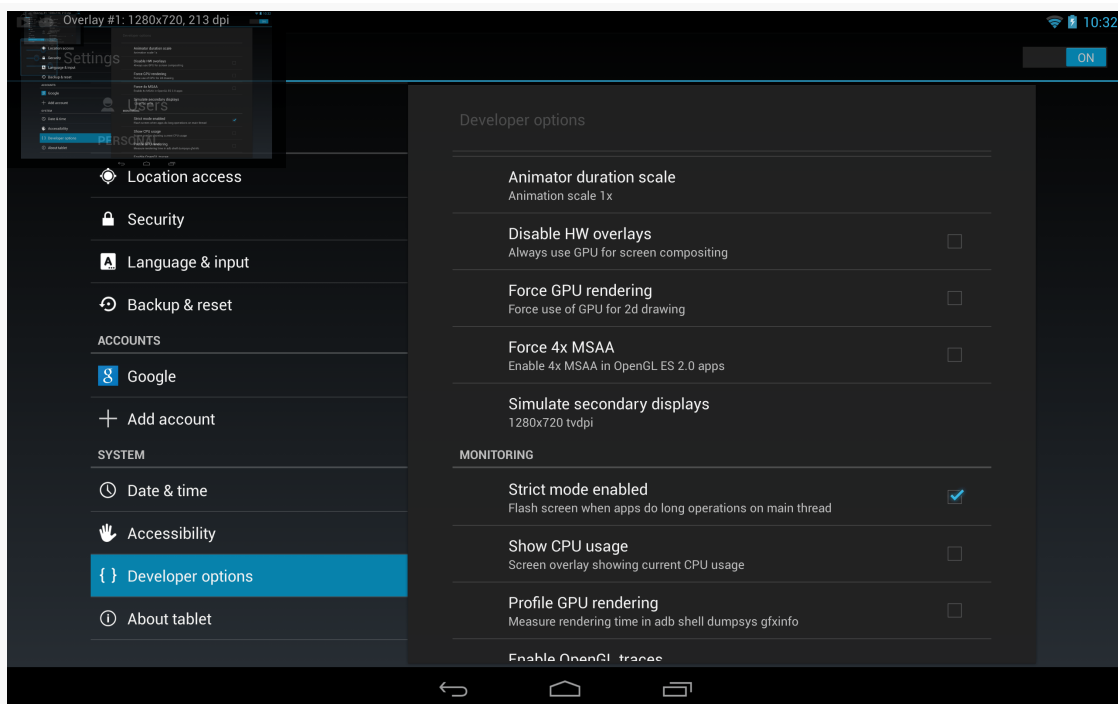

Figure 704: Nexus 10, Simulating a 720p external display

Normally, that will show a mirrored version of the primary screen, but with a Presentation-enabled app, it will show what is theoretically shown on the real external display.

However, there are limits with this technology:

- You will see this option on an Android emulator, but it may not work, particularly if you are not capable of using the “Host GPU Support” option. At the time of this writing, it works on the x86 Android 4.2 emulator image, but not the x86 Android 4.3 or 4.4 emulator image, and the ARM emulators are likely to be far too slow.
- The external display is rather tiny, making it difficult for you to accurately determine if everything is sized appropriately.
- The external display occludes part of the screen, overlaying your activities, though you can at least drag it around the screen to move it out of your way as needed.

In practice, before you ship a Presentation-capable app, you will want to test it with an actual physical external display.

HDMI

If you have a device with HDMI-out capability, and you have the appropriate cable, you can simply plug that cable between your device and the display. “Tuning” the display to use that specific HDMI input port should cause your device’s screen contents to be mirrored to that display. Once this is working, you should be able to control the contents of that display using *Presentation*.

MHL

Mobile High-Definition Link, or MHL for short, is a relatively new option for connections to displays. On many modern Android devices, the micro USB port supports MHL as well. Some external displays have MHL ports, in which case a male-to-male MHL direct cable will connect the device to the display. Otherwise, MHL can be converted to HDMI via adapters, so an MHL-capable device can attach to any HDMI-compliant display.

SlimPort

SlimPort is another take on the overload-the-micro-USB-port-for-video approach. MHL is used on substantially more devices, but SlimPort appears on several of the Nexus-series devices (Nexus 4, Nexus 5, and the 2013 generation of the Nexus 7). Hence, while users will be more likely to have an MHL device, *developers* may be somewhat more likely to have a SlimPort device, given the popularity of Nexus devices among Android app developers.

From the standpoint of your programming work, MHL and SlimPort are largely equivalent — there is nothing that you need to do with your *Presentation* to address either of those protocols, let alone anything else like native HDMI.

USB 3.1 Type C

The new USB 3.1 Type C specification has enough hooks for video display that we may see Android devices starting to use it (along with USB->HDMI adapters) for supporting external displays.

Miracast

There are a few wireless display standards available. Android 4.2 supports Miracast, based upon WiFiDirect. This is also supported by some devices running earlier

SUPPORTING EXTERNAL DISPLAYS

versions of Android, such as some Samsung devices (where Miracast is sometimes referred to as “AllShare Cast”). However, unless and until those devices get upgraded to Android 4.2, you cannot control what they display, except perhaps through some manufacturer-specific APIs.

On a Miracast-capable device, going into Settings > Displays > Wireless display will give you the ability to toggle on wireless display support and scan for available displays:

Figure 705: Nexus 4 Wireless Display Settings

You can then elect to attach to one of the available wireless displays and get your screen mirrored, and later use this with your Presentation-enabled app.

Of course, you also need some sort of Miracast-capable display. As of early 2013, there were few of these. However, you can also get add-on boxes that connect to normal displays via HDMI and make them available via Miracast. One such box is the [Netgear PTV3000](#), whose current firmware supports Miracast along with other wireless display protocols.

Note that Miracast uses a compressed protocol, to minimize the bandwidth needed to transmit the video. This, in turn, can cause some lag.

Note that Intel's WiDi is an extended version of Miracast.

WirelessHD

An up-and-coming competitor to Miracast is WirelessHD. WirelessHD has greater bandwidth requirements. On the other hand, it avoids compression, and therefore the lag that you experience with Miracast. At the time of this writing, though, no WirelessHD-native Android devices are available.

Detecting Displays

Of course, we can only present a `Presentation` on an external display if there is, indeed, such a screen available. There are two approaches for doing this: using `DisplayManager` and using `MediaRouter`. We examined `MediaRouter` for detecting live video routes [in a preceding chapter](#), so let's focus here on `DisplayManager`.

`DisplayManager` is a system service, obtained by calling `getSystemService()` and asking for the `DISPLAY_SERVICE`.

Once you have a `DisplayManager`, you can ask it to give you a list of all available displays (`getDisplay()` with zero arguments) or all available displays in a certain category (`getDisplay()` with a single `String` parameter). As of API Level 17, the only available display category is `DISPLAY_CATEGORY_PRESENTATION`. The difference between the two flavors of `getDisplay()` is just the sort order:

- The zero-argument `getDisplay()` returns the `Display` array in arbitrary order
- The one-argument `getDisplay()` will put the `Display` objects matching the identified category earlier in the array

These would be useful if you wanted to pop up a list of available displays to ask the user which `Display` to use.

You can also register a `DisplayManager.DisplayListener` with the `DisplayManager` via `registerDisplayListener()`. This listener will be called when displays are added (e.g., HDMI cable was connected), removed (e.g., HDMI cable was disconnected), or changed. It is not completely clear what would trigger a "changed" call, though possibly an orientation-aware display might report back the revised height and width.

Note that while `DisplayManager` was added in API Level 17, `Display` itself has been around since API Level 1, though some additions have been made in more recent Android releases. But, this may mean that you can pass the `Display` object around to code supporting older devices without needing to constantly check for SDK level or add the `@TargetApi()` annotation.

Also note that the `support-v4` library contains a `DisplayManagerCompat`, allowing you to call `DisplayManager`-like methods going all the way back to API Level 4. This does not give older devices the ability to work with external displays — that would require a time machine — but it can make it incrementally easier for you to write your app, without having to worry about API level. `DisplayManagerCompat` just gracefully degrades to returning information only about the device's standard touchscreen.

A Simple Presentation

Let's take a look at a small sample app that demonstrates how we can display custom content on an external display using a `Presentation`. The app in question can be found in the [Presentation/Simple](#) sample project.

The Presentation Itself

Since `Presentation` extends from `Dialog`, we provide the UI to be displayed on the external display via a call to `setContentView()`, much like we would do in an activity. Here, we just create a `WebView` widget in Java, point it to some Web page, and use it:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private class SimplePresentation extends Presentation {
    SimplePresentation(Context ctxt, Display display) {
        super(ctxt, display);
    }

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        WebView ww=new WebView(getContext());

        ww.loadUrl("https://commonsware.com");

        setContentView(ww);
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

However, there are two distinctive elements of our implementation:

- Our constructor takes a Context (typically the Activity), along with a Display object indicating where the UI should be presented.
- Our call to the WebView constructor uses getContext(), instead of the Activity object. In this case, that may have no real-world effect, as WebView is not going to be using any of our resources. But, had we used a LayoutInflater for inflating our UI, we would need to use one created from getContext(), not from the activity itself.

Detecting the Displays

We need to determine whether there is a suitable external display when our activity comes into the foreground. We also need to determine if an external display was added or removed while we are in the foreground.

So, in onStart(), if we are on an Android 4.2 or higher device, we will get connected to the MediaRouter to handle those chores:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onStart() {
    super.onStart();

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        if (cb==null) {
            cb=new RouteCallback();
            router=(MediaRouter) getSystemService(MEDIA_ROUTER_SERVICE);
        }

        handleRoute(router.getSelectedRoute(MediaRouter.ROUTE_TYPE_LIVE_VIDEO));
        router.addCallback(MediaRouter.ROUTE_TYPE_LIVE_VIDEO, cb);
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

Specifically, we:

- Create an instance of RouteCallback, an inner class of our activity that extends SimpleCallback
- Use getSystemService() to obtain a MediaRouter
- Call a handleRoute() method on our activity that will update our UI based upon the current video route, obtained by calling getSelectedRoute() on the MediaRouter
- Register the RouteCallback object with the MediaRouter via addCallback()

SUPPORTING EXTERNAL DISPLAYS

The `RouteCallback` object simply overrides `onRoutePresentationDisplayChanged()`, which will be called whenever there is a change in what screens are available and considered to be the preferred modes for video. There, we just call that same `handleRoute()` method that we called in `onStart()`:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN)
private class RouteCallback extends SimpleCallback {
    @Override
    public void onRoutePresentationDisplayChanged(MediaRouter router,
                                                RouteInfo route) {
        handleRoute(route);
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](https://commonsware.com/android/preso/simple/MainActivity.java))

Hence, our business logic for showing the presentation is isolated in one method, `handleRoute()`.

Our `onStop()` method will undo some of the work done by `onStart()`, notably removing our `RouteCallback`. We will examine that more closely in the next section.

Showing and Hiding the Presentation

Our `handleRoute()` method will be called with one of two parameter values:

- The `RouteInfo` of the active route we should use for displaying the Presentation
- `null`, indicating that there is no route for such content, other than the primary screen

If we are passed the `RouteInfo`, it may represent the route we are already using, or possibly it may represent a different route entirely.

We need to handle all of those cases, even if some (switching directly from one route to another) may not necessarily be readily testable.

Hence, our `handleRoute()` method does its best:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void handleRoute(RouteInfo route) {
    if (route == null) {
        clearPreso();
    }
    else {
```

SUPPORTING EXTERNAL DISPLAYS

```
Display display=route.getPresentationDisplay();

if (route.isEnabled() && display != null) {
    if (preso == null) {
        showPreso(route);
        Log.d(getClass().getSimpleName(), "enabled route");
    }
    else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
        clearPreso();
        showPreso(route);
        Log.d(getClass().getSimpleName(), "switched route");
    }
    else {
        // no-op: should already be set
    }
}
else {
    clearPreso();
    Log.d(getClass().getSimpleName(), "disabled route");
}
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

There are five possibilities handled by this method:

- If the route is null, then we should no longer be displaying the Presentation, so we call a `clearPreso()` method that will handle that
- If the route exists, but is disabled or is not giving us a `Display` object, we also assume that we should no longer be displaying the Presentation, so we call `clearPreso()`
- If the route exists and seems ready for use, and we are not already showing a Presentation (our `preso` data member is null), we need to show the Presentation, which we delegate to a `showPreso()` method
- If the route exists, seems ready for use, but we are already showing a Presentation, and the ID of the new `Display` is different than the ID of the `Display` our Presentation had been using, we use *both* `clearPreso()` and `showPreso()` to switch our Presentation to the new `Display`
- If the route exists, seems ready for use, but we are already showing a Presentation on this `Display`, we do nothing and wonder why `handleRoute()` got called

Showing the Presentation is merely a matter of creating an instance of our `SimplePresentation` and calling `show()` on it, like we would a regular `Dialog`:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void showPreso(RouteInfo route) {
    preso=new SimplePresentation(this, route.getPresentationDisplay());
}
```

SUPPORTING EXTERNAL DISPLAYS

```
preso.show();
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

Clearing the Presentation calls `dismiss()` on the Presentation, then sets the `preso` data member to `null` to indicate that we are not showing a Presentation:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void clearPreso() {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

Our `onPause()` uses `clearPreso()` and `removeCallback()` to unwind everything:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onStop() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        clearPreso();

        if (router != null) {
            router.removeCallback(cb);
        }
    }

    super.onStop();
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

The Results

If you run this with no external display, you will just see a plain `TextView` that is the UI for our primary screen:

SUPPORTING EXTERNAL DISPLAYS

If you run this *with* an external display, the external display will show our WebView:

A Simpler Presentation

There was a fair bit of code in the previous sample for messing around with `MediaRouter` and finding out about changes in the available displays.

To help simplify apps using `Presentation`, the author of this book maintains a library, [CWAC-Presentation](#), with various reusable bits of code for managing `Presentations`.

One piece of this is `PresentationHelper`, which isolates all of the display management logic in a single reusable object. In this section, we will examine how to use `PresentationHelper`, then how `PresentationHelper` itself works, using `DisplayManager` under the covers.

Getting a Little Help

Our [Presentation/Simpler](#) sample project uses the `CWAC-Presentation` artifact:

```
apply plugin: 'com.android.application'
```

SUPPORTING EXTERNAL DISPLAYS

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:presentation:0.4.+ '
}

android {
    compileSdkVersion 19
    buildToolsVersion "21.1.2"
}
```

(from [Presentation/Simpler/app/build.gradle](#))

This gives us access to `PresentationHelper`. Our `MainActivity` in the sample creates an instance of `PresentationHelper` in `onCreate()`, stashing the object in a data member:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);
    helper=new PresentationHelper(this, this);
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

The constructor for `PresentationHelper` takes two parameters:

- a `Context` object, one that should be valid for the life of the helper, typically the `Activity` that creates the helper, and
- a implementation of `PresentationHelper.Listener` — in this case, the interface is implemented on `MainActivity` itself

The activity that creates the helper must forward `onPause()` and `onResume()` lifecycle methods to the equivalent methods on the helper:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

SUPPORTING EXTERNAL DISPLAYS

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

The implementer of `PresentationHelper.Listener` also needs to have `showPreso()` and `clearPreso()` methods, much like the ones from the original `Presentation` sample in this chapter. `showPreso()` will be passed a `Display` object and should arrange to display a `Presentation` on that `Display`:

```
@Override
public void showPreso(Display display) {
    preso=new SimplerPresentation(this, display);
    preso.show();
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

`clearPreso()` should get rid of any outstanding `Presentation`. It is passed a boolean value, which will be true if we simply lost the `Display` we were using (and so the activity might want to display the `Presentation` contents elsewhere, such as in the activity itself), or false if the activity is moving to the background (triggered via `onPause()`):

```
@Override
public void clearPreso(boolean showInline) {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

The implementations here are pretty much the same as the ones used in the previous example. `PresentationHelper` has handled all of the `Display`-management events – our activity can simply focus on showing or hiding the `Presentation` on demand.

Help When You Need It

In many respects, the `PresentationHelper` from the `CWAC-Presentation` project works a lot like the logic in the original `Presentation` sample's `MainActivity`, detecting various states and calling `showPreso()` and `clearPreso()` accordingly. However, `PresentationHelper` uses a different mechanism for this — `DisplayManager`.

SUPPORTING EXTERNAL DISPLAYS

The PresentationHelper constructor just stashes the parameters it is passed in data members and obtains a DisplayManager via getSystemService(), putting it in another data member:

```
public PresentationHelper(Context ctxt, Listener listener) {
    this.listener=listener;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        mgr=
            (DisplayManager)ctxt.getSystemService(Context.DISPLAY_SERVICE);
    }
}
```

onResume() calls out to a private handlePreso() method to initialize our state, and tells the DisplayManager to let it know as displays are attached and detached from the device, by means of registerDisplayListener():

```
public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        handleRoute();
        mgr.registerDisplayListener(this, null);
    }
}
```

The PresentationHelper itself implements the DisplayListener interface, which requires three callback methods:

- onDisplayAdded() is called when a new output display is available
- onDisplayChanged() is called when an existing attached display changes its characteristics
- onDisplayRemoved() is called whenever a previously-attached output display has been detached

In our case, all three methods route to the same handleRoute() method, to update our state:

```
@Override
public void onDisplayAdded(int displayId) {
    handleRoute();
}

@Override
public void onDisplayChanged(int displayId) {
    handleRoute();
}

@Override
public void onDisplayRemoved(int displayId) {
    handleRoute();
}
```

SUPPORTING EXTERNAL DISPLAYS

handleRoute() is where the bulk of the “business logic” of PresentationHelper resides:

```
private void handleRoute() {
    if (isEnabled()) {
        Display[] displays=
            mgr.getDisplays(DisplayManager.DISPLAY_CATEGORY_PRESENTATION);

        if (displays.length == 0) {
            if (current != null || isFirstRun) {
                listener.clearPreso(true);
                current=null;
            }
        }
        else {
            Display display=displays[0];

            if (display != null && display.isValid()) {
                if (current == null) {
                    listener.showPreso(display);
                    current=display;
                }
                else if (current.getDisplayId() != display.getDisplayId()) {
                    listener.clearPreso(true);
                    listener.showPreso(display);
                    current=display;
                }
                else {
                    // no-op: should already be set
                }
            }
            else if (current != null) {
                listener.clearPreso(true);
                current=null;
            }
        }

        isFirstRun=false;
    }
}
```

We get the list of attached displays from the DisplayManager by calling getDisplays(). By passing in DISPLAY_CATEGORY_PRESENTATION, we are asking for returned array of Display objects to be ordered such that the preferred display for presentations is the first element.

If the array is empty, and we already had a current Display from before (or if this is the first time handlePreso() has run), we call clearPreso() to inform the listener that there is no Display for presentation purposes.

If we do have a valid Display:

- If we were not displaying anything before, we call `showPreso()` to inform the listener to start displaying things, plus keep track of the current `Display` in a data member
- If we were displaying something before, but now the preferred `Display` for a `Presentation` is different (the ID value of the `Display` objects differ), we call `clearPreso()` and `showPreso()` to get the listener to switch to the new `Display`
- Otherwise, this was a spurious call to `handlePreso()`, so we do not do anything of note

If, for whatever reason, the best `Display` is not valid, we do the same thing as if we had no `Display` at all: call `clearPreso()`.

Finally, in `onPause()`, we call `clearPreso()` to ensure that we are no longer attempting to display anything, plus call `unregisterDisplayListener()` so we are no longer informed about changes to the mix of `Display` objects that might be available:

```
public void onPause() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        listener.clearPreso(false);
        current=null;

        mgr.unregisterDisplayListener(this);
    }
}
```

Presentations and Configuration Changes

One headache when using `Presentation` comes from the fact that it is a `Dialog`, which is owned by an `Activity`. If the device undergoes a configuration change, the activity will be destroyed and recreated by default, forcing you to destroy and recreate your `Dialog`. This, in turn, causes flicker on the external display, as the display briefly reverts to mirroring while this goes on.

Devices that support external displays may be orientation-locked to landscape when an external display is attached (e.g., an HDMI cable is plugged in). This reduces the odds of a configuration change considerably, as the #1 configuration change is an orientation change. However, that is not a guaranteed “feature” of Android external display support, and there are other configuration changes that could go on (e.g., devices gets plugged into a keyboard dock).

You can either just live with the flicker, or use `android:configChanges` to try to avoid the destroy/re-create cycle for the configuration change. As was noted back in [the chapter on configuration changes](#), this is a risky approach, as it requires you to remember all your resources that might change on the configuration change and reset them to reflect the configuration change.

A “middle ground” approach is to ensure that your activity running the Presentation is orientation-locked to landscape mode, by adding `android:orientation="landscape"` to your `<activity>` in the manifest, then use `android:configChanges` to handle the configuration changes related to orientation:

- `orientation`
- `keyboardHidden`
- `screenSize`
- `screenLayout`

For those configuration changes, nothing should be needed to be modified in your activity, since you want to be displaying in landscape all of the time, and so you will not need to modify your use of resources. This leaves open the possibility of other configuration changes that would cause flicker on the external display, but those are relatively unlikely to occur while your activity is in the foreground, and so it may not be worth trying to address the flicker in all those cases.

Yet another possibility is to have your presentation be delivered by a service, as we will discuss [later in this chapter](#).

Presentations as Fragments

Curiously, the support for Presentation is focused on View. There is nothing built into Android 4.2 that ties a Presentation to a Fragment. However, this can be a useful technique, one we can roll ourselves... with a bit of difficulty.

The Reuse Reality

There will be a few apps that will only want to deliver content if there is a external display on which to deliver it. However, the vast majority of apps supporting external displays will do so optionally, still supporting regular Android devices with only primary screens.

In this case, though, we have a problem: we need to show that UI *somewhere* if there is no external display to show it on. Our only likely answer is to have it be part of our primary UI.

Fragments would seem to be tailor-made for this. We could “throw” a fragment to the external display if it exists, or incorporate it into our main UI (e.g., as another page in a `ViewPager`) if the external display does not exist, or even have it be shown by some separate activity on smaller-screen devices like phones. Our business logic will already have been partitioned between the fragments — it is merely a question of where the fragment shows up.

Presentations as Dialogs

The nice thing is that `Presentation` extends `Dialog`. We already have a `DialogFragment` as part of Android that knows how to display a `Dialog` populated by a `Fragment` implementation of `onCreateView()`. `DialogFragment` even knows how to handle either being part of the main UI *or* as a separate dialog.

Hence, one could imagine a `PresentationFragment` that extends `DialogFragment` and adds the ability to either be part of the main UI on the primary screen *or* shown on an external display, should one be available.

And, in truth, it is possible to create such a `PresentationFragment`, though there are some limitations.

The Context Conundrum

The biggest limitation comes back to the `Context` used for our UI. Normally, there is only one `Context` of relevance: the `Activity`. In the case of `Presentation`, though, there is a separate `Context` that is tied to the display characteristics of the external display.

This means that `PresentationFragment` must manipulate *two* `Context` values:

- The `Activity`, if the fragment should be part of our main UI
- Some other `Context` supplied by the `Presentation`, if the fragment should be displayed in the `Presentation` on the external display

This makes creating a `PresentationFragment` class a bit tricky... though not impossible. After all, if it *were* impossible, these past several paragraphs would not be very useful.

A PresentationFragment (and Subclasses)

The [Presentation/Fragment](#) sample project has the same UI as the Presentation/Simple project, if there is an external display. If there is only the primary screen, though, we will elect to display the WebView side-by-side with our TextView in the main UI of our activity. And, to pull this off, we will create a PresentationFragment based on DialogFragment.

Note that this sample project has its `android:minSdkVersion` set to 17, mostly to cut down on all of the “only do this if we are on API Level 17” checks and `@TargetApi()` annotations. Getting this code to work on earlier versions of Android is left as an exercise for the reader.

In a simple DialogFragment, we might just override `onCreateView()` to provide the contents of the dialog. The default implementation of `onCreateDialog()` would create an empty Dialog, to be populated with the View returned by `onCreateView()`.

In our PresentationFragment subclass of DialogFragment, though, we need to override `onCreateDialog()` to use a Presentation instead of a Dialog... if we have a Presentation to work with:

```
package com.commonware.android.preso.fragment;

import android.app.Dialog;
import android.app.DialogFragment;
import android.app.Presentation;
import android.content.Context;
import android.os.Bundle;
import android.view.Display;

abstract public class PresentationFragment extends DialogFragment {
    private Display display=null;
    private Presentation preso=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        if (preso == null) {
            return(super.onCreateDialog(savedInstanceState));
        }

        return(preso);
    }

    public void setDisplay(Context ctxt, Display display) {
        if (display == null) {
            preso=null;
        }
        else {
            preso=new Presentation(ctxt, display, getTheme());
        }
    }
}
```

SUPPORTING EXTERNAL DISPLAYS

```
    this.display=display;
}

public Display getDisplay() {
    return(display);
}

protected Context getContext() {
    if (preso != null) {
        return(preso.getContext());
    }

    return(getActivity());
}
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/PresentationFragment.java](#))

We also expose `getDisplay()` and `setDisplay()` accessors, to supply the `Display` object to be used if this fragment will be thrown onto an external display. `setDisplay()` also creates the `Presentation` object wrapped around the display, using the three-parameter `Presentation` constructor that supplies the theme to be used (in this case, using the `getTheme()` method, which a subclass could override if desired).

`PresentationFragment` also implements a `getContext()` method. If this fragment will be used with a `Display` and `Presentation`, this will return the `Context` from the `Presentation`. If not, it returns the `Activity` associated with this `Fragment`.

This project contains a `WebPresentationFragment`, that pours the same basic Android source code used elsewhere in this book for a `WebViewFragment` into a subclass of `PresentationFragment`:

```
package com.commonsware.android.preso.fragment;

import android.annotation.TargetApi;
import android.os.Build;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebView;

public class WebPresentationFragment extends PresentationFragment {
    private WebView mWebView;
    private boolean mIsWebViewAvailable;

    /**
     * Called to instantiate the view. Creates and returns the
     * WebView.
     */
    @Override
```

SUPPORTING EXTERNAL DISPLAYS

```
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    if (mWebView != null) {
        mWebView.destroy();
    }

    mWebView=new WebView(getContext());
    mIsWebViewAvailable=true;
    return mWebView;
}

/**
 * Called when the fragment is visible to the user and
 * actively running. Resumes the WebView.
 */
@TargetApi(11)
@Override
public void onPause() {
    super.onPause();

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        mWebView.onPause();
    }
}

/**
 * Called when the fragment is no longer resumed. Pauses
 * the WebView.
 */
@TargetApi(11)
@Override
public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        mWebView.onResume();
    }

    super.onResume();
}

/**
 * Called when the WebView has been detached from the
 * fragment. The WebView is no longer available after this
 * time.
 */
@Override
public void onDestroyView() {
    mIsWebViewAvailable=false;
    super.onDestroyView();
}

/**
 * Called when the fragment is no longer in use. Destroys
 * the internal state of the WebView.
 */
@Override
public void onDestroy() {
    if (mWebView != null) {
        mWebView.destroy();
        mWebView=null;
    }
}
```

SUPPORTING EXTERNAL DISPLAYS

```
    }
    super.onDestroy();
}

/**
 * Gets the WebView.
 */
public WebView getWebView() {
    return mIsWebViewAvailable ? mWebView : null;
}
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/WebPresentationFragment.java](#))

(note: the flawed comments came from the original Android open source code from which this fragment was derived)

The only significant difference, besides the superclass, is that the `onCreateView()` method uses `getContext()`, not `getActivity()`, as the `Context` to use when creating the `WebView`.

And, the project has a `SamplePresentationFragment` subclass of `WebPresentationFragment`, where we use the `factory-method-and-arguments` pattern to pass a `URL` into the fragment to use for populating the `WebView`:

```
package com.commonsware.android.preso.fragment;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class SamplePresentationFragment extends WebPresentationFragment {
    private static final String ARG_URL="url";

    public static SamplePresentationFragment newInstance(Context ctxt,
                                                       Display display,
                                                       String url) {
        SamplePresentationFragment frag=new SamplePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();

        b.putString(ARG_URL, url);
        frag.setArguments(b);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                           ViewGroup container,
```

SUPPORTING EXTERNAL DISPLAYS

```
        Bundle savedInstanceState) {  
    View result=  
        super.onCreateView(inflater, container, savedInstanceState);  
  
    getWebView().loadUrl(getArguments().getString(ARG_URL));  
  
    return(result);  
    }  
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/SamplePresentationFragment.java](#))

Using PresentationFragment

Our activity's layout now contains not only a `TextView`, but also a `FrameLayout` into which we will slot the `PresentationFragment` if there is no external display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    xmlns:tools="http://schemas.android.com/tools"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:orientation="horizontal"  
    tools:context=".MainActivity">  
  
    <TextView  
        android:id="@+id/prose"  
        android:layout_width="0px"  
        android:layout_height="wrap_content"  
        android:layout_gravity="center"  
        android:layout_weight="1"  
        android:gravity="center"  
        android:text="@string/secondary"  
        android:textSize="40sp"/>  
  
    <FrameLayout  
        android:id="@+id/preso"  
        android:layout_width="0px"  
        android:layout_height="match_parent"  
        android:layout_weight="1"  
        android:visibility="gone"/>  
  
</LinearLayout>
```

(from [Presentation/Fragment/app/src/main/res/layout/activity_main.xml](#))

Note that the `FrameLayout` is initially set to have gone as its visibility, meaning that only the `TextView` will appear. Based on the widths and weights, the `TextView` will take up the full screen when the `FrameLayout` is gone, or they will split the screen in half otherwise.

In the `onCreate()` implementation of our activity (`MainActivity`), we inflate that layout and grab both the `TextView` and the `FrameLayout`, putting them into data members:

SUPPORTING EXTERNAL DISPLAYS

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);

    inline=findViewById(R.id.preso);
    prose=(TextView)findViewById(R.id.prose);
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

Our `onStart()` method, and our `RouteCallback`, are identical to those from the previous sample. Our `handleRoute()` method is *nearly* identical to the original, as is our `onStop()` method. The difference is that we need to distinguish whether we have lost an external display (and therefore want to move the Web page into the main UI) or if we are going away entirely (and therefore just wish to clean up the external display, if any). Hence, `clearPreso()` takes a boolean parameter (`switchToInline`), `true` if we want to show the fragment in the main UI, `false` otherwise. And, our `onStop()` and `handleRoute()` methods pass the appropriate value to `clearPreso()`:

```
@Override
protected void onStop() {
    clearPreso(false);

    if (router != null) {
        router.removeCallback(cb);
    }

    super.onStop();
}

private void handleRoute(RouteInfo route) {
    if (route == null) {
        clearPreso(true);
    }
    else {
        Display display=route.getPresentationDisplay();

        if (route.isEnabled() && display != null) {
            if (preso == null) {
                showPreso(route);
                Log.d(getClass().getSimpleName(), "enabled route");
            }
            else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
                clearPreso(true);
                showPreso(route);
                Log.d(getClass().getSimpleName(), "switched route");
            }
            else {
                // no-op: should already be set
            }
        }
        else {
            clearPreso(true);
        }
    }
}
```

SUPPORTING EXTERNAL DISPLAYS

```
        Log.d(getClass().getSimpleName(), "disabled route");
    }
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

`showPreso()` is called when we want to display the Presentation on the external display. Hence, we need to remove the `WebPresentationFragment` from the main UI if it is there:

```
private void showPreso(RouteInfo route) {
    if (inline.getVisibility() == View.VISIBLE) {
        inline.setVisibility(View.GONE);
        prose.setText(R.string.secondary);

        Fragment f=getFragmentManager().findFragmentById(R.id.preso);

        getFragmentManager().beginTransaction().remove(f).commit();
    }

    preso=buildPreso(route.getPresentationDisplay());
    preso.show(getFragmentManager(), "preso");
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

Creating the actual `PresentationFragment` is delegated to a `buildPreso()` method, which employs the `newInstance()` method on the `SamplePresentationFragment`:

```
private PresentationFragment buildPreso(Display display) {
    return(SamplePresentationFragment.newInstance(this, display,
        "https://commonsware.com"));
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

`clearPreso()` is responsible for *adding* the `PresentationFragment` to the main UI, if `switchToInline` is true:

```
private void clearPreso(boolean switchToInline) {
    if (switchToInline) {
        inline.setVisibility(View.VISIBLE);
        prose.setText(R.string.primary);
        getFragmentManager().beginTransaction()
            .add(R.id.preso, buildPreso(null)).commit();
    }

    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

SUPPORTING EXTERNAL DISPLAYS

With an external display, the results are visually identical to the original sample. Without an external display, though, our UI is presented side-by-side:

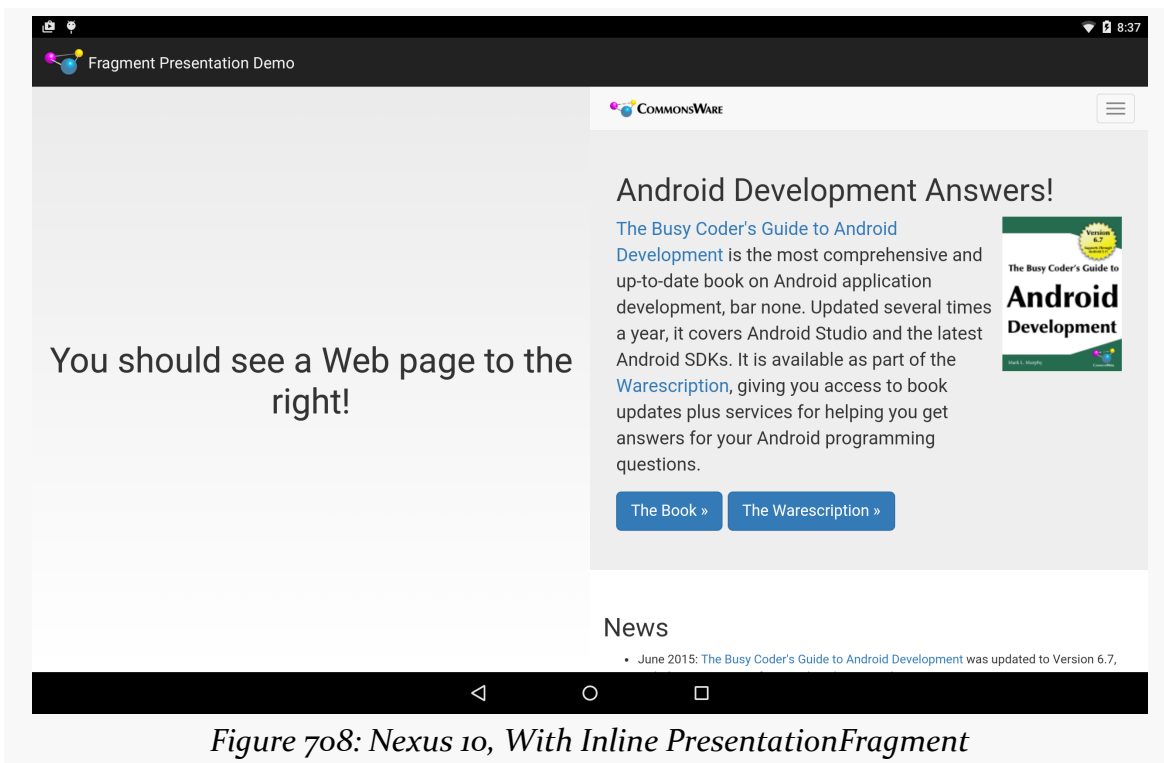

Figure 708: Nexus 10, With Inline PresentationFragment

Limits

This implementation of `PresentationFragment` has its limitations, though.

First, we cannot reuse the same fragment *instance* for both the inline UI and the `Presentation` UI, as they use different `Context` objects. Hence, production code will need to arrange to get data out of the old fragment instance and into the new instance when the screen mix changes. You might be able to leverage `onSaveInstanceState()` for that purpose, with a more-sophisticated implementation of `PresentationFragment`.

Also, depending upon the device and the external display, you *may* see multiple calls to `handleRoute()`. For example, attaching an external display may trigger three calls to your `RouteCallback`, for an attach, a detach, and another attach event. It is unclear why this occurs. However, it may require some additional logic in your app to deal with these events, if you encounter them.

Another Sample Project: Slides

At the 2013 Samsung Developer Conference, the author of this book delivered [a presentation on using Presentation](#). Rather than use a traditional presentation package driven from a notebook, the author used [the Presentation/Slides sample app](#). This sample app shows how to show slides on an external display, controlled by a ViewPager on a device's touchscreen.

What the audience saw, through most of the presentation, were simple slides. What the presenter saw was a ViewPager, with tabs, along with action bar items for various actions:

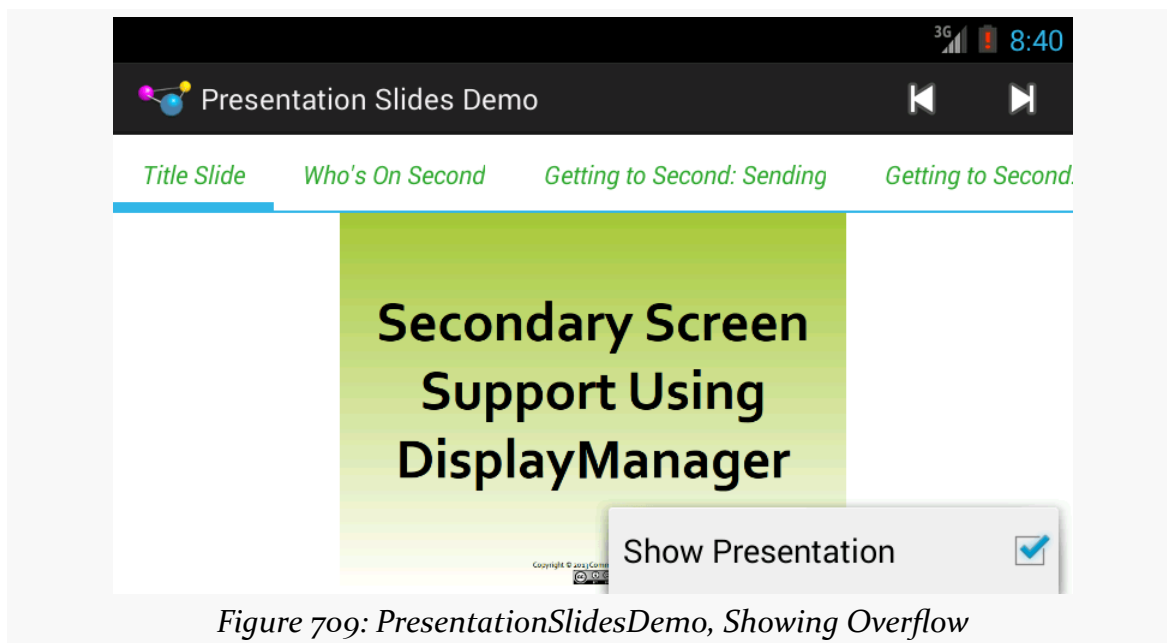

Figure 709: PresentationSlidesDemo, Showing Overflow

The Slides

The slides themselves are a series of 20 drawable resources (img0, img1, etc.), put into the `res/drawable-nodpi/` resource directory, as there is no intrinsic “density” that the slides were prepared for. As we use the slides in `ImageView` widgets, their images will be resized to fit the available `ImageView` space alone, not taking screen density into account.

There is a matching set of 20 string resources (title0, title1, etc.) containing a string representation of the slide titles, for use with getPageTitle() of a PagerAdapter.

The PagerAdapter

That PagerAdapter, named SlidesAdapter, has each slide be visually represented by an ImageView widget. In this case, SlidesAdapter extends PagerAdapter directly, skipping fragments:

```
package com.commonware.android.preso.slides;

import android.content.Context;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;

class SlidesAdapter extends PagerAdapter {
    private static final int[] SLIDES= { R.drawable.img0,
        R.drawable.img1, R.drawable.img2, R.drawable.img3,
        R.drawable.img4, R.drawable.img5, R.drawable.img6,
        R.drawable.img7, R.drawable.img8, R.drawable.img9,
        R.drawable.img10, R.drawable.img11, R.drawable.img12,
        R.drawable.img13, R.drawable.img14, R.drawable.img15,
        R.drawable.img16, R.drawable.img17, R.drawable.img18,
        R.drawable.img19 };
    private static final int[] TITLES= { R.string.title0,
        R.string.title1, R.string.title2, R.string.title3,
        R.string.title4, R.string.title5, R.string.title6,
        R.string.title7, R.string.title8, R.string.title9,
        R.string.title10, R.string.title11, R.string.title12,
        R.string.title13, R.string.title14, R.string.title15,
        R.string.title16, R.string.title17, R.string.title18,
        R.string.title19 };
    private Context ctxt=null;

    SlidesAdapter(Context ctxt) {
        this.ctxt=ctxt;
    }

    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        ImageView page=new ImageView(ctxt);

        page.setImageResource(getPageResource(position));
        container.addView(page,
            new ViewGroup.LayoutParams(
                ViewGroup.LayoutParams.MATCH_PARENT,
                ViewGroup.LayoutParams.MATCH_PARENT));

        return(page);
    }

    @Override
```

SUPPORTING EXTERNAL DISPLAYS

```
public void destroyItem(ViewGroup container, int position,
                        Object object) {
    container.removeView((View)object);
}

@Override
public int getCount() {
    return(SLIDES.length);
}

@Override
public boolean isViewFromObject(View view, Object object) {
    return(view == object);
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
}

int getPageResource(int position) {
    return(SLIDES[position]);
}
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/SlidesAdapter.java](#))

The data for the SlidesAdapter consists of a pair of static int arrays, one holding the drawable resource IDs, one holding the string resource IDs.

Of note, SlidesAdapter has a getPageResource() method, to return the drawable resource ID for a given page position, which is used by instantiateItem() for populating the position's ImageView.

The PresentationFragment

We also want to be able to show the slide on an external display via a Presentation. As with the preceding sample app, this one uses a PresentationFragment, here named SlidePresentationFragment:

```
package com.commonsware.android.preso.slides;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.commonsware.cwac.preso.PresentationFragment;

public class SlidePresentationFragment extends PresentationFragment {
    private static final String KEY_RESOURCE="r";
```

SUPPORTING EXTERNAL DISPLAYS

```
private ImageView slide=null;

public static SlidePresentationFragment newInstance(Context ctxt,
                                                    Display display,
                                                    int initialResource) {
    SlidePresentationFragment frag=new SlidePresentationFragment();

    frag.setDisplay(ctxt, display);

    Bundle b=new Bundle();

    b.putInt(KEY_RESOURCE, initialResource);
    frag.setArguments(b);

    return(frag);
}

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    slide=new ImageView(getContext());

    setSlideContent(getArguments().getInt(KEY_RESOURCE));

    return(slide);
}

void setSlideContent(int resourceId) {
    slide.setImageResource(resourceId);
}
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/SlidePresentationFragment.java](https://commonsware.com/android/preso/slides/SlidePresentationFragment.java))

Here, in addition to the sort of logic seen in the preceding sample app, we also need to teach the fragment which image it should be showing at any point in time. We do this in two ways:

1. We pass in an int named `initialResource` to the factory method, where `initialResource` represents the image to show when the fragment is first displayed. That value is packaged into the arguments `Bundle`, and `onCreateView()` uses that value.
2. Actually putting the drawable resource into the `ImageView` for this Presentation is handled by `setSlideContent()`. This is called by `onCreateView()`, passing in the `initialResource` value.

The Activity

The rest of the business logic for this application can be found in its overall entry point, `MainActivity`.

Setting Up the Pager

`onCreate()` of `MainActivity` is mostly focused on setting up the `ViewPager`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ViewPagerIndicator tabs=(ViewPagerIndicator)findViewById(R.id.titles);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SlidesAdapter(this);
    pager.setAdapter(adapter);
    tabs.setViewPager(pager);
    tabs.setOnPageChangeListener(this);

    helper=new PresentationHelper(this, this);
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

The `ViewPager` and our `SampleAdapter` are saved in data members of the activity, for later reference. We also wire in a `ViewPagerIndicator`, from the `ViewPagerIndicator` library, and arrange to get control in our `OnPageChangeListener` methods when the page changes (whether via the tabs or via a swipe on the `ViewPager` itself).

`onCreate()` also hooks up a `PresentationHelper`, following the recipe used elsewhere in this chapter. And, as `PresentationHelper` requires, we forward along the `onResume()` and `onPause()` events to it:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

Setting Up the Presentation

In the `showPreso()` method, required by the `PresentationHelper.Listener` interface, we create an instance of `SlidePresentationFragment`, passing in the resource ID of the current slide, as determined by the `ViewPager`:

SUPPORTING EXTERNAL DISPLAYS

```
@Override
public void showPreso(Display display) {
    int drawable=adapter.getPageResource(pager.getCurrentItem());

    preso=
        SlidePresentationFragment.newInstance(this, display, drawable);
    preso.show(getFragmentManager(), "preso");
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

We then show() the PresentationFragment, causing it to appear on the attached Display.

The corresponding clearPreso() method follows the typical recipe of calling dismiss() on the PresentationFragment, if one exists:

```
@Override
public void clearPreso(boolean showInline) {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

Controlling the Presentation

However, the SlidesPresentationFragment now is showing the slide that was current when the Display was discovered or attached. What happens if the user changes the slide, using the ViewPager?

In that case, our OnPageChangeListener onPageSelected() method will be called, and we can update the SlidesPresentationFragment to show the new slide:

```
@Override
public void onPageSelected(int position) {
    if (preso != null) {
        preso.setSlideContent(adapter.getPageResource(position));
    }
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

Offering an Action Bar

The activity also sets up the action bar with three items:

SUPPORTING EXTERNAL DISPLAYS

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/first"
        android:icon="@android:drawable/ic_media_previous"
        android:showAsAction="always"
        android:title="@string/first">
    </item>
    <item
        android:id="@+id/last"
        android:icon="@android:drawable/ic_media_next"
        android:showAsAction="always"
        android:title="@string/last">
    </item>
    <item
        android:id="@+id/present"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"
        android:title="@string/show_presentation">
    </item>
</menu>
```

(from [Presentation/Slides/app/src/main/res/menu/activity_actions.xml](#))

Two, first and last, simply set the ViewPager position to be the first or last slide, respectively. This will also update the SlidesPresentationFragment, as onPageSelected() is called when we call setCurrentItem() on the ViewPager.

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.present:
            boolean original=item.isChecked();

            item.setChecked(!original);

            if (original) {
                helper.disable();
            }
            else {
                helper.enable();
            }

            break;

        case R.id.first:
            pager.setCurrentItem(0);
            break;
    }
}
```

```
case R.id.last:
    pager.setCurrentItem(adapter.getCount() - 1);
    break;
}

return(super.onOptionsItemSelected(item));
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](https://github.com/commonsware/android-pres0/slides/MainActivity.java))

The other action bar item, `present`, is a checkable action bar item, initially set to be checked. This item controls what we are showing on the external display:

- If it is checked, we want to show our Presentation
- If it is unchecked, we want to revert to default mirroring

The theory here is that, in a presentation, we could switch from showing the slides to showing the audience what the presenter has been seeing all along.

Switching between Presentation and default mirroring is a matter of calling `enable()` (to show a Presentation) or `disable()` (to revert to mirroring) on the `PresentationHelper`.

Device Support for Presentation

Alas, there is a problem: not all Android 4.2 devices support Presentation, even though they support displaying content on external displays. Non-Presentation devices simply support classic mirroring.

Generally speaking, it appears that devices that *shipped* with Android 4.2 and higher will support Presentation, assuming that they have some sort of external display support (e.g., MHL). Devices that were *upgraded* to Android 4.2 are less likely to support Presentation.

Unfortunately, at the present time, there is no known way to detect whether or not Presentation will work, let alone any means of filtering on this capability in the Play Store via `<uses-feature>`. With luck, [this issue](#) will be addressed in the future.

Presentations from a Service

Since Presentation inherits from Dialog, it also “inherits” one of the limitations of Dialog: you can only show one from an Activity. In many cases, that is not a big

problem. If you are using the external display as an adjunct to your own app's use of the primary touchscreen, you would be using an activity anyway. However, it does prevent one from using `Presentation` to, say, implement a video player app that plays on an external display but does not tie up the touchscreen, so the user can use other apps while the video plays.

However, as it turns out, it is possible to drive the content of an external display from a background app... just not by using a `Presentation`.

The details of this are a bit tricky, derived from [one Stack Overflow answer](#) and another [Stack Overflow question](#).

However, you do not need to deal with all of the details, courtesy of `PresentationService`.

`PresentationService` is a class in the [CWAC-Presentation library](#). `PresentationService` clones some of the logic from `Presentation` and `Dialog`, enough to allow you to define a `View` that will be shown on external display, driven by a `Service`. `PresentationService` is an abstract base class for you to extend, where `PresentationService` handles showing your content on an external display, and you simply manage that content.

The CWAC-Presentation library has [a demoService/ directory](#) containing a sample use of `PresentationService`. The recipe is fairly simple and is outlined in the following sections.

Step #1: Attach the Libraries

The [CWAC-Presentation README](#) contains instructions for attaching the libraries to your project, whether via Gradle dependencies, downloading a pair of JARs, or using the source form of the Android library project.

Step #2: Create a Stub `PresentationService`

As is noted above, `PresentationService` is an abstract class, so you will need to create your own concrete subclass of it, under whatever name you wish. And, as with any service, you will need a `<service>` element in the manifest. None of this is especially unusual.

The sample app is a service-based rendition of [the Presentation/Slides sample app](#) described earlier in this chapter. It has a `SlideshowService` that will display the

slideshow on an external display from the background, switching slides every five seconds.

Step #3: Return the Theme

One of the abstract methods that you will need to implement is `getThemeId()`. This should return the value of the style resource that represents the theme that you wish to use for the widgets you are going to show on the external display.

For example, if your project uses the `@style/AppTheme` approach that is code-generated for you, you can simply return `R.style.AppTheme` from `getThemeId()`, as the sample app does:

```
@Override
protected int getThemeId() {
    return(R.style.AppTheme);
}
```

Step #4: Build the View

The other abstract method you need to implement is `buildPresoView()`. You are passed a `Context` and a `LayoutInflater`, and your job is to use those to build your UI for the external display, returning the root view. The `LayoutInflater` is already set up to use the theme you provided via `getThemeId()`.

Since this will be called shortly before showing the result on the external display, you can also take this time to initialize other aspects of your presentation. For example, the `SlideshowService` implements `Runnable` and has a `Handler` for the main application thread, initialized in `onCreate()`:

```
private Handler handler=null;

@Override
public void onCreate() {
    handler=new Handler(Looper.getMainLooper());
    super.onCreate();
}
```

`buildPresoView()` not only returns an `ImageView` for the slides, but also calls `run()`, which populates the `ImageView` and calls `postDelayed()` on the `Handler` to schedule `run()` to be called again in five seconds, thereby arranging to update the slide every five seconds:

```
@Override
protected View buildPresoView(Context ctxt, LayoutInflater inflater) {
```

```
    iv=new ImageView(ctxt);
    run();

    return(iv);
}

@Override
public void run() {
    iv.setImageResource(SLIDES[iteration % SLIDES.length]);
    iteration+=1;

    handler.postDelayed(this, 5000);
}
```

onDestroy() calls removeCallbacks() to break the Handler postDelayed() loop:

```
@Override
public void onDestroy() {
    handler.removeCallbacks(this);

    super.onDestroy();
}
```

Step #5: Start and Stop the Service

Calling startService() on your service will then trigger the presentation. Or, more accurately, it will trigger PresentationService to work with a PresentationHelper to determine when a presentation should be shown. PresentationService will then use buildPresoView() to populate the external display. Conversely, calling stopService() will stop the presentation.

It is up to you to determine what is the trigger for these calls. The sample app simply starts the service immediately when run and stops the service in response to an action bar item click.

While the service is running, you are welcome to use an [event bus](#) or other means to control the contents of the presentation, by manipulating the widgets you created in buildPresoView().

Note that it is safe to call startService() on the service multiple times, if you do not know whether the service is already running and need to ensure that it is running now.

Hey, What About Chromecast?

In February 2014, Google released a long-awaited SDK to allow anyone to write an app that connects to [Chromecast](#), Google's streaming-media HDMI stick. This Cast SDK also works with other Google Cast-capable devices, like some Android TV models. A natural question coming out of that is whether `Presentation` and `DisplayManager` work with Chromecast.

The answer is: that depends on how you look at the problem.

While Chromecast may physically resemble a wireless display adapter, in truth it is its own device, running a customized mashup of Android and ChromeOS. Chromecast's strength is in playing streaming media from any source, primarily directly off of the Internet.

The classic approach for the Google Cast SDK is that apps are telling the Chromecast what to stream from, not streaming to the Chromecast itself. As such, the Cast API is distinctly different from that of `Presentation`, and while the two both deal with what the Android device would consider an external display, they are not equivalent solutions.

However:

- A Chromecast can also serve as a Miracast endpoint; if a user sets that up, then your app can use `Presentation` with a Chromecast
- In 2015, the Cast SDK added a `Presentation`-workalike API, one that presumably works with Chromecast without having to go through the Miracast setup

More coverage of Chromecast can be found in [the next chapter](#).

Google Cast and Chromecast

A popular target for MediaRouter, in some countries, is Chromecast, Google's lightweight streaming media player for televisions and other HDMI displays. Originally, Chromecast was a "closed box", with no official support for third-party apps (and active work to block unofficial support). In early 2014, though, Google finally opened up Chromecast to developers.

This chapter covers what it takes to enable an Android app to "cast" content to a Chromecast, possibly as part of a broader external display strategy.

Prerequisites

In addition to the core chapters, you should read [the chapter on MediaRouter](#) before reading this chapter.

Here a Cast, There a Cast

You will see two terms used in this chapter and in the online literature regarding all of this: Chromecast and "Google Cast". Despite the similarities in their names, these are fairly distinct items.

What is Chromecast?

Chromecast, as noted earlier in this chapter, is a streaming media receiver, sold by Google under their own brand.

It plugs into an HDMI port of a television or similar display, plus uses micro USB for supplying power.

However, rather than other streaming media receivers, that use Bluetooth or IR (infrared) peripherals for controlling the playback, Chromecast appears to use WiFi, designed to be controlled by a smartphone, tablet, or Chrome Web browser.

Chromecast itself runs its own OS, apparently a hybrid of Android and ChromeOS.

What is Google Cast?

Google Cast can be thought of as a control protocol for Google Cast-enabled receivers. Through a Google-supplied SDK (or other means), Google Cast client apps (“senders”) can direct a Google Cast-enabled receiver to play, pause, rewind, fast-forward, etc. a stream.

Google Cast could, in theory, be “baked into” displays (such as a television), in addition to being supported by dedicated media receivers like the Chromecast.

Google Cast does assume that, in general, the media receiver runs its own OS and is capable of playing streaming media without ongoing assistance from the Google Cast client. Hence, the client is not “locked into” having to keep feeding content to the Google Cast client, allowing the user to go off and do other things with that client while playback is going on.

Common Chromecast Development Notes

Chromecast goes to sleep if it detects that it is plugged into a television or monitor that is turned off (or perhaps even not accepting input from the HDMI port the Chromecast is using). While it is in this sleep mode, it may not appear as an available route. You may need to keep the display active to allow Chromecast to work properly. A 720p-capable pico projector, such as [the Vivitek Qumi series](#), can be a handy way to have a test display for Chromecast (or for live video media routes) at your development station, without the bulk of another monitor, if you have a handy surface to project upon.

Also, note that a Chromecast “uses Google’s DNS regardless of what you have defined locally”, according to [a Google engineer](#). That will preclude you from using any local domains on an organization’s own DNS server, without some tricky firewall configuration to route Google DNS requests to the in-house DNS server. Similarly, you cannot use machine names as pseudo-domain names, the way you might be able to using a regular Web browser.

Your API Choices

Chromecast offers up remote playback media routes and works with `RemotePlaybackClient`, as is discussed in [the chapter on MediaRouter](#). The sample app for `RemotePlaybackClient` was tested on a Chromecast.

If you want greater control than is offered via `RemotePlaybackClient`, though, you can use [the Cast SDK](#). This SDK is part of the Play Services framework, not part of Android itself. It also works solely with Google Cast devices, of which Chromecast is the only known example, whereas other sorts of devices are able to publish remote playback media routes. Hence, using the Cast SDK will tie you to Google Cast — and some of its restrictions, both technical and legal — but will give you greater developer control over the behavior of both the Google Cast device and your app.

This chapter will focus on the Cast SDK. See [the chapter on MediaRouter](#) for coverage of `RemotePlaybackClient`.

Senders and Receivers

There are three major components to the Google Cast environment:

- The sources of streaming media, usually out on the Internet
- The software on the playback device that plays that streaming media (“receiver”)
- The software on the control device (phone, tablet, Chrome Web browser) that directs the receiver about what to play and when (“sender”)

The Sender App

The sender app is responsible for allowing the user to choose some media to play, then to control the actual playback (pause, start, stop, rewind, fast-forward, etc.).

The details of how to choose some media will depend heavily on the nature of the sender app. For example, a subscription-based streaming video service, such as Netflix, would allow the user to browse and search eligible content hosted by Netflix itself. Netflix presumably has its own Web service APIs that its own sender app would use for this purpose, and it is up to Netflix to offer a sensible UI for choosing a piece of media to watch.

Passing a reference (e.g., URL) to the receiver, and issuing control commands, will either be handled by `RemotePlaybackClient` (on Android) or via a Google-supplied SDK (for Android, iOS, or Chrome Web apps).

The Receiver

The details of how a receiver is implemented is up to the manufacturer of the Google Cast-enabled device. In the case of Chromecast, it is a version of the Chrome Web browser. In principle, the implementation could be anything; in practice, it is likely that the same basic software stack will be used, courtesy of licensing Google Cast technology from Google for streaming media devices.

Official Google Cast receiver software comes in three flavors: default, styled, and custom.

Default Receiver

The default receiver is what you get by default, as you might have guessed. If you do nothing else, your sender will be communicating with the default receiver. In effect, the default receiver is a specific Chrome Web app, running on the Chrome browser inside of the Chromecast, that is responsible for playback of your chosen media.

Other than providing the URLs to the media, plus requests to pause, start, stop, etc. the playback, you have no control over the default receiver, particularly from a look-and-feel standpoint.

Styled Receiver

A styled receiver is one where you, the developer, supply light branding information that is applied to what otherwise is the default receiver, such as a logo.

Whereas using the default receiver requires no explicit registration with Google, using the styled receiver does require you to register your sender app with Google, at which point you will be able to provide a URL pointing to a CSS file that contains the custom styles.

Custom Receiver

If you would rather replace the default receiver functionality with your own, either to offer more functionality, or to consume media types that may require additional configuration (e.g., DRM), you can create a custom receiver. This, in effect, is a Chrome Web app, where you provide not only CSS, but the HTML and JavaScript as well. This is substantially more complicated, and it requires registration with Google (as with the styled receiver). However, you have far greater control over what appears on the television.

Supported Media Types

The [list of supported media types](#) is likely to change over time. At present, Google Cast-enabled devices are supposed to support major media types, such as:

- MP4 and VP8 for video
- MP3, AAC, and Ogg Vorbis for audio
- PNG, JPEG, GIF, BMP, and WEBP for still images (e.g., photos)
- HLS and MPEG-DASH for streaming

Cast SDK Dependencies

Using the Cast SDK to develop for Google Cast devices has a fair number of dependencies... and not just dependencies on particular libraries.

Developer Registration

If you are going to be using the default receiver, *and* you do not need to have debugging access to the device (e.g., to examine JavaScript logs from the Web rendering engine on the Google Cast device), you are welcome to develop your apps independently.

However, if you will use a styled or custom receiver, or you wish to gain debugging access to the device, you will need to [register with Google](#).

This process will involve you agreeing to some terms of service (see below), along with paying a \$5 registration fee.

The Terms of Service

The Google Cast SDK has separate [Developer Terms of Service](#) from anything else. If you are going to use the Google Cast SDK, you will be expected to agree to these terms as part of the registration processes. You are strongly encouraged to review these terms with qualified legal counsel. Failure to comply with the terms may cause your app (or, more accurately, your styled or custom receivers) to “be de-registered”, presumably meaning that it will no longer work.

These terms contain some curious clauses, worth discussing with your attorney, including a requirement to adhere to a massive [design checklist](#), controlling the look-and-feel of your sender and receiver. This includes a specific requirement for the precise icon to be used for initiating communications with the Google Cast receiver. Those agreeing to these terms are also barred from doing things that might allow others to display content on a Google Cast receiver without using the SDK or breaking through any access controls on the Google Cast device (e.g., creating an exploit that roots it).

Device Registration and Development Setup

While registering your device is optional, it may be handy for custom receivers, so that you can debug your custom HTML and JavaScript that is being rendered by the Google Cast device.

First, you should configure your device to publish its serial number to Google when it checks for Google Cast software updates. For the Chromecast, this involves using whatever means you used to configure the Chromecast in the first place for your network (e.g., [the Chromecast Android app](#)). There should be an option for “Send this Chromecast’s serial number when checking for updates” — in the Chromecast Android app, this will be in the “Share Data” section of the device’s settings screen.

Once you have registered as a Cast SDK developer, the [Google Cast SDK Developer Console](#) will have an option for you to “Add New Device”. You will need the Google Cast device’s serial number — in the case of the Chromecast, this is etched on the underside of the device.

Note that it may take some time before your device registration will be complete, as the device will not find out about the registration until it checks for another update, and there does not appear to be a way to trigger this. Hence, you may need to wait a few hours. You will know that you have access once you can successfully connect, via a Web browser, to port 9222 on the IP address of the Google Cast device. For the Chromecast, the easiest way to get that IP address is through your Chromecast configuration tool (e.g., the Chromecast Android app). Note that the Web page may not be much (e.g., “Inspectable WebContents”), but it will not return a 404 or similar error code.

If you wish to use a styled or custom receiver, you will also need to register your application, in the same Cast SDK Console area. This will be covered in a future edition of this book.

The Official Libraries

You will need the Google Play Services SDK, which you may have used already for other portions of the Play Services framework, such as [GCM](#), [Maps V2](#), and so on.

You will also need the same mediarouter Android library project covered in [the chapter on MediaRouter](#), along with its dependencies (e.g., the support-v4 library and the appcompat library).

The CastCompanionLibrary... Or Not

The Play Services SDK (and its dependencies) is all that you need to write Cast SDK applications. However, Google has also published [the Cast Companion Library \(CCL\)](#), containing a lot of helper code to make it a bit easier for you to write apps that adhere to the [design checklist](#)

Developing Google Cast Apps

Coverage of the Cast SDK, including sample apps, will be added to this chapter in a future edition of this book.

The “Ten-Foot UI”

Increasingly, Android devices are being used to drive screens that are somewhat larger than those found on your average phone or tablet:

- Many Android phones and tablets [can directly deliver content to TVs, monitors, and projectors](#) via HDMI, MHL, SlimPort, Miracast, and similar technologies
- Android devices can control the behavior of non-Android presentation engines, like [Chromecast](#)
- Some Android devices themselves use a TV or other display as their primary screen, from big names ([Google](#) and [Amazon](#)), mid-range firms (OUYA), and firms you have never heard of (various Android “HDMI sticks” available on eBay, Alibaba, etc.)

Technically, writing for these displays is a bit different than you would do for a phone or tablet. In some cases, such as with Google Cast, writing for these displays is more substantially different.

However, in all cases, the design of the UI needs to be different, owing to different physical and usage characteristics of large screens. This chapter will focus on this so-called “ten-foot UI” and help you understand what sorts of changes will need to be considered.

Prerequisites

Understanding this chapter requires that you have read the chapter on [focus management](#).

The sample of the “leanback” UI is a revised version of a sample app profiled in [the chapter on the MediaStore ContentProvider](#).

What is the “Ten-Foot UI”?

The “ten-foot UI” is not referring to a UI that is 3.048 meters high or 9.87789527 by 10^{-17} parsecs wide.

Rather, the distance referred to by the “ten-foot UI” indicates the approximate distance between the viewer and the screen. People usually sit farther from TVs, monitors, and projectors than they do phones or tablets when using them. Partly, that is because the screens are a lot bigger, so they do not need to sit as closely. Partly, that is because often times the screens are being “used” by more than one person (e.g., an audience watching a presentation on a projector), and everybody needs to be able to see the screen.

The expression “ten-foot UI” refers to the design constraints inherent in developing user interfaces to be used across such a distance. Even though the screen may be bigger, the *apparent* screen size (or “[visual angle](#)” may be no bigger than phones or tablets, or sometimes even less. That, plus user input differences, technical differences between TVs and other displays, and so on all go into the “ten-foot UI” design guidance that UI experts give us.

Overscan

Television standards have been with us for several decades. Television sets from the dawn of television had significantly lower and more variable quality than today’s devices. The delivery of the signal at the outset had significantly lower and more variable quality than today’s over-the-air HDTV or cable connections. As a result of these two characteristics, the engineers devising television standards made some decisions that, while necessary at the time, add some complexity to delivering apps to televisions, in the form of overscan.

Simply put, not all televisions show exactly the same picture. Depending on device and signal, a television may show up to 12% less of the picture, as measured horizontally and vertically. Hence, the theoretical ideal screen size (e.g., 720p = 1280 x 720 pixels) may be achieved in some cases, but you may get less (e.g., 1128 x 634 pixels) in other cases.

THE “TEN-FOOT UI”

Android TV and Fire TV ignore overscan, relying upon developers to take it into account. As a result, the reported screen resolution is *not* necessarily available to you. Instead, you need to avoid putting anything important in the outer ~10% of the screen, centering the important stuff within the available space.

So, for example, you might have a background for your game (e.g., a starfield). Make sure that there is nothing essential on the background image that the user must see that is along the outside edge. Then, if part of the background is lost due to overscan, there is no particular problem.

The bigger issue, of course, is standard foreground widgets and containers. Android developers are used to being able to have layouts that work edge-to-edge, with just a minor amount of margin so text, icons, and the like do not run right into the edge of the screen. Now, you need more than a “minor amount” of margin. Google and Amazon recommend a 27dp margin on the top and bottom sides of your activities, and a 48dp margin on the left and right sides of your activities.

For activity and fragment layouts that are dedicated for TV presentation, you could elect to put those margins in those layouts, or add them via a theme. However, for activity and fragment layouts that may be used both for a touchscreen device (phone or tablet) and a television, adding the margin on the touchscreen device may be unsuitable.

For that, you could use dimension resources in different resource sets. Define `overscan_horizontal` and `overscan_vertical` to be both 0dp (or whatever) in `res/values/dimens.xml`. Define them to be 48dp and 27dp, respectively, in `res/values-television/dimens.xml`, where `-television` is a resource set qualifier that will be used in Android TV and other TV-based Android devices. Then, you can refer to `@dimen/overscan_horizontal` and `@dimen/overscan_vertical` in activity/fragment layouts, to take overscan into account conditionally.

Navigation

Most televisions, monitors, and projectors are not touchscreens. Users will be changing what is shown either by using some sort of remote control (e.g., Fire TV, Android TV) or by using an app that runs on a touchscreen device (e.g., direct monitor connection, Chromecast).

In the remote control scenarios, in-screen navigation becomes important. Those remote controls usually focus on some sort of D-pad or arrow keys for moving focus

and clicking on widgets. This forces users into a sequential-access model (e.g., click “left” three times then “enter” once) rather than the random-access model that touchscreens offer.

The chapter on [focus management](#) covers these sorts of concerns. Bear in mind that getting focus management implemented properly in your app not only helps with the “ten-foot UI”, but also can help other sorts of users, such as the visually impaired or motion impaired who cannot readily use touchscreens.

Also note that text input is a significant chore when you try to do it using a remote control. Hence, even to the extent it is possible, try to limit the number of places that users *have* to type into `EditText` widgets and the like in your UI. If possible, offer a way for users to do that sort of thing via a separate app on their phone or tablet, or perhaps through a Web browser that pushes the information to the TV set-top box.

Stylistic Considerations

In addition to structural issues like overscan and focus management, there are some stylistic issues that you will need to take into account when designing your ten-foot UI.

Fonts

With phones and tablets, if the user has some difficulty reading a bit of text, they can usually fix the problem just by moving their hand a bit, to bring the screen closer.

That becomes less likely of a solution as you get into larger screens. People get annoyed if they have to get up off of their sofa to squint and try to read text on a television. In a presentation setting, people may be unable to move into a better viewing position.

To combat this:

- Err on the side of larger fonts, with a medium weight (i.e., not too light or too heavy of strokes that make up the letters)
- Aim to use simpler fonts, particularly sans-serif fonts, as those tend to be more readable at a distance

THE “TEN-FOOT UI”

- Where practical, give the user control over font size within your application, or allow some other sort of “zoom” mechanism, to help see details that they might otherwise be unable to see
- Light text on a dark background tends to be easier to read on televisions, so consider using a theme that supports this (e.g., `Theme.Holo` as opposed to `Theme.Holo.Light`)
- Use fewer words
- Use more line spacing (e.g., via `android:lineSpacingMultiplier` on a `TextView`), so descenders from one line are clearly distinguished from the tops of characters on the next line

Padding and Margins

In addition to adding more line spacing, consider adding more padding and margins to your ten-foot UIs.

Bear in mind that screen density calculations start to go astray as the user moves further away from the screen. We are used to making those calculations based on actual pixels on phones and tablets (a.k.a., “two-foot UI”). The *apparent* size of a television may be no bigger than that of a tablet, once the user’s distance from the screen is taken into account. However, screen density has no good way to take that distance into account, other than by effectively hard-coding the density (e.g., Fire TV considering everything to be `-xhdpi`). Hence, particularly for padding and margins, you may need to “finesse” your values a bit on televisions and the like.

In cases where Android is directly talking to the television (e.g., HDMI/MHL from a phone or tablet, Fire TV, Android TV, Android HDMI sticks), you can use `-notouch` qualifiers on resource sets to provide different values for dimension resources.

Colors

Usually, with the ten-foot UI, we treat televisions, monitors, and projectors equally. They do differ in one key area: color management.

Televisions, for historical reasons, tend to have different color responses than do monitors or projectors. As [Google puts it](#):

TV screens have higher contrast and saturation levels than computer monitors

THE “TEN-FOOT UI”

Even to the extent that those settings could be adjusted, if the television will be used *as a television*, the factory settings may be the proper ones. Beyond that, few television owners think about changing such things.

As a result, you need to be careful with your color choices:

- Pure white (#FFFFFF) can cause problems, such as “ghosting”, so use a very light gray (e.g., #F1F1F1, #EBEBEB) instead. Pure black (#000000) is not a problem.
- Aim for more muted colors, particularly in the blue/green/violet end of the color spectrum, as opposed to bright red or orange. Warm colors tend to bleed more than cool colors.

Aspect Ratio

Bear in mind that different TVs (or other displays) may have different aspect ratios. While many will be 16:9, also consider 4:3 and 21:9 (also known as 2.35:1).

The Leanback UI

In 2014, Google added the `leanback-v17` library to the Android Support package. This contains code to help you create TV-focused user interfaces. While the intention is for this library to help you create UIs for Android TV, there is nothing strictly tied to the Android TV platform in `leanback-v17`. Your user interfaces can work just fine on other TV environments (e.g., Amazon Fire TV). And they still support touchscreen events, and so they can be used on phones and tablets as well, though perhaps not optimally.

Where to Get Leanback

Android Studio users can add a dependency on the `leanback-v17` artifact from the Android Support Repository:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'com.squareup.picasso:picasso:2.5.2'
    compile 'com.android.support:leanback-v17:21.0.3'
}

android {
    compileSdkVersion 21
    buildToolsVersion "21.1.2"
```

THE “TEN-FOOT UI”

```
defaultConfig {  
    applicationId "com.commonware.android.video.browse"  
}  
}
```

(from [Leanback/VideoBrowse/app/build.gradle](#))

This particular bit of Gradle configuration comes from the [Leanback/VideoBrowse](#) sample application, which will be the focus of this “leanback” UI section. This project depends not only upon `leanback-v17`, but also upon the Picasso image loading library, profiled in [the chapter on Internet access](#).

If you read through [the chapter on MediaStore](#), this sample app will seem familiar. In the `MediaStore` chapter, we created a sample app that would present a list of videos available on the device in a `ListView`, using Picasso for handling the video thumbnails. The `VideoBrowse` “leanback” sample app is the same app, adjusted to use a “leanback” UI instead of a `ListView`.

BrowseFragment

The primary UI element that we get from `leanback-v17` is `BrowseFragment`. `BrowseFragment` is a fragment designed to allow browsing of a roster of content through a two-dimensional scrolling interface. There is a list of “headers” (e.g., categories of videos), and within each header is a horizontal scrolling list of items within that header.

This sort of UI pattern is fairly commonplace in TV-centric apps, as it works well with TV-style remotes:

THE “TEN-FOOT UI”

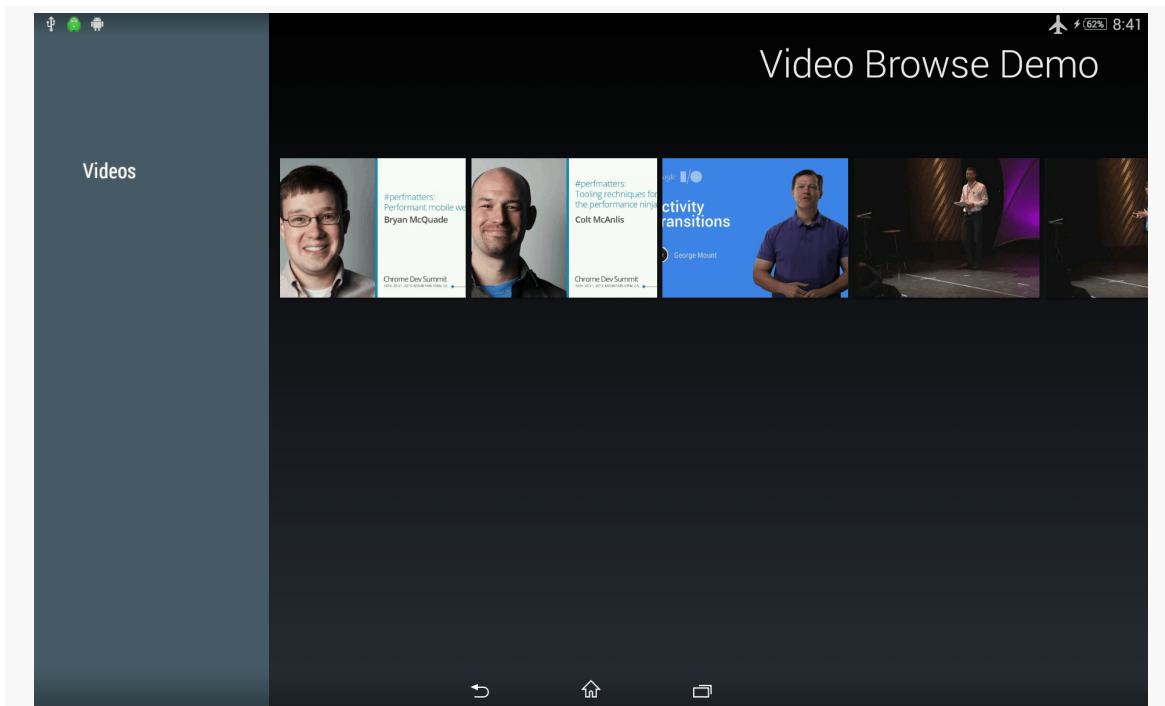

Figure 711: VideoBrowse Sample App, As Initially Launched

The VideoBrowse sample application consists of one activity, hosting a BrowseFragment, that will display the roster of available videos on the device. Clicking on an individual video will bring up the device’s default video player app, just as the VideoList sample did in the chapter on the MediaStore.

Theme and Activity

There is very little specifically required of an activity that hosts a BrowseFragment, particularly on the Java side. So long as the activity gets the BrowseFragment onto the screen, the key work is done.

In the case of our MainActivity, it uses a `res/layout/main.xml` file, pointing to our VideosFragment, which is a subclass of BrowseFragment:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/videos"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:name="com.commonware.android.video.browse.VideosFragment"
/>
```

(from [Leanback/VideoBrowse/app/src/main/res/layout/main.xml](http://leanback.videobrowse.app/src/main/res/layout/main.xml))

THE “TEN-FOOT UI”

The Java code simply loads up the layout containing that static fragment, plus has an `onVideoSelected()` method that will be called if the user clicks on a video:

```
package com.commonware.android.video.browse;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import java.io.File;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void onVideoSelected(String uri, String mimeType) {
        Uri video=Uri.fromFile(new File(uri));
        Intent i=new Intent(Intent.ACTION_VIEW);

        i.setDataAndType(video, mimeType);
        startActivity(i);
    }
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonware/android/video/browse/MainActivity.java](#))

However, there are two other requirements of the activity, in terms of what goes in the manifest:

- The activity needs to use a theme that is, or inherits from, `Theme.Leanback`
- To show up as the “launcher activity” for an Android TV device, the activity needs to have an `<action>` of `MAIN` and a `<category>` of `LEANBACK_LAUNCHER`:

```
<application
    android:allowBackup="false"
    android:hardwareAccelerated="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
        android:name="MainActivity"
        android:label="@string/app_name"
        android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
        android:screenOrientation="sensorLandscape"
        android:theme="@style/Theme.Leanback">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
            <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
        </intent-filter>
    </activity>
</application>
```

THE “TEN-FOOT UI”

(from [Leanback/VideoBrowse/app/src/main/AndroidManifest.xml](#))

In our case, we match on either the LAUNCHER or the LEANBACK_LAUNCHER category, as this particular activity can work on either form factor family (touchscreens or TVs). However, other apps might have separate “launcher activity” implementations for phones/tablets versus televisions, and so having a separate LEANBACK_LAUNCHER category allows us to indicate which activities serve which role.

This activity also sets its `screenOrientation` to `sensorLandscape`, indicating that it will always present itself in landscape mode, no matter how the device is held. It also uses a `configChanges` attribute to opt out of configuration changes due to orientation changes, as the UI is not changing in those cases.

Loading the Videos

`VideosFragment` is responsible for showing the roster of available videos on the device, using a `BrowseFragment` two-dimensional structure. This means, though, that `VideosFragment` needs to be able to find out what videos are available. As with the `VideoList` sample in [the MediaStore chapter](#), `VideosFragment` will query the `MediaStore` `ContentProvider` to find out about the videos, by means of a `CursorLoader`.

In `onViewCreated()`, `VideosFragment` calls `initLoader()` to start loading the videos, in addition to indicating that the fragment itself will serve as the controller handling clicks on individual videos, via the `setOnItemClickListener()` interface:

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    getLoaderManager().initLoader(0, null, this);
    setOnItemClickListener(this);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

For those calls to work, `VideosFragment` needs to implement the `LoaderManager.LoaderCallbacks<Cursor>` interface (for `initLoader()`) and the `OnItemClickListener` (for `setOnItemClickListener()`).

The `initLoader()` call triggers a call to our `onCreateLoader()` method, which queries the `MediaStore` roster of videos for all videos, ordered by title:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
```

THE “TEN-FOOT UI”

```
return(new CursorLoader(  
    getActivity(),  
    MediaStore.Video.Media.EXTERNAL_CONTENT_URI,  
    null, null, null,  
    MediaStore.Video.Media.TITLE));  
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

That, in turn, will eventually trigger a call to `onLoadFinished()`:

```
@Override  
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {  
    mapCursorToModels(c);  
  
    setHeadersState(BrowseFragment.HEADERS_ENABLED);  
    setTitle(getString(R.string.app_name));  
  
    ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());  
    ArrayObjectAdapter listRowAdapter=  
        new ArrayObjectAdapter(new VideoPresenter(getActivity()));  
  
    for (Video v : videos) {  
        listRowAdapter.add(v);  
    }  
  
    HeaderItem header=new HeaderItem(0, "Videos", null);  
  
    rows.add(new ListRow(header, listRowAdapter));  
    setAdapter(rows);  
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

We will get to much of the code in `onLoadFinished()` a bit later in this chapter. However, the first thing that `onLoadFinished()` does is call a `mapCursorToModels()` method. This method will be responsible for taking the data from the `Cursor` we get back from `MediaStore` and using it to populate some model objects that will drive what the `BrowseFragment` displays to the user. `BrowseFragment`'s API is not especially well-suited for working with a `Cursor` directly; it is simpler to have a separate collection of model objects representing the results of the database query.

In our case, the model object will be a `Video`:

```
package com.commonsware.android.video.browse;  
  
class Video {  
    int id;  
    String uri;  
    String mimeType;  
    String title;  
  
    Video(int id, String uri, String mimeType, String title) {  
        this.id=id;  
    }  
}
```

THE “TEN-FOOT UI”

```
this.uri=uri;
this.mimeType=mimeType;
this.title=title;
}

@Override
public String toString() {
    return(title);
}
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/Video.java](#))

There are four pieces of data we need to track for the video:

- Its unique id, so we can get a thumbnail of the video later on
- Its Uri (here, held in a string representation), to be used to play back the video
- Its MIME type, also to be used to play back the video
- Its title, which will be used along with its thumbnail when rendering the video as part of the BrowseFragment roster of content

VideosFragment holds onto a collection of these Video objects in a data member named videos:

```
private ArrayList<Video> videos=new ArrayList<Video>();
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

mapCursorToModels() iterates over the Cursor rows and creates a Video object for each row, adding the Video to the videos, and closing the Cursor when done:

```
private void mapCursorToModels(Cursor c) {
    videos.clear();

    int idColumn=c.getColumnIndex(MediaStore.Video.Media._ID);
    int uriColumn=c.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        c.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
    int titleColumn=
        c.getColumnIndex(MediaStore.Video.Media.TITLE);

    for (c.moveToFirst(); !c.isAfterLast(); c.moveToNext()) {
        videos.add(new Video(c.getInt(idColumn),
            c.getString(uriColumn),
            c.getString(mimeTypeColumn),
            c.getString(titleColumn)));
    }

    c.close();
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

Headers and Contents

So, let’s look at the full `onLoadFinished()` method, called when we have our `Cursor` of videos:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    mapCursorToModels(c);

    setHeadersState(BrowseFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));

    ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
    ArrayObjectAdapter listRowAdapter=
        new ArrayObjectAdapter(new VideoPresenter(getActivity()));

    for (Video v : videos) {
        listRowAdapter.add(v);
    }

    HeaderItem header=new HeaderItem(0, "Videos", null);

    rows.add(new ListRow(header, listRowAdapter));
    setAdapter(rows);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

As mentioned, the first thing that we do is map the `Cursor` contents to `Video` objects.

We then make two general changes to the look of the `BrowseFragment`:

- We enable the headers. In truth, that would not make sense for this particular application, as we only have one header. However, we are enabling the headers to show what that looks like, as many uses of `BrowseFragment` will need the full two-dimensional browsing experience.
- We set the title to be the `app_name` string resource. This title goes in the upper-right corner and is used to remind the user of what app they are in, much like the title in an action bar would on a phone or tablet.

We then build up the two-dimensional data model and rendering rules for the browsing experience. This involves creating instances of an `ObjectAdapter` base class, supplied by `leanback-v17`. `ObjectAdapter` fills a role reminiscent of `Adapter` with `AdapterView`, insofar as it organizes model data and helps with the rendering. However, whereas `Adapter` does that all itself, `ObjectAdapter` splits the roles out: it handles the model data and delegates to `Presenter` implementations for rendering individual items from the model data.

THE “TEN-FOOT UI”

In the two-dimensional browsing model, we need an `ObjectAdapter` that represents our rows, where each row has a header and a nested `ObjectAdapter` for the items to appear in that row.

Just as `ArrayAdapter` is the easiest `Adapter` class to use, `ArrayObjectAdapter` is the easiest `ObjectAdapter` to use. `ArrayObjectAdapter` adapts arrays of objects, where in this case, “array” really means `ArrayList`.

Unlike `ArrayAdapter`, where we primarily build up our array and hand it to the adapter, `ArrayObjectAdapter` has us populate the “array” via methods like `add()` on the `ArrayObjectAdapter`.

So, after calling `setHeadersState()` and `setTitle()` as described above, we:

- Create an `ArrayObjectAdapter`, named `rows`, that uses the `ListRowPresenter` supplied by `leanback-v17` to render the row
- Create another `ArrayObjectAdapter`, named `listRowAdapter`, that uses a custom `VideoPresenter` that we will examine later in this chapter
- Iterate over the `Video` roster and add each to the `listRowAdapter`
- Create an instance of a `HeaderItem`, supplied by `leanback-v17`, that represents the header entry itself, with a title for that header
- Create an instance of a `ListRow`, supplied by `leanback-v17`, that wraps around the `HeaderItem` and the `listRowAdapter` for the items to show in that row
- Put the `ListRow` in the `rows` `ArrayObjectAdapter`, and pass `rows` to `setAdapter()` to tell the `BrowseFragment` what to display

A more complex app might have several `ListRow` objects in `rows`, one per header. For example, you might group videos by some sort of categorization scheme, where each `HeaderItem` names the category and the `ListRow` also contains the videos specific to that category.

Of the classes cited here, all are stock implementations from `leanback-v17`, with the exception of `VideoPresenter`, which is responsible for rendering a `Video` as an item in the horizontal list of videos.

Presenting the Presenters

A `Presenter`, in the `leanback-v17` system, is an object responsible for converting some model object (e.g., a `Video`) into a visual representation that will be used for an `ObjectAdapter`.

THE “TEN-FOOT UI”

The Presenter abstract class enforces a “view holder” approach. A view holder is simply a data structure holding onto a basket of widgets. The idea is that the view holder represents all the widgets for a particular instance of the Presenter. So, we now have two levels of indirection over the Adapter approach used by `ListView` and `kin`: not only does `ObjectAdapter` not do the rendering, but `Presenter` alone does not do the rendering, but instead involves a view holder.

As a result, a `Presenter` implementation will tend to be artificially complex.

First, let’s look at the view holder, implemented as a static class inside `VideoPresenter`, named `Holder`, that extends the stock `Presenter.ViewHolder` class:

```
static class Holder extends Presenter.ViewHolder {
    private final ImageCardView cardView;
    private int targetWidth, targetHeight;

    public Holder(View view) {
        super(view);

        cardView=(ImageCardView)view;

        Resources res=view.getContext().getResources();

        targetWidth=(int)res.getDimension(R.dimen.card_width);
        targetHeight=(int)res.getDimension(R.dimen.card_height);
    }

    protected void updateCardViewImage(Uri uri) {
        Picasso.with(cardView.getContext())
            .load(uri)
            .resize(targetWidth, targetHeight)
            .centerCrop()
            .onlyScaleDown()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(new Target() {
                @Override
                public void onBitmapLoaded(Bitmap bitmap,
                    Picasso.LoadedFrom from) {
                    Drawable bmpDrawable=
                        new BitmapDrawable(
                            cardView.getContext().getResources(),
                            bitmap);

                    cardView.setMainImage(bmpDrawable);
                }

                @Override
                public void onBitmapFailed(Drawable errorDrawable) {
                    cardView.setMainImage(errorDrawable);
                }

                @Override
                public void onPrepareLoad(Drawable placeHolderDrawable) {
                    cardView.setMainImage(placeHolderDrawable);
                }
            });
    }
}
```

THE “TEN-FOOT UI”

```
    }
    });
}
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

The Presenter will set up the UI, in the form of an `ImageCardView` – another stock class provided by `leanback-v17` that is an `ImageView` with an associated caption. As we will want to pour video thumbnails into the `ImageView`, this sample app uses Picasso, the same way the `VideoList` sample does.

We also determine how big the thumbnail should be, based on a pair of dimension resources, `card_width` and `card_height`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="card_width">400dp</dimen>
  <dimen name="card_height">300dp</dimen>
</resources>
```

(from [Leanback/VideoBrowse/app/src/main/res/values/dimens.xml](#))

The `updateCardViewImage()` will be called when we are ready to use this `ViewHolder` to present the contents of some particular `Video`. We receive the `Uri` to the video and set up Picasso to:

- Load the image from that `Uri` (`load()`)
- Resize it to the target dimensions (`resize()`), but only if the image is larger (`onlyScaleDown()`), and then crop to get the image centered in the desired size (`centerCrop()`)
- Use the supplied `ic_media_video_poster` as a placeholder

Then, since Picasso has no knowledge of how to work with an `ImageCardView` from `leanback-v17`, we have to use a different version of `into()`, one that takes a `Target` as parameter. Here, we use an anonymous inner class implementation of a `Target`. The key method is `onBitmapLoaded()`, where we wrap the `Bitmap` in a `BitmapDrawable` and call `setMainImage` on the `ImageCardView` to populate it. Similarly, there are `onBitmapFailed()` and `onPrepareLoad()` methods for handling errors and the placeholder, respectively.

Now, given the `Holder`, we can set up the rest of `VideoPresenter`, starting with its constructor:

```
VideoPresenter(Context ctxt) {
    super();
```

THE “TEN-FOOT UI”

```
this.ctxxt=ctxxt;
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

Here, mostly, we are holding onto a supplied Context for eventually creating our ImageCardView.

At the point in time that the VideoPresenter needs to create a view holder to use for rendering an item, onCreateViewHolder() will be called:

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
    ImageCardView cardView=new ImageCardView(ctxxt);

    cardView.setFocusable(true);
    cardView.setFocusableInTouchMode(true);

    return(new Holder(cardView));
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

Here, we set up an ImageCardView, marking it as focusable both for the D-pad and for touchscreens, and wrap that in our custom Holder.

At the point in time when we are ready to show a Video using the widgets managed by the Holder, onBindViewHolder() is called:

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
                             Object item) {
    Video video=(Video)item;
    Holder h=(Holder)viewHolder;
    Resources res=ctxxt.getResources();

    h.cardView.setTitleText(video.toString());
    h.cardView.setMainImageDimensions((int)res.getDimension(R.dimen.card_width),
                                       (int)res.getDimension(R.dimen.card_height));

    Uri thumbnailUri=
        ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                                   video.id);

    h.updateCardViewImage(thumbnailUri);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

We are passed in a generic Object that is the model data from our ObjectAdapter — in this case, it will be a Video, as we are using VideoPresenter with an

THE “TEN-FOOT UI”

ArrayObjectAdapter that holds the Video instances. We update the ImageCardView caption based on the title of the Video, then set the size of the ImageView based upon the same dimension resources as we used with UIL’s ImageSize. We construct a Uri pointing to the video as known to MediaStore (given the video’s id), and pass the String representation of that into the Holder, which will handle the UIL work.

There is one other abstract method that we need to override to satisfy Presenter: `onUnbindViewHolder()`:

```
@Override
public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](https://github.com/commonsware/android-video/browse/VideoPresenter.java))

`onUnbindViewHolder()` can often be skipped. However, if you have memory-intensive stuff in the view holder — like the bitmap in an ImageView — this is a fine time to take steps to release that memory. In our case, we null out the image in the ImageCardView. Ideally, we would somehow work with UIL to arrange to recycle this Bitmap object, since all of our Bitmap objects should be the same size.

Handling Clicks

BrowseFragment automatically handles a lot of input events, such as:

- arrow key events in the list of headers, to move a selection bar up and down the list
- click events on a header, to allow navigation into the row of items for that header
- arrow key events on an item, to navigate to the next or previous item
- BACK button events on an item, to return to the list of headers

It also captures the click event on an item and routes that to the `onItemClicked()` method of the BrowseFragment, which we override in VideosFragment:

```
@Override
public void onItemClicked(Presenter.ViewHolder viewHolder,
    Object o,
    RowPresenter.ViewHolder rowViewHolder,
    Row row) {
    Video video=(Video)o;
    ((MainActivity) getActivity()).onVideoSelected(video.uri,
        video.mimeType);
}
```

THE “TEN-FOOT UI”

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](https://github.com/Leanback/VideoBrowse/blob/master/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java))

The Object passed as the second parameter to `onItemClicked()` is the Object in our `ObjectAdapter` for the clicked-upon item. In our case, the `ObjectAdapter` is our `ArrayObjectAdapter` wrapped around our `Video` objects, and so the Object passed into `onItemClicked()` is a `Video`. Given that, we can call out to the hosting activity and its `onVideoSelected()` to go play back the selected video.

The Results

Launching the app shows our list of headers (with just the one header), thumbnails of videos in that header, and the “Video Browse Demo” title:

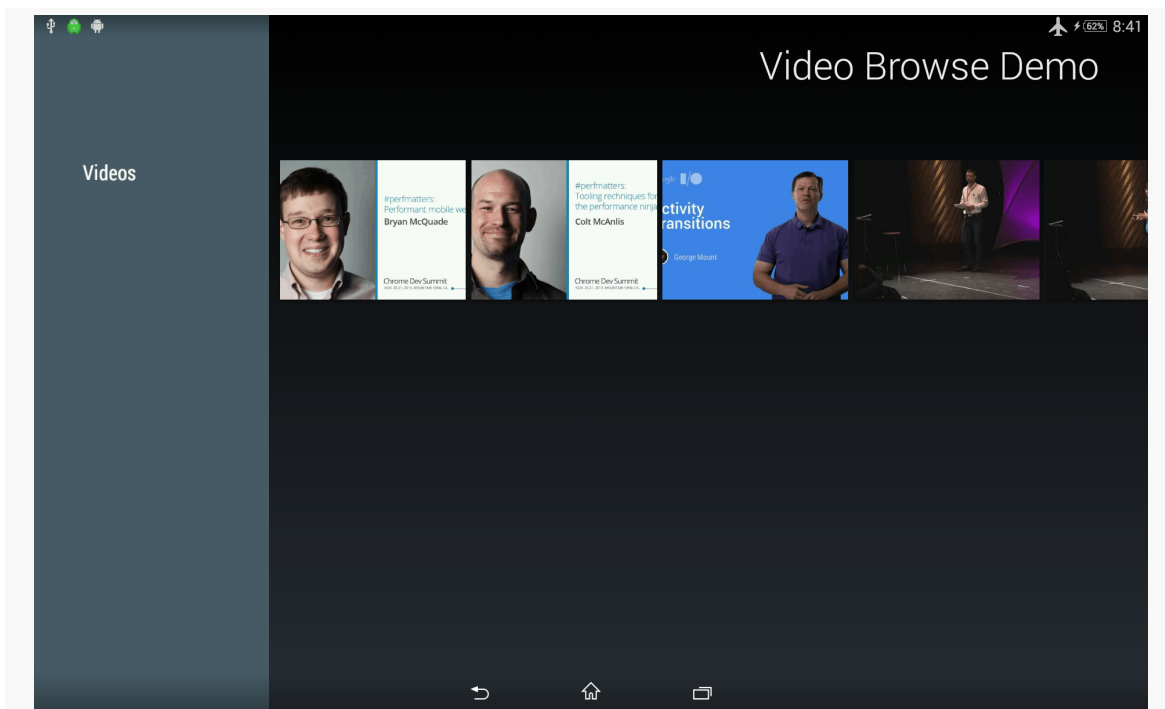

Figure 712: VideoBrowse Sample App, As Initially Launched

Selecting a video slides the headers out of the way and shows the full card for the video, including the video’s title:

THE “TEN-FOOT UI”

Figure 713: VideoBrowse Sample App, With First Video Selected

Clicking on the selected video brings up the default video player for the device.

Note that this UI is not tied strictly to TV-style displays. For example, the screenshots shown in this section came from an Android tablet, as you can tell by the status bar and navigation bar. The BrowseFragment UI is not completely out of place on a tablet, and it works with touch events as well as the key events that would be emitted by a TV-style remote control. On a phone, the BrowseFragment UI gets a bit cramped, particularly in portrait, though it still works.

Testing Your Theories

Ideally, you test your ten-foot UI in a ten-foot experience, using something connected to a television.

This does not have to be expensive:

- If you have a phone or tablet that can connect to a TV via HDMI, MHL, or Miracast, at most you might need a cable or a Miracast adapter

THE “TEN-FOOT UI”

- Android “HDMI sticks” or other Android set-top boxes can be found on eBay, Alibaba, or elsewhere
- Chromecast and the Fire TV Stick are available in some markets fairly inexpensively

Any of those will cost \$10-75. At the \$100 price point, you can start looking at the Fire TV or Nexus Player as well.

If you need to develop using more traditional hardware (phone or a tablet) or an emulator, the big thing will be to make sure that you are estimating the screen size properly. For example, a 10“ tablet, held fully at arm’s length, will have the same visual angle as a modest television (~26”) at a comfortable seating distance. While this will not help with color saturation, using remote controls, or other aspects of the ten-foot UI, you can at least get a sense of whether your text and UI controls will be large enough to be usable.

Putting the TVs All Together: Decktastic

This book profiles many ways of getting content to a TV:

- By means of `Presentation` and related classes, for touchscreen-enabled devices that also happen to presently have a connection to an external display
- By means of `RemotePlaybackClient`, for use with devices like the Chromecast
- By means of directly displaying output on a TV, for devices where the TV is the primary display (e.g., Android TV devices, Amazon's Fire TV and Fire TV Stick)

It is entirely possible to create one app that can support all of these modes from one code base, though you are constrained by the most limited option. In this case, `RemotePlaybackClient` is the most limited option, as its API is designed to tell some external device to play some media, whereas the other options can support comparatively arbitrary user interfaces rendered through normal Android widgets.

In this chapter, we will review the [Presentation/Decktastic](#) sample application. This app is designed to give the user a roster of slide-based presentations to choose from, then deliver one of those presentations. The presentation will appear on the external display (e.g., TV or projector), while the presenter will be able to control the presentation either from a touchscreen-equipped Android device or a remote control.

Prerequisites

You should read the following chapters before this one:

- [Supporting External Displays](#)
- [Google Cast and ChromeCast](#)
- [The “10 Foot UI”](#)

Reading up on specific hardware, like the [Amazon Fire TV](#), is a good idea but not as critical.

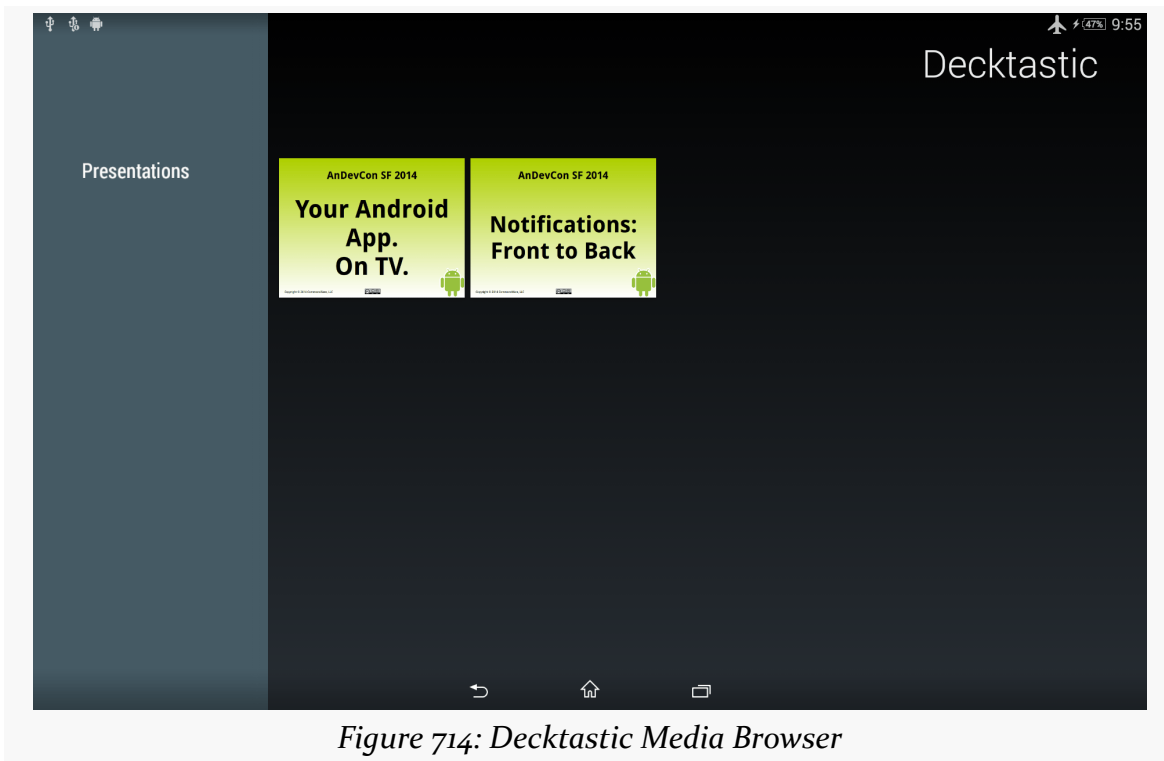

Introducing Decktastic

Before we get into discussing the implementation of Decktastic, we should first review what the app looks like and how it functions.

Launcher UI

If you were to [set up Decktastic](#) on some test device and run it, the first thing that you would see is a media browsing UI built from the leanback-v17 support library, showing you a roster of the available presentations to choose from:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

This UI works fine on TVs and on tablets. On phones... it gets a bit cramped.

Tapping on a presentation selects it:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

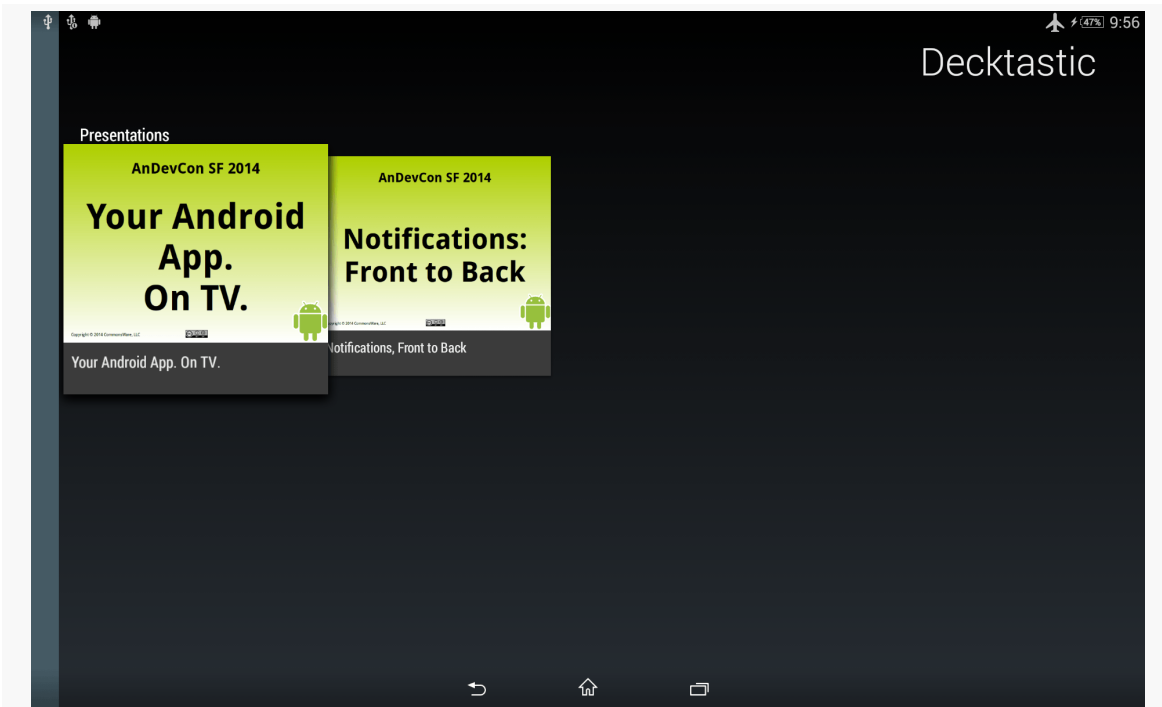

Figure 715: Decktastic Media Browser, With Selected Presentation

Presentation UI

Tapping on the presentation again opens it up into a ViewPager-based UI for the presenter:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

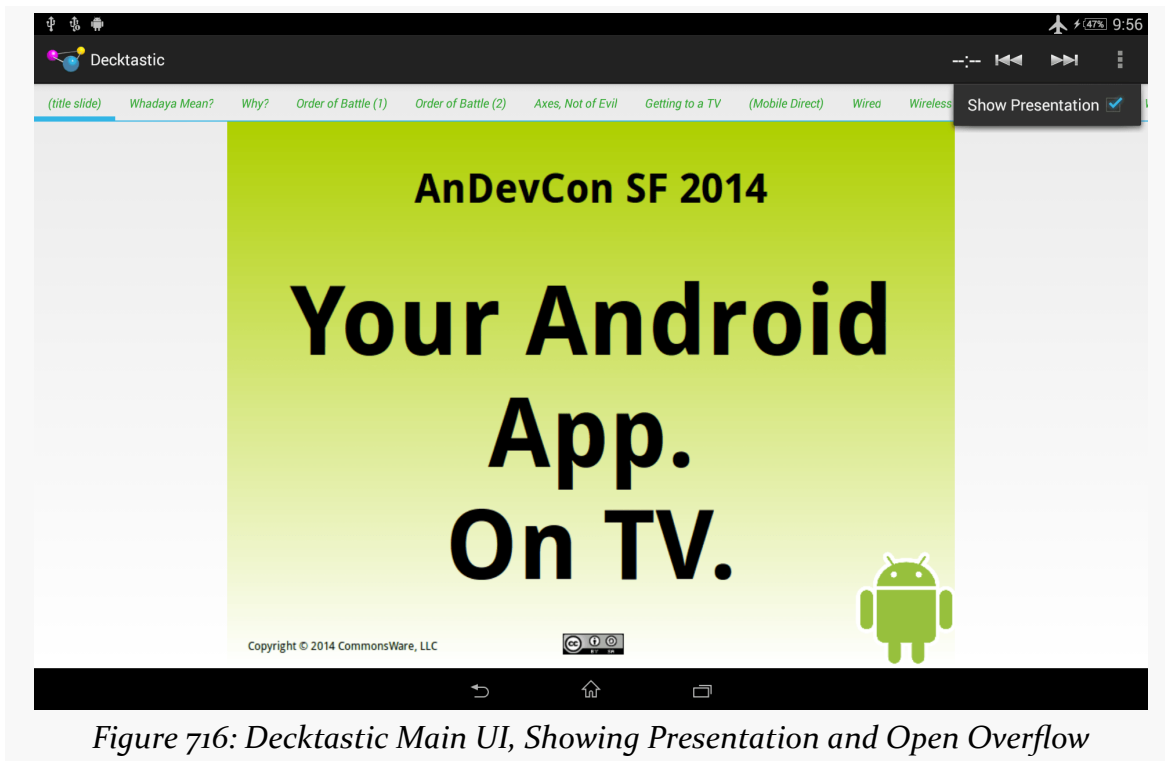

Figure 716: Decktastic Main UI, Showing Presentation and Open Overflow

However, who sees what depends a bit upon the available hardware:

- If you are running this standalone on a phone or tablet, you will see the ViewPager-based UI
- If you are running this on a phone or tablet with a connection to an external display, you will see the ViewPager-based UI, but the *audience* (those looking at the external display) will, by default, just see the slides
- If you are running this on a phone or tablet with a connection to a Chromecast or similar remote playback device, we get the same results as with the external display (you see the full UI, the audience sees the slides)
- If you are running this on an Android TV, Fire TV, or similar device, both you and the audience only see the slides

To move through the slides, you can:

- Swipe the ViewPager
- Use the ViewPager tabs
- Use right or down keys to move forward, or left or up keys to move backward, whether on a QWERTY keyboard (e.g., Bluetooth) or via the D-

pad on some form of remote (for TV-centric scenarios, like Android TV or Fire TV)

Trying Decktastic Yourself

Most of the sample applications in this book stand alone, so all you need to do is run them. Decktastic requires presentations, which means it requires a bit of setup.

If you want to see Decktastic work, you should:

- Run Decktastic once (e.g., from Android Studio). This will show that there are no available presentations. Press BACK to destroy the launcher activity.
- Download [this ZIP archive](#) containing a pair of Decktastic-compatible presentations.
- UnZIP the archive, and copy the contents (not the ZIP file itself) into `Android/data/com.commonware.android.preso.decktastic/files` on your Android device or emulator's external storage.
- Run Decktastic again. This should give you one full presentation ("Your Android App. On TV" from the 2014 AnDevCon San Francisco conference) and one stub presentation (enough to get you a second entry in the list of presentations, but not the full slide set)

Implementing Decktastic

Decktastic is a pair of activities that "stand upon the shoulders of giants", in the form of using eight third-party libraries that provide a lot of the utility code.

The Gradle Dependencies

The project's `build.gradle` file specifies a fair number of dependencies:

```
repositories {
    maven {
        url "http://dl.bintray.com/populov/maven"
    }
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
    mavenCentral()
}

dependencies {
    compile 'com.viewpagerindicator:library:2.4.1@aar'
    compile 'com.commonware.cwac:presentation:0.4.+'
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
compile 'com.android.support:support-v13:21.0.3'  
compile 'com.google.code.gson:gson:2.3'  
compile 'de.greenrobot:eventbus:2.4.0'  
compile 'com.commonware.cwac:mediarouter:0.2.+'  
compile 'com.android.support:leanback-v17:21.0.3'  
compile 'com.squareup.picasso:picasso:2.4.0'  
}
```

(from [Presentation/Decktastic/build.gradle](#))

The project uses:

- Two CWAC libraries, `cwac-presentation` for `PresentationHelper` and `cwac-mediarouter` for the cross-port of the `MediaRouteActionProvider` to the native action bar
- `support-v13`, to pull in `ViewPager` and related classes
- The `ViewPagerIndicator` library
- Google's Gson
- greenrobot's `EventBus`
- Google's `leanback-v17` library, for [“ten-foot UI” elements](#) used in our launcher activity
- Square's `Picasso`, for asynchronously loading images

NOTE: `cwac-mediarouter` has been discontinued, as it is no longer practical to maintain a cross-port of the `mediarouter-v7` library.

The Presentation Format

A Decktastic presentation consists of a JSON file and a series of image files. The image files are the slides themselves, perhaps exported from a traditional presentation package like LibreOffice Impress. The JSON file spells out what the image files are and their order of appearance.

For example, here is a JSON file from the stub presentation included in the aforementioned ZIP archive:

```
{  
  "title": "Notifications, Front to Back",  
  "duration": 70,  
  "baseUrl": "http://misc.commonware.com/andevcon2014/preso2/",  
  "slides": [  
    {  
      "title": "(title slide)",  
      "image": "img0.png"  
    },  
    {  
      "title": "Order of Battle",  
      "image": "img1.png"  
    }  
  ]  
}
```

```
    }  
  ]  
}
```

The `title` is used on the initial “leanback” activity as part of displaying the available presentations.

The `duration` is how long the presentation should run, in minutes. This will be used for a countdown timer to help the presenter know how much time remains in the presentation.

The `baseUrl` is a URL to a directory on a Web server somewhere that contains the same slide images as are available locally. This is needed to support `RemotePlaybackClient`, as Chromecast and similar devices need to be able to download their content over the network. We do not have an easy way to deliver that content from the phone or tablet that runs Decktastic and so we need a network-hosted copy of the slides as well. If you were willing to dispense with Chromecast support, you would not need this `baseUrl` property.

The `slides` array contains JSON objects, each of which provides the title for a slide and the image associated with that slide. The title will be used for the `ViewPager` tabs, so the presenter knows the upcoming slides and can rapidly switch to a specific slide. The images, of course, are what the presenter and the audience see. Of particular importance is the first slide in the array, as this will be used as the “title slide”, shown on the initial “leanback” activity.

The Model Classes

Given that JSON, we need a model class that will represent it, caching the parsed JSON so that we can use that information to render the presentation. We also need a model class that represents the collection of parsed presentations, so that we have the information necessary to render the “leanback” activity that allows the user to find the presentation to display.

There are two model classes in the book that handle this: `PresoContents` and `PresoRoster`.

PresoContents

`PresoContents` represents the parsed JSON, along with a few other bits of information about the presentation:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
package com.commonware.android.preso.decktastic;

import java.io.File;
import java.util.List;

public class PresoContents {
    String title;
    List<Slide> slides;
    int duration;
    String baseURL;
    File baseDir;
    int id=-1;

    static class Slide {
        String image;
        String title;
    }

    @Override
    public String toString() {
        return(title);
    }

    File getSlideImage(int position) {
        return(new File(baseDir, slides.get(position).image));
    }

    String getSlideTitle(int position) {
        return(slides.get(position).title);
    }

    String getSlideURL(int position) {
        return(baseURL+slides.get(position).image);
    }
}
```

(from [Presentation/Decktastic/src/com/commonware/android/preso/decktastic/PresoContents.java](#))

The title, slides, duration, and baseURL fields come straight from the JSON. The baseDir field represents the directory in which the presentation was loaded; all images will be assumed to be relative to this directory. Finally, each presentation is given an id, so we can distinguish one presentation from another in our collection of presentations.

PresoContents also has getter methods to retrieve the local image file (getSlideImage()), title (getSlideTitle()), and remote image URL (getSlideURL()) for a slide given its position in the array of slides.

PresoRoster

PresoRoster is a singleton collection of the available presentations. It also contains the model logic for loading the collection of presentations and parsing the JSON to create an individual PresoContents object for a single presentation:

```
package com.commonware.android.preso.decktastic;

import android.util.Log;
import com.google.gson.Gson;
import java.io.BufferedReader;
import java.io.File;
import java.io.FileInputStream;
import java.io.FileNotFoundException;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.ArrayList;
import java.util.List;

class PresoRoster {
    private static final PresoRoster INSTANCE=new PresoRoster();
    private List<PresoContents> presos=new ArrayList<PresoContents>();

    static PresoRoster getInstance() {
        return(INSTANCE);
    }

    private PresoRoster() {}

    int getPresoCount() {
        return(presos.size());
    }

    PresoContents getPreso(int position) {
        return(presos.get(position));
    }

    PresoContents getPresoById(int id) {
        return(getPreso(id));
    }

    void load(File base) {
        base.mkdirs();

        String[] presoDirs=base.list(new FilenameFilter() {
            @Override
            public boolean accept(File orig, String name) {
                return(new File(orig, name).isDirectory());
            }
        });

        Gson gson=new Gson();

        for (String presoDir : presoDirs) {
            PresoContents c=loadPreso(gson, new File(base, presoDir));
        }
    }
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
    if (c!=null) {
        c.id=presos.size();
        presos.add(c);
    }
}

private PresoContents loadPreso(Gson gson, File base) {
    PresoContents result=null;

    try {
        InputStream is=new FileInputStream(new File(base, "preso.json"));
        BufferedReader reader=
            new BufferedReader(new InputStreamReader(is));

        result=gson.fromJson(reader, PresoContents.class);
        result.baseDir=base;
        is.close();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
    }

    return(result);
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoRoster.java](#))

The class includes:

- Getters to retrieve a presentation by index in the array of presentations (`getPreso()`) and to retrieve a presentation by the ID of the presentation (`getPresoById()`)
- A `getPresoCount()` method that indicates how many presentations were found
- A `load()` method that will scan for subdirectories under a given directory, then attempt to parse a `preso.json` file in the subdirectory (in a private `loadPreso()` method) using `Gson`

The result of `load()` is that the `PresoRoster` should be populated with all known presentations under the specified root directory. Note, though, that this work is done on the current thread, and therefore `load()` needs to be called on a background thread. Also note that `PresoRoster` makes no attempt at thread synchronization, and so `load()` should be called before anything attempts to use the `PresoRoster` getter methods like `getPresoCount()`.

The Launcher Activity: LeanbackActivity

As noted previously, our launcher activity is one that implements Google's "leanback" user interface, specifically a `BrowseFragment` for browsing media content. In this case, that content consists of the roster of available presentations.

The `LeanbackActivity` itself is fairly short:

```
package com.commonware.android.preso.decktastic;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class LeanbackActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager()
                .beginTransaction()
                .add(android.R.id.content, new RosterFragment()).commit();
        }
    }

    public void showPreso(PresoContents preso) {
        startActivity(new Intent(this, MainActivity.class)
            .putExtra(MainActivity.EXTRA_PRESO_ID,
                preso.id));
    }
}
```

(from [Presentation/Decktastic/src/com/commonware/android/preso/decktastic/LeanbackActivity.java](#))

All it does is add a `RosterFragment` to the UI managed by the activity, plus add a `showPreso()` method that will be called by that `RosterFragment` when a presentation is selected. `showPreso()`, in turn, will start a separate activity (`MainActivity`), supplying `EXTRA_PRESO_ID` with the ID of the selected presentation, so `MainActivity` knows what presentation to show.

Manifest Entry

To work properly with the `leanback-v17` classes like `BrowseFragment`, `LeanbackActivity` needs to use `Theme.Leanback`, supplied by `leanback-v17`:

```
<activity
    android:name="com.commonware.android.preso.decktastic.LeanbackActivity"
    android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
    android:label="@string/app_name"
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
    android:screenOrientation="sensorLandscape"
    android:theme="@style/Theme.Leanback">
<intent-filter>
    <action android:name="android.intent.action.MAIN" />

    <category android:name="android.intent.category.LAUNCHER" />
    <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
</intent-filter>
</activity>
```

(from [Presentation/Decktastic/AndroidManifest.xml](#))

Other noteworthy items in the `<activity>` element in the manifest include:

- Locking the screen orientation to `sensorLandscape`, as we want to stick with a landscape-style orientation, but it could either be “regular” or “reverse” landscape without issue
- Handling orientation-related configuration changes, which are not needed since we are locking the screen orientation to `sensorLandscape`, and therefore the UI does not change on an orientation change
- Having the `LEANBACK_LAUNCHER` category as an option in the `<intent-filter>`, as this will cause this activity to appear on Android TV’s home screen launcher (as opposed to the `LAUNCHER` category used by normal Android devices)

RosterFragment

`RosterFragment` is a `BrowseFragment`, designed to provide the two-dimensional navigation of headers and items in a header. In this case, we will have just one header, “Presentations”, containing all of the presentations found by `PresoRoster`.

In `onAttach()`, we check to see how many presentations are known about. If there are none, we make two assumptions:

1. That this is the first time we have needed to look for presentations, and
2. That there are presentations to be found

So, we fork a `LoadThread` to go load those presentations:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    if (PresoRoster.getInstance().getPresoCount()==0) {
        new LoadThread(host).start();
    }
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

Of course, those assumptions are a gross simplification. It could be that the user launched our `LeanbackActivity`, pressed `BACK`, then launched it again for some reason, and therefore the first `LoadThread` did not yet finish before we go and fork a second one. Or, it could be that there are no presentations to be found, in which case we scan unnecessarily. A production-grade version of this app should have a more sophisticated means of ensuring a one- (and only one-) time initialization.

`LoadThread` drops our thread priority to background levels, then tells the `PresoRoster` to load presentations from our app's standard spot on external storage. Then, we raise a `RosterLoadedEvent` on greenrobot's `EventBus`:

```
private static class LoadThread extends Thread {
    private Context ctxt=null;

    LoadThread(Context ctxt) {
        super();

        this.ctxt=ctxt.getApplicationContext();
        android.os.Process.setThreadPriority(android.os.Process.THREAD_PRIORITY_BACKGROUND);
    }

    @Override
    public void run() {
        PresoRoster.getInstance().load(ctxt.getExternalFilesDir(null));

        EventBus.getDefault().postSticky(new RosterLoadedEvent());
    }
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

You will notice that we call `postSticky()`, not `post()` on the `EventBus` instance. This says that we not only want to deliver this event to any current registrants, but that the `EventBus` should cache this event and hand it to future registrants.

To respond to the `RosterLoadedEvent`, we register the `RosterFragment` on the bus in `onResume()` and unregister in `onPause()`:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().registerSticky(this);
}

@Override
public void onPause() {
    EventBus.getDefault().unregister(this);
}
```

PUTTING THE TVS ALL TOGETHER: DECKTASTIC

```
super.onPause();  
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

Specifically, we register using `registerSticky()`. This, in conjunction with `postSticky()`, means that if events were sticky-posted in the past, we are delivered those immediately, in addition to future events. This will allow us to handle configuration changes — even though our activity and fragment might be destroyed on a locale change, or if our device is put into some sort of desk dock, we will get the `RosterLoadedEvent` when our fragment is created anew.

In particular, we have `onEventMainThread()` set up to listen for `RosterLoadedEvent`. At this point, we know that we have our data model and should render it on the screen:

```
public void onEventMainThread(RosterLoadedEvent event) {  
    setHeadersState(BrowseFragment.HEADERS_ENABLED);  
    setTitle(getString(R.string.app_name));  
  
    ArrayAdapter rows=new ArrayAdapter(new ListRowPresenter());  
    PresoRoster roster=PresoRoster.getInstance();  
    ArrayAdapter listRowAdapter=new ArrayAdapter(new PresoPresenter());  
  
    for (int i=0; i < roster.getPresoCount(); ++i) {  
        listRowAdapter.add(roster.getPreso(i));  
    }  
  
    HeaderItem header=new HeaderItem(0, "Presentations", null);  
    rows.add(new ListRow(header, listRowAdapter));  
  
    setAdapter(rows);  
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

In `onEventMainThread()`, we:

- Indicate that we do want headers (though, in reality, since this app only has one header, you could easily skip the headers)
- Set the title to appear in the upper-right corner
- Create an `ArrayAdapter` for the rows that make up the entirety of the `BrowseFragment` contents, using the standard `ListRowPresenter` for our headers and rows
- Create another `ArrayAdapter`, wrapped around a `PresoPresenter`, that will manage the presentations in our one-and-only row
- Pour our `PresoContents` instances into the `ArrayAdapter` for our row
- Attach the “Presentations” title to the row via a standard `ListRow` object

PUTTING THE TVS ALL TOGETHER: DECKTASTIC

- Tell the RosterFragment that the rows represents what it should render

This is all covered in greater detail in the chapter on [the “ten-foot” UI](#).

In `onViewCreated()` of `RosterFragment`, we indicate that the `RosterFragment` itself should be the listener for click events on items (in our case, presentations):

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setOnItemClickListener(this);
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

This works because `RosterFragment` implements the `OnItemClickListener` interface and therefore implements the `onItemClick()` method:

```
@Override
public void onItemClick(Presenter.ViewHolder viewHolder,
    Object o,
    RowPresenter.ViewHolder rowViewHolder,
    Row row) {
    ((LeanbackActivity) getActivity()).showPreso((PresoContents) o);
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

Here, we ask the hosting `LeanbackActivity` to show the clicked-upon presentation, which causes `LeanbackActivity` to launch a `MainActivity` to do just that.

PresoPresenter

The role of `PresoPresenter` is to render the individual items shown in the `BrowseFragment`. In this case, the items are `PresoContents` model objects; `PresoPresenter` will pour the presentation information into `ImageCardView` widgets. `ImageCardView` is supplied by the `leanback-v17` library and is designed to be used for rendering items in a `BrowseFragment`.

The `Presenter` abstract class — which `PresoPresenter` extends — enforces the view holder pattern. A `Presenter` is really responsible for creating and updating `Presenter.ViewHolder` instances, which in turn are responsible for updating the actual widgets themselves. To that end, the `PresoPresenter.Holder` static class is a subclass of `Presenter.ViewHolder`, one that is responsible for pouring a `PresoContents` into an `ImageCardView`:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
static class Holder extends Presenter.ViewHolder {
    private ImageCardView cardView;
    private PicassoImageCardViewTarget viewTarget;

    public Holder(View view) {
        super(view);

        cardView=(ImageCardView)view;
        viewTarget=new PicassoImageCardViewTarget(cardView);
    }

    protected void updateCardViewImage(String path) {
        Picasso.with(cardView.getContext())
            .load("file://" + path)
            .resize(convertDpToPixel(cardView.getContext(), CARD_WIDTH),
                convertDpToPixel(cardView.getContext(), CARD_HEIGHT))
            .into(viewTarget);
    }
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

Here, we are going to use Picasso to load the initial slide off of disk and put it in the ImageCardView. However, Picasso has no built-in knowledge of ImageCardView, the way it has built-in knowledge of ImageView. We need to teach Picasso how to populate an ImageCardView. Picasso's mechanism for this is to define a Target implementation (PicassoImageCardViewTarget in this case) that is responsible for taking a loaded bitmap and updating the UI with it:

```
private static class PicassoImageCardViewTarget implements Target {
    private ImageCardView imageCardView;

    public PicassoImageCardViewTarget(ImageCardView imageCardView) {
        this.imageCardView=imageCardView;
    }

    @Override
    public void onBitmapLoaded(Bitmap bmp, Picasso.LoadedFrom lf) {
        Drawable bmpDrawable=
            new BitmapDrawable(imageCardView.getContext().getResources(),
                bmp);

        imageCardView.setMainImage(bmpDrawable);
    }

    @Override
    public void onBitmapFailed(Drawable d) {
        imageCardView.setMainImage(d);
    }

    @Override
    public void onPrepareLoad(Drawable d) {
        imageCardView.setMainImage(d);
    }
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

PUTTING THE TVS ALL TOGETHER: DECKTASTIC

Target requires implementations of:

- `onBitmapLoaded()`, where we take the image and put it as the “main image” of the `ImageCardView` by means of `setMainImage()`
- `onBitmapFailed()`, where we are given a failure `Drawable` and need to use it, once again by setting it as the `ImageCardView` main image
- `onPrepareLoad()`, where we are given a “loading” `Drawable` and need to use it, once more by setting it as the `ImageCardView` main image

The `PresoPresenter.Holder` class creates an instance of a `PicassoImageCardViewTarget` and uses that for the `into()` method of the `Picasso RequestBuilder` (created via the `with()` static method on the `Picasso` class).

The other thing interesting about our use of Picasso is in the `resize()` call. Particularly since Picasso does not know about `ImageCardView` and how big the image should be, we need to manually tell Picasso what size to make the image. Here, we hard-code the sizes of the card width and height in density-independent pixels:

```
private static final int CARD_WIDTH=400;
private static final int CARD_HEIGHT=300;
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

We then use a static `convertDpToPixel()` method to get the actual number of hardware pixels to use, based upon the current screen density:

```
static int convertDpToPixel(Context ctxt, int dp) {
    float density=ctxt.getResources().getDisplayMetrics().density;

    return(Math.round((float)dp*density));
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

Back up in `PresoPresenter` itself, the `Presenter` abstract class requires us to override `onCreateViewHolder()`, where we are responsible for creating a `Presenter.ViewHolder`. In the case of `PresoPresenter`, that comes in the form of the aforementioned `PresoPresenter.Holder`:

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
    ImageCardView cardView=new ImageCardView(parent.getContext());

    cardView.setFocusable(true);
    cardView.setFocusableInTouchMode(true);
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
return(new Holder(cardView));
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

We also have to override `onBindViewHolder()`, where we are given an eligible `Presenter.ViewHolder` and need to populate its widgets from a supplied item:

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
                             Object item) {
    PresoContents preso=(PresoContents)item;
    Holder h=(Holder)viewHolder;

    h.cardView.setTitleText(preso.toString());
    h.cardView.setMainImageDimensions(CARD_WIDTH, CARD_HEIGHT);
    h.updateCardViewImage(preso.getSlideImage(0).getAbsolutePath());
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

Here, the item is a `PresoContents` and the `Presenter.ViewHolder` is a `PresoPresenter.Holder`. We update the `ImageCardView` title and image size based on the presentation, plus tell the `Holder` to update the image itself, calling the `updateCardViewImage()` method that contained our Picasso request.

Note that we are passing the density-independent pixels values (`CARD_WIDTH`, `CARD_HEIGHT`) to `setMainImageDimensions()`. Unfortunately, this method is undocumented, and so what the units of measure should be are not disclosed.

The `Presenter` abstract class also requires implementations of `onUnbindViewHolder()` (called when we should no longer be populating those widgets) and `onViewAttachedToWindow()` (called when the widgets associated with a `Presenter.ViewHolder` are now “live”):

```
@Override
public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
}

@Override
public void onViewAttachedToWindow(Presenter.ViewHolder viewHolder) {
    // no-op
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

The Guts: MainActivity

All of the above was just to handle the launcher activity, to allow the user to choose a presentation. MainActivity is where we actually show the presentation itself.

This is based upon [the Presentation/Slides sample app](#), profiled in [the chapter on Presentation](#). Some of the basic logic, for managing the ViewPager and displaying the current slide on an external display, is identical to that sample. However, the Decktastic app also supports direct-to-TV devices (e.g., Fire TV, Android TV) and remote playback devices (e.g., Chromecast), and so it blends in some of the techniques covered elsewhere in this book.

Basic Setup

onCreate() of MainActivity is responsible for basic setup.

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    preso=PresoRoster.getInstance()
        .getPresoById(getIntent()
            .getIntExtra(EXTRA_PRESO_ID, 0));

    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    helper=new PresentationHelper(this, this);

    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
            .build();
    router=MediaRouter.getInstance(this);
    router.addCallback(selector, routeCB,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);

    if (isDirectToTV()) {
        getActionBar().hide();
    }

    setupPager();
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

First, we take the EXTRA_PRESO_ID value received via an Intent extra and uses that to find the PresoContents object representing the presentation to be shown. That PresoContents object is then referenced by a data member named preso.

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

Next, we load up the `activity_main` layout resource, containing our `ViewPager` and a `TabPageIndicator`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:keepScreenOn="true">

    <com.viewpagerindicator.TabPageIndicator
        android:id="@+id/titles"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:visibility="gone"/>

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
    </android.support.v4.view.ViewPager>
</LinearLayout>
```

(from [Presentation/Decktastic/res/layout/activity_main.xml](#))

Then, we create a `PresentationHelper`, so that we find out when we should and should not be displaying a `Presentation`. As before, `MainActivity` itself is the `PresentationHelper.Listener` for finding out about these events. We will explore that more [later in this chapter](#).

We then go through some logic for setting up remote playback device support (`MediaRouteSelector.Builder` and kin) and direct-to-TV device support (calling `isDirectToTV()`). Those will be explored later in this chapter, in sections on [remote playback device support](#) and [direct-to-TV device support](#).

Finally, we call `setupPager()`, to populate our `ViewPager`.

The ViewPager

The `setupPager()` method is responsible for putting a `SlidesAdapter` into the `ViewPager` and otherwise setting things up to allow the presenter to control what slide is shown and for us to find out what slide the presenter selects:

```
private void setupPager() {
    durationInSeconds=preso.duration * 60;

    if (rc!=null) {
        rc.setOverallDuration(durationInSeconds);
    }
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
adapter=new SlidesAdapter(this, preso);
pager.setAdapter(adapter);

TabPageIndicator tabs=(TabPageIndicator)findViewById(R.id.titles);

tabs.setViewPager(pager);
tabs.setOnPageChangeListener(this);

if (isDirectToTV()) {
    tabs.setVisibility(View.GONE);
}
else {
    tabs.setVisibility(View.VISIBLE);
}
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](https://github.com/commonsware/android/preso/decktastic/MainActivity.java))

Some of this — specifically the `SlidesAdapter` and `TabPageIndicator` logic — is standard `ViewPager` setup work. The `durationInSeconds` stuff at the top is for setting up a `ReverseChronometer`, as will be discussed [later in this chapter](#). The `isDirectToTV()` call and `if` block will be explained more in the section on [direct-to-TV device support](#) later in this chapter.

`SlidesAdapter` is a fragment-free edition of a `PagerAdapter`, as the slides are purely `ImageView` widgets:

```
package com.commonsware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class SlidesAdapter extends PagerAdapter {
    private PresoContents preso;
    private Context ctxt;

    SlidesAdapter(Context ctxt, PresoContents preso) {
        this.ctxt=ctxt;
        this.preso=preso;
    }

    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        ImageView page=new ImageView(ctxt);

        container.addView(page,
            new ViewGroup.LayoutParams(
                ViewGroup.LayoutParams.MATCH_PARENT,
                ViewGroup.LayoutParams.MATCH_PARENT));
    }
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
Picasso.with(ctxt).load(getSlideImageUri(position)).into(page);

return(page);
}

@Override
public void destroyItem(ViewGroup container, int position,
    Object object) {
    container.removeView((View)object);
}

@Override
public int getCount() {
    return(preso.slides.size());
}

@Override
public boolean isViewFromObject(View view, Object object) {
    return(view == object);
}

@Override
public String getPageTitle(int position) {
    return(preso.getSlideTitle(position));
}

Uri getSlideImageUri(int position) {
    return(Uri.fromFile(preso.getSlideImage(position)));
}
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/SlidesAdapter.java](#))

Of note:

- `instantiateItem()` creates the `ImageView`, adds it to the supplied container (set to fill that container), and tells Picasso to go load the image asynchronously into the `ImageView`
- `destroyItem()` removes the `ImageView` from the container
- `getCount()` returns the number of pages, based on the number of slides in the `PresoContents` supplied to the `SlidesAdapter` via its constructor
- `getPageTitle()` returns the page title, obtained from the `PresoContents` object
- `getSlideImageUri()` gets a `Uri` pointing to a local file from the `PresoContents`, for use both by `instantiateItem()` and by the `Presentation` object that we will use for external display support (as will be covered [later in this chapter](#))

Supporting the Direct-to-TV Scenario

To determine whether or not our activity is natively displaying on a TV-style screen, we check to see whether the device has either `FEATURE_TELEVISION` or `FEATURE_LEANBACK`, in the private `isDirectToTV()` method on `MainActivity`:

```
private boolean isDirectToTV() {
    return(getPackageManager().hasSystemFeature(PackageManager.FEATURE_TELEVISION)
        || getPackageManager().hasSystemFeature(PackageManager.FEATURE_LEANBACK));
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Admittedly, not all Android direct-to-TV devices may advertise that they have one of these features. In particular, minor-brand Android HDMI sticks might just be using a fairly vanilla Android device profile, culled from a tablet. There is no good way of detecting such a scenario, though Decktastic could provide some manual option (e.g., checkable action item) to go into direct-to-TV mode if this proved to be important.

We use `isDirectToTV()` in two places. First, in `onCreate()`, we hide the action bar if we are going direct to a TV:

```
if (isDirectToTV()) {
    getActionBar().hide();
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Second, in `setupPager()`, we hide the `TabPageIndicator` if we are going direct to a TV:

```
if (isDirectToTV()) {
    tabs.setVisibility(View.GONE);
}
else {
    tabs.setVisibility(View.VISIBLE);
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

This eliminates the “chrome” from our activity, leaving us with just the contents of the `ViewPager` itself, in the form of our slides. On the plus side, this gives us the visual output we want. However, it comes at a cost: there is no means for the presenter to change slides. After all, there is no touchscreen in this scenario, and so even though the `ViewPager` could be swiped, that is not possible without a touchscreen.

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

To support standard presentation remotes and similar mechanisms, MainActivity overrides onKeyDown():

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    switch(keyCode) {
        case KeyEvent.KEYCODE_SPACE:
        case KeyEvent.KEYCODE_DPAD_RIGHT:
        case KeyEvent.KEYCODE_DPAD_DOWN:
        case KeyEvent.KEYCODE_PAGE_DOWN:
        case KeyEvent.KEYCODE_MEDIA_NEXT:
            if (pager.canScrollHorizontally(1)) {
                pager.setCurrentItem(pager.getCurrentItem()+1, true);
            }

            return(true);

        case KeyEvent.KEYCODE_DPAD_LEFT:
        case KeyEvent.KEYCODE_DPAD_UP:
        case KeyEvent.KEYCODE_PAGE_UP:
        case KeyEvent.KEYCODE_MEDIA_PREVIOUS:
            if (pager.canScrollHorizontally(-1)) {
                pager.setCurrentItem(pager.getCurrentItem()-1, true);
            }

            return(true);
    }

    return(super.onKeyDown(keyCode, event));
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here, we will advance to the next slide if the user presses:

- the space bar or the Page Down key on a QWERTY keyboard
- right or down arrow keys, D-pad buttons, or the like
- a “next” media button on a media remote

Conversely, we will return to the preceding slide if the user presses:

- the Page Up key on a QWERTY keyboard
- left or up arrow keys, D-pad buttons, or the like
- a “previous” media button on a media remote

This should allow most remotes for direct-to-TV devices to control our slides. Note that we are passing true as the second parameter to the setCurrentItem() method, and therefore the audience will see an animated transition to the next slide. That may or may not be desirable; an enhanced edition of Decktastic might allow that to be configured (e.g., via a checkable action item).

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

Note that this is still a bit limited compared to having touchscreen access, as our `onKeyDown()` method only moves a slide at a time. There is no facility to jump to an arbitrary spot, the way you could by swiping and tapping upon `ViewPager` tabs on a touchscreen.

Supporting External Displays

As noted earlier, in `onCreate()` of `MainActivity`, we create an instance of `PresentationHelper`, supplying the activity itself as both the `Context` and the `PresentationHelper.Listener` for presentation-related events:

```
helper=new PresentationHelper(this, this);
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

That, in turn, requires us to forward along `onPause()` and `onResume()` events from our activity to the `PresentationHelper`:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

We also have to implement `showPreso()` and `clearPreso()` methods to satisfy the `PresentationHelper.Listener` interface:

```
@Override
public void clearPreso(boolean showInline) {
    if (presoFrag != null) {
        presoFrag.dismiss();
        presoFrag=null;
    }
}

@Override
public void showPreso(Display display) {
    Uri slide=adapter.getSlideImageUri(pager.getCurrentItem());

    presoFrag=
        SlidePresentationFragment.newInstance(this, display, slide);
    presoFrag.show(getFragmentManager(), "presoFrag");
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

In `showPreso()`, we obtain the `Uri` for the current slide by calling the `getSlideImageUri()` method we conveniently implemented on the `SlidesAdapter`. Then, we create an instance of a `SlidePresentationFragment`, handing it the slide `Uri`, and we `show()` that fragment. We only `dismiss()` the fragment in `clearPreso()`.

The fragment itself is a `PresentationFragment`, with an `ImageView` as the fragment's UI, populated using `Picasso`, with the `Uri` being transferred from the `newInstance()` factory method to the fragment itself via the arguments `Bundle`:

```
package com.commonsware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.commonsware.cwac.preso.PresentationFragment;
import com.squareup.picasso.Picasso;

public class SlidePresentationFragment extends PresentationFragment {
    private static final String KEY_URI="u";
    private ImageView slide=null;

    public static SlidePresentationFragment newInstance(Context ctxt,
                                                    Display display,
                                                    Uri slideUri) {
        SlidePresentationFragment frag=new SlidePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();

        b.putParcelable(KEY_URI, slideUri);
        frag.setArguments(b);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                            ViewGroup container,
                            Bundle savedInstanceState) {
        slide=new ImageView(getContext());

        setSlideContent((Uri) getArguments().getParcelable(KEY_URI));

        return(slide);
    }
}
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
void setSlideContent(Uri slideUri) {
    Picasso.with(getContext()).load(slideUri).into(slide);
}
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/SlidePresentationFragment.java](#))

This arranges to show the *current* slide, for whatever the current slide is at the time `showPreso()` is called on `MainActivity`. However, we need to update this fragment to reflect changes in the current slide. To accomplish this, we set up `MainActivity` to implement the `OnPageChangeListener` interface, then call `setOnPageChangeListener()` on the `ViewPager` in `setupPager()` to have it forward page-change events to the activity. Of those events, we pay particular attention to `onPageSelected()`, updating the `SlidePresentationFragment` if there is one around:

```
@Override
public void onPageScrollStateChanged(int arg0) {
    // ignored
}

@Override
public void onPageScrolled(int arg0, float arg1, int arg2) {
    // ignored
}

@Override
public void onPageSelected(int position) {
    if (presoFrag != null) {
        presoFrag.setSlideContent(adapter.getSlideImageUri(position));
    }

    if (client!=null) {
        String url=preso.getSlideURL(position);

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

We will get into the `client` stuff from `onPageSelected()` in the next section, as that pertains to supporting remote playback devices.

Supporting Chromecast and Remote Playback Devices

The key limitation of Chromecast and other remote playback devices is that they can only play back media that they can access. While Chromecast supports mirroring, that is handled via the `Presentation` API discussed previously; devices limited to the `RemotePlaybackClient` API need URLs to media files. That is why our JSON for the presentation contains a URL pointing to a copy of each slide up on

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

some public Web server. To push those URLs over to the Chromecast at the appropriate points, we need to set up the RemotePlaybackClient system.

First, in `onCreate()`, we define a `MediaRouteSelector` for remote playback devices, set up a `MediaRouter`, and add a callback to find out about selected route changes, asking `MediaRouter` to scan for possible routes along the way:

```
selector=
    new MediaRouteSelector.Builder()
        .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
        .build();
router=MediaRouter.getInstance(this);
router.addCallback(selector, routeCB,
    MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

All of this is using the `mediarouter-v7` portion of the Android Support package, as the native `MediaRouter` and `kin` do not support remote playback devices.

Our menu resource for our action bar contains, among other things, a `MediaRouteActionProvider`:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
    xmlns:android="http://schemas.android.com/apk/res/android"
    tools:ignore="AppCompatResource">

    <item
        android:id="@+id/countdown"
        android:actionViewClass=
            "com.commonsware.android.preso.decktastic.ReverseChronometer"
        android:showAsAction="always"
        android:title="This Should Not Be Needed">
    </item>
    <item
        android:id="@+id/route_provider"
        android:title="@string/media_route_provider"
        android:actionProviderClass=
            "com.commonsware.cwac.mediarouter.app.MediaRouteActionProvider"
        android:showAsAction="always"/>
    <item
        android:id="@+id/first"
        android:icon="@android:drawable/ic_media_previous"
        android:showAsAction="always"
        android:title="@string/first">
    </item>
    <item
        android:id="@+id/last"
        android:icon="@android:drawable/ic_media_next"
        android:showAsAction="always"
        android:title="@string/last">
    </item>
    <item
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
        android:id="@+id/present"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"
        android:title="@string/show_presentation">
    </item>
</menu>
```

(from [Presentation/Decktastic/res/menu/activity_actions.xml](#))

As part of our work in setting up the action bar in `onCreateOptionsMenu()`, we retrieve the `MediaRouteActionProvider` and configure it with the same `MediaRouteSelector` that we used for the `MediaRouter` callback:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    rc=(ReverseChronometer)menu.findItem(R.id.countdown)
        .getActionView();

    rc.setWarningDuration(5 * 60);
    rc.setOnClickListener(this);
    rc.setOnLongClickListener(this);
    rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
    rc.setTextColor(Color.WHITE);

    if (durationInSeconds>0) {
        rc.setOverallDuration(durationInSeconds);
    }

    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)item.getActionProvider();

    provider.setRouteSelector(selector);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

(the lines in `onCreateOptionsMenu()` pertaining to the `ReverseChronometer` will be explained [later in this chapter](#))

If the user interacts with the `MediaRouteActionProvider` and elects to connect to a remote playback device, our `MediaRouter.Callback` will be notified about the change of route:

```
private MediaRouter.Callback routeCB=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
        MediaRouter.RouteInfo route) {
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
connect(route);
}

@Override
public void onRouteUnselected(MediaRouter router,
                             MediaRouter.RouteInfo route) {
    disconnect();
}
};
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here, we just delegate the `onRouteSelected()` and `onRouteUnselected()` callbacks to `connect()` and `disconnect()` methods on `MainActivity`. `MediaRouter.Callback` is an abstract class, not an interface — otherwise, we would simply have implemented the interface on `MainActivity` and bypassed this anonymous inner class instance.

The `connect()` method on `MainActivity` is responsible for sending over the current slide to the remote playback device:

```
private void connect(MediaRouter.RouteInfo route) {
    client=
        new RemotePlaybackClient(getApplicationContext(), route);

    if (client.isRemotePlaybackSupported()) {
        String url=preso.getSlideURL(pager.getCurrentItem());

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
    else {
        client=null;
    }
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here, we:

- Create an instance of `RemotePlaybackClient`
- Confirm that the remote playback device supports the remote playback protocol (`isRemotePlaybackSupported()`)
- Call `play()`, passing over a URL pointing to the same slide that the `ViewPager` is showing from a local file

The `play()` call requires an `ItemActionCallback` as the last parameter. We really do not need the callback, but passing `null` does not work. So, we have a do-nothing `ItemActionCallback` named `playCB` that we use:

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
ItemActionCallback playCB=new ItemActionCallback() {
    @Override
    public void onResult(Bundle data, String sessionId,
        MediaSessionStatus sessionStatus,
        String itemId, MediaItemStatus itemStatus) {
    }

    @Override
    public void onError(String error, int code, Bundle data) {
    }
};
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

That will show the slide that was current as of the time the user connected to the remote playback device. We need to show a new slide when the presenter switches to a new slide, just as we did in the Presentation scenario. This too is handled in `onPageSelected()`, where we make the same sort of `play()` call that we did in `connect()`:

```
@Override
public void onPageSelected(int position) {
    if (presoFrag != null) {
        presoFrag.setSlideContent(adapter.getSlideImageUri(position));
    }

    if (client!=null) {
        String url=preso.getSlideURL(position);

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Not only is `disconnect()` called from `MediaRouter.Callback`, but it is also called from `onDestroy()` of `MainActivity`, where we also remove that callback from the `MediaRouter`:

```
@Override
public void onDestroy() {
    disconnect();
    router.removeCallback(routeCB);
    super.onDestroy();
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

`disconnect()` releases the `RemotePlaybackClient` and ensures that we are back on our default route:

```
private void disconnect() {
    if (client != null) {
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
    client.release();
    client=null;
}

router.getDefaultRoute().select();
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

The net effect of all of this is that the slides will update on the remote playback device as the presenter switches slides, in addition to when the presenter connects to the remote playback device originally. We are not in control of any transition effects — we simply provide the slides, and it is up to the remote playback device to download and show them, however that device wishes.

The Rest of the Story

One common need of a presenter is to know how much time is remaining in which to deliver the presentation. Presentations are usually time-limited, to fit conference agendas and the like. The JSON structure for a presentation contains the duration of the presentation, and it would be useful to let the presenter know how much of that duration is remaining.

The chapter on custom views has a section outlining the implementation of [a ReverseChronometer widget](#). Chronometer is a standard Android SDK class for counting up time (e.g., a stopwatch). ReverseChronometer is for counting *down* time.

Decktastic puts a ReverseChronometer in the action bar as a custom view, courtesy of our menu XML:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
      xmlns:android="http://schemas.android.com/apk/res/android"
      tools:ignore="AppCompatResource">

    <item
        android:id="@+id/countdown"
        android:actionViewClass=
            "com.commonsware.android.preso.decktastic.ReverseChronometer"
        android:showAsAction="always"
        android:title="This Should Not Be Needed">
    </item>
    <item
        android:id="@+id/route_provider"
        android:title="@string/media_route_provider"
        android:actionProviderClass=
            "com.commonsware.cwac.mediarouter.app.MediaRouteActionProvider"
        android:showAsAction="always"/>
</menu>
```

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

```
<item
    android:id="@+id/first"
    android:icon="@android:drawable/ic_media_previous"
    android:showAsAction="always"
    android:title="@string/first">
</item>
<item
    android:id="@+id/last"
    android:icon="@android:drawable/ic_media_next"
    android:showAsAction="always"
    android:title="@string/last">
</item>
<item
    android:id="@+id/present"
    android:checkable="true"
    android:checked="true"
    android:showAsAction="never"
    android:title="@string/show_presentation">
</item>
</menu>
```

(from [Presentation/Decktastic/res/menu/activity_actions.xml](#))

We customize the `ReverseChronometer` through a handful of lines in the `onCreateOptionsMenu()` method:

```
rc=(ReverseChronometer)menu.findViewById(R.id.countdown)
    .getActionView();

rc.setWarningDuration(5 * 60);
rc.setOnClickListener(this);
rc.setOnLongClickListener(this);
rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
rc.setTextColor(Color.WHITE);

if (durationInSeconds>0) {
    rc.setOverallDuration(durationInSeconds);
}
```

(from [Presentation/Decktastic/src/com/commonware/android/preso/decktastic/MainActivity.java](#))

Here we:

- Retrieve the `ReverseChronometer` from the action item
- Have it change to a “warning” presentation with five minutes remaining
- Set up the activity to respond to click and long-click events
- Set the appearance to be 24sp white text

And, if we already know the presentation’s overall duration, via the `durationInSeconds` data member, we pour that into the `ReverseChronometer` as well.

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

durationInSeconds is populated via a few lines at the top of setupPager():

```
durationInSeconds=preso.duration * 60;

if (rc!=null) {
    rc.setOverallDuration(durationInSeconds);
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

This way, no matter whether setupPager() or onCreateOptionsMenu() is called first, we pour the duration into the ReverseChronometer.

By default, that ReverseChronometer does nothing other than show the remaining time... which remains fixed by default. That is where the click and long-click event handlers come into play:

```
@Override
public void onClick(View v) {
    ReverseChronometer rc=(ReverseChronometer)v;

    if (rc.isRunning()) {
        rc.stop();
    }
    else {
        if (isFirstRCClick) {
            isFirstRCClick=false;
            rc.reset();
        }

        rc.run();
    }
}

@Override
public boolean onLongClick(View v) {
    ReverseChronometer rc=(ReverseChronometer)v;

    rc.reset();

    return(true);
}
```

(from [Presentation/Decktastic/src/com/commonsware/android/preso/decktastic/MainActivity.java](#))

There are three possibilities when the user taps on the ReverseChronometer:

- It was never clicked before (isFirstRCClick is true), in which case we ensure that the ReverseChronometer is reset to the overall duration before calling run() to start the countdown
- It is already running, in which case we call stop() to pause the countdown

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

- It was not already running (but was clicked before), in which case we call `run()` again to resume the countdown

This gives us what from a media standpoint would be play, pause, and resume logic.

A long-click will `reset()` the `ReverseChronometer`, returning the time remaining to the overall duration.

Our action bar also has a few other action items, handled in `onOptionsItemSelected()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.present:
            boolean original=item.isChecked();

            item.setChecked(!original);

            if (original) {
                helper.disable();
            }
            else {
                helper.enable();
            }

            break;

        case R.id.first:
            pager.setCurrentItem(0);
            break;

        case R.id.last:
            pager.setCurrentItem(adapter.getCount() - 1);
            break;
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Presentation/Decktastic/src/com/commonware/android/preso/decktastic/MainActivity.java](https://github.com/CommonWare/android-pres0/decktastic/MainActivity.java))

Specifically:

- There is a checkable action item to determine whether or not we should be showing a `Presentation`. If this is unchecked, and an external display is attached, we still disable the `PresentationHelper`. This will cause normal display mirroring to begin, and the audience will see the same UI that the presenter does, complete with the `ViewPager`, action bar, and so on. Checking it re-enables the `PresentationHelper`, so if an external display is available, we start showing the slides again.

PUTTING THE TVs ALL TOGETHER: DECKTASTIC

- The first and last action bar items are “fast-forward” and “rewind” options, allowing the presenter to quickly jump to the first or the last slide in the presentation. This happens via calls to `setCurrentItem()` on the `ViewPager`, which will in turn invoke `onPageSelected()`, causing us to update our `PresentationFragment` or remote playback device, if needed.

Note that since the direct-to-TV mode hides the action bar, none of these options are available to the presenter on a device like Android TV or a Fire TV. This will require the presenter to use something else to track the remaining time in a presentation, such as a countdown timer app running on a separate Android device.

Creating a MediaRouteProvider

As was noted [earlier in the book](#), you can use `MediaRouter` to identify media routes, such as those published by devices like Google’s Chromecast. Specifically, remote playback routes let you write apps that tell other devices, like the Chromecast, to play back media on your behalf.

However, not only can you write *clients* for remote playback routes, you can write *providers* of those routes. Perhaps you are working with a hardware manufacturer that is creating a Chromecast-like device. Perhaps you want to allow your app, running on a [Fire TV](#) or an Android HDMI stick, to be controlled by a user’s phone or tablet. Or perhaps you are trying to tie Android into specialized media hardware that does not communicate by conventional means (e.g., wireless speakers that do not use normal Bluetooth profiles).

This chapter will outline how you can create code that will publish media routes to users of `MediaRouter`, so that you can then take those requests and forward them to a remote device.

Prerequisites

This chapter assumes that you have read [the chapter on MediaRouter](#).

Terminology

For the purposes of this chapter:

- The “client device” refers to a phone or tablet that runs an app that should be able to direct what is shown on a streaming media player

- The “player device” refers to the streaming media player itself, which may or may not be running Android
- The “player app” refers to an Android app running on an Android-powered player device

DIY Chromecast

Google’s Chromecast is a nice little device. However, it has issues:

- The device itself is not especially open.
- The Cast SDK that Google encourages for writing Chromecast-enabled apps is not especially open.
- The [terms and conditions](#) for using the Cast SDK may be troublesome for many developers.
- Chromecast is not available globally.
- Chromecast is only one device, and there are plenty of other streaming media devices available that need to be considered.

Some of these issues can be mitigated by the use of `MediaRouter` and `RemotePlaybackClient` instead of the proprietary Cast SDK. You are not bound by any particular license terms (beyond the norm for Android development) and the implementation of the media framework is open.

However, to make this work, the client device needs to know how to talk to the player device.

The good news is that the media routing framework in Android supports plug-in media route providers for just this purpose. The OS ships with such a provider for the Chromecast, and you can create your own providers to talk to whatever else you would like to talk to. The user can then install a small app on their client device that implements this media route provider, and *any* apps already on their client device that use classes like `RemotePlaybackClient` will automatically be able to cast their desired content to the player device.

MediaRouteProvider

The guts of this come in the form of a `MediaRouteProvider`. Your custom subclass of `MediaRouteProvider` will:

- Tell Android what general capabilities you support, such as remote playback, session management, and the like
- Advertise what sorts of content your player device is capable of playing (e.g., certain video MIME types, certain URL schemes like http and rtsp)
- Serve as the recipient of commands from `MediaRouter`, `RemotePlaybackClient`, and the like, for you to forward along asynchronously to the player device

Depending upon your use case, you could elect to keep the `MediaRouteProvider` private to your application. That way, your app can cast to the player device, but no other apps can. Or, you can make your `MediaRouteProvider` available to all apps on the device, with the media routing framework taking care of the IPC details to have those apps tell your `MediaRouteProvider` what the player device should do.

Player Device... and Maybe a Player App

Of course, this assumes the existence of some player device that is not supported by Android out of the box. Since Android only really supports Chromecast, external displays (e.g., HDMI, MHL, Miracast), and some Bluetooth options (e.g., external speakers) for media routes, there are countless player devices that need additional help. These will run the gamut from devices from major players (e.g., Amazon's Fire TV) to no-name devices (e.g., Android HDMI "sticks").

Some player devices will run Android. In that case, you would be writing a player app that would run on the player device that would be the recipient of commands sent to it from your `MediaRouteProvider` on the client device. For example, if you write a video player app, you could augment it with remote control capability driven by a `MediaRouteProvider` on a client device, turning your player app and anything it can run on (e.g., Fire TV, OUYA game console) into a Chromecast-like environment.

Some player devices will not run Android. If they offer some existing remote control over-the-air protocol, you could create a `MediaRouteProvider` that speaks that protocol. Or, perhaps the player devices are programmable, just not via Android (e.g., a Linux program for XMBC), in which case you might be able to write both ends of the communications channel.

Communications Protocol

Somehow, the data from the `MediaRouteProvider` needs to get to the player device (and, where relevant, the player app). Likely candidates include Bluetooth, regular WiFi (if both devices are on the same network), and WiFi Direct.

However, in principle, anything is possible. For example, there is nothing stopping you from sending `MediaRouteProvider` commands to some Web server out on the Internet, which forwards them to some distant location for use. That would be a bit unusual – normally, the user of the client device is controlling something she can see — but it certainly could be done.

The biggest thing to watch out for is the addressability of the media to be played back. There is little point in connecting a `MediaRouteProvider` to some player device, then not have the ability for the player device to access the media that the client device is requesting. The expected pattern is that the media is hosted in some (relatively) central location, like a Web server. However, once again, anything is possible. If you want to have some sort of server on the client device, to allow the player device to play back media from it, and you believe that you can adequately secure this, you are welcome to do so.

Creating the `MediaRouteProvider`

As noted earlier, the core of all of this is a custom `MediaRouteProvider`. Google supplies a [sample application](#) for creating such a `MediaRouteProvider`. However, it is overly complex, and it is undocumented.

This chapter will focus instead on the [MediaRouter/RouteProvider](#) sample project. This is a clone of the `MediaRouter/RemotePlayback` sample project covered [earlier in this book](#), with the addition of a custom `MediaRouteProvider`.

Defining the Supported Actions

A `MediaRouteProvider` advertises — whether to its own app's `MediaRouter` or to the entire device — what sorts of actions it can perform. For example, a remote playback route provider needs to support actions like play, pause, resume, and stop of some piece of media.

The way this is handled in the media routing framework is via a series of `IntentFilter` objects.

CREATING A MEDIAROUTEPROVIDER

Since `IntentFilter` objects do not need a `Context` to be created, it is safe to define them statically, if desired. That's what we do in `DemoRouteProvider`, a custom subclass of `MediaRouteProvider`. It declares a pair of static final `IntentFilter` objects, `ifPlay` and `ifControl`, which are then configured in a static initialization block:

```
private static final IntentFilter ifPlay=new IntentFilter();
private static final IntentFilter ifControl=new IntentFilter();

static {
    ifPlay.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
    ifPlay.addAction(MediaControlIntent.ACTION_PLAY);
    ifPlay.addDataScheme("http");
    ifPlay.addDataScheme("https");
    ifPlay.addDataScheme("rtsp");

    try {
        ifPlay.addDataType("video/*");
    }
    catch (MalformedMimeTypeException e) {
        throw new RuntimeException("Exception setting MIME type", e);
    }

    ifControl.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
    ifControl.addAction(MediaControlIntent.ACTION_PAUSE);
    ifControl.addAction(MediaControlIntent.ACTION_RESUME);
    ifControl.addAction(MediaControlIntent.ACTION_STOP);
    ifControl.addAction(MediaControlIntent.ACTION_GET_STATUS);
    ifControl.addAction(MediaControlIntent.ACTION_SEEK);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProvider.java](#))

Both stipulate that they are looking for `Intent` objects in the `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK` category. This category is used for all media routing `Intents` that form the foundation of the routing framework.

`ifPlay` is defined as supporting `MediaControlIntent.ACTION_PLAY`, stating that we know how to play back some content. The qualifications for “some content” are handled via scheme and type constraints placed on the `IntentFilter`. Here, we limit the content to be URLs that might be reachable by a playback device (`http`, `https`, `rtsp`) and have a MIME type matching `video/*`. Hence, we are stating that we can play back streaming video.

`ifControl` sets up the remaining actions that we support:

- `MediaControlIntent.ACTION_PAUSE`
- `MediaControlIntent.ACTION_RESUME`
- `MediaControlIntent.ACTION_STOP`

CREATING A MEDIAROUTEPROVIDER

- `MediaControlIntent.ACTION_GET_STATUS`
- `MediaControlIntent.ACTION_SEEK`

These are placed on an independent `IntentFilter` because, technically, we can support these actions on any type of media. In the case of this specific example, the only media we support is streaming video. But, we could configure other `IntentFilter` objects, like `ifPlay` was, stating yet other media types that we handle.

To fully comply with the `RemotePlaybackClient` API, we must advertise that we handle all of those actions... even if our intended client will not use all of them.

We could also:

- Advertise that we support session management actions, like `MediaControlIntent.ACTION_START_SESSION`
- Advertise that we support the “enqueue” operation for stacking up media to be played (e.g., `MediaControlIntent.ACTION_ENQUEUE`) and manipulating that queue (e.g., `MediaControlIntent.ACTION_REMOVE`)
- Define a custom category for other actions that we support that are “out of band” with respect to the standard media routing actions

All of those are demonstrated in Google’s sample app.

Creating the Descriptors

Just because we have some static `IntentFilter` objects does not mean that anything will pay attention to them. We need to actually register them with the media routing framework, wrapped in a pair of “descriptor” objects.

`DemoRouteProvider` calls a private `handleDiscovery()` method from the constructor, where `handleDiscovery()` sets up the descriptors:

```
private void handleDiscovery() {
    MediaRouteDescriptor.Builder mrdBuilder=
        new MediaRouteDescriptor.Builder(DEMO_ROUTE_ID, "Demo Route");

    mrdBuilder.setDescription("The description of a demo route")
        .addControlFilter(ifPlay)
        .addControlFilter(ifControl)
        .setPlaybackStream(AudioManager.STREAM_MUSIC)
        .setPlaybackType(MediaRouter.RouteInfo.PLAYBACK_TYPE_REMOTE)
        .setVolumeHandling(MediaRouter.RouteInfo.PLAYBACK_VOLUME_FIXED);

    MediaRouteProviderDescriptor.Builder mrpdBuilder=
        new MediaRouteProviderDescriptor.Builder();

    mrpdBuilder.addRoute(mrdBuilder.build());
}
```

CREATING A MEDIAROUTEPROVIDER

```
setDescriptor(mrpdBuilder.build());  
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProvider.java](#))

In the end, we need to provide a `MediaRouteProviderDescriptor` to the `MediaRouteProvider` by means of a `setDescriptor()` method. `MediaRouteProviderDescriptor` is, in effect, metadata about the `MediaRouteProvider` itself. At the present time, the only thing this holds is a set of `MediaRouteDescriptor` objects, one for each media route that the `MediaRouteProvider` claims to support.

A `MediaRouteProvider` is made up of several pieces of information, including:

- The `IntentFilter(s)` representing the supported actions and, where relevant, MIME types and schemes
- A locally-unique ID of the route, to distinguish it from any other one that we might configure
- A name and description, which the user will see when they try to connect to this route (e.g., via a `MediaRouteActionProvider`)
- What audio stream is being used for the playback, from the standpoint of volume management, audio ducking, and the like
- Whether the playback is occurring locally on the device to some peripheral (e.g., speaker) or if the playback is occurring remotely on a player device (e.g., Chromecast)
- Whether playback volume is controlled here on the client device or on the player device
- Etc.

These are all configured on a `MediaRouteProvider` by creating a `MediaRouteProvider.Builder` and supplying the values either in the `Builder` constructor or via fluent setter methods. In the particular case of our simple demo provider, we:

- Use various strings for the ID, name, and description
- Use the two `IntentFilter` objects defined earlier to indicate what actions we can perform
- Indicate that the playback stream is `STREAM_MUSIC`, that the playback type is `PLAYBACK_TYPE_REMOTE`, and that the volume handling is `PLAYBACK_VOLUME_FIXED` (i.e., volume should be managed on the TV or whatever the media is being played upon)

CREATING A MEDIAROUTEPROVIDER

It is very likely that you will elect to have several `MediaRouteDescriptor` objects for different client application scenarios. Google's sample app uses a total of four `MediaRouteDescriptor` objects:

- One set up largely like the one in this sample
- One set up with `PLAYBACK_VOLUME_VARIABLE` (so volume is controllable by a client app)
- One set up with variable volume plus queuing actions
- One set up with variable volume plus queuing and session management actions

Receiving the Actions

Now, we have told the media routing framework what actions we support. Some app will then try to use `RemotePlaybackClient` and ask us to perform those actions. Hence, we need to find out when this happens, so we can do the actual work of having the playback device actually play back the media, pause the media, etc.

To do this, we need to create a custom subclass of `MediaRouteProvider.RouteController`. This contains a series of callback methods which we can override to find out when various events occur.

There are four such callback methods that the `DemoRouteController` subclass of `MediaRouteProvider.RouteController` implements:

- `onSelect()`, which will be called when a client app has selected our `MediaRouteProvider` to handle some media on behalf of that client app
- `onUnselect()` and `onRelease()`, which will be called when the client app disconnects from our `MediaRouteProvider`
- `onControlRequest()`, which will be called when some specific action that we advertised is requested, such as playing back a piece of media

The `DemoRouteController` just logs a message to LogCat for the first three callbacks:

```
@Override
public void onRelease() {
    Log.d(getClass().getSimpleName(), "released");
}

@Override
public void onSelect() {
    Log.d(getClass().getSimpleName(), "selected");
}
```

CREATING A MEDIAROUTEPROVIDER

```
@Override
public void onUnselect() {
    Log.d(getClass().getSimpleName(), "unselected");
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

The `onControlRequest()` method is a bit more complex, as *all* control requests route through here: play, pause, resume, stop, etc. `onControlRequest()` is passed the Intent identifying the particular action that should be performed, and we can examine the Intent action string to determine what needs to be done. In this case, `onControlRequest()` delegates the real work to action-specific methods like `onPlayRequest()`:

```
@Override
public boolean onControlRequest(Intent i, ControlRequestCallback cb) {
    if (i.hasCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)) {
        if (MediaControlIntent.ACTION_PLAY.equals(i.getAction())) {
            return(onPlayRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_PAUSE.equals(i.getAction())) {
            return(onPauseRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_RESUME.equals(i.getAction())) {
            return(onResumeRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_STOP.equals(i.getAction())) {
            return(onStopRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_GET_STATUS.equals(i.getAction())) {
            return(onGetStatusRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_SEEK.equals(i.getAction())) {
            return(onSeekRequest(i, cb));
        }
    }

    Log.w(getClass().getSimpleName(), "unexpected control request"
        + i.toString());

    return(false);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

`onControlRequest()` should return true if we agree to perform the action and will use the supplied `ControlRequestCallback` object to asynchronously deliver our results. If `onControlRequest()` returns false, that means that we are rejecting the action for some reason, such as it being one that is unrecognized. In `DemoRouteController`, that will occur if the category or the action on the Intent is not one of the supported options.

Note that if you opted into variable volume, there are `onSetVolume()` and `onUpdateVolume()` callback methods that will give you access to those events.

Handling the Actions

For those actions that you advertise and receive in `onControlRequest()`, you need to actually do the work for those actions. The details of this will vary widely depending upon your playback device and playback app that you are supporting. For example, you might establish a WiFi Direct connection in `onSelect()`, then use that connection in handling play, pause, etc. actions.

However, a few aspects of handling these actions will be in common across all implementations:

- `onControlRequest()` must return `true` or `false` as was described in the preceding section
- You must call `onResult()` or `onError()` on the `ControlRequestCallback` object to indicate if the action succeeded or failed
- You must supply an appropriate `Bundle` to those methods, particularly to `onResult()`, containing the right set of values to provide more details about the results of the action

The details of what that `Bundle` must contain are documented on the `MediaControlIntent` class, on the definition of each action string (e.g., `ACTION_PLAY`).

With that in mind, let's look at the six actions supported by `DemoRouteController`.

Play

The `Bundle` passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_PLAY`, needs three values:

- `EXTRA_SESSION_ID`: if you are implementing session management, this will be the unique session ID (`String`) for the session you are playing the media in. If you are not implementing session management, then what you are supposed to return is undocumented and (hopefully) unused
- `EXTRA_ITEM_ID`: if you are implementing “enqueue” support, this will be the item ID (`String`) for managing this item in the queue of available items. If you are not supporting a playback queue, then what you are supposed to return is undocumented and (hopefully) unused

CREATING A MEDIAROUTEPROVIDER

- `EXTRA_ITEM_STATUS`: this should point to a `Bundle` created from a `MediaItemStatus` object where you indicate what the status is of the playback of this item

You create a `MediaItemStatus` object via a `MediaItemStatus.Builder`, where you can pass into the constructor a value indicating the overall status (e.g., `MediaItemStatus.PLAYBACK_STATE_PLAYING`), plus use fluent setter methods to define additional characteristics of the status, such as the current seek position.

The `DemoRouteController` logic for `ACTION_PLAY`, in the `onPlayRequest()` method, logs the event to `LogCat` and crafts a valid-but-meaningless result `Bundle` for use with `onResult()`:

```
private boolean onPlayRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "play: "
        + i.getData().toString());

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putString(MediaControlIntent.EXTRA_SESSION_ID, DemoRouteProvider.DEMO_SESSION_ID);
    b.putString(MediaControlIntent.EXTRA_ITEM_ID, DemoRouteProvider.DEMO_ITEM_ID);
    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
        statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

Pause, Resume, and Stop

The `Bundle` passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_PAUSE`, `ACTION_RESUME`, or `ACTION_STOP`, does not need any particular values at the present time. Hence, the `DemoRouteController` methods for those actions just log the event to `LogCat` and pass an empty `Bundle` to `onResult()`:

```
private boolean onPauseRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "pause");

    cb.onResult(new Bundle());

    return(true);
}
```

CREATING A MEDIAROUTEPROVIDER

```
private boolean onResumeRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "resume");

    cb.onResult(new Bundle());

    return(true);
}

private boolean onStopRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "stop");

    cb.onResult(new Bundle());

    return(true);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

Get Status and Seek

The `Bundle` passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_GET_STATUS` or `ACTION_SEEK`, must contain the same sort of `MediaItemStatus`-built nested `Bundle` representing the current status. For `ACTION_GET_STATUS`, the only “work” to be done is to pass back the status; for `ACTION_SEEK`, you should move the playback position to the location indicated by an extra on the `Intent`, then return the revised status.

In the case of `DemoRouteController`, both just log a message to `LogCat` and return a fairly pointless status:

```
private boolean onGetStatusRequest(Intent i,
    ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "get-status");

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
        statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}

private boolean onSeekRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "seek");

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);
```

CREATING A MEDIAROUTEPROVIDER

```
Bundle b=new Bundle();

b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
            statusBuilder.build().asBundle());

cb.onResult(b);

return(true);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

Publishing the Controller

While we have defined our `RouteController`, we still need to teach our `MediaRouteProvider` about it. That is through overriding the `onCreateRouteController()` method and returning an instance of `RouteController`:

```
@Override
public RouteController onCreateRouteController(String routeId) {
    return(new DemoRouteController());
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProvider.java](#))

`onCreateRouteController()` is passed the route ID `String` used in the `MediaRouteDescriptor`. You can either use that to instantiate a different `RouteProvider`, pass the `String` into a common `RouteProvider` so it knows what to do, or ignore it entirely if you have only one published route. In the case of `DemoRouteProvider`, we ignore the route ID and always return a `DemoRouteController`.

Handling Discovery Requests

`DemoRouteProvider` is always available, largely because it does not do much of anything.

In the real world, your `MediaRouteProvider` may not always be relevant. For example, the TV you are set up to talk to may be powered down. Or, the user may not be at home where the TV is, so the client device and the TV are not on the same network.

Rather than constantly polling the outside world to see if a route is possible, we only do this when a client app requests “route discovery”, such as by providing the `MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY` flag on an `addCallback()` call to a

CREATING A MEDIAROUTEPROVIDER

MediaRouter. That in turn triggers an `onDiscoveryRequestChanged()` call on our `MediaRouteProvider`.

There, and in our constructor-triggered setup, we should do work to determine if a route is currently possible and set up our descriptors. This work should be done in a background thread if it involves network I/O.

Note that `onDiscoveryRequestChanged()` is passed a `MediaRouteDiscoveryRequest` object, describing what the consuming app is looking for. If the request is irrelevant for your provider (e.g., the app wants a local audio route, and you provide remote playback routes), simply ignore it.

The `onDiscoveryRequestChanged()` implementation in `DemoRouteProvider` just calls the same `handleDiscovery()` method that the constructor does.

Consuming the MediaRouteProvider

Having a `MediaRouteProvider` is nice, but it is useless if apps are not going to know about it.

You have two main options for consuming the `MediaRouteProvider`: use it only within your own app, or publish it to all apps on the device.

Private Provider

Using a `MediaRouteProvider` for your own app is very simple. Just add a single call to `addProvider()` on your `MediaRouter`, supplying an instance of your `MediaRouteProvider`.

Since our sample project is a fork of the original `RemotePlaybackClient` sample, we still have a `PlaybackFragment` that sets up the `MediaRouter` and `MediaRouteActionProvider`. In `onAttach()` of that `PlaybackFragment`, we can configure our `MediaRouterProvider` after obtaining the `MediaRouter` instance:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    router=MediaRouter.getInstance(host);
    provider=new DemoRouteProvider(getActivity());
    router.addProvider(provider);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/PlaybackFragment.java](#))

CREATING A MEDIAROUTEPROVIDER

At this point, our DemoRouteProvider will be available as an option for the user, along with any other eligible media routes:

Figure 717: MediaRouteProvider Demo, on a Nexus 4, Showing Available Routes

Choosing the DemoRouteProvider (“Demo Route” in the screenshot) will allow you to use it just like you do a Chromecast... if you do not mind the fact that nothing shows up on your television:

CREATING A MEDIAROUTEPROVIDER

Figure 718: *MediaRouteProvider Demo, on a Nexus 4, After Several Commands*

As it turns out, the `DemoRouteProvider` works better than Google's own `MediaRouteProvider` for the Chromecast, insofar as more of the callbacks work. Specifically, we actually receive callbacks for pause, resume, and stop events, as opposed to having to just assume that those events completed.

Also, we remove the demo provider in `onDetach()`:

```
@Override
public void onDetach() {
    router.removeProvider(provider);

    super.onDetach();
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/PlaybackFragment.java](#))

Among other things, this allows us to correctly handle configuration changes — if we fail to call `removeProvider()` and blindly add another provider in `onAttach()`, we wind up with multiple providers, because our `MediaRouter` is a framework-provided singleton and is not re-created with the new fragment.

Public Provider

If you want your `MediaRouteProvider` to be used by other apps, you will need to create one more Java class: a subclass of `MediaRouteProviderService`. This requires only one method, `onCreateMediaRouteProvider()`, where you return an instance of your `MediaRouteProvider`:

```
package com.commonware.android.mrp;

import android.support.v7.media.MediaRouteProvider;
import android.support.v7.media.MediaRouteProviderService;

public class DemoRouteProviderService extends MediaRouteProviderService {
    @Override
    public MediaRouteProvider onCreateMediaRouteProvider() {
        return(new DemoRouteProvider(this));
    }
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonware/android/mrp/DemoRouteProviderService.java](#))

This also needs to be added to your manifest, like any other `Service`. Give it an `<intent-filter>` looking for the `android.media.MediaRouteProviderService` action, so the media routing framework knows that it can obtain a `MediaRouteProvider` from it:

```
<service
    android:name="DemoRouteProviderService"
    tools:ignore="ExportedService">
    <intent-filter>
        <action android:name="android.media.MediaRouteProviderService"/>
    </intent-filter>
</service>
```

However, do *not* do both `addProvider()` *and* have the `<service>` element. If you use the `<service>` element, your app can use the `MediaRouteProvider`, just as can any other app on the device. Hence, in the published source code for this sample, the `<service>` element is commented out — you will need to uncomment it, and comment out the `addProvider()` call, to test the `DemoRouteProvider` with other apps.

Implementing This “For Realz”

Of course, `DemoRouteProvider` is just a demo and does not actually play any media anywhere. It is here to give you the basic steps for responding to `RemotePlaybackClient` requests. For a production `MediaRouteProvider`, in addition to the usual tightening-up of the code (e.g., better exception handling), you will

need to work on other areas as well, ones that are beyond the scope of the sample app.

Communicating with the Playback Device

Of course, the big one is passing the actions over to the playback device, so you actually *do* play back media.

If you are the developer of the playback device and its protocols (e.g., it is an Android device, and you are writing the playback app for it), then you can choose how you wish to handle the communications. You can work with low-level socket protocols directly, or you can leverage libraries like [AllJoyn](#) or [ZeroMQ](#).

If the playback device “is what it is”, and you cannot change it, then you will need to determine what protocols it offers and how best to map the `MediaControlIntent` actions to that protocol.

Also note that `onControlRequest()` is designed for asynchronous operation. The sample app just invoked the `ControlRequestCallback` during the `onControlRequest()` processing. Usually, though, your communications with the playback device will not be as fast as a call to `Log.d()`. You should arrange to do those communications in a background thread, perhaps via a single-thread thread pool as an `ExecutorService`. Simply pass the `ControlRequestCallback` to that thread along with the rest of the action’s data (e.g., the URL of the media to load), and the thread can call `onResult()` or `onError()` as needed.

Handling Other Actions/Protocols

As was noted in the description of the sample app, that app eschews:

- volume control
- session management
- queue management

Any of those may be of interest to your users, and so you may need to consider offering them at some point. Also note that some potential client apps might need those capabilities and therefore will not see or use your published media routes without them.

Custom Actions

When setting up the `MediaRouteProvider`, we create one or more `MediaRouteDescriptor` objects wrapped around one or more `IntentFilter` objects. Those `IntentFilter` objects indicate what actions we support. The `DemoRouteProvider` uses standard actions (e.g., `ACTION_PLAY`) in a standard category (`CATEGORY_REMOTE_PLAYBACK`).

However, you are not limited to that.

You are welcome to also support custom actions in a custom category, to represent other things that your particular `MediaRouteProvider` offers. You can then use those actions from your own client app, or document them for use by third-party apps.

The client app can use `supportsControlRequest()` and `sendControlRequest()` to determine whether a particular media route supports a particular `Intent` that represents an action to be performed by that route's `MediaRouteProvider`. This way, a client app can work both with your custom `MediaRouteProvider` (taking advantage of your custom actions) and with regular providers that lack such support, assuming that the client can gracefully degrade its functionality.

Google's sample app defines a custom `ACTION_GET_STATISTICS` action that their sample client requests where available and their sample provider implements.

Screenshots and Screen Recordings

Android 5.0 debuted the ability for Android apps to take screenshots of whatever is in the foreground. It further allows apps to record full-resolution video of whatever is in the foreground, for screencasts, product demo videos, and the like. For whatever reason, this is called “media projection”, and is based around classes like `MediaProjectionManager`.

In this chapter, we will explore how to use the media projection APIs to record screenshots and screencast-style videos.

Prerequisites

Understanding this chapter requires that you have read the core chapters, plus the chapter on [embedding a Web server](#) in your app for debug and diagnostic purposes.

Having read the chapter on [using the camera APIs](#) would not be a bad idea, particularly for video recording, though it is not essential.

Requesting Screenshots

Here, “screenshot” (or “screen capture”) refers to generating an ordinary image file (e.g., PNG) of the contents of the screen. Most likely, you have created such screenshots yourself for a desktop OS (e.g., using the `PrtSc` key on Windows or Linux). Android’s development tools allow you to take screenshots of devices and emulators, and there is a cumbersome way for users to take screenshots using the volume and power keys.

The media projection APIs allow you to take a screenshot of whatever is in the foreground... which does not necessarily have to be your own app. Indeed, you can take screenshots of any app, plus of system-supplied UI, such as the pull-down notification shade.

Not surprisingly, this has privacy and security issues. As such, in order to be able to take screenshots, the user must agree to allow it. In particular, instead of a durable permission that the user might grant once and forget about, the user has to agree to allow your app to take screenshots every time you want to do so.

Introducing `andprojector`

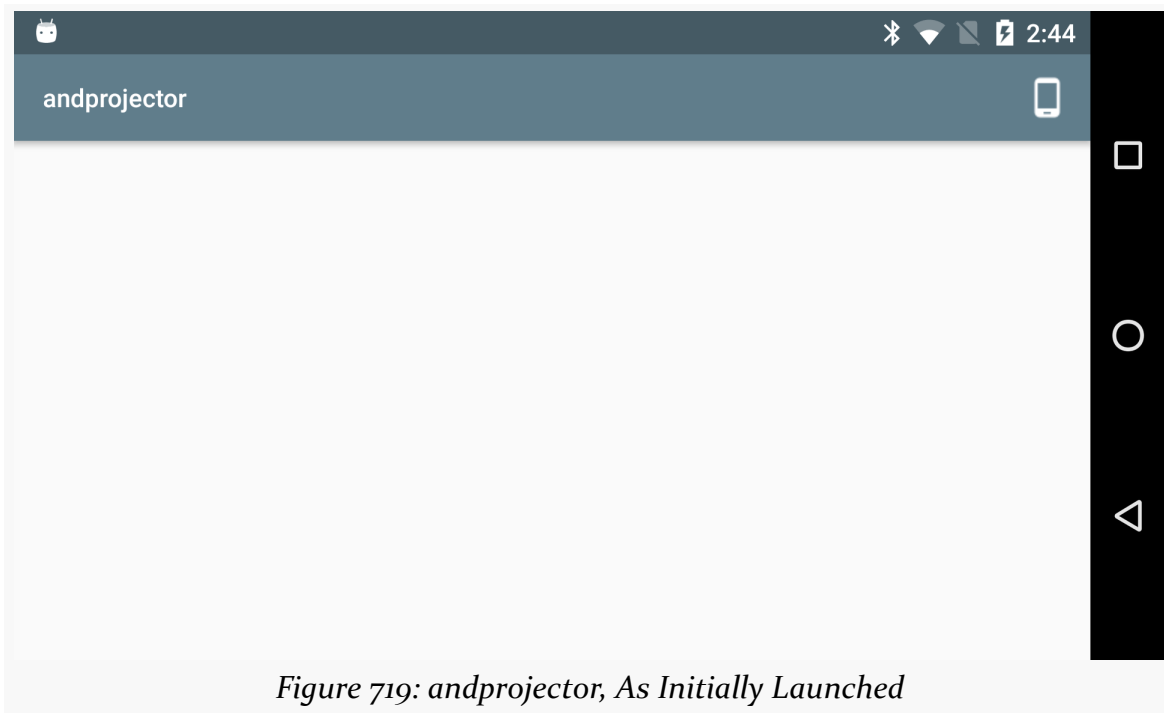

In 2009, the author of this book wrote a utility called DroidEx. This tool ran on a desktop or notebook and served as a “software projector” for an Android device, as opposed to the hardware projectors (e.g., ELMO) usually needed to show an Android screen to a large audience. Under the covers, DroidEx used the same protocol that Android Studio and DDMS use for screenshots, requesting screenshots as fast as possible, drawing them to a Swing `JFrame`. Later, Jens Riboe took DroidEx a bit further, adding more of a Swing control UI, in the form of [Droid@Screen](#).

The [MediaProjection/andprojector](#) sample project has the same objective as did DroidEx: be able to show the contents of an Android screen to an audience. Nowadays, you might be able to do that straight from hardware, using things like an MHL->HDMI adapter. However, sometimes that option is not available (e.g., the projector you are using for your notebook is limited to VGA). `andprojector` differs from DroidEx in a few key ways:

- It is an Android app, not a program that you run on your notebook, and so it can be used without a notebook that has the Android SDK on it (which DroidEx required)
- It “projects” the screen using an embedded Web server to push PNG files to a Web browser, as opposed to DroidEx’s use of a Swing `JFrame` to display the projection in a desktop OS window
- It uses the media projection APIs, which is the point of this chapter

On the device, the UI resembles that of the Web server apps profiled [elsewhere in this book](#). When launched, the screen is mostly empty, except for a phone action bar item:

SCREENSHOTS AND SCREEN RECORDINGS

When you tap the action bar item, a system-supplied dialog appears, asking for permission to take screenshots:

SCREENSHOTS AND SCREEN RECORDINGS

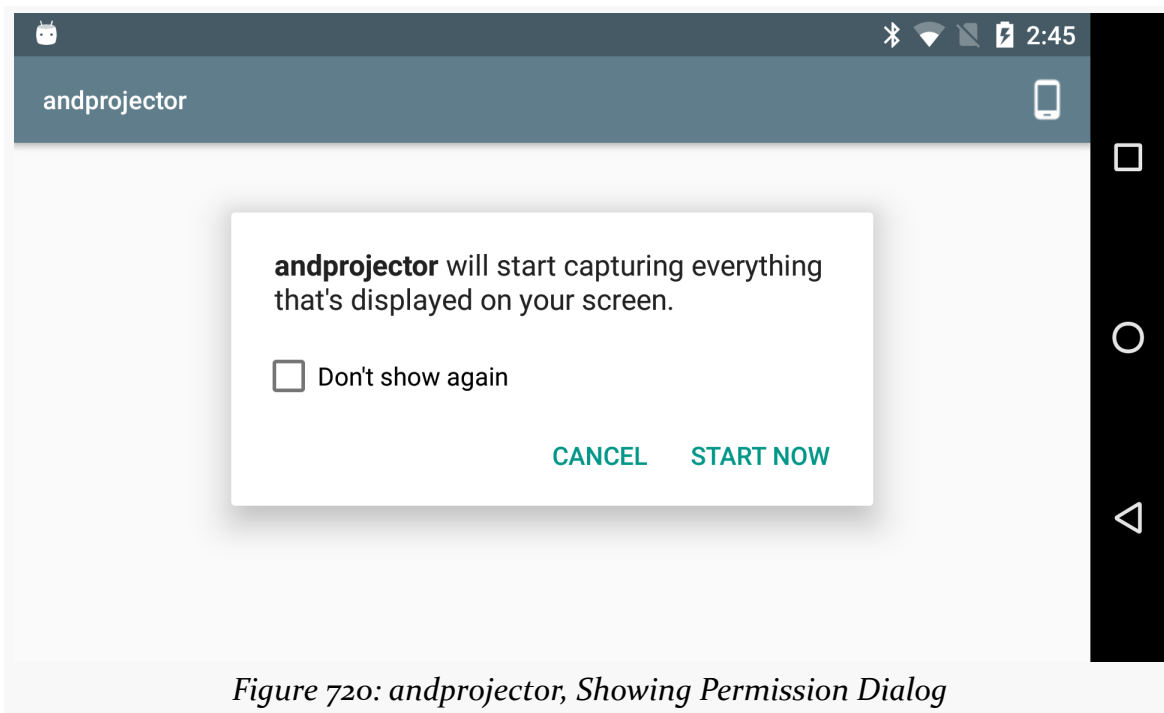

Figure 720: andprojector, Showing Permission Dialog

If you grant permission, you will see URLs that can be used to view what is on the device screen:

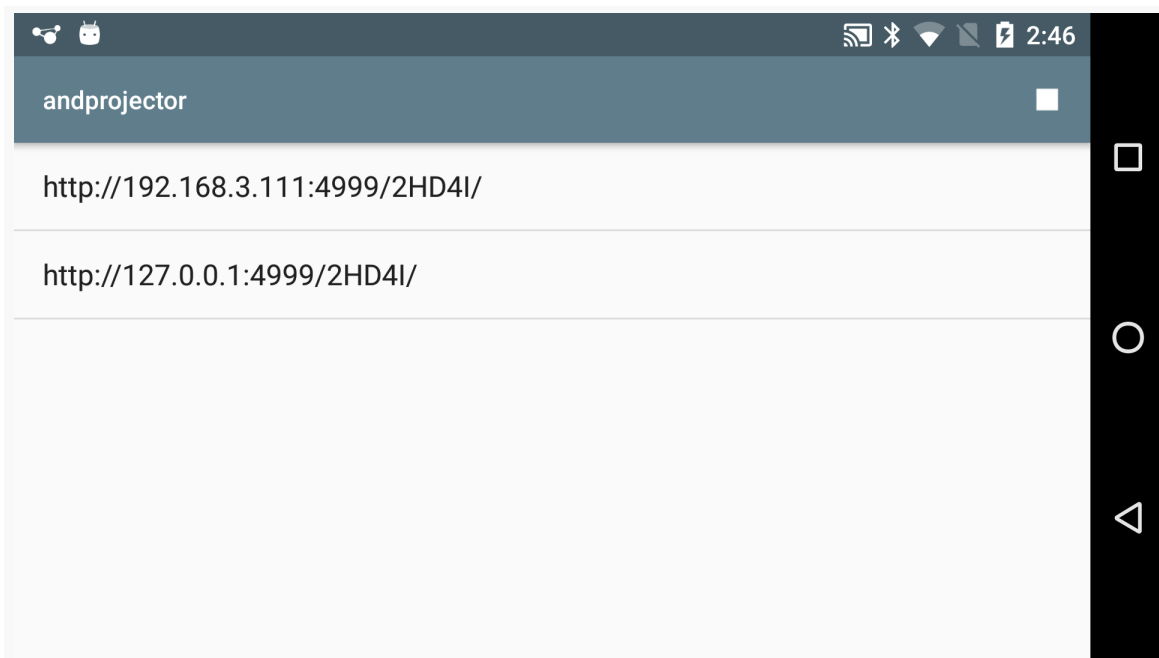

Figure 721: andprojector, Showing URLs

Entering one of those (including the trailing slash!) in a Web browser on some other machine on the same WiFi network will cause it to start showing the contents of the device screen. This can be done in either orientation, though it tends to work better in landscape.

Clicking the “stop” action bar item — which replaced the device action bar item when permission was granted — will stop the presentation and return the app to its original state.

With that in mind, let’s see how andprojector pulls off this bit of magic.

Asking for Permission

In the MainActivity that houses our UI, in onCreate(), we get our hands on a MediaProjectionManager system service, in addition to fussing with Material-style coloring for the status bar:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    Window window=getWindow();
```

SCREENSHOTS AND SCREEN RECORDINGS

```
window.addFlags(WindowManager.LayoutParams.FLAG_DRAWS_SYSTEM_BAR_BACKGROUNDS);
window.clearFlags(WindowManager.LayoutParams.FLAG_TRANSLUCENT_STATUS);
window.setStatusBarColor(
    getResources().getColor(R.color.primary_dark));

mgr=(MediaProjectionManager)getSystemService(MEDIA_PROJECTION_SERVICE);
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/MainActivity.java](#))

MediaProjectionManager, at the time of this writing (October 2015), has a grand total of *two* methods. When the user taps on the device action bar item, we invoke fully 50% of the MediaProjectionManager, calling createScreenCaptureIntent(). This will return an Intent, designed to be used with startActivityForResult(), that brings up the screenshot permission dialog:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.start) {
        startActivityForResult(mgr.createScreenCaptureIntent(),
            REQUEST_SCREENSHOT);
    }
    else {
        stopService(new Intent(this, ProjectorService.class));
    }

    return super.onOptionsItemSelected(item);
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/MainActivity.java](#))

In onActivityResult(), if our request for permission was granted, we pass the details along via Intent extras to a ProjectorService that we start using startService():

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (requestCode==REQUEST_SCREENSHOT) {
        if (resultCode==RESULT_OK) {
            Intent i=
                new Intent(this, ProjectorService.class)
                    .putExtra(ProjectorService.EXTRA_RESULT_CODE,
                        resultCode)
                    .putExtra(ProjectorService.EXTRA_RESULT_INTENT,
                        data);

            startService(i);
        }
    }
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/MainActivity.java](#))

SCREENSHOTS AND SCREEN RECORDINGS

The rest of the MainActivity is mostly doing the same sort of work as was seen in the sample apps from [the chapter on embedding a Web server](#), including populating the ListView with the URLs for our projection.

Creating the MediaProjection

ProjectorService extends WebServerService, our reusable embedded Web server. However, most of its business logic — along with code extracted into a separate ImageTransmogriifier — involves fetching screenshots using the media projection APIs, generating PNGs for them, and pushing them over to the Web browser.

In onCreate() of ProejctorService, we:

- get our hands on a MediaProjectionManager and a WindowManager system service
- set up a HandlerThread and create an associated Handler for it, as the media projection process wants a Handler

```
@Override
public void onCreate() {
    super.onCreate();

    mgr=(MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);
    wmgr=(WindowManager) getSystemService(WINDOW_SERVICE);

    handlerThread.start();
    handler=new Handler(handlerThread.getLooper());
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

That HandlerThread is created in an initializer, since it does not directly depend on a Context:

```
final private HandlerThread handlerThread=new HandlerThread(getClass().getSimpleName(),
    android.os.Process.THREAD_PRIORITY_BACKGROUND);
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

In onStartCommand(), we then use the remaining 50% of the MediaProjectionService API to get a MediaProjection, using the values that were passed to onActivityResult() from our permission request which, in turn, were passed to ProjectorService via Intent extras:

```
projection=
    mgr.getMediaProjection(i.getIntExtra(EXTRA_RESULT_CODE, -1),
        (Intent)i.getParcelableExtra(EXTRA_RESULT_INTENT));
```

SCREENSHOTS AND SCREEN RECORDINGS

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

We then create an instance of `ImageTransmogriifier`, passing in the `ProjectorService` itself as a constructor parameter:

```
it=new ImageTransmogriifier(this);
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

`ImageTransmogriifier`, in its constructor, sets about determining the screen size (using `WindowManager` and `getDefaultDisplay()`). Since high-resolution displays will wind up with *very* large bitmaps, and therefore slow down the data transfer, we scale the width and height until such time as each screenshot will contain no more than 512K pixels.

```
public class ImageTransmogriifier implements ImageReader.OnImageAvailableListener {
    private final int width;
    private final int height;
    private final ImageReader imageReader;
    private final ProjectorService svc;
    private Bitmap latestBitmap=null;

    ImageTransmogriifier(ProjectorService svc) {
        this.svc=svc;

        Display display=svc.getWindowManager().getDefaultDisplay();
        Point size=new Point();

        display.getSize(size);

        int width=size.x;
        int height=size.y;

        while (width*height > (2<<19)) {
            width=width>>1;
            height=height>>1;
        }

        this.width=width;
        this.height=height;

        imageReader=ImageReader.newInstance(width, height,
            PixelFormat.RGBA_8888, 2);
        imageReader.setOnImageAvailableListener(this, svc.getHandler());
    }
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ImageTransmogriifier.java](#))

Finally, we create a new `ImageReader`, which boils down to a class that manages a bitmap `Surface` that can be written to, using our specified width, height, and bit depth. In particular, we are saying that there are two possible outstanding bitmaps at a time, courtesy of the 2 final parameter, and that we should be notified when a new image is ready, by registering the `ImageTransmogriifier` as the listener. The

SCREENSHOTS AND SCREEN RECORDINGS

Handler is used so that we are informed about image availability on our designated background HandlerThread.

Back over in ProjectorService, we then use the MediaProjection to create a VirtualDisplay, tied to the ImageTransmogriifier and its ImageReader:

```
vdisplay=projection.createVirtualDisplay("andprojector",
    it.getWidth(), it.getHeight(),
    getResources().getDisplayMetrics().densityDpi,
    VIRT_DISPLAY_FLAGS, it.getSurface(), null, handler);
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

We need to provide:

- a name for this virtual display, primarily for logging purposes
- the size of the virtual display, in terms of width and height, where we use the scaled width and height computed by the ImageTransmogriifier
- the density of the virtual display, which we set to match the density of the actual device screen
- a set of flags (VIRT_DISPLAY_FLAGS), where the magic values that seem to work are VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY and VIRTUAL_DISPLAY_FLAG_PUBLIC:

```
static final int VIRT_DISPLAY_FLAGS=
    DisplayManager.VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY |
    DisplayManager.VIRTUAL_DISPLAY_FLAG_PUBLIC;
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

- a Surface representing the virtual display, in this case retrieved from the ImageReader inside the ImageTransmogriifier

```
Surface getSurface() {
    return(imageReader.getSurface());
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ImageTransmogriifier.java](#))

- an optional VirtualDisplay.Callback to be notified about events in the lifecycle of the VirtualDisplay (unused here, so we pass null)
- a Handler from a HandlerThread, to be used for that callback (presumably unused here, but since we have the right Handler anyway, we use it)

We also need to know about events surrounding the MediaProjection itself, so we create and register a MediaProjection.Callback, as part of the full onStartCommand() implementation:

SCREENSHOTS AND SCREEN RECORDINGS

```
@Override
public int onStartCommand(Intent i, int flags, int startId) {
    projection=
        mgr.getMediaProjection(i.getIntExtra(EXTRA_RESULT_CODE, -1),
            (Intent)i.getParcelableExtra(EXTRA_RESULT_INTENT));

    it=new ImageTransmogriifier(this);

    MediaProjection.Callback cb=new MediaProjection.Callback() {
        @Override
        public void onStop() {
            vdisplay.release();
        }
    };

    vdisplay=projection.createVirtualDisplay("andprojector",
        it.getWidth(), it.getHeight(),
        getResources().getDisplayMetrics().densityDpi,
        VIRT_DISPLAY_FLAGS, it.getSurface(), null, handler);
    projection.registerCallback(cb, handler);

    return(START_NOT_STICKY);
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

And, at this point, the device will start collecting screenshots for us.

Processing the Screenshots

Of course, it would be useful if we could actually receive those screenshots and do something with them.

We find out when a screenshot is available via the `ImageReader.Callback` we set up in `ImageTransmogriifier`, specifically its `onImageAvailable()` callback. Since `ImageTransmogriifier` itself is implementing the `ImageReader.Callback` interface, `ImageTransmogriifier` has the `onImageAvailable()` implementation:

```
@Override
public void onImageAvailable(ImageReader reader) {
    final Image image=imageReader.acquireLatestImage();

    if (image!=null) {
        Image.Plane[] planes=image.getPlanes();
        ByteBuffer buffer=planes[0].getBuffer();
        int pixelStride=planes[0].getPixelStride();
        int rowStride=planes[0].getRowStride();
        int rowPadding=rowStride - pixelStride * width;
        int bitmapWidth=width + rowPadding / pixelStride;

        if (latestBitmap == null ||
            latestBitmap.getWidth() != bitmapWidth ||
            latestBitmap.getHeight() != height) {
            if (latestBitmap != null) {
```

SCREENSHOTS AND SCREEN RECORDINGS

```
        latestBitmap.recycle();
    }

    latestBitmap=Bitmap.createBitmap(bitmapWidth,
        height, Bitmap.Config.ARGB_8888);
}

latestBitmap.copyPixelsFromBuffer(buffer);

if (image != null) {
    image.close();
}

ByteArrayOutputStream baos=new ByteArrayOutputStream();
Bitmap cropped=Bitmap.createBitmap(latestBitmap, 0, 0,
    width, height);

cropped.compress(Bitmap.CompressFormat.PNG, 100, baos);

byte[] newPng=baos.toByteArray();

svc.updateImage(newPng);
}
}
```

(from [MediaProjection/androidprojector/app/src/main/java/com/commonware/android/projector/ImageTransmogifier.java](https://github.com/Commonware/android-projector/blob/master/app/src/main/java/com/commonware/android/projector/ImageTransmogifier.java))

This is complex.

First, we ask the ImageReader for the latest image, via `acquireLatestImage()`. If, for some reason, there is no image, there is nothing for us to do, so we skip all the work.

Otherwise, we have to go through some gyrations to get the actual bitmap itself from Image object. The recipe for that probably makes sense to somebody, but that “somebody” is not the author of this book. Suffice it to say, the first six lines of the main if block in `onImageAvailable()` get access to the bytes of the bitmap (as a `ByteBuffer` named `buffer`) and determine the width of the bitmap that was handed to us (as an `int` named `bitmapWidth`).

Because `Bitmap` objects are large and therefore troublesome to allocate, we try to reuse one where possible. If we do not have a `Bitmap` (`latestBitmap`), or if the one we have is not the right size, we create a new `Bitmap` of the appropriate size. Otherwise, we use the `Bitmap` that we already have. Regardless of where the `Bitmap` came from, we use `copyPixelsFromBuffer()` to populate it from the `ByteBuffer` we got from the `Image.Plane` that we got from the `Image` that we got from the `ImageReader`.

You might think that this `Bitmap` would be the proper size. However, it is not. For inexplicable reasons, it will be a bit larger, with excess unused pixels on each row on

SCREENSHOTS AND SCREEN RECORDINGS

the end. This is why we need to use `Bitmap.createBitmap()` to create a cropped edition of the original `Bitmap`, for our actual desired width.

We then `compress()` the cropped `Bitmap` into a PNG file, get the byte array of pixel data from the compressed result, and hand that off to the `ProjectorService` via `updateImage()`.

`updateImage()`, in turn, holds onto this most-recent PNG file in an `AtomicReference` wrapped around the byte array:

```
private AtomicReference<byte[]> latestPng=new AtomicReference<byte[]>();
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

This way, when some Web server thread goes to serve up this PNG file, we do not have to worry about thread contention with the `HandlerThread` we are using for the screenshots themselves.

Then, we iterate over all connected browsers' `WebSocket` connections and send a unique URL to them, where the uniqueness (from `SystemClock.uptimeMillis()`) is designed as a “cache-busting” approach to ensure the browser always requests the image

```
void updateImage(byte[] newPng) {
    latestPng.set(newPng);

    for (WebSocket socket : getWebSockets()) {
        socket.send("screen/"+Long.toString(SystemClock.uptimeMillis()));
    }
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

Those `WebSockets` are enabled by `ProjectorService` calling `serveWebSockets()` on its `WebServerService` superclass, in the `configureRoutes()` callback:

```
@Override
protected boolean configureRoutes(AsyncHttpServer server) {
    serveWebSockets("/ss", null);

    server.get(getRootPath()+"/screen/.*",
        new ScreenshotRequestCallback());

    return(true);
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

SCREENSHOTS AND SCREEN RECORDINGS

The `ScreenshotRequestCallback` is an inner class of `ProjectorService`, one that serves the PNG file itself in response to a request:

```
private class ScreenshotRequestCallback
    implements HttpServerRequestCallback {
    @Override
    public void onRequest(AsyncHttpRequest request,
        AsyncHttpResponse response) {
        response.setContentType("image/png");

        byte[] png=latestPng.get();
        ByteArrayInputStream bais=new ByteArrayInputStream(png);

        response.sendStream(bais, png.length);
    }
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

The result is that, whenever a screenshot is ready, we create the PNG file and tell the browser “hey! we have an update!”

The HTML

The Web content that is served to the browser is reminiscent of the HTML and JavaScript used in [the section on implementing WebSockets](#). There, the messages being pushed to the browser were timestamps, shown in a list. Here, the messages being pushed to the browser are URLs to load a fresh screenshot.

Hence, the HTML just has an `` tag for that screenshot, with an id of `screen`, loading `screen/0` at the outset to bootstrap the display:

```
<html>
<head>
  <title>andprojector</title>
</head>
<body>

<script src="js/app.js"></script>
</body>
</html>
```

(from [MediaProjection/andprojector/app/src/main/assets/index.html](#))

The JavaScript registers for a WebSocket connection, then updates that `` with a fresh URL when such a URL is pushed over to the browser:

```
window.onload = function() {
  var screen=document.getElementById('screen');
```

SCREENSHOTS AND SCREEN RECORDINGS

```
var ws_url=location.href.replace('http://', 'ws://')+'ss';
var socket=new WebSocket(ws_url);

socket.onopen = function(event) {
    // console.log(event.currentTarget.url);
};

socket.onerror = function(error) {
    console.log('WebSocket error: ' + error);
};

socket.onmessage = function(event) {
    screen.src=event.data;
};
}
```

(from [MediaProjection/androidprojector/app/src/main/assets/js/app.js](#))

Of course, in principle, there could be much more to the Web UI, including some ability to stop all of this when it is no longer needed. Speaking of which...

Shutting Down

The user can stop the screenshot collection and broadcasting either via the action bar item or the action in the Notification that is raised in support of the foreground service. In either case, in `onDestroy()`, in addition to chaining to `WebServerService` to shut down the Web server, `ProjectorService` stops the `MediaProjection`:

```
@Override
public void onDestroy() {
    projection.stop();

    super.onDestroy();
}
```

(from [MediaProjection/androidprojector/app/src/main/java/com/commonsware/androidprojector/ProjectorService.java](#))

This should also trigger our `VirtualDisplay.Callback`, causing us to release the `VirtualDisplay`.

Dealing with Configuration Changes

However, there is one interesting wrinkle we have to take into account: what happens if the user rotates the screen? We need to update our `VirtualDisplay` and `ImageReader` to take into account the new screen height and width.

`ProjectorService` will be called with `onConfigurationChanged()` when any configuration change occurs. This could be due to a screen rotation or other triggers

SCREENSHOTS AND SCREEN RECORDINGS

(e.g., putting the device into a car dock). So, we need to see if the screen height or width changed — if not, we do not need to do anything. So, we create a new `ImageTransmogriifier` and compare its height and width to the current height and width:

```
@Override
public void onConfigurationChanged(Configuration newConfig) {
    super.onConfigurationChanged(newConfig);

    ImageTransmogriifier newIt=new ImageTransmogriifier(this);

    if (newIt.getWidth()!=it.getWidth() ||
        newIt.getHeight()!=it.getHeight()) {
        ImageTransmogriifier oldIt=it;

        it=newIt;
        vdisplay.resize(it.getWidth(), it.getHeight(),
            getResources().getDisplayMetrics().densityDpi);
        vdisplay.setSurface(it.getSurface());

        oldIt.close();
    }
}
```

(from [MediaProjection/andprojector/app/src/main/java/com/commonsware/andprojector/ProjectorService.java](#))

If a dimension has changed, we tell the `VirtualDisplay` to resize to the new height and width, attach a new `Surface` from the new `ImageReader`, and switch over to the new `ImageTransmogriifier`, closing the old one.

This solution is not perfect — there is a bit of a race condition if a screenshot is taken while the configuration change is going on – but for a non-production-grade app it will suffice.

Recording the Screen

Here, a “screencast” refers to a full-motion video of what goes on the screen. You can think of it as a series of screenshots all written to one video file (e.g., an MP4). Many apps on the Play Store have screencasts as part of their product profile, so you can see what the app looks like when it is run.

Android’s media projection APIs allow you to capture screencasts, using a mechanism similar to the one used to take screenshots. You have to ask permission from the user to be able to record the screen, and that permission will last for the duration of one screen recording. During that period of time, you can direct Android to make a duplicate copy of what goes on the screen to a video file. This winds up using the `MediaRecorder` API along with dedicated media projection APIs, which is a

bit awkward, since `MediaRecorder` is really aimed at using the device camera to record videos of the world outside the device.

Jake Wharton, with his open source [Telecine app](#), helped blaze the trail in how these APIs are supposed to work, since the documentation, as usual, is limited.

This chapter will examine a separate app, [MediaProjection/andcorder](#), that offers screen recording through the media projection APIs. In the end, `andcorder` does the same basic stuff as does `Telecine`, with fewer bells and whistles. Also, the control channel is different: `Telecine` uses a screen overlay, while `andcorder` uses a foreground `Notification` or the command line.

Requesting Media Projection... Without a GUI

The `andprojector` sample app profiled earlier in this chapter used the media projection APIs, just as `andcorder` does. Both have to do the same work at the outset: ask the user for permission to record the screen. In the case of `andprojector`, while we had a foreground `Notification` to stop the projection, starting the projection was done through the `andprojector` activity, via an action bar item. The `andcorder` app, on the other hand, will demonstrate a different approach to this... and highlight a regression introduced in Android 6.0.

`MainActivity` is designed to be an invisible activity, like a few others used elsewhere in this book. We want a launcher icon in the home screen to be able to initialize the app, but we do not need an activity's UI to control it.

So, we skip the `setContentView()` call, and in `onCreate()` just call `startActivityForResult()`, using the `Intents` supplied by `createScreenCaptureIntent()` from `MediaProjectionManager`:

```
package com.commonware.android.andcorder;

import android.app.Activity;
import android.content.Intent;
import android.media.projection.MediaProjectionManager;
import android.os.Bundle;

public class MainActivity extends Activity {
    private static final int REQUEST_SCREENCAST=59706;
    private MediaProjectionManager mgr;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        mgr=(MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);
```

SCREENSHOTS AND SCREEN RECORDINGS

```
startActivityForResult(mgr.createScreenCaptureIntent(),
    REQUEST_SCREENCAST);
}

@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (requestCode==REQUEST_SCREENCAST) {
        if (resultCode==RESULT_OK) {
            Intent i=
                new Intent(this, RecorderService.class)
                    .putExtra(RecorderService.EXTRA_RESULT_CODE, resultCode)
                    .putExtra(RecorderService.EXTRA_RESULT_INTENT, data);

            startService(i);
        }
    }

    finish();
}
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonware/android/andcorder/MainActivity.java](#))

In `onActivityResult()`, we just pass the data along to a `RecorderService`, which is responsible for starting and stopping the screen recording. Then, we `finish()` the activity, as it is no longer needed.

This looks simple enough. It even works well, on Android 5.0 and 5.1. On Android 6.0, though, we have some problems.

The activity is designed to be used with `Theme.NoDisplay`, as the other “invisible activity” book samples use. Most of those samples will work just fine on Android 6.0. In particular, a `Theme.NoDisplay` activity that does its work in `onCreate()` and then calls `finish()` should be just fine on Android 6.0.

But sometimes the work that needs to be done is a bit more involved than that. In particular, calling `startActivityForResult()`, with an eye towards calling `finish()` in `onActivityResult()`, will cause your app to crash with an `IllegalStateException` saying that your activity “did not call `finish()` prior to `onResume()` completing”. This, apparently, is a requirement of `Theme.NoDisplay` activities on Android 6.0+.

So, we have to things a bit differently, to accommodate this undocumented regression in behavior.

Rather than refer to `Theme.NoDisplay` directly in the manifest, we refer to a custom `Theme.Apptheme` resource instead:

SCREENSHOTS AND SCREEN RECORDINGS

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonware.android.andcorder"
  xmlns:android="http://schemas.android.com/apk/res/android">

  <application
    android:icon="@mipmap/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".MainActivity"
      android:theme="@style/AppTheme">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>

    <service
      android:name=".RecorderService"
      android:exported="true"/>

  </application>
</manifest>
```

(from [MediaProjection/andcorder/app/src/main/AndroidManifest.xml](#))

This custom theme inherits from `Theme.NoDisplay` by default, in `res/values/styles.xml`:

```
<resources>

  <style name="AppTheme" parent="android:Theme.NoDisplay">
  </style>

</resources>
```

(from [MediaProjection/andcorder/app/src/main/res/values/styles.xml](#))

But, on Android 6.0 and higher (API Level 23+), it inherits from `Theme.Translucent.NoTitleBar`

```
<resources>

  <style name="AppTheme" parent="android:Theme.Translucent.NoTitleBar">
  </style>

</resources>
```

(from [MediaProjection/andcorder/app/src/main/res/values-v23/styles.xml](#))

This gives the same basic visual result as using `Theme.NoDisplay`, but it behaves better on Android 6.0:

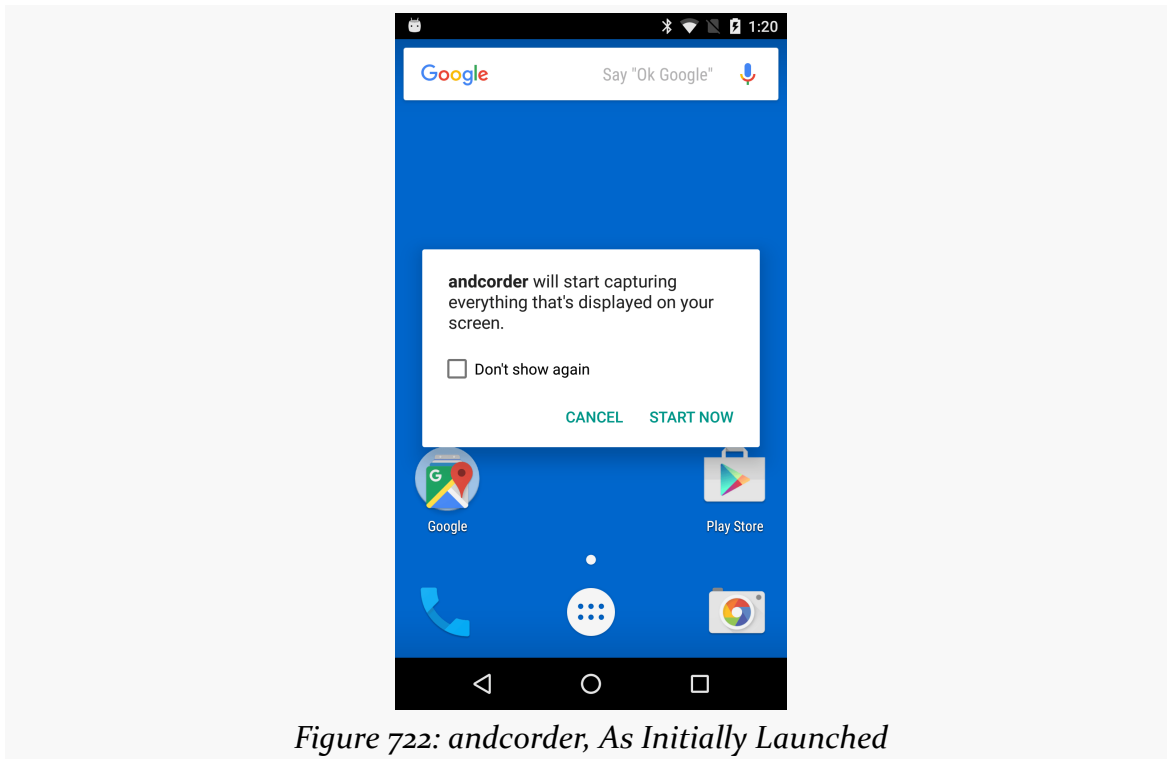

Figure 722: andcorder, As Initially Launched

Technically, this extra theme-related work is not necessary here, as the regression only occurs if your `targetSdkVersion` is set to 23 or higher. Right now, this project sets `targetSdkVersion` to 22. However, not only is the theme setup here to show you how to do it, but it also ensures that this app will survive having its `targetSdkVersion` increased in some future edition of this book, should that prove necessary.

Implementing a Control Channel... Without a GUI

We need to be able to tell andcorder to start and stop screen recording. If we are going to have an invisible activity, we need some other way to tell andcorder what it is supposed to do.

One approach used in andcorder is a `Notification`, tied to the foreground service that manages the actual screen recording.

We will use action strings, in the `Intent` used to start the `RecorderService`, to indicate what is to be done. Those action strings will be the application ID plus a segment at the end that is the specific operation we want:

SCREENSHOTS AND SCREEN RECORDINGS

```
static final String ACTION_RECORD=
    BuildConfig.APPLICATION_ID+".RECORD";
static final String ACTION_STOP=
    BuildConfig.APPLICATION_ID+".STOP";
static final String ACTION_SHUTDOWN=
    BuildConfig.APPLICATION_ID+".SHUTDOWN";
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

Here, we use `BuildConfig.APPLICATION_ID`, a faster, no-Context way to get our application ID, as part of building up these strings. We have three actions: to start recording (RECORD), to stop recording (STOP), and to shut down the RecorderService (SHUTDOWN). An Intent with *no* action string will be used on the initial launch of the service, from MainActivity.

`onStartCommand()` is where all of these commands, triggered by `startService()` calls, will come in:

```
@Override
public int onStartCommand(Intent i, int flags, int startId) {
    if (i.getAction()==null) {
        resultCode=i.getIntExtra(EXTRA_RESULT_CODE, 1337);
        resultData=i.getParcelableExtra(EXTRA_RESULT_INTENT);

        if (recordOnNextStart) {
            startRecorder();
        }

        foregroundify(!recordOnNextStart);
        recordOnNextStart=false;
    }
    else if (ACTION_RECORD.equals(i.getAction())) {
        if (resultData!=null) {
            foregroundify(false);
            startRecorder();
        }
        else {
            Intent ui=
                new Intent(this, MainActivity.class)
                    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK);

            startActivity(ui);
            recordOnNextStart=true;
        }
    }
    else if (ACTION_STOP.equals(i.getAction())) {
        foregroundify(true);
        stopRecorder();
    }
    else if (ACTION_SHUTDOWN.equals(i.getAction())) {
        stopSelf();
    }

    return(START_NOT_STICKY);
}
```

SCREENSHOTS AND SCREEN RECORDINGS

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

If we have no action string, this should be the command from MainActivity, so we grab the resultCode and resultData out of the Intent and stash them in simple fields on the service:

```
private int resultCode;
private Intent resultData;
private boolean recordOnNextStart=false;
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

We also:

- Call startRecorder() if recordOnNextStart is set to true
- Call foregroundify(), with a boolean that indicates whether we should give the user the option to begin recording (true) or to stop existing recording (false)
- Clear the recordOnNextStart flag

We will discuss more about that recordOnNextStart, its role, and why it exists, later in this chapter.

If, instead, a RECORD action string was on the Intent, then ideally we should begin recording the screen contents. The “ideally” part is because there will be scenarios in which the RECORD action is invoked before we actually have permission from the user to record the screen (more on this later).

So, if a RECORD action comes in, *and* we have permission from the user to record the screen (resultData is not null), we call startRecorder() to start recording, plus call foregroundify() to put up a Notification with an action for STOP. If, on the other hand, we do not presently have permission from the user (resultData is null), we start up MainActivity to get that permission, plus set recordOnNextStart to true.

The other two cases are simpler:

- If we get a STOP Intent, we call stopRecorder(), plus call foregroundify() to change the foreground service Notification to one that has an action for RECORD
- If we get a SHUTDOWN Intent, we call stopSelf() to go away entirely

SCREENSHOTS AND SCREEN RECORDINGS

`foregroundify()` is invoked for most of those cases, to put the service in the foreground (if it is not in the foreground already) and show a Notification with the appropriate mix of actions:

```
private void foregroundify(boolean showRecord) {
    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this);

    b.setAutoCancel(true)
      .setDefaults(Notification.DEFAULT_ALL);

    b.setTitle(getString(R.string.app_name))
      .setSmallIcon(R.mipmap.ic_launcher)
      .setTicker(getString(R.string.app_name));

    if (showRecord) {
        b.addAction(R.drawable.ic_videocam_white_24dp,
            getString(R.string.notify_record), buildPendingIntent(ACTION_RECORD));
    }
    else {
        b.addAction(R.drawable.ic_stop_white_24dp,
            getString(R.string.notify_stop), buildPendingIntent(ACTION_STOP));
    }

    b.addAction(R.drawable.ic_eject_white_24dp,
        getString(R.string.notify_shutdown), buildPendingIntent(ACTION_SHUTDOWN));

    if (isForeground) {
        NotificationManager mgr=(NotificationManager) getSystemService(NOTIFICATION_SERVICE);

        mgr.notify(NOTIFY_ID, b.build());
    }
    else {
        startForeground(NOTIFY_ID, b.build());
        isForeground=true;
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](https://github.com/CommonsWare/android-ndcorder/blob/master/src/main/java/com/commonsware/android/ndcorder/RecorderService.java))

In addition to generic `NotificationCompat.Builder` configuration, we:

- add an action to shut down the service, tied to the SHUTDOWN action string
- either add an action to RECORD or STOP the recording, based upon the boolean passed into `foregroundify()`
- either use `startForeground()` to move the service into the foreground and show the Notification or use `NotificationManager` to update the existing Notification (if we are already in the foreground)

The latter distinction may not be necessary. Calling `startForeground()` multiple times does not seem to have any harm, and it also updates the foreground

SCREENSHOTS AND SCREEN RECORDINGS

Notification. Using NotificationManager directly for the already-in-the-foreground scenario, though, may be superfluous.

The addAction() calls delegate to a buildPendingIntent() method, to create the PendingIntent to be triggered when the action is tapped:

```
private PendingIntent buildPendingIntent(String action) {
    Intent i=new Intent(this, getClass());

    i.setAction(action);

    return(PendingIntent.getService(this, 0, i, 0));
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](https://github.com/CommonsWare/android-andcorder/blob/master/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java))

This creates an explicit Intent, tied to RecorderService itself, but also adds the action string. This Intent will always resolve to our RecorderService; the action string is just part of the payload.

That foreground Notification provides the visual way of starting recording:

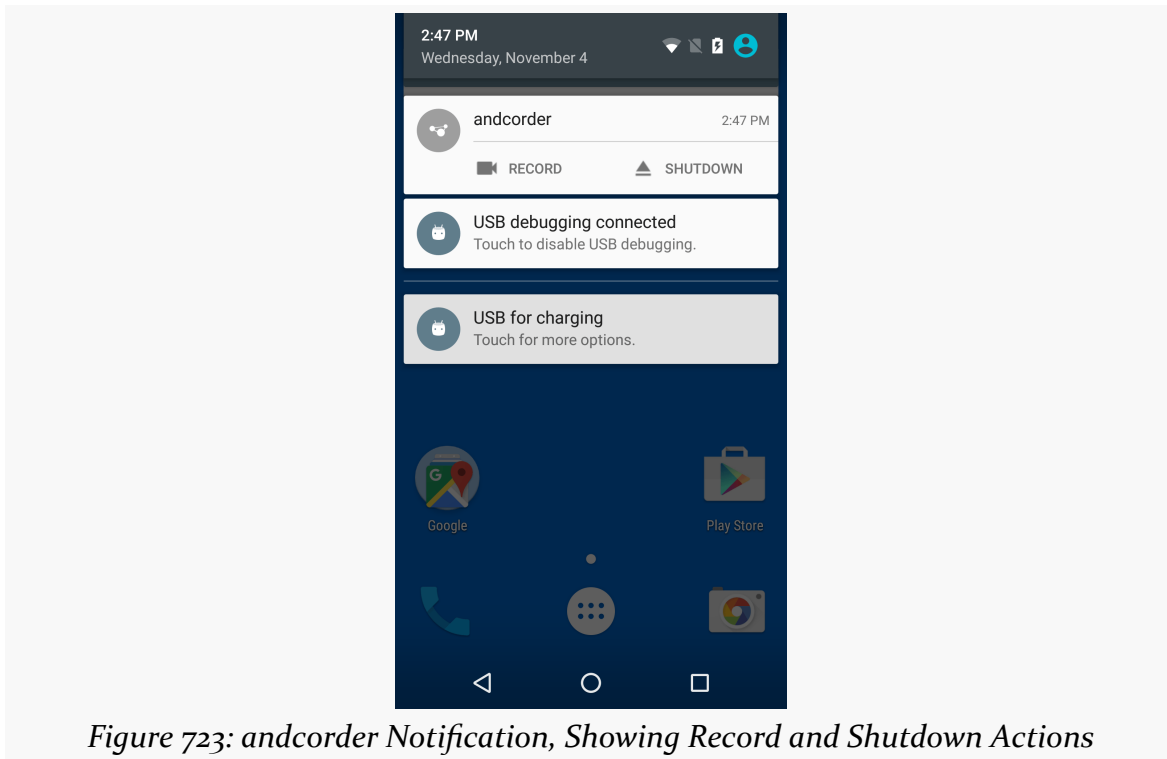

Figure 723: andcorder Notification, Showing Record and Shutdown Actions

...and stopping recording once started:

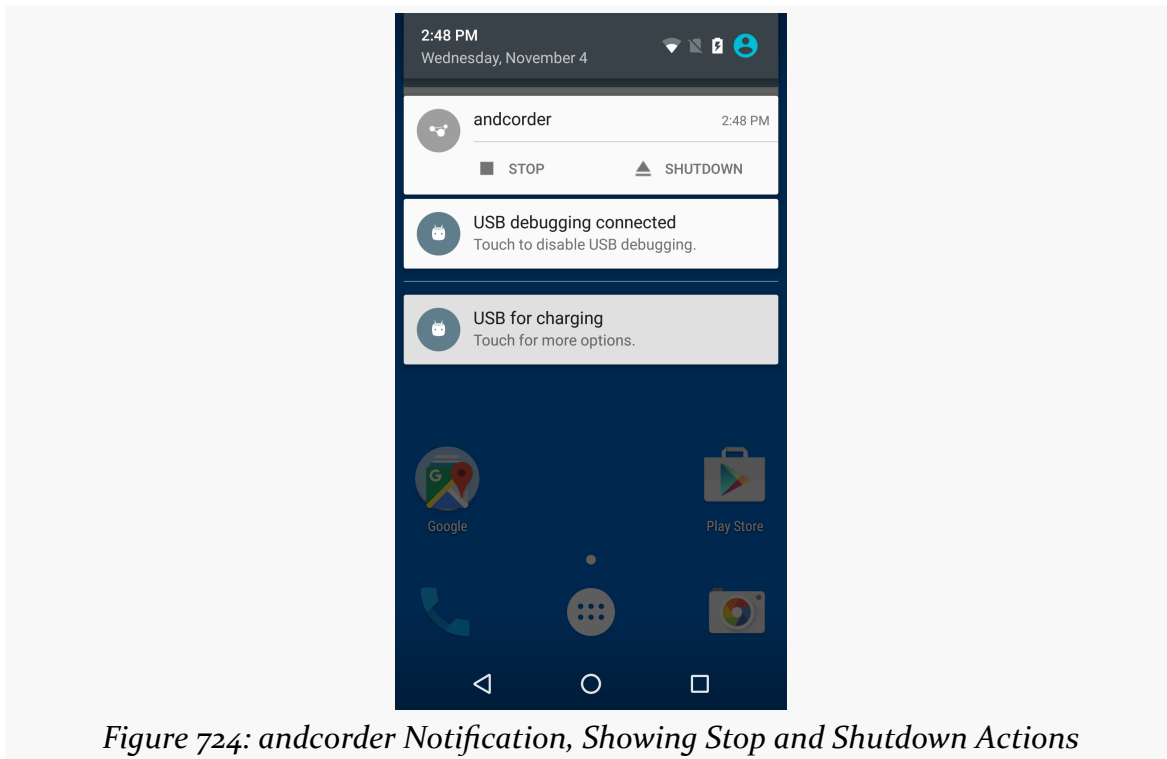

Figure 724: andcorder Notification, Showing Stop and Shutdown Actions

In addition, `onDestroy()` stops the recording and removes us from the foreground, plus we have the obligatory `onBind()` implementation:

```
@Override
public void onDestroy() {
    stopRecorder();
    stopForeground(true);

    super.onDestroy();
}

@Override
public IBinder onBind(Intent intent) {
    throw new IllegalStateException("go away");
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](https://github.com/CommonWare/android-andcorder/blob/master/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java))

Using the Control Channel... From the Command Line

The downside of relying upon a foreground Notification is that the user has to interact with that Notification to start and stop the recording. As a result, that Notification — and the rest of the notification tray — will be visible at the beginning and the end of the recording. While this could be addressed by editing

SCREENSHOTS AND SCREEN RECORDINGS

the video, video editors can be difficult to use. It would be nice to be able to operate `andcorder` without affecting the screen.

Fortunately, we can, courtesy of `adb`.

As is covered in [the chapter on ADB](#), it is possible to use the `adb shell am` command to start an activity, start a service, and send a broadcast. In this case, since we are using a service for managing the recording process, we can use `adb shell am` to trigger the same actions that the Notification does.

This, however, requires that our `RecorderService` be exported. For the `PendingIntent` objects used in the Notification, we would not need to export the service. Invoking the service from the command line, however, does require an exported service, since the command line is not the app itself and therefore is considered to be a third-party client of the app. Moreover, there is no obvious way to validate that the commands were sent from `adb shell am`, which means that when `andcorder` is installed, any app could send commands to `RecorderService`.

From a security standpoint, this is not great. The user still has to be involved to grant permission to record the screen, which limits the security risk a little bit. However, in general, **you should not run `andcorder` on your own personal device**, due to this security hole. Or, at minimum, run `andcorder`, then uninstall it immediately when you are done with it, so it does not linger where malware might try to use it.

The `andcorder` project contains three `bash` scripts to invoke the `RecorderService`. These should be able to be trivially converted to Windows command files; the proof of this is left as an exercise for the reader.

All three scripts use `adb shell am startservice`, and all point to the same component (`-n com.commonware.android.andcorder/.RecorderService`). What varies is the action string supplied to the `-a` switch.

NOTE: the shell script code listings are word-wrapped due to line length limitations in the books; the files themselves have the `adb shell` commands all on one line.

So, the `record` script, for example, passes `com.commonware.android.andcorder.RECORD` as the action string:

```
#!/bin/bash
```

SCREENSHOTS AND SCREEN RECORDINGS

```
adb shell am startservice -n com.commonware.android.andcorder/.RecorderService
-a com.commonware.android.andcorder.RECORD
```

The stop script passes the STOP action string; the shutdown script passes the SHUTDOWN action string.

These, therefore, replicate the Intent structures used in the PendingIntent objects for the Notification actions.

However, there is one key usage difference: it would be nice to be able to run the record script without having to think about whether or not you ran andcorder from the home screen launcher or not. The RECORD action cannot actually do the recording without the result data from the startActivityForResult() call in MainActivity.

This is why the RECORD action logic detects this case and starts up MainActivity — so we can just run the record script and, if we do not presently have screen-recording permission, request it from the user.

The recordOnNextStart flag indicates whether or not RECORD started up MainActivity. If it did, when we get the result data in the no-action onStartCommand() call, we should go ahead and begin recording. This prevents the user from having to run the record script twice, once to pop up the permission dialog and once to actually begin recording.

Starting the Recording

The startRecorder() method on RecorderService is called when it is time to begin screen recording, either because the user asked us to record just now or the user asked us to record (via the command-line script) and we just now got permission from the user to do that.

