            android:layout_height="wrap_content"
            android:freezesText="true"
            android:textSize="20sp"
            android:typeface="monospace" />
    </android.support.v7.widget.CardView>

</FrameLayout>
```

(from [Documents/Diceware/app/src/main/res/layout/activity\\_main.xml](#))

Ordinarily, the contents of a TextView are not part of the saved instance state Bundle, because Android assumes that those values are fixed (e.g., via android:text

in the layout). In our case, we are generating the passphrase at runtime, and so `android:freezesText="true"` tells Android to hold onto our `TextView` content in the saved instance state `Bundle` automatically, the way that it does for `EditText`. Hence, with that one attribute, Android will take care of holding onto the passphrase across configuration changes for us.

## Document Trees

`ACTION_OPEN_DOCUMENT` and `ACTION_CREATE_DOCUMENT` are sufficient for most apps. These roughly correspond to the “file open” and “new file” dialogs that you see in desktop operating systems.

However, there may be cases where you need the equivalent of a “choose folder” dialog, to allow the user to pick a location where you can create (or work with) several documents. For example, suppose that your app offers a report generator, taking data from the database and creating a report with tables and graphs and stuff. Some file formats, like PDF, might have the entire report in a single file — for that, use `ACTION_CREATE_DOCUMENT` to allow the user to choose where to put that report. Other file formats, like HTML, might require several files (e.g., the report body in HTML and embedded graphs in PNG format). For that, you really need a “folder”, into which you can create all of those individual bits of content.

For that, the Storage Access Framework offers document trees... as of Android 5.0 (API Level 21). Android 4.4’s edition of the Storage Access Framework lacked this capability.

### Getting a Tree

Instead of using `ACTION_OPEN_DOCUMENT`, you can use `ACTION_OPEN_DOCUMENT_TREE`. Once again, you will use `startActivityForResult()` to request access to the tree. In `onActivityResult()`, the result `Intent` has a `Uri` (`getData()`) that represents the tree. You should have full read/write access not only to this tree but to anything inside of it.

Another option, starting with Android 7.0, is “scoped directory access”. Here, you work with `StorageManager` to access the device’s `StorageVolume` list. All devices should have at least one `StorageVolume`, representing what we think of as external storage. Some devices may have more than that, representing mounted removable media. Given a `StorageVolume`, you can call `createAccessIntent()` to get an `Intent` that will ask the user permission for access to some portion of that volume, when

called with `startActivityForResult()`. As with `ACTION_OPEN_DOCUMENT_TREE`, you get a `Uri` in `onActivityResult()` that you can then use to work with that tree of files.

### Working in the Tree

The simplest approach for then working with the tree is to use the aforementioned `DocumentFile` wrapper. You can create one representing the tree by using the `fromTreeUri()` static method, passing in the `Uri` that you got from the `ACTION_OPEN_DOCUMENT_TREE` request.

From there, you can:

- Call `listFiles()` to get the immediate children of the root of this tree, getting back an array of `DocumentFile` objects representing those children
- Call `isDirectory()` to confirm that you do indeed have a tree (or, call it on a child to see if that child represents a sub-tree)
- For those existing children that are files (`isFile()` returns true), use `getUri()` to get the `Uri` for this child, so you can read its contents using a `ContentResolver` and `openInputStream()`
- Call `createDirectory()` or `createFile()` to add new content as an immediate child of this tree, getting a `DocumentFile` as a result
- For the `createFile()` scenario, call `getUri()` on the `DocumentFile` to get a `Uri` that you can use for writing out the content using `ContentResolver` and `openOutputStream()`
- and so on

Note that you can call `takePersistableUriPermission()` on a `ContentResolver` to try to have durable access to the document tree, just as you can for a `Uri` to an individual document.

### Getting a Tree: Example

The [Documents/DocumentTree](#) sample application demonstrates how to use `ACTION_OPEN_DOCUMENT_TREE` and `StorageManager/StorageVolume` to get a `Uri` pointing to a directory that you can work with.

### The Objective: a Preference for Storage

The sample app's UI is a `PreferenceFragment`, where we have two preferences: one

## CONSUMING DOCUMENTS

---

to pick a document tree via `ACTION_OPEN_DOCUMENT_TREE` and one to pick a `StorageVolume` from among the available volumes. In theory, an app might include one of these for the user to pick an alternative default storage location for files, for example. However, since the `StorageVolume` APIs for choosing a storage volume are new to API Level 24, we will only enable that preference on compatible devices.

In each case, part of the work to get access to these locations involves `startActivityForResult()`, which is unusual for a preference and adds to the sample's complexity.

### What the User Sees

When the user first launches the app, the preference subtitles are “no value”, because the user has not chosen anything yet:

*Figure 759: DocumentTree Demo, As Initially Launched*

## CONSUMING DOCUMENTS

---

If the user taps the “Document Tree Root” preference, the UI for the Storage Access Framework appears, allowing the user to browse for a directory of interest:

## CONSUMING DOCUMENTS

---

If the user chooses a location, the preference is updated with the Uri of the selected document tree:

*Figure 761: DocumentTree Demo, Showing Selected Document Tree Uri*

## CONSUMING DOCUMENTS

---

If the user taps the “Storage Volume” preference, a ListPreference dialog appears, showing the available storage volumes:

*Figure 762: DocumentTree Demo, Showing Available Storage Volume(s)*

On some devices, there will only be one option (“Internal shared storage”, or what we developer call “external storage”). On other devices, if there is a piece of removable storage mounted, there will be more than one option.

## CONSUMING DOCUMENTS

---

If the user chooses a volume, a permission confirmation dialog may appear, to confirm that the user wants to grant you access to the “Documents” directory inside of that storage volume:

*Figure 763: DocumentTree Demo, Requesting Permission*

## CONSUMING DOCUMENTS

---

If the user grants permission, once again the preference's subtitle will reflect the Uri of the chosen location:

*Figure 764: DocumentTree Demo, Showing Selected Storage Volume Directory*

## CONSUMING DOCUMENTS

---

On Android 5.0-6.0 devices, the app will run, but the storage volume preference is disabled:

*Figure 765: DocumentTree Demo, Running on Android 6.0*

### The Document Tree

Of the two options, `ACTION_OPEN_DOCUMENT_TREE` is the most straight-forward to implement: call `startActivityForResult()` and get your `Uri` in `onActivityResult()`.

But, since preferences are not set up to handle `startActivityForResult()` or receive data via `onActivityResult()`, we have a little bit of work to do.

### The Preference XML

The app has a `res/raw/settings.xml` file containing our preferences:

```
<?xml version="1.0" encoding="utf-8"?>
<PreferenceScreen xmlns:android="http://schemas.android.com/apk/res/android">
  <Preference
    android:key="documentTree"
    android:title="@string/pref_doc_tree" />
</ListPreference
```

## CONSUMING DOCUMENTS

---

```
    android:dialogTitle="@string/dlg_storage_volume"
    android:enabled="@bool/is_nougat"
    android:key="storageVolume"
    android:title="@string/pref_storage_volume" />
</PreferenceScreen>
```

(from [Documents/DocumentTree/app/src/main/res/xml/settings.xml](#))

The first one is our “Document Tree Root” preference... and it is literally a Preference. This is not used all that frequently, since it cannot actually collect any preference data. In cases like this one, where we really want to handle this more like the user tapped on a generic `ListView` row, it is a reasonable choice.

We will explore the `ListPreference` for the “Storage Volume” option later in this section.

### Populating the Preference

The UI is a `PreferenceFragment` subclass named `SettingsFragment`. In `onCreate()`, we call `addPreferencesFromResource()` to inflate that preference XML and populate the fragment:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    addPreferencesFromResource(R.xml.settings);

    prefDocTree=findPreference(PREF_DOC_TREE);
    prefs=prefDocTree
        .getSharedPreferences();
    prefs.registerOnSharedPreferenceChangeListener(this);
    onSharedPreferenceChanged(prefs, PREF_DOC_TREE);
    docTreeHelper=new DocumentHelper(this,
        prefDocTree);

    prefVolumes=(ListPreference)findPreference(PREF_VOLUMES);

    if (prefVolumes.isEnabled()) {
        populateVolumes();
        onSharedPreferenceChanged(prefs, PREF_STORAGE_URI);
        volumeHelper=
            new VolumeHelper(this, prefVolumes,
                PREF_STORAGE_URI, Environment.DIRECTORY_DOCUMENTS);
    }
}
```

## CONSUMING DOCUMENTS

---

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

We then do a few things to set up our “Document Tree Root” preference:

- We call `findPreference()` to get that Preference object, storing it in a `prefDocTree` field.
- We ask the Preference for the SharedPreferences that are being used, holding onto that in a field named `prefs`.
- Register the fragment itself as an `OnSharedPreferenceChangeListener` for the SharedPreferences, then immediately call `onSharedPreferenceChanged()`. That, in turn, fills in the summary of the Preference with the current `Uri`, if we have one:

```
@Override
public void onSharedPreferenceChanged(SharedPreferences prefs,
                                       String key) {
    if (PREF_DOC_TREE.equals(key)) {
        prefDocTree.setSummary(prefs.getString(key, "<no value>"));
    }
    else if (PREF_STORAGE_URI.equals(key)) {
        prefVolumes
            .setSummary(prefs
                .getString(key, "<no value>").replaceAll("%", "%"));
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

- Wrap that Preference in a `DocumentHelper` object, which we will look at shortly.

We will cover the remainder of this code, pertaining to the other preference, later.

### Choosing a Tree

We need some common code between the document-root and the storage-volume options:

- Bridging between a Preference and a hosting activity or fragment that can do the `startActivityForResult()` and `onActivityResult()` work
- Calling `takePersistableUriPermission()`
- Updating the SharedPreferences with the `Uri` that we receive

The `TreeUriPreferenceHelper` abstract class, along with its `DocumentHelper` and

## CONSUMING DOCUMENTS

---

VolumeHelper subclasses, implement this common code.

A TreeUriPreferenceHelper subclass' constructor needs to be passed the Preference that we are "helping", along with some implementation of the Host interface:

```
public interface Host {
    void startActivityForHelper(Intent intent,
                               TreeUriPreferenceHelper helper);
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/TreeUriPreferenceHelper.java](#))

DocumentHelper simply collects those values, passes them to TreeUriPreferenceHelper, and registers itself to be called when the user clicks on the Preference:

```
package com.commonsware.android.documenttree;

import android.content.Intent;
import android.preference.Preference;

public class DocumentHelper extends TreeUriPreferenceHelper
    implements Preference.OnPreferenceClickListener {
    public DocumentHelper(Host host, Preference pref) {
        super(host, pref);
        pref.setOnPreferenceClickListener(this);
    }

    @Override
    protected String getUriKey() {
        return (pref.getKey());
    }

    @Override
    public boolean onPreferenceClick(Preference preference) {
        Intent i=new Intent(Intent.ACTION_OPEN_DOCUMENT_TREE);

        host.startActivityForHelper(i, this);

        return(true);
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/DocumentHelper.java](#))

TreeUriPreferenceHelper, in turn, just holds onto the Host and Preference in host

---

## CONSUMING DOCUMENTS

---

and pref fields, respectively.

When the user clicks on the Preference, the `onPreferenceClick()` method of the `DocumentHelper` is called. There, we create an `ACTION_OPEN_DOCUMENT_TREE` Intent and call `startActivityForHelper()` on the host.

Our Host, in this case, is the `SettingsFragment`, so it has an implementation of `startActivityForHelper()`:

```
@Override
public void startActivityForHelper(Intent intent,
                                   TreeUriPreferenceHelper helper) {
    if (helper==docTreeHelper) {
        startActivityForResult(intent, REQUEST_DOC_TREE);
    }
    else if (helper==volumeHelper) {
        startActivityForResult(intent, REQUEST_STORAGE_VOLUME);
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

It just sees which `TreeUriPreferenceHelper` we are working with, then calls `startActivityForResult()` with an appropriate request code (e.g., `REQUEST_DOC_TREE`).

Eventually, `SettingsFragment` should be called with `onActivityResult()`. If the result is `RESULT_OK`, we forward the result along to the `TreeUriPreferenceHelper`, based on the request code:

```
@Override
public void onActivityResult(int requestCode, int resultCode,
                              Intent data) {
    if (resultCode==Activity.RESULT_OK) {
        if (requestCode==REQUEST_DOC_TREE) {
            docTreeHelper.onActivityResult(data);
        }
        else if (requestCode==REQUEST_STORAGE_VOLUME) {
            volumeHelper.onActivityResult(data);
        }
    }
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

---

## CONSUMING DOCUMENTS

---

TreeUriPreferenceHelper has the common implementation of `onActivityResult()`, where we call `takePersistableUriPermission()` (asking for read/write access) and put the Uri into the SharedPreferences under some key:

```
public void onActivityResult(Intent data) {
    Uri docTree=data.getData();
    ContentResolver cr=pref.getContext().getContentResolver();
    int perms=Intent.FLAG_GRANT_READ_URI_PERMISSION
        | Intent.FLAG_GRANT_WRITE_URI_PERMISSION;

    cr.takePersistableUriPermission(docTree, perms);

    pref
        .getSharedPreferences()
        .edit()
        .putString(getUriKey(), docTree.toString())
        .apply();
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/TreeUriPreferenceHelper.java](#))

In the case of the document-root Preference, that key is the key from the Preference itself (`getKey()`). Saving the value not only persists it, but it also triggers the SettingsFragment to be notified about the new value, causing SettingsFragment to update the Preference summary... which is why we see the Uri show up on the screen right after selecting it.

## The Storage Volume

The StorageVolume scenario is a bit more complicated, in that we have to provide the UI for choosing a volume — this is not provided by Android. That, plus some interesting challenges in the StorageVolume implementation, add to our level of effort.

## The Preference XML

The `settings.xml` file has a ListPreference that will serve as the UI for selecting a StorageVolume:

```
<ListPreference
    android:dialogTitle="@string/dlg_storage_volume"
    android:enabled="@bool/is_nougat"
    android:key="storageVolume"
```

---

## CONSUMING DOCUMENTS

---

(from [Documents/DocumentTree/app/src/main/res/xml/settings.xml](#))

Since the roster of possible volumes is dynamic, we cannot provide our `ListPreference` contents via string-array resources, but instead will need to do so from Java code.

Note that this preference is enabled based upon an `is_nougat` bool resource. That is set to `true` for API Level 24+ (in `res/values-v24/bools.xml`), `false` otherwise (in `res/values/bools.xml`).

### Populating the Preference

Some of the work from `onCreate()` of `SettingsFragment` is for setting up this `ListPreference`:

```
prefVolumes=(ListPreference)findPreference(PREF_VOLUMES);

if (prefVolumes.isEnabled()) {
    populateVolumes();
    onSharedPreferenceChanged(prefs, PREF_STORAGE_URI);
    volumeHelper=
        new VolumeHelper(this, prefVolumes,
            PREF_STORAGE_URI, Environment.DIRECTORY_DOCUMENTS);
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

We store the `ListPreference` in a `prefVolumes` field, before calling a private `populateVolumes()` method to fill in the list contents. We also trigger updating its summary via a manual call to `onSharedPreferenceChanged()`, plus wrap the `ListPreference` in a `VolumeHelper` that we will explore in detail shortly. And all of this is wrapped in a check to see if the preference is enabled; if it is not, we skip this work, as it is unnecessary.

`populateVolumes()` is responsible for providing the entries and values for the `ListPreference`, based on the available volumes:

```
@TargetApi(Build.VERSION_CODES.N)
private void populateVolumes() {
    StorageManager storage=
        (StorageManager)getActivity()
            .getSystemService(Context.STORAGE_SERVICE);
    List<StorageVolume> volumes=storage.getStorageVolumes();
```

## CONSUMING DOCUMENTS

---

```
Collections.sort(volumes, new Comparator<StorageVolume>() {
    @Override
    public int compare(StorageVolume lhs,
        StorageVolume rhs) {
        return(lhs.getDescription(getActivity())
            .compareTo(rhs.getDescription(getActivity())));
    }
});

String[] displayNames=new String[volumes.size()];
String[] uuids=new String[volumes.size()];

for (int i=0;i<volumes.size();i++) {
    displayNames[i]=volumes.get(i).getDescription(getActivity());
    uuids[i]=volumes.get(i).getUuid();

    if (uuids[i]==null) {
        uuids[i]=STORAGE_FAKE_UUID;
    }
}

prefVolumes.setEntries(displayNames);
prefVolumes.setEntryValues(uuids);
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/SettingsFragment.java](#))

We start off by getting a `StorageManager` system service. Here, we are using the newer version of `getSystemService()`, introduced in API Level 21, where we can pass in the Java class of the system service that we want (`StorageManager.class`). This allows Android to return an instance of the actual class, avoiding a cast.

Then, we call `getStorageVolumes()` on the `StorageManager`, to get the roster of available `StorageVolume` objects.

Since those `StorageVolume` objects might arrive in any order, we `sort()` them by their description, which is a human-readable label describing what the volume is. For example, for removable storage, it might be a combination of the manufacturer of the drive or card, plus the stated capacity of the drive or card.

Since `ListPreference` wants two `String` arrays for the entries and values, we set those up, filling them in from the description and UUIDs of the volumes. Each volume is supposed to have a UUID, but that is not guaranteed — in particular, the `StorageVolume` for external storage returns `null` for `getUuid()`. Since `ListPreference` *really* does not like `null` values, we substitute in a non-UUID string

## CONSUMING DOCUMENTS

---

(`STORAGE_FAKE_UUID`, defined to be "fake") to identify it. We then give those two string arrays to the `ListPreference`.

### Choosing a Volume

`VolumeHelper`, like `DocumentHelper`, is designed to help bridge between the preference system, the hosting fragment, and the Android APIs for getting a document tree `Uri`.

`VolumeHelper` takes two additional constructor parameters, beyond the `Host` and `Preference`:

- The key for the `SharedPreferences` under which the `Uri` will be stored. The `ListPreference` will store the `UUID` of the storage volume under its key, but once we get the `Uri`, we need to save it to the `SharedPreferences` as well, for later use.
- The directory on the storage volume to use. `createAccessIntent()` accepts any of the standard `Environment` directories — in this case, we are using `DIRECTORY_DOWNLOADS`

The constructor holds onto those additional parameters in fields, then registers itself to respond to when the `ListPreference` value changes, because the user selected a different `StorageVolume` in the list:

```
package com.commonware.android.documenttree;

import android.content.Intent;
import android.os.storage.StorageManager;
import android.os.storage.StorageVolume;
import android.preference.ListPreference;
import android.preference.Preference;
import java.util.List;

public class VolumeHelper extends TreeUriPreferenceHelper
    implements Preference.OnPreferenceChangeListener {
    private final String uriKey;
    private final String dirName;

    public VolumeHelper(Host host, ListPreference pref, String uriKey,
        String dirName) {
        super(host, pref);

        this.uriKey=uriKey;
        this.dirName=dirName;
    }
}
```

## CONSUMING DOCUMENTS

---

```
    pref.setOnPreferenceChangeListener(this);
}

@Override
protected String getUriKey() {
    return(uriKey);
}

@Override
public boolean onPreferenceChange(Preference pref,
                                   Object o) {
    StorageManager storage=
        pref.getContext().getSystemService(StorageManager.class);
    List<StorageVolume> volumes=storage.getStorageVolumes();
    String uuid=o.toString();

    for (StorageVolume volume : volumes) {
        if ((volume.getUuid()==null &&
            uuid.equals(SettingsFragment.STORAGE_FAKE_UUID)) ||
            (uuid.equals(volume.getUuid()))) {
            Intent i=volume.createAccessIntent(dirName);

            host.startActivityForHelper(i, this);
            break;
        }
    }

    return(true);
}
}
```

(from [Documents/DocumentTree/app/src/main/java/com/commonsware/android/documenttree/VolumeHelper.java](#))

When the user eventually does change the selection in the `ListPreference` and `onPreferenceChange()` is called, we get a fresh `StorageManager`. Unfortunately, `StorageManager` does not have any sort of lookup API to get a `StorageVolume` by UUID, so we have to iterate over the currently-available volumes and find a match, taking into account our fake UUID for the null-UUID case.

When we find a match, we call `createAccessIntent()` on the `StorageVolume`, passing in the directory name. That `Intent` is then given to the `Host` via `startActivityForHelper()`. That will trigger the same process as was used for `DocumentHelper`, eventually resulting in the `Uri` being saved to the `SharedPreferences` under the supplied key.

### Potential Issues

It is unclear if more than one `StorageVolume` could have a null UUID. If it can, the approach of using a fake value in lieu of null will not work. Of course, if more than one `StorageVolume` could have a null UUID, we will have no means of identifying *which* `StorageVolume` the null UUID refers to, making long-term identification of `StorageVolume` objects difficult.

### Scoped Directory Access Bug

The scoped directory access feature — using `StorageVolume` to request access to standard directories — works fairly well on Android 7.0+... with one UX flaw, tied to how the user grants you that access.

The flow of the permission dialogs resembles that of Android 6.0's runtime permissions:

- When you first ask for access, the user can allow or deny
- If the user denied access, and you later ask for access again, the dialog now has a “Don't ask again” checkbox
- If the user checked that checkbox and denied access again, any future attempts you make to request access will be denied immediately, without the user seeing a dialog

One problem is that we have no good way of knowing that the user has previously denied our request, let alone checked the “Don't ask again” checkbox. With Android 6.0's runtime permissions, we have `checkSelfPermission()` and `shouldShowPermissionRequestRationale()` for those things. We have no equivalents for scoped directory access.

However, the bigger problem is that once the user checks “Don't ask again” and denies access, *the user has no further recourse*. With runtime permissions, the user can always go into the Permissions area of an app's page in Settings and manually grant permissions. There is no equivalent of this for the scoped directory access API.

On Android 7.1, the user can use “Clear Data” to reset these dialogs, causing future dialogs to appear again even if “Don't ask again” had been checked. Of course, “Clear Data” has somewhat broader impact than this, and the user might not appreciate wiping out all the app's local data.

Worse, on Android 7.0, not only does “Clear Data” not fix this, but *a full uninstall of the app* does not fix this. Nothing short of a factory reset will allow the app to ask the user for permission and the user have an opportunity again to grant permission.

Admittedly, this is an edge case, but it is one that you should keep in mind if you are using `createAccessIntent()` and the scoped directory access API. Keep an eye on [this issue](#) to try to get some resolution to how the user is supposed to manually revert the “Don’t ask again” status.

## Android 8.0 Changes

Android 8.0 introduced some new options for consuming documents and document trees via the Storage Access Framework.

### Document Tree Traversal

The `DocumentsContract` client interface to the Storage Access Framework now has a `findDocumentPath()` method. Many developers will think that this means that they can get a filesystem path for a document `Uri` from the Framework.

That is not what this method does.

Instead, `findDocumentPath()` returns a list of document IDs representing the hierarchy of document trees leading to the specific document being requested. In other words, if the document is inside of a `goo` tree, which is inside of a `bar` tree, which is inside of a `foo` tree, and `foo` is the top of a provider’s hierarchy, `findDocumentPath()` would return a `List` of document IDs representing `foo`, `bar`, `goo`, and the requested document.

Presumably, the idea is that this would be used by client UIs to help build a way to traverse the relevant set of document trees for a particular document.

For this to work, the corresponding `DocumentsProvider` needs to implement its own `findDocumentPath()` method.

### Web Links for Documents

`DocumentsContract` also has a `createWebLinkIntent()` method, with a corresponding implementation on `DocumentsProvider`. This is very poorly documented, but apparently the idea is that for some cloud document providers,

you can get a URL to the document, given the Storage Access Framework `Uri` for the document. Presumably, this is a publicly-visible document, and the URL could be sent to other parties (e.g., via email) for them to see the document.

Android itself does not ship with a cloud document provider. Google Play devices may ship with Google Drive, and Drive might support this feature.

### Document Settings Activity

If you implement [a DocumentsProvider](#), you have the option of including `FLAG_SUPPORTS_SETTINGS` in the details that you return for `queryChildDocuments()`. If you do that, and you have an activity that supports `ACTION_DOCUMENT_SETTINGS`, the user may be presented with an option to visit that activity. The activity should be given the `Uri` of the particular document that the user wishes to manage. A provider might use this for offering management of metadata for the document: tags, access rights, etc.

# Providing Documents

---

The Storage Access Framework gives developers access to `ACTION_OPEN_DOCUMENT` and related Intent actions to perform operations on a document provider.

However, what if you want to *be* a document provider?

To do that, you will need to create a subclass of `DocumentsProvider`, override some abstract methods, and perhaps put up with some really obtuse error messages.

This chapter will help you in setting up your `DocumentsProvider`. With luck, you will escape without encountering errors.

## Prerequisites

This chapter assumes that you have read [the preceding chapter on consuming documents](#), along with its prerequisites.

## Have Your Content, and Provide it Too

Most apps will not need to implement a document provider. They might not even consume documents, let alone provide them to other apps.

However, if your app has document-style content, and that content is of a MIME type that could reasonably be manipulated by other apps, you should consider implementing a document provider to allow the user to manipulate that content using those other apps.

Historically, developers had two main approaches for content:

## PROVIDING DOCUMENTS

---

1. Store it on internal storage
2. Store it on external storage

The internal storage route would be for content that would not normally be user-accessible, while external storage would be for user-accessible content.

In either of those cases, you will want to consider creating a document provider. In the case of internal storage, the user has no way to get to that content except through your app, and so if your app does not offer some capabilities that other apps do for that content, you limit your user by not having a document provider. In the case of external storage, while users in theory could use a file manager or something to try to get other apps to recognize the content, it will be easier for users if you provide a document provider to proactively publish this content to consuming apps.

However, bear in mind that your app does not have to store its content in either of these places. It could store the content in *somebody else's* document provider, using the mechanisms discussed in [the preceding chapter on consuming documents](#). In this case, you would not need to publish a document provider yourself, as the content is available through the same provider that your code is using.

It may also be the case that while your app is the one directly storing the content on internal or external storage, that content would not reasonably be used by other apps. Perhaps it is in some non-standard format that other apps are unlikely to support. Perhaps the files are not to be used by other apps for security reasons. In these cases, skipping the document provider is reasonable, though not exactly ideal from the user's standpoint. In particular, it restricts them from using those files with apps that can work with any file, such as attaching them to email messages.

So, for example:

- If you are implementing a camera app, and you are not storing the photos in the standard `DIRECTORY_DCIM` location for photos, but you are storing the photos yourself in files consider implementing a document provider so users can get at the photos you are taking. But, if you are implementing a camera app, you might elect to allow the user to indicate some place in somebody else's document provider where you could save the photo on their behalf.
- If you are implementing some sort of network-synced file service (e.g., DropBox, Bittorrent Sync), or some sort of on-device version control system, consider implementing a document provider so users can manipulate the documents that you are managing on their behalf.

## Key Provider Concepts

Creating a document provider is significantly more complex than is creating a document consumer. To help make sense of what is required, here are some key terms that you will need to understand.

### Roots

A document provider can publish one or more “roots”. Basically, a “root” points to a tree of documents. Many providers will have just one root, but it is entirely possible for your provider to have more than one.

### Documents

Documents, in turn, represent what in filesystem terms would be considered files and directories. A document can either have children (e.g., a directory) or it can have content (e.g., a file), but not both.

A root *also* is a document — here, “root” refers to the root of a tree of documents.

### Root and Document IDs

Each root has an ID unique to your app to identify that root as being distinct from any other root. This is a string.

Each document — files and directories alike — will have a string document ID to uniquely identify that document within its root. If you have some natural identifier (e.g., a primary key in some table), feel free to use it. Otherwise, you might consider your document ID to be some path to get to the document.

And, since a root is also a document, a root will have both a root ID and a document ID.

These document IDs need to be durable. Clients, or the Storage Access Framework itself, may wind up caching these IDs. Hence, pick something that not only uniquely identifies this document, but will *continue* to uniquely identify the document even after the document has been modified.

### Pieces of a Provider

The [Documents/Provider](#) sample application implements a document provider, one that serves documents baked into the app itself in `assets/`. Of course, this is a rather artificial scenario — usually, a document provider will be working with a read/write data store, like internal storage.

### The Activity

A document provider app probably needs a real UI. Perhaps that UI is for broader functionality that the app provides on top of serving documents. Perhaps that UI is merely to configure the document store, such as providing account credentials for the online storage service that the document provider exposes on Android.

If nothing else, you will need a do-nothing activity for the user to run, to ensure that your app is moved out of the stopped state.

In the sample app, this is handled by `MainActivity`, which uses `Theme.Translucent.NoDisplay` [to avoid a UI](#) and just shows a `Toast` to indicate that the provider is now activated:

```
package com.commonware.android.documents.provider;

import android.app.Activity;
import android.content.res.AssetManager;
import android.os.Bundle;
import android.util.Log;
import android.widget.Toast;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;

public class MainActivity extends Activity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Toast.makeText(this, R.string.activated, Toast.LENGTH_LONG).show();
        finish();
    }
}
```

(from [Documents/Provider/app/src/main/java/com/commonware/android/documents/provider/MainActivity.java](#))

### The API Level Resources

The document provider itself comes courtesy of a subclass of `DocumentsProvider`. However, the `DocumentsProvider` class only exists on API Level 19 and higher — our subclass is useless on older devices. To ensure that our provider is only used on API Level 19 and higher, we should only enable it on API Level 19+ devices.

To that end, in `res/values/bools.xml`, we have a boolean resource named `min19`, set to `false`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <bool name="min19">false</bool>
</resources>
```

(from [Documents/Provider/app/src/main/res/values/bools.xml](#))

In `res/values-v19/bools.xml`, we redefine that boolean resource to be `true`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <bool name="min19">true</bool>
</resources>
```

(from [Documents/Provider/app/src/main/res/values-v19/bools.xml](#))

Hence, when we refer to the `min19` boolean resource, we will get `true` or `false` depending upon whether we are on API Level 19 or not.

### The Manifest

Since `DocumentsProvider` is a subclass of `ContentProvider`, we will need a `<provider>` element in the manifest pointing to our subclass of `DocumentsProvider`:

```
<provider
  android:name=".DemoDocumentsProvider"
  android:authorities="com.commonware.android.documents.provider"
  android:enabled="@bool/min19"
  android:exported="true"
  android:grantUriPermissions="true"
  android:permission="android.permission.MANAGE_DOCUMENTS">
  <intent-filter>
    <action android:name="android.content.action.DOCUMENTS_PROVIDER" />
  </intent-filter>
</provider>
```

## PROVIDING DOCUMENTS

---

(from [Documents/Provider/app/src/main/AndroidManifest.xml](#))

That element:

- Uses our `@bool/min19` resource from above to indicate that this component should only be enabled on API Level 19 and higher
- Is exported, but requires that applications looking to talk to our provider hold the `MANAGE_DOCUMENTS` permission, which can only be held by the firmware (or apps signed with the firmware's signing key)
- Sets the `android:grantUriPermissions` attribute to `true`, as that will be used by `DocumentsProvider` to allow third-party apps limited, conditional access to our documents
- Has your standard `android:name` and `android:authorities` attributes, as with any other `<provider>`

In addition, the `<provider>` has a nested `<intent-filter>` element. This may seem odd, as this used to be impossible, and it is not intuitively obvious what it would mean for a `ContentProvider` to have an `IntentFilter`. It also is [not documented as being allowed on <provider>](#), so we have no official explanation of what this means. Most likely, the magic `android.content.action.DOCUMENTS_PROVIDER` filter is being used simply as a marker, to indicate to Android that this particular `<provider>` is part of the Storage Access Framework and implements a `DocumentsProvider`.

### The DocumentsProvider

The real business logic of publishing documents comes from your subclass of `DocumentsProvider`. As this class is new to API Level 19, your build target (e.g., `compileSdkVersion` in `build.gradle`) needs to be 19 or higher.

A minimal `DocumentsProvider` implementation will typically need five methods, outlined below.

#### **onCreate()**

As with any `ContentProvider`, your `DocumentsProvider` can override `onCreate()` to perform initialization work. Technically, this is not required, but the odds are very good that you will have *something* that you need to initialize.

In the case of our sample `DocumentsProvider` — named `DemoDocumentsProvider` — `onCreate()` simply obtains access to an `AssetManager` instance that can be used for serving documents:

## PROVIDING DOCUMENTS

---

```
private AssetManager assets;

@Override
public boolean onCreate() {
    assets=getContext().getAssets();

    return(true);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

### queryRoots()

Your `queryRoots()` method needs to return information about the root(s) that your provider will provide.

However, rather than returning this in the form of some clean object model (e.g., a `List of Document.Root` objects or some such), the return value is a `Cursor`. While in principle this `Cursor` could come from a database, in many cases it will be a `MatrixCursor`, which is a `Cursor` interface over a two-dimensional array representing the rows and columns.

From here, you should return all *presently valid* roots. The “presently valid” part is because a root might exist but not be usable at the present time. For example, suppose that you are writing a `DocumentsProvider` that provides a document interface to an Internet-hosted storage service. In this case, you may need the user to authenticate in order to allow access to those files, such as to pass that authentication data along to the Web service to be able to retrieve directory and file data. If the user is not presently logged in, though, not only can you not talk to the Web service right now, but you do not have the ability to force the user to authenticate right now. Instead, you will have to cull the root(s) governed by those authentication credentials. This may mean that the `Cursor` you return has no rows, as you simply do not have anything that can be published right now.

The `Cursor` that you return will have one row per presently valid root. The columns will be ones defined on the `DocumentsContract.Root` class. Your `queryRoots()` method is passed a `String` array representing the columns requested by the Storage Access Framework. As your app may not support all of those columns, you will need to determine the intersection between the requested columns and the ones you support.

The sample app defines a `SUPPORTED_ROOT_PROJECTION` static data member to list

## PROVIDING DOCUMENTS

---

the DocumentsContract.Root columns that are supported in general:

```
private static final String[] SUPPORTED_ROOT_PROJECTION=new String[] {
    Root.COLUMN_ROOT_ID, Root.COLUMN_FLAGS, Root.COLUMN_TITLE,
    Root.COLUMN_DOCUMENT_ID, Root.COLUMN_ICON };
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

And the demo provider has a private netProjection() utility method that computes the intersection between the requested columns and the supported ones:

```
private static String[] netProjection(String[] requested, String[] supported) {
    if (requested==null) {
        return(supported);
    }

    ArrayList<String> result=new ArrayList<String>();

    for (String request : requested) {
        for (String support : supported) {
            if (request.equals(support)) {
                result.add(request);
                break;
            }
        }
    }

    return(result.toArray(new String[0]));
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

That net projection is used in the MatrixCursor constructor, to teach it the available columns, as part of the queryRoots() implementation:

```
@Override
public Cursor queryRoots(String[] projection)
    throws FileNotFoundException {
    String[] netProjection=
        netProjection(projection, SUPPORTED_ROOT_PROJECTION);
    MatrixCursor result=new MatrixCursor(netProjection);
    MatrixCursor.RowBuilder row=result.newRow();

    row.add(Root.COLUMN_ROOT_ID, ROOT_ID);
    row.add(Root.COLUMN_ICON, R.drawable.ic_launcher);
    row.add(Root.COLUMN_FLAGS, Root.FLAG_LOCAL_ONLY);
    row.add(Root.COLUMN_TITLE, getContext().getString(R.string.root));
    row.add(Root.COLUMN_DOCUMENT_ID, ROOT_DOCUMENT_ID);

    return(result);
}
```

---

## PROVIDING DOCUMENTS

---

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

`queryRoots()` then adds a row to the `MatrixCursor`, through a `MatrixCursor.RowBuilder`, containing five columns:

1. `DocumentsContract.Root.COLUMN_ROOT_ID` is the root ID for this root, as described [earlier in this chapter](#).
2. `DocumentsContract.Root.COLUMN_ICON`, which is a reference to a drawable resource that may be used in Storage Access Framework UI to help visually represent this root. In principle, this could be anything; in practice, you will probably choose your launcher icon, as it is the icon that the user will recognize.
3. `DocumentsContract.Root.COLUMN_FLAGS`, indicating which optional capabilities this root supports. In this case, the only flag we are setting is `FLAG_LOCAL_ONLY`, indicating that network I/O is not required to browse the contents of the provider. Our sample app indicates that it is local-only, as its documents are all packaged in `assets/`. A provider backed by a Web service, though, would not include this flag, so the Storage Access Framework knows that calls to some of the other methods (e.g., `queryChildDocuments()`) may take a significant amount of time.
4. `DocumentsContract.Root.COLUMN_TITLE`, which is a string identifying this root. The title and icon will tend to be included in Storage Access Framework-supplied UIs. In this case, with only a single root, the title is hard-coded to be a string resource. In other cases, this might be some other human-grokkable display name (e.g., the name of some storage service account).
5. `DocumentsContract.Root.COLUMN_DOCUMENT_ID`, which returns the document ID representing the document tree for this root.

In this case, the document IDs for this `DocumentsProvider` are the relative paths within `assets/` of the files, starting from a root `docs/` directory. So, while the root ID could be anything, the root document ID should be consistent with the other document ID values. In this case, the sample app uses:

```
private static final String ROOT_ID="thisIsMyBoomstick";
private static final String ROOT_DOCUMENT_ID="docs";
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

### `queryChildDocuments()`

As noted previously, some documents will represent a directory, while others will

---

## PROVIDING DOCUMENTS

---

represent files. For those that represent a directory, `queryChildDocuments()` will need to return the document information for the contents of the directory.

`queryChildDocuments()` is passed:

- the document ID of the directory
- the columns, defined on the `DocumentsContract.Document` class, that the Storage Access Framework wants
- the sort order, expressed as a SQL-style `ORDER BY` clause (minus the actual `ORDER BY` part), that you might use to help control the order in which to return the child documents (or ignore if you wish)

As with `queryRoots()`, we need to come up with the intersection of the columns that the requester asks for and the columns that we support. There is a static string array named `SUPPORTED_DOCUMENT_PROJECTION` that represents the columns that we support:

```
private static final String[] SUPPORTED_DOCUMENT_PROJECTION=  
    new String[] { Document.COLUMN_DOCUMENT_ID, Document.COLUMN_SIZE,  
                  Document.COLUMN_MIME_TYPE, Document.COLUMN_DISPLAY_NAME,  
                  Document.COLUMN_FLAGS};
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

The `queryChildDocuments()` method then uses the same `netProjection()` helper method that `queryRoots()` did to determine the intersection:

```
@Override  
public Cursor queryChildDocuments(String parentDocId,  
                                 String[] projection,  
                                 String sortOrder)  
    throws FileNotFoundException {  
    String[] netProjection=  
        netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);  
    MatrixCursor result=new MatrixCursor(netProjection);  
  
    try {  
        String[] children=assets.list(parentDocId);  
  
        for (String child : children) {  
            addDocumentRow(result, child,  
                           parentDocId + File.separator + child);  
        }  
    }  
    catch (IOException e) {
```

## PROVIDING DOCUMENTS

---

```
    Log.e(getClass().getSimpleName(),
          "Exception reading asset dir", e);
}

return(result);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

As with `queryRoots()`, the return value of `queryChildDocuments()` is a `Cursor` representing the documents contained in this directory. Once again, we use a `MatrixCursor` to build up an in-memory `Cursor`, this time for all files within the `assets/` directory denoted by `parentDocId`, using the `list()` method on `AssetManager` to find out what those files are.

The logic to populate the `MatrixCursor` is delegated to an `addDocumentRow()` private method, as we will be using it elsewhere in this `DocumentsProvider` implementation. `addDocumentRow()` creates a `MatrixCursor.RowBuilder` and fills in the supported columns:

```
private void addDocumentRow(MatrixCursor result, String child,
                             String assetPath) throws IOException {
    MatrixCursor.RowBuilder row=result.newRow();

    row.add(Document.COLUMN_DOCUMENT_ID, assetPath);

    if (isDirectory(assetPath)) {
        row.add(Document.COLUMN_MIME_TYPE, Document.MIME_TYPE_DIR);
    }
    else {
        String ext=MimeTypeMap.getFileExtensionFromUrl(assetPath);

        row.add(Document.COLUMN_MIME_TYPE,
                 MimeTypeMap.getSingleton().getMimeTypeFromExtension(ext));
        row.add(Document.COLUMN_SIZE, getAssetLength(assetPath));
    }

    row.add(Document.COLUMN_DISPLAY_NAME, child);
    row.add(Document.COLUMN_FLAGS, 0);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

Of note:

- the document ID of the child is simply its relative path within `assets/`

## PROVIDING DOCUMENTS

---

- the MIME type is a special one if the child document represents a directory, or else is looked up using `MimeTypeMap` if the child document represents a file
- the “display name” could be something special (e.g., the `<title>` of a Web page), but in this case is just the filename

To determine if an asset path represents a directory, the `isDirectory()` utility method just sees if `list()` returns a non-empty list:

```
private boolean isDirectory(String assetPath) throws IOException {
    return(assets.list(assetPath).length>=1);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

To find the size of a document — to fill in the `COLUMN_SIZE` column in the output — we can ask the `AssetManager` for a `FileDescriptor` on the asset, then obtain the length from that descriptor, as seen in the `getAssetLength()` utility method:

```
private long getAssetLength(String assetPath) throws IOException {
    return(assets.openFd(assetPath).getLength());
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

The net result is that, given the name of a directory in `assets/`, we return a `Cursor` with one row per child of that directory, with columns indicating details of that child.

### queryDocument()

`queryDocument()` is similar to `queryChildDocuments()`. Both return a `Cursor` with the same sorts of columns as output. The difference: `queryDocument()` provides you with the document ID of a file, and you return details of that file. By contrast, `queryChildDocuments()` gives you the document ID of a directory, and you return the details of all documents within that directory.

This is why `addDocumentRow()` was implemented as a separate method, as we need the same business logic (populate a `MatrixCursor` row based on an asset path) from `queryDocument()`:

```
@Override
public Cursor queryDocument(String documentId, String[] projection)
```

## PROVIDING DOCUMENTS

---

```
throws FileNotFoundException {
String[] netProjection=
    netProjection(projection, SUPPORTED_DOCUMENT_PROJECTION);
MatrixCursor result=new MatrixCursor(netProjection);

try {
    addDocumentRow(result, Uri.parse(documentId).getLastPathSegment(),
        documentId);
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(), "Exception reading asset dir", e);
}

return(result);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

In this case, the only thing different is that we need to get the bare filename, for use in the DISPLAY\_NAME field. Here, we cheat a bit and use `getLastPathSegment()` on `Uri` to obtain the filename.

### openDocument()

The `openDocument()` method behaves much like the `openFile()` method of a classic streaming `ContentProvider`: given a path, you return a `ParcelFileDescriptor` representing the file contents. For documents that are true files on the filesystem, you can use the static `open()` method on `ParcelFileDescriptor`. For documents that are not files on the filesystem — such as documents that are assets in the APK — you will need to set up a `ParcelFileDescriptor` pipe and stream the content that way.

That is what `DemoDocumentsProvider` does, using logic copied from the book's streaming `ContentProvider` samples:

```
@Override
public ParcelFileDescriptor openDocument(String documentId,
                                        String mode,
                                        CancellationSignal signal)

    throws FileNotFoundException {
ParcelFileDescriptor[] pipe=null;

try {
    pipe=ParcelFileDescriptor.createPipe();
    AssetManager assets=getContext().getAssets();
```

## PROVIDING DOCUMENTS

---

```
        new TransferThread(assets.open(documentId),
            new ParcelFileDescriptor.AutoCloseOutputStream(pipe[1])).start();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
        throw new FileNotFoundException("Could not open pipe for: "
            + documentId);
    }

    return(pipe[0]);
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

`openDocument()` is passed three parameters:

1. The document ID of the document to stream back
2. A file mode (r, w, or wt) indicating what sort of operations the client wants to perform on the stream
3. A `CancellationSignal` that we can use to find out that our streaming is being interrupted

In this case:

- `openDocument()` ignores the mode, because it did not return `FLAG_SUPPORTS_WRITE` in either `queryChildDocuments()` or `queryDocument()` to indicate that writing is an option, so the mode should always be r
- `openDocument()` ignores the `CancellationSignal`, though in reality it should pay attention to it when streaming back the content and stop streaming when requested

The `TransferThread` that does the actual streaming is, once again, the same as the one used earlier in this book for a streaming `ContentProvider`:

```
static class TransferThread extends Thread {
    InputStream in;
    OutputStream out;

    TransferThread(InputStream in, OutputStream out) {
        this.in=in;
        this.out=out;
    }

    @Override
```

## PROVIDING DOCUMENTS

---

```
public void run() {
    byte[] buf=new byte[8192];
    int len;

    try {
        while ((len=in.read(buf)) >= 0) {
            out.write(buf, 0, len);
        }

        in.close();
        out.flush();
        out.close();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
            "Exception transferring file", e);
    }
}
}
```

(from [Documents/Provider/app/src/main/java/com/commonsware/android/documents/provider/DemoDocumentsProvider.java](#))

### The Results

If you have both this sample app and the one from [the previous chapter](#), then run the one from the previous chapter to bring up the Storage Access Framework UI, you will see our provider among the list of available providers:

*Figure 766: Storage Access Framework Picker, Showing Custom Provider*

The provider's `assets/docs/` directory contains three files, one just off the root and two in a `bar/` subdirectory:

*Figure 767: DocumentsProvider Sample Documents*

## PROVIDING DOCUMENTS

---

Hence, tapping on our provider in the Storage Access Framework picker brings up the contents of the root document:

*Figure 768: Storage Access Framework Picker, Showing Documents in Root*

## PROVIDING DOCUMENTS

---

Tapping on the bar / directory brings up its contents in turn:

*Figure 769: Storage Access Framework Picker, Showing Yet More Documents*

## PROVIDING DOCUMENTS

---

Tapping on one of the files brings up the details for that file:

*Figure 770: Document Consumer, Showing Details of Picked Document*

## Optional Provider Capabilities

A `DocumentsProvider` can do a fair bit more than what the above sample app demonstrates. While the sample will suffice for the basics, it is reasonably likely that a production-grade `DocumentsProvider` will need to implement and provide some other optional capabilities, such as those described in this section.

### Other CRUD Operations

CRUD — Create, Read, Update, and Delete — is a standard shorthand for the basic operations one can perform on data. The sample app handles the “Read” portion of CRUD, but a `DocumentsProvider` can support all of them if desired.

#### Create

It may be that your `DocumentsProvider` is only going to serve up documents that were created in your app, or were created outside of the Android device (e.g., on a

## PROVIDING DOCUMENTS

---

Web app). If, however, you want consumers of your provider to be able to use `ACTION_CREATE_DOCUMENT` to create new documents in your provider, you will need to do a few things.

First, in the `COLUMN_FLAGS` for the relevant root(s) returned by `queryRoots()`, you will need to include `FLAG_SUPPORTS_CREATE`, defined on `DocumentsContract.Root`. This indicates that at least one directory within that root supports creating new documents. Without this flag, your root(s) will be shown for `ACTION_OPEN_DOCUMENT` requests but not `ACTION_CREATE_DOCUMENT` requests.

Next, in one or more directories returned as part of `queryDocument()` and `queryChildDocuments()` calls, in the `COLUMN_FLAGS` column, you will need to include `FLAG_DIR_SUPPORTS_CREATE`, defined on `DocumentsContract.Documents`. This indicates that this document is a directory that supports creating new documents inside of it. Otherwise, a directory will be assumed to not support creating new documents. Note that this flag is only used for documents representing directories, not documents representing files.

Finally, you will need to implement `createDocument()` in your `DocumentsProvider`. This will be called if a consumer app used `ACTION_CREATE_DOCUMENT` and the user chose your provider and one of your directories for the new document. You are passed in:

- the document ID of the directory
- the MIME type of the new file
- a suggested display name to use for the new file, though you can modify this if needed

Your job, in `createDocument()`, is to create the document and return the document ID for the newly-created document. For example, if your documents are held in internal storage, you might create a new file for the document itself plus a database row in some documents table to hold the MIME type and display name.

### Update

For something like files, an “update” is replacing the current contents with something new. In the case of a streaming protocol like `DocumentsProvider`, this implies that your provider can support output as well as input.

This too requires a few changes to your provider.

## PROVIDING DOCUMENTS

---

First, for the file(s) that can be updated, in the results for `queryDocument()` and `queryChildDocuments()`, you will need to include `FLAG_SUPPORTS_WRITE` in `COLUMN_FLAGS`, to indicate that writing to this file should work.

Then, you will need to pay attention to the mode passed into `openDocument()`. If the mode is `w` or `wt`, you would need to arrange to support writing the file, where your background thread reads from an `InputStream` on the pipe and writes the data to wherever your data is being stored.

### Delete

For any documents that the consumer can delete, include `FLAG_SUPPORTS_DELETE` in `COLUMN_FLAGS` in the results for `queryDocument()` and `queryChildDocuments()`.

You will also need to implement `deleteDocument()` in your `DocumentsProvider`. You are supplied the document ID to delete, and your job is to delete it.

If the document represents a directory, you may also need to delete all of its children. That really depends on how you are leveraging the “directory” construct in `DocumentsProvider`:

- If the “directory” is like a filesystem directory, where children have only one parent, you will want to delete the children when you delete the parent
- If the “directory” is more like a category, such as a tag, where children could have multiple parents, you will need to decide how to handle the children that would be orphaned by your deleting the last parent (delete the children? move them to some other default parent? something else?)

### Change Notification

If the data served by your provider changes, it is incumbent upon you to let possible consumers know about the change. For example, if you elect to delete children when you delete their parent, you should let consumers know that those children were deleted. This is not necessary for direct operations performed by consumers (e.g., writing to a document), but is necessary for anything else.

To do that, you call `notifyChange()` on a `ContentResolver`, just as you would for changes to the data in a `ContentProvider`. However, `notifyChange()` takes a `Uri` as a parameter, to indicate the scope of the change. There are static utility methods on `DocumentsContract` that will return a `Uri` that you can use. Notably:

## PROVIDING DOCUMENTS

---

- `buildDocumentUri()`, given your authority and a document ID, provides a `Uri` that points to that document
- `buildChildDocumentsUri()`, given your authority and a document ID, provides a `Uri` that represents the collection of children of that document

So, for example, if by deleting a parent you also delete the children, you would use `buildChildDocumentsUri()` with `notifyChange()` to ensure that consumers know that those children were modified. The Storage Access Framework will use methods like `queryChildDocuments()` to determine that the children were deleted in this case.

### Thumbnails

By default, the Storage Access Framework will use stock icons for directories and files. You can supply your own thumbnails instead, though, if you want. To do this:

- Include `FLAG_SUPPORTS_THUMBNAIL` in the `COLUMN_FLAGS` for the affected document(s) in `queryDocument()` and `queryChildDocuments()`
- Implement `openDocumentThumbnail()` in your `DocumentsProvider`

`openDocumentThumbnail()` is provided the document ID of the document whose thumbnail is required, along with a `Point` object providing a requested size. While your thumbnail does not have to exactly match that size — for example, the aspect ratio that is requested may not match the thumbnail — it should be close.

However, the return value for `openDocumentThumbnail()` is an `AssetFileDescriptor`, which is a wrapper around a `ParcelFileDescriptor`. If your image exists as a file that happens to be the right size, return it by using the static `open()` method on `ParcelFileDescriptor` is fairly straightforward. If, however, you need to scale your source image to fit the desired size, implementing this via a pipe will be moderately tedious.

### Recent Documents

If your app has its own concept of recent documents, you can expose that roster to the Storage Access Framework, which can incorporate it as part of its UI. To do this:

- Have your `queryRoots()` method include `FLAG_SUPPORTS_RECENTS` in the `COLUMN_FLAGS` value for the root(s) that support recent documents
- Implement `queryRecentDocuments()` on your `DocumentsProvider`, where you are given the root ID (*not* a document ID!) of one of your roots, and you

## PROVIDING DOCUMENTS

---

need to return the same sort of `Cursor` as you would from `queryChildDocuments()`, but representing the recent documents for that `root`

The two constraints upon the returned `Cursor` are:

- It should be sorted descending based on last-modified date (e.g., the `COLUMN_LAST_MODIFIED` column in your rows)
- It should be capped at 64 rows, though it can be less if desired

Note that you can, if you wish, have the `Cursor` return rows reflecting both files and directories — you are not limited to one or the other.

### Search

If your provider has its own search capability, you can expose that to the Storage Access Framework, which in turn can make it available to users looking for a certain document. To support this:

- Have your `queryRoots()` method include `FLAG_SUPPORTS_SEARCH` in the `COLUMN_FLAGS` value for the root(s) that support searching
- Implement `querySearchDocuments()` on your `DocumentsProvider`, where you are given the root ID (*not* a document ID!) of one of your roots, and you need to return the same sort of `Cursor` as you would from `queryChildDocuments()`, but representing the results of a search

`querySearchDocuments()` is passed a `String` representing the search expression entered by the user. It is up to you to decide what that expression means. It is also up to you to determine where you are searching for that expression (filenames? file contents?).

Note that the `Cursor` you return should only contain documents that reflect files, not documents that point to directories.

### Other Flags

There are a few other flags that are available to you on `DocumentsContract.Document` that you can use in `COLUMN_FLAGS` for `Cursor` results representing a document or collection of documents, such as the results of `queryDocument()` and `queryChildDocuments()`:

## PROVIDING DOCUMENTS

---

- If the document represents a directory, and you are supporting thumbnails, and you would like the contents of this directory to be represented in a thumbnail grid as opposed to a list, include `FLAG_DIR_PREFERS_GRID`
- If the document represents a directory, and you feel that users will be better served showing the documents in descending order based upon `COLUMN_LAST_MODIFIED`, rather than alphabetical by display name, include `FLAG_DIR_PREFERS_LAST_MODIFIED`

# Encrypted Storage

---

SQLite databases, by default, are stored on internal storage, accessible only to the app that creates them.

At least, that is the theory.

In practice, it is conceivable that others could get at an app's SQLite database, and that those "others" may not have the user's best interests at heart. Hence, if you are storing data in SQLite that should remain confidential despite extreme measures to steal the data, you may wish to consider encrypting the database.

Perhaps the simplest way to encrypt a SQLite database is to use [SQLCipher](#). SQLCipher is a SQLite extension that encrypts and decrypts database pages as they are written and read. However, SQLite extensions need to be compiled into SQLite, and the stock Android SQLite does not have the SQLCipher extension.

[SQLCipher for Android](#), therefore, comes in the form of a replacement implementation of SQLite that you add as an NDK library to your project. It also ships with replacement editions of the `android.database.sqlite.*` classes that use the SQLCipher library instead of the built-in SQLite. This way, your app can be largely oblivious to the actual database implementation, particularly if it is hidden behind a `ContentProvider` or similar abstraction layer.

SQLCipher for Android is a joint initiative of [Zetetic](#) (the creators of SQLCipher) and [the Guardian Project](#) (home of many privacy-enhancing projects for Android). SQLCipher for Android is open source, under the Apache License 2.0.

## Prerequisites

Understanding this chapter requires that you have read the chapter on [database access](#).

## Scenarios for Encryption

So, why might you want to encrypt a database?

Some developers probably are thinking that this is a way of protecting the app's content against "those pesky rooted device users". In practice, this is unlikely to help. As with most encryption mechanisms, SQLCipher uses an encryption key. If the app has the key, such as being hard-coded into the app itself, anyone can get the key by reverse-engineering the app.

Rather, encrypted databases are to help the user defend their data against other people seeing it when they should not. The classic example is somebody leaving their phone in the back of a taxi — if that device winds up in the hands of some group with the skills to root the device, they can get at any unencrypted content they want. While some users will handle this via the whole-disk encryption available since Android 3.0, others might not.

If the database is going anywhere other than internal storage, there is all the more reason to consider encrypting it, as then it may not even require a rooted device to access the database. Scenarios here include:

1. Databases stored on external storage
2. Databases backed up using external storage, BackupManager, or another Internet-based solution
3. Databases explicitly being shared among a user's devices, or between a user's device and a desktop (note that SQLCipher works on many operating systems, including desktops and iOS)

## Obtaining SQLCipher

SQLCipher [is available from Zetetic](#). As of July 2016, the current shipping version was 3.5.0. **It is very important for you to use 3.5.0 or higher**, as earlier versions of SQLCipher for Android will not work on Android 7.0 or higher versions of Android.

In Android Studio, to add SQLCipher for Android to your project, just add the official AAR dependency:

```
dependencies {  
    implementation 'net.zetetic:android-database-sqlcipher:3.5.0@aar'  
}
```

## Using SQLCipher

If you have existing code that uses classic Android SQLite, you will need to change your import statements to pick up the SQLCipher for Android equivalents of the classes. For example, you obtain `SQLiteDatabase` now from `net.sqlcipher.database.sqlcipher`, not `android.database.sqlite`. Similarly, you obtain `SQLException` from `net.sqlcipher.database` instead of `android.database`. Unfortunately, there is no complete list of which classes need this conversion — `Cursor`, for example, does not. Try converting everything from `android.database` and `android.database.sqlite`, and leave alone those that do not exist in the SQLCipher for Android equivalent packages.

Before starting to use SQLCipher for Android, you need to call `SQLiteDatabase.loadLibs()`, supplying a suitable `Context` object as a parameter. This initializes the necessary libraries. If you are using a `ContentProvider`, just call this in `onCreate()` before actually using anything else with your database. If you are not using a `ContentProvider`, you probably will want to create a custom subclass of `Application` and make this call from that class' `onCreate()`, and reference your custom `Application` class in the `android:name` attribute of the `<application>` element in your manifest. Either of these approaches will help ensure that the libraries are ready before you try doing anything with the database.

Finally, when calling `getReadableDatabase()` or `getWritableDatabase()` on `SQLiteDatabase`, you need to supply the encryption key to use. For the purposes of book examples, a hard-coded passphrase is sufficient. However, those can be trivially reverse-engineered, and so they offer little real-world protection. But, they keep the code simple, which is useful when examining APIs.

The [Database/ConstantsSecure-AndroidStudio](#) sample app is yet another variation of the `ConstantsBrowser` sample that we have been using for most of the database examples. From the standpoint of the `ConstantsBrowser` activity and `ConstantsFragment` UI, nothing is different. However, `DatabaseHelper` uses SQLCipher, rather than SQLite.

---

## ENCRYPTED STORAGE

---

In the DatabaseHelper constructor, we call `loadLibs()` on the `SQLiteDatabase` class, which is a required initialization step to get the native libraries set up:

```
public DatabaseHelper(Context context) {
    super(context, DATABASE_NAME, null, SCHEMA);

    SQLiteDatabase.loadLibs(context);
}
```

(from [Database/ConstantsSecure-AndroidStudio/app/src/main/java/com/commonsware/android/sqlcipher/DatabaseHelper.java](#))

It also offers zero-argument `getReadableDatabase()` and `getWritableDatabase()` methods, akin to those offered by the regular `SQLiteOpenHelper`. However, the `DatabaseHelper` editions turn around and invoke the one-argument equivalents on the `SQLCipher` edition of `SQLiteOpenHelper`:

```
SQLiteDatabase getReadableDatabase() {
    return(super.getReadableDatabase(PASSPHRASE));
}

SQLiteDatabase getWritableDatabase() {
    return(super.getWritableDatabase(PASSPHRASE));
}
```

(from [Database/ConstantsSecure-AndroidStudio/app/src/main/java/com/commonsware/android/sqlcipher/DatabaseHelper.java](#))

Here, the `PASSPHRASE` is just a hard-coded string:

```
private static final String PASSPHRASE=
    "hard-coding passphrases is only for sample code;" +
    "nobody does this in production";
```

(from [Database/ConstantsSecure-AndroidStudio/app/src/main/java/com/commonsware/android/sqlcipher/DatabaseHelper.java](#))

That is all the changes that are needed to use `SQLCipher`.

## SQLCipher Limitations

Alas, `SQLCipher` for Android is not perfect.

It will add a few MB to the size of your APK file per CPU architecture. For most modern Android devices, this extra size will not be a huge issue, though it will be an impediment for older devices with less internal storage, or for apps that are getting close to the size limits imposed by the Play Store or other distribution mechanisms.

The chapter on the NDK contains [a section about a technology called libhoudini](#) that can help reduce this bloat, albeit with a significant performance penalty.

However, the size is mostly from code, and that may cause a problem for Eclipse users. Eclipse may crash with its own `OutOfMemoryError` during the final build process. To address that, find your `eclipse.ini` file (location varies by OS and installation method) and increase the `-Xmx` value shown on one of the lines (e.g., change it to `-Xmx512m`).

Other code that expects to be using native SQLite databases will require alteration to work with SQLCipher for Android databases. For example, the `SQLiteAssetHelper` described [elsewhere in this book](#) would need to be ported to use the SQLCipher for Android implementations of `SQLiteOpenHelper`, `SQLiteDatabase`, etc. This is not too difficult for an open source component like `SQLiteAssetHelper`.

## Passwords and Sessions

Given an encrypted database, there are several ways that an attacker can try to access the data, including:

1. Use a brute-force attack via the app itself
2. Use a brute-force attack on the database directly, by copying it to some other machine
3. Obtain the password by the strategic deployment of [a \\$5 wrench](#)

The classic way to prevent the first approach is by having business logic that prevents lots of failed login attempts in a short period of time. This can be built into your login dialog (or the equivalent), tracking the number and times of failed logins and introducing delays, forced app exits, or something to add time and hassle for trying lots of passwords.

Since manually trying passwords is nasty, brutish, and long, many attackers would automate the process by copying the SQLCipher database to another machine (e.g., desktop) and running a brute-force attack on it directly. SQLCipher for Android has many built-in protections to help defend against this. So long as you are using a sufficiently long and complex encryption key, you should be fairly well-protected against such attacks.

Defending against wrenches is decidedly more difficult and is beyond the scope of this book.

## About Those Passphrases...

Having a solid encryption algorithm, like the AES-256 used by default with SQLCipher for Android, is only half the battle. The other half is in using a high-quality passphrase, one that is unlikely to be guessed by anyone looking to break the encryption.

### Upgrading to Encryption

Suppose you have an app already out on the market, and you decide that you want to add the option for encryption. It is fairly likely that the user will be miffed if they lose all their data in the process of switching to an encrypted database. Therefore, you will want to try to retain their data.

SQLCipher for Android does not support in-place encryption of database. However, it *does* support working with unencrypted databases and encrypted databases simultaneously, giving you the option of migration.

The approach boils down to:

- Open the unencrypted database in SQLCipher for Android, using an empty passphrase
- Use the ATTACH statement to open the encrypted database inside the same SQLCipher for Android session
- Use a supplied `sqlcipher_export()` function to migrate most of the data
- Copy the Android database schema version between the databases
- DETACH the encrypted database
- Close the unencrypted database (and, presumably, delete it)
- Use the encrypted database from this point forward

Since both database files will exist at one time, you will find it simplest to use separate names for them (e.g., `stuff.db` and `stuff-encrypted.db`).

To see how this works, take a look at the [Database/SQLCipherPassphrase-AndroidStudio](#), which is a variation of the original, non-ContentProvider “constants” sample app, this time using SQLCipher for Android and supporting an upgrade from a non-encrypted database to an encrypted one.

The bulk of the logic for handling the encryption upgrade is in a static `encrypt()` method on our `DatabaseHelper`:

## ENCRYPTED STORAGE

---

```
static void encrypt(Context ctxt) {
    SQLiteDatabase.loadLibs(ctxt);

    File dbFile=ctxt.getDatabasePath(DATABASE_NAME);
    File legacyFile=ctxt.getDatabasePath(LEGACY_DATABASE_NAME);

    if (!dbFile.exists() && legacyFile.exists()) {
        SQLiteDatabase db=
            SQLiteDatabase.openOrCreateDatabase(legacyFile, "", null);

        db.rawQuerySQL(String.format("ATTACH DATABASE '%s' AS encrypted KEY '%s'",
            dbFile.getAbsolutePath(), PASSPHRASE));
        db.rawQuerySQL("SELECT sqlcipher_export('encrypted')");
        db.rawQuerySQL("DETACH DATABASE encrypted;");

        int version=db.getVersion();

        db.close();

        db=SQLiteDatabase.openOrCreateDatabase(dbFile, PASSPHRASE, null);
        db.setVersion(version);
        db.close();

        legacyFile.delete();
    }
}
```

(from [Database/SQLCipherPassphrase-AndroidStudio/app/src/main/java/com/commonsware/android/constants/DatabaseHelper.java](#))

First, we initialize SQLCipher for Android by calling `loadLibs()` on the SQLCipher version of `SQLiteDatabase`. We could do this someplace else, but for this sample, this is as good a spot as any.

We then create `File` objects pointing at the locations of the old, unencrypted database (with a name represented by a `LEGACY_DATABASE_NAME` static data member) and the new encrypted database (`DATABASE_NAME`). To get the `File` locations of those databases, we use `getDatabasePath()`, a method on `Context`, which returns the correct location for a database file given its name.

If the encrypted database exists, there is nothing that we need to do. Similarly, if it does not exist but the unencrypted database *also* does not exist, there is nothing that we *can* do. In either of those cases, we skip over the rest of the logic. In the first case, we already did the conversion (presumably); in the latter case, this is a new installation, and our `SQLiteOpenHelper` `onCreate()` logic will handle that. But, in the case where we do not have the encrypted database but do have the unencrypted one, we can create the encrypted database from the unencrypted data, which is what the bulk of the `encrypt()` method does.

To that, we:

## ENCRYPTED STORAGE

---

- Use `openOrCreateDatabase()` to open the already-existing unencrypted database file in *SQLCipher for Android*, using "" as the passphrase.
- Use a `rawExecSQL()` method available on the *SQLCipher for Android* version of `SQLiteDatabase` to ATTACH the encrypted database, given its path, to our database session, using the supplied passphrase. This means that we can access the tables from both databases simultaneously, though we need to prefix all references to the attached database via its handle, `encrypted`.
- Use `rawExecSQL()` to execute `SELECT sqlcipher_export('encrypted')`, which copies most of our data from the unencrypted database (the database we have open) into the encrypted database (the one we attached). The big thing that `sqlcipher_export()` does *not* copy is the schema version number that Android maintains.
- Use `rawExecSQL()` to DETACH the attached encrypted database, as we no longer need it.
- Call `getVersion()` on the `SQLiteDatabase` representing the unencrypted database, to retrieve the schema version number that Android maintains.
- Close the unencrypted database and open the encrypted one using `openOrCreateDatabase()`.
- Use `setVersion()` on `SQLiteDatabase` to set the schema version of the encrypted database to the value we had from the unencrypted database.
- Close the encrypted database and delete the unencrypted database file. Note that on API Level 16+, we could use the `deleteDatabase()` method on `SQLiteDatabase` to cleanly delete everything associated with SQLite.

The combination of doing all of that migrates our data from an unencrypted database to an encrypted one.

Then, we simply need to call `encrypt()` before we try loading our constants, from `doInBackground()` of our `LoadCursorTask`:

```
private class LoadCursorTask extends BaseTask<Void> {
    private final Context ctxt;

    LoadCursorTask() {
        this.ctxt=getActivity().getApplicationContext();
    }

    @Override
    protected Cursor doInBackground(Void... params) {
        DatabaseHelper.encrypt(ctxt);
        return(doQuery());
    }
}
```

---

## ENCRYPTED STORAGE

---

(from [Database/SQLCipherPassphrase-AndroidStudio/app/src/main/java/com/commonsware/android/constants/ConstantsFragment.java](#))

To test this upgrade logic, you will need to:

- Run [the original unencrypted version of this sample](#), found in the [Database/Constants](#) sample application
- Add a new constant using the unencrypted version of the app
- Run the encrypted version of the sample from this section, which shares the same package name as the original and therefore will replace it on your emulator

You will see your added constant appear along with all of the standard ones, yet if you examine `/data/data/com.commonsware.android.constants/databases` on your ARM emulator via DDMS, you will see that your database is now named `constants-crypt.db` instead of `constants.db`, as we have replaced the unencrypted database with an encrypted one.

### Changing Encryption Passphrases

Another thing the user might wish to do is change their passphrase. Perhaps they fear that their existing passphrase has been compromised (e.g., a narrow escape from a \$5 wrench). Perhaps they rotate their passphrases as a matter of course. Perhaps they simply keep typing in their current one incorrectly and want to switch to one they think they can enter more accurately.

SQLCipher for Android supports a `rekey` PRAGMA that can accomplish this. Given an open encrypted database `db` — opened using the old passphrase — you can change the password to a `newPassword` string variable via:

```
db.execSQL(String.format("PRAGMA rekey = '%s'", newPassword));
```

Note that this may take some time, as SQLCipher for Android needs to re-encrypt the entire database.

### Dealing with the Version 3.0.x Upgrade

If you are starting with SQLCipher for Android with the 3.0.x release, all is good.

If you have been using SQLCipher for Android from previous releases, but you are still in development mode, all is still good, so long as you can wipe out your old databases.

## ENCRYPTED STORAGE

---

If you have apps in production using SQLCipher for Android from previous releases, you will have a small headache: the database structure has changed. SQLCipher for Android provides us with a `PRAGMA cipher_migrate` that we can run to upgrade the database in place to the new structure, once we have opened the database with our passphrase. However:

1. There is no great built-in place to put the code for calling this pragma
2. You do not want to blindly call this pragma every time you open the database, as it results in extra processing time

SQLCipher for Android, in an attempt to help with this, offers a modified version of methods like `openOrCreateDatabase()` on `SQLiteDatabase`, ones that take a `SQLiteDatabaseHook` implementation as the last parameter. This interface requires two methods:

1. `preKey()`, called after the database is opened but before the passphrase is applied
2. `postKey()`, called after the database is opened and after the passphrase is applied, but before anything else is done (e.g., standard `SQLiteOpenHelper` schema version checking)

Both methods are passed the `SQLiteDatabase` as a parameter, for you to do with as needed. So, for example, you could have a `postKey()` implementation that does the `postKey()` call only if needed:

```
public class SQLCipherV3Hook implements SQLiteDatabaseHook {
    private static final String PREFS=
        "net.sqlcipher.database.SQLCipherV3Helper";

    public static void resetMigrationFlag(Context ctxt, String dbPath) {
        SharedPreferences prefs=
            ctxt.getSharedPreferences(PREFS, Context.MODE_PRIVATE);
        prefs.edit().putBoolean(dbPath, false).commit();
    }

    @Override
    public void preKey(SQLiteDatabase database) {
        // no-op
    }

    @Override
    public void postKey(SQLiteDatabase database) {
        SharedPreferences prefs=
            getBaseContext().getSharedPreferences(PREFS, Context.MODE_PRIVATE);
    }
}
```

## ENCRYPTED STORAGE

---

```
boolean isMigrated=prefs.getBoolean(database.getPath(), false);

if (!isMigrated) {
    database.rawQuery("PRAGMA cipher_migrate;");
    prefs.edit().putBoolean(database.getPath(), true).commit();
}
}
```

You can also pass a `SQLiteDatabaseHook` implementation into the `SQLiteOpenHelper` constructor as the fifth parameter, which will be used when `SQLiteOpenHelper` works with the underlying `SQLiteDatabase`.

## Multi-Factor Authentication

Another way to effectively boost the strength of your security is to implement your own multi-factor authentication. In this case, the passphrase is not obtained solely through the user typing in the whole thing, but instead is synthesized from two or more sources. So, in addition to some `EditText` widget for entering in a portion of the passphrase, the rest could come from things like:

- A value written to an NFC tag that the user must tap
- A value encoded in a QR code that the user must scan
- A value obtained by some Bluetooth-connected device via a custom protocol

You, in code, would concatenate the pieces together, possibly using delimiters that cannot be typed in (e.g., ASCII characters below 32) to denote the sources of each segment of the passphrase. The result would be the actual passphrase you would use with `SQLCipher` for Android.

The objective is to make it easier for users to have more complex passphrases, while not having to type in something complex every time. Tapping an NFC tag is much faster than tapping out a passphrase on a typical phone keyboard, for example. Also, the “something you know and something you have” benefit of multi-factor authentication can help with defending against \$5 wrench attacks: if the NFC tag was destroyed, and the user never knew the portion of the passphrase stored on it, the user cannot divulge it.

Of course, this adds risks, such as the NFC tag being destroyed accidentally (e.g., “my dog ate it”). This can be mitigated in some cases by some “admin” being able to reset the password or supply a new NFC tag. In that case, getting the credentials requires *two* kidnappings and *two* \$5 wrenches (or the serial application of a single

\$5 wrench, if budgets preclude buying two such wrenches), adding to the degree of difficulty for breaking the encryption by that means.

### Detecting Failed Logins

If you try to decrypt a database using the incorrect passphrase — whether an attempt by outsiders to use the app, or the user “fat-fingering” the passphrase and making a typo — you will get an exception:

```
11-19 09:17:22.700: E/SQLiteOpenHelper(1634):  
net.sqlcipher.database.SQLiteException: file is encrypted or is not a  
database
```

Alas, this is not a specific exception, making it a bit difficult to detect failed passphrases specifically. Your options are:

- Assume that your testing is sound and that exceptions when opening a database represent invalid passphrases, or
- Use a generic error message that hints at an invalid passphrase but leaves open the possibility of something else being wrong, or
- Read into the exception’s message looking for “file is encrypted or is not a database”, though this is fragile in the face of changes to SQLCipher for Android

### SQLCipher for Android and Performance

Some developers worry about the overhead that encryption will place on the database I/O, and therefore worry that SQLCipher for Android will make their app unacceptably slow.

The impact of SQLCipher is not that bad, particularly for hardware with faster CPUs. Encryption is CPU-intensive, so faster CPUs reduce the overhead of the encryption. Also, since the disk I/O is comparable between SQLite and SQLCipher, the fact that flash memory is slow will mean that disk I/O, not decryption speed, will be the primary determinant of the speed of your queries. Similarly, disk I/O will count for more than CPU speed for the encryption needed for INSERT/UPDATE/DELETE operations.

For example, porting [one relatively crude benchmark](#) to use SQLCipher for Android showed no statistically significant performance difference from the SQLite edition on a Nexus 5 running Android 4.4.2.

To the extent that encryption adds overhead, it will tend to magnify existing problems. For example, anything that involves a “table scan” (i.e., a non-indexed lookup of database contents) will need more pages to be decrypted and, therefore, more decryption time. If your database I/O is well-tuned for SQLite, such as adding appropriate indexes, then your SQLCipher for Android overhead should be nominal.

Of course, the worse the CPU, the worse the story, and so older/cheaper devices may fare worse with SQLCipher for Android by comparison.

## Encrypted Preferences

There are effectively three forms of data storage in Android:

- SQLite databases
- SharedPreferences
- Arbitrary files, in whatever format you want

You can encrypt SQLite via SQLCipher for Android, as seen in this chapter. You can encrypt arbitrary files as part of your data format, such as via `javax.crypto`.

What is not supported, out of the box, is a way to encrypt SharedPreferences.

There are two approaches for encrypting the contents of SharedPreferences:

1. Encrypt the container in which the SharedPreferences are stored
2. Encrypt each preference value as you store it in the SharedPreferences, and decrypt it when you read the value back out

## Encryption via Custom SharedPreferences

SharedPreferences is an interface. Hence, you can create other implementations of that interface that store their data in something other than unencrypted XML files.

CSharedPreferences is one such implementation. You can find it in the [cwac-prefs project on GitHub](#).

CSharedPreferences handles the SharedPreferences and SharedPreferences.Editor interfaces, along with the in-memory representations of the preferences. It then delegates the work of *storing* the preferences to a strategy object, implementing a strategy interface (`CSharedPreferences.StorageStrategy`).

## ENCRYPTED STORAGE

---

Two such strategy implementations are supplied in the project: one using ordinary SQLite, and one using SQLCipher for Android.

The basic recipe for using CSharedPreferences is:

- Create the strategy object, such as

```
new SQLCipherStrategy(getContext(), NAME, "atestpassword", LoadPolicy.SYNC)
```

(here, NAME is the name of the set of preferences, "atestpassword" is your passphrase, and LoadPolicy.SYNC indicates that the preferences should be loaded from disk immediately, not on a background thread)

- Create a CSharedPreferences that employs your chosen strategy:

```
new CSharedPreferences(yourStrategyObjectGoesHere);
```

- Use the CSharedPreferences as you would any other SharedPreferences implementation
- Call close() on the strategy object, to release any resources that it might hold (e.g., open database connection)

## Encryption via Custom Preference UI and Accessors

The big drawback to the custom SharedPreferences is the fact that you cannot get the PreferenceScreen system to work with it. The preference UI is hard-wired to use the stock implementation of SharedPreferences and does not appear to support any way to substitute in some other implementation.

Hence, another approach is to keep things in standard SharedPreferences' XML files, but encrypt text values on a preference-by-preference basis. Since the data type needs to remain the same, most likely you would restrict this to encrypting strings (e.g., EditTextPreference, ListPreference) rather than numbers, booleans, etc.

To do this, you would need to:

- Implement static methods somewhere for your encryption and decryption algorithms
- Subclass the Preference classes of interest and override methods that would deal with the raw preference data, like onDialogClosed(), to encrypt the values you persist and decrypt the values you read in, using the static

methods mentioned above

- Use your extended Preference classes in your preference XML as needed
- Use those static methods as part of reading (or writing) the preference values directly via SharedPreferences

The downsides to this approach include:

- Only certain preferences are encrypted, rather than all of them
- You lose some of the low-level encryption power of SQLCipher for Android, such as automatic hashing of passphrases, which you would have to handle yourself
- There may not be a library that supplies these extended Preference classes, forcing you to roll your own

## IOCipher

SQLCipher for Android is also used as the backing store for [IOCipher](#). IOCipher is a virtual file system (VFS) for Android, allowing you to write code that looks and works like it uses normal file I/O, yet all of the files are actually saved as BLOBs in a SQLCipher for Android database. The result is a fully-encrypted VFS, inheriting all of SQLCipher's security features, such as default AES-256 encryption. This may be easier for you to use than encrypting and decrypting files individually via `javax.crypto`, for example.

IOCipher is considered to be in pre-alpha state as of November 2012.

# Packaging and Distributing Data

---

Sometimes, you not only want to ship your code and simple resources with your app, but you also want to ship other types of data, such as an initial database that your app will use when first run. This chapter will examine the means by which you can do those sorts of things.

## Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [database access](#)
- [content provider theory](#)
- [content provider implementations](#)

## Packing a Database To Go

Android's support for databases is focused on databases you create and populate entirely at runtime. Even if you want some initial data in the database, the expectation is that you would add that via Java code, such as the series of `insert()` calls we made in the `DatabaseHelper` of the various flavors of the `ConstantsBrowser` sample application.

However, that is tedious and slow for larger initial data sets, even if you make careful use of transactions to minimize the disk I/O.

What would be nice is to be able to ship a pre-populated database with your app. While Android does not offer built-in support for this, there are a few ways you can accomplish it yourself. One of the easiest, though, is to use existing third-party code

that supports this pattern, such as Jeff Gilfelt's `SQLiteAssetHelper`, available via [a GitHub repository](#).

Android Studio users can add a implementation statement to the dependencies closure in `build.gradle` to pull in `com.readystatesoftware.sqliteasset:sqliteassethelper:...` (for some version indicated by ...).

`SQLiteAssetHelper` replaces your existing `SQLiteOpenHelper` subclass with one that handles database creation and upgrading for you. Rather than you writing a lot of SQL code for each of those, you provide a pre-populated SQLite database (for creation) and a series of SQL scripts (for upgrades). `SQLiteAssetHelper` then does the work to set up your pre-populated database when the database is first accessed and running your SQL scripts as needed to handle schema changes. And, `SQLiteAssetHelper` is open source, licensed under the same Apache License 2.0 that is used for Android proper.

To examine `SQLiteAssetHelper` in action, let's look at the [Database/ConstantsAssets-AndroidStudio](#) sample project. This is yet another rendition of the same app as the other flavors of `ConstantsBrowser`, but one where we use a pre-populated database.

### Create and Pack the Database

Whereas normally you create your SQLite database at runtime from Java code in your app, you now create your SQLite database using whatever tools you like, at development time. Whether you use the command-line `sqlite3` utility, the SQLite Manager extension for Firefox, or anything else, is up to you. You will need to set up all of your tables, indexes, and so forth.

Then, you need to:

1. Create an `assets/databases/` directory in your project
2. Copy your database into this directory (or put it there in the first place, if you prefer)

If your `minSdkVersion` is less than 11, you will instead need to have a ZIP or GZIP archive containing the database. The archive should have the same name as the database file, just with the `.zip` or `.gz` extension. The reason for the ZIP compression comes from an Android 1.x/2.x limitation – assets that are compressed by the Android build tools have a file-size limitation (around 1MB). Hence, you need

to store larger files in a file format that will not be compressed by the Android build tools, and those tools will not try to compress a .zip file.

In the ConstantsAssets project, you will see an assets/databases/constants.db file, containing a copy of the SQLite database with our constants table and pre-populated values.

### Unpack the Database, With a Little Help(er)

Your compressed database will ship with your APK. To get it into its regular position on internal storage, you use SQLiteAssetHelper. Simply create a subclass of SQLiteAssetHelper and override its constructor, supplying the same values as you would for a SQLiteOpenHelper subclass, notably the database name and schema revision number. Note that the database name that you use must match the filename of the compressed database (minus the .zip extension, if you needed that).

So, for example, our new DatabaseHelper looks like this:

```
package com.commonware.android.dbasset;

import android.content.Context;
import com.readystatesoftware.sqliteasset.SQLiteAssetHelper;

class DatabaseHelper extends SQLiteAssetHelper {
    static final String TITLE="title";
    static final String VALUE="value";
    static final String TABLE="constants";
    private static final String DATABASE_NAME="constants.db";

    public DatabaseHelper(Context context) {
        super(context, DATABASE_NAME, null, 1);
    }
}
```

(from [Database/ConstantsAssets-AndroidStudio/app/src/main/java/com/commonware/android/dbasset/DatabaseHelper.java](#))

SQLiteAssetHelper will then copy your database out of assets and set it up for conventional use, as soon as you call `getReadableDatabase()` or `getWritableDatabase()` on an instance of your SQLiteAssetHelper subclass.

### Upgrading Sans Java

Traditionally, with SQLiteOpenHelper, to handle a revision in your schema, you

override `onUpgrade()` and do the upgrade work in there. With `SQLiteAssetHelper`, there is a built-in `onUpgrade()` method that uses SQL scripts in your APK to do the upgrade work instead.

These scripts will also reside in your `assets/databases/` directory of your project. The name of the file will be `$NAME_upgrade_$FROM-$TO.sql`, where you replace `$NAME` with the name of your database (e.g., `constants.db`), `$FROM` with the old schema version number (e.g., 1) and `$TO` with the new schema version number (e.g., 2). Hence, you wind up with files like `assets/databases/constants.db_upgrade_1-2.sql`. This should contain the SQL statements necessary to upgrade your schema between the versions.

`SQLiteAssetHelper` will chain these together as needed. Hence, to upgrade from schema version 1 to 3, you could either have a single dedicated 1->3 script, or a 1->2 script and a 2->3 script.

### Limitations

The biggest limitation comes with disk space. Since APK files are read-only at runtime, you cannot delete the copy of the database held as an asset in your APK file once `SQLiteAssetHelper` has unpacked it. This means that the space taken up by your ZIP file will be taken up indefinitely. Note, though, that you could use this to your advantage, offering the user a “start over from scratch” option that deletes their existing database, so `SQLiteAssetHelper` will unpack a fresh original copy on the next run. Or, you could implement a `SQLiteDownloadHelper` that follows the `SQLiteAssetHelper` approach but obtains its database from the Internet instead of from assets.

In principle, SQLite could change their file format. If that ever happens, you will need to make sure that you create a SQLite database in the file format that can be used by Android, more so than what can be used by the latest SQLite standalone tools.

# Advanced Database Techniques

---

This chapter offers tips and techniques for working with SQLite beyond what the previous chapters in the book have covered.

## Prerequisites

This chapter assumes that you have read the core chapters, particularly the ones on [databases](#) and [Internet access](#).

Also, please read [the chapter on advanced action bar techniques](#), particularly [the section on SearchView](#), as that is used in one of the sample apps.

## Full-Text Indexing

Standard SQL databases are great for ordinary queries. In particular, when it comes to text, SQL databases are great for finding rows where a certain column value matches a particular string. They are usually pretty good about finding when a column value matches a particular string prefix, if there is an index on that column. Things start to break down when you want to search for an occurrence of a string in a column, as this usually requires a “table scan” (i.e., iteratively examining each row to see if this matches). And getting more complex than that is often impossible, or at least rather difficult.

SQLite, in its stock form, inherits all those capabilities and limitations. However, SQLite also offers full-text indexing, where we can search our database much like how we use a search engine (e.g., “find all rows where this column has both foo and bar in it somewhere”). While a full-text index takes up additional disk space, the speed of the full-text searching is quite impressive.

For example, if you are reading this book using the Android APK edition (instead of the PDF, EPUB, or Kindle/MOBI editions), tap on the SearchView action bar item and search for FTS4. You will get a list of matches back almost instantaneously, despite the fact that you are searching a multi-megabyte book. That is because this book ships a SQLite-powered full-text index of the book's contents, specifically to power your use of SearchView.

In this section, we will review how you can add full-text indexing to your SQLite database and how you can let the user take advantage of that index using a SearchView.

### First, a Word About SQLite Versions

SQLite has evolved since Android's initial production release in 2008.

In many cases, Android does not incorporate updates to third-party code, for backwards-compatibility reasons (e.g., Apache's HttpClient). In the case of SQLite, newer Android versions do take on newer versions of SQLite... but the exact version of SQLite that a given version of Android uses is undocumented. Worse, some device manufacturers replace the stock SQLite for a version of Android with a different one.

[This Stack Overflow answer](#) contains a mapping of Android OS releases to SQLite versions, including various "anomalies" where manufacturers have elected to ship something else.

In many cases, the SQLite version does not matter. Core SQLite capabilities will have existed since the earliest days of Android. However, full-text indexing did not exist in the first SQLite used by Android, meaning that you will have to pay attention to your `minSdkVersion` and aim high enough that devices should support the full-text indexing option you choose.

Note that you could use an external SQLite implementation, one that gives you a newer SQLite engine than what might be on the device. For example, [SQLCipher for Android](#) ships its own copy of SQLite (with the SQLCipher extensions compiled in), one that is often newer than the one that is baked into the firmware of any given device.

### FTS3 and FTS4

There are two full-text indexing options available in SQLite: FTS<sub>3</sub> and FTS<sub>4</sub>. FTS<sub>4</sub>

can be much faster on certain queries, though overall the speed of the two implementations should be similar. FTS4 has two key limitations:

1. It may take a bit more disk space for its indexes.
2. It was added to SQLite 3.7.4, which was only introduced into standard Android in API Level 11.

The sample app for this section will demonstrate FTS4, as that is available on most Android devices.

Note that the Android developer documentation does not cover FTS3 or FTS4 full-text indexing. The details for the SQL syntax to support these options can be found in [the SQLite documentation](#).

### Creating a Full-Text Indexed Table

A full-text indexed table, using FTS3 or FTS4, uses SQLite's CREATE VIRTUAL TABLE syntax. This indicates that you are opting into some special table-storage behavior, rather than the stock stuff.

In the [Database/FTS](#) sample project, the onCreate() method of our SQLiteOpenHelper subclass (DatabaseHelper) creates such a virtual table, using FTS4 for full-text indexing:

```
@Override
public void onCreate(SQLiteDatabase db) {
    db.execSQL("CREATE VIRTUAL TABLE questions USING fts4("
        + "_id INTEGER PRIMARY KEY, title TEXT, "
        + "link TEXT, profileImage TEXT, creationDate INTEGER, "
        + "order=DESC);");
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/DatabaseHelper.java](#))

There are a few differences here from a typical CREATE TABLE statement, beyond the introduction of the VIRTUAL keyword:

- The USING fts4 indicates that the virtual table is employing the FTS4 full-text indexing engine. To use FTS3, just replace fts4 with fts3.
- You can have key-value pairs in the column list, separated by equals signs, to provide options for configuring the virtual table. In this case, it will provide options for configuring the FTS4 indexing behavior. In this case, we are

providing `order=DESC`, to indicate that the full-text index should be optimized for returning items in descending order. Note that these options only exist for FTS<sub>4</sub>, not FTS<sub>3</sub>. The full roster of available options is covered in [the SQLite documentation](#).

This gives us a table that supports normal table operations but also has a full-text index for its columns. However, there are some limitations, notably that these tables ignore constraints. So, for example, the PRIMARY KEY constraint applied to the `_id` column is ignored.

### Populating a Full-Text Indexed Table

Adding content to an FTS<sub>3</sub> or FTS<sub>4</sub> table uses the same INSERT statements that you might use for a regular table. For example, the DatabaseHelper in the sample app has an `insertQuestions()` method that deletes all existing rows in the questions table, then inserts a bunch of rows based on a supplied List of Item objects:

```
void insertQuestions(Context app, List<Item> items) {
    SQLiteDatabase db=getDb(app);

    db.beginTransaction();

    db.delete("questions", null, null);

    try {
        for (Item item : items) {
            Object[] args={ item.id, item.title, item.link,
                item.owner.profileImage, item.creationDate};

            db.execSQL("INSERT INTO questions (_id, title, "
                +"link, profileImage, creationDate) "
                +"VALUES (?, ?, ?, ?, ?)",
                args);
        }

        db.setTransactionSuccessful();
    }
    finally {
        db.endTransaction();
    }
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/DatabaseHelper.java](#))

If those Item objects look familiar, that is because this app is a modified version of

the Stack Overflow questions apps profiled in [the chapter on Internet access](#).

The reason why we are deleting everything before inserting is just to keep the sample simple. The database table will hold all of the questions pulled from the Stack Exchange API. Each time we run the app, we get the latest questions from that API. The vision was to use INSERT OR REPLACE or INSERT OR IGNORE statements to be able to merge content into the table. However, FTS<sub>3</sub> and FTS<sub>4</sub> tables ignore all constraints, as noted above, which prevents the conflict resolution options (e.g., OR REPLACE) from working. Hence, rather than manually sifting through to find if there is an existing row or not for a given ID value, this sample simply gets rid of all existing rows. A production-grade app would likely apply a more sophisticated algorithm.

### Querying a Full-Text Indexed Table

While you can query a full-text indexed table using normal SELECT statements, usually the point is to apply the MATCH operator, as is seen in the loadQuestions() method from DatabaseHelper:

```
Cursor loadQuestions(Context app, String match) {
    SQLiteDatabase db=getDb(app);

    if (TextUtils.isEmpty(match)) {
        return(db.rawQuery("SELECT * FROM questions ORDER BY creationDate DESC",
            null));
    }

    String[] args={ match };

    return(db.rawQuery("SELECT * FROM questions WHERE title "
        +"MATCH ? ORDER BY creationDate DESC", args));
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/DatabaseHelper.java](#))

The MATCH operator supports a wide range of query structures, including:

- Keyword matches (e.g., Android)
- Prefix matches (e.g., SQL\*)
- Phrase matches (e.g., "open source")
- NEAR, AND, OR, and NOT operators (e.g., sqlite AND database)

The result is the same sort of Cursor that you would get from a regular SELECT

statement against a non-full-text-indexed table.

### Some Notes About the Rest of the Sample App

As noted previously, this sample app is a revised version of the Stack Overflow questions list from [the chapter on Internet access](#). It is specifically derived from [the Picasso version of the sample](#). However, this version is designed to allow the user to full-text search the downloaded question data (e.g., title), above and beyond just seeing the list of latest questions.

This, in turn, requires a few more changes than those outlined so far. The following sections outline some of the highlights.

### Adding a ModelFragment

The original sample had a very simple data model: a list of questions retrieved via Retrofit. Hence, the sample did not include much in the way of model management.

The FTS sample needs a database, which implies more local disk I/O that we are responsible for, which in turn leads us in the direction of implementing a model fragment (ModelFragment), much as the tutorials and a few other samples do:

```
package com.commonware.android.fts;

import android.app.Activity;
import android.content.Context;
import android.database.Cursor;
import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.util.Log;
import org.greenrobot.eventbus.EventBus;
import org.greenrobot.eventbus.Subscribe;
import org.greenrobot.eventbus.ThreadMode;
import retrofit2.Retrofit;
import retrofit2.converter.gson.GsonConverterFactory;

public class ModelFragment extends Fragment {
    private Context app=null;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);

        setRetainInstance(true);
    }

    @Override
    public void onAttach(Activity host) {
        super.onAttach(host);
```

## ADVANCED DATABASE TECHNIQUES

---

```
EventBus.getDefault().register(this);

if (app==null) {
    app=host.getApplicationContext();
    new FetchQuestionsThread().start();
}
}

@Override
public void onDetach() {
    EventBus.getDefault().unregister(this);

    super.onDetach();
}

@Subscribe(threadMode =ThreadMode.BACKGROUND)
public void onSearchRequested(SearchRequestedEvent event) {
    try {
        Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, event.match);

        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception searching database", e);
    }
}

class FetchQuestionsThread extends Thread {
    @Override
    public void run() {
        Retrofit retrofit=
            new Retrofit.Builder()
                .baseUrl("https://api.stackexchange.com")
                .addConverterFactory(GsonConverterFactory.create())
                .build();
        StackOverflowInterface so=
            retrofit.create(StackOverflowInterface.class);

        try {
            SOQuestions questions=so.questions("android").execute().body();

            DatabaseHelper
                .getInstance(app)
                .insertQuestions(app, questions.items);
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception populating database", e);
        }

        try {
            Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, null);

            EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception populating database", e);
        }
    }
}
```

## ADVANCED DATABASE TECHNIQUES

---

```
    }  
  }  
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/ModelFragment.java](#))

In `onCreate()`, we mark this fragment as retained, as that is key to the model fragment pattern, so the fragment retains the model data across configuration changes.

In `onAttach()`, we register for the greenrobot EventBus, plus kick off a `FetchQuestionsThread` if we have not done so already (i.e., this is the first `onAttach()` call we have received). `onDetach()` unregisters us from the event bus.

`FetchQuestionsThread`, in turn, uses Retrofit to download the questions from Stack Overflow, then uses `DatabaseHelper` to insert the questions into the FTS-enabled database table, then uses the `DatabaseHelper` again to retrieve all existing questions in the form of a `Cursor`, which it wraps in a `ModelLoadedEvent` and posts to the EventBus. This time, though, it posts it as a sticky event.

That sticky event is consumed by a revised version of the `QuestionsFragment`, in its `onModelLoaded()` method:

```
@Subscribe(sticky = true, threadMode = ThreadMode.MAIN)  
public void onModelLoaded(ModelLoadedEvent event) {  
    ((SimpleCursorAdapter)getListAdapter()).changeCursor(event.model);  
  
    if (sv != null) {  
        sv.setEnabled(true);  
    }  
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

But because this is a sticky event, we will get this event both when it is raised (because the data is loaded) and any time thereafter when the fragment registers with the EventBus. This allows `QuestionsFragment` to *not* be retained, as it will get back the bulk of its model data automatically from greenrobot's EventBus.

`QuestionsFragment` also is modified from the Picasso sample to deal with the fact that its model data is now a `Cursor`, so it uses `SimpleCursorAdapter` to populate the list. To handle loading avatar images from the URLs, `QuestionsFragment` adds a `QuestionBinder` implementation of `ViewBinder` to the `SimpleCursorAdapter`, where `QuestionBinder` handles the Picasso logic from before:

## ADVANCED DATABASE TECHNIQUES

---

```
private class QuestionBinder implements SimpleCursorAdapter.ViewBinder {
    int size;

    QuestionBinder() {
        size=getActivity()
            .getResources()
            .getDimensionPixelSize(R.dimen.icon);
    }

    @Override
    public boolean setViewValue (View view, Cursor cursor, int columnIndex) {
        switch (view.getId()) {
            case R.id.title:
                ((TextView)view).setText(Html.fromHtml(cursor.getString(columnIndex)));

                return(true);

            case R.id.icon:
                Picasso.with(getActivity()).load(cursor.getString(columnIndex))
                    .resize(size, size).centerCrop()
                    .placeholder(R.drawable.owner_placeholder)
                    .error(R.drawable.owner_error).into((ImageView)view);

                return(true);
        }

        return(false);
    }
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

The main activity (MainActivity) sets up the ModelFragment in onCreate(), at least when one does not already exist due to a configuration change:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
        getSupportFragmentManager().beginTransaction()
            .add(android.R.id.content,
                new QuestionsFragment()).commit();
    }

    model=(ModelFragment)getSupportFragmentManager().findFragmentByTag(MODEL);

    if (model==null) {
        model=new ModelFragment();
        getSupportFragmentManager().beginTransaction().add(model, MODEL).commit();
    }
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/MainActivity.java](#))

This description, though, has skipped over the onEventBackgroundThread() method on the ModelFragment, which we will get to later in this overview.

### Adding a SearchView

As is covered in [the chapter on advanced action bar techniques](#), a SearchView can be used to provide the standard “magnifying glass” search icon in the action bar. When tapped, the action bar item expands into a field where the user can type something, which our code can then receive and use to update the UI. In the SearchView sample from the action bar chapter, we saw using a SearchView for filtering. This time, we will use a SearchView for searching.

For a search, we need to know when the user is done typing, which is usually done by the user clicking a submit button. Hence, our code to configure the SearchView (a configureSearchView() method in QuestionsFragment) calls setSubmitButtonEnabled(true):

```
private void configureSearchView(Menu menu) {
    MenuItem search=menu.findItem(R.id.search);

    search.setOnActionExpandListener(this);
    sv=(SearchView)search.getActionView();
    sv.setOnQueryTextListener(this);
    sv.setSubmitButtonEnabled(true);
    sv.setIconifiedByDefault(true);

    if (initialQuery != null) {
        sv.setIconified(false);
        search.expandActionView();
        sv.setQuery(initialQuery, true);
    }
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

This, in turn, means that we need to pay attention to onQueryTextSubmit() in our SearchView.OnQueryTextListener implementation. That interface is implemented on QuestionsFragment itself, and delegates its work to a doSearch() method:

```
@Override
public boolean onQueryTextSubmit(String query) {
    doSearch(query);

    return(true);
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

## ADVANCED DATABASE TECHNIQUES

---

That method, in turn, confirms that the search is different than the last one we did (so we do not waste time running the search again), disables the `SearchView`, and posts a `SearchRequestedEvent` on the `EventBus` with the user's search string:

```
private void doSearch(String match) {
    if (!match.equals(lastQuery)) {
        lastQuery=match;

        if (sv != null) {
            sv.setEnabled(false);
        }

        EventBus.getDefault().post(new SearchRequestedEvent(match));
    }
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

That event is picked up by `onSearchRequested()` on `ModelFragment`. The `@Subscribe(threadMode =ThreadMode.BACKGROUND)` annotation means that the event will be delivered to us on an `EventBus`-supplied background thread, so we can perform database I/O. In it, we call `loadQuestions()` on the `DatabaseHelper` to perform the search, and post another sticky `ModelLoadedEvent` to update the UI with the search results and re-enable the `SearchView`:

```
@Subscribe(threadMode =ThreadMode.BACKGROUND)
public void onSearchRequested(SearchRequestedEvent event) {
    try {
        Cursor results=DatabaseHelper.getInstance(app).loadQuestions(app, event.match);

        EventBus.getDefault().postSticky(new ModelLoadedEvent(results));
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(),
            "Exception searching database", e);
    }
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/ModelFragment.java](#))

When the user clears the `SearchView`, such as by pressing the `BACK` button a few times, the `onMenuItemActionCollapse()` method of `QuestionsFragment` calls a `clearSearch()` method:

```
@Override
public boolean onMenuItemActionCollapse(MenuItem item) {
    clearSearch();
}
```

## ADVANCED DATABASE TECHNIQUES

---

```
return(true);  
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

That `clearSearch()` method simply posts another `SearchRequestedEvent`, this time to load a fresh roster of all questions:

```
private void clearSearch() {  
    if (lastQuery!=null) {  
        lastQuery=null;  
  
        sv.setEnabled(false);  
        EventBus.getDefault().post(new SearchRequestedEvent(null));  
    }  
}
```

(from [Database/FTS/app/src/main/java/com/commonsware/android/fts/QuestionsFragment.java](#))

## The Results

When you run the app, you are initially presented with the list of questions pulled from the Stack Exchange API:

Figure 771: FTS Demo, As Initially Launched

## ADVANCED DATABASE TECHNIQUES

---

Tapping on the SearchView opens it up, as normal, though this time with the “submit” button (the rightward-pointing arrowhead):

## ADVANCED DATABASE TECHNIQUES

---

Typing in a search, then tapping the “submit” button, will reload the list with those questions that match the search criteria in the question title:

Figure 773: FTS Demo, Showing Basic Search

Figure 774: FTS Demo, Showing Boolean Search

Using the BACK button to get out of the SearchView reloads the full list of questions.

### Getting Snippets

Usually, the content that is being indexed is a lot longer than Stack Overflow question titles. For example, it might be chapters in a book on Android application development. In that case, it would be useful to not only find out what chapters match the search expression, but what the prose is around the search expression, to help the user determine which search results are likely to be useful.

The APK edition of this book stores each paragraph and bullet as a separate entry in a SQLite database in an FTS<sub>3</sub>-enabled table. The query used when the reader types in a search expression in the app's SearchView is:

```
SELECT ROWID as _id, file, node, snippet(booksearch) AS snippet FROM
booksearch WHERE prose MATCH ?
```

Here, `file` and `node` are used to identify where this passage came from within the book, so when the user taps on a search result in the list, the book reader can jump to that particular location.

## ADVANCED DATABASE TECHNIQUES

The `snippet()` auxiliary function will return, as the name suggests, a snippet of the indexed text, with the search match highlighted. It takes the name of the table `booksearch` as a mandatory parameter. It also supports optional parameters for what to bracket the search match with (defaults to `<b>` and `</b>`) and what to use for an ellipsis for extended prose segments (defaults to `[b> . . . </b]`). In the case of this query, the default formatting of the result is used. The resulting text can then be fed into `Html.fromHtml()` to generate the text for the `ListView` row, showing the search match within the snippet highlighted in bold:

*Figure 775: This Book's Reader App, Showing Search Results*

The app also shows the name of the chapter in the lower-right corner of each row, to help provide larger context for where this snippet comes from.

# Data Backup

---

Backing up your PC used to be essential. To some extent, it still is, but as more and more stuff moves to “the cloud”, local machine backups become less and less important.

Backing up mobile devices historically has been an afterthought, as a lot of what people use these devices for are gateways to Internet-hosted content and services. However, as more and more stuff becomes local to the device — for disconnected operation, for example — the greater the need for backing up that local data.

Android does not have a full-device backup as part of the OS. It does have some hooks that Google advertises as being “backup”, but IT professionals would not consider Google’s definition to match their own for “backup”. And, what hooks there are exist at the level of an app, not the device, providing opportunity — and requirements — for developers to tailor what gets backed up and, to a lesser extent, how it gets backed up.