```
synchronized private void startRecorder() {
    if (session==null) {
        MediaProjectionManager mgr=
            (MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);
        MediaProjection projection=
            mgr.getMediaProjection(resultCode, resultData);

        session=
            new RecordingSession(this, new RecordingConfig(this),
                projection);
        session.start();
    }
}
```

SCREENSHOTS AND SCREEN RECORDINGS

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

Here, as with the `andprojector` sample, we use a `MediaProjectionManager` to turn the `resultCode` `int` and `resultData` `Intent` into a `MediaProjection`. Then, we create a `RecordingSession`, wrapped around a `RecordingConfig` and the `MediaProjection`, and call `start()` on the `RecordingSession`.

Both `RecordingSession` and `RecordingConfig` are classes that are part of the app, not the Android SDK. `RecordingConfig` holds onto information about the nature of what is being recorded (notably, the video resolution) to capture. `RecordingSession` handles the stateful work of actually recording the video.

Of the two, you might expect `RecordingSession` to be far more complex. In truth, it is decidedly more straightforward than is `RecordingConfig`. Determining the resolution and other information about our screen recording is annoyingly complicated.

Deciding How Big Our Recording Is

The job of `RecordingConfig` is to derive and hold onto five pieces of data regarding the screen recording that we are about to initiate:

- The width and height of the video, in pixels
- The bit rate at which the video should be recorded
- The frame rate (frames per second) at which the video should be recorded
- The screen density

These are held in five `final int` fields, as `RecordingConfig` is designed to be immutable:

```
final int width;  
final int height;  
final int frameRate;  
final int bitRate;  
final int density;
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

All five of these values will be initialized in the constructor (since they are `final`). In fact, all the business logic for `RecordingSession` is just in the constructor, to derive these five values.

That constructor starts off simple enough:

SCREENSHOTS AND SCREEN RECORDINGS

```
RecordingConfig(Context ctxt) {
    DisplayMetrics metrics=new DisplayMetrics();
    WindowManager wm=(WindowManager)ctxt.getSystemService(Context.WINDOW_SERVICE);

    wm.getDefaultDisplay().getRealMetrics(metrics);

    density=metrics.densityDpi;

    Configuration cfg=ctxt.getResources().getConfiguration();

    boolean isLandscape=
        (cfg.orientation==Configuration.ORIENTATION_LANDSCAPE);
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

Here, we:

- Populate a DisplayMetrics data structure, given a WindowManager
- Save the screen density in its final field
- Get the current Configuration and determine if we are in landscape mode or not

Where things start to get messy is with the other four fields, as they need to be populated based on the device's video recording capabilities. For various reasons, screen recording is actually handled mostly by MediaRecorder, the same class used to [record videos from a device camera](#). Hence, we are limited by not only the actual resolution of the screen but by the capabilities of the video recording engine.

The classic way to handle this is by using CamcorderProfile objects. These standardize video recording support for various resolutions. We can find out which of these profiles the device supports and use that to help determine our video resolution, frame rate, and bitrate.

However, we also have to take into account the resolution of the screen itself. If MediaRecorder is capable of 1080p (1920 x 1080) video recording, but the device has a low-end WXGA (1280 x 800) screen, we will waste a lot of space recording that screen at 1080p. What we want is the smallest resolution that is bigger than the screen, to minimize wasted space while not losing data. If, for some reason, we do not have a CamcorderProfile that is bigger than the screen, we will have to settle for one that is as big as we can manage.

To that end, the CAMCORDER_PROFILES static field on RecordingConfig lists the major CamcorderProfile IDs, in descending order based on resolution:

```
private static final int[] CAMCORDER_PROFILES={
    CamcorderProfile.QUALITY_2160P,
    CamcorderProfile.QUALITY_1080P,
```

SCREENSHOTS AND SCREEN RECORDINGS

```
CamcorderProfile.QUALITY_720P,  
CamcorderProfile.QUALITY_480P,  
CamcorderProfile.QUALITY_CIF,  
CamcorderProfile.QUALITY_QVGA,  
CamcorderProfile.QUALITY_QCIF  
};
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

If we simply iterate over this list and choose either the first one we find, or one that is smaller yet is bigger than the screen, we will get the right CamcorderProfile for our use case:

```
CamcorderProfile selectedProfile=null;  
  
for (int profileId : CAMCORDER_PROFILES) {  
    CamcorderProfile profile=null;  
  
    try {  
        profile=CamcorderProfile.get(profileId);  
    }  
    catch (Exception e) {  
        // not documented to throw anything, but does  
    }  
  
    if (profile!=null) {  
        if (selectedProfile==null) {  
            selectedProfile=profile;  
        }  
        else if (profile.videoFrameWidth>=metrics.widthPixels &&  
            profile.videoFrameHeight>=metrics.heightPixels) {  
            selectedProfile=profile;  
        }  
    }  
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

To get a CamcorderProfile given its ID, you call the static `get()` method on CamcorderProfile. This is supposed to return the CamcorderProfile if it is supported or null if it is not. In actuality, it may throw an exception if the profile is not supported, which is why we have to wrap the `get()` call in a try/catch block. Then, if profile exists, we hold onto it as the selectedProfile if either:

- selectedProfile is null, meaning this is the largest available profile, or
- the profile has a resolution bigger than the screen on both axes

If, after all that is done, we have a null selectedProfile, that means that *none* of the CamcorderProfile values were available. That is very strange, and rather than take a random guess as to what will work, we just blow up with an

SCREENSHOTS AND SCREEN RECORDINGS

`IllegalStateException`. Obviously, a production-grade app would need to blow up more nicely.

Otherwise, we can collect our remaining data... which once again is more complex than you might expect:

```
if (selectedProfile==null) {
    throw new IllegalStateException("No CamcorderProfile available!");
}
else {
    frameRate=selectedProfile.videoFrameRate;
    bitRate=selectedProfile.videoBitRate;

    int targetWidth, targetHeight;

    if (isLandscape) {
        targetWidth=selectedProfile.videoFrameWidth;
        targetHeight=selectedProfile.videoFrameHeight;
    }
    else {
        targetWidth=selectedProfile.videoFrameHeight;
        targetHeight=selectedProfile.videoFrameWidth;
    }

    if (targetWidth>=metrics.widthPixels &&
        targetHeight>=metrics.heightPixels) {
        width=metrics.widthPixels;
        height=metrics.heightPixels;
    }
    else {
        if (isLandscape) {
            width=targetHeight*metrics.widthPixels/metrics.heightPixels;
            height=targetHeight;
        }
        else {
            width=targetWidth;
            height=targetWidth*metrics.heightPixels/metrics.widthPixels;
        }
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

Getting the frame rate and the bitrate are easy enough, as they are just fields on the `CamcorderProfile`. Where things start to get strange is in determining what we should tell the `MediaRecorder` that we want recorded in terms of resolution.

Partly, this is a problem of orientation. `MediaRecorder` thinks that everything is recorded in landscape, but we may well want to record the screen held in portrait mode.

SCREENSHOTS AND SCREEN RECORDINGS

Partly, this is a problem of aspect ratios. There is no requirement that the `MediaRecorder` advertise support for resolutions that match the screen size, or even match the screen's aspect ratio. So, if the `MediaRecorder` is capable of recording our full screen, we ask it to record the full screen (as determined from the `DisplayMetrics`). If, however, we are on some odd device whose `MediaRecorder` is not capable of recording video at the screen's own resolution, we try to at least maintain the aspect ratio of the screen when deriving the resolution to use for recording.

The net of all that work is that we have the details of how we want the screen recording to be done, encapsulated in the `RecordingConfig` object, ready for use by the `RecordingSession`.

Actually Recording Stuff

None of that actually records the screen, though. That is the responsibility of the `RecordingSession`.

In the `RecordingSession` constructor, we:

- Hold onto the `RecordingConfig` and `MediaProjection`
- Hold onto the application `Context`, as we will need a `Context` later on
- Create an instance of a `ToneGenerator` to use for audible feedback about the state of the recording
- Create a `File` object pointing at our desired output: an `andcorder.mp4` file in our app's portion of external storage

```
RecordingSession(Context ctxt, RecordingConfig config,
                 MediaProjection projection) {
    this.ctxt=ctxt.getApplicationContext();
    this.config=config;
    this.projection=projection;
    this.beeper=new ToneGenerator(
        AudioManager.STREAM_NOTIFICATION, 100);

    output=new File(ctxt.getExternalFilesDir(null), "andcorder.mp4");
    output.getParentFile().mkdirs();
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](https://commonsware.com/android/andcorder/RecordingSession.java))

The actual work to record the video is handled in the `start()` method on `RecordingSession`, where we set up the `MediaRecorder` and a `VirtualDisplay`, the latter being the same thing that we used in the `andprojector` sample:

SCREENSHOTS AND SCREEN RECORDINGS

```
void start() {
    recorder=new MediaRecorder();
    recorder.setVideoSource(MediaRecorder.VideoSource.SURFACE);
    recorder.setOutputFormat(MediaRecorder.OutputFormat.MPEG_4);
    recorder.setVideoFrameRate(config.frameRate);
    recorder.setVideoEncoder(MediaRecorder.VideoEncoder.H264);
    recorder.setVideoSize(config.width, config.height);
    recorder.setVideoEncodingBitRate(config.bitRate);
    recorder.setOutputFile(output.getAbsolutePath());

    try {
        recorder.prepare();
        vdisplay=projection.createVirtualDisplay("andcorder",
            config.width, config.height, config.density,
            VIRT_DISPLAY_FLAGS, recorder.getSurface(), null, null);
        beeper.startTone(ToneGenerator.TONE_PROP_ACK);
        recorder.start();
    }
    catch (IOException e) {
        throw new RuntimeException("Exception preparing recorder", e);
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

First, we create an instance of `MediaRecorder` and configure it. As is discussed in [the chapter on working with the camera](#), `MediaRecorder` is a very fussy class, requiring a fairly specific order of method calls to configure it without messing things up too bad. The values for the configuration come from:

- the `RecordingConfig`, notably the requested resolution, frame rate, and bitrate
- the output `File` created in the `RecordingSession` constructor
- hardcoded values for the video source, output format, and encoder format

Of particular interest is the call to `setVideoSource()`. Usually, you would set this to `CAMERA`, to record from a device-supplied camera. Here, though, we set it to `SURFACE`, indicating that `MediaRecorder` should supply a `Surface` onto which we can render what should get recorded.

We then:

- Prepare the `MediaRecorder`, which might throw an `IOException` if there is some problem with the output file
- Create a `VirtualDisplay`, as we did in `andprojector`, tied to the details of the display we got from `DisplayMetrics` by way of the `RecordingConfig`
- Play a tone using `ToneGenerator` to let the user know that recording has begun
- Actually begin the recording, via a call to `start()` on the `MediaRecorder`

SCREENSHOTS AND SCREEN RECORDINGS

The `VIRT_DISPLAY_FLAGS` used here are the same ones used for `andprojector`:

```
static final int VIRT_DISPLAY_FLAGS=  
    DisplayManager.VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY |  
    DisplayManager.VIRTUAL_DISPLAY_FLAG_PUBLIC;
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

And, at this point, the screen is being recorded.

Stopping the Recording

Eventually, we will want to stop that recording, whether triggered via the Notification or the command-line script. That eventually results in a call to `stopRecorder()` on the `RecorderService`, which just calls `stop` on the `RecordingSession` before setting the field to `null`:

```
synchronized private void stopRecorder() {  
    if (session!=null) {  
        session.stop();  
        session=null;  
    }  
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

The `stop()` method on `RecordingSession` unwinds everything we set up, via `stop()` and `release()` calls on the `MediaProjection`, `MediaRecorder`, and `VirtualDisplay`. `stop()` also calls `scanFile()` on `MediaScannerConnection`, so that our video gets indexed by the `MediaStore` and therefore can be seen in on-device video players and via the MTP connection to your developer machine:

```
void stop() {  
    projection.stop();  
    recorder.stop();  
    recorder.release();  
    vdisplay.release();  
  
    MediaScannerConnection.scanFile(ctxt,  
        new String[]{output.getAbsolutePath()}, null, this);  
}  
  
@Override  
public void onScanCompleted(String path, Uri uri) {  
    beeper.startTone(ToneGenerator.TONE_PROP_NACK);  
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

SCREENSHOTS AND SCREEN RECORDINGS

When the scan is complete, another beep signals to the user that the screen recording is finished.

Usage Notes

On the plus side, andcorder has no built-in duration limitation, the way that [adb shell screenrecord](#) does.

However, it does not optimize configuration changes. If you rotate the device during the recording, the recording will continue, but the screen will be shrunk to fit within the original dimensions. So, for example, if you start recording in landscape, then rotate the device to portrait, the video will still be landscape, with part of the video showing a small portrait rendition of the screen.

Advanced Permissions

Adding basic permissions to your app to allow it to, say, access the Internet, is fairly easy. However, the full permissions system has many capabilities beyond simply asking the user to let you do something. This chapter explores other uses of permissions, from securing your own components to using signature-level permissions (your own or Android's).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on permissions](#) and the chapter on [signing your app](#). The discussion of signature-level permissions will make a bit more sense if you read through [the chapter on plugins](#) as well.

Securing Yourself

Principally, at least initially, permissions are there to allow the user to secure their device. They have to agree to allow you to do certain things, such as reading contacts, that they might not appreciate.

The other side of the coin, of course, is to secure your own application. If your application is mostly activities, security may be just an “outbound” thing, where you request the right to use resources of other applications. If, on the other hand, you put content providers or services in your application, you will want to implement “inbound” security to control which applications can do what with the data.

Note that the issue here is less about whether other applications might “mess up” your data, but rather about privacy of the user's information or use of services that

ADVANCED PERMISSIONS

might incur expense. That is where the stock permissions for built-in Android applications are focused – can you read or modify contacts, can you send SMS, etc. If your application does not store information that might be considered private, security is less an issue. If, on the other hand, your application stores private data, such as medical information, security is much more important.

The first step to securing your own application using permissions is to declare said permissions, once again in the `AndroidManifest.xml` file. In this case, instead of `uses-permission`, you add `permission` elements. Once again, you can have zero or more `permission` elements, all as direct children of the root `manifest` element.

Declaring a permission is slightly more complicated than using a permission. There are three pieces of information you need to supply:

- The symbolic name of the permission. To keep your permissions from colliding with those from other applications, you should use your application's Java namespace as a prefix
- A label for the permission: something short that would be understandable by users
- A description for the permission: something a wee bit longer that is understandable by your users

```
<permission
  android:name="vnd.tlagency.sekritis.SEE_SEKRITS"
  android:label="@string/see_sekritis_label"
  android:description="@string/see_sekritis_description" />
```

This does not enforce the permission. Rather, it indicates that it is a possible permission; your application must still flag security violations as they occur.

Enforcing Permissions via the Manifest

There are two ways for your application to enforce permissions, dictating where and under what circumstances they are required. The easier one is to indicate in the manifest where permissions are required.

Activities, services, and receivers can all declare an attribute named `android:permission`, whose value is the name of the permission that is required to access those items:

```
<activity
  android:name=".SekritApp"
  android:label="Top Sekrit"
```

ADVANCED PERMISSIONS

```
android:permission="vnd.tlagency.sekrits.SEE_SEKRITS">
<intent-filter>
  <action android:name="android.intent.action.MAIN" />
  <category
    android:name="android.intent.category.LAUNCHER"
  />
</intent-filter>
</activity>
```

Only applications that have requested your indicated permission will be able to access the secured component. In this case, “access” means:

1. Activities cannot be started without the permission
2. Services cannot be started, stopped, or bound to an activity without the permission
3. Intent receivers ignore messages sent via `sendBroadcast()` unless the sender has the permission

Enforcing Permissions Elsewhere

In your code, you have two additional ways to enforce permissions.

Your services can check permissions on a per-call basis via `checkCallingPermission()`. This returns `PERMISSION_GRANTED` or `PERMISSION_DENIED` depending on whether the caller has the permission you specified. For example, if your service implements separate read and write methods, you could require separate read versus write permissions in code by checking those methods for the permissions you need from Java.

Also, you can include a permission when you call `sendBroadcast()`. This means that eligible broadcast receivers must hold that permission; those without the permission are ineligible to receive it. We will examine `sendBroadcast()` in greater detail elsewhere in this book.

Requiring Standard System Permissions

While normally you require your own custom permissions using the techniques described above, there is nothing stopping you from reusing a standard system permission, if it would fit your needs.

For example, suppose that you are writing YATC (Yet Another Twitter Client). You decide that in addition to YATC having its own UI, you will design YATC to be a “Twitter engine” for use by third party apps:

- Send timeline updates via broadcast Intents
- Publish the timeline, the user's own tweets, @-mentions, and the like via a `ContentProvider`
- Offer a command-based service interface for posting updates to the timeline
- And so on

You could, and perhaps should, implement your own custom permission. However, since any app can get to Twitter just by having the `INTERNET` permission, one could argue that a third-party app should just need that same `INTERNET` permission to use your API (rather than integrating JTwitter or another third-party JAR).

Signature Permissions

Each permission in Android is assigned a protection level, via an `android:protectionLevel` attribute on the `<permission>` element. By default, permissions are at a normal level, but they can also be flagged as dangerous, `signatureOrSystem`, or `signature`. In the latter two cases, “signature” means that the app requesting the permission and the app requiring the permission should have been signed by the same signing key. In the case of `signatureOrSystem` — only used by the firmware — the app requesting the permission either needs to be signed by the firmware's signing key or reside on the system partition (e.g., come pre-installed with the device).

Firmware-Only Permissions

Most of Android's permissions mentioned in this book are ones that any SDK application can hold, if they ask for them and the user grants them. `INTERNET`, `READ_CONTACTS`, `ACCESS_FINE_LOCATION`, and `kin` all are normal permissions.

`BRICK` is not.

There was a permission in Android, named `BRICK`, that, in theory, allows an application to render a phone inoperable (a.k.a., “brick” the phone). While there is no `brickMe()` method in the Android SDK tied to this permission, presumably there might be something deep in the firmware that was protected by this permission. Though, since Android 6.0 removed the `BRICK` permission from the SDK, it is clearly not something Google expects us to use.

The `BRICK` permission could not be held by ordinary Android SDK applications. You could request it all you want, and it will not be granted.

However, applications that are signed with the same signing key that signed the firmware *could* hold the BRICK permission.

That is because [the system's own manifest](#) used to have the following <permission> element:

```
<permission android:name="android.permission.BRICK"  
    android:label="@string/permlab_brick"  
    android:description="@string/permdesc_brick"  
    android:protectionLevel="signature" />
```

Your Own Signature Permissions

You too can require signature-level permissions. That will restrict the holders of that permission to be other apps signed by your signing key. This is particularly useful for inter-process communication between apps in a suite — by using signature permissions, you ensure that only your apps will be able to participate in those communications.

This is what was used in the ContentProvider-based plugin sample [from elsewhere in this book](#). The plugin required a permission that was declared with `android:protectionLevel="signature"`, and the host application requested that permission.

One nice thing about these sorts of signature-level permissions is that the user is not bothered with them. It is assumed that the user will agree to the communication between the apps signed by the same signing key. Hence, the user will not see signature-level permissions at install or upgrade time.

Since in some cases, you may not be sure which app will be installed first, it is best to have all apps in the suite include the *same* <permission> element, in addition to the corresponding <uses-permission> element. That way, no matter which app is installed first, it can declare the permission that all will share.

Though, that has its own problems, as you will see in the next section.

The Custom Permission Vulnerability

NOTE: Some of the material in this section originally appeared in material hosted in [the CWAC-Security project repository](#). In addition, the author would like to thank Mark Carter and “Justin Case” for their contributions in this topic area).

ADVANCED PERMISSIONS

Unfortunately, custom permissions have some undocumented limitations that make them intrinsically risky. Specifically, custom permissions can be defined by anyone, at any time, and “first one in wins”, which opens up the possibility of unexpected behavior.

Here, we will walk through some scenarios and show where the problems arise, plus discuss how to mitigate them as best we can.

Scenarios

All of the following scenarios focus on three major app profiles.

App A is an app that defines a custom permission in its manifest, such as:

```
<permission
  android:name="com.commonware.cwac.security.demo.OMG"
  android:description="@string/perm_desc"
  android:label="@string/perm_label"
  android:protectionLevel="normal"/>
```

App A also defends a component using the `android:permission` attribute, referencing the custom permission:

```
<provider
  android:name="FileProvider"
  android:authorities="com.commonware.cwac.security.demo.files"
  android:exported="true"
  android:grantUriPermissions="false"
  android:permission="com.commonware.cwac.security.demo.OMG">
  <grant-uri-permission android:path="/test.pdf"/>
</provider>
```

App B has a `<uses-permission>` element to declare to the user that it wishes to access components defended by that permission:

```
<uses-permission android:name="com.commonware.cwac.security.demo.OMG"/>
```

App C has the same `<uses-permission>` element. The difference is that App B *also* has the `<permission>` element, just as App A does, albeit with different descriptive information (e.g., `android:description`) and, at times, a different protection level.

All three apps are signed with different signing keys, because in the real world they would be from different developers.

So, to recap:

ADVANCED PERMISSIONS

- A defines a permission and uses it for defense
- B defines the same permission and requests to hold it
- C just requests to hold this permission

With all that in mind, let's walk through some possible scenarios, focusing on two questions:

1. What is the user told, when the app is installed through normal methods (i.e., not via adb), regarding this permission?
2. What access, if any, does App B or App C have to the ContentProvider from App A?

The Application SDK Case (A, Then C)

Suppose the reason why App A has defined a custom permission is because it wants third-party apps to have the ability to access its secured components... but only with user approval. By defining a custom permission, and having third-party apps request that permission, the user should be informed about the requested permission and can make an informed decision.

Conversely, if an app tries to access a secured component but has not requested the permission, the access attempt should fail.

App C has requested the custom permission via the `<uses-permission>` element. If the permission — defined by App A — has an `android:protectionLevel` of `normal` or `dangerous`, the user will be informed about the requested permission at install time. If the user continues with the installation, App C can access the secured component.

If, however, the `android:protectionLevel` is `signature`, the user is not informed about the requested permission at install time, as the system can determine on its own whether or not the permission should be granted. In this case, App A and App C are signed with different signing keys, so Android silently ignores the permission request. If the user continues with installation, then App C tries to access App A's secured component, App C crashes with a `SecurityException`.

In other words, this all works as expected.

The Application SDK Problem Case (C, Then A)

However, in many cases, there is nothing forcing the user to install App A before App C. This is particularly true for publicly-distributed apps on common markets, like the Play Store.

When the user installs App C, the user is not informed about the request for the custom permission, presumably because that permission has not yet been defined. If the user later installs App A, App C is not retroactively granted the permission, and so App C's attempts to use the secured component fail.

This works as expected, though it puts a bit of a damper on custom permissions. One way to work around this would be for the user to uninstall App C, then install it again (with App A already installed). This returns us to the original scenario from the preceding section. However, if the user has data in App C, losing that data may be a problem (as in a "let's give App C, or perhaps App A, one-star ratings on the Play Store" sort of problem).

The Peer Apps Case, Part One (A, Then B)

Suppose now we augment our SDK-consuming app (formerly App C) to declare the same permission that App A does, in an attempt to allow the two apps to be installed in either order. That is what App B is: the same app as App C, but where it has the same `<permission>` element as does App A in its manifest.

This scenario is particularly important where both apps could be of roughly equal importance to the user. In cases where App C is some sort of plugin for App A, it is not unreasonable for the author of App A to require App A to be installed first. But, if Twitter and Facebook wanted to access components of each others' apps, it would be unreasonable for either of those firms to mandate that their app must be installed first. After all, if Twitter wants to be installed first, and Facebook wants to be installed first, one will be disappointed.

If the user installs App A (the app defending a component with the custom permission) before App B, the user will be notified at install time about App B's request for this permission. Notably, the information shown on the installation security screen will contain App A's description of the permission. And, if the user goes ahead and installs App B, App B can indeed access App A's secured component, since it was granted permission by the user.

Once again, everything is working as expected. Going back to the two questions:

ADVANCED PERMISSIONS

1. The user is informed when App B or App C requests the permission defined by App A.
2. App B and App C can hold that permission if and only if they meet the requirements of the protection level

The Peer Apps Case, Part Two (B, Then A)

What happens if we reverse the order of installation? After all, if App A and App B are peers, from the standpoint of the user, there is roughly a 50% chance that the user will install App B before App A.

Here is where things go off the rails.

The user is not informed about App B's request for the custom permission.

The user will be informed about any platform permissions that the app requests via other `<uses-permission>` elements. If there are none, the user is told that App B requests no permissions... despite the fact that it does.

When the user installs App A, the same thing occurs. Of course, since App A does not have a `<uses-permission>` element, this is not all that surprising.

However, at this point, **even though the user was not informed**, App B holds the custom permission and can access the secured component.

This is bad enough when both parties are ethical. App B could be a piece of malware, though, designed to copy the data from App A, ideally without the user's knowledge. And, if App B is installed before App A, that would happen.

So, going to the two questions:

1. The user is **not** informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component

The Downgraded-Level Malware Case (B, Then A, Again)

You might think that the preceding problem would only be for normal or dangerous protection levels. If App A defines a permission as requiring a matching signature, and App A marks a component as being defended by that permission, Android must require the signature match, right?

Wrong.

The behavior is identical to the preceding case. Android does not use the *defender's* protection level. It uses the *definer's* protection level, meaning the protection level of whoever was installed first and had the <permission> element.

So, if App A has the custom permission defined as signature, and App B has the custom permission defined as normal, if App B is installed first, the behavior is as shown in the preceding section:

1. The user is **not** informed about App B's request for the permission...
2. ...but App B gets it anyway and can access the secured component, despite the signatures not matching

The Peer Apps Case With a Side Order of C

What happens if we add App C back into the mix? Specifically, what if App B is installed first, then App A, then App C?

When App C eventually gets installed, the user is prompted for the custom permission that App C requests via <uses-permission>. However, the description that the user sees is from App B, the one that first defined the custom <permission>. Moreover, the protection level is whatever App B defined it to be. So if App B downgraded the protection level from App A's intended signature to be normal, App C can hold that permission and access the secured App A component, even if it is signed by another signing key.

Not surprisingly, the same results occur if you install App B, then App C, then App A.

Behavior Analysis

The behavior exhibited in these scenarios is consistent with two presumed implementation "features" of Android's permission system:

1. First one in wins. In other words, the first app (or framework, in the case of the OS's platform permissions) that defines a <permission> for a given android:name gets to determine what the description is and what the protection level is.

2. The user is only prompted to confirm a permission if the app being installed has a `<uses-permission>` element, the permission was already defined by some other app, and the protection level is not signature.

Risk Assessment

The “first one in wins” rule is a blessing and a curse. It is a curse, insofar as it opens up the possibility for malware to hold a custom permission without the user’s awareness of that, and even to downgrade a signature-level permission to normal. However, it is a blessing, in that the malware would have to be installed first; if it is installed second, either its request to hold the permission will be seen by the user (normal or dangerous) or the request to hold the permission will be rejected (signature).

This makes it somewhat unlikely for a piece of malware to try to sneakily make off with data. Eventually, if enough users start to ask publicly why App B needs access to App A’s data (for cases where App A was installed first and the user knows about the permission request), somebody in authority may eventually realize that this is a malware attack. Of course, “eventually” may be a rather long time.

However, there are some situations where Android’s custom permission behavior presents risk even greater than that. If the attacker has a means of being *sure* that their app was installed first, they can hold any permission from any third-party app they want to that was known at install time.

For example:

- Somebody could sell a used Android device, and the buyer could neglect to factory-reset it, and the malware could be installed by the seller
- Somebody could sell a used Android device with a ROM mod preinstalled, based on a normal ROM mod (e.g., CyanogenMod), but with an additional bit of malware installed, to prevent a factory reset from foiling the attack’
- Somebody could distribute devices to users who might think the device is “factory clean” and not laden with malware (e.g., devices given as gifts)
- Somebody could distribute devices to users who might think that the pre-installed malware is actually a legitimate app (e.g., devices given to employees by an employer wishing to monitor usage by examining protected data from third-party apps)

Android 5.0's "Fix"

Android 5.0 now prevents two apps from defining the same `<permission>` ("same" based on `android:name`) unless they are signed by the same signing key. First one in wins; the second app installation will fail.

On the plus side:

- This solves the security problem, as an attacker (B) cannot get at a defender's (A's) data by virtue of having been installed first, as A simply cannot be installed in this case.
- This has no impact on developers using signature-level `<permission>` elements for their own app suite.

However, it does pose significant limitations on legitimate public uses of custom `<permission>` elements. Only the defender should have the `<permission>` element now. Some client of the defender's app (C) should not have the `<permission>` element and should simply rely upon the fact that the defender should be installed first. If the client were to define the `<permission>`, then either the client or the defender cannot be installed, which is pointless.

This has usability issues:

- A client should check, on first run of their app, if an expected defender (and its `<permission>` element) exists. If not, the client should alert the user to this fact and perhaps stop the app from proceeding further. The user would have to uninstall the client, install the defender, then reinstall the client, to get everything working properly, and the more the user uses the client app, the more painful the uninstall might be.
- It is impossible for two apps to be clients of each other. By definition, one app has to be installed first and the other second, which means only the first-to-be-installed app can have a custom `<permission>`. If Facebook wanted to hold a custom Twitter permission, and Twitter wanted to hold a custom Facebook permission, one of them is out of luck — if Facebook is installed first, it cannot request Twitter's permission (as it does not yet exist) nor can it define Twitter's permission (as if it does, Twitter cannot be installed). This *might* be able to be overcome for apps that are pre-loaded as part of a ROM mod or other custom Android build.

And, of course, this fix is only for Android 5.0 and above.

Mitigation Using PermissionUtils

The “first one in wins” rule also leads us to a mitigation strategy: On first run of our app, see if any other app has defined permissions that we have defined. If that has happened, then we are at risk, and take appropriate steps. If, however, no other app has defined our custom permissions, then the Android permission system should work for us, and we can proceed as normal.

[The CWAC-Security library](#) provides some helper code, in the form of the `PermissionUtils` class, to detect other apps defining the same custom permissions that you define.

The idea is that you call `checkCustomPermissions()` — a static method on `PermissionUtils` — on the first run of your app. It will return details about what other apps have already defined custom permissions that your app defines. If `checkCustomPermissions()` returns nothing, you know that everything is fine, and you can move ahead. Otherwise, you can:

- Check to see if the offending app is on some whitelist, or otherwise meets criteria that suggests that it is OK
- Alert the user, indicating that these already-installed apps will have access to your app secured components
- Upload details about the offending apps to your server, so you can try to track down whether they are legitimate users of some API that you are exposing or are malware
- Whatever else you feel is necessary

Example: Permission Proxy

[The section on ContentProvider proxy plugins](#) involves the use of a custom signature-level permission, to secure communications between the proxy and the host app that uses the proxy.

The idea is that the proxy holds some permission (e.g., `READ_CONTACTS`) and proxies data to some `ContentProvider` protected by that proxy (e.g., `CallLog`). The host app, rather than holding the permission and accessing the protected `ContentProvider` directly, can talk to the proxy. That way, the user only needs to grant permission if they elect to install the proxy; otherwise, the host app is blocked from having access to the protected content.

ADVANCED PERMISSIONS

However, to prevent arbitrary other apps from using the proxy themselves, the host and proxy agree on a custom signature-level permission. The proxy defends itself using that permission, and the host requests the permission. In theory, this would limit communications with the proxy to only be from the host, or from other apps signed with the same signing key as the proxy and host use.

But, as is described above, another app could define the *same* permission, with a normal protection level. If that other app is installed first, not only can any other app access the proxy just by requesting the permission, but the attacker could have requested the same permission that it defined, so the user is unaware that the attacker holds this permission.

Hence, these proxies need to use some defensive measures, and the samples shown in this book employ `PermissionUtils` from the CWAC-Security library to do just that.

What the Proxy Does

The proxy is a `ContentProvider`. Specifically, there is an `AbstractCPPProxy` subclass of `ContentProvider` that does the “heavy lifting”, and a `CallLogProxy` subclass of `AbstractCPPProxy` that handles some of the details of proxying the `CallLog` versus something else.

In `onCreate()` of the `AbstractCPPProxy`, we use `PermissionUtils` and `checkCustomPermissions()` to determine whether or not anything was installed before us, that defined our custom permission, *other* than our known host app:

```
@Override
public boolean onCreate() {
    SharedPreferences prefs=
        PreferenceManager.getDefaultSharedPreferences(getContext());

    if (prefs.getBoolean(PREFS_FIRST_RUN, true)) {
        SharedPreferences.Editor editor=
            prefs.edit().putBoolean(PREFS_FIRST_RUN, false);

        HashMap<PackageInfo, ArrayList<PermissionLint>> entries=
            PermissionUtils.checkCustomPermissions(getContext());

        for (Map.Entry<PackageInfo, ArrayList<PermissionLint>> entry : entries.entrySet()) {
            if (!"com.commonware.android.cproxy.consumer".equals(entry.getKey().packageName)) {
                tainted=true;
                break;
            }
        }

        editor.putBoolean(PREFS_TAINTED, tainted).apply();
    }
}
```

ADVANCED PERMISSIONS

```
    }  
    else {  
        tainted=prefs.getBoolean(PREFS_TAINTED, true);  
    }  
  
    return(true);  
}
```

(from [Introspection/CPProxy/Provider/src/com/commonsware/android/cproxy/provider/AbstractCPProxy.java](#))

We use SharedPreferences to hold onto two key pieces of data:

1. Have we already done the check, as determined by PREFS_FIRST_RUN? If yes, we can just look up the results of the previous check. This is not merely an optimization — we do not have to worry about apps installed *after* us somehow redefining our custom permission.
2. When we did the check, did we find some package that had been installed before us, other than the host, that defined our custom permission, as determined by PREFS_TAINTED?

The actual check is accomplished by calling `checkCustomPermissions()` and iterating over the results. If there is an entry in the HashMap that represents a package other than ours, our environment is tainted.

The implementation in the book then uses the tainted data member in a `checkTainted()` private method:

```
private void checkTainted() {  
    if (tainted) {  
        throw new RuntimeException(getContext().getString(R.string.tainted_abort));  
    }  
}
```

(from [Introspection/CPProxy/Provider/src/com/commonsware/android/cproxy/provider/AbstractCPProxy.java](#))

This is called at the top of each ContentProvider method that we are proxying, such as `insert()`:

```
@Override  
public Uri insert(Uri uri, ContentValues values) {  
    checkTainted();  
  
    return(getContext().getContentResolver().insert(convertUri(uri),  
                                                    values));  
}
```

(from [Introspection/CPProxy/Provider/src/com/commonsware/android/cproxy/provider/AbstractCPProxy.java](#))

The result is that if we feel that our environment is compromised, we fail any attempt to use the proxy.

Note that the proxy makes no attempt to confirm that the host app really *is* the host app, versus some other app with the same package name, perhaps distributed through other channels. We could augment the proxy with additional logic to handle that case, covered [elsewhere in this book](#), if we wanted.

Also, we could, in theory, use `Binder.getCallingUid()` to confirm whether the request did come from the host app, and in that case, allow the proxy to do its work, failing in all other cases. We could even consider jettisoning the custom permission in this case, as if we know the UID of the other party, we can validate it instead of relying on a permission as a means of validation. However, that only works well in cases where the list of possible valid callers is knowable inside the app — this is fine for host-and-plugin or similar sorts of “hub-and-spoke” architectures but may be impractical in other cases.

What the Provider Could Do

The proxy has no decent means of alerting the user as to the reason for the lockdown. After all, it is a `ContentProvider`, not an `Activity`. In principle, it could use a `Notification`.

Another approach is to have the host app perform the same sorts of checks as does the proxy, and use that information to inform the user on first run of the app.

Finding the Available Permissions

On the one hand, developers should try to stick to documented permissions.

On the other hand, documentation is sometimes lacking. This is particularly true for permissions other than those defined by the OS itself, ones that come from other apps that change more frequently, including the Play Services SDK and framework.

You might find that you need to determine what permissions have been defined on a given device. Perhaps that need is at runtime — if you request a permission that does not exist, you cannot actually get it, and that may lead to problems in the future. Perhaps that need is just during development itself, to inspect some device and determine what it does and does not have in terms of permissions.

PackageManager offers methods to allow you to examine the device's permissions and permission groups. The [Permissions/PermissionReporter](#) sample app uses these methods to build up a tabbed UI listing the defined permissions, broken down by protection level.

PackageManager and Permission Groups

`getAllPermissionGroups()` on `PackageManager` will return a list of `PermissionGroupInfo` objects. This method takes an `int` value; 0 generally will be fine for your use cases.

On its own, `PermissionGroupInfo`s are not especially useful. However, you can turn around and call `queryPermissionsByGroup()` on `PackageManager`, passing in the name from the `PermissionGroupInfo`, to get all of the permissions in that group.

This method also takes an `int` value as the second parameter, where 0 will be fine.

`queryPermissionsByGroup()` returns a `List` of `PermissionInfo` objects. `PermissionInfo` has a few interesting values:

- `name`, which is the fully-qualified name of the permission
- `descriptionRes`, which is the string resource ID from the permission's `android:description` attribute
- `protectionLevel`, which is a set of flags indicating the nature of the permission's security

Note that to get the actual text of the description, there is a `loadDescription()` method on `PermissionInfo` that will do all the work to find the actual string for the description, based upon the app that defined the permission and the current locale.

To get the details of all the permissions defined on a device, we will have to call `queryPermissionsByGroup()` for each permission group. Each of those calls will involve IPC, and so this *might* be slow enough to warrant its own thread.

With that in mind, the `PermissionReporter` sample app has a `PermissionLoadThread` that collects information about the permissions on the system. That information is aggregated in a `PermissionRosterLoadedEvent`, which will be used with `greenrobot's EventBus` to provide the results to the UI when the data is ready:

ADVANCED PERMISSIONS

// inspired by <https://stackoverflow.com/a/32063384/115145>

```
class PermissionLoadThread extends Thread {
    private final Context ctxt;
    private final PermissionRosterLoadedEvent result=
        new PermissionRosterLoadedEvent();

    PermissionLoadThread(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
    }
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionLoadThread.java](#))

When the thread runs, the run() method loops over the permission groups:

```
@Override
public void run() {
    PackageManager pm=ctxt.getPackageManager();

    addPermissionsFromGroup(pm, null);

    for (PermissionGroupInfo group :
        pm.getAllPermissionGroups(0)) {
        addPermissionsFromGroup(pm, group.name);
    }

    EventBus.getDefault().postSticky(result);
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionLoadThread.java](#))

As it turns out, not all permissions are part of a group. To find out the details of these un-grouped permissions, you need to call queryPermissionsByGroup() with a null permission group name.

For each permission group (plus the magic null group), we call a private addPermissionsFromGroup() method to collect the details of the permissions in that group:

```
private void addPermissionsFromGroup(PackageManager pm,
    String groupName) {
    try {
        for (PermissionInfo info :
            pm.queryPermissionsByGroup(groupName, 0)) {
            int coreBits=
                info.protectionLevel &
                PermissionInfo.PROTECTION_MASK_BASE;

            switch (coreBits) {
                case PermissionInfo.PROTECTION_NORMAL:
                    result.add(PermissionType.NORMAL, info);
                    break;

                case PermissionInfo.PROTECTION_DANGEROUS:
                    result.add(PermissionType.DANGEROUS, info);
            }
        }
    }
}
```

ADVANCED PERMISSIONS

```
        break;

        case PermissionInfo.PROTECTION_SIGNATURE:
            result.add(PermissionType.SIGNATURE, info);
            break;

        default:
            result.add(PermissionType.OTHER, info);
            break;
    }
}
}
catch (PackageManager.NameNotFoundException e) {
    throw new IllegalStateException(
        "And you may ask yourself... how did I get here?");
}
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionLoadThread.java](#))

The `protectionLevel` field on a `PermissionInfo` contains a number of different sorts of flags. The `PROTECTION_MASK_BASE` is a bitmask that restricts the bits we are looking at to the ones for basic protections. We then divide the permissions into four groups based on protection level:

- normal
- dangerous
- signature
- other (which, on older devices, will include `system` or `signatureOrSystem` permissions)

Those `PermissionInfo` objects are then poured into the `PermissionRosterLoadedEvent` object, with each `PermissionInfo` added to a list based on those four groups:

```
package com.commonsware.android.permreporter;

import android.util.SparseArray;

public enum PermissionType {
    NORMAL(0),
    DANGEROUS(1),
    SIGNATURE(2),
    OTHER(3);

    private static final SparseArray<PermissionType> BY_VALUE=
        new SparseArray<PermissionType>(4);

    static {
        for (PermissionType type : PermissionType.values()) {
            BY_VALUE.put(type.value, type);
        }
    }
}
```

ADVANCED PERMISSIONS

```
private final int value;

private PermissionType(int value) {
    this.value=value;
}

static PermissionType forValue(int value) {
    return(BY_VALUE.get(value));
}
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionType.java](#))

PermissionType is an enum defined by this project for the four groups and includes some Java shenanigans for being able to convert back and forth between integer values and the enum values:

```
package com.commonsware.android.permreporter;

import android.content.pm.PermissionInfo;
import java.util.ArrayList;
import java.util.HashMap;

public class PermissionRosterLoadedEvent {
    HashMap<PermissionType, ArrayList<PermissionInfo>> roster=
        new HashMap<PermissionType, ArrayList<PermissionInfo>>();

    void add(PermissionType type, PermissionInfo info) {
        ArrayList<PermissionInfo> list=roster.get(type);

        if (list==null) {
            list=new ArrayList<PermissionInfo>();
            roster.put(type, list);
        }

        list.add(info);
    }

    ArrayList<PermissionInfo> getListForType(PermissionType type) {
        return(roster.get(type));
    }
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionRosterLoadedEvent.java](#))

run() then posts the PermissionRosterLoadedEvent on the event bus.

The Rest of the Sample

Of course, having a PermissionLoadThread and PermissionRosterLoadedEvent in isolation is not especially useful. Something needs to start the thread and something needs to consume the event. All of that is handled by the sample app's UI layer.

The Activity and ViewPager

The MainActivity has a ViewPager, along with [a third-party tab implementation](#). onCreate() sets up a PermissionTabAdapter as the PagerAdapter and kicks off the PermissionLoadThread:

```
package com.commonware.android.permreporter;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.ViewPager;
import io.karim.MaterialTabs;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        pager.setAdapter(new PermissionTabAdapter(this, getFragmentManager()));

        MaterialTabs tabs=(MaterialTabs)findViewById(R.id.tabs);
        tabs.setViewPager(pager);

        new PermissionLoadThread(this).start();
    }
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonware/android/permreporter/MainActivity.java](#))

PermissionTabAdapter sets up four tabs, one per PermissionType, with labels pulled from string resources, and with instances of PermissionListFragment as the tab contents:

```
package com.commonware.android.permreporter;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class PermissionTabAdapter extends FragmentPagerAdapter {
    private static final int[] TITLES={
        R.string.normal,
        R.string.dangerous,
        R.string.signature,
        R.string.other};
    private final Context ctxt;

    public PermissionTabAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);

        this.ctxt=ctxt;
    }
}
```

ADVANCED PERMISSIONS

```
}

@Override
public int getCount() {
    return(4);
}

@Override
public Fragment getItem(int position) {
    return(PermissionListFragment.newInstance(PermissionType.forValue(position)));
}

@Override
public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
}
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionTabAdapter.java](#))

The `PermissionListFragment` instances are provided the `PermissionType` associated with their position in the `ViewPager`, courtesy of the `forValue()` lookup method implemented on `PermissionType`

The Tab Content

`PermissionListFragment` uses the factory method pattern to hold onto that `PermissionType` in the arguments `Bundle`, so it survives a configuration change:

```
public class PermissionListFragment extends ListFragment {
    private static final String KEY_TYPE="type";

    static PermissionListFragment newInstance(PermissionType type) {
        PermissionListFragment frag=new PermissionListFragment();
        Bundle args=new Bundle();

        args.putSerializable(KEY_TYPE, type);
        frag.setArguments(args);

        return(frag);
    }
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionListFragment.java](#))

The `PermissionListFragment` registers for events on the event bus in `onResume()` and unregisters in `onPause()`:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().registerSticky(this);
}
}
```

ADVANCED PERMISSIONS

```
@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionListFragment.java](#))

By using sticky events with greenrobot's EventBus, we do not have to worry about configuration changes, as we can pick up the last-delivered PermissionRosterLoadedEvent after the change.

Speaking of that event, there is an onLoadMainThread() method to pick up that PermissionRosterLoadedEvent, sort the permissions by name, and populate the ListView associated with this ListFragemnt:

```
public void onLoadMainThread(PermissionRosterLoadedEvent event) {
    PermissionType type=(PermissionType)getArguments().getSerializable(KEY_TYPE);
    ArrayList<PermissionInfo> perms=event.getListForType(type);

    if (perms!=null && perms.size(>)0) {
        Collections.sort(perms, new Comparator<PermissionInfo>() {
            @Override
            public int compare(PermissionInfo one, PermissionInfo two) {
                return (one.name.compareTo(two.name));
            }
        });

        setListAdapter(new PermissionAdapter(perms));
    }
    else {
        setListAdapter(new PermissionAdapter(new ArrayList<PermissionInfo>()));
        setEmptyText(getActivity().getString(R.string.msg_no_perms));
    }
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionListFragment.java](#))

The permissions are shown via a PermissionAdapter, which just uses the permission name for the contents:

```
private class PermissionAdapter extends ArrayAdapter<PermissionInfo> {
    PermissionAdapter(ArrayList<PermissionInfo> perms) {
        super(getActivity(), android.R.layout.simple_list_item_1, perms);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);
        TextView tv=(TextView)result.findViewById(android.R.id.text1);

        tv.setText(getItem(position).name);
    }
}
```

ADVANCED PERMISSIONS

```
return(result);  
}  
}
```

(from [Permissions/PermissionReporter/app/src/main/java/com/commonsware/android/permreporter/PermissionListFragment.java](#))

This is required because `PermissionInfo` lacks a useful `toString()` implementation, so a simple `ArrayAdapter` is insufficient.

The Results

Running the app gives you four tabs for the four different `PermissionType` values:

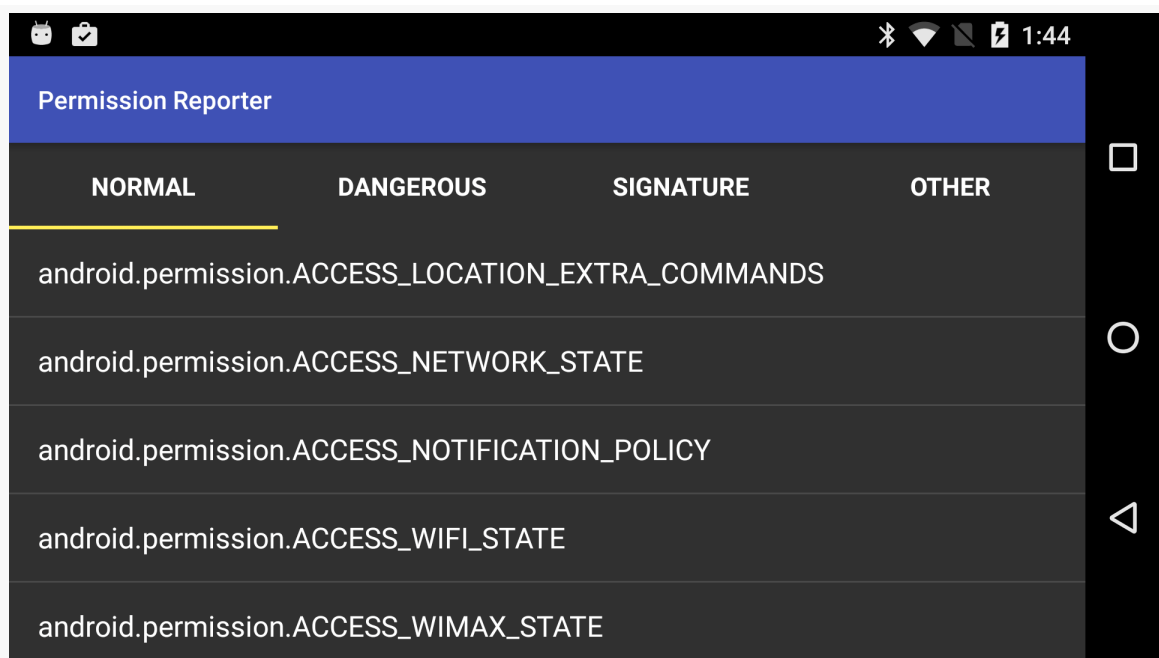

Figure 725: PermissionReporter, Normal Tab, on Android 6.0

The fourth tab, for “other” permissions, is typically empty:

ADVANCED PERMISSIONS

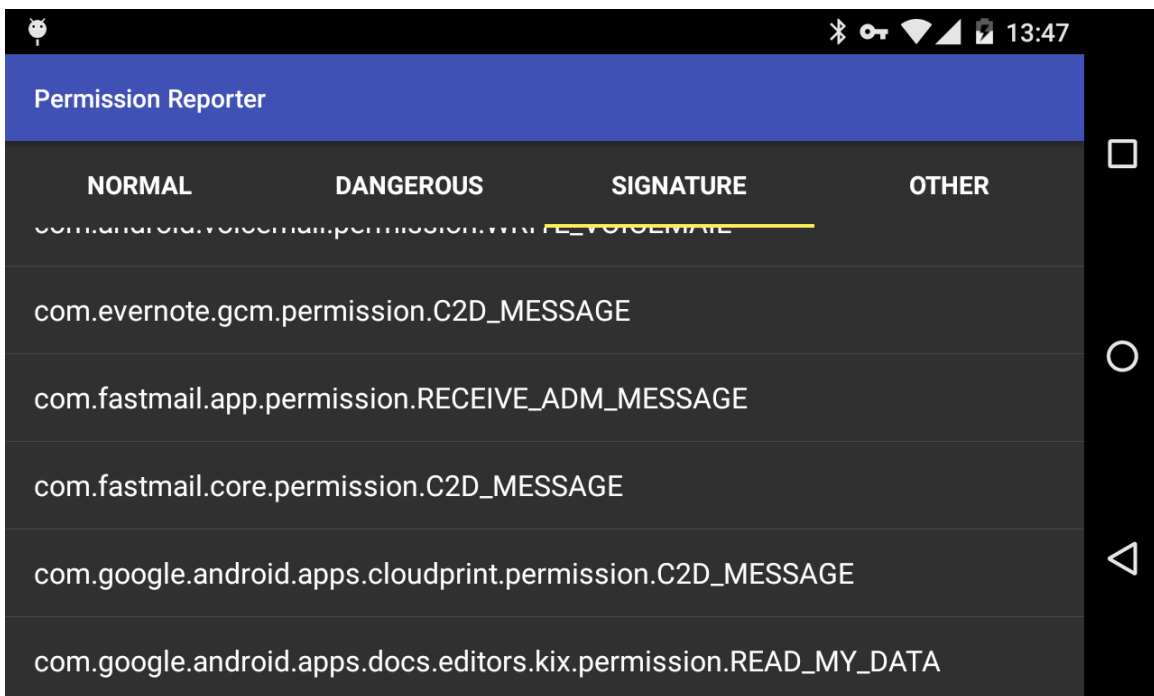

Figure 726: PermissionReporter, Other Tab, on Android 6.0

The roster will include both system permissions, Play Services-defined permissions, and third-party permissions:

Restricted Profiles and UserManager

Android 4.2 introduced the concept of having multiple distinct users of a tablet. Each user would get their own portion of internal and external storage, as if they each had their own tablet.

Android 4.3 extends this a bit further, with the notion of setting up restricted profiles. As the name suggests, a restricted profile is restricted, in terms of what it can do on the device. Some restrictions will be device-wide (e.g., can the user install apps?), and some restrictions will be per-app. You can elect to allow your app to be restricted, where you define the possible ways in which your app can be restricted, and the one setting up the restricted profile can then configure the desired options for some specific profile.

This chapter will explain how users set up these restricted profiles, what you can learn about the device-wide restrictions, and how you can offer your own restrictions for your own app.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on files](#) and its [section on multiple user accounts](#).

Android Tablets and Multiple User Accounts

The theory is that tablets are likely to be shared, whether among family members, among team members in a business, or similar sorts of group settings. There are three levels of “user” in an Android 4.3+ tablet that we will need to consider.

Primary User

The primary user is whoever first set up the tablet after initial purchase. In a family, this is probably a parent; in a corporate setting, this might be an IT administrator.

Prior to Android 4.2, there was only one user per device, and that user could (generally) do anything. In Android 4.2+, the primary user holds this role.

One thing that the primary user can do is set up other users, via the Users option in the Settings app:

Figure 727: Users Screen in Settings

Tapping the “Add user or profile” entry allows the primary user to set up another user or restricted profile:

RESTRICTED PROFILES AND USERMANAGER

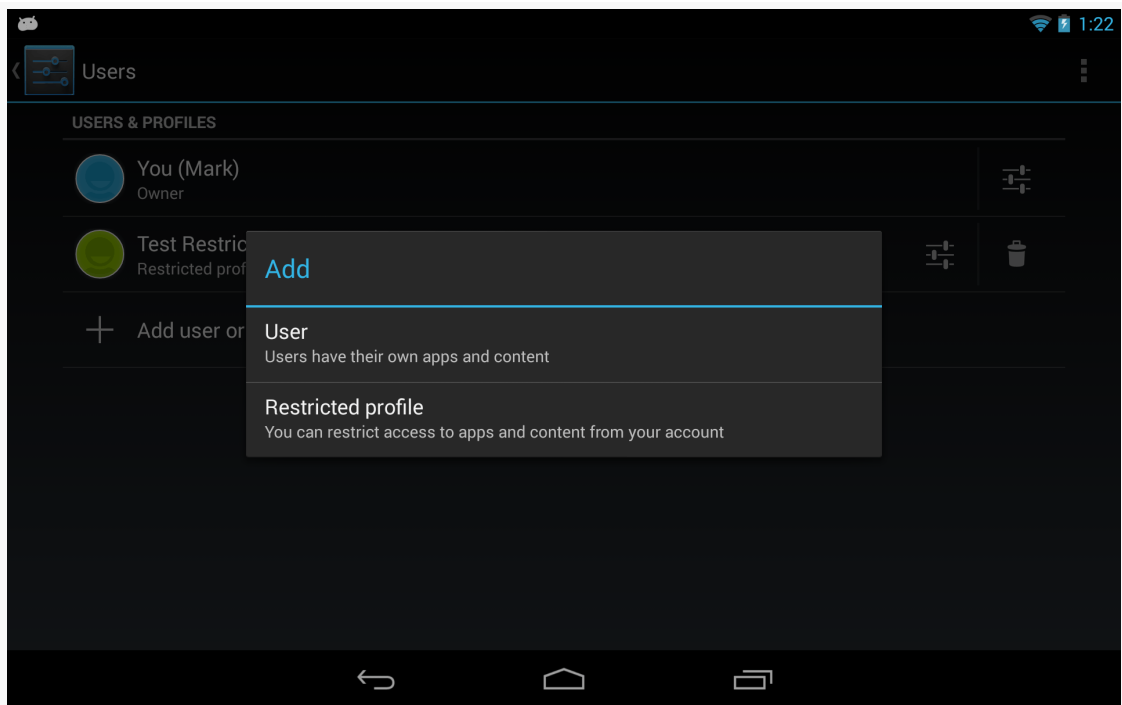

Figure 728: Add Dialog in Users Screen in Settings

Secondary User

Choosing “User” from the Add dialog will define a secondary user of the device. This user has much of the same control as the primary user, in terms of being able to install and run whatever apps are desired.

RESTRICTED PROFILES AND USERMANAGER

Figure 729: Add New User Warning Dialog in Users Screen in Settings

Restricted Profile

A restricted profile is akin to a secondary user, in that it gets its own separate portion of internal and external storage. Beyond that, though, the primary user can further configure what the restricted profile can access:

RESTRICTED PROFILES AND USERMANAGER

Figure 730: Restricted Profile Configuration Screen in Settings

The bulk of the restricted profile configuration screen is a list of apps, with Switch widgets to allow the primary user to allow or deny access to each app.

Some apps will have the “settings” icon to the left of the Switch. Tapping that will either bring up a dedicated activity for restricting operations within that app, or it will add new rows to the list with individual restriction options for that app. For example, tapping the settings icon for the Settings app adds a row where the primary user can block location sharing:

RESTRICTED PROFILES AND USERMANAGER

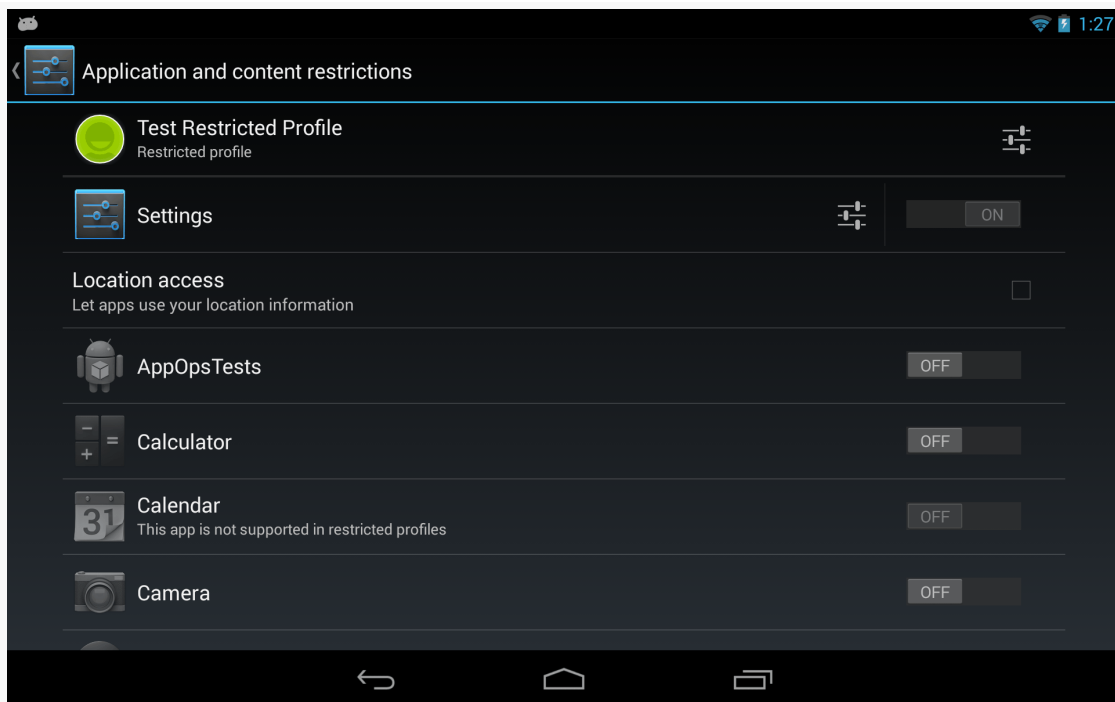

Figure 731: Location Sharing Restrictions

The “settings” icon in the first row, for the profile itself, will allow the primary user to control things for the entire profile, notably its name.

Switching to the restricted profile (e.g., via the lockscreen) will show the constrained set of available apps:

Figure 732: Apps in a Restricted Profile

Determining What the User Can Do

Your app can find out what device-level restrictions were placed on the current user by means of the UserManager system service. Specifically, as you can see in MainActivity of the [RestrictedProfiles/Device](#) sample project, all you need to do is:

- Acquire an instance of a UserManager by calling `getSystemService()` on a Context, passing in `USER_SERVICE` as the service's name
- Calling `getUserRestrictions()` on the UserManager:

```
package com.commonware.android.profile.device;

import android.app.Activity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

RESTRICTED PROFILES AND USERMANAGER

```
UserManager mgr=(userManager) getSystemService(USER_SERVICE);
Bundle restrictions=mgr.getUserRestrictions();

if (restrictions.keySet().size() > 0) {
    setContentView(R.layout.activity_main);

    RestrictionsFragment f=
        (RestrictionsFragment) getFragmentManager().findFragmentById(R.id.contents);

    f.showRestrictions(restrictions);
}
else {
    Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
        .show();
    finish();
}
}
```

(from [RestrictedProfiles/Device/app/src/main/java/com/commonsware/android/profile/device/MainActivity.java](#))

`getUserRestrictions()` returns a `Bundle`, whose keys are documented on `UserManager` for various device-level restrictions that theoretically can be placed on the user. Here, “theoretically” means that while `UserManager` documents several `DISALLOW_*` constants, only two seem to be directly accessible to the primary user for configuration via `Settings`:

- `DISALLOW_MODIFY_ACCOUNTS`, to prevent a restricted profile from, among other things, modifying restricted profiles
- `DISALLOW_SHARE_LOCATION`, to prevent the apps run in this restricted profile from gathering location data

`MainActivity` examines the `Bundle` and, if it is empty, just displays a `Toast` and exits via `finish()`. This is the behavior you will see if you run this sample app on a non-restricted profile, such as the primary user. If, however, the `Bundle` has one or more keys, we inflate an `activity_main` layout that contains a `RestrictionsFragment` in a `<fragment>` element:

```
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/contents"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    class="com.commonsware.android.profile.device.RestrictionsFragment" />
```

(from [RestrictedProfiles/Device/app/src/main/res/layout/activity_main.xml](#))

We then retrieve the `RestrictionsFragment` from the `FragmentManager` and call `showRestrictions()` on it, passing in the `Bundle`.

RESTRICTED PROFILES AND USERMANAGER

RestrictionsFragment is a ListFragment employing a custom RestrictionsAdapter. The RestrictionsAdapter wraps around the Bundle and an ArrayList of its keys. The RestrictionsAdapter constructor creates the ArrayList by sorting the keySet() of the Bundle. getView() on RestrictionsAdapter lets the superclass handle inflating the row (android.R.layout.simple_list_item_1), then puts an icon on the right side by using setCompoundDrawablesWithIntrinsicBounds(), which can tuck a drawable resource onto any of the four sides of a TextView.

The resulting list will show green icons for keys where the Bundle has stored a true Boolean value, and a red icon for false:

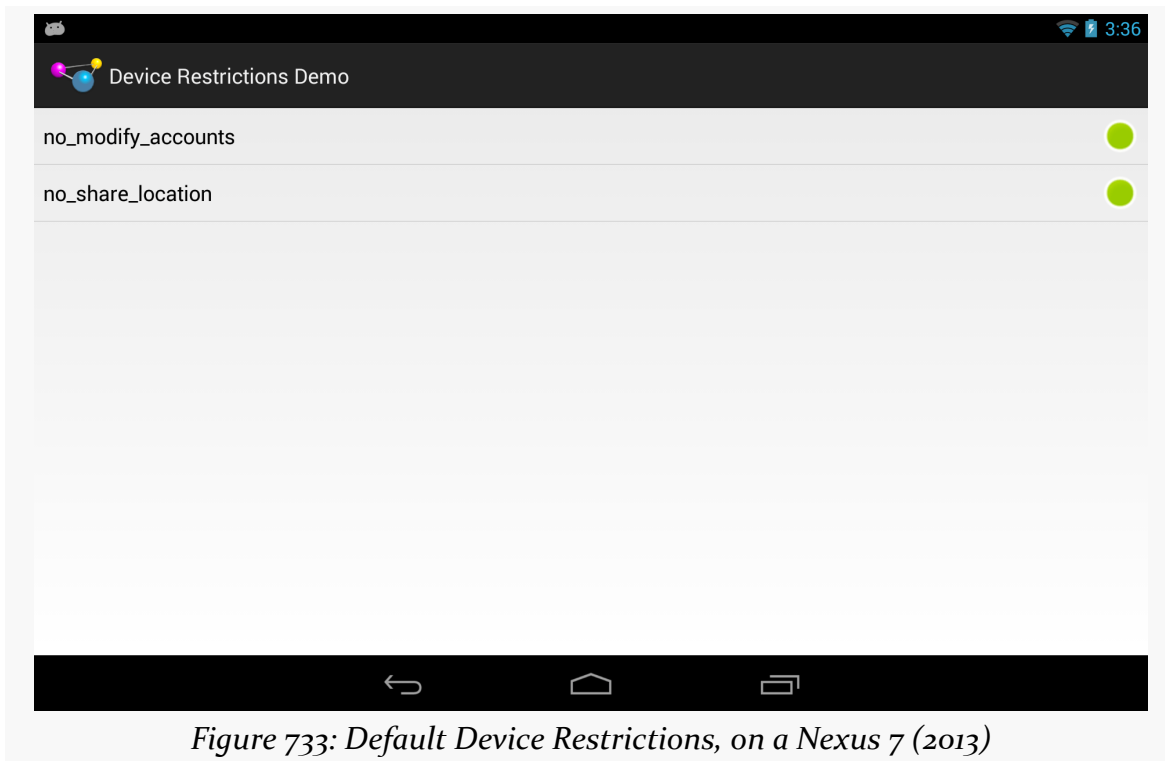

Figure 733: Default Device Restrictions, on a Nexus 7 (2013)

Since the keys are negative in tone (e.g., DISALLOW_MODIFY_ACCOUNTS), true means that the restriction is enforced and the underlying operation (e.g., modifying accounts) *cannot* be done.

Impacts of Device-Level Restrictions

Your app's functionality may be limited by these device-level restrictions. This section outlines some of the results you should expect from a restricted profile.

Restricting Location Access

If a restricted profile is prevented from sharing the device's location with apps, those apps simply will not receive location updates. There is no good way to detect this via the location API (e.g., `isProviderEnabled()` returns `true`), so you will have to detect this via `getUserRestrictions()` on `UserManager` as noted above.

Uninstalling Apps

Even without specific configuration, the restricted profile can only uninstall apps that they are available to that profile. However, since apps are really shared between profiles, this only removes that app from the restricted profile; it does not actually uninstall the app from the device as a whole.

Enabling Custom Restrictions

As noted earlier, the list of apps that is shown on the restricted profile configuration screen in Settings can have “settings” icons. The Settings app itself will have a settings icon, to allow the primary user to configure device-level restrictions.

But, what if you want *your* app to have such a settings icon? Maybe it makes sense for your app to allow the primary user to restrain restricted profiles from doing certain things within your app:

- Block in-app purchases
- Only show certain categories of content, not the full roster
- Only allow operation during certain times of the day

The means by which the Settings app restricts profiles is also available to you. You can declare to Android what aspects of your app can be restricted. Android will then collect that restriction data for you. Your app, at runtime, can then determine what restrictions are in place (if any) and take appropriate steps.

All of this will be illustrated using the [RestrictedProfiles/App](#) sample project.

Stating Your Restrictions

The biggest thing that you need to do to restrict your app is teach Android how to collect restrictions. In other words, you need to tell Android what to do when the user taps that settings icon in the restricted profile entry for your app.

You have two major options:

- Provide a list of the restrictions that Android should render and collect itself, or
- Provide an Intent that can be used to start up an activity of your own design where you collect those restrictions

Either approach will require you to set up a manifest-registered BroadcastReceiver, set to respond to the `android.intent.action.GET_RESTRICTION_ENTRIES` action:

```
<receiver android:name="RestrictionEntriesReceiver">
  <intent-filter>
    <action android:name="android.intent.action.GET_RESTRICTION_ENTRIES"/>
  </intent-filter>
</receiver>
```

(from [RestrictedProfiles/App/app/src/main/AndroidManifest.xml](#))

That BroadcastReceiver will be called with `sendOrderedBroadcast()`, not so much to affect ordering, but to allow the BroadcastReceiver to send back a result via its `setResultExtras()` method. This provides a `Bundle` that the broadcaster can eventually retrieve, in this case providing details of what restrictions we wish to collect from the primary user to restrict the profile.

Option #1: RestrictionEntry List

To collect restrictions the way the Settings app does — with restriction rows appearing below your app in the restricted profile screen in Settings – your BroadcastReceiver will need to put an entry into the return `Bundle`, under the key of `EXTRA_RESTRICTIONS_LIST` (a constant defined on the Intent class). The value needs to be an `ArrayList` of `RestrictionEntry` objects, with each `RestrictionEntry` describing one restriction to collect.

Another thing that the `RestrictionEntry` objects contain is their current value. Android itself retains these values and supplies them to your BroadcastReceiver via an `EXTRA_RESTRICTIONS_BUNDLE` extra on the incoming Intent. Your app needs to

RESTRICTED PROFILES AND USERMANAGER

use those current values when constructing its list of `RestrictionEntry` objects to return.

So, let's take a look at `RestrictionEntriesReceiver`, the receiver we have set up to handle the `android.intent.action.GET_RESTRICTION_ENTRIES` action for this sample app.

The entry point for `RestrictionEntriesReceiver` is `onReceive()`, as it is for any basic `BroadcastReceiver`:

```
@Override
public void onReceive(Context ctxt, Intent intent) {
    Bundle current=
        (Bundle)intent.getParcelableExtra(Intent.EXTRA_RESTRICTIONS_BUNDLE);
    ArrayList<RestrictionEntry> restrictions=
        new ArrayList<RestrictionEntry>();

    restrictions.add(buildBooleanRestriction(ctxt, current));
    restrictions.add(buildChoiceRestriction(ctxt, current));
    restrictions.add(buildMultiSelectRestriction(ctxt, current));

    Bundle result=new Bundle();

    result.putParcelableArrayList(Intent.EXTRA_RESTRICTIONS_LIST,
        restrictions);

    setResultExtras(result);
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java](#))

In `onReceive()`, `RestrictionEntriesReceiver` pulls out the `Bundle` of current restrictions, by retrieving the `EXTRA_RESTRICTIONS_BUNDLE` extra from the `Intent` passed into `onReceive()`. Note that this `Bundle` could very well be empty, if this is the first time we are being asked for restrictions.

`RestrictionEntriesReceiver` creates an empty `ArrayList` of `RestrictionEntry` objects, then calls a series of builder methods to create a total of three such `RestrictionEntry` objects, adding each to the list. `onReceive()` goes on to create a `Bundle` representing the results to be returned, packages the `ArrayList` in that `Bundle` under the `EXTRA_RESTRICTIONS_LIST` key, and returns that `Bundle` to the caller by means of `setResultExtras()`.

The three builder methods are each responsible for defining a single `RestrictionEntry`, including populating it with the current value from the current `Bundle`.

RESTRICTED PROFILES AND USERMANAGER

There are three types of `RestrictionEntry`, for boolean, single-selection lists (“choice”), and multi-selection lists. The `RestrictionEntry` constructor takes two parameters:

- The `String` key under which we will later retrieve this restriction value
- The current value of the restriction

The current value is:

- A boolean for boolean restrictions
- A `String` for choice restrictions
- A `String` array for multi-select restrictions

Our first builder, `buildBooleanRestriction()`, populates and returns a `RestrictionEntry` designed to collect a boolean value from the primary user, via a `CheckBox`:

```
private RestrictionEntry buildBooleanRestriction(Context ctxt,
                                                Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_BOOLEAN,
                            current.getBoolean(RESTRICTION_BOOLEAN,
                                                false));

    entry.setTitle(ctxt.getString(R.string.boolean_restriction_title));
    entry.setDescription(ctxt.getString(R.string.boolean_restriction_desc));

    return(entry);
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java](#))

`buildBooleanRestriction()` retrieves the current value from current `Bundle` to use with the `RestrictionEntry` constructor. In this case, if there is no such entry in the `Bundle`, the overall default value is `false`.

Each `RestrictionEntry` can have a title (`setTitle()`), supplying a string which will be displayed to describe what this restriction is. A boolean restriction can also have a description (`setDescription()`), containing another string with a bit more text. Note that, at the present time, the other two types of restrictions will ignore any description that you include. Also note that the values supplied to `setTitle()` and `setDescription()` need to be strings, and so if you wish to use a string resource, you will need to get the actual string value yourself via `getString()`.

The remaining two builder methods have a similar structure:

RESTRICTED PROFILES AND USERMANAGER

```
private RestrictionEntry buildChoiceRestriction(Context ctxt,
                                                Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_CHOICE,
                            current.getString(RESTRICTION_CHOICE));

    entry.setTitle(ctxt.getString(R.string.choice_restriction_title));
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);

    return(entry);
}

private RestrictionEntry buildMultiSelectRestriction(Context ctxt,
                                                      Bundle current) {
    RestrictionEntry entry=
        new RestrictionEntry(RESTRICTION_MULTI,
                            current.getStringArray(RESTRICTION_MULTI));

    entry.setTitle("A Multi-Select Restriction");
    entry.setChoiceEntries(ctxt, R.array.display_values);
    entry.setChoiceValues(ctxt, R.array.restriction_values);

    return(entry);
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionEntriesReceiver.java](#))

As with a `ListPreference`, you provide two string arrays to the `RestrictionEntry`, representing the values the primary user sees (`setChoiceEntries()`) and the corresponding values to be supplied to your app based upon the choice(s) (`setChoiceValues()`). You can supply these either as Java string arrays or as `<string-array>` resources – `RestrictionEntriesReceiver` goes with the latter approach.

Option #2: Custom Restriction Activity

It may be that what you want to collect, in terms of restrictions, cannot readily be represented in the form of `Switch` widgets and list dialogs. For example, to restrict use of your app based on time, it would be nice to use a `TimePickerDialog` or the equivalent.

The alternative to returning an `EXTRA_RESTRICTIONS_LIST` roster of `RestrictionEntry` objects from your `BroadcastReceiver` is to have the result `Bundle` contain `EXTRA_RESTRICTIONS_INTENT`. This key should point to an `Intent` that identifies the activity that you want to start up when the user taps the settings icon. Android will call `startActivityForResult()` on that `Intent` when the user taps on the settings icon.

RESTRICTED PROFILES AND USERMANAGER

Your job is to collect the restrictions from the user, using the `EXTRA_RESTRICTIONS_BUNDLE` from the incoming Intent to pre-populate your activity, if desired. When the user is done, you should call `setResult()`, passing in an Intent that contains another `EXTRA_RESTRICTIONS_BUNDLE` with the revised data, or optionally a `EXTRA_RESTRICTIONS_LIST` (with the `RestrictionEntry` objects containing the values to be used).

What the Primary User Sees

Given the `RestrictionEntriesReceiver` described above, when the primary user goes to configure a restriction profile, your app will appear with a settings icon next to it:

Figure 734: Restricted Profile, Showing App Settings Icon

Tapping that settings icon will “unfold” and display the restrictions that you configured via the `RestrictionEntry` objects:

RESTRICTED PROFILES AND USERMANAGER

Figure 735: Restricted Profile, Showing App Restrictions

The primary user can then interact with your restrictions, toggling checkboxes and popping up the list dialogs:

RESTRICTED PROFILES AND USERMANAGER

Figure 736: Restricted Profile, Showing Choice Restriction

Figure 737: Restricted Profile, Showing Multi-Select Restriction

Finding Out the Current Restrictions

Now, the rest of your app needs to find out what restrictions are placed upon it, so behavior can be tailored accordingly. To do this, call `getApplicationRestrictions()` on `UserManager`, passing in your package name, as seen here in `MainActivity`:

```
package com.commonware.android.profile.app;

import android.app.Activity;
import android.os.Bundle;
import android.os.UserManager;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        UserManager mgr=(UserManager)getSystemService(USER_SERVICE);
        Bundle restrictions=
            mgr.getApplicationRestrictions(getPackageName());

        if (restrictions.keySet().size() > 0) {
            setContentView(R.layout.activity_main);

            RestrictionsFragment f=
                (RestrictionsFragment)getFragmentManager().findFragmentById(R.id.contents);

            f.showRestrictions(restrictions);
        }
        else {
            Toast.makeText(this, R.string.no_restrictions, Toast.LENGTH_LONG)
                .show();
            finish();
        }
    }
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonware/android/profile/app/MainActivity.java](#))

This `Bundle` could be empty, or it could have values specified by the primary user to restrict the profile that is running your app.

In the case of this sample, we once again set up a `RestrictionsAdapter` to show the results, if the `Bundle` is not empty. However, our adapter is a bit more complicated, as there are more than boolean restrictions now. `getView()` has been updated to handle all three possible restrictions, showing the icon for the boolean restriction, and showing the value(s) from the lists in the other restrictions:

```
package com.commonware.android.profile.app;

import android.app.ListFragment;
import android.os.Bundle;
```

RESTRICTED PROFILES AND USERMANAGER

```
import android.text.TextUtils;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.TextView;
import java.util.ArrayList;
import java.util.Collections;

public class RestrictionsFragment extends ListFragment {
    public void showRestrictions(Bundle restrictions) {
        setListAdapter(new RestrictionsAdapter(restrictions));
    }

    class RestrictionsAdapter extends ArrayAdapter<String> {
        Bundle restrictions;

        RestrictionsAdapter(Bundle restrictions) {
            super(getActivity(), android.R.layout.simple_list_item_1,
                new ArrayList<String>());

            ArrayList<String> keys=
                new ArrayList<String>(restrictions.keySet());

            Collections.sort(keys);
            addAll(keys);

            this.restrictions=restrictions;
        }

        @Override
        public View getView(int position, View convertView, ViewGroup parent) {
            TextView row=
                (TextView)super.getView(position, convertView, parent);
            String key=getItem(position);

            if (RestrictionEntriesReceiver.RESTRICTION_BOOLEAN.equals(key)) {
                int icon=
                    restrictions.getBoolean(key) ? R.drawable.ic_true
                    : R.drawable.ic_false;

                row.setCompoundDrawablesWithIntrinsicBounds(0, 0, icon, 0);
            }
            else if (RestrictionEntriesReceiver.RESTRICTION_CHOICE.equals(key)) {
                row.setText(String.format("%s (%s)", key,
                    restrictions.getString(key)));
            }
            else {
                String value=
                    TextUtils.join(" | ", restrictions.getStringArray(key));

                row.setText(String.format("%s (%s)", key, value));
            }

            return(row);
        }
    }
}
```

(from [RestrictedProfiles/App/app/src/main/java/com/commonsware/android/profile/app/RestrictionsFragment.java](https://commonsware.com/android/profile/app/RestrictionsFragment.java))

The result, when run on a restricted profile with restrictions placed upon our app, is to show those restrictions:

Figure 738: App Restrictions Demo, on a Restricted Profile

Implicit Intents May Go “Boom”

The primary user of a tablet, when setting up a restricted profile, can control what apps are available to that profile. In many cases, if the user is setting up a restricted profile in the first place, the list of apps available to that profile will be fairly limited, such as only allowing a young child to access a few games and educational apps.

`startActivity()` always has the chance of throwing an `ActivityNotFoundException`. However, for certain Intent actions, we often ignore this possibility, because we are certain that there will be an app that can handle our request:

- All Android devices have Web browsers, right?
- All Android devices have some sort of mapping application, right?
- All Android devices let you pick a contact, right?

RESTRICTED PROFILES AND USERMANAGER

Now, with restricted profiles, you will need to deal with the `ActivityNotFoundException` case all of the time. You have three basic approaches for this:

1. Wrap all `startActivity()` and `startActivityForResult()` calls in a try/catch block that catches `ActivityNotFoundException` and intelligently handle the problem
2. Use `PackageManager` and `resolveActivity()` *before* trying to start the activity, where if `resolveActivity()` returns null, you know that there is no activity available to handle your desired operation
3. Switch out some of your `startActivity()` and `startActivityForResult()` calls for implementations in your app (e.g., embed [Maps V2](#) rather than try to launch a potentially-nonexistent activity)

You might consider implementing a `safeStartActivity()` utility method that wraps up your particular plan, so you can debug it once.

Miscellaneous Security Techniques

This chapter outlines some additional security measures that you can consider for your applications that do not necessarily warrant a full chapter on their own at this time.

In other words, it's just a pile of interesting security stuff.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. In addition, you should review the [app signing chapter](#) if you are unfamiliar with the signing process.

Public Key Validation

We sign our apps with signing keys all the time. By default, we are signing with a so-called “debug signing key”, created automatically by the build tools. For production, we sign with a different signing key. The primary use of that signing key is to determine equivalence of authorship:

- Is this APK, representing an upgrade to an already-installed app, signed by the same signing key that signed that app?
- Is this APK, that requests firmware-defined signature-level permissions, signed by the same signing key that signed the firmware?

However, as it turns out, information about the public key that signed an APK is visible to us, for our own APK as well as for any other APK on the device. We can leverage that to help determine whether a given APK was signed by something we

recognize. This goes above and beyond using Android's built-in signature-based defenses (e.g., using a custom signature-level permission).

Scenarios

There are several scenarios in which we might imagine that we could employ our own public key validation. How well the technique will work, though, depends on what we are checking and the nature of the attack we are defending against.

Checking Yourself

You might consider checking your own app's public key. After all, if your app is not signed with your production signing key, something very strange is going on, and the natural reaction is that "something strange" is unlikely to be a good thing for you.

However, there are some issues here.

First and foremost, checking your own signing key assumes that whatever caused you to *not* be signed by that key did not also modify your validation algorithm. For example, suppose that you validate your signing key to determine if somebody perhaps reverse-engineered and modified your app, perhaps to remove some license checks. This will only catch an attacker that removed the licensing checks and did not *also* remove your signature validation, or modify the validation to use the attacker's signing key. While it is possible that an attacker will modify one part but not another, it remains unclear how well this defense will work in practice.

Also, bear in mind that you, as a developer, may be opting into services that intentionally change your app's signature. Various providers will "wrap" your app, whether for interstitial ad banners or for quasi-DRM. There are three possible ways that they wrap your app:

1. They sign it with their signing key, which means that your runtime validation of the key will fail, as your app is now signed by their key, not yours. This is also *very* risky, as if for whatever reason you are no longer able to use their service (e.g., they go out of business), you may have difficulty in upgrading your app, as you will not have the right key to use.
2. They sign it with *your* signing key, either one that you upload, or one that they generate for you. In this case, your runtime public key validation logic could still work. On the other hand, now this other firm is perfectly capable

- of upgrading your app, or shipping other apps, signed with your production signing key, and this has its own set of risks.
3. They allow you to download the “wrapped” app and have you sign it yourself with your own signing key. This is the best alternative from a security standpoint, but it is the most tedious, as now you have additional work to do to publish your app.

Checking Arbitrary Other Apps

What will tend to be more reliable is to check *other* applications’ public keys. While they might have been cracked, it is unlikely that the same attacker also attacked *your* app, and so you can help detect problems in others.

For example, let us consider a specific scenario: a client-side JAR for integration to a third-party app.

This book outlines many forms of IPC, from content providers to remote services to broadcast Intent objects. If you are creating an app that offers such IPC endpoints, you may wish to consider also shipping a JAR to make using those endpoints a bit easier. You might create a library that handles all of the details of sending commands to your remote service, or you might create a library that provides a wrapper around the AIDL-generated Java proxy classes for remote binding.

Another thing such a JAR could do is check the integrity of your app. The JAR’s code is in the client’s app, not yours, and while your app might be cracked, the client’s app might not. You could check the validity of the public key of your own app from the client’s app, and fail if there is a detected problem.

This might be especially important depending upon the nature of the app and the JAR that is providing access to it. If the app is an app offering on-device payments (e.g., a Google Wallet sort of app), and the app offers an API for other apps to do payments, it is fairly important that those other apps can trust the payment app. By checking the public key, your JAR can help provide that level of trust... or at least ensure that nobody else has done something specifically to degrade that trust.

This is particularly important for avoiding device-hosted man-in-the-middle attacks on your IPC from client apps to your app. In an ideal world, you would only allow IPC via signature-level permissions, but that will not work in cases where third parties are writing the clients.

If your IPC is based upon a service (command pattern or binding pattern), if multiple service implementations all advertise the same `<intent-filter>`, Android needs to decide which service will handle the request. First, it will take into account the `android:priority` value on the `<intent-filter>` (even though this behavior is currently undocumented). For multiple services with the same priority (e.g., no priority specified), the first one that was installed will be the one that is chosen. In either case, the client has no way to know, short of examining the service's public key, whether the service that will respond to the requests for IPC is the legitimate service or something else advertising that it supports the same Intent action. Even with Android 5.0 blocking your ability to bind via an implicit Intent, you wind up with the same sorts of problems when you use `resolveService()` to try to determine the `ComponentName` of the service to make an explicit Intent for it.

The Easy Solution: SignatureUtils

The author of this book has published [the CWAC-Security library](#). Among other things, this library has a `SignatureUtils` class that makes it relatively easy for you to compare the signature of some Android app to a known good value.

All you need to do is call the static `getSignatureHash()` method, supplying some `Context` (any will do) and the package name of the app that you wish to check. This will return the SHA-256 hash of the signing key of the app, as a set of capitalized, colon-delimited hex values.

You can get the same sort of hash by running the Java 7 version of `keytool`. Hence, if the app you wish to test is another one of yours, perhaps signed with a different signing key, you can use `keytool` to get the value to compare with the result of `getSignatureHash()`. Or, during development, create a little utility app that will dump the `getSignatureHash()` value for the third-party app, and run it on a device containing a known good version of that app (i.e., one that does not appear to have been replaced by malware).

Ideally, over time, we will be able to get app developers to publish their SHA-256 hashes on their Web sites, as another means of getting a known value of the hash to compare at runtime.

If you determine that `getSignatureHash()` does *not* return the right value, this means that the app that is installed on the device is written by somebody other than the app's original author. Often times, this will mean the app has malware in it. It is up to you to determine how you wish to respond to this scenario:

- Alert the user?
- Send data back to your server, or to your analytics collection point, with details of the bad APK?
- Block usage of your app, or usage of features that depend upon the flawed third party?
- Something else?

Examining Public Keys

Under the covers, SignatureUtils uses PackageManager and related classes to examine what they somewhat erroneously refer to as “signatures”. The [MiscSecurity/SigDump](#) sample project will allow us to browse the list of installed packages, see a decoded public key on the screen for a package that we select, plus dump the “signature” as a binary file for later comparison using another app.

The UI Structure

In this sample, we use a SlidingPanelLayout for a master-detail pattern presentation, as was demonstrated in [the chapter on dealing with multiple screen sizes](#). The “master” fragment will be the list of packages; the “detail” fragment will be the decoded public key for the selected package.

The master fragment is implemented as PackagesFragment. It implements a typical ListFragment for use with the master/detail pattern, utilizing the activated state to show the context for the detail fragment. The detail will be SignatureFragment, which will display portions of the decoded public key in a TableLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:shrinkColumns="1"
    android:stretchColumns="1">

    <TableRow>

        <TextView
            android:layout_gravity="center"
            android:layout_margin="4dp"
            android:text="@string/subject"
            android:textStyle="bold"/>

        <TextView android:id="@+id/subject"/>
    </TableRow>

    <TableRow>
```

MISCELLANEOUS SECURITY TECHNIQUES

```
<TextView
    android:layout_gravity="center"
    android:layout_margin="4dp"
    android:text="@string/issuer"
    android:textStyle="bold"/>

<TextView android:id="@+id/issuer"/>
</TableRow>

<TableRow>

<TextView
    android:layout_gravity="center"
    android:layout_margin="4dp"
    android:text="@string/valid_between"
    android:textStyle="bold"/>

<TextView android:id="@+id/valid"/>
</TableRow>
</TableLayout>
```

(from [MiscSecurity/SigDump/app/src/main/res/layout/sig.xml](#))

Listing the Packages

Our PackagesFragment needs the list of packages to display. It expects the hosting activity to supply that, by using the contract pattern, and having a `getPackageList()` method on its Contract:

```
interface Contract {
    void onPackageSelected(PackageInfo pkgInfo);

    List<PackageInfo> getPackageList();
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/PackagesFragment.java](#))

The hosting activity — `MainActivity` — retrieves a `PackageManager` instance in `onCreate()`, caching it in a `mgr` data member. `getPackageList()` then calls `getInstalledPackages()` on `PackageManager`, specifically requesting to retrieve signature information via the `GET_SIGNATURES` flag. The list we get back from `getInstalledPackages()` can be in any order, so we sort the results before returning it for display purposes:

```
@Override
public List<PackageInfo> getPackageList() {
    List<PackageInfo> result=
        mgr.getInstalledPackages(PackageManager.GET_SIGNATURES);

    Collections.sort(result, new Comparator<PackageInfo>() {
        @Override
        public int compare(final PackageInfo a, final PackageInfo b) {
```

MISCELLANEOUS SECURITY TECHNIQUES

```
        return(a.packageName.compareTo(b.packageName));
    }
});

return(result);
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

Note that this is a List of PackageInfo objects, so we need an ArrayAdapter subclass to handle rendering that. Here, we have a PackageListAdapter that knows how to populate list rows using the packageName field of a PackageInfo object, plus using an activated row layout for API Level 11+ devices:

```
package com.commonsware.android.signature.dump;

import android.annotation.TargetApi;
import android.content.pm.PackageInfo;
import android.os.Build;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.TextView;

class PackageListAdapter extends ArrayAdapter<PackageInfo> {
    PackageListAdapter(PackagesFragment packagesFragment) {
        super(packagesFragment.getActivity(), getRowResourceId(),
            packagesFragment.getContract().getPackageList());
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        ((TextView)result).setText(getItem(position).packageName);

        return(result);
    }

    @TargetApi(Build.VERSION_CODES.HONEYCOMB)
    private static int getRowResourceId() {
        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
            return(android.R.layout.simple_list_item_activated_1);
        }

        return(android.R.layout.simple_list_item_1);
    }
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/PackageListAdapter.java](#))

The result is that our master list is a list of all installed packages, sorted by package name, with the detail TableLayout peeking out of the right edge when shown on a phone-sized screen:

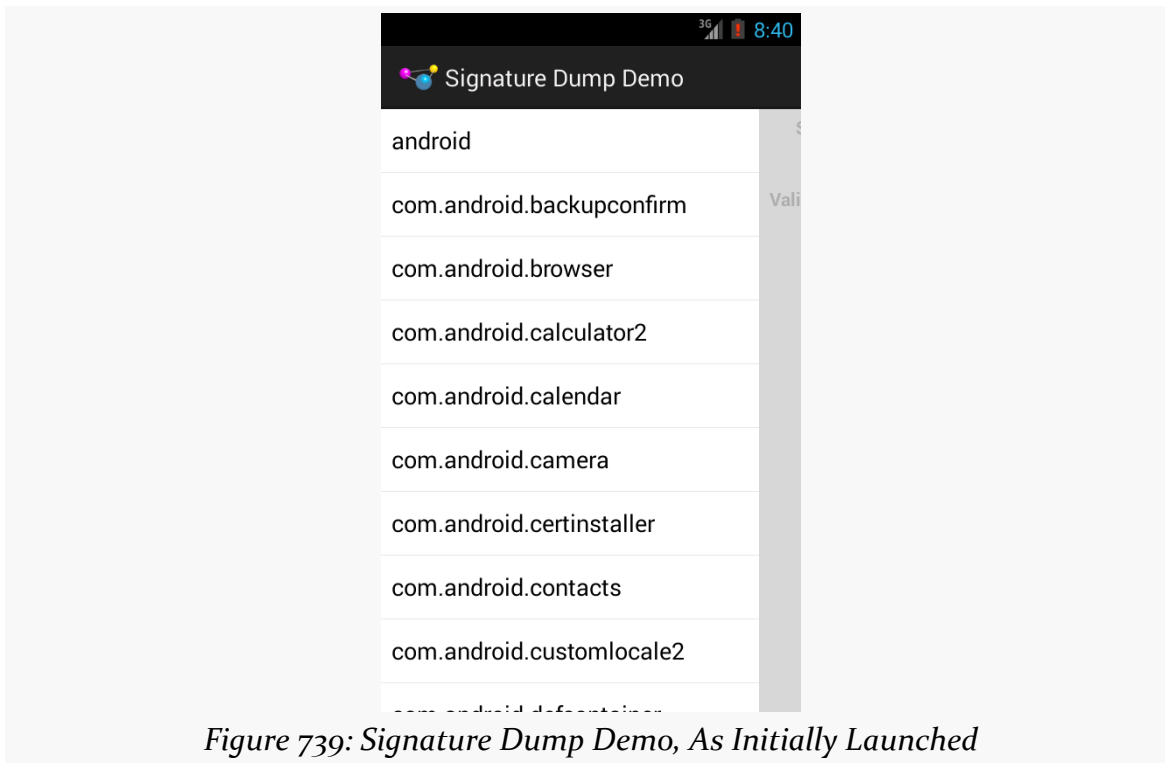

Figure 739: Signature Dump Demo, As Initially Launched

Dumping the Key

`onListItemClick()` of our `PackagesFragment` routes control to `onPackageSelected()` of the `Contract` interface, which in our case is `MainActivity`. There, we need to do some useful stuff based upon the fact that the user tapped on a particular package:

```
@Override
public void onPackageSelected(PackageInfo pkgInfo) {
    Signature[] signatures=pkgInfo.signatures;
    byte[] raw=signatures[0].toByteArray();

    sigDisplay.show(raw);
    panes.closePane();

    File output=
        new File(getExternalFilesDir(null),
            pkgInfo.packageName.replace('.', '_') + ".bin");

    new WriteThread(output, raw).start();
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/MainActivity.java](#))

MISCELLANEOUS SECURITY TECHNIQUES

First, we get the Signature array from the PackageInfo object. While this is an array, usually an app will only be signed once. Signing more than once is not especially useful, as an upgraded app needs to match the count and contents of each signature. Hence, we will only pay attention to the first signature. If you are using these techniques as the basis for your client JAR checking the public key of your app for IPC protection purposes, *and* your app is signed with multiple keys, you will want to check all of those keys.

The public key itself is represented as a byte array in the Signature. onPackageSelected() does two things with this byte array:

- Writes it to a file on external storage using a background thread, with a filename based on the app's package name, with . characters replaced by _ characters
- Passes the byte array to the detail fragment (a SignatureFragment) and updates the SlidingPanelLayout to ensure that detail fragment is now visible

Decoding the Key

SignatureFragment is mostly comprised of the show() method that MainActivity uses to pass us the byte array of the “signature” to display:

```
package com.commonware.android.signature.dump;

import android.app.Fragment;
import android.os.Bundle;
import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.TextView;
import java.io.ByteArrayInputStream;
import java.security.cert.CertificateException;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.Locale;

public class SignatureFragment extends Fragment {
    DateFormat fmt=new SimpleDateFormat("yyyy-MM-dd HH:mm:ss", Locale.US);

    @Override
    public View onCreateView(LayoutInflater inflater,
                            ViewGroup container,
                            Bundle savedInstanceState) {
        return(inflater.inflate(R.layout.sig, container, false));
    }
}
```

MISCELLANEOUS SECURITY TECHNIQUES

```
void show(byte[] raw) {
    CertificateFactory cf=null;

    try {
        cf=CertificateFactory.getInstance("X509");
    }
    catch (CertificateException e) {
        Log.e(getClass().getSimpleName(),
            "Exception getting CertificateFactory", e);
        return;
    }

    X509Certificate c=null;
    ByteArrayInputStream bin=new ByteArrayInputStream(raw);

    try {
        c=(X509Certificate)cf.generateCertificate(bin);
    }
    catch (CertificateException e) {
        Log.e(getClass().getSimpleName(),
            "Exception getting X509Certificate", e);
        return;
    }

    TextView tv=(TextView)getView().findViewById(R.id.subject);

    tv.setText(c.getSubjectDN().toString());

    tv=(TextView)getView().findViewById(R.id.issuer);
    tv.setText(c.getIssuerDN().toString());

    tv=(TextView)getView().findViewById(R.id.valid);
    tv.setText(fmt.format(c.getNotBefore()) + " to "
        + fmt.format(c.getNotAfter()));
}
```

(from [MiscSecurity/SigDump/app/src/main/java/com/commonsware/android/signature/dump/SignatureFragment.java](#))

That byte array *really* represents an X509 certificate, serialized to a byte array. `show()` goes through the work to get the `X509Certificate` object representing that same data, assuming the byte array is not corrupted somehow. Then, `show()` populates some `TextView` widgets in our `TableLayout` with the:

- The subject of the signature
- The issuer of the signature
- The range of dates in which this signature is valid

A debug signing key output will resemble:

MISCELLANEOUS SECURITY TECHNIQUES

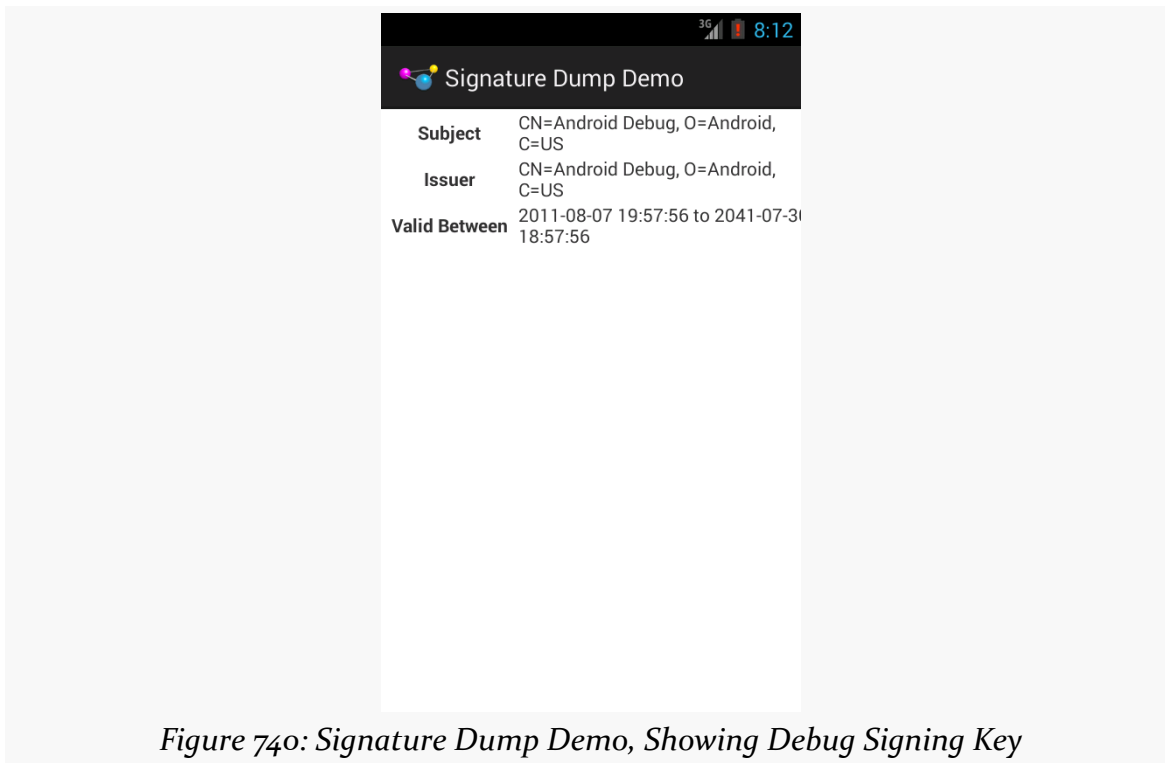

Figure 740: Signature Dump Demo, Showing Debug Signing Key

A self-signed production signing key will resemble:

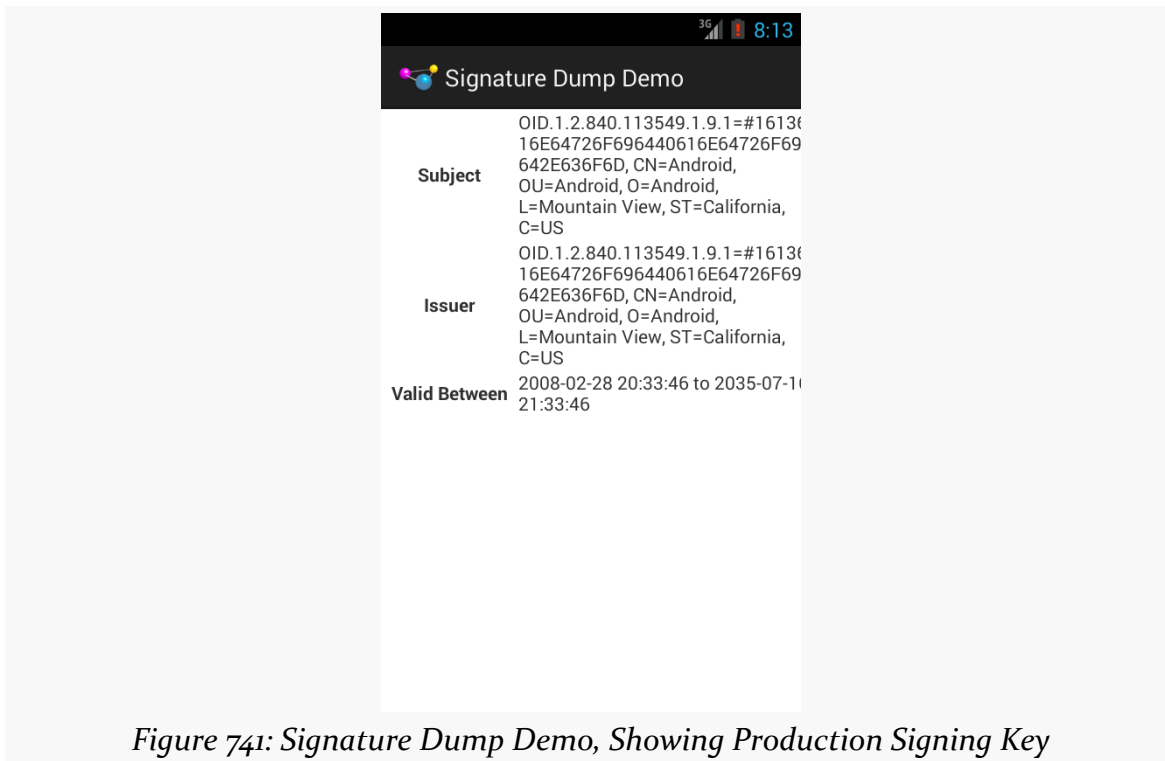

Figure 741: Signature Dump Demo, Showing Production Signing Key

A signing key created by some signing authority would have a subject that is distinct from its issuer.

Choosing Your Signing Keysize

[The documentation for app signing](#) contains a small side note about the `-keysize` parameter to `keytool`, the utility used to generate our signing keys:

The size of each generated key (bits). If not supplied, Keytool uses a default key size of 1024 bits. In general, we recommend using a key size of 2048 bits or higher.

The reason for the 2,048-bit key size recommendation is that 1,024-bit RSA (the `keytool` default) has been considered at risk for a few years.

The recent revelations about state-sponsored decryption research should be hammering this home. Even if today, forging a 1,024-bit digital signature is still impractical for all but the largest security agencies, it is well within reason that this will fall within the reach of large botnets in the not-too-distant future. Once signing

MISCELLANEOUS SECURITY TECHNIQUES

keys can be cracked, apps will be able to be replaced with hacked editions, without tripping up the signature check, or signature-level permission checks might start passing due to forged signatures.

Switching to a larger keysize is not that hard... for new apps. Just specify `-keysize 4096` when creating your production signing key, and you should be good for a long time, barring a major decryption breakthrough for RSA signatures.

For existing apps with existing signing keys, though, you cannot change the key without breaking your ability to update the app.

Create a new, stronger production signing key, as a separate key from whatever you are using for production. Make note to use that new signing key for any new apps you create. And, if you have other reasons why you are migrating an existing user base to a new app (e.g., free app for which you are now offering a paid-app option), consider using the new signing key.

If you are a consultant, and you create unique signing keys per project, just cut over to using a stronger key for new clients and projects.

And if you are [creating apps for which security is paramount](#), you might consider whether it is worthwhile to move your user base to a new version of the app with a new signing key at some point, just for the added protection.

Avoiding Accidental APIs

One place where developers create their own security problems is with “accidental APIs”.

An API, of course, is where one code base exposes some interface that another code base can use. An accidental API is when one code base does not intend to expose an interface, but does anyway, possibly to the app’s detriment.

Bear in mind that if your app becomes popular, other developers will poke and prod at it, to see if they can connect to your app by one means or another. Perhaps they want to offer features that you have not gotten to yet. Perhaps they have more nefarious aims. Regardless, making sure that other code can only work with your app the way that *you* intend for such code to work with your app.

Export Only What's Necessary

A component of your app is only reachable by a third-party app if it is exported. Otherwise, it is inaccessible to third-party apps.

(Admittedly, content providers have an exception to this rule, which we will get to shortly)

You normally do not think about exporting components, except when it comes to content providers. However, your choices for how you implement your app may lead you to accidentally export things that you did not realize were exported.

Export Defaults

The official way to declare whether or not a component is exported is to have an `android:exported` attribute for that component in the manifest (e.g., on an `<activity>` element). However, many times, we do not have such an attribute, but instead rely on the default export behavior.

Activities, services, and broadcast receivers have a simple rule for the default: if the component has an `<intent-filter>`, it is exported by default. Otherwise, it is not exported by default.

This, in turn, leads to a fairly simple development rule: only use an `<intent-filter>` and implicit Intent objects for working with your components if you *also* want third party apps to work with those components. Otherwise, do not use `<intent-filter>`, and instead communicate with your components using explicit Intent objects (e.g., the kind that take a Java class as the second constructor parameter).

For example, the classic MAIN/LAUNCHER `<intent-filter>` on your launcher activity is specifically there because you *want* a third party app — the launcher — to be able to start your activity. Most, if not all, of your other activities probably do not need an `<intent-filter>`, as they are likely to be private to your app.

The Chooser Bug

Some developers choose to still use an `<intent-filter>` and implicit Intent objects for their own private activities, yet then use `android:exported` to enforce the privacy.

MISCELLANEOUS SECURITY TECHNIQUES

This is not a good plan.

The rest of the system, notably PackageManager, does not pay much attention to `android:exported` *until the time when the component is to be used*, such as when the activity is to be started. Then, and only then, does Android realize that the component is not exported, and it fails the request, usually with a cryptic `SecurityException`.

A classic example of where this can cause problem came to light in 2012, with the UPS Mobile app. The rest of this section is an excerpt from [the author's blog post on this incident](#):

The [UPS Mobile app](#) allows you to track packages and do a handful of other things that you might ordinarily do via the UPS Web site. It generally seems to be well-regarded, but it has an annoying flaw:

It claims to be Barcode Scanner, and does a lousy job at it.

[Barcode Scanner](#), from [ZXing](#), is a favorite among Android developers for its integration possibilities. However, some people do not like having a dependence upon the Barcode Scanner app, so they grab the open source code and attempt to blend it into their own apps. This is neither endorsed nor supported by the ZXing team, but since it is open source, it is also perfectly legitimate.

However, UPS (or whoever they hired to build the app) screwed up. They not only copied the source code, but they copied the manifest entry for the scanning activity. And, their activity has:

```
<intent-filter>
  <action android:name="com.google.zxing.client.android.SCAN" />
  <category android:name="android.intent.category.DEFAULT" />
</intent-filter>
```

This means that on any device that has UPS Mobile installed, they will be an option for handling Barcode Scanner Intent objects. What happened was that the person asking the question was manually invoking `startActivityForResult()` to bring up Barcode Scanner, was getting a chooser with UPS Mobile in it, and then was crashing upon choosing UPS Mobile... because UPS Mobile declared this activity to be not exported.

Due to [this bug](#), Android will display non-exported activities in a chooser, despite the fact that they can never be successfully used by the user.

So, what should we learn from this?

First, UPS Mobile should not have used that `<intent-filter>`. As Dianne Hackborn has pointed out, your `<intent-filter>` mix [is effectively part of your app's API](#), and so you need to think long and hard about every `<intent-filter>` you publish. UPS Mobile is not Barcode Scanner and should not be advertising that they handle such Intent objects, despite the activity being not exported.

Second, UPS Mobile probably should not have had *any* `<intent-filter>` elements for this activity, if they intend to use it purely internally. They could just as easily use an explicit Intent to identify the activity and avoid all of this nonsense.

Third, the person who filed the SO question ideally would have been using ZXing's IntentIntegrator. As Sean Owen of the ZXing project noted in a comment on my answer, IntentIntegrator ensures that only Barcode Scanner or official brethren will handle any scan requests, so this problem would not have appeared.

Fourth, Android really should not be showing non-exported activities in a chooser, which means probably that PackageManager should be filtering out non-exported activities from methods like `queryIntentActivities()`, which I presume lies at the heart of the chooser.

In summary, if your component is truly private, do not have an `<intent-filter>` on it, lest you cause yourself, and your users, problems with other apps.

The ContentProvider Behavior Change

Content providers are a little different... in lots of ways. In the specific scenarios being covered here, there are two primary differences.

First, third-party apps *can* still access a provider that has `android:exported="false"`. However, they can only do so in response to some operation initiated by your application, using `android:grantUriPermissions` and flags like `FLAG_GRANT_READ_URI_PERMISSION`. A third-party app will have no *independent* access to your non-exported provider.

Second, the default value for `android:exported` not only does not depend upon `<intent-filter>` (since few providers use one), but it has changed over the years:

- For apps with `android:minSdkVersion` *and* `android:targetSdkVersion` set to 16 or lower, the provider is exported by default

- All other apps, the provider is *not* exported by default

Lint will complain about your manifest having a `<provider>` without an `android:exported` attribute.

Sanitize Your Input Extras

If you do expose one or more of your components to third-party apps, and you are supporting certain Intent extras on any Intent objects used to talk to those components, make sure that the extras' values make sense.

Even Google makes this error, as was seen in [the PreferenceActivity bug](#). PreferenceActivity supports an extra, named `:android:show_fragment`, to indicate that the activity should immediately jump to a specific fragment, rather than start at the top level of the preference navigation. The problem is that PreferenceActivity did not — and, at the time, could not — validate that the fragment to be loaded is a fragment that is *supposed* to be loaded. This would allow attackers to force apps, like Settings, to load arbitrary fragments, including those not normally accessible to the current user. This is the reason why we now need to override `isValidFragment()` in our PreferenceActivity implementations, so we can declare whether or not a particular requested fragment is a legitimate choice or not.

The equivalent behavior for a ContentProvider is to sanitize the inputs to methods like `query()`, `update()`, `openFile()`, and so on, to make sure that you do not expose something that you should not. For example, blindly accepting paths to `openFile()` could get you in trouble, if the Uri contains relative paths (e.g., `content://your.authority.here/./databases/your-private.db`), perhaps allowing third parties to get at files that you did not intend for them to access.

Secure Your Output Extras

Similarly, if you send broadcasts or otherwise use IPC to talk to third-party apps, bear in mind that others might be able to see some of that interaction, depending on the IPC in question.

The obvious case is with a broadcast Intent for an implicit Intent. Any app with a registered receiver will be able to “tune into” that broadcast and get whatever data is inside the Intent. In cases where you cannot use permissions to limit the scope of the broadcast, you need to make sure that there is nothing in the Intent that is private to the user.

Sometimes, though, non-obvious cases will emerge. For a few years, Intent extras on activities might be viewed by third-party apps that held the `GET_TASKS` permission, courtesy of the recent-tasks list. The Intent used to launch the task is available via `ActivityManager` and `getRecentTasks()`. While this specific problem was resolved in Android 4.1.1, there may be other similar scenarios lurking about.

Other Ways to Expose Data

Sometimes, we expose data to third-party apps by using standard Android APIs. We focus on the normal publisher and consumer of data using those APIs and forget about other apps that might be monitoring those communications. Or, we might not realize that one party in those communications may not have the user's best interests at heart. This section outlines some examples.

App Widgets

Any data that is put into the widgets inside of your `RemoteViews` for an app widget is visible to the home screen, lockscreen, or other app widget host. Those apps are the ones actually converting the `RemoteViews` into a view hierarchy, and they can inspect those views, reading the text in your `TextViews`, and so forth.

As a result, be careful about exposing potentially sensitive data via an app widget.

Notifications

Custom notifications also use `RemoteViews` and therefore could suffer from the same problem.

On the surface, you might not be worried quite so much about this, because the `Notification` object goes to the `NotificationManager`, for display by the OS itself.

However, as of Android 4.3 (API Level 18), apps can register to listen to added and removed notifications via a `NotificationListenerService`. Not only can such a service read the text from your `Notification`, but it can also access your `RemoteViews`. This includes any `RemoteViews` that may be generated for you by the expanded notification classes (e.g., `BigPictureStyle`).

As a result, be careful about exposing potentially sensitive data via a `Notification`.

Clipboard

Any app can retrieve text off of the clipboard. After all, that's the point behind a clipboard.

However, this does mean that you need to be careful what you put on the clipboard in the first place. The quintessential problem case is a password manager: putting a password on the clipboard for easy pasting into an app's `EditText` password field will be popular, but it allows that password to be retrieved by other apps.

You can attempt to help reduce the window of risk by clearing the clipboard after a period of time. However, bear in mind that your process might be terminated before that occurs. Also, only clear the clipboard if the clipboard text is still yours — do not clear the clipboard if another app has already put its own contents there, lest you confuse and irritate the user in the middle of some other paste operation.

ServerSocket and Kin

If you open up any sort of server-style socket connection — TCP/IP, Bluetooth, etc. — bear in mind that the Android security framework may not be able to help you much. You cannot secure a `ServerSocket` with an `android:permission` attribute, for example. It is up to you to validate whether a particular request is expected and allowed, or not.

Jacking Attacks

Jacking attacks, in general, refer to cases where what the user *thinks* they are interacting with on-screen is not *actually* what they are interacting with. Instead, something else has interposed itself between the user and the activity that the user is trying to use. That “something else” might be trying to intercept user input (tapjacking, activity jacking) or confuse the user about what is actually being interacted with (window jacking).

Classic Tapjacking

Tapjacking refers to another program intercepting and inspecting touch events that are delivered to your foreground activity (or related artifacts, such as the input method editor). At its worst, tapjackers could intercept passwords, PINs, and other private data.

The term “tapjacking” seems to have been coined by Lookout Mobile Security, in a [blog post](#) that originally demonstrated this issue.

The Problem

You may recall that there are three axes to consider with Android user interfaces. The X and Y axes are the ones you typically think about, as they control the horizontal and vertical positioning of widgets in an activity. The Z axis — effectively “coming out the screen towards the user’s eyes” — can be used in applications for sophisticated techniques, such as a pop-up panel.

Normally, you think of the Z axis within the scope of your activity and its widgets. However, there are ways to display “system alerts” – widgets that can float over the top of any activity. A Toast is the one you are familiar with, most likely. A Toast displays something on the screen, yet touch events on the Toast itself will be passed through to the underlying activity. Lookout demonstrated that it is possible to create a fully-transparent Toast. However, the lifetime of a Toast is limited (3.5 seconds maximum), which would limit how long it can try to grab touch events.

However, any application holding the `SYSTEM_ALERT_WINDOW` permission can display their own “system alerts” with custom look and custom duration. By making one that is fully transparent and lives as long as possible, a tapjacker can obtain touch events for any application in the system, including lock screens, home screens, and any standard activity.

On the surface, this might not seem terribly useful, since the `View` cannot see what is being tapped upon.

However, a savvy malware author would identify what activity is in the foreground and log that information along with the tap details and the screen size, periodically dumping that information to some server. The malware author can then scan the touch event dumps to see what interesting applications are showing up. With a minor investment – and possibly collaboration with other malware authors — the author can know what touch events correspond to what keys on various input method editors, including the stock keyboards used by a variety of devices. Loading a pirated version of the APK on an emulator can indicate which activity has the password, PIN, or other secure data. Then, it is merely a matter of identifying the touch events applied to that activity and matching them up with the soft keyboard to determine what the user has entered. Over time, the malware author can perhaps develop a script to help automate this conversion.

Hence, the on-device tapjacker does not have to be very sophisticated, other than trying to avoid detection by the user. All of the real work to leverage the intercepted touch events can be handled offline.

How to Address This

In principle, Android 4.0.3 fixed this, by preventing touch events from being delivered to two separate applications. Either the tapjacking View gets the touch event (and consumes it), or the tapjacking View does not get the touch event (and therefore does not know about it).

For Android 2.2 and 2.3 devices, you also have the option of `setFilterTouchesWhenObscured()`, which will be examined [later in this chapter](#).

Activity Jacking

In August 2014, a number of media outlets [reported](#) on a [research paper](#) and [USENIX conference presentation](#) describing a way by which your users could be tricked into providing confidential information — passwords, credit card information, and such — to a piece of malware, rather than to your app. This flew in the face of conventional wisdom, which said that the tapjacking fixes from Android 4.0.3 cleared up this sort of problem.

The paper points out that there are ways of writing malware such that:

- the malware can pop an *activity* in front of yours, and
- do so at just the right time, to mimic one of your activities, such that the user thinks that the malware’s activity is actually yours and enters the confidential data into the malware activity

The authors describe it as a UI inference attack; to keep with the theme of this chapter, this section refers to it as “activity jacking”.

The Problem

The details of how to execute the attack are rather esoteric, using lots of curious approaches to find out when an activity comes onto the screen and, more specifically, *which* activity of an app being attacked it is. Readers are encouraged to [review the paper](#) if you want details of exactly how to execute this sort of attack their way.

However, one simpler way of knowing this stuff is to implement an `AccessibilityService`. Officially, such services are supposed to help with accessibility, such as providing TalkBack-style audio announcements as the user navigates the UI by touch alone. In practice, a lot of apps use `AccessibilityService` to be able to monitor user inputs across the device and, in some cases, modify those inputs. Some password managers, for example, implement an `AccessibilityService` to help them auto-fill login dialogs. As a result, many users install and enable an `AccessibilityService` without really thinking about whether they can trust that service.

Given that you know when a particular activity appears on the screen, the attack is simple: launch your own activity that looks much like the original. The user might miss the fact that two activities just appeared, then go ahead and interact with your activity, thinking that it is from the real app. For example, you might interpose your own authentication dialog in front of the one for the banking app, thereby getting the user's PIN or passcode.

You can further take steps to try to “cover your tracks” and deal with the fact that the real activity is waiting for user input:

- If you are using an `AccessibilityService`, you can use `performGlobalAction()` to initiate a BACK button press, right after dismissing your own activity, to dismiss the original activity.
- Otherwise, you can pretend that the user input is flawed and needs to be re-entered. In the case of an authentication dialog, you can pop up a regular `AlertDialog` that says that their password was not recognized. When the user dismisses that dialog, you also `finish()` your intercepting activity, returning the user to the real activity, where they can complete the real authentication.

How to Address This

An activity jack attack has two key weaknesses:

1. The attacker cannot see the screen, because on non-buggy devices, the attacker has no means of silently capturing a screenshot of our activity as it comes into the foreground. Hence, while the attacker can create an activity that tries to mimic ours, they can only do so statically, analyzing our activity's UI on their development machine and creating their own lookalike.

MISCELLANEOUS SECURITY TECHNIQUES

2. We know that our activity has left the foreground, as we are called with `onPause()` (and perhaps other lifecycle methods, depending upon the nature of the attacker).

Hence, one defense can be to include in our activity a **secure element** that cannot be mimicked ahead of time, then **hide that element** (or our whole UI) when we are no longer in the foreground.

This concept of a secure element is not new. Some financial services Web sites have taken this approach. As part of the user setting up their online banking account, the user chooses an image from a collection of clipart. On the Web page that collects the user's passphrase, the page also shows this secure element. The user is taught that if they do not see their chosen image, then the Web page they are looking at is not really from their bank, and therefore they should not type in their passphrase.

This is not that hard to implement in Android. You too would allow the user to choose a piece of clipart, displaying that in an `ImageView` on your secure activity in `onResume()`. In `onPause()` you would hide that `ImageView` via `setVisibility(View.INVISIBLE)`. That way:

- Since the image is chosen by the user, the attacker is unlikely to mimic the same image
- Since you are hiding the image when you are not in the foreground, the attacker cannot use a transparent region in their activity to have your image "peek through" their attacking activity

As a result, if the user is paying attention, the user should see either the wrong image or no image at all, and the user should realize that they are being activity jacked and therefore fail to proceed.

You might be tempted to do something else in response to your secure activity being replaced in the foreground by another app's activity, such as pop up a warning dialog. However, there are plenty of valid scenarios when this would occur, such as an incoming phone call, and you have no reliable means of whitelisting all possible valid scenarios. There will be a high incidence of false positives, and that may not help the user. Having this as an user-selectable option is fine, but I would not go this route by default.

Window Jacking

Sometimes, the objective of the attacker is not to prevent the user from entering in information, or even to see what the user enters. Sometimes, the objective is to confuse the user, tricking them into clicking on things that they might not want to click on.

The Problem

A great example of this comes from Android 6.0's runtime permission system.

Apps with `targetSdkVersion` of 23 or higher will need to call `requestPermissions()` at various points, to ask the user to grant runtime permissions not previously granted (or granted but later revoked). That brings up a system-supplied dialog-themed activity:

Figure 742: Runtime Permission System Dialog

Perhaps the attacker wants the user to agree to the permission but fears that the user might deny it instead. The attacker could use `SYSTEM_ALERT_WINDOW` to put a *View on top of the system dialog*, replacing the real permission explanation with something seemingly benign. The user — who may not have a lot of Android

experience – clicks “Allow”, where if the user were presented with the *real* message, the user might have clicked “Deny”.

How to Address This

Quoting [the Android documentation](#):

Sometimes it is essential that an application be able to verify that an action is being performed with the full knowledge and consent of the user, such as granting a permission request, making a purchase or clicking on an advertisement. Unfortunately, a malicious application could try to spoof the user into performing these actions, unaware, by concealing the intended purpose of the view. As a remedy, the framework offers a touch filtering mechanism that can be used to improve the security of views that provide access to sensitive functionality.

To enable touch filtering, call `setFilterTouchesWhenObscured(boolean)` or set the `android:filterTouchesWhenObscured` layout attribute to `true`. When enabled, the framework will discard touches that are received whenever the view’s window is obscured by another visible window. As a result, the view will not receive touches whenever a toast, dialog or other window appears above the view’s window.

For the runtime permission window jacking, using `setFilterTouchesWhenObscured()` would prevent the user from clicking on either the “Allow” or the “Deny” buttons. The alternative message would be in its own window, floating over the dialog. Hence, that should cause `FLAG_WINDOW_IS_OBSCURED` to be set on any `MotionEvent`s delivered to the dialog, and those touch events would be dropped.

For example, take a look at the `res/layout/main.xml` file in the [Tapjacking/RelativeSecure](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:filterTouchesWhenObscured="true">
    <TextView android:id="@+id/label"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="URL:"
        android:layout_alignBaseline="@+id/entry"
```

MISCELLANEOUS SECURITY TECHNIQUES

```
    android:layout_alignParentLeft="true" />
<EditText
    android:id="@id/entry"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_toRightOf="@id/label"
    android:layout_alignParentTop="true" />
<Button
    android:id="@+id/ok"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_below="@id/entry"
    android:layout_alignRight="@id/entry"
    android:text="OK" />
<Button
    android:id="@+id/cancel"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_toLeftOf="@id/ok"
    android:layout_alignTop="@id/ok"
    android:text="Cancel" />
</RelativeLayout>
```

(from [Tapjacking/RelativeSecure/app/src/main/res/layout/main.xml](#))

Here, we have `android:filterTouchesWhenObscured="true"` on the `RelativeLayout` at the root of the layout resource. This property cascades to a container's children, and so if a tapjacker (or Toast or whatever) is above any of the widgets in the `RelativeLayout`, none of the touch events will be processed.

More fine-grained control can be achieved in custom widgets by overriding `onFilterTouchEventForSecurity()`, which gets control before the regular touch event methods. You can determine if a touch event had been intercepted by looking for the `FLAG_WINDOW_IS_OBSCURED` flag in the `MotionEvent` passed to `onFilterTouchEventForSecurity()`, and you can make the decision of how to handle this on an event-by-event basis.

The Problem with the Solution

According to Iwo Banaś, this approach [may not actually work](#) due to bugs in Android's implementation. The filter-when-obscured logic depends upon a `FLAG_WINDOW_IS_OBSCURED` value being on the `MotionEvent`, and that may be getting lost somewhere along the way.

The author of this book has not yet attempted to replicate Mr. Banaś' findings.

Google's Line of Defense: Obscuring the Foreground

Google's focus, besides the fixes listed above, is to make it increasingly difficult for one app to find out when another app is in the foreground. This is a key component of jacking attacks, as the jacker needs to know what is behind it. For example, with window jacking, obscuring the permission message only makes sense when the permission dialog appears — having some floating message appear at other points in time will be a giveaway that something is amiss.

As a result, methods on `ActivityManager` that used to provide details of all running processes have been neutered, frequently only providing details about your own process. Similarly, in Android N, attempts by apps to find out about other processes through Linux-isms, like `/proc`, are being locked down.

Using FLAG_SECURE

By default, your activity's UI contents can be captured for any number of things:

- the overview screen (a.k.a., recent-tasks list)
- screenshots and screencasts, whether via the [media projection APIs](#) or some other device-supplied means
- the [Assist API](#), such as Google's "Now On Tap" feature

However, you may have some activities that should not be captured in this fashion, due to potential privacy issues.

For that, you can apply `FLAG_SECURE` to an Activity:

```
public class FlagSecureTestActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        getWindow().setFlags(LayoutParams.FLAG_SECURE,
            LayoutParams.FLAG_SECURE);

        setContentView(R.layout.main);
    }
}
```

Call `setFlags()` before `setContentView()`, in this case setting `FLAG_SECURE`.

In theory, this will prevent any of the aforementioned capture options from working.

MISCELLANEOUS SECURITY TECHNIQUES

Unfortunately, the Android framework sometimes creates its own Window instances, such as the drop-down in a Spinner. Even if you set `FLAG_SECURE` on the Window for an activity, the Android framework does not pass that flag to any other windows created on behalf of that activity, and those windows show up in:

- Screenshots and screencasts taken by the media projection APIs on Android 5.0+
- The Assist API (e.g., Now On Tap) on Android 6.0+
- Android Studio screen recordings on Android 4.4+

This has been demonstrated to affect:

- `AutoCompleteTextView`
- Spinner (both dropdown and dialog modes)
- the overflow menu of the framework-supplied action bar
- `ShareActionProvider`
- Dialog and subclasses (e.g., `AlertDialog`)
- Toast

Of these, only the Dialog offers us access to its Window, on which we could apply `FLAG_SECURE`, for developers that realize that this is required.

Google has officially stated that [all of this is working as intended](#).

If you are using `FLAG_SECURE`, you should thoroughly exercise your app's UI on Android 4.4+ while recording a screencast — the Android Studio screen recorder would be a simple tool to use. Then, play back that screencast, see what windows show up, and identify those that contain sensitive information that should not appear. Some of the windows that appear will not contain sensitive information — here, the risk is that you might add sensitive information to them in the future but forget about this bug.

Then, you have two main courses of action: rewrite your UI to avoid the UI elements that are leaking this information, or attempt to patch the problem.

The author of this book has published a `FlagSecureHelper` in his [CWAC-Security library](#) that tries to limit the scope of the leakage. Specifically, it attempts to add `FLAG_SECURE` to all windows that are created “behind your back” by the Android framework.

AlarmManager and the Scheduled Service Pattern

Many applications have the need to get control every so often to do a bit of work. And, many times, those applications need to get control in the background, regardless of what the user may be doing (or not doing) at the time.

The solution, in most cases, is to use `AlarmManager`, which is roughly akin to `cron` on Linux and OS X and `Scheduled Tasks` in Windows. You teach `AlarmManager` when you want to get control back, and `AlarmManager` will give you control at that time.

Scenarios

The two main axes to consider with scheduled work are frequency and foreground (vs. background).

If you have an activity that needs to get control every second, the simplest approach is to use a `postDelayed()` loop, scheduling a `Runnable` to be invoked after a certain delay, where the `Runnable` reschedules itself to be invoked after the delay in addition to doing some work. We saw this in [the chapter on threads](#). This has the advantages of giving you control back on the main application thread and avoiding the need for any background threads.

On the far other end of the spectrum, you may need to get control on a somewhat slower frequency (e.g., every 15 minutes), and do so in the background, even if nothing of your app is presently running. You might need to poll some Web server for new information, such as downloading updates to an RSS feed. This is the scenario that `AlarmManager` excels at. While `postDelayed()` works *inside* your process (and therefore does not work if you no longer have a process), `AlarmManager`

maintains its schedule *outside* of your process. Hence, it can arrange to give you control, even if it has to start up a new process for you along the way.

JobScheduler, added to Android 5.0, also does this. If your `minSdkVersion` is 21 or higher, JobScheduler is definitely worth considering, as it not only takes time into account, but other environmental factors as well. For example, if you need an Internet connection to do your work, JobScheduler will only give you control if there is an Internet connection. JobScheduler is covered a bit [later in the book](#).

Options

There are a variety of things you will be able to configure about your scheduled alarms with AlarmManager.

Wake Up... Or Not?

The biggest one is whether or not the scheduled event should wake up the device.

A device goes into a sleep mode shortly after the screen goes dark. During this time, nothing at the application layer will run, until something wakes up the device. Waking up the device does not necessarily turn on the screen — it may just be that the CPU starts running your process again.

If you choose a “wakeup”-style alarm, Android will wake up the device to give you control. This would be appropriate if you need this work to occur even if the user is not actively using the device, such as your app checking for critical email messages in the middle of the night. However, it does drain the battery some.

Alternatively, you can choose an alarm that will not wake up the device. If your desired time arrives and the device is asleep, you will not get control until something else wakes up the device.

Repeating... Or Not?

You can create a “one-shot” alarm, to get control once at a particular time in the future. Or, you can create an alarm that will give you control periodically, at a fixed period of your choice (e.g., every 15 minutes).

If you need to get control at multiple times, but the schedule is irregular, use a “one-shot” alarm for the nearest time, where you do your work *and* schedule a “one-shot”

alarm for the next-nearest time. This would be appropriate for scenarios like a calendar application, where you need to let the user know about upcoming appointments, but the times for those appointments may not have any fixed schedule.

However, for most polling operations (e.g., checking for new messages every NN minutes), a repeating alarm will typically be the better answer.

Inexact... Or Not?

If you do choose a repeating alarm, you will have your choice over having (relatively) precise control over the timing of event or not.

If you choose an “inexact” alarm, while you will provide Android with a suggested time for the first event and a period for subsequent events, Android reserves the right to shift your schedule somewhat, so it can process your events and others around the same time. This is particularly important for “wakeup”-style alarms, as it is more power-efficient to wake up the device fewer times, so Android will try to combine multiple apps’ events to be around the same time to minimize the frequency of waking up the device.

However, inexact alarms are annoying to test and debug, simply because you do not have control over when they will be invoked. Hence, during development, you might start with an exact alarm, then switch to inexact alarms once most of your business logic is debugged.

Note that Android 4.4 changes the behavior of `AlarmManager`, such that it is more difficult to actually create an exact-repeating alarm schedule. This will be examined in greater detail shortly, as we review the various methods and flags for scheduling `AlarmManager` events.

Absolute Time... Or Not?

As part of the alarm configuration, you will tell Android when the event is to occur (for one-shot alarms) or when the event is to *first* occur (for repeating alarms). You can provide that time in one of two ways:

- An absolute “real-time clock” time (e.g., 4am tomorrow), or
- A time relative to now

For most polling operations, particularly for periods more frequent than once per day, specifying the time relative to now is easiest. However, some alarms may need to tie into “real world time”, such as alarm clocks and calendar alerts — for those, you will need to use the real-time clock (typically by means of a Java Calendar object) to indicate when the event should occur.

What Happens (Or Not???)

And, of course, you will need to tell Android what to do when each of these timer events occurs. You will do that in the form of supplying a PendingIntent. First mentioned in [the chapter on services](#), a PendingIntent is [a Parcelable object](#), one that indicates an operation to be performed upon an Intent:

- start an activity
- start a service
- send a broadcast

While the service chapter discussed an Android activity using `createPendingResult()` to craft such a PendingIntent, that is usually not very useful for AlarmManager, as the PendingIntent will only be valid so long as the activity is in the foreground. Instead, there are static factory methods on PendingIntent that you will use instead (e.g., `getBroadcast()` to create a PendingIntent that calls `sendBroadcast()` on a supplied Intent). That being said, our next sample will use `createPendingResult()`, to keep the sample as simple as possible.

A Simple Example

A trivial sample app using AlarmManager can be found in [AlarmManager/Simple](#).

This application consists of a single activity, `SimpleAlarmDemoActivity`, that will both set up an alarm schedule and respond to alarms:

```
package com.commonware.android.alarm;

import android.app.Activity;
import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.os.SystemClock;
import android.util.Log;
import android.widget.Toast;
```

ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

```
public class SimpleAlarmDemoActivity extends Activity {
    private static final int ALARM_ID=1337;
    private static final int PERIOD=5000;
    private PendingIntent pi=null;
    private AlarmManager mgr=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        mgr=(AlarmManager)getSystemService(ALARM_SERVICE);
        pi=createPendingResult(ALARM_ID, new Intent(), 0);
        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
            SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
    }

    @Override
    public void onDestroy() {
        mgr.cancel(pi);

        super.onDestroy();
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode,
        Intent data) {
        if (requestCode == ALARM_ID) {
            Toast.makeText(this, R.string.toast, Toast.LENGTH_SHORT).show();
            Log.d(getClass().getSimpleName(), "I ran!");
        }
    }
}
```

(from [AlarmManager/Simple/app/src/main/java/com/commonsware/android/alarm/SimpleAlarmDemoActivity.java](#))

In `onCreate()`, in addition to setting up the “hello, world”-ish UI, we:

- Obtain an instance of `AlarmManager`, by calling `getSystemService()`, asking for the `ALARM_SERVICE`, and casting the result to be an `AlarmManager`
- Create a `PendingIntent` by calling `createPendingResult()`, supplying an empty `Intent` as our “result” (since we do not really need it here)
- Calling `setRepeating()` on `AlarmManager`

The call to `setRepeating()` is a bit complex, taking four parameters:

1. The type of alarm we want, in this case `ELAPSED_REALTIME`, indicating that we want to use a relative time base for when the first event should occur (i.e., relative to now) and that we do not need to wake up the device out of any sleep mode
2. The time when we want the first event to occur, in this case specified as a time delta in milliseconds (`PERIOD`) added to “now” as determined by

`SystemClock.elapsedRealtime()` (the number of milliseconds since the device was last rebooted)

3. The number of milliseconds to occur between events
4. The `PendingIntent` to invoke for each of these events

When the event occurs, since we used `createPendingResult()` to create the `PendingIntent`, our activity gets control in `onActivityResult()`, where we simply display a `Toast` (if the event is for our alarm's request ID). This continues until the activity is destroyed (e.g., pressing the `BACK` button), at which time we `cancel()` the alarm, supplying a `PendingIntent` to indicate which alarm to cancel. While here we use the same `PendingIntent` object as we used for scheduling the alarm, that is not required — it merely has to be an *equivalent* `PendingIntent`, meaning:

- The `Intent` inside the `PendingIntent` matches the scheduled alarm's `Intent`, in terms of component, action, data (`Uri`), MIME type, and categories
- The ID of the `PendingIntent` (here, `ALARM_ID`) must also match

Running this simply brings up a `Toast` every five seconds until you `BACK` out of the activity.

The Five set...() Varieties

There are five methods that you can call on `AlarmManager` to establish an alarm, including the `setRepeating()` demonstrated above.

On Android 4.4 (API Level 19) and higher, `setExact()` is used for a one-shot alarm, where you want to get control at one specific time in the future. This would be used for specific events or for irregular alarm schedules.

On Android 4.3 and below, and for apps whose `targetSdkVersion` is set to 18 or lower, `set()` has the same behavior as `setExact()`. However, on Android 4.4 and above, apps with their `targetSdkVersion` set to be 19 or higher will have different, *inexact* behavior for `set()`. The time of the event is considered a minimum — your `PendingIntent` will not be invoked before your desired time, but it can occur any time thereafter... and you do not have control over how long that delay will be. As with all “inexact” schedules, the objective is for Android to be able to “batch” these events, to do several around the same time, for greater efficiency, particularly when waking up the device.

On Android 4.4 and higher, you have a `setWindow()` option that is a bit of a hybrid between the new-style `set()` and `setExact()`. Here, you specify the time you want the event to occur and an amount of time that Android can “flex” the actual event. So, for example, you might set up an event to occur every hour, with a “window” of five minutes, to allow Android the flexibility to invoke your `PendingIntent` within that five-minute window. This allows for better battery optimization than with `setExact()`, while still giving you some control over how far “off the mark” the event can occur.

On Android 4.3 and below, and for apps whose `targetSdkVersion` is set to 18 or lower, `setRepeating()` is used for an alarm that should occur at specific points in time at a specific frequency. In addition to specifying the time of the first event, you also specify the period for future events. Android will endeavor to give you control at precisely those times, though since Android is not a real-time operating system (RTOS), microsecond-level accuracy is certainly not guaranteed. However, note that as of Android 5.1, your minimum period is one minute (60000ms) — values less than that will be rounded up to one minute. This minimum period is enforced regardless of your `targetSdkVersion` value.

`setInexactRepeating()` is used for an alarm that should occur on a general frequency, such as every 15 minutes. In addition to specifying the time of the first event, you also specify a general frequency, as one of the following public static data members on `AlarmManager`:

- `INTERVAL_FIFTEEN_MINUTES`
- `INTERVAL_HALF_HOUR`
- `INTERVAL_HOUR`
- `INTERVAL_HALF_DAY`
- `INTERVAL_DAY`

Android guarantees that it will give your app control somewhere during that time window, but precisely *when* within that window is up to Android.

Note that on Android 4.4 and above, for apps with their `targetSdkVersion` set to be 19 or higher, `setRepeating()` behaves identically to `setInexactRepeating()` – in other words, all repeating alarms are inexact. The only way to get exact repeating would be to use `setExact()` and to re-schedule the event yourself, rather than relying upon Android doing that for you automatically. Ideally, you use `setInexactRepeating()`, to help extend battery life.

And, note that on Android 5.1 and higher, alarms must be set to occur at least 5 seconds in the future from now. You cannot trigger an alarm to occur in the future sooner than 5 seconds.

The Four Types of Alarms

In the above sample, we used `ELAPSED_REALTIME` as the type of alarm. There are three others:

- `ELAPSED_REALTIME_WAKEUP`
- `RTC`
- `RTC_WAKEUP`

Those with `_WAKEUP` at the end will wake up a device out of sleep mode to execute the `PendingIntent` — otherwise, the alarm will wait until the device is awake for other means.

Those that begin with `ELAPSED_REALTIME` expect the second parameter to `setRepeating()` to be a timestamp based upon `SystemClock.elapsedRealtime()`. Those that begin with `RTC`, however, expect the second parameter to be based upon `System.currentTimeMillis()`, the classic Java “what is the current time in milliseconds since the Unix epoch” method.

When to Schedule Alarms

The sample, though, begs a bit of a question: when are we supposed to set up these alarms? The sample just does so in `onCreate()`, but is that sufficient?

For most apps, the answer is “no”. Here are the three times that you will need to ensure that your alarms get scheduled:

When User First Runs Your App

When your app is first installed, none of your alarms are set up, because your code has not yet run to schedule them. There is no means of setting up alarm information in the manifest or something that might automatically kick in.

Hence, you will need to schedule your alarms when the user first runs your app.

As a simplifying measure — and to cover another scenario outlined below — you might be able to simply get away with scheduling your alarms *every* time the user runs your app, as the sample app shown above does. This works for one-shot alarms (using `set()`) and for alarms with short polling periods, and it works because setting up a new alarm schedule for an equivalent `PendingIntent` will replace the old schedule. However, for repeating alarms with slower polling periods, it may excessively delay your events. For example, suppose you have an alarm set to go off every 24 hours, and the user happens to run your app 5 minutes before the next event was to occur — if you blindly reschedule the alarm, instead of going off in 5 minutes, it might not go off for another 24 hours.

There are more sophisticated approaches for this (e.g., using a `SharedPreferences` value to determine if your app has run before or not).

On Boot

The alarm schedule for alarm manager is wiped clean on a reboot, unlike `cron` or Windows Scheduled Tasks. Hence, you will need to get control at boot time to re-establish your alarms, if you want them to start up again after a reboot. We saw how to get control at boot time, via an `ACTION_BOOT_COMPLETED` `BroadcastReceiver`, back in [the chapter on broadcasts](#).

After a Force-Stop

There are other events that could cause your alarms to become unscheduled. The best example of this is if the user goes into the Settings app and presses “Force Stop” for your app. At this point, on Android 3.1+, nothing of your code will run again, until the user manually launches some activity of yours.

If you are rescheduling your alarms every time your app runs, this will be corrected the next time the user launches your app. And, by definition, you cannot do anything until the user runs one of your activities, anyway.

If you are trying to avoid rescheduling your alarms on each run, though, you have a couple of options.

One is to record the time when your alarm-triggered events occur, each time they occur, such as by updating a `SharedPreferences`. When the user launches one of your activities, you check the last-event time — if it was too long ago (e.g., well over your polling period), you assume that the alarm had been canceled, and you reschedule it.

Another is to rely on `FLAG_NO_CREATE`. You can pass this as a parameter to any of the `PendingIntent` factory methods, to indicate that Android should only return an *existing* `PendingIntent` if there is one, and not create one if there is not:

```
PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, PendingIntent.FLAG_NO_CREATE);
```

If the `PendingIntent` is null, your alarm has been canceled — otherwise, Android would already have such a `PendingIntent` and would have returned it to you. This feels a bit like a side-effect, so we cannot rule out the possibility that, in future versions of Android, this technique could result in false positives (null `PendingIntent` despite the scheduled alarm) or false negatives (non-null `PendingIntent` despite a canceled alarm).

Archetype: Scheduled Service Polling

The classic `AlarmManager` scenario is where you want to do a chunk of work, in the background, on a periodic basis. This is fairly simple to set up in Android, though perhaps not quite as simple as you might think.

The Main Application Thread Strikes Back

When an `AlarmManager`-triggered event occurs, it is very likely that your application is not running. This means that the `PendingIntent` is going to have to start up your process to have you do some work. Since everything that a `PendingIntent` can do intrinsically gives you control on your main application thread, you are going to have to determine how you want to move your work to a background thread.

One approach is to use a `PendingIntent` created by `getService()`, and have it send a command to an `IntentService` that you write. Since `IntentService` does its work on a background thread, you can take whatever time you need, without interfering with the behavior of the main application thread. This is particularly important when:

- The `AlarmManager`-triggered event happens to occur when the user happens to have one of your activities in the foreground, so you do not freeze the UI, or
- You want the same business logic to be executed on demand by the user, such as via an action bar item, as once again you do not want to freeze the UI

Examining a Sample

An incrementally-less-trivial sample app using AlarmManager for the scheduled service pattern can be found in [AlarmManager/Scheduled](#).

This application consists of three components: a BroadcastReceiver, a Service, and an Activity.

This sample demonstrates scheduling your alarms at two points in your app:

- At boot time
- When the user runs the activity

For the boot-time scenario, we need a BroadcastReceiver set up to receive the ACTION_BOOT_COMPLETED broadcast, with the appropriate permission. So, we set that up, along with our other components, in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.schedsvc"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name=".ScheduledServiceDemoActivity"
            android:label="@string/app_name"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>

        <receiver android:name="PollReceiver">
            <intent-filter>
                <action android:name="android.intent.action.BOOT_COMPLETED"/>
            </intent-filter>
        </receiver>

        <service android:name="ScheduledService">
        </service>
    </application>
```

ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

```
</manifest>
```

(from [AlarmManager/Scheduled/app/src/main/AndroidManifest.xml](#))

The PollReceiver has its onReceive() method, to be called at boot time, which delegates its work to a scheduleAlarms() static method, so that logic can also be used by our activity:

```
package com.commonware.android.schedsvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=5000;

    @Override
    public void onReceive(Context ctxt, Intent i) {
        scheduleAlarms(ctxt);
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, ScheduledService.class);
        PendingIntent pi=PendingIntent.getService(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
            SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
    }
}
```

(from [AlarmManager/Scheduled/app/src/main/java/com/commonware/android/schedsvc/PollReceiver.java](#))

The scheduleAlarms() method retrieves our AlarmManager, creates a PendingIntent designed to call startService() on our ScheduledService, and schedules an exact repeating alarm to have that command be sent every five seconds.

The ScheduledService itself is the epitome of “trivial”, simply logging a message to LogCat on each command:

```
package com.commonware.android.schedsvc;

import android.app.IntentService;
import android.content.Intent;
import android.util.Log;

public class ScheduledService extends IntentService {
    public ScheduledService() {
```

ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

```
    super("ScheduledService");
}

@Override
protected void onHandleIntent(Intent intent) {
    Log.d(getClass().getSimpleName(), "I ran!");
}
}
```

(from [AlarmManager/Scheduled/app/src/main/java/com/commonsware/android/schedsvc/ScheduledService.java](#))

That being said, because this is an `IntentService`, we could do much more in `onHandleIntent()` and not worry about tying up the main application thread.

Our activity — `ScheduledServiceDemoActivity` — is set up with `Theme.NoDisplay` in the manifest, never calls `setContentView()`, and calls `finish()` right from `onCreate()`. As a result, [it has no UI](#). It simply calls `scheduleAlarms()` and raises a `Toast` to indicate that the alarms are indeed scheduled:

```
package com.commonsware.android.schedsvc;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class ScheduledServiceDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        PollReceiver.scheduleAlarms(this);

        Toast.makeText(this, R.string.alarms_scheduled, Toast.LENGTH_LONG)
            .show();
        finish();
    }
}
```

(from [AlarmManager/Scheduled/app/src/main/java/com/commonsware/android/schedsvc/ScheduledServiceDemoActivity.java](#))

On Android 3.1+, we also need this activity to move our application out of the stopped state and allow that boot-time `BroadcastReceiver` to work.

If you run this app on a device or emulator, after seeing the `Toast`, messages will appear in `LogCat` every five seconds, even though you have no activity running.

Staying Awake at Work

The sample shown above works... most of the time.

However, it has a flaw: the device might fall asleep before our service can complete its work, if we woke it up out of sleep mode to process the event.

To understand where this flaw would appear, and to learn how to address it, we need to think a bit more about the event flows and timing of the code we are executing.

Mind the Gap

For a `_WAKEUP`-style alarm, Android makes precisely one guarantee: *if* the `PendingIntent` supplied to `AlarmManager` for the alarm is one created by `getBroadcast()` to send a broadcast `Intent`, Android will ensure that the device will stay awake long enough for `onReceive()` to be completed. Anything beyond that is not guaranteed.

In the sample shown above, we are not using `getBroadcast()`. We are taking the more straightforward approach of sending the command directly to the service via a `getService()` `PendingIntent`. Hence, Android makes no guarantees about what happens after `AlarmManager` wakes up the device, and the device could fall back asleep before our `IntentService` completes processing of `onHandleIntent()`.

The WakefulIntentService

For our trivial sample, where we are merely logging to `LogCat`, we could simply move that logic out of an `IntentService` and into a `BroadcastReceiver`. Then, Android would ensure that the device would stay awake long enough for us to do our work in `onReceive()`.

The problem is that `onReceive()` is called on the main application thread, so we cannot spend much time in that method. And, since our alarm event might occur when nothing else of our code is running, we need to have our `BroadcastReceiver` registered in the manifest, rather than via `registerReceiver()`. A side effect of this is that we cannot fork threads or do other things in `onReceive()` that might live past `onReceive()` yet be “owned” by the `BroadcastReceiver` itself. Besides, Android only ensures that the device will stay awake until `onReceive()` returns, so even if we did fork a thread, the device might fall asleep before that thread can complete its work.

Enter the `WakefulIntentService`.

`WakefulIntentService` is a reusable component, published by the author of this book.

ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

WakefulIntentService allows you to implement “the handoff pattern”:

- You add the JAR, AAR, or library project to your project
- You create a subclass of WakefulIntentService to do your background work, putting that business logic in a doWakefulWork() method instead of onHandleIntent() (though it is still called on a background thread)
- You set up your alarm to route to a BroadcastReceiver of your design
- Your BroadcastReceiver calls sendWakefulWork() on the WakefulIntentService class, identifying your own subclass of WakefulIntentService
- You add a WAKE_LOCK permission to your manifest

WakefulIntentService will perform a bit of magic to ensure that the device will stay awake long enough for your work to complete in doWakefulWork(). Hence, we get the best of both worlds: the device will not fall asleep, and we will not have to worry about tying up the main application thread.

Android Studio users can add a reference to the CommonsWare Maven artifact repository in their top-level repositories closure:

```
repositories {  
    mavenCentral()  
    maven {  
        url "https://repo.commonsware.com.s3.amazonaws.com"  
    }  
}
```

(here shown alongside an existing mavenCentral() statement)

Then, adding the WakefulIntentService is merely a matter of adding a compile 'com.commonsware.cwac:wakeful:...' statement to the top-level dependencies closure (for some version of the library, denoted by ...).

WakefulIntentService is open source, licensed under the Apache License 2.0.

The Polling Archetype, Revisited

With that in mind, take a peek at the [AlarmManager/Wakeful](#) sample project. This is a near-clone of the previous sample, with the primary difference being that we will use WakefulIntentService.

Android Studio users will pull the AAR from the CommonsWare artifact repository:

ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    compile 'com.commonsware.cwac:wakeful:1.0.+'
}
```

(from [AlarmManager/Wakeful/app/build.gradle](#))

Our manifest includes the WAKE_LOCK permission:

```
<uses-permission android:name="android.permission.WAKE_LOCK"/>
```

(from [AlarmManager/Wakeful/app/src/main/AndroidManifest.xml](#))

Our PollReceiver will now serve two roles: handling ACTION_BOOT_COMPLETED *and* handling our alarm events. We can detect which of these cases triggered onReceive() by inspecting the broadcast Intent, passed into onReceive(). We will use an explicit Intent for the alarm events, so any Intent with an action string must be ACTION_BOOT_COMPLETED:

```
package com.commonsware.android.wakesvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonsware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=900000; // 15 minutes
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
```

ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

```
        PERIOD, pi);  
    }  
}
```

(from [AlarmManager/Wakeful/app/src/main/java/com/commonsware/android/wakesvc/PollReceiver.java](#))

If the Intent is our explicit Intent, we call `sendWakefulWork()` on `WakefulIntentService`, identifying our `ScheduledService` class as being the service that contains our business logic.

The other changes to `PollReceiver` is that we use `getBroadcast()` to create our `PendingIntent`, wrapping our explicit Intent identifying `PollReceiver` itself, and that we use more realistic polling periods (5 second initial delay, every 15 minutes thereafter).

`ScheduledService` has only two changes: it extends `WakefulIntentService` and has the LogCat logging in `doWakefulWork()`:

```
package com.commonsware.android.wakesvc;  
  
import android.content.Intent;  
import android.util.Log;  
import com.commonsware.cwac.wakeful.WakefulIntentService;  
  
public class ScheduledService extends WakefulIntentService {  
    public ScheduledService() {  
        super("ScheduledService");  
    }  
  
    @Override  
    protected void doWakefulWork(Intent intent) {  
        Log.d(getClass().getSimpleName(), "I ran!");  
    }  
}
```

(from [AlarmManager/Wakeful/app/src/main/java/com/commonsware/android/wakesvc/ScheduledService.java](#))

How the Magic Works

A `WakefulIntentService` keeps the device awake by using a `WakeLock`. A `WakeLock` allows a “userland” (e.g., Android SDK) app to tell the Linux kernel at the heart of Android to keep the device awake, with the CPU powered on, indefinitely, until the `WakeLock` is released.

This can be a wee bit dangerous, as you can accidentally keep the device awake much longer than you need to. That is why using a library like `WakefulIntentService` can be useful — to use more-tested code rather than rolling your own.

Warning: Not All Android Devices Play Nice

Some Android devices take liberties with the way AlarmManager works, in ways that may affect your applications.

One example of this today is the SONY Xperia Z. It has a “[STAMINA mode](#)” that the user can toggle on via the “Power Management” screen in Settings. This mode will be entered when the device’s screen turns off, if the device is not plugged in and charging. The user can add apps to a whitelist (“Apps active in standby”), where STAMINA mode does not affect those apps’ behavior.

`_WAKEUP` style alarms do not wake up the device when it is in STAMINA mode. The behavior is a bit reminiscent of non-`_WAKEUP` alarms. Alarms that occur while the device is asleep are suppressed, and you get one invocation of your `PendingIntent` at the point the device wakes back up. At that point, the schedule continues as though the alarms had been going off all along. Apps on the whitelist are unaffected.

Mostly, you need to be aware of this from a support standpoint. If Xperia Z owners complain that your app behaves oddly, and you determine that your alarms are not going off, see if they have STAMINA mode on, and if they do, ask them to add your app to the whitelist.

If you are using “if my alarm has not gone off in X amount of time, the user perhaps force-stopped me, so let me reschedule my alarms” logic, you should be OK. Before one of your activities gets a chance to make that check, your post-wakeup alarm should have been invoked, so you can update your event log and last-run timestamp. Hence, you should not be tripped up by STAMINA and accidentally reschedule your alarms (potentially causing duplicates, depending upon your alarm-scheduling logic).

Other devices with similar characteristics include Sony’s Xperia P, Xperia U, Xperia sola, and Xperia go.

Debugging Alarms

If you are encountering issues with your alarms, the first thing to do is to ensure that the alarm schedule in AlarmManager is what you expect it to be. To do that, run `adb shell dumpsys alarm` from a command prompt. This will dump a report of all the scheduled alarms, including when they are set to be invoked next (with portions replaced by vertical ellipses to keep this listing from being too long):

ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

```

You are given details of each outstanding alarm, including the all-important when value indicating the time the alarm should be invoked next, if it is not canceled first (e.g., when=+5d15h10m7s782ms), along with the package requesting the alarm. You can use this to identify your app’s alarms and see when they should be invoked next.

You are also given:

- Per-app details about how frequently their alarms have gone off, which can be useful for battery impact analysis
- A list of “top alarms” by number of occurrences, also for device performance analysis

Note, though, that for inexact alarms, the when value may not indicate when the event will actually occur.

WakefulBroadcastReceiver

The Android Support package has added a WakefulBroadcastReceiver, which offers an alternative to WakefulIntentService for arranging to do work, triggered by a broadcast (such as an AlarmManager event), that may take a while.

WakefulBroadcastReceiver has its pros and cons compared to WakefulIntentService, making it worth considering.

Using WakefulBroadcastReceiver

Using WakefulBroadcastReceiver with AlarmManager is slightly different than is using WakefulIntentService. The [AlarmManager/WakeCast](#) sample project is a clone of the WakefulIntentService project, but one using WakefulBroadcastReceiver instead.

The activity is unchanged — it simply calls `scheduleAlarms()` on `PollReceiver`. `scheduleAlarms()` itself is unchanged, as it still uses `setRepeating()` on `AlarmManager` to arrange to periodically invoke a `PendingIntent`, targeting the `PollReceiver`.

But `PollReceiver` itself is now a `WakefulBroadcastReceiver` rather than just an ordinary `BroadcastReceiver`. This in turn requires a slightly different implementation of `onReceive()`:

```
package com.commonware.android.wakecast;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.WakefulBroadcastReceiver;

public class PollReceiver extends WakefulBroadcastReceiver {
    private static final int PERIOD=900000; // 15 minutes
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            startWakefulService(ctxt,
                new Intent(ctxt, ScheduledService.class));
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
```

ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

```
        PERIOD, pi);  
    }  
}
```

(from [AlarmManager/WakeCast/app/src/main/java/com/commonsware/android/wakecast/PollReceiver.java](#))

Now, when the AlarmManager broadcast arrives, we call `startWakefulService()`, passing it the Context supplied to `onReceive()`, plus an Intent identifying the service to start up. Under the covers, this works much like `sendWakefulWork()` on `WakefulIntentService` — it starts the identified service, but acquires a `WakeLock` first.

Our `ScheduledService` is now a regular `IntentService`, instead of a `WakefulIntentService`. This means that our background work moves back to the standard `onHandleIntent()` method, instead of `doWakefulWork()`. However, we have one extra bit of bookkeeping to do: we must call the static `completeWakefulIntent()` method on `WakefulBroadcastReceiver` (or, as shown, on `PollReceiver`, as that will point to the same static method):

```
package com.commonsware.android.wakecast;  
  
import android.app.IntentService;  
import android.content.Intent;  
import android.util.Log;  
  
public class ScheduledService extends IntentService {  
    public ScheduledService() {  
        super("ScheduledService");  
    }  
  
    @Override  
    protected void onHandleIntent(Intent intent) {  
        Log.d(getClass().getSimpleName(), "I ran!");  
  
        PollReceiver.completeWakefulIntent(intent);  
    }  
}
```

(from [AlarmManager/WakeCast/app/src/main/java/com/commonsware/android/wakecast/ScheduledService.java](#))

We pass the Intent supplied to `onHandleIntent()` to `completeWakefulIntent()`. Behind the scenes, `completeWakefulIntent()` will release the `WakeLock` that has been keeping our CPU powered on while we do our work.

Comparing to WakefulIntentService

One might think that `WakefulIntentService` would now be obsolete with the addition of `WakefulBroadcastReceiver`. In truth, there are some advantages to the current implementation of `WakefulBroadcastReceiver`:

- It uses a time-limited `WakeLock`, one set to auto-release after one minute, so there is no risk of an app somehow failing to release the lock and thereby keeping the CPU on indefinitely.
- To make the time-limited locks work, `WakefulBroadcastReceiver` uses one `WakeLock` per request, rather than the single static `WakeLock` that `WakefulIntentService` uses, making `WakefulBroadcastReceiver` incrementally more resilient in the face of various potential problems.
- Because it is not strictly tied to being used with an `IntentService`, `WakefulBroadcastReceiver` may offer greater flexibility. For example, an `IntentService` is not a good choice if the work you do is intrinsically asynchronous, such as trying to find the device's location. Any place where you find yourself registering a listener from a service, an `IntentService` will not work well, as the `IntentService` wants to shut down before your listener has received a result. A regular `Service` can work well, though, in this case, and `WakefulBroadcastReceiver` might be of use in this pattern (though the author has not tried this yet).

On the other hand:

- `WakefulBroadcastReceiver` requires an explicit call to `completeWakefulIntent()`, which a developer can easily forget, possibly causing the `WakeLock` to be leaked. While this is not disastrous, since the `WakeLock` will auto-release after a minute, it may still represent wasted power. `WakefulIntentService` is more “idiot-proof” and therefore avoids this issue.
- The time for the `WakefulBroadcastReceiver` `WakeLock` is locked to being one minute — no more, no less. This offers limited flexibility and can cause problems if the work you intend to do could easily exceed a minute. Unfortunately, the implementation of `WakefulBroadcastReceiver` offers no easy way to override this one-minute timeout value.
- If Android terminates your process and restarts your service, the restarted service will *not* be under the control of a `WakeLock`, as Android will be starting the service directly, not via `WakefulBroadcastReceiver`. `WakefulIntentService` will suffer the same fate, but it will automatically grab a `WakeLock` for you when it detects this condition. In the case of

WakefulBroadcastReceiver, your service will run without a WakeLock, unless you detect this case yourself (via a custom onStartCommand() that examines the passed-in flags, looking for START_FLAG_REDELIVERY) and grab your own WakeLock.

A future generation of WakefulIntentService will aim to adopt some of the advantages of WakefulBroadcastReceiver while avoiding its disadvantages. As it stands, either component is a reasonable choice if you are willing to live within their respective constraints.

Android 6.0 and the War on Background Processing

Android 6.0 introduced some changes to the behavior of AlarmManager that significantly affect its use on Android 6.0+ devices. These changes also affect JobScheduler, and so this topic is covered in grand detail [at the end of the JobScheduler chapter](#).

PowerManager and WakeLocks

There are going to be times when you want the device to keep running, even though it ordinarily would go into a sleep mode, with the CPU powered down and the screen turned off. Sometimes, that will be based upon user interactions, or the lack thereof, such as keeping the screen on while playing back a video. Sometimes, that will be to allow background scheduled work to run to completion, as was introduced in the chapter on `AlarmManager`.

This chapter looks a bit more at the details of this sort of power management, including coverage of how `AlarmManager` works.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on `AlarmManager`](#).

Keeping the Screen On, UI-Style

If your objective is to keep the screen (and CPU) on while your activity is in the foreground, the simplest solution is to add `android:keepScreenOn="true"` to something in the activity's layout. So long as that widget or container is visible, the screen will stay on.

If you wish to do this conditionally, `setKeepScreenOn()` allows you to toggle this setting at runtime.

Once your activity is no longer in the foreground, or the widget or container is no longer visible, the effect lapses, and screen operation returns to normal.

The Role of the WakeLock

Most of the time in Android, you are developing code that will run while the user is actually using the device. Activities, for example, only really make sense when the device is fully awake and the user is tapping on the screen or keyboard.

Particularly with scheduled background tasks, though, you need to bear in mind that the device will eventually “go to sleep”. In full sleep mode, the display, main CPU, and keyboard are all powered off, to maximize battery life. Only on a low-level system event, like an incoming phone call, will anything wake up the device.

Another thing that will partially wake up the phone is an Intent raised by the AlarmManager. So long as broadcast receivers are processing that Intent, the AlarmManager ensures the CPU will be running (though the screen and keyboard are still off). Once the broadcast receivers are done, the AlarmManager lets the device go back to sleep.

You can achieve the same effect in your code via a WakeLock.

One of the changes that the core Android team made to the Linux kernel was to introduce the concept of the “wakelock”. In simple terms, a wakelock allows a Linux userland application — such as our Android SDK apps — to control whether or not the CPU can be powered down as part of a sleep mode. While a wakelock is in force, the CPU will remain on and processing instructions from the processes and threads that are on the device.

From the SDK, to access a wakelock, you use a WakeLock object, obtained from the PowerManager system service. When you call `acquire()` on that WakeLock, the CPU will remain on; when you call `release()` on that WakeLock, the CPU can fall back asleep, if there are no other outstanding WakeLocks from SDK apps or the operating system itself.

There are four types of WakeLock objects. All will keep the CPU on. They vary in their effects on the screen (leave it off, have it display with dim backlight, have it display with normal backlight) and any physical keys (ignore or accept). You will pass a flag into `newWakeLock()` on the PowerManager system service to indicate what type of WakeLock you want. The most common is the `PARTIAL_WAKE_LOCK`, which keeps the CPU on but leaves the screen and keyboard off — ideal for periodic background work triggered by an AlarmManager event.

What WakefulIntentService Does

For a `_WAKEUP` alarm, the `AlarmManager` will arrange for the device to stay awake, via a `WakeLock`, for as long as the `BroadcastReceiver`'s `onReceive()` method is executing. For some situations, that may be all that is needed. However, `onReceive()` is called on the main application thread, and Android will kill off the receiver if it takes too long.

Your natural inclination in this case is to have the `BroadcastReceiver` arrange for a `Service` to do the long-running work on a background thread, since `BroadcastReceiver` objects should not be starting their own threads. Perhaps you would use an `IntentService`, which packages up this “start a `Service` to do some work in the background” pattern. And, given the preceding section, you might try acquiring a partial `WakeLock` at the beginning of the work and release it at the end of the work, so the CPU will keep running while your `IntentService` does its thing.

This strategy will work... some of the time.

The problem is that there is a gap in `WakeLock` coverage, as depicted in the following diagram:

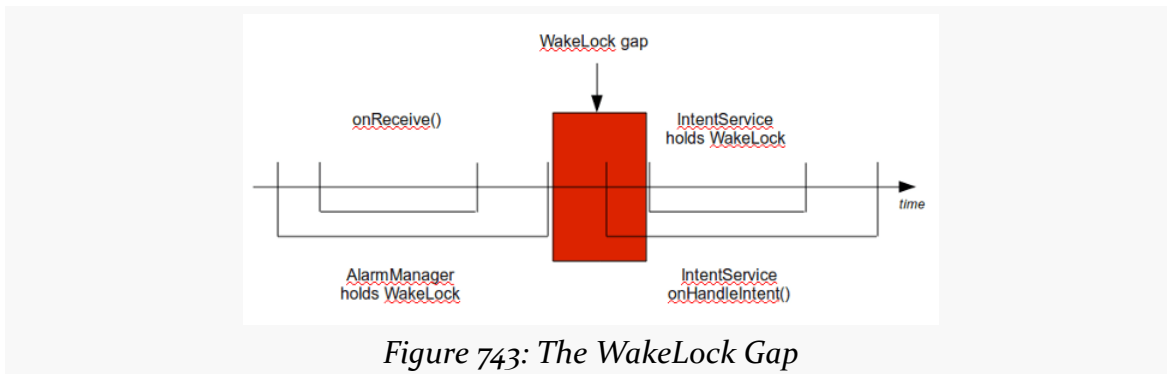

Figure 743: The WakeLock Gap

The `BroadcastReceiver` will call `startService()` to send work to the `IntentService`, but that service will not start up until after `onReceive()` ends. As a result, there is a window of time between the end of `onReceive()` and when your `IntentService` can acquire its own `WakeLock`. During that window, the device might fall back asleep. Sometimes it will, sometimes it will not.

What you need to do, instead, is arrange for overlapping `WakeLock` instances. You need to acquire a `WakeLock` in your `BroadcastReceiver`, during the `onReceive()`

POWERMANAGER AND WAKELOCKS

execution, and hold onto that `WakeLock` until the work is completed by the `IntentService`:

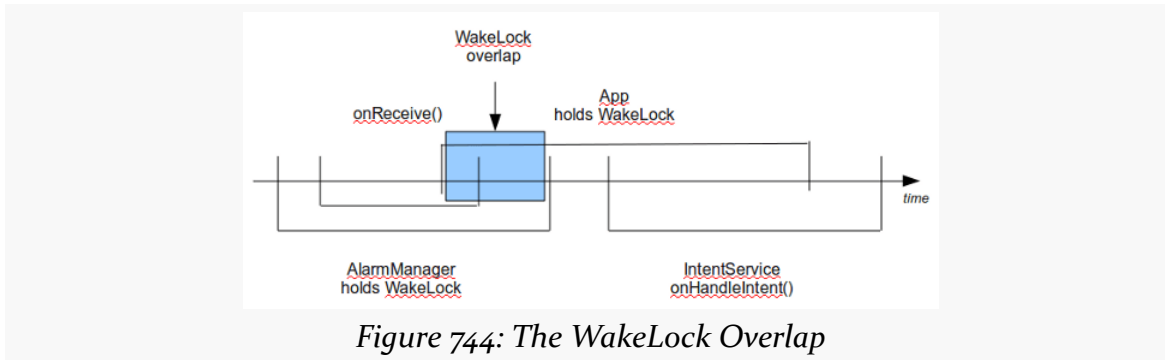

Figure 744: The WakeLock Overlap

Then you are assured that the device will stay awake as long as the work remains to be done.

The `WakefulIntentService` recipe described in [its chapter](#) does not have you manage your own `WakeLock`. That is because `WakefulIntentService` handles it for you. One reason why `WakefulIntentService` exists is to manage that `WakeLock`, because `WakeLocks` suffer from one major problem: they are [not Parcelable](#), and therefore cannot be passed in an `Intent` extra. Hence, for our `BroadcastReceiver` and our `WakefulIntentService` to use the same `WakeLock`, they have to be shared via a static data member... which is icky. `WakefulIntentService` is designed to hide this icky part from you, so you do not have to worry about it.

`WakefulIntentService` also handles various edge and corner cases, such as:

- What happens if Android elects to get rid of your process due to low memory conditions?
- What happens if your `doWakefulWork()` crashes, so we do not leak the acquired `WakeLock`?
- What if your UI also sends commands to the `WakefulIntentService`, or your processing takes longer than your polling period in `AlarmManager`, so that we have more than one piece of work outstanding at a point in time?

The one requirement related to a `WakeLock` that `WakefulIntentService` imposes upon you is the `WAKE_LOCK` permission. Any code in your process that is directly manipulating `WakeLock` objects needs this permission, even if that code is from a third-party JAR like `WakefulIntentService`.

JobScheduler

AlarmManager was our original solution for doing work on a periodic basis. However, AlarmManager can readily be misused, in ways that impact the battery — this is why API Level 19 put renewed emphasis on “inexact” alarm schedules. Worse, AlarmManager will give us control at points in time that may be useless to us, such as giving us control when there is no Internet access, when the point of the scheduled work is to transfer some data over the Internet.

Android 5.0 introduced JobScheduler, which offers a more sophisticated API for handling these sorts of scenarios. This chapter will explore how to set up JobScheduler and use it for one-off and periodic work.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on AlarmManager](#). Also, you should have read [the chapter on PowerManager and wakelocks](#).

The Limitations of AlarmManager

AlarmManager does its job, and frequently does it well. However, it is far from perfect:

- It does not persist its alarm schedule across reboots, forcing us to implement an ACTION_BOOT_COMPLETED BroadcastReceiver to re-establish our alarms
- It does not keep the device awake after waking it up with a _WAKEUP alarm, forcing us to use tools like WakefulBroadcastReceiver to make sure that we can get our work done without the device falling back asleep

- It gives us control even if the work we want to do is not possible, such as wanting to download material from the Internet but being woken up at points in time when we lack a working Internet connection (e.g., a WiFi-only tablet in a location for which it does not recognize any access points)
- In cases where the criteria we want cannot be met, we cannot readily implement any sort of back-off policy, except by doing the calculations ourselves and perhaps abandoning the convenient “repeating” API outright

And so on. AlarmManager is nice, but it would be better to have another solution.

Enter the JobScheduler

JobScheduler was designed to handle those four problems outlined above:

- It persists its roster of jobs and will re-establish them automatically after a reboot. Note, though, that you still have to hold the ACTION_BOOT_COMPLETED permission for this to work. Also note that you do not *have* to have jobs be persisted — this is an opt-in capability of JobScheduler.
- It handles “wakefulness” for us, via its own WakeLock, so we do not have to worry about it ourselves.
- It offers an API where we can specify criteria to be satisfied before we should be given control, notably a criteria indicating that we need a working network connection.
- If our criteria cannot be met, JobScheduler implements a configurable back-off policy, so we can slow down our attempts to get control when those attempts are regularly failing.

Employing JobScheduler

The [JobScheduler/PowerHungry](#) sample project demonstrates the use of JobScheduler, by way of comparing its use to that of AlarmManager.

The UI for JobScheduler allows you to pick from three types of event schedules: exact alarm, inexact alarm, and JobScheduler. You can also choose from one of four polling periods: 1 minute, 15 minutes, 30 minutes, and 60 minutes:

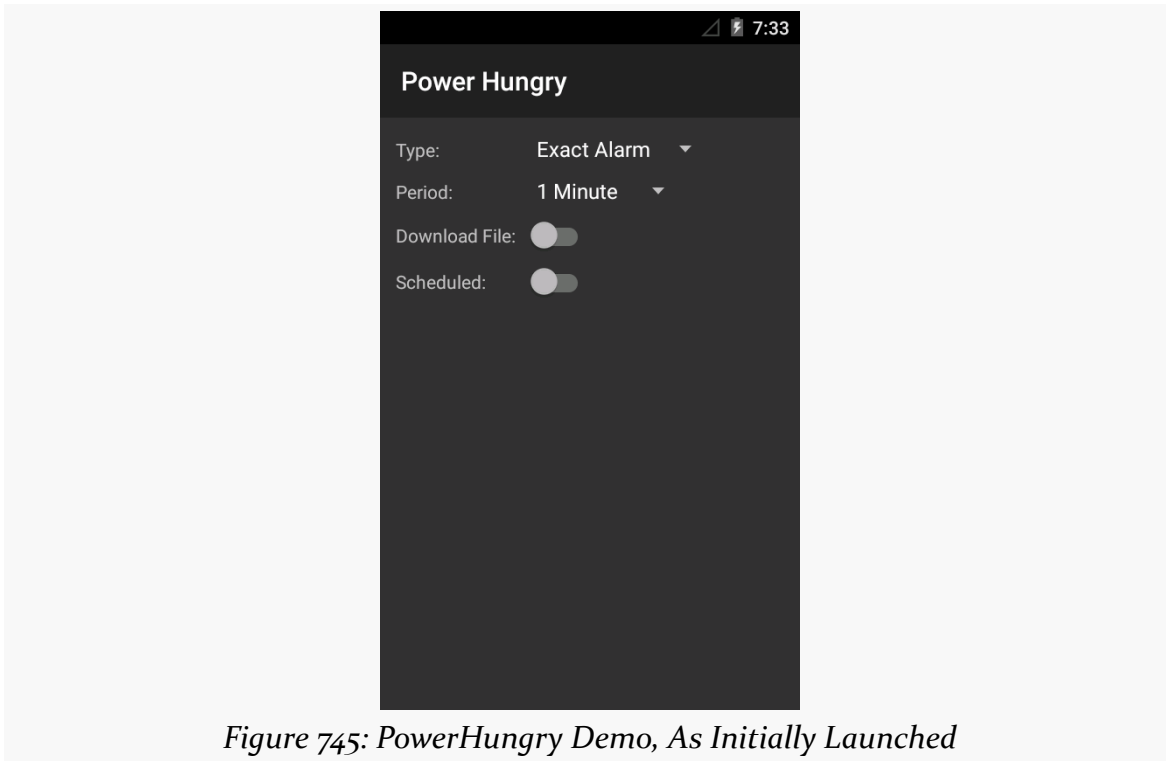

Figure 745: PowerHungry Demo, As Initially Launched

A `Switch` (in its `Theme.Material` styling) allows you to determine whether you are simply getting control at those points in time to just log to `LogCat`, or whether you are going to try to do some work at those points in time. Specifically, the “work” is to download a file, using `URLConnection`.

The bottom `Switch` toggles on and off the event schedules. When the event schedules are toggled on, you cannot manipulate the rest of the UI — you need to turn off the events in order to change the event configuration.

Note that none of this information is persisted. This is a lightweight demo; it is expected that you are keeping this UI in the foreground while a test is running.

Defining and Scheduling the Job

The “job” is defined as an instance of `JobInfo`, typically created using an instance of `JobInfo.Builder` to configure a `JobInfo` using a fluent builder-style API. We teach the `JobInfo` the work to do and when to do it, then use a `JobScheduler` to actually schedule the job.

JOB SCHEDULER

In the sample app, this work is mostly accomplished via a `manageJobScheduler()` method on the `MainActivity` class:

```
private void manageJobScheduler(boolean start) {
    if (start) {
        JobInfo.Builder b=new JobInfo.Builder(JOB_ID,
            new ComponentName(this, DemoJobService.class));
        PersistableBundle pb=new PersistableBundle();

        if (download.isChecked()) {
            pb.putBoolean(KEY_DOWNLOAD, true);
            b.setExtras(pb).setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY);
        } else {
            b.setRequiredNetworkType(JobInfo.NETWORK_TYPE_NONE);
        }

        b.setPeriodic(getPeriod()).setPersisted(false)
            .setRequiresCharging(false).setRequiresDeviceIdle(true);

        jobs.schedule(b.build());
    }
    else {
        jobs.cancel(JOB_ID);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

The `start` parameter to `manageJobScheduler()` is driven by the bottom `Switch` widget. A `start` value of `true` means that we should start up the job; a value of `false` means that we should cancel any existing job.

If `start` is `true`, we begin by creating a `JobInfo.Builder`, supplying two key pieces of data:

- an `int` that will serve as the job ID, which needs to be unique to our app but does not have to be unique for the whole device
- a `ComponentName` identifying the `JobService` that will actually implement the work of the job itself

The primary way of passing data from the scheduling code (our activity) and the job-implementing code (`JobService`) is by means of a `PersistableBundle` – a `Bundle`-like object that can be persisted to disk. `PersistableBundle` was introduced in API Level 21, but at that time it inexplicably lacked support for boolean values. API Level 22 added `getBoolean()` and `putBoolean()` to `PersistableBundle`, and this sample project has `minSdkVersion` of 22 to be able to take advantage of it. If you wanted to use this sample on API Level 21, you would need to convert the boolean into something else, such as 0 and 1 `int` values.

JOB_SCHEDULER

Our `PersistableBundle` can have more data than just this one extra, though that is all we need in this case. We attach the `PersistableBundle` to the `JobInfo` via the `setExtras()` method on the `JobInfo.Builder`.

We can also call methods on the `JobInfo.Builder` to configure the criteria that should be satisfied before giving us control. In our case, one criterion that we need is to have a network connection, but only if we are supposed to be downloading a file. So, we call `setRequiredNetworkType()` in either case, indicating that we either want ANY type of network connection (metered or unmetered) or NONE.

Other criteria-defining methods that we invoke include `setRequiresCharging()` (set to false to indicate we want control even if we are on battery) and `setRequiresDeviceIdle()` (set to true to indicate that we want control only if the user is not using it).

In the case of this sample, we want to do this work every so often, based upon the period chosen by the user in the bottom `Spinner` and retrieved via the `getPeriod()` method. So, we call `setPeriodic()` on the `JobInfo.Builder` to request getting control with that frequency, bearing in mind that this is merely a hint, not a requirement, and we may get control more or less frequently than this.

We also call `setPersisted(false)` to indicate that we do not need for this job to be persisted, so it will be lost on a reboot. If we instead called `setPersisted(true)`, the manifest would need to request the `RECEIVE_BOOT_COMPLETED` permission to have the job be re-created at boot time.

Finally, we call `schedule()` on a `JobScheduler` instance named `jobs` to schedule the job.

The `jobs` data member is populated up in `onCreate()` of the activity:

```
jobs=(JobScheduler)getSystemService(JOB_SCHEDULER_SERVICE);
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

While this may look like an ordinary request for a system service, it has one issue: your version of `Android Studio` may not know anything about it. In that case, this code will fail a `Lint` check, complaining that the service is not recognized. [This is a bug](#) that should be fixed in `Android Studio 0.8.14`. The workaround is to add `@SuppressWarnings("ResourceType")` to the method where you are making this `getSystemService()` call to suppress this `Lint` check.

If the start parameter to `manageJobScheduler()` is false, we call `cancel()` on the `JobScheduler`, passing in our unique job ID (`JOB_ID`) to indicate what job to cancel. Or, we could have called `cancelAll()`, which would cancel all jobs scheduled by our application.

Implementing the Job

The work for the job itself is handled by a `JobService`. This is a subclass of `Service` that we, in turn, extend ourselves, overriding two job-specific callback methods to actually do the work: `onStartJob()` and `onStopJob()`.

The `JobService` in our sample app is `DemoJobService`:

```
package com.commonware.android.job;

import android.app.job.JobParameters;
import android.app.job.JobService;
import android.os.PersistableBundle;
import android.util.Log;

public class DemoJobService extends JobService {
    private volatile Thread job=null;

    @Override
    public boolean onStartJob(JobParameters params) {
        PersistableBundle pb=params.getExtras();

        if (pb.getBoolean(MainActivity.KEY_DOWNLOAD, false)) {
            job=new DownloadThread(params);
            job.start();

            return(true);
        }

        Log.d(getClass().getSimpleName(), "job invoked");

        return(false);
    }

    @Override
    synchronized public boolean onStopJob(JobParameters params) {
        if (job!=null) {
            Log.d(getClass().getSimpleName(), "job interrupted");
            job.interrupt();
        }

        return(false);
    }

    synchronized private void clearJob() {
        job=null;
    }

    private class DownloadThread extends Thread {
```

JOB SCHEDULER

```
private final JobParameters params;

DownloadThread(JobParameters params) {
    this.params=params;
}

@Override
public void run() {
    Log.d(getClass().getSimpleName(), "job begins");
    new DownloadJob().run();
    Log.d(getClass().getSimpleName(), "job ends");
    clearJob();
    jobFinished(params, false);
}
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/DemoJobService.java](#))

`onStartJob()` is passed a `JobParameters`. This serves both as a “handle” identifying a particular job invocation and giving us access to the job ID (`getJobId()`) and `PersistableBundle` of extras (`getExtras()`) that were set up by our `JobInfo` when we scheduled the job.

`onStartJob()` needs to return `true` if we have successfully forked a background thread to do the work, or `false` if no work needs to be done. In our case, this is determined by whether or not we want to try to download a file. In a production-grade app, this may be determined by whether there is any work to be done (e.g., “do we have entries in the upload queue?”).

In `onStartJob()`, we check the `PersistableBundle` to see if we are supposed to download a file. If we are, we fork a `DownloadThread` to do that work, then return `true`. Otherwise, we return `false`.

Because this sample app illustrates the difference in behavior between `JobScheduler` and `AlarmService`, we want to isolate the actual download-the-file logic into a common implementation that can be used from either code path. That takes the form of a `DownloadJob`, which implements `Runnable` and does the download work when it is `run()`:

```
package com.commonsware.android.job;

import android.net.Uri;
import android.os.Environment;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
```

JOB SCHEDULER

```
import java.net.HttpURLConnection;
import java.net.URL;

class DownloadJob implements Runnable {
    static final Uri TO_DOWNLOAD=
        Uri.parse("https://commonsware.com/Android/excerpt.pdf");

    @Override
    public void run() {
        try {
            File root=
                Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

            root.mkdirs();

            File output=new File(root, TO_DOWNLOAD.getLastPathSegment());

            if (output.exists()) {
                output.delete();
            }

            URL url=new URL(TO_DOWNLOAD.toString());
            HttpURLConnection c=(HttpURLConnection)url.openConnection();

            FileOutputStream fos=new FileOutputStream(output.getPath());
            BufferedOutputStream out=new BufferedOutputStream(fos);

            try {
                InputStream in=c.getInputStream();
                byte[] buffer=new byte[8192];
                int len=0;

                while ((len=in.read(buffer)) >= 0) {
                    out.write(buffer, 0, len);
                }

                out.flush();
            }
            finally {
                fos.getFD().sync();
                out.close();
                c.disconnect();
            }
        }
        catch (IOException e2) {
            Log.e("DownloadJob", "Exception in download", e2);
        }
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/DownloadJob.java](#))

DownloadThread delegates to DownloadJob to do the actual work. However, when the work is complete, it then calls jobFinished() on the DemoJobService.

jobFinished(), as the name suggests, tells the framework that we are finished doing the work associated with this job. If the job succeeded, we pass false as the second parameter, to indicate that this job does not need to be rescheduled. If, on the other

hand, we were unable to actually do the work (e.g., we cannot connect to the desired server, perhaps due to server maintenance), we would pass true as the second parameter, to request that this job be rescheduled to be invoked again shortly, so that we can retry the operation.

Our `onStopJob()` method will be called by Android if environmental conditions have changed and we should stop the background work that we are doing. For example, we asked to do this work when the device was idle — if the user picks up the device and starts using it, we should stop our background work. In this case, if the job thread is still outstanding, we `cancel()` it. `onStopJob()` should return true if this job is still needed and should be retried, or false otherwise. Most short-period periodic jobs should return false, to just worry about the next job in the next period, and that is what `onStopJob()` does here. One-time jobs, or jobs with long periods (e.g., a day), may wish to return true to ensure that they will get another chance to do the desired work. We will cover more about this issue [later in this chapter](#).

Wiring in the Job Service

Since a `JobService` is a `Service`, we need the corresponding `<service>` element in the manifest. For a `JobService`, the `<service>` element is perfectly normal... with one exception:

```
<service
  android:name=".DemoJobService"
  android:permission="android.permission.BIND_JOB_SERVICE"
/>
```

(from [JobScheduler/PowerHungry/app/src/main/AndroidManifest.xml](#))

You need to defend the service with the `BIND_JOB_SERVICE` permission. This only allows code that holds the `BIND_JOB_SERVICE` permission to start or bind to this service, which should limit it to the OS itself.

The Rest of the Sample

As noted earlier, the UI for our activity is a pair of Spinner widgets, along with a pair of Switch widgets:

```
<?xml version="1.0" encoding="utf-8"?>
<GridLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
```

JOB SCHEDULER

```
android:layout_height="match_parent"
android:padding="8dp"
android:useDefaultMargins="true">

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/type_label"
    android:layout_row="0"
    android:layout_column="0"/>

<Spinner
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/type"
    android:layout_row="0"
    android:layout_column="1"/>

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/period_label"
    android:layout_row="1"
    android:layout_column="0"/>

<Spinner
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/period"
    android:layout_row="1"
    android:layout_column="1"/>

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/download_label"
    android:layout_row="2"
    android:layout_column="0"/>

<Switch
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/download"
    android:layout_row="2"
    android:layout_column="1"/>

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/scheduled_label"
    android:layout_row="3"
    android:layout_column="0"/>

<Switch
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/scheduled"
    android:layout_row="3"
    android:layout_column="1"/>
</GridLayout>
```

JOB SCHEDULER

(from [JobScheduler/PowerHungry/app/src/main/res/layout/main.xml](#))

onCreate() of MainActivity sets up the UI, including populating the two Spinner widgets based on <string-array> resources and hooking up the activity to respond to changes in the checked state of the scheduled Switch widget:

```
@SuppressWarnings("ResourceType")
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.main);
    type=(Spinner)findViewById(R.id.type);

    ArrayAdapter<String> types=
        new ArrayAdapter<String>(this,
            android.R.layout.simple_spinner_item,
            getResources().getStringArray(R.array.types));

    types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    type.setAdapter(types);

    period=(Spinner)findViewById(R.id.period);

    ArrayAdapter<String> periods=
        new ArrayAdapter<String>(this,
            android.R.layout.simple_spinner_item,
            getResources().getStringArray(R.array.periods));

    periods.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    period.setAdapter(periods);

    download=(Switch)findViewById(R.id.download);
    scheduled=(Switch)findViewById(R.id.scheduled);
    scheduled.setOnCheckedChangeListener(this);

    alarms=(AlarmManager) getSystemService(ALARM_SERVICE);
    jobs=(JobScheduler) getSystemService(JOB_SCHEDULER_SERVICE);
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

When the user toggles the scheduled Switch widget, we examine the type Spinner and route control to a method dedicated for handling that particular type of periodic request, such as the manageJobScheduler() method we saw earlier in this chapter:

```
@Override
public void onCheckedChanged(CompoundButton buttonView, boolean isChecked) {
    toggleWidgets(!isChecked);

    switch(type.getSelectedItemPosition()) {
        case 0:
            manageExact(isChecked);
            break;
    }
}
```

JOB SCHEDULER

```
    case 1:
        manageInexact(isChecked);
        break;

    case 2:
        manageJobScheduler(isChecked);
        break;
}
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

Our `onCheckedChanged()` for the schedule Switch also calls a `toggleWidgets()` method that enables or disables the other widgets, depending upon whether the schedule Switch is checked or unchecked:

```
private void toggleWidgets(boolean enable) {
    type.setEnabled(enable);
    period.setEnabled(enable);
    download.setEnabled(enable);
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

If the user had chosen an exact alarm, `onCheckedChanged()` routes control to `manageExact()`:

```
private void manageExact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleExactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

It, in turn, routes control over to a `PollReceiver`, a `WakefulBroadcastReceiver` that is set up for handling our alarms:

```
package com.commonsware.android.job;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import android.support.v4.content.WakefulBroadcastReceiver;

public class PollReceiver extends WakefulBroadcastReceiver {
```

JOB SCHEDULER

```
static final String EXTRA_PERIOD="period";
static final String EXTRA_IS_DOWNLOAD="isDownload";

@Override
public void onReceive(Context ctxt, Intent i) {
    boolean isDownload=i.getBooleanExtra(EXTRA_IS_DOWNLOAD, false);
    startWakefulService(ctxt,
        new Intent(ctxt, DemoScheduledService.class)
            .putExtra(EXTRA_IS_DOWNLOAD, isDownload));

    long period=i.getLongExtra(EXTRA_PERIOD, -1);

    if (period>0) {
        scheduleExactAlarm(ctxt,
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE),
            period, isDownload);
    }
}

static void scheduleExactAlarm(Context ctxt, AlarmManager alarms,
    long period, boolean isDownload) {
    Intent i=new Intent(ctxt, PollReceiver.class)
        .putExtra(EXTRA_PERIOD, period)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.setExact(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+period, pi);
}

static void scheduleInexactAlarm(Context ctxt, AlarmManager alarms,
    long period, boolean isDownload) {
    Intent i=new Intent(ctxt, PollReceiver.class)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.setInexactRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+period, period, pi);
}

static void cancelAlarm(Context ctxt, AlarmManager alarms) {
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.cancel(pi);
}
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/PollReceiver.java](#))

This sample app has a `targetSdkVersion` of 21. Hence, on Android 5.0 devices — the ones that have `JobScheduler`, we cannot set up exact repeating alarms. Our only option is to handle the repeating work ourselves.

Hence, `scheduleExactAlarm()` creates a broadcast `PendingIntent`, on an `Intent` pointing at our `PollReceiver`, with a pair of extras indicating the polling period and

whether or not we should be downloading a file. It then uses `setExact()` on an `AlarmManager` to schedule a *one-off* event to occur one polling period from now.

That, in turn, will trigger `onReceive()` of the `PollReceiver`. Here, we call `startWakefulService()` to have our work be done by a `DemoScheduledService`. In addition, if we have a polling period, that means that this is an exact alarm, and we call `scheduleExactAlarm()` to set up the next occurrence of this “repeating” event.

`DemoScheduledService` is simply an `IntentService` wrapper around the `DownloadJob` that we used with `DemoJobService`, logging the fact that it ran and calling `completeWakefulIntent()` to indicate that the work initiated by the `WakefulBroadcastReceiver` was done.

`cancelAlarm()` on `PollReceiver` — called by `manageExact()` when we are stopping the repeating event — creates an equivalent `PendingIntent` to the ones used for the `AlarmManager` events, and uses that with `cancel()` on `AlarmManager` to cancel those events.

If the user had chosen an exact alarm, `onCheckedChanged()` routes control to `manageInexact()`:

```
private void manageInexact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleInexactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

It uses the same recipe as `manageExact()`, except that it calls `scheduleInexactAlarm()` on `PollReceiver`. `scheduleInexactAlarm()`, in turn, uses `setInexactRepeating()` on `AlarmManager` to arrange to get control every so often.

Pondering Backoff Criteria

Sometimes, even with the Internet-availability checks offered by `JobScheduler`, you find that you cannot actually do the job you scheduled. Perhaps the server is down for maintenance, or has been replaced by [a honeycomb frame](#), or something. In this case, while you failed to do the job now, you may want to try again later.

Sometimes, “later” can just be handled by your existing `JobScheduler` setup. If the job in question is a periodic job, and missing a whole period is not a big problem, you might just continue on normally.

However, sometimes you will want the job to be retried, either because:

- it was a one-shot job, not a periodic one, or
- the period of the job is fairly long (e.g., once per day) and you want to retry well before the job is scheduled to happen again

Requesting that a job be retried is handled by the `boolean` parameter to `jobFinished()` or the `boolean` return value from `onStopJob()`. `true` means that you want the job to be rescheduled; `false` means that it is OK to skip the job entirely.

Given that you use `true` for either `jobFinished()` or `onStopJob()`, there are three possible options for how to request and retry a failed job:

- What happens for a job which you requested only run when the device is idle
- What happens for other jobs by default
- How you can influence the timing of when the job is retried, known as the “backoff criteria”

Idle Jobs

If you requested idle-only jobs, if the user wakes up the device while the job is going on, you will be called with `onStopJob()`. Ideally, you then stop the background work and return `true` or `false` from `onStopJob()` to determine if the job should be rescheduled.

If you request a job be rescheduled, when that job is set up to only run when the device is idle, the job is simply “put back in the queue” to be tried again during the next idle window.

Default Behavior

If, for a non-idle-only job, you use `true` for `jobFinished()` or `onStopJob()`, the next time to try will be calculated using the default backoff criteria, which has a time of 30 seconds and a policy of `BACKOFF_POLICY_EXPONENTIAL`.

What this means is that the first time you use `true`, your job will be tried again 30 seconds later. If you use `true` again for that job, it will be tried again 60 seconds later. If you use `true` again, it would be tried 120 seconds later — in other words, each job failure will reschedule using the formula $2^{(n-1)} * t$, where n is the number of failures and t is 30 seconds.

However, there is a cap of 18,000,000 milliseconds, or what normal people would refer to as “5 hours”. That is the most your job will be delayed, regardless of how many failures you have.

Custom Backoff Criteria

You can change the backoff criteria for non-idle-only jobs via a call to `setBackoffCriteria()` on your `JobInfo.Builder`, where you provide your own time (measured in milliseconds) and policy (`BACKOFF_POLICY_EXPONENTIAL` or `BACKOFF_POLICY_LINEAR`).

As noted above, the formula for exponential backoff rescheduling is $2^{\min(n-1, \text{cap})} * t$, where n is the number of failures and t is your chosen time.

The formula for linear backoff rescheduling is $n * t$, where n is the number of failures and t is your chosen time.

Other JobScheduler Features

There are a few other options for scheduling jobs that may be of use to you in select circumstances:

- `JobInfo.Builder` has `setOverrideDeadline()`, which indicates a maximum delay for this job before it will be executed even if other criteria (e.g., idleness) have been met. Note that this is only available on one-shot jobs, not periodic jobs.
- The `JobParameters` passed to `onStartJob()` has an `isOverrideDeadlineExpired()` method. This will return `true` if the job was executed early due to a `setOverrideDeadline()` value being met. This will indicate to you that your requirements may not be met (e.g., Internet access) and you will need to double-check those things yourself.
- `JobInfo.Builder` has `setMinimumLatency()` which sets a minimum delay time; the job will not be considered until at least this amount of time has elapsed. Note that this is only available on one-shot jobs, not periodic jobs.

Also, `JobScheduler` has a `getAllPendingJobs()` method, that returns a `List` of `JobInfo` objects representing “the jobs registered by this package that have not yet been executed”. Presumably, this includes the next occurrence of any periodic jobs and any jobs that are blocked pending a backoff delay, though the documentation is unclear on this point.

Android 6.0 and “the War on Background Processing”

Google has been increasingly aggressive about trying to prevent background work, particularly while the device is deemed to be idle, in an effort to improve battery life. In Android 4.4 (API Level 19), we were given a strong “nudge” to use inexact alarms. In Android 5.0 (API Level 21), we were given `JobScheduler` as a smarter `AlarmManager`, but one that also emphasizes inexact schedules.

In Android 6.0, Google broke out more serious weaponry in the war against background work, in ways that are going to cause a fair bit of pain and confusion for users.

Doze Mode

If the device’s screen is off, the device is not being charged, and the device does not appear to be moving (as determined via sensors, like the accelerometer), an Android 6.0+ device will go into “Doze mode”. This mode is reminiscent of similar modes used by specific device manufacturers, such as [SONY’s STAMINA mode](#).

While in “Doze mode”, your scheduled alarms (with `AlarmManager`), jobs (with `JobScheduler`), and syncs (with `SyncManager`) will be ignored by default, except during occasional “idle maintenance windows”. In short, much of what your user thinks will happen in the background will not happen.

App Standby Mode

Further compounding the problem from “Doze mode” is “app standby”.

After some undefined period of time, an app that has not been in the foreground (or is showing a `Notification`) will be put into “standby” state. While the app is in “standby”:

- If the device is unplugged, the app behaves as though the device is in “Doze mode”, with background access degrading over time to a point where the app will only get network access in the background around once per day
- If the device is plugged in, the app behaves normally

How to Win the War

The vision behind “the war on background processing” is to improve battery life, particularly while the device is not being used (Doze mode) or for apps that are not being used (app standby). However, any number of apps will have their behavior severely compromised by these changes.

Here are some techniques for helping your app behave better on Android 6.0+.

GCM

If you are using [Google Cloud Messaging](#) (GCM), and you send a “high-priority tickle” to the app on a device, that may allow you to run then, despite being in Doze mode or app standby mode. However, this implies that you have all the plumbing set up for GCM, that the device has an active network connection, etc. Also, this requires you to adopt GCM, which has its issues (no service-level agreement, Google has access to all of the messages, etc.).

...`AndAllowWhileIdle()`

`AlarmManager` now has two additional methods:

- `setAndAllowWhileIdle()`
- `setExactAndAllowWhileIdle()`

These work better in Doze mode and app standby mode, allowing you to get control briefly even if otherwise you would not. However:

- While in those modes, these alarms will occur at most once every 15 minutes, except during the aforementioned “idle maintenance windows”
- There is no guarantee of how long you will be able to keep the device awake
- There is no guarantee that you can access the Internet

Use a Foreground Service

While not officially documented, Dianne Hackborn (a core Android developer) wrote in a comment on [a Google+ post](#):

Apps that have been running foreground services (with the associated notification) are not restricted by doze.

The Whitelist

Users have the ability to disable these “battery optimizations” for an individual app, allowing it to run closer to normally. On the “Apps” screen in Settings, there is now a gear icon in the action bar:

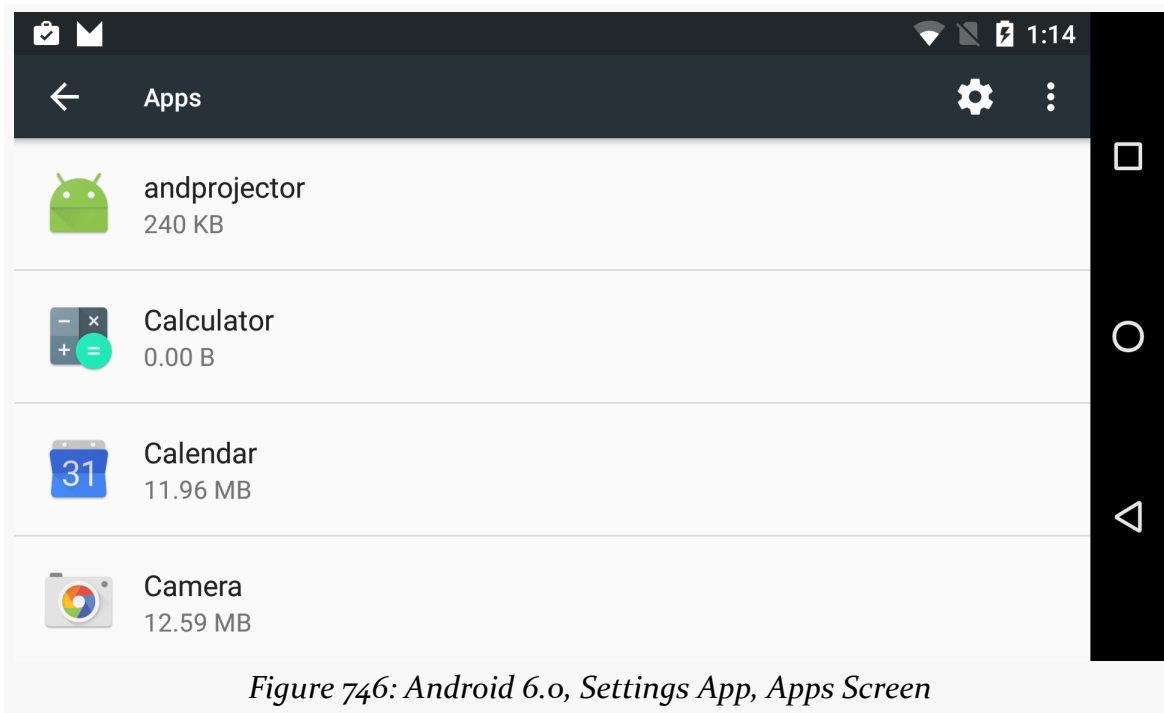

Figure 746: Android 6.0, Settings App, Apps Screen

Tapping that brings up a “Configure apps” screen. On there is a “Battery optimization” entry. Tapping on that will initially show the apps for which battery optimizations will be ignored (a.k.a., “Not optimized”):

Figure 747: Android 6.0, Settings App, Battery Optimization Screen

If the user toggles the “Not optimized” drop-down to “All apps” and taps on one of those apps, the user can elect to decide whether to “optimize” the app (and cause app standby to trigger) or not:

Figure 748: Android 6.0, Settings App, Battery Optimization Options Dialog

This “whitelist” of apps allows you to hold wakelocks and access the network. It does *not* change the behavior of AlarmManager, JobScheduler, or SyncManager — those things will still fire far less frequently in Doze mode or in app standby.

To determine if your app is already on the whitelist, you can call `isIgnoringBatteryOptimizations()` on a `PowerManager` instance.

If you would like to lead the user over to the screen where they can generally configure the whitelist, use an `ACTION_IGNORE_BATTERY_OPTIMIZATION_SETTINGS` Intent with `startActivity()`:

```
startActivity(new Intent(Settings.ACTION_IGNORE_BATTERY_OPTIMIZATION_SETTINGS));
```

If you would like to drive the user straight to the screen where they can add your specific app to the whitelist:

- Request the `REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` permission via a `<uses-permission>` element in the manifest
- Create a package: `Uri` pointing to your app
- Wrap that `Uri` in an `ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` Intent
- Call `startActivity()` with that Intent

JOB SCHEDULER

```
Intent i=new Intent(Settings.ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS,
    Uri.parse("package:" + getPackageName()));

startActivity(intent);
```

Note, though, that using this [may cause your app to be banned on the Play Store](#), even though it is a legitimate part of the Android SDK.

While the whitelist existed in the first developer preview of Android 6.0, its role was expanded very late in the process, as originally it did not affect Doze mode. The rationale appears to be for apps that cannot use GCM as the trigger mechanism to do background work, particularly if they need something else network-based as the trigger. For example, SIP clients, XMPP clients, MQTT clients, and so on are idle until a message comes in on an open network connection, yet none of those can be readily converted to use GCM. The whitelist allows apps to behave as they did prior to Android 6.0, though it requires user involvement.

However, any app can use this whitelist approach to return to more-normal behavior. The biggest limitation is for apps that relied upon `AlarmManager`, `JobScheduler`, or `SyncAdapter` as their triggers, as those are still crippled, regardless of whitelist status. The best you can get is ~15 minute periods, via `setExactAndAllowWhileIdle()`.

If you are sure that you need polling more frequently than that, and you are sure that the user will value that polling, your primary option is to use a foreground `Service` (or whitelisted app) and Java's `ScheduledExecutorService` to get control every so often, using a partial wakelock to keep the CPU powered on *all the time*. From a battery standpoint, this is horrible, far worse than the behavior you would get on Android 5.1 and earlier using `AlarmManager`. But, it's the ultimate workaround, which is why it is demonstrated in the [AlarmManager/AntiDoze](#) sample application.

The `AntiDoze` sample is based off of the greenrobot's `EventBus` sample from [the chapter on event bus alternatives](#). In that app, we used `AlarmManager` to get control every 15 seconds to either update a fragment (if the UI was in the foreground) or show a `Notification` (if not). `AntiDoze` gets rid of the every-event `Notification`, replacing it with appending an entry to a log file. And, it replaces `AlarmManager` with `ScheduledExecutorService` inside of a foreground `Service`, trying to run forever and get control every 15 seconds along the way.

This app has two product flavors defined in its `app/build.gradle` file, `normal` and `foreground`:

JOB SCHEDULER

```
apply plugin: 'com.android.application'

dependencies {
    compile 'de.greenrobot:eventbus:2.4.0'
    compile 'com.android.support:support-v13:23.0.1'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.1"

    defaultConfig {
        minSdkVersion 19
        targetSdkVersion 23
    }

    productFlavors {
        foreground {
            buildConfigField "boolean", "IS_FOREGROUND", "true"
        }

        normal {
            buildConfigField "boolean", "IS_FOREGROUND", "false"
        }
    }
}
```

(from [AlarmManager/AntiDoze/app/build.gradle](#))

A normal build will use a regular Service; a foreground build will use a foreground Service.

The launcher activity is EventDemoActivity. Its onCreate() method will do three things:

1. If we are on Android 6.0 or higher, it will use `isIgnoringBatteryOptimizations()` on `PowerManager` to see if we are already on the battery optimization whitelist, and if not, display a system-supplied dialog-themed activity to ask the user to add our app to the whitelist
2. If we do not already have the `EventLogFragment`, add it
3. If we do not already have the `EventLogFragment`, also start up the `ScheduledService`, as probably it is not already running

```
package com.commonware.android.antidoze;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Build;
import android.os.Bundle;
import android.os.PowerManager;
import android.provider.Settings;
```

JOB SCHEDULER

```
public class EventDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (Build.VERSION.SDK_INT > Build.VERSION_CODES.LOLLIPOP_MR1) {
            String pkg = getPackageName();
            PowerManager pm = getSystemService(PowerManager.class);

            if (!pm.isIgnoringBatteryOptimizations(pkg)) {
                Intent i =
                    new Intent(Settings.ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS)
                        .setData(Uri.parse("package:" + pkg));

                startActivity(i);
            }
        }

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new EventLogFragment()).commit();
            startService(new Intent(this, ScheduledService.class));
        }
    }
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/EventDemoActivity.java](#))

To be able to use `ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS`, we need to request and hold the `REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` permission, which we handle in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
    package="com.commonsware.android.antidoze"
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission android:name="android.permission.WAKE_LOCK" />
    <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED" />
    <uses-permission android:name="android.permission.REQUEST_IGNORE_BATTERY_OPTIMIZATIONS" />

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name="EventDemoActivity"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />

                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
    </application>
</manifest>
```

JOB SCHEDULER

```
<receiver android:name="PollReceiver">
  <intent-filter>
    <action android:name="android.intent.action.BOOT_COMPLETED"/>
  </intent-filter>
</receiver>

<receiver android:name="StopReceiver"/>

<service android:name="ScheduledService"/>
</application>
</manifest>
```

(from [AlarmManager/AntiDoze/app/src/main/AndroidManifest.xml](#))

The rest of the UI layer is unchanged. Where the differences really creep in is with `ScheduledService`. This used to be a `WakefulIntentService`, triggered by an alarm event. Now, it is a regular service, designed to run all the time.

As part of initializing the `ScheduledService` class, we create an instance of `ScheduledExecutorService`, through the `newSingleThreadScheduledExecutor()` static method on the `Executors` utility class:

```
private ScheduledExecutorService sched=
    Executors.newSingleThreadScheduledExecutor();
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

In `onCreate()`, we:

- Acquire a partial wakelock
- Call a private `foregroundify()` method to make our service be a foreground service with a suitable `Notification`, if our `IS_FOREGROUND` value is true based upon on our product flavor
- Set up a `File` for use with logging (named `log`), including creating the directory for it if needed
- Call `scheduleAtFixedRate()` on the `ScheduledExecutorService` to get control every 15 seconds

```
@Override
public void onCreate() {
    super.onCreate();

    PowerManager mgr=(PowerManager) getSystemService(POWER_SERVICE);

    wakeLock=mgr.newWakeLock(PowerManager.PARTIAL_WAKE_LOCK,
        getClass().getSimpleName());
    wakeLock.acquire();

    if (BuildConfig.IS_FOREGROUND) {
```

JOB SCHEDULER

```
foregroundify();
}

log=new File(getExternalFilesDir(null), "antidoze-log.txt");
log.getParentFile().mkdirs();
sched.scheduleAtFixedRate(this, 0, 15, TimeUnit.SECONDS);
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

We can pass the service itself to `scheduleAtFixedRate()` because it implements the `Runnable` interface. Its `run()` method uses greenrobot's `EventBus` to tell the UI layer about our event, plus it calls an `append()` method to log that event to our log file:

```
@Override
public void run() {
    RandomEvent event=new RandomEvent(rng.nextInt());

    EventBus.getDefault().post(event);
    append(log, event);
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

`append()` simply uses Java file I/O to append a line to the log file:

```
private void append(File f, RandomEvent event) {
    try {
        FileOutputStream fos=new FileOutputStream(f, true);
        Writer osw=new OutputStreamWriter(fos);

        osw.write(event.when.toString());
        osw.write(" : ");
        osw.write(Integer.toHexString(event.value));
        osw.write('\n');
        osw.flush();
        fos.flush();
        fos.getFD().sync();
        fos.close();

        Log.d(getClass().getSimpleName(),
            "logged to "+f.getAbsolutePath());
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
            "Exception writing to file", e);
    }
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

The `foregroundify()` method, called from `onCreate()`, creates a `Notification` and calls `startForeground()` to make the service be a foreground service:

JOB SCHEDULER

```
private void foregroundify() {
    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this);
    Intent iActivity=new Intent(this, EventDemoActivity.class);
    PendingIntent piActivity=
        PendingIntent.getActivity(this, 0, iActivity, 0);
    Intent iReceiver=new Intent(this, StopReceiver.class);
    PendingIntent piReceiver=
        PendingIntent.getBroadcast(this, 0, iReceiver, 0);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL)
        .setContentTitle(getString(R.string.app_name))
        .setContentIntent(piActivity)
        .setSmallIcon(R.drawable.ic_launcher)
        .setTicker(getString(R.string.app_name))
        .addAction(R.drawable.ic_stop_white_24dp,
            getString(R.string.notif_stop),
            piReceiver);

    startForeground(NOTIFY_ID, b.build());
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

The Notification includes a “stop” action, pointing to a StopReceiver, which just uses stopService() to stop the service. This allows the user to shut down our background service at any point, just via the Notification.

When the service is stopped, onDestroy() tidies things up, notably releasing the wakelock:

```
@Override
public void onDestroy() {
    sched.shutdownNow();
    wakeLock.release();
    stopForeground(true);

    super.onDestroy();
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

Running this overnight on an Android 6.0 device shows that, indeed, we get control every 15 seconds, as desired. The device’s battery drains commensurately, considering that we are keeping the CPU powered on all of the time. Either the whitelist keeps us going (normal flavor) or the foreground service keeps us going (foreground flavor).

setAlarmClock()

AlarmManager also has a `setAlarmClock()` method, added in API Level 21. This works a bit like `setExact()` (and, hence, `setExactAndAllowWhileIdle()`), in that you provide a time to get control and a `PendingIntent` to be invoked at that time. From the standpoint of power management, Doze mode leaves `setAlarmClock()` events alone, and so they are executed at the appropriate time regardless of device state. However, at the same time, `setAlarmClock()` has some user-visible impacts that make it suitable for certain apps (e.g., calendar reminders) and unsuitable for others (e.g., polling).

The [AlarmManager/AlarmClock](#) sample application demonstrates the use of `setAlarmClock()` as an alternative to `setExactAndAllowWhileIdle()`.

This app is reminiscent of the `AntiDoze` sample from earlier in this chapter. Once again, we have a fork off of an earlier demo of using greenrobot's `EventBus` to handle notifications from periodic work. In this case, rather than using `AlarmManager` and `setRepeating()` (as the original demo used) or using `ScheduledExecutorService` (as `AntiDoze` used), we use `setAlarmClock()` on `AlarmManager`.

`PollReceiver` now has a substantially different `scheduleAlarms()` implementation, along with a slightly different `onReceive()` implementation:

```
package com.commonware.android.alarmclock;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;
import com.commonware.cwac.wakeful.WakefulIntentService;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=15000; // 15 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction()==null) {
            WakefulIntentService.sendWakefulWork(ctxt, ScheduledService.class);
        }

        scheduleAlarms(ctxt);
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
```

JOB SCHEDULER

```
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);
    Intent i2=new Intent(ctxt, EventDemoActivity.class);
    PendingIntent pi2=PendingIntent.getActivity(ctxt, 0, i2, 0);

    AlarmManager.AlarmClockInfo ac=
        new AlarmManager.AlarmClockInfo(System.currentTimeMillis()+PERIOD,
            pi2);

    mgr.setAlarmClock(ac, pi);
}
}
```

(from [AlarmManager/AlarmClock/app/src/main/java/com/commonsware/android/alarmclock/PollReceiver.java](#))

`scheduleAlarms()` creates a `PendingIntent` identifying the `PollReceiver` itself, as was done in the original demo. This sample app is using `WakefulIntentService`, and the rules for wakeup-style alarms is that you should have the `PendingIntent` be a broadcast one. While it is unclear if `setAlarmClock()` has the same requirement, it seems reasonably likely.

However, `scheduleAlarms()` then creates a *second* `PendingIntent`, one pointing to the `EventDemoActivity`. That `PendingIntent` is supplied to the constructor to `AlarmManager.AlarmClockInfo`, along with the time we want the alarm to go off, expressed in the RTC-style timebase (i.e., milliseconds since the Unix epoch, `System.currentTimeMillis()`). We will see in a bit where that `PendingIntent` gets used.

Then, we call `setAlarmClock()` on `AlarmManager`, providing the `AlarmClockInfo` object and the first `PendingIntent`, to be invoked at the time indicated in the `AlarmClockInfo`.

As with the original example, `onReceive()` is used both for `ACTION_BOOT_COMPLETED` and for the one `AlarmManager` `PendingIntent`. To distinguish between these cases, `onReceive()` examines the action string of the incoming `Intent` — if this is not null, it must be the `ACTION_BOOT_COMPLETED` broadcast, as we did not put an action string in the `Intent` used to create the `PendingIntent` in `scheduleAlarms()`. If the `Intent` action is null, though, this is our `PendingIntent` invocation, so we call `sendWakefulWork()` to have the `ScheduledService` do something (in this case, log a message to a file and use `EventBus` to let the UI layer know about the event). However, in either case (`Intent` action is null or not), we call `scheduleAlarms()` to set up the next event, as `setAlarmClock()` is a one-shot alarm, not a recurring alarm.

The net effect is that if you run this app, your code gets control every 15 seconds, updating the fragment (via the event bus) and logging a line to a log file (using an

JOB SCHEDULER

`append()` method akin to the one from `AntiDoze`). More importantly, this will continue working despite Doze mode, even without your app being on the whitelist.

The biggest issue with `setAlarmClock()` is that it is visible to the user:

- The user will see the alarm clock icon in their status bar, as if they had set an alarm with their device's built-in alarm clock app
- The user will see the time of the alarm when they fully slide open their notification shade

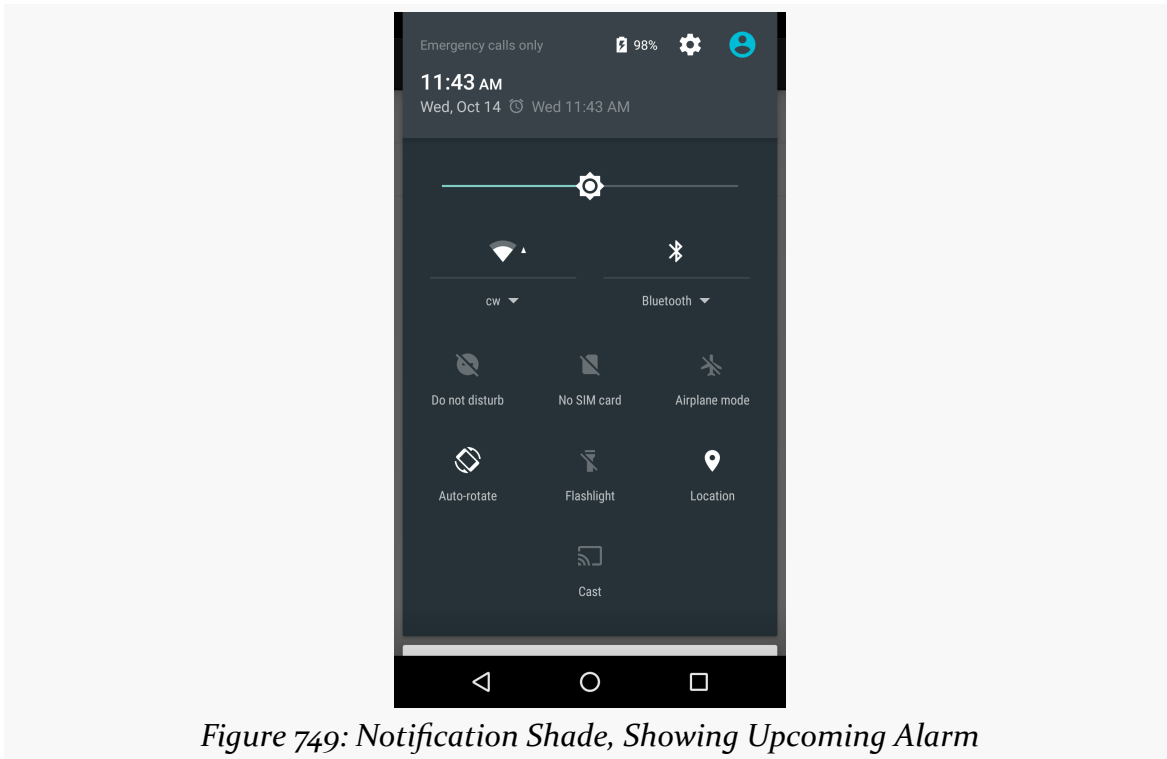

Figure 749: Notification Shade, Showing Upcoming Alarm

- Tapping on the alarm time in the notification shade will invoke the `PendingIntent` that you put into the `AlarmClockInfo` object

By default, executing this `PendingIntent` will start up the activity in a new task, and so you will need to consider using `android:launchMode` or `android:taskAffinity` to redirect the activity back to your original task.

For an app offering calendar-style reminders, none of this is necessarily a bad thing. You would tie the `PendingIntent` for the `AlarmClockInfo` object to the activity that

shows details of that particular appointment, so the user can review the details, remove the reminder request, etc.

For an app looking to do periodic work, the ever-present icon may aggravate some users, particularly those using alarm clock apps for actual alarm clock work and wondering why an alarm is set.

Also note that the manual rescheduling means that you are likely to have a bit of drift for periodic work. In the case of the sample app, each event will occur at least 15000 milliseconds apart. In reality, it will be slightly more, reflecting the execution time between when the system recognizes that it is time to invoke the alarm and the time when we call `setAlarmClock()` again. Many apps can just live with the drift. If this is an issue for you, you can try to minimize the drift by doing a more elaborate calculation of the next alarm time, one that cancels out previous drift.

Hope Somebody Else Does Something

Doze mode is for the entire device. Hence, your app may wind up getting control more frequently than you might expect, even without any code changes, simply because *somebody else* is doing something to get control more frequently.

GCM Network Manager

As noted earlier in this chapter, Android 5.0 added `JobScheduler`. However, Google did not release any sort of backport of this, as that would be difficult to do on a whole-device basis. They did not even implement a `JobSchedulerCompat`, hampering adoption.

Google Cloud Messaging (GCM) now has [a `GcmNetworkManager`](#) that, despite the name, is basically a backport of `JobScheduler`. In fact, it will delegate to `JobScheduler` on Android 5.0+ devices. It is unclear how old of an Android OS version `GcmNetworkManager` supports, but it is likely to work on more devices than does `JobScheduler`.

Trail: Hardware and System Services

Accessing Location-Based Services

A popular feature on current-era mobile devices is GPS capability, so the device can tell you where you are at any point in time. While the most popular use of GPS service is mapping and directions, there are other things you can do if you know your location. For example, you might set up a dynamic chat application where the people you can chat with are based on physical location, so you are chatting with those you are nearest. Or, you could automatically “geotag” posts to Twitter or similar services.

GPS is not the only way a mobile device can identify your location. Alternatives include:

1. Cell tower triangulation, where your position is determined based on signal strength to nearby cell towers
2. Proximity to public WiFi “hotspots” that have known geographic locations
3. GPS alternatives, such as [GLONASS](#) (Russia), [Galileo](#) (European Union, still under development), and [Compass](#) (China, still under development)

Android devices may have one or more of these services available to them. You, as a developer, can ask the device for your location, plus details on what providers are available. There are even ways for you to simulate your location in the emulator, for use in testing your location-enabled applications.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on threads](#).

Location Providers: They Know Where You're Hiding

Android devices can have access to several different means of determining your location. Some will have better accuracy than others. Some may be free, while others may have a cost associated with them. Some may be able to tell you more than just your current position, such as your elevation over sea level, or your current speed.

Android, therefore, has abstracted all this out into a set of `LocationProvider` objects. Your Android environment will have zero or more `LocationProvider` instances, one for each distinct locating service that is available on the device. Providers know not only your location, but also their own characteristics, in terms of accuracy, cost, etc. There are two main providers: `GPS_PROVIDER` (which uses GPS) and `NETWORK_PROVIDER` (which uses cell tower triangulation and WiFi hotspot proximity).

You, as a developer, will use a `LocationManager`, which holds the `LocationProvider` set, to figure out which `LocationProvider` is right for your particular circumstance. You will also need a permission in your application, or the various location APIs will fail due to a security violation.

Depending on which location providers you wish to use, you may need `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. Note that `ACCESS_COARSE_LOCATION` may intentionally “fuzz” or filter out location fixes that are “too good” (i.e., more accurate than a city block), such as those obtained from being near a known WiFi hotspot. The `GPS_PROVIDER` specifically requires `ACCESS_FINE_LOCATION` to work, at least on modern versions of Android. Also note that these permissions are dangerous, and therefore if your `targetSdkVersion` is 23 or higher, you need to ask for these permissions at runtime.

Finding Yourself

The obvious thing to do with a location service is to figure out where you are right now.

To do that, you need to get a `LocationManager` — call `getSystemService(LOCATION_SERVICE)` from your activity or service and cast it to be a `LocationManager`.

ACCESSING LOCATION-BASED SERVICES

The next step to find out where you are is to get the name of the `LocationProvider` you want to use. Here, you have two main options:

- Ask the user to pick a provider
- Find the best-match provider based on a set of criteria

If you want the user to pick a provider, calling `getProviders()` on the `LocationManager` will give you a `List` of providers, which you can then present to the user for selection.

Or, you can create and populate a `Criteria` object, stating the particulars of what you want out of a `LocationProvider`, such as:

1. `setAltitudeRequired()` to indicate if you need the current altitude or not
2. `setAccuracy()` to set a minimum level of accuracy, in meters, for the position
3. `setCostAllowed()` to control if the provider must be free or if it can incur a cost on behalf of the device user

Given a filled-in `Criteria` object, call `getBestProvider()` on your `LocationManager`, and Android will sift through the criteria and give you the best answer. Note that not all of your criteria may be met – all but the monetary cost criterion might be relaxed if nothing matches.

You are also welcome to hard-wire in a `LocationProvider` name (e.g., `GPS_PROVIDER`), perhaps just for testing purposes.

Once you know the name of the `LocationProvider`, you can call `getLastKnownLocation()` to find out where you were recently. However, unless something else is causing the desired provider to collect fixes (e.g., unless the GPS radio is on), `getLastKnownLocation()` will return `null`, indicating that there is no known position. On the other hand, `getLastKnownLocation()` incurs no monetary or power cost, since the provider does not need to be activated to get the value.

This method returns a `Location` object, which can give you the latitude and longitude of the device in degrees as a Java `double`. If the particular location provider offers other data, you can get at that as well:

1. For altitude, `hasAltitude()` will tell you if there is an altitude value, and `getAltitude()` will return the altitude in meters.

ACCESSING LOCATION-BASED SERVICES

2. For bearing (i.e., compass-style direction), `hasBearing()` will tell you if there is a bearing available, and `getBearing()` will return it as degrees east of true north.
3. For speed, `hasSpeed()` will tell you if the speed is known and `getSpeed()` will return the speed in meters per second.

A more likely approach to getting the `Location` from a `LocationProvider`, though, is to register for updates, as described in the next section.

On the Move

Not all location providers are necessarily immediately responsive. GPS, for example, requires activating a radio and getting a fix from the satellites before you get a location. That is why Android does not offer a `getMeMyCurrentLocationNow()` method. Combine that with the fact that your users may well want their movements to be reflected in your application, and you are probably best off registering for location updates and using that as your means of getting the current location.

The [Internet/Weather](#) sample application shows how to register for updates — call `requestLocationUpdates()` on your `LocationManager` instance. This takes four parameters:

- The name of the location provider you wish to use
- How long, in milliseconds, *should* have elapsed before we might get a location update
- How far, in meters, must the device have moved before we might get a location update
- An implementation of the `LocationListener` interface that will be notified of key location-related events

`LocationListener` requires four methods, the big one being `onLocationChanged()`, where you will receive your `Location` object when an update is ready:

```
@Override
public void onLocationChanged(Location location) {
    FetchForecastTask task=new FetchForecastTask();

    task.execute(location);
}
```

(from [Internet/Weather/app/src/main/java/com/commonsware/android/weather/WeatherFragment.java](#))

Bear in mind that the time parameter is only a guide to help steer Android from a power consumption standpoint. You may get many more location updates than this. To get the maximum number of location updates, supply 0 for both the time and distance constraints.

When you no longer need the updates, call `removeUpdates()` with the `LocationListener` you registered. If you fail to do this, your application will continue receiving location updates even after all activities and such are closed up, which will also prevent Android from reclaiming your application's memory.

There is another version of `requestLocationUpdates()` that takes a `PendingIntent` rather than a `LocationListener`. This is useful if you want to be notified of changes in your position even when your code is not running. For example, if you are logging movements, you could use a `PendingIntent` that triggers a `BroadcastReceiver` (`getBroadcast()`) and have the `BroadcastReceiver` add the entry to the log. This way, your code is only in memory when the position changes, so you do not tie up system resources while the device is not moving.

Are We There Yet? Are We There Yet? Are We There Yet?

Sometimes, you want to know not where you are now, or even when you move, but when you get to where you are going. This could be an end destination, or it could be getting to the next step on a set of directions, so you can give the user the next turn.

To accomplish this, `LocationManager` offers `addProximityAlert()`. This registers a `PendingIntent`, which will be fired off when the device gets within a certain distance of a certain location. The `addProximityAlert()` method takes, as parameters:

1. The latitude and longitude of the position that you are interested in
2. A radius, specifying how close you should be to that position for the Intent to be raised
3. A duration for the registration, in milliseconds — after this period, the registration automatically lapses. A value of -1 means the registration lasts until you manually remove it via `removeProximityAlert()`.
4. The `PendingIntent` to be raised when the device is within the “target zone” expressed by the position and radius

Note that it is not guaranteed that you will actually receive an Intent, if there is an interruption in location services, or if the device is not in the target zone during the period of time the proximity alert is active. For example, if the position is off by a bit, and the radius is a little too tight, the device might only skirt the edge of the target zone, or go by so quickly that the device's location isn't sampled while in the target zone.

It is up to you to arrange for an activity or receiver to respond to the Intent you register with the proximity alert. What you then do when the Intent arrives is up to you: set up a notification (e.g., vibrate the device), log the information to a content provider, post a message to a Web site, etc. Note that you will receive the Intent whenever the position is sampled and you are within the target zone – not just upon entering the zone. Hence, you will get the Intent several times, perhaps quite a few times depending on the size of the target zone and the speed of the device's movement.

Testing... Testing...

The Android emulator does not have the ability to get a fix from GPS, triangulate your position from cell towers, or identify your location by some nearby WiFi signal. So, if you want to simulate a moving device, you will need to have some means of providing mock location data to the emulator.

You can send location fixes via `telnet` to an emulator. The port number is in your emulator's title bar (usually 5554 for the first running emulator instance). You can then run:

```
telnet localhost 5554
```

to access the Android Console within the emulator. Running the `geo fix NNN NNN` command, where `NNN NNN` is your latitude and longitude, will have the emulator respond as if those coordinates came from GPS.

Alternative Flavors of Updates

There are more ways to get updates from `LocationManager` than the versions of `requestLocationUpdates()` we have seen so far. There are four major axes of difference:

ACCESSING LOCATION-BASED SERVICES

1. Some versions of `requestLocationUpdates()` take a `Criteria` object, having Android give you fixes based on the best-available provider given the requirements stipulated in the `Criteria`
2. Some versions of `requestLocationUpdates()` take a `Looper` as a parameter, allowing you to receive updates on a background `HandlerThread` instead of the main application thread
3. Some versions of `requestLocationUpdates()` take a `PendingIntent` which will be executed, instead of calling your `LocationListener`
4. There are a few flavors of `requestSingleUpdate()`, which, as the name suggests, gives you just one location fix, rather than a stream until you remove the request for updates

For the `Criteria`-flavored versions of `requestLocationUpdates()` and `requestSingleUpdate()`, bear in mind that your code will still crash if there are no possible providers for your `Criteria`. For example, even if you use an empty `Criteria` object (for maximum possible matches), but GPS is disabled and the device lacks telephony (e.g., a tablet), you can get a crash like this one:

```
02-09 13:29:21.549: E/AndroidRuntime(2236): FATAL EXCEPTION: main
02-09 13:29:21.549: E/AndroidRuntime(2236): java.lang.RuntimeException: Unable to resume activity

02-09 13:29:21.549: E/AndroidRuntime(2236): at dalvik.system.NativeStart.main(Native Method)
02-09 13:29:21.549: E/AndroidRuntime(2236): Caused by: java.lang.IllegalArgumentException: no providers
found for criteria
02-09 13:29:21.549: E/AndroidRuntime(2236): at android.os.Parcel.readException(Parcel.java:1331)
02-09 13:29:21.549: E/AndroidRuntime(2236): at android.os.Parcel.readException(Parcel.java:1281)
02-09 13:29:21.549: E/AndroidRuntime(2236): ... 19 more
```

Hence, you will still want to use `getProviders()` or `getBestProvider()` to ensure that your `Criteria` will resolve to *something* before you try using the `Criteria` to actually request fixes.

The Fused Option

Google Play Services — the proprietary API set supported by many Android devices — offers a fused location provider that simplifies location tracking. This capability is covered in [the next chapter](#).

The Fused Location Provider

At the 2013 Google I/O conference, Google announced an update to Google Play Services that offers a “fused location provider”, one that seamlessly uses all available location data to give you as accurate of a location as possible, as quickly as possible, with as little power consumption as possible. This serves as an adjunct to the traditional `LocationManager` approach for finding one’s position. The fused location provider has a different API, though one that is similar in some respects to the `LocationManager` API.

In this chapter, we will examine how to use the fused location provider.

Prerequisites

This chapter assumes that you have read the preceding chapter on [location-based services](#), along with that chapter’s prerequisites.

Why Use the Fused Location Provider?

The traditional recipes for using location providers are a bit complicated, if you want to maximize results. Simply asking for a GPS fix is not that hard, but:

- What if GPS is disabled?
- What if GPS signals are unavailable (e.g., the device is indoors)?
- What about the GPS power drain?

The fused location provider is designed to address these sorts of concerns. Its implementation will blend data from GPS, cell tower triangulation, and WiFi hotspot proximity to determine the device’s location, without your having to

manually set all of that up. The fused location provider will also take advantage of sensor data, so it does not try to update your location as frequently if the accelerometer indicates that you are not moving.

The net result is better location data, delivered more quickly, with (reportedly) less power consumption.

Why Not Use the Fused Location Provider?

The fused location provider is part of Google Play Services. Google Play Services is available on hundreds of millions of Android devices. However:

- It is closed source, and so we do not know what the Play Services all do, and whether anything that it does might be detrimental.
- It is proprietary, and so Play Services will not be available on the Kindle Fire series and other devices working solely from the Android open source project.
- Play Services is only available on devices that have the Play Store, as opposed to the old Android Market, and so older devices (e.g., Android 2.2 and older) are far less likely to have Play Services available.

If you are aiming to distribute your app solely through the Play Store, relying upon the Play Services framework is reasonable. If, however, you are distributing through other channels, you will either need to *conditionally* use the fused location provider on devices that offer it, or *avoid* the fused location provider entirely, falling back to the traditional `LocationManager` solution.

Finding Our Location, Once

The fused location provider requires a fair bit of setup, because of its dependence upon the Play Services framework. However, once that is established, the fused location provider is as easy to use, if not easier, than is `LocationManager`.

This section will review the [Location/FusedNew](#) sample application, which is a clone of the Internet/Weather sample application from [the previous chapter](#), revised to use the fused location provider to get a one-off weather forecast.

Installing and Attaching Google Play Services

If you have not done so already (e.g., for [Maps V2](#)), you will need to install the Play Services framework in your development environment.

Android Studio users should install the “Google Repository” entry in the SDK Manager. At that point, you can add a dependency upon the `com.google.android.gms:play-services-location` artifact for some appropriate version, such as `com.google.android.gms:play-services-location:7.8.0`.

Checking for Google Play Services

There is a fair bit of programming overhead to check for whether or not the Play Services Framework exists on the user’s device and is up to date. Much of this will be the same for any app that uses Play Services, particularly for apps that use the `GoogleApiClient` as we will here.

The chapter on Play Services has [an extensive section covering this overhead](#).

Permissions

To use the fused location provider, you still need the `ACCESS_FINE_LOCATION` or `ACCESS_COARSE_LOCATION` permissions. If you only hold `ACCESS_COARSE_LOCATION`, the data you get back will be limited to data that is sufficiently “fuzzy”. Typically, if you are bothering using this provider, you will request `ACCESS_FINE_LOCATION` — if coarse location data is all you need, using `LocationManager` should be just as good and is compatible with more devices.

For Android 6.0+ devices, if your `targetSdkVersion` is 23 or higher, you are going to need to deal with the runtime permissions model. Both `ACCESS_FINE_LOCATION` and `ACCESS_COARSE_LOCATION` are considered to be dangerous permissions. You will need both the `<uses-permission>` elements *and* specifically ask for user permission at runtime.

The previously-mentioned [section on setting up Play Services](#) also covers requesting runtime permissions.

Clients, Connections, and Callbacks

Play Services runs in its own process, one that appears to be continuously monitoring the user's location. In order to get location data from this process, we need to establish some sort of IPC (inter-process communication) with it. The low-level implementation of this is handled by the Play Services Android library project. However, we do need to set some things up ourselves.

Specifically, we need to create and use an instance of `GoogleApiClient`, our gateway to the Play Services SDK. The `AbstractGoogleApiClientActivity` — described in the [section on setting up Play Services](#) — handles a lot of this for us. What we need to do is override a few methods in our concrete `WeatherDemo` subclass of `AbstractGoogleApiClientActivity`:

```
package com.commonware.android.weather2;

import android.Manifest;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import com.google.android.gms.common.api.GoogleApiClient;
import com.google.android.gms.location.LocationServices;

public class WeatherDemo extends AbstractGoogleApiClientActivity {
    private static final String[] PERMS=
        {Manifest.permission.ACCESS_FINE_LOCATION};

    @Override
    protected GoogleApiClient.Builder configureApiClientBuilder(
        GoogleApiClient.Builder b) {
        return(b.addApi(LocationServices.API));
    }

    @Override
    protected String[] getDesiredPermissions() {
        return(PERMS);
    }

    @Override
    protected void handlePermissionDenied() {
        Toast
            .makeText(this, R.string.msg_no_perm, Toast.LENGTH_LONG)
            .show();
        finish();
    }

    @Override
    public void onConnected(Bundle bundle) {
        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new WeatherFragment()).commit();
        }
    }
}
```

THE FUSED LOCATION PROVIDER

```
}  
  
@Override  
public void onConnectionSuspended(int i) {  
    Log.w(((Object)this).getClass().getSimpleName(),  
        "onConnectionSuspended() called, whatever that means");  
}  
}
```

(from [Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

Specifically:

- `configureApiClientBuilder()` needs to flesh out the details of what sorts of APIs we are looking to use in this app. In this case, we call `addApi()` on the supplied `GoogleApiClient.Builder`, requesting the `LocationServices.API`, to be able to get at the relevant portion of the Play Services SDK.
- `getDesiredPermissions()` returns an array of the names of the runtime permissions that we need in order to use this API. In this case, we are asking for `ACCESS_FINE_LOCATION` (though, in truth, `ACCESS_COARSE_LOCATION` would suffice for getting weather forecasts). The manifest also has the `<uses-permission>` element for `ACCESS_FINE_LOCATION`.
- `handlePermissionDenied()` will be called if we request the permission and we do not have it when we get control back. This means that either the user denied it now or the user denied it earlier and checked the “Don’t ask again” checkbox to stop being bothered about runtime permissions. We could use `shouldShowPermissionRequestRationale()` and perhaps take some steps to educate the user. This is a book example, so we just `finish()` the activity and move along with our day.
- `onConnected()`, from the `GoogleApiClient.ConnectionCallbacks`, will be called if we now have access to the `LocationServices.API` that we requested. At this point, it is safe for us to show a `WeatherFragment` that will use this API to go get the location and, from that, get the weather forecast.
- `onConnectionSuspended()`, also from the `GoogleApiClient.ConnectionCallbacks`, might get called, for uncertain reasons. Here, we are largely ignoring this condition.

The upshot is that, if things go as expected, we will show the `WeatherFragment` when we can get the location and the subsequent forecast.

Finding the Current Location

Given all that setup, actually getting the location is almost anti-climactic.

THE FUSED LOCATION PROVIDER

To find the current location, given a connected `GoogleApiClient`, just call the static `getLastLocation()` method on `LocationServices.FusedLocationApi`, passing in the `GoogleApiClient` instance as a parameter. This usually will return a non-null `Location` object, using the same `Location` class that you would use with `LocationManager`.

In the sample, the `run()` method checks to see if `getLastLocation()` returns null or not. If the location is null, it schedules `run()` to be invoked again in one second, using `postDelayed()` on some suitable `View` (in this case, the `WebView` for displaying the results). If, however, we do have a valid location, `run()` invokes a `FetchForecastTask`, as did the original version of this sample:

```
@Override
public void run() {
    Location loc=LocationServices.FusedLocationApi
        .getLastLocation(getPlayServices());

    if (loc == null) {
        getListView().postDelayed(this, 1000);
    }
    else {
        FetchForecastTask task=new FetchForecastTask();

        task.execute(loc);
    }
}
```

(from [Location/FusedNew/app/src/main/java/com/commonsware/android/weather2/WeatherFragment.java](https://github.com/CommonWare/android-weather2/blob/master/WeatherFragment.java))

The fact that we are using `postDelayed()` here is why we use `removeCallbacks()` in `onPause()`, to stop polling for `getLastLocation()` when we are disconnecting from the `LocationClient`.

Note that the documentation for `getLastLocation()` states “If a location is not available, which should happen very rarely, null will be returned.” The “very rarely” part indicates that Play Services is constantly checking for the user’s location, possibly because [location providers are not available](#).

The Rest of the Sample

The rest of the sample follows some examples from earlier in the book for fetching data and displaying it.

`run()`, once it gets a location from `getLastLocation()`, executes a `FetchForecastTask`, which is a subclass of `AsyncTask`. This task, in `doInBackground()`, calls `getForecastXML()`, which uses `URLConnection` to

THE FUSED LOCATION PROVIDER

retrieve the weather forecast XML. The task also calls `buildForecasts()`, which parses that XML using the Java DOM and builds an `ArrayList` of `Forecast` objects, where each `Forecast` holds a time, the predicted temperature, and a code indicating the expected cloud cover and precipitation.

In the task's `onPostExecute()` method, it creates a `ForecastAdapter`, wrapped around our list of `Forecast` objects, and puts that adapter in the `ListView` for our `ListFragment`. `ForecastAdapter` follows the same pattern as was seen in [the Picasso sample](#), using Picasso to load in icons associated with each cloud cover/precipitation prediction and show those alongside the time and temperature.

The result looks like:

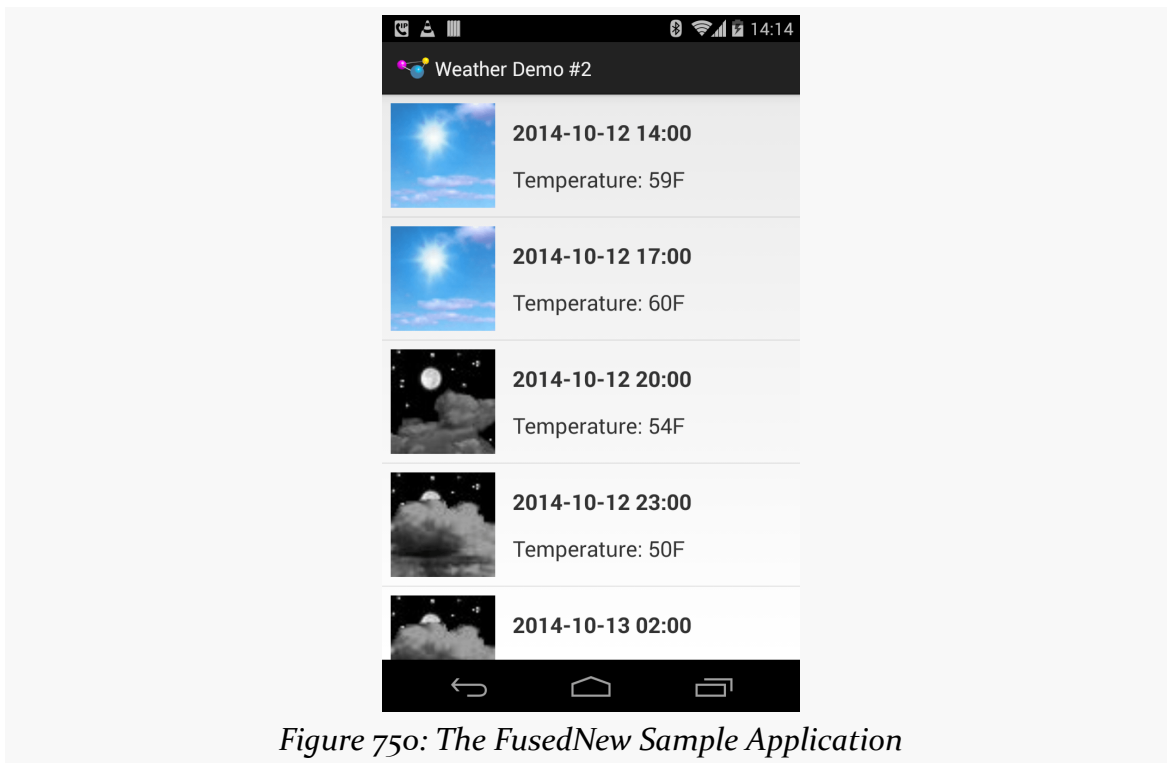

Figure 750: The FusedNew Sample Application

Requesting Location Updates

As with `LocationManager`, you can use `LocationClient` to be delivered location updates as the device moves, via `requestLocationUpdates()`. There are two major axes of control you have over these updates: the way the locations are delivered to you, and the `LocationRequest` that configures what updates you receive.

Delivery Options

A foreground application would use forms of `requestLocationUpdates()` that take a `LocationListener` as a parameter. Despite the class being named the same, this is a separate implementation of the `LocationListener` interface. The Play Services one (`com.google.android.gms.location.LocationListener`) only requires a single method: `onLocationChanged()`, which is handed a `Location` object representing a location fix.

A background application would use the `requestLocationUpdates()` that takes a `PendingIntent` instead of a `LocationListener`, where that `PendingIntent` can do whatever you wish (start an activity, start a service, send a broadcast). The location itself is delivered in the form of an `Intent` extra, keyed as `KEY_LOCATION_CHANGED`, with a value in the form of a `Location` object.

Request Options

All forms of `requestLocationUpdates()` take a `LocationRequest` object describing what you want in terms of updates. Unlike with `LocationManager`, you do not specify specific location technologies (e.g., GPS). You also lack the fine-grained control of the `Criteria` object (e.g., to require the location to have speed data). However, you do have some measure of control, via various setters on `LocationRequest`.

Frequency

Calling `setInterval()` indicates approximately how frequently you wish to receive location updates. The key word here is “approximately”, as you will receive updates more or less frequently than the number of milliseconds you specify as the desired interval. However, your requested interval is taken into account, and the longer of an interval you provide, the less power your app will consume.

To help prevent being flooded with location data, you can also call `setFastestInterval()`, which will throttle the actual updates to be no more frequent than the number of milliseconds that you state.

Priority

`setPriority()` allows you to control the accuracy and power consumption of your app’s request, by specifying one of four possible priority levels:

THE FUSED LOCATION PROVIDER

- `PRIORITY_HIGH_ACCURACY` will tend to use GPS and therefore will consume more power
- `PRIORITY_BALANCED_POWER_ACCURACY` will try to consume somewhat less power
- `PRIORITY_LOW_POWER` will try to consume even less power
- `PRIORITY_NO_POWER` indicates that you want to consume no additional power over any other requests, but to get what you can (akin to the “passive provider” available with `LocationManager`)

Duration

You can proactively cancel receiving further updates by calling `removeUpdates()`, passing in your delivery option from `requestLocationUpdates()`:

- The same `LocationListener` as you used to request the updates, or
- An equivalent `PendingIntent` to the one that you used to request the updates

You can also automatically expire your requested updates by one of three means:

- `setNumUpdates()` indicates exactly how many location fixes that you want to receive (e.g., 1) and discontinues the updates after that number
- `setExpirationDuration()` indicates how long you wish to receive updates, expressed as a number of milliseconds from now
- `setExpirationTime()` indicates when you wish to discontinue updates, expressed in the form of the number of milliseconds since the device turned on (e.g., the same time base as is used by `elapsedRealtime()` on the `SystemClock` class)

For example, an improved version of the sample shown in this chapter would use a `LocationRequest` with `setNumUpdates(1)`, instead of the one-second polling of `getLastLocation()`. In fact, we will see such an improved version in the next section.

I Can Haz Location?

One common complaint among Android developers is that there is no way for developers to enable location providers, like GPS. This is for privacy reasons. Users should be able to control whether apps can track their movements. However, to

THE FUSED LOCATION PROVIDER

enable location providers, the user had to go into the Settings app, which was aggravating.

In early 2015, Google added `SettingsApi` to the fused location provider portion of the Play Services SDK. This allows apps to find out if we are capable of using the fused location provider, and if not, pop up a dialog where the user can agree to enable location tracking.

The [Location/FusedPeriodic](#) sample application demonstrates this, plus the APIs used for periodic location updates. In truth, we will only get a single location fix, as hinted in the previous section, but this example could be extended to update more than once if needed.

The business logic, and some of the code, is the same as in the previous sample: fetch the location, then show a weather forecast for that location. What differs is in how we are fetching the location, as we use `SettingsApi` and `requestLocationUpdates()`.

Defining a Location Request

Core to both finding out whether we can use the fused location provider, and later getting location fixes, will be to define a `LocationRequest` object. Fortunately, this is a pure POJO, without any ties to any `Context` or other existing Play Services SDK objects. Hence, we can declare it as an ordinary data member and initialize it in `onCreate()` of the revised `WeatherFragment`:

```
public class WeatherFragment extends ListFragment implements
    ResultCallback<LocationSettingsResult>,
    LocationListener {
    static final int SETTINGS_REQUEST_ID=1338;
    private String template=null;
    private LocationRequest request=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setRetainInstance(true);

        template=getActivity().getString(R.string.url);
        request=new LocationRequest()
            .setNumUpdates(1)
            .setExpirationDuration(60000)
            .setInterval(1000)
            .setPriority(LocationRequest.PRIORITY_LOW_POWER);
    }
}
```

(from [Location/FusedPeriodic/app/src/main/java/com/commonsware/android/weather3/WeatherFragment.java](#))

THE FUSED LOCATION PROVIDER

(you will also notice that we are now implementing some new interfaces — more about those later in this section)

In `onCreate()`, we indicate that the `LocationRequest`:

- Only needs to provide us with a single location fix (`setNumUpdates(1)`)
- Can give up automatically if we do not get a location fix within the first minute (`setExpirationDuration(60000)`)
- Should start working fairly quickly to get us our fix (`setInterval(1000)`)
- Can optimize for power over accuracy (`setPriority(LocationRequest.PRIORITY_LOW_POWER)`)

The `setInterval()` call may seem odd, given that we are only seeking one fix. Leaving this out, though, means that you *never* get a fix, for unclear reasons.

Also, while we are requesting `PRIORITY_LOW_POWER`, and we do not need a particularly accurate fix just to get a weather forecast, we still request `ACCESS_FINE_LOCATION` in the manifest. Without this, once again we seem to never get a fix.

Another issue comes with the expiration value. `setExpirationDuration()` calculates the expiration time based on when the `LocationRequest` object is *created*, not when it is *used*. That's bad, and we will see where that can bite us a bit later in this chapter.

Requesting and Reacting to Settings Status

In the original example, once we were connected to the Play Services engine and our `WeatherFragment` was created, we would get the last-known location and try to fetch a forecast. If there was no location, we would just ask again every second. This is not a great solution:

- We might never get a location, because the user has disabled location tracking
- We might never get a location, because the environment is unsuitable (e.g., underground parking garage)
- It does not give Play Services much information about what we need in terms of a location fix

THE FUSED LOCATION PROVIDER

Therefore, this sample changes `onViewCreated()` to call a private `requestSettings()` method, so we can find out if location tracking is enabled and, if not, perhaps ask the user to enable it:

```
private void requestSettings() {
    LocationSettingsRequest.Builder b=
        new LocationSettingsRequest.Builder()
            .addLocationRequest(request);
    PendingResult<LocationSettingsResult> result=
        LocationServices.SettingsApi.checkLocationSettings(getPlayServices(),
            b.build());

    result.setResultCallback(this);
}
```

(from [Location/FusedPeriodic/app/src/main/java/com/commonsware/android/weather3/WeatherFragment.java](#))

Here, we create a `LocationSettingsRequest.Builder` and pass it our already-defined `LocationRequest` via `addLocationRequest()`. This way, Play Services will know the sort of location data that we will be looking for later and can tell us whether or not that is presently possible.

We then `build()` the `LocationSettingsRequest` and pass it to `checkLocationSettings()` on the `LocationServices.SettingsApi` class. This returns a `PendingResult`, specifically of a `LocationSettingsResult` type. We call `setResultCallback()` to indicate that the fragment itself should be notified about the results of this request. That is why `WeatherFragment` now implements the `ResultCallback` interface for `LocationSettingsResult`, which in turn requires us to implement an `onResult()` method that takes a `LocationSettingsResult` as a parameter:

```
@Override
public void onResult(LocationSettingsResult result) {
    boolean thingsPlumbBusted=true;

    switch(result.getStatus().getStatusCode()) {
        case LocationSettingsStatusCodes.SUCCESS:
            requestLocations();
            thingsPlumbBusted=false;
            break;

        case LocationSettingsStatusCodes.RESOLUTION_REQUIRED:
            try {
                result
                    .getStatus()
                    .startResolutionForResult(getActivity(),
                        SETTINGS_REQUEST_ID);

                thingsPlumbBusted=false;
            }
            catch (IntentSender.SendIntentException e) {
                // oops
            }
    }
}
```

THE FUSED LOCATION PROVIDER

```
    }
    break;

    case LocationSettingsStatusCodes.SETTINGS_CHANGE_UNAVAILABLE:
        // more oops
        break;
}

if (thingsPlumbBusted) {
    Toast
        .makeText(getActivity(),
            R.string.settings_resolution_fail_msg,
            Toast.LENGTH_LONG)
        .show();
    getActivity().finish();
}
}
```

(from [Location/FusedPeriodic/app/src/main/java/com/commonsware/android/weather3/WeatherFragment.java](#))

What we are hoping for is `LocationSettingsStatusCodes.SUCCESS` as the status code out of the result's `Status` object (obtained via `getStatus()`). This means that our proposed location updates should succeed, and we can go ahead and make that request. We do that via a call to a private `requestLocations()` method that we will explore a bit later.

However, instead we might get `LocationSettingsStatusCodes.RESOLUTION_REQUIRED`. This means that the user has disabled location providers necessary to fulfill the request, but that we could prompt the user to enable location tracking. To do this, we call `startResolutionForResult()` on that `Status` object, passing in our `Activity` along with a locally-unique integer.

This will display the following dialog-themed `Activity`:

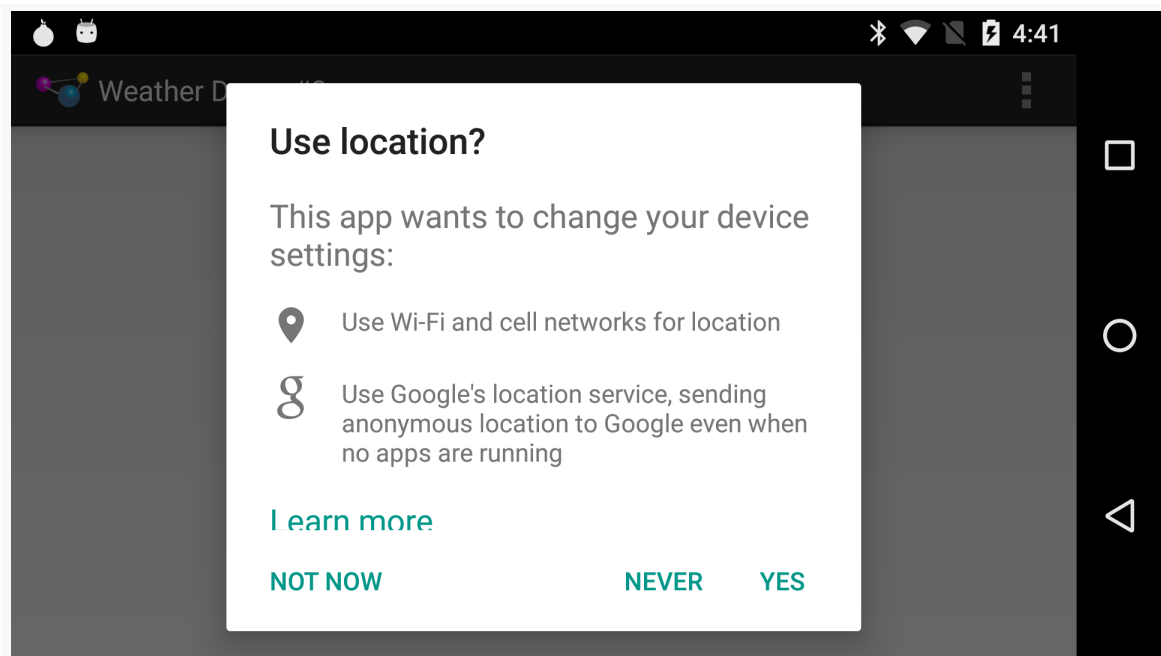

Figure 751: Location Enable Dialog

Google Maps users will recognize it as being akin to the one that appears if you try using certain Maps features (e.g., navigation) and do not have location tracking enabled in Settings.

The user has three choices:

1. Click “Yes”
2. Click “No”
3. Click “Never”, which not only has an immediate effect akin to “No” but also will immediately fail all future attempts at resolution from your app, until such time as the user clears the app’s data or reinstalls the app from scratch

You can block that “Never” option via a call to `setAlwaysShow(true)` on the `LocationSettingsRequest.Builder` before calling `checkLocationSettings()`.

That should eventually trigger a call to `onActivityResult()` *on the activity* – `startResolutionForResult()` knows nothing about fragments. There are two possibilities here: the user accepts our request to enable location tracking, or the user denies it. If the user accepts our request, `onResult()` will be called again with `LocationSettingsStatusCodes.SUCCESS`, at which time we can request location updates. If the user rejects the request, we need to arrange to stop asking. By default,

THE FUSED LOCATION PROVIDER

if we do nothing, if the user rejects the request, we will be called with `LocationSettingsStatusCodes.RESOLUTION_REQUIRED` again and will pop up the dialog again. That is why, in the `WeatherDemo` activity, we have an `onActivityResult()` to catch when the user completes the dialog triggered by `startResolutionForResult()`:

```
@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (requestCode==WeatherFragment.SETTINGS_REQUEST_ID) {
        if (resultCode==Activity.RESULT_CANCELED) {
            finish();
        }
        else {
            // this should not be needed, but apparently is in 8.1
            WeatherFragment f=
                (WeatherFragment)getFragmentManager().findFragmentById(android.R.id.content);
            f.requestLocations();
        }
    }
}
```

(from [Location/FusedPeriodic/app/src/main/java/com/commonsware/android/weather3/WeatherDemo.java](#))

The locally-unique integer provided to `startResolutionForResult()`, under the covers, is used for a `startActivityForResult()` call, which is why we get control in `onActivityResult()`. If the request is for this settings dialog, and if the user canceled our request, we `finish()` the activity, as we cannot do anything anymore and may as well close up shop. There are probably other ways of handling this condition that will prevent `onResult()` from getting called again.

If the `resultCode` is `Activity.RESULT_OK`, though, then the user presumably is allowing us to request locations, having clicked “Yes” on the dialog. For some reason, on version 8.1 of the Play Services SDK, this does *not* trigger a fresh call to the `onResult()` method, the way it used to. So, we have to get our `WeatherFragment` and call `requestLocations()` from `onActivityResult()` instead.

Speaking of `onResult()`, it is possible that the status code is neither of those values. In those cases, we are also stuck — Play Services is indicating that we will not be able to get the locations that we are requesting. So, there, we show a `Toast` and `finish()` the activity.

Requesting “Periodic Locations”

The `requestLocations()` method will be triggered once `SettingsApi` gives us “the go-ahead” via the `onResult()` method:

THE FUSED LOCATION PROVIDER

```
void requestLocations() {
    PendingResult<Status> result=
        LocationServices.FusedLocationApi
            .requestLocationUpdates(getPlayServices(), request, this);

    result.setResultCallback(new ResultCallback<Status>() {
        @Override
        public void onResult(Status status) {
            if (status.isSuccess()) {
                Toast
                    .makeText(getActivity(),
                        R.string.location_req_success_msg,
                        Toast.LENGTH_LONG)
                    .show();
            } else {
                Toast
                    .makeText(getActivity(), status.getStatusMessage(),
                        Toast.LENGTH_LONG)
                    .show();
                getActivity().finish();
            }
        }
    });
}
```

(from [Location/FusedPeriodic/app/src/main/java/com/commonsware/android/weather3/WeatherFragment.java](#))

Here, we start off by calling `requestLocationUpdates()`, passing in the `LocationRequest` that we created before, along with our `LocationListener` implementation, which happens to be the fragment itself.

We can, if we want, attach another `ResultCallback` object to the `PendingResult` returned by `requestLocationUpdates()`. This way, we can find out if our request for location updates was successfully queued or not. Here, we do that, using an instance of an anonymous inner class of `PendingResult`. We show a `Toast` regardless of success or failure; we also `finish()` the method on failure.

What should happen, if the request was successful, is that we will get one fix delivered to `onLocationChanged()` on our `LocationListener`. There, we kick off the `FetchForecastTask`, this time using `executeOnExecutor()`:

```
@Override
public void onLocationChanged(Location location) {
    new FetchForecastTask()
        .executeOnExecutor(AsyncTask.THREAD_POOL_EXECUTOR, location);
}
```

(from [Location/FusedPeriodic/app/src/main/java/com/commonsware/android/weather3/WeatherFragment.java](#))

If, after a minute of trying, we do not get the location fix, Play Services will stop trying, based on our `setExpirationDuration()` value on the `LocationRequest` object.

THE FUSED LOCATION PROVIDER

However, this is where we run into a problem with using that `LocationRequest` created originally. It appears that the `LocationRequest` calculates the time to give up based on when the `LocationRequest` is created. It is not based on the time when we call `requestLocationUpdates()`. In many cases, there will be little delay between those two points in time, and so the different is negligible. But if the user gets the enable-location dialog and leaves it open for a minute, when we call `requestLocationUpdates()`, *we are already expired*. However, we do not find out about this, and we just never get a location fix. Hence, rather than creating a single instance of `LocationRequest`, have a `buildLocationRequest()` method that can return the instance to you, newly created, so you have the full expiration time to work with.

Also, in `onPause()`, we call `removeLocationUpdates()`, so that we minimize power drain while we are not in the foreground.

This sample app is less-than-optimal in its handling of configuration changes. Everything works, but we wind up re-requesting location updates on each configuration change. A better implementation would note if we already have our location fix and therefore no longer need to request location updates.

Working with the Clipboard

Being able to copy and paste is something that mobile device users seem to want almost as much as their desktop brethren. Most of the time, we think of this as copying and pasting text, and for a long time that was all that was possible on Android. Android 3.0 added in new clipboard capabilities for more rich content, which application developers can choose to support as well. This section will cover both of these techniques.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Using the Clipboard on Android 1.x/2.x

Android has a `ClipboardManager` that allows you to interact with the clipboard manually, in addition to built-in clipboard facilities for users (e.g., copy/paste context menus on `EditText`). `ClipboardManager`, like `AudioManager`, is obtained via a call to `getSystemService()`:

(from [SystemServices/ClipIP/app/src/main/java/com/commonsware/android/clipip/IPClipper.java](#))

From there, you have three simple methods:

1. `getText()` to retrieve the current clipboard contents
2. `hasText()`, to determine if there are any clipboard contents, so you can react accordingly (e.g., disable “paste” menus when there is nothing to paste)
3. `setText()`, to put text on the clipboard

WORKING WITH THE CLIPBOARD

For example, the [SystemServices/ClipIP](#) sample project contains a little application that puts your current IP address on the clipboard, for pasting into some EditText of an application.

The IPClipper activity's onCreate() does the work of putting text onto the clipboard via setText() and notifying the user via a Toast:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        String addr=getLocalIPAddress();

        if (addr == null) {
            Toast.makeText(this,
                "IP address not available -- are you online?",
                Toast.LENGTH_LONG).show();
        }
        else {
            ClipboardManager cm=
                (ClipboardManager) getSystemService(CLIPBOARD_SERVICE);

            try {
                cm.setText(addr);

                Toast.makeText(this, "IP Address clipped!",
                    Toast.LENGTH_SHORT).show();
            }
            catch (Exception e) {
                Log.e(getClass().getSimpleName(), "Exception clipping IP", e);
                Toast.makeText(this, "Exception: " + e.getMessage(),
                    Toast.LENGTH_SHORT).show();
            }
        }
    }
    catch (Exception e) {
        Log.e("IPClipper", "Exception getting IP address", e);
        Toast.makeText(this, "Could not obtain IP address",
            Toast.LENGTH_LONG).show();
    }

    finish();
}
```

(from [SystemServices/ClipIP/app/src/main/java/com/commonsware/android/clipip/IPClipper.java](#))

The work of figuring out what the IP address is can be found in the getLocalIPAddress() method:

```
public String getLocalIPAddress() throws SocketException {
    Enumeration<NetworkInterface> nics=
        NetworkInterface.getNetworkInterfaces();

    while (nics.hasMoreElements()) {
```

WORKING WITH THE CLIPBOARD

```
NetworkInterface intf=nics.nextElement();
Enumeration<InetAddress> addrs=intf.getInetAddresses();

while (addrs.hasMoreElements()) {
    InetAddress addr=addrs.nextElement();

    if (!addr.isLoopbackAddress()) {
        return(addr.getHostAddress().toString());
    }
}

return(null);
}
```

(from [SystemServices/ClipIP/app/src/main/java/com/commonsware/android/clipip/IPClipper.java](#))

This uses the `NetworkInterface` and `InetAddress` classes from the `java.net` package to loop through all network interfaces and find the first one that has a non-localhost (loopback) IP address. The emulator will return `10.0.2.15` all of the time; your device will return whatever IP address it has from WiFi, 3G, etc. If no such address is available, it returns `null`.

The activity itself has no UI, as the application uses `Theme.NoDisplay`. The activity avoids a call to `setContentView()`, and calls `finish()` when all the work is done in `onCreate()`. Hence after starting the activity, the user will hopefully see the “successful” Toast, and nothing else:

Figure 752: The IPClipper, shortly after launching

Then, if the user long-taps on an `EditText` and chooses `Paste`, the IP address is added to the `EditText` contents. Note that the clipboard is system-wide, not merely application-wide, which is why you can successfully paste the IP address into any application's fields.

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setText()` call wrapped in a `try/catch` block, even though `setText()` does not throw a checked exception. The rationale for this will be discussed [later in this chapter](#).

Advanced Clipboard on Android 3.x and Higher

Android 3.0 added in new ways of working with `ClipboardManager` to clip things that transcend simple text. In part, this is expected to be used for advanced copy and paste features between applications. However, this also forms the foundation for a rich drag-and-drop model within an application.

Note that they also moved `ClipboardManager` to the `android.content` package. You can still refer to it via the `android.text` package, for backwards compatibility. However, if your project will be on API Level 11 or higher only, you might consider using the new `android.content` package edition of the class.

Copying Rich Data to the Clipboard

In addition to methods like `setText()` to put a piece of plain text on the clipboard, `ClipboardManager` (as of API Level 11) offers `setPrimaryClip()`, which allows you to put a `ClipData` object on the clipboard.

What's a `ClipData`? In some respects, it is whatever you want. It can hold:

1. plain text
2. a `Uri` (e.g., to a piece of music)
3. an `Intent`

The `Uri` means that you can put anything on the clipboard that can be referenced by a `Uri`... and if there is nothing in Android that lets you reference some data via a `Uri`, you can invent your own content provider to handle that chore for you.

Furthermore, a single `ClipData` can actually hold as many of these as you want, each represented as individual `ClipData.Item` objects. As such, the possibilities are endless.

There are static factory methods on `ClipData`, such as `newUri()`, that you can use to create your `ClipData` objects. In fact, that is what we use in the [SystemServices/ClipMusic](#) sample project and the `MusicClipper` activity.

`MusicClipper` has the classic two-big-button layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="Pick"
        android:onClick="pickMusic"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
    />
```

WORKING WITH THE CLIPBOARD

```
        android:layout_weight="1"
        android:text="Play"
        android:onClick="playMusic"
    />
</LinearLayout>
```

(from [SystemServices/ClipMusic/app/src/main/res/layout-land/main.xml](#))

Figure 753: The Music Clipper main screen

In `onCreate()`, we get our hands on our `ClipboardManager` system service:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    clipboard=(ClipboardManager) getSystemService(CLIPBOARD_SERVICE);
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

Tapping the “Pick” button will let you pick a piece of music, courtesy of the `pickMusic()` method wired to that `Button` object:

```
public void pickMusic(View v) {
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);
    i.setType("audio/*");
```

WORKING WITH THE CLIPBOARD

```
startActivityForResult(i, PICK_REQUEST);  
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

Here, we tell Android to let us pick a piece of music from any available audio MIME type (audio/*). Fortunately, Android has an activity that lets us do that:

Figure 754: The XOOM tablet's music track picker

We get the result in `onActivityResult()`, since we used `startActivityForResult()` to pick the music. There, we package up the `content://Uri` to the music into a `ClipData` object and put it on the clipboard:

```
@Override  
protected void onActivityResult(int requestCode, int resultCode,  
                                Intent data) {  
    if (requestCode == PICK_REQUEST) {  
        if (resultCode == RESULT_OK) {  
            ClipData clip=  
                ClipData.newUri(getContentResolver(), "Some music",  
                               data.getData());  
  
            try {  
                clipboard.setPrimaryClip(clip);  
            }  
            catch (Exception e) {  
                Log.e(getClass().getSimpleName(), "Exception clipping Uri", e);  
            }  
        }  
    }  
}
```

WORKING WITH THE CLIPBOARD

```
        Toast.makeText(this, "Exception: " + e.getMessage(),
                       Toast.LENGTH_SHORT).show();
    }
}
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setPrimaryClip()` call wrapped in a try/catch block, even though `setPrimaryClip()` does not throw a checked exception. The rationale for this will be discussed [later in this chapter](#).

Pasting Rich Data from the Clipboard

The catch with rich data on the clipboard is that somebody has to know about the sort of information you are placing on the clipboard. Eventually, the Android development community will work out common practices in this area. Right now, though, you can certainly use it within your own application (e.g., clipping a note and pasting it into another folder).

Since putting `ClipData` onto the clipboard involves a call to `setPrimaryClip()`, it should not be surprising that the reverse operation — getting a `ClipData` from the clipboard — uses `getPrimaryClip()`. However, since you do not know where this clip came from, you need to validate that it has what you expect and to let the user know when the clipboard contents are not something you can leverage.

The “Play” button in our UI is wired to a `playMusic()` method. This will only work when we have pasted a `Uri` `ClipData` to the clipboard pointing to a piece of music. Since we cannot be sure that the user has done that, we have to sniff around:

```
public void playMusic(View v) {
    ClipData clip=clipboard.getPrimaryClip();

    if (clip == null) {
        Toast.makeText(this, "There is no clip!", Toast.LENGTH_LONG)
            .show();
    }
    else {
        ClipData.Item item=clip.getItemAt(0);
        Uri song=item.getUri();

        if (song != null
            && getContentResolver().getType(song).startsWith("audio/")) {
            startActivity(new Intent(Intent.ACTION_VIEW, song));
        }
    }
}
```

WORKING WITH THE CLIPBOARD

```
else {
    Toast.makeText(this, "There is no song!", Toast.LENGTH_LONG)
        .show();
}
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

First, there may be nothing on the clipboard, in which case the `ClipData` returned by `getPrimaryClip()` would be `null`. Or, there may be stuff on the clipboard, but it may not have a `Uri` associated with it (`getUri()` on `ClipData`). Even then, the `Uri` may point to something other than music, so even if we get a `Uri`, we need to use a `ContentResolver` to check the MIME type (`getContentResolver().getType()`) and make sure it seems like it is music (e.g., starts with `audio/`). Then, and only then, does it make sense to try to start an `ACTION_VIEW` activity on that `Uri` and hope that something useful happens. Assuming you clipped a piece of music with the “Pick” button, “Play” will kick off playback of that song.

ClipData and Drag-and-Drop

Android 3.0 also introduced Android’s first built-in drag-and-drop framework. One might expect that this would be related entirely to `View` and `ViewGroup` objects and have nothing to do with the clipboard. In reality, the drag-and-drop framework leverages `ClipData` to say what it is that is being dragged and dropped. You call `startDrag()` on a `View`, supplying a `ClipData` object, along with some objects to help render the “shadow” that is the visual representation of this drag operation. A `View` that can receive objects “dropped” via drag-and-drop needs to register an `OnDragListener` to receive drag events as the user slides the shadow over the top of the `View` in question. If the user lifts their finger, thereby dropping the shadow, the recipient `View` will get an `ACTION_DROP` drag event, and can get the `ClipData` out of the event.

Monitoring the Clipboard

Android 3.0 added the capability for an app to monitor what is put on the clipboard, including things put on the clipboard by other apps.

This is a somewhat esoteric feature, but one that perhaps has some valid use cases. Mostly, it would be used by something *not* in the foreground, since the foreground activity is probably what is adding material to the clipboard. A service, or perhaps an activity that has moved to the background, could use this feature to find out about new clipboard entries.

WORKING WITH THE CLIPBOARD

To monitor the clipboard, you simply call `addPrimaryClipChangedListener()` on `ClipboardMonitor`, passing an implementation of an `OnPrimaryClipChangedListener` interface. That object, in turn, will be called with `onPrimaryClipChanged()` whenever there is a new clipboard entry. Later on, you can call `removePrimaryClipChangedListener()` to stop being notified about new clipboard entries.

For example, here is `MainActivity` from the [SystemServices/ClipboardMonitor](#) sample project:

```
package com.commonware.android.clipmon;

import android.app.Activity;
import android.content.ClipboardManager;
import android.content.ClipboardManager.OnPrimaryClipChangedListener;
import android.os.Bundle;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnPrimaryClipChangedListener {
    private ClipboardManager cm=null;
    private TextView lastClip=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        lastClip=(TextView)findViewById(R.id.last_clip);
        cm=(ClipboardManager) getSystemService(CLIPBOARD_SERVICE);
    }

    @Override
    public void onResume() {
        super.onResume();
        cm.addPrimaryClipChangedListener(this);
    }

    @Override
    public void onPause() {
        cm.removePrimaryClipChangedListener(this);
        super.onPause();
    }

    @Override
    public void onPrimaryClipChanged() {
        lastClip.setText(cm.getPrimaryClip().getItemAt(0)
            .coerceToText(this));
    }
}
```

(from [SystemServices/ClipboardMonitor/app/src/main/java/com/commonware/android/clipmon/MainActivity.java](#))

Here, we:

- Retrieve the ClipboardManager in onCreate()
- Register for clipboard events via addPrimaryClipChangedListener() in onResume()
- Unregister from clipboard events via removePrimaryClipChangedListener() in onPause()
- Convert the first item (getItemAt(0)) of the primary clip (getPrimaryClip()) to text (coerceToText(this)), and stuff the results into a TextView

In theory, this activity will display new clipboard entries as they arrive. In practice, it will only do so while it is in the foreground, and so it would require something in the background to add something to the clipboard. That is not a particularly useful example... except to test the bug outlined in the next section.

The Android 4.3 Clipboard Bug

[AndroidPolice](#) reported on [a fairly unpleasant bug in Android 4.3](#). While this bug was fixed in Android 4.4, there is little evidence that Google will be releasing a fix for Android 4.3 devices, which means that this problem will plague developers into 2015 and perhaps beyond.

The bug stems from [the clipboard monitoring facility](#). If an app has used addPrimaryClipChangedListener(), *any other app* that tries to paste to the clipboard will crash.

The first crash will be a SecurityException:

```
java.lang.SecurityException: uid ... does not have
android.permission.UPDATE_APP_OPS_STATS
```

The second and subsequent times this occurs on the device, it will be an IllegalStateException:

```
java.lang.IllegalStateException: beginBroadcast() called while already
in a broadcast
```

The only resolution is to unregister the clipboard listener... and hope that the first crash has not occurred. If it has, a **full reboot of the device is required** to fix the broken system.

If Your App Monitors the Clipboard...

If you have a component, such as a long-running service, that is monitoring the clipboard, please ensure that the users have an easy way to stop that behavior, even if it means stopping your whole service. While this may mean that your app has seriously degraded functionality, the alternative is that the user has to keep rebooting their device while your app is installed.

If Your App Pastes to the Clipboard...

If you are pasting to the clipboard, with `setPrimaryClip()` or the older `setText()`, you will want to throw a try/catch block around those calls, so you catch the `RuntimeExceptions` that will be thrown.

However, you will need to tell your users that they are now fairly well screwed, needing to both find the clipboard-monitoring app and learn how to control it (or uninstall/disable it, if needed), plus reboot their device, in order to paste to the clipboard again.

Telephony

Many, if not most, Android devices will be phones. As such, not only will users be expecting to place and receive calls using Android, but you will have the opportunity to help them place calls, if you wish.

Why might you want to?

1. Maybe you are writing an Android interface to a sales management application (a la Salesforce.com) and you want to offer users the ability to call prospects with a single button click, and without them having to keep those contacts both in your application and in the phone's contacts application
2. Maybe you are writing a social networking application, and the roster of phone numbers that you can access shifts constantly, so rather than try to "sync" the social network contacts with the phone's contact database, you let people place calls directly from your application
3. Maybe you are creating an alternative interface to the existing contacts system, perhaps for users with reduced motor control (e.g., the elderly), sporting big buttons and the like to make it easier for them to place calls

Whatever the reason, Android has the means to let you manipulate the phone just like any other piece of the Android system.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on working with multiple activities](#).

Report To The Manager

To get at much of the phone API, you use the `TelephonyManager`. That class lets you do things like:

1. Determine if the phone is in use via `getCallState()`, with return values of `CALL_STATE_IDLE` (phone not in use), `CALL_STATE_RINGING` (call requested but still being connected), and `CALL_STATE_OFFHOOK` (call in progress)
2. Find out the SIM ID (IMSI) via `getSubscriberId()`
3. Find out the phone type (e.g., GSM) via `getPhoneType()` or find out the data connection type (e.g., GPRS, EDGE) via `getNetworkType()`

You Make the Call!

You can also initiate a call from your application, such as from a phone number you obtained through your own Web service. To do this, simply craft an `ACTION_DIAL` Intent with a `Uri` of the form `tel:NNNNN` (where `NNNNN` is the phone number to dial) and use that Intent with `startActivity()`. This will not actually dial the phone; rather, it activates the dialer activity, from which the user can then press a button to place the call.

For example, let's look at the [Phone/Dialer](#) sample application. Here's the crude-but-effective layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <LinearLayout
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        >
        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Number to dial:"
            />
        <EditText android:id="@+id/number"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:cursorVisible="true"
            android:editable="true"
            android:singleLine="true"
            />
    />
```

TELEPHONY

```
</LinearLayout>
<Button android:id="@+id/dial"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_weight="1"
    android:text="Dial It!"
    android:onClick="dial"
/>
</LinearLayout>
```

(from [Phone/Dialer/app/src/main/res/layout/main.xml](#))

We have a labeled field for typing in a phone number, plus a button for dialing said number.

The Java code simply launches the dialer using the phone number from the field:

```
package com.commonware.android.dialer;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class DialerDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
    }

    public void dial(View v) {
        EditText number=(EditText)findViewById(R.id.number);
        String toDial="tel:"+number.getText().toString();

        startActivity(new Intent(Intent.ACTION_DIAL, Uri.parse(toDial)));
    }
}
```

(from [Phone/Dialer/app/src/main/java/com/commonware/android/dialer/DialerDemo.java](#))

The activity's own UI is not that impressive:

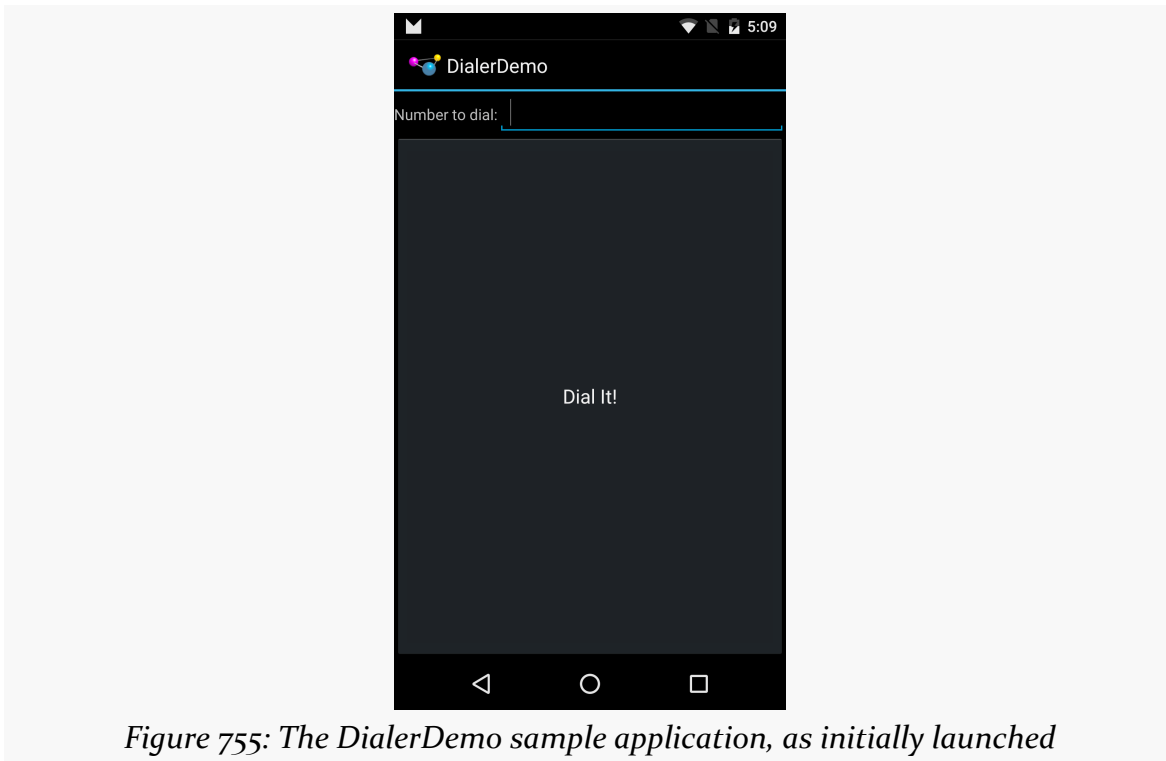

Figure 755: The DialerDemo sample application, as initially launched

However, the dialer you get from clicking the dial button is better, showing you the number you are about to dial:

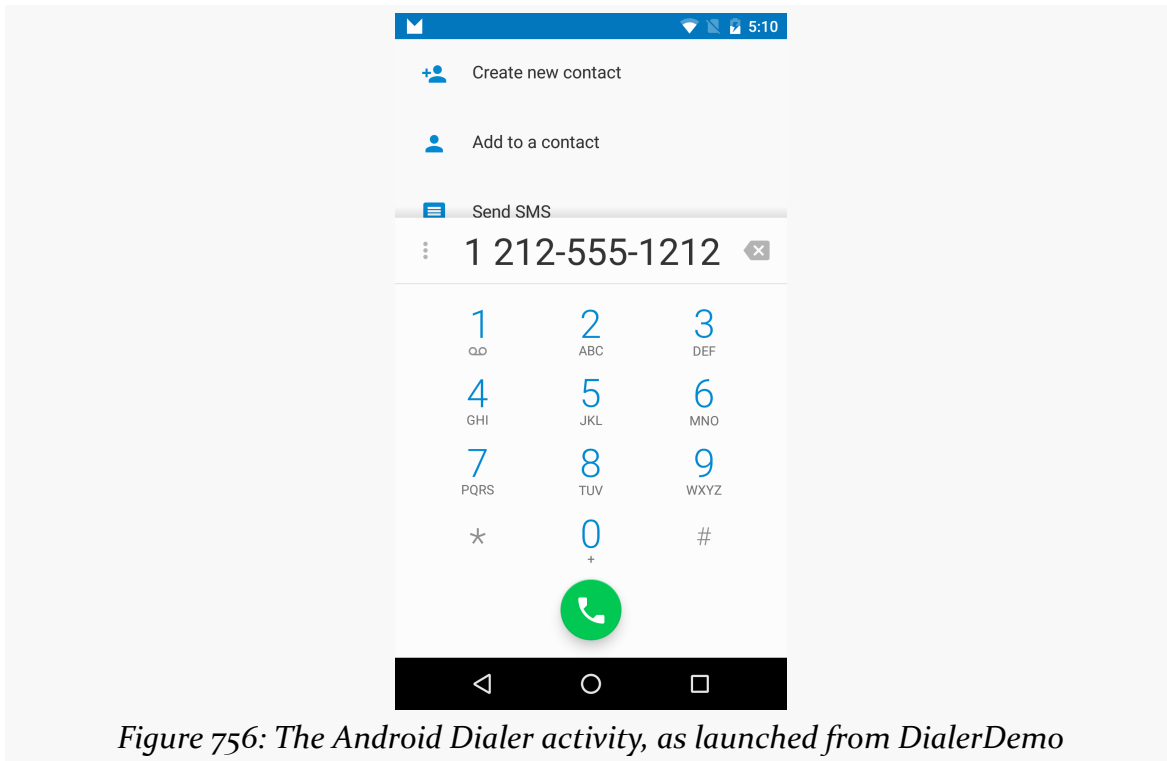

Figure 756: The Android Dialer activity, as launched from DialerDemo

No, Really, You Make the Call!

The good news is that `ACTION_DIAL` works without any special permissions. The bad news is that it only takes the user to the Dialer – the user still has to take action (pressing the green call button) to actually place the phone call.

An alternative approach is to use `ACTION_CALL` instead of `ACTION_DIAL`. Calling `startActivity()` on an `ACTION_CALL` Intent will immediately place the phone call, without any other UI steps required. However, you need the `CALL_PHONE` [permission](#) in order to use `ACTION_CALL`.

Working With SMS

Oh, what a tangled web we weave

When first we practice to work with SMS on Android, Eve

(with apologies to [Sir Walter Scott](#))

Android devices have had SMS capability since Android 1.0. However, from a programming standpoint, for years, SMS and Android were intensely frustrating. When the Android SDK was developed, some aspects of working with SMS were put into the SDK, while others were held back. This, of course, did not stop many an intrepid developer from working with the undocumented, unsupported SMS APIs, with varying degrees of success.

After much wailing and gnashing of teeth by developers, Google finally formalized a more complete SMS API in Android 4.4. However, this too has its issues, where some apps that worked fine with the undocumented API will now fail outright, in irreparable fashion, on Android 4.4+.

This chapter starts with the one thing you can do reasonably reliably across Android device versions – [send an SMS](#), either directly or by invoking the user's choice of SMS client. The chapter then examines how to monitor or receive SMS messages (both pre-4.4 and 4.4+) and the SMS-related ContentProvider (both pre-4.4 and 4.4+).

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on [broadcast Intents](#). One of the samples uses [the](#)

[ContactsContract provider](#), so reading that chapter will help you understand that particular sample.

Sending Out an SOS, Give or Take a Letter

While much of Android's SMS capabilities are not in the SDK, sending an SMS is. You have two major choices for doing this:

- Invoke the user's choice of SMS client application, so they can compose a message, track its progress, and so forth using that tool
- Send the SMS directly yourself, bypassing any existing client

Which of these is best for you depends on what your desired user experience is. If you are composing the message totally within your application, you may want to just send it. However, as we will see, that comes at a price: an extra permission.

Sending Via the SMS Client

Sending an SMS via the user's choice of SMS client is very similar to the use of ACTION_SEND described [elsewhere in this book](#). You craft an appropriate Intent, then call startActivity() on that Intent to bring up an SMS client (or allow the user to choose between clients).

The Intent differs a bit from the ACTION_SEND example:

1. You use ACTION_SENDTO, rather than ACTION_SEND
2. Your Uri needs to begin with smsto:, followed by the mobile number you want to send the message to
3. Your text message goes in an sms_body extra on the Intent

For example, here is a snippet of code from the [SMS/Sender](#) sample project:

```
Intent sms=new Intent(Intent.ACTION_SENDTO,
    Uri.parse("smsto:"+c.getString(2)));

sms.putExtra("sms_body", msg.getText().toString());

startActivity(sms);
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/Sender.java](#))

Here, our phone number is coming out of the third column of a `Cursor`, and the text message is coming from an `EditText` — more on how this works later in this section, when we review the `Sender` sample more closely.

Sending SMS Directly

If you wish to bypass the UI and send an SMS directly, you can do so through the `SmsManager` class, in the `android.telephony` package. Unlike most Android classes ending in `Manager`, you obtain an `SmsManager` via a static `getDefault()` method on the `SmsManager` class. You can then call `sendTextMessage()`, supplying:

1. The phone number to send the text message to
2. The “service center” address — leave this `null` unless you know what you are doing
3. The actual text message
4. A pair of `PendingIntent` objects to be executed when the SMS has been sent and delivered, respectively

If you are concerned that your message may be too long, use `divideMessage()` on `SmsManager` to take your message and split it into individual pieces. Then, you can use `sendMultipartTextMessage()` to send the entire `ArrayList` of message pieces.

For this to work, your application needs to hold the `SEND_SMS` permission, via a child element of your `<manifest>` element in your `AndroidManifest.xml` file.

For example, here is code from `Sender` that uses `SmsManager` to send the same message that the previous section sent via the user’s choice of SMS client:

```
SmsManager
    .getDefault()
    .sendTextMessage(c.getString(2), null,
        msg.getText().toString(),
        null, null);
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/Sender.java](https://commonsware.com/android/sms/sender/Sender.java))

Inside the Sender Sample

The `Sender` example application is fairly straightforward, given the aforementioned techniques.

WORKING WITH SMS

The manifest has both the SEND_SMS and READ_CONTACTS permissions, because we want to allow the user to pick a mobile phone number from their list of contacts, rather than type one in by hand:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.sender"
    android:installLocation="preferExternal"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission android:name="android.permission.READ_CONTACTS" />
    <uses-permission android:name="android.permission.SEND_SMS" />

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="Sender"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />

                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [SMS/Sender/app/src/main/AndroidManifest.xml](#))

If you noticed the android:installLocation attribute in the root element, that is to allow this application to be installed onto external storage, such as an SD card.

The layout has a Spinner (for a drop-down of available mobile phone numbers), a pair of RadioButton widgets (to indicate which way to send the message), an EditText (for the text message), and a “Send” Button:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Spinner android:id="@+id/spinner"
```

WORKING WITH SMS

```
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:drawSelectorOnTop="true"
    />
    <RadioGroup android:id="@+id/means"
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        >
        <RadioButton android:id="@+id/client"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="Via Client" />
        <RadioButton android:id="@+id/direct"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Direct" />
    </RadioGroup>
    <EditText
        android:id="@+id/msg"
        android:layout_width="match_parent"
        android:layout_height="0px"
        android:layout_weight="1"
        android:singleLine="false"
        android:gravity="top|left"
    />
    <Button
        android:id="@+id/send"
        android:text="Send!"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="sendMessage"
    />
</LinearLayout>
```

(from [SMS/Sender/app/src/main/res/layout/main.xml](#))

Sender uses the same technique for obtaining mobile phone numbers from our contacts as is seen in the [chapter on contacts](#). To support Android 1.x and Android 2.x devices, we implement an abstract class and two concrete implementations, one for the old API and one for the new. The abstract class then has a static method to get at an instance suitable for the device the code is running on:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.os.Build;
import android.widget.SpinnerAdapter;

abstract class ContactsAdapterBridge {
    abstract SpinnerAdapter buildPhonesAdapter(Activity a);

    public static final ContactsAdapterBridge INSTANCE=buildBridge();

    private static ContactsAdapterBridge buildBridge() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();
```

WORKING WITH SMS

```
    if (sdk<5) {
        return(new OldContactsAdapterBridge());
    }

    return(new NewContactsAdapterBridge());
}
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/ContactsAdapterBridge.java](#))

The Android 2.x edition uses ContactsContract to find just the mobile numbers:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.CommonDataKinds.Phone;
import android.widget.AdapterView;
import android.widget.SimpleCursorAdapter;

class NewContactsAdapterBridge extends ContactsAdapterBridge {
    SpinnerAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts._ID,
                                           Contacts.DISPLAY_NAME,
                                           Phone.NUMBER
                                           };

        String[] ARGS={String.valueOf(Phone.TYPE_MOBILE)};
        Cursor c=a.managedQuery(Phone.CONTENT_URI,
                               PROJECTION, Phone.TYPE+"=?",
                               ARGS, Contacts.DISPLAY_NAME);

        SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
                                                           android.R.layout.simple_spinner_item,
                                                           c,
                                                           new String[] {
                                                               Contacts.DISPLAY_NAME
                                                           },
                                                           new int[] {
                                                               android.R.id.text1
                                                           }
                                                           );

        adapter.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);

        return(adapter);
    }
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/NewContactsAdapterBridge.java](#))

... while the Android 1.x edition uses the older Contacts provider to find the mobile numbers:

```
package com.commonsware.android.sms.sender;
```

WORKING WITH SMS

```
import android.app.Activity;
import android.database.Cursor;
import android.provider.Contacts;
import android.widget.SimpleCursorAdapter;
import android.widget.SpinnerAdapter;

@SuppressWarnings("deprecation")
class OldContactsAdapterBridge extends ContactsAdapterBridge {
    SpinnerAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts.Phones._ID,
            Contacts.Phones.NAME,
            Contacts.Phones.NUMBER
        };

        String[] ARGS={String.valueOf(Contacts.Phones.TYPE_MOBILE)};
        Cursor c=a.managedQuery(Contacts.Phones.CONTENT_URI,
            PROJECTION,
            Contacts.Phones.TYPE+"=?", ARGS,
            Contacts.Phones.NAME);

        SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
            android.R.layout.simple_spinner_item,
            c,
            new String[] {
                Contacts.Phones.NAME
            },
            new int[] {
                android.R.id.text1
            });

        adapter.setDropDownViewResource(
            android.R.layout.simple_spinner_dropdown_item);

        return(adapter);
    }
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/OldContactsAdapterBridge.java](https://commonsware.com/android/sms/sender/OldContactsAdapterBridge.java))

For more details on how those providers work, please see the [chapter on contacts](#).

The activity then loads up the Spinner with the appropriate list of contacts. When the user taps the Send button, the `sendMessage()` method is invoked (courtesy of the `android:onClick` attribute in the layout). That method looks at the radio buttons, sees which one is selected, and routes the text message accordingly:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.os.Bundle;
import android.telephony.SmsManager;
import android.view.View;
import android.widget.EditText;
import android.widget.RadioGroup;
```

WORKING WITH SMS

```
import android.widget.Spinner;

public class Sender extends Activity {
    Spinner contacts=null;
    RadioGroup means=null;
    EditText msg=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        contacts=(Spinner)findViewById(R.id.spinner);

        contacts.setAdapter(ContactsAdapterBridge
            .INSTANCE
            .buildPhonesAdapter(this));

        means=(RadioGroup)findViewById(R.id.means);
        msg=(EditText)findViewById(R.id.msg);
    }

    public void sendTheMessage(View v) {
        Cursor c=(Cursor)contacts.getSelectedItem();

        if (means.getCheckedRadioButtonId()==R.id.client) {
            Intent sms=new Intent(Intent.ACTION_SENDTO,
                Uri.parse("smsto:"+c.getString(2)));

            sms.putExtra("sms_body", msg.getText().toString());

            startActivity(sms);
        }
        else {
            SmsManager
                .getDefault()
                .sendTextMessage(c.getString(2), null,
                    msg.getText().toString(),
                    null, null);
        }
    }
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/Sender.java](#))

SMS Sending Limitations

Apps running on Android 1.x and 2.x devices are limited to sending 100 SMS messages an hour, before the user starts getting prompted with each SMS message request to confirm that they do indeed wish to send it.

Apps running on Android 4.x devices, the limits are now 30 SMS messages in 30 minutes, [according to some source code analysis by Al Sutton](#).

Monitoring and Receiving SMS

For the purposes of this section, “monitoring” refers to the ability to inspect incoming SMS messages, including reading their contents. In contrast, “receiving” SMS messages is actually consuming the message and storing it somewhere for the user to use.

As it turns out, “monitoring” and “receiving” are much the same thing prior to Android 4.4, but are significantly different in the new API made available in Android 4.4

The Undocumented, Unsupported, Pre-Android 4.4 Way

It is possible for an application to monitor or receive an incoming SMS message... if you are willing to listen on the undocumented `android.provider.Telephony.SMS_RECEIVED` broadcast Intent. That is sent by Android whenever an SMS arrives, and it is up to an application to implement a `BroadcastReceiver` to respond to that Intent and do something with the message. The Android open source project has such an application — `Messaging` — and device manufacturers can replace it with something else.

Note that to listen for this broadcast, your app must hold the `RECEIVE_SMS` permission.

The `BroadcastReceiver` can then turn around and use the `SmsMessage` class, in the `android.telephony` package, to get at the message itself, through the following undocumented recipe:

1. Given the received Intent (`intent`), call `intent.getExtras().get("pdus")` to get an `Object` array representing the raw portions of the message
2. For each of those “pdus” objects, call `SmsMessage.createFromPdu()` to convert the `Object` into an `SmsMessage` — though to make this work, you need to cast the `Object` to a byte array as part of passing it to the `createFromPdu()` static method

The resulting `SmsMessage` object gets you access to the text of the message, the sending phone number, etc.

WORKING WITH SMS

The `SMS_RECEIVED` broadcast Intent is broadcast a bit differently than most others in Android. It is an “ordered broadcast”, meaning the Intent will be delivered to one `BroadcastReceiver` at a time. This has two impacts of note:

- In your receiver’s `<intent-filter>` element, you can have an `android:priority` attribute. Higher priority values get access to the broadcast Intent earlier than will lower priority values. The standard Messaging application has the default priority (undocumented, appears to be 0 or 1), so you can arrange to get access to the SMS before the application does.
- Your `BroadcastReceiver` can call `abortBroadcast()` on itself to prevent the Intent from being broadcast to other receivers of lower priority. In effect, this causes your receiver to consume the SMS — the Messaging application will not receive it. So, aborting the broadcast means that your app chose to “receive” the SMS; not aborting the broadcast means that your app is merely “monitoring” the SMS messages that come in.

However, just because the Messaging application has the default priority does not mean all SMS clients will, and so you cannot reliably intercept SMS messages this way. That, plus the undocumented nature of all of this, means that applications you write to receive SMS messages are likely to be fragile in production, breaking on various devices due to device manufacturer-installed apps, third-party apps, or changes to Android itself... such as the changes that came about in Android 4.4.

The Android 4.4+ Way: Monitoring SMS

The code described above still works on Android 4.4, though the formerly-hidden `android.provider.Telephony` class is now part of the SDK.

The biggest difference, though, is that even if you call `abortBroadcast()`, the user’s chosen SMS messaging client will still receive the message. It is not possible for an app listening for `SMS_RECEIVED` broadcasts to prevent the user’s chosen SMS messaging client from receiving those same messages. This is a substantial change, one that will break or make obsolete many Android applications.

Regardless, if monitoring SMS fits your needs, `SMS_RECEIVED` can do it.

So, for example, the [SMS/Monitor](#) sample project implements a `BroadcastReceiver` for `SMS_RECEIVED`, one with slightly elevated priority:

WORKING WITH SMS

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.monitor"
    android:versionCode="1"
    android:versionName="1.0">

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <uses-permission android:name="android.permission.RECEIVE_SMS"/>

    <uses-sdk
        android:minSdkVersion="3"
        android:targetSdkVersion="19"/>

    <application
        android:icon="@drawable/cw"
        android:label="@string/app_name">
        <receiver
            android:name="Monitor"
            android:permission="android.permission.BROADCAST_SMS">
            <intent-filter android:priority="2">
                <action android:name="android.provider.Telephony.SMS_RECEIVED"/>
            </intent-filter>
        </receiver>

        <activity
            android:name="BootstrapActivity"
            android:theme="@android:style/Theme.NoDisplay">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [SMS/Monitor/app/src/main/AndroidManifest.xml](#))

You will notice that the `BroadcastReceiver` not only has the slightly-elevated priority (`android:priority="2"`), but also a required permission (`android:permission="android.permission.BROADCAST_SMS"`). Only apps that hold this permission can send this broadcast in a way that will be picked up by the receiver. Since this permission can only be held by the device firmware, you are protected from “spoof” SMS messages from rogue apps on the device, sending the `SMS_RECEIVED` themselves.

The app also has a do-nothing activity, solely there to activate the manifest-registered `BroadcastReceiver`, which will not work until some component of the app is manually started.

WORKING WITH SMS

The bulk of the business logic — what little there is of it — lies in the Monitor class that is the BroadcastReceiver:

```
package com.commonware.android.sms.monitor;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.telephony.SmsMessage;
import android.util.Log;

public class Monitor extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Object[] rawMsgs=(Object[])intent.getExtras().get("pdus");

        for (Object raw : rawMsgs) {
            SmsMessage msg=SmsMessage.createFromPdu((byte[])raw);

            if (msg.getMessageBody().toUpperCase().contains("SEKRIT")) {
                Log.w("SMS:"+msg.getOriginatingAddress(),
                    msg.getMessageBody());

                abortBroadcast();
            }
        }
    }
}
```

(from [SMS/Monitor/app/src/main/java/com/commonware/android/sms/monitor/Monitor.java](#))

Here, we retrieve the raw messages from the Intent extra, iterate over them, and convert each to an SmsMessage. Those that have the magic word in their message body will result in the message being dumped to LogCat, plus the broadcast is aborted. On Android 4.3 and below, this will prevent lower-priority receivers from receiving the SMS. On Android 4.4, the abort request is ignored.

The Android 4.4+ Way: Receiving SMS

Receiving SMS messages, on Android 4.4+, means that you are implementing an SMS client application, one the user might be willing to set as their default SMS client application in Settings. There are other sorts of apps that may temporarily want to be the default SMS client, such as a backup/restore utility, as only the default SMS client will be able to work with the SMS ContentProvider suite, such as the inbox.

Receiving the Broadcasts

The default SMS client should be able to handle both SMS and MMS. This is a problem, as while supporting SMS is poorly documented, supporting MMS has almost no documentation whatsoever. However, unless the default SMS client handles MMS, nobody else can (at least, while saving MMS details to the ContentProvider suite).

Hence, Google is expecting you to have two BroadcastReceivers registered in the manifest: one for SMS and one for MMS. Unfortunately, these cannot readily be combined into a single receiver, because each has its own permission requirement:

- the SMS receiver should require senders to hold BROADCAST_SMS
- the MMS receiver should require senders to hold BROADCAST_WAP_PUSH

In practice, probably both are held by the OS component that is sending these broadcasts in response to incoming messages of either type. In principle, though, they could be separate, and an individual <receiver> can only specify one such permission.

[The Android documentation](#) illustrates the <receiver> elements that Google expects your SMS client application to have:

```
<!-- BroadcastReceiver that listens for incoming SMS messages -->
<receiver android:name=".SmsReceiver"
    android:permission="android.permission.BROADCAST_SMS">
    <intent-filter>
        <action android:name="android.provider.Telephony.SMS_DELIVER" />
    </intent-filter>
</receiver>

<!-- BroadcastReceiver that listens for incoming MMS messages -->
<receiver android:name=".MmsReceiver"
    android:permission="android.permission.BROADCAST_WAP_PUSH">
    <intent-filter>
        <action android:name="android.provider.Telephony.WAP_PUSH_DELIVER" />
        <data android:mimeType="application/vnd.wap.mms-message" />
    </intent-filter>
</receiver>
```

Notice that the MMS receiver has both an <action> and a <data> element in its <intent-filter>, which is rather unusual.

On the SMS side, the Intent you receive should be the same as the Intent you would receive for the SMS_RECEIVED broadcast, where you can decode the message(s) and deal with them as you see fit. On the MMS side... there is little documentation.

Other Expectations

Google expects the default SMS client to be able to handle ACTION_SEND and ACTION_SENDTO for relevant schemes:

```
<!-- Activity that allows the user to send new SMS/MMS messages -->
<activity android:name=".ComposeSmsActivity" >
  <intent-filter>
    <action android:name="android.intent.action.SEND" />
    <action android:name="android.intent.action.SENDTO" />
    <category android:name="android.intent.category.DEFAULT" />
    <category android:name="android.intent.category.BROWSABLE" />
    <data android:scheme="sms" />
    <data android:scheme="smsto" />
    <data android:scheme="mms" />
    <data android:scheme="mmsto" />
  </intent-filter>
</activity>
```

That may not be terribly surprising. What *is* surprising is that Google also expects you to have an exported *service* for handling “quick response” requests. These requests come when the user receives a phone call and taps on an icon to reply with a text message, rather than accept the call. In those cases, Android will invoke a service in the default SMS client, with an action of `android.intent.action.RESPOND_VIA_MESSAGE`. The Intent that you receive in `onStartCommand()` (or `onHandleIntent()`, if you elect to use an `IntentService`) will have an `EXTRA_TEXT` and optionally an `EXTRA_SUBJECT` as extras, representing the message to be sent. The `Uri` in the Intent will indicate the intended recipient of the message. Your job is to use `SmsManager` to actually send the message.

The Android documentation cites this as the relevant `<service>` element:

```
<!-- Service that delivers messages from the phone "quick response" -->
<service android:name=".HeadlessSmsSendService"
  android:permission="android.permission.SEND_RESPOND_VIA_MESSAGE"
  android:exported="true" >
  <intent-filter>
    <action android:name="android.intent.action.RESPOND_VIA_MESSAGE" />
    <category android:name="android.intent.category.DEFAULT" />
    <data android:scheme="sms" />
    <data android:scheme="smsto" />
    <data android:scheme="mms" />
    <data android:scheme="mmsto" />
  </intent-filter>
</service>
```

Note:

- The `<service>` requires that the sender have the `SEND_RESPOND_VIA_MESSAGE` permission, to reduce spoofing
- The `android:exported="true"` shown in the sample should be superfluous, as since the `<service>` has an `<intent-filter>`, it should be exported by default
- The `<category>`, and possibly the `<data>`, elements may be erroneous... and since the author cannot find anything in the OS that uses `RESPOND_VIA_MESSAGE`, the author cannot validate that these elements should be here or represent copy-and-paste errors in the documentation

Handling Both Receive Options

If you want to support receiving SMS using both the legacy approach and the Android 4.4+ approach, you can have two `BroadcastReceiver` implementations, one for `android.provider.Telephony.SMS_RECEIVED` and one for `android.provider.Telephony.SMS_DELIVER`. However, you will only need the latter one on Android 4.4, and by default you would receive both broadcasts.

To handle that, you can define a boolean resource in the `res/values-v19/` directory (e.g., `isPreKitKat`) to be `false`, with a default definition in `res/values/` of `true` for the same resource. Then, in your manifest, you can have `android:enabled="@bool/isPreKitKat"` on your `SMS_RECEIVED` `<receiver>` element. This will only enable this component on API Level 18 and below, disabling it on API Level 19+.

You can also define a counterpart resource for the positive case (e.g., `@bool/isKitKat`), and use that to selectively enable the SMS and MMS receivers, if desired.

The SMS Inbox

Many users keep their text messages around, at least for a while. These are stored in an “inbox”, represented by a `ContentProvider`. How you work with this `ContentProvider` — or if you can work with it at all, varies upon whether you are running on Android 4.4+ or not.

The Undocumented, Unsupported, Pre-Android 4.4 Way

When perusing the Internet, you will find various blog posts and such referring to the SMS inbox `ContentProvider`, represented by the `content://sms/inbox` Uri.

WORKING WITH SMS

This `ContentProvider` is undocumented and is not part of the Android SDK, because it is not part of the Android OS.

Rather, this `ContentProvider` is used by the aforementioned Messaging application, for storing saved SMS messages. And, as noted, this application may or may not exist on any given Android device. If a device manufacturer replaces Messaging with their own application, there may be nothing on that device that responds to that `Uri`, or the schemas may be totally different. Plus, Android may well change or even remove this `ContentProvider` in future editions of Android.

For all those reasons, developers should not be relying upon this `ContentProvider`.

The Android 4.4+ Way

Android 4.4 has exposed a series of `ContentProviders`, in the `android.provider.Telephony` namespace, for storing SMS and MMS messages. These include:

- the `Inbox` for received messages
- the `Outbox` for a log of sent messages
- the `Draft` for messages that were written but have not yet been sent
- etc.

Some are duplicated, such as separate providers for the SMS inbox versus the MMS inbox. Some are distinct, such as `Sms.Conversations` and `Mms.Rate`.

All are largely undocumented.

The user's chosen default SMS client can write to these providers. Apps with `READ_SMS` permission should be able to read from them.

Asking to Change the Default

There are many areas in Android where the user must do two things to use an app:

1. Install the app (from the Play Store or elsewhere)
2. Go into Settings (or sometimes elsewhere) and indicate that a certain capability of the newly-installed app should become active

WORKING WITH SMS

You see this with app widgets, input method editors, device administrators, and many others.

On Android 4.4+, you also see this with SMS/MMS clients. Devices usually ship with one. If the user wants a replacement, the user must indicate in Settings that this new SMS/MMS client should be the default, so it can write to the SMS/MMS ContentProvider suite.

Your app can determine what the default client is by calling `getDefaultSmsPackage()` on the `Telephony.Sms` class. This will return the package name of the current default client.

If this is not your package, and you would like the user to make you the default, you can start an activity to request this change:

```
Intent i = new Intent(Sms.Intents.ACTION_CHANGE_DEFAULT);
i.putExtra(Sms.Intents.EXTRA_PACKAGE_NAME, getPackageName());
startActivity(i);
```

The `EXTRA_PACKAGE_NAME` will trigger the UI to ask the user if the user wishes to change the current default to your package (versus anything else on the device that might also be a possible SMS/MMS client).

Hence, the recommended flow for a backup/restore app is to:

- Make note of the current default, via `getDefaultSmsPackage()`
- Request to the user to make you the default, via `ACTION_CHANGE_DEFAULT`
- Confirm that they did this, via `getDefaultSmsPackage()`
- If they did, do your backup or restore work
- Request to the user to restore the original default, via `ACTION_CHANGE_DEFAULT`

SMS and the Emulator

The “Emulator Control” view in DDMS allows you to send fake SMS messages to a running emulator. This is very useful for light testing.

You can also send fake SMS messages to an emulator via the emulator console. This can be accessed via `telnet`, where the console is available on `localhost` on your development machine, via the port number that appears in the title bar of your emulator window (e.g., 5554). In the `telnet` session, you can enter `sms send`

WORKING WITH SMS

[`sendingNumber`> `<txt>`, replacing `<sendingNumber>` with the phone number of the pretend sender of the SMS, and replacing `<txt>` with the text message itself.

NFC, courtesy of high-profile boosters like Google Wallet, is poised to be a significant new capability in Android devices. While at the time of this writing, only a handful of Android devices have NFC built in, other handsets are slated to be NFC-capable in the coming months. Google is hoping that developers will write NFC-aware applications to help further drive adoption of this technology by device manufacturers.

This, of course, raises the question: what is NFC? Besides being where the Green Bay Packers play, that is?

(For those of you from outside of the United States, that was an American football joke. We now return you to your regularly-scheduled chapter.)

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on [broadcast Intents](#) and [services](#).

What Is NFC?

NFC stands for Near-Field Communications. It is a wireless standard for data exchange, aimed at very short range transmissions — on the order of a couple of centimeters. NFC is in wide use today, for everything from credit cards to passports. Typically, the NFC data exchange is for simple data — contact information, URLs, and the like.

NFC

In particular, NFC tends to be widely used where one side of the communications channel is “passive”, or unpowered. The other side (the “initiator”) broadcasts a signal, which the passive side converts into power enough to send back its response. As such, NFC “tags” containing such passive targets can be made fairly small and can be embedded in a wide range of containers, from stickers to cards to hats.

The objective is “low friction” interaction — no pairing like with Bluetooth, no IP address shenanigans as with WiFi. The user just taps and goes.

... Compared to RFID?

NFC is often confused with or compared to RFID. It is simplest to think of RFID as being an umbrella term, under which NFC falls. Not every RFID technology is NFC, but many things that you hear of being “RFID” may actually be NFC-compliant devices or tags.

... Compared to QR Codes?

In many places, NFC will be used in ways you might consider using QR codes. For example, a restaurant could use either technology, or both, on a sign to lead patrons to the restaurant’s [Yelp](#) page, as a way of soliciting reviews. Somebody with a capable device could either tap the NFC tag on the sign to bring up Yelp or take a picture of the QR code and use that to bring up Yelp.

NFC’s primary advantage over QR codes is that it requires no user intervention beyond physically moving their device in close proximity to the tag. QR codes, on the other hand, require the user to launch a barcode scanning application, center the barcode in the viewfinder, and then get the results. The net effect is that NFC will be faster.

QR’s advantages include:

1. No need for any special hardware to generate the code, as opposed to needing a tag and something to write information into the tag for NFC
2. The ability to display QR codes in distant locations (e.g., via Web sites), whereas NFC requires physical proximity

To NDEF, Or Not to NDEF

RFID is a concept, not a standard. As such, different vendors created their own ways of structuring data on these tags or chips, making one vendor's tags incompatible with another vendor's readers or writers. While various standards bodies, like ISO, have gotten involved, it's still a bit of a rat's nest of conflicting formats and approaches.

The NFC offshoot of RFID has had somewhat greater success in establishing standards. NFC itself is an ISO and ECMA standard, covering things like transport protocols and transfer speeds. And a consortium called the NFC Forum created NDEF — the NFC Data Exchange Format — for specifying the content of tags.

However, not all NFC tags necessarily support NDEF. NDEF is much newer than NFC, and so lots of NFC tags are out in the wild that were distributed before NDEF even existed.

You can roughly divide NFC tags into three buckets:

- Those that support NDEF “out of the box”
- Those that can be “formatted” as NDEF
- Those that use other content schemes

Android has some support for non-NDEF tags, such as the MIFARE Classic. However, the hope and expectation going forward is that NFC tags will coalesce around NDEF.

NDEF, as it turns out, maps neatly to Android's Intent system, as you will see as we proceed through this chapter.

NDEF Modalities

Most developers interested in NFC will be interested in reading NFC tags and retrieving the NDEF data off of them. In Android, tapping an NDEF tag with an NFC-capable device will trigger an activity to be started, based on a certain `IntentFilter`.

Some developers will be interested in writing to NFC tags, putting URLs, vCards, or other information on them. This may or may not be possible for any given tag.

And while the “traditional” thinking around NFC has been that one side of the communication is a passive tag, Android will help promote the “peer-to-peer” approach — having two Android devices exchange data via NFC and NDEF. Basically, putting the two devices back-to-back will cause each to detect the other device’s “tag”, and each can read and write to the other via this means. This is referred to as “Android Beam” and will be discussed [later in this chapter](#).

Of course, all of these are only available on hardware. At the present time, there is no emulator for NFC, nor any means of accessing a USB NFC reader or writer from the emulator.

NDEF Structure and Android’s Translation

NDEF is made up of messages, themselves made up of a series of records. From Android’s standpoint, each tag consists of one such message.

Each record consists of a binary (byte array) payload plus metadata to describe the nature of the payload. The metadata primarily consists of a type and a subtype. There are quite a few combinations of these, but the big three for new Android NFC uses are:

- A type of `TNF_WELL_KNOWN` and a subtype of `RTD_TEXT`, indicating that the payload is simply plain text
- A type of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, indicating that the payload is a URI, such as a URL to a Web page
- A type of `TNF_MIME_MEDIA`, where the subtype is a standard MIME type, indicating that the payload is of that MIME type

When Android scans an NDEF tag, it will use this information to construct a suitable Intent to use with `startActivity()`. The action will be `android.nfc.action.NDEF_DISCOVERED`, to distinguish the scanned-tag case from, say, something simply asking to view some content. The MIME type in the Intent will be `text/plain` for the first scenario above or the supplied MIME type for the third scenario above. The data (`Uri`) in the Intent will be the supplied URI for the second scenario above. Once constructed, Android will invoke `startActivity()` on that Intent, bringing up an activity or an activity chooser, as appropriate.

NFC-capable Android devices have a Tags application pre-installed that will handle any NFC tag not handled by some other app. So, for example, an NDEF tag with an

HTTP URL will fire up the Tags application, which in turn will allow the user to open up a Web browser on that URL.

The Reality of NDEF

The enthusiasm that some have with regards to Android and NFC technology needs to be tempered by the reality of NDEF, NFC tags in general, and Android's support for NFC. It is easy to imagine all sorts of possibilities that may or may not be practical when current limitations are reached.

Some Tags are Read-Only

Some tags come “from the factory” read-only. Either you arrange for the distributor to write data onto them (e.g., blast a certain URL onto a bunch of NFC stickers to paste onto signs), or they come with some other pre-established data. Touchatag, for example, distributes NFC tags that have Touchatag URLs on them — they then help you set up redirects from their supplied URL to ones you supply.

While these tags will be of interest to consumers and businesses, they are unlikely to be of interest to Android developers, since their use cases are already established and typically do not need custom Android application support. Android developers seeking customizable tags will want ones that are read-write, or at least write-once.

Some Tags Can't Be Read-Only

Conversely, some tags lack any sort of read-only flag. An ideal tag for developers is one that is write-once: putting an NDEF message on the tag and flagging it read-only in one operation. Some tags do not support this, or making the tag read-only at any later point. The MIFARE Classic 1K tag is an example — while technically it can be made read-only, it requires a key known only to the tag manufacturer.

Some Tags Need to be Formatted

The MIFARE Classic 1K NFC tag is NDEF-capable, but must be “formatted” first, supplying the initial NDEF message contents. You have the option of formatting it read-write or read-only (turning the Classic 1K a write-once tag).

This is not a problem — in fact, the write-once option may be compelling. However, it is something to keep in mind.

Also, note that the MIFARE Classic 1K, while it can be formatted as NDEF, uses a proprietary protocol “under the covers”. Not all Android devices will support the Classic 1K, as the device manufacturers elect not to pay the licensing fee. Where possible, try to stick to tags that are natively NDEF-compliant (so-called “NFC Forum Tag Types 1-4”).

Tags Have Limited Storage

The “1K” in the name “MIFARE Classic 1K” refers to the amount of storage on the tag: 1 kilobyte of information.

And that’s far larger than other tags, such as the MIFARE Ultralight C, some of which have ~64 bytes of storage.

Clearly, you will not be writing an MP3 file or JPEG photo to these tags. Rather, the tags will tend to either be a “launcher” into something with richer communications (e.g., URL to a Web site) or will use the sorts of data you may be used to from QR codes, such as a vCard or iCalendar for contact and event data, respectively.

NDEF Data Structures Are Documented Elsewhere

The Android developer documentation is focused on the [Android classes](#) related to NFC and on [the Intent mechanism used for scanned tags](#). It does not focus on the actual structure of the payloads.

For TNF_MIME_MEDIA and RTD_TEXT, the payload is whatever you want. For RTD_URI, however, the byte array has a bit more structure to it, as the NDEF specification calls for a single byte to represent the URI prefix (e.g., http://www. versus http:// versus https://www.). The objective, presumably, is to support incrementally longer URLs on tags with minuscule storage. Hence, you will need to convert your URLs into this sort of byte array if you are writing them out to a tag.

Generally speaking, the rules surrounding the structure of NDEF messages and records is found at the [NFC Forum site](#).

Tag and Device Compatibility

Different devices will have different NFC chipsets. Not all NFC chipsets can read and write all tags. The expectation is that NDEF-formatted tags will work on all devices,

but if you wander away from that, things get dicier. For example, NXP's Mifare Classic tag can only be read and written by NXP's NFC chip.

This is increasingly a challenge for Android developers, as a Broadcom NFC chip is becoming significantly more popular. Many new major Android devices, such as the Samsung Galaxy S4, the Nexus 4, the Nexus 10, and the 2013/2nd generation version of the Nexus 7, all use the Broadcom chip. Those devices are incompatible with the Mifare tags, such as the popular Mifare Classic 1K.

That is because NXP is the maker of the Mifare Classic series, and those tags broke the NFC Forum's standards to create a tag that was NXP-specific.

Right now, NTAG203 and Topaz tags (like the Topaz 512), are likely candidate tags that will work across all NFC-capable Android devices, due to their adherence to NFC standard protocols.

Sources of Tags

NFC tags are not the sort of thing you will find on your grocer's shelves. In fact, few, if any, mainstream firms sell them today.

Here are some online sites from which you can order rewritable NFC tags, listed here in alphabetical order:

1. [Andytags](#)
2. [Buy NFC Tags](#)
3. [Smartcard Focus](#)
4. [tagstand](#)

Note that not all may ship to your locale.

Writing to a Tag

So, let's see what it takes to write an NDEF message to a tag, formatting it if needed. The code samples shown in this chapter are from the [NFC/URLTagger](#) sample application. This application will set up an activity to respond to ACTION_SEND activity Intents, with an eye towards receiving a URL from a browser, then waiting for a tag and writing the URL to that tag. The idea is that this sort of application could be used by non-technical people to populate tags containing URLs to their company's Web site, etc.

Getting a URL

First, we need to get a URL from the browser. As we saw in the chapter on integration, the standard Android browser uses `ACTION_SEND` of `text/plain` contents when the user chooses the “Share Page” menu. So, we have one activity, `URLTagger`, that will respond to such an Intent:

```
<activity
  android:name="URLTagger"
  android:label="@string/app_name">
  <intent-filter android:label="@string/app_name">
    <action android:name="android.intent.action.SEND"/>

    <data android:mimeType="text/plain"/>

    <category android:name="android.intent.category.DEFAULT"/>
  </intent-filter>
</activity>
```

(from [NFC/URLTagger/app/src/main/AndroidManifest.xml](#))

Of course, lots of other applications support `ACTION_SEND` of `text/plain` contents that are not URLs. A production-grade version of this application would want to validate the `EXTRA_TEXT` Intent extra to confirm that, indeed, this is a URL, before putting in an NDEF message claiming that it is a URL.

Detecting a Tag

When the user shares a URL with our application, our activity is launched. At that point, we need to go into “detect a tag” mode – the user should then tap their device to a tag, so we can write out the URL.

First, in `onCreate()`, we get access to the `NfcAdapter`, which is our gateway to much of the NFC functionality in Android:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    nfc=NfcAdapter.getDefaultAdapter(this);
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

We use a boolean data member — `inWriteMode` — to keep track of whether or not we are set up to write to a tag. Initially, of course, that is set to be `false`. Hence,

NFC

when we are first launched, by the time we get to `onResume()`, we can go ahead and register our interest in future tags:

```
@Override
public void onResume() {
    super.onResume();

    if (!inWriteMode) {
        IntentFilter discovery=new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
        IntentFilter[] tagFilters=new IntentFilter[] { discovery };
        Intent i=new Intent(this, getClass())
            .addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP|
                Intent.FLAG_ACTIVITY_CLEAR_TOP);
        PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

        inWriteMode=true;
        nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

When an NDEF-capable tag is within signal range of the device, Android will invoke `startActivity()` for the `NfcAdapter.ACTION_TAG_DISCOVERED` Intent action. However, it can do this in one of two ways:

- Normally, it will use a chooser (via `Intent.createChooser()`) to allow the user to pick from any activities that claim to support this action.
- The foreground application can request via `enableForegroundDispatch()` for it to handle all tag events while it is in the foreground, superseding the normal `startActivity()` flow. In this case, while Android still will invoke an activity, it will be our activity, not any other one.

We want the second approach right now, so the next tag brought in range is the one we will try writing to.

To do that, we need to create an array of `IntentFilter` objects, identifying the NFC-related actions that we want to capture in the foreground. In this case, we only care about `ACTION_TAG_DISCOVERED` – if we were supporting non-NDEF NFC tags, we might also need to watch for `ACTION_TECH_DISCOVERED`.

We also need a `PendingIntent` identifying the activity that should be invoked when such a tag is encountered while we are in the foreground. Typically, this will be the current activity. By adding `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to the `Intent` as flags, we ensure that our current specific instance of the activity will be given control again via `onNewIntent()`.

NFC

Armed with those two values, we can call `enableForegroundDispatch()` on the `NfcAdapter` to register our request to process tags via the current activity instance.

In `onPause()`, if the activity is finishing, we call `disableForegroundDispatch()` to undo the work done in `onResume()`:

```
@Override
public void onPause() {
    if (isFinishing()) {
        nfc.disableForegroundDispatch(this);
        inWriteMode=false;
    }

    super.onPause();
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

We have to see if we are finishing, because even though our activity never leaves the screen, Android still calls `onPause()` and `onResume()` as part of delivering the `Intent` to `onNewIntent()`. Our approach, though, has flaws — if the user presses HOME, for example, we never disable the NFC dispatch logic. A production-grade application would need to handle this better.

For any of this code to work, we need to hold the NFC permission via an appropriate line in the manifest:

```
<uses-permission android:name="android.permission.NFC"/>
```

Also note that if you have several activities that the user can reach while you are trying to also capture NFC tag events, you will need to call `enableForegroundDispatch()` in each activity — it's a per-activity request, not a per-application request.

Reacting to a Tag

Once the user brings a tag in range, `onNewIntent()` will be invoked with the `ACTION_TAG_DISCOVERED` `Intent` action:

```
@Override
protected void onNewIntent(Intent intent) {
    if (inWriteMode &&
        NfcAdapter.ACTION_TAG_DISCOVERED.equals(intent.getAction())) {
        Tag tag=intent.getParcelableExtra(NfcAdapter.EXTRA_TAG);
        byte[] url=buildUrlBytes(getIntent().getStringExtra(Intent.EXTRA_TEXT));
        NdefRecord record=new NdefRecord(NdefRecord.TNF_WELL_KNOWN,
            NdefRecord.RTD_URI,
            new byte[] {}, url);
    }
}
```

NFC

```
NdefMessage msg=new NdefMessage(new NdefRecord[] {record});  
  
new WriteTask(this, msg, tag).execute();  
}  
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

If we are in write mode and the delivered Intent is indeed an ACTION_TAG_DISCOVERED one, we can get at the Tag object associated with the user's NFC tag via the NfcAdapter.EXTRA_TAG [Parcelable extra on the Intent](#).

Writing an NDEF message to the tag, therefore, is a matter of crafting the message and actually writing it. An NDEF message consists of one or more records (though, typically, only one record is used), with each record wrapping around a byte array of payload data.

Getting the Shared URL

We did not do anything to get the URL out of the Intent back in onCreate(), when our activity was first started up. Now, of course, we need that URL. You might think it is too late to get it, since our activity was effectively started again due to the tag and onNewIntent().

However, getIntent() on an Activity always returns the Intent used to create the activity in the first place. The getIntent() value is not replaced when onNewIntent() is called.

Hence, as part of the buildUrlBytes() method to create the binary payload, we can go and call getIntent().getStringExtra(Intent.EXTRA_TEXT) to retrieve the URL.

Creating the Byte Array

Given the URL, we need to convert it into a byte array suitable for use in a TNF_WELL_KNOWN, RTD_URI NDEF record. Ordinarily, you would just call toByteArray() on the String and be done with it. However, the byte array we need uses a single byte to indicate the URL prefix, with the rest of the byte array for the characters after this prefix.

This is efficient. This is understandable. This is annoying.

First, we need the roster of prefixes, defined in URLTagger as a static data member cunningly named PREFIXES:

NFC

```
static private final String[] PREFIXES={"http://www.", "https://www.",
    "http://", "https://",
    "tel:", "mailto:",
    "ftp://anonymous:anonymous@",
    "ftp://ftp.", "ftps://",
    "sftp://", "smb://",
    "nfs://", "ftp://",
    "dav://", "news:",
    "telnet://", "imap:",
    "rtsp://", "urn:",
    "pop:", "sip:", "sips:",
    "tftp:", "btsp://",
    "bt12cap://", "btgoep://",
    "tcpobex://",
    "irdaobex://",
    "file://", "urn:epc:id:",
    "urn:epc:tag:",
    "urn:epc:pat:",
    "urn:epc:raw:",
    "urn:epc:", "urn:nfc:"};
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

Then, in `buildUrlBytes()`, we need to find the prefix (if any) and use it:

```
private byte[] buildUrlBytes(String url) {
    byte prefixByte=0;
    String subset=url;
    int bestPrefixLength=0;

    for (int i=0;i<PREFIXES.length;i++) {
        String prefix = PREFIXES[i];

        if (url.startsWith(prefix) && prefix.length() > bestPrefixLength) {
            prefixByte=(byte)(i+1);
            bestPrefixLength=prefix.length();
            subset=url.substring(bestPrefixLength);
        }
    }

    final byte[] subsetBytes = subset.getBytes();
    final byte[] result = new byte[subsetBytes.length+1];

    result[0]=prefixByte;
    System.arraycopy(subsetBytes, 0, result, 1, subsetBytes.length);

    return(result);
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

We iterate over the PREFIXES array and find a match, if any, and the best possible match if there is more than one. If there is a match, we record the NDEF value for the first byte (our PREFIXES index plus one) and create a subset string containing the characters after the prefix. If there is no matching prefix, the prefix byte is 0 and we will include the full URL.

Given that, we construct a byte array containing our prefix byte in the first slot, and the rest taken up by the byte array of the subset of our URL.

Creating the NDEF Record and Message

Given the result of `buildUrlBytes()`, our `onNewIntent()` implementation creates a `TNF_WELL_KNOWN, RTD_URI NdefRecord` object, and pours that into an `NdefMessage` object.

The third parameter to the `NdefRecord` constructor is a byte array representing the optional “ID” of this record, which is not necessary here.

Finally, we delegate the actual writing to a `WriteTask` subclass of `AsyncTask`, as writing the `NdefMessage` to the Tag is... interesting.

Writing to a Tag

Here is the aforementioned `WriteTask` static inner class:

```
static class WriteTask extends AsyncTask<Void, Void, Void> {
    Activity host=null;
    NdefMessage msg=null;
    Tag tag=null;
    String text=null;

    WriteTask(Activity host, NdefMessage msg, Tag tag) {
        this.host=host;
        this.msg=msg;
        this.tag=tag;
    }

    @Override
    protected Void doInBackground(Void... arg0) {
        int size=msg.toByteArray().length;

        try {
            Ndef ndef=Ndef.get(tag);

            if (ndef==null) {
                NdefFormatable formatable=NdefFormatable.get(tag);

                if (formatable!=null) {
                    try {
                        formatable.connect();

                        try {
                            formatable.format(msg);
                        }
                    }
                    catch (Exception e) {
                        text="Tag refused to format";
                    }
                }
            }
        }
    }
}
```

NFC

```
    }
    catch (Exception e) {
        text="Tag refused to connect";
    }
    finally {
        formatable.close();
    }
}
else {
    text="Tag does not support NDEF";
}
}
else {
    ndef.connect();

    try {
        if (!ndef.isWritable()) {
            text="Tag is read-only";
        }
        else if (ndef.getMaxSize()<size) {
            text="Message is too big for tag";
        }
        else {
            ndef.writeNdefMessage(msg);
        }
    }
    catch (Exception e) {
        text="Tag refused to connect";
    }
    finally {
        ndef.close();
    }
}
}
catch (Exception e) {
    Log.e("URLTagger", "Exception when writing tag", e);
    text="General exception: "+e.getMessage();
}

return(null);
}

@Override
protected void onPostExecute(Void unused) {
    if (text!=null) {
        Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }

    host.finish();
}
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](https://commonsware.com/android/nfc/url/URLTagger.java))

In `doInBackground()`, after making note of how big the message is in bytes, we first try to get the Ndef aspect of the Tag object, by calling the static `get()` method on the Ndef class. If the tag is an NDEF tag, this should return an Ndef instance. If it does not, we try to get an NdefFormatable aspect by calling `get()` on the NdefFormatable

class. If the tag is not NDEF now but can be formatted as NDEF, this should give us an `NdefFormatable` object. If both aspect attempts fail, we bail out, displaying a Toast to let the user know that while the tag they used is NFC, it is not NDEF-compliant.

If the tag turned out to be `NdefFormatable`, to put the `NdefMessage` on it, we first `connect()` to the tag, then `format()` it, supplying the message. `NdefFormatable` also supports `formatReadOnly()` for tags that support that mode — this will write the message on the tag, then block it from further updates. When we are done, we `close()` the connection.

If the tag turned out to be `Ndef` already, we `connect()` to it, then see if it is writable and has enough room. If it meets both of those criteria, we can emit the message via `writeNdefMessage()`, which overwrites the NDEF message that had already existed on the tag (if any). If the tag supported it, a call to `makeReadOnly()` would block further updates to the tag. Again, when we are done, we `close()` the connection.

All of the actual NFC I/O is performed in `doInBackground()`, because this I/O may take some time, and we do not want to block the main application thread while doing it.

Responding to a Tag

Writing to a tag is a bit complicated. Responding to an NDEF message on a tag is significantly easier.

If the foreground activity is not consuming NFC events — as `URLTagger` does in write mode — then Android will use normal Intent resolution with `startActivity()` to handle the tag. To respond to the tag, all you need to do is have an activity set up to watch for an `android.nfc.action.NDEF_DISCOVERED` Intent. To get control ahead of the built-in Tags application, also have a `<data>` element that describes the sort of content or URL you are expecting to find on the tag.

For example, suppose you used the Android browser to visit [some page on the CommonsWare Web site](#), and you wrote that to a tag using `URLTagger`. The `URLTagger` application has another activity, `URLHandler`, that will respond when you tap the newly-written tag from the home screen or anywhere else. It accomplishes this via a suitable `<intent-filter>`:

```
<activity
  android:name="URLHandler"
```

NFC

```
android:label="@string/app_name">
<intent-filter android:label="@string/app_name">
  <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

  <data
    android:host="commonsware.com"
    android:scheme="http"/>

  <category android:name="android.intent.category.DEFAULT"/>
</intent-filter>
</activity>
```

(from [NFC/URLTagger/app/src/main/AndroidManifest.xml](#))

The `URLHandler` activity can then use `getIntent()` to retrieve the key pieces of data from the tag itself, if needed. In particular, the `EXTRA_NDEF_MESSAGES` `Parcelable` array extra will return an array of `NdefMessage` objects. Typically, there will only be one of these. You can call `getRecords()` on the `NdefMessage` to get at the array of `NdefRecord` objects (again, typically only one). Methods like `getPayload()` will allow you to get at the individual portions of the record.

The nice thing is that the URL still works, even if `URLTagger` is not on the device. In that case, the Tags application would react to the tag, and the user could tap on it to bring up a browser on this URL. A production application might create a Web page that tells the user about this great and wonderful app she can install, and provide links to the Play Store (or elsewhere) to go get the app.

Expected Pattern: Bootstrap

Tags tend to have limited capacity. Even in peer-to-peer settings, the effective bandwidth of NFC is paltry compared to anything outside of dial-up Internet access.

As a result, NFC will be used infrequently as the complete communications solution between a publisher and a device. Sometimes it will, when the content is specifically small, such as a contact (vCard) or event (iCalendar). But, for anything bigger than that, NFC will serve more as a convenient bootstrap for more conventional communications options:

1. Embedding a URL in a tag, as the previous sample showed, allows an installed application to run or a Web site to be browsed
2. Embedding a Play Store URL in a tag allows for easy access to some specialized app (e.g., menu for a restaurant)

3. A multi-player game might use peer-to-peer NFC to allow local participants to rapidly connect into the same shared game area, where the game is played over the Internet or Bluetooth
4. And so on.

Mobile Devices are Mobile

Reading and writing NFC tags is a relatively slow process, mostly due to low bandwidth. It may take a second or two to actually complete the operation.

Users, however, are not known for their patience.

If a user moves their device out of range of the tag while Android is attempting to read it, Android simply will skip the dispatch. If, however, the tag leaves the signal area of the device while you are writing to it, you will get an `IOException`. At this point, the state of the tag is unknown.

You may wish to incorporate something into your UI to let the user know that you are working with the tag, encouraging them to leave the phone in place until you are done.

Enabled and Disabled

There are two separate system settings that control NFC behavior:

- The user could have NFC disabled outright, which you would detect by calling `isEnabled()` on your `NfcAdapter`
- The user could have NFC enabled but have Android Beam disabled, which you would detect by calling `isNdefPushEnabled()` on your `NfcAdapter`

As with most enabled/disabled settings, you cannot change these values yourself. On newer Android SDK versions, though, you can try to bring up the relevant Settings screens for the user to enable these features, by using the following activity action strings from the `android.provider.Settings` class:

- `ACTION_NFC_SETTINGS` for the main NFC settings screen (added in API Level 16)
- `ACTION_NFCSHARING_SETTINGS` for the Android Beam settings screen (added in API Level 14)

Android Beam

Android Beam is Google’s moniker for peer-to-peer NFC messaging, with an emphasis — obviously — on Android apps. Rather than you tapping your NFC-capable Android device on a smart tag, you put it back-to-back with another NFC-capable Android device, and romance ensues.

Partially, this is simply one side of the exchange “pushing” an NDEF record, in a fashion that makes the other side of the exchange think that it is picking up a smart tag.

Partially, this is the concept of the “Android Application Record” (AAR), another NDEF record you can place in the NDEF message being pushed. This will identify the app you are trying to push the message to. If nothing on the device can handle the rest of the NDEF message, the AAR will lead Android to start up an app, or even lead the user to the Play Store to go download said app.

As the basis for explaining further how this all works, let’s take a look at the [NFC/ WebBeam](#) sample application. The UI consists of a `WebViewFragment`, in which we can browse to some Web page. Then, running this app on two NFC-capable devices, one app can “push” the URL of the currently-viewed Web page to the other app, which will respond by displaying that page. In this fashion, we are “sharing” a URL, without one side having to type it in by hand. And, while we are using this to share a URL, you could use Android Beam to share any sort of bootstrapping data, such as the user IDs of each person, for use in connecting to some common game server.

The Fragment

The fragment that implements our UI, `BeamFragment`, extends from `WebViewFragment`. In `onActivityCreated()`, we configure the `WebView`, load up Google’s home page, and indicate that would like to participate in the action bar (via a call to `setHasOptionsMenu()`):

```
@SuppressWarnings("SetJavaScriptEnabled")
@Override
public void onActivityCreated(Bundle savedInstanceState) {
    super.onActivityCreated(savedInstanceState);

    getWebView().setWebViewClient(new BeamClient());
    getWebView().getSettings().setJavaScriptEnabled(true);
    loadUrl("http://google.com");
    setHasOptionsMenu(true);
}
```

NFC

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/BeamFragment.java](#))

To keep all links within the WebView, we attached a WebViewClient implementation, named BeamClient, that just loads all requested URLs back into the WebView:

```
class BeamClient extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView wv, String url) {
        wv.loadUrl(url);

        return(true);
    }
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/BeamFragment.java](#))

We add one item to the action bar: a toolbar button (`R.id.beam`) that will be used to indicate we wish to beam the URL in our WebView to another copy of this application running on another NFC-capable Android device:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    if (getContract().hasNFC()) {
        inflater.inflate(R.menu.actions, menu);
    }

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.beam) {
        getContract().enablePush();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/BeamFragment.java](#))

So, when the app is initially launched, it will look something like this:

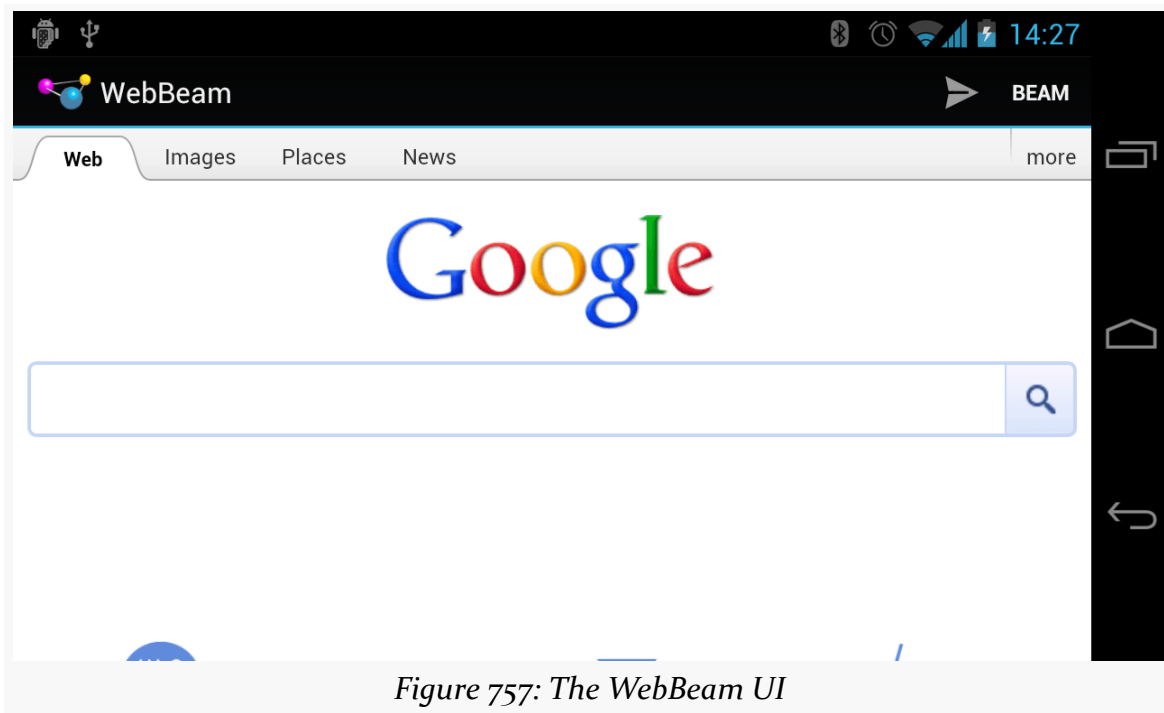

Figure 757: The WebBeam UI

The user can use Google to find a Web page worth beaming.

Requesting the Beam

Our hosting activity, `WebBeamActivity`, gets access to our `NfcAdapter`, as we did in the previous example:

```
adapter=NfcAdapter.getDefaultAdapter(this);
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](https://commonsware.com/android/webbeam/WebBeamActivity.java))

When the user taps on our action bar item, the fragment calls `enablePush()` on the activity. `WebBeamActivity`, in turn, calls `setNdefPushMessageCallback()` on the `NfcAdapter`, supplying two parameters:

1. An implementation of the `NfcAdapter.CreateNdefMessageCallback` interface, used to let us know when another device is in range for us to beam to (in our case, `WebBeamActivity` implements this interface)
2. Our activity that is participating in this push

NFC

If something else comes to the foreground, `onStop()` will call a corresponding `disablePush()`, which also calls `setNdefPushMessageCallback()`, specifying a null first parameter, to turn off our request to beam:

```
void enablePush() {
    adapter.setNdefPushMessageCallback(this, this);
}

void disablePush() {
    adapter.setNdefPushMessageCallback(null, this);
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

In between the calls to `enablePush()` and `disablePush()`, if another NFC device comes in range that supports the NDEF push protocols, we're beamin'.

Sending the Beam

When our beam-enabled device encounters another beam-capable device, our `NfcAdapter.CreateNdefMessageCallback` is called with `createNdefMessage()`, where we need to prepare the `NfcMessage` to beam to the other party:

```
@Override
public NdefMessage createNdefMessage(NfcEvent arg0) {
    NdefRecord uriRecord=
        new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
            MIME_TYPE.getBytes(Charset.forName("US-ASCII")),
            new byte[0],
            beamFragment.getUrl()
                .getBytes(Charset.forName("US-ASCII")));
    NdefMessage msg=
        new NdefMessage(
            new NdefRecord[] {
                uriRecord,
                NdefRecord.createApplicationRecord("com.commonsware.android.webbeam") });
    return(msg);
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

We first create a typical `NfcRecord`, in this case of `TNF_MIME_MEDIA`, with a MIME type defined in a static data member and payload consisting of the URL from our `WebView`:

```
private static final String MIME_TYPE=
    "application/vnd.commonsware.sample.webbeam";
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

NFC

You might wonder why we are using `TNF_MIME_MEDIA`, instead of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, since our payload is a URL. The reason is that we need to have a unique MIME type for our message for the whole beam process to work properly, and `TNF_WELL_KNOWN` does not support MIME types. This is also why the MIME type is something distinctive, and not just `text/plain` — it has to be something only we will pick up.

Our `NfcMessage` then consists of *two* `NfcRecord` objects: the one we just created, and one created via the static `createApplicationRecord()` method on `NfcRecord`. This helper method creates an AAR record, identifying our application by its Android package name. This record must go last – Android will try to find an app to work with based on the other records first, before “failing over” to use the AAR.

Receiving the Beam

To receive our beam, our `WebBeamActivity` must be configured in the manifest to respond to `NDEF_DISCOVERED` actions with our unique MIME type:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.webbeam"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET"/>
    <uses-permission android:name="android.permission.NFC"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name=".WebBeamActivity"
            android:label="@string/app_name"
            android:launchMode="singleTask"
            android:screenOrientation="landscape">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

                <category android:name="android.intent.category.DEFAULT"/>
            </intent-filter>
            <data android:mimeType="application/vnd.commonware.sample.webbeam"/>
        </activity>
    </application>
</manifest>
```

NFC

```
</intent-filter>
</activity>
</application>
</manifest>
```

(from [NFC/WebBeam/app/src/main/AndroidManifest.xml](#))

You will also notice that we set `android:launchMode="singleTask"` on this activity. That is so we will only have one instance of this activity, regardless of whether it is in the foreground or not. Otherwise, if we already have an instance of this activity, and we receive a beam, Android will create a *second* instance of this activity — when the user later presses BACK, they return to our first instance, and wonder why our app is broken.

If we receive the beam, we will get the Intent for the NDEF_DISCOVERED action *either* in `onCreate()` (if we were not already running) or `onNewIntent()` (if we were). In either case, we want to handle it the same way: pass the URL from the first record's payload to our BeamFragment. However, we cannot do that from `onCreate()` — the fragment will not have created the `WebView` yet. So, we use a trick: calling `post()` with a `Runnable` puts that `Runnable` on the *end* of the work queue for the main application thread. We can delay our processing of the Intent by this mechanism, so we can safely assume the `WebView` exists.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    beamFragment=
        (BeamFragment)getManager().findFragmentById(android.R.id.content);

    if (beamFragment == null) {
        beamFragment=new BeamFragment();

        getFragmentManager().beginTransaction()
            .add(android.R.id.content, beamFragment)
            .commit();
    }

    adapter=NfcAdapter.getDefaultAdapter(this);

    findViewById(android.R.id.content).post(new Runnable() {
        public void run() {
            handleIntent(getIntent());
        }
    });
}

@Override
public void onNewIntent(Intent i) {
    handleIntent(i);
}
```

NFC

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

```
private void handleIntent(Intent i) {
    if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
        Parcelable[] rawMsgs=
            i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);
        NdefMessage msg=(NdefMessage)rawMsgs[0];
        String url=new String(msg.getRecords()[0].getPayload());

        beamFragment.loadUrl(url);
    }
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

The Scenarios

There are three possible scenarios, when we try beaming from one device to another:

1. The other device has our application installed, and it is running. In that case, our activity is brought to the foreground and the Intent is delivered to it, courtesy of our NDEF_DISCOVERED <intent-filter> with our unique MIME type.
2. The other device has our application installed, but it is not running. Android's Intent system handles this in the same general fashion as the first scenario, though it starts up a process for us and creates our activity instance anew in this case.
3. The other device does not have our application installed. Since nothing (hopefully) claims to support our unique MIME type, the AAR takes effect, and the user is led to the Play Store to go download our app (or, in this case, display an error message, as WebBeam is not in the Play Store).

Beaming Files

Android 4.1 (a.k.a., Jelly Bean) added in a far simpler facility for an app to beam a file to another device using the Android Beam system. You can use `setBeamPushUri()` or `setBeamPushUriCallback()` on an `NfcAdapter` to hand Android one or more `Uri` objects representing files to be transferred. While the initial connection will be made via NFC and Android Beam, the actual data transfer will be via Bluetooth or WiFi, much more suitable than NFC for bulk data.

The difference between the two approaches is mostly when you provide the array of `Uri` objects. With `setBeamPushUri()`, you initiate the beam operation and supply

NFC

the `Uri` values immediately. With `setBeamPushUriCallback()`, you initiate the beam but do not supply the `Uri` values until the beam connection is established with the peer app.

The [NFC/FileBeam](#) sample application shows file-based beaming in action.

In our activity (`MainActivity`), in `onCreate()`, we check to make sure that Android Beam is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`. If it is, then we use `ACTION_GET_CONTENT` to retrieve some file from the user (MIME type wildcard of `*/*`):

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    adapter=NfcAdapter.getDefaultAdapter(this);

    if (!adapter.isNdefPushEnabled()) {
        Toast.makeText(this, R.string.sorry, Toast.LENGTH_LONG).show();
        finish();
    }
    else {
        Intent i=new Intent(Intent.ACTION_GET_CONTENT);

        i.setType("*/*");
        startActivityForResult(i, 0);
    }
}
```

(from [NFC/FileBeam/app/src/main/java/com/commonsware/android/filebeam/MainActivity.java](#))

In `onActivityResult()`, if we actually got a file (e.g., the result is `ACTION_OK`), we turn around and call `setBeamPushUri()` to pass that file to some peer device. We also set up a `Button` as our UI — clicking the `Button` will `finish()` the activity:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode==0 && resultCode==RESULT_OK) {
        adapter.setBeamPushUri(new Uri[] {data.getData()}, this);

        Button btn=new Button(this);

        btn.setText(R.string.over);
        btn.setOnClickListener(this);
        setContentView(btn);
    }
}
```

(from [NFC/FileBeam/app/src/main/java/com/commonsware/android/filebeam/MainActivity.java](#))

That is all there is to it. If you run this app and pick a file, then hold the device up to another Android 4.1+ device, you will be prompted to “Touch to Beam” — doing so

NFC

will kick off the transfer. Once the transfer is shown on the receiving device, you can pull the devices apart a bit, as the transfer will be proceeding over Bluetooth or WiFi. However, while Bluetooth ranges are much longer than NFC, you still need to keep the devices within a handful of meters of one another.

Note that the receiving device is not running our app. The OS handles the receipt of the transferred file, not our code. Similarly, the OS on the sending device is really the one responsible for the file transfer, so our app does not need the `INTERNET` or `BLUETOOTH` permissions. The downside is that we have no control over anything on the receiving side — the file is stored wherever the OS elects to put it, and the Notification it displays when complete will simply launch `ACTION_VIEW` on the pushed file.

Another Sample: SecretAgentMan

To provide another take on using these features of `NfcAdapter`, let's examine the [NFC/SecretAgentMan](#) sample application, originally written for a presentation at the 2012 droidcon UK conference. This combines writing to tags, directly beaming text to another device, and using `Uri`-based beaming, all in one app.

The UI of the app is a large `EditText` widget with an action bar:

Figure 758: The SecretAgentMan UI

NFC

There are three action bar items, one each for the three operations: writing to a tag, directly beaming to another device, and beaming a file (represented via a `Uri`).

Configuration and Initialization

Our app is comprised of a single activity, named `MainActivity`. As part of our manifest setup, we request the NFC permission. And, since the app needs NFC to be useful, we also have a `<uses-feature>` element, stipulating that the device needs to have NFC, otherwise the app should not be shown in the Play Store:

```
<uses-permission android:name="android.permission.NFC"/>

<uses-feature
    android:name="android.hardware.nfc"
    android:required="true"/>
```

(from [NFC/SecretAgentMan/app/src/main/AndroidManifest.xml](#))

In `onCreate()` of `MainActivity`, we can then safely get access to an `NfcAdapter`, since the NFC hardware should exist and we have rights to use NFC:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    nfc=NfcAdapter.getDefaultAdapter(this);
    secretMessage=(EditText)findViewById(R.id.secretMessage);

    nfc.setOnNdefPushCompleteCallback(this, this);

    if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(getIntent().getAction())) {
        readFromTag(getIntent());
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

We also get our hands on the `EditText` widget, storing a reference to it in a data member named `secretMessage`. We will cover the rest of the initialization work in `onCreate()` later in this section, as we cover the code that needs that initialization.

Writing to the Tag

If the user chooses the “Write to Tag” action bar item, we call a `setUpWriteMode()` method from `onOptionsItemSelected()` of `MainActivity`. We maintain an `inWriteMode` boolean data member to track whether or not we are already trying to

NFC

write to an NFC tag. If `inWriteMode` is false, we go ahead and take control over the NFC hardware to attempt to write to the next tag we see:

```
void setUpWriteMode() {
    if (!inWriteMode) {
        IntentFilter discovery=
            new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
        IntentFilter[] tagFilters=new IntentFilter[] { discovery };
        Intent i=
            new Intent(this, getClass()).addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP
                | Intent.FLAG_ACTIVITY_CLEAR_TOP);
        PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

        inWriteMode=true;
        nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

To do that, we:

- Create an `IntentFilter` for `ACTION_TAG_DISCOVERED`
- Create a `PendingIntent` for an `Intent` pointing back to this same activity instance (using `getClass()` to identify the instance, plus `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to route control back to our running instance)
- Call `enableForegroundDispatch()` on our `NfcAdapter`, to route newly-discovered tags to us, with the `IntentFilter` identifying the tag-related events we are interested in, and the `PendingIntent` identifying what to do when such a tag is encountered

Once our activity is finishing (e.g., the user presses BACK), we need to clean up our write-to-tag logic. This is kicked off in `onPause()` of `MainActivity`:

```
@Override
public void onPause() {
    if (isFinishing()) {
        cleanUpWritingToTag();
    }

    super.onPause();
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

All we do in `cleanUpWritingToTag()` is discontinue our foreground control over the NFC hardware:

```
void cleanUpWritingToTag() {
    nfc.disableForegroundDispatch(this);
}
```

NFC

```
inWriteMode=false;
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

If, before that occurs, the device is tapped on a tag, our activity should regain control in `onNewIntent()` as a result of our `PendingIntent` having been executed:

```
@Override
protected void onNewIntent(Intent i) {
    if (inWriteMode
        && NfcAdapter.ACTION_TAG_DISCOVERED.equals(i.getAction())) {
        writeToTag(i);
    }
    else if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
        readFromTag(i);
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

If we are in write mode, and if the `Intent` that was just used with `startActivity()` was `ACTION_TAG_DISCOVERED`, we call our `writeToTag()` method to actually start writing information to the tag:

```
void writeToTag(Intent i) {
    Tag tag=i.getParcelableExtra(NfcAdapter.EXTRA_TAG);
    NdefMessage msg=
        new NdefMessage(new NdefRecord[] { buildNdefRecord() });

    new WriteTagTask(this, msg, tag).execute();
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

To write to the tag, we get our `Tag` out of its `Intent` extra (keyed by `EXTRA_TAG`). Then, we build an `NfcMessage` to write to the tag, getting its `NfcRecord` from `buildNdefRecord()`:

```
NdefRecord buildNdefRecord() {
    return(new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
        MIME_TYPE.getBytes(), new byte[] {},
        secretMessage.getText().toString().getBytes()));
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

Our NDEF record will be of a specific MIME type, represented by a static data member named `MIME_TYPE`:

```
private static final String MIME_TYPE="vnd.secret/agent.man";
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

NFC

The payload of the NDEF record is our “secret message” from the secretMessage EditText widget.

The writeToTag() method then kicks off the same WriteTagTask that we used earlier in this chapter:

```
package com.commonware.android.jimmyb;

import android.nfc.NdefMessage;
import android.nfc.Tag;
import android.nfc.tech.Ndef;
import android.nfc.tech.NdefFormatable;
import android.os.AsyncTask;
import android.util.Log;
import android.widget.Toast;

class WriteTagTask extends AsyncTask<Void, Void, Void> {
    MainActivity host=null;
    NdefMessage msg=null;
    Tag tag=null;
    String text=null;

    WriteTagTask(MainActivity host, NdefMessage msg, Tag tag) {
        this.host=host;
        this.msg=msg;
        this.tag=tag;
    }

    @Override
    protected Void doInBackground(Void... arg0) {
        int size=msg.toByteArray().length;

        try {
            Ndef ndef=Ndef.get(tag);

            if (ndef == null) {
                NdefFormatable formatable=NdefFormatable.get(tag);

                if (formatable != null) {
                    try {
                        formatable.connect();

                        try {
                            formatable.format(msg);
                        }
                        catch (Exception e) {
                            text=host.getString(R.string.tag_refused_to_format);
                        }
                    }
                    catch (Exception e) {
                        text=host.getString(R.string.tag_refused_to_connect);
                    }
                    finally {
                        formatable.close();
                    }
                }
            }
            else {
```

NFC

```
        text=host.getString(R.string.tag_does_not_support_ndef);
    }
}
else {
    ndef.connect();

    try {
        if (!ndef.isWritable()) {
            text=host.getString(R.string.tag_is_read_only);
        }
        else if (ndef.getMaxSize() < size) {
            text=host.getString(R.string.message_is_too_big_for_tag);
        }
        else {
            ndef.writeNdefMessage(msg);
            text=host.getString(R.string.success);
        }
    }
    catch (Exception e) {
        text=host.getString(R.string.tag_refused_to_connect);
    }
    finally {
        ndef.close();
    }
}
}
catch (Exception e) {
    Log.e("URLTagger", "Exception when writing tag", e);
    text=host.getString(R.string.general_exception) + e.getMessage();
}

return(null);
}

@Override
protected void onPostExecute(Void unused) {
    host.cleanupWritingToTag();

    if (text != null) {
        Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }
}
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/WriteTagTask.java](https://commonsware.com/android/jimmyb/WriteTagTask.java))

The net result is that if the user taps the “Write to Tag” action bar item, then taps and holds the device to a tag, we will write a message to the tag and display a Toast when we are done.

And, yes, this is a surprising amount of code for what really should be a simple operation...

Reading from the Tag

We can set up MainActivity to respond to tags similar to the one we wrote — ones that have the desired MIME Type — via an `android.nfc.action.NDEF_DISCOVERED` `<intent-filter>`:

```
<intent-filter android:label="@string/app_name">
  <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

  <data android:mimeType="vnd.secret.agent.man"/>

  <category android:name="android.intent.category.DEFAULT"/>
</intent-filter>
```

(from [NFC/SecretAgentMan/app/src/main/AndroidManifest.xml](#))

In both `onCreate()` and `onNewIntent()`, if the Intent that started our activity is an `NDEF_DISCOVERED` Intent, we route control to a `readFromTag()` method:

```
void readFromTag(Intent i) {
    Parcelable[] msgs=
        (Parcelable[])i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);

    if (msgs.length > 0) {
        NdefMessage msg=(NdefMessage)msgs[0];

        if (msg.getRecords().length > 0) {
            NdefRecord rec=msg.getRecords()[0];

            secretMessage.setText(new String(rec.getPayload(), US_ASCII));
        }
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

In principle, there could be several NDEF messages on the tag, but we only pay attention to the first element, if any, of the `EXTRA_NDEF_MESSAGES` array of Parcelable objects on the Intent. Similarly, in principle, there could be several NDEF records in the first message, but we only examine the first element out of the array of `NdefRecord` objects contained in the `NdefMessage`. From there, we extract our secret message and display it by means of putting it in the `EditText` widget.

Beaming the Text

This sample only supports beaming — whether of NDEF messages directly or of a file — if we are on API Level 16 or higher. Hence, in `onCreateOptionsMenu()`, we check our version and only enable our default-disabled beam action bar items if:

NFC

- We are on API Level 16 or higher, and
- NDEF push mode is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`:

```
@TargetApi(16)
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_main, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN) {
        menu.findItem(R.id.simple_beam)
            .setEnabled(nfc.isNdefPushEnabled());
        menu.findItem(R.id.file_beam).setEnabled(nfc.isNdefPushEnabled());
    }

    return(super.onCreateOptionsMenu(menu));
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

If the user taps on the “Beam” action bar item, we call an `enablePush()` method from `onOptionsItemSelected()`, which simply enables push mode:

```
void enablePush() {
    nfc.setNdefPushMessageCallback(this, this);
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

We arrange for the activity itself to be the `CreateNdefMessageCallback` necessary for push mode. That requires us to implement `createNdefMessage()`, which will be called if we are in push mode and a push-compliant device comes within range:

```
@Override
public NdefMessage createNdefMessage(NfcEvent event) {
    return(new NdefMessage(
        new NdefRecord[] {
            buildNdefRecord(),
            NdefRecord.createApplicationRecord("com.commonsware.android.jimmyb") }));
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

Here, we create an `NdefMessage` similar to the one we wrote to the tag earlier in this sample. However, we also attach an Android Application Record (AAR), by means of the static `createApplicationRecord()` method on `NdefRecord`. This, in theory, will help route the push to our app on the other device, including downloading it from the Play Store if needed (and, of course, if it actually existed on the Play Store, which it does not).

NFC

Back up in `onCreate()`, we call `setOnNdefPushCompleteCallback()`, to be notified of when a push operation is completed. Once again, we set up `MainActivity` to be the callback, this time by implementing the `OnNdefPushCompleteCallback` interface. That, in turn, requires us to implement `onNdefPushComplete()`, where we disable push mode via a call to `setNdefPushMessageCallback()` with a null listener:

```
@Override
public void onNdefPushComplete(NfcEvent event) {
    nfc.setNdefPushMessageCallback(null, this);
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

To receive the beam, we only need our existing logic to read from the tag, as on the receiving side, a push is indistinguishable from reading a tag, and we are using the same MIME type for both the message written to the tag and the message we are pushing.

Beaming the File

If the user taps the “Beam File” action bar item, we find some file to beam, by means of an `ACTION_GET_CONTENT` request and `startActivityForResult()`:

```
case R.id.file_beam:
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);

    i.setType("*/*");
    startActivityForResult(i, 0);
    return(true);
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

In `onActivityResult()`, if the request succeeded, we use `setBeamPushUri()` to tell Android to beam the selected file to another device. Nothing more is needed on our side, and the receipt of the file is handled entirely by the OS, not our application code, so there is nothing to be written for that.

This code assumes the NFC adapter is enabled. We could check that via a call to `isEnabled()` on our `NfcAdapter`. If it is not enabled, we could — on user request — bring up the Settings activity for configuring NFC, via `startActivity(new Intent(Settings.ACTION_NFC_SETTINGS))`. However, oddly, this Intent action is only available on Android 4.1 (API Level 16) and higher, despite NFC having been available for some time previously.

This code ignores the possibility of doing the simple beam (not the file-based beam) on Android 4.0.x devices. That is because the `isNdefPushEnabled()` method was not added until Android 4.1, and therefore we do not know whether or not we can actually do a beam.

If `isNdefPushEnabled()` returns `false`, we simply disable some action bar items. Alternatively, we could use `startActivity(new Intent(Settings.ACTION_NFC_SHARING_SETTINGS))`, on API Level 14 and higher, to bring up the beam screen in Settings, to allow the user to toggle beam support on.

Additional Resources

To help make sense of the tags that you are trying to use with your app, you may wish to grab the [NFC TagInfo](#) application off of the Google Play Store. This application simply scans a tag and allows you to peruse all the details of that tag, including the supported technologies (e.g., does it support NDEF? is it `NdefFormatable`?), the NDEF records, and so on.

To learn more about NFC on Android — beyond this chapter or the Android developer documentation — [this Google I/O 2011 presentation](#) is recommended.

Device Administration

Balding authors of Android books often point out that enterprises and malware authors have the same interests: they want to take control of a device away from the person that is holding it and give that control to some other party. Android, being a consumer operating system, is designed to defend against malware, and so enterprises can run into issues.

However, Android does have a growing area of device administration APIs, that allow carefully-constructed and installed applications to exert some degree of control over the device, how it is configured, and how it operates.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on [broadcast Intents](#).

Objectives and Scope

One might read the phrase “device administration” and assume that somebody, using these APIs, could do anything they want on the device.

That’s not quite what “device administration” means in this case.

Rather, the device administration APIs serve three main roles:

1. They allow an application to dictate how well a device is secured, from the password required in the OS lock screen to whether the device should have full-disk encryption

2. They allow an application to find out when security issues might arise, notably failed password attempts
3. They allow an application to lock the device, disable its cameras, or even perform a “wipe” (i.e., factory reset)

The user, however, has to agree to enable a device administration app. It does not magically get all these powers simply by being installed. What the user gets from agreeing to this is access to something that otherwise would be denied (e.g., to use Enterprise App X, you must agree to allow it to be a device administrator).

Defining and Registering an Admin Component

There are four pieces for defining and registering a device administration app: creating the metadata, adding the `<receiver>` to the manifest, implementing that `BroadcastReceiver`, and telling Android to ask the user to agree to allow the app to a device administrator.

Here, we will take a peek at the [DeviceAdmin/LockMeNow](#) sample application.

The Feature

Apps implementing device administrators should add a `<uses-feature>` element with a name of `android.software.device_admin`, indicating whether or not they require this device feature to exist. This can be used by the Play Store to filter your app from being available on devices that, for one reason or another, do not offer this capability.

The Metadata

As with [app widgets](#) and other Android facilities, you will need to define a metadata file as an XML resource, describing in greater detail what your device administration app wishes to do. This information will determine what you will be allowed to do once the user approves your app, and what you list here will be displayed to the user when you request such approval.

The `DeviceAdminInfo` class has a series of static data members (e.g., `USES_ENCRYPTED_STORAGE`) that represent specific policies that your device administrator app could use. The documentation for each of those static data members lists the corresponding element that goes in this XML metadata file (e.g., `<encrypted-storage>`). These elements are wrapped in a `<uses-policies>` element,

DEVICE ADMINISTRATION

which itself is wrapped in a `<device-admin>` element. The range of possible policies is shown in the following sample XML metadata file:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-camera />
    <encrypted-storage />
    <expire-password />
    <force-lock />
    <limit-password />
    <reset-password />
    <watch-login />
    <wipe-data />
  </uses-policies>
</device-admin>
```

Here, we:

- Intend to disable the cameras, if needed
- Will ask the user to encrypt their device storage, if it has not been done already
- Will set an expiration time for the user's password, after which they will need to set up a new one
- Intend to lock the device, if needed
- Will set criteria for password quality, such as minimum length
- Intend to forcibly reset the user's password, if needed
- Intend to monitor for failed and successful login attempts
- Intend to wipe the device, if needed

Choose which of those policies you need — the fewer you request, the more likely it is the user will not wonder about your intentions. In your project's `res/xml/` directory, create a file that looks like the above with the policies you wish. You can name this file whatever you want (e.g., `device_admin.xml`), within standard Android resource naming rules.

The Manifest

In the manifest, you will need to declare a `<receiver>` element for the `DeviceAdminReceiver` component that you will write. This component not only is the embodiment of the device admin capabilities of your app, but it will be the one notified of failed logins and other events.

For example, here is the `<receiver>` element from the `LockMeNow` sample app:

DEVICE ADMINISTRATION

```
<receiver
  android:name="AdminReceiver"
  android:permission="android.permission.BIND_DEVICE_ADMIN">
  <meta-data
    android:name="android.app.device_admin"
    android:resource="@xml/device_admin" />

  <intent-filter>
    <action android:name="android.app.action.DEVICE_ADMIN_ENABLED" />
  </intent-filter>
</receiver>
```

(from [DeviceAdmin/LockMeNow/app/src/main/AndroidManifest.xml](#))

There are three things distinctive about this element compared to your usual `<receiver>` element:

1. It requires that whoever sends broadcasts to it hold the `BIND_DEVICE_ADMIN` permission. Since that permission is protected and can only be held by apps signed with the firmware's signing key, you can be reasonably assured that any events sent to you are real.
2. It has the `<meta-data>` child element pointing to our device administration metadata from the previous section.
3. It registers for `android.app.action.DEVICE_ADMIN_ENABLED` broadcasts via its `<intent-filter>` — this is the broadcast that will be used to notify you about failed logins or other events.

The Receiver

The `DeviceAdminReceiver` itself needs to exist as a component in your app, registered in the manifest as shown above. At minimum, though, it does not need to override any methods, such as the implementation from the `LockMeNow` sample app:

```
package com.commonware.android.lockme;

import android.app.admin.DeviceAdminReceiver;

public class AdminReceiver extends DeviceAdminReceiver {
}
```

(from [DeviceAdmin/LockMeNow/app/src/main/java/com/commonware/android/lockme/AdminReceiver.java](#))

By requesting the `DEVICE_ADMIN_ENABLED` broadcasts, we could get control when we are enabled by overriding an `onEnabled()` method. We could also register for other broadcasts (e.g., `ACTION_PASSWORD_FAILED`) and implement the corresponding callback method on our `DeviceAdminReceiver` (e.g., `onPasswordFailed()`).

The Demand for Device Domination

Simply having this component in our manifest, though, is insufficient. The user must proactively agree to allow us to administer their device. And, since this is potentially very dangerous, a simple permission was deemed to also be insufficient. Instead, we need to ask the user to approve us as a device administrator from our app, typically from an activity.

In the case of LockMeNow, the UI is just a really big button, tied to a `lockMeNow()` method on our `LockMeNowActivity`:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/Button1"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:onClick="lockMeNow"
        android:text="@string/lock_me"
        android:textColor="#FFF000"
        android:textSize="40sp"
        android:textStyle="bold" />

</LinearLayout>
```

(from [DeviceAdmin/LockMeNow/app/src/main/res/layout/main.xml](#))

In `onCreate()` of the activity, in addition to loading up the UI via `setContentView()`, we create a `ComponentName` object identifying our `AdminReceiver` component. We also request access to the `DevicePolicyManager`, via a call to `getSystemService()`. `DevicePolicyManager` is our gateway for making direct requests for device administration operations, such as locking the device:

```
package com.commonware.android.lockme;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class LockMeNowActivity extends Activity {
    private DevicePolicyManager mgr=null;
    private ComponentName cn=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

DEVICE ADMINISTRATION

```
super.onCreate(savedInstanceState);

setContentView(R.layout.main);
cn=new ComponentName(this, AdminReceiver.class);
mgr=(DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);
}

public void lockMeNow(View v) {
    if (mgr.isAdminActive(cn)) {
        mgr.lockNow();
    }
    else {
        Intent intent=
            new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
        intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
        intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
            getString(R.string.device_admin_explanation));
        startActivity(intent);
    }
}
}
```

(from [DeviceAdmin/LockMeNow/app/src/main/java/com/commonsware/android/lockme/LockMeNowActivity.java](#))

In `lockMeNow()`, we ask the `DevicePolicyManager` if we have already been registered as a device administrator, by calling `isAdminActive()`, supplying the `ComponentName` of our `DeviceAdminReceiver` that should be so registered. If that returns false, then the user has not approved us as a device administrator yet, so we need to ask them to do so. To do that, you:

- Create an Intent for the `DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN` action
- Add the `ComponentName` of our `DeviceAdminReceiver` as an extra, keyed as `DevicePolicyManager.EXTRA_DEVICE_ADMIN`
- Add another extra, `DevicePolicyManager.EXTRA_ADD_EXPLANATION`, which is some text to show the user as part of the authorization screen, to explain why we need to be a device admin
- Start up an activity using that Intent, via `startActivity()`

If you run this on a device, then tap the button, the first time you do so the user will be prompted to agree to making the app be a device administrator:

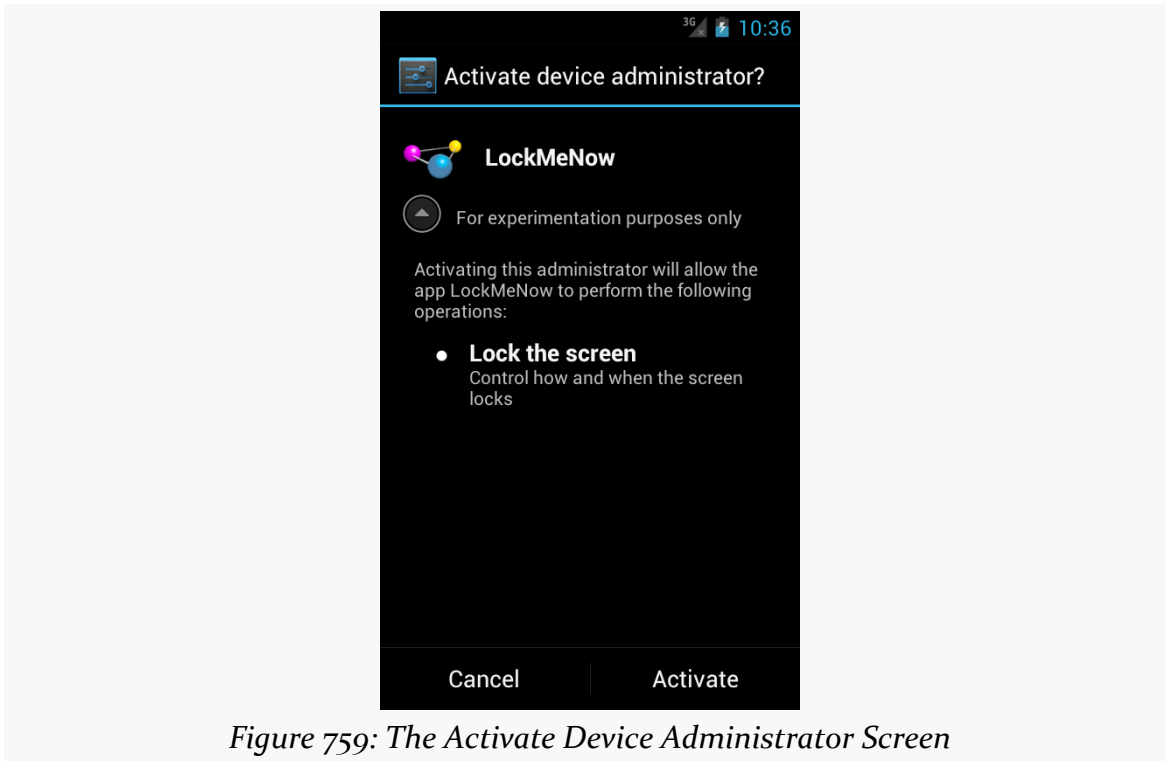

Figure 759: The Activate Device Administrator Screen

The “For experimentation purposes only” is the value of our `DevicePolicyManager.EXTRA_ADD_EXPLANATION` extra, loaded from a string resource.

If the user clicks “Activate”, and you override `onEnabled()` in your `DeviceAdminReceiver`, that will be called to let you know that you have been approved and can perform device administration functions. Your component will also appear in the list of device administrators in the Settings app:

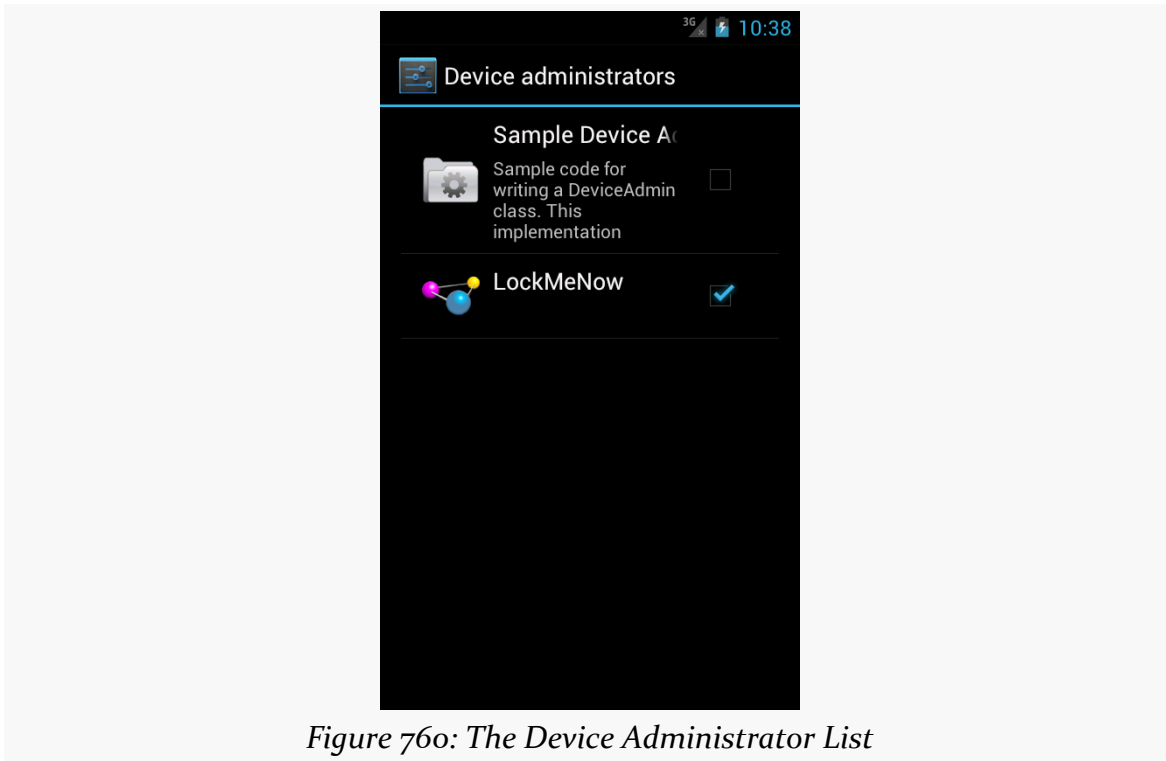

Figure 760: The Device Administrator List

The user can, at any time, uncheck you in this list and disable you. You can find out about this by having your `DeviceAdminReceiver` listen for `ACTION_DEVICE_ADMIN_DISABLE_REQUESTED` broadcasts and overriding the `onDisableRequested()` method, where you can return the text of a message to be displayed to the user confirming that they do indeed wish to go ahead with the disable operation. To find out if they go through with it, your `DeviceAdminReceiver` can listen for `ACTION_DEVICE_ADMIN_DISABLED` broadcasts and override `onDisabled()`.

Going Into Lockdown

Given that the user has approved your device administration request, and given that you requested `<force-lock>` in your metadata, you can call `lockNow()` on a `DevicePolicyManager`. That will immediately lock the device and (generally) turn off the screen. It is as if the user pressed the `POWER` button on the device. If anything, `lockNow()` will offer tighter security.

The `LockItNow` sample app does this if, when the user clicks the really big button, it detects that it is already a device administrator. If you test this on a device, it will

behave as though the user pressed POWER; on an emulator, you will need to press the HOME button to “power on” the screen and be able to re-enter your emulator.

You can also call:

- `setCameraDisabled()` to disable all cameras, if you requested `<disable-camera>` in the metadata. Note that this disables all cameras; there is no provision at this time to disable individual cameras separately.
- `wipeData()`, which performs what amounts to a factory reset — it leaves external storage alone but wipes the contents of internal storage as part of a reboot. This requires the `<wipe-data>` policy in the metadata.
- `setKeyguardDisabledFeatures()`, to control whether or not the lockscreen allows direct access to the camera and/or app widgets (lockscreen app widgets are described in [the chapter on app widgets](#))

For example, the latter feature, while available in the Android SDK, is not built into the Settings app of Android 4.2. As a result, users need a third-party app to toggle on or off lockscreen access to the camera and app widgets. One such third-party app is [LockscreenLocker](#), released as open source by the author of this book.

Basically, the app presents you with two Switch widgets to control the camera and app widgets on the lock screen. First, though, it shows you a message and a Button, if the app is not set up as a device administrator:

DEVICE ADMINISTRATION

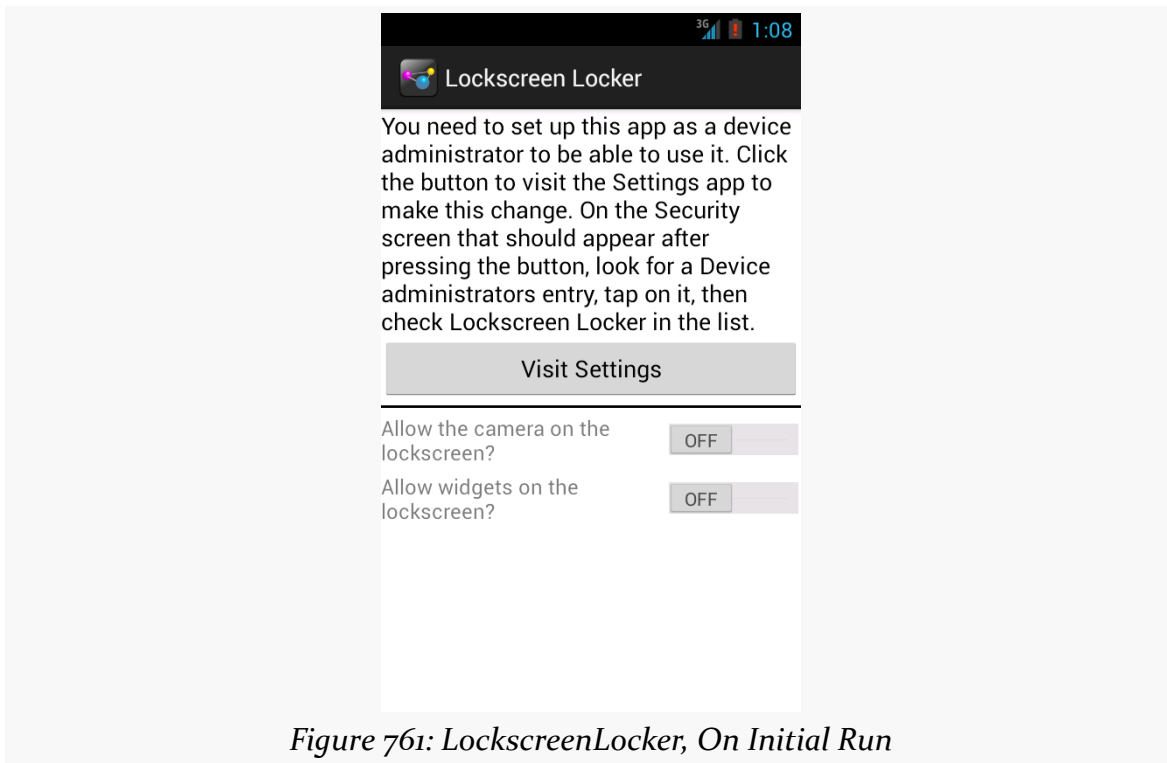

Figure 761: LockscreenLocker, On Initial Run

Once that is complete, the Switch widgets become enabled and usable:

DEVICE ADMINISTRATION

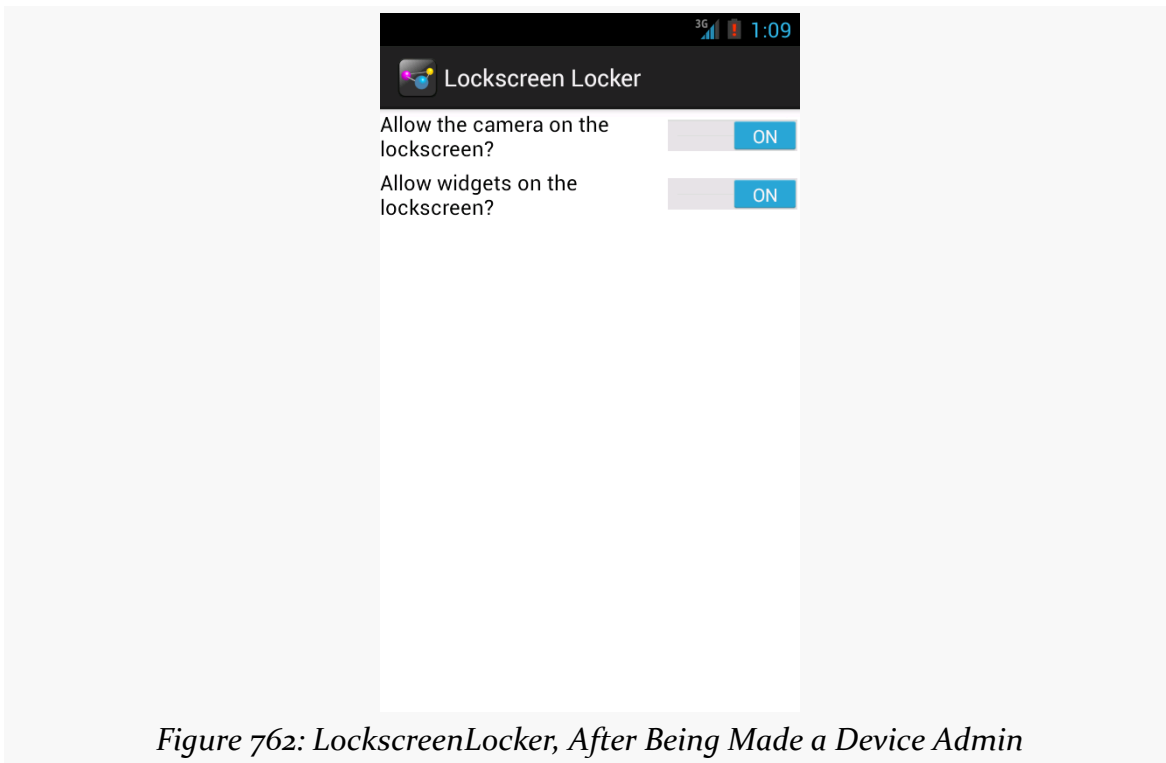

Figure 762: LockscreenLocker, After Being Made a Device Admin

The device admin metadata for this app specifies that we want to control keyguard features:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-keyguard-features/>
  </uses-policies>
</device-admin>
```

Note that, at the time of this writing, there is a flaw in the Android developer documentation — the correct element to have in the metadata is `<disable-keyguard-features/>`, not `<disable-keyguard-widgets/>`. You can track [this issue](#) to see when this documentation bug has been repaired.

Our device admin component, `LockscreenAdminReceiver`, is empty, because there are no events that we are trying to listen to:

```
public class LockscreenAdminReceiver extends DeviceAdminReceiver {
}
```

DEVICE ADMINISTRATION

However, we still need the `LockscreenAdminReceiver`, as it is the component that is tied to our device admin metadata and indicates to the system that we should be an option in Settings for available device administrators.

Our activity layout contains all the requisite widgets: a `TextView` for the message, a `Button` to jump to the Settings app, a `View` to serve as a divider, and a pair of `Switch` widgets to manage the lockscreen settings:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <TextView
        android:id="@+id/setupMessage"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/setup_message"
        android:textAppearance="?android:attr/textAppearanceMedium"
        android:visibility="gone"/>

    <Button
        android:id="@+id/setup"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="showSettings"
        android:text="@string/visit_settings"
        android:visibility="gone"/>

    <View
        android:id="@+id/divider"
        android:layout_width="match_parent"
        android:layout_height="2dip"
        android:layout_marginBottom="4dip"
        android:layout_marginTop="4dip"
        android:background="#FF000000"
        android:visibility="gone"/>

    <Switch
        android:id="@+id/camera"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="@string/allow_camera"/>

    <Switch
        android:id="@+id/widgets"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginTop="4dip"
        android:text="@string/allow_widgets"/>

</LinearLayout>
```

DEVICE ADMINISTRATION

In `onCreate()` of our activity (`MainActivity`), we request a `DevicePolicyManager`, set up a `ComponentName` identifying our `DeviceAdminReceiver` implementation (`LockscreenAdminReceiver`), and hook up the activity to know about changes in the state of the Switch widgets:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(DevicePolicyManager) getSystemService(DEVICE_POLICY_SERVICE);
    cn=new ComponentName(this, LockscreenAdminReceiver.class);

    camera=(CompoundButton)findViewById(R.id.camera);
    camera.setOnCheckedChangeListener(this);

    widgets=(CompoundButton)findViewById(R.id.widgets);
    widgets.setOnCheckedChangeListener(this);
}
```

In `onResume()`, we check to see if our `DeviceAdminReceiver` is active — in other words, whether the user has set us up as being a device administrator or not:

```
@Override
public void onResume() {
    super.onResume();

    if (mgr.isAdminActive(cn)) {
        toggleWidgets(true);

        int status=mgr.getKeyguardDisabledFeatures(cn);

        camera.setChecked(!((status & DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA) ==
DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA));
        widgets.setChecked(!((status & DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL) ==
DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL));
    }
    else {
        toggleWidgets(false);
    }
}
```

We toggle the visibility and enabled settings of our widgets based upon whether we are a device administrator or not, in a `toggleWidgets()` private method:

```
private void toggleWidgets(boolean enable) {
    int visibility=(enable ? View.GONE : View.VISIBLE);

    camera.setEnabled(enable);
    widgets.setEnabled(enable);

    findViewById(R.id.divider).setVisibility(visibility);
    findViewById(R.id.setup).setVisibility(visibility);
}
```

DEVICE ADMINISTRATION

```
findViewById(R.id.setupMessage).setVisibility(visibility);
}
```

`onResume()` also sets the state of our Switch widgets based upon the current state of the keyguard features, by calling `getKeyguardDisabledFeatures()` on the `DevicePolicyManager`. This returns a bit set of which features are disabled, with `DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA` and/or `DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL` possibly being set.

At the outset, after being installed, we will not be a device administrator, so the Switch widgets will be disabled and the Button will be visible. We simply send the user to the security screen in the Settings app if they click that button:

```
public void showSettings(View v) {
    startActivity(new Intent(Settings.ACTION_SECURITY_SETTINGS));
}
```

When the user toggles a Switch, our activity will be called with `onCheckedChanged()`. There, we need to call `setKeyguardDisabledFeatures()` with a new bit set, toggling on or off a bit based on the user's chosen values in the UI:

```
@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {
    int status=mgr.getKeyguardDisabledFeatures(cn);

    if (buttonView == camera) {
        if (isChecked) {
            mgr.setKeyguardDisabledFeatures(cn, status
                & ~DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
        }
        else {
            mgr.setKeyguardDisabledFeatures(cn, status
                | DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
        }
    }
    else {
        if (isChecked) {
            mgr.setKeyguardDisabledFeatures(cn, status
                & ~DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
        }
        else {
            mgr.setKeyguardDisabledFeatures(cn, status
                | DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
        }
    }
}
```

Note that we have the Switch widgets set up for positive statements (e.g., “enable the camera”), while the bit set uses negative statements (e.g., “disable the camera”).

That makes toggling the bit set a “bit” more complicated, to ensure that we are applying the user’s choices correctly.

Passwords and Device Administration

One popular facet of the device administration APIs is for an app to mandate a certain degree of password quality. The app might then fail to operate if the current password does not meet the requested quality standard.

Mandating Quality of Security

You can call various setters on `DevicePolicyManager` to dictate your minimum requirements for the password that the user uses to get past the lock screen. Examples include:

- `setPasswordMinimumLength()`
- `setPasswordQuality()` (with an integer flag describing the type of “quality” you seek, such as `PASSWORD_QUALITY_NUMERIC` if a PIN is OK, or `PASSWORD_QUALITY_COMPLEX` if you require mixed case and numbers and such)
- `setPasswordMinimumLowerCase()` (indicating how many lowercase letters are required at minimum in the user’s password)

All of these require the `<limit-password>` policy be requested in the metadata.

Then, you can call `isActivePasswordSufficient()` to determine if the current password meets your requirements. If it does not, you might elect to disable certain functionality. Or, if you requested the `<reset-password>` policy in the metadata, you can call `resetPassword()` to force the user to come up with a password meeting your requirements.

Similarly, you can also call `getStorageEncryptionStatus()` on `DevicePolicyManager` to find out whether full-disk encryption is active, inactive, or unavailable on this particular device. If it is inactive, and you requested the `<encrypted-storage>` policy in your metadata, you can call `setStorageEncryption()` to demand it, and start the encryption process via starting the `ACTION_START_ENCRYPTION` activity.

Establishing Password Requirements

To see password quality enforcement in action, let us examine the [DeviceAdmin/PasswordEnforcer](#) sample application.

The activity (MainActivity) is fairly short, and much of its code is based on the earlier LockMeNow sample:

```
package com.commonware.android.pwenforce;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        ComponentName cn=new ComponentName(this, AdminReceiver.class);
        DevicePolicyManager mgr=
            (DevicePolicyManager)getSystemService(DEVICE_POLICY_SERVICE);

        if (mgr.isAdminActive(cn)) {
            int msgId;

            if (mgr.isActivePasswordSufficient()) {
                msgId=R.string.compliant;
            }
            else {
                msgId=R.string.not_compliant;
            }

            Toast.makeText(this, msgId, Toast.LENGTH_LONG).show();
        }
        else {
            Intent intent=
                new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
            intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
            intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
                getString(R.string.device_admin_explanation));
            startActivity(intent);
        }

        finish();
    }
}
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/java/com/commonware/android/pwenforce/MainActivity.java](#))

In `onCreate()`, after obtaining a `DevicePolicyManager`, we see if our app has been designated by the user as a device administrator. If not — which will be the case

DEVICE ADMINISTRATION

when the app is first installed — we use an `ACTION_ADD_DEVICE_ADMIN` Intent and `startActivity()` to steer the user towards making our app be a device administrator.

If the user does make our app be a device administrator, our `AdminReceiver` will get control in `onEnabled()`, as we have registered it for `DEVICE_ADMIN_ENABLED` broadcasts in the manifest. In `onEnabled()`, we mandate that the password for the device must be alphanumeric, via a call to `setPasswordQuality()` on the `DevicePolicyManager`:

```
@Override
public void onEnabled(Context ctxt, Intent intent) {
    ComponentName cn=new ComponentName(ctxt, AdminReceiver.class);
    DevicePolicyManager mgr=
        (DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);

    mgr.setPasswordQuality(cn,
        DevicePolicyManager.PASSWORD_QUALITY_ALPHANUMERIC);

    onPasswordChanged(ctxt, intent);
}
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/java/com/commonsware/android/pwenforce/AdminReceiver.java](#))

We will see the role of the `onPasswordChanged()` method, called late in `onEnabled()`, later in this chapter.

Back in `onCreate()` of our `MainActivity`, if we *are* a device administrator, then we know that the `setPasswordQuality()` call has been made, and so we can check to see if the current password meets our standards via a call to `isActivePasswordSufficient()` on the `DevicePolicyManager`. The app displays a Toast showing whether the password is or is not currently “sufficient”.

Password-Related Events

Via appropriate actions in our `<intent-filter>` for our `DeviceAdminReceiver`, and associated callback methods, we can find out other things that go on with respect to the password:

- `ACTION_PASSWORD_CHANGED` informs us when the user has changed her password
- `ACTION_PASSWORD_FAILED` informs us when somebody tries to enter a password, and the password was incorrect

DEVICE ADMINISTRATION

- ACTION_PASSWORD_SUCCEEDED informs us when the user has successfully entered the password and unlocked the device... after an attempt had previously failed

The PasswordEnforcer sample registers for all of these in the manifest:

```
<receiver
  android:name="AdminReceiver"
  android:permission="android.permission.BIND_DEVICE_ADMIN">
  <meta-data
    android:name="android.app.device_admin"
    android:resource="@xml/device_admin"/>

  <intent-filter>
    <action android:name="android.app.action.DEVICE_ADMIN_ENABLED"/>
    <action android:name="android.app.action.ACTION_PASSWORD_CHANGED"/>
    <action android:name="android.app.action.ACTION_PASSWORD_FAILED"/>
    <action android:name="android.app.action.ACTION_PASSWORD_SUCCEEDED"/>
  </intent-filter>
</receiver>
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/AndroidManifest.xml](#))

The implementations of the corresponding onPasswordChanged(), onPasswordFailed(), and onPasswordSucceeded() methods simply display Toast messages about those events:

```
@Override
public void onPasswordChanged(Context ctxt, Intent intent) {
    DevicePolicyManager mgr=
        (DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);
    int msgId;

    if (mgr.isActivePasswordSufficient()) {
        msgId=R.string.compliant;
    }
    else {
        msgId=R.string.not_compliant;
    }

    Toast.makeText(ctxt, msgId, Toast.LENGTH_LONG).show();
}

@Override
public void onPasswordFailed(Context ctxt, Intent intent) {
    Toast.makeText(ctxt, R.string.password_failed, Toast.LENGTH_LONG)
        .show();
}

@Override
public void onPasswordSucceeded(Context ctxt, Intent intent) {
    Toast.makeText(ctxt, R.string.password_success, Toast.LENGTH_LONG)
        .show();
}
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/java/com/commonsware/android/pwenforce/AdminReceiver.java](#))

However, these will illustrate some quirks in the behavior of the device administration APIs:

- `onPasswordSucceeded()` is not called on *every* successful password entry, only those that come after a prior `onPasswordFailed()` call. One imagines that perhaps `onPasswordSucceededAfterItHadFailedBefore()` was deemed to be too wordy.
- `isActivePasswordSufficient()` will return a value based on the *previous* password in `onPasswordChanged()`, not the newly-changed password. Since the system will prevent the user from entering a new password that is insufficient, you should not need to call `isActivePasswordSufficient()` from `onPasswordChanged()`.
- A Toast cannot display over the lockscreen, and so the `onPasswordFailed()` Toast will never be seen.

Getting Along with Others

Bear in mind that you might not be the only device administrator on any given device. If there are multiple administrators, the most secure requirements are in force. So, for example, if Admin A requests a minimum password length of 7, and Admin B requests a minimum password length of 10, the user will have to supply a password that is at least 10 characters long, to meet both device administrators' requirements.

This also means that certain requests you make may fail. For example, if you decide to say that you do *not* need encryption (`setStorageEncryption()` with a value of `false`), if something *else* needs encryption, the user will still need to encrypt their device.

Basic Use of Sensors

“Sensors” is Android’s overall term for ways that Android can detect elements of the physical world around it, from magnetic flux to the movement of the device. Not all devices will have all possible sensors, and other sensors are likely to be added over time. In this chapter, we will explore the general concept of Android sensors and how to receive data from them.

Note, however, that this chapter will not get into details of detecting movement via the accelerometer, etc.

Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on threads](#). Having experience with other system-service-and-listener patterns, such as [fetching locations with LocationManager](#), is helpful but not strictly required.

The Sensor Abstraction Model

When fetching locations from `LocationManager`, you do not have dedicated APIs per location-finding technology (e.g., GPS vs. WiFi hotspot proximity vs. cell-tower triangulation vs. ...). Instead, you work with a `LocationManager` system service, asking for locations using a single API, where location technologies are identified by name (e.g., `GPS_PROVIDER`).

Similarly, when working with sensors, you do not have dedicated APIs to get sensor readings from each sensor. Instead, you work with a `SensorManager` system service,

asking for sensor events using a single API, where sensors are identified by name (e.g., `TYPE_LINEAR_ACCELERATION`).

Note, though, that there are some dedicated methods on `SensorManager` to help you *interpret* some of the sensors, particularly the accelerometer. However, those are merely helper methods; getting at the actual accelerometer data uses the same APIs that you would use to, say, access the barometer for atmospheric pressure.

Considering Rates

Usually, when working with sensors, you want to find out about changes in the sensor reading over a period of time. For example, in a driving game, where the user holds their device like a steering wheel and uses it to “turn” their virtual car, you need to know information about acceleration and positioning so long as game play is going on.

Hence, when you request a feed of sensor readings from `SensorManager`, you will specify a desired rate at which you should receive those readings. You do that by specifying an amount of delay in between readings; Android will drop sensor readings that arrive before the delay period has elapsed.

There are four standard delay periods, defined as constants on the `SensorManager` class:

1. `SENSOR_DELAY_NORMAL`, which is what most apps would use for broad changes, such as detecting a screen rotating from portrait to landscape
2. `SENSOR_DELAY_UI`, for non-game cases where you want to update the UI continuously based upon sensor readings
3. `SENSOR_DELAY_GAME`, which is faster (less delay) than `SENSOR_DELAY_UI`, to try to drive a higher frame rate
4. `SENSOR_DELAY_FASTEST`, which is the “firehose” of sensor readings, without delay

The more sensor readings you get, the faster your code has to be for using those readings, lest you take too long and starve your thread of time to do anything else. This is particularly important given that you receive these sensor events on the main application thread, and therefore the time you spend processing these events is time unavailable for screen updates. Hence, choose the slowest rate that you can that will give you acceptable granularity of output.

Reading Sensors

Sensors are event-driven. You cannot ask Android for the value of a sensor at a point in time. Rather, you register a listener for a sensor, then process the sensor events as they come in. You can unregister the listener when you are done, either because you have the reading that you need, or the user has done something (like move to another activity) that indicates that you no longer need the sensor events.

To demonstrate this, we will examine the [Sensor/Monitor](#) sample application, which will list all of the available sensors, plus show the incoming readings from a selected sensor.

Obtaining a SensorManager

The gateway to the sensor roster on the device is the SensorManager system service. You obtain one of these by calling `getSystemService()` on any Context, asking for the `SENSOR_SERVICE`, and casting the result to be a SensorManager, as seen in the `onCreate()` method of our MainActivity:

```
mgr=(SensorManager)getSystemService(Context.SENSOR_SERVICE);
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

Identifying a Sensor of Interest

There are sensor types, and then there are sensors.

You might think that there would be a one-to-one mapping between these. In truth, there might be more than one sensor for a given type, the way the SensorManager API is set up. Regardless, somewhere along the line, you will need to identify the Sensor that you want to work with.

The most common pattern, if you know the type of sensor that you want, is to call `getDefaultSensor()` on SensorManager, supplying the type of the sensor (e.g., `TYPE_ACCELEROMETER`, `TYPE_GYROSCOPE`), where the type names are constants defined on the Sensor class. If there is more than one possible Sensor for that type, Android will give you the “default” one, which is usually a reasonable choice.

Another approach, and the one used by this sample application, is to call `getSensorList()` on SensorManager, which returns a List of all Sensor objects

BASIC USE OF SENSORS

available on this device. The sample's MainActivity has a `getSensorList()` that returns this list, after a bit of manipulation:

```
@Override
public List<Sensor> getSensorList() {
    List<Sensor> unfiltered=
        new ArrayList<Sensor>(mgr.getSensorList(Sensor.TYPE_ALL));
    List<Sensor> result=new ArrayList<Sensor>();

    for (Sensor s : unfiltered) {
        if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT
            || !isTriggerSensor(s)) {
            result.add(s);
        }
    }

    Collections.sort(result, new Comparator<Sensor>() {
        @Override
        public int compare(final Sensor a, final Sensor b) {
            return(a.toString().compareTo(b.toString()));
        }
    });

    return(result);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

Android 4.4 started introducing some “trigger sensors”, ones that are designed to deliver a single reading, then automatically become unregistered. This sample app is designed to display results from more traditional sensors that provide ongoing readings. So, `getSensorList()` calls an `isTriggerSensor()` method on API Level 19+ devices, and throws out sensors that are trigger sensors. The `isTriggerSensor()` method simply checks the sensor type against a list of trigger sensors:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isTriggerSensor(Sensor s) {
    int[] triggers=
        { Sensor.TYPE_SIGNIFICANT_MOTION, Sensor.TYPE_STEP_DETECTOR,
          Sensor.TYPE_STEP_COUNTER };

    return(Arrays.binarySearch(triggers, s.getType()) >= 0);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

The reason for isolating `isTriggerSensor()` into a separate method, and not having the array of sensor types as a static final array, is because these sensor types are not available in all Android versions. Having the array of sensor types as a static final data member would require putting the `@TargetApi` annotation on the entire class, which is unwise if the class will be used on older devices. This way, we can

isolate the new-target code into a dedicated method, with a more locally-scoped `@TargetApi` annotation.

Getting Sensor Events

To get sensor events, you need a `SensorEventListener`. This is an interface, calling for two method implementations:

1. `onAccuracyChanged()`, where you are informed about a significant change in the accuracy of the readings that you are going to get from the sensor
2. `onSensorChanged()`, where you are passed a `SensorEvent` representing one of those readings

To receive events for a given `Sensor`, you call `registerListener()` on the `SensorManager`, supplying the `Sensor`, the `SensorEventListener`, and one of the `SENSOR_DELAY_*` values to control the rate of events. Later on, you need to call `unregisterListener()`, supplying the same `SensorEventListener`, to break the connection. **Failing to unregister the listener is bad.** The sensor subsystem is oblivious to things like activity lifecycles, and so if you leak a listener, not only will you perhaps leak the component that registered the listener, but you will continue to get sensor events until the process is terminated. As active sensors do consume power, users will not appreciate the battery drain your leaked listener will incur.

The `List` of `Sensor` objects from that `getSensorList()` method shown previously will be used to populate a `ListView`. When the user taps on a `Sensor` in the list, an `onSensorSelected()` method is called on the `MainActivity`. Here, we unregister our listener (a `SensorLogFragment` that we will discuss more in a bit), in case we were registered for a prior `Sensor` choice, before registering for the newly-selected `Sensor`:

```
@Override
public void onSensorSelected(Sensor s) {
    mgr.unregisterListener(log);
    mgr.registerListener(log, s, SensorManager.SENSOR_DELAY_NORMAL);
    log.init(isXYZ(s));
    panes.closePane();
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

We will discuss the remainder of the `onSensorSelected()` method a bit later in this chapter.

BASIC USE OF SENSORS

Since `SensorLogFragment` implements `SensorEventListener` — so we can use it with `registerListener()` — we need to implement `onAccuracyChanged()` and `onSensorChanged()`:

```
@Override
public void onAccuracyChanged(Sensor sensor, int accuracy) {
    // unused
}

@Override
public void onSensorChanged(SensorEvent e) {
    Float[] values=new Float[3];

    values[0]=e.values[0];
    values[1]=e.values[1];
    values[2]=e.values[2];

    adapter.add(values);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

Once again, we will get into the implementation of `onSensorChanged()` a bit later in this chapter.

The big thing to note now about `onSensorChanged()`, though, is that **the `SensorEvent` object comes from an object pool and gets recycled**. It is not safe for you to hold onto this `SensorEvent` object past the call to `onSensorChanged()`. Hence, you need to do something with the data in the `SensorEvent`, then let go of the `SensorEvent` itself, so that instance can be used again later. This is to help prevent excessive garbage collection, particularly for low-delay requests for sensor readings (e.g., `SENSOR_DELAY_FASTEST`).

Interpreting Sensor Events

The key piece of data in the `SensorEvent` object is `values`. This is a six-element float array containing the actual sensor reading. What those values *mean* will vary by sensor. For example:

- For accelerometer readings (e.g., `TYPE_ACCELEROMETER`), the first three elements of the array represent the reported acceleration, in m/s^2 , along the X, Y, and Z axes respectively (X = out the right side of the device, Y = out the top edge of the device, Z = out the screen towards the user's eyes)
- `TYPE_PRESSURE` uses the first element of the `values` array to report the barometric pressure in millibars

BASIC USE OF SENSORS

- TYPE_LIGHT uses the first element of the values array to report the light level in lux

And so on.

The SensorEvent documentation contains instructions on how to interpret these events on a per-sensor-type basis.

That being said, sensors can be roughly divided into two groups:

1. Sensors whose readings take into account three axes (X/Y/Z). These include TYPE_ACCELEROMETER, TYPE_GRAVITY, TYPE_GYROSCOPE, TYPE_LINEAR_ACCELERATION, and TYPE_MAGNETIC_FIELD.
2. Sensors that have simple single-value readings, such as TYPE_PRESSURE and TYPE_LIGHT

The isXYZ() method on MainActivity simply returns a boolean indicating whether or not this particular Sensor is one that uses all three axes (true) or not (false). As the roster of sensors has changed over the years, it also does some checks based on API level:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isXYZ(Sensor s) {
    switch (s.getType()) {
        case Sensor.TYPE_ACCELEROMETER:
        case Sensor.TYPE_GRAVITY:
        case Sensor.TYPE_GYROSCOPE:
        case Sensor.TYPE_LINEAR_ACCELERATION:
        case Sensor.TYPE_MAGNETIC_FIELD:
        case Sensor.TYPE_ROTATION_VECTOR:
            return(true);
    }

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR2) {
        if (s.getType() == Sensor.TYPE_GAME_ROTATION_VECTOR
            || s.getType() == Sensor.TYPE_GYROSCOPE_UNCALIBRATED
            || s.getType() == Sensor.TYPE_MAGNETIC_FIELD_UNCALIBRATED) {
            return(true);
        }
    }

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        if (s.getType() == Sensor.TYPE_GEOMAGNETIC_ROTATION_VECTOR) {
            return(true);
        }
    }

    return(false);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](https://commonsware.com/android/sensor/monitor/MainActivity.java))

Wiring Together the Sample

Overall, this sample app uses the `SlidingPaneLayout` first seen back in [the chapter on large-screen support](#). We have two fragments, in a master-detail pattern, where the “master” will be a list of all available sensors, and the “detail” will be a log of sensor readings from a selected sensor.

Our layout (`res/layout/activity_main.xml`) wires in a `SensorsFragment` (master) and `SensorLogFragment` (detail) in a `SlidingPaneLayout`:

```
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <fragment
        android:id="@+id/sensors"
        android:name="com.commonware.android.sensor.monitor.SensorsFragment"
        android:layout_width="300sp"
        android:layout_height="match_parent"/>

    <fragment
        android:id="@+id/log"
        android:name="com.commonware.android.sensor.monitor.SensorLogFragment"
        android:layout_width="400dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>

</android.support.v4.widget.SlidingPaneLayout>
```

(from [Sensor/Monitor/app/src/main/res/layout/activity_main.xml](#))

The `SensorsFragment` is reminiscent of `CountriesFragment` from the `SlidingPaneLayout` variant of the `EU4You` sample. The biggest differences are that we use a `SensorListAdapter` for representing the list of sensors, that we use `getSensorList()` on our `SensorsFragment.Contract` class to retrieve the model data, and that we call `onSensorSelected()` on the contract to report of selections:

```
package com.commonware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Bundle;
import android.view.View;
import android.widget.ListView;
import java.util.List;

public class SensorsFragment extends
    ContractListFragment<SensorsFragment.Contract> {
    static private final String STATE_CHECKED=
        "com.commonware.android.sensor.monitor.STATE_CHECKED";
    private SensorListAdapter adapter=null;
```

BASIC USE OF SENSORS

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    adapter=new SensorListAdapter(this);
    getListView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    setListAdapter(adapter);

    if (state != null) {
        int position=state.getInt(STATE_CHECKED, -1);

        if (position > -1) {
            getListView().setItemChecked(position, true);
            getContract().onSensorSelected(adapter.getItem(position));
        }
    }
}

@Override
public void onListItemClick(ListView l, View v, int position, long id) {
    l.setItemChecked(position, true);

    getContract().onSensorSelected(adapter.getItem(position));
}

@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    state.putInt(STATE_CHECKED, getListView().getCheckedItemPosition());
}

interface Contract {
    void onSensorSelected(Sensor s);

    List<Sensor> getSensorList();
}
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonware/android/sensor/monitor/SensorsFragment.java](#))

SensorListAdapter illustrates another approach for handling the difference in “activated” row support. The EU4You samples used an activated style to apply the “activated” support on Android 3.0 and higher. Here, our custom ArrayAdapter subclass dynamically chooses between android.R.layout.simple_list_item_activated_1 (an activated-capable built-in row layout) and the classic android.R.layout.simple_list_item_1 based upon API level:

```
package com.commonware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Build;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
```

BASIC USE OF SENSORS

```
import android.widget.TextView;

class SensorListAdapter extends ArrayAdapter<Sensor> {
    SensorListAdapter(SensorsFragment sensorsFragment) {
        super(sensorsFragment.getActivity(), getRowResourceId(),
            sensorsFragment.getContract().getSensorList());
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        ((TextView)result).setText(getItem(position).getName());

        return(result);
    }

    private static int getRowResourceId() {
        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {
            return(android.R.layout.simple_list_item_activated_1);
        }

        return(android.R.layout.simple_list_item_1);
    }
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorListAdapter.java](#))

We also have to override `getView()`, as our model is `Sensor`, whose `toString()` is not what we want, so we have to manually populate the list row with `getName()` instead.

`SensorLogFragment` is another `ListFragment`. In particular, though, we set it up for `TRANSCRIPT_MODE_NORMAL`, which means that Android will automatically scroll the `ListView` to the bottom if we add new rows to the list *and* the user has not scrolled up in the list to view past data:

```
@Override
public void onActivityCreated(Bundle state) {
    super.onActivityCreated(state);

    getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

However, we do not initialize our `ListAdapter` in `onActivityCreated()`, as we might normally do. Instead, we have a dedicated `init()` method, to be called by `MainActivity`, where we set up the `SensorLogAdapter` and keep track of whether the `Sensor` that we are logging is designed to report three-dimensional values (`isXYZ` is true) or not:

BASIC USE OF SENSORS

```
void init(boolean isXYZ) {
    this.isXYZ=isXYZ;
    adapter=new SensorLogAdapter(this);
    setListAdapter(adapter);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

The `init()` method, in turn, was called by `onSensorSelected()` of `MainActivity`. Hence, whenever the user taps on a sensor, we set up a fresh log. `init()` can do this because `MainActivity` retrieved our `SensorLogFragment` up in `onCreate()`, stashing it in a log data member:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
    log=
        (SensorLogFragment) getFragmentManager().findFragmentById(R.id.log);

    panes=(SlidingPaneLayout) findViewById(R.id.panes);
    panes.openPane();
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

Our `onSensorChanged()` method in `SensorLogFragment` copies the values from the `SensorEvent` into a separate `Float` array that is our list's model data:

```
@Override
public void onSensorChanged(SensorEvent e) {
    Float[] values=new Float[3];

    values[0]=e.values[0];
    values[1]=e.values[1];
    values[2]=e.values[2];

    adapter.add(values);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

`SensorLogAdapter` uses the `isXYZ` value to determine how it should format the rows:

- For single-value sensors, we just show the first `Float` from the array
- For three-dimensional sensors, we show all three dimensions, plus the “net” (square root of the sum of the squares), separated by slashes

```
class SensorLogAdapter extends ArrayAdapter<Float[]> {
    public SensorLogAdapter(SensorLogFragment sensorLogFragment) {
        super(sensorLogFragment.getActivity(),
```

BASIC USE OF SENSORS

```
        android.R.layout.simple_list_item_1,
        new ArrayList<Float[]>());
    }

    @SuppressWarnings("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row=
            (TextView)super.getView(position, convertView, parent);
        String content=null;
        Float[] values=getItem(position);

        if (isXYZ) {
            content=
                String.format("%7.3f / %7.3f / %7.3f / %7.3f",
                    values[0],
                    values[1],
                    values[2],
                    Math.sqrt(values[0] * values[0] + values[1]
                        * values[1] + values[2] * values[2]));
        }
        else {
            content=String.format("%7.3f", values[0]);
        }

        row.setText(content);

        return(row);
    }
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

The rest of MainActivity simply manages the SlidingPaneLayout, much like the EU4YouSlidingPane sample did.

The Results

When the user taps on a sensor in the list, we get a log of readings:

BASIC USE OF SENSORS

Sensor	Reading
BH1721fvc Light sensor	-0.406 / 2.730 / 9.410 / 9.807
BMP182 Pressure sensor	-0.394 / 3.178 / 9.269 / 9.807
Corrected Gyroscope Sensor	-0.381 / 2.950 / 9.345 / 9.807
Gravity Sensor	-0.383 / 2.449 / 9.488 / 9.807
Linear Acceleration Sensor	-0.381 / 2.090 / 9.574 / 9.807
MPL Accelerometer	-0.392 / 2.487 / 9.478 / 9.807
MPL Gravity	-0.396 / 3.184 / 9.267 / 9.807
MPL Gyroscope	-0.369 / 3.434 / 9.178 / 9.806
MPL Linear Acceleration	-0.359 / 3.129 / 9.287 / 9.807
MPL Magnetic Field	-0.390 / 2.737 / 9.409 / 9.807
MPL Orientation	-0.407 / 2.678 / 9.425 / 9.807
MPL Raw Gyro	-0.399 / 3.096 / 9.297 / 9.807
MPL Rotation Vector	-0.389 / 3.355 / 9.206 / 9.806
Orientation Sensor	-0.369 / 3.130 / 9.287 / 9.807

Figure 763: SensorMonitor, On a Nexus 10, Showing Gravity Readings While Being Wiggled by the Author

Batching Sensor Readings

API Level 19 (Android 4.4) added a new feature to the sensor subsystem: batched sensor events. Now, `registerListener()` can take a batch period in microseconds, and Android may elect to deliver events to you delayed by up to that amount of time. The objective will be to reduce the power draw of the sensors, for sensor hardware that supports this sort of batching behavior. Not all hardware will, in which case your requested batch latency will be ignored.

Printing and Document Generation

Mobile devices are continuing to close the gap on capabilities that had formerly been the sole province of desktop systems or servers. After all, if the vision is that people should be able to use phones and tablets *instead of* desktops and notebooks, phones and tablets need to do whatever it is that those people need to have done.

One such capability is the ability to print to networked printers. While various third-party printing options had been available for some time, it is only starting with the Android 4.4 release that the OS and framework itself has support for printing. Hence, at this time, a significant majority of Android devices will be natively capable of printing, and so users will be more likely to expect that your app supports such printing.

As it turns out, the print engine in Android is centered upon the PDF document format, and Android supports converting HTML into PDF, albeit on a somewhat limited basis.

The API seems simple and clean. It actually *is* simple and clean... so long as you are printing very simple contents (bitmaps or HTML). Once you get into anything more complicated than that, the threading alone starts to make things rather messy.

This chapter describes how to use the Android 4.4 print system, including how to print HTML and PDF files. It will also cover how to generate HTML and PDF files, whether for printing or for other purposes (e.g., reports to be emailed or uploaded somewhere).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Also, you should read the chapter on [advanced uses of WebView](#).

The Android Print System

Writing programs that print on desktop operating systems historically has been tedious. The fine-grained control that is needed for high-quality output makes the APIs complicated, and these tend to be only partially masked by high-level wrappers to simplify common scenarios.

Android's print system is no different.

Starting with Android 4.4, you can request access to a `PrintManager` system service (via `getSystemService()`, called on any `Context`). It offers a `print()` method that lets you describe what should be printed, in the form of a `PrintAttributes` (e.g., what size paper are you looking for?) and a `PrintDocumentAdapter`. The latter is responsible for working with Android to actually create the content to be printed.

`print()` returns a `PrintJob`, which you can use to examine the status of the print request. `PrintManager` also offers a `getPrintJobs()` method that returns all of *your* outstanding print requests. Note that you cannot access print jobs from other applications.

Hence, the real complexity of printing lies in the `PrintDocumentAdapter` implementation. This class is responsible for generating a PDF that represents the content to be printed. This leads to four basic ways of working with a `PrintDocumentAdapter`:

1. Have one created for you, such as via a `WebView` for printing HTML content
2. Create one that takes a PDF generated elsewhere and uses it for the output
3. Create one that uses Android's Canvas-based PDF generation class, called `PrintedPdfDocument`
4. Use APIs that avoid all of this entirely, such as `printBitmap()` on `PrintHelper`

About the Sample App

The [Printing/PrintManager](#) sample project demonstrates all but the Canvas option.

The UI is just a large EditText, designed for you to type in a message.

The action bar overflow contains four options:

- “Bitmap”, to print an image from your device or emulator
- “Web Page”, to print [the Web page for this book](#)
- “TPS Report”, which prints a report containing the message from the EditText
- “PDF”, which prints a copy of the cover of Version 5.8 of this book, which is packaged in the app as an asset

Figure 764: Print Demo App, Showing Overflow

Printing a Bitmap

Google helpfully supplies a `PrintHelper` class in the Android Support package that makes it trivially easy to print a bitmap. Just call `printBitmap()` on the `PrintHelper`, after some minor configuration, and it takes over from there.

In `onOptionsItemSelected()` of the sample app's `MainActivity`, when the user chooses the “Bitmap” item, we call `startActivityForResult()` on an `ACTION_GET_CONTENT` Intent, to allow the user to pick an image from the device or emulator:

```
Intent i=
    new Intent(Intent.ACTION_GET_CONTENT).setType("image/*");

startActivityForResult(i, IMAGE_REQUEST_ID);
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

This, in turn, will trigger a call to `onActivityResult()`, once the user has (presumably) chosen an image:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (requestCode == IMAGE_REQUEST_ID
        && resultCode == Activity.RESULT_OK) {
        try {
            PrintHelper help=new PrintHelper(this);

            help.setScaleMode(PrintHelper.SCALE_MODE_FIT);
            help.printBitmap("Photo!", data.getData());
        }
        catch (FileNotFoundException e) {
            Log.e(getClass().getSimpleName(), "Exception printing bitmap",
                e);
        }
    }
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

If the user did indeed choose an image, we create an instance of `PrintHelper`, call `setScaleMode()` to tell it fit the image to the page, and then call `printBitmap()` to print the image.

`setScaleMode()` takes one of two values:

1. `SCALE_MODE_FIT` will show the entire image, blown up as big as possible

PRINTING AND DOCUMENT GENERATION

2. `SCALE_MODE_FILL` will fill the entire page, at the cost of cropping the image along one axis, if the image's aspect ratio does not match the paper's aspect ratio

`printBitmap()` takes the name of the print job (so the user, when reviewing the outstanding print jobs, knows what it is) and either a `Uri` or a `Bitmap` for the image itself. In the case of a `Uri`, the `Uri` could be malformed, in which case the `FileNotFoundException` may be thrown, which is why we catch it.

What the user sees, after choosing an image to print (and a printer, if the user has more than one available), is a print configuration dialog appear, much like those you might see in a desktop OS:

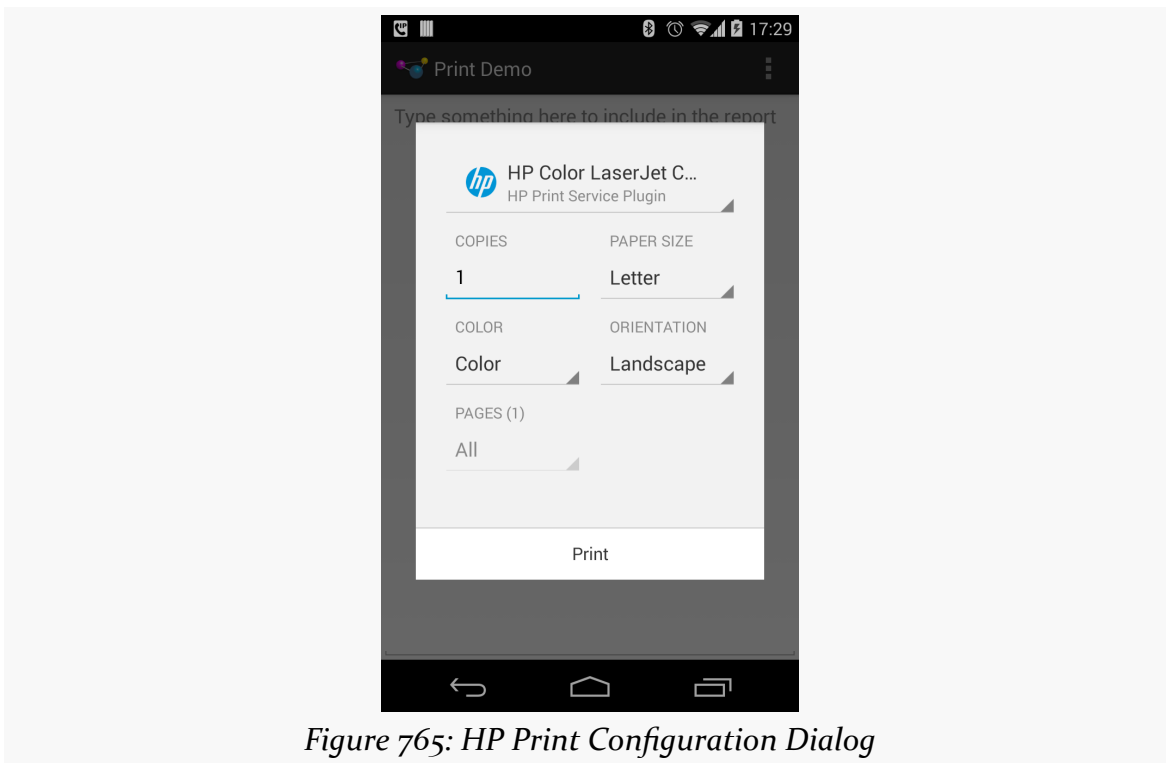

Figure 765: HP Print Configuration Dialog

The dialog itself is provided by Android; the contents of the dialog is provided by a `PrintService` that is responsible for taking our print job and actually dispatching it to the printer.

Here, the user can make typical changes, like portrait/landscape printing and the number of copies, before pressing the “Print” button. At that point, the user’s chosen image will be printed.

Note that, in Android 4.4, the print dialog does not work especially well in landscape on smaller screen sizes, forcing the user to scroll to get to all of the widgets, including the “Print” button.

Printing an HTML Document

Printing a bitmap is nice. It is not especially useful, as it implies that we have a bitmap worth printing by itself. That is certainly possible, but it is unlikely. Even in the case where we want to print a photo, there is a very good chance that we will need to print some additional information along with the photo (caption, date when photo was taken, etc.).

Being able to print something over which we have greater control of the rendering would be more useful. The easiest way to do that is to print some HTML. [Later in this chapter](#) we will cover how to generate some dynamic HTML representing what you want to print. For the moment, though, let’s focus on the printing itself.

Printing and WebView

Starting in API Level 19, `WebView` is capable of participating in the print process. You can load up a `WebView` with your desired content, then print that content.

Some apps will already be using a `WebView` as part of the UI, and that `WebView` will contain what needs to be printed. For example, a Web browser can easily add a “Print” action bar overflow item that would print the contents of the active `WebView` in the browser.

For cases where you want to print something, but you are not using the `WebView` for anything but printing, you do *not* need to add the `WebView` to the UI. You can create a `WebView` instance via its constructor, passing in your `Activity` as the `Context` required by that constructor. You can then populate that `WebView` with what needs to be printed, then print it. That is the technique that the sample application demonstrates, in part because it is likely to be the more common scenario — only so many apps use a `WebView` in the UI, and more are likely to need to print.

Printing a URL

The sample app’s “Web Page” action bar overflow item is tied to an `R.id.web MenuItem`. When that is tapped by the user, `onOptionsItemSelected()` calls `printWebPage()` to print a Web page loaded from a URL:

PRINTING AND DOCUMENT GENERATION

```
private void printWebPage() {
    WebView print=prepPrintWebView(getString(R.string.web_page));

    print.loadUrl("https://commonsware.com/Android");
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

Here, `getString(R.string.web_page)` is returning a string resource that will be used for the name of a print job. `prepPrintWebView()` returns the `WebView` that will be used for printing. `loadUrl()` is the standard `WebView` method for populating the `WebView` from a URL. Note that this causes the sample app to need the `INTERNET` permission, since we are downloading a Web page and its related assets (CSS, images) from the Internet.

You will notice that we are not actually printing anything directly in `printWebPage()`, which may seem a bit odd given the name of the method. That is because we cannot print anything until the page is loaded — after all, it is only then that we have what we want to print.

The job of `prepPrintWebView()` is to arrange to get control when the page is loaded and actually print the desired page:

```
private WebView prepPrintWebView(final String name) {
    WebView result=getWebView();

    result.setWebViewClient(new WebViewClient() {
        @Override
        public void onPageFinished(WebView view, String url) {
            print(name, view.createPrintDocumentAdapter(),
                new PrintAttributes.Builder().build());
        }
    });

    return(result);
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

`getWebView()` is just a lazy-initialization method, populating a `wv` data member of the activity with a `WebView`. This way, we avoid creating the `WebView` up front, as if the user does not elect to print any HTML, we do not need the `WebView`, and a `WebView` is expensive to initialize:

```
private WebView getWebView() {
    if (wv == null) {
        wv=new WebView(this);
    }
}
```

PRINTING AND DOCUMENT GENERATION

```
return(wv);  
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

We are holding onto the `WebView` in a data member to ensure that it will not be garbage-collected. A `WebView` that is part of our UI is being strongly held by its parent in the View hierarchy, so we do not normally need to worry about this. However, in this case, we are creating a `WebView` dynamically and are *not* adding it to the UI, so we are responsible for holding onto it, at least as long as is needed. In this sample, we just hold onto it for the rest of the life of the activity.

Back in `prepPrintWebView()`, we call `setWebViewClient()`, to attach an anonymous inner class extending `WebViewClient` to the `WebView`. Back in [the chapter introducing WebView](#), we saw `WebViewClient` in the context of `shouldOverrideUrlLoading()`. Another popular method to override on a `WebViewClient` is `onPageFinished()`. This is called when the HTML and related assets (CSS, images, etc.) have been loaded and rendered within the `WebView`. At this point, for the particular URL we are loading, it is safe to print the page.

In `onPageFinished()`, we call a `print()` method on `MainActivity` itself:

```
private PrintJob print(String name, PrintDocumentAdapter adapter,  
    PrintAttributes attrs) {  
    startService(new Intent(this, PrintJobMonitorService.class));  
  
    return(mgr.print(name, adapter, attrs));  
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The first line of `print()` calls `startService()` to start a `PrintJobMonitorService`. We will see more about why we are doing that [later in this chapter](#). For the moment, take it on faith that this service will help ensure that our process stays around long enough for our print job to finish.

The second line of `print()` calls a `print()` method on a `mgr` data member. Here, `mgr` is a `PrintManager`, initialized up in `onCreate()` of the activity, by calling `getSystemService()`, asking for the `PRINT_SERVICE`, and casting the result to be a `PrintManager`.

```
@Override  
protected void onCreate(Bundle savedInstanceState) {  
    super.onCreate(savedInstanceState);  
    setContentView(R.layout.main);  
    prose=(EditText)findViewById(R.id.prose);  
}
```

PRINTING AND DOCUMENT GENERATION

```
mgr=(PrintManager)getSystemService(PRINT_SERVICE);  
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](https://commonsware.com/android/print/MainActivity.java))

The `print()` method tells the `PrintManager` to go print something. `print()` takes three parameters:

1. The name of the print job, which is kept along with the print job itself in case something (e.g., the print driver) wishes to show the user a roster of print jobs. In our case, this is that string resource passed in as the name parameter to `prepPrintWebView()`. That parameter is marked `final`, so the call to `setWebViewClient()` will include the value of that parameter in the anonymous inner class' implementation of `onPageFinished()`.
2. A `PrintDocumentAdapter`. For the case of printing HTML, we get one of those by calling `createPrintDocumentAdapter()` on our populated `WebView`.
3. A `PrintAttributes` object, describing any particular requirements that you have for the printed output (e.g., media size, margins, color/monochrome). If you will let the user control all of that via the print dialog, an empty `PrintAttributes` is fine to use with `print()`. You typically create a `PrintAttributes` by creating a `PrintAttributes.Builder`, calling setters on the `Builder` to configure the `PrintAttributes`, and getting the resulting `PrintAttributes` via a call to `build()`.

And that's it. Android — in particular, `WebView` and its `PrintDocumentAdapter` — takes over from here and prints the Web page.

Limitations and Concerns

Alas, we do not have infinite flexibility with printing HTML from a `WebView`. Here are some limitations and potential problem areas that you will encounter:

- While you can use JavaScript in the loaded HTML, it cannot trigger the print itself using any standard DOM methods.
- Also, if your JavaScript is going to fire off some asynchronous operations, like an AJAX request, bear in mind that `onPageFinished()` does *not* take those operations into account. You will need to use `addJavascriptInterface()` to inject a Java object into the JavaScript realm, then have your asynchronous work arrange to call some method on that Java object, to signal to you that the document is ready for printing.
- Print CSS rules, like headers, footers, page numbers, landscape properties, and the like are ignored at present.

- A `WebView` can only do one print job at a time. Printing occurs asynchronously, and so you have to be careful that you do not accidentally start off a second print job while an earlier one is in process. The `print()` method returns a `PrintJob` that you can use to monitor the print job status, and this object will be covered in a bit more detail [later in this chapter](#). You may wish to set up a `WebView` pool, where you reuse an existing `WebView` only if its associated `PrintJob` is completed, creating a new `WebView` instance if there is no available `WebView` at the moment. Or, you might disable printing options in the UI until the `PrintJob` is done, so you can reuse the `WebView`. The sample app does none of this, to keep things simpler.
- Printing HTML is “an all-or-nothing affair”. You cannot print a subset of the HTML, whether denoted by HTML constructs (e.g., `<div>` IDs) or by page numbers. Hence, you need to load into the `WebView` *exactly* what you want to print, no more, no less.

Also, any direct use of `PrintManager` will only work on API Level 19. You will need to ensure that you only try using it on API Level 19+ devices, using Java version guard blocks. You will also need to set your build target (i.e., `compileSdkVersion` in Android Studio) to at least API Level 19 to be able to reference the `PrintManager` and related classes.

Finally, while loading and printing HTML are both intrinsically asynchronous, *generating* HTML locally is not. We will discuss this issue a bit more [later in this chapter](#).

Printing a PDF File

As will be seen in [the next section](#), even if we “hand-roll” our printed output using a `Canvas`, the result seems to be a PDF file. Hence, you would think that the printing framework would provide convenience code to print a PDF file that we obtained by other means.

Alas, [that is not the case](#).

The sample app contains some code demonstrating how this is possible, inspired by [this Stack Overflow answer](#), though it may cut a few corners that Google would prefer not be cut. However, it also illustrates how to create your own `PrintDocumentHandler`, which you will need for any print job not involving a bitmap or HTML.

The PrintDocumentAdapter Protocol

We supply a `PrintDocumentAdapter` to the `print()` method on `PrintManager`. In the HTML case, we got a `PrintDocumentAdapter` from the `WebView`, and so it is Google's job to implement that adapter. Similarly, `PrintHelper` has its own internal implementation of a `PrintDocumentAdapter` that it uses for printing the bitmap.

For anything else, you need to create your own `PrintDocumentAdapter`, or find a third-party implementation that you can perhaps reuse.

`PrintDocumentAdapter`'s job is to supply the `PrintManager` with the content to be printed, in the form of a PDF file. To do that, there are four callback methods that `PrintManager` (and related classes) will call on the `PrintDocumentAdapter`:

1. `onStart()` is called first. If you are planning on using the same `PrintDocumentAdapter` instance for multiple print jobs, this would be a spot to initialize the work for a new job. Otherwise, if you were only planning on using a `PrintDocumentAdapter` instance once, you may as well just put your initialization logic in the constructor.
2. `onLayout()` is called next. Here is where you do enough work to determine what the resulting output will be later on as printing continues. In particular, if you want to provide an accurate page count, this is where you will need to perform the necessary calculations to determine that.
3. `onWrite()` is called next, asking you to write one or more PDF pages out to a supplied `ParcelFileDescriptor` (on which you can create an `OutputStream`).
4. `onFinish()` is called last, when the printing request is completed, so you can free up any necessary resources.

Introducing ThreadedPrintDocumentAdapter

All four of those callback methods are called on the main application thread. Your `onStart()` and `onFinish()` methods need to be fast enough to complete their work on that thread, and that may not be a problem. The work that `onLayout()` and `onWrite()` do may take a while, though, and so the protocol is designed to allow you to do that work on a background thread. Both methods are passed a callback object that you use to pass along the results of your work, and both are passed a `CancellationSignal` to indicate if the user cancels the print job while you are doing the work.

What `PrintDocumentAdapter` does *not* do is actually give you a thread to use.

PRINTING AND DOCUMENT GENERATION

So, the sample app contains a `ThreadedPrintDocumentAdapter` that moves the `onLayout()` and `onFinish()` work to a background thread:

```
package com.commonware.android.print;

import android.content.Context;
import android.os.Bundle;
import android.os.CancellationSignal;
import android.os.ParcelFileDescriptor;
import android.print.PageRange;
import android.print.PrintAttributes;
import android.print.PrintDocumentAdapter;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;

abstract class ThreadedPrintDocumentAdapter extends
    PrintDocumentAdapter {
    abstract LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
        PrintAttributes newAttributes,
        CancellationSignal cancellationSignal,
        LayoutResultCallback callback,
        Bundle extras);

    abstract WriteJob buildWriteJob(PageRange[] pages,
        ParcelFileDescriptor destination,
        CancellationSignal cancellationSignal,
        WriteResultCallback callback,
        Context ctxt);

    private Context ctxt=null;
    private ExecutorService threadPool=Executors.newFixedThreadPool(1);

    ThreadedPrintDocumentAdapter(Context ctxt) {
        this.ctxt=ctxt;
    }

    @Override
    public void onLayout(PrintAttributes oldAttributes,
        PrintAttributes newAttributes,
        CancellationSignal cancellationSignal,
        LayoutResultCallback callback, Bundle extras) {
        threadPool.submit(buildLayoutJob(oldAttributes, newAttributes,
            cancellationSignal, callback,
            extras));
    }

    @Override
    public void onWrite(PageRange[] pages,
        ParcelFileDescriptor destination,
        CancellationSignal cancellationSignal,
        WriteResultCallback callback) {
        threadPool.submit(buildWriteJob(pages, destination,
            cancellationSignal, callback, ctxt));
    }

    @Override
    public void onFinish() {
        threadPool.shutdown();
    }
}
```

```
    super.onFinish();
}

protected abstract static class LayoutJob implements Runnable {
    PrintAttributes oldAttributes;
    PrintAttributes newAttributes;
    CancellationSignal cancellationSignal;
    LayoutResultCallback callback;
    Bundle extras;

    LayoutJob(PrintAttributes oldAttributes,
              PrintAttributes newAttributes,
              CancellationSignal cancellationSignal,
              LayoutResultCallback callback, Bundle extras) {
        this.oldAttributes=oldAttributes;
        this.newAttributes=newAttributes;
        this.cancellationSignal=cancellationSignal;
        this.callback=callback;
        this.extras=extras;
    }
}

protected abstract static class WriteJob implements Runnable {
    PageRange[] pages;
    ParcelFileDescriptor destination;
    CancellationSignal cancellationSignal;
    WriteResultCallback callback;
    Context ctxt;

    WriteJob(PageRange[] pages, ParcelFileDescriptor destination,
            CancellationSignal cancellationSignal,
            WriteResultCallback callback, Context ctxt) {
        this.pages=pages;
        this.destination=destination;
        this.cancellationSignal=cancellationSignal;
        this.callback=callback;
        this.ctxt=ctxt;
    }
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/ThreadedPrintDocumentAdapter.java](#))

This class uses a single-thread thread pool, managed by an `ExecutorService`. In principle, a well-written `PrintDocumentAdapter` could handle multiple print jobs in parallel — if you attempt this and are using `ThreadedPrintDocumentAdapter` for inspiration, simply increase the size of the thread pool.

The `onLayout()` and `onWrite()` methods package up their parameters (described in [the next section](#)) into job objects. Those objects implement `Runnable`, and they are then handed to the `ExecutorService` to be run on the next-available thread. `onFinish()` shuts down the `ExecutorService`, though if you wanted to use the `ThreadedPrintDocumentAdapter` for multiple print jobs, you would come up with

some other logic to clean up the ExecutorService when you were done with *all* of the jobs.

Subclasses of ThreadedPrintDocumentAdapter need to:

- Create subclasses of the LayoutJob and WriteJob static inner classes, implementing their respective run() methods, to do the work required of onLayout() and onWrite()
- Implement buildLayoutJob() and buildWriteJob() methods that return instances of those custom subclasses

(fans of dependency injection no doubt can find better solutions for wiring up a ThreadedPrintDocumentAdapter)

A PdfDocumentAdapter

However, we still need to actually be able to print a PDF, which ThreadedPrintDocumentAdapter does not do on its own. The sample app also has a PdfDocumentAdapter, which extends ThreadedPrintDocumentAdapter and demonstrates a crude way of printing a PDF through the PrintDocumentAdapter protocol.

PdfDocumentAdapter does not use onStart() or onFinish(). And, since the onLayout() and onWrite() methods are handled by ThreadedPrintDocumentAdapter, PdfDocumentAdapter does not have those either.

It does, however, have the buildLayoutJob() and buildWriteJob() methods required by ThreadedPrintDocumentAdapter. These return instances of a PdfLayoutJob and PdfWriteJob, respectively:

```
@Override
LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
                        PrintAttributes newAttributes,
                        CancellationSignal cancellationSignal,
                        LayoutResultCallback callback, Bundle extras) {
    return(new PdfLayoutJob(oldAttributes, newAttributes,
                           cancellationSignal, callback, extras));
}

@Override
WriteJob buildWriteJob(PageRange[] pages,
                      ParcelFileDescriptor destination,
                      CancellationSignal cancellationSignal,
                      WriteResultCallback callback, Context ctxt) {
    return(new PdfWriteJob(pages, destination, cancellationSignal,
```

PRINTING AND DOCUMENT GENERATION

```
        callback, ctxt));  
    }
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PdfDocumentAdapter.java](#))

PdfLayoutJob needs to fulfill the bulk of the onLayout() contract:

- Monitor the CancellationSignal and call onLayoutCancelled() on the supplied LayoutResultCallback if the job has been canceled
- Populate a PrintDocumentInfo object to provide metadata about the document to be printed, and pass that to onLayoutFinished() on the LayoutResultCallback

```
private static class PdfLayoutJob extends LayoutJob {  
    PdfLayoutJob(PrintAttributes oldAttributes,  
                PrintAttributes newAttributes,  
                CancellationSignal cancellationSignal,  
                LayoutResultCallback callback, Bundle extras) {  
        super(oldAttributes, newAttributes, cancellationSignal, callback,  
              extras);  
    }  
  
    @Override  
    public void run() {  
        if (cancellationSignal.isCanceled()) {  
            callback.onLayoutCancelled();  
        }  
        else {  
            PrintDocumentInfo.Builder builder=  
                new PrintDocumentInfo.Builder("CHANGE ME PLEASE");  
  
            builder.setContentType(PrintDocumentInfo.CONTENT_TYPE_DOCUMENT)  
                .setPageCount(PrintDocumentInfo.PAGE_COUNT_UNKNOWN)  
                .build();  
  
            callback.onLayoutFinished(builder.build(),  
                                     !newAttributes.equals(oldAttributes));  
        }  
    }  
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PdfDocumentAdapter.java](#))

PdfLayoutJob also has access to two PrintAttributes objects, the “old” attributes and the “new” attributes. In principle, onLayout() could be called a couple of times, perhaps based upon changes the user makes in the print dialog. These PrintAttributes objects describe the nature of the output, including things like page size and margins. PdfLayoutJob totally ignores these, because the PDF is a packaged asset in this case and cannot be changed. If you are dynamically generating a PDF file, you may wish to pay attention to the new PrintAttributes and take them into account.

PRINTING AND DOCUMENT GENERATION

`PdfLayoutJob` also has access to a `Bundle` of “extras”, not unlike the “extras” associated with an `Intent`. At the present time, there is only one semi-documented “extra”, `EXTRA_PRINT_PREVIEW`, which will be true if `onLayout()` is being called to generate a print preview of the printed output, false otherwise.

What `PdfLayoutJob` does do is create a `PrintDocumentInfo.Builder` to set up a `PrintDocumentInfo` object indicating that:

- The output is a “document” (`CONTENT_TYPE_DOCUMENT`) versus a “photo” (`CONTENT_TYPE_PHOTO`) or “unknown” (`CONTENT_TYPE_UNKNOWN`). This information is passed to the `PrintService` that functions as a bridge between `PrintManager` and the printer, and the `PrintService` might optimize output based upon this setting (e.g., lower quality print output for a “document” instead of a “photo”).
- The page count of the output is unknown (`PAGE_COUNT_UNKNOWN`). In principle, the page count is known, insofar as the PDF that will be printed is an asset baked into the app, and so we could hard-code the page count in addition to hard-coding other details (like the asset’s filename).

The boolean second parameter to `onLayoutFinished()` is supposed to be true if the layout changed, false otherwise. In practice, the value does not seem to matter on the first `onLayout()` call. The implementation here compares the two `PrintAttributes` objects using `equals()`.

The last piece is the `PdfWriteJob`, which performs the work required of the `onWrite()` callback:

```
private static class PdfWriteJob extends WriteJob {
    PdfWriteJob(PageRange[] pages, ParcelFileDescriptor destination,
                CancellationSignal cancellationSignal,
                WriteResultCallback callback, Context ctxt) {
        super(pages, destination, cancellationSignal, callback, ctxt);
    }

    @Override
    public void run() {
        InputStream in=null;
        OutputStream out=null;

        try {
            in=ctxt.getAssets().open("cover.pdf");
            out=new FileOutputStream(destination.getFileDescriptor());

            byte[] buf=new byte[16384];
            int size;

            while ((size=in.read(buf)) >= 0
                && !cancellationSignal.isCanceled()) {
```

```
        out.write(buf, 0, size);
    }

    if (cancellationSignal.isCanceled()) {
        callback.onWriteCancelled();
    }
    else {
        callback.onWriteFinished(new PageRange[] { PageRange.ALL_PAGES });
    }
}
catch (Exception e) {
    callback.onWriteFailed(e.getMessage());
    Log.e(getClass().getSimpleName(), "Exception printing PDF", e);
}
finally {
    try {
        in.close();
        out.close();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
            "Exception cleaning up from printing PDF", e);
    }
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PdfDocumentAdapter.java](#))

At its core, PdfWriteJob simply writes our PDF (culled from a cover .pdf asset) to an OutputStream. The OutputStream is built from the ParcelFileDescriptor, indicating where the PDF content should be written to.

The InputStream-to-OutputStream “bucket brigade” is augmented with checks on the CancellationSignal, to abandon the loop if the print job was canceled by the user. At the end, we call one of three methods on the WriteResultCallback:

- onWriteCancelled() if the CancellationSignal indicates that the job was canceled
- onWriteFinished() if everything succeeded
- onWriteFailed() (with an error message) if there was some problem, such as failed I/O

PdfWriteJob has access to a PageRange array, representing the particular pages out of a larger document to be printed. The parameter to onWriteFinished() is another PageRange array that should indicate what pages were printed. Once again, since the PDF is fixed, PdfWriteJob ignores the input PageRange array, and it indicates that we wrote all pages (PageRange.ALL_PAGES) in the output. In principle, if you have more control over your environment, you should only print the requested pages, in which

case the output parameter to `onWriteFinished()` might be the same array as was passed into `onWrite()`.

Using PdfDocumentAdapter

Back in `MainActivity`, the “PDF” action bar overflow item triggers a call to `print()` on the `PrintManager`, supplying our `PdfDocumentAdapter` and another empty `PrintAttributes`:

```
print("Test PDF",
      new PdfDocumentAdapter(getApplicationContext()),
      new PrintAttributes.Builder().build());
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The `PdfDocumentAdapter` needs a `Context`, in order to access the `cover.pdf` asset. If your PDF file is being generated, or is saved as a file on external storage, you would not need this. Since it is theoretically possible that our activity could be destroyed while the printing is going on in background threads, rather than briefly leak an `Activity`, we provide the `Application Context` to `PdfDocumentAdapter`, as that is a singleton and cannot be leaked.

The result of all of this is that when the user chooses the “PDF” action bar overflow item, the book cover copy is printed.

Printing Using a Canvas

What Google *really* wants you to do — if bitmaps and HTML are insufficient — is to create PDF documents using `PdfPrintedDocument` and a `Canvas`.

The concept is simple:

- Create a `PrintedPdfDocument` instance, given a `PrintAttributes` that describes the page size, margins, etc.
- Call `startPage()` to add a page to the document, which returns a `PdfDocument.Page`
- Call `getCanvas()` on the `Page` and use the standard Android 2D drawing APIs to draw lines, text, shaded areas, and so forth
- Call `finishPage()` on the `PdfPrintedDocument` when you are done rendering that page
- Repeat the preceding three steps for all needed pages

PRINTING AND DOCUMENT GENERATION

- Call `writeTo()` on the `PrintedPdfDocument` to write the PDF to an `OutputStream`, such as the one you get from the `ParcelFileDescriptor` in the `onWrite()` callback of your `PrintDocumentAdapter`
- Call `close()` on the `PrintedPdfDocument` when you are done

For example, let's look at the `onWrite()` implementation used by `PrintHelper` to print a bitmap:

```
@Override
public void onWrite(PageRange[] pageRanges, ParcelFileDescriptor fileDescriptor,
                   CancellationSignal cancellationSignal,
                   WriteResultCallback writeResultCallback) {
    PrintedPdfDocument pdfDocument = new PrintedPdfDocument(mContext,
        mAttributes);
    try {
        Page page = pdfDocument.startPage(1);
        RectF content = new RectF(page.getInfo().getContentRect());

        // Compute and apply scale to fill the page.
        Matrix matrix = getMatrix(mBitmap.getWidth(), mBitmap.getHeight(),
            content, fittingMode);

        // Draw the bitmap.
        page.getCanvas().drawBitmap(mBitmap, matrix, null);

        // Finish the page.
        pdfDocument.finishPage(page);

        try {
            // Write the document.
            pdfDocument.writeTo(new FileOutputStream(
                fileDescriptor.getFileDescriptor()));
            // Done.
            writeResultCallback.onWriteFinished(
                new PageRange[]{PageRange.ALL_PAGES});
        } catch (IOException ioe) {
            // Failed.
            Log.e(LOG_TAG, "Error writing printed content", ioe);
            writeResultCallback.onWriteFailed(null);
        }
    } finally {
        if (pdfDocument != null) {
            pdfDocument.close();
        }
        if (fileDescriptor != null) {
            try {
                fileDescriptor.close();
            } catch (IOException ioe) {
                /* ignore */
            }
        }
    }
}
```

(note: the preceding code snippet is Copyright (C) 2013 The Android Open Source Project)

Here, they:

- Create the `PrintedPdfDocument`
- Add a page using `startPage()`
- Calculate a scaling `Matrix` based upon the image size, the page size, and the scale type (FIT or FILL)
- Draw the bitmap on the `Canvas` using that `Matrix`
- Finish the page
- Write the result to an `OutputStream` for the supplied `ParcelFileDescriptor`
- Close the document

Curiously, they do not do this work in a background thread, though the `onLayout()` implementation does use a background thread (since the image `Uri` may require an Internet download).

If you are comfortable with the `Canvas` API, writing PDF pages is much the same as drawing to your custom `View`. On the other hand, Android's `Canvas` API is not the same as any other drawing system's API, so there will be distinct differences from any other 2D drawing API that you might have used previously.

Print Jobs

The `print()` method that we have been calling on `PrintManager` returns a `PrintJob`, representing the print job. This object has a number of status inquiry methods, including (in rough order of when the events occur):

- `isStarted()`
- `isQueued()` (i.e., waiting for the print system to process it)
- `isBlocked()` (i.e., permanently stuck, but needs to be canceled)
- `isCompleted()`
- `isFailed()`
- `isCancelled()`

It also has a `cancel()` method that you can call to cancel the print job (e.g., based on user request). `PrintJob` also offers a `restart()` method that you can use to re-try a failed (but not canceled) print job.