This chapter will explore the steps to back up your app’s data, with and without Google’s assistance.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the ones on [file access](#) and [Internet access](#).

Having read the chapters on [SSL](#) and [SQLCipher for Android](#) are not required but may prove to be useful background for some of the side topics in this chapter.

## First, Some Terminology

One key concept when it comes to backups is what, exactly, we are backing up. The general rule is that you focus your backup regimen on the “system of record”. This is the one and only system that has the master copy of the data. While it may be one “system”, that “system” may be rather complex (e.g., cluster of database servers). However, anything else outside of that system — such as clients for those servers — are not part of the system of record. While they may have some data that is also held by the system of record, that data is considered to be a cached local copy; the system of record has the “real” copy of the data.

## Differing Definitions of “Backup”

The problem is that we toss around the term “backup” as though there is a universal canonical definition for that term. Hence, what Google will tell users is “backup” will not necessarily line up with what an IT department will consider “backup” to mean.

## What Google Thinks “Backup” Means

Google’s focus is on the cloud. Therefore, their focus is on apps using data resident in the cloud, with some servers forming the system of record. Google (presumably) does some sort of backup for their own systems of record, for their own Internet-based services, and Google assumes that other firms are doing the same.

The side-effect of this definition, though, is that Google does not view an app as having much in the way of local data that needs to be backed up. Cached data can always be reloaded from the system of record, after all. What Google expects needs to be backed up will be local preferences and perhaps authentication or authorization credentials for working with the system of record. This dataset is small and does not necessarily change all that often.

Because the dataset does not change that often, Google only really cares about restoring that data in case of a total device replacement. In other words, if your phone gets run over by a bakery truck, and you wind up replacing that phone with another Android phone, Google is interested in making sure that your old phone’s apps get restored along with the old phone’s last backup of the tiny dataset. After that, you are on your own. In particular, because the dataset does not change that often and does not have much in the way of critical data, Google is not concerned with allowing users to restore app data from backup for any reason *other* than

replacing the device outright. In other words, Google is only concerned with disaster recovery.

Google does not offer any configurability for where backups themselves are stored. Whatever Google backs up, Google stores where Google wants. Terms of service and related agreements give Google — at least in Google’s eyes — the right to do pretty much anything they want with that data. While they will tout the fact that Android 6.0+ backups are stored in an encrypted fashion, they fail to note that Google — not the developer, not the user — holds the encryption keys. Thus, the security offered by this encryption is nominal, perhaps slowing down somebody who breaks into Google’s network, but otherwise not preventing anyone from accessing the data.

Also, there is a 25MB data cap on the size of the backup, so if your app might have data in excess of that, you need to handle backups yourself.

Finally, the author of this book cannot get Google’s backup system to work on production hardware, as will be explained a bit more [later in this chapter](#).

### What IT Thinks “Backup” Means

Apps may well be the system of record for the data that they work with. There is no requirement that all apps be front-ends for some server, any more than there is a requirement that all desktop OS apps be front-ends for some server. There may be plenty of business or technical reasons why an app will be the system of record for its data, either all of the time or in between specific sync operations with some central data store.

As a result, an IT department will recognize that apps need a much more robust backup and restoration service, one that takes into account conventional IT backup concepts.

Most IT-grade backup regimens have the notion of “backup aging”. Rather than Google’s approach of considering only one backup to be relevant, an IT department will maintain a series of backups (e.g., 14 days of nightly backups, plus 3 months of weekly backups, plus 5 years of monthly backups), to be able to handle data that might be lost, but where that loss is not detected for some time.

Most IT-grade backups regimens allow data to be restored, in part or completely, at any point, not just in case a device is stepped on by an elephant or otherwise destroyed. Disaster recovery is a *scenario* of a backup regimen, not the sole objective.

IT departments also tend to be very concerned about where their business data goes. The idea that the data should be available, unencrypted, to arbitrary third parties would be an anathema. Business data should be backed up on by IT-supplied technology on IT-supplied backup media, employing whatever security the IT department thinks is necessary.

Suffice it to say, Google’s approach to “backup” does not align well with what an IT department will want.

### What Your Legal Counsel Thinks “Backup” Means

Legal counsel, at some point, should be brought into the discussion of backups, as, for better or worse, there are legal risks involved in backups.

Particularly with Google-style, send-the-data-to-a-third-party backups, you need to ensure that this will not get you in legal trouble. From European Union privacy laws to HIPAA in the US, there are plenty of laws that prohibit the careless distribution of data.

Beyond that, legal counsel will be worried about “the Ashley Madison scenario”. A firm’s IT department will be responsible for ensuring that their servers are not hacked into. However, once you start passing data to third parties, now you are at risk of *those* servers getting hacked into. Legal counsel can advise you on what your legal exposure is, in terms of potential lawsuits from people whose data might get leaked by these sorts of attacks.

### Implementing IT-Style Backup

So, if we want to add backup and restore capability to our app, what is needed? To explore that, we will use the [Backup/BackupClient](#) sample project as an illustration. This is a clone of a sample that originally appeared in [the chapter on files](#). We have a three-tab ViewPager, with a large EditText widget in each tab. The three tabs differ in where they persist their data:

- `getFilesDir()`
- `getExternalFilesDir()`
- `DIRECTORY_DOCUMENTS` — the user’s Documents/ directory on API Level 19+ devices

This revised sample adds backup-and-restore functionality to this app.

## DATA BACKUP

---

The app also has one other change: it stores the most-recently-visited tab in SharedPreferences. To that end, MainActivity has a PrefsLoadThread static inner class that asynchronously loads the SharedPreferences, then delivers them via greenrobot's EventBus:

```
private static class PrefsLoadThread extends Thread {
    private final Context ctxt;

    PrefsLoadThread(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
        SharedPreferences prefs=
            PreferenceManager.getDefaultSharedPreferences(ctxt);
        PrefsLoadedEvent event=new PrefsLoadedEvent(prefs);

        EventBus.getDefault().post(event);
    }
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/MainActivity.java](#))

MainActivity picks up this event in onPrefsLoaded(), an EventBus method that takes PrefsLoadedEvent as a parameter and updates the current page of the ViewPager (named pager):

```
@Subscribe(threadMode =ThreadMode.MAIN)
public void onPrefsLoaded(PrefsLoadedEvent event) {
    this.prefs=event.prefs;

    int lastVisited=prefs.getInt(PREF_LAST_VISITED, -1);

    if (lastVisited>-1) {
        pager.setCurrentItem(lastVisited);
    }
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/MainActivity.java](#))

The PrefsLoadThread is kicked off in onStart(), and the PREF\_LAST\_VISITED value is saved in onStop(), along with the registration and unregistration from the event bus:

```
@Override
```

---

## DATA BACKUP

---

```
protected void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);

    if (prefs==null) {
        new PrefsLoadThread(this).start();
    }
}

@Override
protected void onStop() {
    EventBus.getDefault().unregister(this);

    if (prefs!=null) {
        prefs
            .edit()
            .putInt(PREF_LAST_VISITED, pager.getCurrentItem())
            .apply();
    }

    super.onStop();
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/MainActivity.java](#))

The net effect is that we retain the last-visited tab across invocations of MainActivity. This forms part of the data that we would like to back up.

### Choosing the Backup Scope

The first question is: what exactly are we backing up? Files? Databases? SharedPreferences? Stuff that is out in common areas, like top-level directories on external storage (e.g., DIRECTORY\_DOCUMENTS) or the ContactsContract ContentProvider?

Typically, an individual app will focus on backing up only that app's data, which would exclude the common areas from consideration. That does not mean that you *can't* back up common data, but it makes restoration a bit more challenging, as you do not want to overwrite changes to that data that the user made from another app.

In BackupClient, we are backing up:

- the contents of `getFilesDir()`, which will hold onto one of our tabs' contents

## DATA BACKUP

---

- the contents of `getExternalFilesDir()`, which will hold onto another of our tabs' contents
- some of the contents of the directory that holds the `SharedPreferences` for the app, which will pick up the preference value we are using for the last-visited tab

Notably, we are not backing up the file out on shared storage (the “Public” tab, set to store its data in

`Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOCUMENTS)`). Hence, whatever is in that tab will be left alone when we restore the data from the backup.

### Choosing a Backup Trigger

The next question is: when are we backing up the data?

There are any number of possibilities:

- A push message, such as through [GCM](#), could request that the app back up its data
- Time-based triggers, using [AlarmManager](#) or [JobScheduler](#), could be used to periodically make backups
- You could offer backups on demand, such as through an action bar item

The automated options (push message, `AlarmManager`, `JobScheduler`) are great, so users do not forget to make a backup. On the other hand, there is the risk that the user is using the app at the time the automated backup is supposed to happen, which means you will need some additional logic to ensure that you postpone that backup until a quieter time. It is difficult to back up data that is actively in use.

The `BackupClient` sample will settle for a simple manual trigger, via a “Backup” action bar item in the main activity. We also have a “Restore” action bar item, to request to restore the data from a backup. So, `MainActivity` will load in a menu resource that contains these two options:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/backup"
    android:icon="@drawable/ic_backup_white_24dp"
    android:title="@string/menu_backup"/>
  <item
```

---

## DATA BACKUP

---

```
    android:id="@+id/restore"
    android:icon="@drawable/ic_restore_white_24dp"
    android:title="@string/menu_restore" />
</menu>
```

(from [Backup/BackupClient/app/src/main/res/menu/actions.xml](#))

It uses a pair of icons culled from [Google's material design icon set](#).

That resource is inflated in `onCreateOptionsMenu()`. If the user chooses the “Backup” option, we start a `BackupService` to do the work:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);

    return(super.onCreateOptionsMenu(menu));
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.backup) {
        BackupService.enqueueWork(this);

        return(true);
    }
    else if (item.getItemId()==R.id.restore) {
        startActivity(new Intent(this, RestoreRosterActivity.class));

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/MainActivity.java](#))

We will get into the restore scenario a bit later in this chapter.

## Generating the Dataset

Next, we need to actually collect the data to be backed up and package it in some form to send to a server to serve as the backup dataset.

There are any number of ways to package this sort of data, but a ZIP file seems like a likely candidate:

## DATA BACKUP

---

- It is fairly easy to work with on Android
- It is fairly easy to work with on servers that might need to unpack the data
- It is fairly easy to examine using desktop tools, for development, diagnostics, etc.

It is the job of the BackupService to create a ZIP file of our desired data, then send that ZIP file to a backup server.

BackupService itself is a JobIntentService, as this sort of work is a nice “fire-and-forget” sort of request, where we no longer need the service once the work is done.

In onHandleWork(), we orchestrate the major steps in this process:

```
@Override
public void onHandleWork(@NonNull Intent i) {
    try {
        File backup=buildBackup();

        uploadBackup(backup);
        backup.delete();

        EventBus.getDefault().post(new BackupCompletedEvent());
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
            "Exception creating ZIP file", e);
        EventBus.getDefault().post(new BackupFailedEvent());
    }
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

We:

- Call a buildBackup() method that creates our backup dataset
- Call an uploadBackup() method to send the dataset to some backup server
- Delete the local backup when that is done, as we no longer need it
- Raise events on an event bus for the UI layer’s use, for when a backup succeeds or fails

Those events can then trigger UI responses. In the case of this trivial sample app, they just result in Toast messages to the user:

```
@Subscribe(threadMode =ThreadMode.MAIN)
```

## DATA BACKUP

---

```
public void onCompleted(BackupService.BackupCompletedEvent event) {
    Toast
        .makeText(this, R.string.msg_backup_completed, Toast.LENGTH_LONG)
        .show();
}

@Subscribe(threadMode = ThreadMode.MAIN)
public void onFailed(BackupService.BackupFailedEvent event) {
    Toast
        .makeText(this, R.string.msg_backup_failed, Toast.LENGTH_LONG)
        .show();
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/MainActivity.java](#))

A production-grade app would do something more sophisticated, particularly for error messages, given that a Toast is ephemeral, and so the user might not see it.

`buildBackup()` is responsible for creating a file that contains our desired dataset and returning the File object pointing to that file:

```
private File buildBackup() throws IOException {
    File zipFile=new File(getCacheDir(), BACKUP_FILENAME);

    if (zipFile.exists()) {
        zipFile.delete();
    }

    FileOutputStream fos=new FileOutputStream(zipFile);
    ZipOutputStream zos=new ZipOutputStream(fos);

    zipDir(ZIP_PREFIX_FILES, getFilesDir(), zos);
    zipDir(ZIP_PREFIX_PREFS, getSharedPreferencesDir(this), zos);
    zipDir(ZIP_PREFIX_EXTERNAL, getExternalFilesDir(null), zos);
    zos.flush();
    fos.getFD().sync();
    zos.close();

    return(zipFile);
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

We put the backup ZIP file in internal storage cache (`getCacheDir()`), as that is not something that we are backing up, and therefore we do not need to worry about somehow trying to back up the backup file itself.

## DATA BACKUP

---

We then call `zipDir()` three times, one for each directory of data to be backed up. Two of the three locations have SDK-supplied methods to get the `File` object pointing at those directories: `getFilesDir()` and `getExternalFilesDir()`. Unfortunately, the SDK does not provide any direct method that returns a `File` pointing at the directory for `SharedPreferences`. So, we have to hack one ourselves, in the form of `getSharedPrefsDir()`:

```
static File getSharedPrefsDir(Context ctxt) {
    return(new File(new File(ctxt.getApplicationInfo().dataDir),
        "shared_prefs"));
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

`getApplicationInfo()` returns the `ApplicationInfo` object describing our app. That has a `dataDir` field that points to *all* of our internal storage (whereas `getFilesDir()` points to a subdirectory off of `dataDir`). The `SharedPreferences` are stored in XML files in a `shared_prefs/` directory off of the location pointed to by the `dataDir` field. This is not an ideal solution, as in theory the `SharedPreferences` storage location could move. However, this code should work for all API levels from 1 through 23, and therefore it is reasonably likely that it will hold up over time.

`zipDir()` not only takes the `File` of data to be backed up and a `ZipOutputStream` representing where to package the data, but it also takes a path prefix. ZIP files do not really have a directory structure; that structure is faked based on path-style names associated with each entry. The prefix is added to each of those names, giving the effect of putting each directory's contents into a separate "directory" within the ZIP archive. Those three prefixes are defined as simple `String` constants:

```
static final String ZIP_PREFIX_FILES="files/";
static final String ZIP_PREFIX_PREFS="shared_prefs/";
static final String ZIP_PREFIX_EXTERNAL="external/";
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

`zipDir()` itself (mostly) is a typical recursive put-the-files-in-the-archive method:

```
private void zipDir(String basePath, File dir,
    ZipOutputStream zos) throws IOException {
    byte[] buf=new byte[16384];

    if (dir.listFiles()!=null) {
        for (File file : dir.listFiles()) {
            if (file.isDirectory()) {
```

## DATA BACKUP

---

```
String path=basePath+file.getName()+"/";

zos.putNextEntry(new ZipEntry(path));
zipDir(path, file, zos);
zos.closeEntry();
}
else if (!file.getName().equals(BACKUP_PREFS_FILENAME)) {
    FileInputStream fin=new FileInputStream(file);
    int length;

    zos.putNextEntry(
        new ZipEntry(basePath+file.getName()));

    while ((length=fin.read(buf))>0) {
        zos.write(buf, 0, length);
    }

    zos.closeEntry();
    fin.close();
}
}
}
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

The one wrinkle is that we filter out files with a particular name, denoted by the `BACKUP_PREFS_FILENAME` constant:

```
private static final String BACKUP_PREFS_FILENAME=
    "com.commonsware.android.backup.BackupService.xml";
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

We will explore what this file is, and why we are not backing it up, later in this chapter.

This backup approach has its flaws, in the interests of keeping the example simple:

- The UI layer is not saving all in-flight data before doing the backup. Hence, any changes in the current tab, since we moved to that tab, are not saved to disk or backed up. And, since we only save what the current tab is in `onStop()`, that too has not been adjusted since our activity moved to the foreground, and so it may be out of date. A production-grade app will need to decide what data that has not been saved through ordinary means should be saved prior to a manual backup, assuming that the app has a manual

- backup option in the first place.
- The UI layer is not preventing the user from changing data that is being backed up while the backup is happening. In this sample app, the data to be backed up is small enough that it will probably happen quickly enough to not be a problem. A production-grade app, though, should take steps to prevent data entry (though perhaps not navigation through the app) while the backup is going on. Any such steps, though, need to take into account the possibility that the backup may fail — we do not want a failed backup to block the user from working in the app for hours.

### Transmitting the Dataset

Given the data to be backed up in a nice convenient package, we need to get that dataset off the device and someplace safe, where we can later download and restore it if needed. There are any number of possible solutions here, including many existing public Web services (Dropbox, Amazon's AWS S3, Google Drive, etc.). If you are only worried about manual backups, you could even consider using `ACTION_SEND` to send the dataset as an email attachment, though size and content limitations on email attachments may make this impractical for many users.

`BackupService` works with some implementation of a particular REST-style API for backing up and restoring the data. This API is fairly lightweight, light enough that it can be implemented in ~70 lines of Ruby code, as will be seen [later in this chapter](#). You could implement the same sort of API in any number of Web frameworks.

For backing up data, there are two REST operations that we need to perform:

- We need to create a new backup entry, via an HTTP POST request to `/api/backups` on the backup server
- We need to upload the dataset itself, via an HTTP PUT request to `/api/backups/.../dataset` on the backup server, where the `...` is a backup ID that we get from the response to the original POST request

To implement the client side, `BackupService` employs the `OkHttp` library profiled in [the chapter on Internet access](#). Specifically, `uploadBackup()` does both of the HTTP requests necessary to back up the data, given the `File` pointing to the ZIP archive that is our dataset:

```
private void uploadBackup(File backup) throws IOException {
    Request request=new Request.Builder()
        .url(URL_CREATE_BACKUP)
```

## DATA BACKUP

---

```
.post(RequestBody.create(JSON, "{}"))
    .build();
Response response=OKHTTP_CLIENT.newCall(request).execute();

if (response.code()==201) {
    String backupURL=response.header("Location");

    request=new Request.Builder()
        .url(backupURL+RESOURCE_DATASET)
        .put(RequestBody.create(ZIP, backup))
        .build();
    response=OKHTTP_CLIENT.newCall(request).execute();

    if (response.code()==201) {
        String datasetURL=response.header("Location");
        SharedPreferences prefs=
            getSharedPreferences(getClass().getName(),
                Context.MODE_PRIVATE);

        prefs
            .edit()
            .putString(PREF_LAST_BACKUP_DATASET, datasetURL)
            .commit();
    }
    else {
        Log.e(getClass().getSimpleName(),
            "Unsuccessful request to upload backup");
    }
}
else {
    Log.e(getClass().getSimpleName(),
        "Unsuccessful request to create backup");
}
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

We create an OkHttp Request.Builder representing our POST request. The URL is defined as a constant, URL\_CREATE\_BACKUP:

```
private static final String URL_CREATE_BACKUP=
    BuildConfig.URL_SERVER+"/api/backups";
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

This, in turn, is built up from the fixed REST endpoint path (/api/backups), with the rest of the URL coming from BuildConfig.URL\_SERVER. This is defined out in

## DATA BACKUP

---

our `build.gradle` file, allowing us to have different backup server locations based upon build types (or, in principle, product flavors):

```
buildTypes {
    debug {
        buildConfigField "String", "URL_SERVER", "'http://10.0.2.2:4567'"
    }

    release {
        buildConfigField "String", "URL_SERVER", "'http://10.0.2.2:4567'"
    }
}
```

(from [Backup/BackupClient/app/build.gradle](#))

Here, they happen to both point to the same value at the moment, the IP address that, on an Android emulator, represents localhost of your development machine. However, you could easily change the release build type to point to some production instance of a backup server.

The body of the POST request is a JSON object containing whatever we want, in case we need to provide some sort of identifiers with the backup for server-side use or analysis. In this case, we are passing an empty JSON object (`{}`), using the `JSON MediaType` declared as another constant:

```
private static final MediaType JSON=
    MediaType.parse("application/json; charset=utf-8");
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

We then use an instance of an `OkHttpClient` object to perform the request, getting the `Response` synchronously (since we are already on a background thread). If multiple components in your app will all be using `OkHttp`, the recommendation is to use a singleton instance of `OkHttpClient`, here defined on `BackupService` itself:

```
static final OkHttpClient OKHTTP_CLIENT=new OkHttpClient();
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

The REST protocol to the backup server is that a 201 response code (“Created”) means that our backup metadata has been saved and an ID has been generated for our backup. The `Location` header in the response contains a REST URL pointing to the backup itself (`/api/backups/...` for some value of `...`). We then use that to generate the URL for the dataset (`/api/backups/.../dataset`), and perform a PUT request for the dataset, using the `ZIP MediaType` defined as yet another constant:

---

## DATA BACKUP

---

```
private static final MediaType ZIP=  
    MediaType.parse("application/zip");
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/BackupService.java](#))

Once again, a 201 response indicates that our resource was created, and the Location header provides the URL for the backup dataset. We stuff that URL in a SharedPreferences object unique to BackupService, under a PREF\_LAST\_BACKUP\_DATASET key. We will use that — at least, in theory — if we are restored from a Google disaster recovery process. We will explore that more later in the chapter.

If we get an unexpected response from the server, the sample app logs a message to Logcat and otherwise quietly fails. A production-grade app would handle these scenarios better, including informing the user about the problem.

Of course, a production-grade backup implementation might want more than what we have here, such as [better security](#). For apps being publicly distributed through the Play Store or similar channels, you may want to offer multiple ways of saving off the backup, through some common API with multiple implementations. That way, users can choose whether to back up data via a private server or a public one (e.g., Amazon S3) or some other means that you offer.

### Initiating a Restore

Unfortunately, on occasion, the user may have a need to restore the app's data from a backup.

There are three primary possible triggers for this work to be done:

- The user could ask for data to be restored manually, through some option in the app's UI, such as an action bar item
- The request to restore the data could be pushed to the device, such as through GCM, perhaps in response to an IT department staff member initiating a remote restore
- The user could have gotten a new device, and if the user had chosen automatic disaster recovery “backups” on their old device, they could have our app and its data automatically restored onto the new device

There is also the question of *which* backup to restore. Frequently, the user will want the most recent backup, but that is not always the case. The user might realize that the data has been wrong for days and needs to restore an earlier backup than the

## DATA BACKUP

---

most recent one.

To that end, the BackupClient demo app will allow the user to manually request that data be restored, via a “Restore” action bar item. We will fetch a list of available backups from the backup server, so the user can choose what backup to restore from.