What `PrintJob` does not have is a listener interface to be proactively notified when the job changes state.

`PrintManager` also has `getPrintJobs()`, which will return a list of the `PrintJob` objects representing the jobs you have requested in this process, rather than having to keep track of all of those yourself.

Printing, Threads, and Services

If you are going to create a report in HTML, you will want to consider doing that work in an `AsyncTask`'s `doInBackground()` method, so the I/O involved in creating the report happens in the background. However, `PrintManager` requires that `print()` be called on the main application thread, so you would call `print()` from `onPostExecute()` of the `AsyncTask`.

Similarly, if you are creating your own `PrintDocumentAdapter`, you will want to consider moving the `onLayout()` and `onWrite()` work into background threads, such as is illustrated in the sample app via `ThreadedPrintDocumentAdapter`.

The problem with bare threads or an `AsyncTask` is that they do not indicate to Android that your process is still doing some work. It is possible that the user could request that you print something, then switch to another app (e.g., HOME, recent-tasks list). Android might consider your process to be relatively low priority and could terminate it before your print job completes.

The obvious solution is to involve a service, perhaps even a foreground service, to indicate to Android that your process is doing work that the user will notice if it does not complete. You could start the service when you do the print job, and then stop the service when the print job is completed, to return your process to normal priority.

However, actually having a service do the printing is a serious pain:

- `WebView`'s `PrintDocumentAdapter` really wants the `Context` that created the `WebView` to be an `Activity`
- The key parameters to `onLayout()` and `onWrite()` are [not Parcelable](#) and so cannot be passed in `Intent` extras via `startService()` to the service

One possibility would be to create a `PrintJobMonitorService`, which is what the sample app does. `PrintJobMonitorService` takes advantage of that

PRINTING AND DOCUMENT GENERATION

`listPrintJobs()` method on `PrintManager` to keep tabs on all of our requested print jobs. So long as there is one or more print jobs in an active state, the service keeps running. Otherwise, the service stops. Hence, while the service is not actually doing the printing, it is running while the printing is going on, flagging to the OS to leave our process alone during this critical juncture.

```
package com.commonware.android.print;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.os.SystemClock;
import android.print.PrintJob;
import android.print.PrintJobInfo;
import android.print.PrintManager;
import java.util.concurrent.Executors;
import java.util.concurrent.ScheduledExecutorService;
import java.util.concurrent.TimeUnit;

public class PrintJobMonitorService extends Service implements Runnable {
    private static final int POLL_PERIOD=3;
    private PrintManager mgr=null;
    private ScheduledExecutorService executor=
        Executors.newSingleThreadScheduledExecutor();
    private long lastPrintJobTime=SystemClock.elapsedRealtime();

    @Override
    public void onCreate() {
        super.onCreate();

        mgr=(PrintManager)getSystemService(PRINT_SERVICE);
        executor.scheduleAtFixedRate(this, POLL_PERIOD, POLL_PERIOD,
            TimeUnit.SECONDS);
    }

    @Override
    public int onStartCommand(Intent intent, int flags, int startId) {
        return(super.onStartCommand(intent, flags, startId));
    }

    @Override
    public void onDestroy() {
        executor.shutdown();

        super.onDestroy();
    }

    @Override
    public void run() {
        for (PrintJob job : mgr.getPrintJobs()) {
            if (job.getInfo().getState() == PrintJobInfo.STATE_CREATED
                || job.isQueued() || job.isStarted()) {
                lastPrintJobTime=SystemClock.elapsedRealtime();
            }
        }

        long delta=SystemClock.elapsedRealtime() - lastPrintJobTime;
```

```
    if (delta > POLL_PERIOD * 2) {
        stopSelf();
    }
}

@Override
public IBinder onBind(Intent intent) {
    return(null);
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PrintJobMonitorService.java](#))

PrintJobMonitorService uses a single-thread ScheduledExecutorService, to get control every three seconds in its run() method. The run() method iterates over the PrintJob objects associated with our app and looks for any that are in one of three states:

- “started”, meaning that printing has begun
- “queued”, meaning that the user has accepted the print dialog values, but printing has not yet started
- “created”, meaning that the job has been created, but it is not yet considered queued, such as when the print dialog is up on the screen

The first two states have simple test methods on PrintJob (isStarted() and isQueued()). The “created” state does not, for some reason, so we have to get the underlying PrintJobInfo object and manually check its state (getState()) to see if it is started (PrintJobInfo.STATE_STARTED).

PrintJobMonitorService tracks the last time we saw an in-progress print job. If we have gone through two three-second polling periods without any in-progress print jobs, the service assumes that it is no longer needed and calls stopSelf().

Printing Prior to Android 4.4

Before Android 4.4, printing in Android was limited and clunky.

The primary approach was to use Google Cloud Print. In effect, Google Cloud Print is a Web-managed print server. You would teach Google how to talk to your printers, and then any authorized device could print to those printers. By sharing your content (particularly PDFs) via ACTION_SEND, the user could choose Google Cloud Print as an option if they had Google Cloud Print set up for their device and printer. Note that the Android 4.4 printing framework includes a PrintService that works

with Google Cloud Print, so users who have set up Google Cloud Print can still use it even with the new printing framework.

Various printer manufacturers or third parties also created their own apps that would fill a similar role, albeit perhaps working with printers on the local network. Or, you could write your own low-level code to talk to a network printer via relevant printing protocols like IPP, though this would be unpleasant at best.

HTML Generation

[Earlier in this chapter](#), we saw how to print HTML. However, the HTML we printed was loaded from a URL. That is fine, but, as with printing bitmaps, it may not be a very popular scenario. What will be more likely is that you want to print some sort of report, generated on the device. And, since printing using the Canvas is a bit complicated, creating the report via HTML may be an easier route to take.

The typical approach for this involves creating an HTML template that sets up the basic page (e.g., references to CSS), then uses some sort of “macros” in the template to indicate portions that should be replaced dynamically with something from outside of the template.

This approach has been used since the early days of the original “dot-com revolution” of the 1990’s, pioneered by tools like Cold Fusion. In Java, there are any number of [available template engines](#).

However, for HTML, it is reasonably likely that a Web designer is going to want to get involved, to style the report. Ideally, you choose a template engine that is either something the designer is already using, or is one that is something the designer might wish to use elsewhere in the future. Forcing the designer to learn some new template syntax, just for the purposes of creating these reports, may not be the best use of the designer’s time (or your time, for answering all of the designer’s questions).

One of the more popular template structures used today use braces (a.k.a., curly brackets) as the macro delimiters (e.g., `{{ something }}`). In particular, the macro syntax popularized by [mustache](#) is used by many template engine implementations. There is a very good chance that your Web designer already has used mustache-style templates, or at least has heard about them.

And, conveniently enough, there is a Java implementation – [jmustache](#) — that is Android-friendly. The sample app in this chapter implements a “[TPS Report](#)” that is generated from a mustache template using `jmustache`.

Adding `jmustache` To Your App

The “[Get It](#)” section of the [jmustache documentation](#) contains up-to-date instructions for adding it to a project.

Developers using Gradle for Android — including Android Studio users – should reference the Maven Central artifact (`com.samskivert:jmustache`) from `build.gradle`.

Writing the Report Template

A report template for `jmustache` can be a `String` or a `Reader`, with the latter allowing you to pull in files, assets, or raw resources (the latter two via an `InputStreamReader`).

In the case of the sample app, the template is small, and is packaged as a string resource. However, since the template involves HTML tags, we have to use `CDATA` notation to allow those tags to be left alone within the XML of the string resource:

```
<string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of this week\'s TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
```

Figure 766: TPS Report Mustache Template

The template contains `{{reportDate}}` and `{{message}}` variables to be replaced at runtime with dynamic data from our app. Also note that, despite the `CDATA`, we still need to escape the apostrophe with a leading backslash (`\'`).

Creating a Report Context

What will fill in the `{{reportDate}}` and `{{message}}` variables will be values from a “context”. Here, “context” is not referring to `Context`, but rather an object that we pass to `jmustache` to serve as the source of data to blend into the report.

`jmustache` has fairly flexible rules for how it can resolve template variables, including calling Java getter methods based on the variable names. Hence, we can create a “context” that has `getReportDate()` and `getMessage()` methods, such as the `TpsReportContext` class in the sample app:

```
private static class TpsReportContext {
    private static final SimpleDateFormat fmt=
        new SimpleDateFormat("yyyy-MM-dd", Locale.US);
    String msg;

    TpsReportContext(String msg) {
        this.msg=msg;
    }

    @SuppressWarnings("unused")
    String getReportDate() {
        return(fmt.format(new Date()));
    }

    @SuppressWarnings("unused")
    String getMessage() {
        return(msg);
    }
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

Printing the Report

The “TPS Report” action bar overflow item eventually routes to a `printReport()` method on `MainActivity`:

```
private void printReport() {
    Template tmpl=
        Mustache.compiler().compile(getString(R.string.report_body));
    WebView print=prepPrintWebView(getString(R.string.tps_report));

    print.loadData(tmpl.execute(new TpsReportContext(prose.getText()
        .toString()),
        "text/html", "UTF-8");
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The first statement creates a `jmustache Template` object representing the report template. This is created by getting the singleton `compiler()` from `Mustache`, and calling `compile()` on it to interpret the string resource. Note that since this `Template` only depends upon the string resource, we could cache the `Template`, rebuilding it only on configuration changes, if desired.

Note that we load the template on the main application thread, as `printReport()` is called from `onOptionsItemSelected()`. For a small string resource, that is OK. If you are loading a more complex report template, you will want to do that in a background thread.

The second statement mirrors one from printing the Web page from before, where we call `prepPrintWebView()` to lazy-create our `WebView` and set it up to print when the page is loaded. Here, we use a different print job name than before, one reflecting the fact that this is a TPS report.

Finally, we use `execute()` on the `Template` to generate our HTML for printing, then pass that HTML to the `loadData()` method on `WebView`. `execute()` takes our “context” Object, which in this case is an instance of our `TpsReportContext` class, with the value typed into the `EditText` widget in our UI as the “message” to go into the report.

Note that we `execute()` the `Template` on the main application thread as well as having loaded it on that thread in the first place. Once again, the more complex the report, the more likely it is that you will want to move this logic into a background thread. However, remember that `print()` needs to be called on the main application thread.

The result is that the user gets a printed TPS report, containing today’s date and whatever message they typed into the `EditText`.

PDF Generation Options

Perhaps you feel that generating HTML does not give you enough control, yet using the `Canvas` options directly was *too* much control. Perhaps you then think that generating a PDF to print, using something other than `PdfDocument`, is the right answer. Or perhaps you are generating a PDF for other reasons, such as to use with `ACTION_SEND` as output from your app.

You have two basic options for getting this PDF: generate it on the device, or offload the generation to a server.

There are various [open source and commercial libraries](#) for generating PDF on Android. The best-known open source Java PDF library – iText — has a dedicated Android version ([iTextG](#)), though the AGPL license may make it unsuitable for your use case. The commercial libraries range from fixed-price to per-device licenses. How much advantage these have over using `PrintedPdfDocument` from the Android SDK depends upon your needs.

If the bulk of the data needed for generating the PDF resides on a server, rather than downloading that data and using an underpowered Android device to create the PDF, you could upload the device-specific data to the server, have it create the PDF, and download the result from the server. There are plenty of server-side PDF generation tools, ranging from open source (e.g., [wkhtmltopdf](#), [unoconv](#), [prawn](#)) to commercial (e.g., [Prince](#), used to generate the PDF edition of this book). You also get to work in your preferred programming language, in case that is not Java, and perhaps leverage the PDF generation logic for other uses (e.g., generate reports from your Web app).

Dealing with Different Hardware

While a lot of focus is placed on screen sizes, there are many other possible hardware differences among different Android devices. For example, some have telephony features, while others do not.

There is a three-phase plan for dealing with these variations:

1. **Filter** out devices that cannot possibly run your app successfully, so your app will not appear to them in the Play Store and they will be unable to install your app if obtained by other means
2. **React** to varying hardware that you can support, but perhaps might support differently (e.g., choosing a particular flash mode for a device having a camera with a flash)
3. **Cope** with device bugs or regressions that impact your application

This chapter will go through each of these topics.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Filtering Out Devices

Elsewhere in the book, we discussed a few manifest entries that will serve to filter out devices that cannot run your app:

DEALING WITH DIFFERENT HARDWARE

- [android:minSdkVersion in the <uses-sdk> element](#), to stipulate that devices must run a certain version of Android (or higher)
- [<supports-screens> and <compatible-screens>](#), which indicate which screens sizes and densities you are capable of supporting

This section outlines other “advertisements” that you can put in the manifest to restrict which devices run your app.

uses-feature

The `<uses-feature>` element restricts your app to devices that have certain hardware features. For each element, you supply the name of a feature (e.g., `android.hardware.telephony`) and whether or not it is required:

```
<uses-feature
  android:name="android.hardware.camera"
  android:required="false" />
```

By default, `android:required` is set to `true`, so typically you will only see it in a manifest when it is set to `false`.

You might wonder why we would bother ever setting `android:required` to `false`. After all, that should have the same effect as not listing it at all. In practice, though, it has two major uses.

First, markets like the Play Store might highlight the fact that you *can* use a particular hardware capability, even though you do not strictly require it.

More importantly, you can use `android:required="false"` to *undo* a *requirement* that Android infers from your permissions. Requesting some permissions causes Android to assume — for backwards-compatibility reasons — that your app needs the affiliated hardware. For example, requesting the `CAMERA` permission causes Android to assume that you need a camera (`android.hardware.camera`) *and* that the camera support auto-focus (`android.hardware.camera.autofocus`). If, however, you are requesting the permission because you would like to use the hardware if available, but can live without it, you need to expressly add a `<uses-feature>` element declaring that the hardware feature is not required.

For example, in February 2010, the Motorola XOOM tablet was released. This was the first Android device that had the Play Store on it and truly had no telephony capability. As such, the XOOM would be filtered out of the then-Android Market (now Play Store) for any app that required permissions like `SEND_SMS`. Many

developers requested this permission, even though their apps could survive without SMS-sending capability. However, their apps were still filtered out if they did not have the `<uses-feature>` element declaring that telephony was not required.

You can find a table listing Android permissions and assumed hardware feature requirements in [the Android developer documentation](#).

uses-configuration

The `<uses-configuration>` element is very reminiscent of `<uses-feature>`: it dictates hardware requirements. The difference is two-fold:

1. It focuses on hardware elements that represent different device configurations, meaning that you might use different resources for them
2. It allows you to specify *combinations* of capabilities that you need

There are three capabilities that you can require via `<uses-configuration>`:

1. The existence of a five-way navigation control, whether a specific type (D-pad, trackball, etc.) or any such control
2. The existence of a physical keyboard, whether a specific type (QWERTY, 12-key numeric keypad, etc.) or any such keyboard
3. A touchscreen

You can have as many `<uses-configuration>` elements as you need – any device that matches at least one such configuration will be eligible to install your app.

For example, the following `<uses-configuration>` element restricts your app to devices that have some sort of navigation control but do not necessarily have a touchscreen, such as an Android TV device:

```
<uses-configuration
  android:reqFiveWayNav="true"
  android:reqTouchScreen="notouch" />
```

uses-library

The `<uses-library>` element tells Android that your application wishes to use a particular *firmware*-supplied library. The most common case for this was Maps V1, which is shipped in the form of an SDK add-on and firmware library. This, however, has been deprecated for quite some time.

However, there are other firmware libraries that you might need. These will typically be manufacturer-specific libraries, allowing your application to take advantage of particular beyond-the-Android-SDK capabilities of a particular device. This is very uncommon nowadays.

The Google Play Store will filter out your application from devices that lack a firmware library that you require via `<uses-library>`. If the user tries installing your app by some other means (e.g., download from a Web site), your app will fail to install on devices that lack the firmware library.

If you conditionally want the firmware library — you will use it if available but can cope if it is not — you can add `android:required="false"` to your `<uses-library>` element. That will allow your app to install and run on devices missing the library in question. Detecting whether or not the library exists in your process at runtime is a matter of using `Class.forName()` to see if you have access to some class from that library, where a `ClassNotFoundException` means that you do not have the library.

Runtime Capability Detection

Reacting to device capabilities is the second phase of dealing with different devices. Some features you might want (e.g., telephony for sending SMSes) but can live without. Other features may have subtle variations that you cannot filter against and therefore need to adapt to at runtime (e.g., possible picture resolutions off of a camera).

This section will cover various techniques for determining what a device can do, at runtime, so you can react accordingly.

Features

Any feature you do not make required via `<uses-feature>` can be detected at runtime by calling `hasSystemFeature()` on `PackageManager`. For example, if you would like to send SMS messages, but only on telephony-capable devices, you could have the following `<uses-feature>` element:

```
<uses-feature
  android:name="android.hardware.telephony"
  android:required="false" />
```

Then, at runtime, you can call `hasSystemFeature(PackageManager.FEATURE_TELEPHONY)` on a `PackageManager`

instance to find out if, indeed, the device has telephony capability and sending SMSes should work.

Other Capabilities

Various subsystems have their own means of helping you determine what is possible or not:

- The [camera APIs](#) can let you know the capabilities of a camera (e.g., whether or not it has a flash, and what specific flash modes are supported).
- The [LocationManager](#) will help you determine what location providers are available that meet your `Criteria`.
- The sensor subsystem lets you find out what sensors are installed, either overall or for a particular type (e.g., accelerometer).

Dealing with Device Bugs

Alas, devices are not perfect. Even though [the Compatibility Test Suite](#) attempts to ensure that all Android devices legitimately running the Play Store faithfully implement the Android SDK, some device manufacturers make changes that introduce bugs.

Just as Web developers can “sniff” on the User-Agent HTTP header to determine what sort of browser is requesting a page, you can use the `Build` class to determine what sort of device is running your app. If you encounter problems with a specific device, you may be able to use `Build` to identify that device at runtime and “route around the damage”.

Trail: Integration and Introspection

Writing and Using Parcelables

Parcelable is a marker interface, reminiscent of `Serializable`, that shows up in many places in the Android SDK. Parcelable objects can be put into Intent extras or Bundle objects, for example. Making your own custom classes implement Parcelable greatly increases their flexibility.

At the same time, Parcelable is something that can be overused. In most Android apps, few if any custom classes really need to have Parcelable capabilities.

In this chapter, we will review how to modify classes to implement Parcelable and what the limitations are on using Parcelable.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

The Role of Parcelable

A Parcelable object is one that can be placed into a Parcel. A Parcel is the primary vehicle for passing data between processes in Android's inter-process communication (IPC) framework.

IPC abounds in Android, even in places where you may not expect it. Every time you call `startActivity()`, for example, IPC occurs, even if the activity that calls `startActivity()` and the activity to be started are in the same process. A core OS process is the one that is responsible for identifying the activity to be started and routing control to it, so `startActivity()` performs IPC from the original activity's

process to a core OS process. The core OS process then eventually performs IPC to the target process for the activity to be started.

If you see an `Intent` or a `Bundle` in the Android SDK, odds are that those objects are involved in IPC. That is not always the case — `LocalBroadcastManager`, for example, uses `Intent` objects purely in-process — but it is a reasonable rule of thumb. Hence, there is keen interest in being able to implement `Parcelable` on specific classes, either to pass to other components via `Intent` extras, or to become part of the saved instance state `Bundle`.

`Parcelable` objects are also important for use with [remote services via the binding pattern](#).

Writing a Parcelable

You have three major approaches for adding `Parcelable` capabilities to your classes in Android:

1. Use an annotation processor that will add in the appropriate bits of magic for you
2. Use a code generator site or tool that will take your existing class as input and give you the `Parcelable`-enabled rendition as output
3. Just do it yourself

By Annotations

Enterprising developers have created annotation processing libraries that can be used to add `Parcelable` capabilities to a Java class in an Android app.

One approach is used by [Parceler](#). Here, you just add a `@Parcel` annotation to the Java class, and it code generates what is needed. However, it does *not* actually make the Java class `Parcelable`. Rather, it creates a runtime wrapper class that *is* `Parcelable` and that knows how to convert instances of your own Java class to and from the wrapper. You wind up calling static `wrap()` and `unwrap()` methods on a `Parcels` class to handle the conversion between your class and the generated `Parcelable` class.

[AutoParcel](#) takes a slightly different approach. In this case, you need to:

- Add the `@AutoParcel` annotation to the class

WRITING AND USING PARCELABLES

- Make the class abstract and have it implement `Parcelable`
- Write abstract method signatures for getters for the data members

`AutoParcel` then code-generates a Java class that implements the getters, data members, and `Parcelable` logic, along with other niceties like `equals()` and `hashCode()`. That Java class will be named `AutoParcel_`, followed by the name of the class with the `@AutoParcel` annotation (e.g., annotating a `Foo` class gives you an `AutoParcel_Foo` class). The `AutoParcel`-generated class is a concrete subclass of the abstract base class, and so you can just work with the abstract class' public API and let `AutoParcel` handle the details.

However, neither of these give you classes that play well with the other children. Other code that expects to work with your classes — whether that is passing a `Parceler`-defined `Parcelable` to a third-party app or using something like `Gson` to handle JSON parsing — will not like either `Parceler` or `AutoParcel` that much.

By Code Generator Sites and Tools

[The Parcelabler Web site](#) is a code generator. You paste in a simple Java class, with the class declaration and data members:

```
class Book {
    String isbn;
    String title;
    int pubYear;
}
```

and it gives you an output class that adds the `Parcelable` logic:

```
class Book implements Parcelable {
    String isbn;
    String title;
    int pubYear;

    protected Book(Parcel in) {
        isbn = in.readString();
        title = in.readString();
        pubYear = in.readInt();
    }

    @Override
    public int describeContents() {
        return 0;
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeString(isbn);
        dest.writeString(title);
    }
}
```

WRITING AND USING PARCELABLES

```
        dest.writeInt(pubYear);
    }

    @SuppressWarnings("unused")
    public static final Parcelable.Creator<Book> CREATOR = new Parcelable.Creator<Book>() {
        @Override
        public Book createFromParcel(Parcel in) {
            return new Book(in);
        }

        @Override
        public Book[] newArray(int size) {
            return new Book[size];
        }
    };
}
```

We will see in the next section what all of that code does for us, as part of understanding how to build it by hand.

However, the Parcelabler Web site has some limitations in its Java parsing, and so the more complex your Java class, the more likely it is that the Parcelabler site will have difficulty understanding it and blending in the Parcelable logic.

[The ParcelableCodeGenerator project](#) implements a command-line code generator that takes a JSON schema and gives you a Java class that, among other things, has the Parcelable implementation.

By Hand

Adding Parcelable support yourself is not especially difficult, though it is a bit tedious.

The Parcelable Interface

The first step is to add implements Parcelable to the class. Immediately, your IDE should start complaining that you need to implement two methods to satisfy the Parcelable interface.

The easier of the two methods is describeContents(), where you will return 0, most likely.

The other method you will need to implement is writeToParcel(). You are passed in two parameters: a very important Parcel, and a usually-ignored int named flags.

WRITING AND USING PARCELABLES

Your job, in `writeToParcel()`, is to call a series of `write...()` methods on the `Parcel` to write out all data members of this object that should be considered part of the object as it is passed across process boundaries. There are dozens of type-safe methods for writing data into the `Parcel`:

- methods that write individual primitives (e.g., `writeInt()`) or Java arrays of primitives (e.g., `writeStringArray()`)
- `writeBundle()`, for writing out a `Bundle`
- `writeParcelable()` and `writeParcelableArray()`, for writing out other objects that implement `Parcelable`
- `writeFileDescriptor()`, for putting a `FileDescriptor` into the `Parcel`, with an eye towards allowing whoever reconstitutes the `Parcelable` to be able to read or write a stream based on that `FileDescriptor`
- methods to write other “active objects”, such as `IBinder` objects from [a remote service binding](#)
- various specialized methods for particular data types (e.g., `writeSizeF()`) or interfaces (e.g., `writeSerializable()`)

If, in `writeToParcel()`, you called `writeFileDescriptor()`, you will want to have `describeContents()` return `CONTENTS_FILE_DESCRIPTOR` instead of `0`, as apparently the `Parcelable` support logic needs to know that a file descriptor is in the `Parcel`.

In the case of the generated `Book` code shown earlier in this chapter, `writeToParcel()` writes out the two `String` and one `int` data member:

```
@Override
public int describeContents() {
    return 0;
}

@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeString(isbn);
    dest.writeString(title);
    dest.writeInt(pubYear);
}
```

The CREATOR

When Android tries reading objects in from a `Parcel`, and it encounters an instance of your `Parcelable` class, it will retrieve a static `CREATOR` object that must be defined on that class. The `CREATOR` is an instance of `Parcelable.Creator`, using generics to tie it to the type of your class:

WRITING AND USING PARCELABLES

```
@SuppressWarnings("unused")
public static final Parcelable.Creator<Book> CREATOR = new Parcelable.Creator<Book>() {
    @Override
    public Book createFromParcel(Parcel in) {
        return new Book(in);
    }

    @Override
    public Book[] newArray(int size) {
        return new Book[size];
    }
};
```

The `@SuppressWarnings("unused")` annotation is because the IDE will think that this `CREATOR` instance is not referred to anywhere. That is because it will only be used via Java reflection.

The `CREATOR` will need two methods. `createFromParcel()`, given a `Parcel`, needs to return an instance of your class populated from that `Parcel`. `newArray()`, given a size, needs to return a type-safe array of your class.

The typical implementation of `createFromParcel()` will delegate the actual work to a protected or private constructor on your class that takes the `Parcel` as input:

```
protected Book(Parcel in) {
    isbn = in.readString();
    title = in.readString();
    pubYear = in.readInt();
}
```

You need to read in the *same* values that you wrote out to the `Parcel`, and in the same order.

By Hand, With a Little Bit of Help

Android Studio 1.3 and higher have a template for a new `Parcelable` class. Right-click over your desired Java package and choose `New > Other > New Parcelable Type` from the context menu. Fill in your class and the template will create a new standalone Java class, akin to this one:

```
import android.os.Parcel;
import android.os.Parcelable;

public class Item implements Parcelable {

    // TODO declare your real class members
    // Members must be either primitives, primitive arrays or parcelables
    private int mFoo;
    private String mBar;
```

WRITING AND USING PARCELABLES

```
// TODO implement your constructors, getters & setters, methods

private Item(Parcel in) {
    // TODO read your class members from the parcel
    // Note: order is important - you must read in the same order
    // you write in writeToParcel!
    mFoo=in.readInt();
    mBar=in.readString();
}

@Override
public void writeToParcel(Parcel out, int flags) {
    // TODO write your class members to the parcel
    // Note: order is important - you must write in the same order
    // you read in your private parcelable constructor!
    out.writeInt(mFoo);
    out.writeString(mBar);
}

@Override
public int describeContents() {
    // TODO return Parcelable.CONTENTS_FILE_DESCRIPTOR if your class members
    // include a FileDescriptor, otherwise you can simply return 0
    return 0;
}

public static final Parcelable.Creator<Item> CREATOR=new Parcelable.Creator<Item>() {
    public Item createFromParcel(Parcel in) {
        return new Item(in);
    }

    public Item[] newArray(int size) {
        return new Item[size];
    }
};
}
```

You would have to adjust the stock fields (mFoo, mBar) to be what you need, and adjust the writeToParcel() and private constructor to match.

However, this template is designed for starting from scratch; it is not that useful when you have an existing class and wish to now make it be Parcelable.

The [ParcelablePlease](#) library saves you from having to do all of the reading and writing to and from the Parcel yourself. Putting the @ParcelablePlease annotation on the class generates a class for you (your class name followed by ParcelablePlease, so FooParcelablePlease for a Foo class). This class *only* marshals your data members to and from a Parcel, via static readFromParcel() and writeToParcel() methods. You still have to have the rest of the Parcelable boilerplate. Hence, this library is not as powerful as the annotation processors mentioned earlier in this chapter, but you wind up with a “real” complete Java class

that can work better with other annotation-based libraries like Gson. On the other hand, it still makes it difficult for you to distribute your code to third parties, as they will need to also have this annotation processing library in their project builds.

The Limitations of Parcelable

While the mechanics of writing a Parcelable are not hard, this does not mean that every model object or other POJO in your app should be made Parcelable. Overuse of Parcelable is a bit of a code smell, as it suggests that the developer is not necessarily considering all of the limitations and effects of the use of Parcelable.

The 1MB Limit

The biggest one (pun lightly intended) is the size limitation. A Parcel – the IPC structure that is used to pass Parcelable objects across process boundaries — has a 1MB size limit. If you get over this limit, you will likely crash with a “Failed Binder Transaction” message as part of the exception’s stack trace.

There are two main ways you can reach this limit:

1. Have a Parcelable that individually is too large. A common case for this is wrapping a Bitmap or other large byte array in some Parcelable object.
2. Have too many Parcelable objects. For example, you might have performed a database query, converted the results into a collection of model objects, then tried to pass that collection to another activity via an Intent extra. Syntactically, this can work fine, if the collection and its model objects are all Parcelable. But now your risk of hitting the 1MB limit is determined by how many rows there are in the query’s result set, and that can vary by user.

Large data like this need to be managed by singletons or other static data members and shared among your application components, rather than passed via Parcelable objects.

Pass-By-Value

Suppose we have two activities, A and B. Activity A calls `startActivity()`, identifying activity B in the Intent. The Intent also includes a custom Parcelable object, one that takes up 1KB of space.

Question: how much system RAM is taken up by that Parcelable?

Wrong Answer: 1KB.

Right Answer: At least 3KB, as there are at least three copies of the Parcelable data:

- One copy is the original Parcelable object, the one that is stored as an extra in the Intent
- Another copy is the one in the Parcel that is held by a core OS process, for handling things like configuration changes and the recent-tasks list, where that Intent (and its extras, including your Parcelable) are needed
- A third copy is the one in the Intent that Activity B receives

Parcelable is, in effect “pass-by-value”, as the Parcelable object is copied as part of getting it across the process boundary twice, once from your process to the core OS, and once from the core OS back to your process.

This means that modifications that Activity B makes to the Parcelable object will not be seen by Activity A, as they are working on separate copies of the object. Similarly, changes that Activity B makes to the Parcelable will not affect the copy held by the core OS process and re-delivered to Activity B on a configuration change.

The safest way to help defend against mistakes related to this is to consider a Parcelable object to be an immutable object. Only configure it through a constructor (possibly with the assistance of some Builder if you want a cleaner API). Offer getters for the values in the Parcelable, but do not offer any setters, so once the instance is created, it cannot be changed.

Also note that these copies magnify the effects of having a large Parcelable object, or too many Parcelable objects in a Parcel. A 900KB Parcel might fit within the 1MB size limit, but it would consume at least 2.7MB if the Parcel is part of some IPC.

Conversely, there are cases where Intent objects are not passed across process boundaries, such as LocalBroadcastManager. In those cases, neither the 1MB limit nor the pass-by-value effect are an issue. Only if the Intent is “flattened” into a Parcel, and later converted back into an Intent, do these extra copies and the 1MB limit come into play.

The ClassLoader Conundrum

Sometimes, weird stuff happens, particularly when trying to read in other Parcelable objects that you wrote to the Parcel. In this case, the Parcel system needs to use Java reflection to find the Java class associated with the Parcelable objects, and sometimes it gets a bit lost.

When you use `readParcelable()` to read in the Parcelable objects out of the Parcel, you may need to supply the ClassLoader that you know has those Parcelable classes.

For example, [the CWAC-Pager project](#) implements a PagerAdapter named `ArrayPagerAdapter`. The use of `ArrayPagerAdapter` is covered [elsewhere in the book](#), but it makes it easier for you to add, insert, and remove pages on the fly from a `ViewPager`. To accomplish this, it holds onto a series of `PageEntry` objects, where `PageEntry` implements `Parcelable`. `PageEntry`, in turn, holds onto two other Parcelable objects:

1. a `PageDescriptor` named `descriptor`
2. a `Fragment.SavedState` named `state`

To reliably be able to read in these values from a Parcel, it was necessary to manually stipulate the ClassLoader to use:

```
PageEntry(Parcel in) {  
    this.descriptor=in.readParcelable(getClass().getClassLoader());  
    this.state=in.readParcelable(getClass().getClassLoader());  
}
```

Here, we are using the same ClassLoader that has this `PageEntry` class.

Sharing Between Apps

Parcelable objects need to read and write the same values to and from the Parcel. This sounds simple, but it gets into some nasty issues when multiple code bases need to work with the Parcelable.

For example, suppose your app offers an SDK, such as a remote service. You have some custom Parcelable objects that you can either give to third-party clients of your app or get as input from those clients. Now, your SDK needs to ship implementations of the Parcelable classes; without them, clients cannot use you exposed service API.

WRITING AND USING PARCELABLES

What happens now, if you change the definition of the Parcelable? Bear in mind that:

- You may not be able to control when third-party developers take on some new version of your SDK
- You may not be able to control when end users update your app
- You may not be able to control when end users update third-party client apps

As a result, it is reasonably likely that your Parcelable implementations will be out of sync on a user's device, with your app having one implementation and a third-party app having another implementation. The results of this may not be pretty.

This is not a problem for purely internal uses of Parcelable, such as for holding onto data across a configuration change.

Responding to URLs

You may have noticed that Android supports a `market:` URL scheme. Web pages can use such URLs so that, if they are viewed on an Android device's browser, the user can be transported to a Play Store page, perhaps for a specific app or a list of apps for a publisher.

Fortunately, that mechanism is not limited to Android's code — you can get control for various other types of links as well. You do this by adding certain entries to an activity's `<intent-filter>` for an `ACTION_VIEW` Intent.

However, be forewarned that this capability is browser-specific. What works on the original Android “Browser” app and Google's Chrome may not necessarily work on Firefox for Android or other browsers.

Prerequisites

Understanding this chapter requires that you have read the chapter on [Intent filters](#).

Manifest Modifications

First, any `<intent-filter>` designed to respond to browser links will need to have a `<category>` element with a name of `android.intent.category.BROWSABLE`. Just as the `LAUNCHER` category indicates an activity that should get an icon in the launcher, the `BROWSABLE` category indicates an activity that wishes to respond to browser links.

You will then need to further refine which links you wish to respond to, via a `<data>` element. This lets you describe the URL and/or MIME type that you wish to respond

RESPONDING TO URLS

to. For example, here is the `AndroidManifest.xml` file from the [Introspection/URLHandler](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.urlhandler"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="19"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity
            android:name="URLHandler"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.intent.action.VIEW"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>

                <data android:mimeType="application/pdf"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.intent.action.VIEW"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>

                <data
                    android:host="www.this-so-does-not-exist.com"
                    android:path="/something"
                    android:scheme="http"/>
            </intent-filter>
            <intent-filter>
                <action android:name="com.commonware.android.MY_ACTION"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

RESPONDING TO URLS

(from [Introspection/URLHandler/app/src/main/AndroidManifest.xml](#))

Here, we have four `<intent-filter>` elements for our one activity:

- The first is a standard “put an icon for me in the launcher, please” filter, with the LAUNCHABLE category
- The second claims that we handle PDF files (MIME type of `application/pdf`), and that we will respond to browser links (BROWSABLE category)
- The third claims that we will handle any HTTP request (scheme of “http”) for a certain Web site (host of “`www.this-so-does-not-exist.com`” and path of `/something`), and that we will respond to browser links (BROWSABLE category)
- The last is a custom action, for which we will generate a URL that Android will honor, and that we will respond to browser links (BROWSABLE category) — we will examine this more closely in [the next section](#)

What happens for the first two links varies based on browser.

The original Android “Browser” app, and Google Chrome, will do the following:

- Tapping the link to the PDF, on Android 2.3+, will trigger a download of the PDF. When the user taps on the downloaded file (e.g., from the Notification in the status bar), the user will have URLHandler as one of the options in the chooser to view the PDF file.
- Tapping the link to `http://www.this-so-does-not-exist.com/something` will bring up a chooser showing all available Web browser, plus URLHandler, as expected

Firefox for Android will treat the PDF link the same way. However, Firefox for Android does not check the URL for the second link to see if there is anything else supporting ACTION_VIEW for the URL, and so it always loads up the Web page. You see this effect with the link to Barcode Scanner as well — even though a device has Barcode Scanner installed, Firefox never offers that as an option.

Creating a Custom URL

Responding to MIME types makes complete sense... if we implement something designed to handle such a MIME type.

Responding to certain schemes, hosts, paths, or file extensions is certainly usable, but other than perhaps the file extension approach, it makes your application a bit

RESPONDING TO URLS

fragile. If the site changes domain names (even a sub-domain) or reorganizes its site with different URL structures, your code will break.

If the goal is simply for you to be able to trigger your own application from your own Web pages, though, the safest approach is to use an intent: URL. These can be generated from an Intent object by calling `toUri(Intent.URI_INTENT_SCHEME)` on a properly-configured Intent, then calling `toString()` on the resulting `Uri`.

For example, the intent: URL for the fourth `<intent-filter>` from above is:

```
intent:#Intent;action=com.commonware.android.MY_ACTION;end
```

This is not an official URL scheme, any more than `market:` is, but it works for Android devices. When the Android built-in Browser encounters this URL, it will create an Intent out of the URL-serialized form and call `startActivity()` on it, thereby starting your activity. Chrome also supports this URL structure. Firefox for Android does not, indicating instead that it cannot recognize the URL.

Reacting to the Link

Your activity can then examine the Intent that launched it to determine what to do. In particular, you will probably be interested in the `Uri` corresponding to the link — this is available via the `getData()` method. For example, here is the `URLHandler` activity for this sample project:

```
package com.commonware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        TextView uri=(TextView)findViewById(R.id.uri);

        if (Intent.ACTION_MAIN.equals(getIntent().getAction())) {
            String intentUri=(new Intent("com.commonware.android.MY_ACTION"))
                .toUri(Intent.URI_INTENT_SCHEME)
                .toString();
```

RESPONDING TO URLS

```
uri.setText(intentUri);
Log.w("URLHandler", intentUri);
}
else {
    Uri data=getIntent().getData();

    if (data==null) {
        uri.setText("Got com.commonware.android.MY_ACTION Intent");
    }
    else {
        uri.setText(getIntent().getData().toString());
    }
}
}

public void visitSample(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW,
        Uri.parse("https://commonware.com/sample")));
}
}
```

(from [Introspection/URLHandler/app/src/main/java/com/commonware/android/urlhandler/URLHandler.java](#))

This activity's layout has a `TextView` (`uri`) for showing a `Uri` and a `Button` to launch a page of links, found on the CommonsWare site (<https://commonware.com/sample>). The `Button` is wired to call `visitSample()`, which just calls `startActivity()` using the aforementioned URL to display it in the user's chosen Web browser.

When the activity starts up, though, it first loads up the `TextView`. What goes in there depends on how the activity was launched:

1. If it was launched via the launcher (e.g., the action is `MAIN`), then we display in the `TextView` the `intent: URL` shown in the previous section, generated from an `Intent` object designed to trigger our fourth `<intent-filter>`. This also gets dumped to `LogCat`, and is how the author got this URL in the first place to put on the sample Web page of links.
2. If it was not launched via the launcher, it was launched from a Web link. If the `Uri` from the launching `Intent` is `null`, though, that means the activity was launched via the custom `intent: URL` (which only has an action string), so we put a message in the `TextView` to match.
3. Otherwise, the `Uri` from the launching `Intent` will have something we can use to process the link request. For the PDF file, it will be the local path to the downloaded PDF, so we can open it. For the `www.this-so-does-not-exist.com` URL, it will be the URL itself, so we can process it our own way.

RESPONDING TO URLS

Note that for the PDF case, clicking the PDF link in the Browser will download the file in the background, with a Notification indicating when it is complete. Tapping on the entry in the notification drawer will then trigger the `URLHandler` activity.

Also, bear in mind that the device may have multiple handlers for some URLs. For example, a device with a real PDF viewer will give the user a choice of whether to launch the downloaded PDF in the real view or `URLHandler`.

App Links

We have had the ability to have activities with `<intent-filter>` elements that support custom schemes (e.g., `myapp://`) since Android 1.0. The benefit over using a custom scheme is that, if it is unique on the device, an Intent for that custom scheme will go straight to the desired activity. However, this approach had a lot of flaws:

- There is no guarantee of uniqueness
- Few apps would recognize the custom scheme and issue an `ACTION_VIEW` Intent on the desired `Uri`
- If the user *did* encounter a link that would try to issue the `ACTION_VIEW` Intent, and the app handling that custom scheme was not installed, the request would simply fail

Using an `<intent-filter>` advertising support for some `http` or `https` URL would improve the results for the latter two issues, as many more apps would recognize the URL as being a URL, and usually the fallback would be to have a browser open up on that URL. However, now it is guaranteed that the scheme is *not* unique. Users would initially get a chooser, to determine what activity should handle the request. This can be confusing, particularly since the chooser does not really indicate the scope of the choice (would I be saying that XYZ app is now handling all Web links?).

Android 6.0 added an interesting solution for this. If you use a `<intent-filter>` for a domain that you control, you can publish a bit of metadata, as a JSON file, on the Web server. Android can be taught to sniff for that metadata and use it to validate that the app was developed by the same person or group that runs the server for the identified domain. In that case, Android will bypass the chooser and go straight to the activity with the domain-specific `<intent-filter>`. The cited example would be Twitter doing this, so any link click on a `twitter.com` URL would bring up the Twitter app, not a Web browser.

Of course, these links are only so useful. They are fine for when a link appears in an ordinary app. Web browsers, however, tend not to actually see whether a URL they encounter is handled by some on-device app. Android 6.0 does not change this behavior. So, links on Web pages viewed in 2015 versions of Firefox will not honor your desired `<intent-filter>` regardless of whether you are using this new app link system or not. Chrome's behavior varies by version.

That being said, app links still have their uses (e.g., responding to links from social media posts).

Setting Up the IntentFilter

Supporting an `<intent-filter>` for some http or https URL has been possible since Android 1.0. The only thing that is different is that now you can add an `android:autoVerify="true"` to the `<intent-filter>` element, to tell Android that you would like it to verify the connection between the app and the domain used in the `<intent-filter>`, to skip the chooser when URLs for that domain trigger your `<intent-filter>`.

For example, the [Introspection/URLHandlerMNC](#) sample project is a revised version of the `URLHandler` sample, one that switches its http `<intent-filter>` to look for `https://commonsware.com` URLs, and it incorporates `android:autoVerify="true"`:

```
<intent-filter android:autoVerify="true">
  <action android:name="android.intent.action.VIEW"/>

  <category android:name="android.intent.category.DEFAULT"/>
  <category android:name="android.intent.category.BROWSABLE"/>

  <data
    android:host="commonsware.com"
    android:scheme="https"/>
</intent-filter>
```

(from [Introspection/URLHandlerMNC/app/src/main/AndroidManifest.xml](#))

On pre-Marshmallow versions of Android, this attribute will be ignored, as it will not be recognized. But, on Android 6.0+, this attribute will be used to attempt to validate that your app was written by somebody who owns the specified domain.

The author of this book owns the `commonsware.com` domain. To actually run this project and have the updated app linking work, you would need to switch this to be some domain that *you* control.

RESPONDING TO URLS

Note that while `android:autoVerify="true"` is written at the scope of a single `<intent-filter>`, it affects *all* activities and *all* `<intent-filter>` structures. *All* of them that use `http` or `https` as the `android:scheme` must support the app links protocol described in this chapter. You cannot have some filters supporting app links and others not — either they *all* support app links, or none will.

Setting Up the JSON

When Android installs an app that has one or more `<intent-filter>` elements with `android:autoVerify="true"`, it will attempt to find a JSON file on the identified server. Specifically, for the sample app, the Android 6.0 will create a URL of the form:

```
https://commonsware.com/.well-known/assetlinks.json
```

In your app, `commonsware.com` would be replaced with the domain you have in your `<intent-filter>`.

This URL is part of a [proposed IETF standard](#) that unfortunately does not appear to be formally documented.

Android 6.0+ will use HTTPS to retrieve your `assetlinks.json` file, regardless of the scheme that you use in the `<intent-filter>`. Also, the JSON needs to be publicly accessible, without any forms of authentication.

The JSON content itself is an array of JSON objects, one object per application ID that you publish as an app:

```
[
  {
    "relation": ["delegate_permission/common.handle_all_urls"],
    "target": {
      "namespace": "android_app",
      "package_name": "com.commonsware.android.urlhandler",
      "sha256_cert_fingerprints": ["A9:99:84:D8:....:60:5B:CB:E3"]
    }
  }
]
```

(the `sha256_cert_fingerprints` value is shown truncated for easier reading)

Here, the only two variable bits are:

1. The `package_name`, which will be your application ID, and

RESPONDING TO URLS

2. The `sha256_cert_fingerprints` array, which will list the SHA256 hashes of your public signing keys, for whatever keystores you might be using for this app (e.g., your debug keystore and your production keystore)

To get the SHA256 hash of your public signing key, you will need to use the `keytool` command from your Java SDK (Java 7 or higher required):

```
keytool -list -v -keystore ...
```

where `...` is the path to your keystore (e.g., `~/ .android/debug.keystore` for your debug keystore on OS X and Linux).

You will need to provide the password to the keystore. For the debug keystore, this is `android`.

As part of the output, you will get the SHA256 hash:

```
Keystore type: JKS
Keystore provider: SUN

Your keystore contains 1 entry

Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate[1]:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
  MD5:  98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
  SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
  SHA256: A9:99:84:D8:....:60:5B:CB:E3
Signature algorithm name: SHA1withRSA
Version: 3

*****
*****
```

(the SHA256 value is shown truncated for easier reading)

That long set of hex digits will need to go in the `sha256_cert_fingerprints` JSON array.

The rest of the JSON is fixed. Try not to introduce other JSON properties and such into this file, as they may cause your file to fail validation. However, you can have

RESPONDING TO URLS

multiple JSON objects for multiple apps, each providing the relation and target properties.

According to [this Google+ post](#), there are some undocumented things to note about the `assetlinks.json` file:

- The `/.well-known/assetlinks.json` for your scheme and host must return the result directly, not via a redirect (HTTP 30x) response. This was documented as being the case for the M Developer Preview; the [official documentation](#) does not mention this.
- To help overcome the above limitation, instead of having the actual JSON file at that path, you can have a stub JSON file that uses an `include` value to point to some other URL which will have the real `assetlinks.json` file:

```
[{ "include": "https://someother.com/this_is_my_boomstick.json" }]
```

Note that the author has not tested the `include` option, nor is the author presently in possession of a boomstick.

Results

Our `URLHandler` activity not only responds to `http://misc.commonsware.com` URLs, but it uses one if the user taps the “view-sample” button:

```
package com.commonsware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        if (Intent.ACTION_VIEW.equals(getIntent().getAction())) {
            findViewById(R.id.visit).setEnabled(false);
        }
    }

    public void visitSample(View v) {
        startActivity(new Intent(Intent.ACTION_VIEW,
            Uri.parse("https://commonsware.com/Android/")));
    }
}
```

RESPONDING TO URLS

```
}  
}
```

(from [Introspection/URLHandlerMNC/app/src/main/java/com/commonsware/android/urlhandler/URLHandler.java](https://github.com/commonsware/android-urlhandler/blob/master/src/main/java/com/commonsware/android/urlhandler/URLHandler.java))

There, we launch an ACTION_VIEW Intent on a `http://commonsware.com/Android` URL via `startActivity()`.

On a pre-Marshmallow device, this `startActivity()` request will normally bring up a chooser, offering the URLHandler activity along with Web browsers and potentially other apps.

On an Android 6.0+ device, in the normal case, if the server is configured properly with the above JSON, and if the app was compiled by the author of this book, the chooser is bypassed, and the user gets another instance of URLHandler. The “another instance” part can be controlled via Intent flags or manifest entries, as is covered in [the chapter on tasks](#).

However, this is not assured:

- If you compile and run the app, your signing key should not match the JSON-published fingerprint, and so the validation will fail and normal chooser behavior will return. You would have to substitute some URL of your own with a corresponding JSON file on that server that contains your hash.
- If the server is mis-configured (e.g., JSON not available via HTTPS), the validation will fail and normal chooser behavior will return.
- If the app is not signed with the correct signing key — such as the user is really running a copy of your app with injected malware and somebody else’s signing key — the validation will fail and normal chooser behavior will return.
- If there is no connectivity at the time the user installs the app (e.g., they are side-loading it), the validation will fail and normal chooser behavior will return. The device may try to validate again in the future, though.

User Intervention

Another thing that can change the behavior to return is if the user revokes the app link. Users can do this by going to the app’s screen in the Settings app and clicking the “Open by default” option:

RESPONDING TO URLS

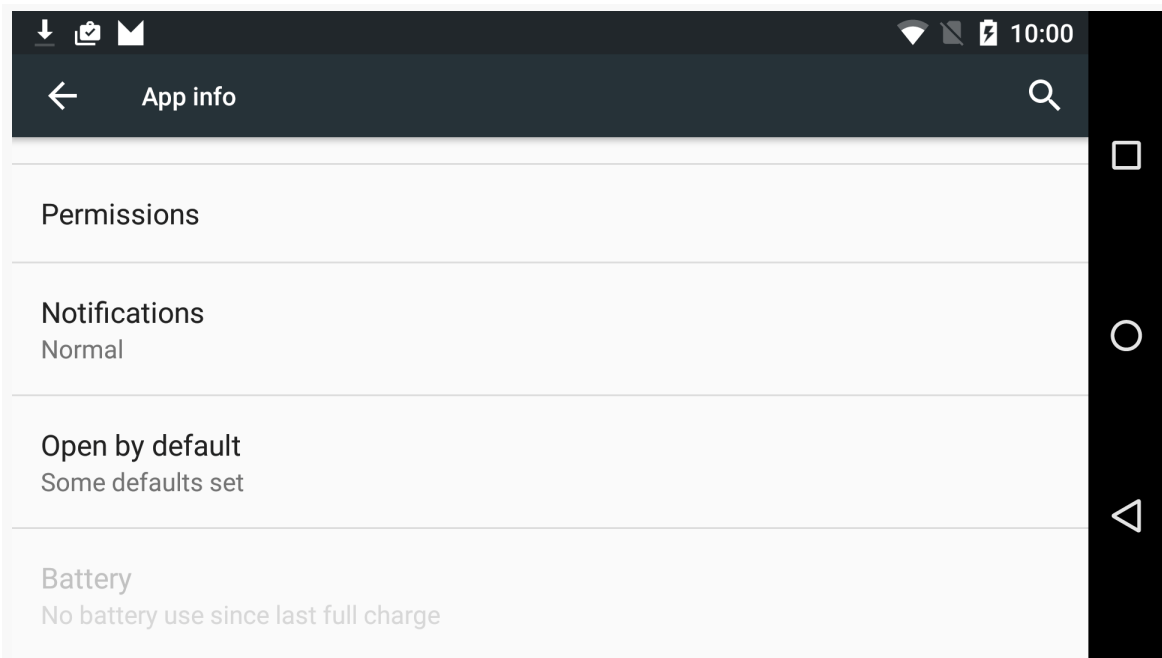

Figure 767: URLHandlerMNC in Settings, “Open by default” Visible

If the user taps that entry, one section of the next screen is entitled “App links” and gives the user the option to toggle the app link behavior off:

RESPONDING TO URLS

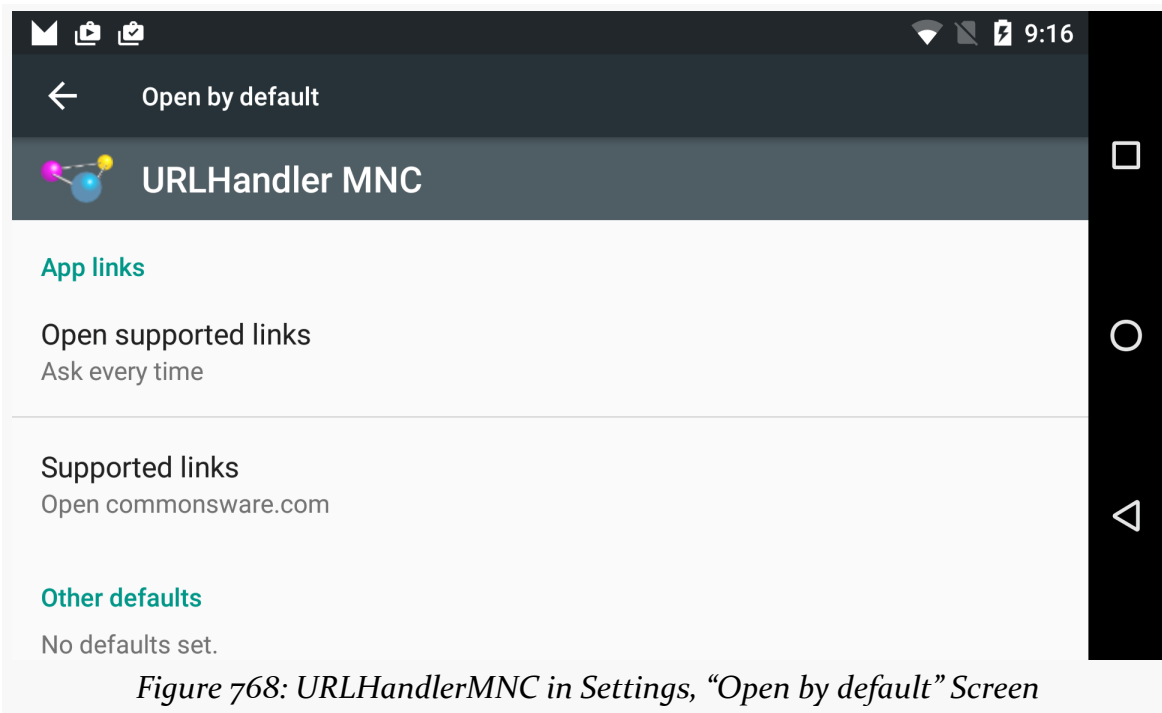

Figure 768: URLHandlerMNC in Settings, “Open by default” Screen

Unfortunately, the labeling here does not seem to work properly. The “Ask every time” choice shown selected here actually bypasses the chooser. The available choices are “open in this app”, “ask every time”, and “don’t open in this app”:

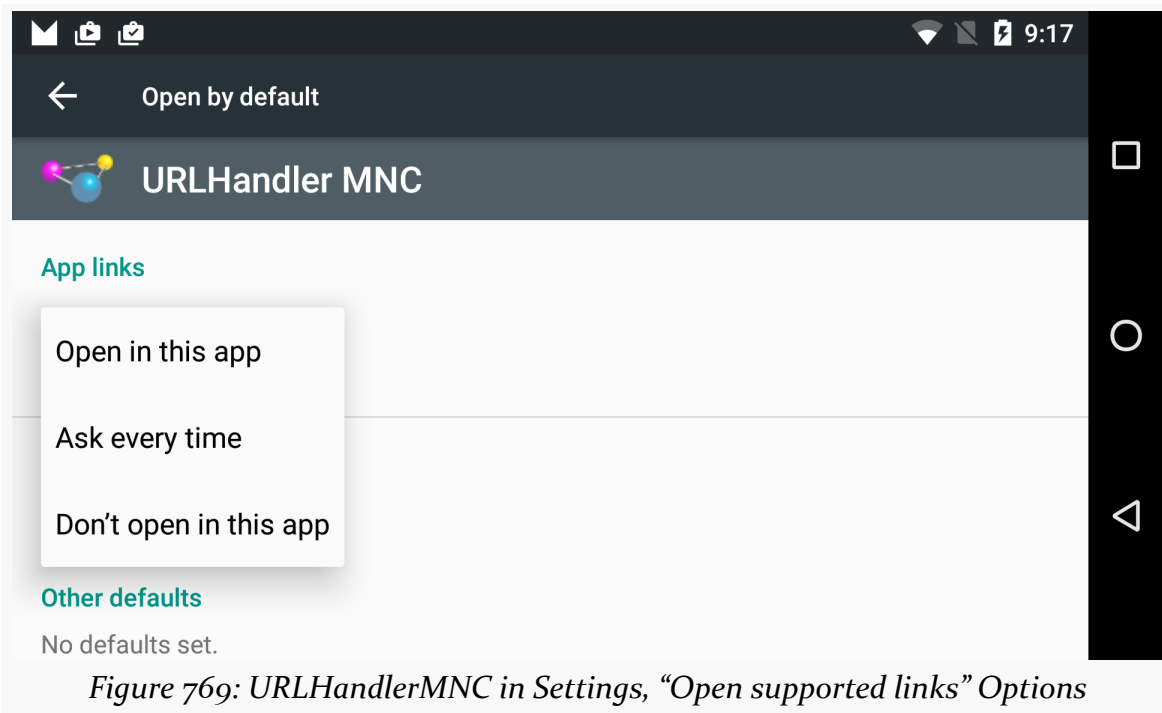

Figure 769: URLHandlerMNC in Settings, “Open supported links” Options

Testing Your Setup

You can confirm that other parties can see your `assetlinks.json` file by visiting the following URL:

```
https://digitalassetlinks.googleapis.com/v1/statements:list?  
source.web.site=https://DDDDD&  
relation=delegate_permission/common.handle_all_urls
```

(NOTE: the URL shown above is split across several lines for readability but should be all on one line when actually using the URL)

Replace DDDDD with the domain name for your site, and you should get a JSON document back that, among other things, contains the details from your `assetlinks.json` file:

```
{  
  "statements": [  
    {  
      "source": {  
        "web": {  
          "site": "https://commonsware.com."  
        }  
      },  
      "relation": "delegate_permission/common.handle_all_urls",  
    }  
  ]  
}
```

RESPONDING TO URLS

```
"target": {
  "androidApp": {
    "packageName": "com.commonware.android.urlhandler",
    "certificate": {
      "sha256Fingerprint": "A9:99:84:D8:...:60:5B:CB:E3"
    }
  }
},
],
"maxAge": "3213.779933024s"
}
```

(sha256Fingerprint truncated for readability)

If you try visiting that URL, and there is no `assetlinks.json` file available for that domain, you will get a JSON response back containing a `debugString` indicating the nature of the problem.

You can see if an Android device in your lab has successfully performed the app link validation by running the `adb shell dumpsys package domain-preferred-apps` command. This will list all of the apps that have app links, and your app should appear among them, in a stanza like this one:

```
Package: com.commonware.android.urlhandler
Domains: commonware.com
Status: never
```

The status will reflect the user's choice of how to handle your app link inside of Settings (the `never` shown above indicates that the user decided to ignore your app link and have your app never handle such URLs).

Plugin Patterns

Plugins have historically been a popular model for extending the functionality of a base application. Browsers, for example, have long used plugins for everything from playing Flash animations to displaying calendars.

While Android does not have a specific “plugin framework”, many techniques exist in Android to create plugins. Which of these patterns is appropriate for you will depend upon the nature of the host application and, more importantly, on the nature of the plugin. This chapter will explore some of these plugin patterns.

Prerequisites

Having read the chapters on [app widgets](#) (to be exposed to RemoteViews) and [the Loader framework](#) would be useful, though neither is essential for grasping the core concepts presented in this chapter. Similarly, this chapter has a case study that covers a [lockscreen widget](#), so knowing a bit about those will help, but is not absolutely essential. Another sample involves the use of custom permissions, which are subject to a [vulnerability covered in another chapter](#).

Definitions, Scenarios, and Scope

For the purposes of this chapter, a “plugin model” refers to an app (the plugin “host”) that is being extended by other apps (the “plugins”) that are largely dedicated to that job.

Certainly, there are plenty of ways that apps can work together without one being a plugin to another. The user’s Web browser is not a plugin of your app when you call `startActivity()` to view a Web page, for example.

By contrast, the [Locale app](#) can be extended via plugins, written either by two forty four a.m. (the authors of Locale) or third parties. These plugins have no real value to the user other than by how they improve what Locale itself can do. This sort of structure, therefore, qualifies as a plugin model.

In particular, this chapter will focus on two general scenarios for wanting a plugin model, though others certainly exist:

1. You want to allow third parties to extend the capability of your app, much as two forty four a.m. wanted with Locale, or
2. You want to reduce the number of permissions in your core app by delegating some permissions to plugins, so users can “opt into” those permissions

The Keys to Any Plugin System

There are four essential ingredients for any plugin model:

1. Somehow, the user has to be able to find, download, and install plugins for the host.
2. Somehow, the host app has to know what plugins are installed and available for use.
3. Somehow, the host app and the plugin need to communicate, usually through one form or another of inter-process communication (IPC)
4. All of this needs to be done without compromising the user’s privacy or security

Depending upon the nature of the host app and plugin system, there may need to be additional ingredients (e.g., allowing users to configure the behavior of plugins).

Discovery... By the User

A popular thought experiment is:

If a tree falls in a forest and no one is around to hear it, does it make a sound?

The analog to plugins is:

If an app offers a plugin model, and the user cannot find any plugins, is there really a plugin model?

Somehow, users need to know about available plugins, and frequently that means that *you* will need to help steer them towards those plugins.

If you are focused solely on distributing through the Play Store, you could invite all of your plugin authors to use some particular keyword or phrase, likely to be unique for your plugins, then use `market://search?q=...&c=apps` (with `...` replaced by your keyword or phrase) as a `Uri` for an `ACTION_VIEW` Intent passed to `startActivity()`. This will show the user a list of all apps on the Play Store with that keyword or phrase. For example, SONY suggested that developers writing extensions for the SONY SmartWatch use “smartwatch” as a keyword.

Of course, you are welcome to maintain your own roster of available plugins, where your app can download that roster as needed and display the candidates to your users. For example, you might have a JSON file on your Web server at a well-known URL that contains the current lineup of available plugins.

Or, you are welcome to simply offer this sort of information via your Web site, not from within your app. Depending upon how frequently users will be visiting your Web site, this may or may not be helpful to them, but it may be simpler than doing something custom built into your app. For example, you could maintain a simple static Web page with links to the plugins.

Discovery... By Your App

Once a user installs one or more plugins, your plugin host app needs to know that they are there. Continuing with the thought experiments:

If an app offers a plugin model, but fails to recognize any plugins, is there really a plugin model?

Conversely, once a user *removes* a plugin, your host app needs to know about that as well, so that you do not try to use a plugin that no longer exists.

There are any number of possible strategies for finding available plugins; the following sections outline a few candidates.

Broadcast-and-Response

One approach is to send a custom broadcast Intent, at relevant points in time, that is an advertisement to plugins, saying “Hey! Tell me that you exist!”. Plugins, as part of your instructions for writing a plugin, are obligated to respond to that broadcast by doing something to let you know about them, such as:

- Sending their own broadcast back to your host app, providing details about the plugin
- Inserting or updating an entry in a host-published ContentProvider
- Sending a command to a host-supplied IntentService
- Etc.

Any previously-existing plugins that do not respond within some specific period of time are considered “gone”, possibly with the host app using PackageManager and getPackageInfo() to confirm that it is gone.

This is fairly easy to set up, but suffers from non-deterministic timing of broadcasts. The host app can only guess when the broadcast has had enough time to reach all of the plugins and gather responses. It also forces all of those plugin apps to run (to respond to the broadcast), which will cause Android to eject other apps from memory, possibly irritating the user.

Another limitation is that a newly-installed plugin will not respond to a broadcast, on Android 3.1+, until something manually runs one of that plugin’s components, such as the user tapping on the plugin’s activity in the launcher. Not only does this require the plugin to have such an activity (which might not otherwise be needed), but it means that the plugin is useless until this happens. We will discuss this issue a bit more [later in this chapter](#).

Scanning with PackageManager

You could skip the broadcast and directly use PackageManager to find plugins. The benefit here is that the timing is deterministic — you know precisely when you are done with PackageManager. However, somehow, you will need to know what is and is not a plugin, in a way that you can determine by information returned from PackageManager.

If you happen to know the complete list of possible plugins, you could iterate over that list and use getPackageInfo() to see which ones exist and do not exist.

However, this reduces your flexibility, as it requires you to know up front the package names of all possible plugins.

Or, you could use `queryIntentActivities()`, `queryIntentServices()`, or `queryBroadcastReceivers()`, providing an `Intent` that identifies some operation a plugin is obligated to implement, to see what matches are found.

There is also a `queryContentProviders()`, but as it does not take an `Intent`, you would have to iterate over each returned `ProviderInfo` to try to determine if it is a `ContentProvider` representing a plugin.

Alternatively, you could call `getInstalledPackages()` on `PackageManager`, to find out about *everything* that is installed, then iterate over them looking for something.

Watching Package-Related Broadcasts

If using `PackageManager` to examine all possible plugins is still too slow, you could optimize things a bit by watching for `ACTION_PACKAGE_ADDED`, `ACTION_PACKAGE_REPLACED`, and `ACTION_PACKAGE_REMOVED` broadcasts, to monitor *changes* to the mix of installed packages. If a known plugin is removed, you can remove it from your roster of installed plugins. When packages are added or replaced, you could use `PackageManager` and `getPackageInfo()` to learn about that specific package, to determine if it represents one of your plugins.

This, however, increases the complexity of your app, as now you need to monitor these broadcasts and maintain your own roster of available plugins somewhere.

Discovery and Usage of the IPC Endpoints

Given that you know that you have a certain number of plugins, represented by a certain set of packages, you can work on actually communicating with them, using any of the available IPC mechanisms. Also, for static data, you have the option of using manifest metadata or well-known resources to publish that data.

No matter what you settle upon, though, you need to consider the impacts of changes to your host app, that might require changes to your interaction with plugins. Everything in this section qualifies as an API that your host app offers to plugins; changes to that API will require you to consider versioning and backwards compatibility.

Component IPC Options

Your plugin could:

- Have an activity, supporting an agreed-upon Intent structure, that your app opens as needed
- Have a service, supporting an agreed-upon Intent structure, that your app sends commands to or binds to as needed
- Have a BroadcastReceiver, supporting an agreed-upon Intent structure, that your app can send broadcasts to as needed

For any of those, you would use `setComponentName()` as part of the Intent, to specifically identify the plugin that you are talking to.

Your plugin could also have a `ContentProvider` that your host communicates with. That, however, requires that you somehow find out the appropriate authority to use. That authority might be obtained by an agreed-upon algorithm based upon the package name (e.g., the authority is the plugin's package name plus `.PROVIDER`). Or, that authority might be determined by some static data, techniques for which are described in the next section.

In any of these cases, your host's plugin model would document the expectations the host would have of the plugins:

- What Intent extras are supported, what their meanings are, and what the data types are for the extras' keys
- What the schema is for the `ContentProvider`
- Etc.

Your host could also be publishing activities, services, receivers, or providers for the plugin to use. So, for example, your host could send a command to a plugin's `IntentService`, that turns around and modifies data in your host's exported `ContentProvider`.

What data is transferred between the host and plugin, of course, is up to you. Bear in mind, though, that IPC cannot handle arbitrary objects. You will need to stick to primitives and basic collections, framework-supplied `Parcelable` classes (e.g., `Bundle`), or [your own custom Parcelable classes](#).

Static Data Options

Some information that you might need about the plugin is static. In those cases, you do not need to use IPC to get the data, thereby saving the cost of loading the plugin into memory just to invoke some component inside of it.

One option for static data is to use manifest metadata. Any `<activity>`, `<service>`, or `<receiver>` element can have one or more child `<meta-data>` elements. These can hold static data that your host app can read in. There are two major flavors of `<meta-data>` elements:

- A simple key/value pair, where the key is provided by `android:name` and the value is provided by `android:value`
- A key pointing to a resource ID to some other resource, frequently an XML resource (i.e., file in `res/xml/`), providing more details, where the key is in `android:name` and the resource ID is `android:resource`

You will see this approach used in places like app widgets, which use a `<meta-data>` element to point to the app widget metadata, which resides in a separate XML resource.

Your app reads in these values — as literals or identifiers to resources — by retrieving an `ActivityInfo` or `ServiceInfo` object from `PackageManager` for the component (e.g., `getActivityInfo()`, `getReceiverInfo()`, `getServiceInfo()`), then examining the `Bundle` in the `metaData` field of that `...Info` object.

There is nothing stopping you from requiring your plugins implement certain resources or assets in agreed-upon paths. You could then access those resources — or ones from `android:resource` in a `<meta-data>` element — via a `Context` created from `createPackageContext()`. `createPackageContext()` is available on any `Context`, such as an `Activity` or `Service`. Given the package name of your plugin, it gives you a `Context` object that you can use to retrieve resources (`getResources()`) or assets (`getAssets()`) much as you do with one of your own contexts.

Versioning

Any time you are providing programmatic access to your app to others, or any time you are expecting others to provide programmatic access to their apps based upon your specification, you need to bear in mind that your needs may change over time. You may want additional extras, or new bits of static data, or new Intent actions. And while you can change your app to take into account your new requirements:

PLUGIN PATTERNS

- You have no means of forcing third-party developers to update their apps in lock-step with yours
- You have no means of forcing users to update their plugins and such in lock-step with updating your host app

Hence, you are going to need to deal with versioning your plugin API and supporting older API versions, to offer backwards compatibility for not-yet-updated plugins.

A `<meta-data>` element is perhaps the easiest way to have plugins declare what API version they support. This way, you can find out what “language” the plugin speaks before you try talking to it.

When you then communicate via IPC to the plugins, you will need to take into account what API version the plugin speaks, and adjust your communications accordingly. For example, if you are binding to a plugin’s service, you would need to make sure that you are using the right AIDL, to get the right client-side proxy object, one that has the methods and parameters that the plugin supports.

Conversely, if you are providing ways for plugins to initiate communications back to you, you will have to take into account that plugins could be using any outstanding API version. You might elect to use different Intent actions or provider authorities to help distinguish the API versions. For example, the plugin sending a command to your service might use `com.suchandso.app.ACTION_PLUGIN.V1` or `com.suchandso.app.ACTION_PLUGIN.V2` in its Intent, so you have the flexibility of having a single Service handle both of those operations, or splitting them into separate Service classes if you feel that will help improve maintainability.

On the whole:

- Be careful in what you send to the plugins. If you claim that certain extras are of certain data types, stick with that, trying to avoid sending other data types that the plugins might not expect.
- Be generous in what you accept from the plugins, particularly where you are changing what you accept from version to version of your API. If you declared that an extra sent to you was originally an `int` and now is a `String`, ideally your new-version code would accept *either* an `int` or a `String`, to help ease the transition.
- Be slow to discontinue support for old API versions. You might use analytics or other data collection mechanisms to get a sense for how many devices are using plugins that speak a particular API version, to give you an idea of how

much grief you will get from users if you drop support for that API version and therefore disable certain plugins in an upgrade to your app.

Security

Any time you have inter-process communication, you open up security risks. Hence, intentionally doing IPC means that you intentionally have to consider how best to secure that IPC, to reduce those risks.

Here are three areas of security for you to consider with your plugin model:

User Safe from Permission Leakage

Your plugins, and perhaps the plugin host, may hold various Android permissions, like `READ_CONTACTS` or `INTERNET`. It is incumbent upon you to make sure that either:

- You do not expose information tied to such permissions through your plugin model API (either the host talking to a plugin or vice versa) in a way that other apps could intercept, or
- You ensure that the other party holds the same permission, so that the user knows that the secured information is moving from point to point

For example, suppose that your host app does not hold `READ_CONTACTS`, but a plugin does, specifically to allow the host app to get access to contact information. You need to make sure that, while the host app can get this contact information from the plugin, nobody else can.

Ideally, a plugin developer can be confident that, when the plugin sends information via IPC to the host app, that it is *really* the host app that the plugin is talking to. If some other app can pretend to be the host app, and intercept that information, that other app could potentially use that information to nefarious ends.

Partially, this is an extension of the permission leakage issue described above. It's bad enough that a plugin might leak data to a host app that is not authorized for that data; it is worse if some other app can intercept that data as well.

However, it may be that the data being transferred is not covered by an explicit Android permission, yet might represent information that the user is expecting to keep secure. A financial planner host app using plugins to collect a user's financial data from various banks and brokerages should be taking steps to ensure that the plugin data *only* flows back to the host app, and not to any other apps. This comes

despite the fact that Android does not have an `ACCESS_FINANCIAL_DATA` permission as part of the core operating system.

Mostly, this involves having the plugin explicitly state the component that it is communicating with via IPC, rather than relying upon Android derive that information via Intent resolution or similar approaches. So, for example, rather than calling `startService()` with just an Intent action identifying the host, also set the `ComponentName` on the Intent to specifically direct the command to the host app, not to something else advertising that same Intent action.

If the host and all its plugins are written by the same firm, you can also use [signature-level permissions](#) to restrict access, limiting the IPC to only apps signed by the same signing key.

Host Safe from Trojans

Conversely, if the host app supplies information to the plugins that might represent private or secure data, we need to make sure that the user is comfortable with that data being transferred.

Partially, this involves creating a [custom permission](#) that plugins must hold, letting the user know at the time of installing the plugin that this data will be transferred.

Partially, this is making sure that this data is only delivered to the plugins (and, if possible, only to the plugins that specifically need this data). Hence, rather than broadcast Intents — even ones where you require a specific permission be held by the receiver — consider using other IPC options that are more “point-to-point”, such as sending commands to a specific service identified by its `ComponentName`.

Case Study: DashClock

A Googler’s take on an app with a plugin model can be found in [DashClock](#), written by Roman Nurik. DashClock is [open source](#), making it easy to see how he elected to implement his plugin model.

What is DashClock?

Android 4.2 added the notion of [lockscreen widgets](#), app widgets that can go on the lockscreen. DashClock is one such lockscreen widget, designed to replace the standard clock. But, more importantly, it offers a plugin model, so third-party apps

can provide dynamic data to be displayed by DashClock, without themselves having to have a lockscreen widget. Similarly, the user can just add DashClock to the lockscreen, not a whole bunch of individual lockscreen widgets.

Discovery... By the User

DashClock helps users find extensions by linking to the Play Store via the following URL: <http://play.google.com/store/search?q=DashClock+Extension&c=apps>.

Anyone publishing a DashClock extension merely needs to describe their app as having (or being) a DashClock extension, and they will automatically show up when the user requests to get more extensions from within DashClock's configuration activity.

DashClock extensions do not *have* to be installed via the Play Store, but DashClock will not directly help improve the “findability” of extensions distributed by other means.

Discovery... By Your App

At its core, DashClock finds extensions by scanning via `PackageManager`. Each extension is obligated to implement a service that advertises an `<action>` of `com.google.android.apps.dashclock.Extension`. DashClock then uses `queryIntentServices()` on `PackageManager` to find these services.

DashClock, however, has the notion of installed versus active extensions. Just because a user installed some app that happens to implement a DashClock extension does not necessarily mean that the user *wants* that app's content cluttering up her DashClock lockscreen widget. Instead, the user not only has to install the app, but tell DashClock to activate that extension. Hence, DashClock has an activity that shows a list of all installed extensions and allows the user to toggle them between active and inactive states (plus order them, etc.).

It is conceivable that the user installs a DashClock extension while this extension-configuration activity is running. Hence, while this activity is running, DashClock registers a `BroadcastReceiver`, via `registerReceiver()`, for the package-management broadcasts (e.g., `ACTION_PACKAGE_ADDED`). Upon receipt of the broadcast, DashClock goes through the original logic to scan using `PackageManager` to find available extensions, then updates the list to match any changes (added extensions, removed extensions, etc.).

DashClock also monitors for the many of the same broadcasts via a manifest-registered receiver, so it knows when extensions are replaced or removed. In those cases, DashClock needs to determine whether the extension had been active, and if so, what is now required (e.g., removing the extension from the lockscreen widget once it is uninstalled).

Discovery and Usage of the IPC Endpoints

The DashClock app, serving as the plugin host, communicates with its plugins in three main ways:

- Via the aforementioned service, usually implemented as a `DashClockExtension`, which allows DashClock to proactively request that plugins publish updates to their data
- Via an optional “settings activity”, which DashClock links to from the extension list, so users can configure the behavior of this specific extension
- Via metadata in the `<service>` element for the `DashClockExtension`

One of the key pieces of metadata is the `protocolVersion`, which tells DashClock what version of the DashClock plugin API the plugin supports.

The plugin turns around and communicates back to DashClock via a service, exported by DashClock under an agreed-upon action. The extension uses this service to publish updates to the data that should be shown for this extension in DashClock’s lockscreen widget, much along the lines of how an `AppWidgetProvider` tells the `AppWidgetManager` to update an app widget.

Security

DashClock defines a custom `READ_EXTENSION_DATA` permission. Extensions protect their services by requiring this permission (`android.permission = "com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA"`), so that the user knows about apps seeking to communicate with the extension. Such apps need to hold the `READ_EXTENSION_DATA` permission, meaning that the user will be informed at installation time about the app wishing to speak with DashClock extensions.

Other Plugin Examples

DashClock shows one way of implementing a plugin model, but it is certainly not the only possible implementation. The following sections review some other approaches, to contrast with DashClock's approach.

Plugins by Remote

The biggest challenge with plugins comes at the UI level. While there are many ways to integrate applications for background work (remote services, broadcast Intents, etc.), blending user interfaces is a problem. It is unsafe to have an application execute some plugin's code in its own process, as the plugin may be malicious in nature. Yet, the plugin cannot directly add widgets to the host app's activities any other way.

The key word in that last sentence, of course, is "directly".

There is an indirect way of having one app supply UI components to another app, in the form of the `RemoteViews` object. This is used by app widgets and custom Notifications, covered elsewhere in this book.

The plugin can create a `RemoteViews` structure describing the desired UI and deliver that `RemoteViews` to the host app, which can then render that `RemoteViews` wherever it is needed.

This section will outline some of the mechanics behind creating such a UI-centric plugin mechanism.

RemoteViews, Beyond App Widgets

`RemoteViews` are used in a few other places besides app widgets, such as custom Notification views. However, you can use `RemoteViews` yourself easily enough. You create one as you would for any other circumstance, like an app widget. To display one, you can use the `apply()` method on the `RemoteViews` object. The `apply()` method takes two parameters:

1. Your Context, typically your Activity
2. The container into which the contents of the `RemoteViews` will eventually reside

The `apply()` method returns the `View` specified by the rules poured into the `RemoteViews` object... but it does not add it to the container specified in that second parameter. Hence, `apply()` is a bit like calling the three-parameter `inflate()` on a `LayoutInflater` and passing `false` for the third parameter — you are still responsible for actually adding the `View` to the parent when appropriate.

And that's pretty much it.

Since a `RemoteViews` object implements the `Parcelable` interface, you can store a `RemoteViews` in an `Intent` extra, a `Bundle`, or anything else that works with `Parcelable` (e.g., AIDL-defined remote service interfaces). This is what makes `RemoteViews` so valuable – you can pass one to another process, which can `apply()` it to its own UI.

As a result, `RemoteViews` are a secure way for a plugin to contribute to some host activity's UI. In fact, you can think of an app widget as being a “plugin” for the UI of the home screen.

Thinking About Plugins

So, what does our plugin implementation need?

You have one application (the host) that will be able to display the `RemoteViews` supplied by other applications (the plugins). Somehow, the host will need to know:

1. What plugins are installed
2. How to get `RemoteViews` from the plugins to the host
3. Whether there are plugins that are installed that the user does not want (e.g., app widgets not added to the home screen) or if the user wants to see multiple `RemoteViews` from the same plugin (e.g., multiple instances of an app widget)

As is discussed earlier in this chapter, there are any number of ways of implementing these. The sample shown below will use a broadcast `Intent` to find plugins and another broadcast `Intent` to retrieve `RemoteViews` on demand, while assuming that each plugin will deliver exactly one `RemoteViews`.

Similarly, the plugin will need to know:

1. How it will be activated by the host

PLUGIN PATTERNS

2. How it is supposed to deliver RemoteViews to the host (broadcast Intent? remote service API? something else?)
3. When it is supposed to deliver RemoteViews to the host (pulled by the host? pushed to the host? both?)
4. How many distinct instances of the plugin does the user want (e.g., multiple instances of the app widget), and what is the configuration data for each instance that makes one distinct from the next?

Let's take a look at the [RemoteViews/Host](#) and [RemoteViews/Plugin](#) sample applications. These are two apps, each in their own package, implementing a host/plugin relationship, with RemoteViews being generated by the plugin and displayed by the host.

In this sample, the plugin will respond to a broadcast Intent from the host with a broadcast of its own, signaling that it wishes to serve as a plugin. When the host sends a broadcast to retrieve the RemoteViews, the plugin will send a broadcast in response that contains the RemoteViews. And, to keep things simple, each plugin will only have one instance (and we will only have one plugin).

Finding Available Plugins

Our host is a simple activity containing a TextView as its only content. The expectation is that when the user chooses a Refresh options menu item, we will pull a RemoteViews from the plugin and display it.

That, of course, assumes that we have a plugin.

To find plugins, we will send a broadcast, with a custom action, ACTION_CALL_FOR_PLUGINS. Any plugin implementation would need a BroadcastReceiver set up in the manifest to respond to such an action.

To keep things simple, the host will only have one plugin. The plugin itself will be represented by a ComponentName object, identifying the implementation of the plugin, held in a pluginCN data member:

```
private ComponentName pluginCN=null;
```

(from [RemoteViews/Host/src/com/commonsware/android/rv/host/RemoteViewsHostActivity.java](#))

In onResume(), if we do not have a plugin yet, we send the broadcast to try to find one:

PLUGIN PATTERNS

```
@Override
public void onResume() {
    super.onResume();

    IntentFilter pluginFilter=new IntentFilter();

    pluginFilter.addAction(ACTION_REGISTER_PLUGIN);
    pluginFilter.addAction(ACTION_DELIVER_CONTENT);

    registerReceiver(plugin, pluginFilter, PERM_ACT_AS_PLUGIN, null);

    if (pluginCN == null) {
        sendBroadcast(new Intent(ACTION_CALL_FOR_PLUGINS));
    }
}
```

(from [RemoteViews/Host/src/com/commonsware/android/rv/host/RemoteViewsHostActivity.java](#))

Responding to the Call for Plugins

Over in our plugin implementation, we do indeed have a BroadcastReceiver — cunningly named Plugin — with a manifest entry set up to respond to our ACTION_CALL_FOR_PLUGINS broadcast.

What the host wants in response is to receive a broadcast from the plugin, with an action of ACTION_REGISTER_PLUGIN, and an extra of EXTRA_COMPONENT, containing the ComponentName of the BroadcastReceiver that is the plugin implementation. So, when Plugin receives an ACTION_CALL_FOR_PLUGINS broadcast, it does just that:

```
package com.commonsware.android.rv.plugin;

import android.content.BroadcastReceiver;
import android.content.ComponentName;
import android.content.Context;
import android.content.Intent;
import android.widget.RemoteViews;

public class Plugin extends BroadcastReceiver {
    public static final String ACTION_CALL_FOR_PLUGINS=
        "com.commonsware.android.rv.host.CALL_FOR_PLUGINS";
    public static final String ACTION_REGISTER_PLUGIN=
        "com.commonsware.android.rv.host.REGISTER_PLUGIN";
    public static final String ACTION_CALL_FOR_CONTENT=
        "com.commonsware.android.rv.host.CALL_FOR_CONTENT";
    public static final String ACTION_DELIVER_CONTENT=
        "com.commonsware.android.rv.host.DELIVER_CONTENT";
    public static final String EXTRA_COMPONENT="component";
    public static final String EXTRA_CONTENT="content";
    private static final String HOST_PACKAGE="com.commonsware.android.rv.host";

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (ACTION_CALL_FOR_PLUGINS.equals(i.getAction())) {
            Intent registration=new Intent(ACTION_REGISTER_PLUGIN);
```

PLUGIN PATTERNS

```
        registration.setPackage(HOST_PACKAGE);
        registration.putExtra(EXTRA_COMPONENT,
            new ComponentName(ctxt, getClass()));

        ctxt.sendBroadcast(registration);
    }
    else if (ACTION_CALL_FOR_CONTENT.equals(i.getAction())) {
        RemoteViews rv=
            new RemoteViews(ctxt.getPackageName(), R.layout.plugin);
        Intent update=new Intent(ACTION_DELIVER_CONTENT);

        update.setPackage(HOST_PACKAGE);
        update.putExtra(EXTRA_CONTENT, rv);
        ctxt.sendBroadcast(update);
    }
}
}
```

(from [RemoteViews/Plugin/src/com/commonsware/android/rv/plugin/Plugin.java](#))

For added security, we use `setPackage()` in the plugin, so the `ACTION_REGISTER_PLUGIN` broadcast can only be received by the host.

The host activity needs to receive `ACTION_REGISTER_PLUGIN` broadcasts. Hence, it has a `BroadcastReceiver` implementation, in the plugin data member, that it registers for `ACTION_REGISTER_PLUGIN` in `onResume()`. The plugin `BroadcastReceiver`, upon receiving an `ACTION_REGISTER_PLUGIN` broadcast, grabs the `ComponentName` out of the `EXTRA_COMPONENT` extra and stores it in `pluginCN`:

```
private BroadcastReceiver plugin=new BroadcastReceiver() {
    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (ACTION_REGISTER_PLUGIN.equals(i.getAction())) {
            pluginCN=(ComponentName)i.getParcelableExtra(EXTRA_COMPONENT);
        }
        else if (ACTION_DELIVER_CONTENT.equals(i.getAction())) {
            RemoteViews rv=(RemoteViews)i.getParcelableExtra(EXTRA_CONTENT);
            ViewGroup frame=(ViewGroup)findViewById(android.R.id.content);

            frame.removeAllViews();

            View pluginView=rv.apply(RemoteViewsHostActivity.this, frame);

            frame.addView(pluginView);
        }
    }
};
```

(from [RemoteViews/Host/src/com/commonsware/android/rv/host/RemoteViewsHostActivity.java](#))

At this point, we wait for the user to click the Refresh options menu item.

Requesting RemoteViews

When the user does indeed choose Refresh, we call a `refreshPlugin()` method on the host activity:

```
private void refreshPlugin() {
    Intent call=new Intent(ACTION_CALL_FOR_CONTENT);

    call.setComponent(pluginCN);
    sendBroadcast(call);
}
```

(from [RemoteViews/Host/src/com/commonsware/android/rv/host/RemoteViewsHostActivity.java](https://commonsware.com/android/rv/host/RemoteViewsHostActivity.java))

Here, we send an `ACTION_CALL_FOR_CONTENT` broadcast, with the target component set to be the plugin implementation, as identified by its `ComponentName`. This ensures that this broadcast will only go to that plugin app and nobody else.

Responding with RemoteViews

Our `Plugin` is also registered in the manifest to respond to `ACTION_CALL_FOR_CONTENT`. So, when that broadcast arrives, it can create the `RemoteViews` in response, sending it out via an `ACTION_DELIVER_CONTENT` broadcast back to the host. Once again, we use `setPackage()` to restrict the broadcast to be the host's package. The broadcast also has the `RemoteViews` tucked in an `EXTRA_CONTENT` extra.

Our host activity registered the plugin `BroadcastReceiver` for `ACTION_DELIVER_CONTENT` as well. So, when that broadcast arrives, it can utilize the `RemoteViews`. We find the `ViewGroup` that is the root of our content (`android.R.id.content`), wipe out whatever is in it now, `apply()` the `RemoteViews` to that `ViewGroup`, and add the resulting `View` to the `ViewGroup`. This has the net effect of getting rid of our original `TextView` content, replacing it with whatever the plugin poured into the `RemoteViews`. Or, if the user chooses Refresh again, the older `RemoteViews`-generated content is replaced with fresh content.

Dealing with Android 3.1+

To test this, install the Host application, followed by the Plugin application. On Android 3.0 and older, running the Host and choosing the Refresh options menu item will change the display from its original state to the one with the plugin's `RemoteViews`.

PLUGIN PATTERNS

However, that will not work right away on Android 3.1 and higher.

On these versions of Android, applications are installed into a “stopped” state, where no BroadcastReceiver in the manifest will work, until the user manually runs the application. The simplest way to do that is via an activity. So, the Plugin project has a trivial activity that just displays a Toast and exits:

```
package com.commonware.android.rv.plugin;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class PluginActivationActivity extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);

        Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

(from [RemoteViews/Plugin/src/com/commonware/android/rv/plugin/PluginActivationActivity.java](#))

You will need to run this activity on Android 3.1 and higher first, then run the Host project’s activity, to get the plugin to work.

If you happen to install these on an Android 3.0 or older device, though, you may wonder if the author has lost his marbles. That is because you will not see any activity associated with the Plugin application.

Since the author has not owned marbles in a few decades, clearly there must be some other answer. In this case, we use a variation of a trick pointed out by Daniel Lew.

Our <activity> element in the manifest has an android:enabled attribute. A disabled activity does not show up in the launcher. But rather than have android:enabled specifically tied to true or false in the manifest, it references a boolean resource:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.rv.plugin"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk android:minSdkVersion="7" />
```

PLUGIN PATTERNS

```
<uses-permission android:name="com.commonware.android.rv.host.ACT_AS_PLUGIN" />

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <receiver
        android:name="Plugin"
        android:permission="com.commonware.android.rv.host.ACT_AS_HOST">
        <intent-filter>
            <action android:name="com.commonware.android.rv.host.CALL_FOR_PLUGINS" />
            <action android:name="com.commonware.android.rv.host.CALL_FOR_CONTENT" />
        </intent-filter>
    </receiver>

    <activity
        android:name="PluginActivationActivity"
        android:enabled="@bool/i_has_needs_activity"
        android:excludeFromRecents="true"
        android:theme="@android:style/Theme.NoDisplay">
        <intent-filter>
            <action android:name="android.intent.action.MAIN" />

            <category android:name="android.intent.category.LAUNCHER" />
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [RemoteViews/Plugin/AndroidManifest.xml](#))

In `res/values/booleans.xml`, we define that boolean resource to be false, meaning the activity will not appear in the launcher:

```
<resources>

    <bool name="i_has_needs_activity">false</bool>

</resources>
```

(from [RemoteViews/Plugin/res/values/booleans.xml](#))

But, in `res/values-v12/booleans.xml`, we define that boolean resource to be true, causing the activity to appear on Android 3.1 and higher:

```
<resources>

    <bool name="i_has_needs_activity">true</bool>

</resources>
```

(from [RemoteViews/Plugin/res/values-v12/booleans.xml](#))

This way, our extraneous activity does not clutter up older devices where it is not needed. [Mr. Lew's blog post](#) on this subject points out that this trick can be used to

have different implementations of an app widget for different Android versions (e.g., one that uses a `ListView` for API Level 11 and higher, plus one that does not for older devices).

The Permission Scheme

Another thing that these sample projects use are custom permissions, to help with security.

To serve as a plugin host, you must hold the `ACTS_AS_HOST` permission. To serve as a plugin implementation, you must hold the `ACTS_AS_PLUGIN` permission. These are defined in the Host project's manifest:

```
<permission
  android:name="com.commonware.android.rv.host.ACT_AS_HOST"
  android:description="@string/host_desc"
  android:label="@string/host_label">
</permission>
<permission
  android:name="com.commonware.android.rv.host.ACT_AS_PLUGIN"
  android:description="@string/plugin_desc"
  android:label="@string/plugin_label">
</permission>
```

(from [RemoteViews/Host/AndroidManifest.xml](#))

Each application then has its appropriate `<uses-permission>` element for the role that it plays, such as the Plugin holding the `ACTS_AS_PLUGIN` permission:

```
<uses-permission android:name="com.commonware.android.rv.host.ACT_AS_PLUGIN"/>
```

(from [RemoteViews/Plugin/AndroidManifest.xml](#))

The `BroadcastReceiver` defined by the Plugin project has, in its `<receiver>` element, the `android:permission` attribute, indicating that whoever sends a broadcast to this receiver must hold `ACTS_AS_HOST`:

```
<receiver
  android:name="Plugin"
  android:permission="com.commonware.android.rv.host.ACT_AS_HOST">
  <intent-filter>
    <action android:name="com.commonware.android.rv.host.CALL_FOR_PLUGINS"/>
    <action android:name="com.commonware.android.rv.host.CALL_FOR_CONTENT"/>
  </intent-filter>
</receiver>
```

(from [RemoteViews/Plugin/AndroidManifest.xml](#))

PLUGIN PATTERNS

Similarly, the `BroadcastReceiver` defined dynamically by the host activity uses a version of `registerReceiver()` that takes the permission the sender must hold:

```
registerReceiver(plugin, pluginFilter, PERM_ACT_AS_PLUGIN, null);
```

(from [RemoteViews/Host/src/com/commonsware/android/rv/host/RemoteViewsHostActivity.java](#))

That permission is defined in a static data member:

```
public static final String PERM_ACT_AS_PLUGIN=  
    "com.commonsware.android.rv.host.ACT_AS_PLUGIN";
```

(from [RemoteViews/Host/src/com/commonsware/android/rv/host/RemoteViewsHostActivity.java](#))

This way, the user is informed about the host/plugin relationship and can make appropriate decisions when they install plugins.

Note, though, that for this to work, the host application must be installed first, to define the custom permissions. If a plugin is installed before the host, there is no error, but the plugin will not be granted the as-yet-undefined custom permissions, and so the plugin will not work. The user would have to uninstall and reinstall the plugin after installing the host to fix this problem.

Other Plugin Features and Issues

It is possible for the `apply()` method on `RemoteViews` to throw a `RuntimeException`. For example, the `RemoteViews` might contain a reference to a widget ID that does not exist within the inflated views of the `RemoteViews` itself. Since `apply()` does not throw a checked exception, it is easy to do what we did in the sample app and assume `apply()` will succeed, but it very well may not. A robust implementation of this plugin system would wrap the `apply()` call in an exception handler that would do something useful if the plugin's `RemoteViews` has a bug.

You need to be a bit careful to make sure that a plugin can only update itself. The sample app assumes that the only thing that will send an `ACTION_DELIVER_CONTENT` broadcast to it will be the plugin, but that is not necessarily the case. In principle, anything that holds the `ACTS_AS_PLUGIN` permission could send an `ACTION_DELIVER_CONTENT` to the host, and thereby specify what the `RemoteViews` are. A robust plugin system would have some sort of shared secret, such as an identifier, between the host and the plugin, so another component cannot readily masquerade as being the plugin itself.

ContentProvider Plugins

Another way to extend your application at runtime is via plugins implemented via the ContentProvider framework. You could create new ContentProvider implementations that offer up data, perhaps using a consistent schema. Then, you could find those providers via a naming convention (e.g., for a main application with a package of `com.foo.abc`, your plugin apps would be `com.foo.abc.plugin.*`) and PackageManager, perhaps using a provider Uri naming convention to allow the host to know how to query the plugin.

However, there are other ways of employing a ContentProvider to help as a plugin, and this section explores one specific scenario: reducing the host app's permission requirements.

The Problem: Permission Creep

At the moment, for standard versions of Android, apps cannot request “conditional” or “optional” permissions, that the user could elect to opt out of. Instead, apps must request in their manifest all possible permissions that they could need. This is considered by many to be a significant limitation, but Google has stated repeatedly that they are not considering alternative strategies.

The net effect, though, is that an app often times needs a lot of permissions, or needs to add new permissions (requiring existing users to agree to the new permission list). Such lists of permissions can dissuade potential users from installing the app in the first place.

However, even though Android does not provide a simple and clean way for users to opt into (or out of) certain permissions for certain apps, plugins can offer a similar model. The base app can require some permissions for some features, with other features (and their respective permissions) added via plugins. Users can elect to install the plugins and agree to those permissions, or abandon or never install the plugins in the first place.

The hassle, of course, is in implementing the plugin APK and connecting to it from the main app. The plugin needs to have all the functionality that must directly use classes and methods secured by the permission. This can increase the complexity in maintaining the overall app.

A Solution: ContentProvider Proxies

Some permissions exist primarily to protect a ContentProvider, such as `READ_CONTACTS` and `WRITE_CONTACTS` for the `ContactsContract` provider.

The nice thing about the ContentProvider framework is that it is simply a contract. You use a `ContentResolver` and some magic values (`Uri`, “projection” of columns to return, etc.), and you get results. In fact, you can even change some of those magic values – any `Uri` supporting the same columns could be used with all the same client Java code, just by changing the `Uri` itself.

That allows us to create a proxy for ContentProvider. The proxy APK will hold the permission and call the real ContentProvider as needed. The proxy APK will expose its own ContentProvider, with a different `Uri`. Done properly — such that only the host app can use the proxy — the proxy will isolate the permission(s) for the real ContentProvider in the plugin. A `ContactsContract` proxy, for example, could hold `READ_CONTACTS` and `WRITE_CONTACTS`, proxying requests on behalf of a main app that lacks those permissions.

To secure the proxy, we need to ensure that only our apps can use the proxy, not anyone else’s apps. Otherwise, those third-party apps could get at, say, contacts without the `READ_CONTACTS` permission.

The simplest way to accomplish this is to use a signature-level custom permission.

Any app can declare a new permission via the `<permission>` element in the manifest. Normally, any app can request to hold this permission via `<uses-permission>`, and the user will be able to grant or deny this request at install time, just like any system-defined permission.

However, it is possible to add an `android:protectionLevel="signature"` attribute to the `<permission>` element. In this case, only apps signed by the same signing key will be able to request the permission — everyone else is automatically denied. Furthermore, apps signed by the same signing key will automatically get the permission without the user having to approve it.

So, you can have the proxy require a signature-level custom permission, thereby limiting possible consumers of the proxy to be signed by the same signing key.

PLUGIN PATTERNS

Let's look at a pair of projects that create and consume a proxy for the CallLog ContentProvider. These projects are located in the Introspection/CppProxy directory and are named [Provider](#) and [Consumer](#), respectively.

Note that this sample works only on API Level 11 and higher, due to the consumer's use of the native implementation of the Loader framework.

Provider

Most of the logic for our provider proxy can be found in the AbstractCppProxy base class. It implements the mandatory methods for the ContentProvider contract — such as insert() — and simply turns around and forwards those requests along to another provider:

```
@Override
public Cursor query(Uri uri, String[] projection, String selection,
                   String[] selectionArgs, String sortOrder) {
    checkTainted();

    Cursor result=
        getContext().getContentResolver().query(convertUri(uri),
                                                projection, selection,
                                                selectionArgs,
                                                sortOrder);

    return(new CrossProcessCursorWrapper(result));
}

@Override
public Uri insert(Uri uri, ContentValues values) {
    checkTainted();

    return(getContext().getContentResolver().insert(convertUri(uri),
                                                    values));
}

@Override
public int update(Uri uri, ContentValues values, String selection,
                 String[] selectionArgs) {
    checkTainted();

    return(getContext().getContentResolver().update(convertUri(uri),
                                                    values, selection,
                                                    selectionArgs));
}

@Override
public int delete(Uri uri, String selection, String[] selectionArgs) {
    checkTainted();

    return(getContext().getContentResolver().delete(convertUri(uri),
                                                    selection,
                                                    selectionArgs));
}
```

PLUGIN PATTERNS

```
}  
  
@Override  
public String getType(Uri uri) {  
    checkTainted();  
  
    return(getContext().getContentResolver().getType(convertUri(uri)));  
}
```

(from [Introspection/CppProxy/Provider/src/com/commonsware/android/cpproxy/provider/AbstractCppProxy.java](#))

The `checkTainted()` calls are part of our confirming that our custom permission is OK, and that is covered in [the chapter on advanced permissions](#). For the purposes of this chapter, just ignore them (along with the `onCreate()` method not shown here).

It is up to a subclass of `AbstractCppProxy` to implement the `convertUri()` method, which takes the `Uri` supplied by the consumer and transforms it into the proper `Uri` to use for making the real request. In this case, our subclass is `CallLogProxy`:

```
package com.commonsware.android.cpproxy.provider;  
  
import android.content.ContentUris;  
import android.net.Uri;  
import android.provider.CallLog;  
  
public class CallLogProxy extends AbstractCppProxy {  
    protected Uri convertUri(Uri uri) {  
        long id=ContentUris.parseId(uri);  
  
        if (id >= 0) {  
            return(ContentUris.withAppendedId(CallLog.Calls.CONTENT_URI, id));  
        }  
  
        return(CallLog.Calls.CONTENT_URI);  
    }  
}
```

(from [Introspection/CppProxy/Provider/src/com/commonsware/android/cpproxy/provider/CallLogProxy.java](#))

Here, we grab the instance ID off the end of the `Uri` (if it exists) and generate a new `Uri` based on `CallLog.CONTENT_URI`, indicating that we want to forward our requests to the `CallLog`.

The biggest complexity of the standard CRUD `ContentProvider` methods comes with `query()`. The `Cursor` returned by `query()` must implement the `CrossProcessCursor` interface. The `SQLiteCursor` implementation supports this interface, which is why typical providers do not worry about this requirement. However, the `Cursor` returned by `query()` on `ContentResolver` is not necessarily a `CrossProcessCursor`. Hence, we need to wrap it in a `CursorWrapper` that does implement `CrossProcessCursor`:

PLUGIN PATTERNS

```
@Override
public Cursor query(Uri uri, String[] projection, String selection,
    String[] selectionArgs, String sortOrder) {
    checkTainted();

    Cursor result=
        getContext().getContentResolver().query(convertUri(uri),
            projection, selection,
            selectionArgs,
            sortOrder);

    return(new CrossProcessCursorWrapper(result));
}
```

(from [Introspection/CPPProxy/Provider/src/com/commonsware/android/cpproxy/provider/AbstractCPPProxy.java](https://github.com/commonsware/android-cpproxy-provider/blob/master/src/com/commonsware/android/cpproxy/provider/AbstractCPPProxy.java))

The resulting CrossProcessCursorWrapper, as originally shown in [a Stack Overflow answer](#), looks like this:

```
// following from
// http://stackoverflow.com/a/5243978/115145

public class CrossProcessCursorWrapper extends CursorWrapper
    implements CrossProcessCursor {
    public CrossProcessCursorWrapper(Cursor cursor) {
        super(cursor);
    }

    @Override
    public CursorWindow getWindow() {
        return null;
    }

    @Override
    public void fillWindow(int position, CursorWindow window) {
        if (position < 0 || position > getCount()) {
            return;
        }
        window.acquireReference();
        try {
            moveToPosition(position - 1);
            window.clear();
            window.setStartPosition(position);
            int columnNum=getColumnCount();
            window.setNumColumns(columnNum);
            while (moveToNext() && window.allocRow()) {
                for (int i=0; i < columnNum; i++) {
                    String field=getString(i);
                    if (field != null) {
                        if (!window.putString(field, getPosition(), i)) {
                            window.freeLastRow();
                            break;
                        }
                    }
                }
            }
        } else {
            if (!window.putNull(getPosition(), i)) {
                window.freeLastRow();
                break;
            }
        }
    }
}
```

PLUGIN PATTERNS

```
    }
    }
    }
}
catch (IllegalStateException e) {
    // simply ignore it
}
finally {
    window.releaseReference();
}
}

@Override
public boolean onMove(int oldPosition, int newPosition) {
    return true;
}
}
```

(from [Introspection/CProxy/Provider/src/com/commonsware/android/cpproxy/provider/AbstractCProxy.java](https://github.com/CommonWare/android-cpproxy-provider/blob/master/src/com/commonsware/android/cpproxy/provider/AbstractCProxy.java))

Note that this implementation has been largely untested by this book's author, though it appears to work.

The manifest for this project has three items of note:

- It has the `<uses-permission>` element for `READ_CONTACTS`, while our consumer project will not
- It has a `<permission>` element, defining a custom `com.commonsware.android.cpproxy.PLUGIN` permission that has signature-level protection
- It has our `<provider>`, requiring that custom permission, and declaring its authority to be `com.commonsware.android.cpproxy.CALL_LOG`

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.cpproxy.provider"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="9"
        android:targetSdkVersion="11"/>

    <uses-permission android:name="android.permission.READ_CONTACTS"/>

    <permission
        android:name="com.commonsware.android.cpproxy.PLUGIN"
        android:protectionLevel="signature">
    </permission>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
```

PLUGIN PATTERNS

```
<provider
  android:name=".CallLogProxy"
  android:authorities="com.commonware.android.cproxy.CALL_LOG"
  android:permission="com.commonware.android.cproxy.PLUGIN">
</provider>
</application>
</manifest>
```

(from [Introspection/CPPProxy/Provider/AndroidManifest.xml](#))

Note that a complete AbstractCPPProxy implementation should forward along all the other methods as well (e.g., call()).

Consumer

Our Consumer project is nearly identical to the CalendarContract sample [from elsewhere in this book](#).

However, instead of the READ_CONTACTS permission, we declare that we need the com.commonware.android.cproxy.PLUGIN permission instead:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.cproxy.consumer"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="11"
    android:targetSdkVersion="11"/>

  <uses-permission android:name="com.commonware.android.cproxy.PLUGIN" />

  <permission
    android:name="com.commonware.android.cproxy.PLUGIN"
    android:protectionLevel="signature">
  </permission>

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name=".CPPProxyConsumerActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
</manifest>
```

PLUGIN PATTERNS

(from [Introspection/CPProxy/Consumer/AndroidManifest.xml](#))

Also, our CONTENT_URI is no longer the one found on CallLog, but rather one identifying our proxy:

```
private static final Uri CONTENT_URI=  
    Uri.parse("content://com.commonware.android.cproxy.CALL_LOG");
```

(from [Introspection/CPProxy/Consumer/src/com/commonware/android/cproxy/consumer/CPProxyConsumerActivity.java](#))

And there are minor changes because we are querying CallLog (indirectly) rather than CalendarContract, such as a change in the columns for our projection:

```
private static final String[] PROJECTION=new String[] {  
    CallLog.Calls._ID, CallLog.Calls.NUMBER, CallLog.Calls.DATE };
```

(from [Introspection/CPProxy/Consumer/src/com/commonware/android/cproxy/consumer/CPProxyConsumerActivity.java](#))

Otherwise, the consumer projects are the same. The difference is that our consumer project does not need the READ_CONTACTS permission the same way that the original needed the READ_CALENDAR permission.

In this case, the consumer project depends entirely upon the existence of the plugin — otherwise, the consumer project has no value. Hence, in this case, going the plugin route is silly. But an application that could use the CallLog but does not depend upon it could use this approach to isolate the READ_CONTACTS requirement in a plugin, so users could elect to install the plugin or not, and the main app would not need to request READ_CONTACTS and add to the roster of permissions the user must agree to up front.

Note that, in principle, the consumer should contain some of the same defenses against custom permission changes that the proxy does (in the form of those checkTainted() calls). This is covered in greater detail in [the chapter on advanced permissions](#).

Limitations of the Approach

There will be additional overhead in using the proxy, which will hamper performance. Ideally, this plugin mechanism is only used for features that need light use of the protected ContentProvider, so the overhead will not be a burden to the user.

PackageManager Tricks

`PackageManager` is your primary means of introspection at the component level, to determine what else is installed on the device and what components they export (activities, etc.). As such, there are many ways you can use `PackageManager` to determine if something you want is possible or not, so you can modify your behavior accordingly (e.g., disable action bar items that are not possible).

This chapter will outline some ways you can use `PackageManager` to find out what components are available to you on a device.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Asking Around

The ways to find out whether there is an activity that will respond to a given `Intent` are by means of `queryIntentActivityOptions()` and the somewhat simpler `queryIntentActivities()`.

The `queryIntentActivityOptions()` method takes the caller `ComponentName`, the “specifics” array of `Intent` instances, the overall `Intent` representing the actions you are seeking, and the set of flags. It returns a `List` of `Intent` instances matching the stated criteria, with the “specifics” ones first.

PACKAGEMANAGER TRICKS

If you would like to offer alternative actions to users, but by means other than `addIntentOptions()`, you could call `queryIntentActivityOptions()`, get the `Intent` instances, then use them to populate some other user interface (e.g., a toolbar).

A simpler version of this method, `queryIntentActivities()`, is used by the [Introspection/Launchalot](#) sample application. This presents a “launcher” — an activity that starts other activities — but uses a `ListView` rather than a grid like the Android default home screen uses.

Here is the Java code for `Launchalot` itself:

```
package com.commonware.android.launchalot;

import android.app.ListActivity;
import android.content.ComponentName;
import android.content.Intent;
import android.content.pm.ActivityInfo;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.ArrayAdapter;
import android.widget.ImageView;
import android.widget.ListView;
import android.widget.TextView;
import java.util.Collections;
import java.util.List;

public class Launchalot extends ListActivity {
    ArrayAdapter adapter=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        PackageManager pm=getPackageManager();
        Intent main=new Intent(Intent.ACTION_MAIN, null);

        main.addCategory(Intent.CATEGORY_LAUNCHER);

        List<ResolveInfo> launchables=pm.queryIntentActivities(main, 0);

        Collections.sort(launchables,
            new ResolveInfo.DisplayNameComparator(pm));

        adapter=new ArrayAdapter(pm, launchables);
        setListAdapter(adapter);
    }

    @Override
    protected void onItemClick(ListView l, View v,
        int position, long id) {
        ResolveInfo launchable=adapter.getItem(position);
```

PACKAGEMANAGER TRICKS

```
ActivityInfo activity=launchable.activityInfo;
ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                     activity.name);
Intent i=new Intent(Intent.ACTION_MAIN);

i.addCategory(Intent.CATEGORY_LAUNCHER);
i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
           Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
i.setComponent(name);

startActivity(i);
}

class AppAdapter extends ArrayAdapter<ResolveInfo> {
    private PackageManager pm=null;

    AppAdapter(PackageManager pm, List<ResolveInfo> apps) {
        super(Launchalot.this, R.layout.row, apps);
        this.pm=pm;
    }

    @Override
    public View getView(int position, View convertView,
                       ViewGroup parent) {
        if (convertView==null) {
            convertView=newView(parent);
        }

        bindView(position, convertView);

        return(convertView);
    }

    private View newView(ViewGroup parent) {
        return(getLayoutInflater().inflate(R.layout.row, parent, false));
    }

    private void bindView(int position, View row) {
        TextView label=(TextView)row.findViewById(R.id.label);

        label.setText(getItem(position).loadLabel(pm));

        ImageView icon=(ImageView)row.findViewById(R.id.icon);

        icon.setImageDrawable(getItem(position).loadIcon(pm));
    }
}
}
```

(from [Introspection/Launchalot/app/src/main/java/com/commonsware/android/launchalot/Launchalot.java](https://commonsware.com/android/launchalot/Launchalot.java))

In onCreate(), we:

1. Get a PackageManager object via getPackageManager()
2. Create an Intent for ACTION_MAIN in CATEGORY_LAUNCHER, which identifies activities that wish to be considered “launchable”

PACKAGEMANAGER TRICKS

3. Call `queryIntentActivities()` to get a List of `ResolveInfo` objects, each one representing one launchable activity
4. Sort those `ResolveInfo` objects via a `ResolveInfo.DisplayNameComparator` instance
5. Pour them into a custom `AppAdapter` and set that to be the contents of our `ListView`

`AppAdapter` is an `ArrayAdapter` subclass that maps the icon and name of the launchable Activity to a row in the `ListView`, using a custom row layout.

Finally, in `onListItemClick()`, we construct an `Intent` that will launch the clicked-upon Activity, given the information from the corresponding `ResolveInfo` object. Not only do we need to populate the `Intent` with `ACTION_MAIN` and `CATEGORY_LAUNCHER`, but we also need to set the component to be the desired Activity. We also set `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_RESET_TASK_IF_NEEDED` flags, following Android's own launcher implementation from the Home sample project. Finally, we call `startActivity()` with that `Intent`, which opens up the activity selected by the user.

The result is a simple list of launchable activities:

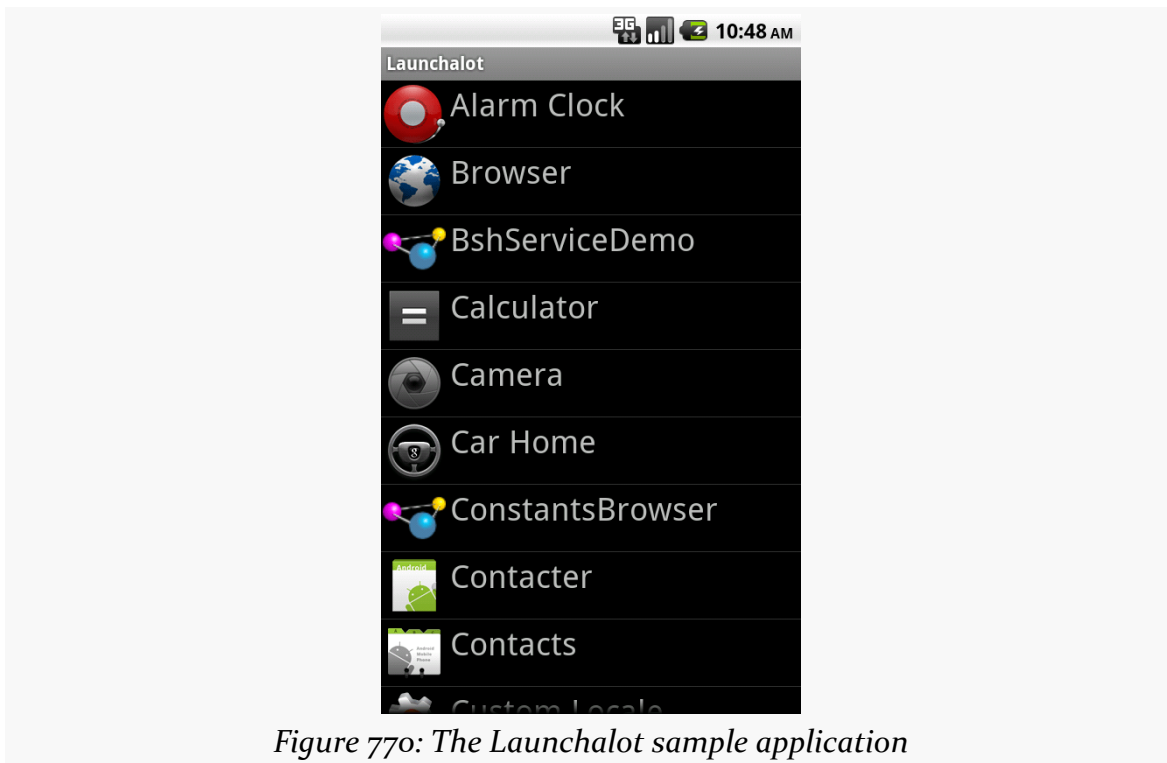

Figure 770: The Launchalot sample application

There is also a `resolveActivity()` method that takes a template `Intent`, as do `queryIntentActivities()` and `queryIntentActivityOptions()`. However, `resolveActivity()` returns the single best match, rather than a list.

NOTE: On modern versions of Android, there is a `LauncherApps` class that simplifies a lot of this and takes things like Android Work profiles into account. For really implementing a home screen-style launcher, you will probably want to use `LauncherApps`. However, using `PackageManager` to find what can handle certain `Intent` structures is used for other purposes beyond home screen launchers.

Preferred Activities

Users, when presented with a default activity chooser, usually have the option to make their next choice be the default for this action for now on. The next time they do whatever they did to bring up the chooser, it should go straight to this default. This is known in the system as the “preferred activity” for an `Intent` structure, and is stored in the system as a set of pairs of `IntentFilter` objects and the corresponding `ComponentName` of the preferred activity.

To find out what the preferred activities are on a given device, you can ask `PackageManager` to `getPreferredActivities()`. You pass in a `List<IntentFilter>` and a `List<ComponentName>`, and Android fills in those lists with the preferred activity information.

To see this in action, take a look at the [Introspection/PrefActivities](#) sample application. This simply loads all of the information into a `ListView`, using `android.R.layout.simple_list_item_2` as a row layout for a title-and-description pattern.

The `PackageManager` logic is confined to `onCreate()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    PackageManager mgr=getPackageManager();

    mgr.getPreferredActivities(filters, names, null);
    setListAdapter(new IntentFilterAdapter());
}
```

(from [Introspection/PrefActivities/app/src/main/java/com/commonsware/android/prefact/PreferredActivitiesDemoActivity.java](#))

In this case, the two lists are data members of the activity:

PACKAGEMANAGER TRICKS

```
ArrayList<IntentFilter> filters=new ArrayList<IntentFilter>();
ArrayList<ComponentName> names=new ArrayList<ComponentName>();
```

(from [Introspection/PrefActivities/app/src/main/java/com/commonsware/android/prefact/PreferredActivitiesDemoActivity.java](https://github.com/CommonsWare/android-prefact/blob/master/PreferredActivitiesDemoActivity.java))

Most of the logic is in formatting the ListView contents. IntentFilter, unfortunately, does not come with a method that gives us a human-readable dump of its definition. As a result, we need to roll that ourselves. Compounding the problem is that IntentFilter tends to return Iterator objects for its collections (e.g., roster of actions), rather than something Iterable. The activity leverages an Iterator-to-Iterable wrapper culled from [a Stack Overflow answer](#) to help with this. The IntentFilterAdapter and helper code looks like this:

```
// from http://stackoverflow.com/a/8555153/115145

public static <T> Iterable<T> in(final Iterator<T> iterator) {
    class SingleUseIterable implements Iterable<T> {
        private boolean used=false;

        @Override
        public Iterator<T> iterator() {
            if (used) {
                throw new IllegalStateException("Already invoked");
            }
            used=true;
            return iterator;
        }
    }
    return new SingleUseIterable();
}

class IntentFilterAdapter extends ArrayAdapter<IntentFilter> {
    IntentFilterAdapter() {
        super(PreferredActivitiesDemoActivity.this,
            android.R.layout.simple_list_item_2, android.R.id.text1,
            filters);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        TextView filter=(TextView)row.findViewById(android.R.id.text1);
        TextView name=(TextView)row.findViewById(android.R.id.text2);

        filter.setText(buildTitle(getItem(position)));
        name.setText(names.get(position).getClassName());

        return(row);
    }

    String buildTitle(IntentFilter filter) {
        StringBuilder buf=new StringBuilder();
        boolean first=true;

        if (filter.countActions() > 0) {
            for (String action : in(filter.actionsIterator())) {
```

PACKAGEMANAGER TRICKS

```
        if (first) {
            first=false;
        }
        else {
            buf.append('/');
        }

        buf.append(action.replaceAll("android.intent.action.", ""));
    }
}

if (filter.countDataTypes() > 0) {
    first=true;

    for (String type : in(filter.typesIterator())) {
        if (first) {
            buf.append(" : ");
            first=false;
        }
        else {
            buf.append('|');
        }

        buf.append(type);
    }
}

if (filter.countDataSchemes() > 0) {
    buf.append(" : ");
    buf.append(filter.getDataScheme(0));

    if (filter.countDataSchemes() > 1) {
        buf.append(" (other schemes)");
    }
}

if (filter.countDataPaths() > 0) {
    buf.append(" : ");
    buf.append(filter.getDataPath(0));

    if (filter.countDataPaths() > 1) {
        buf.append(" (other paths)");
    }
}

return(buf.toString());
}
}
```

(from [Introspection/PrefActivities/app/src/main/java/com/commonsware/android/prefact/PreferredActivitiesDemoActivity.java](#))

The resulting activity shows a simple description of the IntentFilter along with the class name of the corresponding activity in each row:

Figure 771: Preferred Activities on a Stock HTC One S

Another way to think about preferred activities is to determine what specific activity will handle a `startActivity()` call on some `Intent`. If there is only one alternative, or the user chose a preferred activity, that activity should handle the `Intent`. Otherwise, the activity handling the `Intent` *should* be one implementing a chooser. The `resolveActivity()` method on `PackageManager` can let us know what will handle the `Intent`.

To examine what `resolveActivity()` returns, take a look at the [Introspection/Resolver](#) sample application.

The activity — which uses `Theme.NoDisplay` and so has no UI of its own — is fairly short:

```
package com.commonware.android.resolver;

import android.app.Activity;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.net.Uri;
import android.os.Bundle;
import android.widget.Toast;
```

PACKAGEMANAGER TRICKS

```
public class ResolveActivityDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        PackageManager mgr=getPackageManager();
        Intent i=
            new Intent(Intent.ACTION_VIEW,
                Uri.parse("https://commonsware.com"));
        ResolveInfo ri=
            mgr.resolveActivity(i, PackageManager.MATCH_DEFAULT_ONLY);

        Toast.makeText(this, ri.loadLabel(mgr), Toast.LENGTH_LONG).show();

        startActivity(i);
        finish();
    }
}
```

(from [Introspection/Resolver/app/src/main/java/com/commonsware/android/resolver/ResolveActivityDemoActivity.java](https://github.com/commonsware/android-resolver/blob/master/src/main/java/com/commonsware/android/resolver/ResolveActivityDemoActivity.java))

We get a PackageManager, create an Intent to test, and pass the Intent to resolveActivity(). We include MATCH_DEFAULT_ONLY so we only get activities that have CATEGORY_DEFAULT in their <intent-filter> elements. We then use loadLabel() on the resulting ResolveInfo object to get the display name of the activity, toss that in a Toast, and invoke startActivity() on the Intent to confirm the results.

On a device with only one option, or with a default chosen, the Toast will show the name of the preferred activity (e.g., Browser). On most devices with more than one option, the startActivity() call will display a chooser, and the Toast will show the display name of the chooser (e.g., “Android System”).

However, on some devices — notably newer models from HTC distributed in the US — resolveActivity() indicates that HTCLinkifyDispatcher is the one that will handle ACTION_VIEW on a URL... even if there is more than one browser installed and no default has been specified. This is part of a workaround that HTC added in 2012 to help deal with a patent dispute with Apple.

Middle Management

The PackageManager class offers much more than merely queryIntentActivities() and queryIntentActivityOptions(). It is your gateway to all sorts of analysis of what is installed and available on the device where your application is installed and available. If you want to be able to intelligently connect to third-party applications based on whether or not they are around, PackageManager is what you will want.

Finding Applications and Packages

Packages are what get installed on the device — a package is the in-device representation of an APK. An application is defined within a package's manifest. Between the two, you can find out all sorts of things about existing software installed on the device.

Specifically, `getInstalledPackages()` returns a List of `PackageInfo` objects, each of which describes a single package. Here, you can find out:

1. The version of the package, in terms of a monotonically increasing number (`versionCode`) and the display name (`versionName`)
2. Details about all of the components — activities, services, etc. — offered by this package
3. Details about the permissions the package requires

Similarly, `getInstalledApplications()` returns a List of `ApplicationInfo` objects, each providing data like:

1. The user ID that the application will run as
2. The path to the application's private data directory
3. Whether or not the application is enabled

In addition to those methods, you can call:

1. `getApplicationIcon()` and `getApplicationLabel()` to get the icon and display name for an application
2. `getLaunchIntentForPackage()` to get an `Intent` for something launchable within a named package
3. `setApplicationEnabledSetting()` to enable or disable an application

Finding Resources

You can access resources from another application, apparently without any security restrictions. This may be useful if you have multiple applications and wish to share resources for one reason or another.

The `getResourcesForActivity()` and `getResourcesForApplication()` methods on `PackageManager` return a `Resources` object. This is just like the one you get for your own application via `getResources()` on any `Context` (e.g., `Activity`). However, in

this case, you identify what activity or application you wish to get the Resources from (e.g., supply the application's package name as a String).

There are also `getText()` and `getXml()` methods that dive into the Resources object for an application and pull out specific String or XmlPullParser objects. However, these require you to know the resource ID of the resource to be retrieved, and that may be difficult to manage between disparate applications.

Finding Components

Not only does Android offer “query” and “resolve” methods to find activities, but it offers similar methods to find other sorts of Android components:

1. `queryBroadcastReceivers()`
2. `queryContentProviders()`
3. `queryIntentServices()`
4. `resolveContentProvider()`
5. `resolveService()`

For example, you could use `resolveService()` to determine if a certain remote service is available, so you can disable certain UI elements if the service is not on the device. You could achieve the same end by calling `bindService()` and watching for a failure, but that may be later in the application flow than you would like.

There is also a `setComponentEnabledSetting()` to toggle a component (activity, service, etc.) on and off. While this may seem esoteric, there are a number of possible uses for this method, such as:

1. Flagging a launchable activity as disabled in your manifest, then enabling it programmatically after the user has entered a license key, achieved some level or standing in a game, or any other criteria
2. Controlling whether a BroadcastReceiver registered in the manifest is hooked into the system or not, replicating the level of control you have with `registerReceiver()` while still taking advantage of the fact that a manifest-registered BroadcastReceiver can be started even if no other component of your application is running

Remote Services and the Binding Pattern

Earlier in this book, we covered using services by sending commands to them to be processed. That “command pattern” is one of two primary means of interacting with a service — the binding pattern is the other. With the binding pattern, your service exposes a more traditional API, in the form of a “binder” object with methods of your choosing. On the plus side, you get a richer interface. However, it more tightly ties your activity to your service, which may cause you problems with configuration changes.

Either the command pattern or the binding pattern can be used, if desired, across process boundaries, with the client being some third-party application. In either case, you will need to export your service via an `<intent-filter>`. And, in the case of the binding pattern, your “binder” implementation will have some restrictions.

This chapter covers the binding pattern for local services, plus inter-process commands and binding (a.k.a., remote services).

Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [broadcast Intents](#)
- [service theory](#)

The Binding Pattern

Implementing the binding pattern requires work on both the service side and the client side. The service will need to have a full implementation of the `onBind()` method, which typically just returns `null` or throws some sort of runtime exception for a service solely implementing the command pattern. And, the client (e.g., an activity) will need to ask to bind to the service, instead of (or perhaps in addition to) starting the service.

What the Service Does

The service implements a subclass of `Binder` that represents the service's exposed API. For a local service, your `Binder` can have pretty much whatever methods you want: method names, parameters, return types, and exceptions thrown are up to you. When you get into remote services, your `Binder` implementation will be substantially more constrained, to support inter-process communication.

Then, your `onBind()` method returns an instance of the `Binder`.

What the Client Does

Clients call `bindService()`, supplying the `Intent` that identifies the service, a `ServiceConnection` object representing the client side of the binding, and an optional `BIND_AUTO_CREATE` flag. As with `startService()`, `bindService()` is asynchronous. The client will not know anything about the status of the binding until the `ServiceConnection` object is called with `onServiceConnected()`. This not only indicates the binding has been established, but for local services it provides the `Binder` object that the service returned via `onBind()`. At this point, the client can use the `Binder` to ask the service to do work on its behalf.

Note that if the service is not already running, and if you provide `BIND_AUTO_CREATE`, then the service will be created first before being bound to the client. If you skip `BIND_AUTO_CREATE`, and the service is not already running, `bindService()` is supposed to return `false`, indicating there was no existing service to bind to. However, in actuality, Android returns `true`, due to [an apparent bug](#).

Eventually, the client will need to call `unbindService()`, to indicate it no longer needs to communicate with the service. For example, an activity might call `bindService()` in its `onCreate()` method, then call `unbindService()` in its `onDestroy()` method. Once you call `unbindService()`, your `Binder` object is no

longer safe to be used by the client. If there are no other bound clients to the service, Android will shut down the service as well, releasing its memory. Hence, we do not need to call `stopService()` ourselves — Android handles that, if needed, as a side effect of unbinding.

Your `ServiceConnection` object will also need an `onServiceDisconnected()` method. This will be called only if there is an unexpected disconnection, such as the service crashing with an unhandled exception.

A Binding Sample

In the chapter introducing services, we saw a sample app that would [download a file off of a Web server](#). That sample used the command pattern, telling the service what to download via an Intent extra. In this chapter, we will review a few variations of that sample, all of which use the binding pattern instead of the command pattern.

Right now, we are focused on local services, and so the [Binding/Local](#) sample project does the download via a local bound service.

We start by defining an interface that will serve as the “contract” between the client (fragment) and service. This interface, `IDownload`, contains a single `download()` method:

```
package com.commonware.android.advservice.binding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

(from [Binding/Local/app/src/main/java/com/commonware/android/advservice/binding/IDownload.java](#))

Our service, `DownloadService`, implements just one method, `onBind()`, which returns an instance of a `DownloadBinder`:

```
package com.commonware.android.advservice.binding;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Binder;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
```

REMOTE SERVICES AND THE BINDING PATTERN

```
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
    @Override
    public IBinder onBind(Intent intent) {
        return(new DownloadBinder());
    }

    private static class DownloadBinder extends Binder implements IDownload {
        @Override
        public void download(String url) {
            new DownloadThread(url).start();
        }
    }

    private static class DownloadThread extends Thread {
        String url=null;

        DownloadThread(String url) {
            this.url=url;
        }

        @Override
        public void run() {
            try {
                File root=
                    Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

                root.mkdirs();

                File output=new File(root, Uri.parse(url).getLastPathSegment());

                if (output.exists()) {
                    output.delete();
                }

                HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

                FileOutputStream fos=new FileOutputStream(output.getPath());
                BufferedOutputStream out=new BufferedOutputStream(fos);

                try {
                    InputStream in=c.getInputStream();
                    byte[] buffer=new byte[8192];
                    int len=0;

                    while ((len=in.read(buffer)) >= 0) {
                        out.write(buffer, 0, len);
                    }

                    out.flush();
                }
                finally {
                    fos.getFD().sync();
                    out.close();
                    c.disconnect();
                }
            }
        }
    }
}
```

REMOTE SERVICES AND THE BINDING PATTERN

```
    catch (IOException e2) {
        Log.e("DownloadJob", "Exception in download", e2);
    }
}
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadService.java](#))

DownloadBinder implements the IDownload interface. Its download() method, in turn, forks a DownloadThread to perform the download in the background — remember, for local services, the methods you invoke on the Binder are executed on whatever thread you call them on.

Our fragment, DownloadFragment, loads our layout, res/layout/main.xml, containing a Button to trigger the download:

```
<?xml version="1.0" encoding="utf-8"?>
<Button xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/go"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="@string/go"/>
```

(from [Binding/Local/app/src/main/res/layout/main.xml](#))

The implementation of onCreateView() simply loads that layout, gets the Button, sets up the fragment as being the click listener for the Button, and disables the Button:

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.main, container, false);

    btn=(Button)result.findViewById(R.id.go);
    btn.setOnClickListener(this);
    btn.setEnabled(binding!=null);

    return(result);
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

The reason why we disable the Button is because we are not connected to our service at this point, and until we are, we cannot allow the user to try to download a file.

In onCreate() of our fragment, we mark the fragment as retained and bind to the service:

REMOTE SERVICES AND THE BINDING PATTERN

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();
    appContext.bindService(new Intent(getActivity(),
        DownloadService.class),
        this, Context.BIND_AUTO_CREATE);
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

You will notice something curious here: `getApplicationContext()`. Technically, we could bind to the service directly from the Activity, by calling `bindService()` on it, as `bindService()` is a method on Context. However, our service binding represents some state, and it is possible that this state will hold a reference to the Context that created the binding. In that case, we run the risk of leaking our original activity during a configuration change. The `getApplicationContext()` method returns the global Application singleton, which is a Context suitable for binding, but one that cannot be leaked, since it is already in a global scope. In effect, it is “pre-leaked”.

The call to `setRetainInstance()` allows the fragment – serving as our ServiceConnection — to survive a configuration change, so we can cleanly unbind from the service later on, when `onDestroy()` is called.

Some time after `onCreate()` is called and we call `bindService()`, our `onServiceConnected()` method will be called, as we designated our fragment to be the ServiceConnection. Here, we can cast the IBinder object we receive to be our IDownload interface to the service, and we can enable the Button:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
    binding=(IDownload)binder;
    btn.setEnabled(true);
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

Since we are implementing the ServiceConnection interface, our fragment also needs to implement the `onServiceDisconnected()` method, invoked if our service crashes. Here, we delegate responsibility to a `disconnect()` private method, which removes our link to the IDownload object and disables our Button:

```
@Override
public void onServiceDisconnected(ComponentName className) {
    disconnect();
}
```

REMOTE SERVICES AND THE BINDING PATTERN

```
private void disconnect() {
    binding=null;
    btn.setEnabled(false);
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

And, when our fragment is destroyed, we unbind from the service (using the same Context as before, from `getApplicationContext()`) and `disconnect()`:

```
@Override
public void onDestroy() {
    appContext.unbindService(this);
    disconnect();

    super.onDestroy();
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

However, in between `onServiceConnected()` and either `onServiceDisconnected()` or `onDestroy()`, the user can click the Button, which will trigger the download via a call to `download()` on our `IDownload` instance:

```
@Override
public void onClick(View view) {
    binding.download(TO_DOWNLOAD);
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

The `DownloadBindingDemo` activity adds our `DownloadFragment` via a `FragmentManager`:

```
package com.commonsware.android.advservice.binding;

import android.app.Activity;
import android.os.Bundle;

public class DownloadBindingDemo extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new DownloadFragment()).commit();
        }
    }
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadBindingDemo.java](#))

Starting and Binding

Some developers will use *both* `startService()` and `bindService()` at the same time. The typical argument is that they need frequent updates from the service (e.g., percentage of progress, for updating a `ProgressBar`) in the client and are concerned about the overhead of sending broadcasts.

With the advent of [LocalBroadcastManager and other event bus implementations](#), binding to a service you are using with `startService()` should no longer be necessary.

When IPC Attacks!

If you wish to extend the binding pattern to serve in the role of IPC, whereby other processes can get at your `Binder` and call its methods, you will need to use AIDL: the Android Interface Description Language. If you have used IPC mechanisms like SOAP, XML-RPC, DCOM, CORBA, or the like, you will recognize the notion of IDL. AIDL describes the public IPC interface, and Android supplies tools to build the client and server side of that interface.

With that in mind, let's take a look at AIDL and IPC.

Write the AIDL

IDLs are frequently written in a “language-neutral” syntax. AIDL, on the other hand, looks a lot like a Java interface file. For example, here is some AIDL:

```
package com.commonware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

(from [Binding/Remote/Service/app/src/main/aidl/com/commonware/android/advservice/remotebinding/IDownload.aidl](#))

As you will notice, this looks suspiciously like the regular Java interface we used in the simple binding example earlier in this chapter.

As with a Java interface, you declare a package at the top. As with a Java interface, the methods are wrapped in an interface declaration (`interface IDownload { ... }`). And, as with a Java interface, you list the methods you are making available.

The differences, though, are critical.

First, not every Java type can be used as a parameter. Your choices are:

1. Primitive values (int, float, double, boolean, etc.)
2. String and CharSequence
3. List and Map (from `java.util`)
4. Any other AIDL-defined interfaces
5. Any Java classes that implement the `Parcelable` or `Serializable` interface

In the case of the latter two categories, you need to include import statements referencing the names of the classes or interfaces that you are using (e.g., `import com.commonware.android.ISomething`). This is true even if these classes are in your own package — you have to import them anyway.

Next, parameters can be classified as `in`, `out`, or `inout`. Values that are `out` or `inout` can be changed by the service and those changes will be propagated back to the client. Primitives (e.g., `int`) can only be `in`.

Also, you cannot throw any exceptions. You will need to catch all exceptions in your code, deal with them, and return failure indications some other way (e.g., error code return values).

Name your AIDL files with the `.aidl` extension and place them in the proper directory based on the package name:

- For native Android Studio projects, this will be an `aidl/` directory in your `src/` sourceset, as a peer of your `java/` directory, with the same sort of subdirectories-based-on-the-Java-package approach as you use for regular Java source code
- For Eclipse-compatible projects, the `.aidl` files will go alongside your `.java` files in the `src/` directory tree

When you build your project, either via an IDE or via command-line build tools, the `aidl` utility from the Android SDK will translate your AIDL into a server stub and a client proxy.

Implement the Interface

Given the AIDL-created server stub, now you need to implement the service, either directly in the stub, or by routing the stub implementation to other methods you have already written.

The mechanics of this are fairly straightforward:

1. Create a subclass of the AIDL-generated `.Stub` class (e.g., `IDownload.Stub`)
2. Implement methods matching up with each of the methods you placed in the AIDL
3. Return an instance of this subclass from your `onBind()` method in the `Service` subclass

Note that AIDL IPC calls are synchronous, and so the caller is blocked until the IPC method returns. Hence, your services need to be quick about their work.

We will see examples of service stubs later in this chapter.

Service From Afar

So, given our AIDL description, let us examine a sample implementation, using AIDL for a remote service.

Our sample applications — shown in the [Binding/Remote/Service](#) and [Binding/Remote/Client](#) sample projects — simply move the service logic into a separate project from the client logic.

Service Names

To bind to a service's AIDL-defined API, you need to craft an Intent that can identify the service in question. In the case of a local service, that Intent can use the local approach of directly referencing the service class.

Obviously, that is not possible in a remote service case, where the service class is not in the same process, and may not even be known by name to the client.

When you define a service to be used by remote, you need to add an `<intent-filter>` element to your service declaration in the manifest, indicating

REMOTE SERVICES AND THE BINDING PATTERN

how you want that service to be referred to by clients. The manifest for RemoteService is shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.advservice.remotebinding.svc"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET" />
    <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <service android:name=".DownloadService">
            <intent-filter>
                <action android:name="com.commonware.android.advservice.remotebinding.IDownload" />
            </intent-filter>
        </service>
    </application>
</manifest>
```

(from [Binding/Remote/Service/app/src/main/AndroidManifest.xml](#))

Here, we say that the service can be identified by the name `com.commonware.android.advservice.IDownload`. So long as the client uses this name to identify the service, it can bind to that service's API.

In this case, the name is not an implementation, but the AIDL API, as you will see below. In effect, this means that so long as some service exists on the device that implements this API, the client will be able to bind to something.

Remote Services and Implicit Intents

We are used to a device having multiple activities that can respond to the same `<intent-filter>`. In that case, by default, the user will see a chooser if we try to start one of those activities.

We are used to a device having multiple `BroadcastReceiver` components that can respond to the same `<intent-filter>` (or `IntentFilter`). In that case, in a regular broadcast, all eligible receivers will receive it.

REMOTE SERVICES AND THE BINDING PATTERN

We are used to it being impossible to have multiple ContentProvider components with the same authority, as the second one fails on install with an `INSTALL_FAILED_CONFLICTING_PROVIDER` error.

What happens if there are *two* (or more) services installed on the device that claim to support the same `<intent-filter>`, but have different package names? You might think that this would fail on install, as happens with providers with duplicate authorities. Alas, it does not... prior to Android 5.0. Instead, the higher-priority `<intent-filter>` gets it (set via the `android:priority` attribute). If 2+ implementations have the same priority, the first one installed wins.

So, if we have `BadService` and `GoodService`, both responding to the same `<intent-filter>`, and a client app tries to communicate to `GoodService` via the implicit Intent matching that `<intent-filter>`, it might *actually* be communicating with `BadService`, simply because `BadService` was installed first. The user is oblivious to this.

Android 5.0 solves this by preventing binding using an implicit Intent. This, however, presents a conundrum:

- We cannot bind using an implicit Intent
- We do not know how to construct an explicit Intent identifying the desired service, as that might be from a third-party app

As you will see, when we examine the client side of this sample, we have to use `PackageManager` to convert an implicit Intent into a valid explicit Intent for our service. This not only allows us to comply with the Android 5.0 binding restriction, but it gives us an opportunity to detect and handle the cases where there is no matching service (e.g., the service app has not yet been installed) or when there is more than one matching service (e.g., `BadService` and `GoodService`). And the techniques that all of this uses works on pretty much any version of Android, so while we *need* them for Android 5.0 and higher, we can *use* them anywhere.

The Service

Beyond the manifest, the service implementation is not too unusual. There is the AIDL interface, `IDownload`:

```
package com.commonware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
```

REMOTE SERVICES AND THE BINDING PATTERN

```
void download(String url);
}
```

(from [Binding/Remote/Service/app/src/main/aidl/com/commonsware/android/advservice/remotebinding/IDownload.aidl](#))

And there is the actual service class itself, DownloadService:

```
package com.commonsware.android.advservice.remotebinding.svc;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import com.commonsware.android.advservice.remotebinding.IDownload;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
    @Override
    public IBinder onBind(Intent intent) {
        return(new DownloadBinder());
    }

    private static class DownloadBinder extends IDownload.Stub {
        @Override
        public void download(String url) {
            new DownloadThread(url).start();
        }
    }

    private static class DownloadThread extends Thread {
        String url=null;

        DownloadThread(String url) {
            this.url=url;
        }

        @Override
        public void run() {
            try {
                File root=
                    Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

                root.mkdirs();

                File output=new File(root, Uri.parse(url).getLastPathSegment());

                if (output.exists()) {
                    output.delete();
                }

                HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();
```

REMOTE SERVICES AND THE BINDING PATTERN

```
FileOutputStream fos=new FileOutputStream(output.getPath());
BufferedOutputStream out=new BufferedOutputStream(fos);

try {
    InputStream in=c.getInputStream();
    byte[] buffer=new byte[8192];
    int len=0;

    while ((len=in.read(buffer)) >= 0) {
        out.write(buffer, 0, len);
    }

    out.flush();
}
finally {
    fos.getFD().sync();
    out.close();
    c.disconnect();
}
}
catch (IOException e2) {
    Log.e("DownloadJob", "Exception in download", e2);
}
}
}
```

(from [Binding/Remote/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/svc/DownloadService.java](#))

This is identical to the local binding example, with one key difference: DownloadBinder now extends `IDownload.Stub` rather than the generic Binder class.

The Client

The client — a revised version of `DownloadFragment` — connects to the remote service to ask it to download the file on the user's behalf. This has three changes of note over our original local implementation.

First, when we call `download()` on the `IDownload` object, we need to catch a `RemoteException`. This will be thrown if the service crashes during our request or otherwise is unable to return properly:

```
@Override
public void onClick(View view) {
    try {
        binding.download(TO_DOWNLOAD);
    }
    catch (RemoteException e) {
        Log.e(getClass().getSimpleName(), "Exception requesting download", e);
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
    }
}
```

REMOTE SERVICES AND THE BINDING PATTERN

(from [Binding/Remote/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/client/DownloadFragment.java](#))

Second, our `onServiceConnected()` uses `IDownload.Stub.asInterface()` to convert the raw `IBinder` into an `IDownload` object for use:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
    binding=IDownload.Stub.asInterface(binder);
    btn.setEnabled(true);
}
```

(from [Binding/Remote/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/client/DownloadFragment.java](#))

Third, our binding logic in `onCreate()` is significantly more complicated:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();

    Intent implicit=new Intent(IDownload.class.getName());
    List<ResolveInfo> matches=getActivity().getPackageManager()
        .queryIntentServices(implicit, 0);

    if (matches.size() == 0) {
        Toast.makeText(getActivity(), "Cannot find a matching service!",
            Toast.LENGTH_LONG).show();
    }
    else if (matches.size() > 1) {
        Toast.makeText(getActivity(), "Found multiple matching services!",
            Toast.LENGTH_LONG).show();
    }
    else {
        Intent explicit=new Intent(implicit);
        ServiceInfo svcInfo=matches.get(0).serviceInfo;
        ComponentName cn=new ComponentName(svcInfo.applicationInfo.packageName,
            svcInfo.name);

        explicit.setComponent(cn);
        appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
    }
}
```

(from [Binding/Remote/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/client/DownloadFragment.java](#))

Here, we:

- Get the Application singleton Context as before

- Craft an implicit Intent for the service, using the appropriate action string (which, in this case, happens to be the fully-qualified name of the `IDownload` interface)
- Use `PackageManager` and `queryIntentServices()` to find out all services that implement a matching `<intent-filter>` for that implicit Intent
- Fail with a `Toast` if there is not exactly one such service
- Use the `ServiceInfo` object from our `queryIntentServices()` call to craft an explicit Intent, with the same structure as the implicit Intent had, but also with the actual matched component (via `setComponent()`)
- Use the explicit Intent to bind to the service

Note that the client needs its own copy of `IDownload.aidl`. After all, it is a totally separate application, and therefore does not share source code with the service. In a production environment, we might craft and distribute a JAR file that contains the `IDownload` classes, so both client and service can work off the same definition (see [the upcoming chapter on reusable components](#)). For now, we will just have a copy of the AIDL.

If you compile both applications and upload them to the device, then start up the client, you can have the service download the file.

Tightening Up the Security

The previous sample confirms that there is exactly one service that matches the desired Intent. This catches the zero-service scenario (requiring the user to install the other app) and catches the multiple-service scenario (where one service is an attacker, presumably).

However, what happens if there is only one service installed, and it is not the desired service, but rather is an attacker? The preceding binding code will still go ahead and bind with that service.

You might consider just examining the package name/application ID of the other service, to see if it matches an expected value. However, that will not help you if the attacker is a modified version of the real service, one that kept its original package name but changed the service to do evil things.

Checking the digital signature of the other service is a more robust check, as that cannot readily be forged. Even if somebody modifies and repackages the app with

the service, that app would wind up being signed by a different signing key, which you can detect.

Moreover, this approach can be used in both directions: the client can validate the service, and the service can validate the client. For example, perhaps as part of a licensing scheme, your service can only be used by apps developed by certain firms, based upon their signing keys.

The [Binding/SigCheck/Client](#) sample project illustrates a client that will perform this signature check on the client side. The corresponding service project – [Binding/SigCheck/Service](#) – will perform a signature check on the service side.

Adding the Dependency

Both projects use the CWAC-Security library, described [elsewhere in this book](#), to do the signature checking. Hence, their Gradle build files have a dependency on that library:

```
buildscript {
    repositories {
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:2.1.2'

        // NOTE: Do not place your application dependencies here; they belong
        // in the individual module build.gradle files
    }
}
```

(from [Binding/SigCheck/Client/build.gradle](#))

Adding the Signature Check: Client

The client's `DownloadFragment` is nearly the same as before, with an adjustment to `onCreate()` to check the signature if there is exactly one service that matches the Intent:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();

    Intent implicit=new Intent(IDownload.class.getName());
    List<ResolveInfo> matches=getActivity().getPackageManager()
        .queryIntentServices(implicit, 0);
```

```
if (matches.size() == 0) {
    Toast.makeText(getActivity(), "Cannot find a matching service!",
        Toast.LENGTH_LONG).show();
}
else if (matches.size() > 1) {
    Toast.makeText(getActivity(), "Found multiple matching services!",
        Toast.LENGTH_LONG).show();
}
else {
    ServiceInfo svcInfo=matches.get(0).serviceInfo;

    try {
        String otherHash=SignatureUtils.getSignatureHash(getActivity(),
            svcInfo.applicationInfo.packageName);
        String expected=getActivity().getString(R.string.expected_sig_hash);

        if (expected.equals(otherHash)) {
            Intent explicit=new Intent(implicit);
            ComponentName cn=new ComponentName(svcInfo.applicationInfo.packageName,
                svcInfo.name);

            explicit.setComponent(cn);
            appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
        }
        else {
            Toast.makeText(getActivity(), "Unexpected signature found!",
                Toast.LENGTH_LONG).show();
        }
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(), "Exception trying to get signature hash", e);
    }
}
```

(from [Binding/SigCheck/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/sigcheck/DownloadFragment.java](#))

In the one-match scenario, we get the signature of the other app, by using `getSignatureHash()` on `SignatureUtils`, passing in the package name of the other app. We then compare that with a hard-coded expected hash, pulled from a string resource, one that is unfortunately too long to represent in this book.

Only if those two match do we go ahead with the binding.

Adding the Signature Check: Service

This gets a bit more complicated, as we first need to figure out who the client is, before we can validate the signature. In the case of the client connecting to the service, we know the application ID of the service courtesy of the `queryIntentServices()` call. On the service side, we need to use a different approach to identify who the client is.

REMOTE SERVICES AND THE BINDING PATTERN

To do this work, DownloadBinder now needs a Context with which to work, so onBind() passes one to a revised DownloadBinder constructor:

```
@Override
public IBinder onBind(Intent intent) {
    return(new DownloadBinder(this));
}
```

(from [Binding/SigCheck/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/sig/DownloadService.java](#))

The constructor holds on to three things:

- a Context, in this case the Application obtained from the Service
- a PackageManager, as we will need this for the signature lookup
- the expected hash of the client's signing key, pulled once again from a string resource

```
private static class DownloadBinder extends IDownload.Stub {
    private final PackageManager pm;
    private final String expectedHash;
    private final Context ctxt;

    public DownloadBinder(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
        this.pm=this.ctxt.getPackageManager();
        this.expectedHash=this.ctxt.getString(
            R.string.expected_sig_hash);
    }
}
```

(from [Binding/SigCheck/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/sig/DownloadService.java](#))

A Binder can find out who is invoking one of its exposed methods via Binder.getCallingUid(). This returns the Linux user ID (uid) that the client uses.

Normally, this will be tied to one application ID. However, it is possible for a suite of apps to share a Linux user ID, via the android:sharedUserId option in the manifest. Hence, the call to map the user ID to an application ID is getPackagesForUid() on PackageManager, which returns a *list* of application IDs.

So, the revised download() method iterates over those application IDs to see if any of them have the expected signature:

```
@Override
public void download(String url) {
    boolean ok=false;

    for (String pkg :
        pm.getPackagesForUid(Binder.getCallingUid())) {
        try {
            String otherHash=
```

REMOTE SERVICES AND THE BINDING PATTERN

```
SignatureUtils.getSignatureHash(ctxt, pkg);

    if (expectedHash.equals(otherHash)) {
        ok=true;
        break;
    }
}
catch (Exception e) {
    Log.e(getClass().getSimpleName(),
        "Exception finding signature hash", e);
}
}

if (ok) {
    new DownloadThread(url).start();
}
else {
    Log.e(getClass().getSimpleName(),
        "Could not validate client signature");
}
}
```

(from [Binding/SigCheck/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/sig/DownloadService.java](#))

In practice, Android itself will ensure that if there are several application IDs sharing a Linux user ID, they will all be signed by the same signing key.

If and only if we find a signature match do we actually do the download; otherwise, we log an error.

This happens to be a very simple service with a single-method Binder. In a more complicated service, where there are several methods exposed by the Binder, the signature-check logic could be refactored into a common private method that the AIDL-defined Binder methods could all use to validate the client.

So, Where Do We Get the Expected Hash From?

Today, there are two main ways you can get the expected hash:

- Since this is really a hash of the public part of the app's signing key, the author of the other app might publish it as part of integration documentation, where the hash is generated via `keytool`
- You might call `getSignatureHash()` from your app and log the results, running it against a known good copy of the other app

Servicing the Service

However, we do not get any result back from the service to know if the download succeeded or failed. That is likely to be rather important information for the user.

In principle, `download()` could return some success-or-failure indication... but then we would have a blocking call. Neither the client nor the service could proceed until the download is completed. That would require the client to manage its own background thread, which is a minor hassle. It also means that the service ties up one of a limited number of “Binder threads”, which is not a good idea.

Another approach would be to pass some sort of callback object with `download()`, such that the server could run the script asynchronously and invoke the callback on success or failure. This, though, implies that there is some way to have the client export an API to the service.

Fortunately, this is eminently doable, as you will see in this section, and the accompanying samples ([Binding/Callback/Service](#) and [Binding/Callback/Client](#)).

Callbacks via AIDL

AIDL does not have any concept of direction. It just knows interfaces, proxies, and stub implementations. In the preceding example, we used AIDL to have the service flesh out the stub implementation and have the client access the service via the AIDL-defined interface. However, there is nothing magic about services implementing interfaces and clients accessing them — it is equally possible to reverse matters and have the client implement something the service uses via an interface.

So, for example, we could create an `IDownloadCallback.aidl` file:

```
package com.commonware.android.advservice.callbackbinding;

// Declare the interface.
interface IDownloadCallback {
    void onSuccess();
    void onFailure(String msg);
}
```

(from [Binding/Callback/Service/app/src/main/aidl/com/commonware/android/advservice/callbackbinding/IDownloadCallback.aidl](#))

REMOTE SERVICES AND THE BINDING PATTERN

Then, we can augment `IDownload` itself, to pass an `IDownloadCallback` with `download()`:

```
package com.commonware.android.advservice.callbackbinding;

import com.commonware.android.advservice.callbackbinding.IDownloadCallback;

// Declare the interface.
interface IDownload {
    void download(String url, IDownloadCallback cb);
}
```

(from [Binding/Callback/Service/app/src/main/aidl/com/commonware/android/advservice/callbackbinding/IDownload.aidl](#))

Notice that we need to specifically import `IDownloadCallback`, just like we might import some “regular” Java interface. And, as before, we need to make sure the client and the server are working off of the same AIDL definitions, so these two AIDL files need to be replicated across each project.

But other than that one little twist, this is all that is required, at the AIDL level, to have the client pass a callback object to the service: define the AIDL for the callback and add it as a parameter to some service API call.

Of course, there is a little more work to do on the client and server side to make use of this callback object.

Revising the Client

On the client, we need to implement an `IDownloadCallback`. In `onSuccess()` and `onFailure()` we can do something like raise a `Toast`.

The catch is that we cannot be certain we are being called on the UI thread in our callback object. In fact, it is almost assured that we are not. So, we need to get our work moved over to the main application thread. To do that, this sample uses greenrobot’s `EventBus`, having the `IDownloadCallback.Stub` post a `CallbackEvent` indicating success or failure:

```
IDownloadCallback.Stub cb=new IDownloadCallback.Stub() {
    @Override
    public void onSuccess() throws RemoteException {
        EventBus.getDefault().post(new CallbackEvent(true, null));
    }

    @Override
    public void onFailure(String msg) throws RemoteException {
        EventBus.getDefault().post(new CallbackEvent(false, msg));
    }
};
```

REMOTE SERVICES AND THE BINDING PATTERN

```
static class CallbackEvent {
    boolean succeeded=false;
    String msg=null;

    CallbackEvent(boolean succeeded, String msg) {
        this.succeeded=succeeded;
        this.msg=msg;
    }
}
```

(from [Binding/Callback/Client/app/src/main/java/com/commonsware/android/advservice/callbackbinding/client/DownloadFragment.java](#))

The fragment itself registers for the event bus, and in `onEventMainThread()`, it raises the Toast:

```
public void onEventMainThread(CallbackEvent event) {
    if (getActivity()!=null) {
        if (event.succeeded) {
            Toast.makeText(getActivity(), "Download successful!", Toast.LENGTH_LONG).show();
        }
        else {
            Toast.makeText(getActivity(), event.msg, Toast.LENGTH_LONG).show();
        }
    }
}
```

(from [Binding/Callback/Client/app/src/main/java/com/commonsware/android/advservice/callbackbinding/client/DownloadFragment.java](#))

And, of course, we need to pass the `IDownloadCallback` object in our `download()` call:

```
@Override
public void onClick(View view) {
    try {
        binding.download(TO_DOWNLOAD, cb);
    }
    catch (RemoteException e) {
        Log.e(getClass().getSimpleName(), "Exception requesting download", e);
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
    }
}
```

(from [Binding/Callback/Client/app/src/main/java/com/commonsware/android/advservice/callbackbinding/client/DownloadFragment.java](#))

Revising the Service

The service also needs changing, to use the supplied callback object for the end results of the download.

REMOTE SERVICES AND THE BINDING PATTERN

DownloadBinder now receives an IDownloadCallback proxy in its download() method, which it passes along to the DownloadThread:

```
private static class DownloadBinder extends IDownload.Stub {
    @Override
    public void download(String url, IDownloadCallback cb) {
        new DownloadThread(url, cb).start();
    }
}
```

(from [Binding/Callback/Service/app/src/main/java/com/commonsware/android/advservice/callbackbinding/svc/DownloadService.java](#))

Notice that the service's own API just needs the IDownloadCallback parameter, which can be passed around and used like any other Java object. The fact that it happens to cause calls to be made synchronously back to the remote client is invisible to the service.

DownloadThread, in turn, invokes onSuccess() or onFailure() as appropriate:

```
private static class DownloadThread extends Thread {
    String url=null;
    IDownloadCallback cb=null;

    DownloadThread(String url, IDownloadCallback cb) {
        this.url=url;
        this.cb=cb;
    }

    @Override
    public void run() {
        try {
            File root=
                Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

            root.mkdirs();

            File output=new File(root, Uri.parse(url).getLastPathSegment());

            if (output.exists()) {
                output.delete();
            }

            HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

            FileOutputStream fos=new FileOutputStream(output.getPath());
            BufferedOutputStream out=new BufferedOutputStream(fos);

            try {
                InputStream in=c.getInputStream();
                byte[] buffer=new byte[8192];
                int len=0;

                while ((len=in.read(buffer)) >= 0) {
                    out.write(buffer, 0, len);
                }
            }
        }
    }
}
```

```
        out.flush();

        try {
            cb.onSuccess();
        }
        catch (RemoteException e) {
            Log.e("DownloadJob", "Exception when calling onSuccess()", e);
        }
    }
    finally {
        fos.getFD().sync();
        out.close();
        c.disconnect();
    }
}
catch (IOException e2) {
    Log.e("DownloadJob", "Exception in download", e2);

    try {
        cb.onFailure(e2.getMessage());
    }
    catch (RemoteException e) {
        Log.e("DownloadJob", "Exception when calling onFailure()", e2);
    }
}
}
```

(from [Binding/Callback/Service/app/src/main/java/com/commonsware/android/advservice/callbackbinding/svc/DownloadService.java](#))

Thinking About Security

Remote services, by definition, are available for anyone to connect to. This may or may not be a good idea.

If the only client of your remote service is some other app of yours, you could protect the service using [a custom signature-level permission](#).

If you anticipate third-party apps communicating with your service, you should strongly consider protecting the service with [an ordinary custom permission](#), so the *user* can vote on whether the communication is allowed.

For local services, the simplest way to secure the service is to not export it, typically by not having an `<intent-filter>` element for the `<service>` in the manifest. Then, your app is the only app that can work with the service.

The “Everlasting Service” Anti-Pattern

One anti-pattern that is all too prevalent in Android is the “everlasting service”. Such a service is started via `startService()` and never stops — the component starting it does not stop it and it does not stop itself via `stopSelf()`.

Why is this an anti-pattern?

1. The service takes up memory all of the time. This is bad in its own right if the service is not continuously delivering sufficient value to be worth the memory.
2. Users, fearing services that sap their device’s CPU or RAM, may attack the service with so-called “task killer” applications or may terminate the service via the Settings app, thereby defeating your original goal.
3. Android itself, due to user frustration with sloppy developers, will terminate services it deems ill-used, particularly ones that have run for quite some time.

Occasionally, an everlasting service is the right solution. Take a VOIP client, for example. A VOIP client usually needs to hold an open socket with the VOIP server to know about incoming calls. The only way to continuously watch for incoming calls is to continuously hold open the socket. The only component capable of doing that would be a service, so the service would have to continuously run.

However, in the case of a VOIP client, or a music player, the user is the one specifically requesting the service to run forever. By using `startForeground()`, a service can ensure it will not be stopped due to old age for cases like this.

As a counter-example, imagine an email client. The client wishes to check for new email messages periodically. The right solution for this is the `AlarmManager` pattern described [elsewhere in this book](#). The anti-pattern would have a service running constantly, spending most of its time waiting for the polling period to elapse (e.g., via `Thread.sleep()`). There is no value to the user in taking up RAM to watch the clock tick. Such services should be rewritten to use `AlarmManager`.

Most of the time, though, it appears that services are simply leaked. That is one advantage of using `AlarmManager` and an `IntentService` – it is difficult to leak the service, causing it to run indefinitely. In fact, `IntentService` in general is a great implementation to use whenever you use the command pattern, as it ensures that

REMOTE SERVICES AND THE BINDING PATTERN

the service will shut down eventually. If you use a regular service, be sure to shut it down when it is no longer actively delivering value to the user.

Advanced Manifest Tips

If you have been diligent about reading this book (versus having randomly jumped to this chapter), you will already have done a fair number of things with your project's `AndroidManifest.xml` file:

1. Used it to define components, like activities, services, content providers, and manifest-registered broadcast receivers
2. Used it to declare permissions your application requires, or possibly to define permissions that other applications need in order to integrate with your application
3. Used it to define what SDK level, screen sizes, and other device capabilities your application requires

In this chapter, we continue looking at things the manifest offers you, starting with a discussion of controlling where your [application gets installed](#) on a device, and wrapping up with a bit of information about [activity aliases](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Just Looking For Some Elbow Room

On October 22, 2008, the [HTC Dream](#) was released, under the moniker of “T-Mobile G1”, as the first production Android device.

Complaints about the lack of available storage space for applications probably started on October 23rd.

The Dream, while a solid first Android device, offered only 70MB of on-board flash for application storage. This storage had to include:

1. The Android application (APK) file
2. Any local files or databases the application created, particularly those deemed unsafe to put on the SD card (e.g., privacy)
3. Extra copies of some portions of the APK file, such as the compiled Dalvik bytecode, which get unpacked on installation for speed of access

It would not take long for a user to fill up 70MB of space, then have to start removing some applications to be able to try others.

Users and developers alike could not quite understand why the Dream had so little space compared to the available iPhone models, and they begged to at least allow applications to install to the SD card, where there would be more room. This, however, was not easy to implement in a secure fashion, and it took until Android 2.2 for the feature to become officially available.

If your app's `android:minSdkVersion` is 11 or higher, you can probably ignore all of this. At that time, what the Android SDK refers to as “internal storage” and “external storage” were moved to be part of one filesystem partition, and so there is no artificial division of space between the two.

But, if you are still supporting Android 2.2 and 2.3, you may wish to consider supporting having your app be installed to, or moved to, external storage.

Configuring Your App to Reside on External Storage

Indicating to Android that your application can reside on the SD card is easy... and necessary, if you want the feature. If you do not tell Android this is allowed, Android will *not* install your application to the SD card, nor allow the user to move the application to the SD card.

All you need to do is add an `android:installLocation` attribute to the root `<manifest>` element of your `AndroidManifest.xml` file. There are three possible values for this attribute:

ADVANCED MANIFEST TIPS

- `internalOnly`, the default, meaning that the application cannot be installed to the SD card
- `preferExternal`, meaning the application would like to be installed on the SD card
- `auto`, meaning the application can be installed in either location

If you use `preferExternal`, then your application will be initially installed on the SD card in most cases. Android reserves the right to still install your application on internal storage in cases where that makes too much sense, such as there not being an SD card installed at the time.

If you use `auto`, then Android will make the decision as to the installation location, based on a variety of factors. In effect, this means that `auto` and `preferExternal` are functionally very similar – all you are doing with `preferExternal` is giving Android a hint as to your desired installation destination.

Because Android decides where your application is initially installed, and because the user has the option to move your application between the SD card and on-board flash, you cannot assume any given installation spot. The exception is if you choose `internalOnly`, in which case Android will honor your request, at the potential cost of not allowing the installation at all if there is no more room in on-board flash.

For example, here is the manifest from the [SMS/Sender](#) sample project, profiled in [another chapter](#), showing the use of `preferExternal`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.sender"
    android:installLocation="preferExternal"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission android:name="android.permission.READ_CONTACTS" />
    <uses-permission android:name="android.permission.SEND_SMS" />

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11" />

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false" />

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="Sender"
```

ADVANCED MANIFEST TIPS

```
    android:label="@string/app_name">
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
</activity>
</application>
</manifest>
```

(from [SMS/Sender/app/src/main/AndroidManifest.xml](#))

Since this feature only became available in Android 2.2, to support older versions of Android, just have your build tools target API level 8 (e.g., `compileSdkVersion` of 8 or higher in `build.gradle` for Android Studio users) while having your `minSdkVersion` attribute in the manifest state the lowest Android version your application supports overall. Older versions of Android will ignore the `android:installLocation` attribute. So, for example, in the above manifest, the Sender application supports API level 4 and above (Android 1.6 and newer), but still can use `android:installLocation="preferExternal"`, because the build tools are targeting API level 8.

What the User Sees

On newer devices, such as those running Android 4.2, the user will see nothing different. That is because internal and external storage share a common pool of space, and therefore there is no advantage in having your application installed to external storage.

However, on, say, Android 2.3, you will see a difference in behavior.

For an application that wound up on external storage, courtesy of your choice of `preferExternal` or `auto`, the user will have an option to move it to the phone's internal storage. This can be done by choosing the application in the Manage Applications list in the Settings application, then clicking the "Move to phone" button.

Conversely, if your application is installed in on-board flash, and it is movable to external storage, they will be given that option with a "Move to SD card" button.

What the Pirate Sees

Ideally, the pirate sees nothing at all.

One of the major concerns with installing applications to the SD card is that the SD card is usually formatted FAT₃₂ (vfat), offering no protection from prying eyes. The concern was that pirates could then just pluck the APK file off external storage and distribute it, even for paid apps from the Play Store.

Apparently, they solved this problem.

To quote the [Android developer documentation](#):

The unique container in which your application is stored is encrypted with a randomly generated key that can be decrypted only by the device that originally installed it. Thus, an application installed on an SD card works for only one device.

Moreover, this “unique container” is not normally mounted when the user mounts external storage on their host machine. The user mounts `/mnt/sdcard`; the “unique container” is `/mnt/asec`.

What Your App Sees... When External Storage is Inaccessible

So far, this has all seemed great for users and developers. Developers need to add a single attribute to the manifest, and Android 2.2+ users gain the flexibility of where the app gets stored.

Alas, there is a problem, and it is a big one: on Android 1.x and 2.x, either the host PC or the device can have access to the SD card, but not both. As a result, if the user makes the SD card available to the host PC, by plugging in the USB cable and mounting the SD card as a drive via a Notification or other means, that SD card becomes unavailable for running applications.

So, what happens?

1. First, your application is terminated forcibly, as if your process was being closed due to low memory. Notably, your activities and services will not be called with `onDestroy()`, and instance state saved via `onSaveInstanceState()` is lost.
2. Second, your application is unhooked from the system. Users will not see your application in the launcher, your `AlarmManager` alarms will be canceled, and so on.

ADVANCED MANIFEST TIPS

3. When the user makes external storage available to the phone again, your application will be hooked back into the system and will be once again available to the user (for example, your icon will reappear in the launcher)

The upshot: if your application is simply a collection of activities, otherwise not terribly connected to Android, the impact on your application is no different than if the user reboots the phone, kills your process via a so-called “task killer” application, etc. If, however, you are doing more than that, the impacts may be more dramatic.

Perhaps the most dramatic impact, from a user’s standpoint, will be if your application implements app widgets. If the user has your app widget on her home screen, that app widget will be removed when the SD card becomes unavailable to the phone. Worse, your app widget cannot be re-added to the home screen until the phone is rebooted (a limitation that hopefully will be lifted sometime after Android 2.2).

The user is warned about this happening, at least in general:

Figure 772: Warning when unmounting the SD card

Two broadcast Intents are sent out related to this:

ADVANCED MANIFEST TIPS

- ACTION_EXTERNAL_APPLICATIONS_UNAVAILABLE, when the SD card (and applications installed upon it) become unavailable
- ACTION_EXTERNAL_APPLICATIONS_AVAILABLE, when the SD card and its applications return to normal

Note that the documentation is unclear as to whether your own application, that had been on the SD card, can receive ACTION_EXTERNAL_APPLICATIONS_AVAILABLE once the SD card is back in action. There is an [outstanding issue on this topic](#) in the Android issue tracker.

Also note that all of these problems hold true for longer if the user physically removes the SD card from the device. If, for example, they replace the card with a different one — such as one with more space — your application will be largely lost. They will see a note in their applications list for your application, but the icon will indicate it is on external storage, and the only thing they can do is uninstall it:

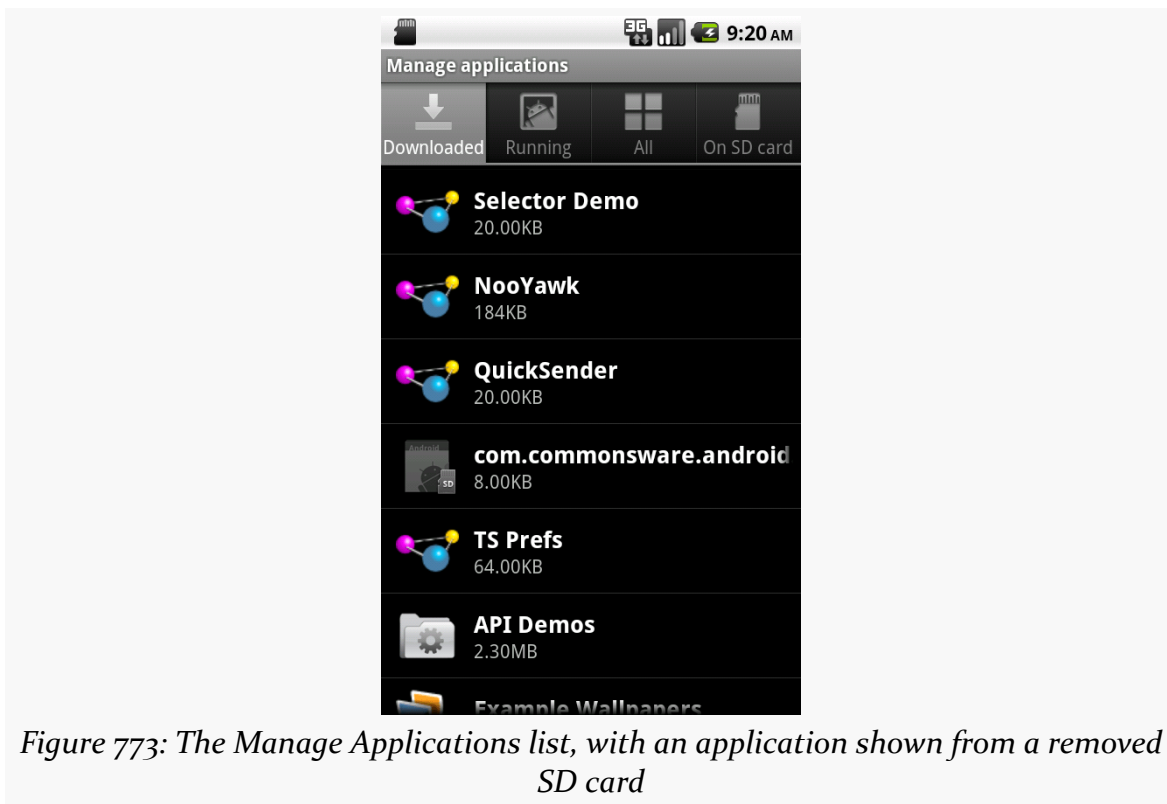

Figure 773: The Manage Applications list, with an application shown from a removed SD card

Choosing Whether to Support External Storage

Given the huge problem from the previous section, the question of whether or not your application should support external storage is far from clear.

As the [Android developer documentation](#) states:

Large games are more commonly the types of applications that should allow installation on external storage, because games don't typically provide additional services when inactive. When external storage becomes unavailable and a game process is killed, there should be no visible effect when the storage becomes available again and the user restarts the game (assuming that the game properly saved its state during the normal Activity lifecycle).

Conversely, if your application implements any of the following features, it may be best to not support external storage:

1. Polling of Web services or other Internet resources via a scheduled alarm
2. Account managers and their corresponding sync adapters, for custom sources of contact data
3. App widgets, as noted in the previous section
4. Device administration extensions
5. Live folders
6. Custom soft keyboards ("input method engines")
7. Live wallpapers
8. Custom search providers

But, as noted earlier, this is not even usually necessary on API Level 11+ devices. Hence, even if your app would otherwise qualify for being installed to external storage, you may not wish to bother. If few devices (Android 2.2 and Android 2.3) might need the capability, it may not be worth the extra testing burden.

Android 6.0 and "Adoption" of Removable Storage

When Android 3.0 did away with the required separate partitions for internal storage and external storage, the `android:installLocation` option fell out of use, as there was no particular value in having the apps on external storage. For single-partition devices — meaning, for most devices — users did not even have the option for moving their apps to external storage.

ADVANCED MANIFEST TIPS

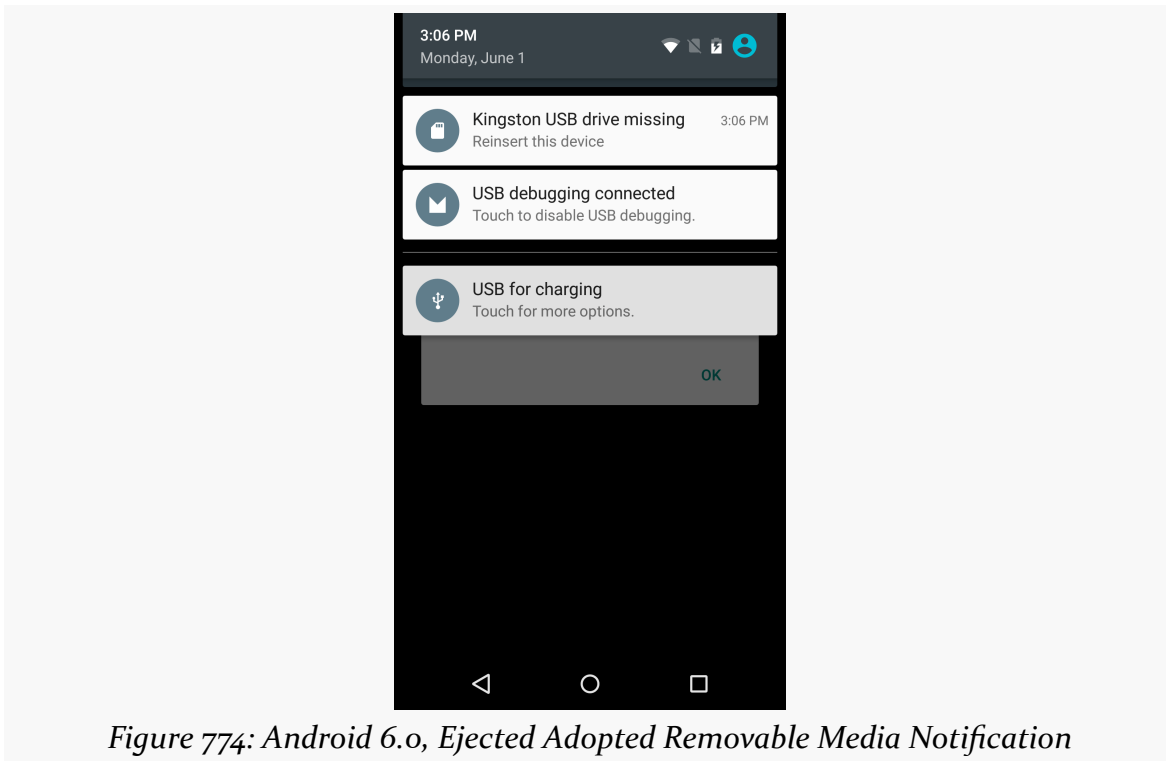

However, `android:installLocation` is returning to relevance, once again courtesy of removable media.

On Android 6.0+, users with removable storage options, such as micro SD card slots, have the option of “adopting” those as an extension of the device’s internal storage. Once done, apps set with `auto` or `preferExternal` for `android:installLocation` can be moved to the removable media. However, there appears to be one key difference: not only is the APK on the removable media, but so is all of that app’s portion of internal storage. The removable media is encrypted, so the material copied to the removable media should remain fairly inaccessible.

From the user’s standpoint, for low-end devices with minimal on-board flash, they have additional storage space that they can use for apps.

However:

- Removable media tends to be slow, and some cards will be slower than others. For developers, this makes it all that much more important for you to move disk I/O off of the main application thread.
- Removable media tends to be removable. If the user removes the removable media, while your app is installed on that removable media, your app will no longer work.
- All the [old rules](#) for apps that allow themselves to be installed on external storage will still hold true. Basically, any app that does periodic work, or will respond to incoming GCM messages, or has an app widget, or is always possibly needed (e.g., custom soft keyboard), should not allow itself to be moved to removable media. If the user *does* eject the media, they will get a permanent Notification telling them to put it back:

The user does have an “Erase & Format” option that will reformat the removable media and allow it to be permanently removed from the device. It does not appear that this will automatically move any apps back to internal storage. The users would need to move those apps back to internal storage by means of the Apps list in Settings.

Normally, it appears this system will be limited to internal card slots for things like micro SD cards. While USB On-The-Go (OTG) allows Android devices to access thumb drives, those are likely to be accidentally removed by the user (not to mention they usually tie up the charging port). However, for development testing purposes, you can run the `adb shell sm set-force-adoptable true` command to allow the device to adopt USB OTG drives. Note though that once you do this, the drive is more or less owned by that Android device until you “Erase & Format” it, and you will lose everything on the drive as part of this whole process.

Using an Alias

As was mentioned in the [chapter on integration](#), you can use the `PackageManager` class to enable and disable components in your application. This works at the

ADVANCED MANIFEST TIPS

component level, meaning you can enable and disable activities, services, content providers, and broadcast receivers. It does not support enabling or disabling individual `<intent-filter>` stanzas from a given component, though.

Why might you want to do this?

1. Perhaps you have an activity you want to be available for use, but not necessarily available in the launcher, depending on user configuration or unlocking “pro” features or something
2. Perhaps you want to add browser support for certain MIME types, but only if other third-party applications are not already installed on the device

While you cannot control individual `<intent-filter>` stanzas directly, you can have a similar effect via an activity alias.

An activity alias is another manifest element — `<activity-alias>` – that provides an alternative set of filters or other component settings for an already-defined activity. For example, here is the `AndroidManifest.xml` file from the [Manifest/Alias](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest android:versionCode="1"
    android:versionName="1.0"
    package="com.commonsware.android.alias"
    xmlns:android="http://schemas.android.com/apk/res/android">

    <supports-screens android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false" />
    <application android:icon="@drawable/cw"
        android:label="@string/app_name">
        <activity android:label="@string/app_name"
            android:name="AliasActivity">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity>
        <activity-alias android:label="@string/app_name2"
            android:name="ThisIsTheAlias"
            android:targetActivity="AliasActivity">
            <intent-filter>
                <action android:name="android.intent.action.MAIN" />
                <category android:name="android.intent.category.LAUNCHER" />
            </intent-filter>
        </activity-alias>
    </application>
</manifest>
```

(from [Manifest/Alias/app/src/main/AndroidManifest.xml](#))

ADVANCED MANIFEST TIPS

Here, we have one `<activity>` element, with an `<intent-filter>` to put the activity in the launcher. We also have an `<activity-alias>` element... which puts a second icon in the launcher for the same activity implementation.

An activity alias can be enabled and disabled independently of its underlying activity. Hence, you can have one activity class have several independent sets of intent filters and can choose which of those sets are enabled at any point in time.

For testing purposes, you can also enable and disable these from the command line. Use the `adb shell pm disable` command to disable a component:

```
adb shell pm disable
com.commonware.android.alias/com.commonware.android.alias.ThisIsTheAlias
```

... and the corresponding `adb shell pm enable` command to enable a component:

```
adb shell pm enable
com.commonware.android.alias/com.commonware.android.alias.ThisIsTheAlias
```

In each case, you supply the package of the application (`com.commonware.android.alias`) and the class of the component to enable or disable (`com.commonware.android.alias.ThisIsTheAlias`), separated by a slash.

Getting Meta (Data)

Sometimes, you may want to put more data in the manifest, associated with your components. You will frequently see this for use with libraries or plugin distribution models, where sharing some configuration data between parties could eliminate a bunch of API code that a reuser might need to implement.

To support this, Android offers a `<meta-data>` element as a child of `<activity>`, `<activity-alias>`, `<receiver>`, or `<service>`. Each `<meta-data>` element has an `android:name` attribute plus an associated value, supplied by either an `android:value` attribute (typically for literals) or an `android:resource` attribute (for references to resources).

Other parties can then get at this information via `PackageManager`. So, for example, the implementer of a plugin could have `<meta-data>` elements indicating details of how the plugin should be used (e.g., desired polling frequency), and the host of the plugin could then get that configuration data without the plugin author having to mess around with implementing some Java API for it.

ADVANCED MANIFEST TIPS

For example, Roman Nurik's [DashClock](#) is a [lockscreen app widget](#) designed to serve as a replacement for the clock app widget that ships with many Android 4.2+ devices. Not only does it display the time, but it is a plugin host, allowing third party developers to supply “extensions” that can also display data in the app widget. This way, users can set up a single lockscreen app widget and get at a bunch of useful information.

DashClock's extension API makes use of `<meta-data>` to pass configuration data from the extension to DashClock itself. The implementation of a DashClock extension is a service, and so the extension's `<service>` element will have a batch of `<meta-data>` elements with this configuration data:

```
<service android:name=".ExampleExtension"
  android:icon="@drawable/ic_extension_example"
  android:label="@string/extension_title"
  android:permission="com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA">
  <intent-filter>
    <action android:name="com.google.android.apps.dashclock.Extension" />
  </intent-filter>
  <meta-data android:name="protocolVersion" android:value="1" />
  <meta-data android:name="description"
    android:value="@string/extension_description" />
  <!-- A settings activity is optional -->
  <meta-data android:name="settingsActivity"
    android:value=".ExampleSettingsActivity" />
</service>
```

(sample from [the DashClock documentation](#))

Here, the developer can specify:

- What version of the communications protocol is supported, so DashClock can update its protocol over time yet remain backwards-compatible with older extensions, via the `protocolVersion` entry
- What the description is for the extension, used in DashClock's configuration screens to let the user know what available extensions there are, via the `description` entry
- What activity, if any, does the extension supply that allows the user to configure that extension, that DashClock should provide access to from its own settings activity, via the `settingsActivity` entry

In all three cases, DashClock uses `android:value`. Note that `android:value` *does* support the use of resources — the value of `description` is a reference to the `extension_description` string resource, for example.

ADVANCED MANIFEST TIPS

To retrieve that metadata, an app can ask for `PackageManager.GET_META_DATA` as a flag on `PackageManager` [methods for introspection](#), like `queryIntentActivities()`. In the case of DashClock, it retrieves all implementations of its plugin by asking Android what *services* have an `<intent-filter>` with an `<action>` of `com.google.android.apps.dashclock.Extension`, via `queryIntentServices()`, asking for `PackageManager` to also supply each service's metadata:

```
List<ResolveInfo> resolveInfos = pm.queryIntentServices(  
    new Intent(DashClockExtension.ACTION_EXTENSION), PackageManager.GET_META_DATA);
```

(from [the ExtensionManager.java file](#) in the DashClock source code)

Each `ResolveInfo` object that comes back in the list will have a `serviceInfo` field containing details of the service. Because `GET_META_DATA` was passed in as a flag, the `serviceInfo` will have a `Bundle` named `metaData` which will contain the key/value pairs specified by the `<meta-data>` elements. DashClock can then grab that data and use it to populate its own object model:

```
for (ResolveInfo resolveInfo : resolveInfos) {  
    ExtensionListing listing = new ExtensionListing();  
    listing.componentName = new ComponentName(resolveInfo.serviceInfo.packageName,  
        resolveInfo.serviceInfo.name);  
    listing.title = resolveInfo.loadLabel(pm).toString();  
    Bundle metaData = resolveInfo.serviceInfo.metaData;  
    if (metaData != null) {  
        listing.protocolVersion = metaData.getInt("protocolVersion");  
        listing.description = metaData.getString("description");  
        String settingsActivity = metaData.getString("settingsActivity");  
        if (!TextUtils.isEmpty(settingsActivity)) {  
            listing.settingsActivity = ComponentName.unflattenFromString(  
                resolveInfo.serviceInfo.packageName + "/" + settingsActivity);  
        }  
    }  
}
```

(from [the ExtensionManager.java file](#) in the DashClock source code)

The `<meta-data>` element supports five data types for `android:value`:

- String
- Integer
- Boolean (specified as `true` or `false` in the `android:value` attribute)
- Float

It also supports colors, specified in `#AARRGGBB` and similar formats, which, according to [the documentation](#), is returned as a string.

ADVANCED MANIFEST TIPS

In this fashion, extension developers can supply enough information for DashClock to allow the user to see the list of installed extensions, choose which one(s) they want, and configure those (where applicable). Actually getting the *content* to display will need to be done at runtime, in this case via making requests of the service to supply a `ExtensionData` structure with the messages, icon, and so forth to be displayed.

Miscellaneous Integration Tips

This chapter is a collection of other miscellaneous integration and introspection tips and techniques that you might find useful in your Android apps.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Direct Share

The classic means of “sharing” content between apps is via `ACTION_SEND`. You create an `ACTION_SEND` Intent, identifying the content to share, and use it with `startActivity()`. The decision of what the candidates are to share with is based solely on the MIME type of the content in question.

Sometimes, sharing of content with another app really means sharing that content with some other person, folder, or finer-grained context within the other app. `ACTION_SEND`, on its own, does not do anything for this. The user chooses the other app, then inside that app chooses the finer-grained context. While `ACTION_SENDTO` supports the sender indicating who to share the content with, that only works for select Uri schemes (`mailto` and `smsto`, mostly), and it requires that the sender have a suitable Uri to identify the recipient. As a result, few apps support `ACTION_SENDTO`.

Android 6.0 introduced “direct share targets”. Now, the recipients of sharing operations can elect to serve up specific share targets, pointing not only to the app but to the finer-grained context within the app. The user will then see these targets listed in the “chooser” window, alongside other standard share targets.

MISCELLANEOUS INTEGRATION TIPS

This involves creating a subclass of `ChooserTargetService` and tying it via some `<meta-data>` to your activity supporting the `ACTION_SEND <intent-filter>`. That service will then be called with `onGetChooserTargets()`, where it is told what activity and `<intent-filter>` was matched, and the service can return a list of `ChooserTarget` objects. Those `ChooserTarget` objects each represent a single direct share target, where the `ChooserTarget` wraps up a dedicated caption, icon, and `PendingIntent` for each. Those may be presented to the user in the chooser; if the user chooses one, the `PendingIntent` is invoked.

The [Intents/FauxSenderMNC](#) sample project is a revised version of the `FauxSender` sample. `FauxSender` has an implementation of an `ACTION_SEND` activity, plus a `LAUNCHER` activity that just uses `startActivity()` to trigger an `ACTION_SEND` Intent. `FauxSenderMNC` augments the original sample with direct-share functionality.

The ChooserTargetService

The bulk of the business logic goes in your subclass of `ChooserTargetService`, here named `CTService`:

```
package com.commonware.android.fsendermnc;

import android.app.PendingIntent;
import android.content.ComponentName;
import android.content.Intent;
import android.content.IntentFilter;
import android.graphics.drawable.Icon;
import android.os.Bundle;
import android.service.chooser.ChooserTarget;
import android.service.chooser.ChooserTargetService;
import java.util.ArrayList;
import java.util.List;

public class CTService extends ChooserTargetService {
    private String titleTemplate;

    @Override
    public void onCreate() {
        super.onCreate();

        titleTemplate=getString(R.string.title_template);
    }

    @Override
    public List<ChooserTarget> onGetChooserTargets(ComponentName sendTarget,
        IntentFilter matchedFilter) {
        ArrayList<ChooserTarget> result=new ArrayList<ChooserTarget>();

        for (int i=1;i<=6;i++) {
            result.add(buildTarget(i));
        }
    }
}
```

MISCELLANEOUS INTEGRATION TIPS

```
return(result);
}

private ChooserTarget buildTarget(int targetId) {
    String title=String.format(titleTemplate, targetId);
    int iconId=getResources().getIdentifier("ic_share" + targetId,
        "drawable", getPackageName());
    Icon icon=Icon.createWithResource(this, iconId);
    float score=1.0f-((float)targetId/40);
    ComponentName cn=new ComponentName(this, FauxSender.class);
    Bundle extras=new Bundle();

    extras.putInt(FauxSender.EXTRA_TARGET_ID, targetId);

    return(new ChooserTarget(title, icon, score, cn, extras));
}
}
```

(from [Intents/FauxSenderMNC/app/src/main/java/com/commonsware/android/fsendermnc/CTService.java](https://github.com/commonsware/android-fsendermnc/blob/master/CTService.java))

You are welcome to override the `onCreate()` and `onDestroy()` lifecycle methods in your `ChooserTargetService` if you want, though it is not required. Here, we override `onCreate()` just to grab a string resource value that will be used as a template, stashing it in a data member.

The one method that you have to implement is `onGetChooserTargets()`. This will be called when direct-share is triggered, as directed by some manifest entries that we will examine in a bit. Your job is to return a `List` of `ChooserTarget` objects that represent specific ways to share the content into your app, such as sharing to particular contacts or folders or something.

Note that whatever you return from `onGetChooserTargets()` is included *along with your regular ACTION_SEND activity itself*. Hence, you only want to return `ChooserTarget` objects that improve the user flow beyond your base `ACTION_SEND` activity — you do not need to have a `ChooserTarget` that simply replicates what the user would get from the `ACTION_SEND` activity itself.

In this case, `onGetChooserTargets()` returns a six-element `ArrayList` of `ChooserTarget` objects, each built using a private `buildTarget()` method.

A `ChooserTarget` is a simple wrapper around five pieces of data:

- A `String` to use as a caption for your direct-share icon
- An `Icon` that represents the icon itself
- A `float` “score” that represents the relative importance of this direct-share target over any others that you return, where `1.0f` means “the user is really going to like this one”, `0.0f` means “the user could conceivably want this, but

probably not”, and values in between 0 and 1 represent shades of gray in the realm of importance

- A `ComponentName` identifying either an activity in your app (the typical answer) or an exported activity in another app (rather unusual)
- A `Bundle` of extras to go into the `Intent` that the framework will create, using that `ComponentName`, to trigger the activity in question

Note that the `ComponentName` does *not* have to start the same activity that is your `ACTION_SEND` activity. In this sample, it happens to use the same activity. But that is not a requirement, and frequently you will use some other activity. For example, if your normal `ACTION_SEND` flow would first have the user choose a folder, then provide additional information about the shared item (e.g., confirm the title, add tags), if you create direct-share targets that specify particular folders, you would want to bypass the folder-selection step in your own UI. If the `ACTION_SEND` activity implements the folder-selection logic and forwarded the user along to some other activity to handle the rest, your `ChooserTarget` `ComponentName` objects might just drive straight to the second activity, skipping the folder-selection UI.

Also note that you may be creating several `ChooserTarget` objects, probably having each pointing to the same activity. You will need to ensure that the extras `Bundle` contains what you need to distinguish one request from the next. However, do not put custom `Parcelable` objects in this `Bundle`, as Android will attempt to un-parcel them as part of its work, and it will fail to do so since Android does not have your custom `Parcelable` class.

An `Icon` is a new construct in Android 6.0, serving as a wrapper around multiple possible image sources. You can create an `Icon` from a drawable resource (as the sample app does), from a `Bitmap`, from a byte array representing PNG or JPEG data, from a file path pointing to a PNG or JPEG file, or from a `Uri` to a `ContentProvider` pointing to an image.

The Manifest Entries

Your `ChooserTargetService` will have a typical `<service>` manifest entry, with two special bits:

- An `android:permission="android.permission.BIND_CHOOSER_TARGET_SERVICE"` attribute, to limit access to your service to the framework, rather than being spoofed by other clients, and

MISCELLANEOUS INTEGRATION TIPS

- An `<intent-filter>` for the `android.service.chooser.ChooserTargetService` action

```
<service
  android:name=".CTService"
  android:permission="android.permission.BIND_CHOOSER_TARGET_SERVICE">
  <intent-filter>
    <action android:name="android.service.chooser.ChooserTargetService"/>
  </intent-filter>
</service>
```

(from [Intents/FauxSenderMNC/app/src/main/AndroidManifest.xml](#))

Your ACTION_SEND activity will have its normal `<activity>` element, with just one change: a `<meta-data>` element pointing to your `ChooserTargetService`:

```
<activity
  android:name="FauxSender"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.NoDisplay">
  <intent-filter android:label="@string/app_name">
    <action android:name="android.intent.action.SEND"/>

    <data android:mimeType="text/plain"/>

    <category android:name="android.intent.category.DEFAULT"/>
  </intent-filter>
  <meta-data
    android:name="android.service.chooser.chooser_target_service"
    android:value=".CTService"/>
</activity>
```

(from [Intents/FauxSenderMNC/app/src/main/AndroidManifest.xml](#))

It is possible that your app has multiple ACTION_SEND activities. In that case, each could have its own `ChooserTargetService`. However, you could elect to have all of your ACTION_SEND activities route to the same `ChooserTargetService` if you prefer. `onGetChooserTargets()` is passed two parameters to help identify where the direct-share request is coming from:

- the `ComponentName` of the ACTION_SEND activity that was tied to your service, and
- the `IntentFilter` that triggered that activity in the first place, so you can determine things like the MIME type of the to-be-shared content

Note that you are *not* given the content itself, in the form of the `Intent` that will eventually be delivered to your ACTION_SEND activity or to your direct-share target via its `ComponentName`. This is for privacy reasons; otherwise, an app could ask to share anything and be able to peek at anything the user tried sharing with any app.

The Results

The FauxSender activity — the one handling the ACTION_SEND Intent and the direct-share Intent — now looks for the EXTRA_TARGET_ID that the CTService put in its Intent and includes it in the Toast:

```
package com.commonware.android.fsendermnc;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.widget.Toast;

public class FauxSender extends Activity {
    public static final String EXTRA_TARGET_ID="targetId";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        String epilogue="";

        super.onCreate(savedInstanceState);

        int targetId=getIntent().getIntExtra(EXTRA_TARGET_ID, -1);

        if (targetId>0) {
            epilogue=" for target ID #"+targetId;
        }

        String msg=getIntent().getStringExtra(Intent.EXTRA_TEXT);

        if (TextUtils.isEmpty(msg)) {
            msg=getIntent().getStringExtra(Intent.EXTRA_SUBJECT);
        }

        if (TextUtils.isEmpty(msg)) {
            msg=getString(R.string.no_message_supplied);
        }

        Toast.makeText(this, msg+epilogue, Toast.LENGTH_LONG).show();

        finish();
    }
}
```

(from [Intents/FauxSenderMNC/app/src/main/java/com/commonware/android/fsendermnc/FauxSender.java](#))

If you run the sample app from Android Studio, the launcher activity will trigger an ACTION_SEND of some text. That, in turn, will bring up the chooser panel... but on an Android 6.0 device, that panel will start off with our six direct-share targets:

MISCELLANEOUS INTEGRATION TIPS

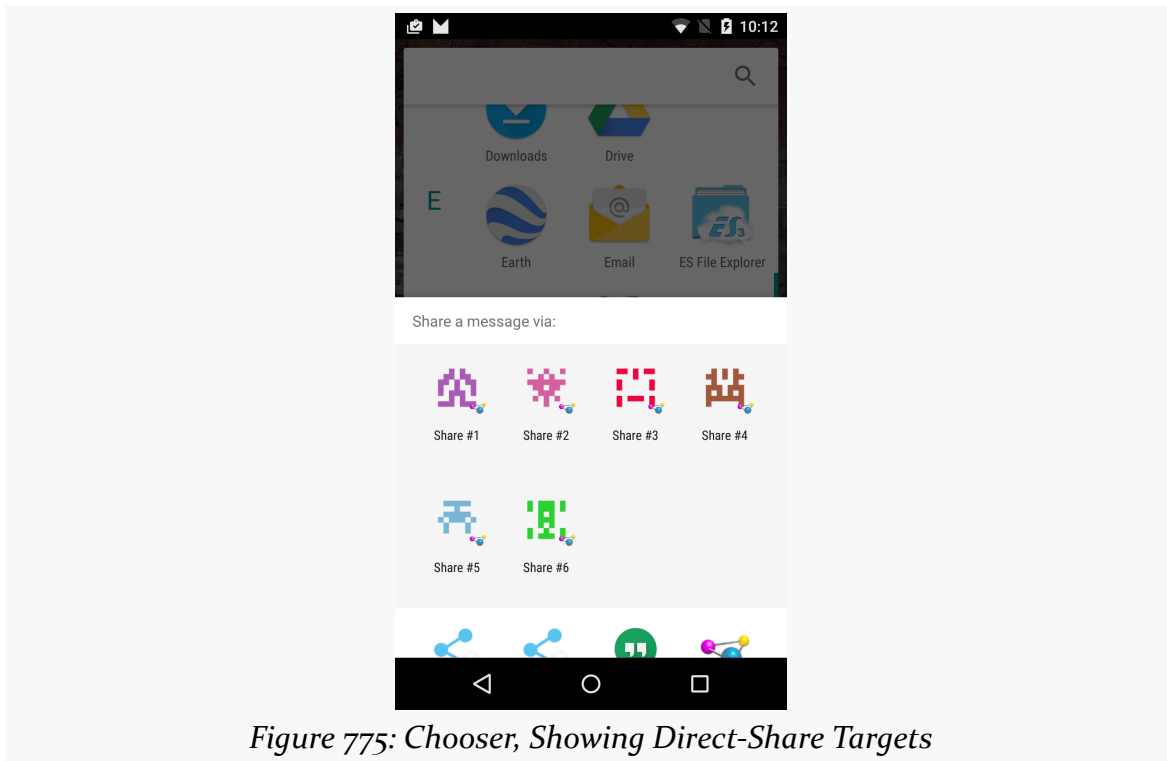

Figure 775: Chooser, Showing Direct-Share Targets

Expanding the panel shows that our original ACTION_SEND activity is also there, after the direct-share targets:

MISCELLANEOUS INTEGRATION TIPS

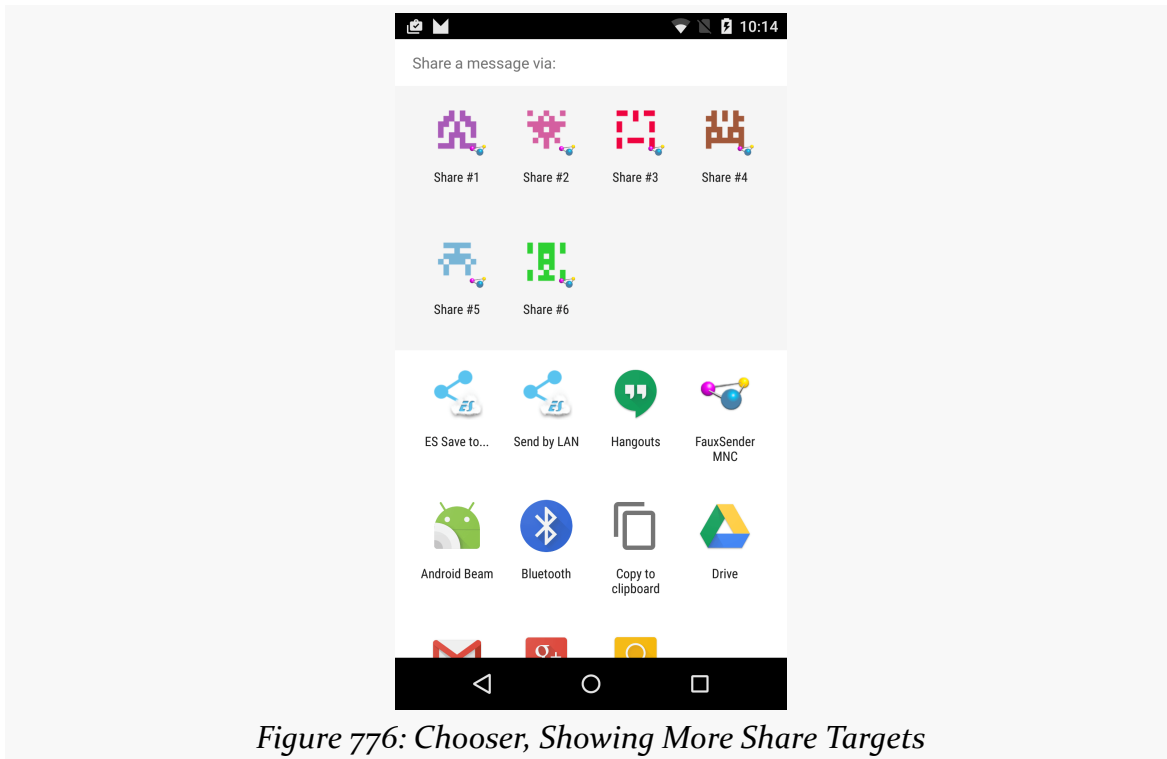

Figure 776: Chooser, Showing More Share Targets

If the user taps on the regular ACTION_SEND activity icon, the sample works as it did originally, showing a Toast with the text supplied by the launcher activity. If, however, the user taps on one of the direct-share targets, the Toast also shows which target was chosen:

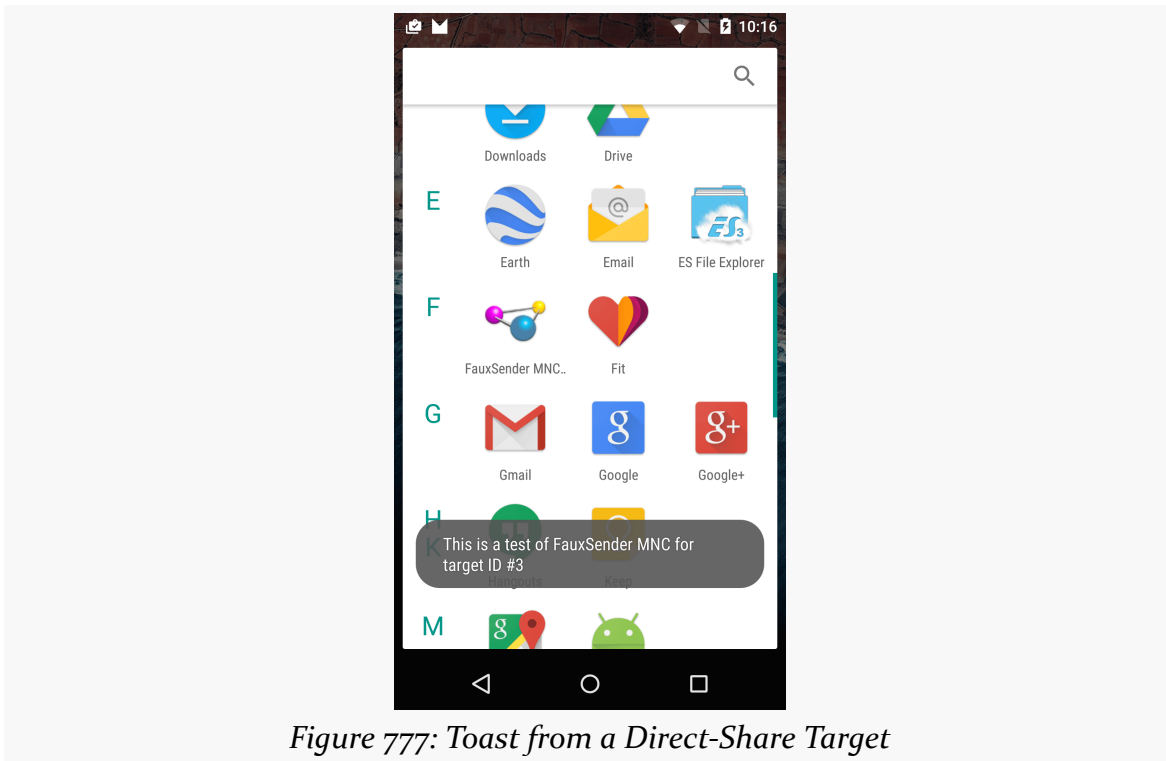

Figure 777: Toast from a Direct-Share Target

Now, our Bundle for the direct-share target did not include the shared text, because we did not have it. Instead, the regular ACTION_SEND extras are merged in with our own extras, so our activity gets all of the relevant extras.

But... I Got Nothin'!

If you do not have any direct-share targets for a particular request, returning an empty list is perfectly fine.

If you know in advance that you will not have any direct-share targets — for example, the user has not really worked with your app yet after installation — you can disable the service (`android:enabled="false"`). Even though the `<meta-data>` will point to the service, the framework seems to detect the disabled service and continues on unabated.

Even if you elect to leave the service enabled at the outset for Android 6.0, you should consider disabling the service for earlier versions of Android, since it is useless on those devices. You could do this using boolean resources:

- Have a `res/values/booleans.xml` file with a `bool` resource (e.g., `offer_direct_share`) set to `false`
- Have a `res/values-v23/booleans.xml` file redefining that resource to `true`
- Have `android:enabled="@bool/offer_direct_share"` on your service, to have it be enabled only on Android 6.0 and higher

Best Practices

At the moment, it appears that Android 6.0 is limiting the number of share targets, only showing 8 of them. If you provide more than 8, Android will choose the ones with the highest score.

Since returning the list of direct-share targets should be involving IPC, there may be capacity limitations, for the number and size of the direct-share targets. Do not be surprised if you get a “FAILED BINDER TRANSACTION” exception if your roster of direct-share targets exceeds 1MB.

Hence, between those two limitations, you will want to constrain how many share targets you try returning from your `ChooserTargetService`.

As with other places in Android 5.0+ (e.g., large icons in notifications), your app’s icon will be applied as a badge over the icons that you use for direct-share targets. Make sure that your app’s icon will work both as a launcher icon and as a direct-share target badge.

Take the Shortcut

Another way to integrate with Android is to offer custom shortcuts. Shortcuts are available from the home screen. Whereas app widgets allow you to draw on the home screen, shortcuts allow you to wrap a custom `Intent` with an icon and caption and put that on the home screen. You can use this to drive users not just to your application’s “front door”, like the launcher icon, but to some specific capability within your application, like a bookmark.

In our case, in the [Introspection/QuickSender](#) sample project, we will allow users to create shortcuts that use `ACTION_SEND` to send a pre-defined message, either to a specific address or anywhere, as we have seen [before in this chapter](#).

Once again, the key is in the intent filter.

Registering a Shortcut Provider

Here is the manifest for QuickSender:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
  package="com.commonware.android.qsender"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="15"
    android:targetSdkVersion="15"/>
  <application
    android:icon="@drawable/cw"
    android:label="@string/app_name">
    <activity
      android:name="QuickSender"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.CREATE_SHORTCUT"/>
        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

(from [Introspection/QuickSender/app/src/main/AndroidManifest.xml](#))

Our single activity does not implement a traditional launcher `<intent-filter>`. Rather, it has one that watches for a `CREATE_SHORTCUT` action. This does two things:

- It means that our activity will show up in the list of possible shortcuts a user can configure
- It means this activity will be the recipient of a `CREATE_SHORTCUT` Intent if the user chooses this application from the shortcuts list

Implementing a Shortcut Provider

The job of a shortcut-providing activity is to:

1. Create an Intent that will be what the shortcut launches
2. Return that Intent and other data to the activity that started the shortcut provider
3. Finally, `finish()`, so the caller gets control

You can see all of that in the QuickSender implementation:

MISCELLANEOUS INTEGRATION TIPS

```
package com.commonware.android.qsender;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.widget.TextView;

public class QuickSender extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void save(View v) {
        Intent shortcut=new Intent(Intent.ACTION_SEND);
        TextView addr=(TextView)findViewById(R.id.addr);
        TextView subject=(TextView)findViewById(R.id.subject);
        TextView body=(TextView)findViewById(R.id.body);
        TextView name=(TextView)findViewById(R.id.name);

        if (!TextUtils.isEmpty(addr.getText())) {
            shortcut.putExtra(Intent.EXTRA_EMAIL,
                new String[] { addr.getText().toString() });
        }

        if (!TextUtils.isEmpty(subject.getText())) {
            shortcut.putExtra(Intent.EXTRA_SUBJECT, subject.getText()
                .toString());
        }

        if (!TextUtils.isEmpty(body.getText())) {
            shortcut.putExtra(Intent.EXTRA_TEXT, body.getText().toString());
        }

        shortcut.setType("text/plain");

        Intent result=new Intent();

        result.putExtra(Intent.EXTRA_SHORTCUT_INTENT, shortcut);
        result.putExtra(Intent.EXTRA_SHORTCUT_NAME, name.getText()
            .toString());
        result.putExtra(Intent.EXTRA_SHORTCUT_ICON_RESOURCE,
            Intent.ShortcutIconResource.fromContext(this,
                R.drawable.icon));

        setResult(RESULT_OK, result);
        finish();
    }
}
```

(from [Introspection/QuickSender/app/src/main/java/com/commonware/android/qsender/QuickSender.java](https://github.com/Commonware/android-qsender/blob/master/src/main/java/com/commonware/android/qsender/QuickSender.java))

The shortcut Intent is the one that will be launched when the user taps the shortcut icon on the home screen. The result Intent packages up shortcut plus the icon and caption, where the icon is converted into an

MISCELLANEOUS INTEGRATION TIPS

`Intent.ShortcutIconResource` object. That result `Intent` is then used with the `setResult()` call, to pass that back to whatever called `startActivityForResult()` to open up `QuickSender`. Then, we finish().

At this point, all the information about the shortcut is in the hands of Android (or, more accurately, the home screen application), which can add the icon to the home screen.

Using the Shortcuts

Exactly how `CREATE_SHORTCUT` implementations like this are handled depends on the home screen implementation. Some might not offer them at all. Other home screens might have dedicated options for shortcuts.

The Nexus series devices, running Android 6.0, lump `CREATE_SHORTCUT` implementations in with the app widgets. You can add one to your home screen by long-tapping on the home screen, choosing “Widgets”, and scrolling down to the shortcut that you want:

Figure 778: Android 6.0, Widgets List, Showing Sample App

MISCELLANEOUS INTEGRATION TIPS

Tap-and-hold on the “widget”, and you will be able to place it on the screen. Once that is done, our activity will appear, with the form to define what to send:

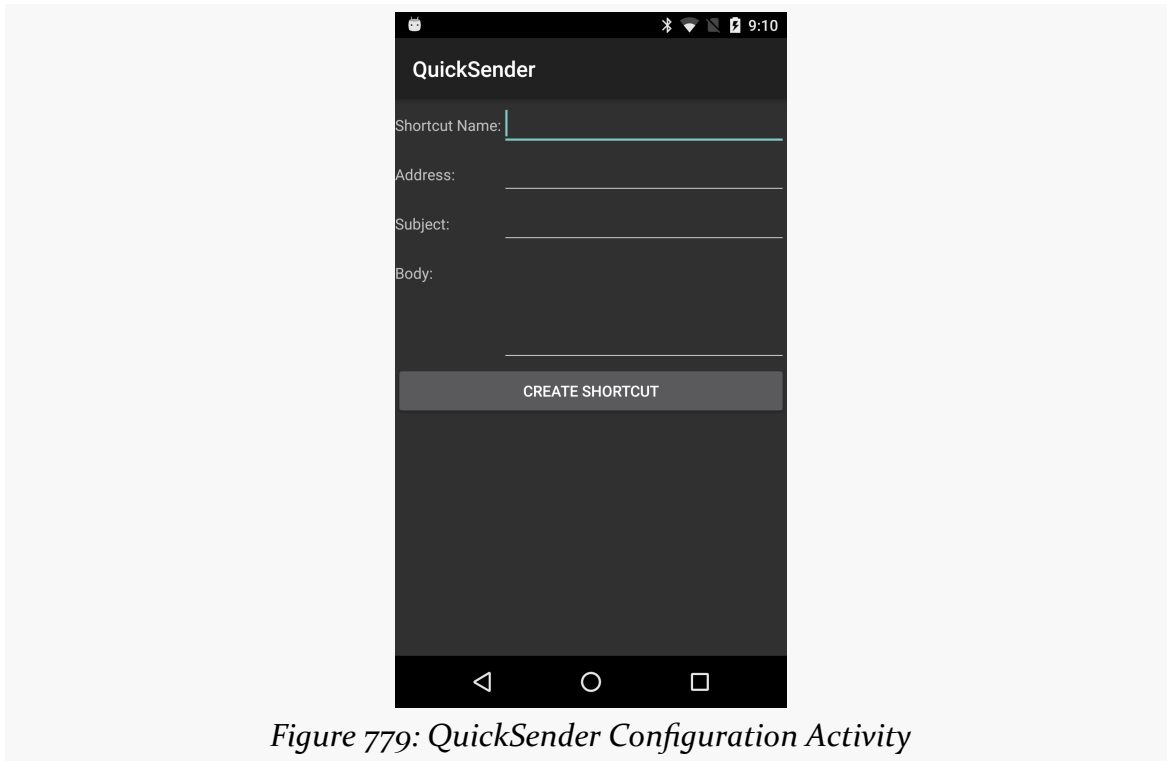

Figure 779: QuickSender Configuration Activity

Fill in the name, either the subject or body, and optionally the address. Then, click the Create Shortcut button, and you will find your shortcut sitting on your home screen, with your chosen shortcut name as the label:

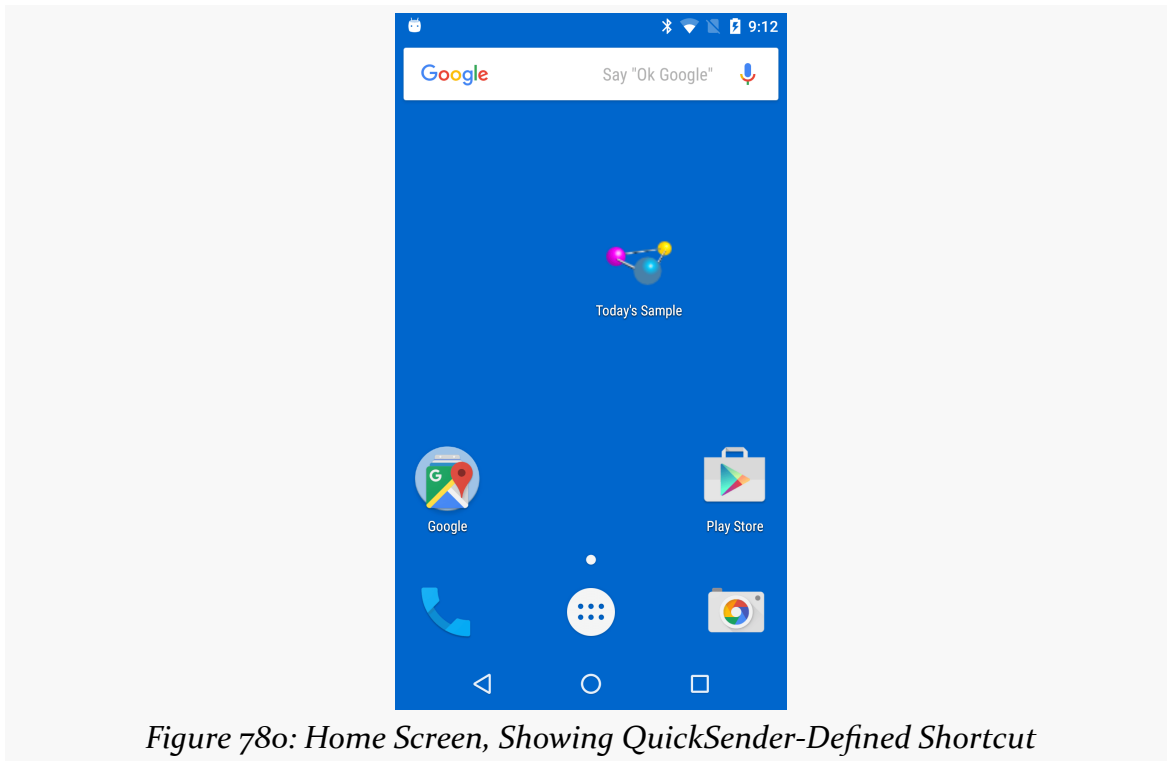

Figure 780: Home Screen, Showing QuickSender-Defined Shortcut

If you launch that shortcut, and if there is more than one application on the device set up to handle `ACTION_SEND`, Android will bring up a special chooser, to allow you to not only pick how to send the message, but optionally make that method the default for all future requests:

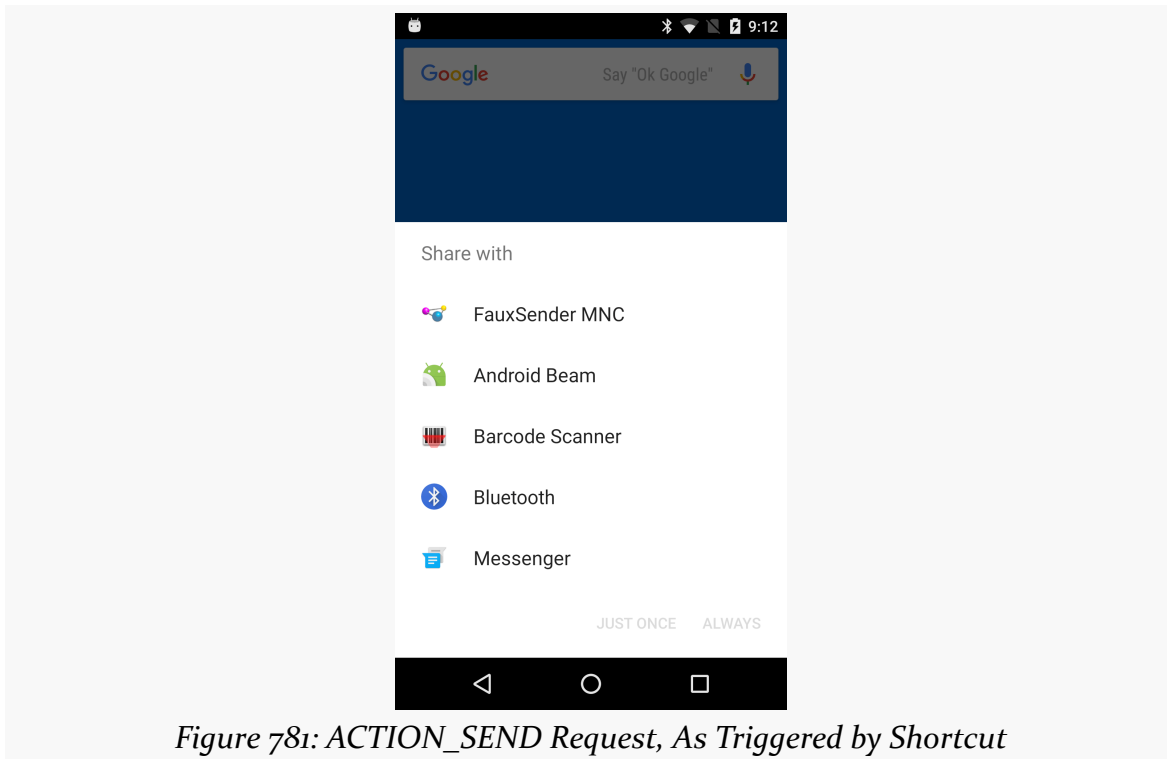

Figure 781: ACTION_SEND Request, As Triggered by Shortcut

Depending on what you choose, of course, will dictate how the message actually gets sent.

Homing Beacons for Intents

If you are encountering problems with Intent resolution — you create an Intent for something and try starting an Activity or Service with it, and it does not work — you can add the `FLAG_DEBUG_LOG_RESOLUTION` flag to the Intent. This will dump information to LogCat about how the Intent resolution occurred, so you can better diagnose what might be going wrong.

Integrating with Text Selection

On Android 6.0+, if you highlight text, you will see a new floating action mode, where cut, copy, and paste operations reside:

MISCELLANEOUS INTEGRATION TIPS

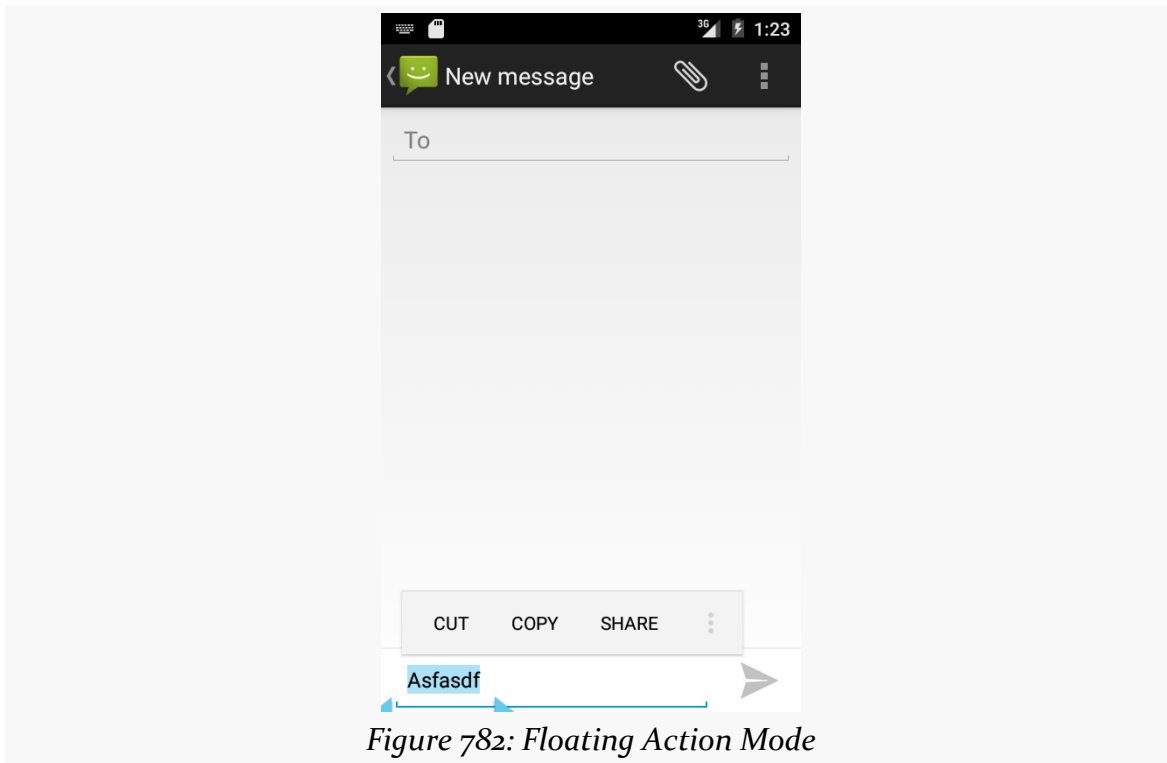

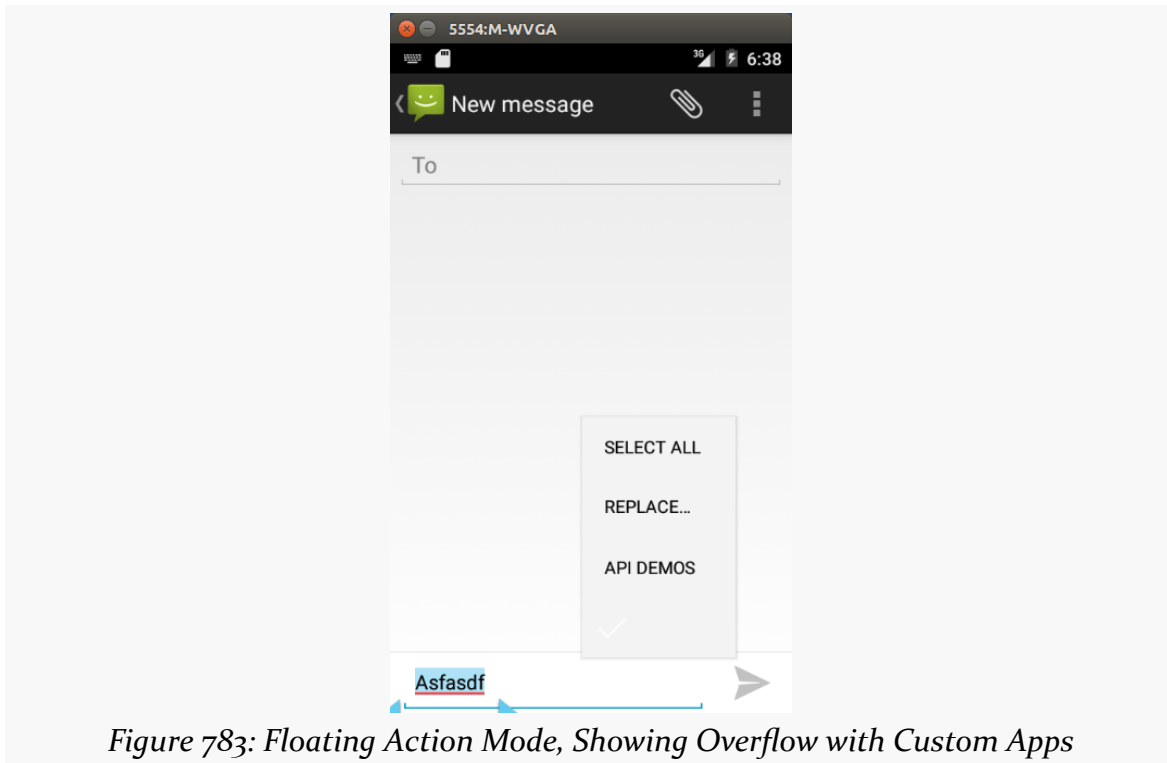

Figure 782: Floating Action Mode

If you tap that overflow indicator on the action mode, a fly-out menu will appear... one that contains arbitrary apps, in addition to system-supplied options:

MISCELLANEOUS INTEGRATION TIPS

In this case, the Android 6.0 “API Demos” app appears as an option. Choosing it pops up an activity *that has access to the highlighted text from the preceding activity*:

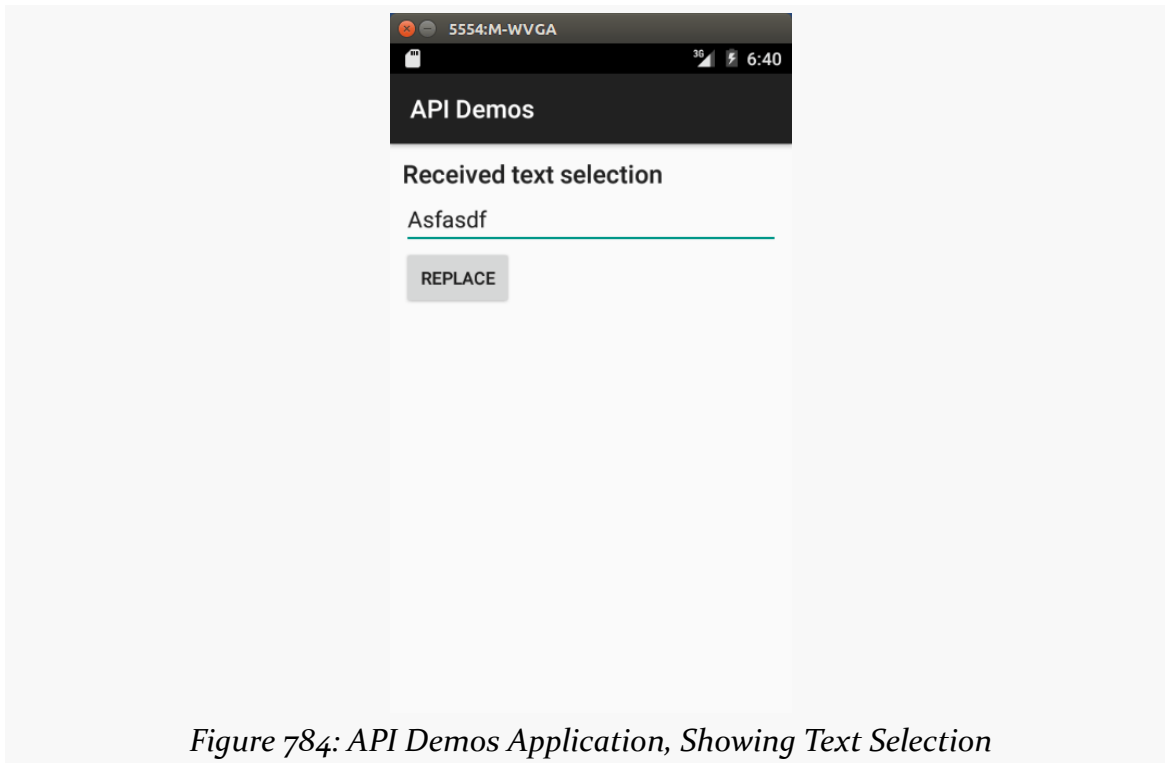

Figure 784: API Demos Application, Showing Text Selection

Replacing the value in the field and clicking the button puts your replacement text in as a replacement for whatever you had highlighted.