The “Restore” action bar item in MainActivity simply launches a RestoreRosterActivity, to allow the user to choose the backup to restore. That activity merely sets up a dynamic fragment, RestoreRosterFragment, in onCreate():

```
package com.commonware.android.backup;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;

public class RestoreRosterActivity extends FragmentActivity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager()
            .findFragmentById(android.R.id.content)==null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new RestoreRosterFragment()).commit();
        }
    }
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonware/android/backup/RestoreRosterActivity.java](#))

RestoreRosterFragment has fairly basic implementations of the onCreate(), onStart(), and onStop() lifecycle methods, to mark the fragment as being a retained fragment, plus to register and unregister from the event bus:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
}

@Override
public void onStart() {
    super.onStart();
}
```

## DATA BACKUP

---

```
EventBus.getDefault().register(this);
}

@Override
public void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

RestoreRosterFragment is a ListFragment, so the ListView will be set up automatically in the inherited implementation of onCreateView(). In onCreateView(), we can kick off a REST request to pull down the list of backups from the backup server. This client assumes that the REST server has an /api/backups endpoint that will return a JSON roster of the available backups, so we can use OkHttpClient to perform the GET request for that data:

```
@Override
public void onCreateView(View view,
                        Bundle savedInstanceState) {
    super.onCreateView(view, savedInstanceState);

    Request request=new Request.Builder()
        .url(URL_BACKUPS)
        .build();

    BackupService.OKHTTP_CLIENT.newCall(request).enqueue(this);
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

Here, we use the same OkHttpClient instance as BackupService uses — since this is a static data member that is automatically initialized, it does not matter whether or not we have used BackupService already in this process. The endpoint URL is found in the URL\_BACKUPS constant:

```
private static final String URL_BACKUPS=
    BuildConfig.URL_SERVER+"/api/backups";
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

Since this is being driven by the UI, and we are calling OkHttpClient from the main application thread, we use enqueue() instead of execute(), to schedule the request

---

## DATA BACKUP

---

to be performed on a background thread supplied and managed by OkHttp. `RestoreRosterFragment` implements the required `Callback` interface needed by `enqueue()`. That interface, in turn, requires two methods. One is `onFailure()`, to be called if there is a problem in executing the HTTP request. Here, we just inform the user about the problem in a `Toast`, though a production-grade app would do something more sophisticated:

```
@Override
public void onFailure(Request request, IOException e) {
    Toast.makeText(getActivity(), R.string.msg_roster_failure,
        Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(),
        "Exception retrieving backup roster", e);
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

The more important method is `onResponse()`, called when we get a valid-looking response from the server:

```
@Override
public void onResponse(Response response) throws IOException {
    Gson gson=new GsonBuilder()
        .setDateFormat("yyyy-MM-dd'T'HH:mm:ssZZZZ")
        .create();

    Type listType=new TypeToken<List<BackupMetadata>>() {}.getType();

    EventBus
        .getDefault()
        .post(
            gson.fromJson(response.body().charStream(), listType));
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

This sample *could* use `Retrofit` for performing this REST-style GET request, in which case `Retrofit` would work with `OkHttp` and Google's `Gson` to parse our response. In this case, we are using `OkHttp` directly, and so we need to arrange to have `Gson` parse the response.

To that end, we:

- Create a `Gson` instance through a `GsonBuilder`, teaching it that the JSON data to be mapped to `Date` objects in our results have a particular serialized

## DATA BACKUP

---

- format
- Create a Type object wrapping our expected response: a List of BackupMetadata objects
- Get the JSON from the response (`response.body().charStream`), and pass that to the Gson object for parsing

And, since `onResponse()` is called on a background thread, we use the event bus to deliver that List of BackupMetadata objects to the fragment itself, so we can pick up that event on the main application thread.

The JSON we get back will be a JSON array containing a list of JSON objects, with each of those objects being mapped to a BackupMetadata instance by Gson:

```
package com.commonware.android.backup;

import java.util.Date;

public class BackupMetadata {
    Date timestamp;
    String dataset;

    @Override
    public String toString() {
        return(timestamp.toString());
    }
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonware/android/backup/BackupMetadata.java](#))

RestoreRosterFragment then has an `onEventMainThread()` method, to pick up the List of BackupMetadata, to wrap that in an ArrayAdapter and put those results in the fragment's ListView:

```
@Subscribe(threadMode =ThreadMode.MAIN)
public void onEventMainThread(List<BackupMetadata> roster) {
    adapter=new ArrayAdapter<BackupMetadata>(getActivity(),
        android.R.layout.simple_list_item_1, roster);

    setListAdapter(adapter);
}
```

## DATA BACKUP

---

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

*Figure 776: RestoreRosterFragment, Showing Two Backups*

### Starting the Restore Activity

When the user clicks on an available backup in the `ListView`, `onListItemClick()` gets called:

```
@Override
public void onListItemClick(ListView l, View v, int position,
                             long id) {
    String url=
        BuildConfig.URL_SERVER+adapter.getItem(position).dataset;
    Intent i=
        new Intent(getActivity(), RestoreProgressActivity.class)
            .setData(Uri.parse(url))
            .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK|
                Intent.FLAG_ACTIVITY_CLEAR_TASK|
                Intent.FLAG_ACTIVITY_EXCLUDE_FROM_RECENTS);

    startActivity(i);
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreRosterFragment.java](#))

## DATA BACKUP

---

The BackupMetadata has a relative URL to the backup's dataset, so we combine that with BuildConfig.URL\_SERVER to get a fully-qualified URL. Then, we start up a RestoreProgressActivity, which will be responsible for kicking off the restore and showing some form of progress indicator along the way.

The tricky part with restoring your app's data is that you cannot have any app components running that rely upon that data, as the data will be changing out from underneath those components. In our case, we need to get rid of our MainActivity.

To do that, we attach a few flags to the Intent used to start up the RestoreProgressActivity:

- FLAG\_ACTIVITY\_NEW\_TASK
- FLAG\_ACTIVITY\_CLEAR\_TASK
- FLAG\_ACTIVITY\_EXCLUDE\_FROM\_RECENTS

These will get rid of all of our previous activities (including the currently-active RestoreRosterActivity) and will prevent the RestoreProgressActivity from showing up in the overview screen.

RestoreProgressActivity has a simple layout with a large centered ProgressBar:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:layout_width="match_parent"
  android:layout_height="match_parent">

  <ProgressBar
    style="@android:style/Widget.ProgressBar.Large"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_gravity="center" />
</FrameLayout>
```

(from [Backup/BackupClient/app/src/main/res/layout/progress.xml](#))

In onCreate() of RestoreProgressActivity, in addition to showing that ProgressBar, we kick off a RestoreService to actually download and restore the backup. We are passed the URL to the backup dataset in the Intent used to start RestoreProgressActivity, and we just pass that same URL along (as a Uri) to the service:

```
@Override
```

## DATA BACKUP

---

```
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.progress);

    if (savedInstanceState==null) {
        RestoreService.enqueueWork(this);
    }
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreProgressActivity.java](#))

However, we only do that if we are not being recreated after a configuration change, so this only happens on the first invocation of the activity.

RestoreProgressActivity also registers for events on the event bus, using the typical onStop()/onStart() pattern:

```
@Override
protected void onStart() {
    super.onStart();

    EventBus.getDefault().register(this);
}

@Override
protected void onStop() {
    EventBus.getDefault().unregister(this);

    super.onStop();
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreProgressActivity.java](#))

## Downloading and Restoring the Dataset

Meanwhile, over in RestoreService, we download and unpack the dataset:

```
package com.commonsware.android.backup;

import android.content.Context;
import android.content.Intent;
import android.support.annotation.NonNull;
import android.support.v4.app.JobIntentService;
import android.util.Log;
import com.squareup.okhttp.Request;
import com.squareup.okhttp.Response;
```

## DATA BACKUP

---

```
import org.greenrobot.eventbus.EventBus;
import java.io.File;
import okio.BufferedSink;
import okio.Okio;

public class RestoreService extends JobIntentService {
    private static final int UNIQUE_JOB_ID=1337;

    static void enqueueWork(Context ctxt) {
        enqueueWork(ctxt, RestoreService.class, UNIQUE_JOB_ID,
            new Intent(ctxt, RestoreService.class));
    }

    @Override
    public void onHandleWork(@NonNull Intent i) {
        Request request=new Request.Builder()
            .url(i.getData().toString())
            .build();

        try {
            Response response=
                BackupService.OKHTTP_CLIENT.newCall(request).execute();
            File toRestore=new File(getCacheDir(), "backup.zip");

            if (toRestore.exists()) {
                toRestore.delete();
            }

            BufferedSink sink = Okio.buffer(Okio.sink(toRestore));

            sink.writeAll(response.body().source());
            sink.close();

            ZipUtils.unzip(toRestore, getFilesDir(),
                BackupService.ZIP_PREFIX_FILES);
            ZipUtils.unzip(toRestore,
                BackupService.getSharedPrefsDir(this),
                BackupService.ZIP_PREFIX_PREFS);
            ZipUtils.unzip(toRestore, getExternalFilesDir(null),
                BackupService.ZIP_PREFIX_EXTERNAL);

            EventBus.getDefault().post(new RestoreCompletedEvent());
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception restoring backup", e);
            EventBus.getDefault().post(new RestoreFailedEvent());
        }
    }
}
```

## DATA BACKUP

---

```
}  
  
static class RestoreCompletedEvent {  
  
}  
  
static class RestoreFailedEvent {  
  
}  
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonsware/android/backup/RestoreService.java](#))

The URL for the dataset is coming in via the Intent passed into `onHandleIntent()`. We use that to build the OkHttp Request, then do a synchronous call via `execute()` to get the Response.

Previous uses of OkHttp in this chapter focused on REST responses, where we could either just use Location headers or pass the text of the response over to Gson. Here, we are expecting a ZIP file, and possibly a large one. The right way to get that written to disk (so we can unpack it) is to stream the data down and write that data out to disk, rather than attempting to read everything into memory first.

To that end, we take advantage of the fact that OkHttp itself is built atop [Square's Okio library](#), which offers a nice Java API for handling streams, based on sinks and sources. The recipe for streaming an HTTP response to disk involves:

- Creating a sink for the destination file (in this case, a `backup.zip` file placed in `getCacheDir()`)
- Wrapping that in a `BufferedSink`
- Telling the sink to write everything from the `source()` we get from OkHttp representing the ZIP data
- Closing the sink

At that point, we need to unpack the dataset into the places we got the data from in the first place when we backed it up:

- `getFilesDir()`
- the directory for `SharedPreferences`
- `getExternalFilesDir()`

To that end, we use a slightly modified version of the `ZipUtils` class first referenced in the [tutorials](#). The one used in the tutorials comes from the CWAC-Security

## DATA BACKUP

---

library. However, that `ZipUtils` class does not handle two things that we need here:

- Unpacking a subset of the files, from one virtual directory within the ZIP archive
- Restoring them to an already-existing directory without deleting and recreating that directory.

The `BackupClient` project has its own modified version of `ZipUtils` that handles those cases. Beyond that, the `unzip()` method is the same as before, taking:

- The ZIP file to unpack
- The filesystem directory where the unpacked files should go
- The virtual directory within the ZIP archive that we want (as opposed to the entire contents)

When that is done, we post a `RestoreCompletedEvent`. If there is some problem, we post a `RestoreFailedEvent`, in addition to logging details to Logcat.

`RestoreProgressActivity` listens for both of those events:

```
@Subscribe(threadMode =ThreadMode.MAIN)
public void onCompleted(RestoreService.RestoreCompletedEvent event) {
    startActivity(new Intent(this, MainActivity.class));
    finish();
}

@Subscribe(threadMode =ThreadMode.MAIN)
public void onFailed(RestoreService.RestoreFailedEvent event) {
    Toast.makeText(this, R.string.msg_restore_failed,
        Toast.LENGTH_LONG).show();
    finish();
}
```

(from [Backup/BackupClient/app/src/main/java/com/commonware/android/backup/RestoreProgressActivity.java](#))

In the success case, we can now start up a fresh `MainActivity` (since the original was destroyed as part of launching `RestoreProgressActivity`), and it can read the restored data.

In the failure case... we are really screwed. We may have partially restored the data, but perhaps not all of it, and there is no telling what state the data is in. A production-grade app would handle this by:

## DATA BACKUP

---

- Moving all of the existing data to a safe location on the device
- Attempting to restore the data
- If there is an unhandled exception in the restoration process, deleting the partially-restored data and moving the original data back into position

This would reduce the odds of some catastrophic problem wiping out the app. In this sample, though, we just show a `Toast`, `finish()` the activity (thereby exiting the app, as we have no other active activities), and hoping the user uninstalls and reinstalls the app, or just uninstalls the app, or something.

### Trying This Yourself... With a Little Help from Ol' Blue Eyes

Everything discussed so far assumes the existence of some REST-style Web server that we can interact with for backups. As it so happens, the `BackupClient` project has a crude implementation of such a server, in the form of a Ruby script using the [Sinatra](#) gem:

```
require 'fileutils'
require 'time'
require 'sinatra'
require 'json'

BACKUP_ROOT='/tmp/backups'

get '/' do
  'Hello world!'
end

get '/api/backups' do
  result=[]

  if File.exist?(BACKUP_ROOT)
    Dir.foreach(BACKUP_ROOT) do |item|
      next if item == '.' or item == '..'

      subdir=File.join(BACKUP_ROOT, item)

      if File.directory?(subdir)
        f=File.join(subdir, "metadata.json")

        if File.exist?(f)
          metadata=JSON.load(open(f))
          metadata['dataset']="/api/backups/#{item}/dataset"

          result << metadata
        end
      end
    end
  end
end
```

## DATA BACKUP

---

```
        end
      end
    end
  end

  result.sort_by!{|metadata| metadata['timestamp']}
  result.reverse!

  JSON.pretty_generate(result)
end

post '/api/backups' do
  id=SecureRandom.uuid
  dir=File.join(BACKUP_ROOT, id)
  FileUtils.mkdir_p(dir)
  f=File.join(dir, "metadata.json")
  metadata={'timestamp'=>Time.new.xmlschema}
  File.open(f, 'w') {|io| io.write(JSON.generate(metadata))}

  redirect to('/api/backups/'+id), 201
end

put '/api/backups/:id/dataset' do
  dir=File.join(BACKUP_ROOT, params[:id])

  if File.exist?(dir)
    f=File.join(dir, "backup.zip")
    File.open(f, 'w') {|io| io.write(request.body.read)}

    redirect to("/api/backups/#{params[:id]}/dataset"), 201
  else
    status 404
  end
end

get '/api/backups/:id/dataset' do
  dir=File.join(BACKUP_ROOT, params[:id])
  f=File.join(dir, "backup.zip")

  if File.exist?(f)
    send_file f
  else
    status 404
  end
end
end
```

(from [Backup/BackupClient/server.rb](#))

If you have familiarity with Ruby, you can:

- install the `sinatra` and `json` gems in your environment
- run the script (`ruby server.rb`)

That will give you a server, listening to `localhost:4567...` which happens to be what the `BackupClient` Android app is looking to talk to, if that app is running on an emulator. If you want to test with an actual Android device, the `-o` switch lets you specify the IP address to listen to, and `-p` lets you change up the port number if you wish.

## The Google Backup Bootstrap

Once you get your real backup system going, then, if you wish, you can play around with Google's disaster recovery bootstrap. By opting into what Google terms "backup", you can have some of your data automatically backed up, then restored when the user replaces their device.

### What to Bootstrap?

The biggest decision that you will need to make is what should be included in Google's bootstrap backup and what should not.

The primary considerations are privacy and security. Any data included in the bootstrap is visible to other parties. If that data is not encrypted with a user-supplied passphrase, other parties will be able to do what they want with the data, without much recourse.

One option, therefore, is to opt out of these bootstrap backups entirely, and handle disaster recovery like any other restore process.

Another is to only include some identifying information in the bootstrap backup, to help expedite the restore process, but without really compromising security much. In the context of the `BackupClient` sample shown earlier in this chapter, if the backup server was adequately secured, including a dataset URL in the bootstrap backup would not be much of a problem. Having the URL itself is probably not that useful, and if only authorized users can download datasets from those URLs, attackers would not gain anything from peeking at the bootstrap. `BackupClient` itself has very little security, to keep the sample (reasonably) simple, but you can imagine requiring user accounts or similar means to try to lock down access to the

backup server.

The far other end of the spectrum is to allow Android to backup “the whole shootin’ match” (i.e., everything), on the grounds that the data you have is not especially private.

You and your qualified legal counsel will need to make this decision before deciding what to do for implementing the bootstrap backup itself.

### Bootstrap Backup on Android 6.0+

Android has had a backup API since Android 2.2. However, not only did developers have to opt into the backups, but they had to write special code to assist in those backups. As such, that API was not used that much.

Android 6.0 has gone the other direction, with opt-out backups of all likely data, if your `targetSdkVersion` is 23 or higher. Specifically:

- Your app’s internal storage (`getFilesDir()`, `SharedPreferences`, `getDatabaseDir()`, etc.) gets backed up, with the exception of `getCacheDir()` and `getNoBackupFilesDir()` (the latter introduced in API Level 21)
- `getExternalFilesDir()` is backed up, but not other locations on external storage

Backups occur approximately once per day, if the device is idle, charging, and on WiFi.

### Configuring the Backup

If what you want to back up is different than what Android 6.0+ will back up by default, you can add manifest entries to better control what is and is not backed up.

To opt out entirely, add `android:allowBackup="false"` to your `<application>` element in the manifest:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/AppTheme"
  tools:replace="android:allowBackup">
```

## DATA BACKUP

---

```
<!-- other cool stuff here -->
</application>
```

Here, the `tools:replace` ensures that no library attempts to override your `allowBackup` value.

Conversely, if you want to participate in the bootstrap backup, but you want to change the roster of what gets backed up, use the `android:fullBackupContent` attribute on the `<application>` element. This needs to point to an XML resource that describes what it is that you do and do not want backed up.

The `BackupClient` sample has this configured. The `<application>` element points to a `res/xml/backup_rules.xml` resource:

```
<application
  android:fullBackupContent="@xml/backup_rules"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@style/Theme.Apptheme">
  <activity
    android:name=".MainActivity"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
  </activity>
  <activity android:name=".RestoreRosterActivity" />
  <activity android:name=".RestoreProgressActivity" />

  <service
    android:name=".BackupService"
    android:permission="android.permission.BIND_JOB_SERVICE" />
  <service
    android:name=".RestoreService"
    android:permission="android.permission.BIND_JOB_SERVICE" />
</application>
```

(from [Backup/BackupClient/app/src/main/AndroidManifest.xml](#))

That XML resource can contain `<include>` and `<exclude>` elements, inside of a root `<full-backup-content>` element. The rules are:

- If there are no `<include>` elements — only `<exclude>` elements — then all

## DATA BACKUP

---

the files that get backed up by default will get backed up, except those blocked by those `<exclude>` elements.

- If there are one or more `<include>` elements (perhaps along with `<exclude>` elements), then *none* of the files that get backed up by default will be backed up. Instead, only the files listed in the `<include>` elements (and not blocked by any `<exclude>` elements) will be backed up.

The BackupClient sample has two `<include>` elements, in effect saying that only what is cited in these elements should be backed up:

```
<?xml version="1.0" encoding="utf-8"?>
<full-backup-content>
  <include
    domain="sharedpref"
    path="com.commonware.android.backup_preferences.xml"/>
  <include
    domain="sharedpref"
    path="com.commonware.android.backup.BackupService.xml"/>
</full-backup-content>
```

(from [Backup/BackupClient/app/src/main/res/xml/backup\\_rules.xml](#))

The `<include>` and `<exclude>` elements must have a domain attribute and a path attribute. These combine to indicate what is being included or excluded.

The domain attribute indicates one of five locations relative to your app:

- root points to all of your internal storage
- file points to the subset of your internal storage used for ordinary files (i.e., `getFilesDir()`)
- database points to the subset of your internal storage used for databases (i.e., `getDatabasePath()`)
- sharedpref points to the subset of your internal storage used for SharedPreferences
- external points to the location used by `getExternalFilesDir(null)`

The path attribute then provides a relative path, from the base location indicated by domain, for the item to be included or excluded.

Hence, the BackupClient backup rules say to include two SharedPreferences files. One is written to by BackupService on every backup, holding a single value, keyed by `lastBackupDataset`, with the URL to the last backup dataset. The other is the default SharedPreferences, used for the last-visited tab by the UI. Because these

---

## DATA BACKUP

---

SharedPreferences files are included in the bootstrap backup, they should be restored in case the user replaces the device. However, they are the *only* things that is supposed to be backed up — everything else in the app should be left alone.

Note that the documentation does not state clearly if the path attribute is required. It is possible that the path attribute is optional, where if it is missing, it means you want to include or exclude everything in the cited domain.

### Testing the Backup and Restore Steps

In theory, to test your backup configuration, you can run three commands on the command line:

```
adb shell setprop log.tag.BackupXmlParserLogging VERBOSE
adb shell bmgr run
adb shell bmgr fullbackup ...
```

where ... is the application ID of the app to be backed up. For the sample app, that is `com.commonware.android.backup`.

(the above assumes that you have `adb` in your `PATH`)

You can then manually initiate a restore operation via:

```
adb shell bmgr restore ...
```

for the same value of ... Presumably, you would do this after modifying or clearing the backed-up data, so you can confirm that the data was restored properly.

For the purposes of conducting lightweight experiments with the auto-backup facility, you do not need to mess around with the entire backup system outlined earlier in this chapter. That backs up the actual content; the auto-backup facility is backing up SharedPreferences, and that happens whether or not we are also backing up the content.

So, for example, you could do the following:

- Run the sample app and switch to some tab other than the default, then press `BACK` to exit the app and save your last-visited tab in SharedPreferences
- Execute the following at the command line of your developer machine, to examine the contents of the SharedPreferences:

## DATA BACKUP

---

```
adb shell run-as com.commonware.android.backup
"cat /data/data/com.commonware.android.backup/
shared_prefs/com.commonware.android.backup_preferences.xml"
```

(NOTE: the above should be all on one line; it is split here across three lines due to the length of the command)

You should see something like:

```
<?xml version='1.0' encoding='utf-8' standalone='yes' ?>
<map>
  <int name="lastVisited" value="2" />
</map>
```

The value will be the index of whatever tab you were on when you exited the activity.

- Run the commands shown earlier to back up those SharedPreferences:

```
adb shell setprop log.tag.BackupXmlParserLogging VERBOSE
adb shell bmgr run
adb shell bmgr fullbackup com.commonware.android.backup
```

You should see output in Logcat indicating that the backup was taken:

```
14936-14936/? D/AndroidRuntime: Calling main entry com.android.commands.bmgr.Bmgr
800-2345/? D/BackupManagerService: fullTransportBackup()
800-14960/? I/PFTBT: Initiating full-data transport backup of ...
800-14961/? D/BackupManagerService: Binding to full backup agent : ...
800-14961/? D/BackupManagerService: awaiting agent for ApplicationInfo{...}
800-810/? D/BackupManagerService: agentConnected pkg=com.commonware...

800-1111/? I/BackupManagerService: Restore complete.
800-1111/? V/BackupManagerService: Clearing restore session and halting timeout
```

- Run the run-as command again to examine the contents of the current SharedPreferences, and see that it contains your original tab.
- Uninstall your application, then try the run-as again, which will give you an error indicating that the file was not found.
- Re-run the app from the IDE. Then, run the run-as command again, to see that your file was restored without manually having to restore it.

### Bootstrap Backup on Android 2.2-5.1

Prior to Android 6.0, Android had a “backup service”, inaugurated in Android 2.2. As with the Android 6.0 approach, the original backup service was mostly for disaster recovery.

Unlike with Android 6.0’s approach, you needed to opt into having these backups. Partly, this opt-in was accomplished via code, as you had to extend a BackupAgentHelper and register it in your manifest as the android:backupAgent, via the <application> element. The BackupAgentHelper subclass would indicate what should be backed up, by instantiating one or more BackupHelper objects (e.g., FileBackupHelper), configuring them to back up certain items, then registering them with the BackupAgentHelper via an addHelper() method.

Partly, though, the opt-in was accomplished via registering for an API key. This process was never integrated into the rest of the Play Services architecture, which now has a standardized approach for registering for various API keys and agreeing to the terms of service for each.

Instead, you would need to visit an [obscure Web page](#), agree to the terms of service, provide information about your app (notably the application ID), get the API key, and add it to your manifest via a <meta-data> element.

However, those terms of service contain some interesting clauses, ones that may give your legal counsel some concern, such as:

- “the form and nature” of the backup service “may change from time to time without prior notice to you”

## DATA BACKUP

---

- “Google may stop... providing the Service (or any features within the Service) to you or to users generally at Google’s sole discretion, without prior notice to you”
- You “agree to use the Service only for purposes that are permitted by... any applicable law... in the relevant jurisdictions (including any laws regarding the export of data or software to and from the United States or other relevant countries)” without ever disclosing what those “relevant countries” are
- You agree to not “sell... access to the Service”, which would seem to preclude its use by paid apps or apps using in-app purchases to upgrade to some “pro” edition that enabled backups
- “you are responsible for maintaining the security... of the Backup Service Key(s)”, despite the fact that these have to be published in the manifest and therefore are readable by anyone
- “you will not transmit any Content through the Service that is copyrighted, protected by trade secret or otherwise subject to third party proprietary rights”, despite the fact that developers have no means of validating these rights for user-supplied content
- “Google may need to change these Terms from time to time... Once the modified Terms are posted, the changes will become effective immediately, and you are deemed to have accepted the modified Terms if you continue to use the Service”, despite the fact that developers have no means of finding out exactly when the terms change or somehow instantaneously preventing installed copies of their apps from using the service

Beyond this, there are no statements about where the data is actually backed up, other than opening it up to just about anyone that Google wishes to characterize as “Subsidiaries and Affiliates”.

Please discuss these terms with legal counsel before registering for this service and integrating it within your app.

Additional documentation about this form of backup, should you choose to pursue it, can be found [online](#).

## Boosting Backup Security

Backups, in effect, are intentional data leaks. You want something other than the device to have access to your app’s data. Hence, it is important to take reasonable steps to ensure that those backups are secure, secure enough that nobody is going to

be able to exploit them for uses that go against the user's wishes. Rest assured that [people will try to exploit backups](#) and will succeed if your security is insufficient.

### Securing Access to the Dataset

The backup dataset that you transfer off the device needs to be secure from attack. Unauthorized people should not be able to get at the dataset.

For a backup system like the one outlined in this chapter, the big thing to secure is access to the dataset via its URL. If anyone who gets the URL can download the dataset, now all an attacker needs to do is determine how to get that URL, such as by exploiting flaws in Google's bootstrap backup. Or, for that matter, Google staff could get at the URL, at least in principle.

In this case, the URL alone must be insufficient. It would need to be combined with other information from the user, such as some sort of site authentication, where that other information is not retained.

If you are holding onto backup datasets yourself, on your own servers, you will also need to ensure that only authorized staff can get at those datasets and that such access is highly visible. Otherwise, you are at risk of an insider attack, whether through so-called "social engineering" or just good old-fashioned extortion.

### Securing Transmission of the Dataset

Another way that an attacker could get at the dataset is to copy the data in motion, as it is sent from your app to the backup server. Make sure that you are using suitable security here:

- HTTPS with certificate pinning
- Corporate VPN
- etc.

Bear in mind that users may wind up making a backup from any sort of network, ranging from your office network to the free WiFi at a local coffee shop. In principle, you could detect this and refuse to back up the data when you do not recognize the network. However, this reduces the value of the backup system, as the user might not be able to make a manual backup at some point when they need it (e.g., on business travel).

### Encrypting the Dataset

The ultimate in protection for the user is to have the data be encrypted by a user-supplied passphrase. Then, even *you* cannot access the data without the user's assistance. There are ways of addressing this, perhaps involving [brute force attacks](#) or [other sorts of brute force attacks](#). However, it certainly slows attackers down.

The simplest way to have encrypted backups — from the standpoint of the person writing the backup code — is to encrypt the data itself. For example, you do not necessarily need to re-encrypt a SQLCipher for Android database as part of a backup dataset, as it is already encrypted. Note, though, that having encrypted data at rest does not mean you can skip encrypting the data in motion, as it is sent to your backup server. While attackers would not be able to *read* the backed-up data readily, they could *replace* the backed-up data sent over the unencrypted communications channel and perhaps cause problems that way.

If, however, you are not in position to encrypt the data at rest within your app, you may wish to consider asking the user for a passphrase and using that to encrypt the backup dataset. Note that this passphrase requirement largely eliminates the ability for you to do unattended automated backups, as you either do not have the passphrase then (and so cannot encrypt the backups) or you are *saving* the passphrase (and so have just made it trivial for somebody to get it and decrypt the data).

### Alternative Approaches

Backing up local data is essential where the device is the system of record, to be able to deal with catastrophe (e.g., the user accidentally uninstalls the app).

That being said, there are a few ways of dealing with backing up local data that might not necessarily seem to the user as though it is a backup process.

### Data Versioning

Beyond the accidental wiping of data, such as through an erroneous install, a backup can also help recover from more fine-grained errors, like accidentally deleting a bit of data (e.g., a row or set of rows from database tables).