This is accomplished via the `ACTION_PROCESS_TEXT` Intent action. Apps can advertise activities that support this action, and they will be added (sometimes) to the floating action mode. Apps that have `EditText` widgets just automatically get these options in the floating action mode, with no additional required code.

Supporting `ACTION_PROCESS_TEXT`

Your app can offer an `ACTION_PROCESS_TEXT` activity, in which case you will appear in Android 6.0+ text-selection floating action modes. This is illustrated in the [Introspection/ProcessText](#) sample application.

The Manifest

To be visible to these text-selection action modes, you need an activity with an `<intent-filter>` calling for `ACTION_PROCESS_TEXT` and a MIME type of `text/plain`:

MISCELLANEOUS INTEGRATION TIPS

```
<activity
  android:name="MainActivity"
  android:label="@string/app_name">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
  <intent-filter >
    <action android:name="android.intent.action.PROCESS_TEXT"/>
    <category android:name="android.intent.category.DEFAULT" />
    <data android:mimeType="text/plain" />
  </intent-filter>
</activity>
```

(from [Introspection/ProcessText/app/src/main/AndroidManifest.xml](#))

Exactly which MIME types are supported is not documented. At the time of this writing, the only examples showed text/plain. It is possible that other formats (e.g., text/html) might also be supported.

The Extras

You will get one of two extras attached to the ACTION_PROCESS_TEXT Intent:

- EXTRA_PROCESS_TEXT is the text to be processed, and also indicates that you can supply replacement text, if you wish
- EXTRA_PROCESS_TEXT_READONLY will be set if EXTRA_PROCESS_TEXT is not, and provides the text to be processed and an indication that you cannot supply replacement text

It is up to you to check for those string extras, grab the right value, and do something useful with it.

In the sample app, in onCreate() of the MainActivity, if we are starting fresh (i.e., there is no QuestionsFragment already), we get the search string and provide it to QuestionsFragment via a newInstance() factory method:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content)==null) {
        String search=null;

        if (Intent.ACTION_PROCESS_TEXT.equals(getIntent().getAction())) {
            search=getIntent().getStringExtra(Intent.EXTRA_PROCESS_TEXT);

            if (search==null) {
                search=getIntent()
```

MISCELLANEOUS INTEGRATION TIPS

```
        .getStringExtra(Intent.EXTRA_PROCESS_TEXT_READONLY);
    }
}

getFragmentManager()
    .beginTransaction()
    .add(android.R.id.content,
        QuestionsFragment.newInstance(search))
    .commit();
}
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/procstext/MainActivity.java](#))

QuestionsFragment, in turn, stuffs that value into the arguments Bundle in newInstance():

```
public class QuestionsFragment extends ListFragment implements
    Callback<SOQuestions> {
    private static final String ARG_SEARCH="search";

    static QuestionsFragment newInstance(String search) {
        QuestionsFragment result=new QuestionsFragment();
        Bundle args=new Bundle();

        args.putString(ARG_SEARCH, search);
        result.setArguments(args);

        return(result);
    }
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/procstext/QuestionsFragment.java](#))

An expanded version of StackOverflowInterface offers not only the original questions() method, but also a search() method, the latter of which searches Stack Overflow for questions in the android tag that have a search term in the title:

```
package com.commonsware.android.procstext;

import retrofit.Callback;
import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
    void questions(@Query("tagged") String tags, Callback<SOQuestions> cb);
    @GET("/2.2/questions?order=desc&sort=creation&site=stackoverflow&tagged=android")
    void search(@Query("intitle") String search, Callback<SOQuestions> cb);
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/procstext/StackOverflowInterface.java](#))

onCreateView() in QuestionsFragment then calls either questions() or search(), depending on whether or not we have a search string from ACTION_PROCESS_TEXT:

MISCELLANEOUS INTEGRATION TIPS

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {

    View result=
        super.onCreateView(inflater, container, savedInstanceState);

    setRetainInstance(true);

    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
            .build();

    StackOverflowInterface so=
        restAdapter.create(StackOverflowInterface.class);
    String search=getArguments().getString(ARG_SEARCH);

    if (search==null) {
        so.questions("android", this);
    }
    else {
        so.search(search, this);
    }

    return(result);
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/processtext/QuestionsFragment.java](#))

The Results (If Any)

If you got a value for EXTRA_PROCESS_TEXT and you wish to return a replacement string, you need to create an Intent with your own EXTRA_PROCESS_TEXT value that is the replacement text, then use that Intent with setResult(). MainActivity does this when the user taps on a list item in QuestionsFragment:

```
}

public void onEventMainThread(QuestionClickedEvent event) {
    if (Intent.ACTION_PROCESS_TEXT.equals(getIntent().getAction()) &&
        getIntent().getStringExtra(Intent.EXTRA_PROCESS_TEXT)!=null) {
        setResult(Activity.RESULT_OK,
            new Intent().putExtra(Intent.EXTRA_PROCESS_TEXT, event.item.link));
        finish();
    }
    else {
        startActivity(new Intent(Intent.ACTION_VIEW,
            Uri.parse(event.item.link)));
    }
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/processtext/MainActivity.java](#))

If the activity was started due to a replaceable bit of text to be processed, we return the URL to the question the user tapped on. In all other cases, we just start up some browser or other app to view that URL.

If you install this app on an Android 6.0+ device, then run some other app that has an EditText, type in some term in portrait mode, highlight it, and choose “PROCESS TEXT DEMO” from the floating action mode, you will be presented with a list of Stack Overflow questions in the android tag that refer to your search term in the title. If you tap on one, your search term will be replaced in the EditText widget by the URL of the question.

Limitations of ACTION_PROCESS_TEXT

Alas, ACTION_PROCESS_TEXT is “not all unicorns and rainbows”. There are a few issues that you will need to take into account.

Security

There is no documented android:permission attribute to place on the <activity> that is offering ACTION_PROCESS_TEXT, to limit callers. Ideally, we could limit invocations of ACTION_PROCESS_TEXT only to the firmware itself. As it stands, any app can call startActivity() (or, worse, startActivityForResult()) for your ACTION_PROCESS_TEXT activity and have your code process the text (with user intervention). Please be sure that if you return data via EXTRA_PROCESS_TEXT that the data not include any private information or anything that needs to be secured.

With luck, [this will be improved in a future version of Android](#).

Landscape

In Android 6.0, the text-selection floating action mode for an EditText does not appear in landscape mode, when the entire UI is dedicated to the text-entry screen with the input method editor:

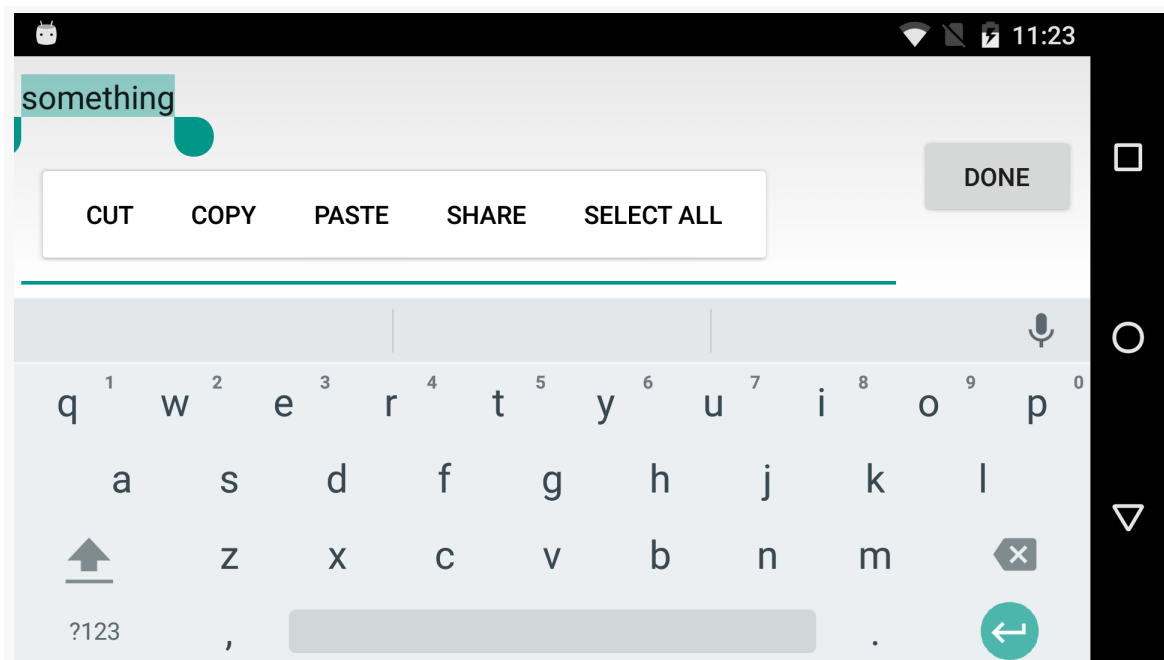

Figure 785: Landscape EditText, Sans ACTION_PROCESS_TEXT Options

With luck, [this too will be fixed in a future version of Android](#).

Supporting ACTION_PROCESS_TEXT in Custom Views

TextView and its subclasses are already capable of offering the user ACTION_PROCESS_TEXT options. However, you may have custom View classes that have the notion of text selection, but where you are rendering the available actions to take upon that selection yourself. In that case, you will need to do the reverse: find the implementers of ACTION_PROCESS_TEXT and add them to your UI.

To do this:

- Create an Intent for ACTION_PROCESS_TEXT and a MIME type of text/plain
- Use queryIntentActivities() on PackageManager to find out the activities that handle that Intent structure
- Organize the results, such as sorting them alphabetically by label using ResolveInfo.DisplayNameComparator
- Create Intent objects for each resolved activity, also with ACTION_PROCESS_TEXT and text/plain, but also with EXTRA_PROCESS_TEXT or EXTRA_PROCESS_TEXT_READONLY filled in with your selection, and also call

- setClassName() to provide the package name and activity class name to make the Intent explicit
- Add appropriate elements to your UI for each of those Intent objects
 - If the user chooses one, call startActivity() (for EXTRA_PROCESS_TEXT_READONLY) or startActivityForResult() (for EXTRA_PROCESS_TEXT) to invoke the other activity
 - In the case of EXTRA_PROCESS_TEXT, watch for your result in onActivityResult() and use the replacement text supplied in the result Intent and its EXTRA_PROCESS_TEXT string extra

The [Android Developers Blog](#) has a post that provides some code for this, assuming that you want to put items in an action bar or action mode for the various resolved activities.

Blocking ACTION_PROCESS_TEXT

There will be cases where you do not want ACTION_PROCESS_TEXT to be offered to your users. For example, perhaps the text contains sensitive information that should not be passed outside of your app.

The best solution, particularly for a TextView, is to mark the text as not being selectable. This is accomplished via android:textIsSelectable="false" in a layout file, or via setTextIsSelectable(false) in Java. false is the default value for TextView.

However, for an EditText widget, true is the default is-selectable state, and you cannot seem to override that with setTextIsSelectable(false).

There is no officially supported option for handling this case, though [perhaps there will be one in the future](#).

One unsupported hack of a workaround relies upon the fact that EditText blocks the floating action mode for password fields. In the source code to EditText, TextView, and related classes, this is handled by seeing if the TransformationMethod associated with the widget is PasswordTransformationMethod. A TransformationMethod is responsible for on-the-fly adjustments between what the user types and what the user sees, such as PasswordTransformationMethod replacing typed-in characters with dots.

Making your EditText widget use PasswordTransformationMethod itself is fine for actual password fields. But suppose you have an EditText whose contents should be

MISCELLANEOUS INTEGRATION TIPS

kept private but should not have the input-shrouding effect of `PasswordTransformationMethod`. To offer this, you would need to create a *subclass* of `PasswordTransformationMethod` (so the block-the-floating-action-mode logic works) that does not actually transform the text (to block the changes that `PasswordTransformationMethod` would ordinarily apply).

A proof-of-concept implementation of this can be found in the [Introspection/ProcessTextBlocker](#) sample application. This is a clone of the `FilesEditor` sample app from [the chapter on files](#), with one change: the use of `DummyTransformationMethod`:

```
private static class DummyTransformationMethod
    extends PasswordTransformationMethod {
    @Override
    public CharSequence getTransformation(CharSequence source,
                                         View view) {
        return(source);
    }

    @Override
    public void onTextChanged(CharSequence s, int start,
                              int before, int count) {
        // no-op
    }

    @Override
    public void onFocusChanged(View view,
                               CharSequence sourceText,
                               boolean focused, int direction,
                               Rect previouslyFocusedRect) {
        // no-op
    }

    @Override
    public void afterTextChanged(Editable s) {
        // no-op
    }

    @Override
    public void beforeTextChanged(CharSequence s, int start,
                                   int count, int after) {
        // no-op
    }
}
```

(from [Introspection/ProcessTextBlocker/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java](#))

This is a do-nothing `TransformationMethod`. Ordinarily, this would be completely useless. However, it inherits from `PasswordTransformationMethod`, which is what we need to block the floating action mode.

MISCELLANEOUS INTEGRATION TIPS

In `onCreateView()` of the `EditorFragment`, we apply a `DummyTransformationMethod` via `setTransformationMethod()`:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    View result=inflater.inflate(R.layout.editor, container, false);

    editor=(EditText)result.findViewById(R.id.editor);
    editor.setTransformationMethod(new DummyTransformationMethod());

    return(result);
}
```

(from [Introspection/ProcessTextBlocker/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java](https://github.com/commonsware/android/fileseditor/blob/master/fileseditor/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java))

However, this approach has limitations:

- It only works in portrait, not landscape, for unclear reasons. Since `ACTION_PROCESS_TEXT` *also* only works in portrait, not landscape, we still succeed in blocking `ACTION_PROCESS_TEXT` options.
- It blocks the entire floating action mode (in portrait), clobbering the existing cut/copy/paste/select-all options that might ordinarily be there.
- Since it is tied to internal implementation (that the floating action mode is suppressed when using an instance of a `PasswordTransformationMethod`), not only is this subject to change across Android versions, but also it is subject to change based on device manufacturer or custom ROM tweaks to the Android source code.

Reusable Components

In the world of Java outside of Android, reusable components rule the roost. Whether they are simple JARs, are tied in via inversion-of-control (IoC) containers like [Spring](#), or rely on enterprise service buses like [Mule](#), reusable Java components are a huge portion of the overall Java ecosystem. Even full-fledged applications, like [Eclipse](#) or [NetBeans](#), are frequently made up of a number of inter-locking components, many of which are available for others to use in their own applications.

Android, too, supports this sort of reuse. In some cases, it follows standard Java approaches. However, in other cases, unique Android aspects, such as resources, steer developers in different directions for reuse.

This chapter will outline what reuse models are in use today and how you can package your own components for reuse.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Where Do I Find Them?

Android historically has not had a “go-to” place to find reusable components. [The Android Arsenal](#) is probably the largest collection at present. Beyond that, look for recommendations in Stack Overflow answers, blog posts, and the like.

How Are They Packaged?

There are three main ways that reusable code gets packaged on Android: as a traditional Java JAR, as an Android library project, or (technically) as an APK. The last approach is usually used by apps that have user value in their own right, but also expose some sort of integration API for use by other apps, that you can take advantage of.

JARs

Android code that is pure *code*, without requiring its own resources, can be packaged into a JAR, no differently than can regular Java code outside of Android.

As was covered [earlier in the book](#), to use such a JAR, just drop it into `libs/`. Its contents will be added to your compile path (so you can reference classes from the library) and its contents will be packaged in your APK (so those references will work at runtime).

Library Projects

Android code that relies upon resources — such as many reusable UI components, such as custom widgets — cannot be packaged as a simple JAR, as there is no way of packaging the Android resources in that JAR. Instead, Google created [the Android library project](#) as the “unit of reuse” for such cases.

Android library projects are sometimes published in full source form (usually open source projects), and sometimes are published as AARs in an artifact repository. Eclipse users can readily use the full-source library projects, but have [limited ability](#) to use AARs. Android Studio users can use either, and AARs may be as simple as adding a single line to `build.gradle`.

APKs

Using JARs or library projects fits in the “traditional” model of compile-time reuse. Android’s many IPC mechanisms offer plenty of options for run-time reuse, where your app communicates with another app, having that app do things on your behalf. In this case, the primary unit of reuse is not the JAR, or the library project, but the APK.

For example, [the ZXing project](#) publishes [the Barcode Scanner app](#). This app not only allows *users* to scan barcodes, but allows *other apps* to scan barcodes, by asking Barcode Scanner to scan the barcodes and return results.

To integrate with such an app, you will need to find the instructions from the app's developers on how to do that. Sometimes, they will tell you things that you would use directly (e.g., “call `startActivityForResult()` with an Intent that contains..”). Sometimes, they will distribute a client-side JAR that you can use that wraps up the low-level IPC details into something a bit easier to consume. For example, ZXing distributes an [IntentIntegrator.java class file](#) that you can use that not only handles requesting the scans, but also helping the user install Barcode Scanner if it is not already installed.

How Do I Create Them?

To create a reusable component, you start by getting a working code base, one that implements whatever it is that you desire. From there, you need to choose which of those aforementioned distribution patterns you believe is appropriate:

- JAR
- Standard library project
- Eclipse-compatible binary-only library project
- APK (with optional client-side JAR)

That, in turn, will drive how you take your code and create such a package. The basics of how to do that for the different alternatives is described in the following sections.

JARs

Creating a JAR for a reusable chunk of Android-related code is not significantly different than is creating a JAR for a reusable chunk of “ordinary” Java code.

First, you need a project that represents the “reusable chunk of Android-related code”. An easy way to do this is to just create a standard Android library project, but one where you do not bother creating any resources.

Once the code is ready for distribution, you can create a JAR from the compiled Java classes by your favorite traditional means. The author of this book, for example, adds custom Gradle tasks for this:

REUSABLE COMPONENTS

```
// from http://stackoverflow.com/a/19484146/115145
android.libraryVariants.all { variant ->
    def name = variant.buildType.name
    if (name.equals(com.android.builder.core.BuilderConstants.DEBUG)) {
        return; // Skip debug builds.
    }
    def task = project.tasks.create "jar${name.capitalize()}", Jar
    task.dependsOn variant.javaCompile
    task.from variant.javaCompile.destinationDir
    task.archiveName = "cwac-${task.archiveName}"
    task.exclude('com/commonsware/cwac/**/BuildConfig.**')
}
```

This will create JAR-building Gradle tasks for all non-debug build types, so you get Gradle tasks like `jarRelease`. It specifically excludes `BuildConfig`, which the CWAC libraries never use, but otherwise takes all of the library classes and packages them in a JAR, named after the library and version, with a `cwac-` prefix.

If your reusable code is pure Java, not involving Android at all, you are welcome to create a plain Java project and create your JAR from that. The only major recommendation would be to ensure that you are using some `android.jar` from the SDK, rather than a `JDK rt.jar`, to ensure that you are sticking with classes and methods that are in Android's subset of the Java SE class library.

Standard Library Projects

In many respects, distributing a standard Android library project is even easier: just ZIP it up. Or, if it is in a public source control repository (e.g., GitHub), reusers can obtain it from that repository.

Of course, this will distribute the source code along with the resources and everything else. This is typical for an open source library project.

Android Studio and Gradle users can create AARs from their library projects. The `assembleRelease` task will create an AAR for the library in `build/outputs/aar`, named after the library and version (e.g., `pager-0.2.3.jar`).

Eclipse-Compatible Binary-Only Library Projects

AARs do not ship Java source code, but rather only binaries. However, AARs are not readily consumable from Eclipse.

It is possible to create an Eclipse-Compatible binary-only library project, one where your source code is replaced by a JAR. This can be useful for proprietary library

REUSABLE COMPONENTS

projects, for example. However, there is one noteworthy limitation with today's tools: the library project cannot itself depend upon a JAR or another library project.

For simpler library projects, the recipe is straightforward, given an already-existing Android library project:

1. Compile the Java source (e.g., via Ant) and turn it into a JAR file.
2. Create a copy of your original Android library project to serve as a distribution Android library project.
3. Place the compiled JAR from step #1 and put it in `libs/` of the distribution library project from step #2.
4. Delete everything in `src/` of the distribution library project (but leave the now-empty `src/` directory there).
5. Distribute the distribution library project (e.g., ZIP it up)

For example, an Ant target to create a distribution ZIP might be:

```
<target name="jar" depends="release">
  <delete file="bin/WhateverYouWantToCallYourLibrary.jar" />
  <jar destfile="bin/WhateverYouWantToCallYourLibrary.jar">
    <fileset dir="bin/classes">
      <exclude name="**/BuildConfig.class" />
      <exclude name="**/R.class" />
      <exclude name="**/R$.class" />
    </fileset>
  </jar>
</target>
<target name="dist" depends="jar">
  <copy todir="/tmp/WhateverYouWantToCallYourLibrary/libs">
    <fileset dir="libs/" />
  </copy>
  <copy todir="/tmp/WhateverYouWantToCallYourLibrary/res">
    <fileset dir="res/" />
  </copy>
  <copy
    file="bin/WhateverYouWantToCallYourLibrary.jar"
    todir="/tmp/WhateverYouWantToCallYourLibrary/libs" />
  <copy
    file="AndroidManifest.xml"
    todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy file="build.xml" todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy
    file="project.properties"
    todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <copy file="LICENSE" todir="/tmp/WhateverYouWantToCallYourLibrary" />
  <mkdir dir="/tmp/WhateverYouWantToCallYourLibrary/src" />
  <zip
    destfile="/tmp/WhateverYouWantToCallYourLibrary.zip"
    basedir="/tmp/"
    includes="WhateverYouWantToCallYourLibrary/**"
    whenempty="create" />
</target>
```

REUSABLE COMPONENTS

```
<delete dir="/tmp/WhateverYouWantToCallYourLibrary" />  
</target>
```

Assuming the existence of a `/tmp/` directory (e.g., OS X or Linux), this will result in a `WhateverYouWantToCallYourLibrary.zip` file in `/tmp/`. Along the way, we:

- Copy the `libs/` and `res/` trees from your source library project to a temporary distribution directory
- Copy your compiled JAR into the `libs/` subdirectory of the temporary distribution directory
- Copy other miscellaneous files, like your `LICENSE` file for your software license terms, into the root of the temporary distribution directory
- Create an empty `src/` subdirectory in the temporary distribution directory
- ZIP up the temporary distribution directory to a ZIP file
- Delete the temporary distribution directory

APK

Most of your work for this distribution model is in writing and distributing the app to your end users, through the Play Store or your other chosen distribution channels.

In addition to that, you need to either document to reusers what sorts of IPC your app supports, or create a JAR or library project that reusers can use to perform that sort of integration. In the latter case, you would have a separate project representing that JAR or library project that you would distribute using any of the aforementioned approaches.

Other Considerations for Publishing Reusable Code

Of course, there is more to publishing a reusable component than code and perhaps Android resources. The following sections outline some other things to consider as you contemplate offering some code base up for reuse by third parties.

Licensing

Your reusable code should be accompanied by adequate licensing information.

Your License

The first license you should worry about is your own. Is your component open source? If so, you will want to ship a license file containing those terms. If your component is not open source, make sure there is a license agreement shipped with the component that lets the reuser know the terms of use.

Bear in mind that not all of your code necessarily has to have the same license. For example, you might have a proprietary license for the component itself, but have sample code be licensed under Apache License 2.0 for easy copy-and-paste.

Third-Party License Impacts

You may need to include licenses for third party libraries that you have to ship along with your own JAR. Obviously, those licenses would need to give you redistribution rights — otherwise, you cannot ship those libraries in the first place.

Sometimes, the third party licenses will impact your project more directly, such as:

1. Incorporating a GPL library may require your project to be licensed under the same license
2. Adding support for Facebook data may require you to limit your API or require reusers to supply API access keys, since you probably do not have rights to redistribute Facebook data

Documenting the Usage

If you are expecting people to reuse your code, you are going to have to tell them how to do that. Usually, these sorts of packages ship documentation with them, sometimes a clone of what is available online. That way, developers can choose the local or hosted edition of the documentation as they wish.

Note that generated documentation (e.g., Javadocs) may still need to be shipped or otherwise supplied to reusers, if you are not providing the source code in the package. Without the source code, reusers cannot regenerate the Javadocs.

Many open source projects eschew formal documentation in favor of simple JavaDocs, plus “documentation in the form of a test suite” or “documentation in the form of sample apps”. While test suites and sample apps are useful supplements, they are not always an effective replacement for written documentation. And, while

JavaDocs are useful for reference material, they are often difficult to comprehend for those trying to get started with the code and not knowing where to begin.

Naming Conventions

Make sure that your Java code is in a package that is likely to be distinct from any others that reusers might already have. Typically, this means that the package name is based on a domain name that you control, much like the package name for Android apps themselves. Whatever you do, please do not publish your own code as `android.*`, unless you are contributing this code to the Android open source project, as `android.*` is reserved for use by Android itself.

(The author of this book would also appreciate it if you would not use `com.commonsware.*`)

Also, be careful about the names of your resources. While your Java code resides in its own namespace, your resources are pooled with all other resources in use by the app. As a result, if you decide to reference `R.layout.main` thinking that it will be *your* `main.xml` layout resource, it might actually be replaced by a `main.xml` resource written by the app developer. You may wish to use some sort of a prefix convention on your resource names to reduce the odds of accidental collision:

- [ActionBarSherlock](#) uses `abs__`
- [ViewPagerIndicator](#) uses `vpi__`
- And so on

Android Studio Editors and Dialogs

Eclipse, with the ADT plugin, had many structured editors and specialized dialogs for modifying Android project files and otherwise configuring Android project behavior.

Android Studio has fewer of those, and they are generally less critical. The editors and dialogs presented in this chapter can be useful, at least in some cases, but you do not need to use any of them to be able to create your Android projects. However, some may speed up your Android development a bit over working with bare resource and Gradle files.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with the chapters on:

- the [Gradle project structure](#)
- [Gradle dependencies](#)

Project Structure

The Project Structure dialog allows you to configure many aspects of your `build.gradle` files from a tabbed property-style dialog, as opposed to having to work with the Gradle scripts directly. On the plus side, this can be easier. However, since Gradle is built on the Groovy scripting language, `build.gradle` files are not simple XML or JSON data structures. It remains to be seen how well the Project Structure dialog will be able to handle complex Gradle scripts.

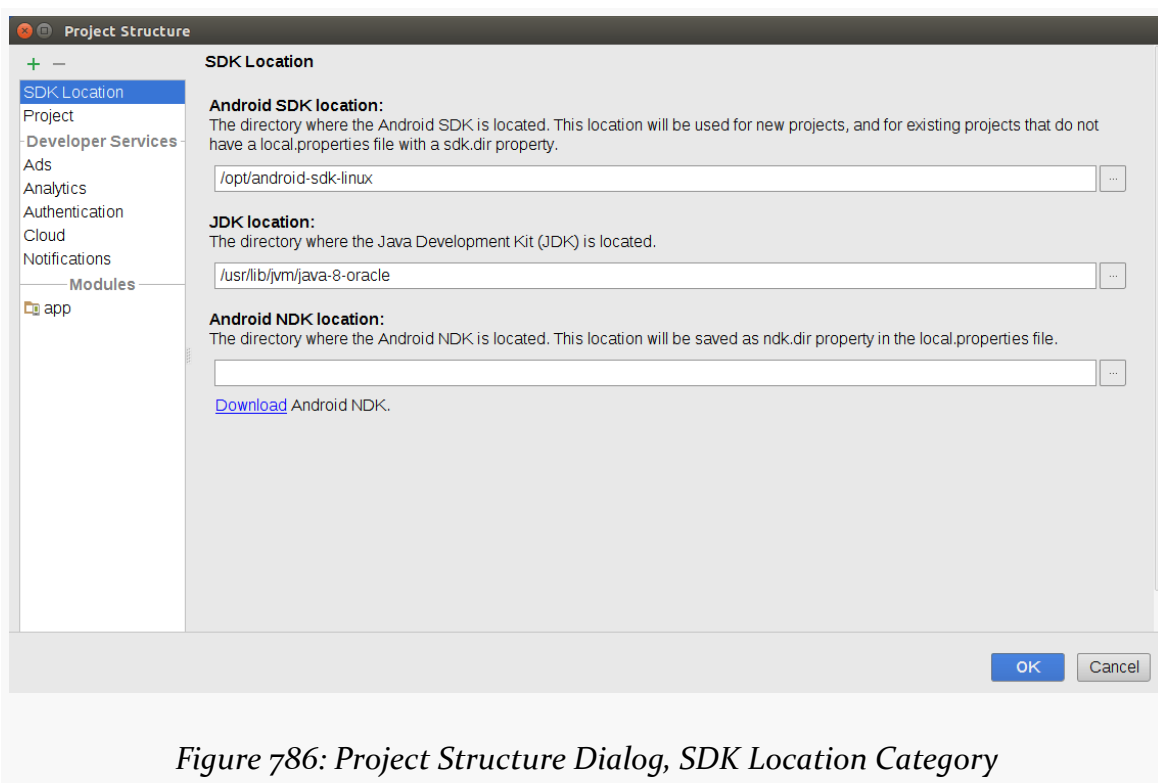

To access the Project Structure dialog, choose File > Project Structure from the main IDE menu.

The left-hand side lists major areas of the dialog; choosing one of those switches to that area's form on the right.

The sections that follow outline each of the major areas and what you can configure in them.

SDK Location

The Project Structure dialog opens up on the SDK Location area, where you can configure where your Android SDK is located, where your JDK is located, and where your NDK is located:

Adjusting these in Project Settings affects this specific project. There is also File > Other Settings > Default Project Structure, where you can edit the default values to be used for new projects and projects that you import in the future.

Project Settings

The second entry in the Project Structure dialog category list is “Project”. This allows you to configure four items found by default in the `build.gradle` file in your project root or in the `gradle-wrapper.properties` file:

- What version of Gradle you wish to use for the Gradle Wrapper
- What version of the Android Plugin for Gradle you wish to use
- What artifact repository should be used for pulling in the Gradle for Android plugin (and any other plugins you may be using)
- What artifact repository should be used by default for standard module artifacts (e.g., those you request via `compile` directives in your module’s `build.gradle` file)

Figure 787: Project Structure Dialog, Project Settings Category

Developer Services

If you are using select portions of the Play Services SDK, the items under the “Developer Services” divider allow you to configure those portions. By default, they amount to checkboxes, to enable certain features:

ANDROID STUDIO EDITORS AND DIALOGS

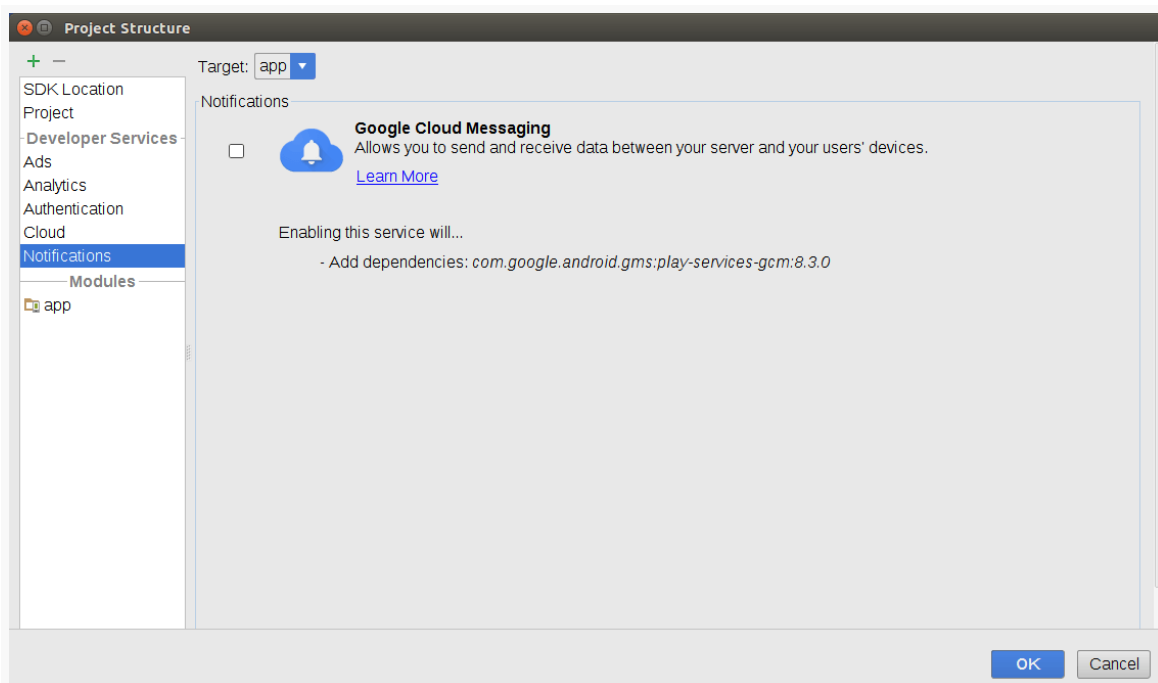

Figure 788: Project Structure Dialog, Notifications Category

Module Settings

Below the “Modules” divider in the category list on the left will come all of your modules. If you are not using modules, there will be a single entry in the category list with the same name as your project, as a quasi-module.

Clicking on a module will bring up a set of tabs on the right to edit various properties of that module, independently of any other module in your project. The following sections outline the contents of those tabs.

Properties

The first tab is labeled “Properties” and allows you to adjust various top-level settings in your module’s `build.gradle` file.

ANDROID STUDIO EDITORS AND DIALOGS

Figure 789: Project Structure Dialog, Module Category, Properties Tab

These include:

- Your `compileSdkVersion` (“Compile Sdk Version” drop-down)
- Your `buildToolsVersion` (“Build Tools Version” drop-down)
- Another artifact repository to use for this module, added to your module’s repositories closure (“Library Repository”)
- The `ignoreAssetsPattern` property in `aaptOptions` (“Ignore Assets Pattern”)
- The `incremental` property in `dexOptions` (“Incremental Dex”)
- The `sourceCompatibility` in `compileOptions` (“Source Compatibility”)
- The `targetCompatibility` in `compileOptions` (“Target Compatibility”)

Signing

If your module’s `build.gradle` file has a `signingConfigs` closure, the “Signing” tab will let you edit those signing configurations:

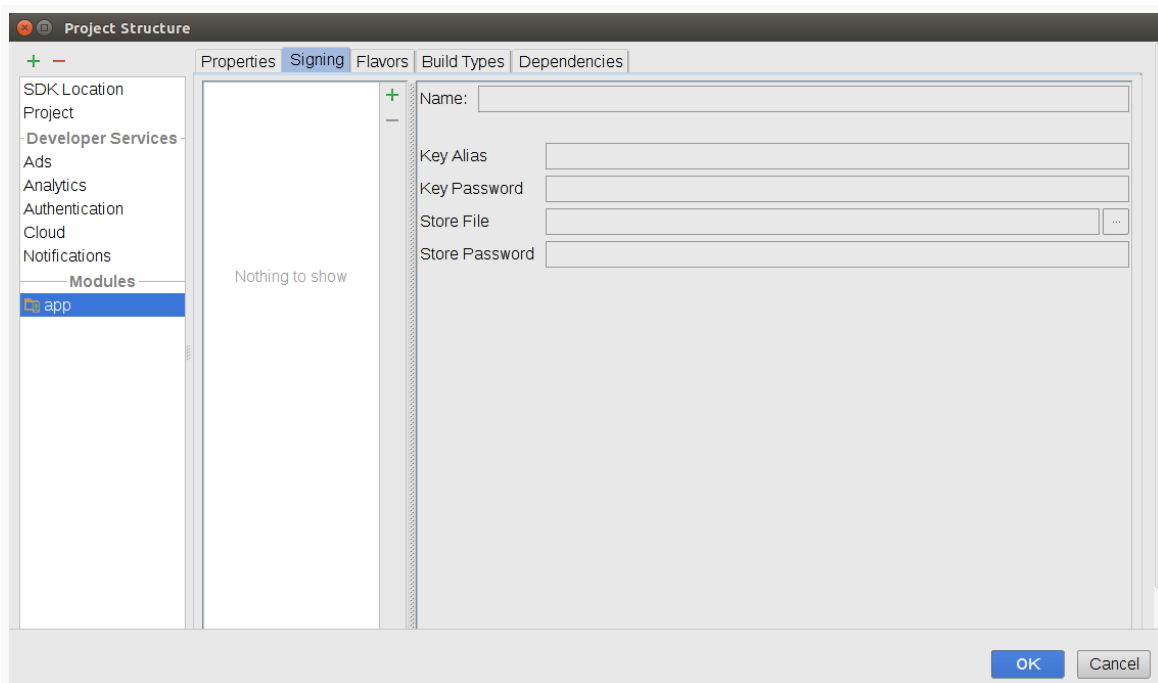

Figure 790: Project Structure Dialog, Module Category, Signing Tab

Each signing configuration that you have defined will appear in the list on the left side of the tab. On the right are fields for you to fill in the signing configuration name, the keystore file and key alias to use, and the passwords to use for accessing that file and alias.

The green plus (“+”) icon on the right side of the list lets you define a new signing configuration, while the red minus (“-”) icon lets you delete an existing signing configuration.

Flavors

The “Flavors” tab starts off with a single “flavor”, representing your `build.gradle` file’s `defaultConfig` settings. The green plus icon next to the list of flavors lets you define a new flavor, while the red minus icon lets you remove an existing flavor. Note that you cannot remove `defaultConfig`, as it is defined by the Gradle for Android plugin.

ANDROID STUDIO EDITORS AND DIALOGS

Figure 791: Project Structure Dialog, Module Category, Flavors Tab

On the right side of the tab, you can set or change the name of the flavor, plus you can adjust various flavor (or defaultConfig) settings, including:

- the `minSdkVersion` value (“Min Sdk Version” drop-down)
- the `applicationId` (“Application Id”)
- the ProGuard rules file to use for builds (“Proguard File”)
- which of your defined signing configurations to use (“Signing Config” drop-down)
- the `targetSdkVersion` value (“Target Sdk Version” drop-down)
- [the `testInstrumentationRunner` to use for instrumentation testing](#) (“Test Instrumentation Runner”)
- [the `testApplicationId` value for instrumentation testing](#) (“Test Application Id”)
- the `versionCode` and `versionName` to use (“Version Code” and “Version Name”)

Build Types

The “Build Types” tab allows you to adjust settings for the debug and release build types. The green plus icon next to the list of build types lets you define a new build type, while the red minus icon lets you remove an existing build type. Note that you cannot remove debug or release, as they are defined by Gradle.

Figure 792: Project Structure Dialog, Module Category, Build Types Tab

On the right side of the tab, you can set or change the name of the build type, plus you can adjust various settings in your `buildTypes` closure, including:

- the value of `debuggable`, to control if the app is considered to be debuggable on production hardware (“Debuggable” drop-down)
- the value of the undocumented `jniDebuggable` flag (“JNI Debuggable”)
- which signing configuration to use (“Signing Config” drop-down)
- the value of the undocumented `renderscriptDebuggable` flag (“Renderscript Debuggable”)
- the value of the undocumented `renderscriptOptimLevel` property (“Renderscript Optim Level”)

ANDROID STUDIO EDITORS AND DIALOGS

- the value of `minifyEnabled`, to control whether the build process should attempt to strip out unused code (“Minify Enabled” drop-down)
- the value of the undocumented `pseudoLocalesEnabled` flag (“Pseudo Locales Enabled”)
- the ProGuard rules file to use for builds (“Proguard File”)
- the suffix to append to the `applicationId` (“Application Id Suffix”)
- the suffix to append to the `versionName` (“Version Name Suffix”)
- whether the resulting APK should be processed by `zipalign` (“Zip Align Enabled”)

Dependencies

If your project has any defined dependencies in a dependencies closure, these will appear in the “Dependencies” tab:

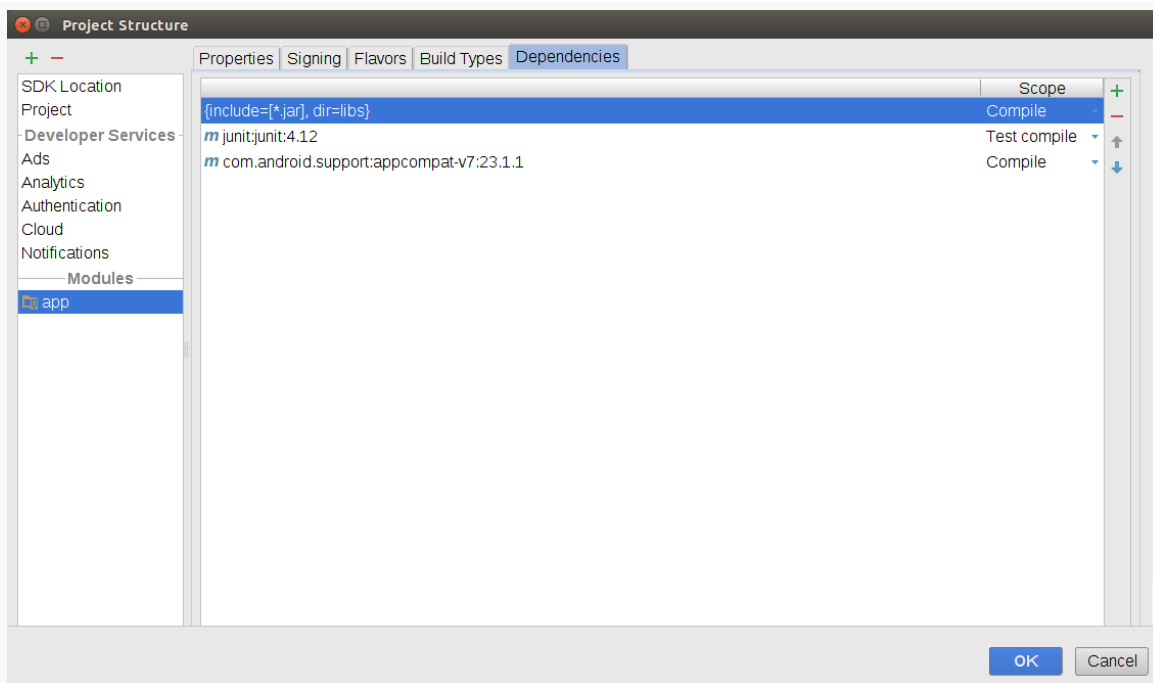

Figure 793: Project Structure Dialog, Module Category, Dependencies Tab

The tab is dominated by a two-column table, where the left column is the dependency itself. The right column is the “scope”, where the cell shows the current scope, and if you click on it, you get a drop-down list of available scopes:

ANDROID STUDIO EDITORS AND DIALOGS

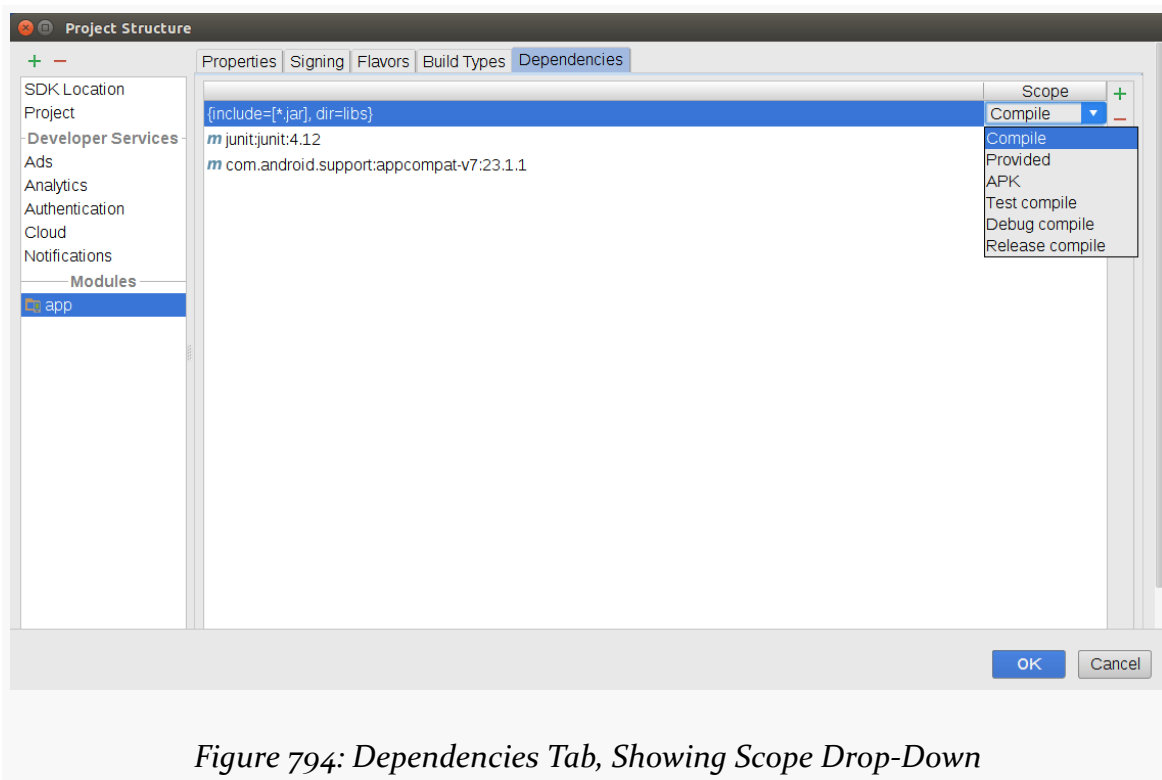

Figure 794: Dependencies Tab, Showing Scope Drop-Down

Those scopes include:

- “Compile”, for a compile dependency
- “Test compile” for an `androidTestCompile` dependency (i.e., one to be used only for instrumentation testing)
- Other “compile” scopes for your build variants (e.g., “Debug compile” for a `debugCompile` dependency)
- “Provided”, for a provided dependency (where the dependency is used only at compile time and its contents are not packaged into the APK file)
- “APK” for an apk dependency (where the dependency is not used at compile time, but its contents are packaged into the APK file)

The latter two scopes will be used infrequently.

ANDROID STUDIO EDITORS AND DIALOGS

Figure 795: Choose Library Dependency Dialog, As Initially Launched

Figure 796: Choose Library Dependency Dialog, With Search Results for “greenrobot”

Translations Editor

On Android Studio, if you open a file containing string resources, you will find a notification banner atop the editor, offering a way for you to “Edit translations for all locales in the translations editor”:

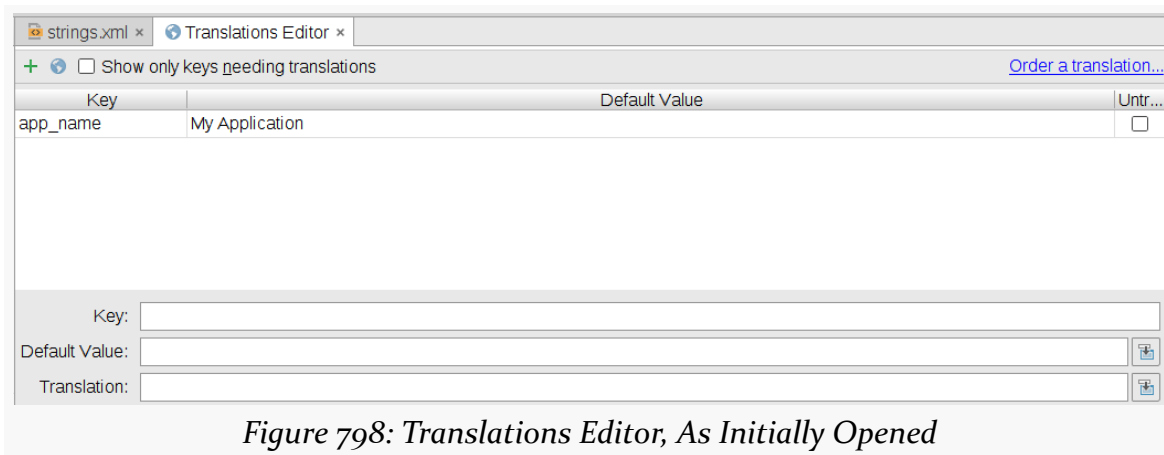

Figure 797: Notification Banner for Translations Editor

ANDROID STUDIO EDITORS AND DIALOGS

Clicking the “Open editor” link will open the Translations Editor. You can also get to this editor by right-clicking over the resource file in the Project or Android view on the left and choosing “Open Translation Editor” from the context menu.

For an un-translated project — such as one newly-created from the new-project wizard — when you open the Translations Editor, you will just see all of the existing strings:

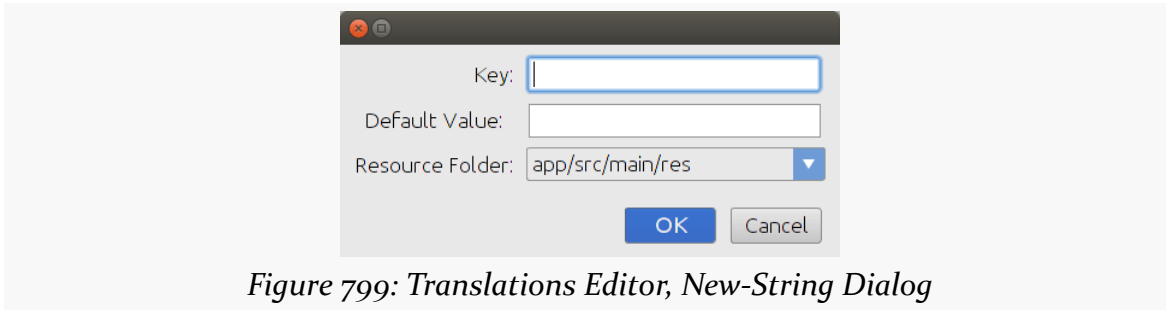

These are labeled as “default value” because, in this case, the values are coming from the default resource set (`res/values/strings.xml`), not some specific language translation.

You can edit an existing default value either by clicking on the cell containing the default value (e.g., clicking the “My Application” cell), or by clicking anywhere on the row and then editing the value in the “Default Value” field towards the bottom of the editor. Note that you cannot edit keys via this editor.

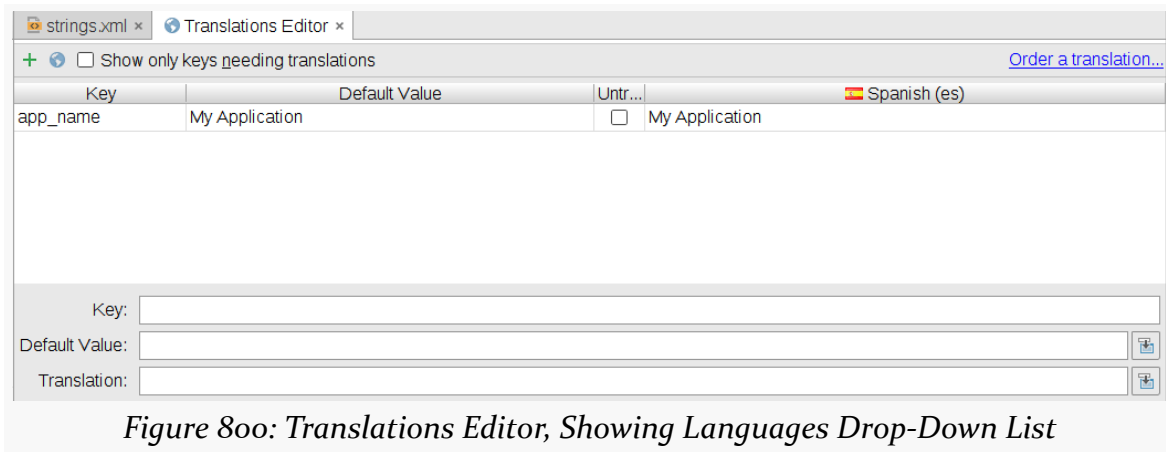

The right-hand column of the table has checkboxes, with a column heading of “Untranslatable”. Checking one of those adds a `translatable="false"` attribute to the `<string>` element in the XML. The IDE and related tools can use this to not warn you that this string lacks translations. This would be good for strings that you elected to put in string resources yet are not user-facing and therefore do not need translation.

The + icon in the toolbar, when clicked, pops up a dialog where you can define a new string:

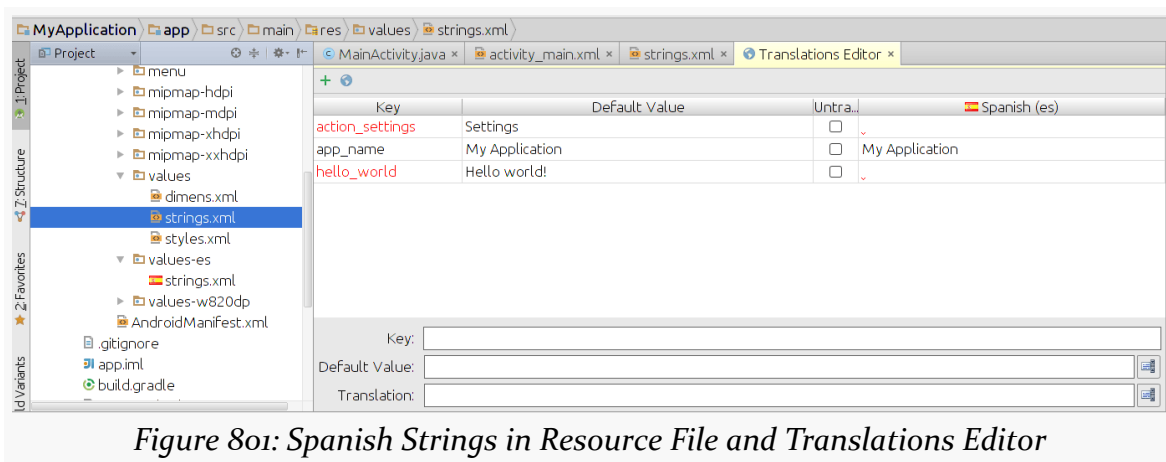

ANDROID STUDIO EDITORS AND DIALOGS

Where the fun begins, though, is if you click the globe icon in the toolbar. This displays a drop-down list of languages:

Choosing a language has two main effects. First, it creates a corresponding `res/values-*/` directory for your chosen language. Second, it adds a column to the Translations Editor for that language:

ANDROID STUDIO EDITORS AND DIALOGS

You can then click on a cell representing a word and its language, and fill in the translation in the form:

Figure 802: Translations Editor, Showing Spanish Translation

The icons to the right of the “Default Value” and “Translation” fields in the form simply pop up a dialog giving you a bit more room to type:

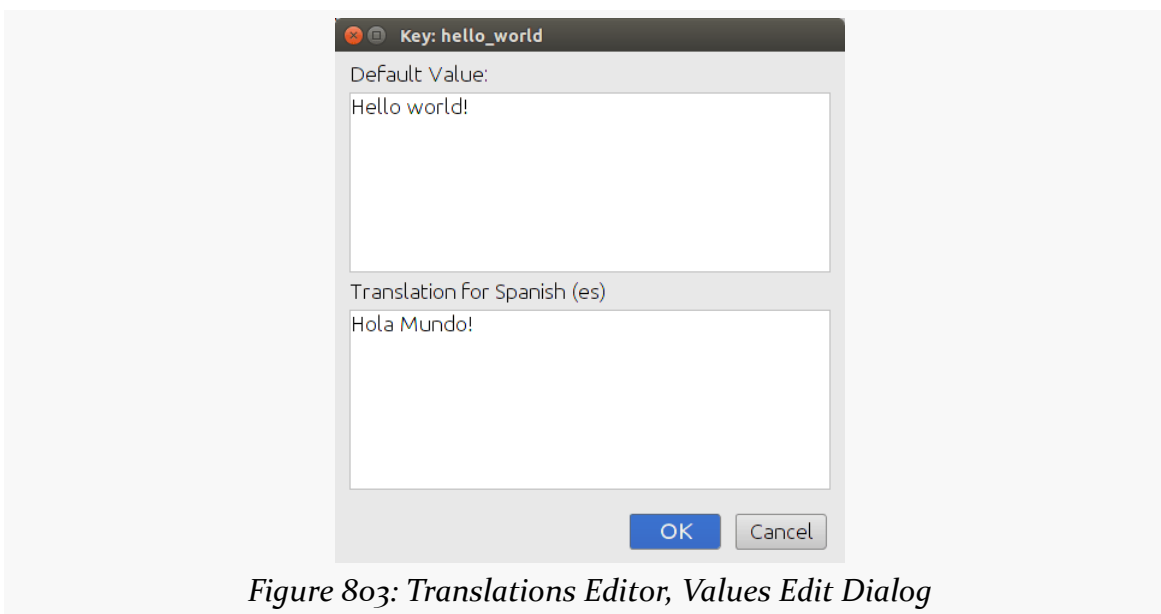

Figure 803: Translations Editor, Values Edit Dialog

Keys rendered in red represent string resources for which you are missing one or more translations. The languages for which you are missing translations have a small red downward-pointing caret in them.

Trail: Other Tools

Advanced Emulator Capabilities

The Android emulator, at its core, is not that complex. Once you have one or more Android virtual devices (AVDs) defined, using them is a matter of launching the emulator and installing your app upon it. With Android Studio, those two steps can even be combined — the IDE will automatically start an emulator instance if one is needed.

However, there is much more to the Android emulator. This chapter will explore various advanced features of the emulator and how you can use them.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

x86 Images

Normally, the Android emulator emulates a device with an ARM-based CPU. That matches with most Android devices available to users today. However, most developers are developing on an x86-based development machine, not one powered by ARM. As a result, the normal Android emulator has to convert ARM instructions to x86 instructions before executing them, slowing down performance.

Some versions of the Android emulator, though, have an x86 version as well. Where available, these *can* run much more quickly than will their ARM counterparts on an x86 development machine.

ADVANCED EMULATOR CAPABILITIES

The emphasis on *can* is that your development machine must have things set up properly first. Linux users need KVM, while Mac and Windows users need the “Intel Hardware Accelerated Execution Manager” (available from the SDK Manager). The latter must be manually installed once downloaded — please consult [the Android tools documentation](#) for details.

Also, this only works for certain CPU architectures, ones that support virtualization in hardware:

- Intel Virtualization Technology (VT, VT-x, vmx) extensions
- AMD Virtualization (AMD-V, SVM) extensions (Linux only)

Those virtualization extensions must also be enabled in your device’s BIOS, and other OS-specific modifications may be required.

When you are defining an AVD in the AVD Manager, you should see x86 entries in the “ABI” column on the “Recommended” tab, and there is also the dedicated “x86 Images” tab:

Release Name	API Level	ABI	Target
N	N	x86	Android 6.X
N Download	N	x86_64	Android 6.X
Marshmallow	23	x86	Android 6.0
Marshmallow	23	x86_64	Android 6.0
Lollipop	22	x86_64	Android 5.1
Lollipop	22	x86	Android 5.1
Lollipop Download	21	x86	Android 5.0 (with Google APIs)
Lollipop Download	21	x86_64	Android 5.0 (with Google APIs)
L	L	x86	Android 5.0
Lollipop	21	x86	Android 5.0
Lollipop	21	x86_64	Android 5.0
KitKat	19	x86	Android 4.4 (with Google APIs)
KitKat	19	x86	Android 4.4
Jelly Bean	18	x86	Android 4.3
Jelly Bean	17	x86	Android 4.2
Jelly Bean	16	x86	Android 4.1 (with Nokia X software)
Jelly Bean	16	x86	Android 4.1
Gingerbread	10	x86	Android 2.3.3

Figure 8o4: Android Studio AVD Manager Tabs, Showing x86 Emulator ABIs

You may need to download some images, if you do not already have them in your Android SDK. The AVD Manager will help you do that, if you click on the blue Download links.

There are also emulators for 64-bit versions of Android, notably 64-bit x86. These have the same underlying system requirements as their 32-bit counterparts.

Other Notable Configuration Options

When defining an AVD, or editing an existing AVD definition, there are many other configuration options at your disposal.

Hardware Graphics Acceleration

Another way to speed up the emulator is to have it use the graphic card or GPU of your development machine to accelerate the graphics rendering of the emulator window. By default, the emulator will use software-based rendering, without the GPU, which is slow in general and worse when running an ARM-based image.

Whether this will work or not for you will depend in part upon your graphics drivers of your development machine. Also, their use might conflict with other things you might want to do — on Linux, using hardware GPU mode might break your ability to take screenshots, for example.

This setting is toggled within the AVD Manager, for new and existing AVDs, via the “Graphics” drop-down list in the “Emulated Performance” group:

ADVANCED EMULATOR CAPABILITIES

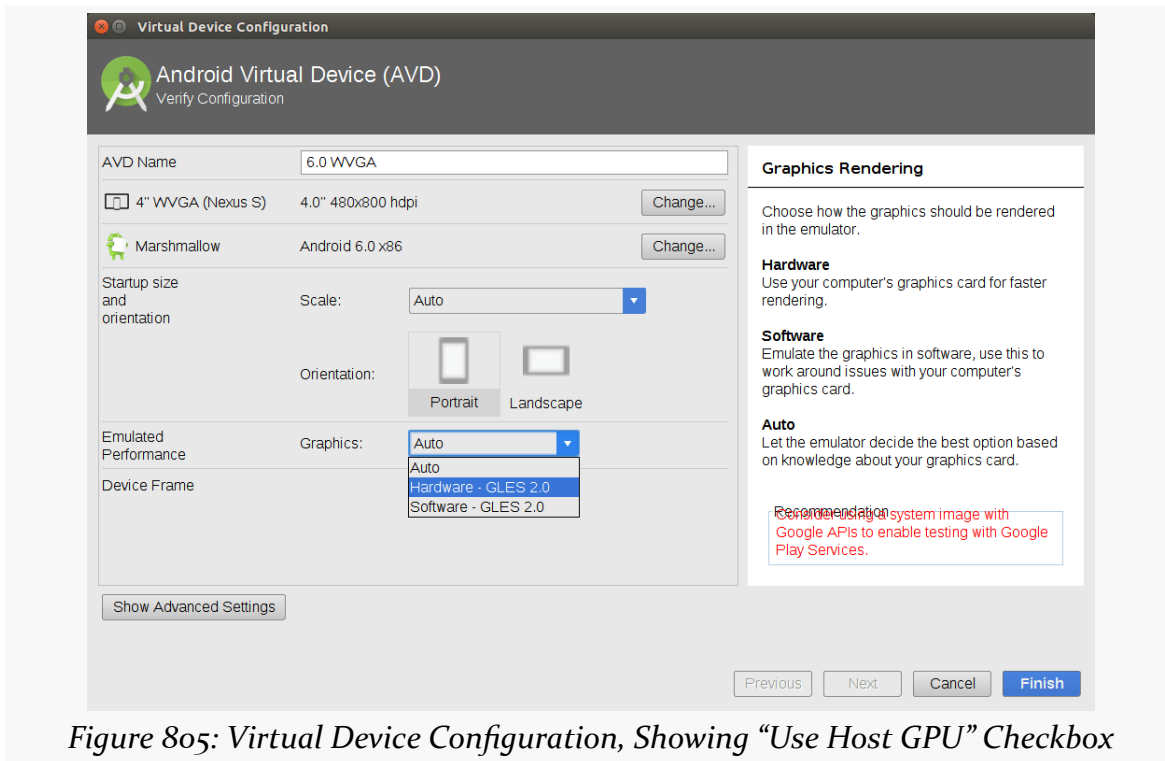

Figure 805: Virtual Device Configuration, Showing “Use Host GPU” Checkbox

There are three options:

- “Software” says to render the graphics purely within the emulator software
- “Hardware” says to render the graphics using the GPU of your development machine
- “Auto” (the default) delegates the decision to the emulator itself, based on its own heuristics of what will work well

Keyboard Behavior

The Android emulator can emulate devices that have, or do not have, a physical keyboard. Most Android devices do not have a physical keyboard, and so the emulator is set up to behave the same. However, this means that typing on your development machine’s keyboard will not work in `EditText` widgets and the like — you have to tap out what you want to type on the on-screen keyboard.

If you wish to switch your emulator to emulate a device with a physical keyboard – either “for realz” or just to simplify working with the emulator on your development machine — you can do so.

ADVANCED EMULATOR CAPABILITIES

In the Android Studio AVD Manager, in the “Advanced Settings” area, there is an “Enable keyboard input” checkbox that determines whether hardware keyboard input is honored in the AVD or not:

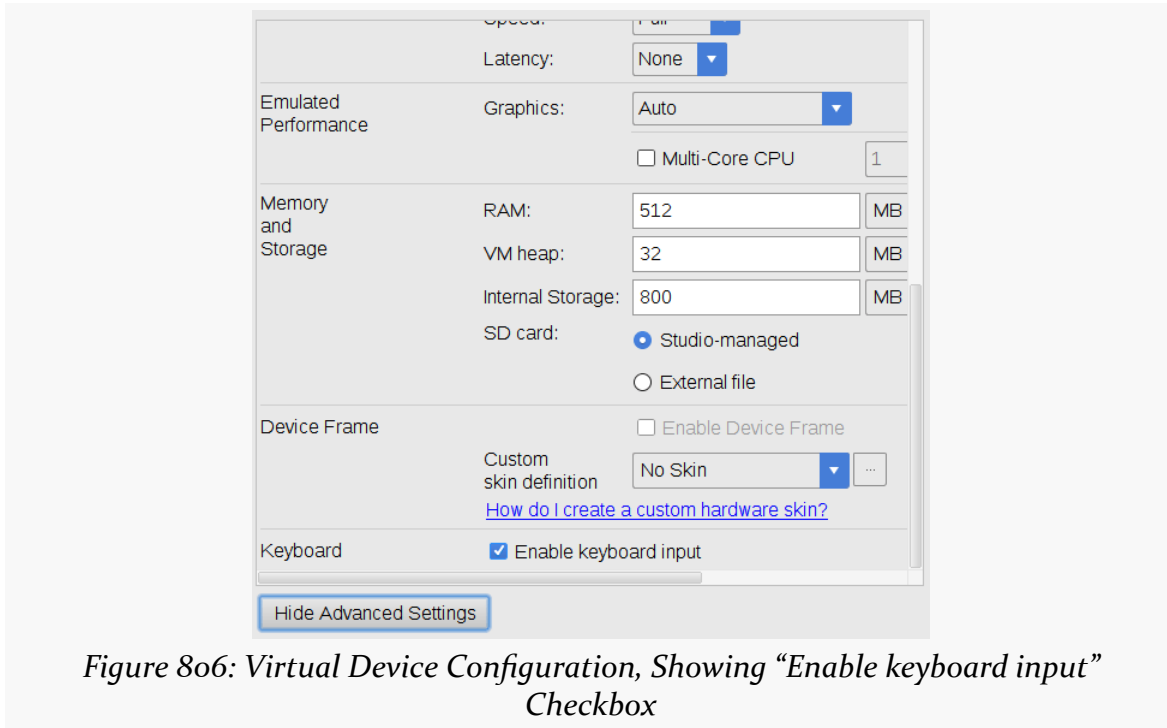

Figure 8o6: Virtual Device Configuration, Showing “Enable keyboard input” Checkbox

Startup Settings

Pixels on your development machine’s monitor probably are substantially larger than the pixels on most Android devices. If the emulator tries to use one hardware pixel on your monitor for every emulated pixel of the device screen, your emulator may be bigger than your monitor can fit. The “Scale” drop-down controls how the emulator scales its output to deal with your monitor. “Auto” — the default value — probably is your best option, though you are welcome to use one of the other options to control the scaling more directly (e.g., 4dp on the device maps to 1px on your monitor):

ADVANCED EMULATOR CAPABILITIES

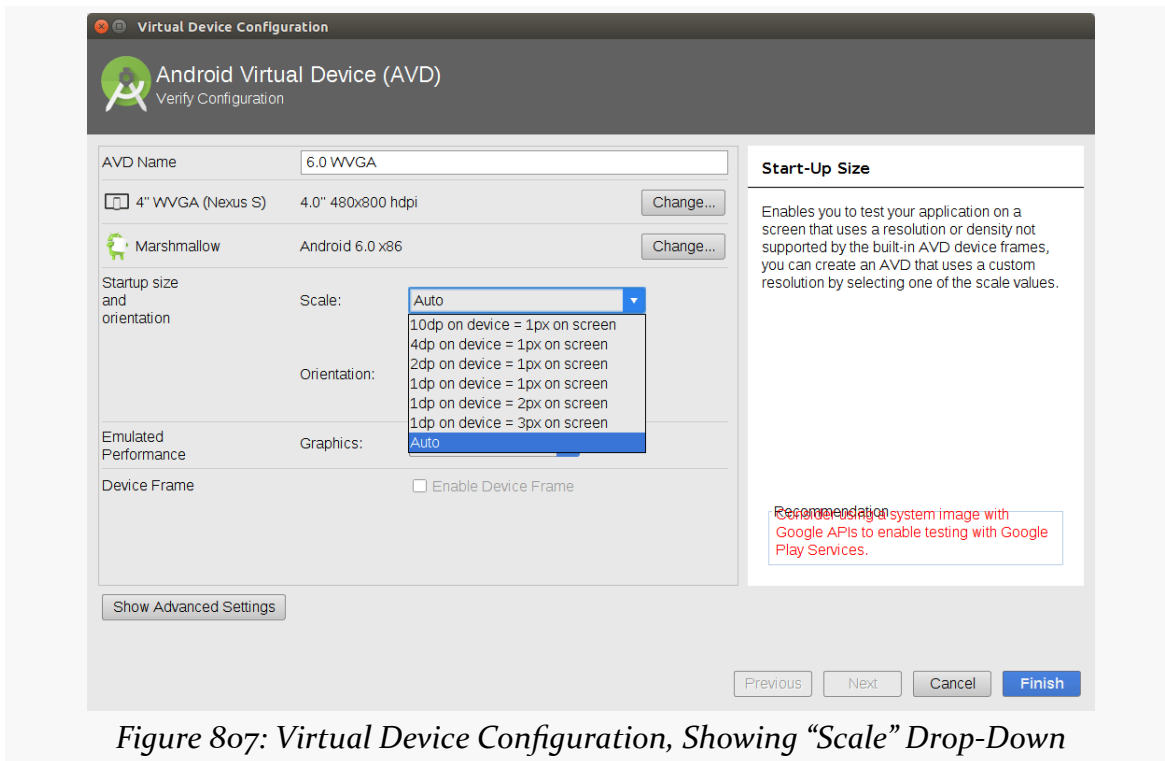

Figure 807: Virtual Device Configuration, Showing “Scale” Drop-Down

You can also control whether the device starts up in portrait or landscape mode at the outside, by the toggle buttons labeled “Orientation”.

Note that scaling and orientation can also be controlled while the emulator is running; these settings merely control the startup conditions.

Camera Options

In the “Advanced Settings” area, you can control whether or not the emulator emulates a device with a camera:

ADVANCED EMULATOR CAPABILITIES

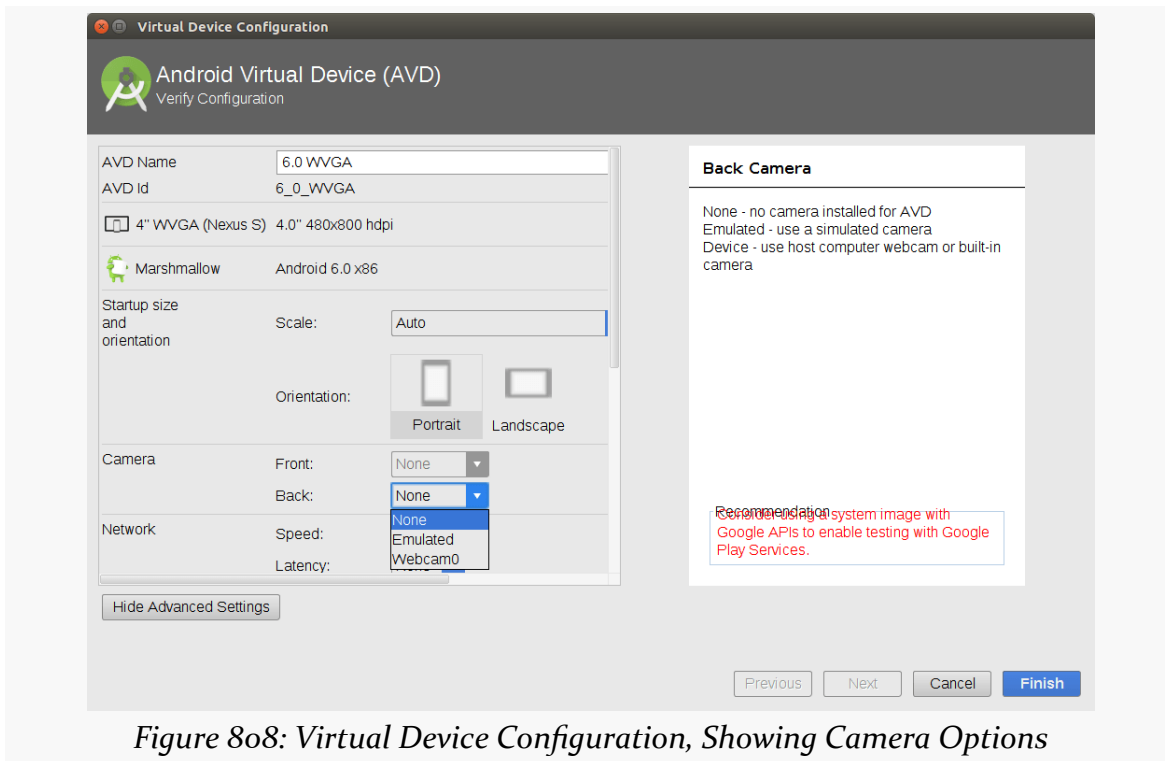

Figure 8o8: Virtual Device Configuration, Showing Camera Options

Whether you can configure both front and back cameras, or just one, is indeterminate. If you can configure a camera, your options are:

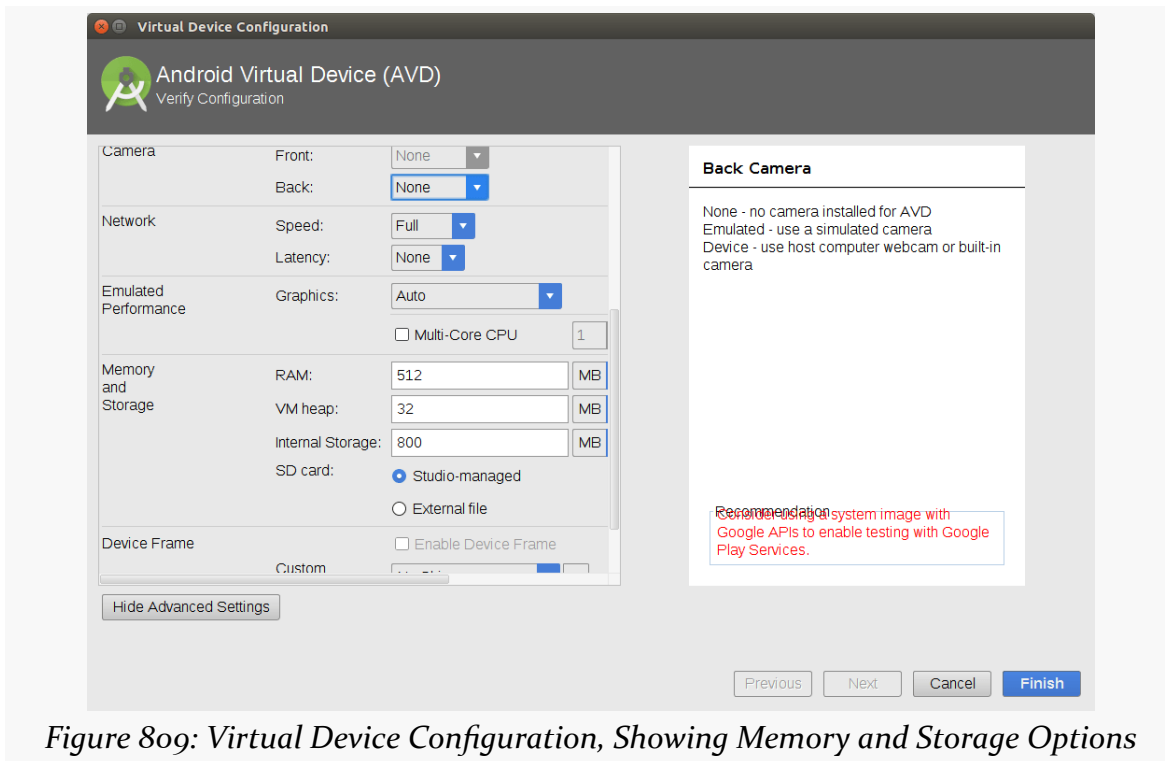

- “None”, to emulate a device without a camera
- “Emulated”, which emulates a device with a camera, but where the camera images themselves are emulated
- some hardware indicator (e.g., “Webcam0”), which emulates a device with a camera, where the camera images are pulled from some camera hardware on your development machine (e.g., a notebook webcam)

However, the emulator’s ability to truly emulate the way Android cameras behave is very limited. Serious camera testing needs to be done using Android hardware, not the emulator.

Memory and Storage Configuration

In the “Advanced Settings” area, you can control how much RAM and storage is used by the emulator:

ADVANCED EMULATOR CAPABILITIES

Specifically:

- “RAM” controls how much system RAM the emulator emulates. This will be a subset of the overall RAM of your development machine that the emulator consumes.
- “VM heap” appears to control the Dalvik/ART heap limit assigned to applications.
- “Internal Storage” indicates how much space is allocated for the main device partitions in the emulated device.
- “SD card” is still the misnomer for external storage. Your options are either to have Android Studio manage this for you, or for you to use tools like `mksdcard` to create your own disk image that you attach to the emulator.

Usually, the defaults are fine.

Frames and Skins

By default, the emulator appears in a bare window, showing the contents of the “touchscreen”. Of course, an actual Android device will have more around it, such as bezels, optional hardware buttons, and so on.

ADVANCED EMULATOR CAPABILITIES

In the “Device Frame” group in the “Advanced Settings” area, you can check “Enable Device Frame” and choose a skin to wrap around the touchscreen and make your emulator look a bit more like a real device:

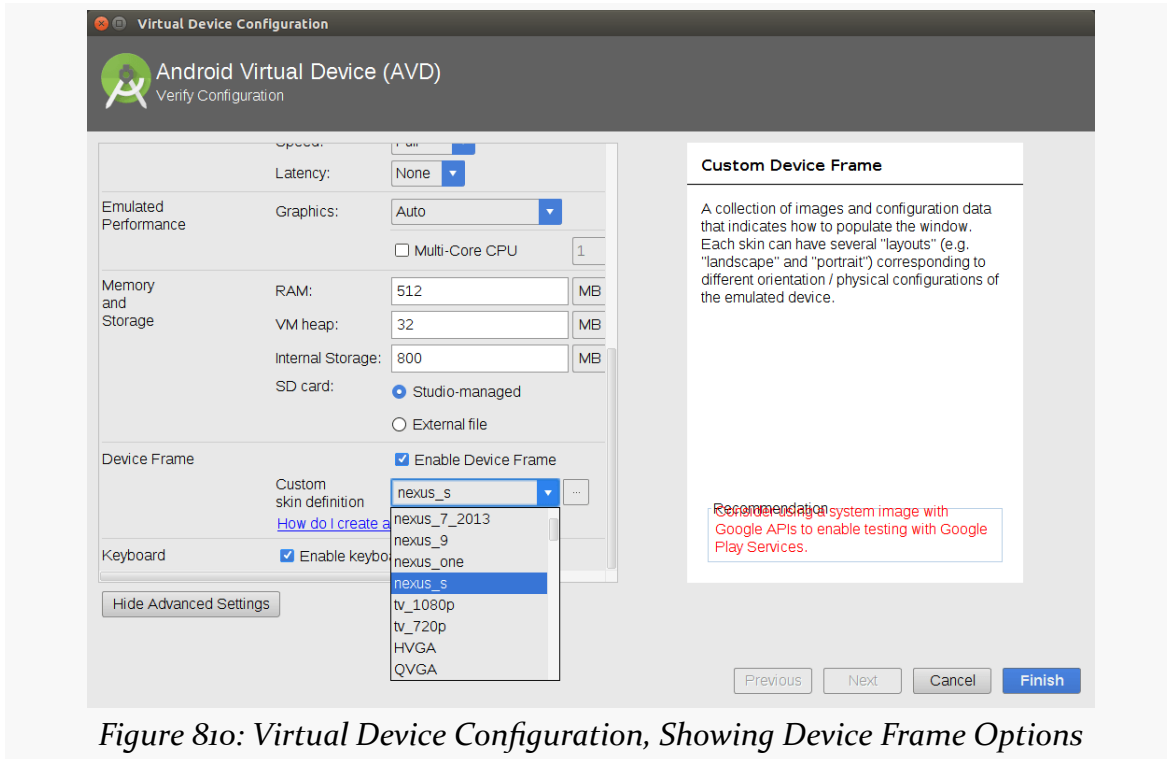

Figure 810: Virtual Device Configuration, Showing Device Frame Options

The Emulator Sidebar

Starting with Android Studio 2.0, the emulator sports a “sidebar” that runs alongside the main emulator window:

ADVANCED EMULATOR CAPABILITIES

Figure 811: Android Emulator, with Sidebar on the Right

This provides you with rapid access to a number of emulator features and controls. Some of those are hidden behind the “More” button, at the bottom of the sidebar (looks like an ellipsis, “…”).

Note that the sidebar buttons have tooltips that will tell both the button’s purpose and the keyboard shortcut, if any, for that button.

Power and Navigation Controls

The top icon in the sidebar is a power button. A quick click on it will close your emulator. A long-click will behave like the POWER button on an Android device, bringing up the power menu:

ADVANCED EMULATOR CAPABILITIES

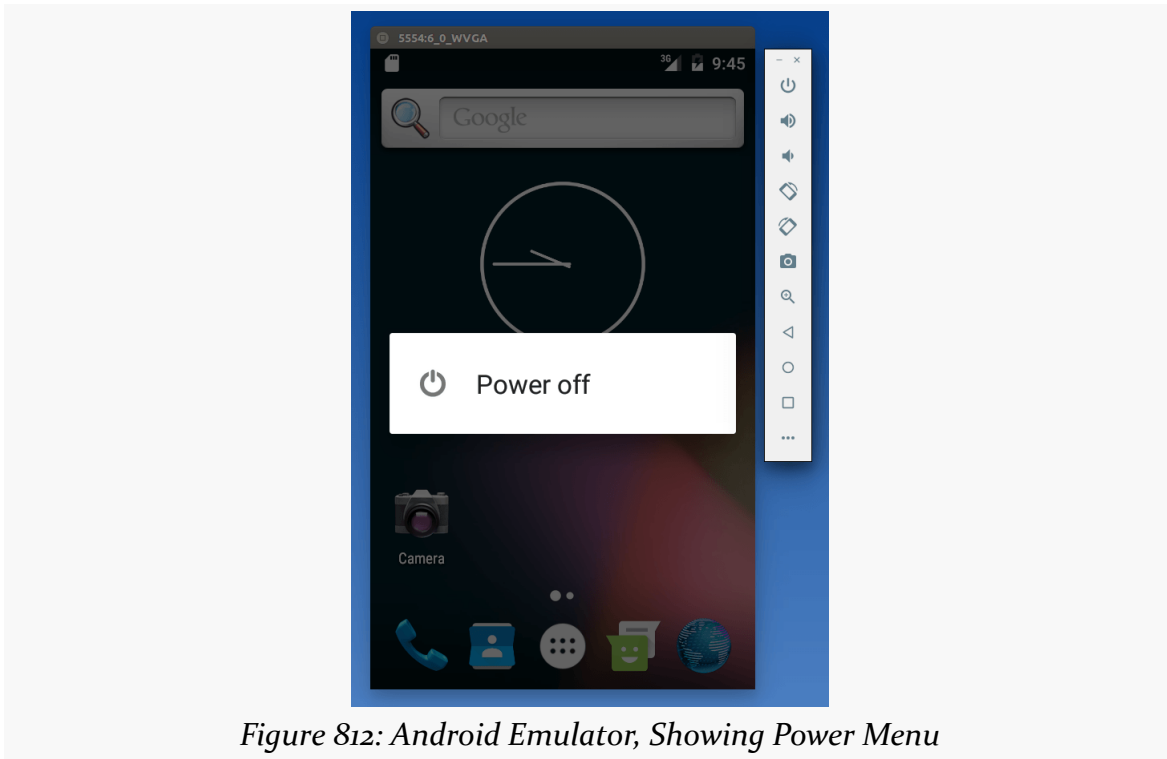

Figure 812: Android Emulator, Showing Power Menu

Towards the bottom of the sidebar are BACK, HOME, and RECENTS buttons for navigation:

Figure 813: Android Emulator Sidebar Navigation Buttons

If you click the “More” button, you will open up the “Extended Controls” window:

ADVANCED EMULATOR CAPABILITIES

Figure 814: Android Emulator with Extended Controls

Clicking the “Directional pad” category on the left of the “Extended Controls” gives you D-pad and media buttons for in-app navigation:

ADVANCED EMULATOR CAPABILITIES

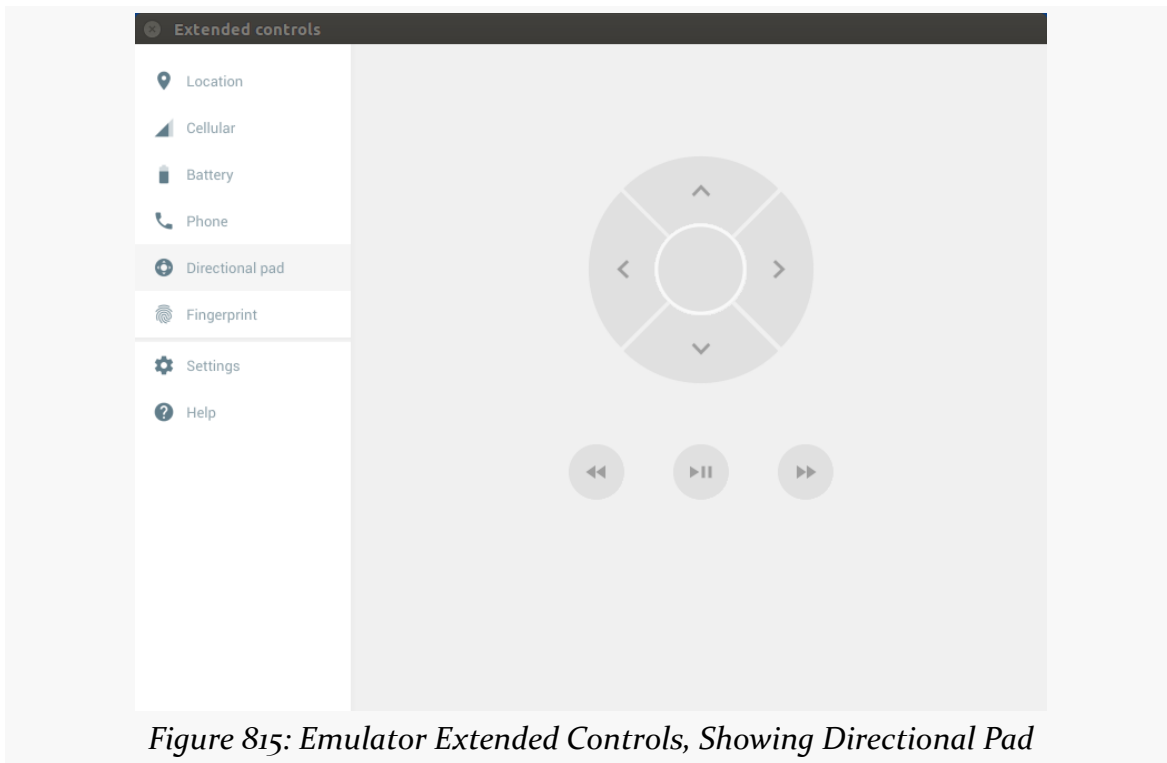

Figure 815: Emulator Extended Controls, Showing Directional Pad

Screen Orientation and Zoom

Two buttons on the sidebar allow you to rotate the device clockwise or counter-clockwise:

Figure 816: Android Emulator Sidebar Rotation Buttons

The magnifying glass icon allows you to zoom and out of the emulator screen contents:

Figure 817: Android Emulator Sidebar Zoom Button

When in zoom mode, the mouse cursor changes to a magnifying glass, and left-mouse clicks will zoom in at the clicked-upon point. Right-mouse clicks will zoom out. To return the mouse to normal behavior, tap the zoom sidebar button again. However, note that you will remain zoomed in on the last-selected zoom state; to return the emulator fully to normal, zoom out all the way first.

Screenshots

The camera button on the sidebar allows you to rapidly take screenshots of the emulator window:

ADVANCED EMULATOR CAPABILITIES

Figure 818: Android Emulator Sidebar Screenshot Button

These will be stored in a directory controlled by the “Settings” category in the “Extended controls” window:

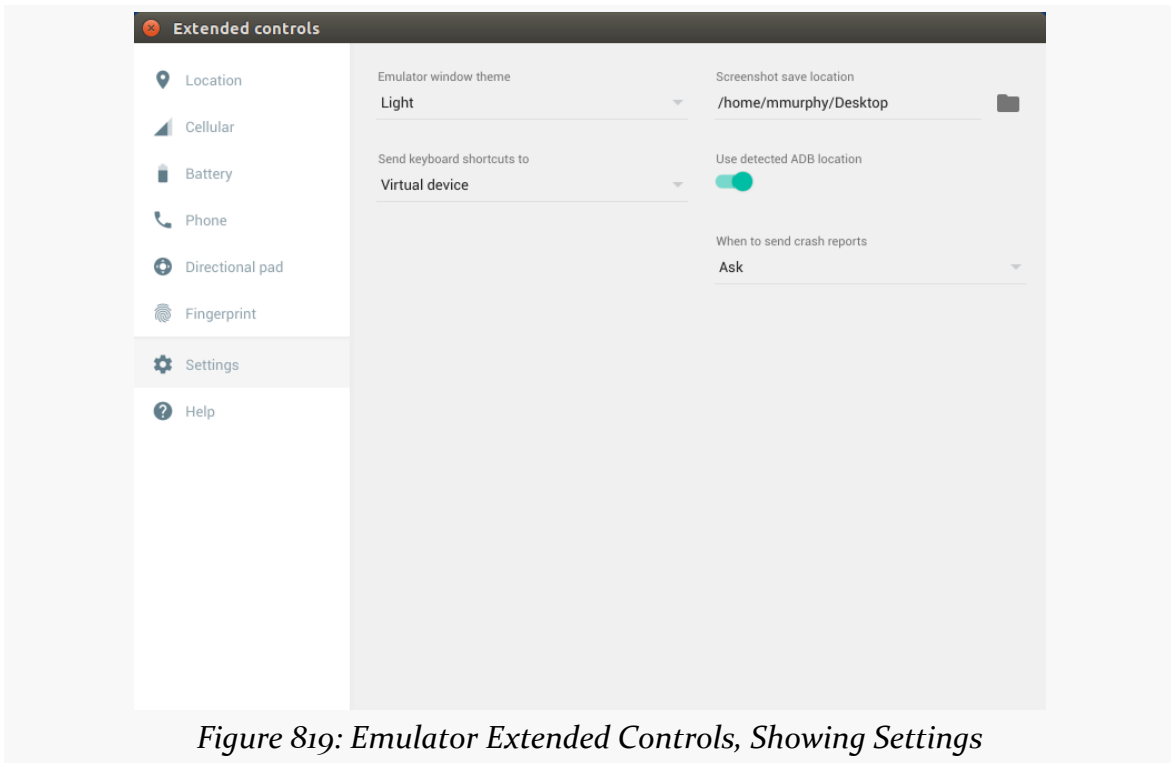

Figure 819: Emulator Extended Controls, Showing Settings

Faking the Real World

The “Extended controls” panel also allows you to fake real world behavior in your emulator. These are reminiscent of similar capabilities in the Android Device Monitor.

Location

The “Location” category lets you fake GPS fixes:

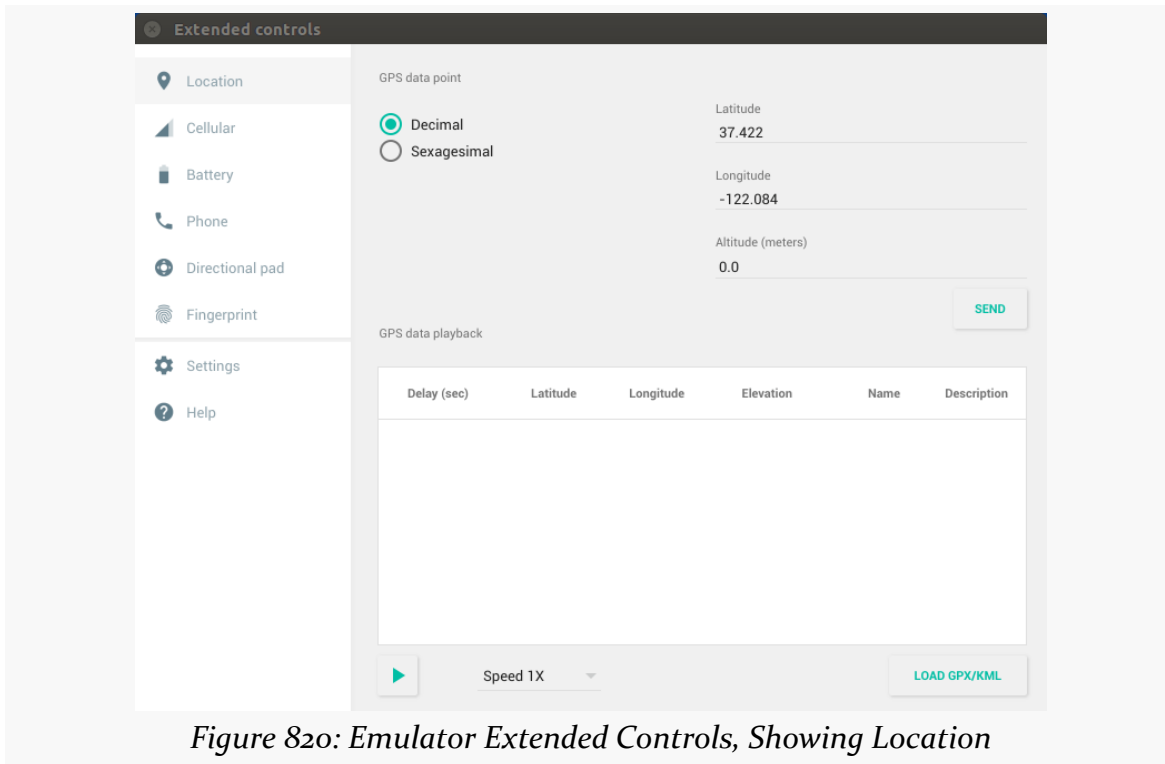

Figure 820: Emulator Extended Controls, Showing Location

The upper half allows you to specify a single GPS fix and “send” that to the emulator, which should respond the same way as if an actual Android device received a GPS fix.

The bottom half allows you to load a GPX or KML file containing a series of waypoints and the time between them, then play those back, either at normal speed or at an accelerated pace (if you get bored easily).

Network Status

The “Cellular” category controls how the emulator emulates its cellular network connection:

ADVANCED EMULATOR CAPABILITIES

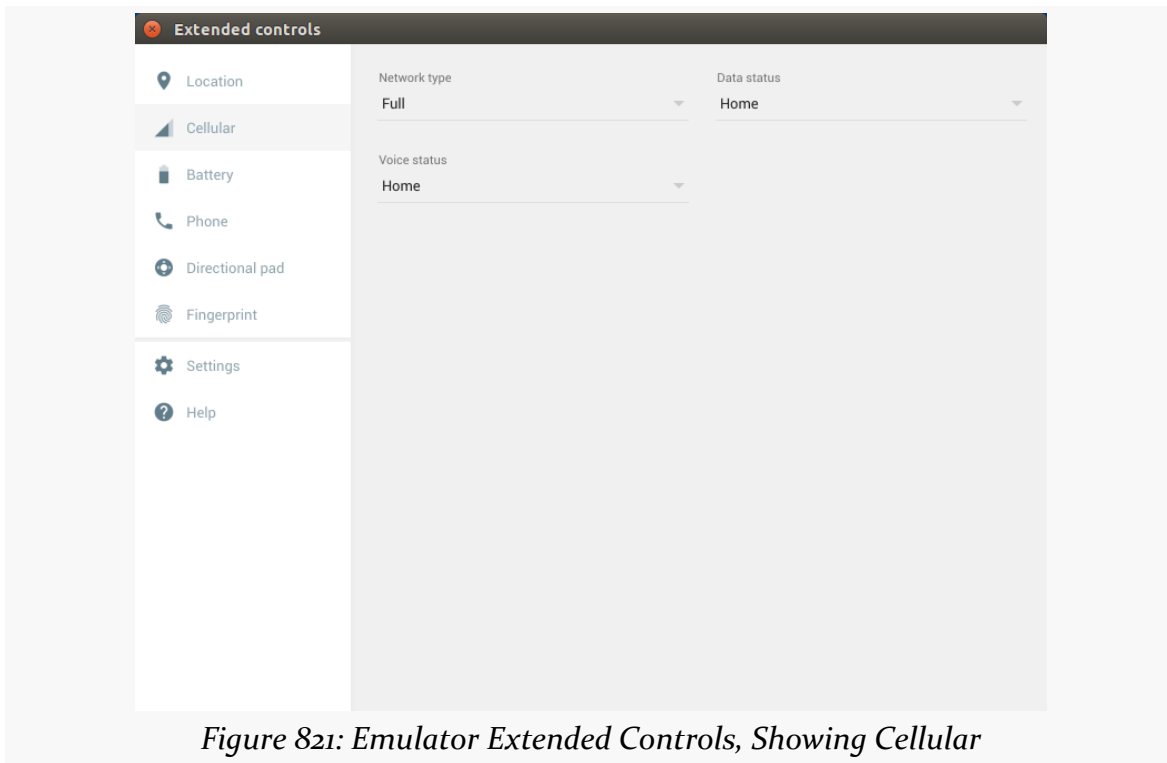

Figure 821: Emulator Extended Controls, Showing Cellular

Battery

The “Battery” category allows you to simulate changes in the power status of the emulator:

ADVANCED EMULATOR CAPABILITIES

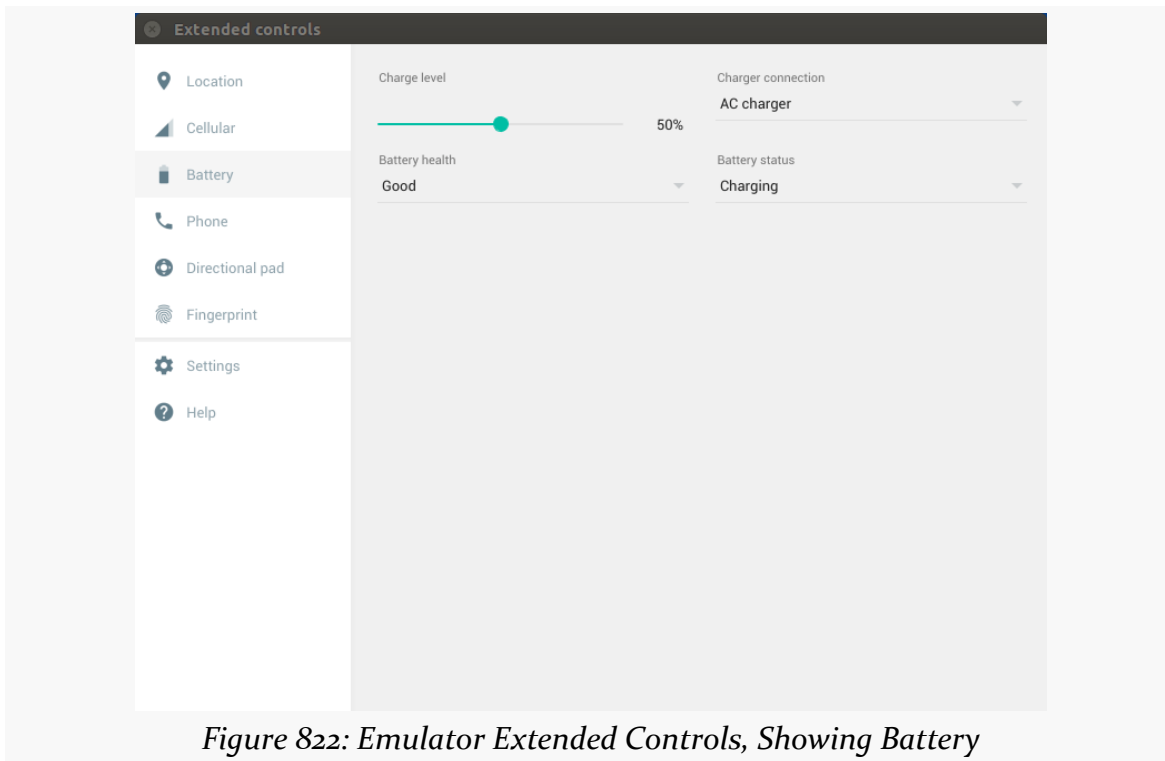

Figure 822: Emulator Extended Controls, Showing Battery

Not only will your code be able to receive events like `ACTION_BATTERY_CHANGED`, but you can see the changes in the status bar of the emulator, such as the battery icon showing charging status and current charge level.

Telephony

The “Telephony” category allows you to simulate incoming phone calls and text messages:

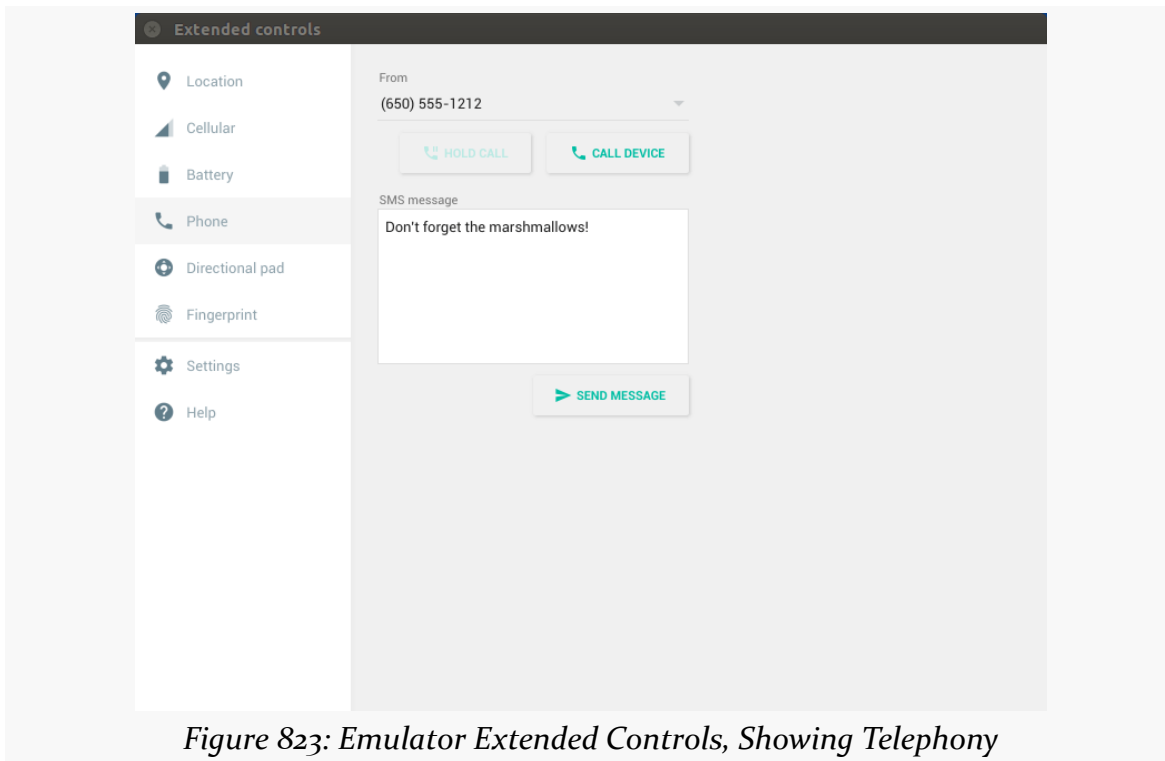

Figure 823: Emulator Extended Controls, Showing Telephony

Emulator Window Operations

Dragging a window edge of the emulator window will change the scale used by the emulator. The entire emulator window is still there, just smaller or larger than before. The resulting window will have the proper aspect ratio, so if you drag the left or right side and shrink the window, it will shrink both vertically and horizontally.

Using your development machine's native file manager (e.g., Nautilus on Ubuntu Linux), you can drag-and-drop files into the emulator window. If the file is an APK, it will be installed automatically, as if you had installed it through the `adb install` command. If the file is anything else, it will be uploaded into the emulator's `Download/` directory on external storage. If your app has permission to work with external storage, it can read the file from there.

Headless Operation

Sometimes, you want an emulator without a GUI. Typically, this is used for continuous integration or some other server-based testing solution — you use the “headless” emulator to run tests, even on a machine that lacks any GUI capability.

ADVANCED EMULATOR CAPABILITIES

To do this, you will need to run the emulator from the command-line. Run `emulator -no-window -avd ...`, where ... is the name of your AVD (e.g., the value in the left column of the list of AVDs in the AVD Manager). To test this first in normal mode, run the command without the `-no-window` switch.

The simplest solution to get rid of the emulator instance is to kill its process.

There are many other [command-line switches for the emulator](#) that you may wish to investigate. While most of these have UI analogues in the AVD Manager, the switches would be necessary to replicate some of those for headless operation.

Lint and the Support Annotations

As C/C++ developers are well aware, lint is not merely something that collects in pockets and belly buttons.

Lint is a long-standing C/C++ utility that points out issues in a code base that are not errors or warnings, but are still indicative of a likely flaw in the code. After all, what might be legal from a syntax standpoint may still be a bug when used.

Android Studio and the Android Plugin for Gradle have their own equivalent Lint tool, for reporting similar sorts of issues with an Android project's Java code, resources, and manifest. You can also get Lint reports from the command line, such as via Gradle for Android, perhaps as part of integrating your builds into a continuous integration server.

To help Lint catch problems stemming from your own code, Google has released the support-annotations library, to help catch things like passing a widget ID, instead of a layout ID, into `setContentView()`. You can also use these annotations to help those using your code – whether in the same project or in consumers of a library that you publish – make sure that they do not make similar mistakes.

This chapter will explore how you use Lint to detect problems and how you can add annotations to your code to help Lint catch even more problems.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

What It Is

Lint can be best described as “a pest, but a good pest”.

Normally, what stops you from building your app are compiler errors: bad Java syntax, malformed XML resource files, and the like. At the command line, these stop an in-progress build and dump error messages to the console. In Android Studio, these are noted in a log and also by notations in the source code, frequently as red squiggle lines underneath the offending Java or XML when viewed in an editor. You also may get yellow squiggle lines for warnings — things the compiler will allow but the compiler thinks may be a problem.

However, there are many things that might be syntactically valid but are not a good idea from an Android standpoint. For example, if you specify a minimum SDK version of API Level 8, and you try using a class that only exists on API Level 11, that’s a problem if you are not handling it correctly and avoiding this class on the older-yet-supported devices. Yet, if your build target (i.e., `compileSdkVersion` in Android Studio) is API Level 11 or higher, it is perfectly valid syntax and would compile just fine.

Lint is designed to encapsulate rules that transcend syntax, to add more errors and warnings that reflect good Android practices beyond simple validity.

When It Runs

Running Lint sometimes happens automatically (e.g., from your IDE) or sometimes happens manually. The following sections outline the various possibilities.

Android Studio

By default, in Android Studio, Lint will run when you save a file, giving you error (red) or warning (yellow) squiggles for things that run afoul of Lint rules:

```
finishAffinity();
```

Figure 824: Android Studio Lint Error

You can manually invoke it via `Analyze > Inspect Code...` from the main menu, though this also performs other analyses that are not necessarily relevant for you as an Android developer, such as “J2ME issues”.

LINT AND THE SUPPORT ANNOTATIONS

Figure 825: Android Studio Inspection Results

Command Line

You can also invoke Lint via `gradle lint` or a per-variant edition (e.g., `gradle lintRelease`). This will write results to an XML file in `build/outputs/` based upon product variant (e.g., `build/outputs/lint-results-release.xml` for a `gradle lintRelease` run). It will also emit an HTML file with the same base name in the same directory. These contain the same basic information as you get from the command-line output, with the XML in particular designed to be consumed by other tools, such as a continuous integration server.

What to Fix

In Android Studio, clicking on a red or yellow squiggle will pop up an adjacent “lightbulb” drop-down offering ways to fix the problem:

Figure 826: Android Studio Lint Fix Suggestions

You can also bring up this “quick fixes” list via `Alt-Enter`. For example:

- Errors related to accessing classes or methods higher than your `minSdkVersion` have “quick fixes” to add the `@TargetApi` annotation to the class or method containing your code
- Warnings related to hard-coded strings in layouts or the manifest have “quick fixes” to convert those strings into string resources

All warnings and errors will have “quick fixes” to suppress that warning or error in the future, by adding notations to the file to that effect.

What to Configure

You have some measure of control over Lint’s behavior, though the mechanics of doing this varies by tool.

Android Studio

In Android Studio, you can configure Lint’s behavior via the Project Settings dialog, accessible via File > Settings:

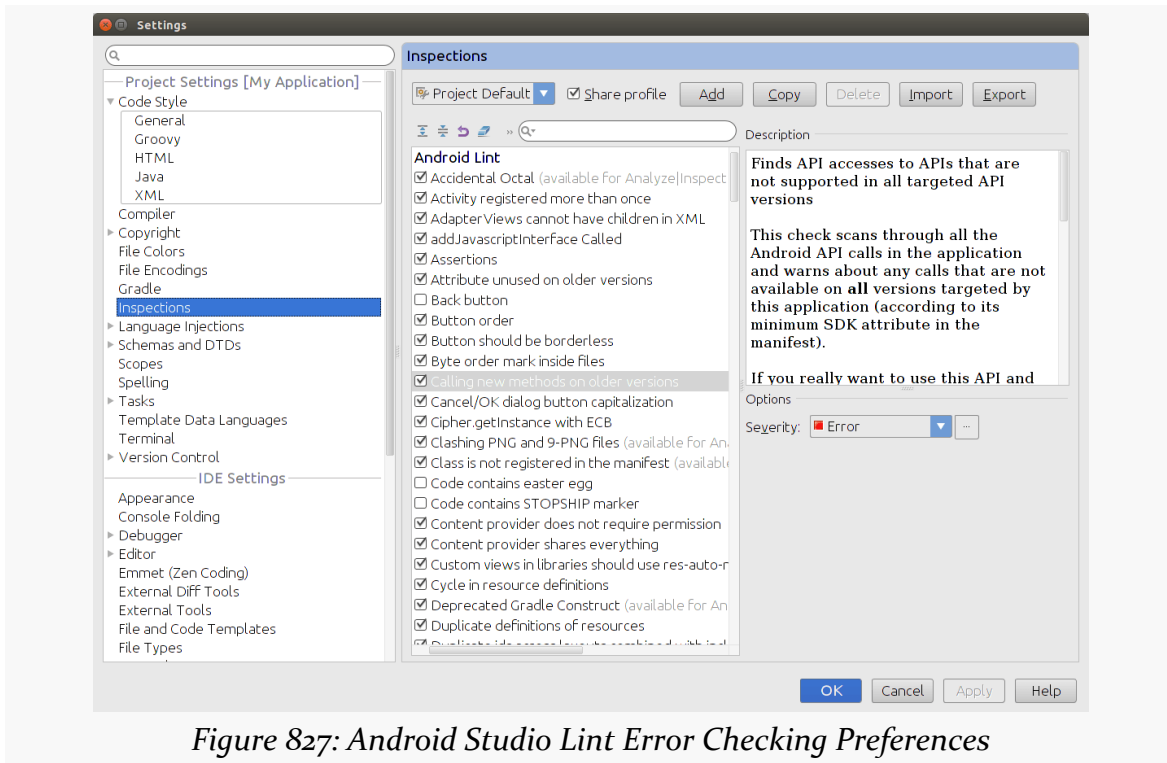

Figure 827: Android Studio Lint Error Checking Preferences

You can change some details about the specific checks that Lint makes:

- the severity of the issue, usually set to Warning or Error
- whether the specific issue should be ignored rather than executed

LINT AND THE SUPPORT ANNOTATIONS

To do this, you may wish to create your own inspection profile, rather than modifying the stock “Project Default” profile. To do this, just click the “Copy” button in the Inspections page of the Settings dialog and supply a name for the new profile.

The above recipe changes the inspections for the individual project. To change them for new projects, go into File > Other Settings > Default Settings, and make your changes there.

Command Line

To block certain Lint checks in Gradle, you can create a `lint.xml` file, in the root directory of your project, containing information about which particular issues should be suppressed for that project. The benefit here is that you can configure suppression at a finer granularity, blocking issues for certain files or directories and allowing them for others. The sample `lint.xml` from [the Lint documentation](#) looks like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<lint>
  <!-- Disable the given check in this project -->
  <issue id="IconMissingDensityFolder" severity="ignore" />

  <!-- Ignore the ObsoleteLayoutParam issue in the given files -->
  <issue id="ObsoleteLayoutParam">
    <ignore path="res/layout/activation.xml" />
    <ignore path="res/layout-xlarge/activation.xml" />
  </issue>

  <!-- Ignore the UselessLeaf issue in the given file -->
  <issue id="UselessLeaf">
    <ignore path="res/layout/main.xml" />
  </issue>

  <!-- Change the severity of hardcoded strings to "error" -->
  <issue id="HardcodedText" severity="error" />
</lint>
```

You can also configure lint via a `lintOptions` closure inside the `android` closure of your `build.gradle` file. In particular, you can have a `disable` statement to list the Lint checks that you would like to block:

```
android {
  lintOptions {
    disable 'IconMissingDensityFolder', 'InefficientWeight'
    ...
  }
}
```

LINT AND THE SUPPORT ANNOTATIONS

The names used in `lint.xml` or `lintOptions` are the “issue IDs”. You can get a roster of these by running `lint --list` for brief summaries:

```
Valid issue categories:
  Correctness
  Correctness:Messages
  Security
  Performance
  Usability:Typography
  Usability:Icons
  Usability
  Accessibility
  Internationalization
  Bi-directional Text

Valid issue id's:
"ContentDescription": Image without contentDescription
"AddJavascriptInterface": addJavascriptInterface Called
"ShortAlarm": Short or Frequent Alarm
"AlwaysShowAction": Usage of showAsAction=always
"ShiftFlags": Dangerous Flag Constant Declaration
"LocalSuppress": @SuppressWarnings on invalid element
"UniqueConstants": Overlapping Enumeration Constants
"InlinedApi": Using inlined constants on older versions
"Override": Method conflicts with new inherited method
"NewApi": Calling new methods on older versions
...
```

...or `lint --show` for a set of more elaborate descriptions:

```
Available issues:

Correctness
=====

AdapterViewChildren
-----
Summary: AdapterViews cannot have children in XML

Priority: 10 / 10
Severity: Warning
Category: Correctness

AdapterViews such as ListViews must be configured with data from Java code,
such as a ListAdapter.

More information:
http://developer.android.com/reference/android/widget/AdapterView.html

OnClick
-----
Summary: onClick method does not exist

Priority: 10 / 10
Severity: Error
Category: Correctness
```

LINT AND THE SUPPORT ANNOTATIONS

The `onClick` attribute value should be the name of a method in this View's context to invoke when the view is clicked. This name must correspond to a public method that takes exactly one parameter of type View.

Must be a string value, using `'\';` to escape characters such as `'\n'` or `'\uxxxx'` for a unicode character.

StopShip

Summary: Code contains STOPSHIP marker

Priority: 10 / 10

Severity: Warning

Category: Correctness

NOTE: This issue is disabled by default!

You can enable it by adding `--enable StopShip`

Using the comment `// STOPSHIP` can be used to flag code that is incomplete but checked in. This comment marker can be used to indicate that the code should not be shipped until the issue is addressed, and lint will look for these.

MissingPermission

Summary: Missing Permissions

Priority: 9 / 10

Severity: Error

Category: Correctness

This check scans through your code and libraries and looks at the APIs being used, and checks this against the set of permissions required to access those APIs. If the code using those APIs is called at runtime, then the program will crash.

...

The `lint` command can be found in the `tools/` directory of your Android SDK installation.

Support Annotations

The `support-annotations` library, from the Android Support set of libraries, offers a series of annotations that you can add to methods, method parameters, and the like to teach Lint certain types of bugs to check for. Some of the Android Support libraries use these annotations, so Lint can help catch problems when you use those public APIs. You, in turn, can add these annotations to *your* code, to catch certain problems at compile time that otherwise might be missed.

However, the important thing is that these are compile-time checks, not assertions at runtime. Lint will see if there is a likely bug at compile time and point it out to the developer, but there are many places where Lint simply has no way to know if

LINT AND THE SUPPORT ANNOTATIONS

everything is OK or not. These annotations are not a replacement for defensive programming. In fact, they not only help *users* of some API you publish to use it correctly, they help *you* by serving as a reminder that these should be checked at runtime as well.

Pretty much all of the Android Support libraries pull in `support-annotations`, courtesy of Gradle and transitive dependencies. If you do not seem to have `support-annotations` in your project, just add it to your dependencies closure, as you would any other of the Android Support libraries:

```
dependencies {
    compile 'com.android.support:support-annotations:23.1.0'
}
```

You may occasionally run into version conflicts over this library, where Library A wants one version and Library B wants another version. In those cases, you may need to teach Gradle to not try to load the `support-annotations` version that a particular library might want, so you can use a different version:

```
dependencies {
    compile 'com.android.support:support-annotations:23.1.0'
    compile('com.davemorrissey.labs:subsampling-scale-image-view:3.4.0') {
        exclude module: 'support-annotations'
    }
}
```

In this case, `com.davemorrissey.labs:subsampling-scale-image-view:3.4.0` wants version `20.0.0` of the `support-annotations`, which is rather old. Hence, we block that dependency and substitute our own, for version `23.1.0`. In general, newer versions of this library should be backwards-compatible with older versions of this library, so in case of conflict, use the newer version.

Permissions, Again

You can indicate that certain bits of your app require callers to hold certain permissions, using the `@RequiresPermission` annotation. This is mostly for libraries, where other projects might use the library.

Methods

The most common place to put this annotation will be on a method, to indicate that the method requires that callers hold a certain permission.

LINT AND THE SUPPORT ANNOTATIONS

The simplest scenario is where the method requires that callers hold a single permission, in which case you just list the permission as a parameter to the annotation:

```
@RequiresPermission(Manifest.permission.CAMERA)
public void takeSelfie() {
    // do work here
}
```

If the caller does not have a `<uses-permission>` element for the CAMERA permission, Lint will complain at the point where the app calls `takeSelfie()`.

Sometimes, you may need callers to hold more than one permission. In that case, you can use `allOf` to list permissions; callers have to have requested all of them in the manifest:

```
@RequiresPermission(
    allOf = {
        Manifest.permission.CAMERA,
        Manifest.permission.WRITE_EXTERNAL_STORAGE
    }
)
public void takeSelfie() {
    // do work here
}
```

On occasion, you may need the caller to hold one of a set of possible permissions. The quintessential example here is location, where your code might dynamically adapt based upon whether the app has `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. In that case, you can use `anyOf` to list the possibilities; if the app has any of those permissions requested in the manifest, Lint will be happy:

```
@RequiresPermission(
    anyOf = {
        Manifest.permission.ACCESS_COARSE_LOCATION,
        Manifest.permission.ACCESS_FINE_LOCATION
    }
)
public void makeNoteOfWhereWeAt() {
    // do work here
}
```

It is unclear if there is a way to combine `anyOf` and `allOf` in a single annotation (e.g., a `takeSelfie()` method that wants to geotag the photo with the user's current location).

Intent Actions

If you have a custom Intent action string, and the operation tied to that action string requires a permission, you can teach Lint about that by putting a `@RequiresPermission` annotation on a static String for that action string:

```
@RequiresPermission(Manifest.permission.CAMERA)
public static final String ACTION_TAKE_SELFIE="com.commonware.intent.action.SELFIE";
```

Basically, Lint keeps track of such strings, and if any Intent in the app is created using those strings as actions, Lint will check to see if the permission was requested.

ContentProviders

Similarly, you can annotate a static Uri that serves as the base Uri for a ContentProvider. Any calls to ContentObserver that have a Uri based on the static base will trigger Lint to check to see if permissions were requested.

Frequently, though, a ContentProvider will have separate read and write permissions. To handle that, you have to use some fairly clunky syntax, wrapping the `@RequiresPermission` annotation in `@RequiresPermission.Read` or `@RequiresPermission.Write` annotations. For example, the `ContactsContract` class could, in theory, have:

```
public static final String AUTHORITY = "com.android.contacts";
public static final Uri AUTHORITY_URI = Uri.parse("content://" + AUTHORITY);

@RequiresPermission.Read(@RequiresPermission(Manifest.permission.READ_CONTACTS))
@RequiresPermission.Write(@RequiresPermission(Manifest.permission.WRITE_CONTACTS))
public static final Uri CONTENT_URI = Uri.withAppendedPath(AUTHORITY_URI, "contacts");
```

(it actually does not have these; any Lint checks for this `CONTENT_URI` are being handled through rules internal to the tools, not through the support annotations)

What Permissions Should I Annotate?

If the method (or whatever) absolutely needs the permission, in all significant cases, then having the annotation will be useful.

However, there will be scenarios in which a permission may or may not be needed, depending upon circumstances.

For example, let's go back to:

LINT AND THE SUPPORT ANNOTATIONS

```
@RequiresPermission(  
    allOf = {  
        Manifest.permission.CAMERA,  
        Manifest.permission.WRITE_EXTERNAL_STORAGE  
    }  
)  
public void takeSelfie() {  
    // do work here  
}
```

Here, we are implying that `takeSelfie()` will need both of those permissions, and probably all of the time. For example, perhaps the method is set up to write to `Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DCIM)`. That directory requires `WRITE_EXTERNAL_STORAGE` all of the time.

But, suppose the method were implemented where the destination was a `Uri`, instead? You would have:

```
@RequiresPermission(  
    allOf = {  
        Manifest.permission.CAMERA,  
        Manifest.permission.WRITE_EXTERNAL_STORAGE  
    }  
)  
public void takeSelfie(Uri dest) {  
    // do work here  
}
```

That `Uri` could point to any number of locations, only some of which might require `WRITE_EXTERNAL_STORAGE`. For example, the caller could provide a `file:Uri` pointing to `getExternalFilesDir()`, which does not need `WRITE_EXTERNAL_STORAGE` on API Level 19+.

There are two major strategies here, with respect to these annotations:

- Be conservative, and annotate for both permissions, as shown in the example above. The caller can always suppress the warning, if the caller is sure that `WRITE_EXTERNAL_STORAGE` is not required. However, this may confuse people not familiar with your API or with Android overall.
- Be liberal, and only annotate for the `CAMERA` permission (which `takeSelfies()` always needs). Here, you are relying on the caller to read the documentation for your library, use common sense, or perform adequate testing to ensure that `WRITE_EXTERNAL_STORAGE` is requested in cases where it is needed.

A “middle ground” approach would be to be conservative in cases where the permission might require significant work, and liberal otherwise. For example,

WRITE_EXTERNAL_STORAGE is a dangerous permission on Android 6.0+, and so the caller has to go through all of the runtime permission request stuff for that if the app's targetSdkVersion is 23 or higher. But, if takeSelfie() really needed CAMERA and VIBRATE (to shake the device once the selfie is taken, perhaps based on user preferences), requesting VIBRATE is merely a single line in the manifest, and so demanding it via the annotation when it might not be needed would be excessive.

Type Roles, and the War on Enums

In 2015, a [kerfuffle](#) erupted in the world of Android development, one that quickly got tagged with the label, “the War on Enums”.

Google developer advocates started promoting the idea that using the Java enum construct was bad, and that you should use int constants instead, the way the Android SDK does. Core Android engineers slowly backed away from those developer advocates, but explained the reason why all through the Android SDK we are passing around int values.

In a nutshell, an enum reference will consume more heap space than will an int. If every place we passed around int flags or int resource IDs, we passed around enum objects, we would put greater pressure on our available heap space.

For most Android developers, for their own code, this particular concern is unimportant, compared to the type safety one gets from using an enum properly. However, the Android SDK team decided that, in general, they should use int values rather than enum values, so they would not be the ones to blame for consuming too much heap space.

However, this does bring us back to the core problem of passing the *wrong* int values into the *wrong* methods, such as:

- passing a widget ID or a string resource ID into setContentView()
- passing in Intent flags (e.g., FLAG_ACTIVITY_NEW_TASK) to PendingIntent methods like getActivity()
- passing in a color resource ID to a method that takes an actual ARGB color value

Instead, we get a convoluted set of annotations to try to help developers using public APIs to provide the smarts that ordinarily would be handled simply by enum.

Resources

Ideally, resource IDs would use Java's enum, so that you could not pass a string resource ID to a method that is expecting a menu resource ID. Alas, that is not the case.

Instead, if you accept resource IDs as parameters on methods or as return values from those methods, you can use a set of annotations to indicate what specific role the int values play.

- @AnimatorRes
- @AnimRes
- @ArrayRes
- @AttrRes
- @BoolRes
- @ColorRes (i.e., the int should be a color resource ID)
- @DimenRes
- @DrawableRes (i.e., the int should be a drawable resource ID)
- @FractionRes
- @IdRes
- @InterpolatorRes
- @LayoutRes
- @MenuRes
- @PluralsRes
- @RawRes
- @StringRes (i.e., the int should be a string resource ID)
- @StyleableRes
- @StyleRes
- @TransitionRes
- @XmlRes

Documentation for these, such as it is, can be found in [the JavaDocs for the android.support.annotation package](#).

There is also @AnyRes, which indicates that the int needs to be a resource, but does not imply a particular type of resource.

So, for example, you could have:

```
public void loadConfig(@XmlRes int xmlResId) {  
    // do work here  
}
```

If Lint is uncertain whether the parameter passed to `loadConfig()` is really an `R.xml` value, it can warn the caller.

Custom Enum Replacement

Sometimes, the `int` values are replacing what would have been a custom Java enum.

For example, [the CWAC-Cam2 library](#) has a `FlashMode` enum:

```
public enum FlashMode {
    OFF,
    ALWAYS,
    AUTO,
    REDEYE
}
```

Apparently, the author of that library is evil and therefore supports the use of an enum.

(note: the author of that library is also the author of this book)

An alternative would be to define those as a series of `int` flags:

```
public class FlashMode {
    public static final int OFF=0x0;
    public static final int ALWAYS=0x1;
    public static final int AUTO=0x2;
    public static final int REDEYE=0x3;
}
```

However, we are then back in the state where we do not know if some arbitrary `int` that we are passed as a parameter really is a `FlashMode`, as a method might expect. With the enum, we can have methods like:

```
public void setFlashMode(FlashMode mode) {
    // do work
}
```

The support-annotations library makes it possible to write a `setFlashMode()` that warns developers if they pass in the wrong `int`, but it takes a bit of work.

The [documented recipe](#) is:

```
public class FlashMode {
    @IntDef({OFF, ALWAYS, AUTO, REDEYE})
    @Retention(RetentionPolicy.SOURCE)
    public @interface FlashModeInt {}
}
```

LINT AND THE SUPPORT ANNOTATIONS

```
public static final int OFF=0x0;
public static final int ALWAYS=0x1;
public static final int AUTO=0x2;
public static final int REDEYE=0x3;
}
```

Then, elsewhere, we could reference that custom `FlashModeInt` annotation:

```
public void setFlashMode(@FlashMode.FlashModeInt int mode) {
    // do work
}
```

Then, if Lint cannot confirm that the supplied mode is one of those constants, Lint can warn the caller.

Flags

One benefit of `int` over `enum` is that it is easier to implement parameters and return values that represent a combination of values rather than single values.

For example, there are a wide range of flags that you can put on an `Intent`, like `FLAG_ACTIVITY_CLEAR_TOP` and `FLAG_ACTIVITY_SINGLE_TOP`. An `Intent` can have zero, one, or several of these flags.

With an `enum` for those flags, you would need to be passing around a `Set` of `enum` instances. With `int` values, though, you can use bitfields, where each flag is assigned a bit within the `int`. For example, `FLAG_ACTIVITY_CLEAR_TOP` is `0x04000000` and `FLAG_ACTIVITY_SINGLE_TOP` is `0x20000000`. Having both of those on a single `Intent` is merely a matter of using a `OR` bit operation:

```
yourIntent.setFlags(Intent.FLAG_ACTIVITY_CLEAR_TOP|FLAG_ACTIVITY_SINGLE_TOP)
```

This takes up a lot less space, and is more efficient from a CPU standpoint, than a `Set` of `enum` values. However, once again, type safety becomes a problem.

`@IntDef` also supports a “flag” mode, where Lint will validate that the value passed in is comprised of the designated constants, either used individually or in combination using boolean bit operators. For example, perhaps we can support several possible flash modes in a camera API, and the caller can indicate the various modes of interest using flags:

```
@IntDef(flag=true, value={
    FLAG_OFF,
    FLAG_ALWAYS,
})
```

LINT AND THE SUPPORT ANNOTATIONS

```
    FLAG_ON,  
    FLAG_REDEYE  
})  
@Retention(RetentionPolicy.SOURCE)  
public @interface FlashModeOptions {}
```

Now, methods and parameters annotated with `@FlashModeOptions` will be validated to ensure they are passing valid flags and combinations of flags.

Does It Null?

The `@NonNull` annotation can be used for parameters that are not allowed to be null. If, at compile time, the caller is clearly passing a null value, the caller will be warned.

```
public void doSomethingContextual(@NonNull Context ctxt) {  
    // do work here  
}
```

This could also be used on methods where you are sure that the return value cannot be null. This is particularly important with abstract methods, methods you expect other developers to override, callbacks, and the like — putting `@NotNull` on return values for those methods indicate that *you* are requiring that the implementer not hand you back a null value.

Conversely, the `@Nullable` annotation can be used on methods that explicitly *can* return null as valid value:

```
@Nullable  
public Context getContextIfWeHaveOne() {  
    // do work here  
  
    return(result);  
}
```

Any caller of `getContextIfWeHaveOne()` will get a Lint warning, pointing out that they need to check for null results. That warning will remain there until the developer suppresses it or, in Lint's estimation, appears to check the result for a null value and handle that case.

This can be used to help find `@NonNull` violations elsewhere, by helping Lint see where things might be null.

Data Validation

A variety of other annotations can be used for checking parameter values at compile time, to perhaps catch bugs earlier.

Size

For parameters and return values that implement `java.util.Collection` – such as `ArrayList`, you can use the `@Size` annotation to provide some compile-time guidance with regards to your expectations for that collection. This also works for ordinary Java arrays.

A simple number in the `@Size` annotation means you are expecting exactly that number of items in the collection, no more, no less:

```
public void growPair(@Size(2) ArrayList<String> values) {  
    // do something  
}
```

You can use `min` and `max` to constrain the size, without tying it down to a particular value:

```
public void sortInPlace(@Size(min=1) List<Comparable> unsorted) {  
    // do a sort  
}  
  
public @Size(min=1, max=6) float[] getReading(SensorEvent e) {  
    return(e.values);  
}
```

Occasionally, you might have a collection that does not have a specific size, but the size it *does* have has to be evenly divisible by some number. For that, there is the `multiple` option:

```
@RequiresPermission(Manifest.permission.VIBRATE)  
public void shakeItOff(@Size(multiple=2) long[] vibrationPattern) {  
    // use Vibrator system service  
}
```

Ranges

`@IntRange` and `@FloatRange` help validate that the annotated value lies within a particular range of values. The range is inclusive: values equal to the ends of the range are assumed to be valid.

LINT AND THE SUPPORT ANNOTATIONS

These work somewhat like @Size, except they directly examine a value, instead of examining the length of a collection or string.

```
public void howManyRoadsMustAManWalkDown(@IntRange(from=0,to=42) int roads) {  
    // do something involving a towel  
}
```

Colors

If you have a method that expects a color resource ID as a parameter or return value, use the @ColorRes annotation, as noted previously.

However, more often than not, you will be expecting *colors*, not color resource IDs, to give the other developers flexibility about where the colors come from. In that case, @ColorInt will help identify parameters and return values that are expected to be actual ARGB colors, not just arbitrary integers. In particular, this will catch when somebody tries using a color resource ID where you expect an actual color.

Thread Validation

If a method needs to be invoked on a certain type of thread (e.g., a background thread), you can use annotations to try to catch that sort of bug.

The simple one is @WorkerThread, which indicates that the method needs to be called on a background thread. If Lint thinks that the method is being invoked from something else (e.g., the main application thread), it will flag the caller with a warning.

```
@WorkerThread  
public void thisIsGoingToTakeLikeForEVER() {  
    // do something tedious  
}
```

There are two possible converse annotations: @MainThread and @UiThread. In one bit of documentation, [Google says they are interchangeable](#). In another bit of documentation, [Google tries to point out a disparity between them](#)

There is one and only one main thread in the process. That's the @MainThread. That thread is also a @UiThread. This thread is what the main window of an activity runs on, for example. However it is also possible for applications to create other threads on which they run different windows. This will be very rare; really the main place this distinction matters is the system process. Generally you'll want to annotate methods

associated with the life cycle with `@MainThread`, and methods associated with the view hierarchy with `@UiThread`. Since the `@MainThread` is a `@UiThread`, and since it's usually the case that a `@UiThread` is the `@MainThread`, the tools (lint, Android Studio, etc) treat these threads as interchangeable, so you can call `@UiThread` methods from `@MainThread` methods and vice versa.

Roughly speaking, if the method has to be run on the main application thread for lifecycle reasons, use `@MainThread`. If the method has to be run on a UI thread to avoid “cannot modify views from a non-UI thread” sorts of errors, use `@UiThread`. And, if you're not sure, flip a coin.

Other Annotations

If you have a protected or public method in a class that might be subclassed, and you want to help ensure that if the method is overridden that the developer calls through to your superclass implementation, use `@CallSuper`.

(note: this annotation will not call a building superintendent; it will only be honored by Superman if your name is on the whitelist, e.g., Lois Lane)

```
@CallSuper
protected int heyDontForgetAboutMe() {
    // do something

    return(somethingToo);
}
```

`@CheckResult` allows you to nag any caller of your method, to ensure that they actually look at the value you return, rather than ignore it.

Using Hierarchy View

Android comes with a Hierarchy View tool, designed to help you visualize your layouts as they are seen in a running activity in a running emulator. So, for example, you can determine how much space a certain widget is taking up, or try to find where a widget is hiding that does not appear on the screen.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Launching Hierarchy View

To use the Hierarchy View, you first need to fire up your emulator, install your application, launch your activity, and navigate to the spot you wish to examine. Note that you cannot use Hierarchy View with a production Android device [without some help](#).

To launch Hierarchy View, you can use the Android Device Monitor. In Android Studio, this is available from the Tools > Android menu. From the command line, run the `monitor` program to bring up the Android Device Monitor. In the Android Device Monitor, choose Window > Open Perspective from the main menu, and open Hierarchy View:

USING HIERARCHY VIEW

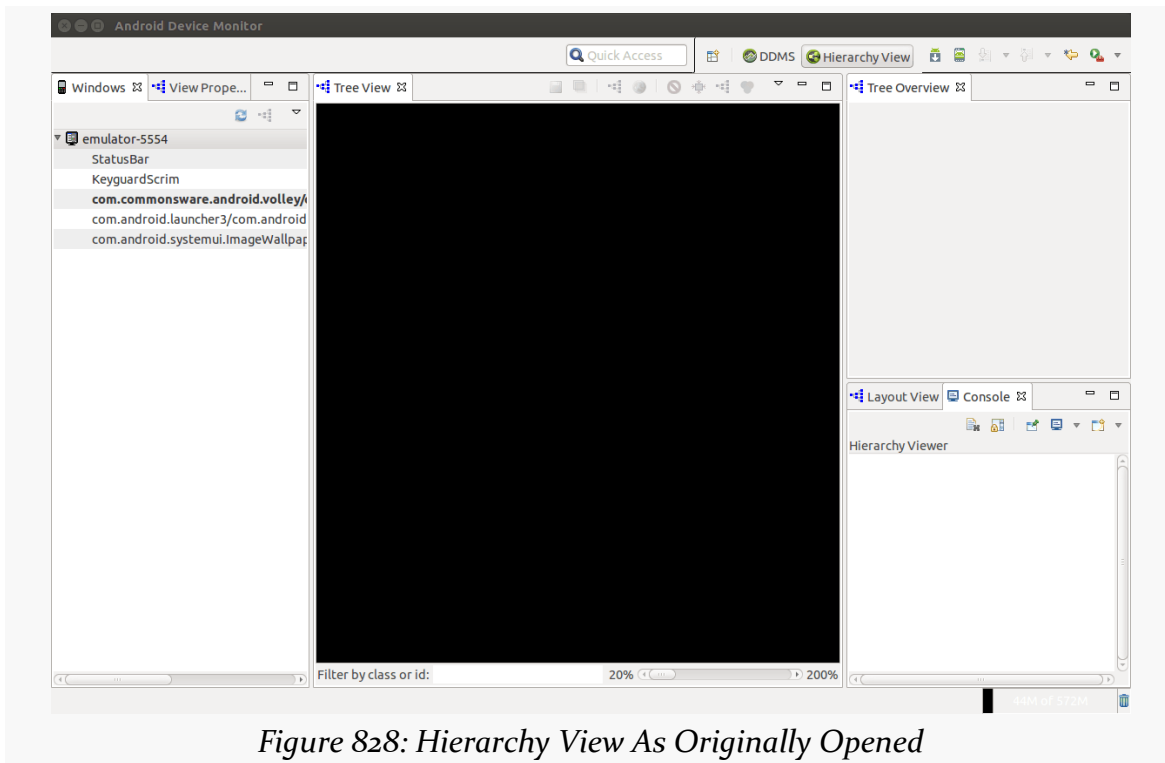

Figure 828: Hierarchy View As Originally Opened

The roots of the tree-table on the left show the emulator instances presently running on your development machine. The leaves represent applications running on that particular emulator. Your activity will be identified by application package and class (e.g., `com.commonware.android.files/...`).

Viewing the View Hierarchy

Where things get interesting, though, is when you double-click on your activity in the tree-table. After a few seconds, the details spring into, er, view:

USING HIERARCHY VIEW

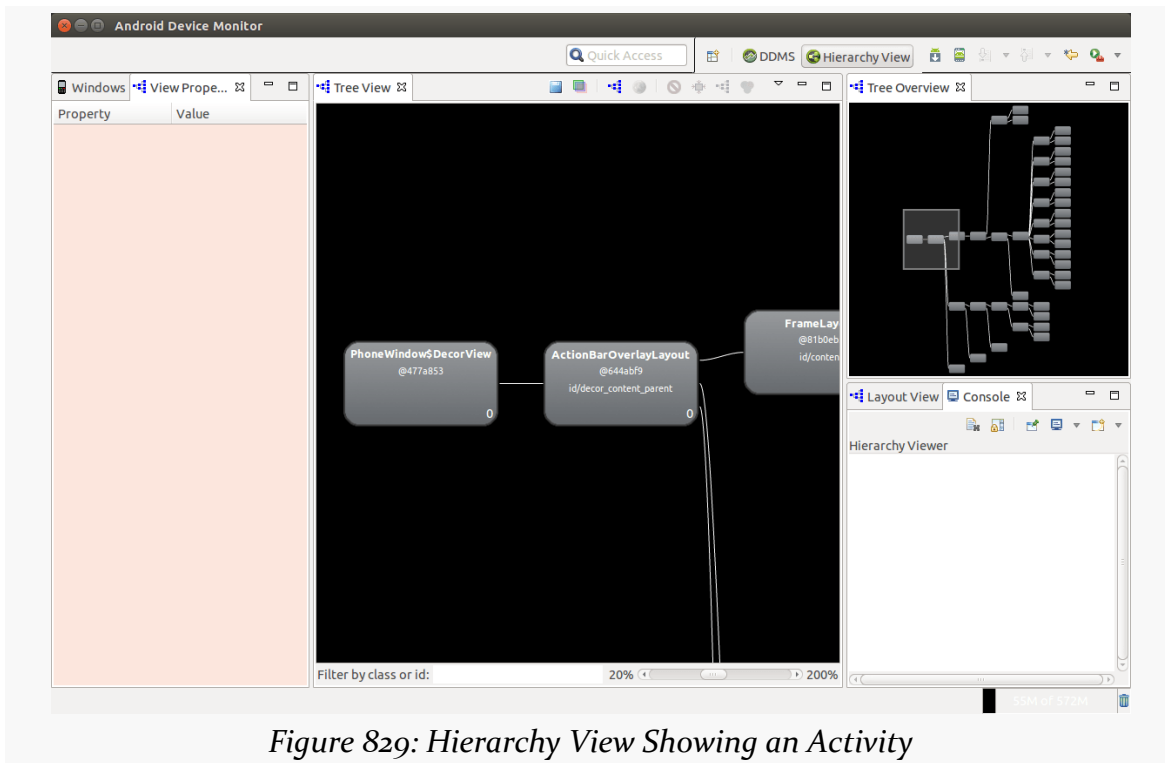

Figure 829: Hierarchy View Showing an Activity

The main area of the Layout View shows a tree of the various widgets and stuff that make up your activity, starting from the overall system window and driving down into the individual UI widgets that users are supposed to interact with. This includes both widgets and containers defined by your application and others that are supplied by the system, including the title bar.

Clicking on one of the views adds more information to this perspective:

USING HIERARCHY VIEW

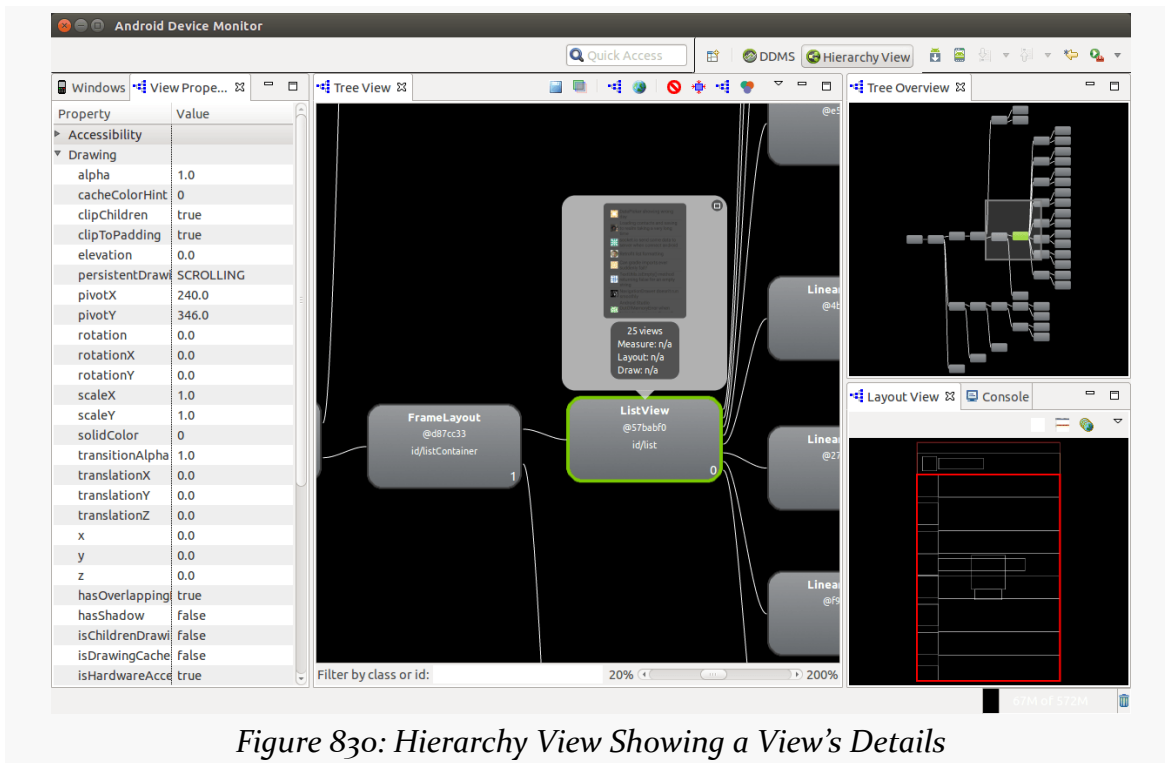

Figure 830: Hierarchy View Showing a View's Details

Now, we get:

- In the left region of the Viewer, we see the properties of the selected widget or container, in its own tree-table.
- In the Tree View in the middle, the selected widget or container has a pop-up bubble with what that particular View looks like on the screen, along with some performance timing data.
- In the Tree Overview in the upper-right portion of the tool, our selected View is highlighted in green.
- In the Layout View in the lower-right portion of the tool, our selected View is highlighted in red in the wireframe.

From the toolbar above the Tree View, you can:

- Save the tree diagram as a PNG file
- Save the UI as a Photoshop PSD file, with different layers for the different widgets and containers
- Force the UI to repaint in the emulator or re-load the hierarchy, in case you have made changes to a database or to the app's contents and need a fresh diagram

ViewServer

One major limitation of Hierarchy View is that it only works with the emulator by default. There is no means for it to pull information from random activities running on production hardware.

However, Romain Guy, one of the core Android engineers, has published [a ViewServer open-source component](#) that gets around this limitation.

If you add the ViewServer source code to your project, and register your activities as they are created (and remove them when they are destroyed), you will be able to use Hierarchy View with them. However, this is a bit dangerous on a production app, so you should strongly consider using `BuildConfig.DEBUG` to only enable this logic in debug builds.

Blending in the `BuildConfig.DEBUG` concept with Mr. Guy's supplied sample usage, we get something like this:

```
public class MyActivity extends Activity {
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        // Set content view, etc.

        if (BuildConfig.DEBUG) ViewServer.get(this).addWindow(this);
    }

    public void onDestroy() {
        if (BuildConfig.DEBUG) ViewServer.get(this).removeWindow(this);

        super.onDestroy();
    }

    public void onResume() {
        super.onResume();

        if (BuildConfig.DEBUG) ViewServer.get(this).setFocusedWindow(this);
    }
}
```

Also note that ViewServer requires that your application hold the `INTERNET` permission, which you may already have requested for other reasons.

Screenshots and Screencasts

They say that [a picture is worth a thousand words](#).

If that were really true, this book would be a lot shorter, mostly consisting of a bunch of screenshots.

That being said, having screenshots of your app is essential for documentation, marketing, and other uses. You are going to want to collect screenshots from your app by one means or another.

Screencasts — videos recording the user’s interaction with a device – are also very useful for the same purposes, even if their nature precludes their practical use in various mediums (e.g., PDFs). These are also a bit more complex to collect, though you have plenty of options for that.

This chapter will outline various ways to get screenshots and screencasts of your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Collecting from Android Studio

The Android Monitor tool has buttons to take a screenshot and record a screencast, in the outer toolbar:

Figure 831: Android Studio Screenshot and Screencast Toolbar Buttons

Screenshots

The top one takes a screenshot, giving you a dialog to control what gets captured:

SCREENSHOTS AND SCREENCASTS

The main area shows the screen at the time you clicked the screenshot toolbar button. Clicking the “Reload” button on the top of the dialog will update the dialog to show the now-current device (or emulator) contents.

Depending on Android Studio version and device characteristics, the dialog may open with the correct orientation. If not, click the “Rotate” button until the image is oriented as you would like it to be.

The “Frame Screenshot” checkbox, if checked, will wrap your screenshot in an image that resembles the hardware from the drop-down list:

SCREENSHOTS AND SCREENCASTS

Figure 833: Android Studio Screenshot Dialog, Framing as Nexus 5

The “chessboard” on the outside edges of the image represent transparent areas in the PNG that will be created when you save the image.

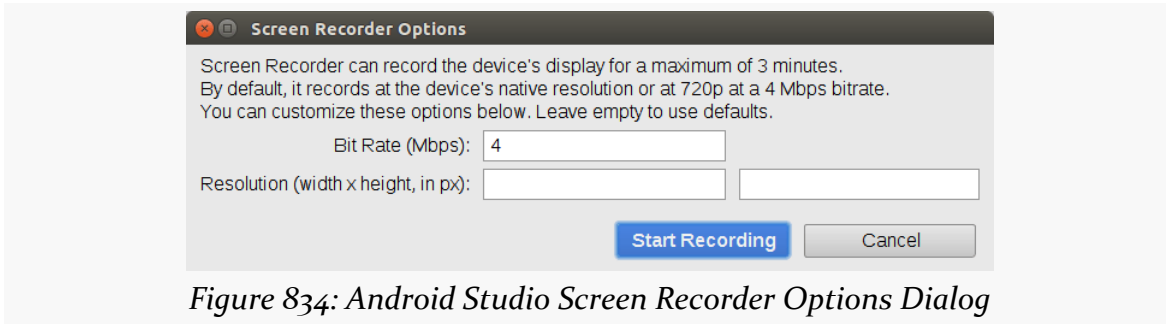

Checking the “Drop Shadow” checkbox updates the fake device frame to make it seem like the device is sitting on its edge on some horizontal surface, with a drop-shadow effect. Similarly, checking the “Screen Glare” checkbox adds a fake bit of lighting to the screenshot, as if a light from the upper right side is causing a glare on the fake glass of the fake device frame. Suffice it to say, none of this looks especially realistic.

When you have the screenshot set to your liking, click the “Save” button on the bottom of the dialog, to get a platform-specific “Save As” dialog for you to save your screenshot to wherever you like.

The resulting screenshot will then open in a tab in your IDE. This tab does not let you edit the picture, but it does have an “eyedropper” toolbar button that allows you to examine the image and identify the exact colors of various pixels.

Screencasts

Clicking the second of the two toolbar icons mentioned above brings up a dialog for configuring a screencast:

The particular technique that Android Studio uses to record the screencast is capped at three minutes, which is one of the reasons why there are other alternatives that this chapter will explore.

The bit rate will determine the size of the resulting MP4 file, where a higher bit rate will give you a larger file. However, too low of a bit rate will degrade the quality of the recording, particularly if there is a lot of motion. You will need to experiment for yourself to see what bit rate value works best for you; 4Mbps is the default.

Similarly, normally, the screencast will be at the resolution of the device screen. However, there will be some low-end devices that are incapable of recording a video at that resolution, due to weak video recording support. For those devices, the screencast will be downgraded to 720p. Or, you can attempt to specify the resolution, though you get odd results from the IDE if you try to specify a resolution that is not supported.

Clicking the “Start Recording” button will then start the screencast recording. The dialog that appears has a corresponding “Stop Recording” button. After clicking that, you will be given a “Save As” dialog to save the video wherever you like.

Collecting from the Command Line

The same capabilities that Android Studio taps into to collect screenshots and screencasts graphically are also available to you from the command line, via `adb`. Since `adb` is in the `platform-tools/` directory of your Android SDK installation, if

that directory is in your PATH, you can run `adb` from any likely directory on your development machine.

Screenshots

`adb shell screencap` captures a screenshot. This sounds easy enough.

The difficulty is that the screenshot is stored directly on the device or emulator, not on your development machine. This means that taking a screenshot is really a two-step process:

1. Capturing the screen to a PNG on the device
2. Moving that PNG from the device to your development machine

`adb shell screencap` takes the path for where the PNG should be saved on the device. Since we want to move that PNG to the development machine, it will be simplest if that path is pointing to external storage. What path you use will be tied to what version of Android you are running the `screencap` command on:

- Android 4.x/5.x: Use `/mnt/shell/emulated/0` as the base, which points to the root of external storage
- Android 6.0+: Use `/storage/emulated/0` as the base, which points to the root of external storage

You can then use `adb pull` to copy that PNG to your development machine, followed by `adb shell rm` to delete the copy that is on the device (to save space, remove clutter, etc.).

For example, the following script would take a screenshot on an Android 6.0 device or emulator and move it to your development machine into whatever the current working directory is:

```
adb shell screencap /storage/emulated/0/screenshot.png
adb pull /storage/emulated/0/screenshot.png .
adb shell rm /storage/emulated/0/screenshot.png
```

Note that the other effects handled by Android Studio, such as rotating the image, are not offered by the command-line interface. Instead, you would use your available image editing tools on your development machine to handle that.

Screencasts

Similarly, `adb shell screenrecord` will record a screencast, saving it as a MP4 file on your device or emulator. And, once again, you will need to use something like `adb pull` to copy that MP4 to your development machine, perhaps followed by `adb shell rm` to remove the copy from the device.

`adb shell screenrecord` is a bit more configurable, though. In addition to the device path to the MP4 file, you can use command-line switches to change the nature of the recording:

- `--size` sets your desired resolution, overriding the default of `1280x720` if your resolution is supported. For example, use `--size 1920x1080` for a 1080p recording.
- `--bit-rate` sets the bit rate, as discussed in the earlier section about screencasts in Android Studio. This is expressed in *bits per second*, so `--bit-rate 8000000` would save at ~8Mbps.
- `--time-limit` will automatically stop the recording after the stipulated number of seconds, capped at a maximum value of three minutes (the equivalent of `--time-limit 180`). Alternatively, while the screencast is recording, press `Ctrl-C` to stop the recording.

For example, the following script would record a 30-second 1080p screencast on an Android 6.0 device or emulator and move it to your development machine into whatever the current working directory is:

```
adb shell screenrecord --size 1920x1080 --time-limit 30 /storage/emulated/0/screencast.mp4
adb pull /storage/emulated/0/screencast.mp4 .
adb shell rm /storage/emulated/0/screencast.mp4
```

Collecting from Another App

The three-minute limitation on screencasts, imposed by Android Studio and `adb shell screenrecord`, can be troublesome in some situations.

On Android 5.0 and higher devices, the media projection APIs allow authorized apps to take screenshots and record screencasts. These screencasts do not have an arbitrary time limitation. However, do bear in mind that the videos are stored on the device itself, so disk space can become an issue.

Various apps on the Play Store and elsewhere are available for “out of the box” screencast recording. On the open source front, Jake Wharton wrote and released Telecine, both in [a GitHub repository](#) and as [an app on the Play Store](#).

[Another chapter in this book](#) shows how you can use the media projection APIs, and one of the sample apps (andcorder) can be used akin to how you would use Telecine or `adb shell screenrecorder`.

Tips and Tricks

Note that none of these approaches will record audio along with the video for the screencasts. You will need to use video editing software to add an audio track to the video, whether that comes in the form of a spoken-word voiceover, a soundtrack, or whatever.

While all of the techniques described here will work with devices and emulators, emulators need “Use Host GPU” enabled, at least for API Level 15+ emulators on Linux. Otherwise, your screenshots and screencasts turn out blank.

For screencasts designed to show users how to use an app, you may wish to enable “Show touches” in the Developer Options area of Settings. This will display a white dot where your finger touches the screen, to help illustrate where you are tapping, sliding, etc. Otherwise, the user may or may not be able to follow exactly what you are doing to cause the app to behave as shown.

ADB Tips and Tricks

Several chapters in this book offer `adb` recipes for doing certain things at the command line. Having the `adb` binary in the `PATH` environment variable for your development machine is very handy, so you can run such commands from anywhere.

However, those other chapters only skim the surface of what sorts of `adb` commands there are and what they can be used for. Several others are presented here.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, and that you know how to work on the command line.

This is the Droid That You Are Looking For

`adb` works well, except when there is more than one visible Android environment, such as two devices, or a device and an emulator. Some commands — notably `adb devices` — work normally. Most other commands will complain that `adb` does not know which of the Android environments the command is supposed to act upon.

There are three switches you can include after `adb` and before the command that control what `adb` will use:

- `-d` says “use the device, there should only be one” (and if there is more than one, you get an error)
- `-e` says “use the emulator, there should only be one” (and if there is more than one, you get an error)
- `-s ...` says “use the environment whose serial number is ...”

That serial number is the value given in the `adb devices` command. For an actual device, the serial number usually is the real serial number. For an emulator, the serial number is `emulator-NNNN`, where `NNNN` is the value before the AVD name in the title bar of the emulator window. Frequently, that value starts with 5554 and increments by two for each subsequent running emulator. Hence, `-e` is roughly equivalent to `-s emulator-5554`.

Installing and Uninstalling Apps

If you have an APK file that you wish to install — such as the APK edition of this book — you can do that at the command line via `adb install /path/to/the.apk`, where `/path/to/the.apk` is where the APK can be found on your development machine.

If the app already exists on the device or emulator, and you wish to replace it with this new APK, you will have to include the `-r` switch: `adb install -r /path/to/the.apk`. This indicates that you wish to reinstall the app.

Conversely, `adb uninstall your.application.id` will uninstall the app identified by the application ID (`your.application.id`).

Playing with Permissions

In an `adb install` command, you can include the `-g` switch to proactively grant all of the Android 6.0+ runtime permissions that ordinarily you would need to grant manually.

You can manually grant permissions via the `adb shell pm grant` command. This takes the application ID of your app and the fully-qualified name of the permission:

```
adb shell pm grant com.commonware.android.perm.tutorial android.permission.CAMERA
```

Similarly, you can use `adb shell pm revoke` to revoke a permission that was already granted to the app:

```
adb shell pm revoke com.commonware.android.perm.tutorial android.permission.CAMERA
```

These can be useful for testing purposes, either to save you some steps when testing manually, or to blend into automated tests. However, do not become overly reliant upon programmatic permission grants — you need to be sure that your permission

flow works for the user, and the user is not going to be using `-g` switches or `adb shell pm grant` commands when using your app.

Starting and Stopping Components

Given an installed app, you can trigger its activities, services, and broadcast receivers from the command line, using `adb shell` to run commands on the device or emulator.

The actual commands are simple:

- `adb shell am start ...` to start an activity
- `adb shell am startservice ...` to start a service
- `adb shell am broadcast ...` to send a broadcast

The challenge is in the `...` part, where you provide command-line switches to construct an Intent that will be used for those operations. Here are some common patterns:

- Simple implicit Intent with just an action string, use `-a` (e.g., `adb shell am start -a android.intent.action.VOICE_COMMAND`)
- Implicit Intent with a Uri, use `-a` and `-d` (e.g., `adb shell am start -a android.intent.action.VIEW -d https://commonsware.com`)
- Implicit Intent with a different category, use `-a` and `-c` (e.g., `adb shell am start -a android.intent.action.MAIN -c android.intent.category.HOME`)
- Explicit Intent: use `-n` (e.g., `adb shell am start -n your.app.id/.YourActivity`)

There are [all sorts of command-line switches](#), for everything from flags to extras, that you can use to build up the Intent.

The [chapter on the media projection APIs](#) covers a sample screencast recorder, one that can be controlled using these sorts of commands. For example, to start the recording, the `record` shell script from the sample project uses:

```
adb shell am startservice -n
com.commonware.android.andcorder/.RecorderService -a
com.commonware.android.andcorder.RECORD
```

This starts the RecorderService, using an explicit Intent (-n) but also providing an action string (-a) to state what sort of command we are sending to the service.

Killing Processes and Clearing Data

`adb shell am kill ...` will kill all processes associated with the application ID (...).

`adb shell am force-stop ...` will force-stop the app associated with the application ID (...), as if the user went into Settings and clicked the “Force Stop” button for the identified app.

`adb shell pm clear ...` will clear the data associated with the application ID (...), as if the user went into Settings and clicked the “Clear Data” button for the identified app. This will erase that app’s portion of internal storage, plus app-specific directories on external storage (e.g., `getExternalFilesDir()`).

Changing Display Metrics

One reason why developers use emulators is because they lack hardware for device scenarios that they wish to test. Two such scenarios are screen size and density. Many developers have only a device or two to test against, and they may need to try out screen sizes and densities that their hardware does not offer directly.

However, if you have a device with a *higher* resolution or density, you can use `adb` to have the device fake operating as a lower-resolution or lower-density device.

Specifically, on Android 4.3 and higher, `adb shell wm size 1280x800` would tell an Android device to pretend to have a WXGA800 display. You will see the smaller area centered within the overall device screen.

Note, though, that the device may no longer honor orientation changes by rotating the device. You will need to stipulate your size based upon the orientation that you are holding the device and the default orientation of the device itself.

For example, running the above command on a Nexus 9 gives you the following, regardless of whether the Nexus 9 is in portrait or landscape:

ADB TIPS AND TRICKS

Figure 835: 1280x800 Display Size, On a Nexus 9, Held in Landscape

If you were planning on testing the Nexus 9 in portrait mode and wanted a landscape WXGA800 display, this is fine. More likely, you will need to change the order of your dimensions in the command. So, running `adb shell wm size 800x1280` gives you:

Figure 836: 800x1280 Display Size, On a Nexus 9, Held in Landscape

Here, at least, the device orientation matches the reduced-size screen orientation, if you were to hold the device in portrait mode.

ADB TIPS AND TRICKS

If you prefer, you can use dp units instead, by appending dp after the values. Using reset instead of a resolution will return the device to its native resolution.

Trail: Tuning Android Applications

Issues with Speed

Mobile devices are never fast enough. Either they are slow in general (e.g., slow CPU) or they are slow for particular operations (e.g., advanced game graphics).

What you do not want is for your application to be unnecessarily slow, where the user determines what is and is not “necessary”. Your opinion of what is “necessary”, alas, is of secondary importance.

This part of the book will focus on speed, including how you can measure and reduce lag in your applications. First, though, let’s take a look at some of the specific issues surrounding speed.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Getting Things Done

In some cases, you simply cannot seem to get the work done that you want to accomplish. Your database query seems slow. Your encryption algorithm seems slow. Your image processing logic seems slow. And so on.

The limits of the device will certainly make this more of a problem than it might otherwise be. Even a current-era multi-core device will be slow compared to your average notebook or desktop, as mobile CPUs cannot readily be directly compared to desktop and notebook CPUs. Also, this sort of speed issue is pervasive throughout

computing, with decades of experience to help developers learn how to write leaner code.

This part of the book will aim to help you identify where the problem spots are, so you know what needs optimization, and then some Android-specific techniques for trying to improve matters.

Your UI Seems... Janky

Sometimes, the speed would be less of an issue for the user, if it was not freezing the UI or otherwise making it appear sluggish and “[janky](#)”.

The Android widget framework operates in a single-threaded mode. All UI changes — from setting the text of a `TextView` to handling scrolling of a `GridView` — are processed as events on an event queue by the main application thread. That same thread is used for most UI callbacks, including activity lifecycle methods (e.g., `onCreate()`) and UI event methods (e.g., `onClick()` of a `Button`, `getView()` of an `Adapter`). Any time you take in those methods on the main application thread tie up that thread, preventing it from processing other GUI events or dispatching user input. For example, if your `getView()` processing in an `Adapter` takes too long, scrolling a `ListView` may appear slow compared to other `ListView` widgets in other applications.

Your objective is to identify where things are slow and move them into background operations. Some of this has been advised since the early days of Android, such as moving all network I/O to background threads. Lots of work has gone into providing libraries for you to be able to easily move common tasks, like loading images, onto background threads.

This part of the book will point out ways for you to find out where you may be doing unfortunate things on the main application thread and techniques for getting that work handled by a background thread, or possibly eliminated outright.

Not Far Enough in the Background

Sometimes, even work you are trying to do in the background will seem to impact the foreground.

For example, you might think that your `Service` is automatically in the background. An `IntentService` does indeed use a background thread for processing commands

via `onHandleIntent()`. However, all lifecycle methods of any `Service`, including `onStartCommand()`, are called on the main application thread. Hence, any time you take in those lifecycle methods will steal time away from GUI processing for the main application thread. The same holds true for `onReceive()` of a `BroadcastReceiver` and all the main methods of a `ContentProvider` (e.g., `query()`).

Even your background threads may not be sufficiently in the background. A process runs with a certain priority, using Linux process management APIs, based upon its state (e.g., if there is an activity in the foreground, it runs at a higher priority than if the process solely hosts some service). This will help to cap the CPU utilization of the background work, but only to a point. Similarly, threads that you fork — directly or via something like `IntentService` — may run at default priority rather than a lower priority. Even with lower priorities for the thread or process, every CPU instruction executed in the background is one clock tick that cannot be utilized by the foreground.

This part of the book will help you identify where you are taking lots of time on various threads and will help you manually manage priorities to help minimize the foreground impact of those threads, in addition to helping you reduce the amount of work those threads have to do.

Playing with Speed

Games, more so than most other applications, are highly speed-dependent. Everyone is seeking the “holy grail” of 60 frames per second (FPS) necessary for smooth animated effects. Not achieving that frame rate overall may mean the application will not appear quite as smooth; sporadically falling below that frame rate will result in jerky animation effects, much like the “janky” UIs in a non-game Android application.

For example, a classic problem with Android game development is garbage collection (GC). The original Android garbage collector was a “stop the world” implementation, that would freeze the game long enough for a bit of GC work to be done before the game could continue. This behavior pretty much guaranteed sporadic failures to maintain a consistent frame rate. This caused game developers to have to take particular steps to avoid generating any garbage, such as maintaining its own object pools, to minimize or eliminate garbage collection pauses. While Android 2.3 and beyond have taken steps to have garbage collection be more concurrent, there are still short pauses (1-2ms, typically), where all threads have to be suspended to wrap up the GC run.

ISSUES WITH SPEED

This book does not focus much on specific issues related to game development, though many of the techniques outlined here will be relevant for game developers.

Finding CPU Bottlenecks

CPU issues tend to manifest themselves in three ways:

- The user has a bad experience when using your app directly — scrolling is sluggish, activities take too long to display, etc.
- The user has a bad experience when your app is running in the background, such as having slower frame rates on their favorite game because you are doing something complex in a service
- The user has poor battery performance, driven by your excessive CPU utilization

Regardless of how the issue appears to the user, in the end, it is a matter of you using too much CPU time. That could be simply because your application is written to be constantly active (e.g., you have an everlasting service that uses `TimerTask` to wake up every second and do something). There is little anyone can do to help that short of totally rethinking the app's architecture (e.g., switch to `AlarmManager` and allow the user to configure the polling period).

However, in many cases, the problem is that you are using algorithms – yours or ones built into Android — that simply take too long when used improperly. This chapter will help you identify these bottlenecks, so you know what portions of your code need to be optimized in general or apply the techniques described in later chapters of this part of the book.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

Android Studio Monitors

In Android Studio, tabs inside the Android Monitor tool allow you to examine the real-time behavior of your app with respect to various system resources, such as the CPU and GPU. These tabs appear alongside the “logcat” tab, in a tab strip towards the top of the Android Monitor tool frame.

CPU

The CPU tab will show you a real-time graph of the CPU usage of your app, where your app is the one shown in the drop-down list at the top of the Android Monitor:

Figure 837: Android Studio, Android Monitor, CPU|GPU Tab, CPU Sub-Tab

The horizontal axis shows the time since the process started, and the vertical axis shows the percent of CPU utilization associated with your app. Within there, you are shown CPU utilization for “userland” operations (i.e., stuff in your app code) and “kernel” operations (e.g., time spent doing work related to I/O). Most Android apps should show much more time spent in the “User” light pink area.

Since this is a real-time graph, you can manipulate your app in the device or emulator and see the impacts of what you are doing on the CPU utilization. There is a slight lag between what you do to the device and when it shows up on the graph, though.

When you do something short in your UI, such as tap an action bar item, ideally you should see a short pulse of CPU utilization. When you do something continuously in your UI, such as scroll a `ListView` or `WebView`, you will see continuous CPU utilization.

The big thing that this graph can help you identify is when you do something in the UI that has longer-term CPU utilization. For example, tapping an action bar item that, in turn, uses an `AsyncTask` or `IntentService` to go download some data, parse

FINDING CPU BOTTLENECKS

it, and integrate it into your app's existing data, will take a chunk of CPU time. Your objectives are:

- The percentage of CPU utilization should be low while this is going on
- The window of time where you are using the CPU after user input ceases should be as short as you can manage

GPU

You may also be interested in the GPU sub-tab, which shows work related to rendering your app's UI:

Figure 838: Android Studio, Android Monitor, CPU|GPU Tab, GPU Sub-Tab

While the sub-tab is labeled “GPU”, really this is showing a mix of actual GPU processing and work done in your app in rendering the user interface.

Method Tracing

The #1 tool in your toolbox for finding out where bottlenecks are occurring in your application is method tracing. This will record your code and how long it takes your various methods to do their work. You can use this to look for outliers:

- Methods that are called way too frequently
- Methods that call other methods way too frequently
- Methods that take a lot of time in their own statements, including things like blocking on I/O

In the realm of Eclipse, the tool used to examine the results of method tracing is called Traceview, and so you will see that term pop up from time to time. Android Studio does not give it a particular name beyond “method tracing”.

OK, What Is Method Tracing, Really?

Technically, the method tracing in Android is performed by the virtual machine, under the direction of either your IDE or requests from your application code. Dalvik or ART will write the “trace data” (call graphs showing methods, what they call, and the amount of time in each) to a file on external storage of the device or emulator. Your IDE then views these trace files in a GUI, allowing you to visualize “hot spots”, drill down to find where the time is being taken, and so forth.

At the time of this writing, method tracing is designed for use on single-core devices. Results on multi-core devices may be difficult to interpret.

Collecting Trace Data

Hence, the first step for finding where your CPU bottlenecks lie comes in the form of collecting trace data for analysis. As mentioned, there are two approaches for requesting trace data be logged: using the `Debug` class, and using your IDE.

Debug Class

If you know what chunk of code you want to profile, one way to arrange for the profile is to call `startMethodTracing()` on the `Debug` class. This takes the name of a trace file as a parameter and will begin recording all activity to that file, stored in the root of your external storage. You need to call `stopMethodTracing()` at some point to stop the trace — failing to do so will leave you with a corrupt trace file in the end.

Note that your application will need the `WRITE_EXTERNAL_STORAGE` permission for this to work. If your application does not normally need this permission, make yourself a note to remove it before you ship the production edition of your product, as there is no sense asking for any more permissions than you absolutely need. Or, put this permission in a debug sourceset’s manifest in Android Studio, and then it will only be included in debug builds.

Also, your device or emulator will need enough external storage to hold the file, which can get very large for long traces — 100MB a minute is well within reason.

FINDING CPU BOTTLENECKS

Android Studio

After you run your app on your device or emulator, and after you get the app set up to the starting point where you want to collect tracing data, open up the Android tool and switch over to the CPU sub-tab, as shown earlier in the chapter:

Figure 839: Android Studio, Android Tool, CPU|GPU Tab, CPU Sub-Tab

In there, tap the toolbar button that looks like a stopwatch, shown in the above screenshot in the right-most of the two vertical toolbars. The toolbar button will take on an “inset” sort of dark background, indicating that trace data is being collected. Do what you wanted to do in the GUI of your app, then tap the same toolbar button to stop the method tracing. The results will show up in a tab in the main editing area of your IDE, and we will explore those results later in this chapter.

Performance While Tracing

Writing out each method invocation to a trace file adds significant overhead to your application. Run times can easily double or more. Hence, absolute times while tracing is enabled are largely meaningless — instead, as you analyze the data generated by method tracing, the goal is to examine relative times (i.e., such-and-so method takes up X% of the CPU time shown in the trace).

Also, running method tracing disables the JIT engine in Dalvik, further harming performance. Notably, this will not affect any native code you have added via the NDK, so an application run while method tracing will give you unusual results (much worse Java performance, more normal native performance). It is unclear what method tracing does with respect to ART in this area.

Displaying Trace Data

Given that we have collected a trace file with data, the next step is to examine the results. These will pop up automatically for you in Android Studio, once the IDE is done parsing the trace data.

In addition to the results tab automatically showing up when the trace is completed, the results will also be added to the Captures tool, normally docked on the left:

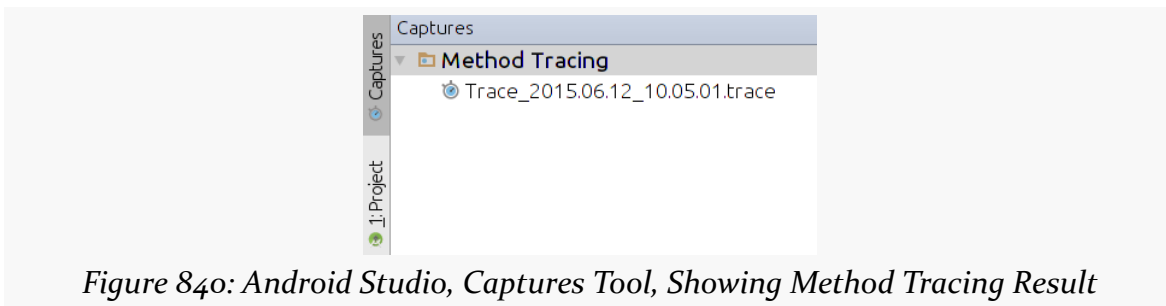

Figure 840: Android Studio, Captures Tool, Showing Method Tracing Result

You can use this to re-open the results tab whenever you wish, to look at the method tracing results in the future.

To remove previous trace results, just highlight the result to delete and choose Delete from the right-mouse context menu, or press the Delete key.

Interpreting Trace Data

Of course, the challenge is in making sense of what the IDE is trying to present.

For example, a classic performance bug in Java development is using string concatenation:

```
package com.commonware.android.traceview;

import android.view.View;
import android.widget.TextView;

public class StringConcatActivity extends BaseActivity {
    StringConcatTask createTask(TextView msg, View v) {
        return(new StringConcatTask(msg, v));
    }

    class StringConcatTask extends BaseTask {
        StringConcatTask(TextView msg, View v) {
            super(msg, v);
        }
    }
}
```

FINDING CPU BOTTLENECKS

```
protected String doTest() {
    String result="This is a string";

    result+=" -- that varies --";
    result+=" and also has ";
    result+=String.valueOf(4);
    result+=" hyphens in it";

    return(result);
}
}
```

Inclusive Time and Exclusive Time

All method tracing results speak in terms of “inclusive time” and “exclusive time” for a method call. Exclusive time refers to the time spent solely in primitive operations within the method itself. This will include things like basic arithmetic, if and switch branches, and so forth. Inclusive time refers to the time spent in this method, including all other methods invoked from this method.

So, for example, suppose we have a method `foo()` that has a loop that, inside the loop, calls another method `bar()` on each pass. `bar()` on its own is not that expensive, but calling it lots of times in a loop will add up. Further suppose that `bar()` does not call any other methods.

What you would expect to see in method tracing results is:

- The exclusive time and the inclusive time of `bar()` to be about the same, as `bar()` is not calling anything else
- The inclusive time of `foo()` and the inclusive time of `bar()` to be about the same, if most of what `foo()` does is just call `bar()` lots of times in a loop
- The exclusive time of `foo()` to be very small, as it is not doing much other than calling `bar()`

The entire method tracing results tab will be difficult to render in this book due to its size and complexity:

FINDING CPU BOTTLENECKS

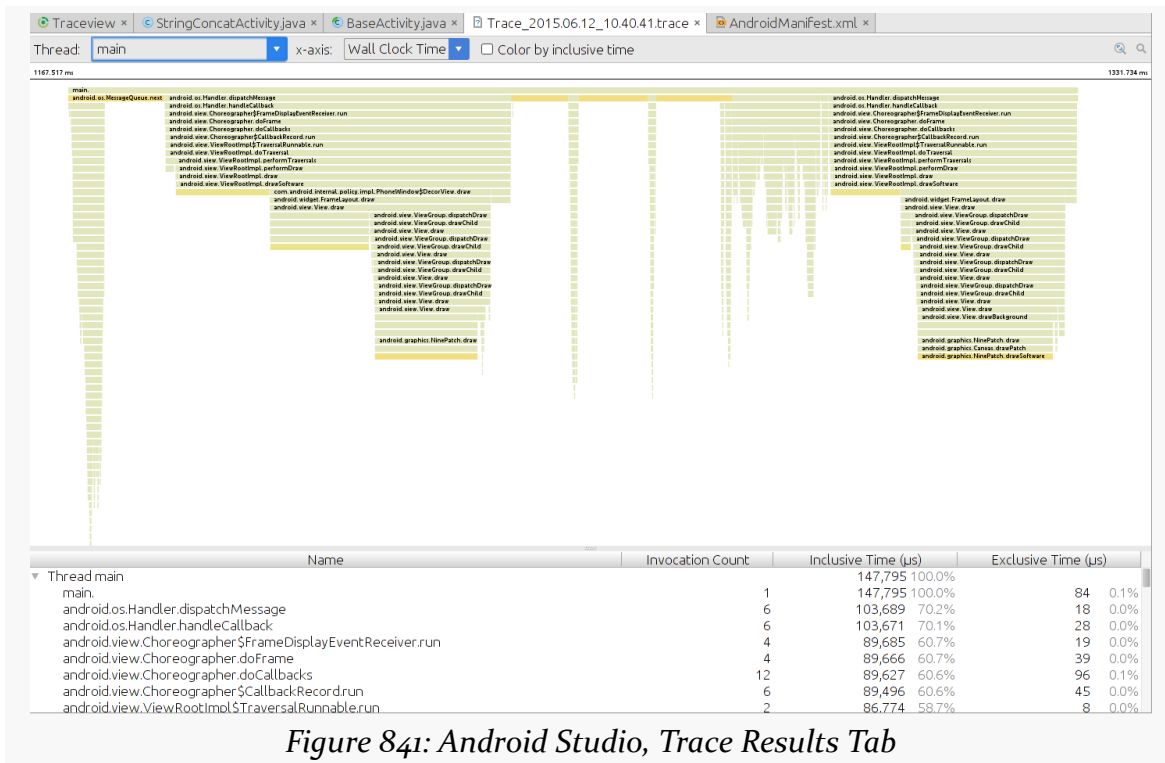

Figure 84: Android Studio, Trace Results Tab

The main portion of the output is a timeline of the processing on a thread. By default, it is the main application thread, and you can control what thread shows up via the Thread drop-down list in the tab’s own toolbar.

Each “row” in that main output area represents a call, or a nested call from the higher-order call, within the calls made on that thread. The width of each “cell” indicates the time spent within that specific call. By default, the X axis represents “Wall Clock Time”, or the time from when the tracing began until the tracing ended. Via the “x-axis” drop-down list in the tab’s toolbar, you can switch this to be “Thread Time”.

The bottom portion of the output shows the same call information for the selected thread, but in a tabular form instead of a timeline. Each method is denoted by how many times that method was called, how much inclusive time was spent in that call, and how much exclusive time was spent in that call. By default, the table is ordered by inclusive time, descending.

In the sample app, the string concatenation work is being done 100,000 times in an AsyncTask kicked off by a StringConcatActivity activity. To see its results in the

FINDING CPU BOTTLENECKS

trace results tab, we have to switch the Thread drop-down to “AsyncTask #1”, which gives us the following output table:

Name	Invocation Count	Inclusive Time (µs)	Exclusive Time (µs)
Thread AsyncTask #1		615,614 100.0%	
AsyncTask #1.	1	615,614 100.0%	2 0.0%
java.lang.Thread.run	1	615,612 100.0%	38 0.0%
java.util.concurrent.ThreadPoolExecutor\$Worker.run	1	615,574 100.0%	6 0.0%
java.util.concurrent.ThreadPoolExecutor.runWorker	1	615,568 100.0%	54 0.0%

Figure 842: Android Studio, Trace Results Tab, Call Table

So, What Are We Learning Here?

Typically, you want to find lines that reference your code. In this case, lines 7-9 are from the `com.commonware` package. Let’s focus on those:

<code>com.commonware.android.traceview.BaseTask.doInBackground</code>	1	615,334 100.0%	4 0.0%
<code>com.commonware.android.traceview.BaseTask.doInBackground</code>	1	615,330 100.0%	3,669 0.6%
<code>com.commonware.android.traceview.StringConcatActivity\$stringConcatTask.doTest</code>	3,348	611,661 99.4%	61,861 10.0%

Figure 843: Trace Results, Showing Sample App Methods

Not surprisingly, 99.4% of our inclusive time is taken up in `doTest()`, where our loop is. To find out more of where we are spending our time, just look at the next few lines:

FINDING CPU BOTTLENECKS

com.commonware.android.traceview.StringConcatActivity\$stringConcatTask.doTest	3,348	611,661	99.4%	61,861	10.0%
java.lang.StringBuilder.append	26,784	364,135	59.1%	44,245	7.2%
java.lang.AbstractStringBuilder.append0	26,784	319,890	52.0%	103,613	16.8%
java.lang.StringBuilder.toString	13,392	103,680	16.8%	24,864	4.0%
java.lang.AbstractStringBuilder.enlargeBuffer	23,436	99,904	16.2%	65,500	10.6%
java.lang.String._getChars	26,784	96,071	15.6%	48,595	7.9%
java.lang.System.arraycopy	53,568	85,430	13.9%	85,430	13.9%
java.lang.AbstractStringBuilder.toString	13,392	78,816	12.8%	33,801	5.5%
java.lang.StringBuilder.<init>	13,392	59,042	9.6%	22,094	3.6%

Figure 844: Trace Results, Showing Other Expensive Calls

We see chunks of time being devoted to `StringBuilder`. This is odd, as we are not using `StringBuilder` explicitly in our app.

It turns out that the `javac` compiler replaces string concatenation with `append()` calls on a `StringBuilder`, created on the fly for that specific concatenation. So, of the time taken up in the entire run by the `doTest()` method, much of it is taken up by creating these temporary `StringBuilder` objects, another chunk is consumed by calling `append()` on the `StringBuilder`, and yet another chunk is used by calling `toString()` to get the resulting `String` out of the `StringBuilder`.

This suggests an optimization: we could create our own `StringBuilder` and use it for concatenating the text, thereby saving us creating a few temporary ones and calling `toString()` extra times:

```
package com.commonware.android.traceview;

import android.view.View;
import android.widget.TextView;

public class StringBuilderActivity extends BaseActivity {
    StringBuildersTask createTask(TextView msg, View v) {
        return(new StringBuildersTask(msg, v));
    }

    class StringBuildersTask extends BaseTask {
        StringBuildersTask(TextView msg, View v) {
            super(msg, v);
        }

        protected String doTest() {
            StringBuilder result=new StringBuilder("This is a string");

            result.append(" -- that varies --");
            result.append(" and also has ");
            result.append(String.valueOf(4));
            result.append(" hyphens in it");

            return(result.toString());
        }
    }
}
```

```
}  
}
```

This implementation of the algorithm runs about twice as fast as the first.

Other General CPU Measurement Techniques

While method tracing can be useful for narrowing down a general performance issue to a specific portion of code, it does assume that you know approximately where the problem is, or that you even have a problem in the first place. There are other approaches to help you identify if and (roughly) where you have problems, which you can then attack with method tracing to try to refine.

Logging

Method tracing can be useful, if you have a rough idea of where your performance problem lies and need to narrow it down further. If you have a large and complicated application, though, trying to sift through all of it in method tracing may be difficult.

However, there is nothing stopping you from using good old-fashioned logging to get a rough idea of where your problems lie, for further analysis via method tracing. Just sprinkle your code with `Log.d()` calls, logging `SystemClock.uptimeMillis()` with an appropriate label to identify where you were at that moment in time. “Eyeballing” the LogCat output can illustrate areas where unexpected delays are occurring — the areas in which you can focus more time using method tracing.

A useful utility class for this is `TimingLogger`, in the `android.util` package. It will collect a series of “splits” and can dump them to LogCat along with the overall time between the creation of the `TimingLogger` object and the corresponding `dumpToLog()` method call. Note, though, that this will only log to LogCat when you call `dumpToLog()` — all of the calls to `split()` to record intermediate times have their results buffered until `dumpToLog()` is called. Also note that logging needs to be set to `VERBOSE` for this information to actually be logged — use the command `adb shell setprop log.tag.LOG_TAG VERBOSE`, substituting your log tag (supplied to the `TimingLogger` constructor) for `LOG_TAG`.

FPS Calculations

Sometimes, it may not even be strictly obvious how bad the problem is. For example, consider scrolling a `ListView`. Some performance issues, like sporadic “hiccups” in

the scrolling, will be visually apparent. However, absent those, it may be difficult to determine whether your particular `ListView` is behaving more slowly than you would expect.

A classic measurement for games is frames per second (FPS). Game developers aim for a high FPS value — 60 FPS is considered to be fairly smooth, for example. However, this sort of calculation can only really be done for applications that are continuously drawing – such as [Romain Guy's WindowBackground sample application](#). Ordinary Android widget-based UIs are only drawing based upon user interaction or, possibly, upon background updates to data. In other words, if the UI will not even be trying to draw 60 times in a second, trying to measure FPS to get 60 FPS is pointless.

You may be able to achieve similar results, though, simply by logging how long it takes to, say, fling a list (use `setOnScrollListener()` and watch for `SCROLL_STATE_FLING` and other events).

UI “Jank” Measurement

A user interface is considered “janky” if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Sometimes, janky behavior is obvious to all. Sometimes, janky behavior is only noticeable to those sensitive to small hiccups in the UI.

This section will outline what “jank” is and how to determine, concretely, if your UI suffers from it.

What, Exactly, is Jank?

Prior to Android 4.0, it was difficult to come up with a concrete definition of jank. In effect, we were stuck with [“I know it when I see it”](#) ad-hoc analysis, rather than being able to rely on concrete measurements.

Project Butter changed that.

Android 4.0 ties all graphic operations to a 60 frames-per-second “vsync” frequency. If everything is working smoothly, your UI will update 60 times per second, uniformly (versus varying amounts of times between changes).

FINDING CPU BOTTLENECKS

The converse is also true: if everything is not working smoothly, your UI will not update 60 times per second. This is the source of the term “dropped frames”: when the time came around for an update, you were not ready, and that frame was skipped.

There are two main ways in which you will drop a frame:

1. You spend too much time on the main application thread, preventing Android from processing your requested UI updates in a timely fashion
2. Your UI changes are too complex to be rendered before time runs out for the current frame, causing your changes to spill over into the next frame

Each frame is ~16ms in duration on-screen (1/60th of a second). Hence, if we cause per-frame work to exceed 16ms, we will skip, or “drop”, a frame.

So, what we need is some way to determine if our code is actually delivering frames on time.

Using gfxinfo

To determine if our problem is in the actual rendering of our UI updates, we can use the GPU profiling feature added in Android 4.2.

Enabling Developer Options

To toggle on GPU profiling, you will need to be able to get to the Developer Options portion of your Settings app. If you see this — typically towards the bottom of the list on the initial Settings screen — just tap on the entry.

If, however, Developer Options is missing, then you will need to use the super-secret trick for enabling Developer Options:

1. Tap on “About Phone”, “About Tablet”, or the equivalent at the bottom of your Settings list
2. Tap on the “Build Number” entry seven times in succession
3. Press BACK, and “Developer Options” should now be in the list

Toggling on GPU Profiling

There are two checkboxes in Developer Options that need to be checked for GPU profiling to be enabled.

The first is “Force GPU rendering”, in the Drawing section. As the name suggests, this will force your application to use the GPU for drawing, even if your application may have requested that hardware acceleration be disabled. Since most applications do not force hardware acceleration to be disabled, this checkbox probably will have no real effect on your app. Note that if you disabled hardware acceleration due to specific rendering problems, this checkbox will probably cause those rendering artifacts to re-appear during your testing.

The second is “Profile GPU rendering”, in the Monitoring section. This will cause the device to keep track of graphics performance on a per-process basis, in a way that we can dump later on.

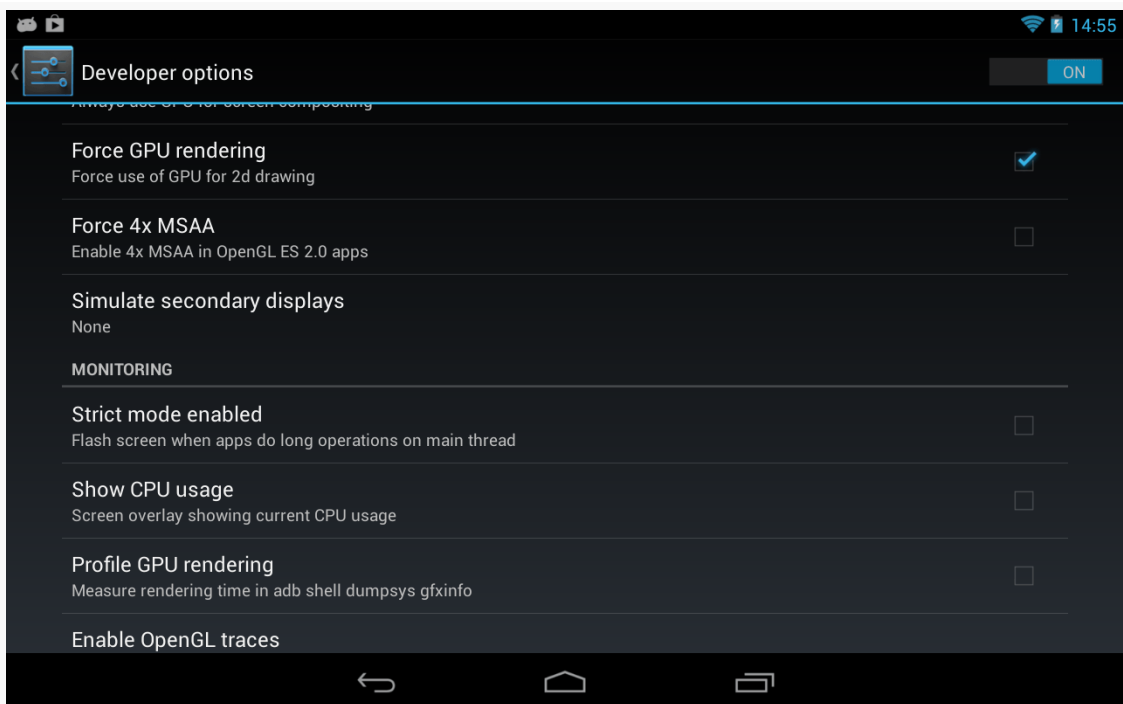

Figure 845: Developer Options, Showing “Force GPU rendering” and “Profile GPU rendering”

If your app was already running, you will need to get rid of its process (e.g., via swiping it off the recent-tasks list) after you check the “Profile GPU rendering”

FINDING CPU BOTTLENECKS

checkbox. At the present time, whether or not this profiling takes effect is determined at process startup time and is not changed on the fly when you toggle the checkbox. Besides, as noted above, starting with a fresh process should give you more accurate results.

Collecting Data

At this point, you can run your app and conduct your specific test, whether manually or via instrumentation (e.g., a targeted [JUnit test suite](#)).

When complete, run `adb shell dumpsys gfxinfo ...` in a terminal window, where ... is replaced by the package name of your app (e.g., `com.commonware.android.anim.threepane`). This will dump a fair amount of information to the terminal display:

```
mmurphy@xps15:~$ adb shell dumpsys gfxinfo com.commonware.android.anim.threepane
Applications Graphics Acceleration Info:
Uptime: 482460 Realtime: 482454
```

```
** Graphics info for pid 3469 [com.commonware.android.anim.threepane] **
```

We will discuss what this means in just a bit.

Disabling GPU Profiling

When you are done with your test, it is a good idea to undo the settings changes you made, at least “Profile GPU rendering”. That way, the act of collecting this data does not itself add overhead to unrelated tests in the future.

Analyzing the Results

The key bit for our performance analysis is that long table labeled “Profile data in ms:”. This reports, for a series of UI requests, how much time is spent:

- drawing your UI changes (e.g., `onDraw()` calls to various widgets and containers)
- processing the low-level drawing commands created via the draw phase, to create the contents of the frame
- executing the frame, sending it to the compositor to display on the screen

One way to interpret this table is to paste it into your favorite spreadsheet program, then use that program to draw a stacked column chart of the data. You can [download a spreadsheet](#) in ODS format (for use with LibreOffice, OpenOffice, or other tools that can handle that format) that contains the above table along with a stacked column chart:

Figure 846: gfxinfo Output, In Stacked Column Chart

What you are looking for are columns that come close to, or exceed, the 16ms mark, with milliseconds on the Y axis. As you can see, many operations towards the end of the table are near or above 16ms, indicating that we are probably dropping some frames.

Using systrace

Another way we could determine whether or not we are dropping frames is to use systrace to collect system-level tracing information about the entire device, including our app.

systrace is a very powerful tool, one that 20 or 30 people on the planet truly understand, due to cryptic output and limited documentation. Using gfxinfo for detecting dropped frames is simple by comparison. On the other hand, systrace works for Android 4.1 and higher, versus the Android 4.2 requirement of gfxinfo.

Using systrace involves collecting a trace, which is saved in the form of an HTML file. The HTML file is then used to determine what went on during the period of the trace itself.

Enabling and Collecting a Trace: Command-Line

The original means of using systrace was from the command line. There is a systrace.py Python script located in the tools/systrace/ directory of your SDK installation. If you have a Python interpreter (e.g., your development machine does not run Windows), you can use this approach.

To indicate what specific bits of information to collect, on Android 4.2 and higher, you can tap the “Enable traces” entry in the Monitoring section of the Developer Options page in Settings. This displays a multi-select dialog of the possible major categories of information that systrace should collect:

FINDING CPU BOTTLENECKS

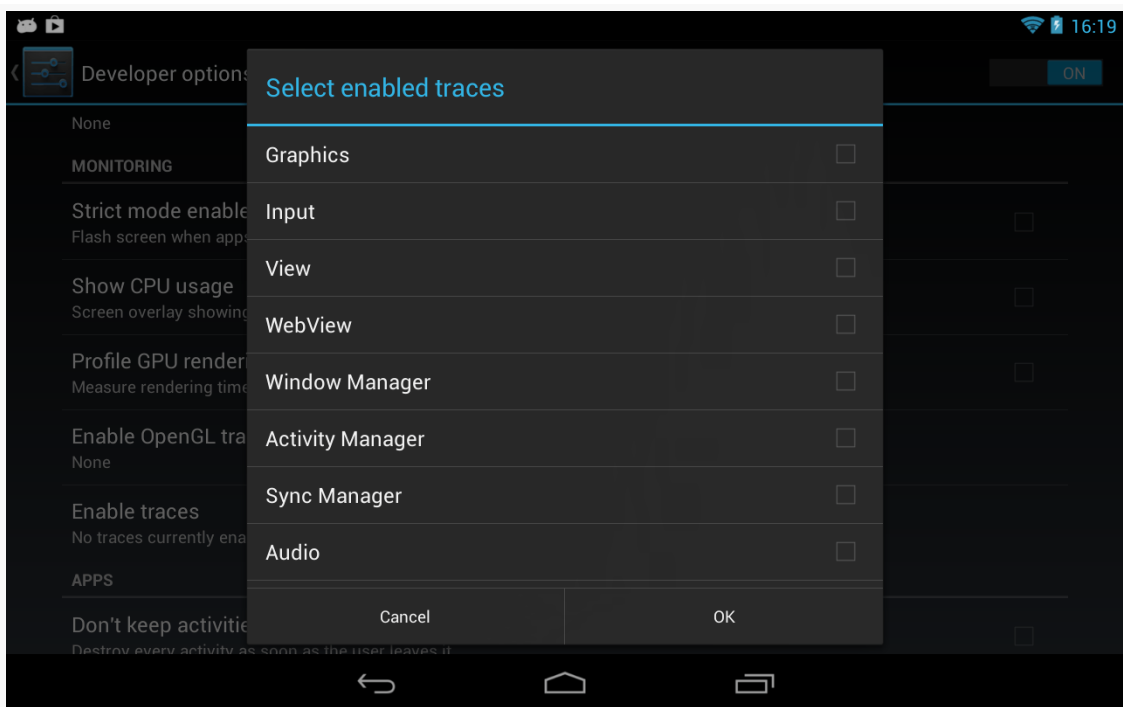

Figure 847: “Enable traces” In Settings

Alternatively, when you run the `systrace.py` script, you can include the `--set-tags` switch, with a comma-delimited list of specific traces (“tags”) that you want to collect. The list of available tag names can be found in [the developer documentation](#).

To actually collect the trace, you run the `systrace.py` script, optionally with `--set-tags` or other command-line switches.

On Android 4.1 and 4.2, this would look like:

```
python systrace.py --set-tags gfx,view,wm
adb shell stop
adb shell start
python systrace.py --time=10 -o trace.html
```

The first `python` command runs `systrace.py` just to set the tags to collect. If you set them using Developer Options in Settings, this would not be required. Restarting `adb shell` is apparently needed, for unclear reasons. The second `systrace.py` run will actually collect the trace, for 10 seconds (`--time=10`), resulting in report written to `trace.html` in the current working directory (`-o trace.html`).

FINDING CPU BOTTLENECKS

The syntax changed for Android 4.3 and higher to simplify matters, combining the two `systrace.py` commands into one:

```
python systrace.py --time=10 -o trace.html gfx view sched wm
```

Note that `--set-tags` is no longer used. Instead, all values not identified by a switch are considered to be tags.

Once you run the script, quickly go to your device and run your test scenario, as the trace starts immediately upon running the script.

Enabling and Collecting a Trace: Android Device Monitor

The Android Device Monitor also allows you to collect a trace using `systrace`. There is a “Capture system wide trace using systrace” button in the toolbar in the Devices view, typically found in the DDMS perspective:

To get to the Android Device Monitor in Android Studio, choose `Tools > Android > Android Device Monitor` from the main menu.

Tapping that toolbar button brings up a dialog that allows you to configure the trace you wish to collect, with checkboxes and fields replacing the variety of command-line switches you might use manually with `systrace.py`:

FINDING CPU BOTTLENECKS

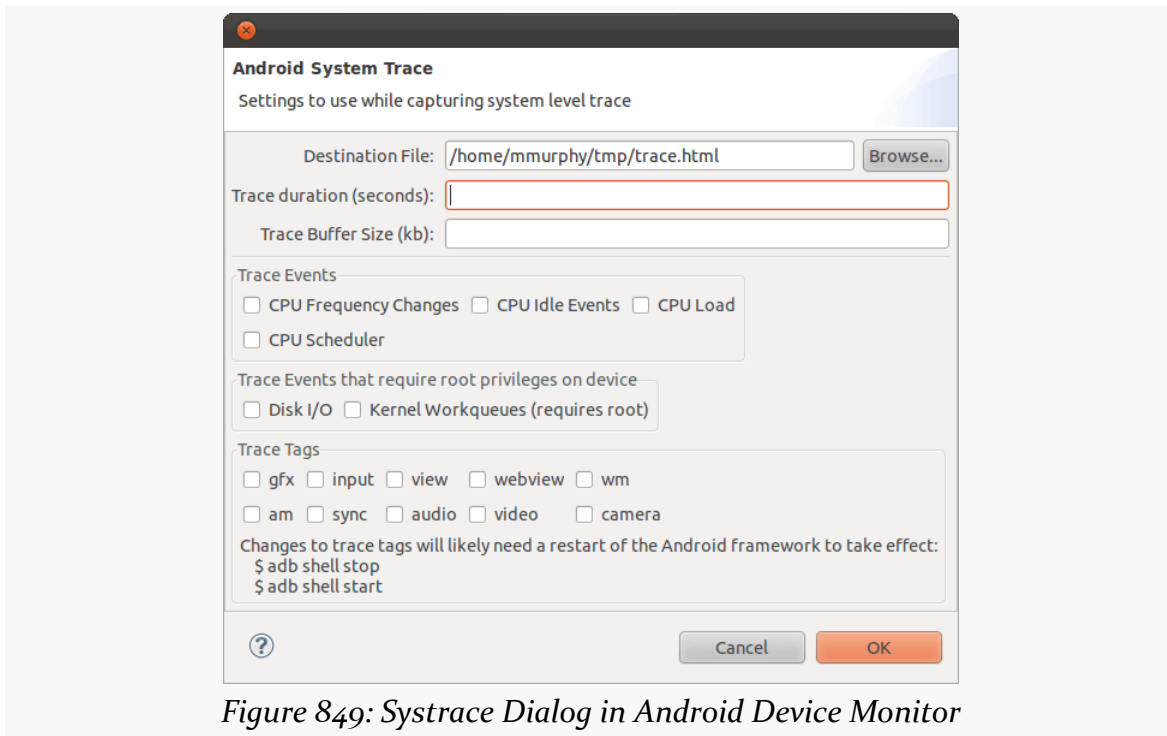

Figure 849: Systrace Dialog in Android Device Monitor

Notable settings that you will wish to tailor include:

- Where the trace will be written (by default, as `trace.html` in your home or user directory)
- The duration of the trace
- Which trace tags you wish to use

Clicking OK will then initiate the trace collection, at which point you will want to go to your test device and run through your test scenario.

Choosing the Trace Tags

All of these instructions have been telling you to specify what systrace tags to collect when you collect the trace data. So, what should you collect?

The big four are:

- `sched` for CPU scheduling
- `gfx` for graphics
- `view` for widget rendering

- `wm` for window management

Apps using `WebView` might consider the `webview` tag. There are [a variety of other tags](#) as well that you might find useful for one analysis or another. However, be careful not to request “everything but the kitchen sink”, as it may make your reports difficult to interpret.

Also note that not all devices support all tags. `python systrace.py --list-categories` should tell you what is possible for your connected device.

Augmenting the Trace from Java

You can effectively add your own tag to the output in Java code, to flag key sections of application processing and see where they fall in the report’s timeline. To do this:

- Add calls to `Trace.beginSection()` and `Trace.endSection()` in your API Level 18+ app. Here, `Trace` is `android.os.Trace`, and `beginSection()` takes a `String` parameter that you would like to have logged. Note that these calls can nest, so you can have one section inside of another, but `endSection()` closes the last-begun section. Hence, make sure that your `beginSection()` and `endSection()` calls match up, typically by using `try/finally` exception handling. Also, your `beginSection()` and `endSection()` calls must match up in terms of threads — you cannot begin a section on one thread and end it on another.
- Add the `--app` switch to name your application’s package if you are running `systrace` from the command line. Or, in DDMS, choose your application in the “Enable Application Traces from” drop-down list.

Viewing and Interpreting the Results

What you get as output is an HTML file that can be viewed in the Chrome browser, though you will tend to want to use a development machine for this instead of, say, an Android tablet. That is because the navigation of the Web page is designed for use with a hardware QWERTY keyboard, which most Android devices lack.

You can find [a sample trace](#) from a Nexus 7 online, though note that the HTML is a bit large and may take a few seconds to download. Initially, you will see something like this:

FINDING CPU BOTTLENECKS

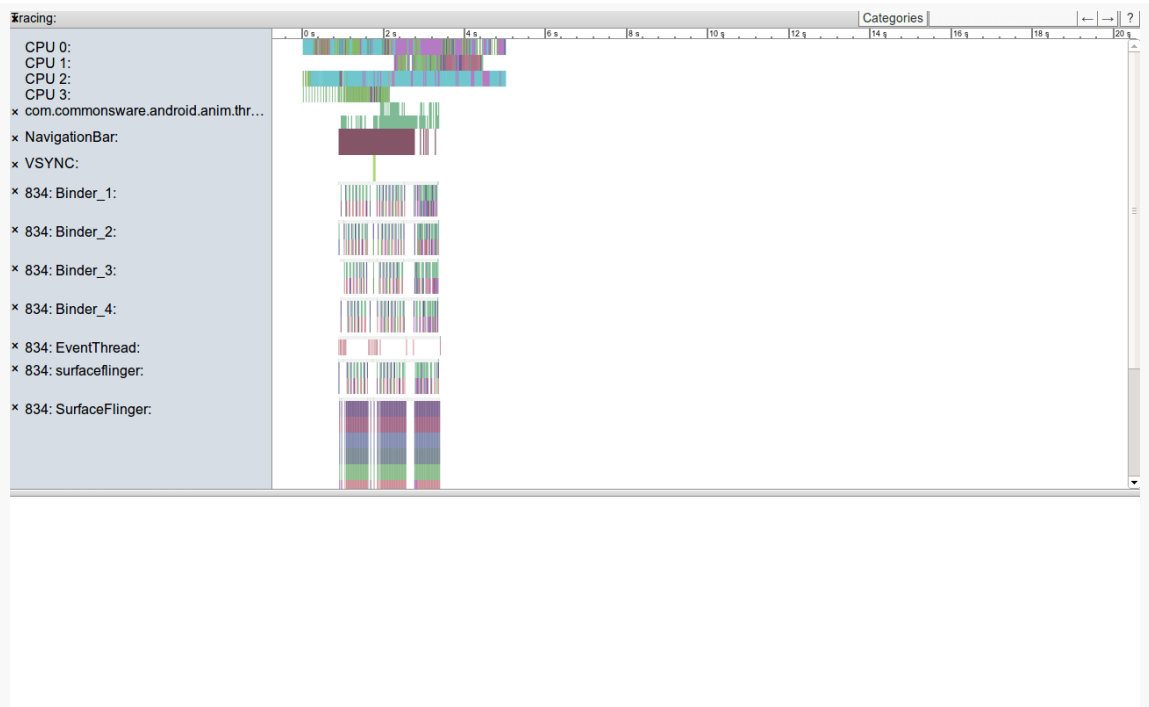

Figure 850: Systrace Output, As Initially Viewed

The left-hand sidebar represents various categories (or “slices” or “tags” or whatever) of data collected by systrace. The main area shows a timeline for the test, with rows corresponding to the sidebar entries for what was occurring at the various times for that particular category. The bottom pane will hold details that will appear when you click on various little blocks within that timeline.

Mostly, your navigation will use the W, A, S, and D keys, presumably chosen to make it appear as though you are playing a video game. Specifically:

- W will zoom in the timeline, while S will zoom out
- A and D will pane the timeline left and right

Jank will show up as gaps in the SurfaceFlinger:

FINDING CPU BOTTLENECKS

Figure 851: Systrace Output, Zoomed In on 0.7 Seconds of Profiling

Each of the major ticks across the timeline represents 0.1 seconds. There should be six frames in those seconds. However, we can see that in the 3.4-3.5 second range, there is a dropped frame, which shows up as a gap where there should be a pulse of SurfaceFlinger activity.

Zooming in further starts to bring up some detail for the threads in our process, showing methods within the view processing hierarchy that we were working on during this period of time:

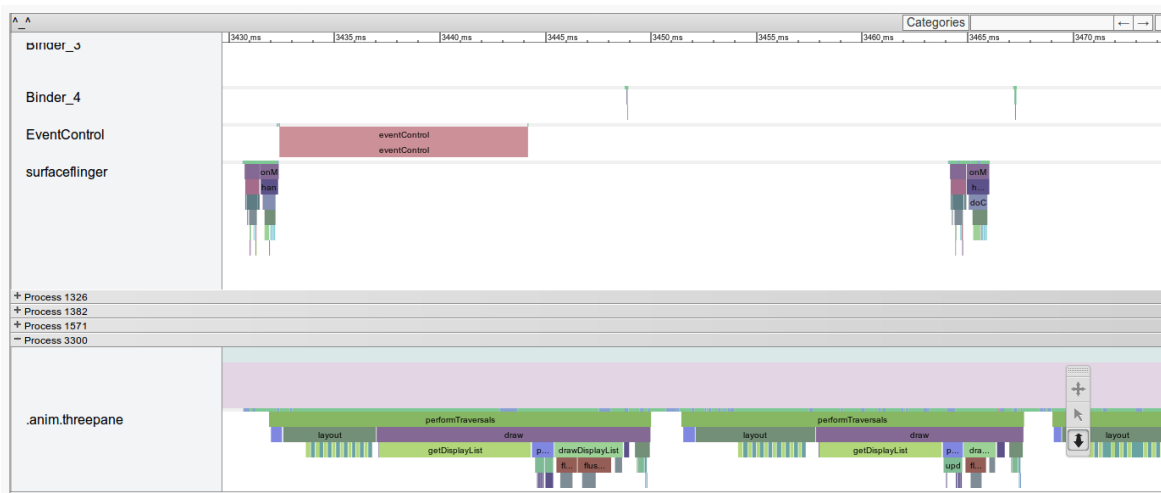

Figure 852: Systrace Output, Zoomed In on 40 Milliseconds of Profiling

FINDING CPU BOTTLENECKS

In our `gfx/view` slice, we will see various blocks for different major operations in the rendering of our UI. Notably, you will see blocks labeled “performTraversals”, referring to the private `performTraversals()` method on `ViewRootImpl`. It turns out that `performTraversals()` wraps around all of the work shown in the three columns of our `gfxinfo` output: draw, process, and execute. The widths of the “performTraversals” blocks in the `systrace` output shows us how long each of those takes. What we want are nice, short blocks. Instead, panning through our trace, you will see several that are too long. [The chapter on “jank busting”](#) will go into further analysis of where this particular sample application went wrong that caused this behavior.

Focus On: NDK

When Android was first released, many a developer wanted to run C/C++ code on it. There was little support for this, other than by distributing a binary executable and running it via a forked process. While this works, it is a bit cumbersome, and the process-based interface limits how cleanly your C/C++ code could interact with a Java-based UI. On top of all of that, the use of such binary executables is not well supported.

In June 2009, the core Android team released the Native Development Kit (NDK). This allows developers to write C/C++ for Android applications in a supported fashion, in the form of libraries linked to a hosting Java-based application via the Java Native Interface (JNI). This offers a wealth of opportunities for Android development, and this part of the book will explore how you can take advantage of the NDK to exploit those opportunities.

This chapter explains how to set up the NDK and apply it to your project. What it does not do is attempt to cover all possible uses of the NDK — game applications in particular have access to many frameworks, like OpenGL and OpenSL, that are beyond the scope of this book.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

This chapter also assumes that you know C/C++ programming.

The Role of the NDK

We start by examining Dalvik's primary limitation — speed. Next, we look at the reasons one might choose the NDK, speed among them. We wrap up with some reasons why the NDK may not be the right solution for every Android problem, despite its benefits.

Dalvik: Secure, Yes; Speedy, Not So Much

Dalvik was written with security as a high priority. Android's security architecture is built around Linux's user model, with each application getting its own user ID. With each application's process running under its own user ID, one process cannot readily affect other processes, helping to contain any single security flaw in an Android application or subsystem. This requires a fair number of processes. However, phones have limited RAM, and the Android project wanted to offer Java-based development. Multiple processes hosting their own Java virtual machines simply could not fit in a phone. Dalvik's virtual machine is designed to address this, maximizing the amount of the virtual machine that can be shared securely between processes (e.g., via “copy-on-write”).

Of course, it is wonderful that Android has security so woven into the fabric of its implementation. However, inventing a new virtual machine required tradeoffs, and most of those are related to speed.

A fair amount of work has gone into making Java fast. Standard Java virtual machines do a remarkable job of optimizing applications on the fly, such that Java applications can perform at speeds near their C/C++ counterparts. This borders on the amazing and is a testament to the many engineers who put countless years into Java.

Dalvik, by comparison, is very young. Many of Java's performance optimization techniques — such as advanced garbage collection algorithms — simply have not been implemented to nearly the same level in Dalvik. This is not to say they will never exist, but it will take some time. Even then, though, there may be limits as to how fast Dalvik can operate, considering that it cannot “throw memory at the problem” to the extent Java can on the desktop or server.

ART has significantly improved matters, with ahead-of-time compilation (AOT) replacing just-in-time compilation (JIT) for getting native opcodes from the Dalvik

bytecodes. However, that code may still be inefficient when compared with writing C/C++ by hand.

Going Native

Java-based Android development via Dalvik and the Android SDK is far and away the option with the best support from the core Android team. HTML5 application development is another option that was brought to you by the core Android development team. The third leg of the official Android development triad is the NDK, provided to developers to address some specific problems, outlined below.

Speed

Far and away the biggest reason for using the NDK is speed, pure and simple. Writing in C/C++ for the device's CPU will be a major speed improvement over writing the same algorithms in Java, despite Android's JIT compiler (Dalvik) and AOT compiler (ART).

There is overhead in reaching out to the C/C++ code from a hosting Java application, and so for the best performance, you will want a coarse interface, without a lot of calls back and forth between Java and the native opcodes. This may require some redesign of what might otherwise be the “natural” way of writing the C/C++ code, or you may just have to settle for less of a speed improvement. Regardless, for many types of algorithms — from cryptography to game AI to video format conversions — using C/C++ with the NDK will make your application perform much better, to the point where it can enable applications to be successful that would be entirely too slow if written solely in Java.

Bear in mind, though, that much of what you think is Java code in your app really is native “under the covers”. Many of the built-in Android classes are thin shims over native implementations. Again, focus on applying the NDK where you are performing lots of work yourself in Java code that might benefit from the performance gains.

Porting

You may already have some C/C++ code, written for another environment, that you would like to use with Android. That might be for a desktop application. That might be for another mobile platform, such as iOS, where C/C++ is an option. That might be for mobile platform, such as Symbian, where C/C++ is the conventional solution,

rather than some other language. Regardless, so long as that code is itself relatively platform-independent, it should be usable on Android.

This may significantly streamline your ability to support multiple platforms for your application, even if down-to-the-metal speed is not really something you necessarily need. This may also allow you to reuse existing C/C++ code written by others, for image processing or scripting languages or anything else.

Knowing Your Limits

Developers love silver bullets. Developers are forevermore seeking The One True Approach to development that will be problem-free. Sisyphus would approve, of course, as development always involves tradeoffs. So while the NDK's speed may make it tantalizing, it is not a solution for general Android application development, for several reasons, explored in this section.

Android APIs

The biggest issue with the NDK is that you have very limited access to Android itself. There are a few libraries bundled with Android that you can leverage, and a few other APIs offered specifically to the NDK, such as the ability to render OpenGL 3D graphics. But, generally speaking, the NDK has no access to the Android SDK, except by way of objects made available to it from the hosting application via JNI.

As such, it is best to view the NDK as a way of speeding up particular pieces of an SDK application — game physics, audio processing, OCR, and the like. All of those are algorithms that need to run on Android devices with data obtained from Android, but otherwise are independent of Android itself.

Cross-Platform Compatibility

While C/C++ *can* be written for cross-platform use, often it is not.

Sometimes, the disparity is one of APIs. Any time you use an API from a platform (e.g., iPhone) or a library (e.g., Qt) not available on Android, you introduce an incompatibility. This means that while a lot of your code — measured in terms of lines — may be fine for Android, there may be enough platform-specific bits woven throughout it that you would have a significant rewrite ahead of you to make it truly cross-platform.

Android itself, though, has a compatibility issue, in terms of CPUs. Android mostly runs on ARM devices today, since Android's initial focus was on smartphones, and ARM-powered smartphones at that. However, the focus on ARM will continue to waver, particularly as Android moves into other devices where other CPU architectures are more prevalent, such as Atom or MIPS for set-top boxes. While your code may be written in a fashion that works on all those architectures, the binaries that code produces will be specific to one architecture. The NDK gives you additional assistance in managing that, so that your application can simultaneously support multiple architectures.

Right now, the NDK supports ARM, x86, and MIPS CPU architectures. Of these, ARM CPUs power the *vast* majority of Android devices. The first generation of Google TV boxes, and a few other devices, use Intel x86 CPUs (usually Atom-based). MIPS is a relative newcomer to Android, with few devices using such CPUs at this time.

NDK Installation and Project Setup

The Android NDK is blissfully easy to install, in some ways even easier than is the Android SDK. Similarly, setting up an NDK-equipped project is rather straightforward. However, the documentation for the NDK is mostly a set of text files (`OVERVIEW.TXT` prominent among them). These are well-written but suffer from the limits of the plain-text form factor, plus are focused strictly on the NDK and not the larger issue of Android projects that use the NDK.

This chapter will fill in some of those gaps.

Installing the NDK

As with the Android SDK, the [Android NDK comes in the form of a ZIP or tar.gz file](#), containing everything you need to build NDK-enabled Android applications. Hence, setting up the NDK is fairly trivial, particularly if you are developing on Linux.

Prerequisites

You will need the GNU `make` and GNU `awk` packages installed. These may be part of your environment already. For example, in Ubuntu, run `sudo apt-get install make gawk`, or use the Software Center, to ensure you have these two packages.

While you can do NDK development directly on Linux or OS X, NDK development on Windows can only be done using the [Cygwin](#) environment. This gives you a Linux-style shell and Linux-style tools on a Windows PC. In addition to a base Cygwin 1.7 (or newer) installation, you will need the make and gawk Cygwin packages installed in Cygwin.

If you encounter difficulties with Cygwin, you may wish to consider whether running Linux in a virtualization environment (e.g., [VirtualBox](#)) might be a better solution for you.

Download and Unpack

The Android NDK per-platform (Linux/OS X/Windows) ZIP files can be downloaded from the [NDK page](#) on the Android Developers site. These ZIP files are not small (~500MB each), because they contain the entire toolchain — that is why there are so few prerequisites.

You are welcome to unpack the ZIP file anywhere it makes sense on your development machine. However, putting it *inside* the Android SDK directory may not be a wise move — a peer directory would be a safer choice. You are welcome to rename the directory if you choose.

Environment Variables

The NDK documentation will cite an NDK environment variable, set to point to the directory in which you unpacked the NDK. This is a documentation convention and does not appear to be required for actual use of the NDK, though it is not a bad idea. You could also consider adding the NDK directory to your PATH, though that too is not required.

Bear in mind that you will be using the NDK tools from the command line, and so being able to conveniently reference this directory is reasonably important.

Setting Up an NDK Project

At its core, an NDK-enhanced Android project is a regular Android project. You still need a manifest, layouts, Java source code, and all the other trappings of a regular Android application. The NDK simply enables you to add C/C++ code to that project and have it included in your builds, referenced from your Java code via the Java Native Interface (JNI).

The examples shown in this section are from the [JNI/WeakBench](#) sample project, which implements a pair of benchmarks in Java and C, to help demonstrate the performance differences between the environments.

Writing Your C/C++ Code

The first step towards adding NDK code to your project is to create a `jni/` directory and place your C/C++ code inside of it. While there are ways to use a different base directory, it is unclear why you would need to. How you organize the code inside of `jni/` is up to you. C++ code should use `.cpp` as file extensions, though this too is configurable.

Your C/C++ code will be made up of two facets:

- The code doing the real work
- The code implementing your JNI interface

If you have never used JNI before, JNI uses naming conventions to tie functions in a C/C++ library to their corresponding hooks in the Java code.

For example, in the WeakBench project, you will find `jni/weakbench.c`:

```
#include <stdlib.h>
#include <math.h>
#include <jni.h>

typedef unsigned char boolean;

static void nsieve(int m) {
    unsigned int count = 0, i, j;
    boolean * flags = (boolean *) malloc(m * sizeof(boolean));
    memset(flags, 1, m);

    for (i = 2; i < m; ++i)
        if (flags[i]) {
            ++count;
            for (j = i << 1; j < m; j += i)
                if (flags[j])
                    flags[j] = 0;
        }

    free(flags);
}

void
Java_com_commonware_android_tuning_weakbench_WeakBench_nsievenative( JNIEnv* env,
                                                                    jobject this )
{
    int i=0;
    for (i = 0; i < 3; i++)
```

FOCUS ON: NDK

```
    nsieve(10000 << (9-i));
}

double eval_A(int i, int j) { return 1.0/((i+j)*(i+j+1)/2+i+1); }

void eval_A_times_u(int N, const double u[], double Au[])
{
    int i,j;
    for(i=0;i<N;i++)
    {
        Au[i]=0;
        for(j=0;j<N;j++) Au[i]+=eval_A(i,j)*u[j];
    }
}

void eval_At_times_u(int N, const double u[], double Au[])
{
    int i,j;
    for(i=0;i<N;i++)
    {
        Au[i]=0;
        for(j=0;j<N;j++) Au[i]+=eval_A(j,i)*u[j];
    }
}

void eval_AtA_times_u(int N, const double u[], double AtAu[])
{ double v[N]; eval_A_times_u(N,u,v); eval_At_times_u(N,v,AtAu); }

void
Java_com_commonsware_android_tuning_weakbench_WeakBench_specnative( JNIEnv* env,
                                                                    jobject this )
{
    int i;
    int N = 1000;
    double u[N],v[N],vBv,vv;
    for(i=0;i<N;i++) u[i]=1;
    for(i=0;i<10;i++)
    {
        eval_AtA_times_u(N,u,v);
        eval_AtA_times_u(N,v,u);
    }
    vBv=vv=0;
    for(i=0;i<N;i++) { vBv+=u[i]*v[i]; vv+=v[i]*v[i]; }
}
```

(from [JNI/WeakBench/jni/weakbench.c](#))

Much of the code shown here comes from the [Great Language Benchmarks Game](#), specifically their nsieve and spectral-norm benchmarks. And, much of the code looks like normal C code.

Two functions, though, serve as JNI entry points:

- `Java_com_commonsware_abj_weakbench_WeakBench_nsievenative`
- `Java_com_commonsware_abj_weakbench_WeakBench_specnative`

As will be seen later in this section, these will map to `nsievenative()` and `specnative()` methods on a `com.commonsware.abj.weakbench.WeakBench` class. The Java class (with package) and method names are converted into a function call name, so JNI can identify the function at runtime.

The implementation of these methods do not make use of any Java objects, nor do they return anything — they just implement the benchmark.

Writing Your Makefile(s)

To tell the NDK tools how to build your code, you will need one or two makefiles.

Android.mk

This makefile will describe the “module” (library) that you are attempting to add to your Android project by way of the NDK. In it, you will specify the source files that should be compiled and linked into the module. This file, by default, resides in the root of your `jni/` directory.

For example, here is `jni/Android.mk` from the `WeakBench` project:

```
LOCAL_PATH := $(call my-dir)

include $(CLEAR_VARS)

LOCAL_MODULE     := weakbench
LOCAL_SRC_FILES  := weakbench.c

include $(BUILD_SHARED_LIBRARY)
```

Here, we give the module a name (`weakbench`) and identify the source files that go into it (`weakbench.c`).

It is possible for you to have multiple `Android.mk` files, in multiple subdirectories of `jni/`, to create multiple modules. There is an `ANDROID-MK.TXT` file in the NDK documentation directory that provides more detail on how you can configure complex scenarios like this one.

Application.mk

There is a separate, optional, makefile that you can have, `Application.mk`, in your `jni/` directory. This is where you can provide compile flags for the build process, which CPU architectures (ARM, x86, etc.) you wish to support, and so on. By

default, if you do not have such a file, the NDK build tools will include all modules defined in your `Android.mk` file(s) in your project, compiled for a generic ARM target with software support for floating-point operations.

For basic NDK applications, skipping `Application.mk` is a reasonable choice. Complex projects, or ones specifically aiming to support other CPU architectures (e.g., ARM-v7 CPUs with hardware floating-point support), will need an `Application.mk` file.

The `WeakBench` project has a one-line `Application.mk` file:

```
APP_ABI := all
```

This tells Android that we want to build the JNI code for all supported CPU architectures. At the time of this writing, that is ARMv5, ARMv7, and x86.

Building Your Library

Any time you modify your C/C++ code, or the makefiles, you will need to build your NDK library. To do that, from a command prompt in your project's root directory, run the `ndk-build` script found in the NDK's root directory. In other words, if you set up an NDK environment variable to point to where you have the NDK installed, execute `$NDK/ndk-build` from your project root.

This will compile and link your C/C++ code into a library (or conceivably several libraries, if you have a complex set of `Android.mk` files). These will wind up in your project's `libs/` directory, in subdirectories based on your CPU architectures indicated by your `Application.mk` file.

For example, if you run `$NDK/ndk-build` from the `WeakBench` project root, you will wind up with a `libs/armeabi/libweakbench.so` file. The `armeabi` portion is because that is the default CPU architecture that the NDK supports, and `WeakBench` did not change the defaults via an `Application.mk` file. The “`weakbench`” portion of `libweakbench.so` is because our `LOCAL_MODULE` value in our `Android.mk` file is `weakbench`. The `lib` prefix is automatically added by the build tools. The `.so` file extension is because our `Android.mk` file indicated that we are building a shared library (via the `BUILD_SHARED_LIBRARY` directive), and `.so` is the standard file extension for shared libraries in Linux (and, hence, Android).

Note that you will also wind up with similar `.so` files in `libs/armeabi-v7a/` and `libs/x86` for those architectures.

You are welcome to add this to your build process, such as adding it to your Ant build script, though it is not automatically included in the build process as defined by Android.

Using Your Library Via JNI

Now that you have your base C/C++ code being successfully compiled by the NDK, you need to turn your attention towards crafting the bridge between the Dalvik VM and the C/C++ code, following in the conventions of the Java Native Interface (JNI).

This section, while explaining the various steps involved in using the JNI, is far from a complete treatise on the subject. If you are going to spend a lot of time working with JNI, you are encouraged to seek additional resources on this topic, such as [Core Java: Volume II](#), which has a chapter on JNI.

We created two C functions for accessing benchmarks:

- `Java_com_commonsware_abj_weakbench_WeakBench_nsievenative`
- `Java_com_commonsware_abj_weakbench_WeakBench_specnative`

Those, in turn, need to be defined as static methods on a `com.commonsware.abj.weakbench.WeakBench` class. Moreover, these methods will need to have the `native` keyword, indicating that their implementation is not found in Java code, but in native C/C++ code. The naming convention of the C functions allows the Dalvik runtime to identify what function names should be used for those native method implementations.

However, that alone will be insufficient — we need to tell Dalvik where it can find the library in the first place. While naming conventions are good enough for the C function names, there is no corresponding naming convention for the library itself.

To do this, we use the `loadLibrary()` static method on the `System` class. A class implementing native methods should call `loadLibrary()` in a static block, so it is executed when the class is first referenced. For the NDK, all we need to do is supply the name we gave the library in the `Android.mk` file.

Here is the portion of the `WeakBench` class that has the native methods and the `loadLibrary()` call:

```
static {  
    System.loadLibrary("weakbench");  
}
```

FOCUS ON: NDK

```
}  
  
public native void nsievenative();  
public native void specnative();
```

(from [JNI/WeakBench/src/com/commonsware/android/tuning/weakbench/WeakBench.java](#))

Now, we can call our `nsievenative()` and `specnative()` methods on `WeakBench`, just as if they were regular Dalvik methods on a regular Dalvik class. The fact that they are really going off and invoking C functions is purely “implementation detail” that the consumers of those methods can be blissfully unaware of.

`WeakBench` itself is an `Activity`, invoking both Dalvik and native implementations of these two benchmarks. It uses a series of `AsyncTask` objects for executing the benchmarks on background threads, then updates `TextView` widgets in the UI to show the results:

```
package com.commonsware.android.tuning.weakbench;  
  
import android.app.Activity;  
import android.os.AsyncTask;  
import android.os.Bundle;  
import android.os.SystemClock;  
import android.widget.TextView;  
  
public class WeakBench extends Activity {  
    static {  
        System.loadLibrary("weakbench");  
    }  
  
    public native void nsievenative();  
    public native void specnative();  
  
    @Override  
    public void onCreate(Bundle savedInstanceState) {  
        super.onCreate(savedInstanceState);  
        setContentView(R.layout.main);  
  
        new JavaSieveTask().execute();  
    }  
  
    /*  
     * Code after this point is adapted from the Great Computer Language  
     * Shootout. Copyrights are owned by whoever contributed this stuff,  
     * or possibly the Shootout itself, since there isn't much information  
     * on ownership there. Licensed under a modified BSD license.  
     */  
  
    private class JavaSieveTask extends AsyncTask<Void, Void, Void> {  
        long start=0;  
        TextView result=null;  
  
        @Override  
        protected void onPreExecute() {  
            result=(TextView)findViewById(R.id.nsieve_java);
```

FOCUS ON: NDK

```
        result.setText("running...");
    }

    @Override
    protected Void doInBackground(Void... unused) {
        start=SystemClock.uptimeMillis();

        int n=9;
        int m=(1<<n)*10000;
        boolean[] flags=new boolean[m+1];

        nsieve(m, flags);

        m=(1<<n-1)*10000;
        nsieve(m, flags);

        m=(1<<n-2)*10000;
        nsieve(m, flags);

        return(null);
    }

    @Override
    protected void onPostExecute(Void unused) {
        long delta=SystemClock.uptimeMillis()-start;

        result.setText(String.valueOf(delta));
        new JavaSpecTask().execute();
    }
}

private class JavaSpecTask extends AsyncTask<Void, Void, Void> {

MultiplyAv(n,v,u);
MultiplyAtv(n,u,AtAv);
}
}
```

(from [JNI/WeakBench/src/com/commonsware/android/tuning/weakbench/WeakBench.java](https://github.com/CommonWare/android-tuning-weakbench/blob/master/src/com/commonsware/android/tuning/weakbench/WeakBench.java))

As with our C implementations of the benchmarks, the Java source code is derived from the [Great Language Benchmarks Game](#).

Building and Deploying Your Project

Given that you have done all of this, the rest is perfectly normal – you build and deploy your Android project no differently than if you did not have any C/C++ code. Your native library is embedded in your APK file, so you do not have to worry about distributing it separately.

However, bear in mind that the more architectures you choose, the more .so files there are and the bigger your app will be. For tiny bits of C/C++ code, like the code in this app, this increase in file size will not be very noticeable. However, it is something to keep in mind for more elaborate NDK applications. Moreover, there are some ways to help reduce the impact of these extra architectures.

libhoudini and the NDK

libhoudini is a proprietary ARM translation layer for x86-powered Android devices. It allows an app that has NDK binaries for ARM, but not x86, to still run on x86 hardware, albeit not as quickly as it would with native x86 binaries.

Given ARM's current dominance in the Android ecosystem, libhoudini is hugely useful for Intel and hardware vendors interested in using Intel's mobile CPUs. Without it, only apps that ship x86 NDK binaries would be compatible with x86-powered devices like the Samsung Galaxy Tab 3 10.1" tablet. Some developers probably skip x86 NDK binaries, because they are not aware of popular x86-powered devices, or lack one for testing, or are concerned over APK size. The Play Store for x86 would shrink substantially from the million-plus apps available to ARM devices, to those that do not use the NDK or happen to ship x86 binaries. libhoudini makes ARM-only NDK binaries usable on x86, giving x86-powered Android devices access to more of the Play Store catalog.

However, it is slower. A test suite for [SQLCipher for Android](#), run on an ASUS MeMO Pad FHD 10, ran about three times as long when using the ARM binaries and `libhoudini`, when compared to the same test run using x86 binaries. On the other hand, supporting x86 in addition to ARM adds another 5MB to the app, on top of the 6.5MB spent for ARM and the platform-neutral pieces. Being able to use SQLCipher for Android without the x86 binaries might be useful, particularly for apps bumping up against APK size limits, like the 50MB limit on the Play Store.

You may wish to do your own testing. Testing is easy enough: just temporarily move the `x86/` directory from `libs/` somewhere else, then recompile and test on `libhoudini`-equipped hardware. If you do not have your own `libhoudini`-equipped hardware, you may be able to take advantage of services like [Samsung's Remote Test Lab](#), which recently added the Galaxy Tab 3 10.1 to its lineup.

If you have the space for it, include the x86 binaries for your NDK-compiled libraries. This will give you maximum speed for little incremental engineering cost. However, if space is at a premium, `libhoudini` may allow you to reach many of the same x86 devices, but be sure that your app will run acceptably given the performance overhead.

Gradle and the NDK

The Android Plugin for Gradle has preliminary support for the NDK. However, this support has its issues, and so you may wish to pursue other approaches, at least in the short term.

Official Support, for Externally-Built Binaries

Sometimes, you may have a project for which you want to use NDK-compiled binaries that somebody else supplies.

For example, at the time of this writing, [SQLCipher for Android](#) is not available as an AAR dependency from any repo. To use it, you need to include a handful of JARs in your project, along with NDK-compiled binaries for the core SQLCipher library and related libraries. Once this is available as an AAR, you could get all of that via a dependency; in the short term, you need to teach Gradle how to pick up the NDK-compiled binaries.

FOCUS ON: NDK

Using the Android Plugin for Gradle, you can have a `jniLibs/` directory in a sourceset. Underneath that directory would go your pre-compiled binaries, in the standard CPU architecture directories (e.g., `jniLibs/x86/`, `jniLibs/armeabi-v7a/`).

The [Gradle/ConstantsSecure](#) sample project is a clone of the same-named project from the SQLCipher for Android chapter, but with the code reorganized into a Gradle sourceset:

```
ConstantsSecure

|   |— ic_launcher.png
|— layout
|   |— add_edit.xml
|   |— main.xml
|   |— row.xml
|— values
|   |— strings.xml
```

(note: above listing includes only files of relevance for the current discussion)

The JARs remain in `libs/`, but the associated NDK `.so` files go in `jniLibs/` of the main sourceset.

When organized this way, the `build.gradle` file needs no changes to incorporate the `.so` files. If you wanted to have the JNI `.so` files in some other directory, you can modify `jniLibs.srcDirs` of your sourceset to point to where you want the files to reside.

Official Support, for Building NDK Binaries

To use the official NDK support for invoking the NDK build process from your `build.gradle` file, you need to have a `local.properties` file, defining an `ndk.dir` property, pointing to where your NDK is installed. This needs to be in the project root directory, not in a module directory.

You can add an `ndk` closure to your `defaultConfig`, describing how your NDK code can be built:

```
defaultConfig {
    ndk {
        moduleName "anddown"
    }
}
```

In addition to `moduleName`, you can specify:

- `cFlags` for compiler flags
- `ldLibs` for libraries to link in

FOCUS ON: NDK

Your productFlavors can also have ndk closures with abiFilter properties, identifying a particular set of NDK binaries to be included in that flavor. For example, here is a build.gradle sample file from [a test project for the Android Plugin for Gradle](#):

```
buildscript {
    repositories {
        maven { url '../../../../../out/host/gradle/repo' }
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:0.7.0-SNAPSHOT'
    }
}
apply plugin: 'android'

android {
    compileSdkVersion 15
    buildToolsVersion "18.0.1"

    defaultConfig {
        ndk {
            moduleName "sanangeles"
            cFlags "-DANDROID_NDK -DDISABLE_IMPORTGL"
            ldLibs "GLSv1_CM", "dl", "log"
            stl "stlport_static"
        }
    }

    buildTypes.debug.jniDebugBuild true

    productFlavors {
        x86 {
            ndk {
                abiFilter "x86"
            }
        }
        arm {
            ndk {
                abiFilter "armeabi-v7a"
            }
        }
        mips {
            ndk {
                abiFilter "mips"
            }
        }
    }
}
```

Note that this sample is seriously out of date, as it uses Gradle for Android 0.7.0, but it helps to illustrate how the product flavors work.

In here, we define three product flavors, one each for x86, ARM, and MIPS. Each resulting binary will only contain that architecture's version of the compiled NDK code.

Also, you need to tell Gradle for Android where your C/C++ source code resides. The default location is a `jni/` directory in your source sets, such as the `main/` source set. However, you can override that using `jni.srcDirs` in your configuration of a source set.

Example: CWAC-AndDown

[CWAC-AndDown](#) is mentioned in passing in [the chapter on rich text handling](#). It is an Android library that wraps [hoedown](#), a C-based Markdown-to-HTML converter. The hoedown project itself is a fork of sundown, which itself was used by many sites, like GitHub, for their Markdown processing. CWAC-AndDown is great for projects that take in Markdown and want to render the results in a `WebView` (though you can use `Html.fromHtml()` to put the results in a `TextView` if you want).

Since CWAC-AndDown uses hoedown's C code, it has a `jni/` directory containing the JNI wrapper C code, the appropriate makefiles, plus a `src/` subdirectory containing the hoedown source code.

The classic way to build the project was to manually run the `ndk-build` script in the project root, then use Ant to compile the demo. CWAC-AndDown itself is an Android library project, designed to be used by apps like the demo app.

To get this library project to build using Ant and Eclipse, in addition to Gradle, we needed to leave the `jni/` directory in its original spot, alongside the `res/`, `src/`, and related directories and files. Since that is not where Gradle for Android goes looking for C/C++ files, we needed to teach Gradle for Android where our JNI code resides, by configuring `jni.srcDirs` for our main source set in `build.gradle`:

```
sourceSets {
    main {
        manifest.srcFile 'AndroidManifest.xml'
        java.srcDirs = ['src']
        resources.srcDirs = ['src']
        aidl.srcDirs = ['src']
        renderscript.srcDirs = ['src']
        res.srcDirs = ['res']
        assets.srcDirs = ['assets']
        jni.srcDirs = ['jni', 'jni/src']
    }

    debug.setRoot('build-types/debug')
```

```
release.setRoot('build-types/release')
}
```

The CWAC-AndDown `build.gradle` file also contains the `ndk` closure shown earlier in this section, to name the module that we are generating.

Unofficial Support for Makefiles

We also needed to reorganize the CWAC-AndDown source code, due to some fundamental limitations in the current official Android support. Specifically, Gradle for Android *ignores* your own makefiles, preferring instead to generate its own. The generation algorithms are rather limited and make some assumptions about the organization of your code. Having all of your C/C++ source and header files in one big directory seems to work; having other structures may or may not work.

The fact that Gradle for Android ignores your makefiles means that if your makefiles do anything beyond very vanilla stuff, your build may well not work.

The alternative to using the built-in NDK support is to add in your own tasks that use the `ndk-build` command with your original makefiles. One such set of tasks was published by David Weinstein in [a GitHub Gist](#). However, this recipe was written for an early beta version of the Gradle for Android plugin and therefore may require some modification.

Mostly, it involves adding the following to the bottom of your `build.gradle` file:

```
task packageNativeLibs_ARM(type: Jar) {
    baseName 'libtestlib'
    classifier 'armeabi'
    from(file('libs/armeabi/')) {
        include '**/*.so'
    }
    into('lib/armeabi')
    destinationDir(file('libs/'))
}

task packageNativeLibs_x86(type: Jar) {
    baseName 'libtestlib'
    classifier 'x86'
    from(file('libs/x86/')) {
        include '**/*.so'
    }
    into('lib/x86')
    destinationDir(file('libs/'))
}

task packageNativeLibs(description: "package native libraries") {
}
```

FOCUS ON: NDK

```
packageNativeLibs.dependsOn 'packageNativeLibs_ARM'
packageNativeLibs.dependsOn 'packageNativeLibs_x86'

task ndkBuild(type: Exec, description: "Task to run ndk-build") {
    commandLine ndkDir + '/ndk-build'
}

packageNativeLibs.dependsOn 'ndkBuild'

tasks.withType(JavaCompile) { compileTask -> compileTask.dependsOn packageNativeLibs }

clean.dependsOn 'cleanPackageNativeLibs'
```

This task also assumes that you have set an `ndkDir` property. To set properties in Gradle, add a `gradle.properties` file to your project, using the typical properties format:

```
ndkDir=/opt/android-ndk
```

The Gradle code snippet does several things:

1. It defines two tasks, one each to package the ARM and x86 version of the binaries. If you have a different mix of NDK build targets (e.g., ARMv7, MIPS), you could add or alter these tasks to suit.
2. It defines a `packageNativeLibs` task, that depends upon each of the CPU architecture-specific tasks from the previous point. If you add, change, or remove those architecture-specific tasks, you will need to add, change, or remove the corresponding `packageNativeLibs.dependsUpon` statements.
3. It defines an `ndkBuild` task, that simply executes the `ndk-build` script found in your NDK directory (defined by that `ndkDir` property).
4. It has `packageNativeLibs` depend upon `ndkBuild`.
5. It has all `JavaCompile` tasks in the build depend upon the `packageNativeLibs` task. This ensures that when we compile our Java code, we also compile the NDK code, if it is not already up to date.
6. It adds the auto-generated `cleanPackageNativeLibs` task as a dependency for the `clean` task, so `gradle clean` will clean the NDK build as well as cleaning everything else.

Gradle supports other ways of defining where the NDK directory is, such as depending upon an environment variable, so you have alternatives.

Improving CPU Performance in Java

Knowing that you have CPU-related issues in your app is one thing — doing something about it is the next challenge. In some respects, tuning an Android application is a “one-off” job, tied to the particulars of the application and what it is trying to accomplish. That being said, this chapter will outline some general-purpose ways of boosting performance that may counter issues that you are running into.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

Reduce CPU Utilization

One class of CPU-related problems come from purely sluggish code. These are the sorts of things you will see in Traceview, for example – methods or branches of code that seem to take an inordinately long time. These are also some of the most difficult to have general solutions for, as often times it comes down to what the application is trying to accomplish. However, the following sections provide suggestions for consuming fewer CPU instructions while getting the same work done.

These are presented in no particular order.

Standard Java Optimizations

Most of your algorithm fixes will be standard Java optimizations, no different than have been used by Java projects over the past decade and change. This section outlines a few of them. For more, consider reading *Effective Java* by Joshua Bloch or *Java Performance Tuning* by Jack Shirazi.

Avoid Excessive Synchronization

Few objects in `java.*` namespaces are intrinsically thread-safe, outside of `java.util.concurrent`. Typically, you need to perform your own synchronization if multiple threads will be accessing non-thread-safe objects. However, sometimes, Java classes have synchronization that you neither expect nor need. Synchronization adds unnecessary overhead.

The classic example here is `StringBuffer` and `StringBuilder`. `StringBuffer` was part of Java from early on, and, for whatever reason, was written to be thread-safe — two threads that append to the buffer will not cause any problems. However, most of the time, you are only using the `StringBuffer` from one thread, meaning all that synchronization overhead is a waste. Later on, Java added `StringBuilder`, with the same basic set of methods as has `StringBuffer`, but without the synchronization.

Similarly, in your own code, only synchronize where it is really needed. Do not toss the synchronized keyword around randomly, or use concurrent collections that will only be used by one thread, etc.

Avoid Floating-Point Math

The first generation of Android devices lacked a floating-point coprocessor on the ARM CPU package. As a result, floating-point math speed was atrocious. That is why the Google Maps add-on for Android uses `GeoPoint`, with latitude and longitude in integer microdegrees, rather than the standard Android `Location` class, which uses Java double variables holding decimal degrees.

While later Android devices do have floating-point coprocessor support, that does not mean that floating-point math is now as fast as integer math. If you find that your code is spending lots of time on floating-point calculations, consider whether a change in units would allow you to replace the floating-point calculations with integer equivalents. For example, microdegrees for latitude and longitude provide

adequate granularity for most maps, yet allow Google Maps to do all of its calculations in integers.

Similarly, consider whether the full decimal accuracy of floating-point values is really needed. While it may be physically possible to perform distance calculations in meters with accuracy to a few decimal points, for example, in many cases the user will not need that degree of accuracy. If so, perhaps changing to fixed-point (integer) math can boost your performance.

Don't Assume Built-In Algorithms are Best

Years upon years of work has gone into the implementation of various algorithms that underlie Java methods, like searching for substrings inside of strings.

Somewhat less work has gone into the implementation of the Apache Harmony versions of those methods, simply because the project is younger, and it is a modified version of the Harmony implementation that you will find in Android. While the core Android team has made many improvements to the original Harmony implementation, those improvements may be for optimizations that do not fit your needs (e.g., optimizing to reduce memory consumption at the expense of CPU time).

But beyond that, there are [dozens of string-matching algorithms](#), some of which may be better for you depending on the string being searched and the string being searched for. Hence, you may wish to consider applying your own searching algorithm rather than relying on the built-in one, to boost performance. And, this same concept may hold for other algorithms as well (e.g., sorting).

Of course, this will also increase the complexity of your application, with long-term impacts in terms of maintenance cost. Hence, do not assume the built-in algorithms are the worst, either — optimize those algorithms that Traceview or logging suggest are where you are spending too much time.

Support Hardware-Accelerated Graphics

An easy “win” is to add `android:hardwareAccelerated="true"` to your `<application>` element in the manifest. This toggles on hardware acceleration for 2D graphics, including much of the stock widget framework. For maximum backwards compatibility, this hardware acceleration is off, but adding the aforementioned attribute will enable it for all activities in your application.

Note that this is only available starting with Android 3.0. It is safe to have the attribute in the manifest for older Android devices, as they simply will ignore your request.

You also should test your application thoroughly after enabling hardware acceleration, to make sure there are no unexpected issues. For ordinary widget-based applications, you should encounter no problems. Games or other applications that do their own drawing might have issues. If you find that some of your code runs into problems, you can override hardware acceleration on a per-activity basis by putting the `android:hardwareAccelerated` on `<activity>` elements in the manifest.

Minimize IPC

Calling a method on an object in your own process is fairly inexpensive. The overhead of the method invocation is fairly minuscule, and so the time involved is simply however long it takes for that method to do its work.

Invoking behaviors in another process, via inter-process communication (IPC), is considerably more expensive. Your request has to be converted into a byte array (e.g., via [the Parcelable interface](#)), made available to the other process, converted back into a regular request, then executed. This adds substantial CPU overhead.

There are three basic flavors of IPC in Android:

1. “Directly” invoking a third-party application’s service’s AIDL-published interface, to which you bound with `bindService()`
2. Performing operations on a content provider that is not part of your application (i.e., supplied by the OS or a third-party application)
3. Performing other operations that, under the covers, trigger IPC

Remote Bound Service

Using a remote service is fairly obvious when you do it — it is difficult to mistake copying the AIDL into your project and such. The proxy object generated from the AIDL converts all your method calls on the interface into IPC operations, and this is relatively expensive.

If you are exposing a service via AIDL, design your API to be coarse-grained. Do not require the client to make 1,000 method invocations to accomplish something that can be done in 1 via slightly more complex arguments and return values.

IMPROVING CPU PERFORMANCE IN JAVA

If you are consuming a remote service, try not to get into situations where you have to make lots of calls in a tight loop, or per row of a scrolled `AdapterView`, or anything else where the overhead may become troublesome.

For example, in the [CPU-Java/AIDLOverhead](#) sample project, you will find a pair of projects implementing the same do-nothing method in equivalent services. One uses AIDL and is bound to remotely from a separate client application; the other is a local service in the client application itself. The client then calls the do-nothing method 1 million times for each of the two services. On average, on a Samsung Galaxy Tab 10.1, 1 million calls takes around 170 seconds for the remote service, while it takes around 170 *milliseconds* for the local service. Hence, the overhead of an individual remote method invocation is small (~170 microseconds), but doing lots of them in a loop, or as the user flings a `ListView`, might become noticeable.

Remote Content Provider

Using a content provider can be somewhat less obvious of a problem. Using `ContentResolver` or a `CursorLoader` looks the same whether it is your own content provider or someone else's. However, you know what content providers you wrote; anything else is probably running in another process.

As with remote services, try to aggregate operations with remote content providers, such as:

1. Use `bulkInsert()` rather than lots of individual `insert()` calls
2. Try to avoid calling `update()` or `delete()` in a tight loop – instead, if the content provider supports it, use a more complex “WHERE clause” to update or delete everything at once
3. Try to get all your data back in few queries, rather than lots of little ones... though this can then cause you issues in terms of memory consumption

Remote OS Operation

The content provider scenario is really a subset of the broader case where you request that Android do something for you and winds up performing IPC as part of that.

Sometimes, this is going to be obvious. If you are sending commands to a third-party service via `startService()`, by definition, this will involve IPC, since the third-party

service will run in a third-party process. Try to avoid calling `startService()` lots of times in close succession.

However, there are plenty of cases that are less obvious:

1. All requests to `startActivity()`, `startService()`, and `sendBroadcast()` involve IPC, as it is a separate OS process that does the real work
2. Registering and unregistering a `BroadcastReceiver` (e.g., `registerReceiver()`) involves IPC
3. All of the “system services”, such as `LocationManager`, are really rich interfaces to an AIDL-defined remote service, and so most operations on these system services require IPC

Once again, your objective should be to minimize calls that involve IPC, particularly where you are making those calls frequently in close succession, such as in a loop. For example, frequently calling `getLastKnownLocation()` will be expensive, as that involves IPC to a system process.

Android-Specific Java Optimizations

The way that the Dalvik VM was implemented and operates is subtly different than a traditional Java VM. Therefore, there are some optimizations that are more important on Android than you might find in regular desktop or server Java.

The Android developer documentation has [a roster of such optimizations](#). Some of the highlights include:

1. Getters and setters, while perhaps useful for encapsulation, are significantly slower than direct field access. For simpler cases, such as `ViewHolder` objects for optimizing an `Adapter`, consider skipping the accessor methods and just use the fields directly.
2. Some popular method calls are replaced by hand-created assembler instructions rather than code generated via the JIT compiler. `indexOf()` on `String` and `arraycopy()` on `System` are two cited examples. These will run much faster than anything you might create yourself in Java.

Reduce Time on the Main Application Thread

Another class of CPU-related problem is when your code may be efficient, but it is occurring on the main application thread, causing your UI to react sluggishly. You

might have tuned your decryption algorithm as best as is mathematically possible, but it may be that decrypting data on the main application thread simply takes too much time. Or, perhaps `StrictMode` complained about some disk or network I/O that you are performing on the main application thread.

The following sections recap some commonly-seen patterns for moving work off the main application thread, plus a few newer options that you may have missed.

Generate Less Garbage

Most developers think of having too many allocations as being solely an issue of heap space. That certainly has an impact, and depending on the nature of the allocations (e.g., bitmaps), it may be the dominant issue.

However, garbage has impacts from a CPU standpoint as well. Every object you create causes its constructor to be executed. Every object that is garbage-collected requires CPU time both to find the object in the heap and to actually clean it up (e.g., execute the finalizer, if any).

Worse still, on older versions of Android (e.g., Android 2.2 and down), the garbage collector interrupts the entire process to do its work, so the more garbage you generate, the more times you “stop the world”. Game developers have had to deal with this since Android’s inception. To maintain a 60 FPS refresh rate, you cannot afford *any* garbage collections on older devices, as a single GC run could easily take more than the ~16ms you have per drawing pass.

As a result of all of this, game developers have had to carefully manage their own object pools, pre-allocating a bunch of objects before game play begins, then using and recycling those objects themselves, only allowing them to become garbage after game play ends.

Most non-game Android applications may not have to go to quite that extreme across the board. However, there are cases where excessive allocation may cause you difficulty. For example, avoiding creating too much garbage is one aspect of view recycling with `AdapterView`, which is covered in greater detail [in the next section](#).

If Traceview indicates that you are spending a lot of time in garbage collection, pay attention to your loops or things that may be invoked many times in rapid succession (e.g., accessing data from a custom `Cursor` implementation that is tied to a `CursorAdapter`). These are the most likely places where your own code might be creating lots of extra objects that are not needed. Examining the heap to see what is

all being created (and eventually garbage collected) will be covered in [an upcoming chapter of the book](#).

View Recycling

Perhaps the best-covered Android-specific optimization is view recycling with `AdapterView`.

In a nutshell, if you are extending `BaseAdapter`, or if you are overriding `getView()` in another adapter, please make use of the `View` parameter supplied to `getView()` (referred to here as `convertView`). If `convertView` is not `null`, it is one of your previous `View` objects you returned from `getView()` before, being offered to you for recycling purposes. Using `convertView` saves you from inflating or manually constructing a fresh `View` every time the user scrolls, and both of those operations are relatively expensive.

If you have been ignoring `convertView` because you have more than one type of `View` that `getView()` returns, your `Adapter` should be overriding `getViewTypeCount()` and `getItemViewType()`. These will allow Android to maintain separate object pools for each type of row from your `Adapter`, so `getView()` is guaranteed to be passed a `convertView` that matches the row type you are trying to create.

A somewhat more advanced optimization — caching all those `findViewById()` lookups — is also possible once your row recycling is in place. Often referred to as “the holder pattern”, you do the `findViewById()` calls when you inflate a new row, then attach the `findViewById()` results to the row itself via some custom “holder” object and the `setTag()` method on `View`. When you recycle the row, you can get your “holder” back via `getTag()` and skip having to do the `findViewById()` calls again.

Background Threads

Of course, the backbone of any strategy to move work off the main application thread is to use background threads, in one form or fashion. You will want to apply these in places where `StrictMode` complains about network or disk I/O, or places where `Traceview` or logging indicate that you are taking too much time on the main application thread during GUI processing (e.g., converting downloaded bitmap images into `Bitmap` objects via `BitmapFactory`).

Sometimes, you will manually dictate where work should be done in the background, either by forking threads yourself or by using `AsyncTask`. `AsyncTask` is a

nice framework, handling all of the inter-thread communication for you and neatly packaging up the work to be done in readily understood methods. However, `AsyncTask` does not fit every scenario — it is mostly designed for “transactional” work that is known to take a modest amount of time (milliseconds to seconds) then end. For cases where you need unbounded background processing, such as monitoring a socket for incoming data, forking your own thread will be the better approach.

Sometimes, you will use facilities supplied by Android to move work to the background. For example, many activities are backed by a `Cursor` obtained from a database or content provider. Classically, you would manage the cursor (via `startManagingCursor()`) or otherwise arrange to refresh that `Cursor` in `onResume()`, so when your activity returns to the foreground after having been gone for a while, you would have fresh data. However, this pattern tends to lead to database I/O on the main application thread, triggering complaints from `StrictMode`. Android 3.0 and the Android Compatibility Library offer a `Loader` framework designed to try to solve the core pattern of refreshing the data, while arranging for the work to be done asynchronously.

Asynchronous BroadcastReceiver Operations

99.44% of the time (approximately) that Android calls your code in some sort of event handler, you are being called on the main application thread. This includes manifest-registered `BroadcastReceiver` components — `onReceive()` is called on the main application thread. So any work you do in `onReceive()` ties up that thread (possibly impacting an activity of yours in the foreground), and if you take more than 10 seconds, Android will terminate your `BroadcastReceiver` with extreme prejudice.

Classically, manifest-registered `BroadcastReceiver` components only live as long as the `onReceive()` call does, meaning you can do very little work in the `BroadcastReceiver` itself. The typical pattern is to have it send a command to a service via `startService()`, where the service “does the heavy lifting”.

Android 3.0 added a `goAsync()` method on `BroadcastReceiver` that can help a bit here. While under-documented, it tells Android that you need more time to complete the broadcast work, but that you can do that work on a background thread. This does not eliminate the 10-second rule, but it does mean that the `BroadcastReceiver` can do some amount of I/O without having to send a command to a service to do it while still not tying up the main application thread.

IMPROVING CPU PERFORMANCE IN JAVA

The [CPU-Java/GoAsync](#) sample project demonstrates `goAsync()` in use, as the project name might suggest.

Our activity's layout consists of two `Button` widgets and an `EditText` widget:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical" android:layout_width="match_parent"
    android:layout_height="match_parent">
    <EditText android:id="@+id/editText1" android:layout_width="match_parent"
        android:layout_height="wrap_content">
    </EditText>
    <Button android:layout_width="match_parent" android:id="@+id/button1"
        android:layout_height="wrap_content" android:text="@string/nonasync"
        android:onClick="sendNonAsync"></Button>
    <Button android:layout_width="match_parent" android:id="@+id/button2"
        android:layout_height="wrap_content" android:text="@string/async"
        android:onClick="sendAsync"></Button>
</LinearLayout>
```

(from [CPU-Java/GoAsync/app/src/main/res/layout/main.xml](#))

The activity itself simply has `sendAsync()` and `sendNonAsync()` methods, each invoking `sendBroadcast()` to a different `BroadcastReceiver` implementation:

```
package com.commonware.android.tuning.goasync;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class GoAsyncActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void sendAsync(View v) {
        sendBroadcast(new Intent(this, AsyncReceiver.class));
    }

    public void sendNonAsync(View v) {
        sendBroadcast(new Intent(this, NonAsyncReceiver.class));
    }
}
```

(from [CPU-Java/GoAsync/app/src/main/java/com/commonware/android/tuning/goasync/GoAsyncActivity.java](#))

The `NonAsyncReceiver` simulates doing time-consuming work in `onReceive()` itself:

```
package com.commonware.android.tuning.goasync;

import android.content.BroadcastReceiver;
```

IMPROVING CPU PERFORMANCE IN JAVA

```
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class NonAsyncReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context arg0, Intent arg1) {
        SystemClock.sleep(7000);
    }
}
```

(from [CPU-Java/GoAsync/app/src/main/java/com/commonsware/android/tuning/goasync/NonAsyncReceiver.java](#))

Hence, if you click the “Send Non-Async Broadcast” button, not only will the button fail to return to its normal state for seven seconds, but the `EditText` will not respond to user input either.