One way to address that is to use some sort of data versioning approach. Many software developers are familiar with this in the form of source code version control,

such as `git`. Here, you never really “delete” anything forever. Instead, you delete (or change) things in your working copy of the data, with the versioning system tracking changes to the data, so you can roll back to some earlier version if the need arises.

This is not limited to source code or similar sorts of documents. One simple example of versioning that has been used for decades is to not actually delete database rows, but instead set some `is_deleted` column to a known value. Then, when you query the database, you filter out the “deleted” rows by excluding from the query those rows where `is_deleted` is set to that specific value. Recovering those deleted rows is then a matter of showing all the deleted ones to the user and clearing `is_deleted` for the ones to be restored.

Obviously, this gets much more complicated once you get into foreign key constraints (i.e., how can you restore `X` if it depends on `Y` that was also deleted?). And it is not a full replacement for a backup-and-restore system, since anything that damages or deletes the entire database cannot be recovered via this sort of versioning. But, if you are looking to implement a robust disk-based “undo” facility for users, just bear in mind that it also helps out for some sorts of cases where you might ordinarily think of restoring from a backup.

### Import and Export

Another feature that you can add that has some relationship to data backups is data import and export. Whatever is exported can be backed up by the user by some other means; if the master copy of the app’s data gets damaged, you might be able to recover from that damage via importing a previous export.

Of course, import and export are also used for data exchange with foreign systems (e.g., exporting tabular data in a format that can be read in by a desktop spreadsheet program). Also, traditionally, import and export are tasks that are manually requested by users. However, you might consider giving the user an option of performing an automatic export as a replacement for, or adjunct to, some other form of regular backup.

### Data Synchronization

The ultimate solution for not having to mess with a robust device-based backup system is to not have the device be the system of record. Instead, some server is the system of record, with the device holding what amounts to a persistent cache of some of that data:

## DATA BACKUP

---

- Data that you retrieved previously, so you do not necessarily have to keep downloading the same data from the server
- Data that the user has modified that you are planning on sending to the server at some time in the future (e.g., during the nightly sync, or when the Internet is available again).

---

## **Trail: Security**

---

The traditional approach to securing HTTP operations is by means of SSL. Android supports SSL, much as ordinary Java does. Most of the time, you can just allow Android to do its thing with respect to SSL, and you will be fine. However, there may be times when you have to play a more direct role in SSL communications, to handle arbitrary SSL-encrypted endpoints, or to help ensure that your app is not the victim of a man-in-the-middle attack.

This chapter will explore various SSL scenarios and how to address them.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, particularly [the chapter on Internet access](#).

## Basic SSL Operation

Generally speaking, SSL “just works”, for ordinary sites with ordinary certificates.

If you use an `https:` URL with `URLConnection` or `WebView`, SSL handshaking will happen automatically, and assuming the certificates check out OK, you will get your result, just as if you had requested an `http:` URL.

However, originally, requesting a download via `DownloadManager` with an `https:` scheme would result in `java.lang.IllegalArgumentException: Can only download HTTP URIs`. As of Android 4.0, SSL is supported. Hence, you need to be careful about making SSL requests via `DownloadManager` if your `minSdkVersion` is less than 14.

For example, the Retrofit and Picasso sample apps from [the chapter on Internet access](#) both use `https://api.stackexchange.com` for their service endpoint. As a result, those requests — for the API JSON, at least — will go over SSL. You would need to log the URLs used for the image avatars to see whether StackExchange gives you `https` URLs or not.

## Problems in Paradise

Ideally, SSL just works.

In practice, it often does, but depending on your app and your situation, you may encounter issues, such as:

- You want to test using SSL, but your test server does not have a domain name, let alone a SSL certificate, and so you need to try using a self-signed certificate
- Your IT department chose an obscure certificate authority for obtaining the SSL certificate used by your production server, and older Android devices do not recognize that certificate authority
- You are worried about MITM (“man-in-the-middle” or “Martian-in-the-middle”) attacks, and you hear all these scary things about certificate authorities being hacked, and so you want to try to ensure that only valid certificates are honored by your app

And so on.

Here are some more details about some common SSL problems.

### Self-Signed Certificate

SSL certificates used for public Web sites are usually backed by a “root certificate authority” that is well-known. That is not always the case.

One case is when the certificate is “self-signed”, meaning that it was generated by somebody without involving a certificate authority. If you have shipped a production Android app, you created a self-signed certificate when you created your production key store. And you have been using a system-generated self-signed certificate throughout your development, known as the “debug signing key”.

Self-signed certificates are rarely used on public-facing Web sites, as Web browsers

---

## SSL

---

are taught to warn users when such certificates are encountered. However, self-signed certificates might be used on internal servers, particularly test servers and other non-production environments.

There are even some benefits for using a self-signed certificate for production servers, if those servers will be talking only to your own apps and not arbitrary Web browsers.

### Wildcard Certificate

Some certificates are difficult to validate because they use wildcards.

For example, Amazon S3 is a file storage and serving “cloud” solution from Amazon.com. They allow you to define “buckets” containing “objects”, where each object then has its own URL. That URL is based on the name of the bucket and the name of the object. One option is for you to have the domain name of the URL be based on the name of the bucket, leaving the path to be solely the name of the object. This works, even with SSL, but Amazon needed to use a “wildcard SSL certificate”, one that matches \*.s3.amazonaws.com, not just a single domain name. By default, this will fail on Android, as Android’s stock TrustManager will not validate wildcards for multiple domain name segments (e.g., http://misc.commonsware.com.s3.amazonaws.com/foo.txt). You will get an exception akin to:

```
javax.net.ssl.SSLHandshakeException: java.security.cert.CertificateException:  
No subject alternative DNS name matching misc.commonsware.com.s3.amazonaws.com found
```

### Custom Certificate Authority

Some larger organizations have set up their own certificate authority. Sometimes, they aspire to become a recognized root certificate authority, but have not been adopted by many browsers. Sometimes, they simply want to have more structure than a pure self-signed certificate but do not necessarily want to have all certificates go through a root certificate authority, perhaps due to expense.

In these cases, Android will reject the SSL certificate, for the same reason it rejects self-signed ones: it cannot validate the certificate chain all the way back to a known root certificate authority. But, with a little work, you can enable Android to support these as well.

### Man in the Middle Attacks

Man-in-the-middle (MITM) attacks are a common way of trying to intercept SSL encrypted communications. The “man” in the “middle” might be a proxy server, a different Web site you wind up communicating with via DNS poisoning, etc. The objective of the “man” is to pretend to be the actual Web site or Web service you are trying to communicate with. If your app “falls for it”, your app will open an encrypted channel to the attacker, not your site, and the attacker will have access to the unencrypted data you send over that channel.

Unfortunately, Android apps have a long history of being victims of man-in-the-middle attacks.

[“Why Eve and Mallory Love Android: An Analysis of Android SSL \(In\)Security”](#), an analysis of possible man-in-the-middle attacks on Android, is depressing. One in six surveyed apps explicitly ignored SSL certificate validation issues, mostly by means of do-nothing TrustManager implementations as noted above. Out of a selected 100 apps, 41 could be successfully attacked using man-in-the-middle techniques, yielding a treasure trove of credit card information, account credentials for all the major social networks, and so forth.

Their paper outlines a few ways in which apps can screw up SSL management — the following sections outline some of them.

#### Disabling SSL Certificate Validation

As mentioned above, if you disable SSL certificate validation, by implementing and using a do-nothing TrustManager, you are wide open for man-in-the-middle attacks. A simple transparent proxy server can pretend to be the real endpoint — apps ignoring SSL validation entirely will trust that the transparent proxy is the real endpoint and, therefore, perform SSL key exchange with the proxy rather than the real site. The proxy, as a result, gets access to everything the app sends.

#### Ignoring Domain Names

A related flaw is when you disable hostname verification. The “common name” (CN) of the SSL certificate should reflect the domain name being requested. Requesting `https://www.foo.com/something` and receiving an SSL certificate for `xkcdhatguy.com` would be indicative of a mis-configured Web server at best and a man-in-the-middle attack at worst.

---

## SSL

---

By default, this is checked, and if there is no match, you will get errors like:

```
javax.net.ssl.SSLException: hostname in certificate didn't match: <...>
```

where the ... is replaced by whatever domain name you were requesting.

But some developers disable this check. Perhaps during development they were accessing the server using a private IP address, and they were getting `SSLExceptions` when trying to access that server. It is very important to allow Android to check the hostname for you, which is the default behavior.

### Hacked CAs

The truly scary issue is when the problem stems from the CA itself.

Comodo, TURKTRUST, and other certificate authorities have been hacked, where nefarious parties gained the ability to create arbitrary certificates backed by the CA. For example, in [the TURKTRUST case](#), Google found that somebody had created a \*.google.com certificate that had TURKTRUST as the root CA. Any browser — or Android app — that implicitly trusted TURKTRUST-issued certificates would believe that this certificate was genuine. This is the ultimate in man-in-the-middle attacks, as code that is ordinarily fairly well-written will believe the CA and therefore happily communicate with the attacker.

Even well-intentioned certificate authorities sometimes make mistakes. StartSSL offered a tool called StartEncrypt to make it easy to request and install certificates on a Web server. However, they made mistakes in the Web service API used by that tool to communicate back to StartSSL's servers. [Attackers could create SSL certificates for a wide range of existing domains](#), including google.com, facebook.com, and other widely-used domains. Those fraudulent certificates could have been used to implement MITM attacks.

## Introducing Network Security Configuration

You can use a “network security configuration” to help address those issues. This comes in the form of an XML resource, which you teach Android to use for your network connections. That resource tailors what you do and do not want to accept for SSL connections, such as “yes, I want to accept this self-signed certificate, at least for debug builds of the app” and “yes, I am willing to accept this additional certificate authority”.

This XML resource will have a `<network-security-config>` root element. That in turn will contain:

- Zero or one `<base-config>` elements, defining global rules
- Zero, one, or several `<domain-config>` elements, defining rules to apply to a specific domain name or set of domain names
- Zero or one `<debug-overrides>` elements, defining global rules that will be applied only for debug builds of your app

### The Native Android 7.0 Version

On Android 7.0 and higher, you can direct Android to apply your network security configuration by having an `android:networkSecurityConfig` attribute on the `<application>` element in your manifest:

```
<application
  android:allowBackup="false"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:networkSecurityConfig="@xml/net_security_config">
  // other stuff here
</application>
```

The name of the XML resource does not matter, so long as your `android:networkSecurityConfig` attribute points to it.

On Android 7.0 and higher, your network security configuration will be applied automatically for all network connections, without any Java configuration.

### The CWAC-NetSecurity Backport

At the time of this writing, Google has not released an official backport of the network security configuration subsystem.

The author of this book converted that subsystem into a library – CWAC-NetSecurity — that serves as a backport, working back to API Level 17 (Android 4.2). It does not support every feature of the native implementation, and it requires a bit of Java code to arrange to use your network security configuration for HTTP requests. However, you can use the same XML resource structure. As with many backports, the vision is that you would use the backport until such time as your `minSdkVersion` rises to 24 or higher, at which point you can just use the native implementation.

## SSL

---

The CWAC-NetSecurity library also offers a `TrustManagerBuilder` and related classes to make it easier for developers to integrate the network security configuration backport, particularly for [OkHttp3](#) and `URLConnection`.

The artifact for this library is distributed via the CWAC repository, so you will need to configure that in your module's `build.gradle` file, along with your implementation statement:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.commonsware.cwac:netsecurity:0.0.1'
    implementation 'com.squareup.okhttp3:okhttp:3.4.0'
}
```

If you are using this library with `OkHttp3`, you also need to have a implementation statement for a compatible `OkHttp3` artifact, as shown above.

If you are using `URLConnection`, or tying this code into some other HTTP client stack, you can skip the `OkHttp3` dependency.

Next, add in this `<meta-data>` element to your manifest, as a child of the `<application>` element:

```
<meta-data
    android:name="android.security.net.config"
    android:resource="@xml/net_security_config" />
```

The value for `android:resource` should be the same XML resource that you used in the `android:networkSecurityConfig` attribute in the `<application>` element for the native network security configuration support on Android 7.0.

Then, in your code where you want to set up your network communications, create a `TrustManagerBuilder` and teach it to load the configuration from the manifest:

```
TrustManagerBuilder tmb=
    new TrustManagerBuilder().withManifestConfig(ctxt);
```

(where `ctxt` is some `Context`)

---

## SSL

---

If you are using `OkHttp3`, create your basic `OkHttpClient.Builder`, then call:

```
OkHttp3Integrator.applyTo(tmb, okb);
```

(where `tmb` is the `TrustManagerBuilder` from before, and `okb` is your `OkHttpClient.Builder`)

At this point, you can create your `OkHttpClient` from the `Builder` and start using it.

If you are using `URLConnection`, you can call `applyTo()` on the `TrustManagerBuilder` itself, passing in the `URLConnection`. Afterwards, you can start using the `URLConnection` to make your HTTP request:

```
URL url=new URL(i.getData().toString());
URLConnection c=
    (URLConnection)url.openConnection();
TrustManagerBuilder tmb=
    new TrustManagerBuilder().withManifestConfig(this);

tmb.applyTo(c);
```

(from [Internet/CA/app/src/main/java/com/commonsware/android/downloader/Downloader.java](#))

In either case, on Android 7.0+ devices, `withManifestConfig()` will *not* use the backport. Instead, the platform-native implementation of the network security configuration subsystem will be used. On Android 4.2-6.0 devices, the backport will be used.

## SSL Problems and Network Security Configuration

With all that as prologue, let's examine how the network security configuration subsystem — native or backport — can address some of the SSL issues outlined earlier in this chapter.

The sample code for these scenarios comes from the [Internet/CA](#) sample application. This application is based on some of the samples from [the chapter on notifications](#), that use `URLConnection` to download a PDF from the CommonsWare site.

### Pinning the Certificate Authority

Your app may only communicate with one server, such as an employee-only server

---

---

## SSL

---

for your organization. To help limit the risk of possible MITM attacks, you might want to lock down your app, to only work with certificates coming from your chosen certificate authority for this server. That way, in addition to the other logistical problems facing attackers, they would need to get a forged SSL certificate from *your* certificate provider, instead of a forged SSL certificate from *any* certificate provider.

To make this work, first, you will need a PEM or DER file representing the root certificate for the certificate authority. Usually, the certificate authority will publish one of these on its Web site. You will need to put that file in `res/raw/` of your project, under a suitable resource name. For this scenario, in the sample app, there are two raw resources of note: `addtrustexternalcaroot.pem` and `verisign_class3.pem`, for Comodo and Verisign, respectively.

Next, you will need to create your network security configuration. As noted above, this is an XML resource, in `res/xml/`, that describes what changes you wish to make to the mix of supported certificate authorities. In the sample app, one such resource is `res/xml/network_comodo.xml`:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">wares.commonsware.com</domain>
    <trust-anchors>
      <certificates src="@raw/addtrustexternalcaroot" />
    </trust-anchors>
  </domain-config>
</network-security-config>
```

(from [Internet/CA/app/src/main/res/xml/network\\_comodo.xml](#))

As mentioned previously, the root element is `<network-security-config>`. In there, you can have one or more `<domain-config>` elements, describing the rules that you wish to apply to certain domains being used by your app.

A `<domain-config>` element will have one or more `<domain>` elements, listing domains that this particular configuration controls. Here, we have just one, for `wares.commonsware.com`. The `includeSubdomains` attribute indicates whether this rule applies to subdomains of the base domain, such as `foo.wares.commonsware.com`.

A `<domain-config>` element can have a `<trust-anchors>` element, listing what certificates to use to validate SSL connections made to this domain. Those certificates are identified by `<certificate>` elements, usually pointing to raw resources that are the PEM or DER files for those certificate authorities. In this case, we point to the `addtrustexternalcaroot` resource.

## SSL

---

To teach Android that you have this network security configuration that you wish to apply, you will need add an `android:networkSecurityConfig` attribute (for the native Android 7.0 code) and perhaps a `<meta-data>` element to the `<application>` element of your manifest (for the CWAC-NetSecurity backport):

```
<application
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:networkSecurityConfig="@xml/${networkSecurityConfig}">
  <activity
    android:name="DownloaderDemo"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
  </activity>

  <service
    android:name="Downloader"
    android:permission="android.permission.BIND_JOB_SERVICE" />

  <provider
    android:name="LegacyCompatFileProvider"
    android:authorities="${applicationId}.provider"
    android:exported="false"
    android:grantUriPermissions="true">
    <meta-data
      android:name="android.support.FILE_PROVIDER_PATHS"
      android:resource="@xml/provider_paths" />
  </provider>

  <meta-data
    android:name="android.security.net.config"
    android:resource="@xml/${networkSecurityConfig}" />
</application>
```

(from [Internet/CA/app/src/main/AndroidManifest.xml](#))

In this case, the resource value used in both places is not a simple XML resource name, like `@xml/network_comodo`, though that will be what most apps will use. This sample application has different product flavors for applying different network security configurations, configured in `build.gradle`. Those product flavors use `manifestPlaceholders` to indicate which XML resource to apply for that flavor:

(from [Internet/CA/app/build.gradle](#))

The CommonsWare Warescription Web site, at the time of this writing, uses an SSL certificate backed by Comodo. Running the `comodoDebug` build variant should successfully download the PDF file, as the SSL certificate will be validated properly. However, running the `verisignDebug` build variant will fail the SSL validation and crash:

```

If you have multiple certificate authorities that you wish to support, you can have multiple `<certificate>` elements, or a `<certificate>` element pointing to a file with multiple PEM or DER entries.

### Unusual Certificate Authorities

Perhaps your organization runs its own certificate authority (e.g., for internal servers). Or perhaps your organization is using a regular certificate authority, but one that is too new to be recognized by Android. You could cover the unexpected certificate authority by using the `<certificate>` elements shown above.

But, what happens if you want to support something custom *and* regular certificate authorities as well?

In that case, there is a special `<certificate>` element that you can add:

```
<certificates src="system"/>
```

---

## SSL

---

The value `system`, instead of a reference to a raw resource, indicates that the default system set of certificate authorities should be considered to be valid.

The `systemDebug` build variant uses a different network security configuration:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">wares.commonsware.com</domain>
    <trust-anchors>
      <certificates src="@raw/verisign_class3" />
      <certificates src="system" />
    </trust-anchors>
  </domain-config>
</network-security-config>
```

(from [Internet/CA/app/src/main/res/xml/network\\_verisign\\_system.xml](#))

Here, first, we pull in Verisign's root certificate. If that were all we had (as you can see in the `network_verisign.xml` resource file), an attempt to download something from `wares.commonsware.com` would fail, as that site uses a Comodo certificate, not a Verisign one. However, we *also* have the `system` set of certificate authorities. Since Comodo is a major certificate authority, it is included in Android's default set, and so our download should succeed.

### Pinning the Certificate

Perhaps even supporting any CA's certificates will be too much of a risk for you and your users. For example, perhaps your site's certificate is from a certificate authority that has issued fraudulent credentials in the past, and so you fear that your users might still be at risk of a MITM attack.

You can *really* narrow things down by pinning your app to your specific certificate. Then, only that one certificate will be accepted, not others that might be issued, for your domain, by your certificate authority, either through social engineering, nation-state duress, or whatever.

To do this, you will use a `<pin-set>` element, instead of a `<certificate>` element, in your network security configuration, as seen in the `network_pin` resource:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">wares.commonsware.com</domain>
    <pin-set expiration="2020-05-01">
      <pin digest="SHA-256">sF1A3ez70181aUjLwU6KiAmmOyPNFQDueJH+4YDwppo=</pin>
    </pin-set>
  </domain-config>
</network-security-config>
```

---

## SSL

---

```
</domain-config>  
</network-security-config>
```

(from [Internet/CA/app/src/main/res/xml/network\\_pin.xml](https://android.googlesource.com/platform/manifest/+/android-9.0.0_r1))

The `<pin-set>` element can include one or more `<pin>` elements, each of which has a `digest` attribute and a value. The `digest` value has to be SHA-256 at the present time, though perhaps other hash algorithms will be supported in the future. The value of the `<pin>` element is the base64-encoded SHA-256 hash of the `SubjectPublicKeyInfo` field of the X509 certificate of the server.

To generate that value, you will need to use a tool like `openssl`. Given a PEM file named `server.crt`, you can generate the hash for that server [using the following command](#):

```
openssl x509 -in server.crt -pubkey -noout | openssl pkey -pubin -outform der |  
openssl dgst -sha256 -binary | openssl enc -base64
```

(NOTE: this should appear all on one line but will be word-wrapped to the size of the book page)

The `<pin-set>` element can also have an expiration attribute, with a date in `yyyy-MM-dd` format. Prior to this date, the SSL certificate of the server must match one of the pins. On or after this date, the pins are ignored. For example, you might choose a date that is a bit before the date when the SSL certificate itself will expire. This has the benefit of allowing the app to work even if you fail to update the app and supply a new pin for a new SSL certificate, or if you do update that app but the user does not install the update in time. On the other hand, manually altering the device date and time can bypass your pin.

This behavior — pin expiration allowing formerly-blocked access — is a bit unusual. Typically, with security, we “fail closed”, meaning that once something has expired, no access is allowed. Instead, `<pin-set>` specifically “fails open”, meaning that once it expires, security is weakened. In this case, Google elected to focus on utility over security.

### Self-Signed Certificates

As [Moxie Marlinspike points out](#), one way to avoid having your app be the victim of a man-in-the-middle attack due to a hijacked certificate authority is to simply *not use a certificate authority*.

Certificate authorities are designed for use by general-purpose clients (e.g., Web

## SSL

---

browsers) hitting general-purpose servers (e.g., Web servers). In the case where you control both the client *and* the server, you don't need a certificate authority. You merely need to have a self-signed certificate that both ends know about.

This works well if the Web server is solely functioning as a Web service to deliver data to your Android app, or perhaps other native apps on other platforms for which you can also support self-signed certificates. Depending upon your server's capabilities, you might be able to arrange to have the same server-side application logic be available both from a self-signed certificate on one domain (for use with apps) and from a CA-rooted certificate for another domain (for use with Web browsers).

However, it is very possible that the staff who manage the servers will reject the notion of using a self-signed certificate, perhaps in an effort to minimize the complexity of supporting multiple SSL paths (for browsers and apps). Or, you may not control the server well enough to go with a self-signed certificate, such as if you are using a cloud computing provider.

However, if self-signed certificates are an option for you, the network security configuration code makes them simple to integrate.

You can use the PEM or DER file from your self-signed certificate much as you would one from a certificate authority: put in `res/raw/` and set up your network security configuration XML to match:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <domain-config>
    <domain includeSubdomains="false" usesCleartextTraffic="false">scrap.commonsware.com</domain>
    <trust-anchors>
      <certificates src="@raw/example" />
    </trust-anchors>
  </domain-config>
</network-security-config>
```

(from [Internet/CA/app/src/main/res/xml/network\\_selfsigned.xml](#))

This is from the `selfSigned` product flavor. Note that it will not work on your development machine, as you do not have a Web server with a self-signed SSL certificate at `scrap.commonsware.com`. However, this shows the basic setup, as being the same as before.

[This site](#) has instructions for setting up a self-signed certificate. The CRT file that is created (e.g., `example.crt`) is what you would put in your app.

### Self-Signed Certificates for Debug Builds

If you are only using a self-signed certificate for debuggable builds (e.g., debug build type), you can use the `<debug-overrides>` XML element in your network security configuration. This adds your self-signed certificates to the roster of trust anchors, but only for debuggable builds. For non-debuggable builds (e.g., release build type), your self-signed SSL certificate will be ignored.

You can see this in the `network_override.xml` resource:

```
<?xml version="1.0" encoding="utf-8"?>
<network-security-config>
  <debug-overrides>
    <trust-anchors>
      <certificates src="@raw/example" />
    </trust-anchors>
  </debug-overrides>
</network-security-config>
```

(from [Internet/CA/app/src/main/res/xml/network\\_override.xml](https://github.com/android/platform_framework_core/blob/master/packages/modules/libnetwork-security-config/src/main/res/xml/network_override.xml))

This is for the override product flavor which, like `selfSigned`, will not work for you, as you will not have a Web server using that SSL certificate.

### Blocking Cleartext Traffic

For a domain, or perhaps for everything in your app, you might want to ensure that you always are using SSL... even to the point of being willing to crash your app if you are *not* using SSL. While this is an extreme measure, some apps have those sorts of security requirements.

The network security configuration subsystem supports a `cleartextTrafficPermitted` attribute on `<base-config>` and `<domain-config>`:

```
<base-config cleartextTrafficPermitted="false">
  <trust-anchors>
    <certificates src="system" />
  </trust-anchors>
</base-config>
```

If set to `false`, this means that you want to block all “cleartext” (non-SSL) traffic for the scope of that element.

## SSL

---

The native implementation of network security configuration supports this flag for most Internet communications. Notably, `WebView` does not support it.

The CWAC-NetSecurity backport, if you are using the `OkHttp3` integration, attempts to honor this, by checking the scheme for requests. If you make an `http` request, but you have `clearTextTrafficPermitted="false"` for the appropriate scope (e.g., for the domain in the URL), the request is rejected. However, this is not quite as strong as the native implementation, and it certainly does not affect anything other than the `OkHttp3` integration.

On Android 6.0, you have [another option of enabling this same sort of check](#). You also have a way to have [StrictMode validate cleartext traffic](#) on Android 6.0+.

### Supporting User-Added Certificates

The native Android 7.0+ network security configuration subsystem not only allows you to use `[certificates src="system" /]` to say “we also allow any standard certificate authorities here”, but also `[certificates src="user" /]`. This indicates that certificate authorities added by the user, through Settings, should be honored as well. By default, for apps with `targetSdkVersion` set to 24 or higher, user-added certificates are ignored unless `[certificates src="user" /]` is included in a network security configuration.