The `AsyncReceiver`, though, uses `goAsync()`:

```
package com.commonsware.android.tuning.goasync;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class AsyncReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        final BroadcastReceiver.PendingResult result=goAsync();

        (new Thread() {
            public void run() {
                SystemClock.sleep(7000);
                result.finish();
            }
        }).start();
    }
}
```

(from [CPU-Java/GoAsync/app/src/main/java/com/commonsware/android/tuning/goasync/AsyncReceiver.java](#))

The `goAsync()` method returns a `PendingResult`, which supports a series of methods that you might ordinarily fire on the `BroadcastReceiver` itself (e.g., `abortBroadcast()`) but want to do on a background thread. You need your background thread to have access to the `PendingResult` — in this case, via a `final` local variable. When you are done with your work, call `finish()` on the `PendingResult`.

If you click the “Send Async Broadcast” button, even though we are still sleeping for 7 seconds, we are doing so on a background thread, and so our user interface is still responsive.

Saving SharedPreferences

The classic way to save `SharedPreferences.Editor` changes was via a call to `commit()`. This writes the preference information to an XML file on whatever thread you are on — another hidden source of disk I/O you might be doing on the main application thread.

If you are on API Level 9, and you are willing to blindly try saving the changes, use the new `apply()` method on `SharedPreferences.Editor`, which works asynchronously.

If you need to support older versions of Android, or you really want the boolean return value from `commit()`, consider doing the `commit()` call in an `AsyncTask` or background thread.

And, of course, to support both of these, you will need to employ tricks like conditional class loading. You can see that used for saving `SharedPreferences` in the [CPU-Java/PrefsPersist](#) sample project. The activity reads in a preference, puts the current value on the screen, then updates the preference with the help of an `AbstractPrefsPersistStrategy` class and its `persist()` method:

```
package com.commonware.android.tuning.prefs;

import android.app.Activity;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.widget.TextView;

public class PrefsPersistActivity extends Activity {
    private static final String KEY="counter";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        SharedPreferences prefs=
            PreferenceManager.getDefaultSharedPreferences(this);
        int counter=prefs.getInt(KEY, 0);

        ((TextView)findViewById(R.id.value)).setText(String.valueOf(counter));

        AbstractPrefsPersistStrategy.persist(prefs.edit().putInt(KEY, counter+1));
    }
}
```

(from [CPU-Java/PrefsPersist/app/src/main/java/com/commonware/android/tuning/prefs/PrefsPersistActivity.java](#))

IMPROVING CPU PERFORMANCE IN JAVA

AbstractPrefsPersistStrategy is an abstract base class that will hold a strategy implementation, depending on Android version. On pre-Honeycomb builds, it uses an implementation that forks a background thread to perform the commit():

```
package com.commonware.android.tuning.prefs;

import android.content.SharedPreferences;
import android.os.Build;

abstract public class AbstractPrefsPersistStrategy {
    abstract void persistAsync(SharedPreferences.Editor editor);

    private static final AbstractPrefsPersistStrategy INSTANCE=initImpl();

    public static void persist(SharedPreferences.Editor editor) {
        INSTANCE.persistAsync(editor);
    }

    private static AbstractPrefsPersistStrategy initImpl() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();

        if (sdk<Build.VERSION_CODES.HONEYCOMB) {
            return(new CommitAsyncStrategy());
        }

        return(new ApplyStrategy());
    }

    static class CommitAsyncStrategy extends AbstractPrefsPersistStrategy {
        @Override
        void persistAsync(final SharedPreferences.Editor editor) {
            (new Thread() {
                @Override
                public void run() {
                    editor.commit();
                }
            }).start();
        }
    }
}
```

(from [CPU-Java/PrefsPersist/app/src/main/java/com/commonware/android/tuning/prefs/AbstractPrefsPersistStrategy.java](#))

On Honeycomb and higher, it uses a separate strategy class that uses the new apply() method:

```
package com.commonware.android.tuning.prefs;

import android.content.SharedPreferences.Editor;

public class ApplyStrategy extends AbstractPrefsPersistStrategy {

    @Override
    void persistAsync(Editor editor) {
        editor.apply();
    }
}
```

```
}  
}
```

(from [CPU-Java/PrefsPersist/app/src/main/java/com/commonsware/android/tuning/prefs/ApplyStrategy.java](https://commonsware.com/android/tuning/prefs/ApplyStrategy.java))

By separating the Honeycomb-specific code out into a separate class, we can avoid loading it on older devices and encountering the dreaded `VerifyError`.

Whether using the built-in `apply()` method is worth dealing with multiple strategies, versus simply calling `commit()` on a background thread, is up to you.

Improve Throughput and Responsiveness

Being efficient and doing work on the proper thread may still not be enough. It could be that your work is not consuming excessive CPU time, but is taking too long in “wall clock time” (e.g., the user sits waiting too long at a `ProgressDialog`). Or, it could be that your work, while efficient and in the background, is causing difficulty for foreground operations.

The following sections outline some common problems and solutions in this area.

Minimize Disk Writes

Earlier in this book, we emphasized moving disk writes off to background threads.

Even better is to get rid of some of the disk writes entirely.

A big culprit here comes in the form of database operations. By default, each `insert()`, `update()`, or `delete()`, or any `execSQL()` invocation that modifies data, will occur in its own transaction. Each transaction involves a set of disk writes. Many times, this is not a problem. But, if you are doing a lot of these – such as importing records from a CSV file — hundreds or thousands of transactions will mean thousands of individual disk writes, and that can take some time. You may wish to wrap those operations in your own transaction, using methods like `beginTransaction()`, simply to reduce the number of transactions and, therefore, disk writes.

If you are doing your own disk I/O beyond databases, you may encounter similar sorts of issues. Overall, it is better to do a few larger writes than lots of little ones.

Set Thread Priority

Threads you fork, by default, run at a default priority: `THREAD_PRIORITY_DEFAULT` as defined on the `Process` class. This is a lower priority than the main application thread (`THREAD_PRIORITY_DISPLAY`).

Threads you use via `AsyncTask` run at a lower priority (`THREAD_PRIORITY_BACKGROUND`). If you fork your own threads, then, you might wish to consider moving them to a lower priority as well, to affect how much time they get compared to the main application thread. You can do this via `setThreadPriority()` on the `Process` class.

The lowest possible priority, `THREAD_PRIORITY_LOWEST`, is described as “only for those who really, really don’t want to run if anything else is happening”. You might use this for “idle-time processing”, but bear in mind that the thread will be paused a lot to allow other threads to run.

Lower-priority threads will help ensure that your background work does not affect your foreground UI. Processes themselves are put in a lower-priority class as they move to the background (e.g., you have no activities visible), which further reduces the amount of CPU time you will be using at any given moment.

Also, note that `IntentService` uses a thread at default (*not* background) priority — you may wish to drop the priority of this thread to something that will be lower than your main application thread, to minimize how much CPU time the `IntentService` steals from your UI.

Do the Work Some Other Time

Just because you could do the work now does not mean you should do the work now. Perhaps a better answer is to do the work later, or do part of the work now and part of the work later.

For example, suppose that you have your own database of points of interest for your custom map application. Periodically, you publish a new database on your Web site, which your Android app should download. Odds are decent that the user is not in desperate need for this new database right away. In fact, the CPU time and disk I/O time to download and save the database might incrementally interfere with the foreground application, despite your best efforts.

IMPROVING CPU PERFORMANCE IN JAVA

In this case, not only should you check for and download the database when the user is unlikely to be using the device (e.g., before dawn), but you should check whether the screen is on via `isScreenOn()` on `PowerManager`, and delay the work to sometime when the screen is off. For example, you could have `AlarmManager` set up to have your code check for updates every 24 hours at 4am. If, at 4am, the screen is on, your code could skip the download and wait until tomorrow, or skip the download and add a one-shot alarm to wake you up in 30 minutes, in hopes that the user will no longer be using the device.

At the same time, you may wish to consider having a “refresh” menu choice somewhere, for when the user specifically wants you to go get the update (if available) *now*, for whatever reason.

Finding and Eliminating Jank

A user interface is considered “janky” if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Finding and eliminating the causes of janky behavior (“jank”) is part science, part art, and part throwing darts at a dartboard.

This chapter will outline some techniques for identifying and removing jank from a user interface. The steps shown here originated in [a blog post by Google’s Romain Guy](#), with a few additional twists and turns due to the different nature of the particular case being studied. Mr. Guy’s blog post is essential reading for all advanced Android developers, and the author is deeply indebted to Mr. Guy for his work in this area.

Prerequisites

The only hard prerequisite for this chapter is having read the core chapters and [the chapter on finding CPU bottlenecks](#).

That being said, having read [the chapter on animators](#) would help understand portions of this chapter a bit better.

The Case: ThreePaneDemoBC

In [the chapter on animators](#), we examined an implementation of the Gmail-style three-pane layout with animated transitions (a.k.a., “[The Three-Fragment Problem](#)”). The implementation shown there originated with [a Stack Overflow question](#) with the solution presented in this book offered as [an answer](#).

[A commenter on that answer](#) pointed out that he detected some stutter, even on decent hardware.

This chapter reviews the steps that were taken to determine if we really are doing things incorrectly, what specifically we are doing wrong, and what can be done to fix it.

Are We Janky?

In the eyes of this book's author, the three-pane implementation presented in the chapter on animators was perfectly reasonable on good hardware.

There are two lessons to take from this:

1. It is better to come up with an objective definition for “jank” and test to see if your code meets that definition at various points
2. The author of this book is very tolerant of janky user interfaces

The results shown in [the chapter on CPU measurement](#) for the `gfxinfo` and `systrace` tools comes from the three-pane demo code. The `gfxinfo` and the `systrace` results both point to the three-pane demo spending too much time doing work and therefore dropping some number of frames. This lines up with the visual report, and indicates that we have some work to do to try to improve matters.

Finding the Source of the Jank

Just because we know that we are janky does not mean that we have any idea what to do about it. We need to conduct some further analysis to determine where, exactly, our jank is coming from.

Traceview

One thing that we can do to help further refine the source of our trouble is to use Traceview. As outlined in [the section on Traceview](#), Traceview reports how many calls were made of various methods in our code (and in the framework code) and how much time was spent there.

Here are some of the results from a Traceview run on the three-pane demo on a Nexus 7:

FINDING AND ELIMINATING JANK

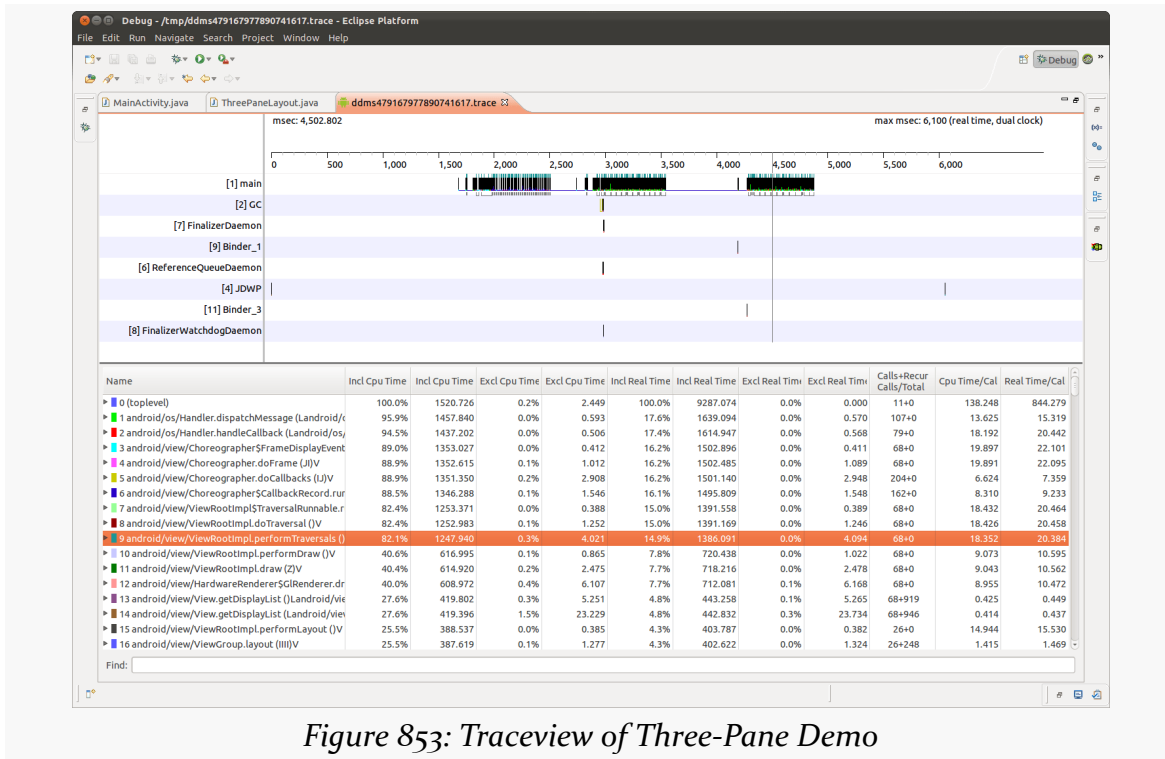

Figure 853: Traceview of Three-Pane Demo

We see that 88.9% of our CPU time is spent in `doFrame()` on `Choreographer` and the calls triggered from it. `doFrame()` is a private method which, as the name suggests, performs the drawing, processing, and executing of a single frame's worth of rendering. More importantly, we see that `doFrame()` was called 68 times during our test run, meaning that our UI changed 68 times during the ~3 seconds of activity during our trace.

Further down the table, we see that `layout()` on `ViewGroup` was called 26 times directly (and 248 more times via recursion), contributing about 25% of the time consumed by `doFrame()`. Since `layout()` is called on less than half of the `doFrame()` calls, the time consumed by `layout()` makes up a fairly significant portion of the `doFrame()` time during those 26 frames.

More importantly, `layout()` is something that we trigger. It implies that we have made some change to our UI content that requires a layout pass of some `ViewGroup`.

Having a layout pass on occasion is perfectly normal, particularly in response to user input. A `layout()` might be triggered by the user tapping on a row in one of our `ListView`s, for example. But we are not doing 26 user input events in our test — all we are doing is tapping one time each on a pair of `ListView` rows, then pressing the

BACK button. This implies that something else in our code is causing `layout()` to be needed.

Unfortunately, at this point, Traceview does not help much, because the calls to `layout()` are asynchronous with respect to our own code, so it will not be all that obvious where the extra calls are coming from. This is where we need some expert help, as we will see [later in this chapter](#).

Overdraw

Another common source of jank is overdraw. Overdraw refers to the act of painting the same pixel several times, due to overlapping components. For example:

- The activity window itself has a background
- You have a container that fills the activity's content, such as a `ListView`, which has a background
- You have children in that container with backgrounds (row), who have their own children with backgrounds and, eventually, content (widgets like `ImageView` and `TextView`)

Places where there is overlap, the OS might set the color of a pixel several times per frame, wasting time.

The easiest way to track down overdraw is to use the “Show GPU overdraw” option in the Developer Options portion of the Settings app:

FINDING AND ELIMINATING JANK

Figure 854: Nexus 7 Developer Options, with “Show GPU overdraw”

This option is only available on Android 4.2 and higher.

When you enable this option, then restart your app’s process (if it was already running), Android will shade pixels that are overdrawn:

- Blue for pixels that are drawn twice
- Green for pixels that are drawn three times
- Pink for pixels that are drawn four times
- Red for pixels that are drawn five or more times

In short: pink and red are bad. Green and blue are OK, though if you have large patches of either shade, you might consider trying to see if there’s a way to get rid of the overdraw.

Of course, the fact that these are shades applied to existing pixel colors may make it a bit difficult to tell exactly where the overdraw is occurring. For example, a red portion of your UI might be red from overdraw... or it might be red because you made it red. Temporarily changing your color scheme to something else (e.g., yellow) will help distinguish what is overdraw and what is just the natural UI coloration.

FINDING AND ELIMINATING JANK

If you enable this option on a Nexus 7 and run the three-pane demo, you will see very little blue or green (beyond the normal blue of the activated state of our ListView rows), and virtually no red:

Figure 855: Three-Pane Demo, As Initially Launched, Showing Overdraw

FINDING AND ELIMINATING JANK

Figure 856: Three-Pane Demo, Left and Middle Panes, Showing Overdraw

Figure 857: Three-Pane Demo, Middle and Right Panes, Showing Overdraw

FINDING AND ELIMINATING JANK

On the other hand, bringing up the Contacts app on the same Nexus 7 shows significantly more overdraw:

FINDING AND ELIMINATING JANK

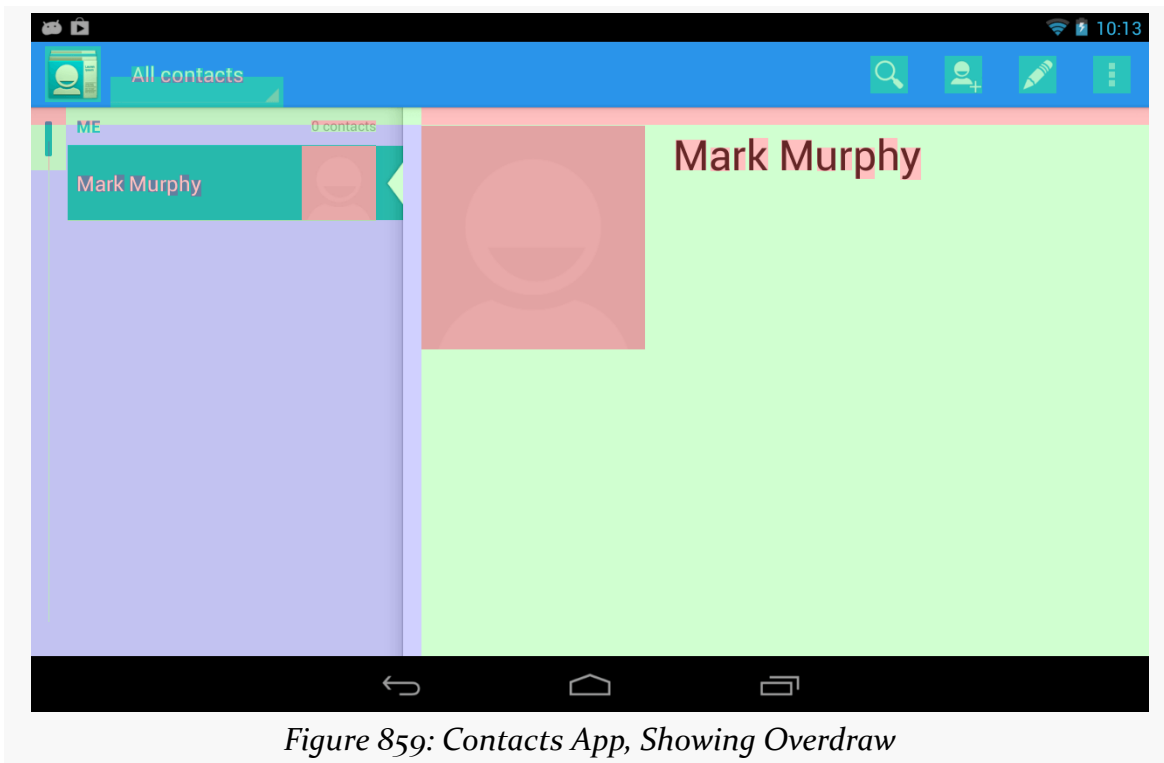

Figure 859: Contacts App, Showing Overflow

The good news is that our app is not suffering performance problems due to overflow.

The bad news is that the Contacts app is.

The good news is that if you are reading this, you are probably not responsible for maintaining the Contacts app.

The Contacts app's major problems come from the contact photos, or placeholders as seen here. Either the `ImageView` has a background, or the `ImageView` fills some container with a background. For example, the `ImageView` might be in some container with a background to provide a bevel effect around the image. Making the portion of the background that is behind the `ImageView` be transparent will eliminate the overflow.

Note: some GPU architectures can automatically fix overflow in select places, while others cannot. Notably, the Tegra 3 cannot. Hence, the Tegra 3 is a good test platform for using this overflow-detection feature of Android.

Extraneous Views

Another related source of jank is having too many extraneous views. Each widget and container contributes to the cost of drawing the overall UI, so having extraneous views adds overhead.

Perhaps the most common scenario for extraneous views is the single-child container. If a container will only ever hold one child, perhaps you can get rid of that container. Not only will this speed up execution at runtime, but it can help avoid running out of stack space.

One likely way to find these extraneous views is to bring up your user interface [in Hierarchy View on an emulator](#) (or possibly on a device by [using ViewServer](#)). In particular, single-child containers are fairly obvious — look for bubbles that have just one child bubble on the right.

There are two such cases in the UI for our three-pane demo, though neither are our fault.

Figure 860: Single-Child FrameLayout in Three-Pane Demo, from Hierarchy View

Here, we have a `FrameLayout` holding onto just one child, our `ThreePaneLayout` custom view. We set up `ThreePaneLayout` as being our activity’s content view. The “content view” of an activity is poured into a `FrameLayout`, supplied by the Android framework — that is the `FrameLayout` seen in Hierarchy View. We have no good way to get rid of this `FrameLayout`. Fortunately, `FrameLayout` is a very cheap container, in terms of runtime execution speed.

FINDING AND ELIMINATING JANK

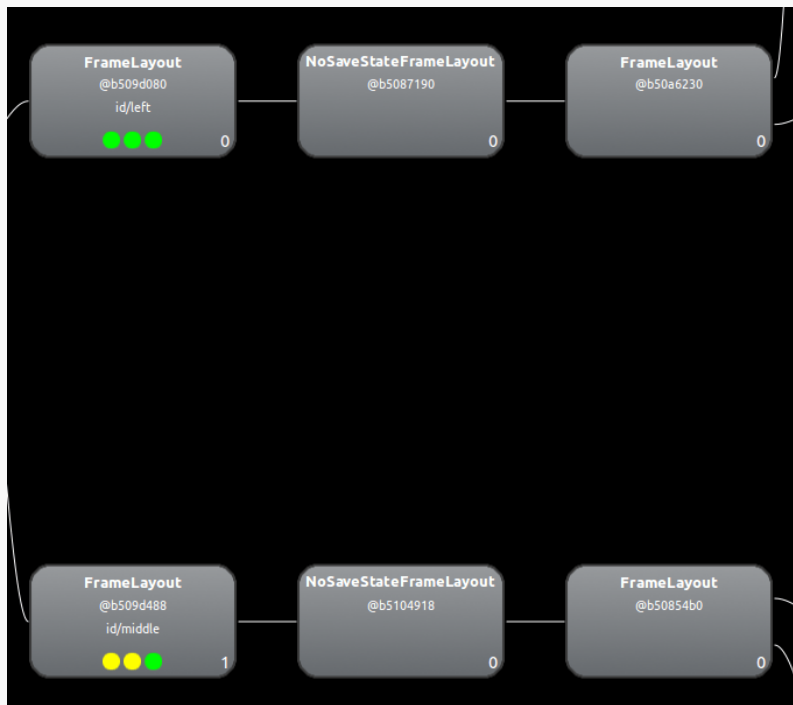

Figure 861: More Single-Child Containers in Three-Pane Demo, from Hierarchy View

Here, we see that our left and middle FrameLayout containers, for our left and middle panes, each contain one child, a NoSaveStateFrameLayout, which in turn each hold one child, a FrameLayout. These containers are added by ListFragment, not directly by our code. A ListFragment is surprisingly complex, adding several widgets and containers beyond the ListView itself:

FINDING AND ELIMINATING JANK

Figure 862: Contents of a ListFragment, from Hierarchy View

Short of writing our own fragment for holding a `ListView`, there is nothing we can do about these extraneous views.

Conclusion: Too Many `layout()` Calls?

Given that overdraw does not seem to be a problem and that we have few extraneous views under our control, it would seem that perhaps we should return our attention to the extra `layout()` calls. While trying to get rid of the `ListFragment` extraneous views would make those `layout()` calls incrementally cheaper, we will get more value by getting rid of the unnecessary calls in the first place, if indeed they are unnecessary.

Where Things Went Wrong

Of course, it doesn't hurt to call in an expert, to try to confirm exactly what is going on.

Chet Haase — Google engineer on Android, [celebrated book author](#), and part-time comedian – [chimed in with an answer](#) to a Stack Overflow question about this three-

pane animation, asked by the person who commented about the dropped frames on the original Stack Overflow question.

The key statement from his answer was:

Sliding things around is fine (translationX/Y), fading things in/out is good (alpha), but actually laying things out on every frame? Just say no.

Specifically, he is referring to our use of `ObjectAnimator` to change the width of the middle pane as we show and hide the right pane. Each time we change the width of the middle pane, we trigger a `layout()` call, to reposition the child widgets within that pane as needed. Our animations are adding ~20 `layout()` calls, introducing overhead that is pushing us over the per-frame limit on the Nexus 7.

Removing the Jank

To remove the jank, we need to remove the `ObjectAnimator` changing the width of the middle pane on the fly. You can see the results of this in the [Jank/ThreePaneBC](#) sample app.

Now, our `showLeft()` and `hideLeft()` methods immediately change the width of the middle pane, rather than arranging its animation:

```
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth=left.getWidth();
        middleWidthNormal=middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }

    translateWidgets(-1 * leftWidth, left, middle, right);
    setMiddleWidth(leftWidth);
}

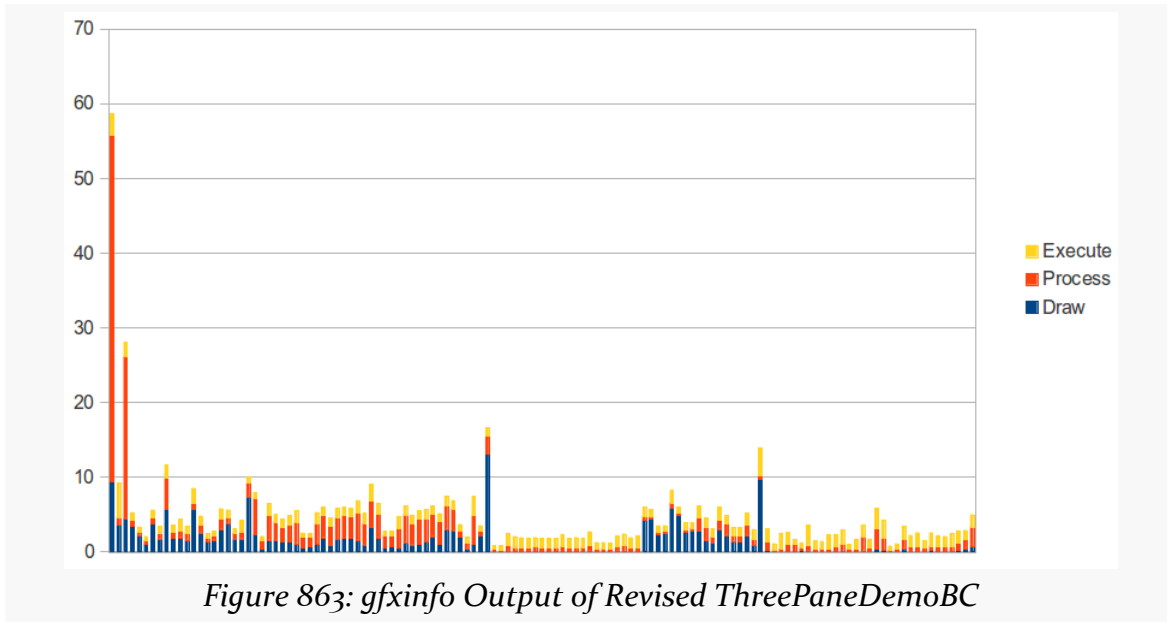

public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);
    setMiddleWidth(middleWidthNormal);
}

private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
}
```

(from [Jank/ThreePaneBC/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

FINDING AND ELIMINATING JANK

This does not provide nearly as good of a UI as the original. However, the revised solution does reduce the jank, as seen in this `gfxinfo` output:

There are probably ways to improve upon the revised jank-free implementation. Lacking that, it is up to you to decide if the amount of jank found in the original implementation is worth the improved animation or not.

Issues with Bandwidth

As anyone who owned an Apple Newton or Palm V PDA back in the 1990's knows, handheld devices have been around for quite some time. For a very long time, they were a niche product, associated with geeks, nerds, and the occasional business executive.

Internet access changed all of that.

Blackberry for enterprise messaging — an outgrowth of its original two-way paging approach — blazed part of the trail, but the concept “crossed the chasm” to ordinary people with the advent of the iPhone, Android devices, and similar equipment.

Therefore, it is not terribly surprising when Android developers want to add Internet capabilities to their apps. To the contrary, it is almost unusual when you encounter an app that does *not* want to use the Internet for something or another.

However, mobile Internet access inherits all of the classic problems of Internet access (e.g., “server not found”) and adds new and exciting challenges, all of which can leave a developer with an app that has performance issues.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

You're Using Too Much of the Slow Stuff

To paraphrase America's Founding Fathers, "all Internet connections are not created equal".

One form of inequality is speed. Different classes of connection have different theoretical upper bounds. WiMAX and other 4G connections are theoretically faster than 3G connections, which are theoretically faster than 2G or EDGE connections. WiFi is theoretically ridiculously fast though it is typically limited by the ISP connection, and ISP connections can run the gamut from really fast to merely good.

However, "theoretical" bounds tend to run afoul of reality. There are plenty of places where high-speed mobile data connections are non-existent, despite what the carriers' coverage maps claim. 2G mobile data works, but is not especially speedy. This layers on top of the typical Internet congestion issues, along with typically transitory problems (e.g., trying to get connectivity while attending a technology conference keynote presentation).

Beyond that, there are financial issues. While WiFi is usually unmetered (no incremental cost per MB/GB), many mobile data connections are metered. Those mobile data connections that are not metered in theory – advertised as "unlimited" — have usage caps that, once exceeded, impose costs or impose speed limits.

Hence, what runs quickly in the lab may run much more slowly in users' hands.

If you followed the instructions in previous chapters on CPU bottlenecks, the limited bandwidth will not cause your UI to become "janky", in that it will be responsive to touches and taps. However, poor connectivity will mean that you are simply slow to respond to user requests. For example, clicking the "check for new email" menu button has no immediate effect. If you feel that you need a splash screen or progress indicator to tell the user that "we are really checking for new email, honest", then you know that your Internet access is slower than is ideal.

Obviously, some of this is unavoidable. However, the objective of the chapters in this part of the book is to give you an idea of ways to reduce your bandwidth consumption, making those delays be that much less annoying for your users.

You're Using Too Much of the Expensive Stuff

Mobile data tends to come with more strings attached than does WiFi.

In the US, it used to be that mobile data connections included unlimited usage. Now, at best, a mobile data plan has “unlimited” usage for a curious definition of the term “unlimited”. More and more carriers are moving towards a hard cap — go above the cap, and you either cannot use more bandwidth, have your speeds curtailed, or pay significantly for additional bandwidth.

Outside of the US, the “pay significantly for bandwidth” approach is fairly typical. So-called “metered” data plans simply charge you such-and-so per MB or GB of bandwidth.

And, to top it off, roaming almost always is a metered plan. So, a US resident traveling overseas, even with a SIM and phone that supports international usage, would pay a ridiculous sum for bandwidth. Stories of phone bills in the tens of thousands of dollars abound, where people simply used their phone as they normally would when they were outside of their home network.

Hence, if you use a fair bit of bandwidth, it would be really nice if you offered users means to consume less of it when they are on mobile data compared to WiFi (which is typically unmetered). You could elect to poll your server less frequently, for example, giving the users the ability to specify separate polling periods depending on which type of connection they have.

And, of course, there are other “costs” for using bandwidth besides direct monetary costs. For example, downloading data over a slower mobile data connection may consume more power than downloading the same data over WiFi — while the WiFi radio might consume additional power, the time difference might account for more power consumption, if the CPU could be powered down for the rest of that time.

These chapters will show you how you can react to changes in connectivity and approaches for how to use that information to reduce costs for the user.

You’re Using Too Much of Somebody Else’s Stuff

It is easy for developers to think that they alone are using a user’s device. Alas, this is infrequently the case, particularly when it comes to background Internet access.

While your application is busily downloading stuff, some other application might be busily downloading stuff. In principle, this should not be an issue, as multiple applications can access the Internet simultaneously. However, bandwidth can become an issue. If you are in the background, and the other application is in the

foreground, the user might notice that bandwidth is an issue. For example, users might be unhappy if your downloads are impeding their ability to watch streaming video, or play their favorite Android-based MMORPG, or whatever.

A polite Android application will test to see whether the foreground application is heavily using the Internet and will curtail its own Internet use while that is going on. This chapter will help you learn how to make that determination and how to respond.

You're Using Too Much... And There Is None

Not only might location dictate how much bandwidth you have, but whether you have any bandwidth at all.

While some people think that the entire planet has connectivity, reality once again dictates otherwise. Major metropolitan areas have connectivity. Outlying areas are much more hit-or-miss. Voice is sometimes a challenge, let alone data. And it only *seems* as though there is a Starbucks every 100 meters in the US, which might actually provide blanket WiFi coverage.

Then, of course, there are planes (many still do not offer in-flight WiFi at this time), international travel without an international-capable phone plan, and so on.

Some Android applications have the potential to still offer near-complete functionality despite this, with a bit of user assistance. For example, Google Maps for Android has an offline caching feature, which will download data for a 10-mile radius from a given point, for use while the device is otherwise offline.

Here, the issue becomes less one of bandwidth (other than detecting that you have no connection) and more one of caching and storage. The space-related issues that these techniques can raise will be covered elsewhere in this book.

Focus On: TrafficStats

To be able to have more intelligent code — code that can adapt to Internet activity on the device — Android offers the `TrafficStats` class. This class really is a gateway to a block of native code that reports on traffic usage for the entire device and per-application, for both received and transmitted data. This chapter will examine how you can access `TrafficStats` and interpret its data.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

TrafficStats Basics

The `TrafficStats` class is not designed to be instantiated — you will not be invoking a constructor by calling `new TrafficStats()` or something like that. Rather, `TrafficStats` is merely a collection of static methods, mapped to native code, that provide access to point-in-time traffic values. No special permissions are needed to use any of these methods. Most of the methods were added in API Level 8 and therefore should be callable on most Android devices in use today.

Device Statistics

If you are interested in overall traffic, you will probably care most about the `getTotalRxBytes()` and `getTotalTxBytes()` on `TrafficStats`. These methods return received and transmitted traffic, respectively, measured in bytes.

You also have:

1. `getTotalRxPackets()` and `getTotalTxPackets()`, if for your case measuring IP packets is a better measure than bytes
2. `getMobileRxBytes()` and `getMobileTxBytes()`, which return the traffic going over mobile data (also included in the total)
3. `getMobileRxPackets()` and `getMobileTxPackets()`, which are the packet counts for the mobile data connection

Per-Application Statistics

Technically, `TrafficStats` does not provide per-application traffic statistics. Rather, it provides per-UID traffic statistics. In most cases, the UID (user ID) of an application is unique, and therefore per-UID statistics map to per-application statistics. However, it is possible for multiple applications to share a single UID (e.g., via the `android:sharedUserId` manifest attribute) — in this case, `TrafficStats` would appear to provide traffic data for all applications sharing that UID.

There are per-UID equivalents of the first four methods listed in the previous section, replacing “Total” with “Uid”. So, to find out overall traffic for an application, you could use `getUidRxBytes()` and `getUidTxBytes()`. However, these are the only two UID-specific methods that were implemented in API Level 8. Equivalents of the others (e.g., `getUidRxPackets()`) were added in API Level 12. API Level 12 also added some TCP-specific methods (e.g., `getUidTcpTxBytes()`). Note, though, that the mobile-only methods are only available at the device level; there are no UID-specific versions of those methods.

Interpreting the Results

You will get one of two types of return value from these methods.

In theory, you will get the value the method calls for (e.g., number of bytes, number of packets). The documentation does not state the time period for that value, so while it is possible that it is really “number of bytes since the device was booted”, we do not know that for certain. Hence, `TrafficStats` results should be used for comparison purposes, either comparing the same value over time or comparing multiple values at the same time. For example, to measure bandwidth consumption, you will need to record the `TrafficStats` values at one point in time, then again later — the difference between them represents the consumed bandwidth during that period of time.

In practice, while the “total” methods seem reliable, the per-UID methods may return -1. Three possible meanings are:

1. The device is old and is not set up to measure per-UID values
2. There has been no traffic of that type on that UID since boot, or
3. You do not have permission to know the traffic of that type on that UID

Hence, the per-UID values are a bit “hit or miss”, which you will need to take into account.

Example: TrafficMonitor

To illustrate the use of `TrafficStats` methods and analysis, let us walk through the code associated with the [Bandwidth/TrafficMonitor](#) sample application. This is a simple activity that records a snapshot of the current traffic levels on startup, then again whenever you tap a button. On-screen, it will display the current value, previous value, and difference (“delta”) between them. In LogCat, it will dump the same information on a per-UID basis.

TrafficRecord

It would have been nice if `TrafficStats` were indeed an object that you would instantiate, that captured the traffic values at that moment in time. Alas, that is not how it was written, so we need to do that ourselves. In the `TrafficMonitor` project, this job is delegated to a `TrafficRecord` class:

```
package com.commonware.android.tuning.traffic;

import android.net.TrafficStats;

class TrafficRecord {
    long tx=0;
    long rx=0;
    String tag=null;

    TrafficRecord() {
        tx=TrafficStats.getTotalTxBytes();
        rx=TrafficStats.getTotalRxBytes();
    }

    TrafficRecord(int uid, String tag) {
        tx=TrafficStats.getUidTxBytes(uid);
        rx=TrafficStats.getUidRxBytes(uid);
        this.tag=tag;
    }
}
```

FOCUS ON: TRAFFICSTATS

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficRecord.java](#))

There are two separate constructors, one for the total case and one for the per-UID case. The total case just logs `getTotalRxBytes()` and `getTotalTxBytes()`, while the per-UID case uses `getUidRxBytes()` and `getUidTxBytes()`. The per-UID case also stores a “tag”, which is simply a `String` identifying the UID for this record — as you will see, `TrafficMonitor` uses this for a package name.

TrafficSnapshot

An individual `TrafficRecord`, though, is insufficient to completely capture the traffic figures at a moment in time. We need a collection of `TrafficRecord` objects, one for the device (“total”) and one per running UID. The work to collect all of that is handled by a `TrafficSnapshot` class:

```
package com.commonsware.android.tuning.traffic;

import java.util.HashMap;
import android.content.Context;
import android.content.pm.ApplicationInfo;

class TrafficSnapshot {
    TrafficRecord device=null;
    HashMap<Integer, TrafficRecord> apps=
        new HashMap<Integer, TrafficRecord>();

    TrafficSnapshot(Context ctxt) {
        device=new TrafficRecord();

        HashMap<Integer, String> appNames=new HashMap<Integer, String>();

        for (ApplicationInfo app :
            ctxt.getPackageManager().getInstalledApplications(0)) {
            appNames.put(app.uid, app.packageName);
        }

        for (Integer uid : appNames.keySet()) {
            apps.put(uid, new TrafficRecord(uid, appNames.get(uid)));
        }
    }
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficSnapshot.java](#))

The constructor uses `PackageManager` to iterate over all installed applications and builds up a `HashMap`, mapping the UID to a `TrafficRecord` for that UID, tagged with the application package name (e.g., `com.commonsware.android.tuning.traffic`). It also creates one `TrafficRecord` for the device as a whole.

TrafficMonitorActivity

TrafficMonitorActivity is what creates and uses TrafficSnapshot objects. This is a fairly conventional activity with a TableLayout-based UI:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/table"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <Button
        android:onClick="takeSnapshot"
        android:text="Take Snapshot"/>

    <TableRow>

        <TextView
            android:layout_column="1"
            android:layout_gravity="right"
            android:text="@string/received"
            android:textSize="20sp"/>

        <TextView
            android:layout_gravity="right"
            android:text="@string/sent"
            android:textSize="20sp"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:text="@string/latest"
            android:textSize="20sp"
            android:textStyle="bold"/>

        <TextView
            android:id="@+id/latest_rx"
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:textSize="20sp"/>

        <TextView
            android:id="@+id/latest_tx"
            android:gravity="right"
            android:textSize="20sp"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:text="@string/previous"
            android:textSize="20sp">
```

FOCUS ON: TRAFFICSTATS

```
        android:textStyle="bold"/>

        <TextView
            android:id="@+id/previous_rx"
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:textSize="20sp"/>

        <TextView
            android:id="@+id/previous_tx"
            android:gravity="right"
            android:textSize="20sp"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:text="@string/delta"
            android:textSize="20sp"
            android:textStyle="bold"/>

        <TextView
            android:id="@+id/delta_rx"
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:textSize="20sp"/>

        <TextView
            android:id="@+id/delta_tx"
            android:gravity="right"
            android:textSize="20sp"/>
    </TableRow>
</TableLayout>
```

(from [Bandwidth/TrafficMonitor/app/src/main/res/layout/main.xml](#))

The activity implementation consists of three methods. There is your typical `onCreate()` implementation, where we initialize the UI, get our hands on the `TextView` widgets for output, and take the initial snapshot:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    latest_rx=(TextView)findViewById(R.id.latest_rx);
    latest_tx=(TextView)findViewById(R.id.latest_tx);
    previous_rx=(TextView)findViewById(R.id.previous_rx);
    previous_tx=(TextView)findViewById(R.id.previous_tx);
    delta_rx=(TextView)findViewById(R.id.delta_rx);
    delta_tx=(TextView)findViewById(R.id.delta_tx);

    takeSnapshot(null);
}
```

FOCUS ON: TRAFFICSTATS

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficMonitorActivity.java](#))

The `takeSnapshot()` method creates a new `TrafficSnapshot` (held in a latest data member) after moving the last `TrafficSnapshot` to a previous data member. It then updates the `TextView` widgets for the latest data and, if the previous data member is not null, also for the previous snapshot and the difference between them. This alone is sufficient to update the UI, but we also want to log per-UID data to LogCat:

```
public void takeSnapshot(View v) {
    previous=latest;
    latest=new TrafficSnapshot(this);

    latest_rx.setText(String.valueOf(latest.device.rx));
    latest_tx.setText(String.valueOf(latest.device.tx));

    if (previous!=null) {
        previous_rx.setText(String.valueOf(previous.device.rx));
        previous_tx.setText(String.valueOf(previous.device.tx));

        delta_rx.setText(String.valueOf(latest.device.rx-previous.device.rx));
        delta_tx.setText(String.valueOf(latest.device.tx-previous.device.tx));
    }

    ArrayList<String> log=new ArrayList<String>();
    HashSet<Integer> intersection=new HashSet<Integer>(latest.apps.keySet());

    if (previous!=null) {
        intersection.retainAll(previous.apps.keySet());
    }

    for (Integer uid : intersection) {
        TrafficRecord latest_rec=latest.apps.get(uid);
        TrafficRecord previous_rec=
            (previous==null ? null : previous.apps.get(uid));

        emitLog(latest_rec.tag, latest_rec, previous_rec, log);
    }

    Collections.sort(log);

    for (String row : log) {
        Log.d("TrafficMonitor", row);
    }
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficMonitorActivity.java](#))

One possible problem with the snapshot system is that the process list may change between snapshots. One simple way to address this is to only log to LogCat data where the application's UID exists in both the previous and latest snapshots. Hence, `takeSnapshot()` uses a `HashSet` and `retainAll()` to determine which UIDs exist in both snapshots. For each of those, we call an `emitLog()` method to record the data to an `ArrayList`, which is then sorted and dumped to LogCat.

FOCUS ON: TRAFFICSTATS

The `emitLog()` method builds up a line with the package name and bandwidth consumption information, assuming that there is bandwidth to report (i.e., we have a value other than -1):

```
private void emitLog(CharSequence name, TrafficRecord latest_rec,
                    TrafficRecord previous_rec,
                    ArrayList<String> rows) {
    if (latest_rec.rx>-1 || latest_rec.tx>-1) {
        StringBuilder buf=new StringBuilder(name);

        buf.append("=");
        buf.append(String.valueOf(latest_rec.rx));
        buf.append(" received");

        if (previous_rec!=null) {
            buf.append(" (delta=");
            buf.append(String.valueOf(latest_rec.rx-previous_rec.rx));
            buf.append(")");
        }

        buf.append(", ");
        buf.append(String.valueOf(latest_rec.tx));
        buf.append(" sent");

        if (previous_rec!=null) {
            buf.append(" (delta=");
            buf.append(String.valueOf(latest_rec.tx-previous_rec.tx));
            buf.append(")");
        }

        rows.add(buf.toString());
    }
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficMonitorActivity.java](#))

Since the lines created by `emitLog()` start with the package name, and since we are sorting those before dumping them to LogCat, they appear in LogCat in sorted order by package name.

Using TrafficMonitor

Running the activity gives you the initial received and sent counts (in bytes):

FOCUS ON: TRAFFICSTATS

Figure 864: The TrafficMonitor sample application, as initially launched

Tapping Take Snapshot grabs a second snapshot and compares the two:

FOCUS ON: TRAFFICSTATS

Figure 865: The TrafficMonitor sample application, after Take Snapshot was clicked

Also, LogCat will show how much was used by various apps:

```
08-15 14:05:10.128: DEBUG/TrafficMonitor(10283): com.amblingbooks.bookplayerpro=880 received (delta=0),

```

Other Ways to Employ TrafficStats

Of course, there are more ways you could use TrafficStats than simply having an activity to report them on a button click. TrafficMonitor is merely a demonstration of using the class and providing a lightweight way to get value out of that data. Depending upon your application's operations, though, you may wish to consider using TrafficStats in other ways, in your production code or in your test suites.

In Production

If your app is a bandwidth monitor, the need to use TrafficStats is obvious. However, even if your app does something else, you may wish to use TrafficStats to understand what is going on in terms of Internet access within your app or on the device as a whole.

For example, you might want to consider bandwidth consumption to be a metric worthy of including in the rest of the “analytics” you generate from your app. If you are using services like [Flurry](#) to monitor which activities get used and so on, you might consider also logging the amount of bandwidth your application consumes. This not only gives you much more “real world” data than you will be able to collect on your own, but it may give you ideas of how users are using your application beyond what the rest of your metrics are reporting.

Another possibility would be to include your app's bandwidth consumption in error logs reported via libraries like [ACRA](#). Just as device particulars can help identify certain bug report patterns, perhaps certain crashes of your app only occur when users are using a lot of bandwidth in your app, or using a lot of bandwidth elsewhere and perhaps choking your own app's Internet access.

The [chapter on bandwidth mitigation strategies](#) will also cover a number of uses of TrafficStats for real-time adjustment of your application logic.

During Testing

You might consider adding TrafficStats-based bandwidth logging for your application in your test suites. While individual tests may or may not give you useful data, you may be able to draw trendlines over time to see if you are consuming more or less bandwidth than you used to. Take care to factor in that you may have changed the tests, in addition to changing the code that is being tested.

From a JUnit-based unit test suite, measuring bandwidth consumption is not especially hard. You can bake it into the `setUp()` and `tearDown()` methods of your test cases, either via inheritance or composition, and log the output to a file or LogCat.

From an external test engine, like [monkeyrunner](#) or [NativeDriver](#), recording bandwidth usage is more tricky, because your test code is not running on the device or emulator. You may have to include a `BroadcastReceiver` in your production code that will log bandwidth usage and trigger that code via the `am broadcast shell` command.

Measuring Bandwidth Consumption

The first step towards addressing bandwidth concerns is to get a better picture of how much bandwidth you are actually consuming, when, and under what conditions. Only then will you be able to determine where your efforts need to be applied and whether those efforts are actually giving you positive results. This chapter will examine a handful of ways you can determine how much bandwidth you are really using in your application.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

On-Device Measurement

Many times, you are best served by measuring your bandwidth consumption right on the device itself:

1. This is your only option for gathering bandwidth metrics from copies of your app in end users' hands, unless they invite you to their home or office and have you sniff on their personal network, which seems unlikely
2. This is your only option for gathering bandwidth metrics when you are using mobile data plans (e.g., 3G) instead of WiFi, since you probably do not control the wireless telecommunications infrastructure in your area
3. This is your simplest option for tying bandwidth metrics to events within your app or occurring on the device

4. This is your only option for using bandwidth metrics to adjust your application behavior in real time, in addition to using the metrics to learn how best to adjust your code in future updates to the app

Hence, in addition to perhaps other off-device techniques, you really should consider one of the on-device approaches outlined in the following sections.

Yourself, via TrafficStats

The [preceding chapter](#) outlined how to use the `TrafficStats` class to collect metrics on the bandwidth consumed by applications (including yours) and for the device as a whole. This gives you the most flexibility, because you can write your own code to collect whatever portion of this data you need. It can address all of the bullets shown above, for example.

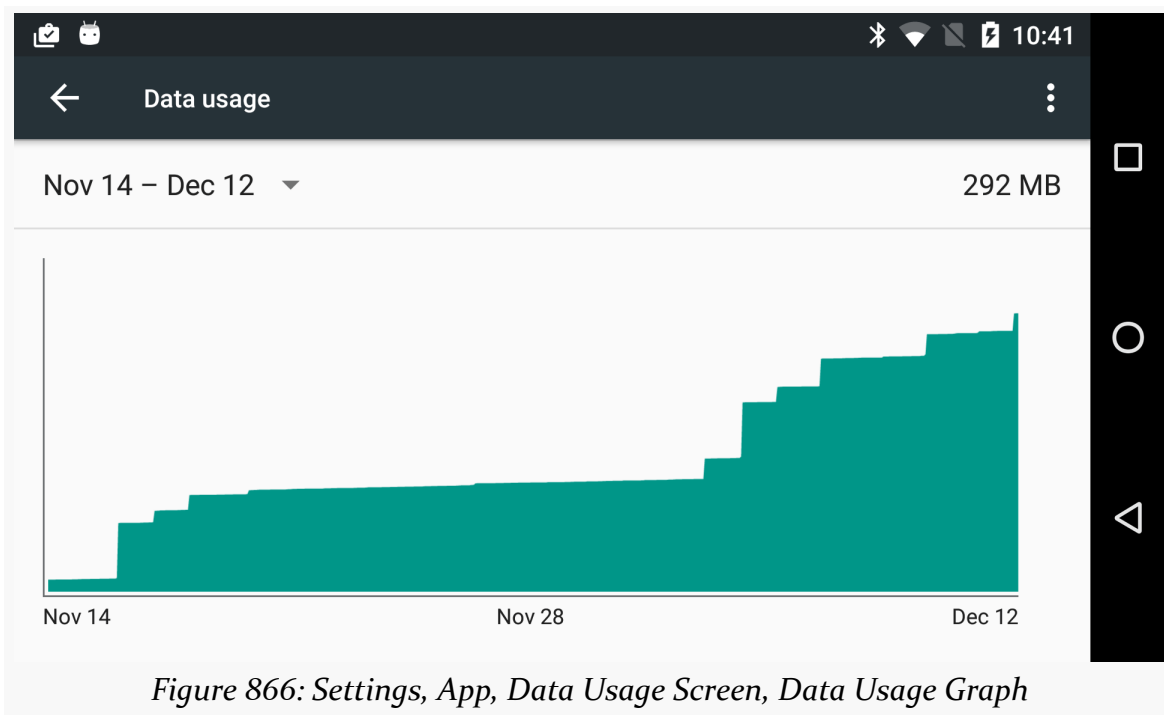

It is not perfect, though:

1. It requires you to write your own code, adding yet more work to your plate
2. Per-UID traffic data may or may not be available, depending upon the device

Data Usage Screen in Settings

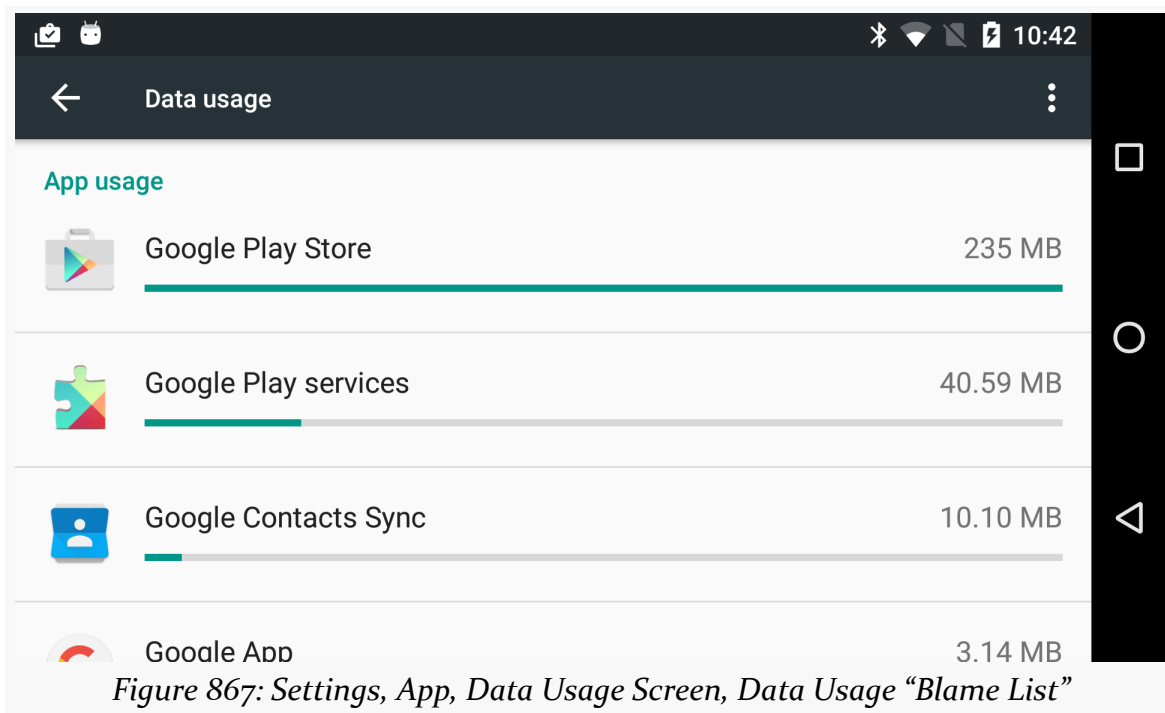

For more casual use, the Settings app in most Android devices offers a “Data Usage” screen that shows how much bandwidth has been consumed over a period of time:

MEASURING BANDWIDTH CONSUMPTION

Scrolling further down will give you details of what apps were involved in that data usage:

MEASURING BANDWIDTH CONSUMPTION

Tapping on any one of those list items will give you a bit more detail, specifically how much of that bandwidth was consumed while the app was in the foreground or the background:

Figure 868: Settings, App, Data Usage Screen, Data Usage App Details

Off-Device Measurement

The biggest limitation of `TrafficStats` is that it only gives you gross metrics: numbers of bytes, packets, and so on. Sometimes, that is not enough to help you understand why those bytes, packets, and so on are actually being sent or received. Sometimes, it would be nice to understand the traffic in more detail, from the ports and IP addresses to perhaps the actual data being transmitted. For obvious security reasons, this is not something an ordinary Android SDK application can do. However, there are techniques for accomplishing this, mostly for use over WiFi in your own home or office network. Some of these are outlined in the following sections.

Wireshark

[Wireshark](#), formerly known as `Ethereal`, is perhaps the world's leading open source network traffic analyzer and packet inspector. Using it, you can learn in great detail what is going on with your local network. And, Android provides additional options for you to leverage `Wireshark` to make sense of application behavior. `Wireshark` is available for Linux, OS X, and Windows.

MEASURING BANDWIDTH CONSUMPTION

There is a lightly-documented `-tcpdump` switch available on the Android emulator. If you launch the emulator from the command line with that switch (plus `-avd` to identify the AVD file you want to use), all network access is dumped to your specified log file. You can then load that data into Wireshark for analysis, via File|Open from the main menu.

For example, here is a screenshot of Wireshark examining data from such an emulator dump file, in which the emulator was used to conduct a Google search:

Figure 869: Wireshark examining captured emulator packets

This screenshot shows an HTTP request in the highlighted line in the list, with the hex and ASCII contents of the request shown in the bottom pane.

In terms of using Wireshark to monitor traffic from actual hardware, that is indubitably possible. However, WiFi packet collection is a tricky process with Wireshark, being very dependent upon operating system and possibly even the WiFi adapter chipset. You also get much lower-level information, making it a bit more challenging to figure out what is going on. Attempting to cover all of this is well beyond the scope of this book and the author's Wireshark expertise.

Networking Hardware

Sophisticated firewalls sometimes have packet tracing/sniffing capability. In this case, “sophisticated” does not necessarily mean “expensive”, as open source router/firewall distributions, like OpenWrt, can be used for this sort of work. In this case, the router captures the packets and, in many cases, routes them to Wireshark for analysis. Some might offer on-board analysis (e.g., Web interface to packet capture logs).

This is particularly useful on a Windows wireless network. Wireshark has limits, imposed by Windows, that cause some problems when trying to capture WiFi packets. By offloading the packet capture to networking hardware, those limits can be bypassed.

Android Studio Network Monitor

TrafficStats is great for measuring gross bandwidth consumption over some period of time. However, it requires coding, logging, and your own analysis mechanism.

In Android Studio, tabs inside the Android Monitor tool allow you to examine the real-time behavior of your app with respect to various system resources, such as bandwidth consumption. These tabs appear alongside the “logcat” tab, in a tab strip towards the top of the Android Monitor tool frame.

Figure 870: Android Studio, Android Monitor, Network Tab

This graph comes from a Picasso demo application from earlier in the book, which retrieves the latest 25 android questions on Stack Overflow and shows them in a ListView, along with the avatar for the person asking the question. The graph shows

MEASURING BANDWIDTH CONSUMPTION

the initial load of data from the Stack Exchange JSON API, followed ~20 seconds later by some scrolling in the app, forcing Picasso to go load more avatars.

Values above the horizontal axis represent downloads (“Rx”, meaning received packets). Values below the horizontal axis represent uploads (“Tx”, meaning transmitted packets).

As this responds in near-real-time to things you do in your app, you can see if the graph shows network accesses at unexpected times, or more bandwidth consumed than you might expect. For example, once all the avatars were loaded, no more bandwidth should be consumed by the Picasso sample app, assuming all the avatars could fit in Picasso’s memory cache.

Being Smarter About Bandwidth

Given that you are [collecting metrics about bandwidth consumption](#), you can now start to determine ways to reduce that consumption. You may be able to permanently reduce that consumption (at least on a per-operation basis). You may be able to shunt that consumption to times or networks that the user prefers. This chapter reviews a variety of means of accomplishing these ends.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Internet access](#).

Bandwidth Savings

The best way to reduce bandwidth consumption is to consume less bandwidth.

(in other breaking news, water is wet)

In recent years, developers have been able to be relatively profligate in their use of bandwidth, pretty much assuming everyone has an unlimited high-speed Internet connection to their desktop or notebook and the desktop or Web apps in use on them. However, those of us who lived through the early days of the Internet remember far too well the challenges that dial-up modem accounts would present to users (and perhaps ourselves). Even today, as Web apps try to “scale to the Moon and back”, bandwidth savings becomes important not so much for the end user, but for the Web app host, so its own bandwidth is not swamped as its user base grows.

Fortunately, widespread development problems tend to bring rise to a variety of solutions — a variant on the “many eyes make bugs shallow” collaborative development phenomenon. Hence, there are any number of tried-and-true techniques for reducing bandwidth consumption that have had use in Web apps and elsewhere. Many of these are valid for native Android apps as well, and a few of them are profiled in the following sections.

Classic HTTP Solutions

Trying to get lots of data to fit on a narrow pipe — whether that pipe is on the user’s end or the provider’s end — has long been a struggle in Web development. Fortunately, there are a number of ways you can leverage HTTP intelligently to reduce your bandwidth consumption.

GZip Encoding

By default, HTTP requests and response are uncompressed. However, you can enable GZip encoding and thereby request that the server compress its response, which is then decompressed on the client. This trades off CPU for bandwidth savings and therefore needs to be done judiciously.

Enabling GZip compression is a two-step process:

- Adding the Accept-Encoding: gzip header to the HTTP request
- Determine if the response was compressed and, if so, decompressing it

Bear in mind that the Web server may or may not honor your GZip request, for whatever reason (e.g., response is too small to make it worthwhile).

If-Modified-Since / If-None-Match

Of course, avoiding a download offers near-100% compression. If you are caching data, you can take advantage of HTTP headers to try to skip downloads that are the same content as what you already have, specifically If-Modified-Since and If-None-Match.

An HTTP response can contain either a Last-Modified header or an ETag header. The former will contain a timestamp and the latter will contain some opaque value. You can store this information with the cached copy of the data (e.g., in a database table). Later on, when you want to ensure you have the latest version of that file,

your HTTP GET request can include an `If-Modified-Since` header (with the cached Last-Modified value) or an `If-None-Match` header (with the cached ETag value). In either case, the server should return either a 304 response, indicating that your cached copy is up to date, or a 200 response with the updated data. As a result, you avoid the download entirely (other than HTTP headers) when you do not need the updated data.

Binary Payloads

While XML and JSON are relatively easy for humans to read, that very characteristic means they tend to be bloated in terms of bandwidth consumption. There are a variety of tools, such as Google's [Protocol Buffers](#) and Apache's [Thrift](#), that allow you to create and parse binary data structures in a cross-platform fashion. These might allow you to transfer the same data that you would in XML or JSON in less space. As a side benefit, parsing the binary responses is likely to be faster than parsing XML or JSON. Both of these tools involve the creation of an IDL-type file to describe the data structure, then offer code generators to create Java classes (or equivalents for other languages) that can read and write such structures, converting them into platform-neutral on-the-wire byte arrays as needed.

Minification

If you are loading JavaScript or CSS into a `WebView`, you should consider standard tricks for compressing those scripts, collectively referred to as “[minification](#)”. These techniques eliminate all unnecessary whitespace and such from the files, rename variables to be short, and otherwise create a syntactically-identical script that takes up a fraction of the space. There are services like [box.js](#) that can even aggregate several scripts into one file and minify them, to further reduce HTTP overhead.

Keep-Alive Semantics

A chunk of the overhead involved in HTTP operations is simply establishing the socket connection with the Web server. Advertising that you want the socket to be kept alive, in anticipation of upcoming follow-on requests, can reduce this overhead.

Using higher-level HTTP clients, like `OkHttp`, helps here, because usually they handle all the details of keeping the socket open.

With SSL, though, keep-alive was not an option, until Google released the SPDY specification. SPDY in turn formed the basis of HTTP/2, the new standard for Web

communications (replacing the venerable HTTP/1.1). OkHttp supports SPDY and HTTP/2.

Push versus Poll

Another way to consume less bandwidth is to only make the requests when it is needed. For example, if you are writing an email client, the way to use the least bandwidth is to download new messages only when they exist, rather than frequently polling for messages.

Off the cuff, this may seem counter-intuitive. After all, how can we know whether or not there are any messages if we are not polling for them?

The answer is to use a low-bandwidth push mechanism. The quintessential example of this is [GCM](#), the Google Cloud Messaging system, available for Android 2.2 and newer. This service from Google allows your application to subscribe to push notifications sent out by your server. Those notifications are delivered asynchronously to the device by way of Google's own servers, using a long-lived socket connection. All you do is register a `BroadcastReceiver` to receive the notifications and do something with them.

For example, Remember the Milk — a task management Web site and set of mobile apps — uses GCM to alert the device of task changes you make through the Web site. Rather than the Remember the Milk app having to constantly poll to see if tasks were added, changed, or deleted, the app simply waits for GCM events.

You could create your own push mechanism, perhaps using a `WebSocket` or [MQTT](#). The downside is that you will need a service in memory all of the time to manage the socket and thread that monitors it. If you only need this while your service is in memory for other reasons, that is fine. However, keeping a service in memory 24x7 has its own set of issues, not the least of which is that users will tend to smack it down using a “task killer” or the Manage Services screen in the Settings app. Doze mode on Android 6.0+ will also cause problems with this approach.

Thumbnails and Tiles

A general rule of thumb is: don't download it until you really need it.

Sometimes, you do not know if you really need a particular item until something happens in the UI. Take a `ListView` displaying thumbnails of album covers for a music app. Assuming the album covers are not stored locally, you will need to

download them for display. However, which covers you need varies based upon scrolling. Downloading a high-resolution album cover that might get tossed in a matter of milliseconds (after an expensive rescale to fit a thumbnail-sized space) is a waste of bandwidth.

In this case, either the album covers are something you control on the server side, or they are not. If they are, you can have the server prepare thumbnails of the covers, stored at a spot that the app can know about (e.g., `.../cover.jpg` it is `.../thumbnail.jpg`). The app can then download thumbnails on the fly and only grab the full-resolution cover if needed (e.g., user clicks on the album to bring up a detail screen). If you do not control the album covers, this option might still be available to you if you can run your own server for the purposes of generating such thumbnails.

You can see a similar effect with the map tiles in Google Maps. When zooming out, the existing map tiles are scaled down, with placeholders (the gridlines) for the remaining spots, until the tiles for those spots are downloaded. When zooming in, the existing map tiles are scaled up with a slight blurring effect, to give the user some immediate feedback while the full set of more-detailed tiles is downloaded. And, if the user pans, you once again get placeholders while the tiles for the newly uncovered areas are downloaded. In this fashion, Google Maps is able to minimize bandwidth consumption by giving users partial results immediately and back-filling in the final results only when needed. This same sort of approach may be useful with your own imagery.

Bandwidth Shaping

Sometimes, you have no ability to reduce the bandwidth itself. Perhaps you do not control both ends of the communications pipeline. Perhaps the data you are trying to exchange is already compressed (e.g., downloading an MP4 video). Perhaps some of the techniques in the preceding section were unavailable to you (e.g., cannot route data through third-party servers like Google's for [GCM](#)).

There still may be ways for you to help your users, by shaping your bandwidth use. Rather than just blindly doing whatever you want whenever you want, you learn what the *user* wants and what *other applications* want and tailor your bandwidth use on the fly to match those needs. The following sections outline some ways of achieving this.

Driven by Preferences

If you are consuming enough bandwidth that this chapter is relevant to you, you probably are consuming enough bandwidth that you should be asking the user how best to consume that bandwidth. After all, they are the one paying the price — in time as well as money — for that consumption.

The following sections present some possible strategies for preference-based bandwidth shaping.

Budgets

One strategy is for the user to give you a budget (e.g., 20MB/day) and for you to stick within that budget.

Collecting the budget is fairly easy — just use `SharedPreferences`. Either use a `ListPreference` with likely budget value or an `EditTextPreference` and a bit of validation for a free-form budget amount.

Next, you will need to have some idea how much bandwidth any given network operation will consume. For some things, this might be an estimate based on your experiments as a developer, or perhaps it is based on historical averages for this user and type of operation. For example, a “podcatcher” (feed reader designed to download podcast episodes) should have some idea how big a given RSS or Atom feed download should be. In some cases, it might be worthwhile to get a better estimate — for example, the podcatcher might use an HTTP HEAD request to determine the size of the MP3 or OGG file before deciding whether to download it.

Then, you need to be keeping track of your budget. This could be a simple flat file with the initial `TrafficStats` bandwidth values for your process. Re-initialize that file on the first network operation of the day (or whatever period you chose for your budget). Before doing another network operation, compare the current `TrafficStats` values with the initial ones and see how close you are to the budget. If the new network operation will exceed the budget, skip the operation, perhaps putting it in a work queue to perform in the next budget. You might even hold a reserve for certain types of operations. For example, the podcatcher might ensure there is at least 10% of the budget available for downloading the feeds, even if it means putting a podcast on the queue for download tomorrow. That way, you can present to the user the latest podcast information, with icons indicating which are

downloaded and which are queued for download — the user might be able to then request to override the budget and download something on demand.

For devices that lack per-UID `TrafficStats` support, you will have to “fake it” a bit. Use your own calculations of how much bandwidth each operation consumes and track that information, even if you wind up missing out on some bytes here or there.

Connectivity

If the user might not care how much bandwidth you consume, so long as it is unmetered bandwidth, you might include a `CheckBoxPreference` to indicate if large network operations should be limited to WiFi and avoid mobile data.

You could then use `ConnectivityManager` and `getActiveNetworkInfo()` to see what connection you have before performing a network operation. If it is a background operation (e.g., the podcatcher checking for new podcasts every hour), if the network is not the desired one, you can skip the operation or put it on a work queue for re-trying later. If it is a foreground operation (e.g., the user clicked a “refresh” menu choice), you could pop up a confirmation `AlertDialog` to warn the user that they are on mobile data — perhaps this time they are interested in doing the operation anyway.

Another approach for handling the background operations is to register a `BroadcastReceiver` for the `CONNECTIVITY_ACTION` broadcast (defined on `ConnectivityManager`). If the connectivity switches to mobile data, cancel your outstanding `AlarmManager` alarms; if connectivity switches to WiFi, re-enable those alarms.

Of course, you should also consider monitoring the background data setting — the global Settings checkbox indicating whether background network operations are allowed. On `ConnectivityManager`, `getBackgroundDataSetting()` tells you the state of this checkbox, and `ACTION_BACKGROUND_DATA_SETTING_CHANGED` allows you to set up a `BroadcastReceiver` to watch for changes in its state.

Windows

If your user is less concerned about the bandwidth or the network, but does care about the time of day (e.g., does not want your application consuming significant bandwidth when they might be getting a VOIP call), you could offer preferences for that as well. Cook up a `TimePreference` and use that to collect start and stop times

for the high-bandwidth window. Then, set up alarms with `AlarmManager` for those points in time. The alarm for the start time of the window sets up a third alarm with your regular polling interval. The alarm for the stop time of the window cancels the polling interval alarm.

Driven by Other Usage

If your network I/O is part of a foreground application, one presumes that you are the most important thing in the user's life right now. Or, at least, the most important thing on the user's phone right now. Hence, what other applications might want to do with the Internet connection is not a major concern.

If, however, your network I/O is part of a background operation, it might be nice to try to avoid doing things that might upset the user. If the user is watching streaming video or is on a VOIP call or otherwise is aware of bandwidth changes, the bandwidth you use might impact the user in ways that the user will not appreciate very much. This is unlikely to be a big problem for small operations (e.g., downloading a 1KB JSON file), but larger operations (e.g., downloading a 5MB podcast) might be more noticeable.

You can use `TrafficStats` to help here. Before doing the actual network I/O, grab the current traffic data, wait a couple of seconds, and compare the latest to the previous values. If little to no bandwidth was consumed during that period, assume it is safe and go ahead and do your work. If, however, a bunch of bandwidth was consumed, you might want to consider:

1. Skipping this polling cycle and trying again later, or
2. Adding a one-off alarm using `set()` on `AlarmManager` to give you control again in a minute, with the current traffic data packaged as an extra on the `Intent`, so you can make a decision after a bigger sample size of bandwidth consumption, or
3. Adding an entry in a persistent work queue, so you know later on to try again if bandwidth contention has improved

You could try to get more sophisticated, by using `ActivityManager` and the per-UID values from `TrafficStats` to see if it is a foreground application that is the one consuming the bandwidth. It is unclear how reliable this will be, both in determining who is consuming the bandwidth (again, per-UID traffic is not available on many devices) and in avoid user angst. It may be simpler just to assume the worst and side-step your I/O until the other apps have quieted down.

Avoiding Metered Connections

Android 4.1 added `isActiveNetworkMetered()` as a method on `ConnectivityManager`. In principle, this will return `true` if Android thinks that the current data connection may involve bandwidth charges. You can examine this value and steer your bandwidth consumption accordingly.

Android 5.0 added `JobScheduler`, as an alternative to `AlarmManager` for arranging periodic work. One feature of `JobScheduler` is that you can indicate that certain jobs require Internet access, in which case Android will not bother giving you control unless such access is available. A further refinement is that you can state that a job requires an unmetered Internet connection, so you avoid doing bandwidth-hogging work on an expensive connection.

Issues with Application Heap

RAM. Developers nowadays are used to having lots of it, and a virtual machine capable of using as much of it as exists (and more, given swap files and page files).

“Graybeards” — like the author of this book — distinctly remember a time when we had 16KB of RAM and were happy for it. Such graybeards would also appreciate it if you would get off their respective lawns.

Android comes somewhere in the middle. We have orders of magnitude more RAM than, say, the TRS-80 Model III. We do not have as much RAM as does the modern notebook, let alone a Web server. As such, it is easy to run out of RAM if you do not take sufficient care.

There are two facets of memory issues with Android:

- What are the problems we encounter inside our own app, in terms of our application heap?
- What problems can we encounter with system RAM overall, and how can we resolve them?

This part of the book examines memory-related issues, with this chapter focusing on the application heap. Another chapter will deal with [system RAM issues](#). These are not to be confused with any memory-related issues inherent to graybeards.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#).

You Are in a Heap of Trouble

When we think of “memory” and Java-style programming, the primary form of memory is the heap. The heap holds all of our Java objects – from an Activity to a widget to a String.

Traditional Java applications have an initial heap size determined by the virtual machine, possibly configured via command-line options when the program was run. Traditional Java applications can also request additional memory from the OS, up to some maximum, also configurable.

Android applications have the same basic structure, with very limited configurability and much lower maximums than you might expect.

The original Android devices had a heap limit of 16MB. As screens increase in resolution, the heap limit tends to rise, but only to a point. 32MB to 64MB of heap space is fairly typical, but less-expensive devices, such as Android One models, will tend towards the lower end of that range.

This heap limit can be problematic. For example, each widget or layout manager instance takes around 1KB of heap space. This is why AdapterView provides the hooks for view recycling — we cannot have a ListView with literally thousands of row views without potentially running out of heap.

API Level 11+ supports applications requesting a “large heap”. This is for applications that specifically need tons of RAM, such as an image editor to be used on a tablet. This is not for applications that run out of heap due to leaks or sloppy programming. Bear in mind that users will feel effects from large-heap applications, in that their other applications will be kicked out of memory more quickly, possibly irritating them. Also, garbage collection on large-heap applications runs more slowly, consuming more CPU time. To enable the large heap, add `android:largeHeap="true"` to the `<application>` element of your manifest. Finally, bear in mind that your “large heap” may not be any bigger than your regular heap would have been, as the “large heap” size is determined by the device manufacturer and takes into account things like available system RAM.

Determining Your Heap Size At Runtime

To get a sense for how much heap you will be able to potentially grow to, you can call `getMemoryClass()` on an `ActivityManager`. This will return your per-process heap limit in megabytes.

If you requested `android:largeHeap="true"` in the manifest, use `getLargeMemoryClass()` on `ActivityManager` to learn how large your “large heap” actually is. Note that it is entirely possible that the “large heap” is not all that large, or potentially is no bigger than the standard heap, depending upon how much RAM is physically present on the device.

Fragments of Memory

The Dalvik garbage collector is a non-compacting implementation, which makes `OutOfMemoryError` messages somewhat more likely than you would find on traditional Java environments.

Here, “non-compacting” means that Dalvik does not try to move objects around in physical memory to “compact” the use of physical memory, leaving a large contiguous block of free physical memory for future allocations.

For example, suppose that we allocate three 1K byte arrays, named A, B, and C. As it turns out, they were allocated using adjacent portions of physical memory, so that the last byte of A immediately precedes the first byte of B, and so on. Hence, we consumed 3K of available heap space to create these three 1K blocks.

If we release all references to A and B, they can be garbage-collected. Dalvik, like Java, will see that A and B are adjacent and will free up their physical memory, such that the memory is available as one contiguous 2K block for future allocations.

If, however, we release all references to A and C instead of A and B, Dalvik would be unable to make their blocks be contiguous, and so our heap would have two free 1K blocks, in addition to whatever other free memory that the heap already had.

Hence, allocating memory not only ties up that memory while it is in use, but it may *fragment* the memory even when it is released, such that our formerly pristine heap is now comprised of lots of little free blocks of space, separated from other such blocks by in-use objects. When we try to make a large allocation, such as setting up a byte array for a large image, it may be that while we have enough *total* heap

available for the request, there is no single block that would meet our request, and so we get an `OutOfMemoryError`.

One technique to help address this is to pre-allocate any large buffers that you know you need, up front when your process starts up, such as via a custom `Application` subclass. Then, use an “object pool” approach to obtain, use, and reuse these pre-allocated buffers, rather than having them be garbage-collected and have to be re-allocated later.

ART — the runtime engine used on Android 5.0+ — has a compacting garbage collector. However, it only compacts the heap when the app is in the background. So long as your application is in the foreground, ART behaves like Dalvik does, and your heap will continue to fragment.

Getting a Trim

It would be nice if we knew when a good time would be to cut back on our heap usage. For example, if we are caching a lot of data in our process, to save on future disk I/O, we could free up those caches at some point to help minimize our heap usage.

Fortunately, Android has some hooks for doing just that.

`onTrimMemory()` Callbacks

Starting in API Level 14, your activities, services, content providers, and custom `Application` classes all offer an `onTrimMemory()` method that you can override. This will be called from time to time to let you know about changes in the state of your app that might indicate it is time to free up some caches or otherwise cut back on memory consumption.

`onTrimMemory()` is passed a “level”, indicating how serious the memory crunch is. At the present time, there are seven such levels, but others may be added in future versions of Android. However, these levels are in priority order, and the documentation indicates that Google will ensure that future levels are slotted into the order as appropriate. Hence, you can watch for levels of a certain severity or *higher* and take appropriate action at those points in time.

ISSUES WITH APPLICATION HEAP

The seven levels are all defined as constants on the `ComponentCallbacks2` interface that defines `onTrimMemory()`. Four were defined in API Level 14, while the remaining three were defined in API Level 16. They are (in order of increasing severity):

- `TRIM_MEMORY_RUNNING_MODERATE` (added in API Level 16)
- `TRIM_MEMORY_RUNNING_LOW` (added in API Level 16)
- `TRIM_MEMORY_RUNNING_CRITICAL` (added in API Level 16)
- `TRIM_MEMORY_UI_HIDDEN` (added in API Level 14)
- `TRIM_MEMORY_BACKGROUND` (added in API Level 14)
- `TRIM_MEMORY_MODERATE` (added in API Level 14)
- `TRIM_MEMORY_COMPLETE` (added in API Level 14)

In particular, `TRIM_MEMORY_BACKGROUND` (or higher) indicates that your process is now on the list of processes to terminate to free up memory, and so the more memory you can free up, the less likely it is that your process will be terminated. Also, at `TRIM_MEMORY_UI_HIDDEN` or higher, your UI is no longer visible to the user, and so this is a fine time to free up UI-related memory that is safe to release, such as perhaps widget hierarchies that you would be rebuilding in `onResume()` later on anyway.

Note that while the focus tends to be on activities implementing `onTrimMemory()` to clean up UI-related resources, you are welcome to implement `onTrimMemory()` in services, content providers, and any custom `Application` subclass, so that you can free up memory that those may be managing as caches.

In the chapter on system RAM, we will get into why freeing up memory may help keep your process around, as we discuss [the relationship between your application heap and available system RAM](#).

Warning: Contains Graphic Images

However, the most likely culprit for `OutOfMemoryError` messages are bitmaps. Bitmaps take up a remarkable amount of heap space. Developers often look at the size of a JPEG file and think that “oh, well, that’s only a handful of KB”, without taking into account:

1. the fact that most image formats, like JPEG and PNG, are compressed, and Android needs the uncompressed image to know what to draw
2. the fact that each pixel may take up several bytes (2 bytes per pixel for `RGB_565`, 3 bytes per pixel for `RGB_888`)

3. what matters is the resolution of the bitmap in its original form, as much (if not more) than the size in which it will be rendered – an 800x480 image displayed in an 80x48 ImageView still consumes 800x480 worth of pixel data
4. there are an awful lot of pixels in an image — 800 times 480 is 384,000

Android can make some optimizations, such as only loading in one copy of a Drawable resource no matter how many times you render it. However, in general, each bitmap you load takes a decent sized chunk of your heap, and too many bitmaps means not enough heap. It is not unheard of for an application to have more than half of its heap space tied up in various bitmap images.

Compounding this problem is that bitmap memory, before Android 3.0, was difficult to measure. In the actual Dalvik heap, a Bitmap would need ~80 bytes or so, regardless of image size. The actual pixel data was held in “native heap”, the space that a C/C++ program would obtain via calls to `malloc()`. While this space was still subtracted from the available heap space, many diagnostic programs — such as MAT, to be examined in the next chapter — will not know about it. Android 3.0 moved the pixel data into the Dalvik heap, which will improve our ability to find and deal with memory leaks or overuse of bitmaps.

Bitmap Caching

Many Android libraries, like [Picasso](#), offer bitmap caching. Using an existing caching implementation is a lot easier than is rolling your own.

However:

- Make sure that the library is intelligently sizing the cache based upon possible heap space, such as via `getMemoryClass()` as is noted earlier in this chapter.
- Where possible, tie your cache to `onTrimMemory()` so that you can flush that cache when appropriate.
- Be careful about using *multiple* libraries, each of which might implement its own cache, that you do not wind up caching too much overall. Each library tends to think that it is The One True Cache for your app and will be oblivious to any other caches — bitmap or otherwise — that you may have in your app. Ideally, the library will have a way for you to set the maximum cache size.

Bitmap Sizing

Sometimes, you do not need a full-size image. For example, if you are showing thumbnails of images in a `ListView`, but only expect to show the full-size image for a few (e.g., rows that the user clicks upon), it is wasteful to load the full-size image for everything in the list.

`BitmapFactory.Options` offers `inSampleSize`, which tells the framework to sample the image as it is loaded, to result in a smaller image. `inSampleSize` of 2 will result in an image that is half the width and half the height; `inSampleSize` of 4 will result in an image that is a quarter the width and a quarter the height; etc. Note that `inSampleSize` is limited to powers of 2 and will round as needed.

If you know ahead of time the size of the image, you can calculate an appropriate `inSampleSize` to use. Otherwise, for local content, you can use `BitmapFactory` twice:

- Once with a `BitmapFactory.Options` set with `inJustDecodeBounds` set to `true`, which will merely tell you how big the image is via `outHeight` and `outWidth` on the `BitmapFactory.Options` itself
- Once with a `BitmapFactory.Options` set with `inSampleSize` set to your desired value and `inJustDecodeBounds` set to `false`, to really load the image, but downsampled to consume less memory

This approach does not work well for images being downloaded directly from the Internet, as you do not want to download the image twice, once just to figure out how big it is. Instead, download the image *without* using `BitmapFactory` to a local file, then use `BitmapFactory` to load in the image. If you are electing to use a two-level cache (memory plus disk), you might download the image to the disk cache, for example.

For example, let's look at the [Bitmaps/InSampleSize](#) sample project, which demonstrates the memory impact (and visual impact) of loading bitmaps at varying sample sizes.

In the `assets/` directory, we have a ~70KB JPEG file of a flower (courtesy of [the Wikimedia Project](#)) and a ~50KB PNG of the CommonsWare logo. Both images are 672 pixels square, which makes them relatively large images. These are in `assets` to ensure that Android will not attempt any sort of density-based conversion of the images, if they were to be in a `drawable` resource directory.

ISSUES WITH APPLICATION HEAP

The MainActivity of the project simply loads up a ViewPager and attaches it to a SampleAdapter:

```
package com.commonware.android.bitmap.iss;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=(ViewPager)findViewById(R.id.pager);

        pager.setAdapter(buildAdapter());
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(this, getFragmentManager()));
    }
}
```

(from [Bitmaps/InSampleSize/app/src/main/java/com/commonware/android/bitmap/iss/MainActivity.java](#))

SampleAdapter, in turn, populates the ViewPager with four instances of a BitmapFragment, where we supply the newInstance() factory method of BitmapFragment with a value of 1, 2, 4, or 8 ($1 \ll \text{position}$), indicating the inSampleSize value we want to use for that fragment instance:

```
package com.commonware.android.bitmap.iss;

import android.app.Fragment;
import android.app.FragmentManager;
import android.content.Context;
import android.support.v13.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(4);
    }

    @Override
    public Fragment getItem(int position) {
        return(BitmapFragment.newInstance(1 << position));
    }
}
```

ISSUES WITH APPLICATION HEAP

```
}  
  
@Override  
public String getPageTitle(int position) {  
    return(BitmapFragment.getTitle(ctxt, 1 << position));  
}  
}
```

(from [Bitmaps/InSampleSize/app/src/main/java/com/commonsware/android/bitmap/iss/SampleAdapter.java](#))

BitmapFragment then:

- Inflates a layout consisting of four ImageView widgets, two at 672dp square for the “natural” size (scaling only for density), and two at 128dp square to illustrate how the images appear when constrained to a smaller space:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent">  
  
    <LinearLayout  
        android:layout_width="match_parent"  
        android:layout_height="wrap_content"  
        android:orientation="vertical">  
  
        <TextView  
            android:id="@+id/byte_count"  
            android:layout_width="wrap_content"  
            android:layout_height="wrap_content"  
            android:layout_gravity="center_horizontal"  
            android:layout_marginBottom="16dp"  
            android:textSize="20sp"  
            android:textStyle="bold"/>  
  
        <ImageView  
            android:id="@+id/flower_large"  
            android:layout_width="672dp"  
            android:layout_height="672dp"  
            android:layout_gravity="center_horizontal"  
            android:layout_marginBottom="16dp"

ISSUES WITH APPLICATION HEAP

(from [Bitmaps/InSampleSize/app/src/main/java/com/commonsware/android/bitmap/iss/BitmapFragment.java](#))

If you run this on a device, you will see the images at the various sample sizes, one sample size per page of the ViewPager. While the quality of the loaded images decreases as `inSampleSize` increases, the smaller `ImageView` widgets are still usable for the flower JPEG, though the line-art PNG suffers.

NOTE: The following screenshots will themselves be modified as part of the publishing process of the book and are here only for illustration purposes. You will want to run the demo and see the results first-hand.

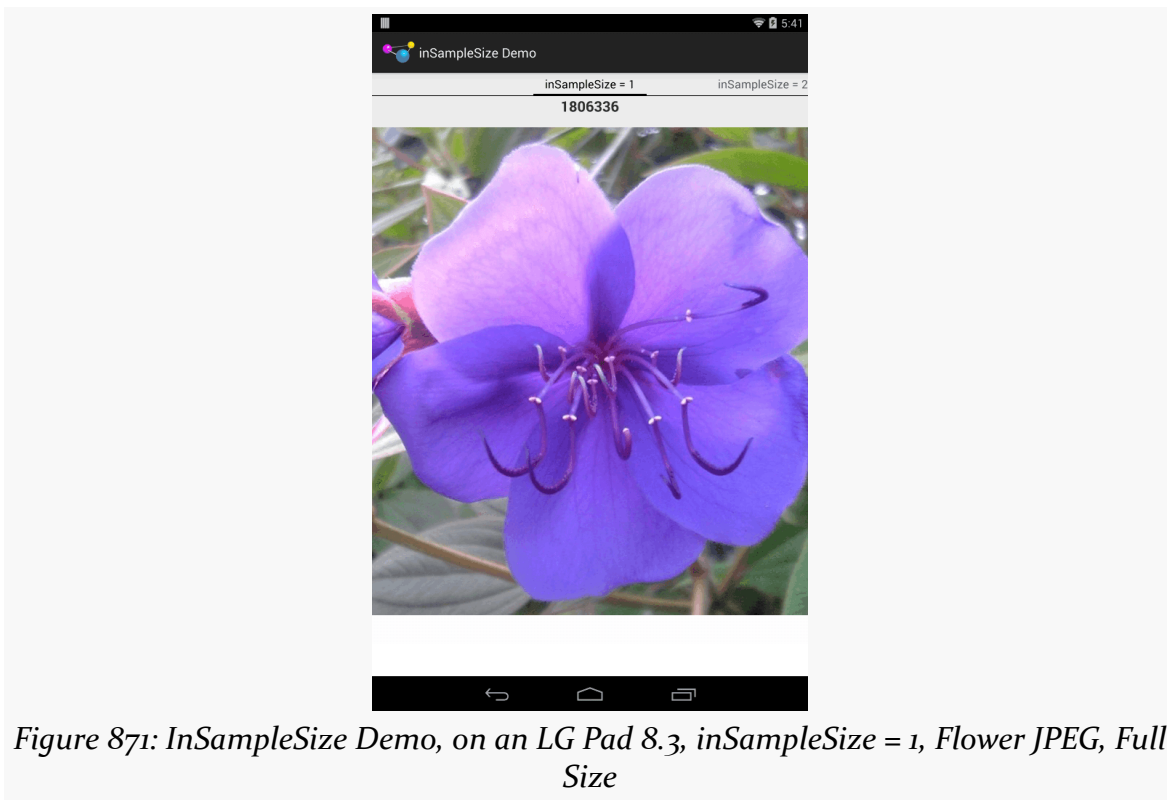

Figure 871: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 1, Flower JPEG, Full Size

ISSUES WITH APPLICATION HEAP

ISSUES WITH APPLICATION HEAP

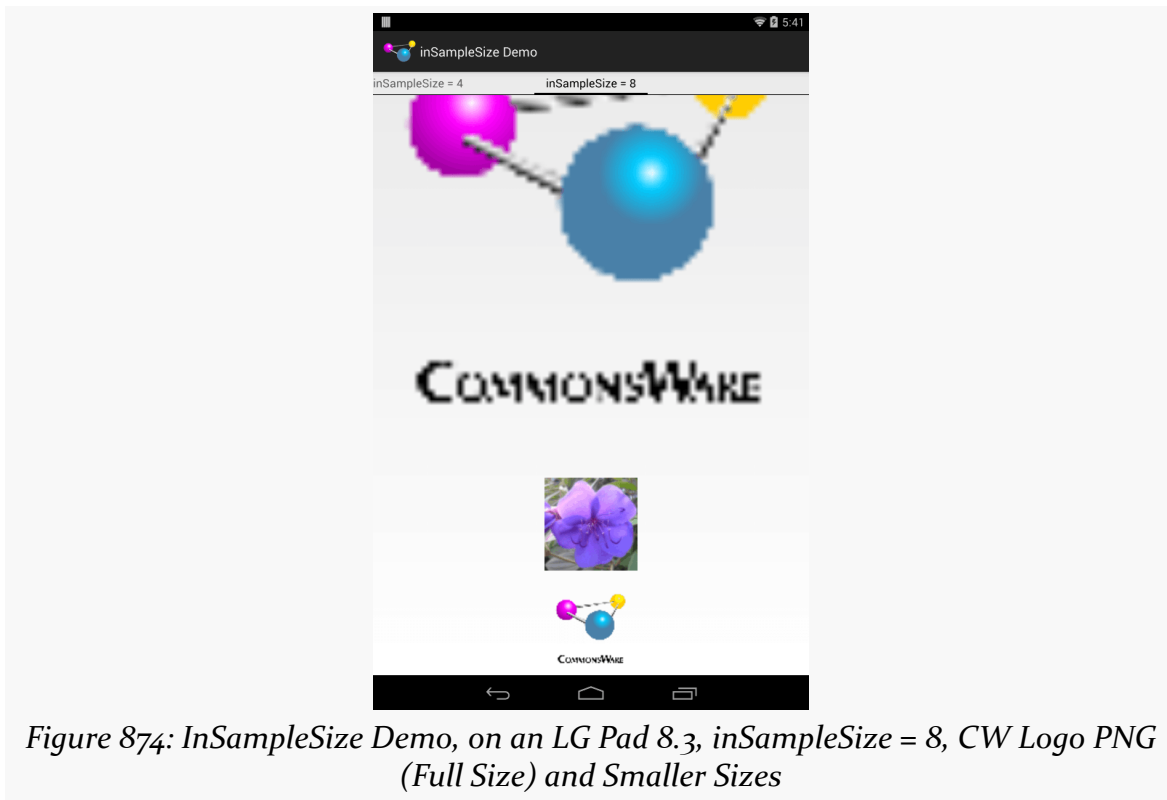

Figure 873: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 8, Flower JPEG, Full Size

The key, though, is the reduced memory footprint. The images loaded without sampling (`inSampleSize` of 1) take up 1,806,336 bytes of heap space (672 x 672 x 4 bytes per pixel). The `inSampleSize` of 8, by contrast, take up 28,244 bytes of heap space, less than 2% of the original.

You should consider experimenting with `inSampleSize` and determine an appropriate sampling level for the types of images you will receive (photos work better than line art) and the sizes you intend to use them in.

Bitmap Color Space

`BitmapFactory` will load images as `ARGB_8888` by default. That means that each pixel takes up four bytes, one each for the red, green, and blue color channels, plus a byte for the alpha channel (transparency).

However, particularly for thumbnails of photographs, where transparency probably does not exist and the image is small when viewed by the user, four bytes per pixel may be overkill.

Instead, you can set `inPreferredConfig` of the `BitmapFactory.Options` to `RGB_565`, which uses only two bytes (five bits for red, six bits for green, five bits for blue, and no transparency). This will cut your memory consumption for the bitmap in half, with no loss of resolution (as you get with `inSampleSize`).

Bitmap Reuse

If you will be doing a lot of work with bitmaps, particularly bitmaps of the same size, an object pool can be of tremendous help to minimize heap fragmentation. You can reuse the same `Bitmap` over and over again, by supplying it via `inBitmap` in the `BitmapFactory.Options` object. If the `Bitmap` is compatible with what you are looking to decode, it will be reused, rather than have a new `Bitmap` (backed by a new hunk of heap space) be created.

Here, “compatible” means:

- The image is the same bit depth configuration (`ARGB_8888` versus `RGB_565`)
- For API Level 18 and below, the resolution is identical; for API Level 19+, the `inBitmap` resolution is the same as or higher than the bitmap to be loaded

Releasing SQLite Memory

SQLite maintains a “page cache” of loaded pages from your database files. Curiously, it does so on a static basis, not on a per-`SQLiteDatabase` basis. Hence, even after you have closed your databases, you might still be consuming more memory than you need to, due to this cache.

From `onTrimMemory()`, you can call the static `releaseMemory()` method on `SQLite`, to try to free up some of this memory. This should not cause any database errors, but it may slow down the next few database accesses, as the necessary pages may no longer be cached and may have to be loaded again from disk.

Cheating

All your efforts at improving memory management may be merely “rearranging deck chairs on the Titanic”. Certain scenarios simply require a lot of system RAM, such as complex image manipulations.

ISSUES WITH APPLICATION HEAP

`android:largeHeap="true"` is one example of “cheating”: working around the heap limits. However, as noted above, you may or may not get a particularly “large” heap, depending upon device capabilities.

The NDK is another option for cheating. The heap limits are for the Dalvik and ART runtime engines. Anything you do in native C/C++ code does not count against that heap limit. Hence, you might consider migrating complex logic into NDK code not only to get a possible boost in execution speed but also to avoid impacting your heap limit.

However, even with the NDK, you may not have enough RAM, because the *system* may not have enough RAM. Android One and similar low-spec devices might have as little as 512MB for the entire *device*, and your app would only be able to use a fraction of that, even from native code. Note that Android devices do not use “swap space” or similar memory paging techniques, and so once system RAM is exhausted, the device is likely to crash.

You can use `isLowRamDevice()` on `ActivityManager` to determine whether the device that your app is running on is considered to have low RAM. Nowadays, that means 512MB or lower of system RAM with a low screen resolution (e.g., 800x480). Before trying to use the NDK to cheat, check whether the device is a low-RAM device. If it is, you may need to disable certain features, rather than potentially crash the system by consuming all available system RAM.

Finding Memory Leaks

Android Studio's heap analyzer is your #1 tool for identifying memory leaks and the culprits behind running out of heap space. Particularly when used with Android 3.0+ versions of Android, the heap analyzer can tell you:

1. Who are the major sources of memory consumption, both directly (e.g., bitmaps) or indirectly (e.g., leaked activities holding onto lots of widgets)
2. What is keeping objects in memory unexpectedly, defying standard garbage collection — the way that you leak memory in a managed runtime environment like Dalvik or ART

Android Studio's heap analyzer builds on the earlier Memory Analysis Tool (MAT), used by Java developers, and by Android developers prior to Android Studio.

However, Android Studio's heap analysis leaves a lot to be desired. Not only do you have to manually examine and check heap dumps, but you get a lot of false positives due to bugs in Android. A library that helps with both of these issues is LeakCanary, and we will examine it in this chapter as well.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#). Reading [the introductory chapter to this trail](#) might be nice.

Android Studio Realtime Monitor

The first question is: when do we bother looking for leaks? Complex apps are complex, and so we might spend a lot of time looking for leaks that either do not exist or do not matter much.

In Android Studio, tabs inside the Android Monitor tool allow you to examine the real-time behavior of your app with respect to various system resources, such as heap space in your app. These tabs appear alongside the “logcat” tab, in a tab strip towards the top of the Android Monitor tool frame.

Figure 875: Android Studio, Android Monitor, Memory Tab

The darker blue shows how much heap space we have allocated, including outstanding garbage. The light blue shows how much free space is in the heap. The overall height indicates the size of our heap.

When you see the dark blue line drop, that means the system performed a garbage collection. Our heap size stayed the same, but memory moved from the allocated state to the free state.

When you see the light blue line rise, that means the system got more memory from the OS and increased the size of our heap. This can continue to the point of reaching the heap limit for the app (`getMemoryClass()` on `ActivityManager`).

On Android 5.0+ devices, the light blue line can also fall... while your app is no longer in the foreground:

FINDING MEMORY LEAKS

Figure 876: Android Studio, Android Monitor, Memory Tab, Showing Shrunken Heap

Here, the app was moved to the background. A little while after that occurs, ART will do a more aggressive garbage collection run, including moving objects in heap space to coalesce free blocks. If this frees up some of the allocated pages from the OS, ART can then free those pages, returning the memory to the OS and reducing our app's overall memory footprint.

You can also perform a manual garbage collection run by tapping the “garbage truck” icon in the toolbar in the memory tab (second down from the top, below the “pause” icon):

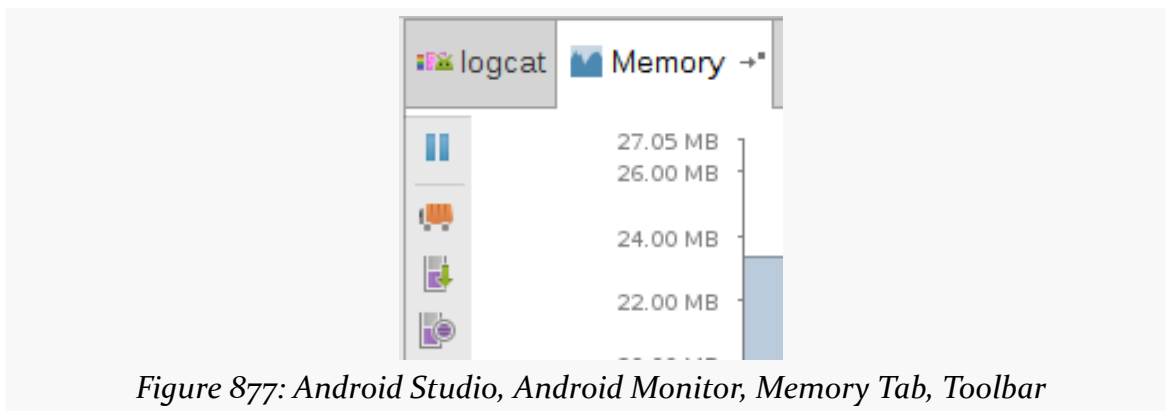

Figure 877: Android Studio, Android Monitor, Memory Tab, Toolbar

Anything in dark blue that survives a full garbage collection (whether manual or ART-induced) represents objects that cannot be garbage collected. If, over time, the level represented by that dark blue area keeps climbing, that suggests a possible memory leak.

FINDING MEMORY LEAKS

Note, though, that the Y axis will automatically rescale, as the overall heap size climbs. That affects everything currently visible in the graph, but that is only ~45 seconds of history. Pay attention to the numbers shown in the legend (in the screenshots, on the right) in addition to the apparent level based upon the graph itself.

If we have a leak, though, while the memory tab will suggest that we have a problem (ever-growing amount of allocated objects after a garbage collection), it will not tell us exactly what is going wrong. For that, we need to analyze our app's heap.

Getting Heap Dumps

The first step to analyzing what is in your heap is to actually get your hands on what is in your heap. This is referred to as creating a “heap dump” — what amounts to a log file containing all your objects and who points to what.

In Android Studio

In the Android Monitor tool in Android Studio, when you have selected a process in the list, a “Dump Java Heap” toolbar button will be enabled in the Memory tab:

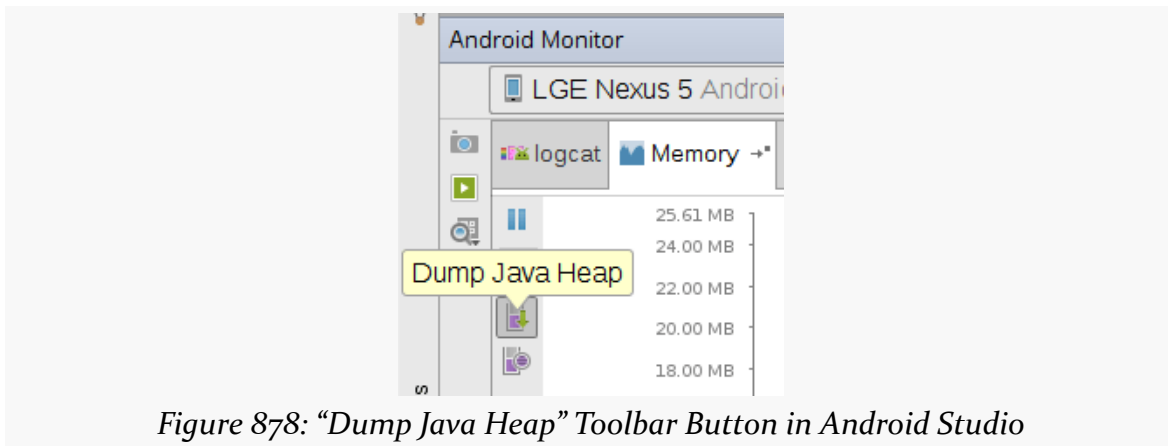

Figure 878: “Dump Java Heap” Toolbar Button in Android Studio

Tapping that, and waiting a few moments, will show the results of the heap dump in a new tab. These results are also saved in your project and are available from the Captures tool later on:

Figure 879: Android Studio, Heap Snapshot in Captures Tool

The actual heap dump data itself — known as an HPROF file — is stored in a `captures/` directory off of your project root. If you wish to use a different tool for analyzing the heap dump, such as MAT, you may be able to use that HPROF file. Note, though, that HPROF files are rather large.

From Code

Another possibility is to trigger the heap dump yourself from code. The `dumpHprofData()` static method on the `Debug` class (in the `android.os` package) will write out a heap dump to the file you indicate. Since these files can be big, and since you will need to transfer them off the device or emulator, it will be best to specify a path to a file on external storage, which means that your project will need the `WRITE_EXTERNAL_STORAGE` permission.

To view the results in Android Studio, you will need to transfer the file to your development machine from wherever you saved it on the device or emulator to your development machine.

Analyzing Heap Dumps in Android Studio

Having a heap dump is nice, but we need tools to determine exactly what is in there and what that means for our app. Fortunately, Android Studio nowadays has an integrated HPROF file tool to let us poke around with the contents of our heap and figure out where we are going wrong.

Navigating the Tab

The tab that you get from viewing a heap dump is... a little difficult to understand at the outset:

FINDING MEMORY LEAKS

The screenshot shows the 'Heap Snapshot Tab' in Android Studio. The main window displays a table with the following columns: Class Name, Total Count, Heap Count, Size of Shallow, and Retained Size. The table lists various classes and their memory usage. Below the table is a 'Reference Tree' section.

Class Name	Total Count	Heap Count	Size of Shallow	Retained Size
FinalizerReference (java.lang.ref)	2379	1103	36	39708
byte[]	5896	3799	0	255685
char[]	69242	19690	0	172206

HttpURLConnection (android.net.http)	1	1	12	12
AndroidShimURLConnection (com.android.okhttp)	1	1	12	12

Figure 880: Android Studio, Heap Snapshot Tab

Let's break this down into component parts.

Class List

The table that comes filled in with data is a list of classes and primitive arrays, sorted by “retained size”. This indicates how much memory those objects, and everything that they point to, consume.

The other columns of particular interest here are:

- **Shallow Size:** how much memory these instances consume in their own primitives, not including any other objects that they point to
- **Total Count:** the number of instances of this class found in your app's heap

(the difference between “Total Count” and “Heap Count” is undocumented, unfortunately)

Heap Selector

The drop-down above the table that defaults to “App heap” will have other options on Android 5.0+ devices. Specifically, you can switch between the regular heap, the undocumented “image heap”, and the equally-undocumented “zygote heap”. The

FINDING MEMORY LEAKS

zygote is a core OS process, started when the device boots; all Android SDK apps are forked off of the zygote. Given that and other announced ART tidbits suggests that:

- the “image heap” may be the large object space, mostly set aside for bitmaps
- the “zygote heap” may be the objects in the heap that were instantiated by the zygote and its initialization of the Android framework classes, as opposed to your code

Package Tree View

The drop-down above the table that defaults to “Class List View” can be toggled to “Package Tree View”, which turns the table into a tree-table, for navigation by Java package name, with primitive arrays interspersed alphabetically:

Class Name	Total Count	Heap Count	Size of Shallow Size	Retained Size
java	106312	41153	965997	74792110
byte[]	5896	3799	0	2556858
char[]	69242	19690	0	1722062
com	8423	7966	183586	859867

17 = {com.commonware.android.picasso.Item@317137216 (0x12e7214)}	10	20	478

Figure 883: Heap Snapshot Tab, Instance List

The “shallow size” refers to the number of bytes consumed directly by that particular instance, such as by primitive fields. The “dominating size” roughly equates to “how much memory can this object be blamed for”. In other words, if that object could be garbage-collected, how much would we recover, not only from the “shallow size” but from other objects uniquely referenced by this object?

The “depth” refers to how many hops away from a garbage collection root (“GC root”) this object is.

This table initially appears as a simple table. In reality, though, it is a tree table. You can expand nodes in the tree to drill down into all the objects referenced by a particular instance:

FINDING MEMORY LEAKS

Figure 884: Heap Snapshot Tab, Instance Tree

Reference Tree

If you highlight an instance in the instance list — or if there is only one instance of the class — the Reference Tree view will be populated. This lists the instance you chose, and drills down into the objects that *reference* this instance. So, if the tree in the instance table shows you what Object X holds onto, the reference tree shows you what holds onto Object X:

Reference Tree	De...	Shallow ...	Dominati...
com.commonware.android.picasso.MainActivity@314742000 (0x12c294f0)	3	204	1140

Figure 885: Heap Snapshot Tab, Reference Tree

You can further expand the tree to see who references some of those references, and so on.

Identifying Leak Candidates

All of that is just great, but you still need to determine if you have a memory leak and, if so, where is it coming from.

Analyzer Tasks

Google recognizes that finding memory leaks is troublesome. The heap snapshot tab has an “Analyzer Tasks” view — by default docked on the right — to try to automate certain checks:

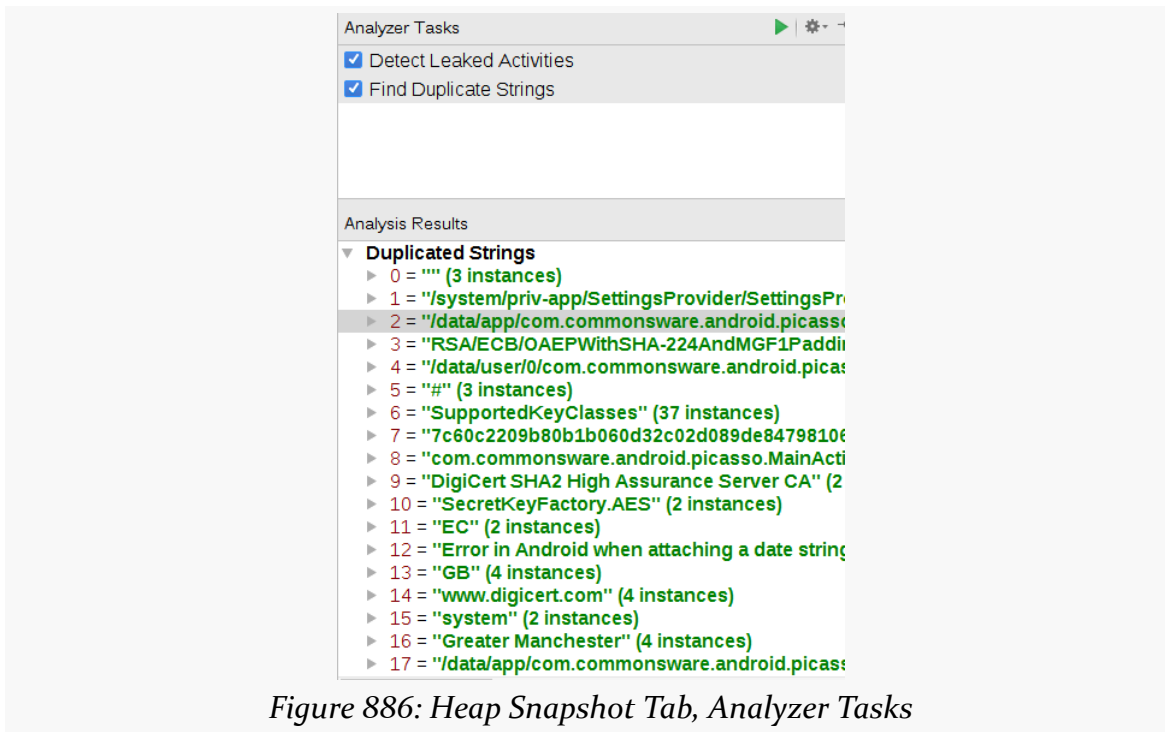

Figure 886: Heap Snapshot Tab, Analyzer Tasks

Clicking the run button in the analyzer tasks toolbar will perform the automated checks.

The two checks that are automated today are finding leaked activities (i.e., activities that have been destroyed but cannot yet be garbage-collected) and duplicate strings. However, most of the duplicate strings are from the framework and zygote, not your code. So, while you may wish to skim through the list of duplicate strings to see if there are any that you recognize, in general they will not be all that useful.

We will see leaked activities more later in this chapter.

By Eyeball

Since the automated checks only catch so many things, you may have to find leak candidates the old-fashioned way: by eyeball. Basically, you rummage through the class list or package tree, looking for classes that either:

- you would not expect to be there (e.g., all instances should have been garbage-collected)
- you would not expect to be so numerous
- you would not expect to retain so much heap space

Bear in mind that the act of generating a heap dump only logs objects that are reachable from other objects, or themselves are considered “garbage collection roots” (a.k.a., “GC roots”). Any objects that are actual garbage, but perhaps have not yet been collected by the garbage collector, do not appear in the dump. Hence, if you see it in the heap snapshot tab, the objects are “real”, not uncollected garbage.

Conversely, just because you find an object in the heap does not mean that it is truly “leaked”. For example:

- Activities that have not been destroyed are not leaked, strictly speaking, though you may wish to consider whether changes to your app’s navigation can allow you to reuse existing activity instances better.
- Objects that are part of a cache, such as Picasso’s memory caching of downloaded images, are intentionally “leaked”. You may use what you see in the heap snapshot tab to elect to reduce the size of those caches, or perhaps better consolidate multiple disparate caches, where possible.
- Objects in use by a running thread are not leaked... unless the thread itself is effectively leaked (i.e., exists, and refers to objects, but you do not know why that thread is still outstanding).

Common Leak Scenarios

With all that in mind, let’s look at a few common scenarios of leaking objects, to see what those leaks look like when we do a heap dump and analyze that dump in Android Studio.

The Static Widget

The [Leaks/StaticWidget](#) sample project does something naughty:

FINDING MEMORY LEAKS

```
package com.commonware.android.button;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;

public class ButtonDemoActivity extends Activity {
    private static Button pleaseDoNotDoThis;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        pleaseDoNotDoThis=(Button)findViewById(R.id.button1);
    }
}
```

(from [Leaks/StaticWidget/app/src/main/java/com/commonware/android/button/ButtonDemoActivity.java](#))

We take a widget (specifically a Button) and put it in a static data member, and never replace it with null.

As a result, even if the user presses BACK to get out of the activity, the static data member holds onto Button, which itself has a reference back to our Activity.

Because we are leaking an activity, the analyzer tasks can automatically find this leak for us:

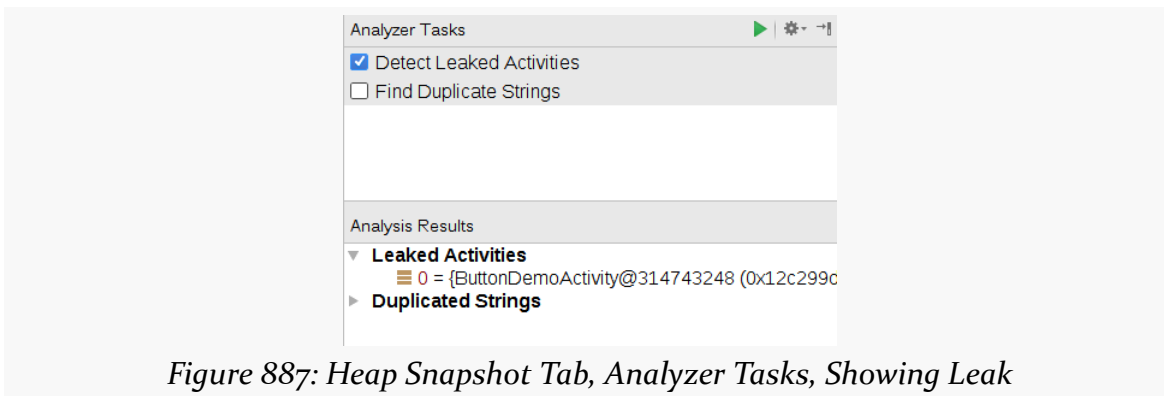

Figure 887: Heap Snapshot Tab, Analyzer Tasks, Showing Leak

Tapping on that ButtonDemoActivity entry in the analyzer tasks brings it up in the instance table and reference tree:

FINDING MEMORY LEAKS

The screenshot shows the Android Studio interface with the Heap Snapshot Tab selected. The Reference Tree is expanded to show the root of the leak: `com.commonware.android.button.ButtonDemoActivity@314743248 (0x12c299d0)`. The tree is sorted by depth, with the root entry at the top. The Analyzer Tasks panel shows 'Detect Leaked Activities' checked. The Analysis Results panel shows 'Leaked Activities' and 'Duplicated Strings'.

Figure 888: Heap Snapshot Tab, Showing Leak

The reference tree is sorted in descending order by depth. Hence, usually, the source of your leak will appear fairly early on in the tree. In our case, it happens to be the first entry:

The screenshot shows the Reference Tree expanded to show the path to the GC root. The root entry is `com.commonware.android.button.ButtonDemoActivity@314743248 (0x12c299d0)`. The tree is expanded to show the path to the leaked object: `mContext in android.widget.Button@314633216 (0x12c0ec00)` -> `pleaseDoNotDoThis in com.commonware.android.button.ButtonDemoActivity`.

Figure 889: Heap Snapshot Tab, Showing Leak and Path to a GC Root

The leaked object (`ButtonDemoActivity`) is referenced by an `mContext` field in a static `pleaseDoNotDoThis` field in `ButtonDemoActivity` itself. The latter item has a depth of 0, so we know that it is a GC root. The hope is that you will recognize some of the items shown here (e.g., field names like `pleaseDoNotDoThis`) and can see how those items affect the ability for Android to garbage collect the leaked object.

Thread References

The [Leaks/LeakedThread](#) sample project does something else naughty:

```
package com.commonware.android.leak.thread;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;

public class LeakedThreadActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        new Thread() {
            public void run() {
                while(true) {
                    SystemClock.sleep(100);
                }
            }
        }.start();
    }
}
```

(from [Leaks/LeakedThread/app/src/main/java/com/commonware/android/leak/thread/LeakedThreadActivity.java](#))

Here, we kick off a Thread from onCreate() of our activity and have it enter a pseudo-polling loop, sleeping for 100ms per pass through the loop.

This is naughty for all sorts of reasons:

- Fast polling loops like this are bad for the battery
- We start a thread and never stop it
- We are using an anonymous inner class for our Thread

The latter two flaws combine to cause a memory leak.

Once again, the analyzer tasks pick up on this leaked activity. However, not all leaks will necessarily show up in the analyzer tasks, in part because not all leaks are leaked activities. What if we were leaking something else?

One way to find leaks is to go through the package tree view, find your Java packages for your code, and see what objects from those packages are outstanding:

FINDING MEMORY LEAKS

Class Name	Total Co...	Heap Co...	Sizeof	Shallow ...	Retained ...
java	64777	1204		33179	4556096
com	58	57		7149	392754
commonsware	2	2		292	264886
android	2	2		292	264886
leak	2	2		292	264886
thread	2	2		292	264886
LeakedThreadActivity\$1 (com.commonsware.android.leak.thread)	1	1	88	88	132516
LeakedThreadActivity (com.commonsware.android.leak.thread)	1	1	204	204	132370

Figure 890: Heap Snapshot Tab, Showing Classes In App Package

Here, we see that we have leaked two objects. One is `LeakedThreadActivity`. The other is an anonymous inner class of `LeakedThreadActivity` (assigned the name `LeakedThreadActivity$1` by the Java compiler).

Clicking on the activity and expanding the first child in the reference tree once again discloses the leak:

Reference Tree	De...	Shallow ...	Dominati ...
com.commonsware.android.leak.thread.LeakedThreadActivity@851902832 (0x32c70170)	1	204	132370
this\$0 in com.commonsware.android.leak.thread.LeakedThreadActivity\$1@851473312 (0x32c073a0)	0	88	132516
referent in java.lang.ref.WeakReference@851453632 (0x32c026c0)	3	24	24
Index 4 in java.lang.Object[5]@1885013408 (0x705b05a0)	2	20	140
array in java.util.ArrayList@1885013384 (0x705b0588)	1	20	160
threadRefs in java.lang.ThreadGroup@1885022864 (0x705b2a90)	0	34	239
val\$Iterable in libcore.util.CollectionUtils\$1@1885013368 (0x705b0578)	1	13	13

Figure 891: Heap Snapshot Tab, Showing Another Leak and Its Path to a GC Root

Our zero-depth entry is `threadRefs`, which is basically the collection of all Java Thread objects that are still alive in this process. One of those is our anonymous inner class (`LeakedThreadActivity$1`), which holds onto the activity instance.

To avoid this sort of leak:

- Do not have everlasting threads — whatever component creates a thread needs to stop the thread when the component is being destroyed
- Do not use anonymous inner classes when creating threads, as an anonymous inner class has an implicit reference back to the outer class instance that created it (in this case, our activity), and that outer class instance cannot be garbage-collected until the thread terminates

Anonymous Handlers

The [Leaks/Downloader](#) sample project is a minor variation on a sample used in this book several years ago, one of the precursors to the downloading samples, such as the one shown in [the chapter introducing services](#).

This early edition of the sample has lots of problems: using HttpClient, doing a bit of network I/O on the main application thread (now removed to avoid the crash), and so on. However, one of the more subtle bugs comes here:

```
private Handler handler=new Handler() {
    @Override
    public void handleMessage(Message msg) {
        Toast
            .makeText(DownloaderDemo.this, "Download complete!",
                Toast.LENGTH_LONG)
            .show();
        finish();
    }
}
```

(from [Leaks/Downloader/app/src/main/java/com/commonsware/android/tuning/downloader/DownloaderDemo.java](#))

Nowadays, this shows up with a yellow warning inspection in Android Studio, with the following explanation:

Since this Handler is declared as an inner class, it may prevent the outer class from being garbage collected. If the Handler is using a Looper or MessageQueue for a thread other than the main thread, then there is no issue. If the Handler is using the Looper or MessageQueue of the main thread, you need to fix your Handler declaration, as follows: Declare the Handler as a static class; In the outer class, instantiate a WeakReference to the outer class and pass this object to your Handler when you instantiate the Handler; Make all references to members of the outer class using the WeakReference object.

And, if you run the app, wait for the activity to finish() itself (which it will do once a download operation completes), and then check with a heap dump, you will see that the activity itself is leaked.

Unfortunately, the nature of Handler makes it a bit difficult to see exactly *why* this results in a leak — the heap inspection tools do not do a great job of pointing this out. With luck, this will be added to a future set of automated checks.

Retaining Too Much

In [the chapter on threads](#), we had an AsyncTask demo app that used a retain fragment to manage the task. That fragment was a ListFragment, and it was responsible for displaying the Latin words as those words were “downloaded” in the background by the task. Google is not a fan of retained fragments having widgets... and the [Leaks/ConfigChange](#) sample project demonstrates why.

The change in this project versus the original mostly comes down to a humble Button, which we will use to restart the download from the beginning once it has completed:

```
<Button
    android:id="@+id/again"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/btn_again"/>
</LinearLayout>
```

(from [Leaks/ConfigChange/app/src/main/res/layout/main.xml](#))

The Button itself is stored as a field in the fragment, named btnAgain. This already raises some concerns, if we are retaining the fragment. However, this approach is safe, if and only if we clear out or refresh that field on a configuration change. For example, if you used findViewById() to get the Button and assign it to btnAgain in onCreateView(), you would not have a problem, as onCreateView() is called as part of the configuration change, even for retained fragments.

However, this sample app instead lazy-initializes that data member, via a getAgain() getter method:

```
private Button getAgain() {
    if (btnAgain==null) {
        btnAgain=(Button)getView().findViewById(R.id.again);
    }

    return(btnAgain);
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

That getter method is used in the rest of the fragment to retrieve the Button, such as in onCreateView():

```
@Override
public void onCreateView(View v, Bundle savedInstanceState) {
    super.onCreateView(v, savedInstanceState);
```

FINDING MEMORY LEAKS

```
getListView().setScrollbarFadingEnabled(false);
setListAdapter(adapter);

getAgain().setOnClickListener(this);

if (task!=null) {
    getAgain().setEnabled(false);
}
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

...onClick() (as the fragment now implements the View.OnClickListener interface):

```
@Override
public void onClick(View v) {
    getAgain().setEnabled(false);
    adapter.clear();
    task=new AddStringTask();
    task.execute();
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

...and onPostExecute() of the AsyncTask:

```
@Override
protected void onPostExecute(Void unused) {
    task=null;
    getAgain().setEnabled(true);
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

Nowhere do we set btnAgain to null, including after a configuration change. So, when the activity starts up, everything is fine. However, when we rotate the screen or otherwise undergo a configuration change, the fragment misbehaves. getAgain() says “hey, btnAgain is already initialized, so I can skip the findViewById() call”. But we have a *different* Button now after the configuration change, and btnAgain is pointing to the original Button. That original Button is tied to the original, pre-configuration change Activity instance, and we have a leak, until the *second* Activity is destroyed.

If you run the app, rotate the screen, and then capture a heap dump, the snapshot will show two outstanding instances of AsyncDemo:

FINDING MEMORY LEAKS

Figure 892: Heap Snapshot Tab, Showing Two Activities Instead of One

However, this leak will be difficult to diagnose, for two reasons:

1. Android Studio's heap analyzer does a poor job of illustrating what is holding onto the activities
2. Not only are you leaking the activities, but so is Android itself, as will be explored in the next section

A Canary in a Leaky Coal Mine

When the author of this book was testing the previous section's demo, he was trying to use Android Studio to confirm that the leak was caused by the Button. As part of that analysis, he went back to the original [Threads/AsyncDemo](#) sample project... and Android Studio said that *it* was leaking the activity.

At this point, a long series of expletives could be heard emanating from the author's office.

To help try to suss out exactly what was going on, the author turned to a library that you may wish to consider: [LeakCanary](#). And, as it turns out, LeakCanary indicates that the Android Studio-reported leak is a false positive, and that there is no serious memory leak.

Introducing LeakCanary

LeakCanary is another library from the indefatigable developers at Square. It allows you to monitor certain objects to see if they get leaked. In particular, if you use the standard setup, it will automatically watch for activities that get leaked. When it detects a leak, it will dump the heap, then read in the heap dump *on the device* and try to determine where the leak is coming from. To help with that, it has a roster of

known false positives that it can filter out, and the authors encourage the community to provide more false positives where possible.

If a leak is detected, but it is a false positive, a message will be dumped to LogCat with the details. If a leak is detected that appears to be genuine, a Notification will appear, leading to an activity that will show you the source of the leak.

Adding LeakCanary to a Project

Adding LeakCanary to a project is fairly easy, courtesy of some well-designed defaults and a tricky use of build type-specific dependencies.

Deal with the Limitations

Unfortunately, LeakCanary has its own set of problems.

First, your project's `compileSdkVersion` needs to be 21 or higher. The author of LeakCanary elected to use `Theme.Material` on Android 5.0+ as the theme for the result activity. Even if you only plan on running your LeakCanary-enabled app on Android 4.4 or below, to compile successfully, you need to have `compileSdkVersion` set to 21 or higher, so that the reference to `Theme.Material` can be recognized. If this is a problem for your project (e.g., team decision to stick with an older `compileSdkVersion` for a while), you are welcome to try to fork LeakCanary and remove that theme.

LeakCanary also has bugs that you might trip over, including:

- [A bug](#) that prevents it from working on Android 6.0
- [A bug](#) that prevents it from working on low-memory environments, including some emulators

Adding the Dependencies

We only want LeakCanary to be used in debug builds, not release builds. Even if we are leaking memory, the effects of LeakCanary (including slow heap dumps) are not the sort of thing that we should be putting users through.

Yet, at the same time, we will need a bit of Java code to hook up LeakCanary itself. Ordinarily, this would require setting up `src/debug/` and `src/release/` source sets and trying to isolate the LeakCanary-specific code to the debug build.

FINDING MEMORY LEAKS

LeakCanary addresses this by publishing two versions of the artifact: the real one (for debug) and a no-op one (for release). The public API for each is identical, so your application code can build in either case. It just so happens that the no-op artifact does nothing in response to the API, as it merely contains stubs necessary to satisfy the API. This is *much* simpler, and for coarse-grained APIs is a technique worth emulating.

The [Leaks/AsyncTask](#) sample project is a clone of the `Threads/AsyncDemo` sample project, but uses LeakCanary. In its app module's `build.gradle` file, we have the twin dependencies, scoped for the appropriate build types:

```
dependencies {
    debugCompile 'com.squareup.leakcanary:leakcanary-android:1.3.1'
    releaseCompile 'com.squareup.leakcanary:leakcanary-android-no-op:1.3.1'
}
```

(from [Leaks/AsyncTask/app/build.gradle](#))

If you have your own custom build types, you would need to adjust the conditional dependencies to match, using the no-op one for any build that should not have the real LeakCanary in it.

Adding the Application

Usually, if you are going to use LeakCanary, it is with the intent of availing yourself of its mostly-automatic detection of leaked activities. The recipe for doing that involves calling `install()` on the LeakCanary class when your process starts, such as in `onCreate()` of a custom Application subclass.

The sample app has such a class, `CanaryApplication`:

```
package com.commonware.android.async;

import android.app.Application;
import com.squareup.leakcanary.LeakCanary;

public class CanaryApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        LeakCanary.install(this);
    }
}
```

(from [Leaks/AsyncTask/app/src/main/java/com/commonware/android/async/CanaryApplication.java](#))

FINDING MEMORY LEAKS

This Application subclass is registered in the manifest, via `android:name` on the `<application>` element:

```
<application
  android:name=".CanaryApplication"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
  <activity
    android:name=".AsyncDemo"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
</application>
```

(from [Leaks/AsyncTask/app/src/main/AndroidManifest.xml](#))

And that is all that you need, for basic integration.

Adding Manual Leak Checks

`LeakCanary.install()` returns a `RefWatcher` object. If all you want to do is use the semi-automatic activity leak detection, you can safely ignore this return value.

However, if you would like to watch for other objects leaking — fragments, domain model objects, threads, etc. — you can hang onto that `RefWatcher` and, where needed, call `watch()` on it to add an object to watch for leaks. Watching for leaks is not terribly expensive but not free, so be judicious in what you are watching.

Testing with LeakCanary

Once you have LeakCanary integrated, you can try out your app and see if it leaks.

Note that the quasi-automatic activity leak detection is based upon the activity lifecycle. LeakCanary considers an activity to be leaked if it is destroyed and there are still unknown strong references to it. This assumes that your activity is destroyed in an ordinary fashion. Hence, how you use your app influences what leaks you find. For example, if you terminate the app process (e.g., swipe away the associated task in the overview screen), you will not find out if any live activities were leaked. Where possible, try to use the BACK button to step your way out of the app when testing, to ensure everything gets destroyed and the most leaks can be found.

The Leak Toast

You will not have a problem determining when a leak is suspected, as a very large Toast-style window appears advertising the fact:

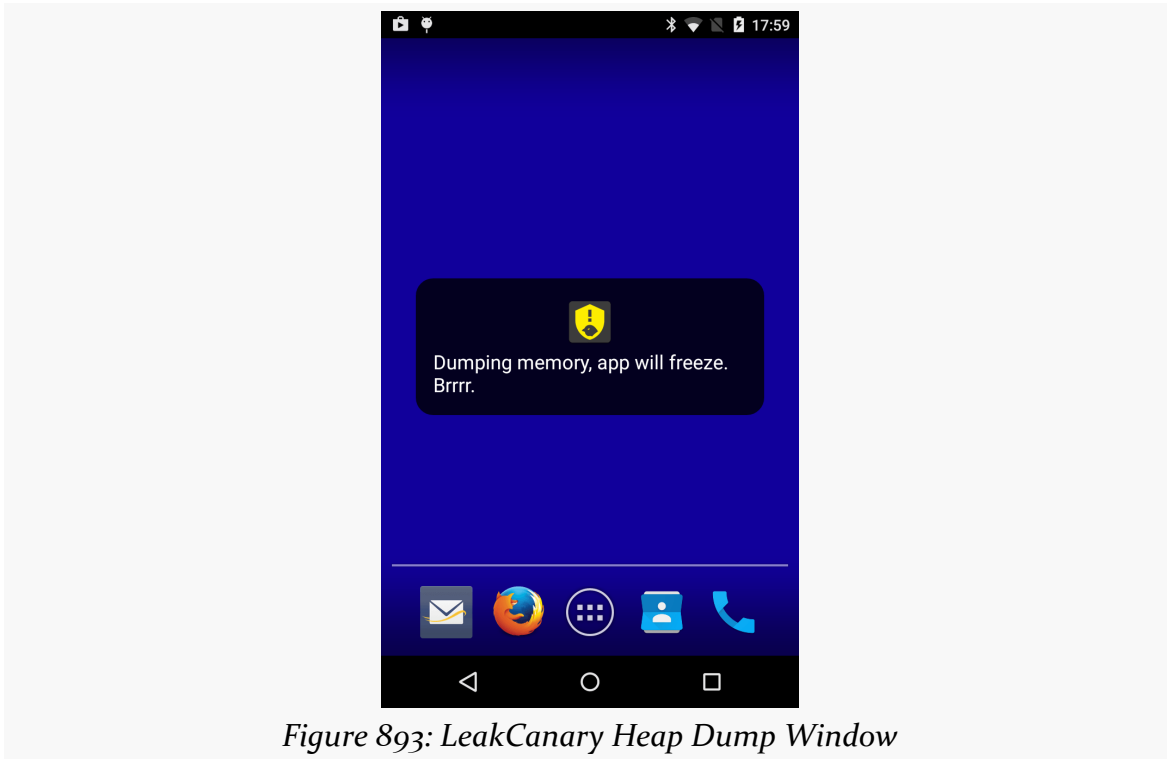

Figure 893: LeakCanary Heap Dump Window

This is another reason not to watch too many objects, as if you get too many false positives, your productivity will suffer, waiting for all the heap dumps.

Note that it may take a few moments after the activity is destroyed before the message appears, and that it may take a long time after the message disappears before you get final results.

LogCat Output

Whether the leak is “for realz” or a false positive, you will get a report in LogCat:

```
12-21 08:23:31.279 7192-8049/com.commonware.android.async D/LeakCanary: In

(the dump of static and instance fields of InputMethodManager goes on for a really long time)

The fact that this just shows up in LogCat (and not via a Notification) and that the LogCat dump has “LEAK CAN BE IGNORED” means that this leak is a known Android issue and is not indicative of a leak in your app.

Notification and Activity Output

The [Leaks/StaticWidgetLC](#) sample project is a clone of the static widget leak scenario from earlier in this chapter. This version has LeakCanary integrated in, though, and LeakCanary catches this leak.

So, after the “Brrr...” window vanishes and you wait several moments for the heap analysis to finish, you will eventually get a Notification from LeakCanary. Tapping that shows a “timeline”-style list of objects, starting with a GC root and ending in the leaked object:

Figure 894: LeakCanary Diagnostic Activity, As Launched From the Notification

Here, we see that `pleaseDoNotDoThis` holds a reference to the `Button`, which holds a reference to the `Activity`.

This has two advantages over using Android Studio’s own leak analysis:

1. It is automatic: we do not have to go and check for leaks ourselves proactively
2. The output can be much easier to read

FINDING MEMORY LEAKS

The “+” icons on the right edge of the rows simply toggle whether the full package name is included in class names:

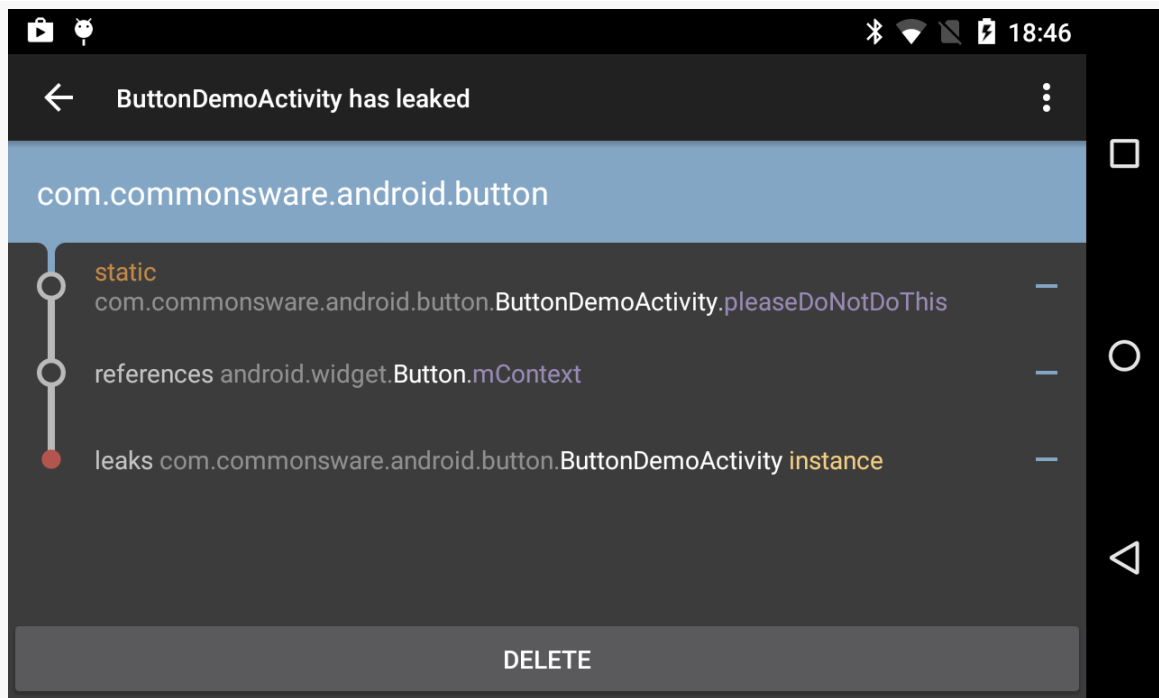

Figure 895: LeakCanary Diagnostic Activity, Showing Full Package Names

The overflow menu has an option to “Share info”, which sends the same information as appears in LogCat to your favorite ACTION_SEND implementation (e.g., an email client). “Share heap dump”, also in the overflow, forwards the heap dump itself via ACTION_SEND, for you to perhaps get over to Android Studio for deeper analysis if that proves necessary.

Pressing the up navigation arrow in the action bar brings up a list of the saved leak reports:

Figure 896: LeakCanary Report Roster

The “DELETE” button on the diagnostic activity deletes that report; the “DELETE ALL” button on the roster activity deletes all saved reports. By default, LeakCanary saves seven reports and heap dumps, though you can configure this by overriding the `__leak_canary_max_stored_leaks` integer resource with some other value.

The LeakCanary project documentation outlines many other possibilities for tailoring LeakCanary’s behavior, including:

- “Whitelisting” certain objects or activity classes, so they do not show up in leak reports
- Sending reports to a server

Issues with System RAM

Your application heap is your little corner of the system RAM on the device that you focus on in your Java development. However, there are other things that you might do that consume system RAM, such as use the NDK to add C/C++ code to your app. How much system RAM you consume overall will have an impact on user acceptance of your app, as the more RAM you use, the more frequently the user's other apps are terminated to make room for you. And, as a result, the more system RAM you use, the more likely it is that *your* process will be terminated when you are not in the foreground, to free up RAM for other apps. Hence, while system RAM is not something you necessarily think about as often as you do your application heap, it is something that you should pay attention to, at least a little bit.

This chapter will explain a bit more about the relationship between your app and system RAM, how you can measure how much system RAM your app is consuming, and how you can reduce that consumption.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#). Reading the chapter on [issues with the application heap](#) is also a good idea.

Can't We All Just Get Along?

Alas, we have not invented the device with infinite RAM, nor the application that takes zero memory. In fact, our devices have fairly limited RAM (e.g., 1GB), and our apps therefore fight over that memory. That includes both apps that the user runs

explicitly (e.g., via the home screen launcher) and apps that run based upon external factors (e.g., the app that receives a [GCM push event](#) and uses that trigger to update some data).

The good news is that the user tends to be a bit oblivious to all of the comings and goings of apps. Android keeps process around while it can and terminates them as needed to free up system RAM for other processes, without the user's explicit involvement. Of course, power users might try to employ "task managers" and the like to be more involved in decision-making, but that's something they opted into, not something that was forced upon them, the way that older mobile operating systems like Windows Mobile required.

However, there is a fundamental assumption in Android that apps play fair. The per-process heap limits — and the fact that apps do not necessarily have to use all the way up to those limits — means that a given Android device can power many processes at once. That starts to break down when apps do various things to consume an excessive amount of system RAM, more than what the per-process heap limit would normally constrain them to. Hence, it is a good idea to keep tabs on how much you use of system RAM, so that you can be a "good citizen" and not cause the user undue angst or force them to employ task managers to try to keep you in line.

Contributors to System RAM Consumption

There are many factors that contribute towards your system RAM consumption, including:

- Your heap usage, up to the per-process heap limit, for each process that you are running
- Your native libraries (.so files) from the NDK
- The system RAM allocated by that native code, which does not count against your per-process heap usage

In addition, the reporting tools usually allocate a portion of shared RAM to your app. Your app's process is forked from the zygote process, which contains the Dalvik runtime environment, framework JAR (for all those `android.*` classes), and related libraries. Your app shares that memory with all other processes forked from the zygote. However, to reflect the fact that there is this overhead, your app's share of it (roughly calculated as the amount of shared RAM divided by the number of processes) tends to get added to your memory consumption totals.

Measuring System RAM Consumption: Tools

Figuring out how much RAM your application is using is not easy. Or, as [Dianne Hackborn](#) put it:

Note that memory usage on modern operating systems like Linux is an extremely complicated and difficult to understand area. In fact the chances of you actually correctly interpreting whatever numbers you get is extremely low. (Pretty much every time I look at memory usage numbers with other engineers, there is always a long discussion about what they actually mean that only results in a vague conclusion.)

Fortunately, particularly in Android 4.4, a fair bit of work has gone into trying to help us determine how much our apps impact system RAM.

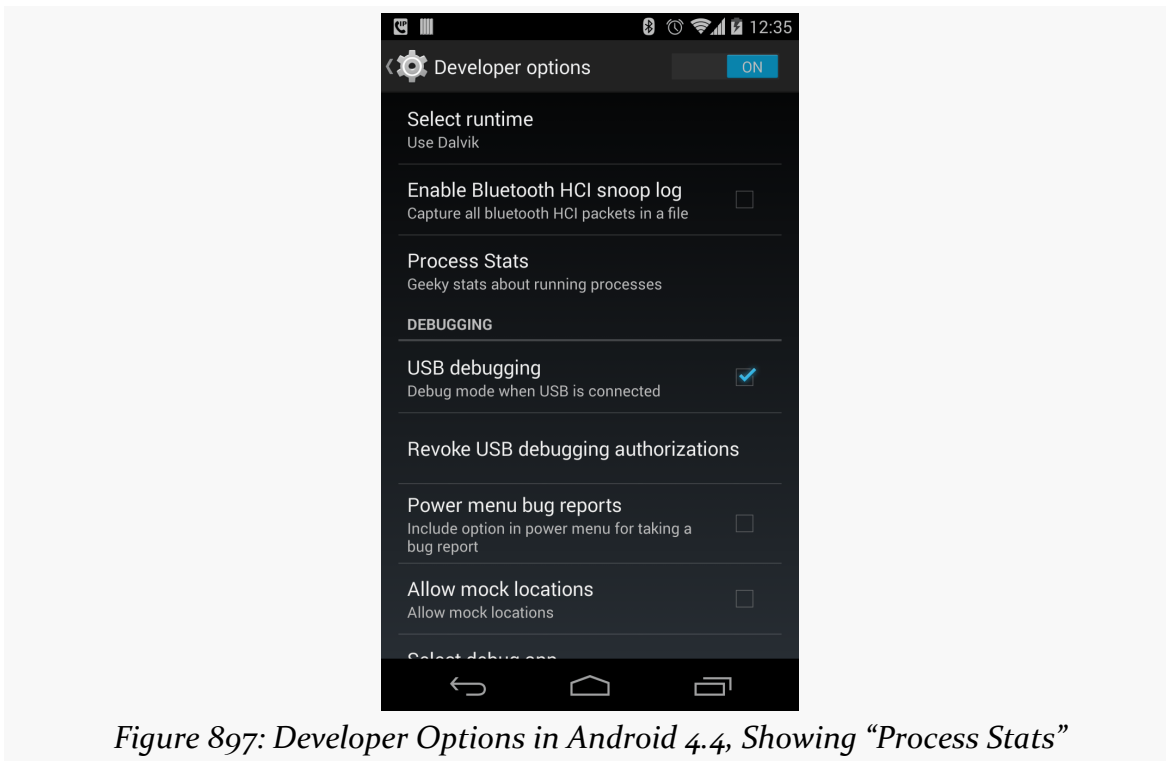

Process Stats in Settings

On Android 4.4, in Settings > Developer Options, you will find:

Process Stats: Geeky stats about running processes

(here, “geeky” is presumably used as a term of endearment)

ISSUES WITH SYSTEM RAM

Tapping on that entry brings up a screen that describes the current state of the system, with respect to RAM:

ISSUES WITH SYSTEM RAM

Figure 898: Process Stats in Android 4.4

While it may look simple, this screen, and its child screens, are remarkably complex, particularly once you start playing around with various options from the action bar overflow.

The Summary

At the top, you will see:

- How much history is being reported in this screen (“1h 47m”)
- What the current status of the system is with respect to RAM (“currently normal”)
- What the status of the system has been over that range of time, as illustrated by the bar, where green is “normal”

The bar is not so much a timeline as a stacked bar chart, where the mix of red and yellow indicates the amount of time the device was in a low-memory state, contrasted with the green “normal” state.

Usually, your device should be “normal” with a mostly-green or completely-green bar.

The Roster

The list beneath the summary shows some running processes. What is included in this list depends on what mode Process Stats is running in. The summary indicates that our mode is “Background apps”. There are three major categories for apps:

1. Foreground, which includes whatever app is truly in the visible foreground, plus any apps that have a foreground service
2. Background, which is pretty much everything else with a service
3. Cached, which are all apps that still have running processes but do not have a service

By default, Process Stats will show background processes.

Each row in the list shows details for a specific process:

- the application label for the app that owns the process (e.g., “K-9 Mail”)
- the percentage of time, for the time period Process Stats is reporting, that this process was running (e.g., “100%”)
- the “relative computed memory load” of that process, as is indicated by the blue bar, with longer blue bars indicating greater load

The list is sorted in order of “relative computed memory load”.

Many background apps will have a running percentage of 100%, indicating that they have an always-running service. Those with a percentage less than 100% indicate an app that had a service running at the point in time of the Process Stats snapshot that you are examining, but did not necessarily have a service running for the entire timeframe (e.g., periodic IntentService doing background work)

Refresh and Duration

There is a “refresh” icon in the action bar that will update the current view to reflect changes since you last opened or refreshed the screen.

How long the timeframe is depends a bit upon device operation and also on the “Duration” entry in the overflow menu:

Figure 899: Process Stats Overflow in Android 4.4

Tapping that gives you a roster of available timeframes:

Figure 900: Process Stats Duration Options in Android 4.4

Even though these items render with checkboxes, they function as radio buttons, so whatever you tap on becomes the new duration. Upon making a change, the summary area will reflect the newly-chosen duration. Note that this choice is not

persistent, as exiting Process Stats via the BACK button and re-entering it returns you to a three-hour duration.

Controlling What is Shown

If your application is not showing up in the background roster, it may be classified as “foreground” (e.g., if you have a foreground service) or “cached” (if not). The “Stats type” overflow option will let you toggle between these categories, to see what processes are reported in each.

Note that an app can appear in more than one roster, since the roster is by *process*. For example, at the time of this writing, Evernote appears in the author’s Nexus 4 both in “foreground” and in “cached”, for separate processes.

As with the duration, the choice of category is not persistent, and you will be returned to the background process roster if you exit Process Stats via the BACK button and later return to it.

Drilling Down Into an App

Tapping on an item in the list will bring up details about that particular app and process:

ISSUES WITH SYSTEM RAM

Figure 901: Process Stats Details for K-9 Mail

The “Average RAM use” value shows how much system RAM is attributed to your app. This will include:

- All system RAM used uniquely by your app (e.g., your heap)
- A portion of system RAM shared by your app and others (e.g., the Dalvik runtime)

This is known as “Proportional Set Size” or “PSS” in Linux, and is a common way of coming up with a simple number for the amount of RAM that a particular process is responsible for.

The blue bar is based on this average RAM use (or PSS) value, multiplied by the percentage of the time that the process was running.

The “Maximum RAM use” value is the highest PSS associated with your process during the period under examination.

Also listed are the services of your app and the percentage of time that they were in a running state. Everlasting services will show up as 100%, while transient services (e.g., IntentService) will show up with a much smaller percentage.

How You Want Your App to Appear

Ideally:

- Your app spends most of its time in the “cached” process list, not the “background” or “foreground” list
- Your app has a low percentage of time spent running
- Your app has a low “relative computed memory load” and, ideally, a low “Average RAM use” value

The better you are in these areas, the more likely it is that you are not seriously impacting system RAM.

procstats

The data that powers the Process Stats screen in Settings is also available as human-readable text output, using the `adb shell dumpsys procstats` command, against your Android 4.4 device or emulator.

Running that command will give you three blocks of information:

- Process memory usage, aggregated over the last 24 hours
- Process memory usage, aggregated over the last 3 hours
- A snapshot of the current memory usage, at the time you ran the command

This can be a long report, even for just one of those blocks. For example, here is the last-3-hours block, run on the author’s personal Nexus 4:

```

ISSUES WITH SYSTEM RAM

Unfortunately, it is rather cryptic and rather long.

There are various command-line switches you can add to help manage the output. Use the `-h` switch to see the full roster. Some notable options:

- `-csv` switches the output to be in CSV format, for importing into a spreadsheet or running through an analysis tool, with other switches (e.g., `-csv-proc`) to control what is included in the CSV output
- `--current` will only report the current snapshot
- `--hours NNN` will only report the aggregate over the stated number of hours
- `--full-details` provides a somewhat more documented report, at the cost of greatly increasing its verbosity

Also, including a package name (e.g., `com.commonware.android.sample`) at the end of the command line will constrain the output to solely that package, which is useful if you are only looking to examine your own app's data.

The numbers in parentheses (e.g., (4.7MB-4.7MB-4.7MB/3.8MB-3.8MB-3.8MB over 2)) report:

- the minimum proportional set size (PSS) seen
- the average PSS seen
- the maximum PSS seen
- the minimum unique set size (USS) seen, where this is the amount of memory consumed by your app that is *not* shared with other processes (i.e., it is how much memory that would be freed if your process were terminated)
- the average USS seen
- the maximum USS seen
- the number of samples taken of the memory during the timeframe being analyzed

The listing also shows the percentage of time your process was in various states (e.g., cached vs. service vs. “important foreground”)

meminfo

Older devices that do not support `procrank` can support `meminfo`, accessed via `adb shell dumpsys meminfo`. Run as-is, it will generate a report of all processes and their PSS, plus the same roster broken down into various process categories (e.g., foreground, cached), and other summary data. The report for the same Nexus 4 that generated the `procrank` shown earlier in this chapter is:

DATABASES

pgsz	dbsz	Lookaside(b)	cache	Dbname
1	6263	17	0/16/1	/data/data/com.commonware.books.android/databases/booksearch.db

This can show you:

- How much memory is being consumed by your Dalvik bytecode (.dex mmap), native libraries used directly by you or by framework components (.so mmap), etc.
- How many objects of various types are in the Dalvik heap, such as views and activities
- How much memory is used by SQLite for its page cache and related process-level buffers, plus which databases you have open that are contributing to memory consumption

Note that the combination of the Private Dirty and Private Clean columns is roughly analogous to the USS reported by procstats, in that it represents the amount of memory private to your process and that would be released should your process be terminated.

Measuring System RAM Consumption: Runtime

Some of the same information that the aforementioned reports contain is available at runtime via `ActivityManager` and other framework classes.

`getMemoryInfo()`

`getMemoryInfo()` on `ActivityManager` will fill in a supplied `ActivityManager.MemoryInfo` object. This will report to you:

- The total memory on the device (`totalMem`)
- The “available memory” (whose definition is a bit unclear) (`availMem`)
- What level of “available memory” is considered “low” and should trigger Android to start terminating processes beyond those that are cached, such as ones with running services (`threshold`)
- Whether we are presently in such a low-memory state (`lowMemory`)

`getMyMemoryState()`

`ActivityManager` also has a `getMyMemoryState()` method, on API Level 16+, that will populate an `ActivityManager.RunningAppProcessInfo` object with information about your process. While not everything in this object will be filled in, you will be able to get:

- The last trim level reported to your activities and `Application` via `onTrimMemory()` (`lastTrimLevel`)
- What importance level the OS considers your process to be in (`importance`), such as `IMPORTANCE_FOREGROUND` and `IMPORTANCE_EMPTY`
- For processes in the `IMPORTANCE_BACKGROUND` category — meaning the process has outstanding activities but is not in the foreground and has no service — the relative standing of the process compared to other background processes from a least-recently-used standpoint (`lru`), where lower numbers mean more recent usage

`getProcessMemoryInfo()`

The `getProcessMemoryInfo()` method on `ActivityManager` returns an array of `Debug.MemoryInfo` objects corresponding to the array of `int` process IDs (`pids`) that you pass in. The `Debug.MemoryInfo` objects report how much memory those

identified processes are consuming. Of particular note, `getTotalPss()` returns the PSS for that process.

To get the `Debug.MemoryInfo` for your own process, you can use `getMemoryInfo()` on the `Debug` class, rather than find your own process ID and use `getProcessMemoryInfo()`. Or, on API Level 14+, you can simply call `getPss()` on `Debug` directly to find out your PSS.

Learn To Let Go (Of Your Heap)

Part of the reason for worrying a bit about your system RAM consumption is simply to “play nice” with the other apps that the user wants to use. However, since part of Android’s decision-making about what processes to terminate tie into how much RAM those processes take up, the lower your system RAM footprint, the more likely it is that you can hang around for a while.

Part of reducing your system RAM consumption involves cleaning up your heap.

The reason the framework calls callback methods like `onTrimMemory()` is to help you reduce your heap usage to avoid `OutOfMemoryError` exceptions. However, allowing objects to be garbage-collected not only gives you more heap space, but it *also may reduce your system RAM footprint*.

To limit your system RAM usage, your process is not allocated all of its possible heap when the process is started up. Instead, the heap starts small and expands as you allocate more and more memory. However, the reverse is also true: if you release memory, the heap can shrink, returning RAM to the system. Android expands the heap on a “paged” basis, allocating more system RAM to add more pages to the heap. If, as a result of garbage collection, Dalvik sees that there are too many totally empty pages, Dalvik can free up those pages, returning them to the OS for use by other processes.

As noted in [the chapter on the application heap](#), Dalvik’s garbage collector is **non-compacting**, meaning that it does not move objects around to try to clean up pages or otherwise coalesce free memory blocks. Hence, a fragmented heap not only limits how well you can allocate new memory, but it also inhibits Dalvik’s ability to reduce your system RAM usage.

Issues with Battery Life

Most Android devices are powered by batteries — Android TV is the biggest class of device that is not. Batteries are wonderful gizmos with one major problem: they are *always* running out of power.

Hence, users are very sensitive to battery consumption. Their ability to use their phones as actual *phones*, let alone for Android apps, depends on having enough battery power. The more apps drain the battery, the more frequently the user has to find a way to recharge the phone, and the more frequently the user fails and their phone shuts down.

The catch is that you may not notice the battery issues in your day-to-day development. The Android emulator's emulated battery does not drain based on you running your app. Your devices are often connected to your development machine via USB for testing and debugging, meaning they are perpetually being charged. Unless you are a regular user of your own app, you might not notice any increased power drain.

This part of the book is focused on helping you understand what is draining power and what you can do to be kinder and gentler on your users' batteries.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

You're Getting Blamed

Users, for better or worse, have limited ability to determine what is responsible for draining the battery of their phone. Their #1 tool for this is the “Power Usage Summary” screen in the Settings app, sometimes referred to as the “battery blame screen”.

Figure 902: Battery Screen from Settings App

This lists both device features (e.g., the display) and applications. Android incrementally improves the accuracy of this screen with each passing release, trying to make sure the user understands what specifically is consuming the power.

If your application starts appearing on this screen, and the user does not feel that it is justified, the user is likely to become irritated with you.

Now, your appearance on this list might be perfectly reasonable. If you have written a video player app, and the user has just watched a few hours' worth of video, it is very likely that you will appear on this list and will be justified in your battery consumption.

However, anything that you can do to not appear on this screen, or appear lower in the list, will help with user acceptance of your app.

This part of the book will show you how to measure your power usage and ways of trying to use less of it.

Not All Batteries Are Created Equal

Roughly speaking, battery capacity is proportional to screen size. Larger screens mean physically larger devices, and since the rest of the components (e.g., CPU) tend to be the same size, a larger device offers more room for a larger battery. This is good, as the screen is one of the major power draws on a device, and bigger screens draw more power.

Conversely, the battery on a “wearable” — whether eyewear like Google Glass, a smartwatch, or other form factors — tends to be much smaller than average, just because the wearables are physically smaller. A wearable is likely to have a battery with less than a third of the capacity of a phone, which in turn may have a battery with less than a third of the capacity of a large tablet.

Hence, depending upon where your app will be running, the amount of battery available in total will vary widely. What might be considered acceptable battery consumption on a tablet would be considered excessive on a wearable.

Stretching Out the Last mWh

Sometimes, what the user wants your app to do in one case is not what the user wants your app to do in other cases. Serious power-draining might be reserved for when the device is plugged in, or when the device has at least such-and-so power remaining. The user may value the last milliwatt-hours (mWh) more than others and want your application to use less power in those circumstances.

Hence, if your application polls the Internet, you might offer a feature to poll less frequently, or perhaps not at all, when power is low. If your application uses GPS to find a location (e.g., automatic “check-ins” to social networks like Foursquare), you might offer to skip such actions when the battery is low. You might want to signal to the user when the battery gets low during playback of a video, or during the game they are in. And so on.

ISSUES WITH BATTERY LIFE

This part of the book will help you identify when the battery is low and strategies for making use of that information.

Power Measurement Options

As with any situation where you are trying to reduce your use of some system resource, you need to be able to accurately measure how much you are using that resource. Otherwise, you will have no idea whether your attempts to reduce usage are helping. It is possible that what you think will consume less of the resource actually consumes *more*, because of unanticipated side-effects. And, if nothing else, if the change makes your code more complicated and does not help much with resource consumption, you may be better served sticking with the original, simpler implementation.

So, when it comes to power usage, it helps to know how much power you are consuming, to determine if your attempts to use less power actually do help.

Unfortunately, compared to things like RAM and bandwidth, power measurement is a significant challenge. You really need to have hardware specifically instrumented to report power consumption for pieces of that hardware (CPU versus screen versus GPS versus mobile data radio versus ...). Even if you cannot get power usage per component, just having accurate power consumption overall is not something you can necessarily get from any Android device. Alas, getting that level of power usage knowledge can be troublesome in its own right, for a variety of reasons.

This chapter will explore a few ways of measuring power usage, along with the pros and cons of that approach.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

batterystats and the Battery Historian

Android 5.0 brought us “Project Volta”, an initiative to reduce the amount of power consumed by apps, the framework classes, and the OS itself.

Part of what we got from Project Volta is batterystats, a dump of data pertaining to power consumption. Since that data dump can be large and inscrutable, we also have the Battery Historian, a tool that can convert key batterystats output into a timeline of events.

However, none of this is especially well-documented at this time, and so the usefulness of these utilities is limited at present. The following sections provide some basic guidance for trying to use these tools.

Running a Test

First, since batterystats is obtained via `adb shell dumpsys`, you will want `adb` to be in your `PATH`, by adding your SDK installation’s `platform-tools/` directory to your `PATH` environment variable.

Then, in a terminal, run:

```
adb shell dumpsys batterystats --enable full-wake-history
adb shell dumpsys batterystats --reset
```

This will ensure that batterystats captures all relevant information about `WakeLock` behavior, and it resets all of the logs.

At this point, run your tests. Ideally, you would do so in a fairly power-neutral environment, such as not using a USB cable for an `adb` connection (as that charges the device).

When your test scenario is complete, run `adb shell dumpsys batterystats`, redirecting the output to some file:

```
adb shell dumpsys batterystats > /tmp/bs.txt
```

You can optionally supply your `applicationId` as part of the `batterystats` command, which will restrict the output to events pertaining to your app. However, some events that are from other processes, like the Play Services Framework, may be

POWER MEASUREMENT OPTIONS

of interest to you. You will need to experiment to determine which mode (full or filtered for your app) will work best for you.

Interpreting the Text Output

Depending on how long your test runs, the information included in the batterystats output can be anywhere from tens of KB to tens of MB in size. The output will also vary by Android OS release.

Battery History

The file will lead off with the “Battery History” section:

```

+6s946ms (2) 100 -wake_lock_in=u0a7:"GCoreFlp"  
+6s968ms (2) 100 -wake_lock_in=1027:"NfcService:mRoutingWakeLock"  
.  
.  
.
```

This contains information about how much the battery was drained during the test run, along with a detailed roster of the power-related events that occurred during the test run. The timestamps on those roster entries are relative to the first entry in the roster. Beyond that, there is little explanation of what the roster entries mean.

Per-PID Stats

Next, there will be a short stanza labeled “Per-PID Stats” and, possibly, “Discharge step durations”:

```
Per-PID Stats:  
PID 0 wake time: +134ms  
PID 536 wake time: +1m35s993ms  
PID 0 wake time: +10s842ms  
PID 881 wake time: +301ms  
PID 536 wake time: +70ms  
PID 989 wake time: +23s167ms  
PID 1136 wake time: +2s974ms  
PID 1193 wake time: +230ms  
PID 0 wake time: +1s123ms  
PID 617 wake time: +187ms  
PID 536 wake time: +18ms  
PID 536 wake time: +13ms  
PID 627 wake time: +586ms  
PID 536 wake time: +184ms  
PID 3690 wake time: +9m42s965ms  
  
Discharge step durations:  
#0: +4h8m36s976ms to 97 (screen-off, power-save-off)  
#1: +3h7m47s132ms to 98 (screen-off, power-save-off)
```

If you determine your process’ PID, you will see how long the process’ “wake time” was. The precise definition of “wake time” is undocumented.

Daily Stats

Next may be a section entitled “Daily stats”:

```
Daily stats:
Current start time: 2015-12-12-05-27-33
Next min deadline: 2015-12-13-01-00-00
Next max deadline: 2015-12-13-03-00-00
Package changes:
  Update com.google.android.dialer vers=20312
  Update com.google.android.apps.cloudprint vers=113
  Update com.android.chrome vers=252608301
  Update com.google.android.marvin.talkback vers=40400003
  Update com.google.android.contacts vers=10307
  Update com.commonware.empublite vers=1
  Update com.commonware.android.picasso vers=1
Daily from 2015-12-11-05-55-34 to 2015-12-12-05-27-33:
Discharge step durations:
  #0: +4h49m4s38ms to 93 (screen-off, power-save-off, device-idle-on)
  #1: +3h53m22s969ms to 94 (screen-off, power-save-off)
  #2: +5h8m4s10ms to 95 (screen-off, power-save-off, device-idle-on)
  #3: +3h33m53s102ms to 96 (screen-off, power-save-off, device-idle-on)
  Discharge total time: 18d 3h 10m 2s 900ms (from 4 steps)
  Discharge screen off time: 18d 3h 10m 2s 900ms (from 4 steps)
  Discharge screen off device idle time: 18d 18h 33m 58s 300ms (from 3 steps)
Package changes:
  Update com.commonware.empublite vers=1
Daily from 2015-12-10-04-55-48 to 2015-12-11-05-55-34:
Discharge step durations:
  #0: +5h1m15s618ms to 98 (screen-off, power-save-off, device-idle-on)
  #1: +42m34s7ms to 98 (screen-off, power-save-off, device-idle-off)
  Discharge total time: 11d 22h 31m 21s 200ms (from 2 steps)
  Discharge screen off time: 11d 22h 31m 21s 200ms (from 2 steps)
  Discharge screen off device idle time: 20d 22h 6m 1s 800ms (from 1 steps)
Package changes:
  Update com.commonware.ct3 vers=1
  Update com.commonware.ct3 vers=1
  Update com.commonware.ct3 vers=1
  Update com.commonware.ct3 vers=1
  Update com.commonware.ct3 vers=1
  Update com.commonware.ct3 vers=1
  Update com.commonware.ct3 vers=1
  Update com.commonware.android.fsendermnc vers=1
...
```

This indicates, for various time slices, what apps were updated and what the “discharge step durations” are (which is undocumented).

“Statistics since last charge” Summary

Next up will be a “Statistics since last charge” header, with a few summary blocks of data:

POWER MEASUREMENT OPTIONS

Statistics since last charge:

System starts: 0, currently on battery: false
Time on battery: 11h 30m 29s 177ms (99.9%) realtime, 16m 13s 306ms (2.3%) uptime
Time on battery screen off: 11h 30m 7s 940ms (99.9%) realtime, 15m 52s 69ms (2.3%) uptime
Total run time: 11h 30m 55s 300ms realtime, 16m 39s 430ms uptime
Start clock time: 2014-10-25-19-54-07
Screen on: 21s 237ms (0.1%) 2x, Interactive: 20s 191ms (0.0%)
Screen brightnesses:
 dark 21s 237ms (100.0%)
Total partial wakelock time: 10m 22s 877ms
Mobile total received: 0B, sent: 0B (packets received 0, sent 0)
Phone signal levels:
 none 11h 30m 29s 177ms (100.0%) 0x
Signal scanning time: 9s 0ms
Radio types:
 none 11h 30m 29s 177ms (100.0%) 0x
Mobile radio active time: 0ms (0.0%) 0x
Wi-Fi total received: 0B, sent: 0B (packets received 0, sent 0)
Wifi on: 11h 30m 29s 177ms (100.0%), Wifi running: 11h 30m 29s 177ms (100.0%)
Wifi states: (no activity)
Wifi supplicant states:
 group-handshake 16ms (0.0%) 12x
 completed 11h 30m 29s 161ms (100.0%) 12x
Wifi signal levels:
 level(4) 11h 30m 29s 177ms (100.0%) 1x
Bluetooth on: 0ms (0.0%)
Bluetooth states: (no activity)

Device battery use since last full charge

Amount discharged (lower bound): 2
Amount discharged (upper bound): 3
Amount discharged while screen on: 0
Amount discharged while screen off: 3

Estimated power use (mAh):

Capacity: 3448, Computed drain: 107, actual drain: 69.0-103
Idle: 40.3
Wifi: 36.4
Uid u0a58: 14.8
Uid 0: 12.8
Uid 1000: 1.75
Uid u0a20: 0.521
Uid u0a7: 0.389
Screen: 0.375
Uid 1013: 0.0775
Uid 1001: 0.0219
Uid u0a42: 0.0168
Uid u0a12: 0.0138
Uid 1027: 0.0110
Uid u0a5: 0.00866
Uid u0a33: 0.00253
Uid u0a16: 0.000867
Uid u0a3: 0.000815
Uid u0a29: 0.000523
Uid u0a2: 0.000474
Over-counted: 4.04

POWER MEASUREMENT OPTIONS

The first block has useful data about how much various radios were on, how much data they transmitted, how long the screen was on, how long the device had an outstanding partial WakeLock, etc.

Also, the “Estimated power use (mAh)” block is basically the data that underlies the “battery blame screen” in Settings. You will see how many milliamp-hours (mAh) were attributed to your process.

WakeLock Summary

Next up may a summary of WakeLock events:

All kernel wake locks:

```
Kernel Wake lock PowerManagerService.WakeLocks: 10m 23s 46ms (717 times) realtime
Kernel Wake lock qcom_rx_wakelock: 9m 9s 836ms (1537 times) realtime
Kernel Wake lock alarm_rtc: 55s 327ms (717 times) realtime
Kernel Wake lock sns_async_ev_wakelock: 16s 525ms (9 times) realtime
Kernel Wake lock power-supply: 15s 730ms (1448 times) realtime
Kernel Wake lock event0-536: 11s 822ms (1484 times) realtime
Kernel Wake lock event2-536: 10s 686ms (1509 times) realtime
Kernel Wake lock event4-536: 10s 234ms (1509 times) realtime
Kernel Wake lock alarm: 7s 972ms (1239 times) realtime
Kernel Wake lock wlan: 1s 608ms (2 times) realtime
Kernel Wake lock PowerManagerService.Display: 611ms (2 times) realtime
Kernel Wake lock main: 608ms (0 times) realtime
Kernel Wake lock KeyEvents: 136ms (1548 times) realtime
Kernel Wake lock mmc0_detect: 38ms (1507 times) realtime
Kernel Wake lock deleted_wake_locks: 28ms (170 times) realtime
Kernel Wake lock event5-536: 20ms (2 times) realtime
```

All partial wake locks:

```
Wake lock u0a58 wake:com.commonsware.android.job/.DemoScheduledService: 9m 0s 153ms (671 times) realtime
Wake lock 1000 *alarm*: 44s 114ms (683 times) realtime
Wake lock u0a7 Checkin Service: 16s 572ms (4 times) realtime
Wake lock 1000 NetworkStats: 7s 347ms (338 times) realtime
Wake lock 1013 AudioMix: 5s 833ms (2 times) realtime
Wake lock 1000 DHCP: 4s 953ms (12 times) realtime
Wake lock u0a7 *net_scheduler*: 1s 504ms (82 times) realtime
Wake lock u0a7 Event Log Service: 1s 98ms (18 times) realtime
Wake lock u0a42 DownloadManager: 322ms (1 times) realtime
Wake lock u0a7 Config Service fetch: 235ms (1 times) realtime
Wake lock u0a7 Icing: 197ms (5 times) realtime
Wake lock u0a7 Event Log Handoff: 143ms (18 times) realtime
Wake lock u0a58 *alarm*: 120ms (24 times) realtime
Wake lock u0a7 GCM_CONN: 61ms (36 times) realtime
Wake lock u0a7 GmsDownloadService: 47ms (1 times) realtime
Wake lock u0a7 *alarm*: 42ms (10 times) realtime
Wake lock u0a7 Wakeful StateMachine: GeofencerStateMachine: 35ms (8 times) realtime
Wake lock 1000 SyncManagerHandleSyncAlarm: 34ms (6 times) realtime
Wake lock u0a7 GCM_HB_ALARM: 34ms (36 times) realtime
Wake lock u0a7 Checkin Handoff: 12ms (4 times) realtime
Wake lock 1000 SyncLoopWakeLock: 8ms (4 times) realtime
Wake lock u0a33 *alarm*: 7ms (4 times) realtime
```

POWER MEASUREMENT OPTIONS

```
Wake lock u0a42 *alarm*: 4ms (3 times) realtime
Wake lock u0a7 GCoreFlp: 2ms (5 times) realtime
```

If you do not have a separate section for these, they may be interleaved in the “Statistics since last charge:” data.

Your code will tend to show up in the “All partial wake locks” section, showing how many WakeLocks you acquired and for how long overall.

And, if you show up here, you can definitely find out your app’s PID — for example, u0a58 is associated with the com.commonware.android.job package.

Per PID Summary

Next up may be summaries of information per process; otherwise, this information is interleaved in the “Statistics since last charge:” section. Your process will show up somewhere in the list:

```
.
.
.
u0a58:
  Wake lock wake:com.commonware.android.job/.DemoScheduledService: 9m 0s 153ms partial (671 times)
  realtime
  Wake lock *alarm*: 120ms partial (24 times) realtime
  TOTAL wake: 9m 0s 273ms partial realtime
  Foreground activities: 7s 817ms realtime (1 times)
  Foreground for: 12s 959ms
  Active for: 3h 58m 47s 853ms
  Running for: 11h 30m 29s 177ms
  Proc com.commonware.android.job:
    CPU: 1m 4s 370ms usr + 21s 140ms krn ; 400ms fg
  Proc *wakeup*:
    CPU: 43s 690ms usr + 1m 19s 590ms krn ; 0ms fg
  Apk com.commonware.android.job:
    672 wakeup alarms
  Service com.commonware.android.job.DemoScheduledService:
    Created for: 11m 14s 174ms uptime
    Starts: 647, launches: 647
.
.
```

As usual, the exact definitions of the information here is largely undocumented.

Installing the Battery Historian

While batterystats is part of the Android 5.0+ runtime environment, and tools like adb are part of the Android SDK, the Battery Historian is neither. Instead, it is a

separate project that you have to download to your development machine from [its GitHub project](#).

The original implementation of the Battery Historian was a Python script. This is still available as the `historian.py` file in that GitHub repository, until such time as Google elects to delete it.

Battery Historian 2.0 is now a server written in the Go programming language. This requires a fair bit more work to set up, as you need to:

- install a Go compiler
- download Go dependencies manually
- modify your `PATH` environment variable, plus add new environment variables
- deal with the intrinsic hassles and risks of running an unnecessary server

This chapter focuses on the original Python script.

Running the Battery Historian

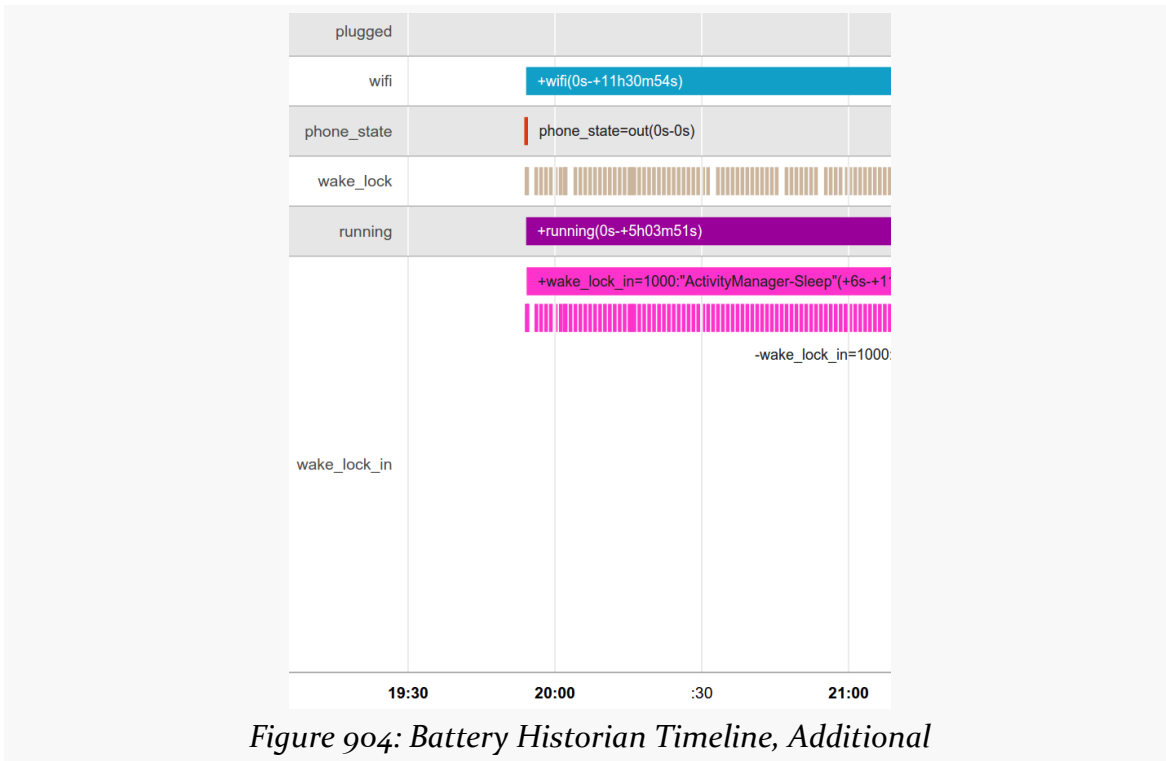

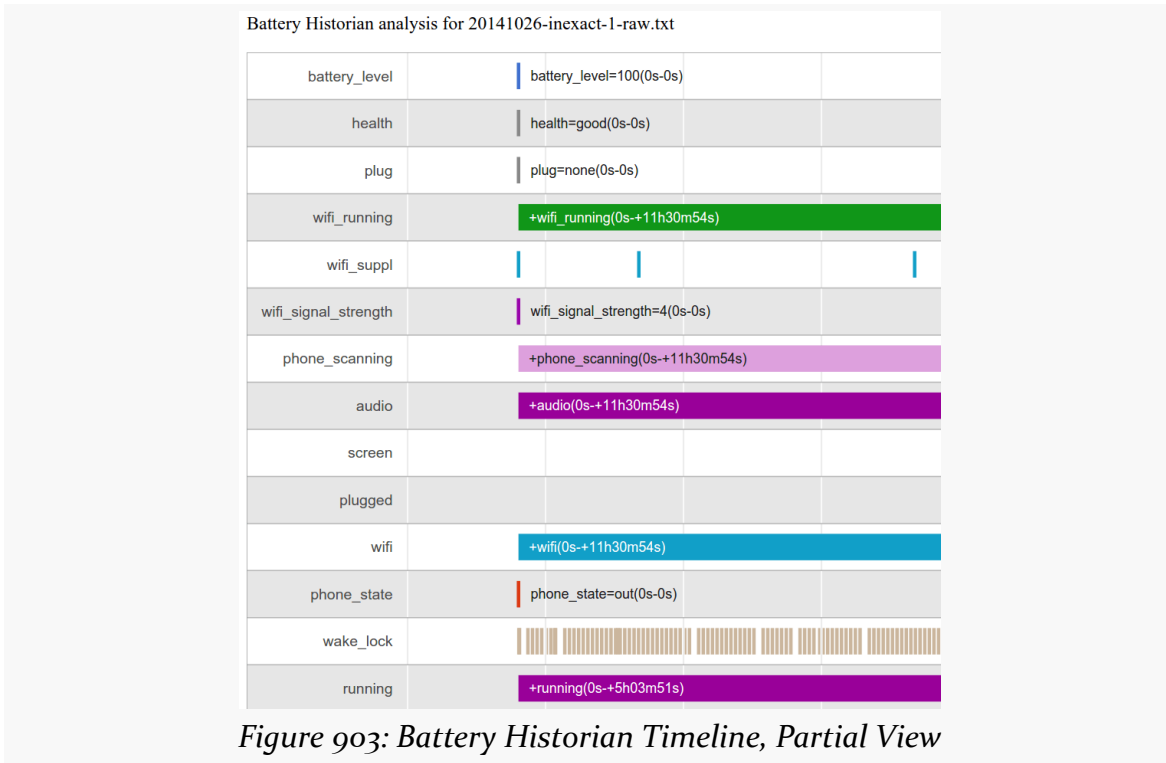

Once you have downloaded that Python script, and assuming that you have a Python interpreter installed, you can run the script, supplying it with the output of your `batterystats` run, and redirecting the script's output to an HTML file:

```
python historian.py /tmp/bs.txt > /tmp/bs-report.html
```

Interpreting the Historian Output

You can then load that HTML into a Web browser (Chrome-flavored ones are probably a good choice, given that it is Google-generated HTML). This will give you a timeline across the horizontal axis, with event categories culled from the “Battery History” section of the `batterystats` output on the vertical axis:

POWER MEASUREMENT OPTIONS

POWER MEASUREMENT OPTIONS

The length of the bar shows the approximate duration of the event, though really short events have a *de minimus* length to give you something to see. Hovering your mouse over one of the bars brings up a pop-up with more details about that event:

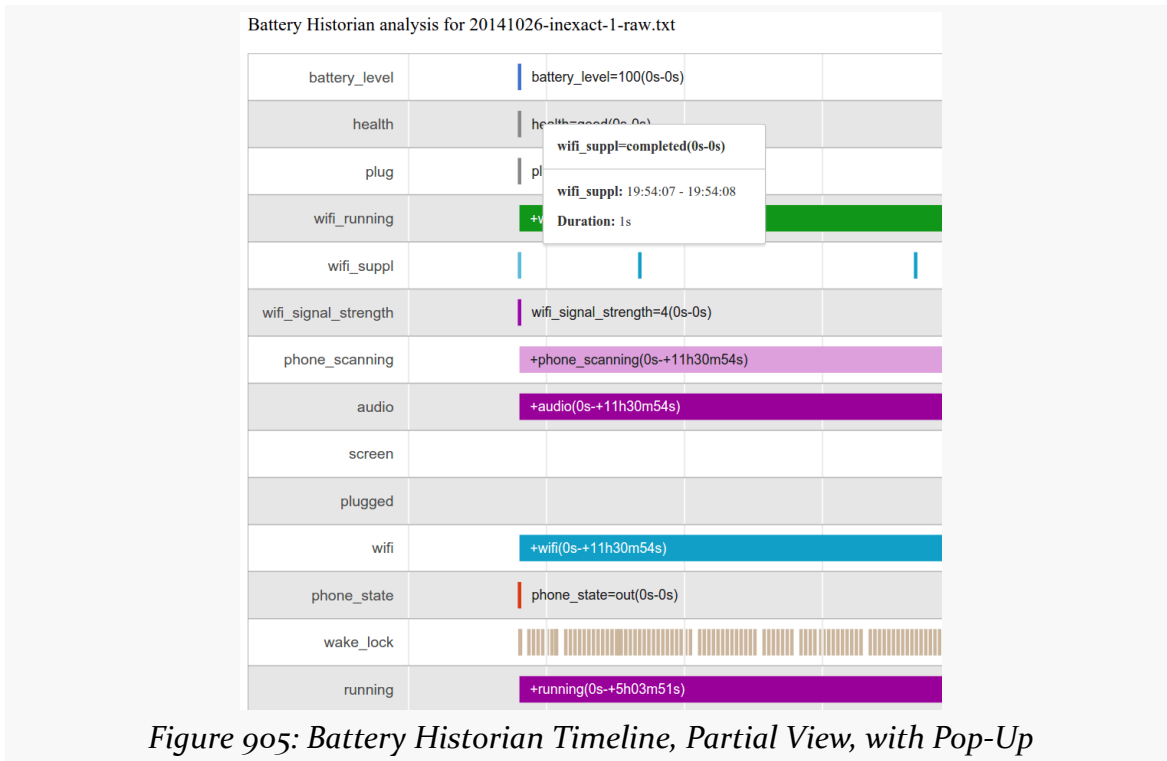

Figure 905: Battery Historian Timeline, Partial View, with Pop-Up

If the bar is really long, you may need to scroll your browser horizontally to see the pop-up, as the rendering of the pop-up location does not seem to pay attention to the browser viewport very well.

Below the main chart is a “Zoom” field that you can use to change the scale of the horizontal axis, along with an “Event summary”:

POWER MEASUREMENT OPTIONS

```
(Local time 19:54:07 - 07:25:01, 690m elapsed)
Zoom: 100% [redraw]
Event summary:

total: 0.000 mAh, 733 events
Process table:
u0a3: "android.process.acore"
```

Figure 906: Battery Historian Timeline, Zoom and “Event summary”

Again, this is largely undocumented.

The Qualcomm Tool (That Must Not Be Named)

Qualcomm makes the chipsets that drive a substantial percentage of Android devices. Qualcomm also offers a number of things to further help Android developers, such as open source libraries like AllJoyn (P2P communications).

Qualcomm makes a tool that can help you measure power consumption. There are two versions of this tool:

1. The best version is designed to run on [the Qualcomm MDP series of reference hardware](#), and takes advantage of specific capabilities of that hardware to provide excellent power consumption data
2. Another version can be used with other Android devices powered by Qualcomm chipsets, providing information about power usage, though not quite as much as you get from the first version

Alas, this book does not cover this tool.

The current versions of this tool have a license agreement containing crudely-implemented non-disclosure terms:

POWER MEASUREMENT OPTIONS

You shall not to disclose or permit the disclosure of the Materials in any form or any information relating to the Materials (including without limitation the results of use or testing) to any third party without QTI's prior written permission... You further acknowledge and agree that if QTI, in its sole discretion, chooses to provide any form of support or information relating to the Materials, such support and information shall be deemed confidential and proprietary to QTI and shall be protected in accordance with this Section 4.

In this case, "Materials" refers to the two versions of the tool, plus accompanying documentation, and QTI is Qualcomm Technologies.

The non-disclosure terms do not come with the normal "you can talk about anything that has been already publicly disclosed" caveats. Hence, even the Qualcomm public Web site regarding this tool falls under the "any form of support or information".

Regardless, you may be interested in visiting [Qualcomm's developer support site](#) in hopes that you can find this unnamed tool.

PowerTutor

Perhaps the best-known third-party power analyzer is [PowerTutor](#). PowerTutor is the outcome of a research project from the University of Michigan, with a bit of assistance from Google. In principle, PowerTutor is capable of letting you know power consumption on a device, much along the lines of what Trepn can record on a Qualcomm MDP. In practice, PowerTutor is significantly less powerful and sophisticated.

PowerTutor was created with the HTC Dream (T-Mobile G1), HTC Magic (T-Mobile G2), and Nexus One in mind. Its power output values will be as accurate as they could make it for those devices. If you run PowerTutor on other hardware, the results will be less accurate.

You can obtain PowerTutor from the Play Store, or from the PowerTutor Web site, or you can [compile it from source](#).

PowerTutor is not tied to testing a particular application. As such, you can simply run PowerTutor whenever you want from its launcher icon, then press "Start Power Profiler" in the main activity:

POWER MEASUREMENT OPTIONS

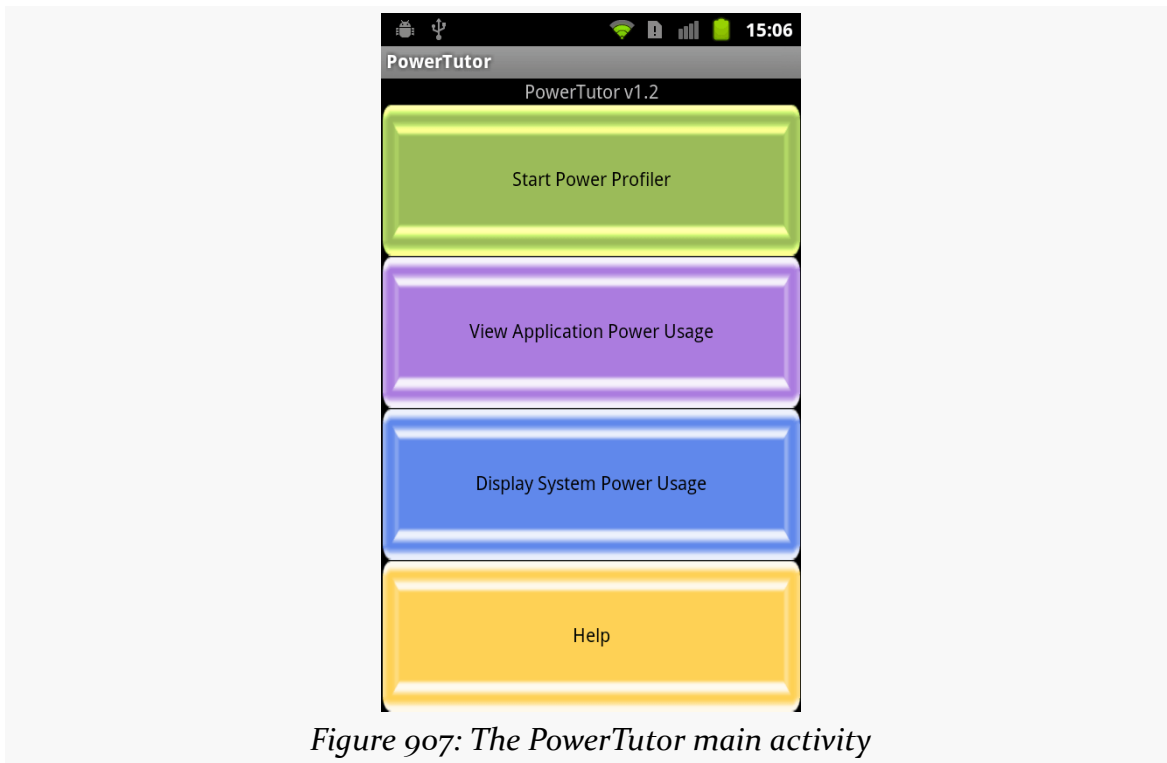

Figure 907: The PowerTutor main activity

At this point, you can start playing with your application, or running your unit test suite, or whatever. When you want to get an idea of how much power you have been consuming, you can switch back to the PowerTutor activity and choose “View Application Power Usage”. This brings up a list of processes and toggle buttons to show various power consumption values for each:

POWER MEASUREMENT OPTIONS

Figure 908: The PowerTutor application roster

Tapping the list entry brings up a graph for that particular process, though since this information is only available while PowerTutor is recording new data, the graph is usually empty unless you have logic running in the background:

POWER MEASUREMENT OPTIONS

Figure 909: The PowerTutor live charts for a single process current power consumption

You can also bring up a chart showing what portion of your power consumption came from various sources for the whole device, such as a pie chart of current consumption:

POWER MEASUREMENT OPTIONS

Given that the source code is available, one might augment PowerTutor to:

1. Saving results, both as data files for offline analysis (akin to Trepn's CSV files) or for viewing charts and tables on the device when data is not being actively collected
2. Allowing one to record application states, akin to Trepn, to better correlate application functionality to saved power results

Battery Screen in Settings Application

Of course, what developers tend to focus on most with power is the battery consumption screen in the Settings application, as shown in [a previous chapter](#):

POWER MEASUREMENT OPTIONS

Figure 911: Battery Screen from Settings App

After all, this is what users will tend to focus on — anything showing up in here is a source of blame for whatever power woes the user believes she is experiencing. Conversely, if your application does not show up in this screen during normal operation, then there is no compelling reason for you to do further analysis, as users will tend to be oblivious to your actual power consumption.

If you do show up in the list, tapping on your entry can give you some more details of what power you consumed and why:

POWER MEASUREMENT OPTIONS

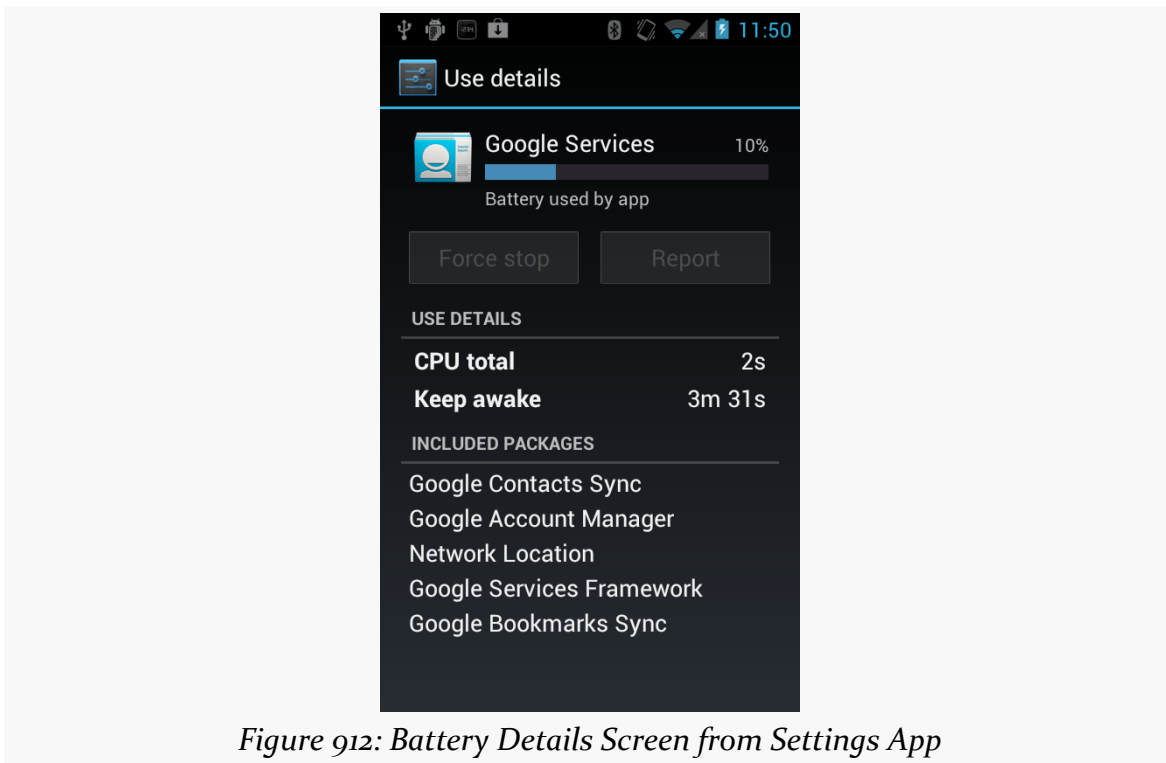

Figure 912: Battery Details Screen from Settings App

However, the information contained in here is mostly guesswork, using a more refined version of the same approach that PowerTutor uses. Ordinary Android hardware simply lacks enough fine-grained power measurement instrumentation to do an accurate job of apportioning power usage among different processes. So, the details of how long you kept the CPU powered on may be accurate, but the percentage of battery consumption associated with your app is just an estimate.

BatteryInfo Dump

Yet another possibility on older Android devices is to use the `adb shell dumpsys batteryinfo` command from your command prompt or terminal on your development workstation. This will emit a fair amount of data that probably means something to somebody, such as general device information:

```
Battery History:

In principle, one might create tools that use this output — or perhaps steal a peek at the data used by the Settings application – to create something a bit more developer-friendly.

Sources of Power Drain

If you can measure power drain well yourself, that is the best way for you to determine precisely where your power consumption is going. Alas, for various reasons, you may not be able to get good power consumption data.

Which means you may have to guess.

We know the general sorts of things that consume power in a device, such as the screen and the CPU. We know that if we use these things less, we will use less power. Eventually, though, we have an app that does nothing, and while this may result in optimal power usage, we are still likely to get poor reviews, because *the app does nothing*.

What we need is some rough idea of how bad certain things are, so we can weigh our use of those system components appropriately.

This chapter will try to give you some “rule of thumb” heuristics of how to estimate power usage of various system components, plus some general recommendations of how to use less of that particular component without necessarily eliminating useful functionality from your app.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Also note that:

- mA = milliamps, where the ampere (or “amp”) is the SI unit of current

SOURCES OF POWER DRAIN

- mAh = milliamp-hours, which is how battery capacities are measured (e.g., 2000mAh can power a 200mA draw for 10 hours)

Screen

Screen size and battery size generally trend together. Tablets have bigger batteries and bigger screens than do phones, which in turn are bigger in both areas than are wearables.

A rough rule of thumb is to expect to consume ~10% of the device's battery for every hour you keep the screen on. Or, to look at it another way, on a phone-sized screen, expect a power draw of ~100-200mA, depending on variations in screen size and display technology (e.g., AMOLED).

Normally, the user is in control over how long your app is in the foreground and therefore is "to blame" for the screen being on. There are a couple of cases where you can make the screen be more of a problem.

The first is if you acquire() a WakeLock (other than a PARTIAL_WAKE_LOCK)... and forget to ever release() it. Since the WakeLock will keep the screen on, the screen will stay on, even if your app is in the background, until such time as your process is terminated or the device shuts down due to low battery.

In fact, such WakeLock types have been deprecated, with the last of them being flagged as deprecated in API Level 17. The recommended alternative is to use `android:keepScreenOn` or `setKeepScreenOn()` on some View. This will keep the screen on, so long as the activity hosting that View is in the foreground. That way, just moving to the background releases the underlying WakeLock, allowing the device to return to sleep.

However, in some cases, even that may be insufficient. Suppose that the user is in your activity, and they get distracted, putting down their device for an extended period. Unless you somehow detect the inactivity, and manually turn off the keep-screen-on mode, the screen will stay on indefinitely, until the power is drained. Hence, if you have a decent way of determining if the user is still using your activity, consider using that as a way to determine when the device is inactive (e.g., a `postDelayed()` that gets canceled and rescheduled when the user does something, so if the `postDelayed()` Runnable gets invoked, you know the user has done nothing for the delay period). Then, if you know the device is inactive, call `setKeepScreenOn(false)` to return the screen to its normal operating mode.

The academic paper [“How is Energy Consumed in Smartphone Display Applications?”](#) has a more extended analysis of screen power draw.

Disk I/O

Disk I/O gets more efficient with bigger operations.

You can see this in something like SQLite, where wrapping a bunch of INSERT statements into a single transaction can have substantial benefits in terms of how long the I/O takes.

Not surprisingly, this has a similar impact on power consumption:

- Writing 1GB of data 1,000 bytes at a time is about twice as expensive as is writing it 10,000,000 bytes at a time
- Writing 1GB of data 100 bytes at a time is about five times as expensive as is writing it 1,000 bytes at a time

Hence, you want to try to batch up your disk I/O, where possible, to do fewer, bigger operations, rather than lots of little ones. This includes:

- Batching database I/O in a transaction, as noted above
- Caching data that you intend to log to disk in memory and only writing when your in-memory buffer reaches a certain size or age (though beware the dangers of your process being terminated before you get a chance to write the data)
- Consider using larger buffer sizes with `BufferedInputStream` and `BufferedOutputStream`, if you can afford the heap space, though the 8KB defaults are not that bad

As a rough model, consider disk I/O to draw ~200mA. The smaller the I/O operations, the more time it takes you to accomplish the work, and hence the less efficient those operations are.

While disk I/O is relatively expensive while it is occurring, most apps are not continuously reading or writing, and therefore the total impact to the battery will not be that bad. Apps that *do* continuously use the disk — such as music or video players — will

WiFi and Mobile Data

Internet access via WiFi and mobile data networks is another area that you, the developer, tend to control. Some apps require continuous Internet access and only while in the foreground, like a streaming media player. But many more apps wind up doing Internet access periodically in the background, looking for new information on some server somewhere. Unfortunately, these are the sorts of “vampire” apps that can drain the battery without users necessarily being aware of it. Individually, these apps might not even appear all that bad, but when a device has dozens of them, the combined impact results in poor battery life.

Moreover, we also have the problem of dealing with multiple ways of getting to the Internet. Simple solutions will leave us totally oblivious to the differences in downloading via WiFi versus mobile data, at the potential cost in battery consumption. Slightly less-simple solutions optimize for mobile data, to try to minimize power drain in that model. More-elaborate solutions detect what sort of connection we have (using `ConnectivityManager`) and choose among different strategies as connectivity changes.

Here are some things you can do to try to help manage your Internet power consumption.

Use Less

The simplest, rough-cut way to consume less power for Internet access is to do less Internet access in the first place. The less time you spend downloading (or uploading) data, the less power you tend to draw while doing so. In a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

And, of course, consuming less bandwidth can have other benefits, particularly for people on metered mobile data plans.

There are chapters [elsewhere in the book](#) that cover ways to deal with bandwidth consumption for bandwidth’s sake.

Use What You Already Downloaded

For data that is likely to be unchanging, use a disk cache, so you can avoid downloading the same content again. Such a cache can be used at two levels:

SOURCES OF POWER DRAIN

1. Simply by having the file in the cache can be a signal to your app that you already have the data and can avoid any sort of request to fetch it again.
2. For HTTP, by recording some additional details (If-Modified-Since and ETag headers), you can make a request to the server to download the content again, where the server can tell you if you already have the current copy of the content (via a 304 response code).

Many of the Internet libraries discussed [earlier in this book](#) offer disk caching as part of their services.

Use In Batches

As noted earlier in this section, in a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

Unfortunately, that approximation is pretty coarse.

We as developers tend to think of Internet access as being like a faucet with two states: on and off. In reality, wireless radios tend to have three states: full power, low power, and standby mode. Opening a socket will bring the radio to full power. An idle radio (no packets transferred) will drop to low power after a while, and eventually back to standby mode. Not surprisingly, the power draw for full power is substantially more than low power, which in turn is more than standby.

However, this model introduces some problems:

- There is some latency to move from standby or low power to full power. This slows down data transfer while the radio “warms up”.
- The idle time needed to transition to a lower power state is substantial, with values in the 5-15 second range well within reason. This means that making a request has lingering power cost even *after* our request has completed.

The net is that you want to bring the radio to full power as few times as possible (to minimize the percentage of time we are slowly dropping back to standby and consuming power while we do). And, while we are at full power, we want to do all necessary — or perhaps possibly necessary — data transfers, to avoid having to go back to full power again any time soon.

In other words, you want to batch your network I/O. This is reminiscent of the recommendations to batch disk I/O from earlier in this chapter.

So, for example, if you are going to upload data to a server, use that same pulse of work to download anything that needs downloading, rather than having separate schedules for uploads and downloads. Doing more in a batch and having fewer batches will reduce the cost of the power state changes.

Use When the Server Wants You To

One common pattern for Internet access is to poll a server. This is fairly easy to code, using something like `AlarmManager` to get control every so often.

However, this approach resembles children in the back seat of a car, frequently pestering their parents with “Are we there yet?”

Just as the parents will tell the children “We will get there when we get there, and we will tell you when we get there”, you can take a similar approach, using [Google Cloud Messaging \(GCM\)](#). Rather than poll the server periodically, have the server contact your app on the device when there is data ready to be downloaded. This works well in cases where polls are likely to result in “yes, we have no data” responses — the pushes can be far less frequent than the polls would be. This can also reduce load on your servers, for not having to respond to poll requests across all your users.

Note, though, that the battery benefits are from using GCM itself. From the standpoint of an app, GCM is “always on”, and the power consumed by GCM is attributed to Android itself, not to the app. Hence, pushes are almost “free” from the standpoint of power cost. This will *not* be the case if you “roll your own” push system (MQTT, WebSockets, etc.). In this case, you are attempting to keep a long-lived socket yourself, *in addition* to the one maintained by GCM. Clearly, there are ways to do this that minimize the power consumption of the long-lived socket connection, but that is not easy to accomplish. Hence, you need to weigh the costs of depending upon the Play Services SDK and routing your communications through Google’s servers with the costs of trying to do your own separate push mechanism in a battery-friendly fashion.

Use When Android Wants You To

If server push through GCM is impractical (e.g., you do not control the server), you can reduce your power use for Internet access by batching *across apps*, in addition to batching within your app.

What Google wants you to use for synchronizing data with a server is the `SyncManager`. This is an overly-complicated framework that, among other things,

gives you control to sync to the server at the same time that other apps needing to sync get control. That way, we can “warm up” the wireless radio once and handle several apps’ worth of data transfers at once. SyncManager will be covered in this book eventually.

Part of the reason why Android moved to make alarms with AlarmManager more “inexact” in API Level 19+ is for this same sort of batching. While AlarmManager certainly can be used for a variety of purposes, a lot of apps use it for Internet data transfer. Allowing Android to control when those alarms occur allows Android to try to coalesce them, and perhaps even time them to happen when SyncManager-led transfers occur, with the objective of minimizing the number of times we bring the wireless radio out of standby mode.

Use Additional Reading

The Android developer documentation has [a series of “training” pages](#) on minimizing power consumption for data transfers. This expands upon Reto Meier’s Google I/O presentations that touch upon this topic.

GPS

In light testing, GPS seems to draw ~35mA. Additional power will be consumed for using those results, though, and so the net effect on the battery will be somewhat higher, depending upon what your app does when it gets a GPS fix.

That figure is corroborated by the academic paper [“An Analysis of Power Consumption in a Smartphone”](#), though that paper tested rather old devices (HTC Dream and Nexus One).

Again, different devices will have different components, and some devices’ GPS modules may be more or less efficient.

Hence, GPS itself is a power drain, but not a massive one... if what you are doing with the GPS fixes itself is efficient. Keeping the GPS on for several hours will certainly take a chunk out of the battery charge, but if you are doing lots of work (e.g., navigation app) in response to those fixes, several hours may be more than the battery can handle.

If you can get by with the dependency on the Play Services SDK, using [LocationClient](#) can help here, particularly in cases where the user may not be

moving much, as Google's fused location provider uses the accelerometer to help determine how much they need to use GPS versus other possible means of determining location.

Camera

The camera will consume power while it is actively receiving input, whether that is for the preview frames or for taking full-resolution pictures or video. Of course, it will also consume additional power when recording images to disk, whether those be still photos or continuous video.

A rough guide is that a camera preview will draw ~200mA *plus* the power for screen, CPU, etc. That could easily total over 350mA, even if you are not doing much. Normally, though, the camera preview is on for short periods of time, and only under user control.

A corresponding value for recording video, including the disk I/O and camera preview, would be ~600mA (plus the screen). That is the sort of thing you only want to do in short bursts, as a couple of hours of video recording can really take a bite out of battery. However, once again, normally the user is the one controlling when video is recorded.

Additional Sources

The above sources of power drain are comparatively easy to model and provide a heuristic for determining your possible power usage.

However, there are plenty of other things that can drain the battery, for which this chapter does not provide such a heuristic. In many cases, the usage patterns of the system component will vary so widely that a simple heuristic is unrealistic. In some cases, the power drain from components from different manufacturers will be very different. In some cases, the author of this book simply lacks sufficient expertise with the technology to provide much help (e.g., Bluetooth).

The sections that follow will try to provide some help, though.

CPU/GPU

Perhaps the biggest source of power drain beyond the components listed above will be the processors: the CPU and the GPU. These draw a fair bit of power, which is why processor manufacturers go to great lengths to try to adapt to varying conditions, turning off cores or switching clock speeds, to try to minimize the power drain.

Usually, so long as we are in the foreground, any CPU/GPU usage impact on power will be considered “normal” by the user. Of course, trying to boost performance here can benefit the user, not only in terms of possibly reduced power consumption, but less lag or other forms of sluggishness. Hence, trying to optimize processor utilization is worthwhile.

However, the bigger complaints from the user will come from power drain while your app is in the background. The biggest source of those complaints will come from your use of WakeLocks, preventing the device from going into a low-power sleep state.

There are some apps available on the Play Store that reportedly can give you some idea of how long you may be holding a WakeLock, however they generally require root, particularly for Android 4.4+.

Sensors

Sensors, more so than many other device components, seem to get sourced from a wide range of manufacturers. They also seem to be tied into the devices differently from device to device. For example, some devices allow sensors to continue collecting data while the device is otherwise in a sleep mode, while many do not.

As such, it is difficult to give much guidance in terms of power drain tied to your use of sensors.

That being said, here are a few notes that may help:

1. Generally speaking, the more you use a sensor, the more likely it is that it will reflect in power drain. However, only some of that power drain will be from the sensor hardware itself. Your application code processing sensor events will bear much of the blame. Reducing the periods of time when you are registered for sensor events, using longer delays between events, and

SOURCES OF POWER DRAIN

sensor event batching are ways that you can reduce the power drain associated with the sensors and your associated code.

2. Conversely, in some environments, use of a particular sensor may be “free”, insofar as the device uses the sensor itself on a continuous basis. For example, the accelerometer and/or gyroscope is used by devices to detect orientation changes. Hence, those sensors must be powered on regularly, and therefore you cannot be “blamed” for the fact that the sensors are drawing power. Your use of the sensor data may contribute to power drain, of course.

Audio Input and Output

Playing audio through the earpiece, speaker, wired headset, or Bluetooth, will consume some amount of power. The amount will vary by how long you are playing the audio and how the audio is played (e.g., Bluetooth may require more power than on-device audio output). However, in both cases, usually the user has control over the audio, particularly if it is to be playing for a lengthy period of time (e.g., music player), and so the power drain associated with audio playback is less likely to be considered to be a problem, as users will get annoyed with *uncontrolled* power drain, more so than power drain that they can manage themselves.

Recording audio via the on-board microphone or Bluetooth should also consume some incremental power. In cases where the user is in control over when recording is happening, the power drain is unlikely to cause the user much distress.

Where both playback and recording of audio may cause a perceived power problem is in places where the user has less control. For example, an alarm clock app should have some sort of timeout to stop playing the ringtone (or whatever) after some period, if the user fails to respond to the alarm. After all, it is possible that the user is not where the device is and is not in position to stop the alarm. In this case, the power drain will be from several components, audio playback being just one, but it is the uncontrolled nature of the power drain that can get you in trouble.

Addressing Application Size Issues

Sometimes, our apps are just too big, where “too big” can be defined as:

- Bigger than the 100MB limit imposed by the Play Store
- Bigger than some other limit imposed by some other distribution channel
- Big enough that we worry about bandwidth costs, particularly for users on metered data plans
- Big enough that we hit some internal Dalvik limitations

This chapter will review various techniques for trying to keep the size of your app down to a reasonable level.

Prerequisites

This chapter assumes that you have read the core chapters of the book.

Java Code, and the 64K Method Limit

In ordinary Java development, there are few limits as to how big your applications can get. You tend to run into physical limitations, such as available system RAM, before you run into any limitations of the programming language or runtime environment.

And, normally, in Android applications, you do not worry about how many classes or methods you have. However, “normally” is not “always”, and there is a specific scenario that complex apps need to worry about.

What Is It?

[Quoting Andy Fadden](#), Android platform engineer:

The issue is not with the Dalvik runtime nor the DEX file format, but with the current set of Dalvik instructions.

You can reference a very large number of methods in a DEX file, but you can only invoke the first 65536, because that's all the room you have in the method invocation instruction.

I'd like to point out that the limitation is on the number of methods referenced, not the number of methods defined. If your DEX file has only a few methods, but together they call 70,000 different externally-defined methods, you're going to exceed the limit.

[An externally-defined method is] a method defined in a separate DEX file. For most apps this would just be framework and core library / uses-library stuff.

Specifically, you will crash at compile time, with an error message akin to:

```
Unable to execute dex: method ID not in [0, 0xffff]: 65536
Conversion to Dalvik format failed: Unable to execute dex: method ID not
in [0, 0xffff]: 65536
```

64K Seems Like a Lot of Typing...

Well, it is, and it isn't.

First, it is not merely your own methods. You can reach the 64K method limit without implementing 64K methods in your application yourself. You can:

- Call lots of methods defined by the framework
- Absorb lots of methods from libraries, particularly larger libraries that offer many more features than your app uses

This still tends to mean that simpler apps are unlikely to run into this limit, while more complex apps might.

Jake Wharton has published [a shell script](#) that can provide you with a count of referenced methods.

Mitigation Tactics

If you are relatively close to the 64K method limit, you may be able to tweak your project to get back under the limit without having to significantly rework your project.

Use Granular Libraries

Some libraries, like Google Play Services, come in two forms: a “kitchen sink” and more granular libraries for individual features. If your need for the library can be met by the granular libraries, use them, and you can remove your dependency on the “kitchen sink”.

In the case of Google Play Services, try *not* to depend upon the `com.google.android.gms:play-services` artifact. Instead, try to depend upon one of the more granular artifacts, such as `com.google.android.gms:play-services-maps` for [Maps V2](#). For services, like [Google Cloud Messaging](#), that have no specific granular artifact, depend instead upon `com.google.android.gms:play-services-base` — while still large, this is far smaller than is `com.google.android.gms:play-services`.

Use Better Libraries

One common culprit of hitting the 64K method limit comes from libraries, as their methods count along with yours. Hence, choosing different libraries can perhaps reduce your method count.

One specific case of this comes from the code generated by Google’s [Protocol Buffers](#). If you are using Protocol Buffers heavily, your generated classes may each be defining hundreds of unused methods. Switching to an alternative implementation can reduce this significantly. Some such implementations include:

- [micro-protobuf](#)
- Square’s [Wire](#)

Use ProGuard

If your debug builds are failing due to the 64K method limit, try a release build. If that works, the reason is ProGuard and its ability to strip out code that is deemed to be unreachable.

In this case, you can “buy yourself some time” by arranging to build your app in debug mode with ProGuard, but without ProGuard’s normal code obfuscation work (e.g., `-dontoptimize -dontobfuscate` switches in the ProGuard configuration).

[Quoting Eric Lafortune](#), ProGuard’s lead developer:

If you apply ProGuard with shrinking enabled but optimization and obfuscation disabled (`-dontoptimize -dontobfuscate`), the code will already be more compact, and you can still use a debugger. The source files, class names, method names, line numbers, etc remain unchanged and any breakpoints in removed unreachable code are irrelevant.

With Gradle-based builds, it should be possible to set this up using `minifyEnabled true` and a custom ProGuard configuration file:

```
android {
    buildTypes {
        debug {
            minifyEnabled true
            proguardFile 'proguard-no-obfuscate.txt'
        }
    }
}
```

(where `proguard-no-obfuscate.txt` contains the `-dontoptimize -dontobfuscate` switches)

Mitigation Strategies

If the aforementioned tactics are insufficient — or if they help somewhat, but you are still near the limit with a lot of development yet to be done — you may need to pursue some more strategic ways of resolving your application size.

Don’t Go Overboard

One source of method explosion comes from too much adherence to server-side Java coding styles.

For example, if you find yourself defining hundreds of interfaces and/or abstract classes, with Factory classes (and perhaps FactoryFactory classes), you are more likely to hit the 64K method limit due to all those separate definitions. Consider whether the flexibility that you believe that you obtain from this coding style is worth the risk.

Smaller Apps, Loosely Connected

It may be that you are simply creating an app that is entirely too complicated for the Android environment. Android's Intent system is designed to enable apps to inter-operate, and so you may need to consider splitting your app into pieces, such as:

- A suite of related apps
- A host app and plugin apps that enable additional functionality
- An app and an affiliated Web app, where certain functionality is handled by the Web app in a standard browser

Splitting Into Separate DEX Files

It is also possible — though rather risky — to split your app into multiple DEX files. The basic technique is outlined by Google in [an Android Developers Blog post](#).

In Google's formulation, the secondary DEX file is packaged as an application asset and is unpacked into internal storage on first run of your app. This keeps all of your code in your one APK file for distribution.

The risk comes in if you decide to *not* ship the secondary DEX file with the APK, but rather obtain it by other means, such as downloading it from your own Web site. If somebody hacks your Web site, or employs a man-in-the-middle attack when users try downloading the DEX file, your DEX could be replaced by one that contains malware or otherwise harms the user. If you elect to distribute the secondary DEX files yourself by this sort of means, *please* consider the security ramifications and take appropriate steps to ensure that the DEX you download is the unmodified DEX file.

Native Code

Native code, implemented as NDK-compiled libraries, represent another source of app bloat. This will occur regardless of whether the NDK code is yours or if you are

using a third-party library that supplies those binaries (e.g., SQLCipher for Android).

Native code is not intrinsically large. However, in some cases, native code is a port from some other environment (or environments) and may contain a lot of stuff that your app does not need. Worse, ProGuard will not strip out unused native code, as its algorithms only work with Java-style bytecode. Hence, it is not out of the question for apps to devote several MB just to the Linux .so files that make up the NDK-compiled libraries.

Fortunately, there are some workarounds.

Mitigation via Per-CPU APKs

Some distribution channels, like the Play Store, support publishing multiple versions of an APK, with different versions for different CPU architectures. Hence, you could have one APK with x86 binaries and one APK with ARM binaries, as opposed to having one “fat binary” with both.

While setting this up using the classic build tools would be a major pain, [Gradle for Android](#) makes this fairly straight-forward, using product flavors for the CPU architectures:

```
productFlavors {
    x86 {
        ndk {
            abiFilter "x86"
        }
    }
    arm {
        ndk {
            abiFilter "armeabi-v7a"
        }
    }
    mips {
        ndk {
            abiFilter "mips"
        }
    }
}
```

Using product flavors this way will give you separate commands for compiling each of the CPU architectures (e.g., `gradle assembleArmRelease`).

More details about using the NDK with Gradle can be found [elsewhere in the book](#).

Mitigation via libhoudini

As is noted in [the chapter on the NDK](#), libhoudini is proprietary Intel code that allows ARM-compiled NDK binaries to run on x86 CPUs, using the same sort of opcode translation that is used by the Android emulator. Many, though not all, x86-powered Android devices have libhoudini. Those that do could run your app even if you only ship ARM NDK binaries and not x86 ones. This gives you the same sort of space savings as you would get by publishing separate ARM vs. x86 APKs (per the previous section), without having to manage multiple APKs yourself. The cost is speed, as the translation layer adds significant overhead, much as you see with the Android emulator running ARM emulator images instead of x86 ones.

Mitigation via Ignoring Non-ARM

Of course, what a lot of developers do is simply only worry about ARM.

While Google does not publish percentages of CPU architectures the way they do Android OS versions, it is safe to say that, as of early 2014, ~1% of Android devices are powered by non-ARM CPUs. That percentage may climb, particularly as Intel pushes more x86 chipsets. But the *vast* majority of Android devices are powered by ARM. So, even if some of those x86 environments lack libhoudini (e.g., the manufacturer did not license libhoudini from Intel), they are so few in number that developers are prone to ignore x86.

Ironically, what drives x86 for developers is the development environment itself, not the production environment. The x86 emulator is nicely responsive, compared to a similarly-configured ARM emulator image. Many developers eschew the ARM emulator entirely, with it being too slow. Hence, developers may be interested in having x86 binaries in the APK to allow the app to run on the x86 emulator (which lacks libhoudini). In this case, it may be worthwhile to have a dedicated release build process that strips out the x86 binaries, if the space that those binaries take up is more than you can afford.

Images

Bitmap images are notorious for taking up lots of heap space. However, they can also swell the size of your APK. While the bitmap PNG or JPEG files will be compressed on disk, if you have enough of them, they can still consume many MB of space in the APK, particularly since the APK cannot compress them further.

Mitigation via Resource Aliases

You may have multiple copies of the same image.

The example cited in the Android documentation is where you want to have locale-specific drawable images. For example, perhaps you want to show a flag, and you use language resource sets to try to map the right flag to the right language. However, some flags are going to be used in multiple languages, such as the Canadian flag being needed for `en-rCA` and `fr-rCA`. By default, you would place your flag icon in each of those resource sets, duplicating your results. This gets worse if you have a few versions of the same flag icon for different densities.

However, you can elect to use a resource aliases to handle this differently.

Suppose that your code refers to a `flag` drawable resource (e.g., `@drawable/flag` or `R.drawable.flag`). For many languages, you would have a unique flag in the appropriate resource set. For cases where the same flag is used in multiple situations:

1. Put the flag in a resource set that is not tied to locale (e.g., `res/drawable-hdpi/` instead of `res/drawable-en-rCA-hdpi/`), for as many densities as you choose, but under a different name (e.g., `flag_canada.png` instead of `flag.png`)
2. Create a small XML file, `flag.xml`, in each of the locale-specific directories (e.g., `res/drawable-en-rCA/` and `res/drawable-fr-rCA/`), pointing to your `flag_canada` drawable:

```
<?xml version="1.0" encoding="utf-8"?>
<bitmap
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/flag_canada" />
```

When you reference `R.drawable.flag` on an `en-rCA` or `fr-rCA` device, Android will read in the XML resource, then turn around and retrieve the `flag_canada` drawable, and use that. Since the two XML files are likely to be smaller than the sum total of the duplicate copies, you save disk space.

Mitigation via pngquant

In practice, the above technique is just not that commonly used, because it addresses a fairly narrow scenario. A more general-purpose solution is to try to tweak the images to be visually nearly identical, yet take up less disk space.

There are a variety of tools for this, mostly aimed at Web development, where smaller image file sizes means faster-loading Web pages.

One such tool is [pngquant](#). Given a PNG file as input, it generates a smaller PNG file as output, one with an optimized color palette, using mathematical techniques to choose colors that will maintain as much of the original look as possible. Many of the images in this book were optimized using [pngquant](#), at a substantial savings in disk size, without materially sacrificing image quality.

APK Expansion Files

The ultimate solution to disk space concerns, for distribution through the Play Store, is to get stuff out of your app entirely and distribute that stuff by other means. The Play Store offers [APK expansion files](#) with this in mind. You can publish one or two expansion files, each containing up to 2GB of files. While these will not be treated as resources or assets, you do have access to the file contents at runtime. Game developers will use these for sound effects, additional artwork, and so on. The biggest limitation is that these files may not be supported by all distribution channels.

Crash Reporting Using ACRA

When you wrote your app, you intended for it to work.

Alas, [the road to a very warm place is paved with good intentions](#).

Hence, it is fairly likely that your app will crash in the hands of your users. In order to be able to fix the underlying problems, you need to learn about the crashes and the state of the app at the time of the crash.

There are any number of solutions to this problem. This chapter will outline a few of them and focus on one open source solution: Application Crash Reports for Android, better known as ACRA.

Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Having read [the chapter on notifications](#) is also a good idea, though not absolutely essential.

What Happens When Things Go “Boom”?

In development, when your app crashes, you get a little dialog box indicating that the app crashed, and you get your Java stack trace in LogCat.

In production, little of that does you any good. In particular, you have no way of seeing LogCat from end user devices. Instead, you need to have some means of capturing that stack trace, along with perhaps additional data, and collect it somewhere.

CRASH REPORTING USING ACRA

App distribution channels may offer this as part of their feature set. The Play Store, in particular, offers its own crash reporting, where crashes “in the field” get reported to you by means of your Developer Console on the Web. However:

- You might not be distributing through the Play Store at all, let alone exclusively, and so the Play Store reporting does not help you for all your users
- The Play Store’s approach makes reporting the crash optional, as the user can elect to not send a report, meaning that you don’t find out about every crash
- You have no control over what data is and is not collected, both for ensuring that you have enough information to have a shot at fixing the bug and for minimizing extraneous data that might have privacy implications
- Google gets a copy of the crash data, which you may or may not find to be appropriate

Various other services, from [Crashlytics](#) to [Crittircism](#), offer their own crash reporting as part of a larger suite of features. However, once again, you may not have control over what data is collected, and you certainly have no control over who all gets the data.

For the privacy-minded app developer, you want something along these lines, but where you can control to a fine degree of detail what gets collected and where the data is sent solely to you, not to some third party.

And that’s where ACRA comes in.

Introducing ACRA

ACRA has been around since 2010, originally on Google Code, and now on [GitHub](#). It comes in the form of a library that you add to your app, with code that will get control when an unhandled exception occurs inside your app. There, ACRA *carefully* will collect information about the crash (e.g., the stack trace) and the environment (e.g., what version of Android the app was running on). ACRA can then deliver that information to you by [any number of means](#), plus optionally provide [feedback to the user](#) about the crash itself.

Since you control what ACRA collects and you control where ACRA sends the data, you can minimize how much information gets into the hands of third parties. The cost is in convenience, as either you have to:

- Fuss with managing your own server for receiving the crashes, or
- Use a third-party service for that server, reducing some of the privacy, or
- Use options that are clunky for everyone involved, such as the user sending emails containing crash reports

Where ACRA Reports Crashes

In the beginning, ACRA logged crashes to a Google Docs spreadsheet. Eventually, Google grumbled about this, and so that option is now deprecated.

That limitation notwithstanding, ACRA supports a range of possible ways for crash reports to get from the user's device to your eyes, so that you can try to fix whatever problems ail your app.

An Existing Crash Logging Service

Some crash logging services allow you to use ACRA in your code, rather than rely upon some proprietary library. You simply configure ACRA to send the data to their servers, which then notify you about crashes and give you dashboards and such to visualize how much your app is crashing.

[HockeyApp](#) and [Splunk Mint](#) are two such services.

The advantage here is convenience coupled with control over the client side. However, you are still sharing crash details with third parties, potentially raising privacy or security issues.

Acralyzer

The official ACRA reporting server is [Acralyzer](#). This, along with its `acra-storage` companion, are CouchApps, powered by Apache CouchDB. You upload the Acralyzer and `acra-storage` CouchApps into your own CouchDB instance, then configure ACRA in your app to talk to those apps.

Acralyzer and `acra-storage` are open source, as is CouchDB. You can either host a CouchDB instance on your own server or use various CouchDB hosting providers.

This solution offers the best blend of [analysis features](#) and user privacy and security. However, it does require you to learn enough about CouchDB to be able to set up and maintain an instance.

Email

The easiest solution to set up is the most awkward for everything else: have the user send you an email. In this model, ACRA prepares a report, then uses `ACTION_SENDTO` to lead the user to an email app to send the report to an email address that you configure in your app. The user can then just send the prepared email from their email client (e.g., Gmail), and the report shows up in the inbox for this email address.

You do not need to set up some sort of server, let alone maintain it. Your app does not even need the `INTERNET` permission.

However:

- The user might not send the email, choosing instead to abandon the mail client
- The user might not use their device for email, and therefore have no good means of getting you the report
- While you get the raw crash data, you do not get any of the nifty charts and such that you can get from a full-fledged crash reporting server

A Host for Testing

The protocol used by ACRA to communicate with a Web server is blissfully simple. Handling ACRA crash reports yourself does not require that much server-side code, in case you wanted to integrate this capability into the rest of your REST-style Web services.

For example, this trivial Ruby script implements an ACRA-compatible endpoint:

```
require 'fileutils'
require 'sinatra'
require 'json'

LOG_ROOT='/tmp/ACRAFier'

put '/reports/:id' do
  acra=JSON.parse(request.body.read)
  FileUtils.mkdir_p(LOG_ROOT) if !File.exist?(LOG_ROOT)

  f=File.join(LOG_ROOT, params[:id]+'.json')
  File.open(f, 'w') {|io| io.write(JSON.pretty_generate(acra))}
end
```

(from [ACRA/Simple/stub_server.rb](#))

CRASH REPORTING USING ACRA

As we will see [later in this chapter](#), you can configure ACRA to use a simple HTTP PUT request to submit a crash report to the server. This Ruby script implements a small REST-style Web service using Sinatra, where crash reports are pushed to a `/reports/.../` URL, where `...` is an ACRA-generated unique ID for the report. This script just logs the JSON that we get from ACRA to a file in a designated directory. With a few more lines of code, you could have it generate a human-readable report and email it to you, along with the JSON as an email attachment. Or, you could do whatever you want.

This Ruby script can be found as `stub_server.rb` in [the book's GitHub repo](#). If you have Ruby installed, just install the `sinatra` and `json` gems, then run `ruby stub_server.rb` to fire up the server.

In practice, you would need a bit more smarts on a publicly-visible Web service, to help prevent people from maliciously flooding your crash reporting server with bogus data. However, the minimal requirements for ACRA are very straightforward and could be implemented in any reasonable server-side Web framework.

ACRA Integration Basics

Given that you have identified how you want to receive the crash reports, the next step is to add ACRA to your project and configure it to send crash reports to your chosen location.

The [ACRA/Simple](#) sample project demonstrates a fairly simple ACRA integration.

Adding the Dependency

ACRA is distributed through standard Maven-style artifact repositories and should be automatically picked up when you add the appropriate `compile` directive to your dependencies:

```
dependencies {  
    compile 'ch.acra:acra:4.9.0'  
}
```

(from [ACRA/Simple/app/build.gradle](#))

Build Types, Product Flavors, and ACRA

It is very likely that you will want to have different ACRA configurations based upon build types and/or product flavors:

CRASH REPORTING USING ACRA

- Have the debug build not use ACRA, but have the jenkins build by your CI server use ACRA to collect crashes and integrate them into the test results, and have the release build use your production ACRA server
- Skip ACRA for your Play Store distribution (because you decide you would rather just use the Play Store's crash reporting), but use ACRA for your amazon product flavor (the version of your app that you distribute through the Amazon AppStore for Android)
- And so on

`buildConfigField` is a great way to manage this. Use your `build.gradle` file to establish values for some constants, then use them in the ACRA configuration code in Java later on.

The sample app defines two such fields for `BuildConfig`:

- `ACRA_INSTALL`, a `boolean` that will be `true` if we should use ACRA, `false` otherwise
- `ACRA_URL`, a `String` that will point to the server to which we wish to push the ACRA-collected crash data

The sample app defines the same values for both fields in both build types (debug and release), simply because you are probably playing around with the sample in a debug build:

```
buildTypes {
    debug {
        buildConfigField "String", "ACRA_URL", "'http://10.0.2.2:4567/reports'"
        buildConfigField "boolean", "ACRA_INSTALL", 'true'
    }

    release {
        buildConfigField "String", "ACRA_URL", "'http://10.0.2.2:4567/reports'"
        buildConfigField "boolean", "ACRA_INSTALL", 'true'
    }
}
```

(from [ACRA/Simple/app/build.gradle](#))

The URL used for `ACRA_URL` points to `10.0.2.2`, the IP address on an Android emulator that refers back to the `localhost` of your developer machine. In particular, this URL is set up for the server Ruby script mentioned previously in this chapter. If you wish to use a different server, not only will you need to consider changing this URL, but you will need to make some other adjustments to the Java code, in all likelihood, as will be seen in the next couple of sections.

Creating a Custom Application

ACRA needs some one-time initialization, and it is set up to do that by means of a custom Application subclass. Most likely, you do not already have one of these, though some libraries will require you to create one, perhaps inheriting from some library-supplied Application subclass.

Regardless, you will need a subclass of Application in your project, and you will need to have the `android:name` attribute of your `<application>` element in the manifest point to that Application subclass:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.button"
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.INTERNET" />

  <uses-sdk
    android:minSdkVersion="21"
    android:targetSdkVersion="21" />

  <application
    android:name=".ACRAApplication"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".ButtonDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
    <activity
      android:name="org.acra.dialog.CrashReportDialog"
      android:excludeFromRecents="true"
      android:finishOnTaskLaunch="true"
      android:launchMode="singleInstance"
      android:process=":error_report"
      android:theme="@style/AppTheme.Dialog"
      tools:replace="android:theme" />
    </application>
</manifest>
```

(from [ACRA/Simple/app/src/main/AndroidManifest.xml](#))

CRASH REPORTING USING ACRA

Here, `android:name` points to an `ACRAApplication` class that we will examine shortly.

Also note that the manifest has a `<uses-permission>` element, asking for the `INTERNET` permission. Unless you use ACRA's built-in support for sending crash reports via the user's email app, you will need the `INTERNET` permission for getting crash reports to some server.

We will cover what that `org.acra.dialog.CrashReportDialog <activity>` is a bit later in this chapter. For the moment, ignore it.

Implementing the Application

The Application subclass that you create needs two items to configure ACRA:

1. A `@ReportsCrashes` annotation, providing the actual ACRA configuration itself
2. A call to `ACRA.init()` from `onCreate()`, to initialize the ACRA crash-detection subsystem and have it use the annotation to configure what to do when crashes occur

```
package com.commonware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.annotation.ReportsCrashes;

@ReportsCrashes(
    formUri=BuildConfig.ACRA_URL,
    httpMethod=org.acra.sender.HttpSender.Method.PUT,
    reportType=org.acra.sender.HttpSender.Type.JSON
)
public class ACRAApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        if (BuildConfig.ACRA_INSTALL) {
            ACRA.init(this);
        }
    }
}
```

(from [ACRA/Simple/app/src/main/java/com/commonware/android/button/ACRAApplication.java](#))

`@ReportsCrashes` has many knobs to turn and switches to flip as part of configuring how ACRA should behave. We will look at a number of them in this chapter. This simple sample configures ACRA to:

CRASH REPORTING USING ACRA

- format the crash data as JSON
(`reportType=org.acra.sender.HttpSender.Type.JSON`)
- send it to the server indicated by the `BuildConfig.ACRA_URL` value we configured in Gradle (`formUri=BuildConfig.ACRA_URL`)
- use an HTTP PUT operation to hand that JSON over to that server
(`httpMethod=org.acra.sender.HttpSender.Method.PUT`)

These values work great with the Ruby script profiled earlier in this chapter. If you use some other server, you may need to change this configuration to match what that server wants.

Note that the `ACRA.init()` call is inside a check of the `BuildConfig.ACRA_INSTALL` boolean that we set up in the Gradle build files. If a particular build type or product flavor sets `ACRA_INSTALL` to `false`, ACRA will not be enabled. For simpler projects, rather than defining your own `ACRA_INSTALL`-style flag, you could just use `!BuildConfig.DEBUG`, to only configure ACRA on release builds. While there is nothing stopping you from using ACRA in development, you may find that it interferes somewhat with how you are used to debugging your crashes.

The approach shown here, using `onCreate()`, is fine for most apps. If your app has a `ContentProvider`, and it does significant work in its own `onCreate()` method, though, you will have a problem: `onCreate()` of `Application` is called *after* `onCreate()` of the provider(s). This means that any crashes in your providers' `onCreate()` will not be caught or reported by ACRA. You can try overriding `attachBaseContext()`, instead of `onCreate()`, in your `Application` subclass and initializing ACRA there, as `attachBaseContext()` appears to be called before `onCreate()` of any providers.

Also, if you have an existing `Application` subclass, you need to consider how [ACRA's error-reporting process](#) will impact your existing logic.

Reporting Crashes

Good news! You're done!

ACRA does not require you to litter your code with magic `try/catch` blocks to catch and report exceptions. After all, some Android exceptions – even those triggered from bugs in your code — are raised by Android framework code and your code appears nowhere in the stack trace.

CRASH REPORTING USING ACRA

Instead, ACRA takes advantage of `Thread` and its `setDefaultUncaughtExceptionHandler()` method, to get control when any unhandled exception occurs. All those crashes that normally would shut down a component or the whole app now go to ACRA and can be reported to your designated server.

Occasionally, you may wish to add some crashes that you *are* handling yourself to ACRA. For example, there may be some edge or corner cases that you are explicitly handling but are uncertain if they ever would happen. You could arrange to pass the `Exception` over to ACRA, which it will treat the same as any other crash that it intercepts.

To do this, call `getErrorReporter()` on the ACRA class, and call either `handleException()` or `handleSilentException()` on the error reporter. The difference is that `handleSilentException()` always reports the error silently, while `handleException()` will process this exception like any other, possibly alerting the user to the crash, as will be seen in the next section.

What the User Sees

The Simple sample app has ACRA configured, but this does us little good if we do not crash. So, the UI for the activity has a `Button`, and tapping that button will trigger a `RuntimeException`:

```
package com.commonware.android.button;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;

public class ButtonDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void earthShatteringKaboom(View v) {
        throw new RuntimeException(getString(R.string.msg_kaboom));
    }
}
```

(from [ACRA/Simple/app/src/main/java/com/commonware/android/button/ButtonDemoActivity.java](#))

...whose message is tied to a string resource.

CRASH REPORTING USING ACRA

When you click the Button, ACRA will send a crash report to your designated server. What the *user* perceives, though, varies based upon configuration.

Default: “Silent”

If you do not specify otherwise in your ACRA configuration, the default behavior will be “silent”. In this case, “silent” means “the user is not told that a report is being sent via ACRA”. Instead, the user sees the traditional Android crash dialog, for whatever version of Android the app is running on:

Figure 913: ACRA-Reported Crash, Silent Mode

However, there are several options that you can use instead of “silent” mode, if you so choose. One — showing a Toast — is not an especially good idea, as the user might not be looking at the screen right then and might not see the message.

Dialog

Another option is the “dialog” approach, where the user is shown a dialog-themed activity, indicating what happened and allowing the user to provide some additional information.

CRASH REPORTING USING ACRA

Figure 914: ACRA-Reported Crash, Dialog Mode

On the plus side, this is more transparent to the user, and the user can provide a bit more detail that might be useful to you. However, the user can also cancel out of the dialog, in which case you do not receive a crash report at all.

To set this up, you need to add a few more options to your ACRA configuration. You can see this in `ACRADialogApplication` in the sample project, which is a clone of `ACRAApplication`, set up for dialog-style reporting:

```
package com.commonware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.ReportingInteractionMode;
import org.acra.annotation.ReportsCrashes;

@ReportsCrashes(
    formUri=BuildConfig.ACRA_URL,
    mode = ReportingInteractionMode.DIALOG,
    resToastText = R.string.msg_acra_toast,
    resDialogText = R.string.msg_acra_dialog,
    resDialogCommentPrompt = R.string.msg_acra_comment_prompt,
    resDialogEmailPrompt = R.string.msg_acra_email_prompt,
    httpMethod=org.acra.sender.HttpSender.Method.PUT,
    reportType=org.acra.sender.HttpSender.Type.JSON
)
public class ACRADialogApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        if (BuildConfig.ACRA_INSTALL) {
```

CRASH REPORTING USING ACRA

```
ACRA.init(this);
    }
}
}
```

(from [ACRA/Simple/app/src/main/java/com/commonsware/android/button/ACRADialogApplication.java](#))

What turns on dialog mode is the `mode = ReportingInteractionMode.DIALOG` entry in the `@ReportsCrashes` annotation. This requires one additional entry, `resDialogText`, pointing to a string resource that is the message to display towards the top of the dialog.

You have a number of other optional settings to use to further customize the dialog. `ACRADialogApplication` demonstrates:

- `resToastText`, a string resource that will be shown in a Toast after the crash occurs and before the dialog appears. It takes ACRA a few seconds to collect the data for the crash report, and ACRA does not display the dialog until that data is collected. The Toast lets the user know that something is going on during this window of time.
- `resDialogCommentPrompt`, a string resource which, if included in `@ReportsCrashes`, enables a large `EditText` widget where the user can type in some comments about what they were doing at the time of the crash. The string resource serves as a label for this `EditText`.
- `resDialogEmailPrompt`, a string resource which, if included in `@ReportsCrashes`, enables an `EditText` widget where the user can type in an email address or other means of contacting the user. This value is saved in an ACRA-specific `SharedPreferences` value, and so it may already be filled in for the user, if the user had supplied a value previously. This, along with the comments, is included in the crash report for your use. The string resource serves as a label for this `EditText`.

You can also configure an icon for the dialog (`resDialogIcon`), a title to go across the top of the dialog (`resDialogText`), and the text for a Toast to be shown when the user taps OK (`resDialogIkToast`).

Of course, your `android:name` attribute of your `<application>` element in the manifest will need to point to this `Application` subclass. If you wish to try the dialog in the sample app, you will need to modify the sample app's manifest to point to `ACRADialogApplication` instead of `ACRAApplication`.

Beyond this, you will need to have the `org.acra.dialog.CrashReportDialog` `<activity>` element in your manifest, as mentioned above:

CRASH REPORTING USING ACRA

```
<activity
    android:name="org.acra.dialog.CrashReportDialog"
    android:excludeFromRecents="true"
    android:finishOnTaskLaunch="true"
    android:launchMode="singleInstance"
    android:process=":error_report"
    android:theme="@style/AppTheme.Dialog"
    tools:replace="android:theme" />
</application>
```

(from [ACRA/Simple/app/src/main/AndroidManifest.xml](#))

Most of this is boilerplate (and, ideally, would come from manifest merger from ACRA, though that is not an option for some reason). The big thing that you need to do is set up dialog themes that the `CrashReportDialog` activity will use. This sample app only runs on API Level 21+ (as it depends upon `Theme.Material` for the main UI), so we only need to provide one theme definition, here called `AppTheme.Dialog`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <style name="AppTheme" parent="android:Theme.Material">
        <item name="android:colorPrimary">@color/primary</item>
        <item name="android:colorPrimaryDark">@color/primary_dark</item>
        <item name="android:colorAccent">@color/accent</item>
    </style>

    <style
        name="AppTheme.Dialog"
        parent="@android:style/Theme.DeviceDefault.Dialog"/>
</resources>
```

(from [ACRA/Simple/app/src/main/res/values/styles.xml](#))

Here, we follow ACRA's advice and have `AppTheme.Dialog` inherit from `Theme.DeviceDefault.Dialog`. `DeviceDefault` is a theme based on the core theme for the Android OS version (`Material` for Android 5.0+), but one that can be tailored by device manufacturers and custom ROM developers. By extending `Theme.DeviceDefault.Dialog`, we are saying that we want our dialog to be styled like other system dialogs.

`Theme.DeviceDefault.Dialog` should be a fine base theme for API Level 11+. If you are supporting older Android devices than that, for those older API levels, use `Theme.Dialog` instead.

Also note that we need to use `tools:replace="android:theme"` to override the theme from the theme used in ACRA itself.

Notification

While the dialog mode is great, it is unsuitable for crashes that may occur in the background. You do not want to pop a dialog box up unexpectedly, as users may not appreciate the interruption.

The default “silent” mode, for crashes originating in the background, will not show a dialog. This is far more suitable for background work, but it does not let the user know that a crash occurred.

The Notification mode serves as middle ground. When a crash occurs in the background, ACRA raises a Notification. Tapping on that Notification, in turn, brings up the same dialog that the dialog mode uses.

To use this, switch your mode to `ReportingInteractionMode.NOTIFICATION` in the `@ReportsCrashes` annotation. Then, in addition to all the dialog configuration, add three more string resource references:

- `resNotifTickerText`, shown as the “ticker text” of the Notification on Android 4.4 and below
- `resNotifTitle`, shown as the title of the Notification in its tile in the notification tray
- `resNotifText`, shown as the text of the Notification in its tile in the notification tray

Optionally, you can also set `resNotifIcon` to a particular drawable resource to use for the icon for the Notification.

The sample app has an `ACRANotificationApplication` that demonstrates this:

```
package com.commonware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.ReportingInteractionMode;
import org.acra.annotation.ReportsCrashes;

@ReportsCrashes(
    formUri=BuildConfig.ACRA_URL,
    mode = ReportingInteractionMode.NOTIFICATION,
    resToastText = R.string.msg_acra_toast,
    resDialogText = R.string.msg_acra_dialog,
    resDialogCommentPrompt = R.string.msg_acra_comment_prompt,
    resDialogEmailPrompt = R.string.msg_acra_email_prompt,
    resNotifTickerText = R.string.msg_acra_notify_ticker,
    resNotifTitle = R.string.msg_acra_notify_title,
```

CRASH REPORTING USING ACRA

```
resNotifText = R.string.msg_acra_notify_text,
httpMethod=org.acra.sender.HttpSender.Method.PUT,
reportType=org.acra.sender.HttpSender.Type.JSON
)
public class ACRANotificationApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        if (BuildConfig.ACRA_INSTALL) {
            ACRA.init(this);
        }
    }
}
```

(from [ACRA/Simple/app/src/main/java/com/commonsware/android/button/ACRANotificationApplication.java](#))

If you switch the android:name of the <application> manifest element over to point to ACRANotificationApplication, crashing the app will bring up the Notification:

Figure 915: ACRA-Reported Crash, Notification Mode

(pro tip: use short strings)

Limitations

The big limitation is that you get exactly one reporting mode for your app, for automatically-collected crashes. This means that your choice of reporting mode will be dictated by whether or not you are doing work in the background, while you do not have a UI in the foreground (e.g., a Service):

- If you are not doing background work, use the dialog or silent modes
- If you are doing background work, use the notification or silent modes

What You See

The sample app asks ACRA to send the crash data over in a JSON structure. That JSON contains all sorts of information by default, including USER_COMMENT and USER_EMAIL properties if you chose the dialog or notification modes.

Here is what we get from a crash of the sample app, using the dialog notification mode:

(note: some property values were truncated with . . . , as they were much too long to try to display in a book)

Your server can parse this and use it to take appropriate action.

Note that the Java stack trace (STACK_TRACE property) is formatted with embedded Java-style/C-style control characters (\n for newlines, \t for tabs). Your server can convert that into plain text with appropriate formatting.

Customizing Where Reports Go

The sample app uses one particular approach for sending crash-reports off-device: use an HTTP PUT operation, applied to a server configured in @ReportsCrashes.

That is not your only option.

HTTP

httpMethod=org.acra.sender.HttpSender.Method.PUT in @ReportsCrashes is what steers ACRA to use an HTTP PUT request to submit the crash report. Without this, by default, it will use an HTTP POST request.

However, with POST, it treats the URL (in the formUri property) a bit differently:

CRASH REPORTING USING ACRA

- For a PUT, the UUID of the crash report is appended to the URL (`http://localhost:10.0.2.2/reports/f4a411b0-7a5a-0133-dd79-14feb5bc72a7`)
- For a POST, the URL is used directly without modification (`http://localhost:10.0.2.2/reports`), where the UUID only appears as the `REPORT_ID` value in the crash report

`reportType=org.acra.sender.HttpSender.Type.JSON` in `@ReportsCrashes` is what tells ACRA to generate a JSON document and submit that as a crash report. If you are using PUT, you probably want JSON. However, the default (no `reportType`) is a classic Web form encoded string, which would be a more natural choice for POST requests, as your server probably already has logic to convert a Web form into more convenient variables in your desired Web app framework and language.

If your server requires HTTP Basic authentication, `formUriBasicAuthLogin` and `formUriBasicAuthPassword` are available as `@ReportsCrashes` properties. Those are of somewhat limited utility, as anyone who can see the whole URL probably can see those HTTP headers without much additional work, and they have to be hard-coded into your app.

Email

Replacing `formUri` and the other HTTP `@ReportsCrashes` properties with `mailto` (`mailto=omgomgomg@foo.com`) will cause ACRA to not attempt to deliver the crash report directly. Instead, it will use `ACTION_SENDTO` with a `mailto Uri`, pointing at your requested email address, to try to bring up an email client. If the user does not have a configured email client, or if the user chooses not to send the email, you do not get the crash report.

DIY

If none of the stock ACRA delivery options works for you, you are welcome to add your own. You can create an implementation of the `ReportSender` interface, complete with a `send()` method that will be called to actually send the crash report. You can then declare a `reportSenderFactoryClasses` attribute in your `@ReportCrashes` annotation, with an array of `ReportSender` classes:

```
@ReportCrashes{
    reportSenderFactoryClasses = {SpecialReportSender.class}
    // other configuration
}
```

It is up to you to then get the crash report somewhere useful to you, by one means or another.

Adding Additional Data

As demonstrated in the preceding section, ACRA throws a lot of data into the crash report. However, you can add more than that, if you wish, to either better diagnose problems or to provide more individualized assistance.

Adding Stack Data to Emails

With any of the HTTP options, the crash report contains, by default, a lot of information. For email, though, rather than have an attachment with the full report, ACRA only sends along a few bits of data, such as the stack trace.

The `customReportContent` property on `@ReportsCrashes` allows you to tailor this, expanding it to include other report fields. There is a `ReportField` class that defines a series of constants that you use to indicate what should be in the report.

LogCat and Other Logs

ACRA uses some undocumented and unsupported means of collecting LogCat data and including it in the crash report. However, for most Android devices (those running Android 4.1+), this will only contain log lines from your app's process, due to some Android changes, for privacy reasons.

If you have elected to do your own logging elsewhere, you can teach ACRA to incorporate its logs into the crash report:

- Add `ReportField.APPLICATION_LOG` to the list of report fields in the `customReportContent` property on `@ReportsCrashes`
- Add an `applicationLogFile` property on `@ReportsCrashes` to indicate where the log file is
- Optionally add an `applicationLogFileLines` property on `@ReportsCrashes` to indicate how many lines from the log file to include in the crash report (where it defaults to 100)

Note, though, that it is unclear how you express the path to the log file (for `applicationLogFile`), as the actual filesystem path may vary by device and user.

Device Identifier

If your app has the `READ_PHONE_STATE` permission, ACRA will try to include a telephony hardware identifier (e.g., IMEI for GSM phones) in the crash report. However:

- This has privacy implications, and so ACRA has a way to allow the user to control whether this value is included, as will be covered [later in this chapter](#).
- `READ_PHONE_STATE` is a dangerous permission, requiring you to request that permission at runtime on Android 6.0+ devices, if your `targetSdkVersion` is 23 or higher. You will not be in position to request this permission at the time of the crash, and so you will need to ask for it at some other point (e.g., on first run of your app).

If your objective is merely to correlate crash reports coming from the same installation of your app, consider storing a UUID in `SharedPreferences` (initialized on first run), as that will be included in your crash report, as is covered in the next section.

Additional SharedPreferences

If you use `PreferenceManager.getDefaultSharedPreferences()`, everything inside of there is included in your ACRA crash report.

If you use other `SharedPreferences` files (e.g., via `getSharedPreferences()`), and you want those `SharedPreferences` included in the crash report, add an `additionalSharedPreferences` property to `@ReportsCrashes`, supplying a list of the preferences filenames:

```
additionalSharedPreferences={"game_stats"}
```

Here, `game_stats` is the `SharedPreferences` filename, passed in as the first parameter to `getSharedPreferences()`.

Your Own Data

ACRA also maintains a process-level `LinkedHashMap` that you can add to, where its contents are included in the crash report. Simply call `ACRA.getErrorReporter().putCustomData()`, supplying the key and value as `String` objects.

Because this is a `LinkedHashMap`, calling `putCustomData()` for some key will replace any past value for that key. The use of `LinkedHashMap` means that the data will be saved (and reported) in alphabetical order. Hence, you are welcome to generate unique keys if you want, perhaps based on `SystemClock.uptimeMillis()`, to use this custom data as an ersatz log.

However, since all of this data is kept in heap space, you will need to be judicious about its use. You are better served using actual file-based logs (whether LogCat or your own) for true logging, reserving this “custom data” for transient state or values that are non-changing.

Note that there is also `removeCustomData()`, which removes a value from the `LinkedHashMap`, given its key. In addition, `getCustomData()` returns the current value given its key, in case you wish to use this `LinkedHashMap` as the master copy of some data, in addition to having that data included in the crash report.

Removing Data

Conversely, you may wish to remove data from the ACRA crash reports. One key reason would be privacy, if there are specific things that you see showing up in the ACRA data that you think users might not like being disclosed. Another reason would be bandwidth, as there is little point in transferring data to be discarded over the Internet, adding load to your servers and perhaps costing your users money on their metered data connections.

Report Fields

As mentioned [earlier in this chapter](#), the `customReportContent` property on `@ReportsCrashes` can be used to add fields to email-based crash reports, which normally only include a small subset of the actual available data.

Conversely, for HTTP-based crash reports — where `customReportContent` defaults to “everything” — `customReportContent` can be used to restrict what is included in the report.

SharedPreferences Values

If there are specific `SharedPreferences` values that you would like to be excluded from crash reports, for privacy or security reasons, you can do that via an `excludeMatchingSharedPreferencesKeys` property on `@ReportsCrashes`. For

CRASH REPORTING USING ACRA

example, if you use `SharedPreferences` to store some limited-life authorization token from a server, it is probably best to exclude that from the crash report.

`excludeMatchingSharedPreferencesKeys` takes a list of regular expression patterns, following the regular expression syntax used by Java's [Pattern class](#). If you do not use any Pattern-specific control characters, the default is basically a plain string match.

So, for example, if you have a `serverToken` `SharedPreferences` value that you would like to exclude, use:

```
excludeMatchingSharedPreferencesKeys={"serverToken"}
```

in your `@ReportsCrashes` annotation.

End-User Configuration

ACRA monitors certain default `SharedPreferences` values and configures its behavior based upon them. By exposing those preferences in your own `PreferenceFragment` or `PreferenceActivity`, you can allow the user to control ACRA's behavior.

The following table outlines the options:

Preference Key	Role	Data Type	Preference Type
<code>acra.disable</code>	Enable or disable ACRA reporting outright	boolean	<code>CheckBoxPreference</code>
<code>acra.syslog.enable</code>	Include LogCat data in crash reports	boolean	<code>CheckBoxPreference</code>
<code>acra.deviceid.enable</code>	Include device ID (e.g., IMEI) in crash reports	boolean	<code>CheckBoxPreference</code>
<code>acra.user.email</code>	Email address to include in reports	String	<code>EditTextPreference</code>
<code>acra.alwaysaccept</code>	If true, reports are always sent, even for dialog or notification modes	boolean	<code>CheckBoxPreference</code>

Note that `acra.disable` has an `acra.enable` counterpart. Only use one of these. A value of `true` for `acra.disable` is equivalent to `false` for `acra.enable`.

Also note that `acra.syslog.enable` is less important nowadays. In earlier versions of Android, where apps could get at everything in LogCat, it is possible that including LogCat data might have privacy implications for users, since that data would include logging from other apps. Since Android 4.1 no longer allows apps to get at LogCat data from other apps, this particular concern is moot.

ACRA and Processes

If you crash with an unhandled exception, your existing process is in a state of disarray. To help ensure that ACRA can report your crash successfully, ACRA by default runs its error-reporting Service in a separate ACRA-specific process.

Most of the time, this does not affect you.

One place where it might is if you have a custom Application subclass for things beyond ACRA. Bear in mind that each process gets its own copy of the virtual machine (Dalvik or ART) and each gets its own independent instance of your designated Application class. Work that you do for your main app's process you may wish to skip for the ACRA-specific background process.

To handle this, you can call `isACRASenderServiceProcess()` on the ACRA class. If this returns true, your Application is being created for ACRA's use, and you can skip any custom initialization work. If this returns false, this is one of your processes, and you can proceed normally.

Note that `isACRASenderServiceProcess()` was added to ACRA 4.9.0.

JVM Scripting Languages

The Java virtual machine (JVM) is a remarkably flexible engine. While it was originally developed purely for Java, it has spawned its own family of languages, just as Microsoft's CIL supports multiple languages for the Windows platform. Some languages targeting the JVM as a runtime will work on Android, since the regular Java VM and Android's Dalvik VM are so similar.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Some of the sample code demonstrates JUnit test cases, so reading [the chapter on unit testing](#) may be useful.

Languages on Languages

Except for the handful of early language interpreters and compilers hand-constructed in machine code, every programming language is built atop earlier ones. C and C++ are built atop assembly language. Many other languages, such as Java itself, are built atop C/C++.

Hence, it should not come as much of a surprise that an environment as popular as Java has spawned another generation of languages whose implementations are in Java.

There are a few flavors of these languages. Some, like Scala and Clojure, are compiled languages whose compilers created JVM bytecodes, no different than would a Java compiler. These do not strictly qualify as a “scripting language”, however, since they typically compile their source code to bytecode ahead of time.

Some Java-based scripting languages use fairly simple interpreters. These interpreters convert scripting code into parsed representations (frequently so-called “abstract syntax trees”, or ASTs), then execute the scripts from their parsed forms. Most scripting languages at least start here, and some, like BeanShell, stick with this implementation.

Other scripting languages try to bridge the gap between a purely interpreted language and a compiled one like Scala or Clojure. These languages turn the parsed scripting code into JVM bytecode, effectively implementing their own just-in-time compiler (JIT). Since many Java runtimes themselves have a JIT to turn bytecode into machine code (“opcode”), languages with their own JIT can significantly outperform their purely-interpreted counterparts. JRuby and Rhino are two languages that have taken this approach.

A Brief History of JVM Scripting

Back in the beginning, the only way to write for the JVM was in Java itself. However, since writing language interpreters is a common pastime, it did not take long for people to start implementing interpreters in Java. These had their niche audiences, but there was only modest interest in the early days — interpreters made Java applets too large to download, for example.

Things got a bit more interesting in 1999, when IBM [released](#) the Bean Scripting Framework (BSF). This offered a uniform API for scripting engines, meaning that a hosting Java application could write to the BSF API, then plug in arbitrary interpreters at runtime. It was even possible, with a bit of extra work, to allow new interpreters to be downloaded and used on demand, rather than having to be pre-installed with the application. BSF also standardized how to inject Java objects into the scripting engines themselves, for access by the scripts. This allowed scripts to work with the host application’s objects, such as allowing scripts to manipulate the contents of the [jEdit](#) text editor.

This spurred interest in scripting. In addition to some IBM languages (e.g., [NetREXX](#)) supporting BSF natively, other languages, like [BeanShell](#), created BSF adapters to allow their languages to participate in the BSF space. On the consumer side, various Web frameworks started supporting BSF scripting for dynamic Web content generation, and so forth.

Interest was high enough that Apache took over stewardship of [BSF](#) in 2003. Shortly thereafter, Sun and others started work on [JSR-223](#), which added the `javax.script`

framework to Java 6. The `javax.script` framework advanced the BSF concept and standardized it as part of Java itself.

At this point, most JVM scripting languages that are currently maintained support `javax.script` integration, and may also support integration with the older BSF API as well.

Android does not include `javax.script` as part of its subset of the Java SE class library from the Apache Harmony project. This certainly does not preclude integrating scripting languages into Android applications, but it does raise the degree of difficulty a bit.

Limitations

Of course, JVM scripting languages do not necessarily work on Android without issue. There may be some work to get a JVM language going on Android.

Android SDK Limits

Android is not Java SE, or Java ME, or even Java EE. While Android has many standard Java classes, it does not have a class library that matches any traditional pattern. As such, languages built assuming Java SE, for example, may have some dependency issues.

For languages where you have access to the source code, removing these dependencies may be relatively straightforward, particularly if they are ancillary to the operation of the language itself. For example, the language may come with miniature Swing IDEs, support for scripted servlets, or other capabilities that are not particularly relevant on Android and can be excised from the source code.

Wrong Bytecode

Android runs Dalvik bytecode, not Java bytecode. The conversion from Java bytecode to Dalvik bytecode happens at compile time. However, the conversion tool is rather finicky — it wants bytecode from Sun/Oracle's Java 1.5 or 1.6, nothing else. This can cause some problems:

1. You may encounter a JAR that is old enough to have been compiled with Java 1.4.2

2. You may encounter JARs compiled using other compilers, such as the GNU Compiler for Java (GCJ), common on Linux distributions
3. Java 7 has bytecode differences from Java 6; users of Java 7 need to compile their Java classes to Java 6 bytecode
4. Languages that have their own JIT compilers will have problems, because their JIT compilers will be generating Java bytecodes, not Dalvik bytecodes, meaning that the JIT facility needs to be rewritten or disabled

Again, if you have the source code, recompiling on an Android-friendly Java compiler should be a simple process.

Age

The heyday of some JVM languages is in the past. As such, you may find that support for some languages will be limited, simply because few people are still interested in them. Finding people interested in those languages on Android — the cross-section of two niches — may be even more of a problem.

SL4A and JVM Languages

SL4A supports three JVM languages today:

1. BeanShell
2. JRuby
3. Rhino (JavaScript)

You can use those within your SL4A environment no different than you can any other scripting language (e.g., Perl, Python, PHP). Hence, if what you are looking for is to create your own personal scripts, or writing small applications, SL4A saves you a lot of hassle. If there is a JVM scripting language you like but is not supported by SL4A, adding support for new interpreters within SL4A is fairly straightforward, though the APIs may change as SL4A is undergoing a fairly frequent set of revisions.

Embedding JVM Languages

While SL4A will drive end users towards writing their own scripts or miniature applications using JVM languages, another use of these languages is for embedding in a full Android application. Scripting may accelerate development, if the developers are more comfortable with the scripted language than with Java. Also, if

the scripts are able to be modified or expanded by users, an ecosystem may emerge for user-contributed scripts.

Architecture for Embedding

Embedding a scripting language is not something to be undertaken lightly, even on a desktop or server application. Mobile devices running Android will have similar issues.

Asynchronous

One potential problem is that a script may take too long to execute. Android's architecture assume that work triggered by buttons, menus, and the like will either happen very quickly or will be done on background threads. Particularly for user-generated scripts, the script execution time is unknowable in advance — it might be a few milliseconds, or it might be several seconds. Hence, any implementation of a scripting extension for an Android application needs to consider executing all scripts in a background thread. This, of course, raises its own challenges for reflecting those scripts' results on-screen, since GUI updates cannot be done on a background thread.

Security

Scripts in Android inherit the security restrictions of the process that runs the script. If an application has the right to access the Internet, so will any scripts run in that application's process. If an application has the right to read the user's contacts, so will any scripts run in that application's process. And so on. If the scripts in question are created by the application's authors, this is not a big deal — the rest of the application has those same permissions, after all. But, if the application supports user-authored scripts, it raises the potential of malware hijacking the application to do things that the malware itself would otherwise lack the rights to do.

Inside the InterpreterService

One way to solve both of those problems is to isolate the scripting language in a self-contained low-permission APK — “sandboxing” the interpreter so the scripts it executes are less able to cause harm. This APK could also arrange to have the interpreter execute its scripts on a background thread. An even better implementation would allow the embedding application to decide whether or not

the “sandbox” is important — applications with a controlled source of scripts may not need the extra security or the implementation headaches it causes.

With that in mind, let us take a look at the [JVM/InterpreterService](#) sample project, one possible implementation of the strategy described above.

The Interpreter Interface

The InterpreterService can support an arbitrary number of interpreters, via a common interface. This interface provides a simplified API for having an interpreter execute a script and return a result:

```
package com.commonware.abj.interp;

import android.os.Bundle;

public interface I_Interpreter {
    Bundle executeScript(Bundle input);
}
```

(from [JVM/InterpreterService/src/com/commonware/abj/interp/I_Interpreter.java](#))

As you can see, it is *very* simplified, offering just a single `executeScript()` method. That method accepts a `Bundle` (a key-value store akin to a Java `HashMap`) as a parameter — that `Bundle` will need to contain the script and any other objects needed to execute the script.

The interpreter will return another `Bundle` from `executeScript()`, containing whatever data it wants the script’s requester to have access to.

For example, here is the implementation of `EchoInterpreter`, which just returns the same `Bundle` that was passed in:

```
package com.commonware.abj.interp;

import android.os.Bundle;

public class EchoInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        return(input);
    }
}
```

(from [JVM/InterpreterService/src/com/commonware/abj/interp/EchoInterpreter.java](#))

A somewhat more elaborate sample is the `SQLiteInterpreter`:

JVM SCRIPTING LANGUAGES

```
package com.commonware.abj.interp;

import android.database.Cursor;
import android.database.sqlite.SQLiteDatabase;
import android.os.Bundle;

public class SQLiteInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        Bundle result=new Bundle(input);
        String script=input.getString(InterpreterService.SCRIPT);

        if (script!=null) {
            SQLiteDatabase db=SQLiteDatabase.create(null);
            Cursor c=db.rawQuery(script, null);

            c.moveToFirst();

            for (int i=0;i<c.getColumnCount();i++) {
                result.putString(c.getColumnName(i), c.getString(i));
            }

            c.close();
            db.close();
        }

        return(result);
    }
}
```

(from [JVM/InterpreterService/src/com/commonware/abj/interp/SQLiteInterpreter.java](#))

This class accepts a script, in the form of a SQLite database query. It extracts the script from the Bundle, using a pre-defined key (InterpreterService.SCRIPT). Assuming there is such a script, it creates an empty in-memory database and executes the SQLite query against that database.

The results come back in the form of a Cursor — itself a key-value store. SQLiteInterpreter takes those results and pours them into a Bundle to be returned.

The Bundle being returned starts from a copy of the input Bundle, so the script requester can embed in the input Bundle any identifiers it needs to determine how to handle the results from executing this script.

SQLiteInterpreter is not terribly flexible, but you can use it for simple numeric and string calculations, such as the following script:

```
SELECT 1+2 AS result, 'foo' AS other_result, 3*8 AS third_result;
```

This would return a Bundle containing a key of result with a value of 3, a key of other_result with a value of foo, and a key of third_result with a value of 24.

Of course, it would be nice to support more compelling interpreters, and we will examine a pair of those later in this chapter.

Loading Interpreters and Executing Scripts

Of course, having a nice clean interface to the interpreters does nothing in terms of actually executing them on a background thread, let alone sandboxing them. The `InterpreterService` class itself handles that.

`InterpreterService` is an `IntentService`, which automatically routes incoming `Intent` objects (from calls to `startService()`) to a background thread via a call to `onHandleIntent()`. `IntentService` will queue up `Intent` objects if needed, and `IntentService` even automatically shuts down if there is no more work to be done.

Here is the implementation of `onHandleIntent()` from `InterpreterService`:

```
@Override
protected void onHandleIntent(Intent intent) {
    String action=intent.getAction();
    I_Interpreter interpreter=interpreters.get(action);

    if (interpreter==null) {
        try {
            interpreter=(I_Interpreter)Class.forName(action).newInstance();
            interpreters.put(action, interpreter);
        }
        catch (Throwable t) {
            Log.e("InterpreterService", "Error creating interpreter", t);
        }
    }

    if (interpreter==null) {
        failure(intent, "Could not create interpreter: "+intent.getAction());
    }
    else {
        try {
            success(intent, interpreter.executeScript(intent.getBundleExtra(BUNDLE)));
        }
        catch (Throwable t) {
            Log.e("InterpreterService", "Error executing script", t);

            try {
                failure(intent, t);
            }
            catch (Throwable t2) {
                Log.e("InterpreterService",
                    "Error returning exception to client",
                    t2);
            }
        }
    }
}
```

JVM SCRIPTING LANGUAGES

(from [JVM/InterpreterService/src/com/commonsware/abj/interp/InterpreterService.java](#))

We keep a cache of interpreters, since initializing their engines may take some time. That cache is keyed by the interpreter's class name, and that key comes in to the service by way of the action on the Intent that was used to start the service. In other words, the script requester tells us, by way of the Intent used in `startService()`, which interpreter to use.

Those interpreters are created using reflection. This way, `InterpreterService` has no compile-time knowledge of any given interpreter class. Interpreters can come and go, but `InterpreterService` remains the same.

Assuming an interpreter was found (either cached or newly created), we have it execute the script, with the input `Bundle` coming from an "extra" on the Intent. Methods named `success()` and `failure()` are then responsible for getting the results to the script requester... as will be seen in the next section.

Delivering Results

Script requesters can get the results of the script back — in the form of the interpreter's output `Bundle` — in one of two ways.

One option is a private broadcast Intent. This is a broadcast Intent where the broadcast is limited to be delivered only to a specific package, not to any potential broadcast receiver on the device.

The other option is to supply a `PendingIntent` that will be sent with the results. This could be used by an Activity and `createPendingIntent()` to have control routed to its `onActivityResult()` method. Or, an arbitrary `PendingIntent` could be created, to start another activity, for example.

The implementations of `success()` and `failure()` in `InterpreterService` simply build up an Intent containing the results to be delivered:

```
private void success(Intent intent, Bundle result) {
    Intent data=new Intent();

    data.putExtras(result);
    data.putExtra(RESET_CODE, SUCCESS);

    send(intent, data);
}

private void failure(Intent intent, String message) {
    Intent data=new Intent();
```

JVM SCRIPTING LANGUAGES

```
data.putExtra(ERROR, message);
data.putExtra(RESULT_CODE, FAILURE);

send(intent, data);
}

private void failure(Intent intent, Throwable t) {
    Intent data=new Intent();

    data.putExtra(ERROR, t.getMessage());
    data.putExtra(TRACE, getStackTrace(t));
    data.putExtra(RESULT_CODE, FAILURE);

    send(intent, data);
}
```

(from [JVM/InterpreterService/src/com/commonsware/abj/interp/InterpreterService.java](#))

These, in turn, delegate the actual sending logic to a `send()` method that delivers the result Intent via a private broadcast or a `PendingIntent`, as indicated by the script requester:

```
private void send(Intent intent, Intent data) {
    String broadcast=intent.getStringExtra(BROADCAST_ACTION);

    if (broadcast==null) {
        PendingIntent pi=(PendingIntent)intent.getParcelableExtra(PENDING_RESULT);

        if (pi!=null) {
            try {
                pi.send(this, Activity.RESULT_OK, data);
            }
            catch (PendingIntent.CanceledException e) {
                // no-op -- client must be gone
            }
        }
    }
    else {
        data.setPackage(intent.getStringExtra(BROADCAST_PACKAGE));
        data.setAction(broadcast);

        sendBroadcast(data);
    }
}
```

(from [JVM/InterpreterService/src/com/commonsware/abj/interp/InterpreterService.java](#))

Packaging the InterpreterService

There are three steps for integrating `InterpreterService` into an application.

First, you need to decide what APK the `InterpreterService` goes in – the main one for the application (no sandbox) or a separate low-permission one (sandbox).

JVM SCRIPTING LANGUAGES

Second, you need to decide what interpreters you wish to support, writing `I_Interpreter` implementations and getting the interpreters' JARs into the project's `libs/` directory.

Third, you need to add the source code for `InterpreterService` along with a suitable `<service>` entry in `AndroidManifest.xml`. This entry will need to support `<intent-filter>` elements for each scripting language you are supporting, such as:

```
<service
  android:name=".InterpreterService"
  android:exported="false">
  <intent-filter>
    <action android:name="com.commonware.abj.interp.EchoInterpreter"/>
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.abj.interp.SQLiteInterpreter"/>
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.abj.interp.BshInterpreter"/>
  </intent-filter>
  <intent-filter>
    <action android:name="com.commonware.abj.interp.RhinoInterpreter"/>
  </intent-filter>
</service>
```

(from [JVM/InterpreterService/AndroidManifest.xml](#))

From there, it is a matter of adding in appropriate `startService()` calls to your application wherever you want to execute a script, and processing the results you get back.

Using the InterpreterService

To use the `InterpreterService`, you need to first determine which `I_Interpreter` engine you are using, as that forms the action for the `Intent` to be used with the `InterpreterService`. Create an `Intent` with that action, then add in an `InterpreterService.BUNDLE` extra for the script and other data to be supplied to the interpreter. Also, you can add an `InterpreterService.BROADCAST_ACTION`, to be used by `InterpreterService` to send results back to you via a broadcast `Intent`. Finally, call `startService()` on the `Intent`, and the results will be delivered to you asynchronously.

For example, here is a test method from the `EchoInterpreterTests` test case:

```
package com.commonware.abj.interp;
import android.os.Bundle;
```

JVM SCRIPTING LANGUAGES

```
public class EchoInterpreterTests extends InterpreterTestCase {
    protected String getInterpreterName() {
        return("com.commonware.abj.interp.EchoInterpreter");
    }

    public void testNoInput() {
        Bundle results=execServiceTest(new Bundle());

        assertNotNull(results);
        assertEquals(results.size(), 0);
    }

    public void testWithSomeInputJustForGrins() {
        Bundle input=new Bundle();

        input.putString("this", "is a value");

        Bundle results=execServiceTest(input);

        assertNotNull(results);
        assertEquals(results.getString("this"), "is a value");
    }
}
```

(from [JVM/InterpreterService/tests/src/com/commonware/abj/interp/EchoInterpreterTests.java](#))

The echo “interpreter” simply echoes the input Bundle into the output. The `execServiceTest()` method is inherited from the `InterpreterTestCase` base class:

```
protected Bundle execServiceTest(Bundle input) {
    Intent i=new Intent(getInterpreterName());

    i.putExtra(InterpreterService.BUNDLE, input);
    i.putExtra(InterpreterService.BROADCAST_ACTION, ACTION);

    getContext().startService(i);

    try {
        latch.await(5000, TimeUnit.MILLISECONDS);
    }
    catch (InterruptedException e) {
        // just keep rollin'
    }

    return(results);
}
```

(from [JVM/InterpreterService/tests/src/com/commonware/abj/interp/InterpreterTestCase.java](#))

The `execServiceTest()` method uses a `CountDownLatch` to wait on the interpreter to do its work before proceeding (or 5000 milliseconds, whichever comes first). The broadcast Intent containing the results, registered to watch for `com.commonware.abj.interp.InterpreterTestCase` broadcasts, stuffs the output Bundle in a results data member and drops the latch, allowing the main test thread to continue.

BeanShell on Android

What if Java itself were a scripting language? What if you could just execute a snippet of Java code, outside of any class or method? What if you could still import classes, call static methods on classes, create new objects, as well?

That was what BeanShell offered, back in its heyday. And, since BeanShell does not use sophisticated tricks with its interpreter – like JIT compilation of scripting code — BeanShell is fairly easy to integrate into Android.

What is BeanShell?

[BeanShell](#) is Java on Java.

With BeanShell, you can write scripts in loose Java syntax. Here, “loose” means:

1. In addition to writing classes, you can execute Java statements outside of classes, in a classic imperative or scripting style
2. Data types are optional for variables
3. Not every language feature is supported, particularly things like annotations that did not arrive until Java 1.5
4. Etc.

BeanShell was originally developed in the late 1990’s by Pat Niemeyer. It enjoyed a fair amount of success, even being considered as a standard interpreter to ship with Java ([JSR-274](#)). However, shortly thereafter, BeanShell lost momentum, and it is no longer being actively maintained. That being said, it works quite nicely on Android... once a few minor packaging issues are taken care of.

Getting BeanShell Working on Android

BeanShell has two main problems when it comes to Android:

- The publicly-downloadable JAR was compiled for Java 1.4.2, and Android requires Java 5 or newer
- The source code includes various things, like a Swing-based GUI and a servlet, that have no real place in an Android app and require classes that Android lacks

Fortunately, with BeanShell being open source, it is easy enough to overcome these challenges. You could download the source into an Android library project, then remove the classes that are not necessary (e.g., the servlet), and use that library project in your main application. Or, you could use an Android project for creating a JAR file that was compiled against the Android class library, so you are certain everything is supported.

However, the easiest answer is to use SL4A's BeanShell JAR, since they have solved those problems already. The JAR can be found in the [SL4A source code repository](#), though you will probably need to check out the project using Mercurial, since JARs cannot readily be downloaded from the Google Code Web site.

Integrating BeanShell

The BeanShell engine is found in the `bsh.Interpreter` class. Wrapping one of these in an `I_Interpreter` interface, for use with `InterpreterService`, is fairly simple:

```
package com.commonware.abj.interp;

import android.os.Bundle;
import bsh.Interpreter;

public class BshInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        Interpreter i=new Interpreter();
        Bundle output=new Bundle(input);
        String script=input.getString(InterpreterService.SCRIPT);

        if (script != null) {
            try {
                i.set(InterpreterService.BUNDLE, input);
                i.set(InterpreterService.RESULT, output);

                Object eval_result=i.eval(script);

                output.putString("result", eval_result.toString());
            }
            catch (Throwable t) {
                output.putString("error", t.getMessage());
            }
        }

        return(output);
    }
}
```

(from [JVM/InterpreterService/src/com/commonware/abj/interp/BshInterpreter.java](#))

BeanShell interpreters are fairly inexpensive objects, so we create a fresh `Interpreter` for each script, so one script cannot somehow access results from prior

scripts. After setting up the output `Bundle` and extracting the script from the input `Bundle`, we inject both `Bundle` objects into `BeanShell` itself, where they can be accessed like global variables, named `_bundle` and `_result`.

At this point, we evaluate the script, using the `eval()` method on the `Interpreter` object. If all goes well, we convert the object returned by the script into a `String` and tuck it into the output `Bundle`, alongside anything else the script may have put into the `Bundle`. If there is a problem, such as a syntax error in the script, we put the error message into the output `Bundle`.

So long as the `InterpreterService` has an `<intent-filter>` for the `com.commonsware.abj.interp.BshInterpreter` action, and so long as we have a `BeanShell` JAR in the project's `libs/` directory, `InterpreterService` is now capable of executing `BeanShell` scripts as needed.

With our inherited `execServiceTest()` method handling invoking the `InterpreterService` and waiting for responses, we can “simply” put our script as the `InterpreterService.SCRIPT` value in the input `Bundle`, and see what we get out. The first test script returns a simple value; the second test script directly calls methods on the output `Bundle` to return its results.

Rhino on Android

JavaScript arrived on the language scene hot on the heels of Java itself. The name was chosen for marketing purposes more so than for any technical reason. Java and JavaScript had little to do with one another, other than both adding interactivity to Web browsers. And while Java has largely faded from mainstream browser usage, JavaScript has become more and more of a force on the browser, and even now on Web servers.

And, along the way, the Mozilla project put JavaScript on Java and gave us Rhino.

What is Rhino?

If `BeanShell` is Java in Java, [Rhino](#) is JavaScript in Java.

As part of Netscape's failed “Javagator” attempt to create a Web browser in Java, they created a JavaScript interpreter for Java, code-named Rhino after the cover of O'Reilly Media's [JavaScript: The Definitive Guide](#). Eventually, Rhino was made available to the Mozilla Foundation, which has continued maintaining it. At the

present time, Rhino implements JavaScript 1.7, so it does not support the latest and greatest JavaScript capabilities, but it is still fairly full-featured.

Interest in Rhino has ticked upwards, courtesy of interest in using JavaScript in places other than Web browsers, such as server-side frameworks. And, of course, it works nicely with Android.

Getting Rhino Working on Android

Similar to BeanShell, Rhino has a few minor source-level incompatibilities with Android. However, these can be readily pruned out, leaving you with a still-functional JavaScript interpreter. However, once again, it is easiest to use [SL4A's Rhino JAR](#), since all that work is done for you.

Integrating Rhino

Putting an `I_Interpreter` facade on Rhino is incrementally more difficult than it is for BeanShell, but not by that much:

```
package com.commonware.abj.interp;

import android.os.Bundle;
import org.mozilla.javascript.*;

public class RhinoInterpreter implements I_Interpreter {
    public Bundle executeScript(Bundle input) {
        String script=input.getString(InterpreterService.SCRIPT);
        Bundle output=new Bundle(input);

        if (script != null) {
            Context ctxt=Context.enter();

            try {
                ctxt.setOptimizationLevel(-1);

                Scriptable scope=ctxt.initStandardObjects();
                Object jsBundle=Context.javaToJS(input, scope);
                ScriptableObject.putProperty(scope, InterpreterService.BUNDLE,
                    jsBundle);

                jsBundle=Context.javaToJS(output, scope);
                ScriptableObject.putProperty(scope, InterpreterService.RESULT,
                    jsBundle);

                String result=
                    Context.toString(ctxt.evaluateString(scope, script,
                        "<script>", 1, null));

                output.putString("result", result);
            }
            finally {
```

JVM SCRIPTING LANGUAGES

```
        Context.exit();
    }
}

return(output);
}
}
```

(from [JVM/InterpreterService/src/com/commonsware/abj/interp/RhinoInterpreter.java](#))

As with BshInterpreter, RhinoInterpreter sets up the output Bundle and extracts the script from the input Bundle. Assuming there is a script, RhinoInterpreter then sets up a Rhino Context object, which is roughly analogous to the BeanShell Interpreter object. One key difference is that you need to clean up the Context, by calling a static `exit()` method on the Context class, whereas with a BeanShell Interpreter, you just let garbage collection deal with it.

Rhino has a JIT compiler, one that unfortunately will not work with Android, since it generates Java bytecode, not Dalvik bytecode. However, Rhino lets you turn that off, by calling `setOptimizationLevel()` on the Context object with a value of `-1` (meaning, in effect, disable all optimizations).

After that, we:

1. Create a language scope for our script and inject standard JavaScript global objects into that scope
2. Wrap our two Bundle objects with JavaScript proxies via calls to `javaToJS()`, then injecting those objects into the scope as

`_bundle` and `_result` via `putProperty()` calls

1. Execute the script via a call to `evaluateString()` on the Context object, converting the resulting object into a String and pouring it into the output Bundle

If our InterpreterService has an `<intent-filter>` for the `com.commonsware.abj.interp.RhinoInterpreter` action, and so long as we have a Rhino JAR in the project's `libs/` directory, InterpreterService can now invoke JavaScript.

Other JVM Scripting Languages

As mentioned previously, there are many languages that, themselves, are implemented in Java and can be ported to Android, with varying degrees of difficulty. Many of these languages are fairly esoteric. Some, like JRuby, have evolved to the point where they transcend a simple “scripting language” on Android.

However, there are two other languages worth mentioning, as they are fairly well-known in Java circles: Groovy and Jython.

Groovy

[Groovy](#) is perhaps the most popular Java-based language that does not have its roots in some other previous language (Java, JavaScript, Python, etc.). Designed in some respects to be a “better Java than Java”, Groovy gives you access to Java classes while allowing you to write scripts with dynamic typing, closures, and so forth. Groovy has an extensive community, complete with a fair number of Groovy-specific libraries and frameworks, plus some books on the market.

At the time of this writing, it does not appear that Groovy has been successfully ported to work on Android, though.

Jython

[Jython](#) is an implementation of a Python language interpreter in Java. It has been around for quite some time, and gives you Python syntax with access to standard Java classes where needed. While the Jython community is not as well-organized as that of Groovy, there are plenty of books covering the use of Jython.

Jython’s momentum has flagged a bit in recent months, in part due to Sun’s waning interest in the technology and the departure of Sun employees from the project. One [attempt](#) to get Jython working with Android has been shut down, with people steered towards SL4A. It is unclear if others will make subsequent attempts.

Trail: Miscellaneous Topics

In-App Diagnostics

Android has many tools to help you make sense of what is going on in your app, from complex tools like [Traceview](#) to simpler things like LogCat. Plus, if you are using an IDE, you have access to a debugger, which can let you step through code, inspect data members and other variables, and so on.

However, they all have one element in common: they are general-purpose tools. They know nothing specifically about your app, just Android apps in general. As a result, there may be information that *you* can gather that would be of immense benefit for debugging and diagnostic purposes, but that the general-purpose tools cannot collect for you.

More importantly, you need some way to see any diagnostic data that you collect. Logging stuff to LogCat can sometimes work, but then you have to worry about accidentally shipping that logging code in production, which would be less than ideal. And there are many cases where LogCat itself will not be a great visualization of the information.

What would be better is if we could add our own diagnostic tools to our app, for use while debugging, while excluding them from our release builds. And it would be great if we could add in these tools without changing much, if anything, of our production code to reference them. This chapter will explore how to implement such tools.

Prerequisites

In addition to the core chapters, it would be a good idea if you had read:

- the chapter on [Gradle and the new project structure](#), to understand more about the debug sourceset
- the chapter on [manifest merging](#), to understand how the debug sourceset can contribute to the overall app's manifest

Also, one of the techniques bears some resemblance to [the tapjacking attack](#), though fortunately without the privacy and security ramifications.

One of the sample apps is based on a RecyclerView sample app, and so you may wish to skim [the RecyclerView material](#) to ensure that you understand enough about what is going on with the sample.

One of the sample apps uses an [embedded Web server](#), based on concepts and a module covered in another chapter.

The Diagnostic Activity

Having a “back door” to get at diagnostic information about a program is a time-honored technique. Alas, far too many of those back doors wind up in production code, and too many of those wind up resulting in privacy or security flaws. Yet, the approach is still used to this day.

From a GUI standpoint, these back doors usually required some sort of special key sequence to initiate (e.g., press  three times in less than a second). The objective was to make them easy enough to get to but not something that would routinely get in the way. And, for those back doors that wound up shipping, eventually word would get out about the magic key sequence, leading to all sorts of trouble.

In Android, we can dispense with the magic key sequence (which is good, since we often are not using keyboards). An app can have as many launcher icons as it needs, so we just need a launcher icon to get into some custom diagnostic activity that we want. However, now we *really* do not want to ship this code in production, as the diagnostic activity is no longer hidden, but rather is in plain view in the user's home screen launcher.

Fortunately, the advent of sourcesets with Gradle for Android, plus a reasonably robust manifest merger process, makes setting up this sort of tool fairly easy, yet keeps it out of the production code. Most of the work will be in actually writing the activity to report on whatever it is that you wanted reported on.

The [Diagnostics/Activity](#). sample project will illustrate this process.

This app is a clone of a [previous sample](#) that retrieves Stack Overflow questions in the android tag via Square's Retrofit library. It also uses Square's Picasso library to load in the avatars of the people asking the questions. Picasso has an API for getting at statistics about the images that were downloaded: how many, how big, how many were already cached, and so on. The revised sample shown in this section will create a diagnostic activity that reports this information, as an illustration of having such an activity supply statistics that may be useful in tuning, debugging, etc.

The Sourceset

This project has two sourcesets, main and debug. main is where the production code lies; debug is where the diagnostic activity resides. The debug sourceset is tied to the debug build type, so only when doing a debug build will our debug code be included in the app. Since your production signing key is (hopefully) only being used by your release build type, this helps ensure that the diagnostic code does not ship with your production app.

The Manifest

Both sourcesets have manifests. For debug builds, the debug sourceset's manifest will be merged with the main sourceset's manifest to create the combined result.

The objective is to have the debug sourceset's manifest have the minimum elements and attributes required to have it successfully add what it needs to the app. The more stuff in a sourceset's manifest, the more likely it is that the stuff will conflict with similar stuff from main or other manifests and cause build problems.

Here, the debug manifest simply declares a new <activity>:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android">

  <application>
    <activity
      android:name="com.commonware.android.debug.util.PicassoDiagnosticActivity"
      android:label="@string/picasso_diagnostics"
      android:taskAffinity="com.commonware.android.debug.activity.PicassoDiagnosticActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
```

IN-APP DIAGNOSTICS

```
</application>
</manifest>
```

(from [Diagnostics/Activity/app/src/debug/AndroidManifest.xml](#))

Note that the class name for the `PicassoDiagnosticActivity` is fully-qualified (`com.commonware.android.debug.util.PicassoDiagnosticActivity`). For the purposes of this particular diagnostic, the activity does not have to be in the same package as the rest of the app. In fact, this activity could be in a library that could be referenced by many apps, if desired.

Also note the `taskAffinity` for the `<activity>` is set to its fully-qualified class name. This helps ensure that this activity will reside in a different task than does our main UI, so that the diagnostics activity does not artificially alter BACK button processing and the like from the regular task.

Since the main sourceset will not contain this particular `<activity>` element, there are no collisions, and the manifest merger will turn out clean.

The Activity

The activity itself is rather boring.

It loads in a layout resource containing a `TableLayout` that will contain our Picasso diagnostic report:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="8dp"
        android:shrinkColumns="1"
        android:stretchColumns="1">

        <TableRow>

            <TextView
                android:id="@+id/last_updated"
                style="@style/TableText.Title"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:text="Last Updated"/>

            <TextView
```

IN-APP DIAGNOSTICS

```
        android:id="@+id/last_updated_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content" />
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/avg_download_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Download Size" />

    <TextView
        android:id="@+id/avg_download_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content" />
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/avg_orig_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Original Bitmap Size" />

    <TextView
        android:id="@+id/avg_orig_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content" />
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/avg_xform_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Transformed Bitmap Size" />

    <TextView
        android:id="@+id/avg_xform_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content" />
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/cache_hits"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
```

IN-APP DIAGNOSTICS

```
        android:layout_height="wrap_content"
        android:text="Cache Hits"/>

<TextView
    android:id="@+id/cache_hits_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

<TextView
    android:id="@+id/cache_misses"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Cache Misses"/>

<TextView
    android:id="@+id/cache_misses_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

<TextView
    android:id="@+id/download_count"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Download Count"/>

<TextView
    android:id="@+id/download_count_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

<TextView
    android:id="@+id/max_size"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Max Size"/>

<TextView
    android:id="@+id/max_size_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>
```

```
<TextView
    android:id="@+id/orig_bitmap_count"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Original Bitmap Count"/>

<TextView
    android:id="@+id/orig_bitmap_count_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

<TextView
    android:id="@+id/size"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Size"/>

<TextView
    android:id="@+id/size_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

<TextView
    android:id="@+id/total_dl_size"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Total Download Size"/>

<TextView
    android:id="@+id/total_dl_size_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

<TextView
    android:id="@+id/total_orig_size"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Total Original Size"/>

<TextView
    android:id="@+id/total_orig_size_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
```

```
</TableRow>

<TableRow>

  <TextView
    android:id="@+id/total_xform_size"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Total Transformed Size"/>

  <TextView
    android:id="@+id/total_xform_size_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

  <TextView
    android:id="@+id/xform_count"
    style="@style/TableText.Title"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="Transformed Count"/>

  <TextView
    android:id="@+id/xform_count_value"
    style="@style/TableText.Value"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"/>
</TableRow>
</TableLayout>
</ScrollView>
```

(from [Diagnostics/Activity/app/src/debug/res/layout/main.xml](#))

That layout, in turn, references some custom styles, to avoid having to repeat the configuration of each of the TextView widgets quite so much:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <style name="TableText">
    <item name="android:textSize">12sp</item>
    <item name="android:layout_margin">8dp</item>
  </style>

  <style name="TableText.Title">
    <item name="android:textStyle">bold</item>
  </style>

  <style name="TableText.Value">
    <item name="android:typeface">monospace</item>
  </style>
</resources>
```

(from [Diagnostics/Activity/app/src/debug/res/values/styles.xml](#))

IN-APP DIAGNOSTICS

The activity loads the layout, gets a StatsSnapshot from Picasso containing a snapshot of the results of using Picasso, and pours the data into the various TextView widgets:

```
package com.commonware.android.debug.util;

import android.app.Activity;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.widget.TextView;
import com.commonware.android.debug.activity.R;
import com.squareup.picasso.Picasso;
import com.squareup.picasso.StatsSnapshot;

public class PicassoDiagnosticActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        StatsSnapshot ss=Picasso.with(this).getSnapshot();

        TextView tv=(TextView)findViewById(R.id.last_updated_value);

        tv.setText(DateUtils.formatDateTime(this, ss.timeStamp,
            DateUtils.FORMAT_SHOW_TIME));

        tv=(TextView)findViewById(R.id.avg_download_size_value);
        tv.setText(Long.toString(ss.averageDownloadSize));

        tv=(TextView)findViewById(R.id.avg_orig_size_value);
        tv.setText(Long.toString(ss.averageOriginalBitmapSize));

        tv=(TextView)findViewById(R.id.avg_xform_size_value);
        tv.setText(Long.toString(ss.averageTransformedBitmapSize));

        tv=(TextView)findViewById(R.id.cache_hits_value);
        tv.setText(Long.toString(ss.cacheHits));

        tv=(TextView)findViewById(R.id.cache_misses_value);
        tv.setText(Long.toString(ss.cacheMisses));

        tv=(TextView)findViewById(R.id.download_count_value);
        tv.setText(Long.toString(ss.downloadCount));

        tv=(TextView)findViewById(R.id.max_size_value);
        tv.setText(Long.toString(ss.maxSize));

        tv=(TextView)findViewById(R.id.orig_bitmap_count_value);
        tv.setText(Long.toString(ss.originalBitmapCount));

        tv=(TextView)findViewById(R.id.size_value);
        tv.setText(Long.toString(ss.size));

        tv=(TextView)findViewById(R.id.total_dl_size_value);
        tv.setText(Long.toString(ss.totalDownloadSize));

        tv=(TextView)findViewById(R.id.total_orig_size_value);
```

IN-APP DIAGNOSTICS

```
tv.setText(Long.toString(ss.totalOriginalBitmapSize));

tv=(TextView)findViewById(R.id.total_xform_size_value);
tv.setText(Long.toString(ss.totalTransformedBitmapSize));

tv=(TextView)findViewById(R.id.xform_count_value);
tv.setText(Long.toString(ss.transformedBitmapCount));
}
}
```

(from [Diagnostics/Activity/app/src/debug/java/com/commonsware/android/debug/util/PicassoDiagnosticActivity.java](#))

The Results

If you install the app on a device or emulator from a debug build, you will get two launcher icons. The one labeled “Picasso Diagnostics” will be the `PicassoDiagnosticsActivity`. If you bring up that activity after having run the main activity, you will see some information about the images that Picasso loaded:

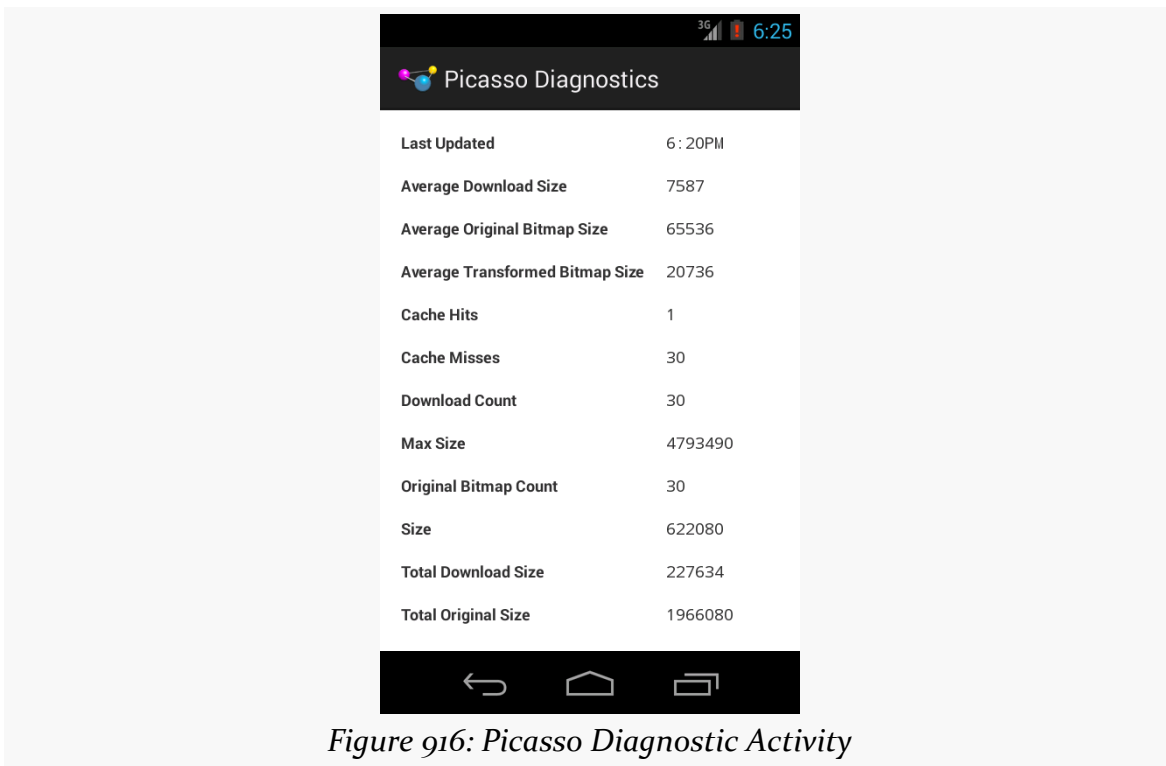

Figure 916: Picasso Diagnostic Activity

A release build, on the other hand, does not include the extra activity, its resources, or its manifest entry, since those are all in the debug sourceset.

Also, nothing from this affected our main sourceset contents. We did not have to add things to the manifest, or adjust our Java code, or anything of the sort.

The Limitations

While this sample is fairly trivial, these sorts of diagnostic activities can be as elaborate as is needed. In some cases, as with this sample, the results are reusable — so long as the app has Picasso, this code can add in the diagnostic activity.

However, this is only good for post-mortem sorts of diagnostics, where you do something in the “real” app, then head over to the diagnostic activity to see what it has to report. In many cases, this is perfectly reasonable. In other cases, the act of switching to the diagnostic activity might affect the diagnostics, if those diagnostics are dependent upon things like activity lifecycle methods. You also cannot learn anything in real time, seeing both the app and the diagnostics simultaneously (or nearly so).

However, there are other options that can improve in these areas, for situations that need such improvement.

The Diagnostic Web App

If switching the content of our device’s screen impedes our ability to use the diagnostic information, is there a way we could get another screen involved?

One likely screen would be your development machine (desktop, notebook, etc.). After all, you can get that with LogCat messages. However, LogCat messages are limited in terms of formatting and rendering control. What would be interesting is if we could get information from our app to the development machine, in real time, other than via LogCat.

For example, we could have a Web app embedded in our Android app, to allow us to serve up Web pages to our development machine.

The What, Now?

We are used to having Web apps, but usually running on Web servers, whether shared hosts or cloud providers (e.g., Amazon’s AWS) or that Web server box you have tucked in the corner of the office.

There is nothing stopping you from embedding a Web server in an Android app. After all, Android has access to Java's `ServerSocket`, just as Java EE servers do. It is merely a matter of having some HTTP server stack that is small enough to be embeddable but reasonably robust for whatever the targeted use is. In our case, the "targeted use" is being able to provide us with diagnostic data, which means we are not aiming for lots of simultaneous users, terabyte-scale data stores, or any of the typical things that you see "serious" Web developers have to deal with.

On the other hand, most "serious" Web developers do not have to worry about their Web servers hooking up to the WiFi in a coffee shop, either.

The Security Ramifications

Having any sort of open port on an Android device is a scary proposition from a security standpoint. At minimum, anyone on the same WiFi LAN segment can access that port. Some mobile carriers assign public IP addresses to devices on their networks, and in those cases, *anyone* can access that port.

In our case, we will only be using this Web server for debug builds, which limits the harm that can be caused. Now the only people who might be attacked are... ourselves.

When using this technique, you will also want to ensure that you have adequate controls to be able to stop the server, so it is only open and accepting requests when you want it to.

The Sample App

The [Diagnostics/WebServer](#). sample project is based off of the previous project, where we are trying to get diagnostic information about Picasso's operation and image cache. But, whereas the preceding project used a dedicated activity, this app will surface this information via an embedded Web server.

Once again, we will use the debug sourceset to minimize the amount of code changes needed to the main sourceset code and so we can feel confident that our Web server will not sneak into our production app somehow.

However, while Android has support for activities built in, it does not have a Web server built in, nor much in the way of a modern template engine for generating dynamic Web content. For those, we will turn to third parties.

The chapter on [embedding a Web server](#) covers the custom Web server implementation that we will be extending. If you have not read that chapter yet, probably you should do so before continuing. This section will not make much sense otherwise.

Adding the Library Module

This sample relies upon the reusable Web server module outlined in [the chapter on embedding a Web server](#) in your Android app.

This sample references the reusable Web server module directly, rather than via an AAR artifact, by hacking the relative path into `settings.gradle` for the project:

```
include ':app', ':webservice'

project(':webservice').projectDir=new File('../..../WebServer/Reusable/webservice')
```

(from [Diagnostics/WebServer/settings.gradle](#))

The app module, in turn, has some changes in its `build.gradle` file as well.

First, we have a dependency on the `:webservice` module added to `settings.gradle`. And, for whatever reason, Gradle and Android Studio are happier if we duplicate the `support-v13` dependency, which is already being pulled in via the dependency on `:webservice`:

```
dependencies {
    compile 'com.squareup.picasso:picasso:2.5.2'
    compile 'com.squareup.retrofit:retrofit:1.9.0'
    debugCompile project(':webservice')
    debugCompile 'com.android.support:support-v13:23.0.0'
}
```

(from [Diagnostics/WebServer/app/build.gradle](#))

Also, Android's build tools will want to compress HTML and JavaScript assets, even though that will interfere with our serving them. Hence, in the `android` closure, we have an `aaptOptions` closure that specifically requests to not compress those assets:

```
aaptOptions {
    noCompress 'html', 'js'
}
```

(from [Diagnostics/WebServer/app/build.gradle](#))

The Web Content

This app will use Handlebars.java as a template engine, since that is part of our reusable Web server module. It would help to have some actual templates. In our case, we really only need one, one that will show the Picasso diagnostic output. So, the sample app has a 1995-era Web page (sans `<blink>` tag, though) that has a simple table showing those Picasso values:

```
<html>
<head><title>Picasso Diagnostics</title></head>
<body>
<h1>Picasso Diagnostics</h1>
<table>
<tr><th style="text-align:right; padding-right:16px;">Timestamp</th><td>{{timeStamp}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Average Download
Size</th><td>{{averageDownloadSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Average Original Bitmap
Size</th><td>{{averageOriginalBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Average Transformed Bitmap
Size</th><td>{{averageTransformedBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Cache Hits</th><td>{{cacheHits}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Cache Misses</th><td>{{cacheMisses}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Download Count</th><td>{{downloadCount}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Max Size</th><td>{{maxSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Original Bitmap
Count</th><td>{{originalBitmapCount}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Size</th><td>{{size}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Total Download
Size</th><td>{{totalDownloadSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Total Original Bitmap
Size</th><td>{{totalOriginalBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Total Transformed Bitmap
Size</th><td>{{totalTransformedBitmapSize}}</td></tr>
<tr><th style="text-align:right; padding-right:16px;">Transformed Bitmap
Count</th><td>{{transformedBitmapCount}}</td></tr>
</table>
<hr />
<a href="/stop">Stop Service</a>
</body>
</html>
```

(from [Diagnostics/WebServer/app/src/debug/assets/picasso.hbs](#))

The values themselves are represented as mustache-style value references (e.g., `{{cacheHits}}`). Those will be replaced at runtime by actual values pulled from Picasso and supplied to Handlebars.java.

This template resides in `assets/` of the debug sourceset. That means that the template will not ship with the production app.

PicassoDiagnosticService

PicassoDiagnosticService is a subclass of the reusable WebServerService that will publish our Picasso diagnostic information to Web browsers.

Many of the methods in PicassoDiagnosticService are there to satisfy WebServerService and its abstract methods. So, our `getPort()`, `getMaxIdleTimeSeconds()`, and `getMaxSequentialInvalidRequests()` methods are fairly rote:

```
@Override
protected int getPort() {
    return(4999);
}

@Override
protected int getMaxIdleTimeSeconds() {
    return(120);
}

@Override
protected int getMaxSequentialInvalidRequests() {
    return(10);
}
```

(from [Diagnostics/WebServer/app/src/debug/java/com/commonsware/android/debug/webserver/PicassoDiagnosticService.java](#))

Similarly, `buildForegroundNotification()` just sets up our Notification with a pointer back to PicassoDiagnosticActivity, the activity that we will use to start and stop the server:

```
@Override
protected void buildForegroundNotification(NotificationCompat.Builder b) {
    Intent iActivity=new Intent(this, PicassoDiagnosticActivity.class);
    PendingIntent piActivity=PendingIntent.getActivity(this, 0,
        iActivity, 0);

    b.setTitle(getString(R.string.app_name))
        .setContentIntent(piActivity)
        .setSmallIcon(R.drawable.ic_launcher)
        .setTicker(getString(R.string.app_name));
}
```

(from [Diagnostics/WebServer/app/src/debug/java/com/commonsware/android/debug/webserver/PicassoDiagnosticService.java](#))

In addition to stopping the server from PicassoDiagnosticActivity, it might be nice to be able to stop it from a link in the Web page being served up. So, that page has a link to a stop relative path, and we set up that route in `configureRoutes()`:

```
@Override
protected boolean configureRoutes(AsyncHttpServer server) {
```

IN-APP DIAGNOSTICS

```
server.get("/stop", new StopRequestCallback());

return(true);
}
```

(from [Diagnostics/WebServer/app/src/debug/java/com/commonsware/android/debug/webserver/PicassoDiagnosticService.java](#))

Returning true tells `WebServerService` to handle standard `serve-content-from-assets` logic itself, which we will be using for serving up a Web page based on the Handlebars template.

`StopRequestCallback` is a fairly trivial `HttpServerRequestCallback` implementation, just sending back some stub content and calling `stopSelf()` to stop the service (and, thereby, tear down the Web server):

```
private class StopRequestCallback implements HttpServerRequestCallback {
    @Override
    public void onRequest(AsyncHttpRequest request, AsyncHttpResponse response) {
        response.send("Goodbye, cruel world!");
        stopSelf();
    }
}
```

(from [Diagnostics/WebServer/app/src/debug/java/com/commonsware/android/debug/webserver/PicassoDiagnosticService.java](#))

Most of the business logic for this server lies in `getContextForPath()`. This will be called on our service whenever one of our Handlebars templates is requested, so we can provide the Handlebars Context (not to be confused with an Android Context). The Context is used to fill in all of the macros used in the template.

In our case, most of the macros are pulling from the Picasso `StatsSnapshot`, so we need to make sure that our Context has it. However, it would be nice to include the timestamp of when the snapshot was taken, formatted in a more conventional format than “milliseconds since the Unix epoch”. While `StatsSnapshot` has the timestamp, we need to do the formatting.

So, `getPathForContext()` gets the `StatsSnapshot` and the formatted timestamp and combines them into a suitable Context:

```
@Override
protected Context getContextForPath(String relpath) {
    if ("picasso.hbs".equals(relpath)) {
        StatsSnapshot ss=Picasso
            .with(PicassoDiagnosticService.this)
            .getSnapshot();
        String formattedTime=DateUtils.formatDateTime(PicassoDiagnosticService.this,
            ss.timeStamp,
            DateUtils.FORMAT_SHOW_TIME);
```

IN-APP DIAGNOSTICS

```
return(Context
    .newBuilder(ss)
    .combine("formattedTime", formattedTime)
    .resolver(FieldValueResolver.INSTANCE)
    .build());
}

throw new IllegalStateException("Did not recognize "+reIpath);
}
```

(from [Diagnostics/WebServer/app/src/debug/java/com/commonsware/android/debug/webserver/PicassoDiagnosticService.java](#))

Here, we are saying that the core data comes from the StatsSnapshot (newBuilder(ss)), where macros are interpreted as fields on the object (resolver(FieldValueResolver.INSTANCE)). But, if anyone asks for formattedTime, we supply that separately (combine("formattedTime", formattedTime)).

Note that our manifest has our service, including the action string used by the reusable library to be able to stop our service from the foreground Notification:

```
<service
    android:name="PicassoDiagnosticService"
    android:exported="false">
    <intent-filter>
        <action android:name="com.commonsware.android.webserver.WEB_SERVER_SERVICE"/>
    </intent-filter>
</service>
```

(from [Diagnostics/WebServer/app/src/debug/AndroidManifest.xml](#))

The Launcher Activity

We need to arrange to start the PicassoDiagnosticService at some point.

One possibility would be to add code to the main app that checked to see if we were running a debug build and would start the service then. On the plus side, it would mean that the service would be running all the time, without additional work on the part of the developer. However:

- The service itself will affect the behavior of the app, particularly if we have no other services, such as by keeping the process around longer than normal, and this might affect our testing
- This approach would require modifying the main sourceset to be aware of the debug code, which is not ideal

Instead, we use a clone of the activity used in the other sample apps in the [chapter on the embedded Web server](#):

IN-APP DIAGNOSTICS

```
package com.commonware.android.debug.webserver;

import android.app.ListActivity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.Menu;
import android.view.MenuItem;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.AdapterView.OnItemSelectedListener;
import android.widget.ListView;
import com.commonware.android.webserver.WebServerService;
import java.util.ArrayList;
import de.greenrobot.event.EventBus;

public class PicassoDiagnosticActivity extends ListActivity {
    private MenuItem record, stop;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }

    @Override
    protected void onResume() {
        super.onResume();

        EventBus.getDefault().registerSticky(this);
    }

    @Override
    protected void onPause() {
        EventBus.getDefault().unregister(this);

        super.onPause();
    }

    @Override
    public boolean onCreateOptionsMenu(Menu menu) {
        getMenuInflater().inflate(R.menu.actions, menu);

        record=menu.findItem(R.id.record);
        stop=menu.findItem(R.id.stop);

        WebServerService.ServerStartedEvent event=
            EventBus.getDefault().getStickyEvent(WebServerService.ServerStartedEvent.class);

        if (event!=null) {
            onEventMainThread(event);
        }

        return(super.onCreateOptionsMenu(menu));
    }

    @Override
    public boolean onOptionsItemSelected(MenuItem item) {
        Intent i=new Intent(this, PicassoDiagnosticService.class);

        if (item.getItemId()==R.id.record) {
            startService(i);
        }
    }
}
```

```
    }
    else {
        stopService(i);
    }

    return super.onOptionsItemSelected(item);
}

@Override
protected void onItemClick(ListView l, View v, int position, long id) {
    startActivity(new Intent(Intent.ACTION_VIEW,
        Uri.parse(getListAdapter().getItem(position).toString())));
}

public void onEventMainThread(WebServerService.ServerStartedEvent event) {
    if (record!=null) {
        record.setVisible(false);
        stop.setVisible(true);

        ArrayList<String> diagUrls=new ArrayList<String>();

        for (String url : event.getUrls()) {
            diagUrls.add(url+"picasso.hbs");
        }

        setListAdapter(new ArrayAdapter<String>(this,
            android.R.layout.simple_list_item_1, diagUrls));
    }
}

public void onEventMainThread(WebServerService.ServerStoppedEvent event) {
    if (record!=null) {
        record.setVisible(true);
        stop.setVisible(false);
        setListAdapter(null);
    }
}
}
```

(from [Diagnostics/WebServer/app/src/debug/java/com/commonsware/android/debug/webserver/PicassoDiagnosticActivity.java](#))

Beyond updating class names to refer to our classes instead of ones from the other samples, the only change of significance comes in setting up the URLs for the ListView. Here, we append the `picasso.hbs` portion onto the base URL, so tapping the ListView row will bring up the desired Web page containing our report.

The Diagnostic Overlay

Sometimes, the information that we want needs to be presented to the developer in real time, while the user is looking at the UI of the app.

Take `StrictMode`, for example.

`penaltyDeath()` can be used to totally crash the app when, say, the app detects network I/O on the main application thread. However, this is rather harsh, particularly since Google ships all sorts of code in the framework that does improper things on the main application thread.

`penaltyLog()` is great, in that it gives us the stack trace of where the problem is but does not outright crash the app. However, we might not notice the stack traces, if we are not paying close attention to LogCat.

So, one popular combination is `penaltyFlashScreen()` combined with `penaltyLog()`. `penaltyFlashScreen()` will flash a red border around the edges of the screen, as a hint that “hey, something was detected – please check LogCat for details!” In the absence of this, or some other visual penalty, like `penaltyDialog()`, the developer might not learn what `StrictMode` is trying to tell her.

Another example is `gfxinfo`. As is noted in [the chapter on jank](#), `gfxinfo` can give you some information about how long it takes for frames to be rendered, so you know when you are dropping frames. One option for this is via an overlay that appears on top of the main UI, so you can see in real time a bar chart of frame times, so you can see what user actions can trigger jank.

You can employ the same sorts of techniques yourself, to put an overlay on the screen, whether temporarily (e.g., the `StrictMode` `penaltyFlashScreen()` option) or more durably (e.g., the `gfxinfo` bar chart). The [Diagnostics/Overlay](#) sample project will demonstrate the former, alerting you of slowdowns in the rendering of your items in a `RecyclerView`.

The Gradle Setup

For the purposes of demonstration, we need a sample app that can actually perform poorly, so we detect slowdowns and alert the developer via the screen overlay. At the same time, we need a sample app that does *not* perform poorly, so we can determine if the overlay works properly in both cases.

This sample project toggles between the two modes via a custom `BE_STUPID` field added to the `BuildConfig` class, based upon build type:

```
buildTypes {
    debug {
        buildConfigField "boolean", "BE_STUPID", "true"
    }

    release {
```

```
        buildConfigField "boolean", "BE_STUPID", "false"
    }
}
```

(from [Diagnostics/Overlay/build.gradle](#))

Admittedly, we could have skipped this and used the BUILD_TYPE field on BuildConfig. That will hold whatever the name of the build type was that built the APK that we installed, so it will be debug or release in this project. However, in case you wanted to have different rules for when the app should be stupid or not, we pull it out into a separate BuildConfig field. For example, you might elect to add two product flavors, so switching between true and false for BE_STUPID is based on product flavor instead of build type.

Introducing RVAdapterWrapper

The wrapper pattern in Java can be fairly powerful, allowing you to extend Java objects without changing inheritance hierarchies. Rather, you wrap the object in a wrapper that implements the same interface (or inherits from the same base class). The wrapper can do some things on its own (the extended behavior) and delegate to the wrapped object for everything else. Plus, *subclasses* of the wrapper can basically override stock wrapper behavior and behavior the wrapped object.

Android has a few such wrapper classes, like CursorWrapper and ContextWrapper. The author of this book published an AdapterWrapper, for the AdapterView family of classes, as [a tiny open source library](#). And this chapter has RVAdapterWrapper, which implements a wrapper for RecyclerView.Adapter:

```
package com.commonware.android.debug.videolist;

import android.support.v7.widget.RecyclerView;
import android.view.ViewGroup;

public class RVAdapterWrapper<T extends RecyclerView.ViewHolder> extends RecyclerView.Adapter<T> {
    private final RecyclerView.Adapter<T> wrapped;

    public RVAdapterWrapper(RecyclerView.Adapter<T> wrapped) {
        super();

        this.wrapped=wrapped;
    }

    public RecyclerView.Adapter<T> getWrappedAdapter() {
        return(wrapped);
    }

    @Override
    public T onCreateViewHolder(final ViewGroup parent, final int viewType) {
        return(wrapped.onCreateViewHolder(parent, viewType));
    }
}
```

IN-APP DIAGNOSTICS

```
}

@Override
public void onBindViewHolder(final T holder, final int position) {
    wrapped.onBindViewHolder(holder, position);
}

@Override
public long getItemId(int position) {
    return(wrapped.getItemId(position));
}

@Override
public int getItemViewType(int position) {
    return(wrapped.getItemViewType(position));
}

@Override
public void onAttachedToRecyclerView(RecyclerView recyclerView) {
    wrapped.onAttachedToRecyclerView(recyclerView);
}

@Override
public void onDetachedFromRecyclerView(RecyclerView recyclerView) {
    wrapped.onDetachedFromRecyclerView(recyclerView);
}

@Override
public void onViewAttachedToWindow(T holder) {
    wrapped.onViewAttachedToWindow(holder);
}

@Override
public void onViewDetachedFromWindow(T holder) {
    wrapped.onViewDetachedFromWindow(holder);
}

@Override
public void onViewRecycled(T holder) {
    wrapped.onViewRecycled(holder);
}

@Override
public void registerAdapterDataObserver(RecyclerView.AdapterDataObserver observer) {
    wrapped.registerAdapterDataObserver(observer);
}

@Override
public void setHasStableIds(boolean hasStableIds) {
    wrapped.setHasStableIds(hasStableIds);
}

@Override
public void unregisterAdapterDataObserver(RecyclerView.AdapterDataObserver observer) {
    wrapped.unregisterAdapterDataObserver(observer);
}

@Override
public int getItemCount() {
    return(wrapped.getItemCount());
}
```

```
}  
}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/RVAdapterWrapper.java](#))

The constructor takes the `RecyclerView.Adapter` to be wrapped, and `RVAdapterWrapper` offers a `getWrappedAdapter()` to retrieve that object. Everything else is a simple implementation of the wrapper pattern, overriding all methods from `RecyclerView.Adapter` and delegating them to the wrapped adapter.

TimingWrapper (a.k.a., StrictMode for RecyclerView)

`RVAdapterWrapper` exists mostly to serve as a base class for `TimingWrapper`. `TimingWrapper` arranges to collect the time used by `onCreateViewHolder()` and `onBindViewHolder()`, so we can see if those times exceed some threshold and therefore is worthy of alerting the developer.

Its constructor takes the `RecyclerView.Adapter` to wrap, along with the `Activity` that is hosting this UI. In addition to chaining to the superclass and holding onto that `Activity` (as a data member named `host`), the constructor also retrieves a `WindowManager` system service:

```
public TimingWrapper(RecyclerView.Adapter<T> wrapped, Activity host) {  
    super(wrapped);  
  
    this.host=host;  
    wm=(WindowManager)host.getSystemService(Context.WINDOW_SERVICE);  
}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

`TimingWrapper` overrides `onCreateViewHolder()` and `onBindViewHolder()`, tracking the amount of time that those calls take, and calling a private `warn()` method with the time for the call:

```
@Override  
public T onCreateViewHolder(final ViewGroup parent, final int viewType) {  
    long start=SystemClock.uptimeMillis();  
    T result=super.onCreateViewHolder(parent, viewType);  
  
    warn(SystemClock.uptimeMillis() - start);  
  
    return(result);  
}  
  
@Override  
public void onBindViewHolder(final T holder, final int position) {  
    long start=SystemClock.uptimeMillis();  
  
    super.onBindViewHolder(holder, position);  
}
```

IN-APP DIAGNOSTICS

```
warn(SystemClock.uptimeMillis() - start);
}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

Here, T is the RecyclerView.ViewHolder used by the wrapped adapter and declared by the specific use of the TimingAdapter:

```
public class TimingWrapper<T extends RecyclerView.ViewHolder> extends RVAdapterWrapper<T> {
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

warn() sees if the amount of time the call took exceeds some threshold, set here to be 7ms. If it does, we first log a stack trace to LogCat, following the technique used by StrictMode itself of having a private LogStackTrace Exception that is just there to collect a stack trace:

```
private void warn(long delta) {
    if (delta>7) {
        String msg=String.format("RVAdapterWrapper violation: ~duration= %d ms",
            delta);

        Log.e(TAG, msg, new LogStackTrace());

        if (v==null) {
            WindowManager.LayoutParams params=new WindowManager.LayoutParams(
                WindowManager.LayoutParams.MATCH_PARENT,
                WindowManager.LayoutParams.MATCH_PARENT,
                WindowManager.LayoutParams.TYPE_SYSTEM_OVERLAY,
                WindowManager.LayoutParams.FLAG_NOT_FOCUSABLE
                    | WindowManager.LayoutParams.FLAG_NOT_TOUCHABLE,
                PixelFormat.TRANSLUCENT);

            v=new View(host);
            v.setBackgroundResource(R.drawable.border);
            wm.addView(v, params);

            v.postDelayed(new Runnable() {
                @Override
                public void run() {
                    wm.removeView(v);
                    v=null;
                }
            }, 500);
        }
    }
}

private static class LogStackTrace extends Exception {}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

Then, if we are not presently showing an overlay (i.e., the v data member is not null), we:

IN-APP DIAGNOSTICS

- create a `WindowManager.LayoutParams` that will fill the screen, using `TYPE_SYSTEM_OVERLAY` as the type, and indicating that it has a translucent background
- create a simple `View` and give it a background defined as the border drawable resource
- use the `WindowManager` to show that view
- use `postDelayed()` to get control in 500ms and remove that view, also setting `v` back to `null`

border is defined in `res/drawable-nodpi/` as a `ShapeDrawable`, consisting of a transparent rectangle with a 16dp-wide green border:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <stroke android:color="#ff00ff00" android:width="@dimen/border_width"/>
</shape>
```

(from [Diagnostics/Overlay/res/drawable-nodpi/border.xml](#))

The net effect is that the border will flash a 16dp-wide green line around the edge of the screen for 500ms before being removed.

Note that to use the `TYPE_SYSTEM_OVERLAY`, we have to hold the `SYSTEM_ALERT_WINDOW` permission:

```
<uses-permission android:name="android.permission.SYSTEM_ALERT_WINDOW" />
```

(from [Diagnostics/Overlay/AndroidManifest.xml](#))

We will get more into the ramifications of that permission on Android 6.0+ devices [later in this chapter](#).

The RecyclerViewActivity

You will notice that the `RVAdapterWrapper` and `TimingWrapper` code is in the main sourceset. Hence, those classes will exist on debug and release builds. However, we only *use* them on some builds, courtesy of a tweaked `RecyclerViewActivity`. The revised activity has `getAdapter()` and `setAdapter()` implementations that work with an unwrapped adapter, but hold onto a wrapped adapter, on `DEBUG` builds:

```
package com.commonware.android.debug.videolist;

import android.app.Activity;
import android.os.Build;
import android.provider.Settings;
```

IN-APP DIAGNOSTICS

```
import android.support.v7.widget.RecyclerView;

public class RecyclerViewActivity extends Activity {
    private RecyclerView rv=null;

    public void setAdapter(RecyclerView.Adapter adapter) {
        boolean canDrawOverlays=
            (Build.VERSION.SDK_INT<=Build.VERSION_CODES.LOLLIPOP_MR1);

        if (!canDrawOverlays) {
            canDrawOverlays=Settings.canDrawOverlays(this);
        }

        if (BuildConfig.DEBUG && canDrawOverlays) {
            adapter=new TimingWrapper(adapter, this);
        }

        getRecyclerView().setAdapter(adapter);
    }

    public RecyclerView.Adapter getAdapter() {
        RecyclerView.Adapter result=getRecyclerView().getAdapter();

        if (result instanceof RVAdapterWrapper) {
            result=((RVAdapterWrapper)result).getWrappedAdapter();
        }

        return(result);
    }

    public void setLayoutManager(RecyclerView.LayoutManager mgr) {
        getRecyclerView().setLayoutManager(mgr);
    }

    public RecyclerView getRecyclerView() {
        if (rv==null) {
            rv=new RecyclerView(this);
            setContentView(rv);
        }

        return(rv);
    }
}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/RecyclerViewActivity.java](#))

One criterion for whether we will use the `TimingWrapper` is whether or not we are on a debug build. The other criteria take a bit more explanation, which we will get to [later in this chapter](#).

Being Stupid

The overall sample app is a clone of a `RecyclerView` sample that loads videos from `MediaStore` and shows them in alphabetical order, along with thumbnails of the videos. This version of the sample is augmented with `Advanced Be-Stupid`

Technology™, where RowController does the thumbnail retrieval on the main application thread when being stupid or uses Picasso when not:

```
void bindModel(Cursor row) {
    title.setText(row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    int uriColumn=row.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
    int videoId=row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID));

    videoUri=row.getString(uriColumn);
    videoMimeType=row.getString(mimeTypeColumn);

    if (BuildConfig.BE_STUPID) {
        ContentResolver cr=thumbnail.getContext().getContentResolver();
        BitmapFactory.Options options=new BitmapFactory.Options();

        options.inSampleSize = 1;

        Bitmap thumb=MediaStore.Video.Thumbnails.getThumbnail(cr, videoId,
            MediaStore.Video.Thumbnails.MICRO_KIND, options);

        thumbnail.setImageBitmap(thumb);
    }
    else {
        Uri video=
            ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                videoId);

        Picasso.with(thumbnail.getContext())
            .load(video.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnail);
    }
}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/RowController.java](#))

The Results

The green border will flash if a call to `onCreateViewHolder()` or `onBindViewHolder()` takes more than 7ms. In theory, this should only occur if one of those methods does a non-trivial bit of work on the main application thread.

In practice, this seems to generate a fair number of false positives, presumably due to context-switching between threads on the available device cores.

Areas for Improvement

Those results point at areas where this technique might be improved:

- Pass the timing value into the `TimingWrapper` constructor, rather than hard-coding it to 7ms
- Rather than worrying about individual calls exceeding a 7ms threshold, point out if a rolling average of recent calls exceeds the threshold, to perhaps smooth out the data a bit and avoid the false positives

What Changed in Android 6.0

Let's go back to the `setAdapter()` implementation, where we conditionally apply the `TimingAdapter`:

```
public void setAdapter(RecyclerView.Adapter adapter) {
    boolean canDrawOverlays=
        (Build.VERSION.SDK_INT<=Build.VERSION_CODES.LOLLIPOP_MR1);

    if (!canDrawOverlays) {
        canDrawOverlays=Settings.canDrawOverlays(this);
    }

    if (BuildConfig.DEBUG && canDrawOverlays) {
        adapter=new TimingWrapper(adapter, this);
    }

    getRecyclerView().setAdapter(adapter);
}
```

(from [Diagnostics/Overlay/src/com/commonsware/android/debug/videolist/RecyclerViewActivity.java](#))

As noted earlier, we only use `TimingWrapper` on debug builds, not release builds.

We also only use `TimingAdapter` if one of two things is true:

- Either we are on some version of Android prior to 6.0, or
- We are allowed to draw overlays

Historically, the `SYSTEM_ALERT_WINDOW` permission was merely listed as dangerous. Users would be notified about it at install time, but otherwise it was just a standard permission.

Originally, few apps requested this permission. Over time, more and more apps started using this for things like Facebook's "chatheads" UI.

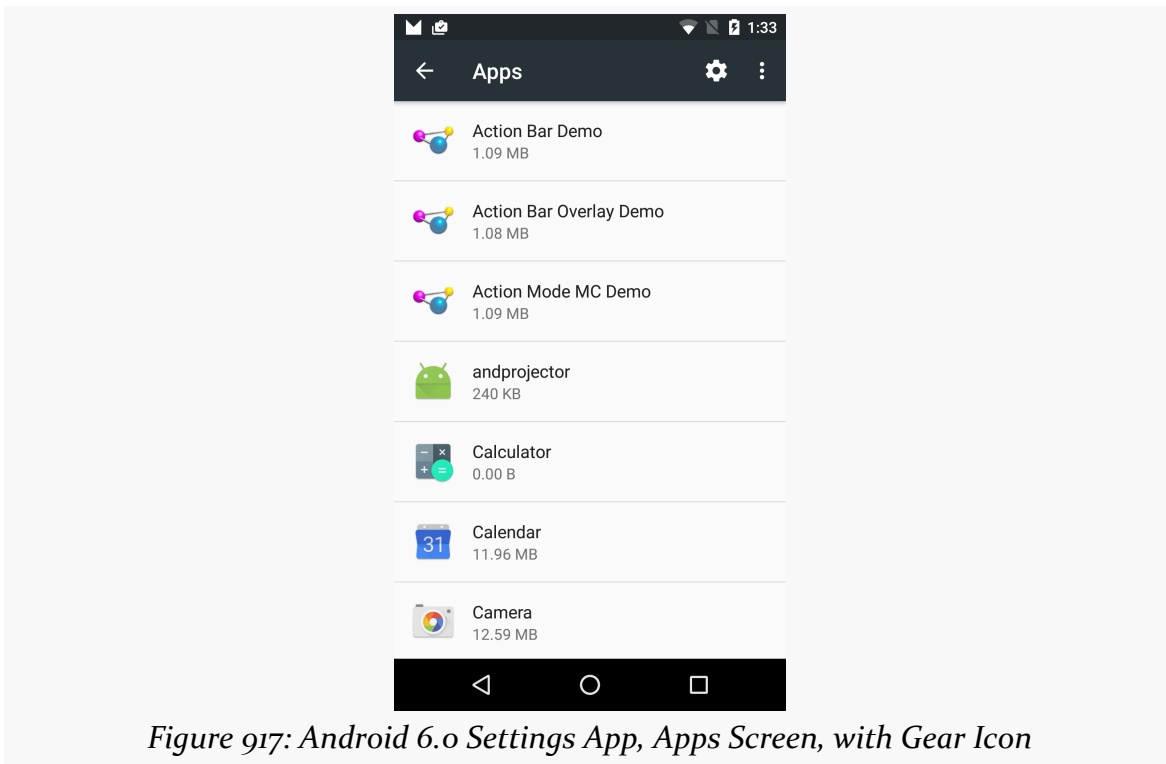

In Android 6.0, `SYSTEM_ALERT_WINDOW` was moved to be a signature-level permission. Ordinarily, the net effect of this change would be that apps could no longer hold the permission, unless they were signed by the signing key that signed

IN-APP DIAGNOSTICS

the firmware. While that's possible for device manufacturers and custom ROM developers, ordinary Android SDK developers would be left out.

However, Android 6.0 provided another means to get the rights to use TYPE_SYSTEM_OVERLAY windows, through a double-opt-in mechanism. The user not only has to install the app, but has to go to a particular screen in the Settings app to agree to grant your app the right to draw over top of other apps.

The default way for a user to get to that screen is to go into Settings > App, then click the gear icon in the action bar of the Settings app:

Tapping that brings up a “Configure apps” screen:

IN-APP DIAGNOSTICS

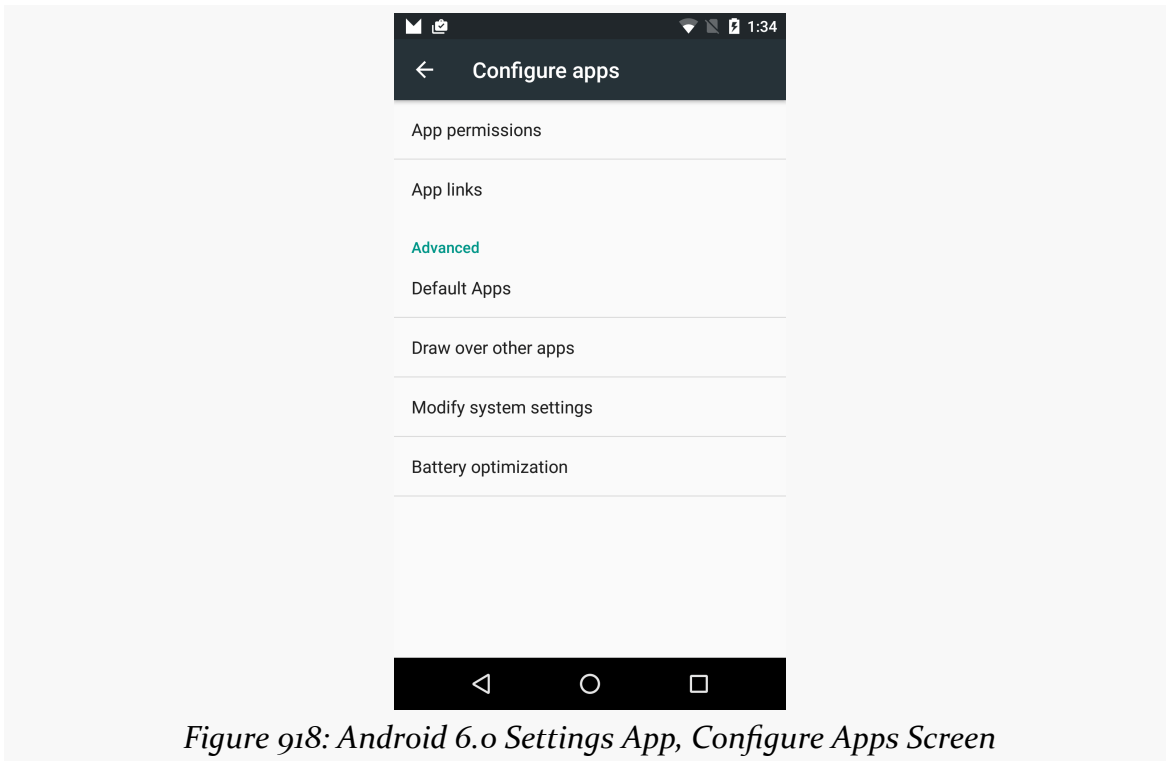

Figure 918: Android 6.0 Settings App, Configure Apps Screen

There, tapping the “Draw over other apps” entry brings up a list of all of the apps that have requested the `SYSTEM_ALERT_WINDOW` permission:

IN-APP DIAGNOSTICS

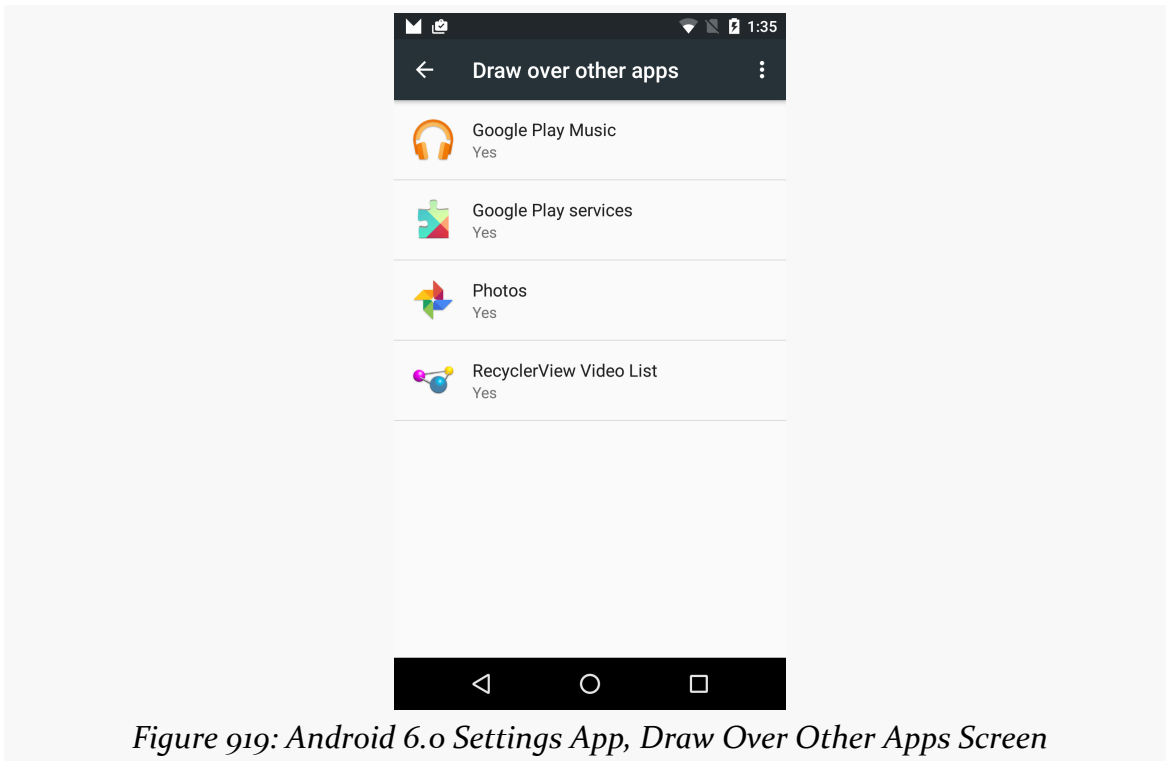

Figure 919: Android 6.0 Settings App, Draw Over Other Apps Screen

Tapping on any one of those allows the user to toggle on or off this access:

IN-APP DIAGNOSTICS

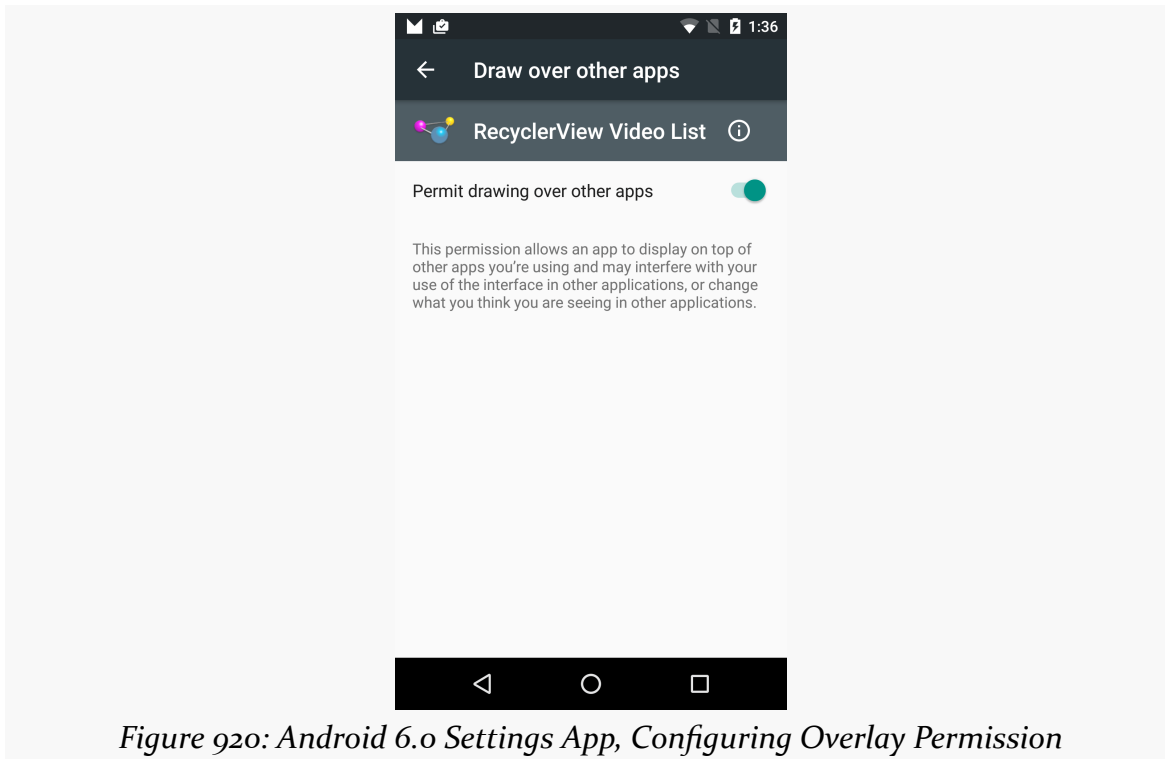

Figure 920: Android 6.0 Settings App, Configuring Overlay Permission

In code, you can find out if the user has enabled this access by calling `canDrawOverlays()` on the `Settings` class, as we did in `setAdapter()` above. However:

- This requires you to have a `compileSdkVersion` of 23 or higher
- You cannot call that method on pre-Android 6.0 devices

On Android 6.0+, if `canDrawOverlays()` returns `false`, you are welcome to lead the user over to the appropriate screen in Settings to try to convince them to allow you to draw over other apps. To do that:

- Create a package: `Uri` that points to your app
- Wrap that in an `ACTION_MANAGE_OVERLAY_PERMISSION` Intent
- Call `startActivity()` to bring up that screen

```
Intent i=new Intent(Settings.ACTION_MANAGE_OVERLAY_PERMISSION,
    Uri.parse("package:" + getPackageName()));
startActivity(intent);
```

IN-APP DIAGNOSTICS

Note that apps with a `targetSdkVersion` of 22 or lower are “grandfathered” into having default access to draw over other apps, simply by having requested the `SYSTEM_ALERT_WINDOW` permission. However, the user can still go into the Settings app and revoke that capability, in which case attempting to draw over another app will result in a `SecurityException`

```

In many cases, there is no good way to recover from this `SecurityException`, in which case you really want to consider switching to `compileSdkVersion` of 23 or higher and calling `canDrawOverlays()` to detect this potential problem before it occurs.

Anti-Patterns

Much of this book has been focused on what you should do. In contrast, this chapter is focused on what you should *not* do.

All platforms have their anti-patterns: things that are technically possible but are not in the best interests of the users of that platform. Android is no exception. Some anti-patterns are simply annoying to users, while other anti-patterns can significantly infringe upon a user's use of their Android device, or even the user's freedom.

Much as the Hippocratic Oath directs doctors to “first, do no harm”, Android application developers owe it to the users of their apps to avoid these anti-patterns to the greatest extent possible.

Prerequisites

This chapter assumes that you have read much of the book, particularly the core chapters.

Leak Threads... Or Things Attached to Threads

Leaking a thread means that you start a thread and never cause it to stop. For example, you might start a thread that runs in an infinite loop, doing some work and then sleeping for a while. The problem with infinite loops is that “infinite” is an awfully long time.

All threads should clean up, in a timely fashion, when the component (e.g., activity, service) that started the thread is destroyed — or, in the case of an activity, perhaps just moved into the background.

How you ensure that the thread gets cleaned up is up to you. For threads doing transactional work, such as literally running a database transaction, it may be fine to just let them run to completion and shut down of their own accord. For “infinite” loops, there should be some way to tell the thread that it is no longer needed, such as via an `AtomicBoolean` flag, or using something more structured than a plain timing loop, such as a `ScheduledExecutorService`.

Also, bear in mind that you are responsible for threads that are created, on your behalf, by other things that you do. The most common leak scenario here comes with listeners associated with system services, like `LocationManager` and `SensorManager`. If you register a `LocationListener` via `requestLocationUpdates()` and fail to unregister that listener, you will not only be leaking the listener, but the component associated with that listener, and every system resource tied to that listener, such as any background threads.

The Costs

Threads are intrinsically static in scope. Hence, any object they can reach, directly or indirectly, cannot be garbage-collected while the thread is still running. Hence, if an activity forks a thread, it might do so using an anonymous inner class:

```
new Thread() {
    public void run() {
        // do something
    }
}.start();
```

Instances of an inner class — anonymous or otherwise — have an implicit reference back to the object that created them. Hence, the `Thread` would hold onto the `Activity` that created the thread, which in turn would hold onto all of its widgets and so forth. None of that can be garbage-collected until after the thread terminates, even if the activity is destroyed.

The Counter-Arguments

I want the thread to keep running even after the activity is destroyed

In this case, the thread should be created and managed by a service, not simply leaked. Not only does this give you an opportunity to clean up the thread when needed, but it also alerts Android that you are still trying to do some work, so Android will not necessarily terminate your process very quickly.

However, be careful about assuming that you can have a thread — even one managed by a service — run forever, as you will see in the next couple of sections.

I do not know when the thread is no longer needed

Then you have a serious design problem.

A common variation on this theme is:

The thread is needed so long as I have an activity in the foreground

This is a bit tricky, as Android does not really expose the concept of *applications* being in the foreground, just activities.

The safest course of action is to have the thread be managed by a service, then keep track of whether or not you have an activity in the foreground. For example, in `onPause()` of each activity, use `postDelayed()` to return control to you after a short delay, and in `onResume()`, update a timestamp of your last return to the foreground (held in a static data member). When the `Runnable` for `postDelayed()` executes, check that timestamp — if it is too old, you know that none of your activities are in the foreground, and you can stop the service, having it stop your thread.

Use Large Heap Unnecessarily

Encountering an `OutOfMemoryError` certainly sucks. These are caused either by a memory leak or by trying to use more memory than is practical given the device. For example, loading up lots of bitmaps can easily chew up your available heap space.

To some, therefore, `android:largeHeap` seems to be the perfect solution.

Added in API Level 11, `android:largeHeap` tells Android to give you a much larger heap size than is normally given to a process. So, instead of having 32MB or 48MB or so of heap, you might have 256MB of heap.

The right solution, in most cases, is to fix the underlying memory problem, not to mask it by requesting an over-sized heap.

The Costs

To you, having hundreds of megabytes of extra heap may be a blessing. To the user, it may be a curse. That memory has to come from somewhere, and the “somewhere” is from other processes. Your app will force other apps’ processes to be terminated far more quickly than normal, which may slow the user down when she tries to switch between your app and others. Your app may even materially harm the functionality of other apps, who have their processes terminated before they can finish their work, just to satisfy your memory craving.

Bear in mind that Android does not employ swap space (the Linux equivalent of a Windows pagefile). Hence, whereas Windows can allocate lots of memory and slows down as it goes, Android is far more limited, in accordance with its mobile roots.

Furthermore, in many cases, adding more heap space does not eliminate the problem, any more than spraying air freshener gets rid of the dead cat in your living room that is causing the odor. With a memory leak, for example, all the larger heap does is increase the time before you eventually run out of memory.

The Counter-Arguments

I really need to be able to manipulate large chunks of memory

There are certainly apps for which `android:largeHeap` is justified, such as complex data editors, such as image editors, video editors, etc.

Hence, in practice, the real anti-pattern is not using `android:largeHeap`, but rather in doing so for apps where the user would not feel that the resulting effects are justified. For example, neither a Twitter client, nor a banking app, should need a large heap, even if the developer is running into memory management issues.

Android makes it too hard to manage memory, so I need a large heap

There is no question that developing mobile applications is challenging, particularly when it comes to memory management. That is not unique to Android — embedded systems developers are used to writing apps where the heap size is better measured in KB instead of MB, for example.

Outside of bitmaps and massive data sets, though, it is a bit difficult to actually run out of memory. While a `TextView` may take up 1KB of heap space, it takes a *lot* of `TextView` widgets to chew through a 48MB heap.

The reason why bitmaps tend to trip up developers is that Android makes using them *too easy*. For example, it is simple to set a bitmap as a background of some container like a `LinearLayout`, where developers then blindly ignore the fact that if the bitmap is not *precisely* the size of the container, Android will need to scale the image, consuming more heap space.

Misuse the MENU Button

The MENU button on Android devices is designed to display either the options menu (on Android 1.x/2.x devices that are not using an action bar backport or the action bar overflow menu).

The MENU button is *not* designed for any other purpose. Some developers have taken to using it for arbitrary aims, and that is a mistake.

The Costs

The MENU button does not exist on many Android devices. In particular, devices designed for Android 3.0 and higher do not *need* a MENU button. Some will have them, but most will not. Hence, anything that requires the MENU button will simply be unavailable on those devices.

And, as of Android 4.4, Google is putting increasing pressure on device manufacturers to dump the MENU button, making it less likely to appear in the future.

The Counter-Arguments

Well, if I keep `targetSdkVersion` below 11, I can have a soft MENU button

This is true, insofar as a menu affordance will be added to the system bar or navigation bar on devices that lack a dedicated MENU button.

Whether the *user* is expecting to use this button is another thing entirely.

As more and more users run Android 3.0+ devices, they will use more and more apps that have `android:targetSdkVersion` set to 11 or higher. The remaining handful of apps that do not will be “weird”. In particular, they may not notice the menu affordance, as they are not looking for one, or they may not know what it does, as they are not used to needing it.

Moreover, eventually, other things will drive you to want an `android:targetSdkVersion` higher than 10, as the menu affordance is not the only feature driven by this value. The sooner you can remove your dependence on a menu affordance, the sooner you can upgrade your `android:targetSdkVersion` to solve other problems that you are encountering.

I think the action bar is ugly, a waste of space, or otherwise bad

That's nice. It does not mean that you need a menu affordance and a tie to a MENU button.

For example, well-written games will have a menu integrated into the game UI itself. This was often done even before Android 3.0, since the options menu UI would not look much like the game's UI, and the developer wanted a consistent look-and-feel.

So long as the user recognizes how to reach the menu (e.g., a three-dots or three-bars icon), the menu does not have to be driven by Android, but instead could be handled by your app directly. You can see this in the Google Navigation app, which avoids an action bar but still displays its own menu from its own on-screen menu affordance.

Interfere with Navigation

Some developers try to take over the device. They attempt to block the use of anything not related to their app: the HOME key, the recent tasks list, the notification drawer, etc.

Android treats such behavior as malware. Android is designed to keep control of the device in the hands of the user and tries very hard to prevent apps from stealing that control.

The Costs

While there are certain cases where blocking navigation outside the app may seem justified (see the counter-arguments, below), there is simply too much opportunity for malfeasance. Users tend to want to use their devices on their terms, not necessarily the terms of some random developer. Malware authors, in particular, love to learn about script-kiddie hacks that allow them to control a device, and by extension, control the users.

The Counter-Arguments

I am writing a lock screen

No, you are not. You are writing something that you *think* is a lock screen. Really what you are writing is something that weakens device security... if the app in question is designed to be downloaded and run on arbitrary devices.

Android devices can be rebooted into “safe mode”. Much like the Windows boot option that bears the same name, “safe mode” only runs apps that are part of the system firmware, not any third-party apps.

So, let’s assume that the user installs your “lock screen”. Inevitably, part of the setup of a third-party “lock screen” is to disable any sort of security that is part of the native lock screen, so the user does not have to unlock things twice. Even though your lock screen may implement all sorts of security, all somebody else has to do is reboot the device in safe mode, and they now have complete access to the device, including the ability to uninstall your lock screen. By contrast, the native lock screen is in force even if the device reboots in safe mode.

I am writing a parental control app

Rebooting in safe mode is within the motor-control skills of your average three-year-old child. Hence, the primary limitation is whether or not the child knows *how* to reboot the device in safe mode, which they can learn from the Internet, friends, etc. And, if the device is really an adult’s device, where the “lock screen” allows access to a subset of child-friendly apps, the real risk is not from the child rebooting the device in safe mode, but from the crook who steals the device rebooting in safe mode.

I am writing a lock screen designed to run on whole-disk-encrypted devices

While whole disk encryption — available on Android 4.0+ — does solve the issue of rebooting in safe mode, bear in mind that users then cannot disable the required password security on the native lock screen, as that is tied into the whole disk encryption process.

I am writing a kiosk app

Here, the term “kiosk app” refers to an app that represents the functionality of a single-purpose device. For example, a restaurant might want to distribute menus to customers in the form of a tablet app; the menu app would be the “kiosk app”.

In this case, the owner of the device is the one trying to lock it down to be single-purpose. That is completely reasonable... except that it runs counter to the behavior of standard consumer builds of Android.

The right solution, in this case, is to create custom firmware for the single-purpose devices. This firmware can set up the kiosk app to be the home screen (thereby blunting the effectiveness of HOME, BACK, etc.), and modifications to the firmware can apply access controls to other aspects of the device (e.g., notifications). Unfortunately, there are few (if any) businesses set up to help create such single-purpose firmware for single-purpose devices.

Use `android:sharedUserId`

If you are creating more than one application, where those applications should be sharing data, you may be tempted to use `android:sharedUserId`. This attribute, applied to the root `<manifest>` element in your manifest, allows two or more apps to share a Linux user account. That will allow these apps full access to the other apps' files. The limitations are that you must use the same value for `sharedUserId` and that all such apps must be signed with the same signing key.

However, this is a fairly crude and somewhat risky approach to sharing information between apps. In most cases, you will be better served using any of the structured IPC options within Android, such as remote services and content providers.

The Costs

First, you must make the decision to use `android:sharedUserId` before you ever ship your app in production. Should you change the `sharedUserId` value — or switch from no value to a new value — when your change is installed, the new version of your app will have no rights to access the old version of your app's files. This is unlikely to turn out well.

Second, it will be up to you to maintain data integrity of these files in the face of simultaneous access from multiple apps. SQLite should handle this for you for your databases, as it is set up to use process-level locking — this is why SQLite can be used as the out-of-the-box database solution for Web frameworks like Rails.

However, any other sort of file, including `SharedPreferences`, will lack that coordination, unless you somehow arrange to do it yourself. And even the SQLite-level coordination has its limits, as one app has no way to know about another app's changes to the data, except by re-querying the database.

Third, using `android:sharedUserId` limits your flexibility. You cannot use it with third-party apps. You cannot readily sell one of your apps in your suite, as then it becomes a third-party app and can no longer be signed by the same signing key as are the rest of your apps. Basically, `sharedUserId` causes multiple separate APKs to behave, in some respects, as one larger APK.

The Counter-Arguments

I need to ensure only my apps can share the data, not others

Use a signature-level permission. This gives you the same level of security as does `android:sharedUserId` without most of the risks.

Writing IPC code is tedious

So is writing cross-process data integrity code.

Implement a “Quit” Button

Perhaps the most contentious question and answer on Stack Overflow's `android` tag is [“Quitting an application - is that frowned upon?”](#). This exchange is nearly three years old (as of the time of this writing), yet the answer receives both upvotes (and a few downvotes) with some regularity.

Other Android experts, such as Reto Meier, have weighed in on the issue and have [offered similar recommendations](#) – that is, do not have a “quit” or “exit” button in your app.

(here, “button” is shorthand for any command-style interface, and includes menu options, action bar items, and the like by extension)

The reason is simple: whatever your “quit” or “exit” button does *should be happening in other conditions as well*, and handling those other conditions should eliminate the need for the button.

If the app moves into the background *for any reason*, you need to treat the user and her device with respect. This means stopping background threads that are not needed, releasing system resources like the GPS radio (immediately or after a modest delay), and the like. The user should not need to “quit” your app to accomplish this, because your app will move to the background for other reasons, such as incoming phone calls, or the user pressing the HOME button.

The Costs

You might think “well, what’s the harm in having the ‘quit’ button that, say, just calls `finish()`?”

First, rarely is it that simple. Calling `finish()` will return the user to the previous activity, and so for any multi-activity app, there will be scenarios where `finish()` is not really “quit”. The only simple thing you can universally do is have “quit” bring up the home screen, in which case all you have done is waste screen real estate duplicating the HOME button functionality. Worse, the developer might say “oh, well, I will just terminate my process when they press ‘quit’”, and *that* anti-pattern [is coming up next in this chapter](#).

Second, the user will start to think that they *need* to press “quit”, or else bad things might happen. They will see an explicit “quit” option and start to wonder “well, gee, when am I supposed to press that, and what happens if I do not?” This, in turn, will lead to the user going out of their way to make sure to press your “quit” button, even if doing so does not actually change anything about the behavior of your app, courtesy of [the placebo effect](#).

The Counter-Arguments

I need to let the user log out of the app, so I need a “quit” button

No, you need a “logout” button that clears your cached authentication credentials (e.g., sets a static data member to `null`), then brings up the login activity using `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to wipe out all other activities in your process. And, probably, you need to have some sort of inactivity-based “timeout” that also logs out the user (e.g., sets that static data member to `null`).

I am running stuff in the background, so I need a “quit” button

No, you need a “stop that background stuff” button, preferably with a shorter, more specific label. And, you need that to also be available from the Notification that you are using with your foreground service, where applicable.

Terminate Your Process

Closely related to the above anti-pattern is to forcibly stop your process, such as via `System.exit()`, `Runtime.exit()`, `Process#killProcess()`, and so forth. These are often used in concert with [an in-app “quit” button](#), or sometimes for other reasons (e.g., could not figure out how to handle an exception gracefully).

The Costs

Simply put, Google has warned, repeatedly, that there may be side effects from terminating your own process, rather than having Android do proper cleanup first.

- “You should really think about not exiting the application. This is not how Android apps usually work.” ([Romain Guy](#))
- “To be clear: using `System.exit()` is strongly recommended against, and can cause some poor interactions with the system. Please don’t design your app to need it.” ([Dianne Hackborn](#))
- “There is no reason or need to call `[exit()]`” ([Dianne Hackborn](#))
- “Nobody has said anything about `Process.kill()` not doing anything. You want to kill your *own* process and cause the user to experience your *own* application having weird behavior at times due to it? Have at it. I just want to be clear that this is not what we recommend doing... and you are likely to cause bad behavior in your app at least at times due to it... There is no API to quit an application, because there is no such concept on Android, and trying to implement such a thing is going to result in fighting against how Android works.” ([Dianne Hackborn](#))

The Counter-Arguments

I am using a C library that is buggy, so I need to terminate my process

Fix the bugs in the library. For example, C libraries that rely too heavily on global variables may need to be adjusted to use session handles that get passed around.

Well, it is not my C library, but one from a third party, so I need to terminate my process

Find a library that is Android-compatible, then. It is likely that you will encounter other problems with this library, if it is not designed to work on Android (e.g., not set up to work properly on ARM CPUs).

There is a bug in Android for which I have found no workaround short of terminating my process

This is one of the few legitimate reasons for terminating a process, but it is so rare that it is difficult to find a citation of a place where such a bug (and workaround) exists.

I need to do *something* from my top-level exception handler!

Set relevant static data members to null, then start up your launcher activity, using FLAG_ACTIVITY_SINGLE_TOP and FLAG_ACTIVITY_CLEAR_TOP to wipe out all other activities in your task. This should reset you to your original state, as if the user had launched the app.

Try to Hide from the User

Some developers view the user as the enemy. These developers try to insulate their app from the user, to make data inaccessible to the user, to make the app “unkillable” by the user, etc. In many cases, this is at the behest of some enterprise, wanting to exert control over the user’s use of the app or even the device.

Android is a consumer operating system. It is designed to put power in the hands of whoever is holding the device and can authenticate themselves to the device (e.g., via a password on the lock screen). Enterprises and malware authors have much the same interests: they wish to take control away from the user and give the control to somebody else. Android defends against malware; enterprises get caught in the crossfire.

Inevitably, the right solution here will be an enterprise remix of Android, designed to be loaded on enterprise-supplied devices, that put the control in the hands of the enterprise.

The Costs

Simply put, you are wasting your time, which could be better spent on other pursuits.

With respect to data, if your app can access that data, by definition, a sufficiently talented user can get at the data:

- If you put it on internal storage, the user can root the device
- If you further encrypt the data, the user can find the encryption algorithm and key in your app, then decrypt the data
- If you try obfuscation or other techniques to mask the encryption algorithm and key, the user will use cracking tools to find this information anyway, or will transfer your app to a ROM mod that contains a modified version of the Android framework that can collect this information when you go to decrypt the data
- And so on

With respect to the process, the user can force-stop any installed app via the Settings app. And, even if you use script-kiddie tricks to try to prevent access to Settings, the user can nuke your app from orbit via the command line, using the full Android SDK or third-party tools.

The Counter-Arguments

I am creating an app for an enterprise, and we need to control the app

Then you further need to control the device, which leads to the “enterprise flavor of Android” solution mentioned earlier in this section.

I am creating a lock screen/parental control app/kiosk app

Please see the counter-arguments for “Interfering with Navigation” from [earlier in this chapter](#).

Use Multiple Processes

Some Android professionals recommend the use of `android:process` to have components run in separate processes from the main one for an application. For example, you might have all of your activities in the main process but isolate a service in a separate process. Or, you might have some memory-intensive activity (e.g., an image editor) run in a separate process.

As with most of these anti-patterns, while the `android:process` feature is valid, it is rarely necessary. To some extent, developers get caught up in process isolation from

its use on servers and forget that mobile devices typically have fewer resources — RAM and CPU — than do their server counterparts. Few of Google’s apps use `android:process`; even complex apps like Gmail or the original Browser avoid it.

The Costs

Each process gets its own heap space, cutting into the heap available for other applications. As with the large-heap anti-pattern [discussed above](#), this will tend to force other apps to be ejected from memory sooner than normal, with commensurate impacts on user experience.

Inter-process communication (IPC) is not cheap, compared with normal method invocation within a process. Hence, tightly-coupled processes will chew through more CPU than their single-process counterparts. While it is unlikely that you will see major performance implications (unless you are doing a preposterous amount of IPC), this will consume more battery than is otherwise warranted.

The Counter-Arguments

I am using a C library that is buggy, and you told me not to terminate my process

As noted earlier, fix the bugs in the library.

Hello? It is not my C library, but one from a third party!

Find a library that is Android-compatible, then.

I need more heap space

On Android 3.0 and higher, `android:largeHeap` is available, though its misuse is [another anti-pattern, discussed above](#). However, prior to Android 3.0, `android:largeHeap` was not an option. One workaround used by some apps is to fork several processes, thereby getting several “small” heap allocations (e.g., 32MB) instead of just one.

In cases where `android:largeHeap` is indeed justified, using multiple processes as a workaround on older Android versions is justified as well. However, bear in mind that IPC overhead is non-trivial, so have a plan to dump the multiple processes and use `android:largeHeap` once you drop support for Android 1.x/2.x.

I want my UI not to freeze when doing background work

Use threads, not processes, for this.

Hog System Resources

Some of these anti-patterns, like the multiple-process one just now, are really concrete sub-types of a more general anti-pattern: assuming yours is the only app running on the device. While your app may be the only one running in the foreground (assuming that you actually *are* in the foreground), there are other apps in the background, and ones that soon will come to the foreground. You need to “play nice” and ensure that these other apps will have their fair share of system resources.

One example is open files on external storage. For some devices — but not all — there is a limit of 1,024 simultaneously open files. In principle, that should be plenty. However, if some app — maybe yours? — opens a whole bunch of files, it is possible that other apps trying to access external storage at that point will crash because the limit was hit.

The Counter-Arguments

Um, well, I’m just more important than those other developers

::facepalm::

Trail: Widget Catalog

Widget Catalog: AdapterViewFlipper

A [regular ViewPager](#) shows only one child widget or container at a time. So does an AdapterViewFlipper. The difference is where the children come from. With a regular ViewPager, you add children much like you would any other standard container class, such as defining the children in your layout XML resource. With AdapterViewFlipper, the children come from an Adapter.

While AdapterViewFlipper does not inherit from ViewPager (or vice versa, for that matter), their public API is largely the same:

- You can control which child is visible, either by index or via `showNext()/showPrevious()` methods to rotate between them.
- You can set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.
- You can set up AdapterViewFlipper to automatically flip between children on a specified period.

There are two key advantages for AdapterViewFlipper:

1. Since it uses an Adapter model, it can be more memory efficient for lots of children, through child view recycling
2. It is available for use in an [app widget](#)

However, AdapterViewFlipper is new to API Level 11 and is unavailable on older versions of Android. It is not included in the Android Support package backport.

Key Usage Tips

All of the usage tips from [ViewPager](#) are relevant for AdapterViewFlipper.

A Sample Usage

The sample project can be found in [WidgetCatalog/AdapterViewFlipper](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<AdapterViewFlipper xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

(from [WidgetCatalog/AdapterViewFlipper/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.avflip;

import android.app.Activity;
import android.os.Bundle;
import android.widget.AdapterViewFlipper;
import android.widget.ArrayAdapter;

public class FlipperDemo2 extends Activity {
    static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
        "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
        "placerat", "ante", "porttitor", "sodales", "pellentesque",
        "augue", "purus" };
    AdapterViewFlipper flipper;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        flipper=(AdapterViewFlipper)findViewById(R.id.details);
        flipper.setAdapter(new ArrayAdapter<String>(this, R.layout.big_button, items));
        flipper.setFlipInterval(2000);
        flipper.startFlipping();
    }
}
```

(from [WidgetCatalog/AdapterViewFlipper/app/src/main/java/com/commonware/android/avflip/FlipperDemo2.java](#))

Visual Representation

There is no visual representation of an AdapterViewFlipper itself, as it renders no pixels on its own. Rather, it simply shows the current child.

Widget Catalog: CalendarView

CalendarView, as you might have guessed, displays a calendar to the user, designed to allow the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Note that this is a small calendar – it is not designed to show details *within* a date, such as appointments and times.

This view is available standalone and also as an optional adjunct to [the DatePicker widget](#).

This view was added in API Level 11 and therefore will not be available on older versions of Android, though [a backport is available](#) that works on Android 2.2 onwards.

Key Usage Tips

If you do nothing, the CalendarView will start with today's date, though you can call a `setDate()` method to pass in a `Calendar` object to use to change the initially-selected date. You can also call `setOnDateChangeListener()` to supply an `OnDateChangeListener` to learn when the user changes the date in the CalendarView.

CalendarView works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the year/month/day-of-month from the CalendarView (as supplied to the `onSelectedDayChange()` method of your `OnDateChangeListener`) and converting it into something you can use in your code.

A Sample Usage

The sample project can be found in [WidgetCatalog/CalendarView](#).

Layout:

```
<CalendarView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/calendar"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

(from [WidgetCatalog/CalendarView/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.wc.calendar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CalendarView;
import android.widget.CalendarView.OnDateChangeListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class CalendarDemoActivity extends Activity implements
    OnDateChangeListener {
    CalendarView calendar=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        calendar=(CalendarView)findViewById(R.id.calendar);
        calendar.setOnDateChangeListener(this);
    }

    @Override
    public void onSelectedDayChange(CalendarView view, int year,
        int monthOfYear, int dayOfMonth) {
        Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

        Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
            .show();
    }
}
```

(from [WidgetCatalog/CalendarView/app/src/main/java/com/commonware/android/wc/calendar/CalendarDemoActivity.java](#))

Visual Representation

This is what a CalendarView looks like in a few different Android versions and configurations, based upon the sample app shown above.

WIDGET CATALOG: CALENDARVIEW

WIDGET CATALOG: CALENDARVIEW

3607

Widget Catalog: DatePicker

DatePicker, as the name might suggest, allows the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Key Usage Tips

If you do nothing, the DatePicker will start with today's date. However, if you want to set up an `OnDateSetListener` to find out when the date changes, you will need to call `init()` to do so, in which you also need to set the date.

DatePicker works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the year/month/day-of-month from the DatePicker and converting it into something you can use in your code.

API Level 11 introduced an optional `CalendarView` adjunct to the DatePicker, determined via `setCalendarViewShown()` or `android:calendarViewShown`. This works well on `-normal` screens in landscape and on `-large/-xlarge` screens. On `-normal` screens in portrait, the year portion of the picker may be chopped off to save room. Using the `CalendarView` option on `-small` screens is probably not a good idea.

However, on Android 5.0+, the `CalendarView` is *always* shown and cannot be removed, as the “picker” itself does not allow the user to pick a date. The user uses the `CalendarView` to pick a date, or taps on the year in the “picker” to choose a year. This means that DatePicker is not a particularly good widget to use, especially on smaller screens.

A Sample Usage

The sample project can be found in [WidgetCatalog/DatePicker](#).

Layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:gravity="center_horizontal">

    <DatePicker
        android:id="@+id/picker"
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="1"
        android:calendarViewShown="true"/>

    <CheckBox
        android:id="@+id/showCalendar"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:checked="true"
        android:text="@string/calendar"/>

</LinearLayout>
```

(from [WidgetCatalog/DatePicker/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.wc.datepick;

import android.app.Activity;
import android.os.Build;
import android.os.Bundle;
import android.view.View;
import android.widget.CheckBox;
import android.widget.CompoundButton;
import android.widget.CompoundButton.OnCheckedChangeListener;
import android.widget.DatePicker;
import android.widget.DatePicker.OnDateChangeListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class DatePickerDemoActivity extends Activity implements
    OnCheckedChangeListener, OnDateChangeListener {
    DatePicker picker=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

WIDGET CATALOG: DATEPICKER

```
CheckBox cb=(CheckBox)findViewById(R.id.showCalendar);

if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.HONEYCOMB) {
    cb.setOnCheckedChangeListener(this);
}
else {
    cb.setVisibility(View.GONE);
}

GregorianCalendar now=new GregorianCalendar();

picker=(DatePicker)findViewById(R.id.picker);
picker.init(now.get(Calendar.YEAR), now.get(Calendar.MONTH),
           now.get(Calendar.DAY_OF_MONTH), this);
}

@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {
    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.HONEYCOMB) {
        picker.setCalendarViewShown(isChecked);
    }
}

@Override
public void onDateChanged(DatePicker view, int year, int monthOfYear,
                          int dayOfMonth) {
    Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

    Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
        .show();
}
}
```

(from [WidgetCatalog/DatePicker/app/src/main/java/com/commonsware/android/wc/datepick/DatePickerDemoActivity.java](https://github.com/CommonWare/android-wc-datepick))

The CheckBox is tied to the visibility of the CalendarView. Since this is only available on API Level 11 and higher, we simply remove the CheckBox on earlier versions of Android, so we do not have to worry about whether or not the CheckBox gets unchecked by the user.

Visual Representation

This is what a DatePicker looks like in a few different Android versions and configurations, based upon the sample app shown above.

Widget Catalog: ExpandableListView

Android does not have a “tree” widget, allowing users to navigate an arbitrary hierarchy of stuff. In large part, that is because such trees are difficult to navigate on small touchscreens with comparatively large fingers.

Android *does* have `ExpandableListView`, a subclass of `ListView` that supports a two-layer hierarchy: groups and children. Groups can be expanded to show their children or collapsed to hide them, and you can get control on various events for the groups or the children.

Key Usage Tips

Android offers an `ExpandableListActivity` as a counterpart to its `ListActivity`. However, it does not offer an `ExpandableListFragment`. This is not a major issue, as you can work with an `ExpandableListView` inside a regular `Fragment` yourself, just as you would for most other widgets not named `ListView`.

Rather than use a `ListAdapter` with `ExpandableListView`, you will use an `ExpandableListAdapter`, where you can control separate details for groups and children. These include:

- `SimpleExpandableListAdapter`, roughly analogous to `ArrayAdapter`, where your data resides in a `List` of `Map` objects for groups, and a `List` of a `List` of `Map` objects for the children
- `CursorTreeAdapter` and `SimpleCursorTreeAdapter`, roughly analogous to `CursorAdapter` and `SimpleCursorAdapter`, for mapping data in a `Cursor` to rows and columns

In many cases, though, the complexity of managing groups and children will steer you down the path of extending `BaseExpandableListAdapter` and handling all of the view construction yourself. There are many methods that you will need to implement:

- `getGroupCount()`, to return the number of groups
- `getGroup()` and `getGroupId()`, to return an `Object` and unique `int` ID for a group given its position
- `getGroupView()`, to return the `View` that should be used to render the group, perhaps using the built-in `android.R.layout.simple_expandable_list_item_1` that is set up for such groups and handles rendering the expanded and collapsed states
- `getChildrenCount()`, to return the number of children for a given group
- `getChild()` and `getChildId()`, to return an `Object` and unique `int` ID for a child given its position (and its group's position)
- `getChildView()`, to return the `View` that should be used to render the child, given its position and its group's position
- `isChildSelectable()`, to indicate if the user can select a given child, given its position and its group's position
- `hasStableIds()`, to indicate if the ID values you returned from `getGroupId()` and `getChildId()` will remain constant for the life of this adapter

There are four major events that you will be able to respond to with respect to the user's interaction with an `ExpandableListView`:

- Clicks on a child (`setOnChildClickListener()`)
- Clicks on a group (`setOnGroupClickListener()`)
- When groups expand (`setOnGroupExpandListener()`) or collapse (`setOnGroupCollapseListener()`)

If you use `setOnGroupClickListener()` to be notified about clicks on a group, be sure to return `false` from your implementation of the `onGroupClick()` method required by the `OnGroupClickListener` interface. If you return `true`, you consume the click event, which prevents `ExpandableListView` from using that event to expand or collapse the group.

A Sample Usage

The sample project can be found in [WidgetCatalog/ExpandableListView](#).

WIDGET CATALOG: EXPANDABLELISTVIEW

Layout:

```
<ExpandableListView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/elv"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
</ExpandableListView>
```

(from [WidgetCatalog/ExpandableListView/app/src/main/res/layout/activity_main.xml](#))

JSON data:

```
{
  "Group A": ["Child A1", "Child A2", "Child A3"],
  "Group B": ["Child B1", "Child B2"],
  "Group C": ["Child C1"],
  "Group D": [],
  "Group E": ["Child E1", "Child E2", "Child E3"]
}
```

    Toast.makeText(this,
        "Collapsing: "
            + adapter.getGroup(groupPosition).toString(),
        Toast.LENGTH_SHORT).show();
}
}
```

WIDGET CATALOG: EXPANDABLELISTVIEW

(from [WidgetCatalog/ExpandableListView/app/src/main/java/com/commonsware/android/wc/elv/MainActivity.java](#))

This activity loads up a JSON file from a raw resource on the main application thread in `onCreate()`, which is not a good idea. It would be better to do that work in a background thread, perhaps an `AsyncTask` managed by a retained fragment. The implementation shown here is designed to keep the sample small, not to demonstrate the best way to load data from a raw resource.

Adapter:

```
package com.commonsware.android.wc.elv;

import android.util.Log;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.BaseExpandableListAdapter;
import android.widget.TextView;
import java.util.Iterator;
import org.json.JSONArray;
import org.json.JSONException;
import org.json.JSONObject;

public class JSONExpandableListAdapter extends
    BaseExpandableListAdapter {
    LayoutInflater inflater=null;
    JSONObject model=null;

    JSONExpandableListAdapter(LayoutInflater inflater, JSONObject model) {
        this.inflater=inflater;
        this.model=model;
    }

    @Override
    public int getGroupCount() {
        return(model.length());
    }

    @Override
    public Object getGroup(int groupPosition) {
        @SuppressWarnings("rawtypes")
        Iterator i=model.keys();

        while (groupPosition > 0) {
            i.next();
            groupPosition--;
        }

        return(i.next());
    }

    @Override
    public long getGroupId(int groupPosition) {
        return(groupPosition);
    }
}
```

WIDGET CATALOG: EXPANDABLELISTVIEW

```
@Override

    return(true);
}

@Override
public boolean hasStableIds() {
    return(true);
}

private JSONArray getChildren(int groupPosition) throws JSONException {
    String key=getGroup(groupPosition).toString();

    return(model.getJSONArray(key));
}
}
```

(from [WidgetCatalog/ExpandableListView/app/src/main/java/com/commonsware/android/wc/elv/JSONExpandableListAdapter.java](https://github.com/CommonsWare/widget-catalog/blob/master/expandablelistview/app/src/main/java/com/commonsware/android/wc/elv/JSONExpandableListAdapter.java))

This adapter wraps a `JSONObject` and assumes that the JSON structure is an object, keyed by strings, whose values are arrays of strings. The object returned by `getGroup()` is the key for that group's position; the object returned by `getChild()` is the string at that child's array index for its group's array. Since the data structure is treated as immutable, and since there are no other better IDs in the data structure itself, the group ID is simply the group's position, and the child's ID is simply a mash-up of the group and child positions.

Visual Representation

This is what an `ExpandableListView` looks like in a few different Android versions and configurations, based upon the sample app shown above.

WIDGET CATALOG: EXPANDABLELISTVIEW

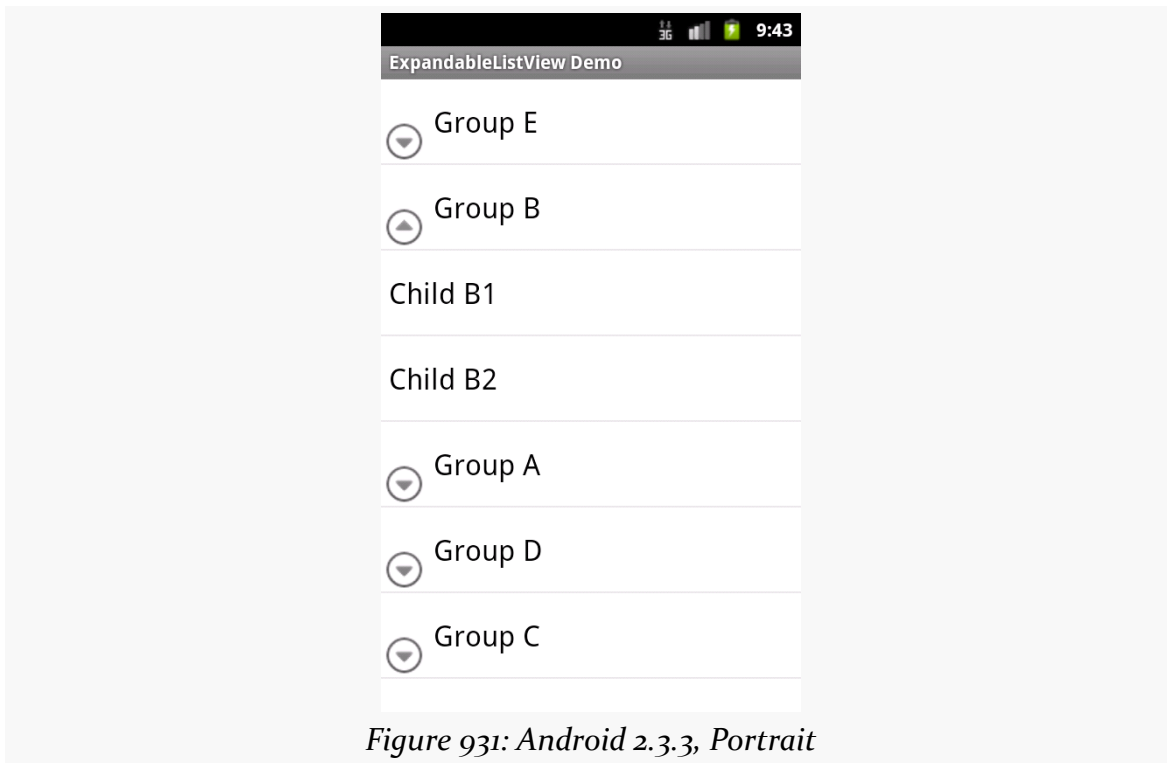

Figure 931: Android 2.3.3, Portrait

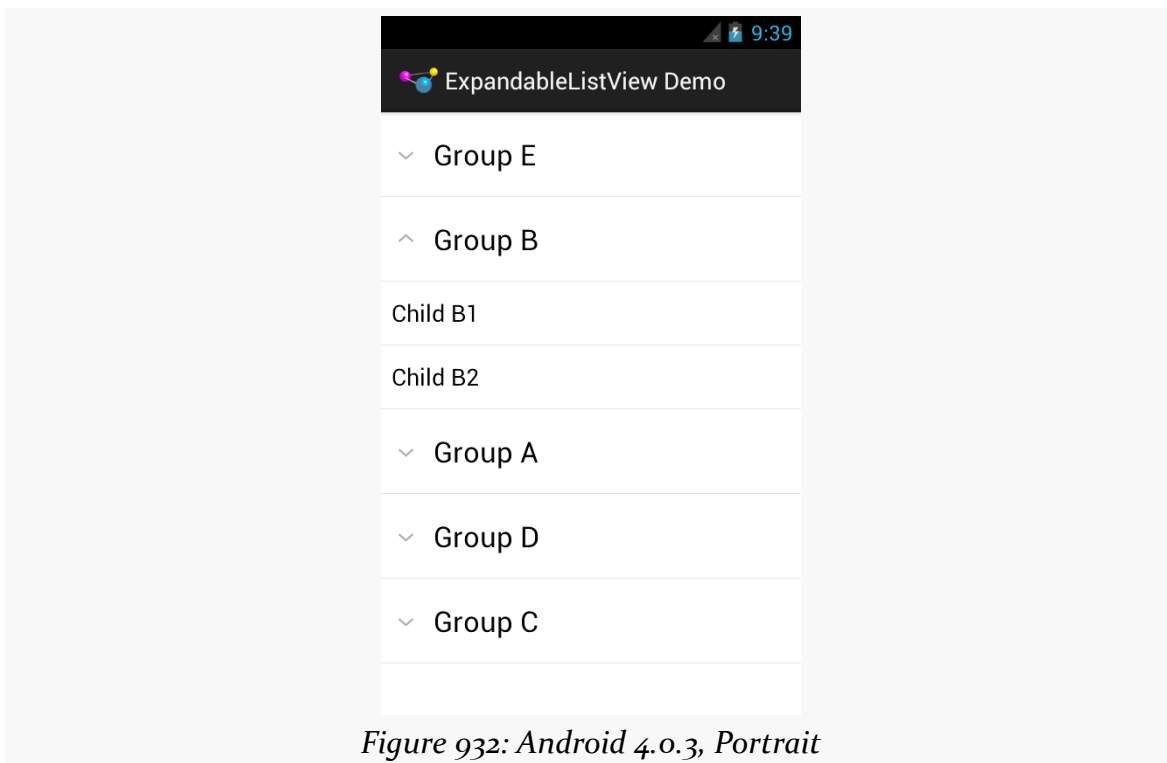

Figure 932: Android 4.0.3, Portrait

WIDGET CATALOG: EXPANDABLELISTVIEW

Note that while the data in the JSON file has the groups sorted alphabetically, because `JSONObject` effectively loads its data into a `HashMap`, the sorting gets lost in the data model, which is why the groups appear out of order.

Also note that the visual representation of the “collapsed” and “expanded” states is controlled by the `ExpandableListAdapter` and the view used for the groups. In this sample, we use `android.R.layout.simple_expandable_list_item_1` for the groups, which gives us the caret designation for expanded versus collapsed states in 4.0.3 and the lower-left arrowhead-in-circle icon for 2.3.3. You can create your own rows with your own indicators as you see fit.

Widget Catalog: SeekBar

SeekBar allows the user to choose a value along a continuous range by sliding a “thumb” along a horizontal line. In effect — and in practice, as it turns out — SeekBar is a user-modifiable ProgressBar.

Key Usage Tips

The value range of a SeekBar runs from 0 to a developer-set maximum value. As with ProgressBar, the default maximum is 100, but that can be changed via an `android:max` attribute or the `setMax()` method. The minimum value is always 0, so if you want a range starting elsewhere, just add your starting value to the actual value (obtained via `getProgress()`) to slide the range as desired.

You can find out about changes in the SeekBar value by attaching an `OnSeekBarChangeListener` implementation. The primary method on that interface is `onProgressChanged()`, where you are notified about changes in the progress value (second parameter) and whether that change was initiated directly by the user interacting with the widget (third parameter). The interface also has `onStartTrackingTouch()` and `onStopTrackingTouch()`, to indicate when the user is attempting to change the position of the thumb via the touchscreen, though these methods are less-commonly used.

A Sample Usage

The sample project can be found in [WidgetCatalog/SeekBar](#).

Layout:

WIDGET CATALOG: SEEKBAR

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:gravity="center_vertical"
    tools:context=".MainActivity">

    <TextView
        android:id="@+id/value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="0"
        android:ems="2"
        android:gravity="right|center_vertical"
        android:layout_marginRight="10dp"
        android:textAppearance="@android:style/TextAppearance.Large"/>

    <SeekBar
        android:id="@+id/seek_bar"
        android:layout_width="0dp"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:layout_marginRight="10dp"
        android:max="50"/>

</LinearLayout>
```

(from [WidgetCatalog/SeekBar/app/src/main/res/layout/activity_main.xml](#))

Activity:

```
package com.commonware.android.wc.seekbar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.SeekBar;
import android.widget.SeekBar.OnSeekBarChangeListener;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnSeekBarChangeListener {
    TextView value=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        value=(TextView)findViewById(R.id.value);

        SeekBar seekBar=(SeekBar)findViewById(R.id.seek_bar);

        seekBar.setOnSeekBarChangeListener(this);
    }

    @Override
    public void onProgressChanged(SeekBar seekBar, int progress,
        boolean fromUser) {
        value.setText(String.valueOf(progress));
    }
}
```

WIDGET CATALOG: SEEKBAR

```
}

WIDGET CATALOG: SEEKBAR

Widget Catalog: SlidingDrawer

Having some form of means of allowing the user to swipe to show more things is an important visual pattern. We saw this earlier in the book with [the ViewPager container](#). And there are other modern techniques for doing this that you will see in apps like Google+.

SlidingDrawer, while implementing a variation on this pattern, is a bit out of date at present. Mostly, that's a question of its UI: tapping a drawer "handle" to open it is not what you tend to see nowadays. That being said, it works perfectly well, wrapping around a container to make it appear or disappear based on user input, complete with a sliding animation effect.

Note that SlidingDrawer was deprecated in API Level 17 (a.k.a., Android 4.2). This means that Google is steering you in other directions, including forking [the AOSP code for SlidingDrawer](#) and maintaining it yourself. The [animator framework](#) offers other ways of implementing sliding widgets that may be better suited for your UI, anyway.

Also note that SlidingDrawer is broken on Android 5.0, and so you *definitely* should be considering alternative widgets at this time.

Key Usage Tips

The SlidingDrawer itself is transparent, except for the button to trigger the slide and its accompanying horizontal bar. Hence, if you want the drawer contents to completely obscure what is outside of the drawer, you will need to use an appropriate background. Otherwise, the drawer contents and what lies outside the drawer will be alpha-blended based on their own translucency, as is seen in [the screenshots later in this chapter](#).

WIDGET CATALOG: SLIDINGDRAWER

The `SlidingDrawer` can be horizontal or vertical; it is vertical by default. However, it only slides one way (bottom-to-top for vertical, right-to-left for horizontal). There is no way to reverse the direction of the sliding effect.

You must supply `android:content` and `android:handle` attributes in `SlidingDrawer`, containing references to the widget that forms the content of the drawer and the drawer's handle, respectively. Typically, the drawer's handle is an `ImageView`. Note that you *must* supply a handle — you cannot skip either of these attributes.

A Sample Usage

The sample project can be found in [WidgetCatalog/SlidingDrawer](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <Button
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:text="@string/drawer_closed"/>

    <SlidingDrawer
        android:id="@+id/drawer"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:content="@+id/content"
        android:handle="@+id/handle">

        <ImageView
            android:id="@id/handle"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:src="@drawable/tray_handle_normal"/>

        <Button
            android:id="@id/content"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:text="@string/drawer_msg"/>
    </SlidingDrawer>
</RelativeLayout>
```

(from [WidgetCatalog/SlidingDrawer/app/src/main/res/layout/main.xml](#))

Activity:

WIDGET CATALOG: SLIDINGDRAWER

```
package com.commonware.android.drawer;

import android.app.Activity;
import android.os.Bundle;

public class DrawerDemo extends Activity
{
    /** Called when the activity is first created. */
    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }
}
```

(from [WidgetCatalog/SlidingDrawer/app/src/main/java/com/commonware/android/drawer/DrawerDemo.java](#))

Visual Representation

This is what a SlidingDrawer looks like in a few different Android versions and configurations, based upon the sample app shown above.

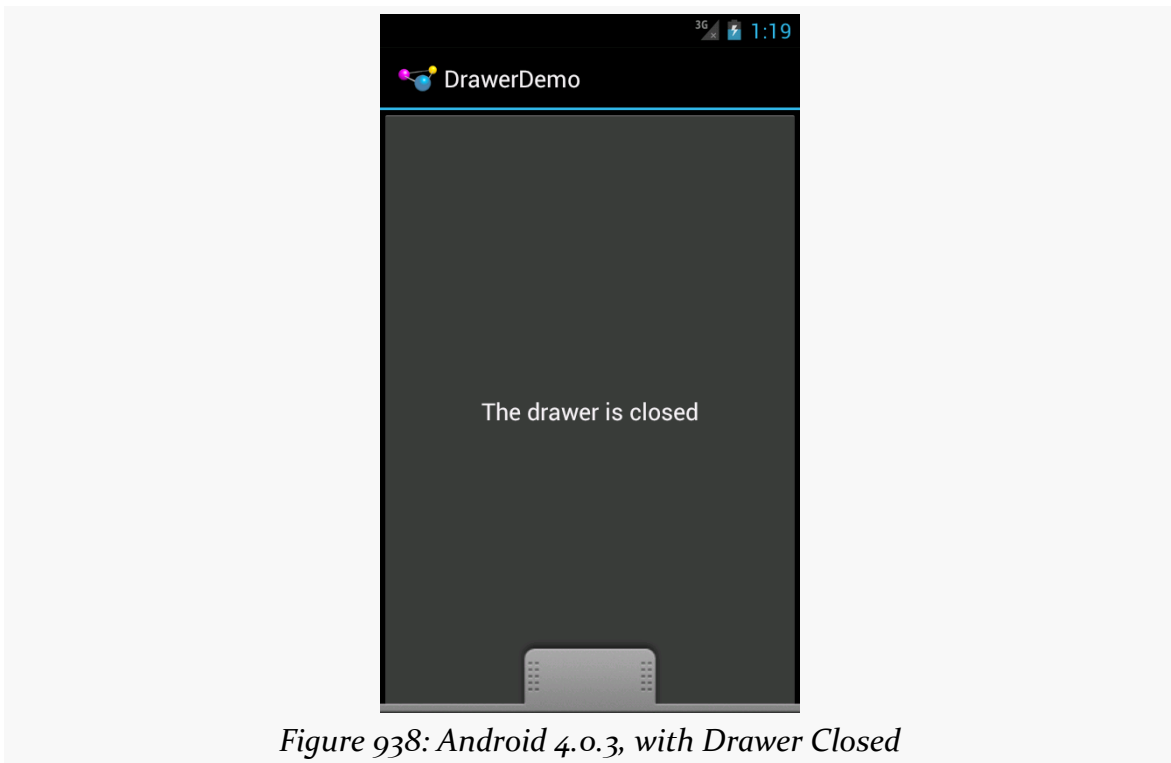

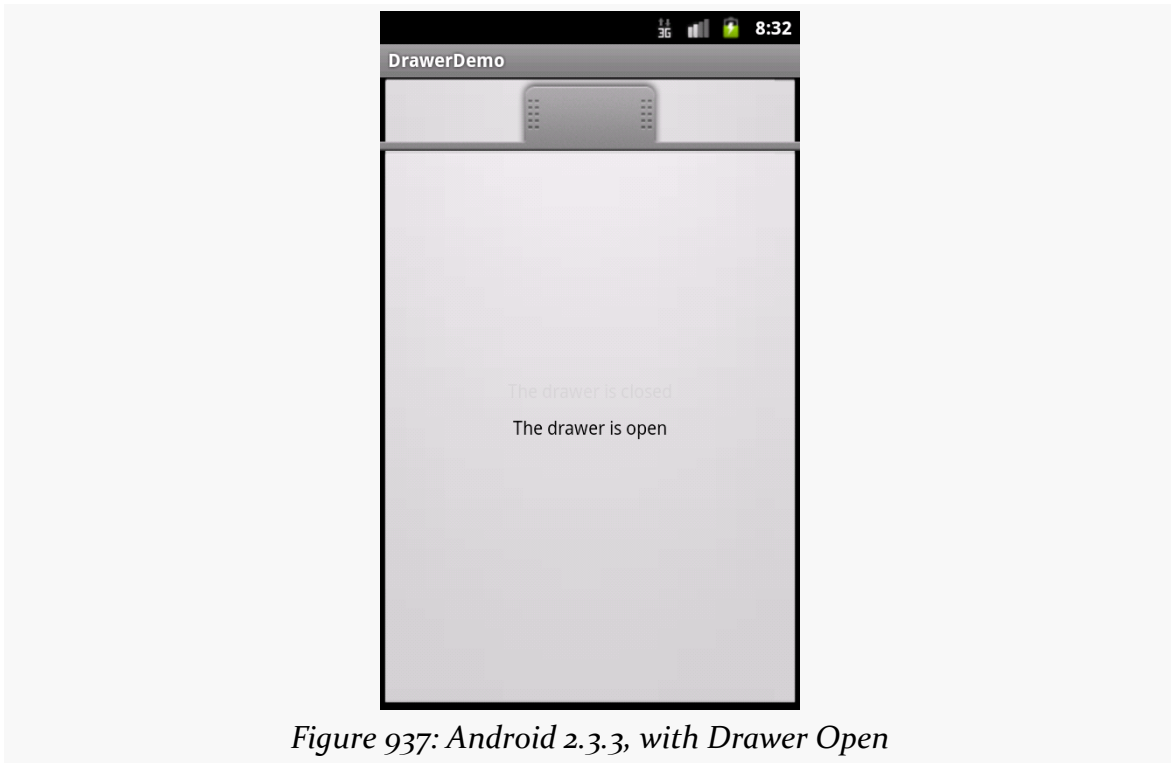

Figure 936: Android 2.3.3, with Drawer Closed

WIDGET CATALOG: SLIDINGDRAWER

3634

Widget Catalog: StackView

StackView is an AdapterView. Whereas ListView uses a horizontal scrolling list as its UI metaphor, StackView uses a stack of cards as its metaphor. Just as ListView shows a handful of rows, StackView shows a handful of cards. These cards can be swiped away via a swipe towards the southwest corner of the screen. The top card is fully visible; the edges of a few other cards can be seen but are otherwise obscured by cards “higher in the stack”.

While certainly usable in activities and fragments, StackView was introduced in support of app widgets. App widgets like bookmarks, Google Books covers, and the like use StackView to show an item and allow users to navigate to the rest of the items by flipping these virtual cards.

Key Usage Tips

Generally speaking, working with StackView is not significantly different than is working with any other AdapterView. You create an Adapter defining the contents (in this case, defining the cards), you attach the Adapter to the StackView, and put the StackView somewhere on the screen.

As the cards overlap, however, transparency becomes an issue. If the top card is not completely opaque, you will see the card beneath it “peeking through” as its contents are blended in via the alpha channel. In some cases, this is a perfectly desirable outcome. However, if that is not what you want, make sure that the backgrounds of your overall container for the card’s contents (e.g., a RelativeLayout) has an opaque background, such as a color with FF for the alpha value.

Also, since the objective is to have the children be visually stacked, the children cannot be the size of the StackView itself (e.g., the children cannot use `match_parent` for a dimension). StackView seems to work best with children that have explicit sizes (e.g., values in dp).

A Sample Usage

The sample project can be found in [WidgetCatalog/StackView](#).

Activity Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<StackView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

(from [WidgetCatalog/StackView/app/src/main/res/layout/main.xml](#))

Item Layout:

```
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="200dp"
    android:layout_height="200dp"
    android:background="#FFF000"
    android:gravity="center"
    android:textAppearance="?android:attr/textAppearanceLarge"/>
```

(from [WidgetCatalog/StackView/app/src/main/res/layout/item.xml](#))

Activity:

```
package com.commonware.android.wc.stack;

import android.app.Activity;
import android.content.Context;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.AdapterView;
import android.widget.StackView;

public class MainActivity extends Activity {
    static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
        "consectetur", "adipiscing", "elit", "morbi", "vel", "ligula",
        "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
        "placerat", "ante", "porttitor", "sodales", "pellentesque",
        "augue", "purus" };
    StackView stack;

    @Override
    public void onCreate(Bundle savedInstanceState) {
```

WIDGET CATALOG: STACKVIEW

```
super.onCreate(icicle);
setContentView(R.layout.main);

stack=(StackView)findViewById(R.id.details);
stack.setAdapter(new ItemAdapter(this, R.layout.item, items));
}

private static class ItemAdapter extends ArrayAdapter<String> {
    public ItemAdapter(Context context, int textViewResourceId,
        String[] objects) {
        super(context, textViewResourceId, objects);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        result.setBackgroundColor(0xFF330000 + (position * 0x0A0A));

        return(result);
    }
}
}
```

(from [WidgetCatalog/StackView/app/src/main/java/com/commonsware/android/wc/stack/MainActivity.java](#))

Visual Representation

This is what a StackView looks like in Android 4.0.3, based upon the sample app shown above:

WIDGET CATALOG: STACKVIEW

Widget Catalog: TabHost and TabWidget

Before we had the action bar and `ViewPager`, we had `TabHost` and `TabWidget` as our means of displaying tabs. Nowadays, in most cases, using tabs with a `ViewPager` is the preferred option. However, there may be cases where the classic tabs are a better solution, or you may have inherited legacy code that still uses `TabHost`.

Deprecation Notes

Just as `ListActivity` helps one use a `ListView`, `TabActivity` helps one use a `TabHost`. However, `TabActivity` is marked as deprecated. That is largely because its parent class, `ActivityGroup`, is deprecated. While you can still use `TabActivity`, it is no longer recommended. It also is not necessary, as there are ways to use `TabHost` and `TabWidget` without using `TabActivity`, as will be demonstrated later in this chapter.

Key Usage Tips

There are a few widgets and containers you need to use in order to set up a tabbed portion of a view:

- `TabHost` is the overarching container for the tab buttons and tab contents
- `TabWidget` implements the row of tab buttons, which contain text labels and optionally contain icons
- `FrameLayout` is the container for the tab contents; each tab content is a child of the `FrameLayout`

You load contents into that `FrameLayout` in one of two ways:

1. You can define the contents simply as child widgets (or containers) of the `FrameLayout` in a layout XML file you are using for the whole tab setup
2. You can define the contents at runtime

Curiously, you do not define what goes in the tabs themselves, or how they tie to the content, in the layout XML file. Instead, you must do that in Java, by creating a series of `TabSpec` objects (obtained via `newTabSpec()` on `TabHost`), configuring them, then adding them in sequence to the `TabHost` via `addTab()`.

The two key methods on `TabSpec` are:

- `setContent()`, where you indicate what goes in the tab content for this tab, typically the `android:id` of the view you want shown when this tab is selected
- `setIndicator()`, where you provide the caption for the tab button and, in some flavors of this method, supply a `Drawable` to represent the icon for the tab

Note that tab “indicators” can actually be views in their own right, if you need more control than a simple label and optional icon.

Also note that you must call `setup()` on the `TabHost` before configuring any of these `TabSpec` objects. The call to `setup()` is not needed if you are using the `TabActivity` base class for your activity.

A Sample Usage

The sample project can be found in [WidgetCatalog/Tab](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<TabHost xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/tabhost"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <LinearLayout
        android:orientation="vertical"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
        <TabWidget android:id="@android:id/tabs"
            android:layout_width="match_parent"
```

WIDGET CATALOG: TABHOST AND TABWIDGET

```
        android:layout_height="wrap_content"
    />
    <FrameLayout android:id="@android:id/tabcontent"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
        <AnalogClock android:id="@+id/tab1"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
        />
        <Button android:id="@+id/tab2"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:text="A semi-random button"
        />
    </FrameLayout>
</LinearLayout>
</TabHost>
```

(from [WidgetCatalog/Tab/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.tabhost;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TabHost;

public class TabDemo extends Activity {
    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);

        TabHost tabs=(TabHost)findViewById(R.id.tabhost);

        tabs.setup();

        TabHost.TabSpec spec=tabs.newTabSpec("tag1");

        spec.setContent(R.id.tab1);
        spec.setIndicator("Clock");
        tabs.addTab(spec);

        spec=tabs.newTabSpec("tag2");
        spec.setContent(R.id.tab2);
        spec.setIndicator("Button");
        tabs.addTab(spec);
    }
}
```

(from [WidgetCatalog/Tab/app/src/main/java/com/commonware/android/tabhost/TabDemo.java](#))

Note that ordinarily you would use icons with your tabs, and so the second parameter to `setIndicator()` would be a reference to a drawable resource. This particular sample skips the icons.

Visual Representation

This is what a TabHost and TabWidget look like in a few different Android versions and configurations, based upon the sample app shown above.

Figure 940: Android 2.3.3

WIDGET CATALOG: TABHOST AND TABWIDGET

Widget Catalog: TimePicker

Just as [DatePicker](#) allows the user to pick a date, TimePicker allows the user to pick a time. This widget is a bit simpler to use, insofar as you do not have the option of the integrated CalendarView as you do with DatePicker. In other respects, TimePicker follows the patterns established by DatePicker.

Note that TimePicker only supports hours and minutes, not seconds or finer granularity.

Key Usage Tips

With DatePicker, the act of supplying an `OnDateSetListener` also required you to supply the year/month/day to use as a starting point. TimePicker is more intelligently designed: setting the `OnTimeSetListener` is independent from adjusting the hour or minute.

As with DatePicker, TimePicker works well with Calendar and GregorianCalendar, in terms of setting and getting the hour/minute/second from the TimePicker and converting it into something you can use in your code.

There is [a bug in Android 4.0/4.0.3](#) in which your `OnTimeSetListener` is not invoked when the user changes between AM and PM when viewing the TimePicker in 12-hour display mode.

A Sample Usage

The sample project can be found in [WidgetCatalog/TimePicker](#).

WIDGET CATALOG: TIMEPICKER

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:gravity="center_vertical">

    <TimePicker
        android:id="@+id/picker"
        android:layout_width="match_parent"
        android:layout_height="wrap_content" />

</LinearLayout>
```

(from [WidgetCatalog/TimePicker/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.wc.timepick;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TimePicker;
import android.widget.TimePicker.OnTimeChangedListener;
import android.widget.Toast;
import java.util.Calendar;

public class TimePickerDemoActivity extends Activity implements
    OnTimeChangedListener {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        TimePicker picker=(TimePicker)findViewById(R.id.picker);

        picker.setOnTimeChangedListener(this);
    }

    @Override
    public void onTimeChanged(TimePicker view, int hourOfDay, int minute) {
        Calendar then=Calendar.getInstance();

        then.set(Calendar.HOUR_OF_DAY, hourOfDay);
        then.set(Calendar.MINUTE, minute);
        then.set(Calendar.SECOND, 0);

        Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_SHORT)
            .show();
    }
}

Widget Catalog: ViewFlipper

A `ViewFlipper` behaves a bit like a `FrameLayout` that is set up such that only one child can be visible at a time. You can control which of those children is visible, either by index or via `showNext()/showPrevious()` methods to rotate between them.

You can also set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.

And, you can set up `ViewFlipper` to automatically flip between children on a specified period, without further developer involvement. This, coupled with the animation, can be used for news tickers, ad banner rotations, or the like where light animations (e.g., fade out and fade in) can be used positively.

Key Usage Tips

`ViewFlipper` can have as many children as needed (within memory constraints), though you will want at least two for it to be meaningful.

By default, the transition between children is an immediate “smash cut” — the old one vanishes and the new one appears instantaneously. You can call `setInAnimation()` and/or `setOutAnimation()` to supply [an Animation object or resource](#) to use for the transitions instead.

By default, the `ViewFlipper` will show its first child and stay there. You can manually flip children via `showNext()`, `showPrevious()`, and `setDisplayChild()`, the latter of which taking a position index of which child to display. You can also have automatic flipping, by one of two means:

WIDGET CATALOG: VIEWFLIPPER

1. In your layout, `android:flipInterval` will set up the amount of time to display each child before moving to the next, and `android:autoStart` will indicate if the automated flipping should begin immediately or not
2. In Java, `setFlipInterval()` serves the same role as `android:flipInterval`, and you can control when flipping is enabled via `startFlipping()` and `stopFlipping()`

A Sample Usage

The sample project can be found in [WidgetCatalog/ViewFlipper](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <ViewFlipper android:id="@+id/details"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        >
    </ViewFlipper>
</LinearLayout>
```

(from [WidgetCatalog/ViewFlipper/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.flipper2;

import android.app.Activity;
import android.os.Bundle;
import android.view.ViewGroup;
import android.widget.Button;
import android.widget.ViewFlipper;

public class FlipperDemo2 extends Activity {
    static String[] items={"lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit",
        "morbi", "vel", "ligula", "vitae",
        "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque",
        "augue", "purus"};

    ViewFlipper flipper;

    @Override
    public void onCreate(Bundle icle) {
        super.onCreate(icle);
        setContentView(R.layout.main);
    }
}
```

WIDGET CATALOG: VIEWFLIPPER

```
flipper=(ViewFlipper)findViewById(R.id.details);

for (String item : items) {
    Button btn=new Button(this);

    btn.setText(item);

    flipper.addView(btn,
        new ViewGroup.LayoutParams(
            ViewGroup.LayoutParams.FILL_PARENT,
            ViewGroup.LayoutParams.FILL_PARENT));
}

flipper.setFlipInterval(2000);
flipper.startFlipping();
}
}
```

(from [WidgetCatalog/ViewFlipper/app/src/main/java/com/commonsware/android/flipper2/FlipperDemo2.java](https://commonsware.com/android/flipper2/FlipperDemo2.java))

Visual Representation

There is no visual representation of a ViewFlipper itself, as it renders no pixels on its own. Rather, it simply shows the current child.

Chrome and Chrome OS

Ever since Android and Chrome were moved under the same executive within Google, rumors abounded that Android and Chrome OS would merge in one form or fashion.

In 2015, Google started down that path, offering the ability for developers to start packaging Android apps to run on Chrome OS. And — albeit via a different mechanism — Chrome OS will get Android apps starting in 2016.

The exact number of Chromebooks that have been sold is subject to some debate. One analyst pegged business (B2B) Chromebook sales in the first half of 2015 at [around 2 million](#), with an upbeat, pro-Chromebook spin. Another analyst indicated that total sales for Chromebooks in 2014 were [6 million](#), a tiny percentage of PC/laptop sales. In mid-2016, IDC estimated that Chromebook sales for the first quarter of 2016 were around 2 million, [exceeding the sales of Apple's line of Mac notebooks](#).

Whether Google will limit this to Chrome OS, or if Google will aim to make Android apps available on Windows, Mac, and Linux desktops, remains to be seen.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

How This Works

From the user's standpoint, Android apps appear alongside their Chrome OS counterparts. For example, the Play Store will be in their app launcher:

CHROME AND CHROME OS

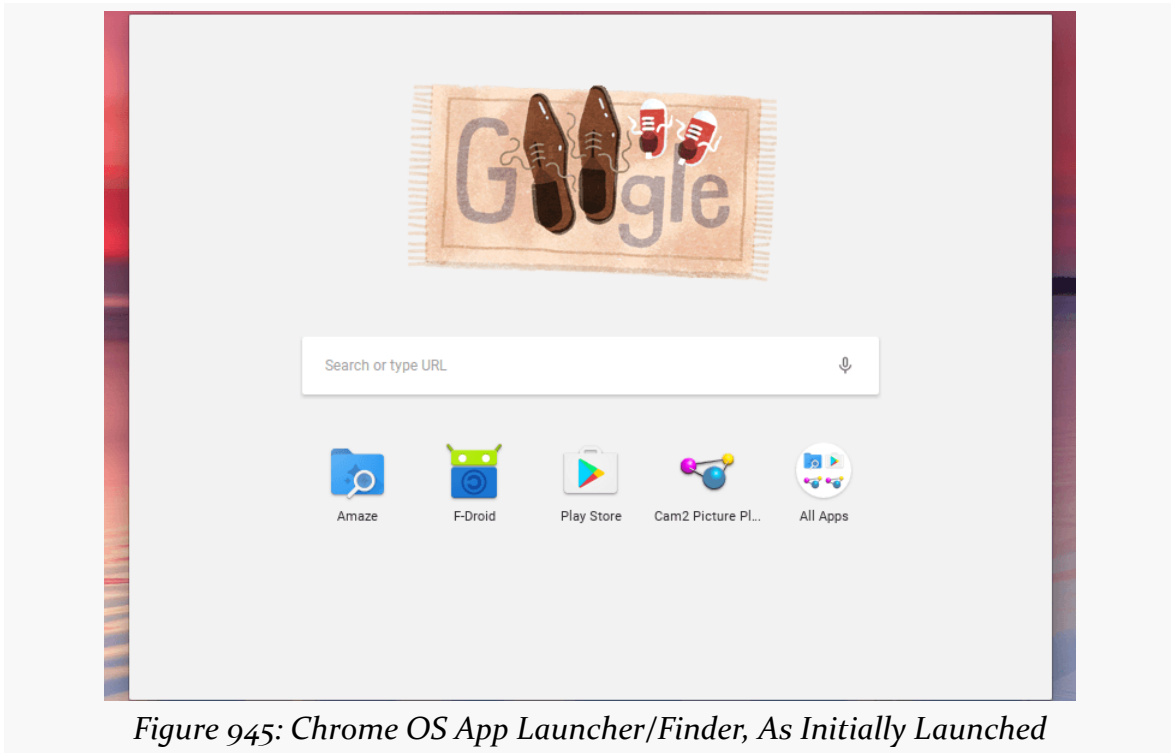

Figure 945: Chrome OS App Launcher/finder, As Initially Launched

Android apps appear in floating windows, similar to their Chrome OS counterparts: |

CHROME AND CHROME OS

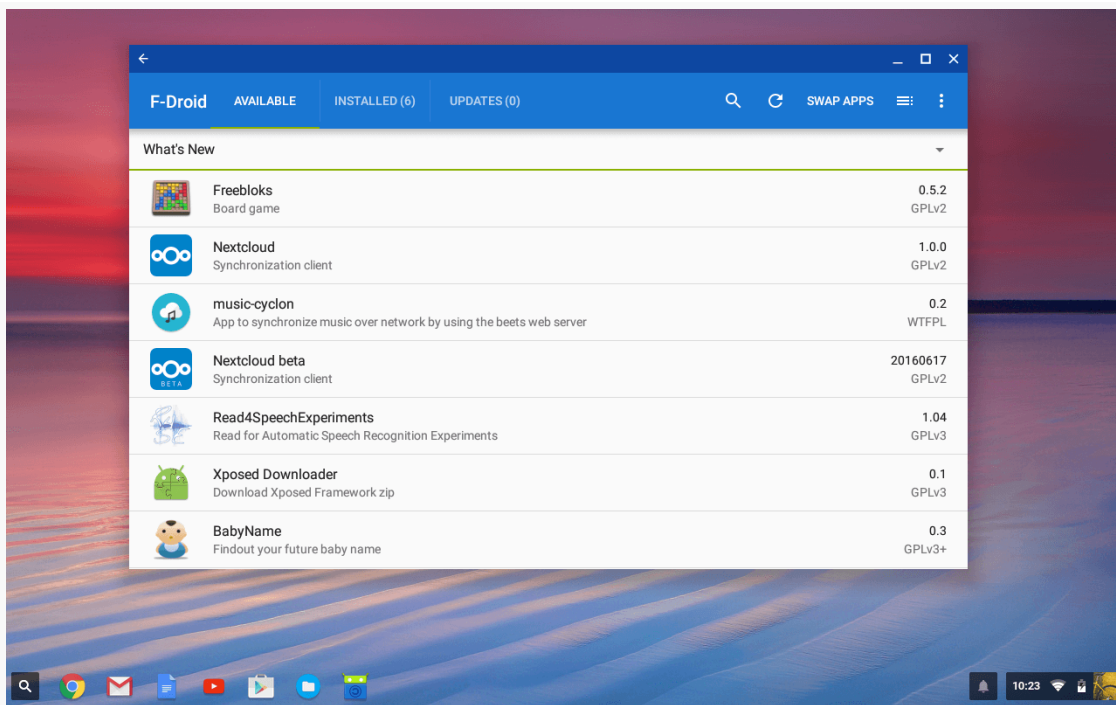

Figure 946: Chrome OS, Showing Android App

Right now, these windows cannot be arbitrarily resized. The user can switch between a floating window and a maximized view, via the title bar decorations in the upper-right corner. However, in the future, users should be able to resize these windows as they see fit, the same way they can do with native Chrome OS windows.

The Android apps see what resembles a normal Android environment. Right now, it is based on Android 6.0, but that should be upgraded to Android N later in 2016. Some aspects of the environment are shared between operating systems — most notably, the Downloads directory is accessible via external storage in Android and via the Files app in Chrome OS.

Testing Your App on Chrome OS

At the present time, there is virtually no documentation on how to test your Android app on Chrome OS. This is unfortunate.

The material in this section is derived from various Stack Overflow answers, Google+ posts, occasional bits of [actual documentation](#), other random data sources, and a lot of experimentation.

Step #1: Get a Compatible Chrome OS Device

Support for Android on Chrome OS will be in a developer preview period until sometime in the late-2016/early-2017 timeframe. Right now, only three devices are scheduled to be part of that developer preview:

- Acer Chromebook R11 / C738T
- Asus Chromebook Flip
- Google Chromebook Pixel (2015 edition)

And, at the time of this writing, the only one of those three that has Android support is the Asus Chromebook Flip.

You will need to obtain one of these devices for testing. There is no Chrome OS emulator, let alone one that has Android app support.

Step #2: Switch the Device to the Dev Channel

To get Android app capability during the developer preview, you will need to switch your Chrome OS device to “the dev channel”. This works much like the “canary channel” for Android Studio releases, or the dev channel for Chrome/Chromium releases. It configures the device to pull from a different update source, one that pushes updates more aggressively than it does to normal users.

To do this:

- In the lower-right corner of the Chrome OS desktop, click on the bar that shows the time, battery level, and your account picture:

Figure 947: Chrome OS Status Bar

- You should then see a popup panel with status information and a few controls, akin to elements of the notification shade in Android:

CHROME AND CHROME OS

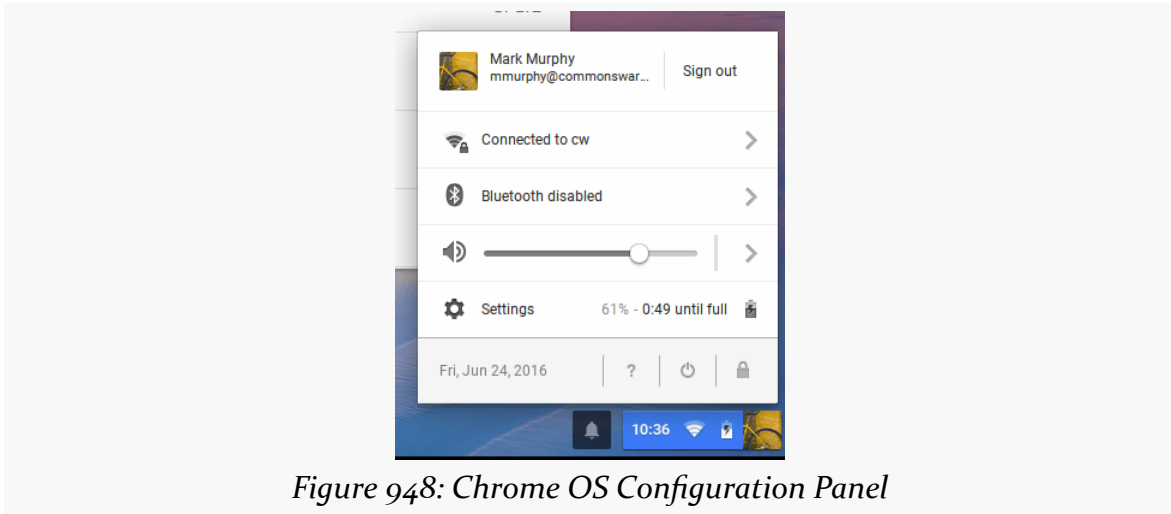

Figure 948: Chrome OS Configuration Panel

- In that panel, tap on “Settings”
- In the “Settings” page, towards the top-center, click on the “About Chrome OS” link
- In the About dialog, click on “Check for and apply updates”, to make sure that you are on the latest stuff for your current channel:

Figure 949: Chrome OS About Screen

CHROME AND CHROME OS

- Once that is done (and you have returned to the About dialog after a reboot, if updates were needed), click the “More info...” link below that updates button
- Click on the “Change channel...” button in the Channel category
- Click on the “Developer - unstable” radio button and accept the dialog

This should apply a new round of updates, pulled from the dev channel, then require you to reboot the Chrome OS device.

When that is done, go back into Settings. You should see a new settings category, named “Android Apps”:

Figure 950: Chrome OS Android Apps Checkbox

Click the “Enable Android Apps to run on your Chromebook” checkbox. At this point, you should gain access to the Play Store and be able to install apps from there.

Also, note the “App Settings” link below that checkbox. This will bring up the *Android Settings* application, which is separate and distinct from the Chrome OS Settings page that you are on. There is no icon for the Android Settings app in the regular Chrome OS app launcher; you have to know to come here to adjust the Android settings.

Step #3: Enable Chrome OS Developer Mode

Those two steps are sufficient to allow you to download and run apps from the Play Store. For seeing if your already-shipping app works on Chrome OS, that may be sufficient. However, you have no access to LogCat, and you have no means of running debug builds or otherwise testing anything *other* than your already-shipping app.

For that sort of stuff, you need to enable Chrome OS developer mode. There is no direct analogue for this in the Android world. The closest match is enabling fastboot, perhaps as part of installing an Android developer preview ROM or some other custom ROM.

CHROME AND CHROME OS

Unfortunately, the instructions for enabling developer mode are device-specific and arcane.

The Asus Chromebook Flip and the 2015 edition of the Chromebook Pixel share the same instructions:

- First, find the hardware power button. On the Flip, this is on the left edge towards the front.
- Next, shut down the device normally.
- Then, hold down the **Esc** and **Refresh** keys, and while holding them down, press the power button to turn on the device. The **Refresh** key looks like a circular arrow and may be denoted as **F3** on your keyboard. This brings up a “recovery screen”.
- On the recovery screen, press **Ctrl-D**. This screen should prompt for confirmation, then reboot the device into developer mode.

From this point forward, your device will be developer mode. However, on subsequent reboots, now that recovery screen will always appear. There, you have three choices:

1. Wait 30 seconds, in which case the device will continue its boot into developer mode
2. Press **Ctrl-D** to skip the 30-second wait
3. Follow the instructions on the screen to leave developer mode and return to normal operation

Step #4: Set Up the Android Environment

At this point, you will need to go through some standard steps for doing development in an Android environment, via the Android edition of the Settings app. You get to this via that “App Settings” link in the “Android Apps” category of the Chrome OS Settings page.

There, you can:

- Go into “About” and tap seven times on the “Build number” entry to enable developer settings
- Go into “Developer options” and enable USB debugging (and anything else that you typically use)
- Go into “Security” and enable “Unknown sources”

Step #5: Side-Load and Install Your App

At this point, you can try out custom builds of your app, by installing them manually (a.k.a., “side-loading”).

Unfortunately, Chrome OS knows nothing about APK files, so you cannot use the Chrome OS Files app to install an APK file.

The simplest way to side-load apps is to have an Android app do it:

- a cloud storage client (e.g., Dropbox)
- an Android-native Web browser
- a file manager, to load an APK you got onto the device by some other means

As mentioned earlier, the Downloads folder in Chrome OS is shared with the same folder on external storage in Android. So, you can also copy an APK over via a USB flash drive, put it in Downloads using Chrome OS, then use a file manager to install it from Downloads.

Step #6: Get adb Working

However, you still do not have access to LogCat, or any ability to use development tools like Android Studio to work on apps on the Chrome OS device. Setting up adb access is possible but a bit complicated, based on the [official instructions](#).

Step #6a: Configure the Chrome OS Device

Press `Ctrl-Alt-T` to open `crash`, a quasi-shell provided in Chrome OS. At that command prompt, run the `shell` command to get to `bash`, a full Linux-style shell.

Then, execute the following statements:

```
sudo /usr/libexec/debugd/helpers/dev_features_rootfs_verification
sudo reboot
```

This will reboot your Chrome OS device, requiring you to go through the whole Play Store acceptance/login process again.

Then, go back into `bash` via `crash`, and execute:

```
sudo /usr/libexec/debugd/helpers/dev_features_ssh
```

CHROME AND CHROME OS

This enables an SSH daemon and presumably makes corresponding adjustments to the iptables-based firewall.

Step #6b: Find Your Chrome OS IP Address

Go into Settings (e.g., tap on the time/WiFi/battery/account bar in the lower-right, then tap the gear icon). Towards the top of the Settings page, there will be an “Internet connection” section.

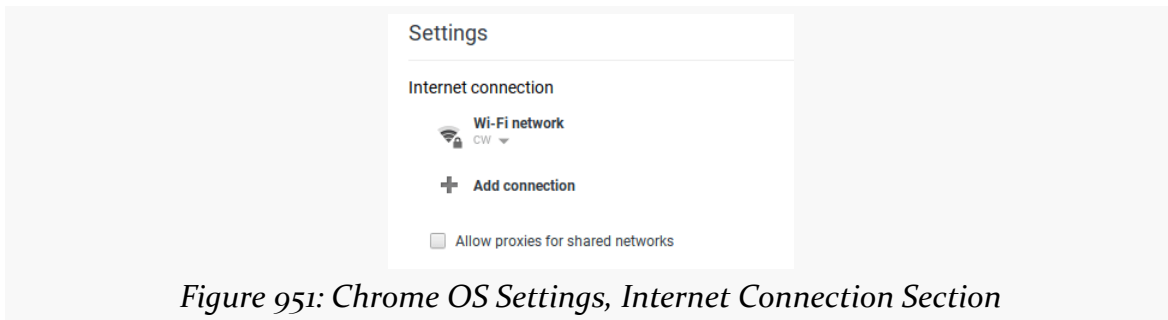

Figure 951: Chrome OS Settings, Internet Connection Section

If you are using WiFi, tap on the “Wi-Fi network” item, then tap on the WiFi network that you are using. That should bring up a three-tab dialog with details about this network connection.

CHROME AND CHROME OS

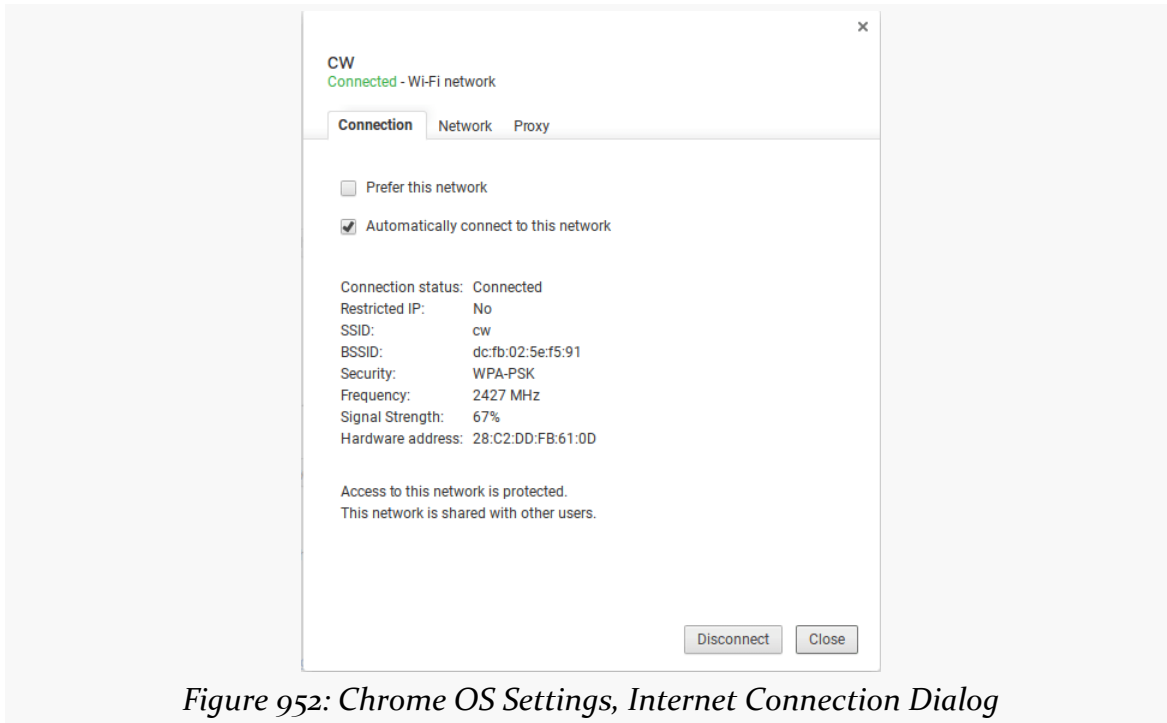

Figure 952: Chrome OS Settings, Internet Connection Dialog

The middle tab — Network — will show your IP address:

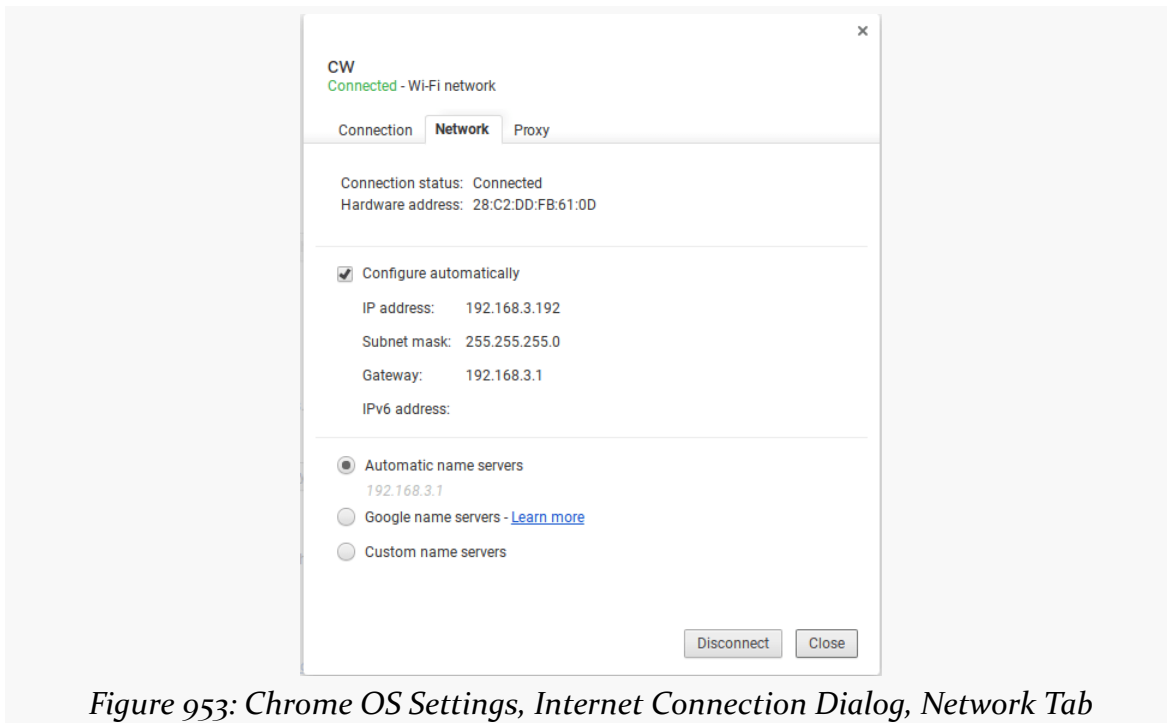

Figure 953: Chrome OS Settings, Internet Connection Dialog, Network Tab

Make note of this address.

Step #6c: Connect to Chrome OS for Development

When you want to develop using the Chrome OS device as the target, execute `adb connect [IP]:22`, where `<IP>` is the same IP address that you used previously. Note that the official docs drop off the `connect` part, which does not work.

This should trigger the standard Android debugging authorization dialog, akin to what you see when you first try USB debugging on a phone or tablet. You will need to accept this dialog before continuing.

At this point, `adb devices` should show your connection, and you should be able to run apps on the Chrome OS device akin to how you do so for locally-connected devices, emulators, etc.

If the Chrome OS device goes to sleep, it will disable its WiFi connection. You will need to wake up the device and run `adb connect` again to be able to work with it from Android Studio.

If you reboot the Chrome OS device, you will need to agree once more to the Play Store terms of service and (try) to sign into the Play Store. The Play Store UI may appear to get stuck, with a never-ending progress bar. However, once you have gotten to that point, you should be able to use `adb connect` to re-connect to the Chrome OS device.

Be Prepared To Be Wiped Out

Some dev channel updates will wipe out your Android environment, deleting all apps and files. Hence, do not store things on the developer preview devices that you will regret losing. Also, you will need to re-do Step #4, and possibly Step #6, to re-establish a developer environment.

Enabling Your App for Chrome OS

You may find that you go through Step #1 and Step #2 above — thereby enabling Android apps for the Chrome OS device — and find that your app is not available on the Play Store.

CHROME AND CHROME OS

If you want your app to appear on the Play Store for Chrome OS devices, make sure that you are not requiring any of the following via a `<uses-feature>` element:

- `android.software.input_methods` (for implementing your own IME)
- `android.software.app_widget` (for apps whose primary purpose is to publish an app widget)
- `android.software.live_wallpaper` (for apps whose primary purpose is to publish some live wallpaper)
- `android.software.home_screen` (for home screen replacement apps)

Also, while the developer preview devices all have touchscreens, not all Chrome OS devices do. Ideally, you test your app using a keyboard and mouse or trackpad and confirm that it works well without a touchscreen. Then, add this to your manifest:

```
<uses-feature
  android:name="android.hardware.touchscreen"
  android:required="false" />
```

This advertises that you are willing to support non-touchscreen environments and therefore can be installed on non-touchscreen Chrome OS devices.

Your App on Chrome OS

On the surface, Android apps will perceive Chrome OS as just another Android device. Other than the manifest entries listed above, there is nothing that you absolutely need to do in your app to run on Chrome OS.

That being said, Chrome OS is going to be somewhat different than a normal Android device. Those differences may be something that you want to try to take into account.

Environment

In the developer preview, Chrome OS has an API Level 23 Android environment. This is supposed to be updated to API Level 24 before Android support rolls out to the stable channel on supported Chrome OS devices.

We can tell what the API level is by logging `Build.VERSION.SDK_INT`, along with other values, as seen in the [Introspection/EnvDump](#) sample app. This has a single activity, designed to collect a bunch of device data and dump it to LogCat:

CHROME AND CHROME OS

```
package com.commonware.android.envdump;

import android.app.Activity;
import android.app.ActivityManager;
import android.content.pm.FeatureInfo;
import android.content.res.Configuration;
import android.os.Build;
import android.os.Bundle;
import android.util.DisplayMetrics;
import android.util.Log;
import android.widget.TextView;

public class MainActivity extends Activity {
    private static final String TAG="EnvDump";
    private final StringBuilder buf=new StringBuilder();

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        logBuildValues();
        logSystemFeatures();
        logActivityManagerStuff();
        logDisplayMetrics();
        logConfiguration();

        TextView tv=(TextView)findViewById(R.id.text);

        tv.setText(buf.toString());
    }

    private void logBuildValues() {
        log("Build.VERSION.SDK_INT="+Build.VERSION.SDK_INT);

        log("Build.BRAND="+Build.BRAND);
        log("Build.DEVICE="+Build.DEVICE);
        log("Build.DISPLAY="+Build.DISPLAY);
        log("Build.HARDWARE="+Build.HARDWARE);
        log("Build.ID="+Build.ID);
        log("Build.MANUFACTURER="+Build.MANUFACTURER);
        log("Build.MODEL="+Build.MODEL);
        log("Build.PRODUCT="+Build.PRODUCT);

        if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
            StringBuilder buf=new StringBuilder();

            for (String abi : Build.SUPPORTED_ABIS) {
                if (buf.length() > 0) {
                    buf.append(',');
                }

                buf.append(abi);
            }

            log("Build.SUPPORTED_APIS=" + buf);
        }
        else {
            log("Build.CPU_ABI="+Build.CPU_ABI);
            log("Build.CPU_ABI2="+Build.CPU_ABI2);
        }
    }
}
```

CHROME AND CHROME OS

```
    }
}

private void logSystemFeatures() {
    for (FeatureInfo feature :
        getPackageManager().getSystemAvailableFeatures()) {
        log("System Feature: "+feature.name);
    }
}

private void logActivityManagerStuff() {
    ActivityManager mgr=(ActivityManager)getService(ACTIVITY_SERVICE);

    log("heap limit="+mgr.getMemoryClass());
    log("large-heap limit="+mgr.getLargeMemoryClass());
}

private void logDisplayMetrics() {
    DisplayMetrics dm=new DisplayMetrics();

    getWindowManager().getDefaultDisplay().getMetrics(dm);

    log("DisplayMetrics.densityDpi="+dm.densityDpi);
    log("DisplayMetrics.xdpi="+dm.xdpi);
    log("DisplayMetrics.ydpi="+dm.ydpi);
    log("DisplayMetrics.scaledDensity="+dm.scaledDensity);
    log("DisplayMetrics.widthPixels="+dm.widthPixels);
    log("DisplayMetrics.heightPixels="+dm.heightPixels);
}

private void logConfiguration() {
    Configuration cfg=getResources().getConfiguration();

    log("Configuration.densityDpi="+cfg.densityDpi);
    log("Configuration.fontScale="+cfg.fontScale);
    log("Configuration.hardKeyboardHidden="+cfg.hardKeyboardHidden);
    log("Configuration.keyboard="+cfg.keyboard);
    log("Configuration.keyboardHidden="+cfg.keyboardHidden);
    log("Configuration.locale="+cfg.locale);
    log("Configuration.mcc="+cfg.mcc);
    log("Configuration.mnc="+cfg.mnc);
    log("Configuration.navigation="+cfg.navigation);
    log("Configuration.navigationHidden="+cfg.navigationHidden);
    log("Configuration.orientation="+cfg.orientation);
    log("Configuration.screenHeightDp="+cfg.screenHeightDp);
    log("Configuration.screenWidthDp="+cfg.screenWidthDp);
    log("Configuration.touchscreen="+cfg.touchscreen);
}

private void log(String msg) {
    Log.d(TAG, msg);
    buf.append(msg);
    buf.append('\n');
}
}
```

(from [Introspection/EnvDump/app/src/main/java/com/commonsware/android/envdump/MainActivity.java](https://commonsware.com/android/envdump/MainActivity.java))

The following sections review the three major areas of the EnvDump output. |

Build Values

```
Build.VERSION.SDK_INT=23
Build.BRAND=google
Build.DEVICE=minnie_cheets
Build.DISPLAY=MASTER dev-keys
Build.HARDWARE=cheets
Build.ID=R53-8459.0.0
Build.MANUFACTURER=google
Build.MODEL=Cheets
Build.PRODUCT=minnie
Build.PRODUCT=minnie
Build.SUPPORTED_APIS=armeabi-v7a,armeabi,armeabi-v7a,armeabi
```

Figure 954: EnvDump Output, ASUS Chromebook Flip, Build Values

Of note, there is nothing obvious in here that indicates that this is a Chrome OS device.

The ASUS Chromebook Flip has an ARM CPU, and so the ARM CPU architecture list is expected.

System Features

```
System Feature: android.hardware.sensor.accelerometer
System Feature: android.hardware.usb.accessory
System Feature: android.software.backup
System Feature: android.hardware.touchscreen
System Feature: org.chromium.arc.device_management
System Feature: android.hardware.touchscreen.multitouch
System Feature: android.software.print
System Feature: android.software.voice_recognizers
System Feature: android.hardware.audio.low_latency
System Feature: android.hardware.bluetooth
System Feature: android.hardware.usb.host
System Feature: android.hardware.audio.output
System Feature: android.hardware.camera.front
System Feature: android.hardware.screen.portrait
System Feature: android.hardware.microphone
System Feature: android.hardware.bluetooth_le
System Feature: android.hardware.sensor.compass
System Feature: android.hardware.screen.landscape
System Feature: android.software.webview
System Feature: android.hardware.camera.any
System Feature: android.hardware.touchscreen.multitouch.distinct
System Feature: android.hardware.location.network
System Feature: android.hardware.wifi
System Feature: android.hardware.location
System Feature: null
```

Figure 955: EnvDump Output, ASUS Chromebook Flip, System Features

Most of the major system features are represented here, including some that one might not expect:

- Accelerometer
- Compass
- USB host and accessory APIs

It also correctly reports:

- Only a front-facing camera
- Only network location (no GPS)

Other Values

```
heap limit=192
large-heap limit=512
DisplayMetrics.densityDpi=160
DisplayMetrics.xdpi=150.518
DisplayMetrics.ydpi=150.518
DisplayMetrics.scaledDensity=1.0
DisplayMetrics.widthPixels=1280
DisplayMetrics.heightPixels=800
Configuration.densityDpi=160
Configuration.fontScale=1.0
Configuration.hardKeyboardHidden=1
Configuration.keyboard=2
Configuration.keyboardHidden=1
Configuration.locale=en_US
Configuration.mcc=0
Configuration.mnc=0
Configuration.navigation=1
Configuration.navigationHidden=2
Configuration.orientation=2
Configuration.screenHeightDp=776
Configuration.screenWidthDp=1280
Configuration.touchscreen=3
```

Figure 956: EnvDump Output, ASUS Chromebook Flip, Other Values

Of note:

- The heap limits are generous (192MB normally, 512MB for large heap)
- The screen density is what you would expect for an ~11" WXGA screen (-mdpi)
- The navigation option claims that there is no 5-way navigation option, despite the availability of arrow keys on the keyboard
- The navigationHidden option claims that the 5-way navigation option is hidden, even though the arrow keys were available when this data was collected

Lifecycle Events

Lifecycle events behave more or less as you might expect:

- While your app's window is the focused window, your app is in the normal running state (i.e., `onResume()` has been called).

- If another window takes over the focus, but your window is still visible, your activity in that window will be paused, then resumed if the window regains the focus.
- If the user minimizes your window, you will be called with `onPause()` and `onStop()`, as your activity is no longer visible.
- If the user switches between the floating-window and the full-screen sizes, your activity will undergo a configuration change and, by default, be destroyed and recreated. Note that there seems to be a bug, as your activity goes through a spurious extra pause/resume cycle before settling down.

Chrome OS remembers your last window size (floating or full-screen). On the next launch of your app, you will return to that size.

One oddity: if another window takes over the full screen, even though your window is no longer visible, your activity is not stopped. It is paused — that will happen once the window loses the focus. The only time you are stopped is if the window is minimized (or the activity is being destroyed).

Touchscreen and Keyboard Input

As is noted earlier in this chapter, while the developer preview Chromebooks have touchscreens, not all Chrome OS devices will. Chromebooks will have trackpads; Chromeboxes will rely on mice. And pretty much all Chrome OS devices will have full keyboards.

For touchscreen-equipped Chromebooks, the full suite of gestures should be available to developers. However, for devices lacking a touchscreen, using Android apps becomes... interesting.

For example, to scroll a `ListView` or `RecyclerView`, you cannot simply drag a scrollbar, because there *is* no scrollbar. Even if you putter around and arrange for scrollbars to become visible, they do not respond to touch input. Instead, users need to know to press a meta key (e.g., `Ctrl`) while “swiping” the list with the mouse to be able to scroll. This is somewhat easier with a trackpad, as a two-finger swipe will scroll the list.

However, you really need to consider [optimizing your app for keyboards and mice](#), rather than assuming touchscreens or trackpads with Chrome OS.

NDK

The good news is that NDK binaries work.

At the time of this writing, only the ASUS Chromebook Flip supports the developer preview Android app environment. The Flip has an ARM CPU, and so Android will look to use ARM binaries.

The original ARC environment for Android apps on Chrome OS *always* used ARM NDK binaries, even on x86 CPUs. It is unclear if the new Android app support uses the same approach, or whether it will use x86 binaries on x86-powered Chrome OS devices.

Storage

Internal and external storage both work fine on Chrome OS. However, outside of debugging tools, you do not have any ability to work with the files themselves as a developer, much like how you are limited in accessing files that are part of an emulator image.

The exception, as noted earlier in this chapter, is the Downloads directory on external storage. This is also available to Chrome OS users via the Files app.

Note that the Storage Access Framework works, for things like ACTION_OPEN_DOCUMENT and ACTION_CREATE_DOCUMENT. You do not have access to removable storage, though, even through the Storage Access Framework.

Notifications

Notifications work... at least to some extent.

Their look and feel gets normalized to Chrome OS styling, so they will not look like standard Android notifications:

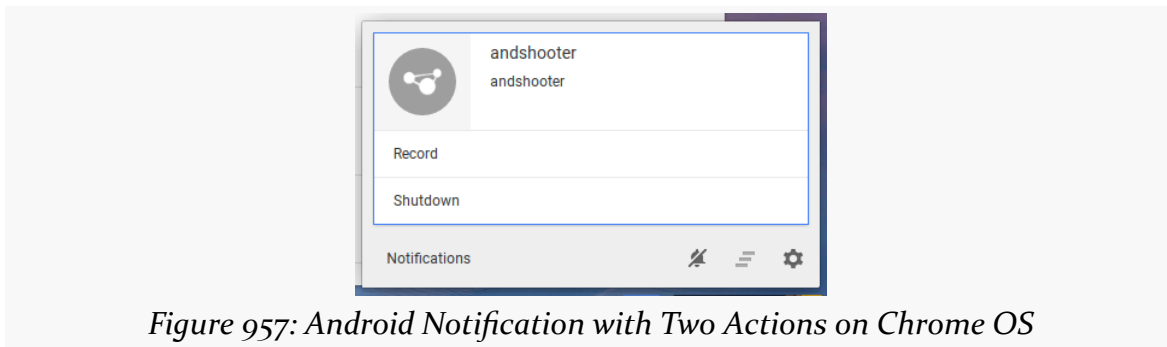

Figure 957: Android Notification with Two Actions on Chrome OS

Also, actions seem to automatically cancel the Notification, even if that is not what you intended.

Internet Access

On the whole, HTTP access “just works”, whether you are using WebView or HttpURLConnection.

SSL also “just works”, subject to the same sorts of limitations that you see in normal Android development, such as what root certificates are available for validating the SSL certificate for a particular `https://` URL.

The author has not tested lower-level socket operations at this time.

Distribution Options

Obviously, with the right manifest settings, you can distribute your app via the Play Store.

However, based upon the developer preview, ordinary users will not be able to flip the “Unknown sources” switch. That is limited to devices in developer mode. Hence, distribution by any other means (F-Droid, download from a Web browser, etc.) is not supported at this time.

Apps Sans Role

Many different sorts of apps will have no real role in a Chrome OS environment, such as:

- home screens and app-widget-only apps

- apps that primarily work in the background, as the user has to keep the app's window open for the process to remain running

Also, apps that go beyond the boundaries of the Android SDK, such as poking at various Linux elements inside of Android, will likely encounter problems as apps in Chrome OS. For example, three tested terminal emulators, for accessing the standard Linux shell in an Android environment, failed to run.

Getting Help

At the time of this writing, there is no centralized location for information about Android app, Chrome OS, and the development process. The [primary page of official information](#) gets updated from time to time. It is linked to from [the main Chromium OS page](#), which also links to [official side-loading instructions](#) and may, in the future, link to other Android-specific resources.

The official support point is the #AndroidAppsOnChromeOS hashtag on [the Android developer Google+ community](#). There is an equivalent [tag on Stack Overflow](#), which briefly was an official support point before being replaced by Google+.

If you encounter bugs, you are supposed to be able to file issues [through this link](#) on the Chromium issue tracker.

Trail: Device Catalog

Device Catalog: Kindle Fire

The most aggressive firm in creating a Google-free Android ecosystem is Amazon. The most visible aspect of that work is Amazon's Kindle Fire series of devices. From 2011 through 2013, each year has brought forth a new generation of Kindle Fire models, each with newer versions of Android and more powerful hardware. However, none support the Play Store or other Google proprietary apps and technologies. As a result, Amazon has also been building their own replacements, which developers can elect to use if they need the capabilities but are targeting the Fire.

This chapter will outline what you should expect as you start working on apps for the Kindle Fire series of devices.

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

Introducing the Kindle Fire series

Once upon a time, there was the Kindle Fire. It was a 7" tablet, made by Amazon.

Nowadays, there is a series of devices in the Kindle Fire family:

- The original first-generation Kindle Fire
- The second-generation Kindle Fire, with an updated OS and slightly faster CPU
- The Kindle Fire HD 7", with a 720p display

- The Kindle Fire HD 8.9” with a 1080p display (available as a WiFi-only device or with mobile data capability)
- The Kindle Fire HDX 7”, with a 1920x1200 display and optional mobile data
- The Kindle Fire HDX 8.9”, with a 2560x1600 display and optional mobile data

This chapter will attempt to point out which of these devices certain statements pertain to. The phrase “the original Kindle Fire” refers to the first-generation Kindle Fire.

What Features and Configurations Does It Use?

Any time you are looking at a device that is known to be a significant departure from conventional Android devices, you need to consider what capabilities the device has and how that relates to your code and graphic assets. Android’s flexibility means that, in many cases, you can work within the limits of the SDK to craft something that will look well on unusual devices. However, you will need to understand what is and is not possible for the device in question, in this case the Kindle Fire.

However, there are now several devices in the Kindle Fire family, which makes this more complicated.

OS Version

Amazon has branded their variation of Android “FireOS”.

The first-generation Kindle Fire runs an Amazon-customized version of Android 2.3.3. The HD models run an Amazon-customized version of Android 4.0.3, while the HDX models run a FireOS based on Android 4.2.2.

Note that these devices will not show up in Google’s “Device Dashboard” pie chart, as Google can only count those devices that use the Play Store, which the Kindle Fire series lacks.

Screen Size and Density

The original Kindle Fire (first and second generation) uses `-large`, `-mdpi` resources. On the surface, this would not be terribly surprising, as the 7” display works out to around 169dpi, and 7” displays are definitely in the `-large` resource bucket.

However, bear in mind that Android 2.3 did not fully support tablets. The only Google-endorsed tablet that shipped with Android 2.x was the original Samsung Galaxy Tab, and that technically was a really large phone that, er, could not place phone calls.

As such, Android 2.3 did not consider a 1024x600 display to be `-large`. It considered such a display to be `-xlarge`. This was corrected in Android 3.1, in preparation for a new line of ~7" Honeycomb tablets.

In general, this should not pose an issue when testing your app on hardware. In practice, it will pose a problem for your emulator, as will be explained [later in this chapter](#).

The Kindle Fire HD 7" and 8.9" are `-large`, though they are `-hdpi` in terms of screen density.

The Kindle Fire HDX 7" is `-large`, while the Kindle Fire HDX 8.9" is `-xlarge`. Both are `xhdpi` in terms of screen density.

Hardware Features

All of the Kindle Fire devices support:

1. An accelerometer, both for direct use and for detecting screen orientation changes
2. Multitouch, but only for two fingers (e.g., pinch-to-zoom)
3. WiFi
4. The USB accessory interface
5. A light/proximity sensor

The Kindle Fire HD devices add:

1. Front-facing camera
2. Network-based location (the Kindle Fire HD 8.9", with the mobile data option, also has GPS)
3. Bluetooth
4. Microphone

The Kindle Fire HDX devices add:

1. GPS

2. Compass

The Kindle Fire HDX 8.9” offers a rear-facing camera in addition to the front-facing camera.

None of the Kindle Fire series support telephony (voice or SMS).

If your application truly needs any of those missing capabilities, you are out of luck.

If your application could use some of those capabilities but can get by without them, be sure to add the appropriate `<uses-feature>` elements to your manifest with `android:required="false"` (e.g., `<uses-feature android:name="android.hardware.camera" android:required="false" />`). Otherwise, your app will not be available for the original Kindle Fire if Android thinks that you really do need the capability (e.g., you have requested the CAMERA permission).

What Is Really Different?

All of the devices profiled in this part of the book are clearly different than what you are used to from an Android development standpoint. Some things, like availability of Bluetooth, will fit within the Android SDK’s framework for optional capabilities. Other things will represent where a device manufacturer has meandered farther from the Android device norm, in ways that may not be completely obvious to you, let alone your code.

The Menu Bar

As was noted previously in this chapter, the original version of the Kindle Fire runs Android 2.3, a version of Android not designed for tablets. Moreover, Android 2.3 was designed for devices that had dedicated off-screen options for HOME, BACK, and MENU buttons. However, Amazon apparently wanted to avoid such buttons, yet they lacked source code access to Honeycomb, where support for the system bar was added.

So, they faked it.

The Kindle Fire supports what Amazon refers to as the “menu bar”. This is akin to the system bar found on tablets running Android 3.0+, insofar as:

DEVICE CATALOG: KINDLE FIRE

1. It appears at the bottom of the screen
2. It contains the HOME, BACK, and MENU buttons, along with a search button

However, unlike the system bar:

1. The menu bar disappears when not in use, in some cases
2. There is still a status bar at the top containing signal strength, battery level, time, etc.

Here, for example, is an application running on the original Kindle Fire:

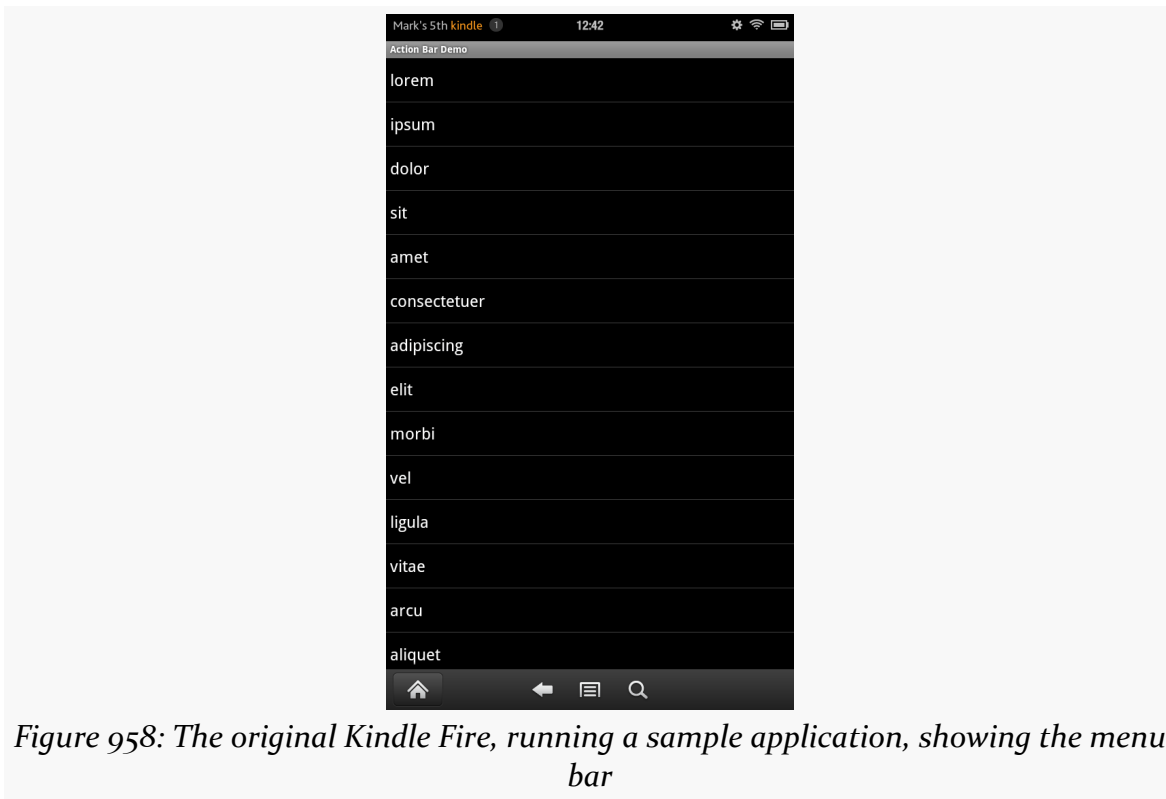

Figure 958: The original Kindle Fire, running a sample application, showing the menu bar

In this case, this is a normal activity, and the menu bar is always visible.

However, here is the same activity with `android:theme="@android:style/Theme.NoTitleBar.Fullscreen"` in the manifest:

Hence, if you set your activity to be full-screen, the status bar at the top goes away, and the menu bar shrinks to a smaller bar. Tapping on that bar brings back the menu bar, but this time overlaying the bottom portion of your activity.

Nothing Googly

The Kindle Fire lacks Google Maps, both the app and the library used for things like MapView.

The Kindle Fire lacks the Play Store and anything that depends upon it, such as [GCM](#).

The Kindle Fire lacks Gmail.

The Kindle Fire lacks anything from Google that is not part of the Android Open Source Project.

If your application depends on one or more of these, your app will not work well on a Kindle Fire without adjustments, though [some have alternatives from Amazon that can be used](#).

Sideloaded Limitations

If you enable the standard Android setting, you can install apps on the Kindle Fire from alternative sources, such as sideloading via USB. This is how the development tools deploy apps to a device when you are working on your app, and anyone can use this technique so long as they have the Android SDK (or at least enough to provide adb access).

However, there is one notable limitation of sideloading: icon quality.

When you submit your app for distribution through the Amazon AppStore, you will upload what they refer to as the “thumbnail” image. This is a 512x512 pixel rendition of your icon and is independent from any icons you may have put as resources in the APK file itself. When your app is installed from the Amazon AppStore, your thumbnail is downloaded as well and is used for the home screen carousel, among other things:

DEVICE CATALOG: KINDLE FIRE

Figure 960: The original Kindle Fire home screen, with a high-resolution version of the QuickOffice icon

However, when you sideload an app, or install it off the Web, there is no “thumbnail”. The Kindle Fire will use your in-APK icon, no different than any other home screen. However, when it blows up your, say, 72x72 pixel icon to the large shelf in the carousel, it does not look very pretty:

DEVICE CATALOG: KINDLE FIRE

Figure 961: The original Kindle Fire home screen, with a not-so-high-resolution version of the stock Android launcher icon

Things are somewhat better on the HD series:

Figure 962: Kindle Fire HD, with CommonsWare App Icon

Getting Your Development Environment Established

Developing for the Kindle Fire series is best accomplished using an actual Kindle Fire device. For example, there is no good way to simulate the behavior of the Kindle Fire menu bar using the standard Android emulator. That being said, having an emulator that at least resembles the Kindle Fire will be useful for debugging purposes, since you can do more with an emulator (e.g., run Hierarchy View) than you can with production devices.

Emulator Configuration

Amazon does not distribute an emulator image for the Fire, meaning that developers have to fake it as best they could using a stock emulator. This is fairly limiting, as the Fire does not look much like a standard Android emulator.

Briefly, Amazon was distributing an SDK add-on with emulator images, but that SDK add-on no longer seems to offer such images.

DEVICE CATALOG: KINDLE FIRE

Note that the emulators in portrait mode get a bit tall, in terms of pixels, so be sure to use the scaling option in the AVD Manager to scale down the emulator so that it will fit your development machine's monitor.

Figure 963: Kindle Fire Emulator

The official original Kindle Fire emulator image also overcomes a limitation in the standard Android emulator image.

As mentioned earlier in this chapter, Gingerbread did not support tablets. More importantly, it had a snippet of code that assumes that devices running with the Kindle Fire's resolution must be `-xlarge`. In reality, the Kindle Fire (and other 7" tablets) should use a `-large` configuration. However, the standard Android emulator will use `-xlarge`. However, the official Kindle Fire emulator will correctly report the emulator as `-large`, matching the device.

Developing on Hardware

The Kindle Fire is ready for use with your development tools, once you teach your development machine how to have `adb` connect to the fire.

Linux and OS X users simply need to run `android update adb`, after having installed the Kindle Fire SDK components, to have the ADB USB entries added to the `adb_usb.ini` file.

On Windows, you will need to do that too, after doing some other things to unpack a local copy of the device drivers. Details for this process can be found in [the Kindle Fire developer documentation](#).

Note that the original Kindle Fire automatically switches into USB Mass Storage mode when you plug it into a PC using the USB cable. This means that apps on the Kindle Fire do not have access to external storage. You will need to unmount the Kindle from your development machine's OS and click the Disconnect button on the Kindle Fire's "You can now transfer files from your computer to Kindle" screen to be both connected via USB *and* allow apps access to external storage.

How Does Distribution Work?

Unlike the vast majority of Android devices, the Kindle Fire series lacks the Play Store. It is quite likely the most popular device ever shipped that does not include the Play Store, though it is far from the first. Hence, if you want your app to be available to Kindle Fire users, you will need to explore other ways of promoting and delivering the app.

Amazon AppStore

The primary way to reach Kindle Fire users is through the Amazon AppStore. This is Amazon's equivalent to the Play Store. And, unlike the Play Store, which is only available pre-installed on devices, any Android device can download an app client for the Amazon AppStore. That, coupled with Amazon's promotions like the "free app of the day", means that your app on the Amazon AppStore has reach beyond just the Kindle Fire series and future Amazon Android devices.

At a high level, publishing on the Amazon AppStore is not significantly different than publishing on the Play Store: you supply the APK and descriptive material to Amazon, and it gets listed. However, the devil, as they say, is in the details:

1. Your app will be reviewed by Amazon before publishing, and it may be rejected for the same sorts of reasons why apps are rejected from the iOS App Store, for anything from content concerns to poor programming practices

2. If you are trying to sell a paid app, Amazon holds final pricing decisions, and your prices on the Amazon AppStore cannot be higher than on other venues
3. Your app will be wrapped in Amazon-supplied code and re-signed by Amazon, so that if a non-Kindle Fire user uninstalls the Amazon AppStore client, your app will no longer run
4. And so on

This is not to say that distributing through the Amazon AppStore is intrinsically a bad idea. Because of some of these hurdles, plus the AppStore's much smaller user base, many developers are skipping it. This results in less competition and greater visibility for your app. However, you need to review all the Amazon AppStore developer rules and make decisions for yourself as to whether it makes sense for you and what you are trying to accomplish with the app.

In April 2013, Amazon also launched Coins, which is their replacement for Google's in-app purchasing model for the Play Store.

Alternatives

Because Amazon did not license the Play Store or other commercial components from Google, you cannot reach Kindle Fire users through the Market (except for those who install pirated versions of the Play Store client on their devices).

However, all other distribution vectors should work as they would on any other device. In addition to sideloading via USB, users can install apps off of the Web by visiting a URL in the device's browser (by default, Amazon Silk) and tapping on the link to the APK. This will trigger a download of the app — users can then tap on the Notification for the download to trigger an install. Similarly, one would imagine that other apps whose job is to download and install apps (e.g., enterprise app “markets”) should work normally as well.

Note, though, that all off-AppStore installs will have rough icons, so you will want to supply your icons in all densities, in hopes that the Kindle Fire will choose a higher-quality rendition of the icon.

Amazon Equivalents of Google Services

Since Amazon does not license the Google proprietary apps, the Kindle Fire series lacks common things like Google Maps.

However, Amazon has their own equivalents for some of these:

- The [Amazon Maps API](#) allows you to embed maps on Kindle Fire devices like you would embed Google Maps on more traditional Android devices
- The [Amazon Device Messaging API](#) is roughly analogous to GCM for pushing messages to a Kindle Fire device
- The [Amazon In-App Purchasing API](#) allows your apps to tie into Amazon Payments and the like for collecting fees from users inside your app

Getting Help with the Kindle Fire

Amazon maintains a set of documentation related to [Kindle Fire](#) and [Kindle Fire HDX](#) development, along with [a set of forums](#) for asking Amazon-specific development questions regarding the Kindle Fire or their various SDKs.

Amazon is also reported to monitor [the kindle-fire tag on Stack Overflow](#).

Device Catalog: BlackBerry

BlackBerry — formerly Research In Motion — has been a long-standing player in mobile devices. Their BlackBerry two-way pagers and early smartphones help set the stage for Android, iOS, and those that followed.

BlackBerry and Android have had an interesting history.

In 2011, BlackBerry leapt into the tablet arena with the Playbook, and the 2.0 version of the Playbook OS supported running carefully repackaged Android applications.

While the Playbook itself had modest success, the ability to distribute Android applications to BlackBerry devices continued with their BlackBerry 10 (BB10) platform, where they offered several phones that could run Android apps. Originally, these had to be specially packaged for BB10, and that is still a common course today. However, in concert with offering the Amazon AppStore for Android on BB10, BlackBerry made it possible to install ordinary APK files as well. Many developers have enjoyed success distributing their app through BlackBerry World (the primary distribution channel for apps to BlackBerry products) and Amazon Appstore for Android.

In 2015, BlackBerry continued their Android push with the BlackBerry Priv, a device designed from the outset to run Android. The Priv comes with a full suite of BlackBerry-related software, including the legendary BlackBerry Messenger (BBM). However, much of that software — including BBM itself — is available on the Play Store for ordinary Android devices. In general, from the standpoint of an Android app developer, the Priv is no different than an Android device from any other major manufacturer. The Priv is even part of the Google Play ecosystem and comes with the Play Store and Google Play Services.

Putting the Priv aside, though, getting your app going on BB10 is a bit more of an adventure. This chapter will describe a bit about what is involved in getting your Android app to BB10 devices.

I Thought BlackBerry Had Their Own OS?

They do.

However, current versions of that OS — this chapter was last updated when version 10.3 was the latest shipping version — contain an Android runtime environment. BlackBerry OS can run Android apps alongside apps written natively for BlackBerry OS or running on other runtimes (e.g., Adobe AIR). This gives developers a wide range of ways to get their app onto modern BlackBerry devices. However, it does mean that our apps may have somewhat less direct access to hardware, as there is another layer between us and that hardware.

What Else Is Different?

At its core, BlackBerry is a device manufacturer, no different than any other manufacturer that you may have dealt with previously. The biggest difference is BlackBerry's ability to run Android applications that you prepare for their devices.

That being said, the world of BlackBerry is a *bit* different than what you may be used to.

Hardware

BlackBerry makes phones with a variety of capabilities, much as do other manufacturers. You should be writing your apps to support a range of device characteristics, such as screen size and density. That will help you with BlackBerry support, just as it helps you with support for other manufacturers' devices.

Note, though, that BlackBerry has some history which will affect their device designs, and your apps by extension. Notably, BlackBerry has been renowned for their hardware keyboards. While not all BlackBerry devices today have such keyboards, it is likely that BlackBerry will ship keyboard-equipped devices for some time to come.

This has three impacts upon you as a developer:

1. Do not assume that the user is using a soft keyboard. Usually, this is not a problem from a programming standpoint, though you may wish to take it into account in documentation.
2. Do not assume that the user always uses the touchscreen to navigate. Some BlackBerry users may use the hardware keyboard for navigation. This is particularly true for users who gravitate towards hardware keyboards for accessibility reasons. Your app should support [proper focus](#) to allow it to be navigated without accessing the touchscreen, to the greatest extent possible.
3. BlackBerry keyboards often have not been “slider” keyboards (i.e., ones that might slide under the display when not in use). Rather, they are always available, below the screen. This will often result in somewhat smaller screen sizes, and odd aspect ratios, compared to what you are used to. There simply is not enough room for a large touchscreen *and* an always-available physical keyboard without having an excessively large device. The BlackBerry Q10, for example, has a 720x720 resolution screen, and most Android developers do not encounter square screen resolutions. You will need to take this into account, but only in cases where such an aspect ratio might cause you problems (e.g., full-screen image backgrounds).

BlackBerry OS 10.3

Beyond the hardware, the BlackBerry OS — and the Android runtime environment that executes our Android apps — puts some limits on what we can do in our apps. Of note:

- BlackBerry OS 10.3’s Android environment uses Android 4.3 (API Level 18), so apps that have an `android:minSdkVersion` higher than that will not be eligible to run on 10.2 devices.
- Some classes will be non-functional, particularly those related to telephony capabilities. You cannot use `SmsManager`, for example.
- Some types of apps will not work well, because the Android runtime runs alongside other non-Android apps on the hardware. Replacement home screen implementations, for example, are unlikely to work. Similarly, background apps that display a UI (e.g., Facebook “chatheads”-style popups) using `SYSTEM_ALERT_WINDOW` are unlikely to work.
- App widgets are not supported. So long as the app widget is a non-essential feature of your app, this should not be a problem — after all, the user does not *have* to use your app widget on any Android device. However, if the *sole purpose* of your app is to provide an app widget, such an app will not be useful on BlackBerry.

- Not all connectivity is surfaced in the Android runtime from the underlying hardware. For example, WiFiDirect and direct USB access are all unavailable.

Navigation

Like most Android tablets, BlackBerry devices offer little in the way of physical or off-screen navigation buttons. For example, there is no BACK button. However, a navigation bar will contain a BACK soft button for users. If your app takes over the full screen, this bar will not be there all the time, but a swipe down from the top of the screen should expose it.

Similarly, your menu will not be accessed via a MENU key, but rather via a downward swipe to expose the menu. This also means that any special MENU-button logic of yours may not work, if you are using the MENU button for things other than displaying the action bar overflow or other form of options menu.

Nothing Googly

As with other devices cited in this book, the BlackBerry series of devices lack support for Google's proprietary apps. For app developers, this means that you lack access to Google Play Services and the various APIs exposed by it, such as [Maps V2](#) and [Google Cloud Messaging](#).

BlackBerry does offer its replacement for GCM, in the form of the [BlackBerry Push Service](#). However, for maps, they steer you towards using [geo: Intent structure and startActivity\(\)](#).

If you are dependent upon other APIs offered by Google Play Services (e.g., [LocationClient](#)), you will need to reconsider your use of those APIs if you wish to ship on devices that are outside the Google ecosystem.

Package Name Length

The BlackBerry Android runtime appears to only support package names of 29 characters or less. The build tools will fail if your package name is longer than 29 characters.

Note that this should only pertain to the “application ID” role of a package name, not the “hey, where does R.java get generated?” role of the package name. Hence, it should be possible to replace the application ID of your app via a [Gradle for Android](#)

[product flavor](#), to give yourself a shorter identifier while not breaking your source code references to resources.

What Are We Making?

This might seem like an odd question. After all, the point of this chapter is to make an Android application that can run on BlackBerry devices.

Up until early 2014, that meant you had one option: write a BAR.

A BAR (BlackBerry ARchive, presumably) is a repackaged version of an Android APK, designed to be distributed by BlackBerry and installed on BlackBerry devices. Most of [the tooling supplied by BlackBerry](#) surrounds this process of validating that an APK should abide by BlackBerry's requirements and converting that APK into a BAR.

Starting with BlackBerry OS 10.2.1, though, BlackBerry device users can download and install an APK directly. That APK still needs to work within the confines of the BlackBerry Android runtime and must avoid things that will not work there (e.g., replacement home screens). But the user is no longer reliant upon the developer going ahead and creating a BAR file.

So, what you are creating depends a bit on how you want to distribute the app:

- If you wish to distribute via BlackBerry world, you will need to repackage your APK as a BAR file
- If you wish to distribute through Amazon Appstore for Android, or if you wish to self-distribute, you can still ship an APK, though you may wish to use some of BlackBerry's tools to help ensure that your APK will be compatible

Getting Your Development Environment Established

By and large, developing an app to run on the BlackBerry OS Android runtime is the same as is developing an app to run on any other Android environment. You have your standard choices of IDEs and other development tools, the ability to use third-party libraries, and so forth.

Where things start to differ is in testing, where BlackBerry OS ships a [Simulator](#) that fills a role similar to that of the Android emulator. To use the Simulator, you will need to package your app into a BAR file, and BlackBerry provides tools to assist you in that process as well.

Checking and Repackaging Your App

There are two basic technical steps for preparing your app for distribution through [the BlackBerry World market](#).

The first is to validate that your app does indeed stick to APIs that are supported by the BlackBerry Android runtime. This helps prevent apps from appearing on BlackBerry World that are guaranteed to fail.

The second is to convert the APK into a BAR file. BAR files are used for all of the BlackBerry OS runtimes, including ones like Adobe AIR. Your BAR will contain the same stuff that is in your APK, plus some additional metadata, in a format shared by all of the other runtimes, for interpretation and use by the BlackBerry OS. Again, if you are not planning on distributing through BlackBerry world, you will not need to worry about a BAR file.

Android Studio Plugin

BlackBerry is distributing [an Android Studio plugin](#) to help with preparing Android apps for BlackBerry. Note, though, that this is an *Android Studio* plugin, not a Gradle plugin. On the plus side, this gives you new BlackBerry-related options in the Android Studio UI. However, since Android Studio evolves frequently, there is a decent chance that the BlackBerry plugin will not work on some newer Android Studio builds, until BlackBerry catches up.

This plugin includes:

- an adb proxy that allows Android Studio to work with BlackBerry devices and running simulators
- a UI for obtaining a “device debug token”, required to allow you to test your apps on BlackBerry devices
- package an APK as a BAR

Standalone GUIs

You also have the option for doing BlackBerry-related chores from [standalone GUIs](#), independent of any IDE.

Basically, both IDE plugins simply provide menu options and toolbar buttons for launching the standalone GUIs from within the IDE. If you are not using Android Studio, those GUIs are available independently that you can run like any other desktop development tool.

BlackBerry 10 Simulator

BlackBerry distributes VMWare images that embody a BlackBerry 10 Simulator. You can use these with VMWare Player (Windows and Linux) or VMWare Fusion (OS X), versions 3.1 or higher.

The Simulator fills a role similar to that of the standard Android emulator, allowing you to test your apps for BlackBerry OS without necessarily having a Blackberry OS 10 device, or for testing scenarios that are difficult to test with actual hardware.

In particular, the Simulator offers a wide range of simulated input and output, including:

- Simulated sensor input for the accelerometer and ambient light sensor
- Using a development machine's Bluetooth adapter for testing Bluetooth
- Simulated NFC tags

In addition, the Simulator supports some of the same types of simulated input that you see with the Android emulator, such as simulated GPS fixes and simulated incoming phone calls.

The VMWare image will have its own IP address, which you can obtain from the Simulator running in the image. You can then deploy your BAR to it using the `adb` proxy, which you can launch from your IDE or the standalone GUI.

Developing on Hardware

A BlackBerry OS 10 device can run either signed or unsigned BAR files. Unsigned BAR files, though, require a one-time upload of a “debug token”, the creation of which requires the same credentials as you would use to sign the BAR in the first place.

How Does Distribution Work?

As with any environment where the Play Store is not available, developers have to determine how best to get their apps to the users of BlackBerry devices.

As with most non-Play Store ecosystems, there is the official solution... and then there are the other solutions.

BlackBerry World

BlackBerry's own "market" is BlackBerry World. This supports native BlackBerry apps, plus those for runtimes like the Android runtime. So long as your app is packaged as a BAR, it should be able to be released through BlackBerry World, much like how you distribute an APK through the Play Store.

BlackBerry World is a curated marketplace, meaning that BlackBerry staff will review your app submissions and may reject them if they violate requirements or other terms.

Beyond that, BlackBerry World has most of the standard capabilities that you would expect from an app market, such as paid apps, in-app purchases, multiple billing options (PayPal and carrier billing), control for distribution to various countries and mobile carriers, etc.

Amazon Appstore for Android

However, many Android developers will probably elect to distribute through Amazon Appstore for Android, now that it ships on new BlackBerry devices.

Partly, it is for improved reach: by distributing through Amazon's channel, you reach the Kindle Fire and Fire TV series of devices, plus any other Android devices that happen to have the Amazon Appstore for Android installed.

Partly, you can distribute in the form of an APK, rather than having to mess around with registering for BlackBerry World, creating BAR files, and the like.

Alternatives

Starting with BlackBerry OS 10.2.1, you can distribute APK files through your Web site or similar means, and BlackBerry users can download and install them.

DEVICE CATALOG: BLACKBERRY

However, nothing is done to validate that the apps you download will work on BlackBerry OS's Android runtime, as they may use APIs that are not available.

Also note that the BlackBerry OS settings have an equivalent to the Android “allow apps from other sources” setting that must be enabled for such installation to occur.

As an example, you can install the [F-Droid “market” app](#) to download free and open source Android apps to a BlackBerry OS device. How many of the apps distributed through F-Droid will work on BlackBerry OS, besides F-Droid itself, is unknown.

Device Catalog: Android TV

Google not only offers the Chromecast, but also offers Android TV as a way to get content “into the living room”. Android TV devices — whether they be set-top boxes or are integrated into televisions directly — run Android apps directly, unlike Chromecast. Android TV, therefore, is a competitor to devices like [Amazon’s Fire TV](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on [“ten-foot” user experiences](#) is also a good idea.

Hey, Wait a Minute... I Thought the Name Was “Google TV”?

You can be forgiven for any confusion over the names.

Google TV was Google’s initial attempt to get content onto televisions. Debuting in 2011, Google TV has some of the same characteristics as does Android TV:

- It ran Android apps directly (at the time, on Android 3.1)
- It could be a dedicated set-top box, integrated into other sorts of media players (e.g., Blu-Ray), or integrated into televisions

However, Google TV did not prove all that popular.

In 2014, Google announced that they were no longer supporting app development for Google TV, much to the consternation of the ~17 people still using Google TV devices.

That being said, designing an app for Android TV resembles designing an app for Google TV or for any other [“ten-foot” user experience](#). Hence, design guidance that you may run across for Google TV may have some tips that are still relevant for Android TV and other TV-centric Android environments.

Some Android TV Hardware

Android TV debuted in 2014. However, as of the end of 2014, there were a total of two Android TV device models... both available from Google. While other manufacturers had announced plans regarding Android TV, none were available at the time of this writing.

ADT-1

When Google TV was announced, there was a similar lack of hardware. To help ensure that there were TV-capable apps at the time of a wider Google TV rollout, Google offered free developer devices to various firms and solo developers.

Google did the same thing with Android TV, where they offered a free ADT-1 device to qualified registrants. While deliveries of the ADT-1 were spread out over a few months, they generally arrived significantly in advance of production Android TV hardware.

Figure 964: ADT-1 Developer Android TV Device

Nexus Player

The first production-grade Android TV device is Google's own Nexus Player. As with the ADT-1, the Nexus Player has an HDMI port for connecting to a TV (or projector, monitor, etc.). It also has its own remote control and power adapter.

Figure 965: Nexus Player Android TV Device

Both the ADT-1 and the Nexus Player are presently running Android 5.0.

What Features and Configurations Does It Use?

Android has built into the SDK a fair bit of device flexibility. Most of this comes in the form of configurations (things that affect resources) and features (other stuff). If your application can handle a range of configurations and features, or can advertise that they need certain configurations or features, they can handle Android TV or arrange to not be available for Android TV on the Play Store.

Screen Size and Density

Android TV devices are always categorized as xlarge screen size.

Densities, however, are a bit more complicated.

Android TV is for use with HDTV, whether Android TV is integrated into the television or it comes as an external set-top box. There are two predominant HDTV resolutions, known as 720p (1280x720) and 1080p (1920x1080). A 1080p television will

be categorized as an `xhdpi` density device. A 720p television will be categorized as a `tvdpi` device. `tvdpi` is for devices around 213dpi, in between `mdpi` and `hdpi`. In practice, you might elect to skip `tvdpi` for your drawable resources, allowing Android to resample your `mdpi`, `hdpi`, or `xhdpi` drawables as needed.

Input Devices

Android TV will not normally be navigated using a touchscreen. Instead, the normal form of input will be a D-pad remote. Developers will need to ensure that their apps are navigable this way.

Other Hardware

Android TV has no sensors, no camera, no microphone, and no telephony features. As such, any application requiring such features will not run on Android TV and will not even show up in the Play Store for such devices.

Bear in mind that some of these will be driven by permissions. If you ask for the `SEND_SMS` permission, Android will assume you need `android.hardware.telephony` unless you specifically state otherwise, via a `<uses-feature>` element for `android.hardware.telephony` with `android:required="false"`.

What Is Really Different?

Beyond the features and configurations, there are other things about Android TV that will depart from what you might expect for an Android environment, due to the nature of the TV set-top box platform and the Android implementation upon it.

Overscan

Since Android TV typically uses a television for its primary output, overscan can be an issue. Addressing overscan is covered as part of [the chapter on the “10 foot UI”](#).

Ethernet

While Android TV devices will generally be connected to the Internet, it may not be via WiFi. Since Android TV devices generally are not portable, some will have Ethernet jacks, and hence some users will elect to wire in their Android TV as opposed to using WiFi.

The upshot is that you should not assume that `WifiManager` will necessarily give you useful results. Also, `ConnectivityManager` should report wired Ethernet as `TYPE_ETHERNET`, added in API Level 13, when you call methods like `getActiveNetworkInfo()`.

Location

Generally speaking, Android TV devices will tend not to move, earthquakes and large dogs notwithstanding.

As such, Android TV devices do not have GPS receivers. Rather, location is determined in an approximate fashion via address-based lookups, using a postal code. Hence, asking Android for a GPS fix on a Android TV device will be ineffective.

However, since users of Android TV devices tend not to be moving much at the time, it is a bit more likely than normal that they will want information about some location other than where they are. If your app is exclusively tied to providing information about their current location, you may wish to consider how you could extend your app to help users get information about other places that they may be interested in.

Media Keys

Android TV devices are usually manipulated by remote controls. Some of these remotes will have lots of buttons, such as media-specific buttons for play, pause, etc.

The `KeyEvent` class has had support for some media buttons since API Level 3, mostly for use with wired headsets. API Level 11 added a bunch more media buttons. Your Android TV application may wish to respond to these, via `onKeyDown()` in a `View` or `Activity`.

In particular, an Android TV application should not be using on-screen controls for play, pause, etc., as they take up screen space that probably could be put to better use. Rather, use layouts that offer such controls for touchscreen devices (e.g., phones and tablets) but rely on the media buttons for non-touchscreen devices.

Getting Your Development Environment Established

Android TV emulator images are available in the SDK Manager for Android 5.0 and above:

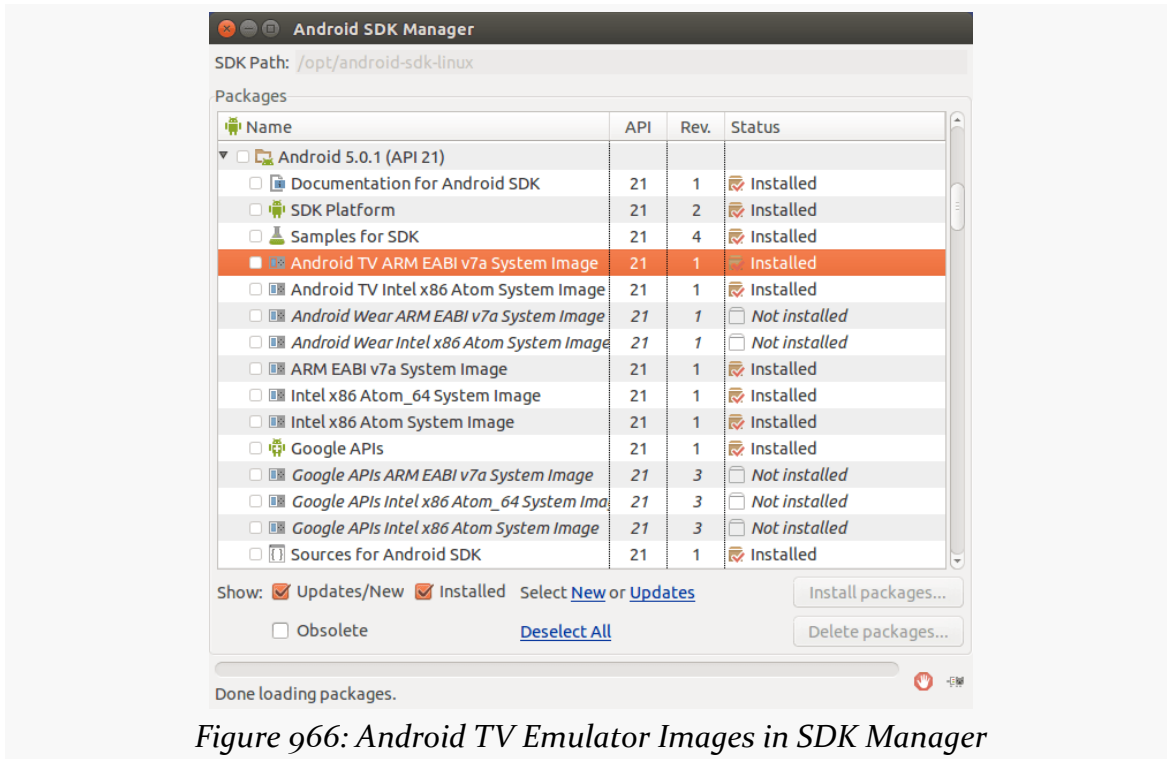

Figure 966: Android TV Emulator Images in SDK Manager

Your AVD Manager can then help you set up TV emulator images, for rather large theoretical screen sizes:

DEVICE CATALOG: ANDROID TV

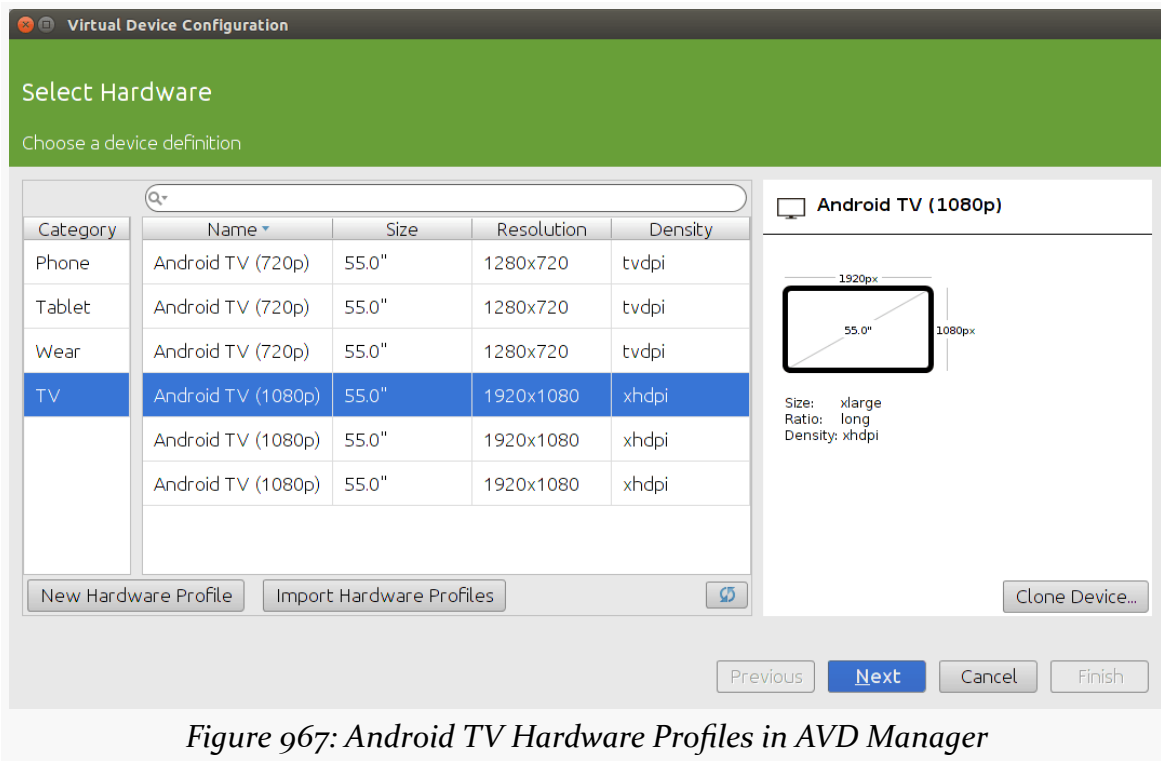

Figure 967: Android TV Hardware Profiles in AVD Manager

The rest of the emulator setup is the same as you would have for phone or tablet emulators.

The emulator even has “leanback” UI characteristics, rather than a standard Android emulator home screen:

Figure 968: Android TV 1080p Emulator, As Initially Launched

Connecting to Physical Devices

The ADT-1 and Nexus Player have micro-USB ports for debugging purposes. This, though, requires that your player and your development machine be within USB cable reach of one another. The author of this book uses [a pico projector](#) to be able to work with TV-native devices (Android TV, Fire TV, etc.) or external displays (HDMI, MHL, etc.).

To enable an Android TV for debugging, you will need to enable developer options, much like you do for a mobile device (click on the build number 7 times in the Setting's About screen). Then, in the "Developer Options" screen, you can go into Debugging and elect to enable "USB debugging".

How Does Distribution Work?

Your app probably falls in one of three buckets: you want it on Android TV (along with other devices), it *only* supports Android TV, or it will not work on Android TV. Whichever of those buckets best fits your device will determine the manifest

settings you will want to ensure that the Play Store (and perhaps other third-party markets in the future) will honor your request.

Getting Your App on Android TV

The first criterion for getting your app visible to Android TV devices on the Play Store is to add a `<uses-feature>` element to your manifest, indicating that you do not require the `android.hardware.touchscreen` feature:

```
<uses-feature android:name="android.hardware.touchscreen" android:required="false"/>
```

By default, Android assumes that you need a touchscreen, and so without this clarification in your manifest, you will not appear in the Play Store.

Also, add similar `<uses-feature>` elements for any hardware that you might like to use where available but do not absolutely need, particularly hardware that Android TV may lack. The [documentation](#) outlines the features that Android TV devices will likely lack.

You need to have an activity that has an `<intent-filter>` for `ACTION_MAIN` and `CATEGORY_LEANBACK_LAUNCHER`. This will be your launcher activity on Android TV devices, instead of your `ACTION_MAIN/CATEGORY_HOME` activity. Of course, you are welcome to have one activity serving as the launcher for both types of devices, if you can come up with one with a solid presentation for both mobile devices and TVs.

In addition, do not have any activities with `android:screenOrientation` set to `portrait`, as Android TV devices always display in landscape

Supporting Only Android TV

If your app only supports Android TV, in addition to the above requirements, you should also add one more `<uses-feature>` element to your manifest:

```
<uses-feature android:name="android.hardware.type.television" android:required="true"/>
```

This will filter you out of the Market for all non-TV environments.

Avoiding Android TV

If your app specifically is untested on Android TV, you need to have something in the manifest that will keep you *off* Android TV devices' views of the Play Store. The easiest is to say that you need a touchscreen:

```
<uses-feature android:name="android.hardware.touchscreen" android:required="true"/>
```

Note that `true` is the default setting for this particular feature, though putting it in your manifest to remind you that you do require a touchscreen is a good idea.

Device Catalog: Amazon Fire TV and Fire TV Stick

Amazon has joined the TV set-top box fray with the Fire TV and, more recently, the Fire TV Stick. These devices are powered by FireOS, Amazon's variation of Android. And, as with other Amazon FireOS devices, like the Kindle Fire tablet series, you can write apps that run on Fire TV and the Fire TV Stick.

This chapter will review these devices from a developer's standpoint, to help you create apps for this platform. Note that the Fire TV line of devices have some elements in common with Amazon's Kindle Fire series of tablets, covered [elsewhere in this book](#).

Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with the chapter on [the Kindle Fire tablets](#). Reading [the chapter on the ten-foot user interface](#) is also recommended, either before or after this chapter.

Also, some sections will make reference to [Android TV](#) as a point of reference.

Introducing the Fire TV Devices

As of January 2015, there were two major flavors of Fire TV device: the original Fire TV, and the Fire TV Stick.

Fire TV

As with most Android-powered set-top boxes, the original Fire TV is small and is designed to connect with your television (or monitor, or projector, or whatever) via HDMI:

Figure 969: Fire TV

It comes with a small wireless remote designed for basic controls, akin to what you might find on other streaming boxes or similar entertainment devices:

Figure 970: Fire TV Remote

Optionally, you can get a gaming controller that works with the Fire TV. While the regular controller is fine for navigating the Fire TV UI, the gaming controller will be more suitable for more serious game play:

Figure 971: Fire TV Gaming Controller

While the Fire TV is powered by Android, the on-device UI is definitely targeting a set-top box environment. The home screen is dominated by media, coming from whatever supported streaming content providers you have set up with the Fire TV (e.g., Amazon Prime):

DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

Figure 972: Fire TV Home Screen

The “Apps” section shows a mix of what is installed and what is available for you to download, with “cloud” icons indicating apps that are available but are not presently installed:

Figure 973: Fire TV “Your Apps Library”

Fire TV Stick

The Fire TV Stick is physically substantially smaller than is the Fire TV, designed to more closely resemble the Chromecast:

Figure 974: Fire TV Stick, with Remote, AC Adapter, and HDMI Extension Cable

The user experience of a Fire TV Stick, though, is largely the same as with a regular Fire TV. Both run the same FireOS environment, with the same sort of browsing metaphor.

The biggest difference is that the Fire TV Stick is less powerful (less RAM, weaker CPU and GPU). For conventional apps, this is unlikely to be a problem, as the Fire TV Stick is as powerful as many standard Android phones and tablets. Games, however, are more likely to stress the hardware.

From the user's standpoint, the Fire TV Stick's big selling point is its low price, about a third of what the Fire TV costs.

What Features and Configurations Do They Use?

The Fire TV device family behaves a bit like a “mashup” of other TV-centric devices (Android TV, OUYA, etc.) and the Kindle Fire series.

OS Version

At the present time, Fire TV devices are powered by a version of FireOS that corresponds to Android 4.2.2 (API Level 17). It is possible that Fire TV devices could be upgraded to a newer version of FireOS in the future, one based on a newer version of Android, but there are no guarantees.

Screen Size, Density, and Orientation

One area where the Fire TV series differs from pretty much anything that came before it comes with the behavior of the screen. As with other TV-centric devices like Android TV and the OUYA, the assumption is that the screen is locked to landscape. However, beyond that, Amazon has struck out on its own in terms of screen characteristics.

With Android TV, the screen size and density are based on the type of display that the Android TV box is plugged into.

With the Fire TV devices, your code deals with a rendering surface of 1920x1080 pixels, regardless of whether the device is plugged into a 1080p screen or something else (720p, 4K, etc.). The density is always treated as `-xhdpi`, giving you a resolution of 960dp by 540dp, and a `-large` screen size. The hardware will handle scaling the output down (or, in theory, up for 4K) as needed.

On the plus side, this simplifies app development, as you do not need to deal with different screen capabilities yourself. However, it remains to be seen how well the Fire TV will scale the output.

Also, note that Fire TV devices do not address [overscan](#) when they apply this scaling. Hence, you will want to keep your content away from the edges of the available space, only showing your background there, in case those edges are not visible on some televisions.

As with any TV-centric device, since the screen is locked to landscape, activities that are locked to portrait (e.g., `android:screenOrientation="portrait"` in the manifest

for the activity) will behave oddly. If you are targeting devices like the Fire TV series, be sure to allow your activities to work in portrait *or* landscape, not just portrait.

Input Devices

As noted earlier, Fire TV devices ship with a simple remote control, designed for media management (play, pause, etc.) and basic D-pad navigation. Some users may also elect to pick up a Fire TV game controller or use other Bluetooth game controllers. Technical details for working with these input devices can be found [later in this chapter](#).

Conversely, Fire TV devices do not have touchscreens. You cannot assume that the user can tap on random portions of the screen. Instead, you need to make sure that your app is completely reachable via a D-pad. This is described in greater detail in [the chapter on the “ten-foot UI”](#).

Hardware Features

As a set-top box, Fire TV devices lack a lot of hardware that you normally associate with phones and tablets, such as:

- GPS
- camera
- microphone
- sensors
- telephony

The microphone is actually a bit complicated. The Fire TV remote has a microphone and a button to activate it. The Fire TV Stick remote does not have a microphone. There is a Fire TV Remote app available on [the Play Store](#) and Amazon Appstore for Android that offers microphone input as well. However, all these microphones are just for Fire TV voice search. There is no means for developers to use these for arbitrary audio input, the way that a microphone on a phone or a tablet can.

What Is Really Different?

Some things are “really different” simply because the output screen is TV-sized, not phone-sized or tablet-sized. See [the chapter on the “ten-foot UI”](#) for more about this.

Some things are “really different” in the same way that they are “really different” for the Kindle Fire series, such as having [nothing “Googly”](#), like Google Maps or Google Cloud Messaging. Note that the Amazon Maps API does not work on the Fire TV series, as those devices have no location services.

The biggest additional “really different” item is the limitation on where apps can come from, which is discussed [later in this chapter](#) as part of the overall app distribution options for Fire TV devices.

Note that Fire TV devices have their own way of representing notifications. A standard Android Notification will not appear anywhere on a Fire TV device. Instead, you will need to support the Fire TV series’ own [notifications API](#). While their API is modeled after Android’s Notification and NotificationManager, they do have their own classes, and the results are more reminiscent of Toasts and Dialogs.

Also note that Fire TV devices do not display an Android action bar, representing those items in a pop-up menu triggered by the MENU button of the Fire TV remote control.

Casting and Fire TV

The success of Chromecast means that TV-connected Android devices will tend to be compared to Chromecast, particularly in terms of how apps on phones and tablets can work with the TV-connected device.

At the time of this writing, Amazon has not shipped anything for Fire TV that would enable apps [using `MediaRouteActionProvider` and `RemotePlaybackClient`](#) to work with Fire TV. In principle, Amazon or somebody else could implement a `MediaRouteProvider` and distribute that as an app that goes on ordinary Android phones and tablets, where that `MediaRouteProvider` enables media routes pointing to a connected Fire TV. The `MediaRouteProvider` would forward requests from the phone or tablet to the Fire TV, which would be displayed by some app on the Fire TV.

Amazon more formally supports [the “Discovery and Launch” \(DIAL\) protocol](#) with Fire TV. DIAL allows an app on a phone or tablet to launch apps on Fire TV. Unfortunately, documentation for this is lacking at the present time.

Also, the Fire TV series can serve as a Miracast endpoint. In Settings > Display & Sounds, you will find an option to “enable display mirroring”. This turns on Miracast support, allowing mobile devices to mirror their screen content via the Fire TV to the connected television, projector, or monitor. This also works with Android’s [Presentation support](#), allowing you to direct separate content to the Fire TV’s “mirror” than what you show on the device’s own screen.

Getting Your Development Environment Established

Developing for the Fire TV series, as with developing for the Kindle Fire series, is best accomplished using an actual Fire TV or Fire TV Stick device. That being said, having an emulator that at least resembles a Fire TV device may be useful for debugging purposes.

Emulator Configuration

Amazon is distributing an SDK add-on that supplies an emulator image you can use, in theory, to emulate a Fire TV device.

To install it:

- Start the SDK Manager, such as via the toolbar button in Android Studio
- Choose Tools > Manage Add-on Sites from the SDK Manager main menu
- Click on the User Defined Sites tab, and click the New... button
- Fill in `https://s3.amazonaws.com/android-sdk-manager/redirect/addon.xml` as the URL in the field in the “Add Add-on Site URL” dialog, then click OK (to close up that dialog), then click Close (to close up the Manage Add-on Sites dialog)
- Wait for the progress bar at the bottom of the SDK Manager to finish
- Install the Fire TV entry in API Level 17

This will give you an “Amazon Fire TV SDK” option as an API level target when setting up an emulator image. However, you will also need to set up a device definition that emulates a suitable screen resolution (e.g., 1080p). And, the resulting emulator does not even vaguely resemble a Fire TV device in terms of the firmware and such.

In truth, at present, you will need to use Fire TV hardware to develop for Fire TV.

Developing on Hardware

The primary thing notably different about testing your app on a Fire TV device is that it does not use a micro USB cable for the adb connection, the way that you may be used to from testing with most Android hardware. If you can find a suitable USB cable to bridge between your development machine and the Fire TV, reportedly you [can use USB debugging](#). Otherwise, you can use adb over the network.

To set this up, you must first enable USB debugging, much like you do with other Android devices. On a Fire TV device, this is in Settings > System > Developer Options:

Figure 975: Fire TV Developer Settings

You will then need the IP address of your Fire TV device. Most likely the easiest way for you to find that is via the Settings > System > About > Network screen:

Figure 976: Fire TV Network Settings

You can then run `adb connect` (followed by the IP address) at a command prompt to make the connection. You may need to stop and restart `adb` before doing this, via `adb kill-server` and `adb start-server`.

At this point, if all is set up properly, `adb devices` will list the Fire TV device's IP address, and the Fire TV device will be accessible from your IDEs and other development tools.

Note that this `adb` setup will persist until `adb` is next restarted, even if the Fire TV device is powered down. You can use `adb disconnect` (followed by the IP address) to break the connection if you no longer need it.

Working with the Remote and Controller

Your Fire TV users will be interacting with their Fire TV using the supplied remote, the Fire TV gaming controller, or other controllers.

Wireless Remote

Mostly, the wireless remote offers buttons that you should be handling already, assuming you are [implementing a ten-foot UI](#) or are otherwise correctly handling [focus management and accessibility](#). BACK and the D-pad buttons will work on the Fire TV much as you would expect.

The Fire TV device remote has a MENU button, which will bring up an old-style Android options menu. Your simple action bar items, particularly those in the overflow, will appear in this menu without issue. Most likely you will want to skip the action bar on your Fire TV apps, though, which means that action views, action providers, and the like will need to be replaced with alternatives.

The remote also offers play/pause, rewind, and fast-forward buttons that map to their corresponding Android KeyEvent types (e.g., KEYCODE_MEDIA_PLAY_PAUSE). You can watch for these events in `onKeyDown()` of your activity to be able to respond to them.

Note that you do not have the ability to intercept home or voice search button presses on the wireless remote. And, the Fire TV Stick's remote does not offer the voice search button.

Gaming Controller

The wireless remote's input options are purely buttons. The Fire TV series gaming controller, like most such controllers, are designed for more “analog” input, where the force you apply to a stick might trigger slightly different behavior in a game.

As such, the gaming controller support in Android and FireOS takes a two-tier approach, with primary and secondary ways of handling events. If your code consumes the primary event, the secondary event is not triggered. The idea is that fairly “vanilla” apps might pay attention to the secondary events, as they tend to be more in common with the events you might get from the wireless remote or non-Fire TV devices. But apps that are more game-centric might pay attention to the primary events instead.

For analog inputs — the left and right sticks and the D-pad — the primary event input is supplied as `MotionEvent` objects, which you can pick up in methods like `onGenericMotionEvent()` in a `View`. Secondary event input comes in the form of standard D-pad events. So, an ordinary app will automatically support the sticks and D-pad, simply by accepting D-pad input.

Some buttons also take the two-tier approach. The A button (bottom one in the button cluster on the upper-right side of the controller) can be picked up either as a `KEYCODE_BUTTON_A` KeyEvent (primary) or a `KEYCODE_DPAD_CENTER` KeyEvent (secondary). The B button (right one) maps to `KEYCODE_BUTTON_B` (primary) and `KEYCODE_BACK` (secondary).

Other buttons just fire simple KeyEvents (e.g., left shoulder is `KEYCODE_BUTTON_L1`), while the two triggers just use MotionEvents (`AXIS_BRAKE` on the left, `AXIS_GAS` on the right).

Amazon's Fire TV site has [full details of the options and how to use them](#), plus a dedicated [game controller API](#) to help you manage multiple controllers and the like.

How Does Distribution Work?

Like the Kindle Fire, Fire TV devices lack the Play Store. If you want your app to be available to Fire TV device users, you will need to explore other ways of promoting and delivering the app.

The principal — and nearly exclusive — way to get apps onto a Fire TV device is by listing them in the Amazon AppStore for Android, [much as you would do for Kindle Fire devices](#).

However, for ordinary users, that is the *only* option. Most Android devices — including the Kindle Fire series — allow the user to download apps from Web sites, if they have the appropriate option checked in Settings. The Fire TV lacks this setting, and therefore ordinary users cannot download an app to the Fire TV from third-party app stores.

“Sideloading” an app using `adb` works, though this is usually only viable for developers or serious power users. Such apps will not appear in the home screen launcher and must be launched instead via Settings > Applications.

Getting Help

Amazon maintains [a set of documentation](#) related to Fire TV device development, along with [a set of forums](#) for asking Amazon-specific development questions regarding the Fire TV device series or their various SDKs.

Trail: Appendices

Appendix A: CWAC Libraries

CommonsWare — the publisher of this book — has also published a series of open source libraries, collectively named the CommonsWare Android Components (CWAC). If you have read through the book, you will have seen many of these libraries.

This appendix lists all of the CWAC libraries. If the library is covered elsewhere in the book, the appendix links you to that coverage. Those that are not covered elsewhere will be described in this appendix, to accompany the online documentation found at the library's GitHub repository.

cwac-adapter

[The cwac-adapter repository](#) contains a small AdapterWrapper class that wraps a ListAdapter. The default implementation of all AdapterWrapper methods is to forward the request along to the wrapped ListAdapter. However, you can subclass AdapterWrapper to override that behavior.

cwac-cam2

[The cwac-cam2 repository](#) holds a CommonsWare library to assist with the use of the hardware cameras on Android devices. This library is covered extensively in [the chapter on using the camera](#).

cwac-colormixer

The [cwac-colormixer repository](#) holds a custom ColorMixer View, along with wrappers for using that View as a dialog, activity, or preference for use with PreferenceScreen.

ColorMixerDialog and ColorPreference are covered in [the chapter on custom dialogs](#). The ColorMixer widget is similar to the implementation found in [the chapter on custom views](#).

This library also contains a ColorMixerActivity, which you can use via startActivityForResult() to obtain a color, rather than by integrating the widget, dialog, or preference.

cwac-layouts

The [cwac-layouts repository](#) contains a series of custom containers and related views.

The current contents of this library — AspectLockedFrameLayout, MirroringFrameLayout, and kin — are covered in [the chapter on custom views](#).

cwac-merge

The [cwac-merge repository](#) contains MergeAdapter. It simply stitches together lots of smaller ListAdapters into one larger ListAdapter to put inside of a ListView or similar AdapterView. It also allows you to blend individual “row” Views with other ListAdapters.

One use of this is for section headers, using row Views for the headers and ListAdapters for the sections.

Another use is where you have multiple disparate data sources (e.g., queries across a few databases or ContentProviders), each with distinct row formatting, but you want to present them as one contiguous list.

cwac-pager

The [cwac-pager repository](#) includes code written in support of the ViewPager widget.

ArrayPagerAdapter is covered in [the chapter on advanced uses of ViewPager](#).

cwac-presentation

The [cwac-presentation repository](#) contains code in support of the Presentation system, for sending alternative content to an external display, independent of the device's primary screen.

All of the classes in this repository are covered in [the chapter on the Presentation system](#).

cwac-provider

The [cwac-provider repository](#) contains StreamProvider, a riff on Google's FileProvider, offering a “canned” implementation of a ContentProvider that can serve files from a variety of sources, such as assets and raw resources from your project.

This is discussed briefly in [the chapter on ContentProvider implementations](#).

cwac-richedit

The [cwac-richedit repository](#) contains the RichEditText widget, a drop-in replacement for EditText that supports “rich text” (a.k.a., formatted text) editing, such as bold and italics. The use of this widget is covered in [the chapter on Android's rich text handling](#).

cwac-sacklist

The [cwac-sacklist repository](#) contains SackOfViewsAdapter, which implements the ListAdapter interface for a collection of individual Views that serve as rows. This is used in support of [the MergeAdapter](#), for example.

cwac-security

[The cwac-security repository](#) contains code to help app developers help their users defend against attacks. At the moment, this contains the `PermissionUtils` class, used to help determine if a custom permission was defined by another app before yours was installed. This is discussed in [the chapter on advanced permission techniques](#).

cwac-strictmodeex

[The cwac-strictmodeex repository](#) contains classes that serve a similar role to Android's `StrictMode`, yelling at you for problematic code.

Specifically, this repository contains `StrictAdapter`, which measures the timing of methods like `getView()`, logging information about slow adapters that may result in sluggish `ListView` scrolling.

cwac-wakeful

[The cwac-wakeful repository](#) contains the `WakefulIntentService` and related support classes, for doing work and keeping the device awake while that work is going on. This is covered in [the chapter on AlarmManager](#).

Appendix B: N Developer Preview

In March 2016, Google released the first edition of the N Developer Preview. This gives developers the opportunity to start playing around with the next version of Android, while Google continues working on it in parallel for a production release later in 2016.

This appendix outlines how to work with the developer preview, what is changing in Android N, and how to start preparing your app for those changes.

A Brief History of Developer Previews

For a long stretch of time — from late 2009 through early 2014 – Google did not offer any sort of developer preview of upcoming Android OS versions. Hence, for most of Android’s history, developers got new versions of Android (and the corresponding Android SDK platform releases) the same time that the public did. This was certainly easy enough for Google, but it caused a fair amount of trouble for developers with shipping apps. Sometimes, new versions of Android break things in existing apps, and without any sort of “beta” of new Android versions, developers had to scramble to get their apps updated while early adopters of the new Android version complained about the problems.

In 2014, Google stabilized their release process to a once-a-year major update to Android. Along with that, they began shipping a developer preview ahead of time, starting with 2014’s “L Developer Preview”, which later turned into Android 5.0 (a.k.a., Lollipop).

The way the developer previews work is that Android developers get early access to the SDK platform, firmware images, and emulators for an upcoming release of Android, before that update is given to ordinary users via over-the-air (OTA)

firmware updates or on new hardware. This way, developers can try out their apps on the newer version, fix bugs, and perhaps start taking advantage of new capabilities that the new version of Android offers.

Google has taken some steps to try to prevent developers from shipping apps ahead of time that use the new Android SDK based on the developer previews. Presumably, the concern is one of compatibility, as Google reserves the right to change the public API between what is released in the preview and what finally officially ships. So, while developers can experiment using the previews, official app updates using the new Android version need to wait until that version is released.

Getting Started with the Preview

If you wish to start playing with the N Developer Preview, you will need to download some materials, adjust a copy of your project to try using the N Developer Preview SDK, and then try it out on devices or emulators.

Downloading the SDK Bits

In your SDK Manager, you can download the platform SDK and emulator images for the N Developer Preview.

In the Android Studio native SDK Manager, you should see an “Android N Preview” entry in the table in the “SDK Platforms” tab.

In the standalone SDK Manager, there will be an “Android N (API 23, N preview)” branch of the tree-table, containing the specific items that are available for download:

APPENDIX B: N DEVELOPER PREVIEW

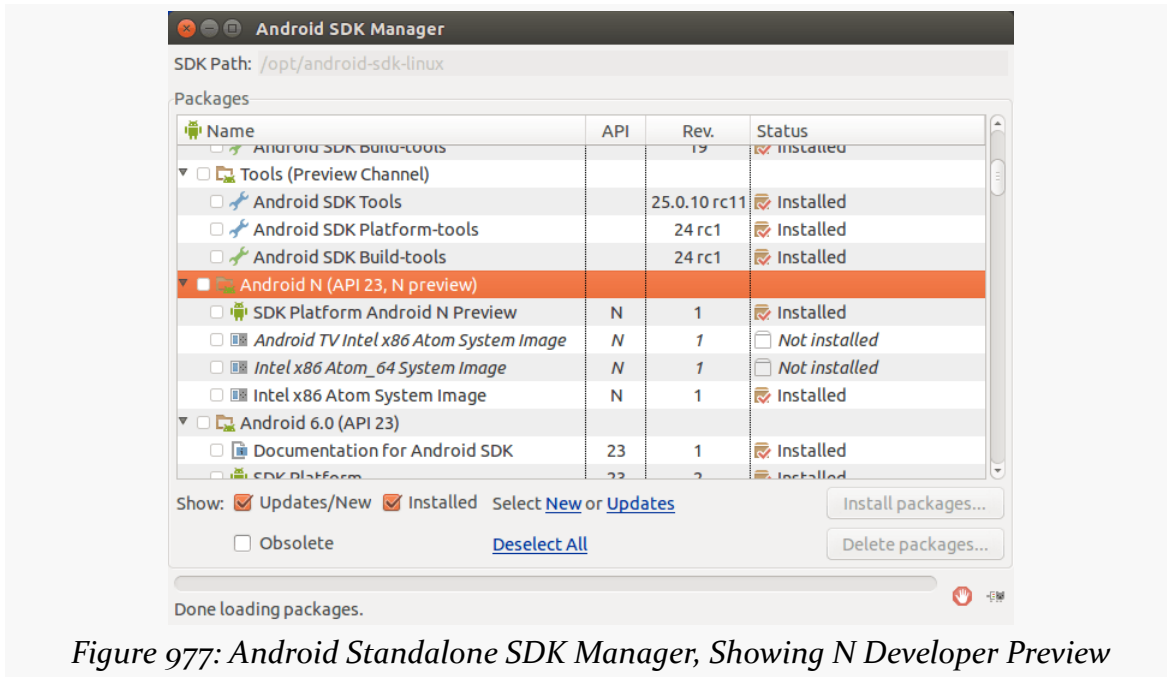

Figure 977: Android Standalone SDK Manager, Showing N Developer Preview

In the above screenshot, the SDK Platform and “Intel x86 Atom System Image” items are installed, as those are the minimum requirements for working with the N Developer Preview. If you are working with Android TV, you may wish to install the Android TV emulator image. If you are doing a lot of work with the NDK and wish to test your app on an x86-64 emulator image, that is available as well. At the present time, emulator images for other CPU architectures, such as ARM, are not available.

Android Tools

Your SDK Manager also has options for downloading preview editions of the command-line tools:

APPENDIX B: N DEVELOPER PREVIEW

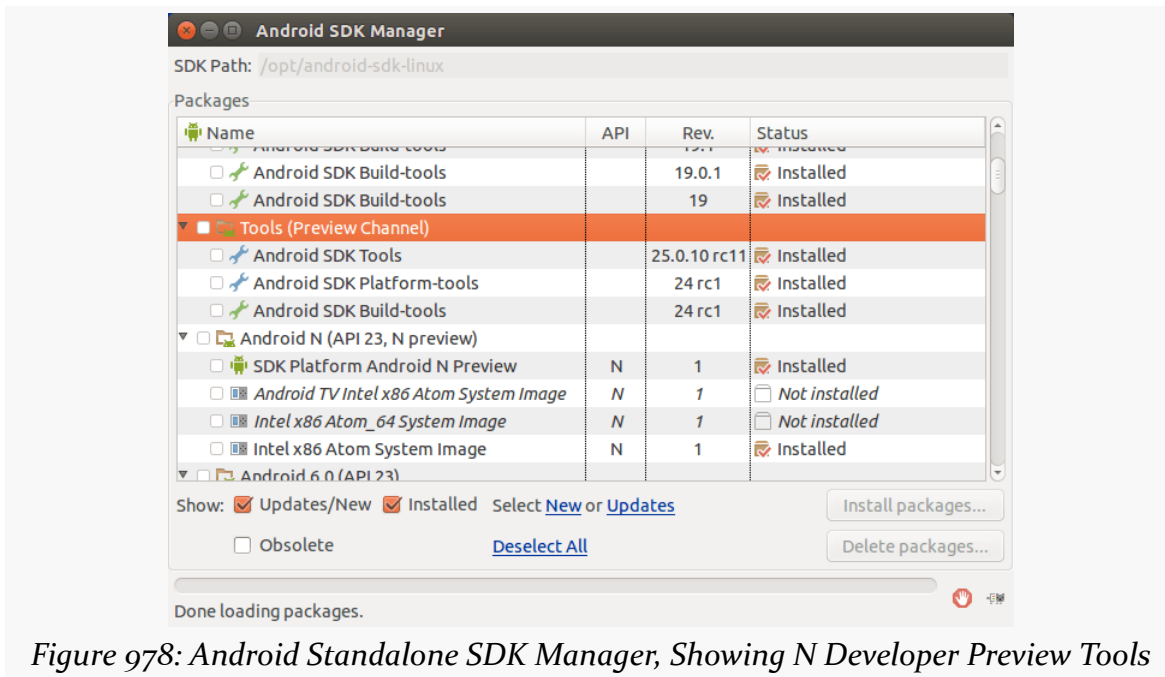

Figure 978: Android Standalone SDK Manager, Showing N Developer Preview Tools

You will need those as well in order to be able to build and test apps using the N Developer Preview.

In terms of Android Studio, the documentation will suggest installing Android Studio 2.1. However, this is a “canary channel” release, and not all developers are interested in bleeding-edge tools like this. Also, it is not necessary, as Android Studio 1.5.1 can build Android N projects, with the proper project configuration. The only thing that you need Android Studio 2.1 for is if you wish to start using Java 8 features in your code, as is covered in the next section.

Java 8

In order to build an Android N application, you need to be using JDK 8. If you are using JDK 7 or 6, you will need to upgrade your Java development environment to 8.

Historically, Java 8 was not needed, or even that useful, for the simple reason that Android itself did not support Java 8 constructs. However, Android is converting its `java.*` and `javax.*` classes to be [based on the OpenJDK](#), rather than be based on the long-since-discontinued Apache Harmony project. And, the new Android Java source compiler — the Java Android Compiler Kit, or Jack — supports Java 8, including generating bytecode that works on older versions of Android.

This, however, comes with some short-term compatibility costs:

- You need to use Android Studio 2.1 or higher, which at the present time relegates you to the canary channel
- Some tools and libraries, such as [Mockito](#) and JaCoCo, will not work with Jack
- This is all rather new, and so there is increased risk of running into runtime compatibility issues that have not been encountered to date, let alone addressed

On the whole, you may wish to hold off on Java 8 until later in 2016. If you wish to try it, though, [you are welcome to do so](#).

Project Settings

To build and run Android N apps, you need to make a few adjustments to your project. By default, these changes will prevent your app from running on older devices. Hence, you may want to make a copy of your project and play with the copy on Android N.

First, you need to be using a newer copy of Gradle, such as 2.10. A typical Android Studio project determines what version of Gradle to use from the Gradle Wrapper configuration file: `gradle/wrapper/gradle-wrapper.properties`. The `distributionUrl` property indicates the specific Gradle to use and incorporates the version number in the filename:

```
#Wed Apr 10 15:27:10 PDT 2013
distributionBase=GRADLE_USER_HOME
distributionPath=wrapper/dists
zipStoreBase=GRADLE_USER_HOME
zipStorePath=wrapper/dists
distributionUrl=https\://services.gradle.org/distributions/gradle-2.10-all.zip
```

(from [MultiWindow/OptIn/gradle/wrapper/gradle-wrapper.properties](#))

If you are using a local installation of Gradle, upgrade that installation to 2.10 or higher.

Next, you need to be using 2.1.0-alpha1 or higher of the Android Plugin for Gradle. In a typical Android Studio project, the plugin version is set in the top-level `build.gradle` file, in the project root:

```
// Top-level build file where you can add configuration options common to all sub-projects/modules.
```

APPENDIX B: N DEVELOPER PREVIEW

```
buildscript {
    repositories {
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:2.1.2'

        // NOTE: Do not place your application dependencies here; they belong
        // in the individual module build.gradle files
    }
}

allprojects {
    repositories {
        jcenter()
    }
}
```

(from [MultiWindow/OptIn/build.gradle](#))

Finally, your module's `build.gradle` file, such as the one for an `app/` module, needs to have:

- `compileSdkVersion` set to 24
- `buildToolsVersion` set to 24.0.0
- `targetSdkVersion` set to 24

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 24
    buildToolsVersion "24.0.0"

    defaultConfig {
        minSdkVersion 24
        targetSdkVersion 24
        applicationId "com.commonware.android.multiwindow.optin"
    }
}
```

(from [MultiWindow/OptIn/app/build.gradle](#))

NOTE: The 24 notation was added with N Developer Preview 4. Prior versions of the N Developer Preview used N for the `targetSdkVersion` and `android-N` for the `compileSdkVersion`. Fortunately, those are no longer needed, and you can treat Android N as you would any other version of Android in terms of build settings.

Emulator and Devices

You can download new emulator images for Android N from the SDK Manager and use them more or less like any other emulator images.

APPENDIX B: N DEVELOPER PREVIEW

If you have a spare Nexus 5X, Nexus 6, Nexus 6P, Nexus 9, Nexus Player, or Pixel C, you can also flash a copy of Android N onto hardware. You have two major options for this:

1. Enroll the device in [the Android Beta Program](#), in which case the firmware updates will arrive over the air (OTA), as do production firmware updates. This, however, requires the device to be set up with a Google account.
2. Manually download and flash the firmware on the device.

To manually flash the firmware:

1. [Download the appropriate image](#) for your device and check the MD5 or SHA-1 checksums when the file is downloaded. Do not install an image where the checksums do not match.
2. Go into Settings > Developer Options on the existing device, see if there is an “OEM Fastboot” option, and enable it.
3. Plug the device into your development machine and get USB debugging going, if you have not done so already for this device.
4. Run `adb reboot bootloader` from the command line. This requires the `platform-tools/` directory of your Android SDK installation to be in your PATH. This command reboots your device into the bootloader.
5. Run `fastboot oem unlock` from the command line, to unlock the bootloader.
6. Unpack the image archive that you downloaded in step #1, go into the directory that it creates, and run the `flash-all` shell script or batch file. This will run for a minute or so. **DO NOT UNPLUG YOUR DEVICE WHILE THIS IS GOING ON.** When completed, the device will reboot, and you will be greeted by the Android N setup wizard, as if you had bought the device with Android N installed.

Also, if you ever plan on taking this device out of the lab, you will want to relock the bootloader. To do this, you will need to set up USB debugging again, run `adb reboot bootloader` again, and run `fastboot oem lock` (as opposed to the `unlock` you ran previously). Note that this may factory reset your device, forcing you to set up the device yet again.

More details about flashing images onto the Nexus devices can be found in [the documentation](#).

Major Changes in Android N

So, with all that behind us, what are we getting in the next version of Android that may be of interest to you?

WARNING: The material that follows is based on what is known as the N Developer Preview 5 (NDP5). The preview itself may be updated by the time that you read this, and the shipping version of Android N may also be different than what you will read here. Please be careful when relying on pre-release information, as APIs and behaviors may change between now and an official release of Android N.

Ban on file: Uri Scheme

The biggest compatibility issue so far with the N Developer Preview is that the `file:` scheme for `Uri` values is banned, in effect. If you attempt to pass a `file: Uri` in an Intent that is going to another app — whether via an extra or as the “data” facet of the Intent — you will crash with a `FileUriExposedException` exception. You will face similar issues with putting `file: Uri` values on the clipboard in `ClipData`.

This is coming from an updated edition of `StrictMode`. `StrictMode.VmPolicy.Builder` has a `penaltyDeathOnFileUriExposure()` method that triggers the detection of `file: Uri` values and the resulting `FileUriExposedException` exceptions. And, it appears that this is pre-configured, much as how `StrictMode` is pre-configured to apply `penaltyDeathOnNetwork()` (the source of your `NetworkOnMainThreadException` crashes).

It is unclear if this is a “trial balloon” and will be rescinded before Android N ships, or whether this is the expected behavior for the final shipping product. You may wish to keep track of [this issue](#) to find out more about these sorts of plans.

Your app might consume `Uri` values:

- From `getIntent()`, such as getting the `Uri` for your `ACTION_VIEW` implementation
- From an extra, such as getting the `EXTRA_STREAM Uri` for your `ACTION_SEND` implementation
- From the Intent passed to `onActivityResult()`, such as getting the `Uri` from [the Storage Access Framework](#) or `ACTION_GET_CONTENT`
- Etc.

You will not be directly affected, insofar as it is the source of the `file: Uri` that will crash, not the recipient. However, it is important that you handle `content: Uri` values properly, by using `ContentResolver` and:

- `open()`, to get an `InputStream` on the content pointed to by the `Uri`
- `getType()`, to get the MIME type of the content pointed to by the `Uri`
- `query()` and the `OpenableColumns`, to get the size and display name of the content pointed to by the `Uri`

Or, pass the `Uri` off to a library, like Picasso, that can handle that sort of work for you.

If you produce `file: Uri` values, you will need to start thinking about employing [FileProvider](#) or similar alternatives. Tactically, once Android N ships, you could keep your `targetSdkVersion` low enough to not trigger the `FileUriExposedException` exceptions. However, eventually, something will force your hand and cause you to need to move your `targetSdkVersion` higher, and at that point, you need to have moved off of `file: Uri` values to `content: Uri` values.

Multi-Window Support

From the standpoint of users, the most visible new capability in the N Developer Preview is multi-window support. Now, the user can be working with more than one Android activity at a time, whether from separate apps or — with the assistance of the app — from the same app. This is akin to the proprietary implementations seen in devices from Samsung, LG, Jide, and other manufacturers.

The good news — more or less — is that support for multi-window is automatic. You do not need to change anything in your Android app to have your app moved into a portion of the screen, instead of taking up the full screen.

However, you may want to tweak your app to behave better in a multi-window environment.

What The User Sees

For most Android devices, the user experience will be what is known as the split-screen view:

APPENDIX B: N DEVELOPER PREVIEW

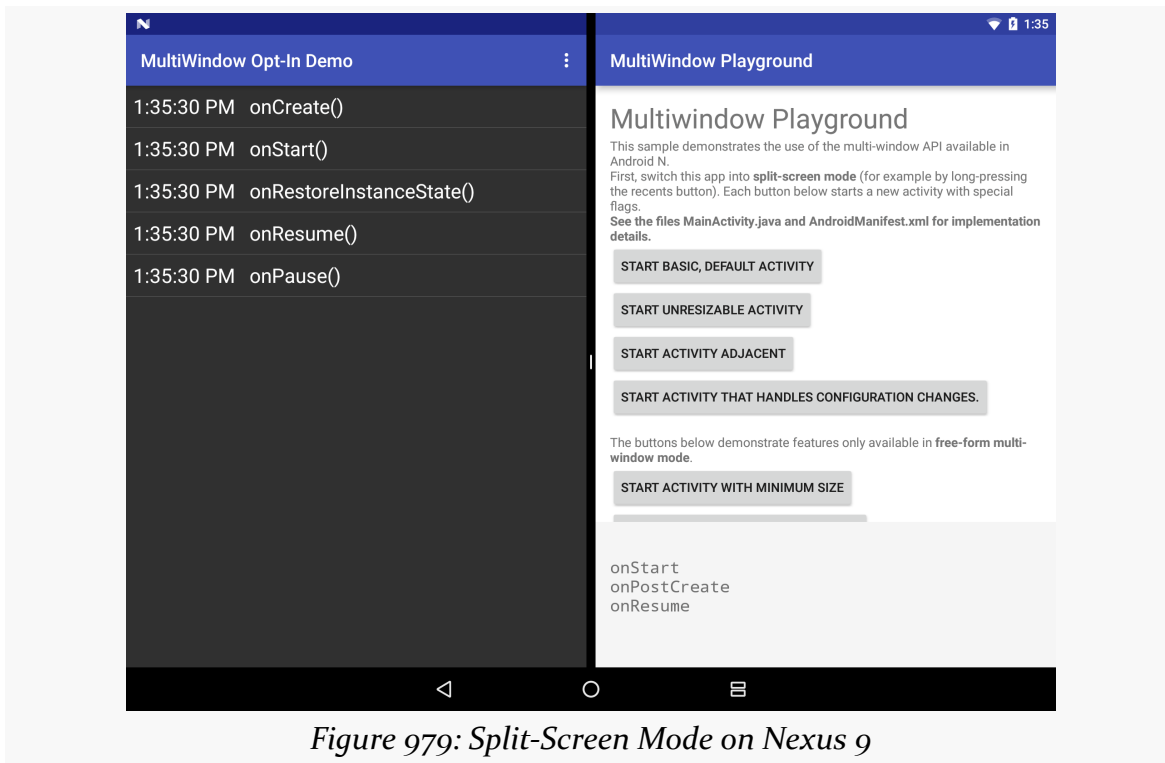

Figure 979: Split-Screen Mode on Nexus 9

The user can enter split-screen mode by long-pressing on the OVERVIEW button (the one that brings up the recent tasks). The existing foreground activity will be put in one pane, with the overview screen in the other pane, where the user can choose another app.

If the user rotates the screen, the split-screen remains, still splitting along the long axis:

APPENDIX B: N DEVELOPER PREVIEW

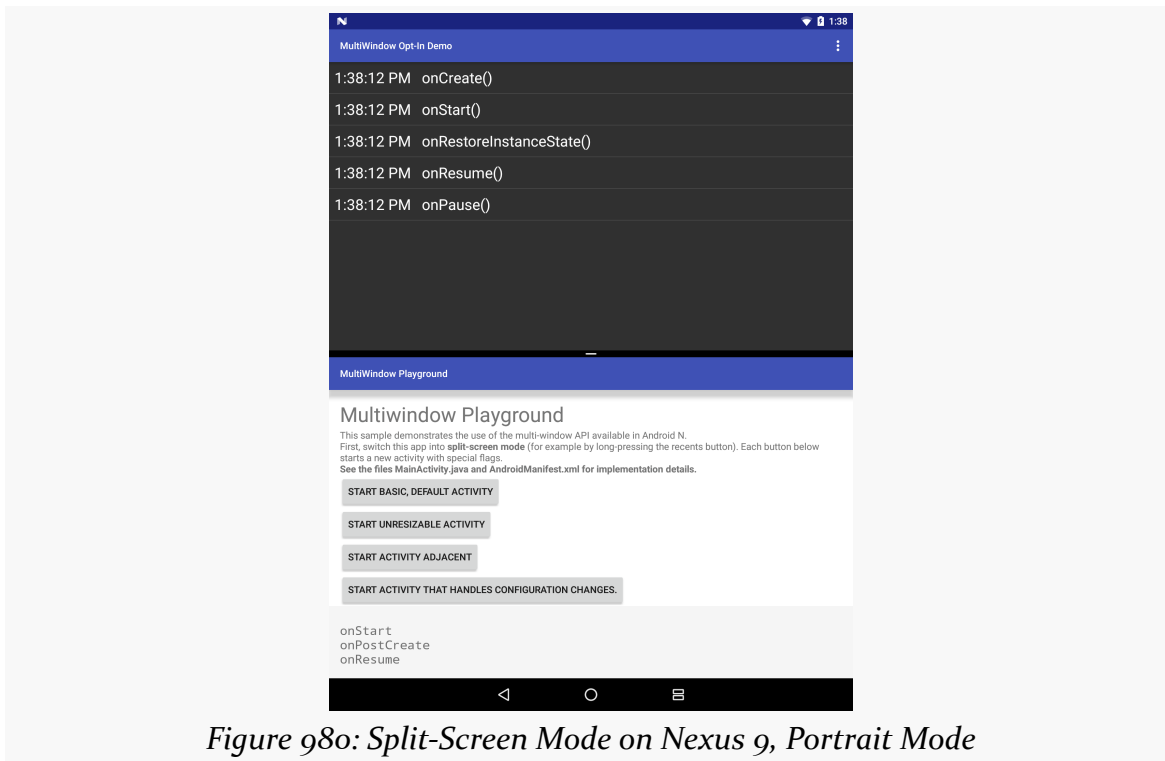

Figure 980: Split-Screen Mode on Nexus 9, Portrait Mode

The divider is movable between three positions, to either equally split the space (default) or to give one pane or the other about two-thirds of the space:

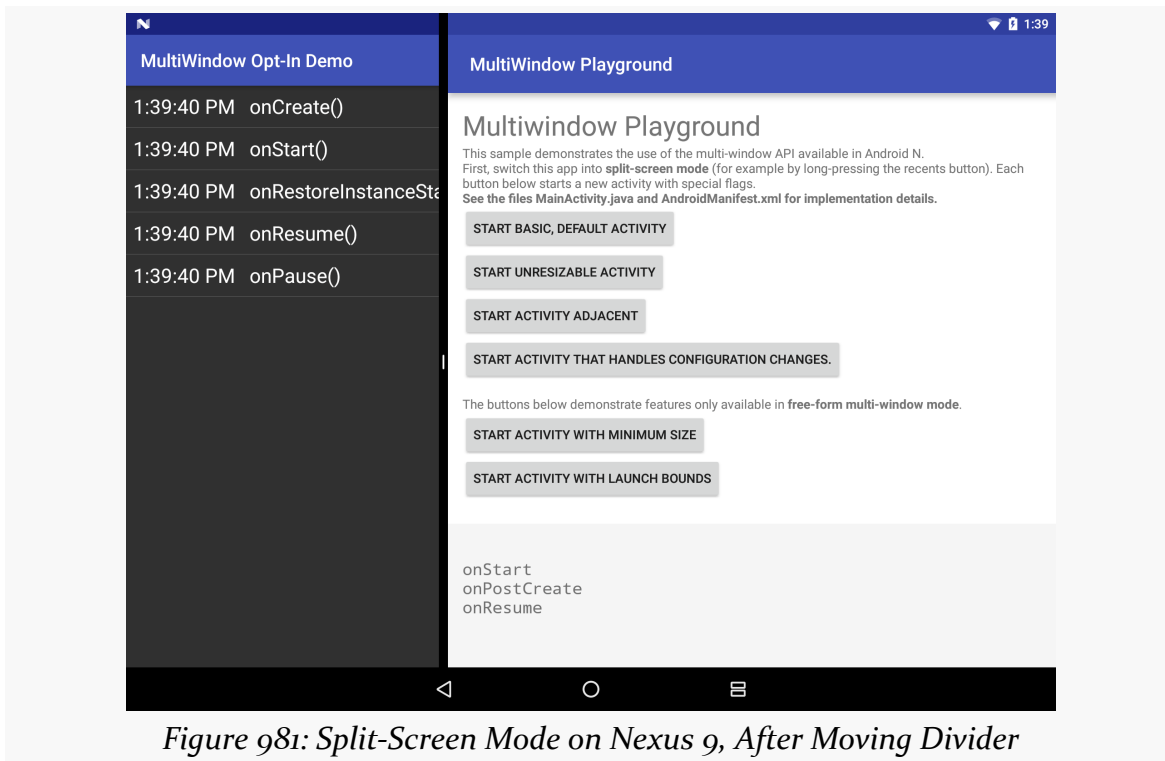

Figure 981: Split-Screen Mode on Nexus 9, After Moving Divider

Android TV devices support a “picture-in-picture” mode instead, where one activity is in a small floating window, overlaying the other activity.

The documentation also describes a “freeform” mode that [is not supported in the current version of the N Developer Preview](#). From the description, freeform mode probably works much like how a desktop OS handles overlapping windows, where users can move them and size them as desired. This is probably with an eye towards getting Android on the desktop.

What Your Code Sees

From your activity’s standpoint, the fact that it once used most of the screen, and now is only smaller part of a screen, is just a configuration change, no different than orientation changes or other screen size changes (e.g., putting the device in a dock that provides a larger screen).

Whatever activity the user tapped on last is considered to be the foreground activity. Other activities that are visible, such as the activity in the adjacent split-screen pane, will be paused. This is in line with the way Android has always worked:

- if your activity is visible, but not in the foreground, it will be paused (e.g., a system-supplied dialog-themed activity is in the foreground)
- if your activity is no longer visible, it will be stopped

You will want to think through what business logic of your activities belongs in `onStart()/onStop()` and what belongs in `onResume()/onPause()`. Historically, since being visible but not in the foreground was an uncommon, short-lived state, we did not necessarily have to worry that much about the distinction between “paused” and “stopped”. Now the distinction takes on much greater importance.

In split-screen mode, if the user moves the divider, your activity initially will be simply redrawn to adopt the extra space. Once the user lets go of the divider, and it settles on its final position, your activity may undergo a configuration change. In the current N Developer Preview, whether you undergo a configuration change seems somewhat random. With luck, this will be more predictable in the future.

If needed, activities and fragments can find out what is going on with respect to multi-window behavior:

- They can call `isInMultiWindowMode()` to find out if they are in multi-window mode presently... in theory
- They can override `onMultiWindowModeChanged()` to find out if the multi-window state changes

There are also variants of these for picture-in-picture mode for Android TV: `isInPictureInPictureMode()` and `onPictureInPictureModeChanged()`. However, picture-in-picture mode is a particular case of multi-window mode. For example, if `isInPictureInPictureMode()` returns true, so will `isInMultiWindowMode()`.

However, [`isInMultiWindowMode\(\)` is unreliable](#), apparently by design. Ideally, avoid doing anything specific for when you are in multi-window mode or not.

Opting Out

For various reasons, you may not want your activity to be eligible to be used in some form of multi-window mode. This may disappoint your users, but you may have valid reasons for this decision.

If your `targetSdkVersion` is N (or whatever that turns into, probably 24, when Android N ships in final form), you can have an `android:resizeableActivity="false"` attribute on a specific `<activity>` element

or on the `<application>` element in your manifest. This will tell Android to always give you the full screen, even if the user tries launch your activity into some form of multi-window mode.

If your `targetSdkVersion` is 23 or lower, whether you support multi-window mode is determined by the `android:screenOrientation` attribute (on an `<activity>` or inherited from the `<application>`). A fixed-orientation activity — such as one that is locked to landscape — will not be put into multi-window mode.

Note that if your `targetSdkVersion` is 23 or lower, and you support any orientation (e.g., you do not have `android:screenOrientation`), Android will allow the user to use your activity in multi-window mode. However, a Toast will appear, advising the user that your activity is not designed for multi-window mode and there may be compatibility issues. However, this will serve as a note to users that your app is out of date with respect to newer versions of Android, which may not be in your best interests.

Opting In

As noted, Android will allow your activity to be put in multi-window mode by default.

To avoid the aforementioned warning Toast, set your `targetSdkVersion` to N. Optionally, you can explicitly have `android:resizeableActivity="true"` in the manifest, though this is the default.

Note that not all activities need to support multi-window mode. For example, you might have some general activities that are fine in multi-window mode, plus a video player that really should be full-screen in landscape. You might put `android:resizeableActivity="false"` on that latter activity, plus have `android:resizeableActivity="true"` on the `<application>` element (for documentation purposes).

If, for some reason, regular multi-window modes are fine, but picture-in-picture will be a problem, you can have `android:supportsPictureInPicture="false"` on an `<activity>`.

Configuring the Layout

You can add a `<layout>` element as a child to your `<activity>` element, to control aspects of how the activity appears on the screen in multi-window mode.

The only facet of `<layout>` that we can use today is the minimal size, represented by `android:minWidth` and `android:minHeight` attributes. These indicate how small you are willing to have your activity be in the stated direction. If the user moves the divider, and the resulting size of your activity is smaller than your requested minimal size, your activity will appear to extend “under” the other pane.

NOTE: The `android:minWidth` and `android:minHeight` attribute names are new to N Developer Preview 4. Prior N Developer Preview editions used `android:minimalWidth` and `android:minimalHeight`.

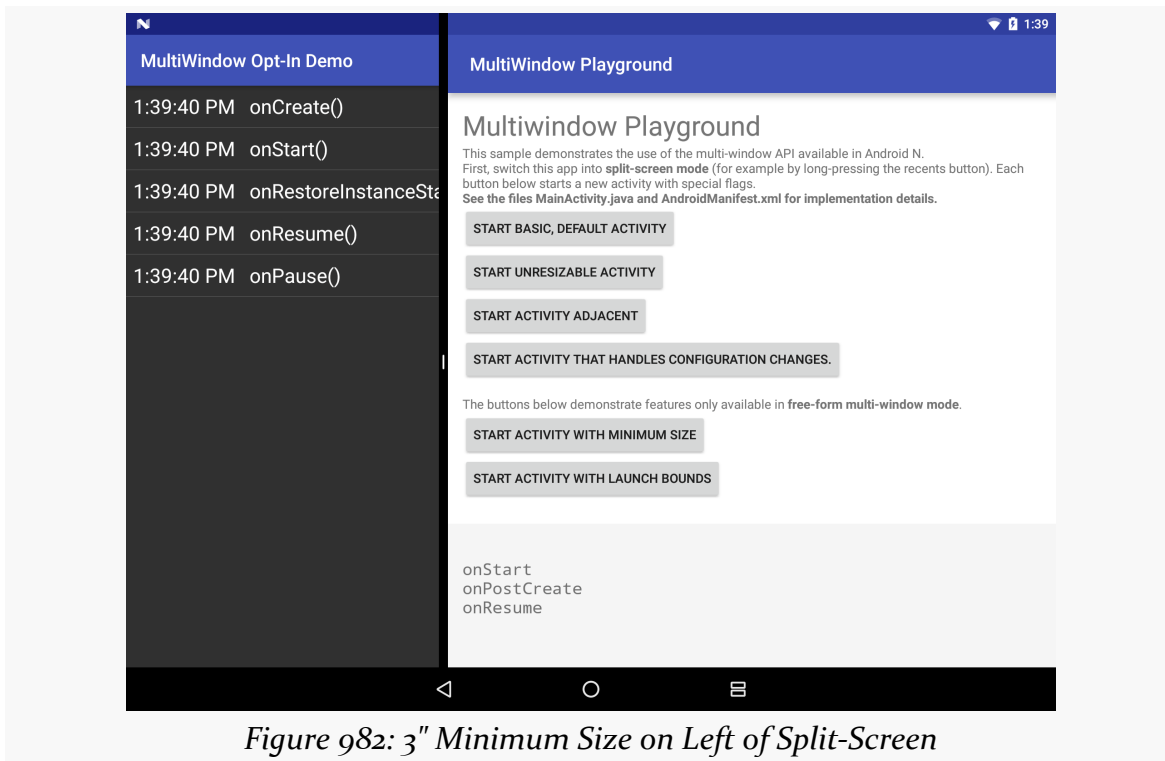

For example, the [MultiWindow/OptIn](#) sample application has its minimal width set to 3 inches (480dp):

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:resizeableActivity="true"
  android:theme="@style/Theme.AppTheme">
  <activity
    android:name="MainActivity">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
    <layout android:minWidth="480dp" />
  </activity>
</application>
</manifest>
```

(from [MultiWindow/OptIn/app/src/main/AndroidManifest.xml](#))

When positioned on the left of the split-screen, with a size less than 3 inches, the activity “extends beneath” the right pane:

The OptIn sample app has a `ListView` showing the events received in the lifetime of this activity instance, so you can see the effect of tapping on one activity versus the other in the split-screen mode.

Also, the other activity shown in these screenshots is [Google's official multi-window sample app](#).

For freeform multi-window mode, you also have:

- `android:defaultWidth` and `android:defaultHeight`, to supply a suggested size for your window, and
- `android:gravity`, which works like the equivalent widget attribute, suggesting where on the screen your window should be opened

Avoiding Stutter

Since resizing an activity in multi-window mode may cause a configuration change, it is very important for you to handle configuration changes quickly:

- For small bits of data that can be put in a Bundle, use the saved instance state Bundle, so that your new activity (and fragments) can not only rapidly handle these configuration changes but also handle other scenarios, such as your process being terminated while in the background.
- For larger chunks of data, or data that cannot be put into a Bundle, use a retained fragment or a process-level cache. Be careful with the latter technique, though, so that you do not consume too much heap space.

What you want to avoid, if at all possible, is having to do I/O of any form due to a configuration change.

In addition, while the user is resizing your activity, it is simply being redrawn using its current UI, pending completion of the resize (at which point, a configuration change may occur). The more work you do to render the UI, the more work that needs to be done to redraw the UI while the user is resizing, and the more likely that it is that the user will perceive some jank. Possible problem areas include:

- Having hundreds of widgets in your activity
- Having custom widgets that are expensive to redraw
- Triggering some sort of controller-style logic due to a redraw that in turn triggers more serious work (e.g., “we want to log every time the widget gets drawn to a file”)

In a pinch, you can optimize certain configuration changes, overriding the default activity destroy-and-recreate cycle, via `android:configChanges`. On the plus side, you can try to make fine-grained changes to your UI and react more responsively. However, *this is an optimization*, not a replacement for proper state management (e.g., saved instance state Bundle), as state management is for more than configuration changes.

If you wish to use `android:configChanges` to opt out of automatic handling of certain configuration changes, the ones of relevance for multi-window are:

- `screenSize`
- `smallestScreenSize`
- `screenLayout`
- `orientation`

If you have not used this technique before, you can read more about it in [the chapter on configuration changes](#).

Managing the Background

While the user is resizing the window, Android does not attempt to re-render your UI. Instead, if the window is being shrunk, your existing UI is clipped. If the window is being expanded, a background is shown over the new area. Only once the resize is done does Android perform the configuration change and re-render your UI.

The `android:windowBackground` and `android:windowBackgroundFallback` theme attributes control what that background looks like. You may wish to set `android:windowBackground` in your app's theme to a value that matches your natural window background, so there is a seamless transition between your regular background and the new background added by Android during the resize operation.

How Low Can You Go?

The smallest window size in split-screen mode is 220dp. Your activity should aim to support a width or height of 220dp for maximum compatibility. Using `android:minWidth` and `android:minHeight` will allow your activity to support those small sizes by having your UI be clipped, but this is not an ideal user experience. Rely on `android:minWidth` and `android:minHeight` only for cases where you have no good way of supporting 220dp directly.

It is unclear whether this 220dp minimum also holds for freeform or picture-in-picture multi-window mode.

Handling the Screen Size Transition

Suppose your activity launches in a window size that, based on your layout rules, pulls in a phone-sized layout resource. Now, the user resizes your window, and the resulting size would pull in a tablet-sized layout resource.

Assuming that you are handling all of this properly via the configuration change, technically your activity should work just fine. But from the user's standpoint, it may result in a jarring transition, if the UI for one screen size is significantly different from the UI for another screen size.

You sometimes see this with Web sites. Some sites apply their site designs based solely on the size of the browser viewport, so they are not dependent upon flaky ways of detecting whether the browser is coming from a mobile device or not. If the viewport is small enough, the page's CSS renders a mobile-friendly UI; larger

viewports result in more of a desktop feel. However, if this is based on CSS, resizing a desktop browser window to be small causes the Web page to dynamically shift from desktop to mobile mode, or vice versa. This puts some stress on the Web page design, so that the design not only works statically (i.e., a small rendition works well on mobile) but also dynamically (i.e., the user does not get too confused when the Web page transitions from one set of CSS rules to another).

We will wind up with the same problem in multi-window on Android, as the user resizes windows past our natural transition points.

Ideally, your app uses one UI for everything from small phones (or small windows in multi-window) to large tablets (or large windows in multi-window), regardless of window orientation. Few UI designs work well this way. And since you cannot reliably determine whether or not you are in multi-window mode via `isInMultiWindowMode()`, you cannot reliably treat that as a separate case.

As such, the community will eventually need to evolve some patterns for handling this scenario.

Parallel Processing

Normally, multi-window is for multiple apps. For example, the user might be watching a video in one pane while taking notes in another.

However, there will be cases where it might help the user to have two activities of yours be in the panes of the split-screen mode. Or, there may be cases where users want to launch some content of yours into a separate window in freeform mode, when that becomes available.

To do this, you can add `FLAG_ACTIVITY_LAUNCH_ADJACENT` to the Intent that starts up another activity. If the device is in some form of multi-window mode, this serves as a hint that you want this new activity to be in a different pane or window than is the current activity. If the device is *not* in multi-window mode, adding this flag has no effect — you cannot force a device into multi-window mode.

Because this is only conditionally available, you will want to set up your UI to reflect that fact. Possible strategies include:

- Only offering a “start in a new pane/window” option if `isInMultiWindowMode()` returns true, or toggling its availability in `onMultiWindowChanged()`

- Always having the option to start the activity in a new pane or window, but if `isInMultiWindowMode()` returns `false` at that point, show a dialog or Snackbar or something to point out that the user has to set up multi-window mode first

However, the two activities (e.g., the ones in each pane of split-screen) need to be part of separate tasks. The recipe for doing this is to not only use `FLAG_ACTIVITY_LAUNCH_ADJACENT`, but also `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_MULTIPLE_TASK`.

For example, `MainActivity` in the `OptIn` sample app has an overflow menu with a “Clone” menu item. This opens a second instance of `MainActivity` into the other split-screen pane:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.clone) {
        Intent i=
            new Intent(this, MainActivity.class)
                .setFlags(Intent.FLAG_ACTIVITY_LAUNCH_ADJACENT |
                    Intent.FLAG_ACTIVITY_NEW_TASK |
                    Intent.FLAG_ACTIVITY_MULTIPLE_TASK);

        startActivity(i);
        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [MultiWindow/OptIn/app/src/main/java/com/commonsware/android/multiwindow/MainActivity.java](#))

Note that the `Intent` gets all three of the aforementioned flags: `FLAG_ACTIVITY_LAUNCH_ADJACENT`, `FLAG_ACTIVITY_NEW_TASK`, and `FLAG_ACTIVITY_MULTIPLE_TASK`.

The chapter on consuming documents using the Storage Access Framework [profiles a TinyTextEditor sample app](#) that further demonstrates how to open a separate window from an existing one. In this case, it will be to move a text editor from a tab in one activity into a separate activity in its own window.

You also have the option of using the two-parameter `startActivity()` that takes a `Bundle`, building that `Bundle` using the `ActivityOptions` class. On `ActivityOptions`, there is `setLaunchBounds()`, to indicate where on the screen the new task’s window should appear. The parameter to `setLaunchBounds()` is either a `Rect` (providing that

size/location in screen coordinates) or null (indicating that the new task's window should occupy the full screen).

Network Security

The N Developer Preview offers some new options for tailoring network access — in particular, HTTP/HTTPS access — within an Android application. Via a specially-crafted bit of XML, registered in the manifest via a `<meta-data>` element, you can:

- Add support for other certificate authorities or certificates, including having debug-only support for a self-signed certificate (e.g., for hitting a test server)
- Replace the stock certificate authorities to be supported by your app with another set, such as to limit the number of valid authorities (and, therefore, reduce the risk of forged certificates)
- Pinning SSL certificates, as another approach to limiting possible forged certificates
- Block non-SSL/TLS traffic

Note, though, that not all of these features may be supported by `WebView` at present.

Of particularly good news is that using this feature does *not* require your app to be compiled against the N Developer Preview SDK or have `targetSdkVersion` set to 24. As a result, you could add this to your app today, if you wanted — the configuration options set here will be ignored on older devices but applied on N devices.

Plus, the author of this book has created a backport of the network security configuration subsystem, so you can use the same features with (mostly) the same code going back to API Level 17.

Network security configuration is covered as part of [the chapter on SSL](#).

Scoped Directory Access

The N Developer Preview adds yet another option for getting access to storage: scoped directory access.

`READ_EXTERNAL_STORAGE` and `WRITE_EXTERNAL_STORAGE` are permissions used to access external storage. They grant access to *all* of external storage, though, not just specific locations. They also do not grant any access to removable storage. Plus,

those permissions are dangerous and therefore require special attention on Android 6.0+.

The [Storage Access Framework](#), added in Android 4.4, can give you access to locations on external or removable storage, without any permissions. Plus, the user gets to choose exactly what storage you can access, by navigating a file manager-style UI. However, the user *has* to go through that process, which may be tedious.

The N Developer Preview’s “scoped directory access” represents a bit of a middle ground:

- Other than a permission-style confirmation dialog, the system does not need to present any UI to the user, such as the Storage Access Framework’s file manager
- You can access common directories on external and removable storage without any special permissions in the manifest

However, you are limited to specific common locations. On external storage, you and the user will be familiar with these locations: the standard spots for digital photos, movies, music, and so on. Android N provides similar directories on removable storage volumes as well. You can ask for permission for one (or more) of these directories at runtime. If you get it, you *only* have access to what you asked for, not arbitrary other locations on external or removable storage.

This comes in the form of an extension to the `StorageManager`. If you ship your app through the Play Store and have been using OBB files for packaging extra data along with your APK, you have already used `StorageManager`. Otherwise, most likely, you had no idea that it even existed.

The `StorageManager` system service now has methods to find out the available `StorageVolume` objects: one for external storage, and zero or more for available removable storage.

Given a `StorageVolume`, you can call `createAccessIntent()` to request access to a particular common directory (e.g., `Environment.DIRECTORY_MUSIC`) on that volume. Calling `startActivityForResult()` will display a confirmation dialog to the user. If the user grants you access, you will get back a `Uri` pointing to that directory, akin to what you get back from the Storage Access Framework.

This topic is tightly coupled to the rest of the Storage Access Framework, and so it is examined in greater detail, with a sample app, in [the chapter on consuming documents](#).

Notifications

A couple of Notification features originally designed for Android Wear are being extended to use on Android proper. The nice thing about these is that you do not need to have a `targetSdkVersion` of 'N' to use them. Some slight changes to how you use `NotificationCompat.Builder` are all that you need to enable them in your app.

Remote Input

Since typing on a watch or pair of glasses is rather difficult, Android Wear supported a voice recognition style of remote input. By adding a `RemoteInput` action to a `WearExtender`, you could give the user the ability to choose a canned response from a list or speak a response. The resulting response would be delivered to your app on the mobile device, for your use (e.g., send as a text message as a response to a received text message).

Now, with Android N, `RemoteInput` is also available for standard device notifications. Rather than using voice input, you get a small `EditText` into which the user can type something and submit it. You get what the user typed in, and can use that as needed.

The [Notifications/RemoteInput](#) sample project is a near-clone of the [Notifications/VoiceInput](#) sample project profiled in [the advanced Notifications chapter](#). Instead of putting the `RemoteInput` in an action on the `WearExtender`, it puts the `RemoteInput` on the main `Notification` itself:

```
package com.commonware.android.remoteinput;

import android.app.Activity;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
    }
}
```

APPENDIX B: N DEVELOPER PREVIEW

```
Intent i=new Intent(this, RemoteInputReceiver.class);
PendingIntent pi=
    PendingIntent.getBroadcast(this, 0, i,
        PendingIntent.FLAG_UPDATE_CURRENT);

RemoteInput remoteInput=
    new RemoteInput.Builder(RemoteInputReceiver.EXTRA_INPUT)
        .setLabel(getString(R.string.talk))
        .build();

NotificationCompat.Action remoteAction=
    new NotificationCompat.Action.Builder(
        android.R.drawable.ic_btn_speak_now,
        getString(R.string.talk),
        pi).addRemoteInput(remoteInput).build();

NotificationCompat.Builder builder=
    RemoteInputReceiver.buildNotificationBase(this)
        .addAction(remoteAction);

NotificationManagerCompat
    .from(this)
    .notify(RemoteInputReceiver.NOTIFY_ID, builder.build());

finish();
}
```

(from [Notifications/RemoteInput/app/src/main/java/com/commonsware/android/remotinput/MainActivity.java](#))

The activity, when launched, will raise the Notification with a “Talk to Me” action:

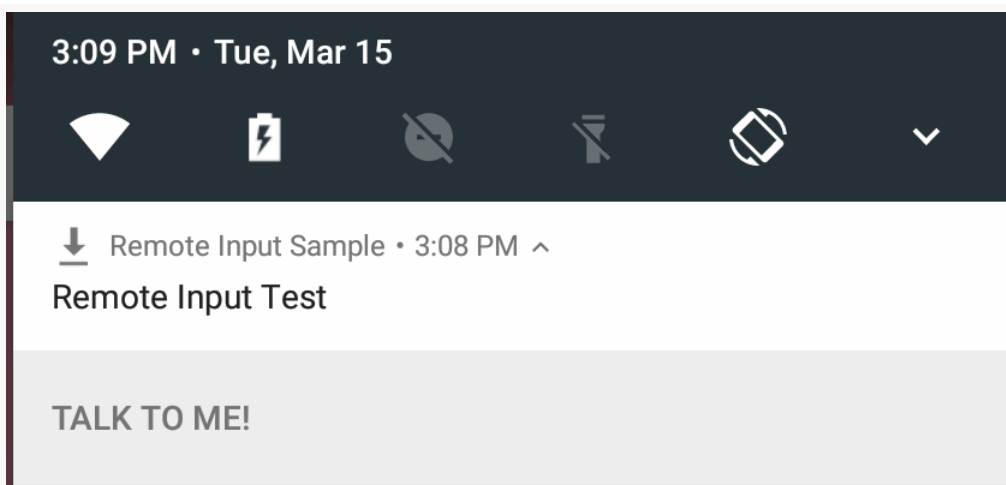

Figure 983: Notification with Action

Tapping on the action converts it into an `EditText`, with your action prompt as the hint, plus an arrow-shaped “send” button:

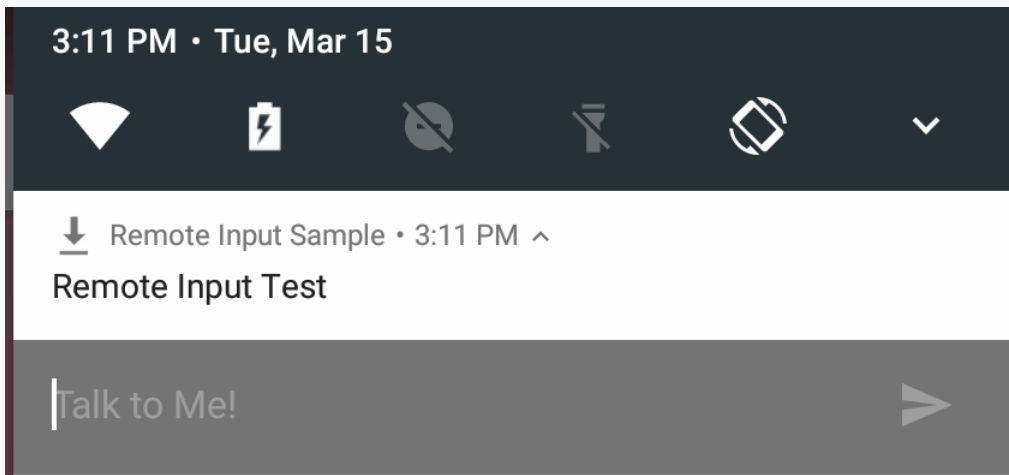

Figure 984: Notification with Remote Input

Typing something in and tapping that button converts the button into a progress spinner:

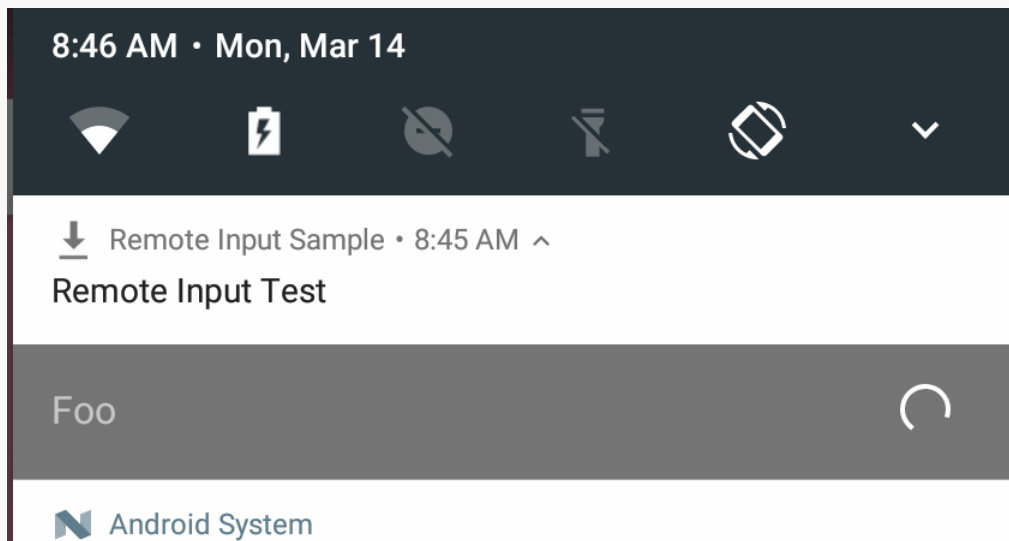

Figure 985: Notification with Remote Input and Progress Spinner

Also, the `PendingIntent` that you associated with the action is invoked. In this case, that triggers a broadcast to `RemoteInputReceiver`:

```
package com.commonware.android.remoteinput;  
  
import android.content.BroadcastReceiver;  
import android.content.Context;  
import android.content.Intent;
```

APPENDIX B: N DEVELOPER PREVIEW

```
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;
import android.util.Log;

public class RemoteInputReceiver extends BroadcastReceiver {
    static final int NOTIFY_ID=1337;
    static final String EXTRA_INPUT="input";

    static NotificationCompat.Builder buildNotificationBase(Context ctxt) {
        NotificationCompat.Builder builder=
            new NotificationCompat.Builder(ctxt)
                .setSmallIcon(
                    android.R.drawable.stat_sys_download_done)
                .setContentTitle(ctxt.getString(R.string.title));

        return(builder);
    }

    @Override
    public void onReceive(Context ctxt, Intent i) {
        Bundle input=RemoteInput.getResultsFromIntent(i);

        if (input!=null) {
            CharSequence speech=input.getCharSequence(EXTRA_INPUT);

            if (speech!=null) {
                Log.d(getClass().getSimpleName(), speech.toString());
            }
            else {
                Log.e(getClass().getSimpleName(), "No voice response speech");
            }
        }
        else {
            Log.e(getClass().getSimpleName(), "No voice response Bundle");
        }

        NotificationCompat.Builder builder=
            buildNotificationBase(ctxt);

        NotificationManagerCompat
            .from(ctxt)
            .notify(RemoteInputReceiver.NOTIFY_ID, builder.build());
    }
}
```

(from [Notifications/RemoteInput/app/src/main/java/com/commonsware/android/remotinput/RemoteInputReceiver.java](#))

Here, we get what the user typed in via our designated extra (EXTRA_INPUT, as requested via the RemoteInput.Builder), which we can use as we see fit, such as logging it to LogCat.

However, we *also* have to update or cancel the Notification. Otherwise, that progress spinner will spin indefinitely. If the Notification still has value to the user after the RemoteInput, just update it, with or without another RemoteInput

(depending on whether one would now be needed). You might also show the user's input in the updated `Notification`. Or, if the `Notification` is no longer needed, just `cancel()` it. In this case, we raise a fresh `Notification` for this ID, just without the `RemoteInput` that the activity added.

Note that `setChoices()` on `RemoteInput` is ignored for regular device notifications. You can use this for Wear notifications to give the user a list of strings to choose from, as an alternative to voice recognition.

Also note that, as of N Developer Preview 2, `RemoteInput` works on the lockscreen. You can see this in action with the sample app — just leave the `Notification` up, then lock the device. Assuming you have some measure of security on the device, when you power on the screen again, you will get the lockscreen, and the `Notification` tile will appear. It will not visibly show any sign of remote input, but if you swipe it down, the remote input field will appear, and you can type in a message. Note, though, that the user can disable this in Settings, blocking remote input from the lockscreen.

As of N Developer Preview 3, you can call `setRemoteInputHistory()` on your `Builder` as well. This takes a `CharSequence` array, though many developers will elect to use a simple `String` array. This represents the inputs supplied by the user and accepted by your app, in reverse chronological order (first element in the array is the most recent input). Some of this history may be added automatically to the `Notification` when you raise the updated `Notification` containing this input history.

Notification Groups

Another concept introduced with Wear in mind was the notification group. With this, you create a summary `Notification`, along with detail `Notifications` for individual events. The quintessential example is an email app, with a summary `Notification` indicating the unread message count, and with detail `Notifications` for individual messages.

The idea for Wear was to allow the user to individually respond to the detail `Notifications` without having to pull out the associated phone or tablet. That phone or tablet would show the summary `Notification`, since the user could just tap on it and bring up the activity to see the detail.

For some reason, Google back-pedaled on that last part, as with Android N, phones and tablets will also show the summary-and-detail `Notification` hierarchy.

The [Notifications/Stacked](#) sample project, presented in [the chapter on advanced Notifications](#), demonstrates this without any modifications. Initially, the user just sees the summary:

Figure 986: Stacked Notification, Showing Summary

A two-finger swipe gesture will expose the full hierarchy:

Figure 987: Stacked Notification, Showing Hierarchy

Notifications and MessagingStyle

Android N offers a new `MessagingStyle` to the roster of expanded `Notification` styles. This one is designed for a chat-style presentation, where you supply a series

APPENDIX B: N DEVELOPER PREVIEW

of chat messages (person, timestamp, and message), and they are rendered in the Notification. It is designed to be used with the RemoteInput option described [earlier in this section](#), for the user to be able to participate in a chat without having to open up your activity.

As usual, there are two implementations of MessagingStyle:

- Notification.MessagingStyle is part of the N Developer Preview 3's SDK and requires you to build for Android N (e.g., compileSdkVersion 'N')
- NotificationCompat.MessagingStyle, from the Android Support libraries, for backwards compatibility

The [Notifications/Messaging](#) sample project demonstrates the use of the latter, along with the RemoteInput support from earlier.

While the RemoteInput and MessagingStyle from NotificationCompat will build and run on older devices, they do not work especially well. You simply get a do-nothing Notification action for the RemoteInput and no real context around the messages. As such, you only want to use these options on Android N devices, gracefully degrading to some other experience on older devices.

Also note that the NotificationCompat.MessagingStyle is from the v24 generation of the Android Support libraries, which at the time of this writing is still in beta:

```
apply plugin: 'com.android.application'

dependencies {
    compile 'com.android.support:support-v13:24.0.0-beta1'
}

android {
    compileSdkVersion 23
    buildToolsVersion "23.0.2"

    defaultConfig {
        minSdkVersion 21
        targetSdkVersion 23
    }
}
```

(from [Notifications/Messaging/app/build.gradle](#))

As with the RemoteInput sample, the MainActivity is here just to provide us with an easy way to get the Notification to appear on the screen. In this case, though, all we do is use NotificationManagerCompat to show a Notification built elsewhere:

APPENDIX B: N DEVELOPER PREVIEW

```
package com.commonware.android.messaging;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.app.NotificationManagerCompat;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        NotificationManagerCompat
            .from(this)
            .notify(RemoteInputReceiver.NOTIFY_ID,
                RemoteInputReceiver.buildNotification(this).build());

        finish();
    }
}
```

(from [Notifications/Messaging/app/src/main/java/com/commonware/android/messaging/MainActivity.java](#))

Our RemoteInputReceiver is more complex as a result:

```
package com.commonware.android.messaging;

import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.Bundle;
import android.support.v4.app.NotificationCompat;
import android.support.v4.app.NotificationManagerCompat;
import android.support.v4.app.RemoteInput;
import android.util.Log;
import java.util.Stack;

public class RemoteInputReceiver extends BroadcastReceiver {
    static final int NOTIFY_ID=1337;
    static final String EXTRA_INPUT="input";
    static final Stack<Message> MESSAGES=new Stack<>();
    static final long INITIAL_TIMESTAMP=System.currentTimeMillis();

    static NotificationCompat.Builder buildNotification(Context ctxt) {
        Intent i=new Intent(ctxt, RemoteInputReceiver.class);
        PendingIntent pi=
            PendingIntent.getBroadcast(ctxt, 0, i,
                PendingIntent.FLAG_UPDATE_CURRENT);

        RemoteInput remoteInput=
            new RemoteInput.Builder(RemoteInputReceiver.EXTRA_INPUT)
                .setLabel(ctxt.getString(R.string.talk))
                .build();

        NotificationCompat.Action remoteAction=
            new NotificationCompat.Action.Builder(
                android.R.drawable.ic_btn_speak_now,
                ctxt.getString(R.string.talk),
                pi).addRemoteInput(remoteInput).build();
    }
}
```

APPENDIX B: N DEVELOPER PREVIEW

```
NotificationCompat.MessagingStyle style=
    new NotificationCompat.MessagingStyle("Me")
        .setConversationTitle("A Fake Chat");

style.addMessage("Want to chat?", INITIAL_TIMESTAMP, "Somebody");

for (Message msg : MESSAGES) {
    style.addMessage(msg.text, msg.timestamp,
        style.getUserDisplayName());
}

NotificationCompat.Builder builder=
    new NotificationCompat.Builder(ctxt)
        .setSmallIcon(
            android.R.drawable.stat_sys_download_done)
        .setContentTitle(ctxt.getString(R.string.title))
        .setStyle(style)
        .addAction(remoteAction);

return(builder);
}

@Override
public void onReceive(Context ctxt, Intent i) {
    Bundle input=RemoteInput.getResultsFromIntent(i);

    if (input!=null) {
        CharSequence text=input.getCharSequence(EXTRA_INPUT);

        if (text!=null) {
            MESSAGES.push(new Message(text));
        }
        else {
            Log.e(getClass().getSimpleName(), "No voice response speech");
        }
    }
    else {
        Log.e(getClass().getSimpleName(), "No voice response Bundle");
    }

    NotificationManagerCompat
        .from(ctxt)
        .notify(RemoteInputReceiver.NOTIFY_ID,
            buildNotification(ctxt).build());
}

private static class Message {
    final CharSequence text;
    final long timestamp;

    Message(CharSequence text) {
        this.text=text;
        timestamp=System.currentTimeMillis();
    }
}
}
```

(from [Notifications/Messaging/app/src/main/java/com/commonsware/android/messaging/RemoteInputReceiver.java](#))

APPENDIX B: N DEVELOPER PREVIEW

For the `MessagingStyle`, we need messages. In a production app, this would be part of your app's data model, probably saved in a file or database somewhere, with an in-memory cache for speed. In this sample app, we just have a static `MESSAGES` Stack, for our messages. Initially, this Stack is empty, but we will eventually fill in `Message` objects, each of which has text and a timestamp. Since this is a sample app, and all `Message` objects will come from our app's user, we do not need `Message` to track the sender of the message — a real chat-style app would need this, in all likelihood.

The `buildNotification()` method starts off with the same basic code shown in the `RemoteInput` sample. But then, mid-way through the method, we build up the `MessagingStyle`:

```
NotificationCompat.MessagingStyle style=
    new NotificationCompat.MessagingStyle("Me")
        .setConversationTitle("A Fake Chat");

style.addMessage("Want to chat?", INITIAL_TIMESTAMP, "Somebody");

for (Message msg : MESSAGES) {
    style.addMessage(msg.text, msg.timestamp,
        style.getUserDisplayName());
}
```

(from [Notifications/Messaging/app/src/main/java/com/commonsware/android/messaging/RemoteInputReceiver.java](#))

The parameter to the `MessagingStyle` constructor is the name associated with the user of this app. That name will appear alongside messages that come from this user. A `MessagingStyle` can have a title, set via `setConversationTitle()`, to provide some context for the chat transcript.

We then add one fake message, ostensibly from the chat partner, via the `addMessage()` method. The version we use here takes the text, timestamp, and name of the other party to use in the message.

Then, if there are messages in the `MESSAGES` stack, we add those to the chat transcript as well. Note that our third parameter is `style.getUserDisplayName()`, which returns the value that we passed into the `MessagingStyle` constructor. According to the documentation, we could get the same effect by passing `null` for the third parameter. Alas, there is [a bug](#) that breaks that functionality, so we just pass in the name more directly.

That `MessagingStyle` then is attached to the `NotificationCompat.Builder` via `setStyle()`.

At the outset, since `MESSAGES` is empty, we get a single message from "Somebody":

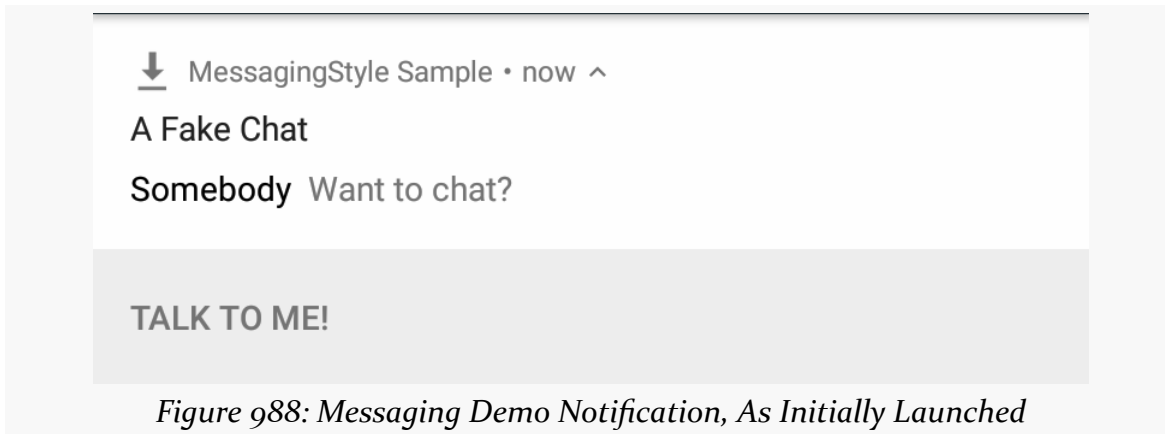

Figure 988: Messaging Demo Notification, As Initially Launched

If the user taps “Talk to Me”, types in a message, and clicks the send button, our `RemoteInputReceiver` will take that text, put it in a `Message`, push that `Message` into the `MESSAGES` Stack, then update the `Notification` with the new transcript:

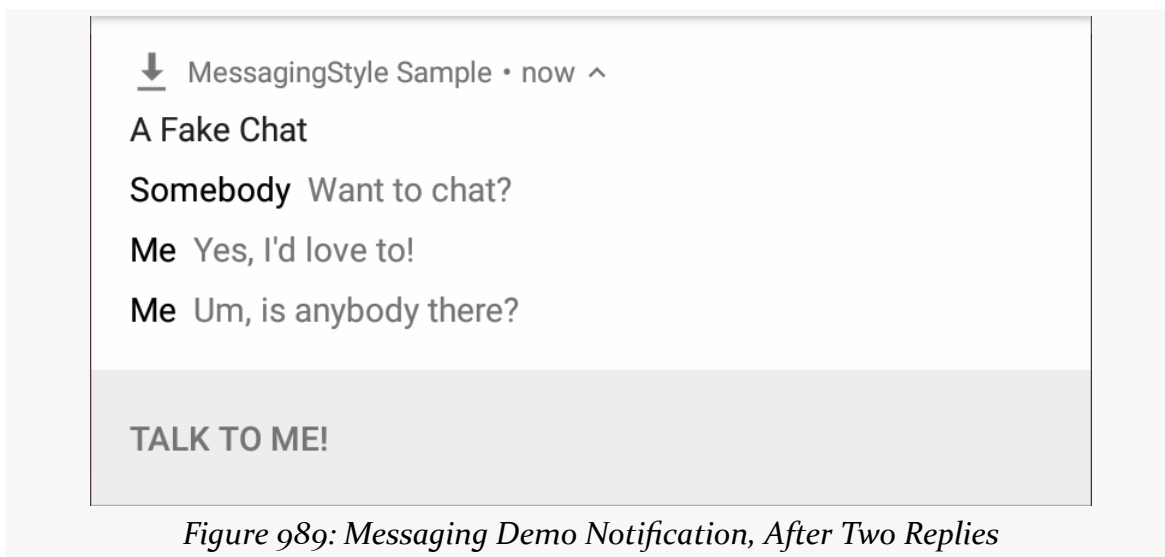

Figure 989: Messaging Demo Notification, After Two Replies

The timestamp does not show up; it is unclear how that is used by Android.

Notifications and Custom Views

A custom view for a `Notification` takes over the entire tile in the notification shade. Sometimes, this may be necessary to achieve the developer’s objective. Other times, though, while the main content area of the `Notification` might need to be custom, the rest of the “frame” around that content area could be left intact. This would

include things like the app's icon, the time the Notification was raised, any action buttons below the content, and so forth.

The N Developer Preview³ offers this via the `Notification.DecoratedCustomViewStyle` and `Notification.DecoratedMediaCustomViewStyle` styles. On your Builder, call `setCustomContentView()` with the RemoteViews for the content area, plus call `setStyle()`, passing in an instance of `DecoratedCustomViewStyle` or `DecoratedMediaCustomViewStyle`, to gain this effect.

Data Saver

Android has had a per-app “data saver” mode for some time, with an eye towards reducing bandwidth consumption when the device is using a known metered data plan. Android N extends this to a device-wide setting,

Apps can be in one of three states as a result:

- The device is normal
- The device is in data-saver mode
- The device is in data-saver mode, but your app is whitelisted by the user

The idea is that if the device is in normal mode, you can do what you want. If the device is in data-saver mode, you should restrict your bandwidth, even if the user whitelists you. Apps that are not whitelisted have no network access while in the background.

To that end, `ConnectivityManager` has three things for you.

First, `isActiveNetworkMetered()` will return `true` if the device is on a metered data connection, `false` otherwise. This has been around for years (API Level 16+), but has not been all that popular, apparently.

Second, Android N has a `getRestrictBackgroundStatus()` method on `ConnectivityManager`. This returns an `int` that resolves to one of three values:

- `RESTRICT_BACKGROUND_STATUS_DISABLED`
- `RESTRICT_BACKGROUND_STATUS_ENABLED`
- `RESTRICT_BACKGROUND_STATUS_WHITELISTED`

If `isActiveNetworkMetered()` is true, and `getRestrictBackgroundStatus()` returns `RESTRICT_BACKGROUND_STATUS_ENABLED`, any attempts to use the network may fail, and so your app should plan accordingly.

If you want to try to react in real-time to changes in the data-saver configuration, you can register a receiver for `ACTION_RESTRICT_BACKGROUND_CHANGED` (defined on `ConnectivityManager`). This will be broadcast for any change in data-saver settings, which means that *your* app's state may not have changed. You will need to call `getRestrictBackgroundStatus()` to find out your current state. Also note that this broadcast is only sent to receivers registered dynamically, via `registerReceiver()`. You cannot register for this broadcast in the manifest.

To try to get on the whitelist, you might be tempted to try using `ACTION_IGNORE_BACKGROUND_DATA_RESTRICTIONS_SETTINGS` to lead the user to add your app to the Data Saver whitelist, so you have normal background network access. However, bear in mind that Google has a similar feature for the battery saver whitelist... and trying to use *that* action [got apps banned from the Play Store](#). At the moment, there is no similar language around the use of the data saver whitelist... but, then again, they did not tell you they were going to ban you for asking to be on the battery saver whitelist until after Android 6.0 shipped.

Multi-Locale Support

Android N users can indicate that they support more than one language:

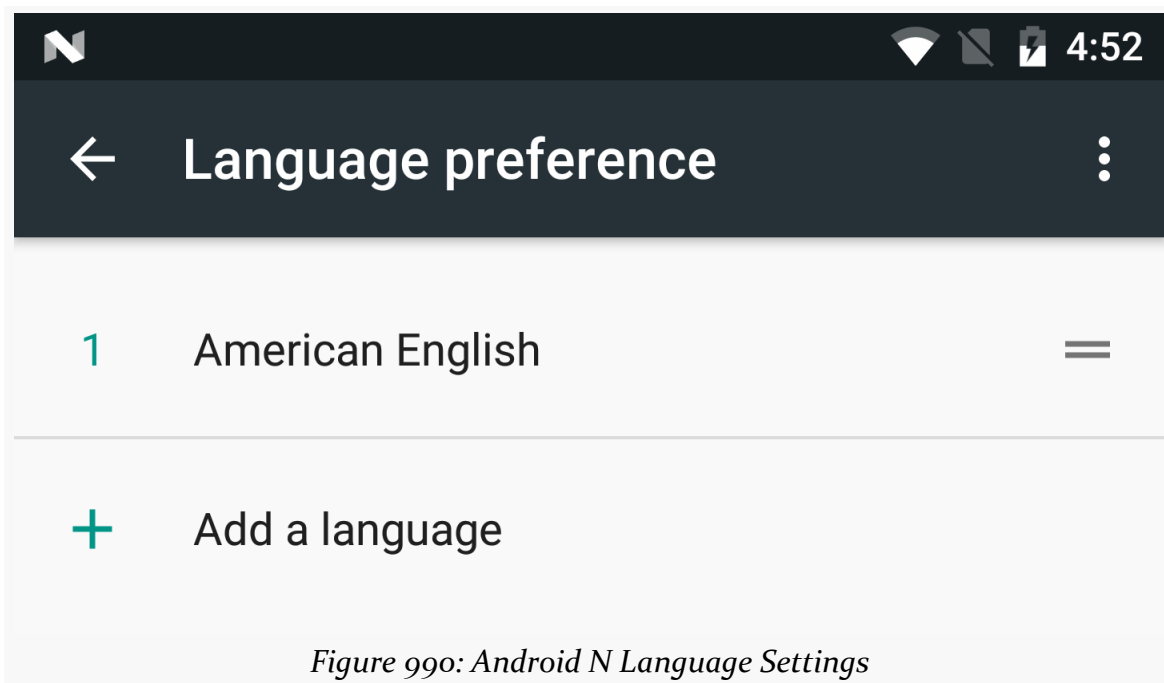

Figure 990: Android N Language Settings

The user can choose the relative priorities of these languages, by grabbing the handle on the right side of the row and dragging the language higher or lower in the list.

This has impacts on resource resolution for any locale-dependent resources, such as strings. Now Android will check multiple languages for resource matches, before falling back to the default language (e.g., whatever you have in `res/values/strings.xml`). Hence, it is important that you ensure that you have a complete set of strings for every language that you support, lest the user perhaps wind up with a mixed set of languages in the UI.

You can find out what languages the user has requested via a `LocaleList` class and its `getDefault()` static method. This, as the name suggests, has a list of `Locale` objects representing the user's preferred languages. If you had previously been using `Locale` alone for this (e.g., for specialized in-app language assistance beyond resources), you will want to switch to `LocaleList` for Android N and beyond.

JobScheduler

One long-standing challenge in Android is finding out when content changes in other apps. While `ContentObserver` is great for this purpose, you have to have a running process for it to work. As a result, some apps try desperately to keep a

process running all the time to find out about changes to foreign ContentProviders, tying up system RAM as a result.

JobScheduler — added in Android 5.0 as an alternative to AlarmManager for scheduled tasks — now has an option to effectively register a ContentObserver for you. You indicate the Uri to monitor, and it invokes your JobService when the data at that Uri changes. This way, you do not need to keep a process around.

To do that, you create a JobInfo.TriggerContentUri object, identifying what to monitor. You pass that to addTriggerContentUri() on your JobInfo.Builder, and schedule the resulting JobInfo with the JobScheduler as before.

For example, the [JobScheduler/Content](#) sample project asks JobScheduler to monitor the ContactsContract provider for new contacts.

MainActivity has virtually nothing to do with any of this, but instead goes through all the work to set up runtime permission access to the READ_CONTACTS permission:

```
package com.commonware.android.jobsched.content;

import android.app.Activity;
import android.content.pm.PackageManager;
import android.os.Bundle;
import android.support.v4.app.ActivityCompat;
import android.support.v4.content.ContextCompat;
import android.view.View;
import android.widget.Toast;
import static android.Manifest.permission.READ_CONTACTS;

public class MainActivity extends Activity {
    private static final String[] PERMS_ALL={
        READ_CONTACTS
    };
    private static final int RESULT_PERMS_INITIAL=1339;
    private static final String STATE_IN_PERMISSION=
        "com.commonware.android.jobsched.content.inPermission";
    private boolean isInPermission=false;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (savedInstanceState!=null) {
            isInPermission=
                savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
        }

        if (!isInPermission) {
            if (hasPermission(READ_CONTACTS)) {
                configureJob();
            }
            else {
```

APPENDIX B: N DEVELOPER PREVIEW

```
        isInPermission=true;
        ActivityCompat.requestPermissions(this, PERMS_ALL,
            RESULT_PERMS_INITIAL);
    }
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
}

@Override
public void onRequestPermissionsResult(int requestCode,
    String[] permissions,
    int[] grantResults) {

    boolean sadTrombone=true;

    isInPermission=false;

    if (requestCode==RESULT_PERMS_INITIAL) {
        if (hasPermission(READ_CONTACTS)) {
            configureJob();
            sadTrombone=false;
        }
    }

    if (sadTrombone) {
        Toast.makeText(this, R.string.msg_no_perm,
            Toast.LENGTH_LONG).show();
    }
}

private void configureJob() {
    Toast.makeText(this, R.string.msg_add,
        Toast.LENGTH_LONG).show();
    DemoJobService.schedule(this);
    finish();
}

private boolean hasPermission(String perm) {
    return(ContextCompat.checkSelfPermission(this, perm)==
        PackageManager.PERMISSION_GRANTED);
}
}
```

(from [JobScheduler/Content/app/src/main/java/com/commonsware/android/jobsched/content/MainActivity.java](#))

Eventually, though, if the user agrees to the permission, MainActivity calls a static `schedule()` method on `DemoJobService`, to set up the content monitor:

```
private static final int ME_MYSELF_AND_I=3493;
private static final int NOTIFY_ID=2343;

static void schedule(Context ctxt) {
    ComponentName cn=
```

APPENDIX B: N DEVELOPER PREVIEW

```
new ComponentName(ctxt, DemoJobService.class);
JobInfo.TriggerContentUri trigger=
new JobInfo.TriggerContentUri(CONTENT_URI,
    JobInfo.TriggerContentUri.FLAG_NOTIFY_FOR_DESCENDANTS);
JobInfo.Builder b=
new JobInfo.Builder(ME_MYSELF_AND_I, cn)
    .addTriggerContentUri(trigger);
JobScheduler jobScheduler=
    (JobScheduler)ctxt.getSystemService(Context.JOB_SCHEDULER_SERVICE);

jobScheduler.schedule(b.build());
}
```

(from [JobScheduler/Content/app/src/main/java/com/commonsware/android/jobsched/content/DemoJobService.java](#))

Here, we:

- Create a `ComponentName` identifying our `JobService`
- Create a `TriggerContentUri`, asking for `ContactsContract.Contacts.CONTENT_URI` (imported via `import static`), and asking to be notified about changes in any “descendants” (i.e., already-existing contacts)
- Pass those two values, plus a job ID, to `JobInfo.Builder`
- Get a `JobScheduler` via `getSystemService()`
- Build the `JobInfo` and `schedule()` it with the `JobScheduler`

The rest of `DemoJobService` handles the results, in this case just raising a `Notification`:

```
@Override
public boolean onStartJob(JobParameters params) {
    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this)
            .setAutoCancel(true)
            .setDefaults(Notification.DEFAULT_ALL)
            .setContentTitle("You added a contact!")
            .setSmallIcon(android.R.drawable.stat_notify_more);

    NotificationManager mgr=
        (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

    mgr.notify(NOTIFY_ID, b.build());

    return(false);
}

@Override
synchronized public boolean onStopJob(JobParameters params) {
    return(false);
}
```

(from [JobScheduler/Content/app/src/main/java/com/commonsware/android/jobsched/content/DemoJobService.java](#))

However, if we wanted, the `JobParameters` passed into `onStartJob()` contains information about what changed.

`getTriggeredContentAuthorities()` returns a `String` array of the names of the authorities whose changes triggered this job, if any. It will return `null` if the job triggered for some other reason, such as a deadline.

If `getTriggeredContentAuthorities()` returns a non-`null` value, then you can try calling `getTriggeredContentUriis()` to find out the specific `Uri` values that changed. However, this may be `null`, if there were too many changes to report (the limit is ~50).

Note that there are limitations on these content-monitoring jobs:

- They cannot be persisted, and so you need to re-request them after a reboot
- They cannot be periodic, though other job restrictions may still work (e.g., must be on a charger, must have a network connection)
- The job is a one-shot event — if you want continuous updates, you need to schedule a fresh job after this one is invoked (either with matches or due to hitting the deadline)

One problem with monitoring content for changes is that those changes may occur too frequently. In the N Developer Preview 3, you have two new `JobInfo.Builder` methods that you can use to manage this:

- `setTriggerContentUpdateDelay()` indicates how long after the last content change before the job will be invoked. For example, suppose that through some sort of sync operation, a provider that you are monitoring is updated 10 times within a second, then is quiet. By default, your job would be invoked 10 times. But, if you pass something like 3000 to `setTriggerContentUpdateDelay()`, your job would be invoked once, 3000 milliseconds after the last of that burst of updates.
- `setTriggerContentMaxDelay()` puts an upper bound for how long you are willing to wait before the job is invoked. If the provider is very busy, and your `setTriggerContentUpdateDelay()` counter keeps getting reset due to updates, it may be quite some time after the burst began before you finally have your job run. `setTriggerContentMaxDelay()` sets a limit for how long we will wait; if this time elapses, your job will be run even if updates are ongoing.

AlarmManager In-Process Alarms

AlarmManager now has in-process alarms. `set()`, `setExact()`, and `setWindow()` have versions that take an `OnAlarmListener` and call a callback method on it when the time arrives. Since the listener is an ordinary Java object, your process still has to be around. As a result, this new feature would be useful mostly for in-process time-based events, but not for cases where your process might go away with you still wanting those events.

For non-wakeup alarms, it is unclear what advantage this has over the standard Java `scheduledExecutorService()`. However, [a tweet from a Google engineer](#) suggests that this callback implementation may work for `_WAKEUP` alarms.

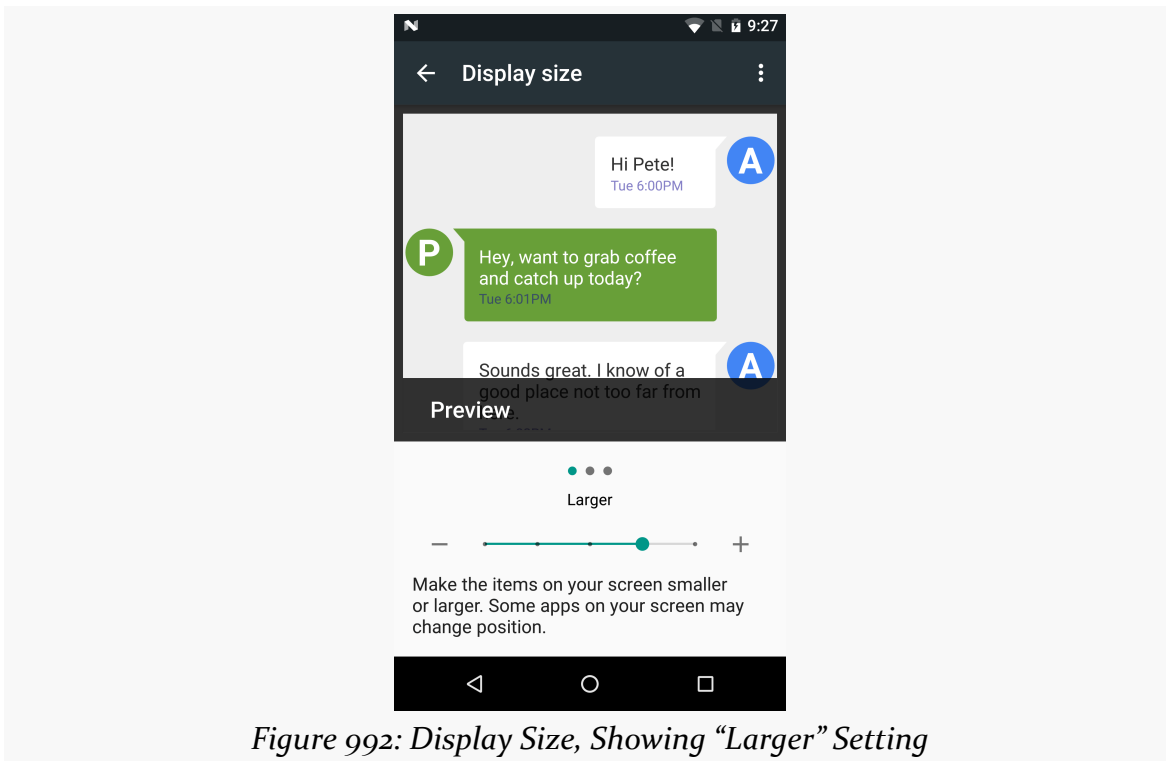

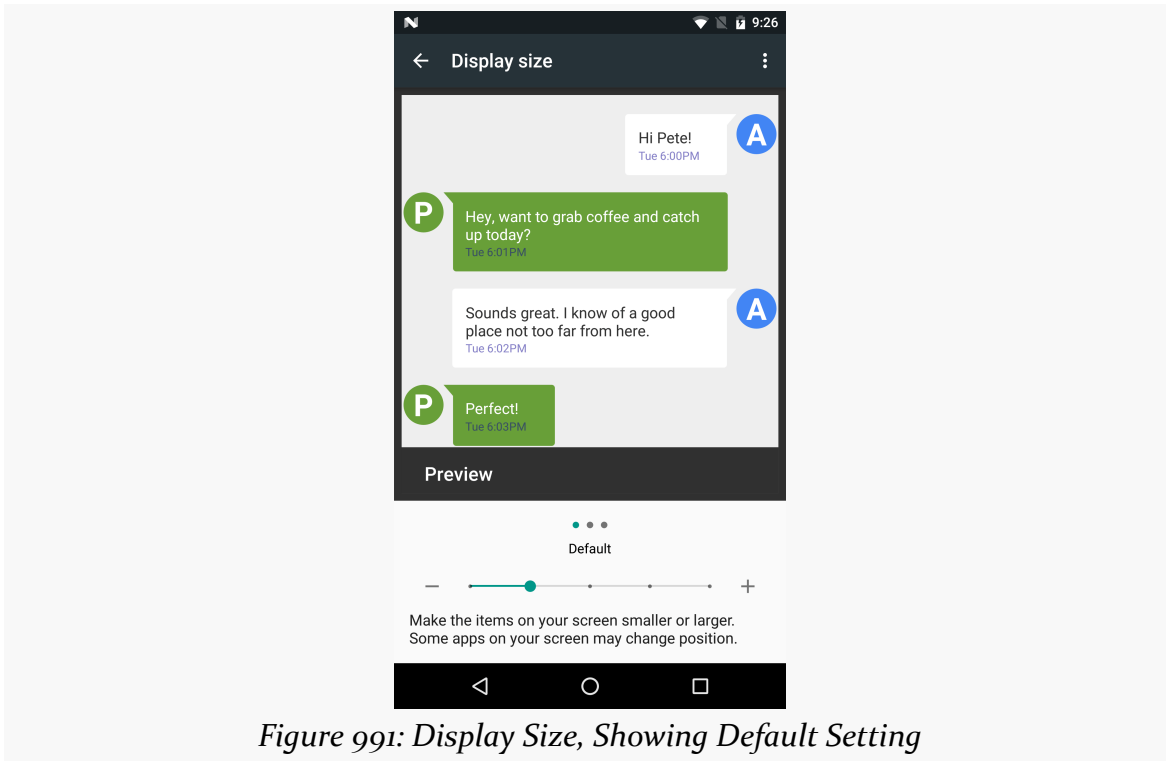

This topic will be explored in greater detail in an upcoming version of this book.

Screen Zoom/Dynamic Density

Developers have had the ability to change the effective density of a device, by [using adb commands](#). Now, users have a similar capability, courtesy of the N Developer Preview.

In Settings > Display > Display Size, the user can choose five different “display sizes”:

APPENDIX B: N DEVELOPER PREVIEW

While this is described to the user as a “size” or “zoom” setting, in reality it is affecting the apparent screen density, with Android scaling things based on a combination of actual density and the user’s stated “display size” preference.

Anything that is already density-independent should work just fine, though you certainly will want to run some tests to ensure that your app is working properly. In fact, this feature makes for a way to easily test your app on a variety of densities, without having to have dedicated hardware for those densities.

If your app is running at the time of the density change, what happens varies:

- Normally, if your `targetSdkVersion` is 23 or below, Android will terminate your process. Since you will be in the background at the time (Settings is in the foreground), this will be little different than if Android terminated your process due to low memory conditions, and your app should already handle this. The documentation suggests that if you have a foreground service, that Android will not terminate the process but instead treat this as a configuration change.
- If your `targetSdkVersion` is 'N' or higher, this will be treated as a configuration change for all processes. It is unclear what configuration change this will actually be, though (`fontScale`? `screenSize`? something new?)

For the configuration-change scenarios, if your app is caching information that depends on screen density, be sure to flush those caches and get fresh information based on the new screen density.

This topic will be explored in greater detail in an upcoming version of this book.

Quick Settings and `TileService`

Android 5.0 added “quick settings” tiles to the notification tray. The N Developer Preview allows developers to define their own tiles.

However, to paraphrase Marvel Comics, “with great power comes great need to actually think this through”.

Such tiles are only needed in cases where:

- You are doing background work that the user might need to configure

- You do not have a Notification tied to that background work, such as through a foreground service (as, in that case, they can and should interact with the Notification)

So, if your work is driven by things like AlarmManager, JobScheduler, or GCM, having your own custom tile may be reasonable. Similarly, if your app is serving as a bridge to some external hardware, via USB, Bluetooth, or other protocols, offering a tile may be useful.

However, [Google seems concerned](#) about the scenarios where this gets used:

Quick Settings tiles are reserved for controls or actions that are either urgently required or frequently used, and should not be used as shortcuts to launching an app.

Hence, be *very* judicious about where you use this capability, lest Google decide to start banning apps for having tiles that do not meet their intended use cases.

Assuming that you feel that your use case is valid, you can implement a `TileService` and publish a `Tile`. The `Tile` contains the icon and caption that will be shown to the user. You can find out when the tile is tapped (e.g., to start an activity to manage whatever the tile is showing) and arrange to update the tile if needed (e.g., reflecting changes in the state of the external hardware or your connection to it).

To see this in action, let's examine part of the [Introspection/SAWMonitorTile](#) sample project. This app uses a manifest-registered `BroadcastReceiver` to monitor for installations of apps and updates of apps. If an app is installed or updated, and that app has requested the `SYSTEM_ALERT_WINDOW` permission (and the app is not on a user-maintained whitelist), the app raises a `Notification`.

Other aspects of the original `Introspection/SAWMonitor` sample app can be found in [the chapter on advanced preferences](#).

While the `SAWMonitor` app works on older Android devices, `SAWMonitorTile` requires Android N, as it implements a `TileService`. This `TileService` enables and disables the monitoring. The user can also accomplish this through the `MainActivity` and its “enabled” `SwitchPreference`. However, since this app does not need an always-on `Notification`, offering the tile to the user gives the user flexibility to use the tile for rapidly enabling or disabling the monitor.

The Manifest Entry

Your app's manifest will need to have a `<service>` element pointing to your `TileService` subclass. That `<service>` element has some specific requirements, if you want your tile to work:

```
android:name=".ToggleTileService"
android:icon="@drawable/ic_new_releases_24dp"
android:label="@string/app_name_short"
android:permission="android.permission.BIND_QUICK_SETTINGS_TILE">
<intent-filter>
  <action android:name="android.service.quicksettings.action.QS_TILE" />
</intent-filter>
<meta-data
  android:name="android.service.quicksettings.ACTIVE_TILE"
  android:value="false" />
</service>
```

(from [Introspection/SAWMonitorTile/app/src/main/AndroidManifest.xml](#))

Specifically:

- It needs the `android.service.quicksettings.action.QS_TILE` `<intent-filter>`, so Android knows that you are publishing a tile
- It needs `android:permission="android.permission.BIND_QUICK_SETTINGS_TILE"`, so that only the system can bind to your service
- It needs the `android:label` and `android:icon` attributes, pointing to resources that will make up the default content of your tile
- Optionally, it can have the `<meta-data>` element, with a name of `android.service.quicksettings.ACTIVE_TILE`, and a boolean value indicating whether this tile is an “active tile” or not (more on this later)

Ordinarily, you could skip the label and icon, inheriting the values from the `<application>`. In this case, the tile's icon needs to more closely resemble a modern Notification icon: an alpha channel mask, not a full-color icon. Hence, most likely you would be overriding these attributes here anyway.

Your tile can be considered “active” or “passive”. The default is “passive”, where you will be told to update the tile's contents when the user slides open the notification shade. For most situations, this will be fine. But, it may be that you need to show real-time updates while that shade is open. In that case, you need an “active” update model. To opt into that, your `<service>` also needs the following child element:

```
<meta-data
  android:name="android.service.quicksettings.ACTIVE_TILE"
```

```
android:value="true" />
```

Then, elsewhere in your code, when the tile content needs to be updated, you can call the static `requestListeningState()` method on `TileService`, to tell Android that you want it to poll your active `TileService` for an update.

The Service

`ToggleTileService` extends `TileService` and is responsible for dynamically changing the tile and responding to clicks on the tile:

```
package com.commonware.android.sawmonitor;

import android.content.SharedPreferences;
import android.graphics.drawable.Icon;
import android.preference.PreferenceManager;
import android.service.quicksettings.Tile;
import android.service.quicksettings.TileService;

public class ToggleTileService extends TileService {
    private SharedPreferences prefs;

    @Override
    public void onStartListening() {
        super.onStartListening();

        updateTile();
    }

    @Override
    public void onClick() {
        super.onClick();

        boolean isEnabled=
            getPrefs()
                .getBoolean(SettingsFragment.PREF_ENABLED, false);

        getPrefs()
            .edit()
            .putBoolean(SettingsFragment.PREF_ENABLED, !isEnabled)
            .commit();
        updateTile();
    }

    private void updateTile() {
        Tile tile=getQsTile();

        if (tile!=null) {
            boolean isEnabled=
                getPrefs()
                    .getBoolean(SettingsFragment.PREF_ENABLED, false);
            int state=isEnabled ?
                Tile.STATE_ACTIVE :
                Tile.STATE_INACTIVE;
```

```
        tile.setIcon(Icon.createWithResource(this,
            R.drawable.ic_new_releases_24dp));
        tile.setLabel(getString(R.string.app_name_short));
        tile.setState(state);
        tile.updateTile();
    }
}

private SharedPreferences getPrefs() {
    if (prefs==null) {
        prefs=PreferenceManager.getDefaultSharedPreferences(this);
    }

    return(prefs);
}
}
```

(from [Introspection/SAWMonitorTile/app/src/main/java/com/commonsware/android/sawmonitor/ToggleTileService.java](https://github.com/CommonWare/android-sawmonitor/blob/master/src/main/java/com/commonsware/android/sawmonitor/ToggleTileService.java))

As with many specialized Service subclasses, the API that you need to implement and consume for a TileService does not bear much resemblance to the regular Service API. You are welcome to override `onCreate()` and `onDestroy()` if needed, though `ToggleTileService` did not really need either of those.

If and when the user adds your tile to their notification shade, by default, you will be called with `onStartListening()`. There is also a corresponding `onStopListening()`. In between those two events, the user has the notification shade open, and so if you have changes that you need to publish to the tile, you should do so. For example, you might register some sort of event listener in `onStartListening()` (e.g., for WiFi signal strength changes) and unregister that listener in `onStopListening()`. While the listener is registered, if there is an event that needs to be reflected in the tile, your TileService might update that tile.

In this case, `onStartListening()` just updates the tile with the current state, in the private `updateTile()` method. `getQsTile()` returns a Tile object representing the current tile state, which you can examine and modify as needed. `getQsTile()` will return null if you cannot update the tile right now, for whatever reason.

In the case of `ToggleTileService`, we want the tile to reflect the state of the enabled boolean value in `SharedPreferences`. So, we lazy-load the `SharedPreferences` and see what enabled is. From there, we derive a state value, choosing between `STATE_ACTIVE` and `STATE_INACTIVE`. There are three possible states to choose from:

- `STATE_ACTIVE` is the normal state, indicating that the tile should be displayed normally and should support click events

- `STATE_INACTIVE` is the same, except that the tile should be displayed in an “inactive” style (e.g., dimmed)
- `STATE_UNAVAILABLE` — the default state until you indicate otherwise – indicates that the tile is disabled and will not respond to click events

`ToggleTileService` then updates the `Tile` with that state, along with setting the icon and label. Those happen to be set to the same values as are defined in the manifest, so this work is superfluous and here only for illustration. Note that `setIcon()` takes an `Icon` object, which can be created from a wide range of sources, including resources and local files.

Once you have the `Tile` configured to your liking, call `updateTile()` to push the changes over to the system, which will update the tile in the notification shade to match.

If the user clicks on the tile, you will be called with `onClick()`, where you can take whatever action makes sense. In this case, we just want to update the `SharedPreferences` to toggle the `enabled` value, then update the tile to match.

The User Experience

When the user installs an app that has a `TileService`, the tile is not automatically put in the user’s notification shade. Instead, it *allows* the user to add the tile if the user wants to.

If the user opens the notification shade, an “Edit” button should appear:

APPENDIX B: N DEVELOPER PREVIEW

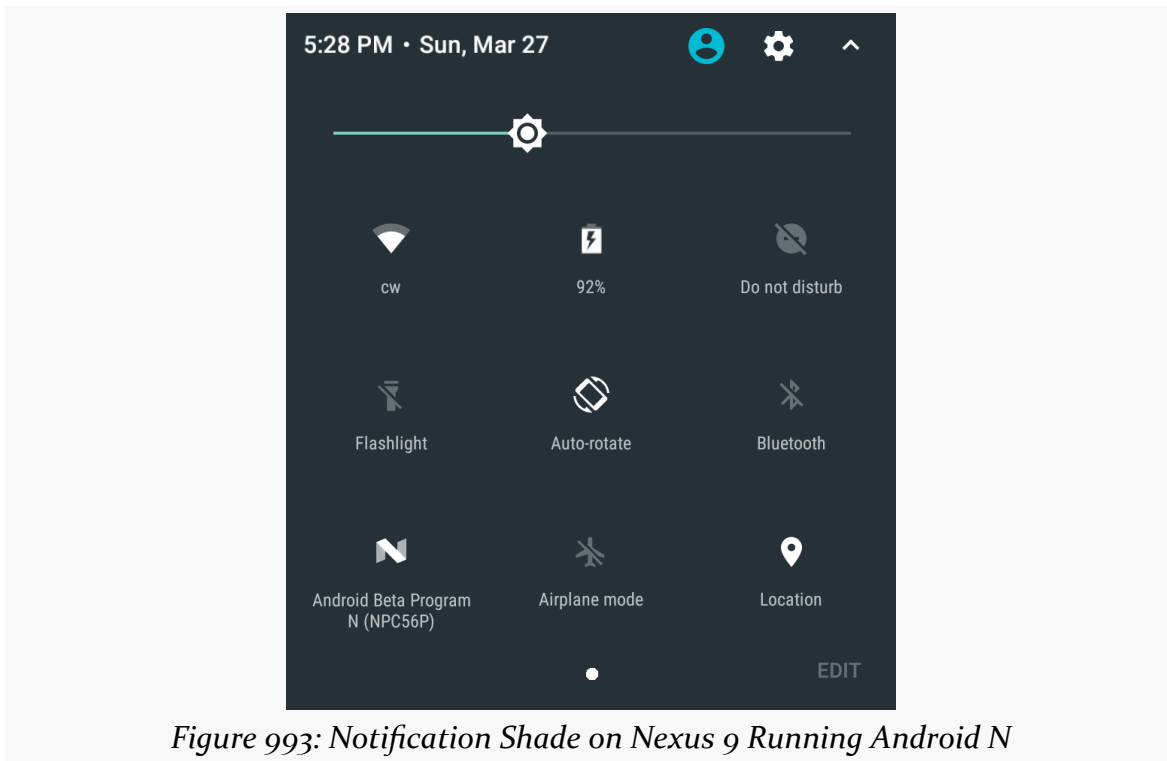

Figure 993: Notification Shade on Nexus 9 Running Android N

Tapping “Edit” brings up the tile roster editor:

APPENDIX B: N DEVELOPER PREVIEW

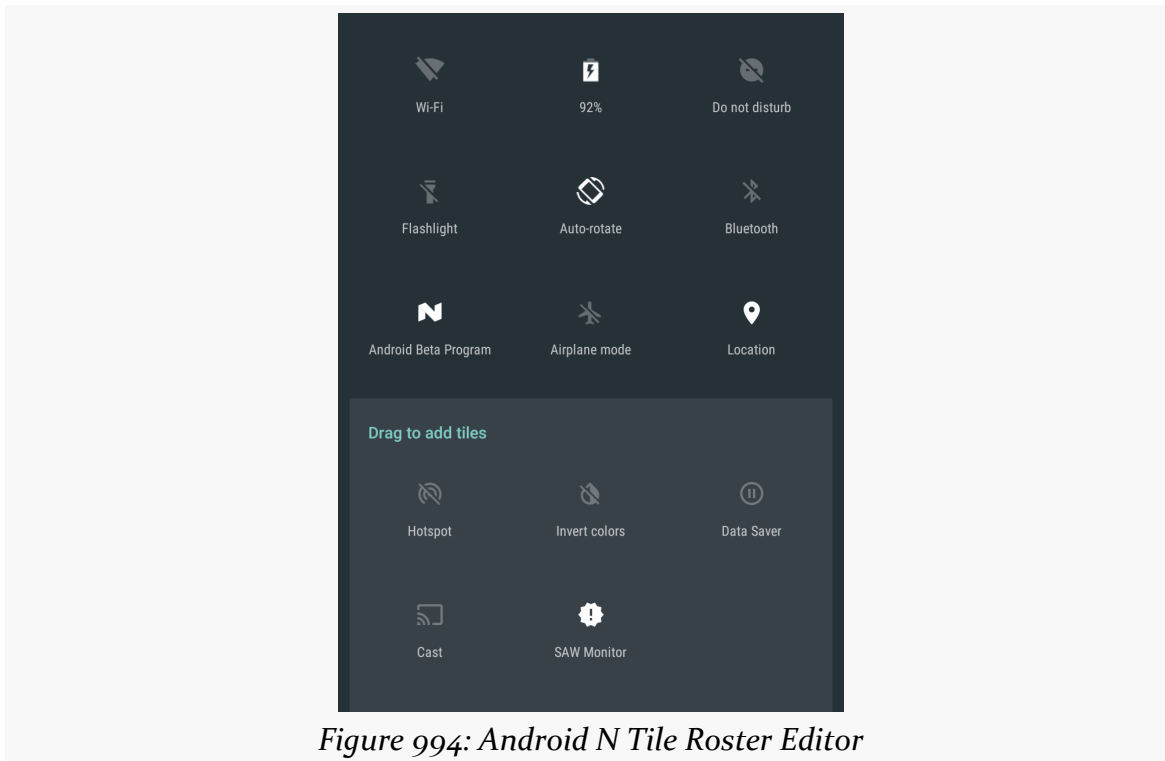

Figure 994: Android N Tile Roster Editor

The tile for the newly-installed app will appear. Since the `TileService` has never been invoked, the tile will display the icon and label from the `<service>` element.

The user can drag and drop from the “Drag to add tiles” area into the mock notification shade itself. Upon closing the editor, the new tile will appear in the notification shade

Figure 995: Notification Shade with SAW Monitor Tile

At this point, the tile should have been updated by the `TileService`. If the user later returns to the notification shade, the `TileService` will get another shot to update the tile via `onStartListening()`, and so forth.

If the user wants to, the user can return to the editor and drag the existing tile out of the mock notification shade back into the “Drag to add tiles” area, thereby removing it.

The Other Features and Limitations

Here are some other items of note related to tiles and `TileService`:

- You can determine if the device is locked by calling `isLocked()` on the `TileService`.
- You can respond to a tap on the tile by showing a dialog (`showDialog()`), launching an activity (`startActivityAndCollapse()`), or asking the user to unlock the device first (`unlockAndRun()`).
- If your tile may show sensitive data, `isSecure()` will tell you if your tile is visible in some “secure state” and therefore whether it is safe to show that sensitive data.

- Each `TileService` has only one tile. For most apps, this will be plenty. But, if for some reason your app needs multiple tiles, you will need multiple `TileService` implementations, one per tile.

Direct Boot

Sometimes, Android devices power down or are rebooted. This might be from explicit user action (e.g., holding down the POWER button), environmental factors (e.g., the battery ran out of power), or bugs (e.g., the device rebooted due to some system crash).

Classic full-disk-encryption on Android can lead to problems, as the user has to type in their password to decrypt the device. Sans password, the device does not boot very far.

Imagine that the device crashes and spontaneously reboots. Suppose that this happens overnight, while the user is sleeping. Further suppose that the user relies upon the device to wake up the user, via an alarm clock app. A full-disk-encrypted device cannot boot without a password, and a sleeping user will not be typing in a password. Hence, the alarm clock app does not run, causing the user to over-sleep and arrive late for work. This, in turn, causes the user to be fired.

The user will not be happy about this, unless the user really hated that job anyway.

The N Developer Preview appears to change the full-disk-encryption rules. By default, the files representing the OS and the apps (e.g., APKs) will be on a “device-encrypted store”, which does not require a user password to decrypt. Regular app data — what we developers think of as internal storage and external storage — resides in a “credential-encrypted store”, requiring a password (or fingerprint or whatever).

However, the N Developer Preview allows apps to store some data in the device-encrypted store, rather than the credential-encrypted store. Such apps can then have access to this data even before the user supplies the password to decrypt the credential-encrypted store. In the case of the alarm-clock app, the app could store details of upcoming alarms in the device-encrypted store, and therefore be able to wake up the user even without the credential-encrypted store being accessible.

This involves registering a `BroadcastReceiver` in the manifest for the `LOCKED_BOOT_COMPLETED` action, also having `android:encryptionAware="true"` on

the `<receiver>` element. This allows the app to get control after a reboot but before the credential-encrypted store is available.

To store data in the device-encrypted store, you call `createDeviceEncryptedStorageContext()` on a `Context` object for your app. This returns *another* `Context` object, one whose file access methods (e.g., `openFileInput()`) will point to the device-encrypted store.

Only use this store for non-sensitive data.

This topic will be explored in greater detail in an upcoming version of this book.

Frame Metrics API

In [the chapter on reducing jank](#), we looked at `gfxtrace`, which gives you a dump of information related to the rendering of your UI, including how much time is spent in different aspects of that work. However, `gfxtrace` is a device-wide data collection, and so there may be a bit of noise in the results due to other things being updated (Notification icons, other status bar icons, status bar clock, third-party app overlay views, etc.). Plus, `gfxtrace` itself represents a chunk of overhead, slowing down the device.

Android N gives us a frame metrics API. We can register a listener to find out the same sorts of information that `gfxtrace` reports, but only to our app, and in Java code. We can log that to LogCat, or do our own [diagnostic overlay](#), or cache it and later send it to a server for analysis. We can also elect to collect this data in our [instrumentation tests](#), to help detect a significant shift in our UI rendering performance.

What Data You Get

Unfortunately, there is virtually no documentation on the data that we get.

We will receive `FrameMetrics` objects, on which we can call `getMetric()` and provide the identifier of one of the specific metrics that we can retrieve. Note that `FrameMetrics` objects get recycled, so when your listener is handed one, you should copy the data you want out of it and save it somewhere else, rather than attempt to hold onto the `FrameMetrics` object itself. This pattern is used elsewhere in Android, such as with [sensors](#).

APPENDIX B: N DEVELOPER PREVIEW

Most of the metrics represent amounts of time, measured in nanoseconds, returned as long values:

Metric ID	Role
ANIMATION_DURATION	Time spent in animation callbacks
COMMAND_ISSUE_DURATION	Time spent issuing draw commands to the GPU
DRAW_DURATION	Time spent building display lists of commands
INPUT_HANDLING_DURATION	Time spent in input-handling callbacks
LAYOUT_MEASURE_DURATION	Time spent in <code>measure()</code> and <code>layout()</code> work for your view hierarchy
SWAP_BUFFERS_DURATION	Time spent sending the frame buffer for this frame to the display
SYNC_DURATION	Time spent synchronizing the display lists with the render thread
UNKNOWN_DELAY_DURATION	Time spent waiting for the UI thread to process the frame

There is also `TOTAL_DURATION`, which should match the sum of the above values. And, there is `FIRST_DRAW_FRAME`, which returns a boolean value encoded as a long (0 for false, 1 for true), indicating whether this frame was the first to draw in a new window layout.

Developers with deep understanding of the graphics rendering pipeline in Android may recognize these values. For everybody else, the objective is for them to be as low as possible, and for the sum to be well under the 16ms (16,000,000ns) we have for a frame.

How You Get That Data

As with many things in the N Developer Preview, [the documentation is inconsistent and sometimes at odds with Android Studio's Lint mechanism](#). Hence, when you import the `Jank/FrameMetrics` sample project, do not be shocked to find a bunch of errors show up in Android Studio when examining `MainActivity`. The project builds and runs successfully (honest!).

Mostly, this sample app is another variation on the “show a list of videos in a `RecyclerView`” sample that was profiled in [the chapter on RecyclerView](#) and elsewhere.

This time, though, we have a menu resource:

APPENDIX B: N DEVELOPER PREVIEW

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/record"
    android:icon="@drawable/ic_record_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_record" />
  <item
    android:id="@+id/stop"
    android:icon="@drawable/ic_stop_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_stop"
    android:visible="false" />
</menu>
```

(from [Jank/FrameMetrics/app/src/main/res/menu/actions.xml](#))

It defines two action bar items: one to record frame metrics, and one to stop the recording, whether the latter is initially invisible.

In MainActivity, we inflate that menu resource, find those two action items, and hold onto them in fields, via onCreateOptionsMenu():

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    record=menu.findItem(R.id.record);
    stop=menu.findItem(R.id.stop);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameetrics/MainActivity.java](#))

In onOptionsItemSelected(), when one of those two is tapped, we invert their visibilities, so when the user taps record, the stop item appears, and vice versa:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.record) {
        record.setVisible(false);
        stop.setVisible(true);
        afm=new AggregateFrameMetrics();
        getWindow()
            .addOnFrameMetricsAvailableListener(this,
                new Handler(handlerThread.getLooper()));

        return(true);
    }
    else if (item.getItemId()==R.id.stop) {
        record.setVisible(true);
        stop.setVisible(false);
        getWindow().removeOnFrameMetricsAvailableListener(this);
        afm.log(getClass().getSimpleName());
        afm=null;
    }
}
```

APPENDIX B: N DEVELOPER PREVIEW

```
    return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameetrics/MainActivity.java](#))

However, in addition, when the user taps record, we:

- Create an instance of an `AggregateFrameMetrics` class and hold onto it in a field (`afm`)
- Call `addOnFrameMetricsAvailableListener()` on the activity's `Window`, passing in a `Window.OnFrameMetricsAvailableListener` implementation (here, our `MainActivity` itself) and a `Handler` on which we want to have that listener's callback method be invoked (here, a `Handler` tied to a `HandlerThread` created when the activity is created)

The result is that when the user taps record, our activity's `onFrameMetricsAvailable()` method will be called on that `HandlerThread`, providing us with metrics on the just-completed frame:

```
@Override
public void onFrameMetricsAvailable(Window window,
                                   FrameMetrics frameMetrics,
                                   int droppedEvents) {
    afm.add(frameMetrics, droppedEvents);
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameetrics/MainActivity.java](#))

`onFrameMetricsAvailable()` is passed three parameters:

- the `Window` which we registered for metrics on
- the `FrameMetrics` for that frame
- an `int` indicating how many `onFrameMetricsAvailable()` calls were missed because we took too long in the last `onFrameMetricsAvailable()` call processing the previous results (ideally, this is always 0)

Here, we pass the metrics and dropped-events values to the `AggregateFrameMetrics` object.

Back up in `onOptionsItemSelected()`, if the user taps on stop, we remove our activity as a listener via `removeOnFrameMetricsAvailableListener()` and call `log()` on the `AggregateFrameMetrics` object.

APPENDIX B: N DEVELOPER PREVIEW

`AggregateFrameMetrics`, in turn, is responsible for maintaining a running total of the various individual metrics and dumping them to LogCat when `log()` is called:

```
package com.commonware.android.jank.frameMetrics;

import android.util.Log;
import android.view.FrameMetrics;

public class AggregateFrameMetrics {
    int droppedReports;
    long animationDuration;
    long commandIssueDuration;
    long drawDuration;
    long inputHandlingDuration;
    long layoutMeasureDuration;
    long swapBuffersDuration;
    long syncDuration;
    long unknownDelayDuration;
    long totalDuration;

    void add(FrameMetrics metrics, int droppedReports) {
        this.droppedReports+=droppedReports;

        animationDuration+=
            metrics.getMetric(FrameMetrics.ANIMATION_DURATION);
        commandIssueDuration+=
            metrics.getMetric(FrameMetrics.COMMAND_ISSUE_DURATION);
        drawDuration+=metrics.getMetric(FrameMetrics.DRAW_DURATION);
        inputHandlingDuration+=
            metrics.getMetric(FrameMetrics.INPUT_HANDLING_DURATION);
        layoutMeasureDuration+=
            metrics.getMetric(FrameMetrics.LAYOUT_MEASURE_DURATION);
        swapBuffersDuration+=
            metrics.getMetric(FrameMetrics.SWAP_BUFFERS_DURATION);
        syncDuration+=metrics.getMetric(FrameMetrics.SYNC_DURATION);
        unknownDelayDuration+=
            metrics.getMetric(FrameMetrics.UNKNOWN_DELAY_DURATION);
        totalDuration+=metrics.getMetric(FrameMetrics.TOTAL_DURATION);
    }

    void log(String tag) {
        Log.d(tag, String.format("animation: %dns", animationDuration));
        Log.d(tag, String.format("command issue: %dns", commandIssueDuration));
        Log.d(tag, String.format("draw: %dns", drawDuration));
        Log.d(tag, String.format("input handling: %dns", inputHandlingDuration));
        Log.d(tag, String.format("layout measure: %dns", layoutMeasureDuration));
        Log.d(tag, String.format("swap buffers: %dns", swapBuffersDuration));
        Log.d(tag, String.format("sync: %dns", syncDuration));
        Log.d(tag, String.format("unknown: %dns", unknownDelayDuration));
        Log.d(tag, String.format("total: %dns", totalDuration));
        Log.d(tag, String.format("%d dropped reports", droppedReports));
    }
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonware/android/jank/frameMetrics/AggregateFrameMetrics.java](#))

The net effect is that between taps on record and stop, we collect information about the UI rendering performance. If you try this on a device that has a bunch of videos on it, scroll through the list while the collection is ongoing. Once you click stop to end the collection, the aggregated results are printed to LogCat.

Keyboard Shortcuts API

Android N also offers a system-wide keyboard shortcuts dialog, accessible via a single keyboard shortcut (described as `Alt-/` in the documentation). This shows both system-wide shortcuts and ones unique to your app. You can override `onProvideKeyboardShortcuts()` in your Activity to add your own shortcuts to the dialog, to help the user learn what is available in your app.

This dialog is covered in greater detail in [the chapter on keyboard and mouse support](#).

Changes to `post()` on View

View offers `post()` and `postDelayed()` methods, as does Handler. This book generally demonstrates the use of the ones on View, as you pretty much always have a widget available, so there is little sense in creating a Handler instance just for `post()` and `postDelayed()`. However, NDP3 makes a slight change here:

If an app posts Runnable tasks to a View, and the View is not attached to a window, the system queues the Runnable task with the View; the Runnable task does not execute until the View is attached to a window.

For a lot of uses of `post()`, this will not be a problem. `postDelayed()` might get more interesting, particularly if you are using a “`postDelayed()` loop” (`postDelayed()` invoking a Runnable that calls `postDelayed()` to schedule itself again). That loop will only work so long as the View you are using is attached to a Window. If you are concerned about this, beyond testing your existing implementation, you might consider switching to a Handler instance for `postDelayed()`.

Other Differences of Note

Here are some other things that are changing in Android N that you may wish to be aware of:

APPENDIX B: N DEVELOPER PREVIEW

- The `java.*` and `javax.*` classes in Android are being replaced. Their implementations through Android 6.0 originated with Apache Harmony, though many classes were patched over the years. Android N swaps in the equivalent classes from the OpenJDK. In theory, this should not be an issue, as they should be compatible. That being said, there may be bugs that get introduced, particularly if developers used reflection to get at the innards of these classes.
- Doze mode, introduced in Android 6.0, is being expanded. Originally, it only took effect when the device was not moving, with the classic example being of the device sitting on a nightstand overnight. Now, Doze mode will kick in partially even while the device is moving, restricting background jobs. However, it appears that outstanding `WakeLocks` will be honored in this light mode. On the whole, relying upon background work is becoming less reliable.
- If you have been listening for `ACTION_NEW_PICTURE` or `ACTION_NEW_VIDEO` broadcasts, those are no longer being sent on Android N.
- `CONNECTIVITY_ACTION` is now restricted to apps that register via `registerReceiver()`; you cannot register for this broadcast via the manifest. Google recommends that you use the `NetworkRequest` approach anyway, at least on Android 5.0+.
- All the classic JUnit test case base classes, like `ActivityInstrumentationTestCase2` and `ActivityTestCase`, are officially deprecated. If you have not done so already, budget time in the next year or so to move over to the JUnit4 testing support.
- If you have been using `inPreferQualityOverSpeed` on `BitmapFactory.Options`, that is now deprecated. The docs state that on N the flag is ignored because “the output will always be high quality”.
- We now have `commitNow()` as an option, for executing a synchronous `FragmentManager.commit()`, by contrast, is asynchronous.
- The `android.webkit` package now has `ServiceWorker`-related classes.
- `WebSettings` has a `setDisabledActionModeMenuItems()`, suggesting that you can block some of the standard cut/copy/paste operations, which is particularly useful if they interfere with the Web content that you are rendering.
- `shouldOverrideUrlLoading(WebView, String)` on `WebViewClient` is deprecated, replaced with `shouldOverrideUrlLoading(WebView, WebResourceRequest)`.
- `AbsSeekBar` supports tick marks, mostly for the benefit of `SeekBar`, presumably.
- `Chronometer` supports a countdown mode, including in app widgets via `RemoteViews`.

- The week number feature on `CalendarView` is now deprecated.
- The embedded `CalendarView` in `DatePicker` is now deprecated and is “not supported by Material-style calendar mode”.
- Some options that we have on `JobScheduler`, such as “only while charging”, and “only while idle”, are now available on `DownloadManager` via methods on `DownloadManager.Request`.
- There is now an `ACTION_SHOW_APP_INFO` Intent action, to “launch an activity showing the app information”. This appears to be tied to the Play Store and other app installation channels, suggesting that you can use this to display information about apps that are not yet installed.
- If you create an `ACTION_CHOOSER` Intent directly (rather than via the `createChooser()` helper method), you can add `EXTRA_EXCLUDE_COMPONENTS` to list particular components that should be excluded from the list of choices. This is very handy for cases where you have your own activity that handles some implicit Intent, but you specifically want to open some `Uri` in any other activity handling that type of content. For example, perhaps you are having difficulty rendering the content, and you want to allow the user to try viewing that content in a third-party app.
- `stopForeground()` on `Service` is being migrated from taking a boolean (whether or not to remove the Notification) to an int, with `STOP_FOREGROUND_REMOVE` and `STOP_FOREGROUND_DETACH` options.
- A new `android.view.PixelCopy` method allows you to asynchronously(?) copy the contents of a `Surface` to a `Bitmap`, with a callback when that work is completed.

Backwards Compatibility

In an ideal world, we would develop apps for Android N using the standard approaches for backwards compatibility:

- setting `minSdkVersion` to the lowest that we support
- using `Build.VERSION.SDK_INT` and the appropriate `Build.VERSION_CODES` value to gracefully degrade on older devices
- testing our app on both old and new devices

When Android N ships in final form, presumably we will be able to do all of that.

However, the N Developer Preview follows in the footsteps of prior developer previews, making it difficult to test apps properly.

Am I On N?

To gracefully degrade on pre-N devices, we need to know whether or not we are running on N. In theory, you would use something like this:

```
if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.N) {  
    // do something N-specific  
}
```

Alas, this does not work, as in the N Developer Preview:

- Build.VERSION.SDK_INT is 23, the same value as for Android 6.0
- Build.VERSION_CODES.N is 10000

Following the approach that Google used for the M Developer Preview, you can check Build.VERSION.CODENAME instead:

```
public static boolean iCanHazN() {  
    return("N".equals(Build.VERSION.CODENAME));  
}
```

Later on, if and when Build.VERSION.SDK_INT and Build.VERSION_CODES.N start behaving properly, you can replace your utility method implementation with one that compares the versions more traditionally.

Getting Help

[The official documentation for the N Developer Preview](#) is available for you.

Note, though, that this does not include JavaDocs. You need to [download those to your development machine](#), as Google does not host them.

If you run into questions, there is [an android-n tag on Stack Overflow](#). You are also welcome to try [a Google+ community for the N Developer Preview](#).

If you have encountered a reproducible bug related to the N Developer Preview, [file an issue](#), including the code and steps necessary to reproduce the problem.

Appendix C: Community Theater and the Appinars

In addition to the book chapters themselves and [the related source code for the sample apps](#), you also have access to “appinars”. Appinars are app-based training, blending video, slides with voiceovers, source code samples, and more.

The APK edition of the book has an embedded appinar player, called Community Theater, along with an embedded roster of available appinars. You can browse through those appinars, download the ones of interest, and play them through Community Theater.

Note that this feature is only available if you are using the APK edition on Android 4.4 or higher.

Viewing the Appinar Roster

In the main book reader, the action bar overflow has a “Community Theater” option:

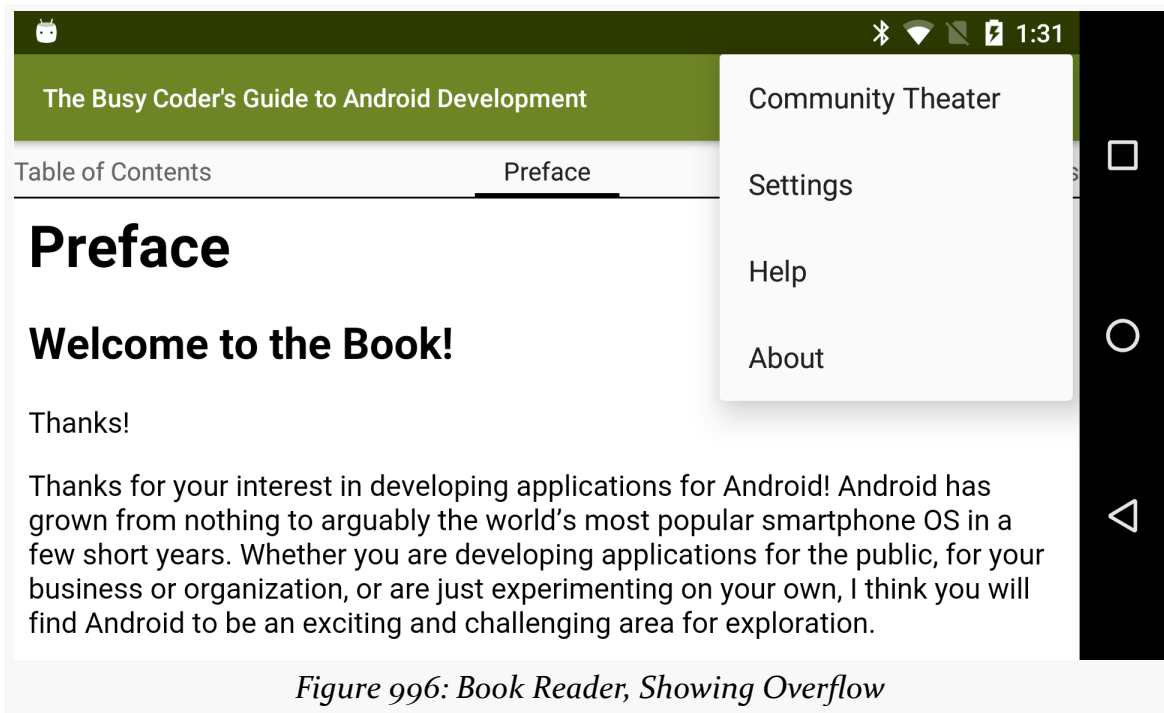

Figure 996: Book Reader, Showing Overflow

Tapping that will bring up a roster of available appinars, broken down into categories:

APPENDIX C: COMMUNITY THEATER AND THE APPINARS

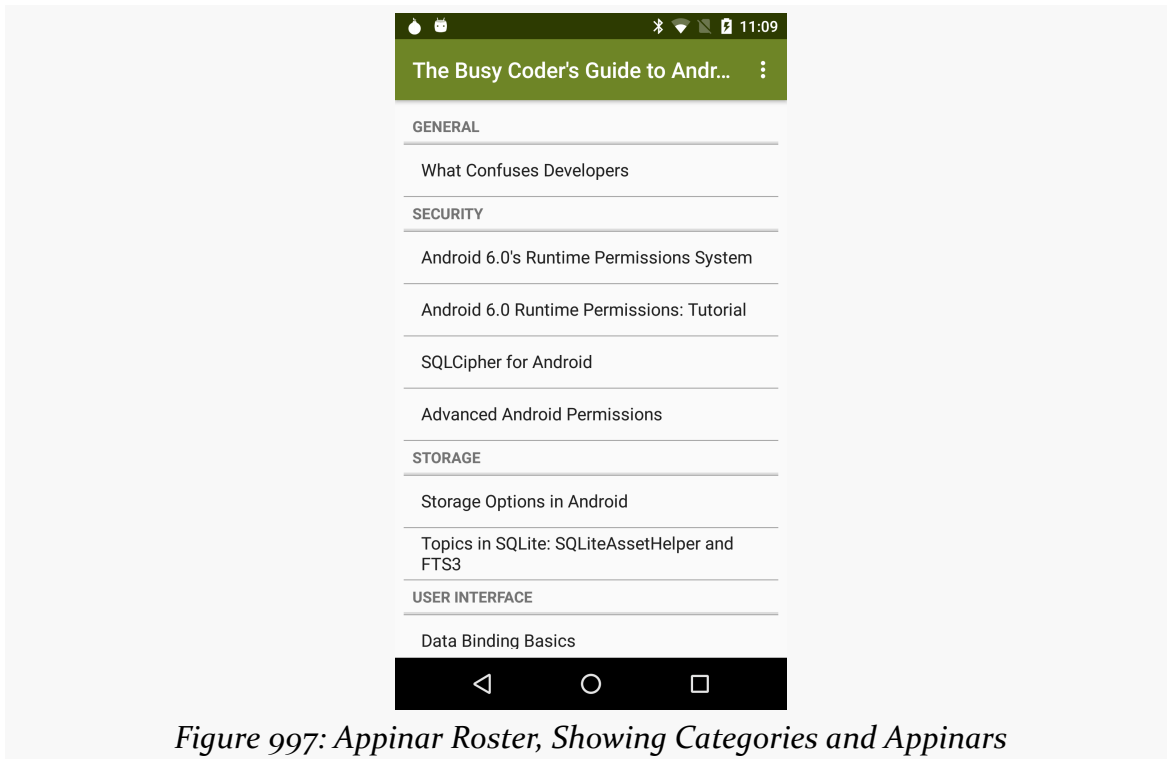

Figure 997: Appinar Roster, Showing Categories and Appinars

Tapping an appinar brings up details for that appinar:

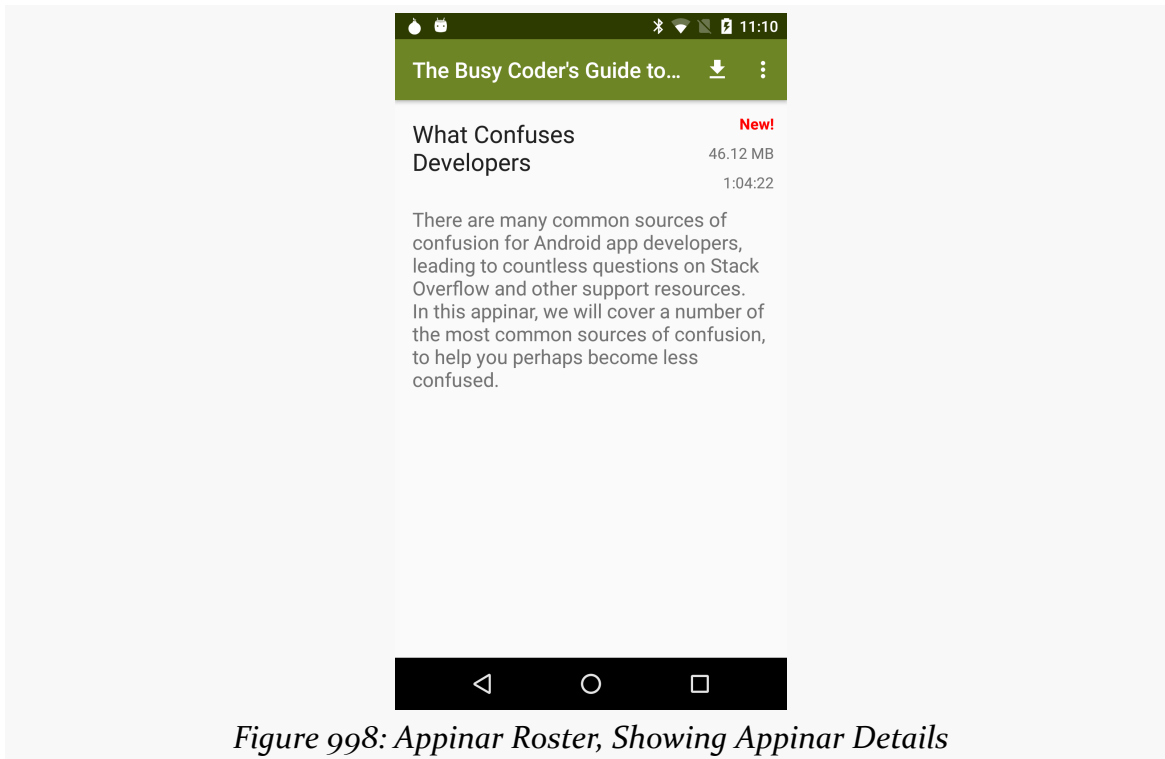

Figure 998: Appinar Roster, Showing Appinar Details

New appinars will be added with each book update. Existing appinars might be updated to reflect new content or to fix egregious bugs.

Managing Appinars

Tapping the “download” action bar item will download the appinar to your machine. The approximate amount of data to be downloaded, in the form of a ZIP file, is shown above the button.

While the download is going on, an progress bar will be visible in the appinar detail screen, as well as in a notification:

APPENDIX C: COMMUNITY THEATER AND THE APPINARS

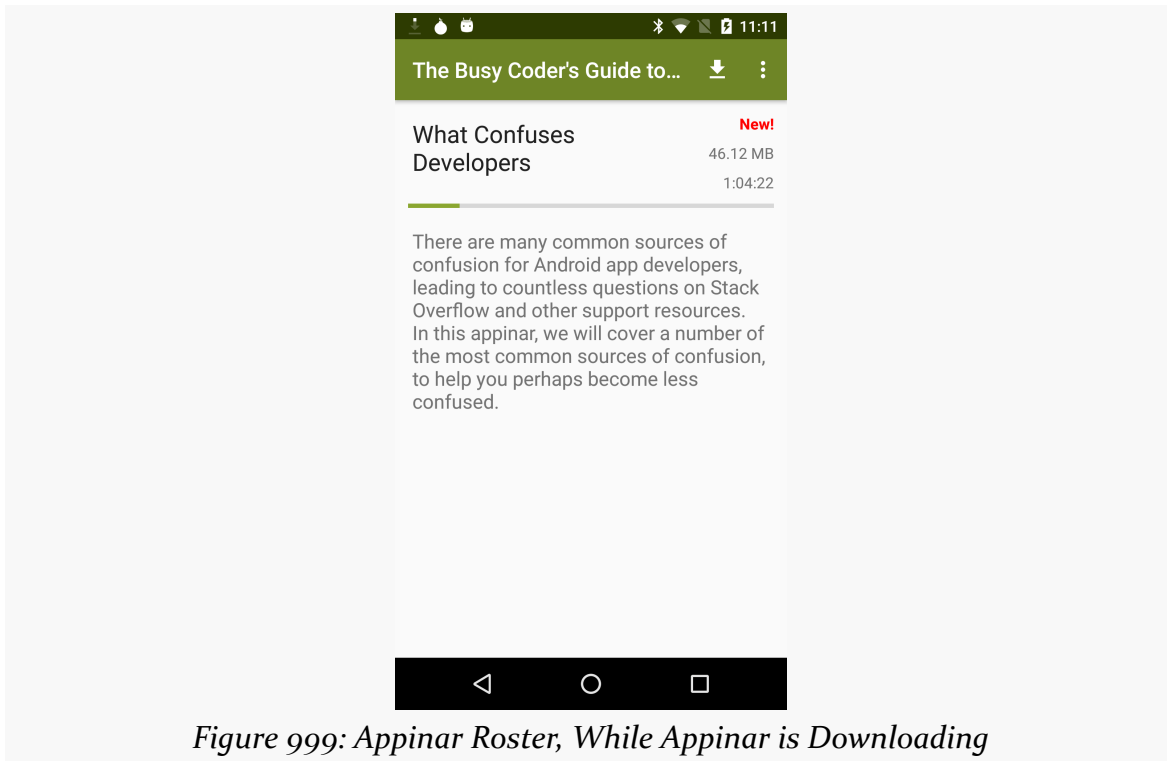

Figure 999: Appinar Roster, While Appinar is Downloading

Once the appinar is downloaded, the action bar will have options to play or delete the appinar:

APPENDIX C: COMMUNITY THEATER AND THE APPINARS

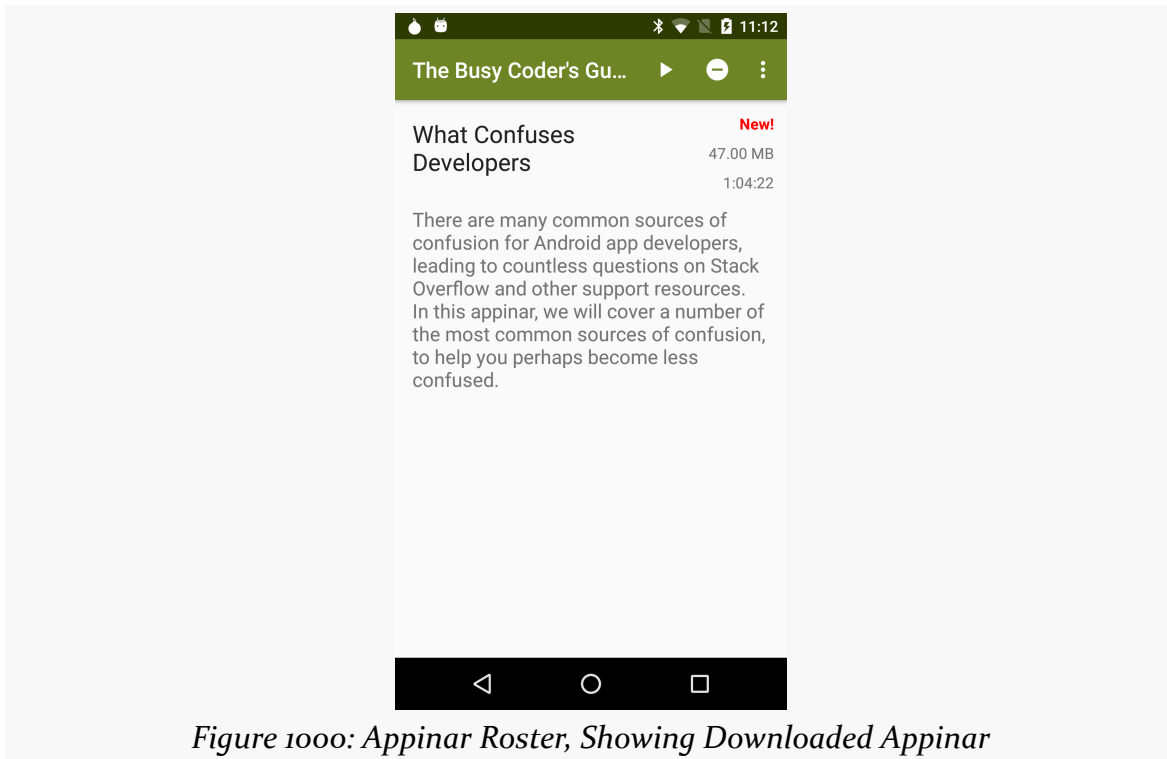

Figure 1000: Appinar Roster, Showing Downloaded Appinar

Tapping the delete action bar item will bring up a confirmation panel:

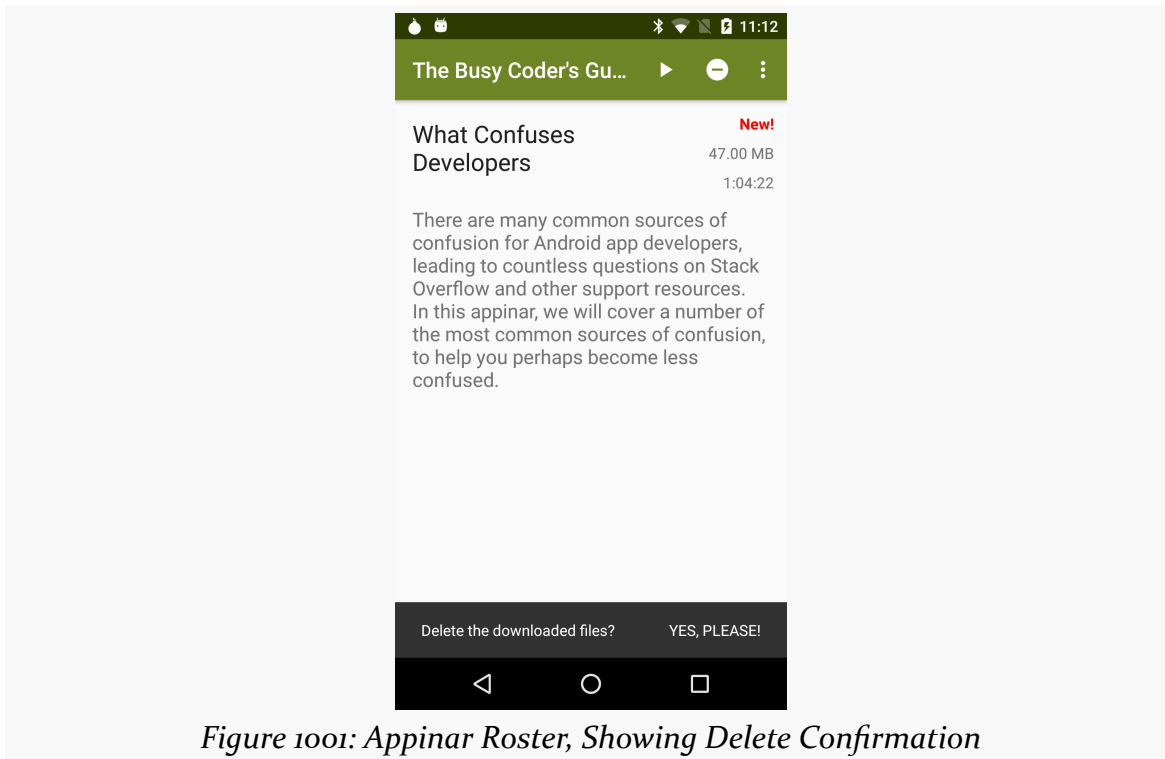

Figure 1001: Appinar Roster, Showing Delete Confirmation

If you confirm the request, the appinar will be deleted.

Viewing an Appinar

Viewing an appinar is merely a matter of downloading it, then tapping the play button in the action bar. Playback should begin immediately, usually with a title slide followed by a brief opening video:

Figure 1002: Player Screen, Showing a Balding Guy

Eventually, when the appinar ends, you will be taken back to the roster of available appinars, where you were when you tapped the play button originally.

Note that while you can view the roster in portrait or landscape mode, playback is locked to landscape, due to the aspect ratio of the videos.

Pausing Playback

If you double-tap the screen while an appinar is playing, playback will be paused. The action bar will appear at the top of the screen, allowing you to [navigate through the appinar](#) and so on.

To resume playback, press the BACK button, or double-tap the screen again.

Navigating the Appinar

When playback is paused via a double-tap, and the action bar is visible, you can open a navigation drawer, via the “hamburger” icon in the action bar:

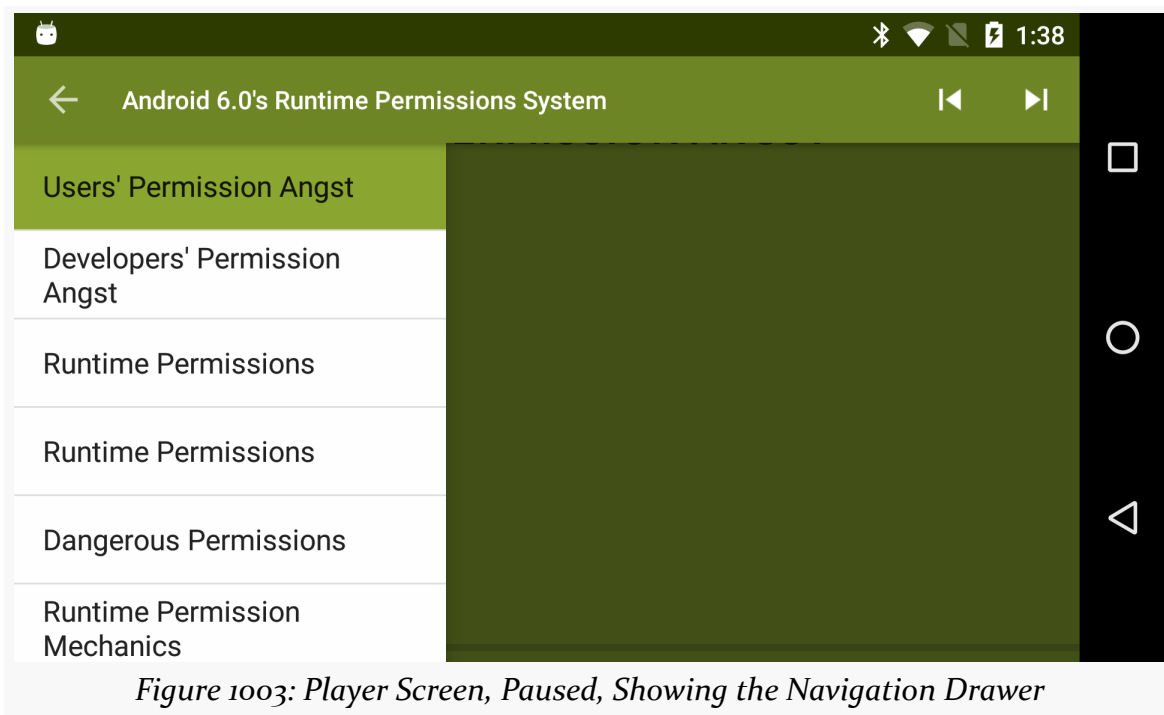

Figure 1003: Player Screen, Paused, Showing the Navigation Drawer

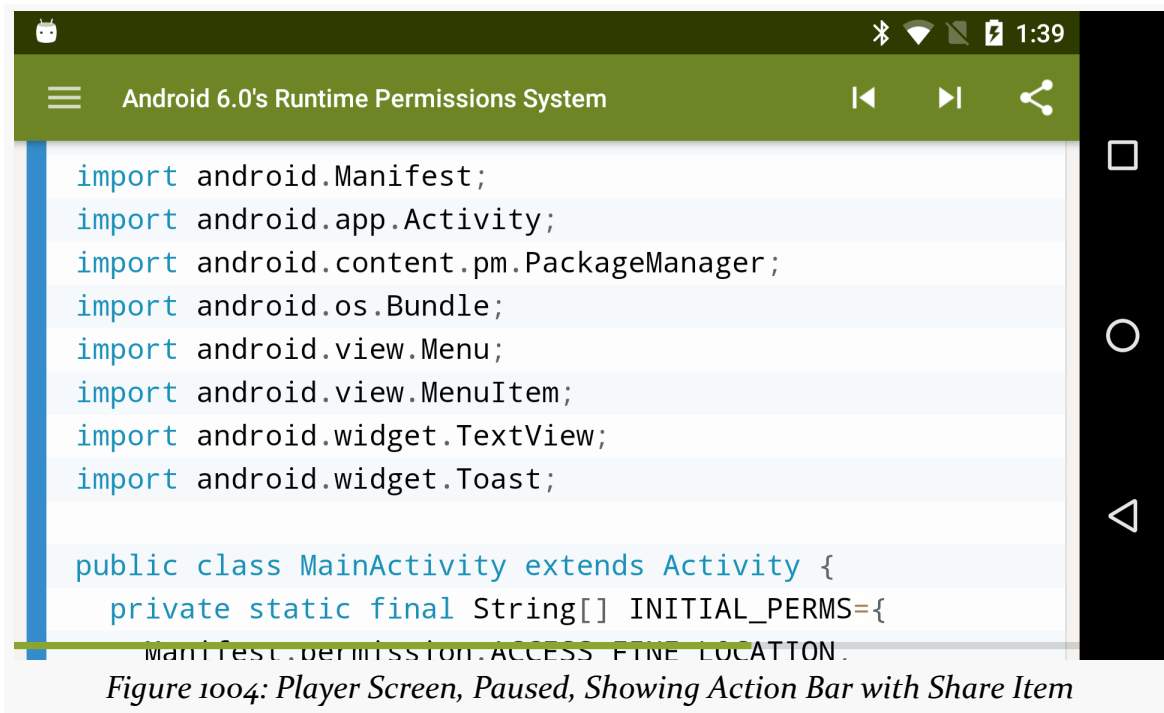

This contains a list of the different “scenes” of the appinar. Tapping on a scene will resume playback, jumping to that particular scene.

The action bar also has “fast-forward” and “rewind” buttons. The fast-forward button jumps to the next scene. The rewind button will start the current scene over from the beginning, if you are well into playback of the scene. If you are close to the start of the scene, the rewind button will take you to the previous scene.

Manipulating the Content

Parts of the appinar may show full source code listings. You can use pinch-zoom gestures to change the font size, if the size is too small for your current display. Pinch-zoom gestures also work on some full-screen images, if the image is significantly larger than your display.

Most of the source code scenes, and a few others noted in the voiceovers, will have “share” action bar items.

When playback is paused and the action bar is visible, you can tap that share icon to view the source code (or Web page or other resource) in a separate app, or send the URL to the resource through some other app to another person or Web service (e.g., forward a URL via email or SMS).