Such user-added certificate authorities are a bit controversial in Android app development. On the one hand, they allow users to add support for unrecognized authorities, in case Android is slow to adopt them, and without apps having to do anything. On the other hand, those user-added certificate authorities are global in scope, rather than being tied to specific domains.

Note that this feature is not available in the CWAC-NetSecurity backport. `[certificates src="user" /]` is ignored. User-added certificate authorities are lumped in with the system-defined certificate authorities, so if you have `[certificates src="system" /]`, you will get certificate authorities from both sources.

### Other SSL Strengthening Techniques

Not everything that one can do to improve SSL security is covered by either the native network security configuration implementation or the CWAC-NetSecurity backport. Here are some other possibilities to consider.

### Certificate Memorizing

If your app needs to connect to arbitrary SSL servers — perhaps ones configured by the user (e.g., email client) or are intrinsic to the app's usage (e.g., URLs in a Web browser) — detecting man-in-the-middle attacks boils down to proper SSL certificate validation... and praying for no hacked CA certificates.

However, one way to incrementally improve security is to use certificate memorizing. With this technique, each time you see a certificate that you have not seen before, or perhaps a different certificate for a site visited previously, you ask the user to confirm that it is OK to proceed.

The idea here is that even if we cannot tell, absolutely, whether a given certificate is genuine or from an attacker, we can detect *differences in certificates over time*. So, if the user has been seeing certificate A, and now all of a sudden receives certificate B instead, there are two main possibilities:

1. The HTTPS server changed certificates for legitimate reasons
2. An attacker is providing an alternative certificate

So, what we do is check certificates against a roster that the user has approved before. If the newly-received certificate is not in that roster, we fail the HTTPS request, but raise a custom exception so that your code can detect this case and ask the user for approval to proceed.

Technically savvy users may be able to deduce whether the certificate is indeed genuine; slightly less-savvy users might simply contact the site to see if this is expected behavior. The downside is that technically unsophisticated users might be baffled by the question of whether or not they should accept the certificate and may take their confusion out on you, the developer of the app that is asking the question.

There is [a standalone implementation of a MemorizingTrustManager](#) that you could consider using. It has been around for a few years, with a slow-but-steady set of updates.

However, that library handles asking the user for acceptance of the certificates for you, rather than raising some event that your app can handle itself. In order to tailor the UI, you would need to modify the library itself.

Moreover, the library attempts to handle this UI *while your SSL request is in process*, by blocking the background thread upon which you are making the HTTPS request.

---

## SSL

---

A side-effect of this is that `MemorizingTrustManager` has some fairly unpleasant code for trying to block this thread while interacting with the user on the main application thread. And, if the user takes too long, your request to the server may time out anyway.

### Requiring Encryption, Android 6.0 Style

Android 6.0 supports an `usesCleartextTraffic` attribute on the `<application>` element in the manifest. This works like the `cleartextTrafficPermitted` option in the network security configuration subsystem. If this is set to `false`, you are saying that your app not only should be using SSL for everything, but that you expressly want to crash the app in case you wind up *not* using SSL.

If you try to perform plain HTTP requests on Android 6.0 with `usesCleartextTraffic` set to `false`, you will crash when you attempt to download the file, with a stack trace akin to:

```
06-19 08:03:46.325    6420-6478/com.commonware.android.downloader E/
com.commonware.android.downloader.Downloader: Exception in download
    java.net.UnknownServiceException: CLEARTEXT communication not supported: []
        at com.android.okhttp.Connection.connect(Connection.java:149)
        at com.android.okhttp.Connection.connectAndSetOwner(Connection.java:185)
        .
        .
        .
```

What is really going on “under the covers” is that this attribute sets a flag that HTTP client APIs can check, electing to fail a request if the flag says that SSL is required and the request’s URL does not have the `https` scheme. Android’s built-in HTTP clients should support this flag, but third-party HTTP stacks that manage their own socket connections may not. Also note that `WebView` does not honor `usesCleartextTraffic`.

### Watching for Encryption

The downside of `usesCleartextTraffic` is that it is “all or nothing” and always terminates your process. The same thing holds true for using `cleartextTrafficPermitted` with the network security configuration in the `<base-config>` element. That is wonderful in situations where SSL is crucial. It is less wonderful if your app crashes in production in situations where SSL would be a really good idea but is unavailable for whatever reason.

`StrictMode` on API Level 23+ devices supports a way to be warned if your app performs unencrypted network operations, via a `detectCleartextNetwork()` method on `StrictMode.VmPolicy.Builder`. You can configure this, and suitable penalties, alongside the rest of your `StrictMode` setup. This can include doing different things for debug versus release builds, for example. So, in a debug build, you might choose `penaltyDeath()` to crash the process, while in a release build, you settle for `penaltyLog()` or something else less drastic.

If you are using a build server, you could set it up to watch for `StrictMode` Logcat messages coming from your test suite to find out about these accesses.

## Advanced Uses of CWAC-NetSecurity

Adding a couple of lines of Java code, along with the dependency, is all that you need to use CWAC-NetSecurity to gain the benefits of the backport of the network security configuration subsystem. However, CWAC-NetSecurity offers a few more features that may be of use to you.

### Using Alternative Network Security Configuration XML

`withManifestConfig()` on `TrustManagerBuilder` uses the resource that you declare in your manifest as the network security configuration to apply. However, that is fairly inflexible, as you can only define this in the manifest once. Also, `withManifestConfig()` performs the version check to only apply the backport on pre-7.0 devices.

You can also use `withConfig()`, where you provide a `Context` and the resource ID of the XML resource to use for the network security configuration. This is useful for cases where:

- You want to always use the backport, for consistent behavior across OS versions
- You want to use different configurations in different settings for the same APK

For example, the test suites use `withConfig()`, as otherwise we would need dozens of separate manifests.

### Using the Backport Directly

You do not have to use `TrustManagerBuilder` to use the network security configuration backport. If you wish to use it directly:

- Create an instance of `ApplicationConfig`, passing in a `ConfigSource` implementation that indicates where the configuration should be pulled from. Two likely `ConfigSource` implementations are `ManifestConfigSource` (to use the one defined in the manifest) and `XmlConfigSource` (to use one defined in an arbitrary XML resource).
- Call `getTrustManager()` on the `ApplicationConfig` to get a `TrustManager` that will implement the requested configuration.
- Add that `TrustManager` to your HTTP client via whatever API that client offers for such things. In many cases, that will be by configuring an `SSLContext` to use the `TrustManager`, then using the `SSLContext` (or an `SSLConnectionFactory` created by the `SSLContext`) with your HTTP client.

### Integrating with Other HTTP Client Libraries

If you want to integrate `TrustManagerBuilder` and the network security configuration backport with some other HTTP client API, start by reviewing the `OkHttp3Integrator` class in the `netsecurity-okhttp3` library. This will give you an idea of what is required and how easy it will be to replicate this class for your particular HTTP client API.

### Adding the TrustManager

Calling `build()` on the `TrustManagerBuilder` gives you a `CompositeTrustManager`, set up to implement your desired network security configuration. You will need to add that to your HTTP client by one means or another. If `size()` on the `CompositeTrustManager` returns 0, though, you can skip it, as it means that there are no rules to be applied (e.g., you used `withManifestConfig()`, and your app is running on an Android 7.0+ device).

So, you might have code that looks like this, where `tmb` is a configured `TrustManagerBuilder`:

```
CompositeTrustManager trustManager=tmb.build();  
  
if (trustManager.size()>0) {  
    SSLContext ssl=SSLContext.getInstance("TLS");
```

## SSL

---

```
X509Interceptor interceptor=new X509Interceptor(trustManager, tmb);

ssl.init(null, new TrustManager[]{trustManager}, null);

// apply the SSLContext or ssl.getSocketFactory() to your HTTP client
}
```

### Handling Cleartext

You can call `isCleartextTrafficPermitted()` on the `CompositeTrustManager` to determine if cleartext traffic should be supported. This takes the domain name of the Web server you are going to be communicating with and returns a simple boolean. If `isCleartextTrafficPermitted()` returns false, you will need to examine the scheme of the URL and accept or reject the HTTP operation accordingly.

If you fail to do this, then cleartext traffic will be allowed in all cases, akin to the stock `URLConnection` integration.

### Handling Redirects

If your HTTP client automatically traverses server-side redirects (making the HTTP request for the redirected-to URL), you will need to handle the cleartext check and the `setHost()` call on every step of the redirection, not just your initial request. In the case of `OkHttp3`, this is accomplished via their interceptor framework.

### Debugging Certificate Chains

You can call `withCertChainListener()` on `TrustManagerBuilder`, providing an implementation of `CertChainListener`. Your listener will be called with `onChain()` each time a certificate chain is encountered. In `onChain()`, you can inspect the certificates, dump their contents to Logcat, or whatever you wish to do.

This is designed for use in development. For example, when writing the `demo/` app, the author used a `CertChainListener` to log what HTTP requests were being made, what domains those were for, and what root certificates are being used. This in turn led to creating the network security configuration that matched.

However, logging certificate chains on a production device may result in security issues. Please only use `CertChainListener` in debug builds.

## NetCipher

[The Guardian Project](#) has released an Android library project called [NetCipher](#) — formerly known as OnionKit — designed to help boost Internet security for Android applications.

In particular, NetCipher helps your application integrate with Orbot, a Tor proxy. [Tor \(“The Onion Router”\)](#) is designed to help with anonymity, having your Internet requests go through a series of Tor routers before actually connecting to your targeted server through some Tor endpoint. Tor is used for everything from mitigating Web site tracking to helping dissidents bypass national firewalls. NetCipher helps your app:

- Detect if Orbot is installed, and help the user install it if it is not
- Detect if Orbot is running, and help you start it if it is not
- Make HTTP requests by means of Orbot instead of directly over the Internet

There is [a dedicated chapter on NetCipher](#), if you have interest in this technology.

[NetCipher](#) is a library from the Guardian Project to improve the privacy and security of HTTP network communications. In particular, it makes it easier for your app to integrate with [Orbot](#), an Android proxy server that forwards HTTP requests via [Tor](#).

This chapter covers:

- An introduction to Tor, Orbot, and NetCipher
- An explanation of how to use a fairly simple API layered atop NetCipher to add its functionality to your app

## Prerequisites

This chapter assumes that you have read the core chapters of the book, particularly the one on [Internet access](#). Having read the chapter on [SSL](#) is also a very good idea.

## Network Security's Got Onions

Maintaining privacy and security on the Internet, in the face of so-called “advanced persistent threats”, is a continuous challenge facing many people, particularly those under threats from hostile forces, ranging from organized crime syndicates to your average rampaging warlord. Tor was created to help deal with this sort of problem; Orbot was created to extend Tor to Android.

### A Quick Primer on Tor

Originally named The Onion Router, Tor was created by researchers in the US Naval Research Laboratory back in the mid-1990's, with an eye towards protecting US

intelligence communications. In 2006, the technology spun out into an independent non-profit organization, which has continued to improve upon the core Tor software and expand the reach of Tor. Through packages like the Tor Browser Bundle, it is fairly easy for at-risk people to start using Tor to help shroud their communications.

Without getting into the full technical details of Tor — which are *well* beyond the scope of this chapter — Tor basically works by routing a request through a series of relay servers, through a process known as onion routing. Requests are secured through layers of encryption, to keep any two connected relays from knowing the full details of the communications. Some relays serve as “exit nodes”, for requests being made of ordinary Web servers. Certain servers — Tor hidden services — are only reachable through Tor; requests made of these servers never leave the Tor network.

Of course, technology like Tor is agnostic in terms of its users and usages, and there have been plenty of examples of people using Tor for illicit purposes, such as the [Silk Road](#). This has a tendency to obscure Tor’s benefits to people who need to remain somewhat hidden online, whether from stalkers or other harassers or from the security forces of dictatorships.

### Introducing Orbot

The entry path into Tor is usually via some sort of proxy server, that a regular Internet client can connect to. Orbot is one such proxy server, that runs on Android. Apps can use Orbot’s HTTP or SOCKS proxies to route requests; those requests will then wind up traversing the Tor network to the end site, whether that site is on the public Internet (reached from a Tor exit node) or a Tor hidden service.

By default, Orbot is limited to localhost use, meaning that it does not have open ports that can be reached from other devices on the local WiFi LAN segment (or some subnet of the mobile carrier, if not on WiFi). For an Android app on the same device, this is not a problem, and it in fact simplifies things a fair bit, as there is no guesswork as to what the IP address should be for the proxy. As we will see, though, finding out exactly how to connect to Orbot is a bit tricky, though with some helper code it is not too bad.

### What NetCipher Provides

While we know that Orbot will be listening on localhost, we do not necessarily know the port that it is using for its HTTP proxy. Partly, that is because the user

might configure it manually. Partly, that is because there are occasional conflicts with Orbot's default port.

Hence, NetCipher contains some code that will help you find out:

- Is Orbot installed? (and, if not, help get it installed)
- Is Orbot running? (and, if not, help get it running)
- What port is used for the HTTP proxy?

## The NetCipher HTTP Integration APIs

NetCipher offers two levels of API for integration. This chapter focuses on the newer of those, a suite that offers simple plug-and-play integration with popular HTTP client APIs: `HttpURLConnection`, `OkHttp`, `Volley`, and Apache's `HttpClient`. This focus stems from two main reasons:

- These integration APIs are much simpler to use
- The author of this book wrote those APIs, and so is biased as to how simple they are to use

The [Internet/HTTPStacks](#) sample application demonstrates all four of the HTTP integration APIs. Each of the four is based on the Stack Overflow sample app from [the chapter on Internet access](#), with NetCipher integration added in.

There are a few simple steps for adding in NetCipher integration: choosing your HTTP stack, adding the dependencies, setting up `OrbotHelper`, and then using a secure connection.

### Choose an HTTP Stack

As noted above, NetCipher offers integration APIs for four major HTTP client implementations (a.k.a., "HTTP stacks"):

- `HttpURLConnection`
- `OkHttp3`
- Apache's independent `HttpClient` package
- `Volley`

`HttpURLConnection` support is part of the core NetCipher library (`info.guardianproject.netcipher:netcipher`), as `HttpURLConnection` is part of

## NETCIPHER

---

standard Java and Android. The other three HTTP stacks have separate libraries:

HTTP Stack	NetCipher Artifact
OkHttp3	<code>info.guardianproject.netcipher:netcipher-okhttp3</code>
HttpClient	<code>info.guardianproject.netcipher:netcipher-httpclient</code>
Volley	<code>info.guardianproject.netcipher:netcipher-volley</code>

### Add the Dependencies

Unfortunately, some packaging issues with the 2.0.0-alpha1 edition of NetCipher, adding the dependencies is more complicated than it needs to be. Your project needs to have dependencies on:

- `info.guardianproject.netcipher:netcipher:2.0.0-alpha1`, for the core of NetCipher
- the NetCipher artifact specifically for your HTTP stack, if you are using something other than `HttpURLConnection`
- the artifact for the HTTP client API itself
- any other artifacts that your project needs for other reasons

So, for example, the `okhttp3` module in the `HTTPStacks` project is a sample app that uses `OkHttp 3.x` for its HTTP client API. It needs three artifacts in its dependencies closure to pull in `OkHttp` and NetCipher's support for `OkHttp`:

```
compile 'info.guardianproject.netcipher:netcipher:2.0.0-alpha1'
compile 'info.guardianproject.netcipher:netcipher-okhttp3:2.0.0-alpha1'
compile 'com.squareup.okhttp3:okhttp:3.8.0'
```

(from [Internet/HTTPStacks/okhttp3/build.gradle](#))

Volley integration has been tested with `com.android.volley:volley:1.0.0`, while the `HttpClient` integration work with the `cz.msebera.android:httpclient:4.4.1.2` independent repackaging of Apache `HttpClient` for Android.

### Set up OrbotHelper

`OrbotHelper` is a singleton that manages a lot of the asynchronous communication between your app and Orbot. It is designed to be initialized fairly early on in your

## NETCIPHER

---

app's lifecycle. One likely candidate is to have a custom `Application` subclass, where you override `onCreate()` and set up `OrbotHelper`.

All of the sample apps do this in a custom `SampleApplication` class:

```
package com.commonware.android.http;

import android.app.Application;
import com.squareup.leakcanary.LeakCanary;
import info.guardianproject.netcipher.proxy.OrbotHelper;

public class SampleApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        LeakCanary.install(this);
        OrbotHelper.get(this).init();
    }
}
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonware/android/http/SampleApplication.java](https://github.com/okhttp/okhttp3/blob/master/src/main/java/com/commonware/android/http/SampleApplication.java))

This custom `Application` also sets up [LeakCanary](#).

`SampleApplication` is then tied into the app via the `android:name` attribute on the `<application>` element in the manifest:

```
<application
    android:name=".SampleApplication"
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
```

(from [Internet/HTTPStacks/okhttp3/src/main/AndroidManifest.xml](https://github.com/okhttp/okhttp3/blob/master/src/main/AndroidManifest.xml))

## Choose and Create a Builder

Each module defines a corresponding builder class that can be used to configure `NetCipher` for use with that stack, with names based on the classes used with those HTTP stacks:

HTTP Stack	Builder Class
URLConnection	StrongConnectionBuilder
OkHttp3	StrongOkHttpClientBuilder
HttpClient	StrongHttpClientBuilder
Volley	StrongVolleyQueueBuilder

You will need an instance of your chosen builder class. The simplest way to do that is to call the `forMaxSecurity()` static method on the builder class. `forMaxSecurity()` takes a `Context` as a parameter, though it only holds onto the `Application` singleton internally, so any `Context` is safe. `forMaxSecurity()` returns a builder configured for the best protection that NetCipher can offer.

### Get a Connection

Then, call `build()` on the builder object. It will take a `StrongBuilder.Callback` object as a parameter, typed for whatever HTTP stack you chose. So, for example, if you went with `StrongConnectionBuilder`, your callback will be a `StrongBuilder.Callback<URLConnection>`.

HTTP Stack	Builder Class	Connection Class
URLConnection	StrongConnectionBuilder	URLConnection
OkHttp3	StrongOkHttpClientBuilder	OkHttpClient
HttpClient	StrongHttpClientBuilder	HttpClient
Volley	StrongVolleyQueueBuilder	RequestQueue

You will need to implement four methods on that `Callback`:

- `onConnected()` will be passed an instance of your connection class (e.g., an `URLConnection` instance), ready for your use, configured to hook into NetCipher
- `onConnectionException()` will be passed an `IOException`, if one of those occurs while trying to set up your connection

- `onTimeout()` will be called if Orbot is not installed or we could not connect to it within 30 seconds
- `onInvalid()` will be called if the Tor connection is established but is deemed to be compromised (more on this later)

## Seeing the Builder in Action

Each of the four modules in the sample app (`hurl`, `httpClient`, `okhttp3`, and `volley`) have a similar `MainActivity` implementation, one that populates a `ListView` with the latest Stack Overflow Android questions. The difference in which HTTP stack the sample uses.

For example, the `okhttp3` module, in `onCreate()` of its `MainActivity`, uses `StrongOkHttpClientBuilder`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongOkHttpClientBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .build(this);
    }
    catch (Exception e) {
        Toast
            .makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception loading SO questions", e);
        finish();
    }
}
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java](https://github.com/Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java))

Here, we use `forMaxSecurity()` to create the `StrongOkHttpClientBuilder`, then configure it further with `withTorValidation()`. This requests that we do a test HTTP request to a Tor status URL to confirm that our request has indeed gone over Tor.

Note that `StrongConnectionBuilder` — for use with `HttpURLConnection` — also requires that you call `connectTo()`, before `build()`, to indicate the specific URL for

## NETCIPHER

---

which you want an `URLConnection`. This is unique among the builders. These sorts of per-builder differences are discussed [later in this chapter](#).

`build()` is passed this, referencing `MainActivity` itself, which is implementing the `StrongBuilder.Callback` interface:

```
public class MainActivity extends ListActivity implements
    StrongBuilder.Callback<OkHttpClient> {
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java](#))

That `Callback` is tied to the particular type of connection we are creating. We are using `OkHttp3` and `StrongOkHttpClientBuilder`, so we are creating an `OkHttpClient` connection.

Our `onConnected()` method for that `Callback` gets the `OkHttpClient` and makes an HTTP request using it:

```
@Override
public void onConnected(final OkHttpClient client) {
    new Thread() {
        @Override
        public void run() {
            try {
                Request request=new Request.Builder().url(SO_URL).build();
                Response response=client.newCall(request).execute();

                final SOQuestions result=
                    new Gson().fromJson(response.body().charStream(), SOQuestions.class);

                runOnUiThread(new Runnable() {
                    @Override
                    public void run() {
                        setListAdapter(new ItemsAdapter(result.items));
                    }
                });
            }
            catch (IOException e) {
                onConnectionException(e);
            }
        }
    }.start();
}
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java](#))

`SO_URL`, passed into `url()`, is a Web service request URL from the Stack Exchange API, looking for Stack Overflow questions tagged with the `android` tag:

```
String SO_URL=
    "https://api.stackexchange.com/2.1/questions?"
```

```
+ "order=desc&sort=creation&site=stackoverflow&tagged=android";
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java](http://Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java))

Note that `onConnected()` will be called on the main application thread, so you will need to get your connection over to whatever background thread will be doing your work. In this case, we create a background thread right here to retrieve the JSON, parse it, and use `runOnUiThread()` to update the `ListActivity` with an `ItemsAdapter` to show the parsed Stack Overflow questions:

```
class ItemsAdapter extends ArrayAdapter<Item> {
    ItemsAdapter(List<Item> items) {
        super(MainActivity.this,
            android.R.layout.simple_list_item_1, items);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        TextView title=(TextView)row.findViewById(android.R.id.text1);

        title.setText(Html.fromHtml(getItem(position).title));

        return(row);
    }
}
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java](http://Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java))

The other three methods that we need to implement for our `Callback` are for error conditions: `onConnectionException()`, `onTimeout()`, and `onInvalid()`:

```
@Override
public void onConnectionException(Exception e) {
    Log.e(getClass().getSimpleName(),
        "Exception loading SO questions", e);

    runOnUiThread(new Runnable() {
        @Override
        public void run() {
            Toast
                .makeText(MainActivity.this, R.string.msg_crash,
                    Toast.LENGTH_LONG)
                .show();
            finish();
        }
    });
}
```

```
}

@Override
public void onTimeout() {
    runOnUiThread(new Runnable() {
        @Override
        public void run() {
            Toast
                .makeText(MainActivity.this, R.string.msg_timeout,
                    Toast.LENGTH_LONG)
                .show();
            finish();
        }
    });
}

@Override
public void onInvalid() {
    runOnUiThread(new Runnable() {
        @Override
        public void run() {
            Toast
                .makeText(MainActivity.this, R.string.msg_invalid,
                    Toast.LENGTH_LONG)
                .show();
            finish();
        }
    });
}
```

(from [Internet/HTTPStacks/okhttp3/src/main/java/com/commonsware/android/http/MainActivity.java](https://github.com/okhttp/okhttp3/blob/master/src/main/java/com/commonsware/android/http/MainActivity.java))

Other than initializing `OrbotHelper`, setting up the builder, and implementing `StrongBuilder.Callback` somewhere to handle the results, the rest of the code is tied to application logic, not NetCipher itself.

## The Rest of the Builder API

The API shown above for getting a NetCipher-secured connection via your favorite HTTP stack is designed for ease of use. However, as shown, it is not very flexible.

The rest of the builder API offers that flexibility, at the cost of some additional code.

## Common Configuration Methods

The StrongBuilder interface defines the common public API for all four of the builder classes:

```

* @return the connection
* @throws IOException
*/
C build(Intent status) throws Exception;

/**
 * Asynchronous version of build(), one that uses OrbotInitializer
 * internally to get the status and checks the validity of the Tor
 * connection (if requested). Note that your callback methods may
 * be invoked on any thread; do not assume that they will be called
 * on any particular thread.
 *
 * @param callback Callback to get a connection handed to you
 *           for use, already set up for NetCipher
 */
void build(Callback<C> callback);
}
```

withTorValidation(), build(), and the Callback nested interface were covered earlier in this chapter, but the others offer finer-grained configuration options.

Five of the methods are tied into choosing what proxy protocol should be used with Orbot.

forMaxSecurity(), under the covers, uses withBestProxy(), which chooses the best proxy for the situation. Right now, the implementation chooses the SOCKS proxy where that is supported, falling back to the HTTP proxy where it is not.

The supportsHttpProxy() and supportsSocksProxy() methods indicate whether a given builder supports these proxy types.

The withHttpProxy() and withSocksProxy() methods tell the builder that you want to use that specific proxy. Use these with care, making sure that the proxy you want is supported. withBestProxy() is a far better choice overall.

withWeakCiphers() expands the roster of SSL ciphers that NetCipher allows the HTTPS connection to use. Normally, NetCipher tries to avoid ciphers with known security issues. However, that may cause problems with some servers, if NetCipher and the server cannot negotiate a common cipher. withWeakCiphers() allows NetCipher to use more ciphers, to perhaps overcome the negotiation problem, with

the cost of possibly weaker security.

`withTrustManagers()` allows you to replace the `TrustManager` implementation that NetCipher would use by default with a different one, perhaps [one that supports certificate pinning or other SSL strengthening techniques](#).

## Differences Between the Stacks

While each of the builders supports the `StrongBuilder` API, there are some differences between the implementations.

### StrongConnectionBuilder

Before calling `build()`, you need to call `connectTo()` to supply the URL (as a `String` or `URL`) that you want to connect to. The other builders give you objects that you can reuse across many requests (e.g., `OkHttp3's OkHttpClient`), but that is not possible with `URLConnection`.

The `hurl` module's `MainActivity` does just that:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongConnectionBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .connectTo(SO_URL)
            .build(this);
    }
    catch (Exception e) {
        Toast
            .makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception loading SO questions", e);
        finish();
    }
}
```

(from [Internet/HTTPStacks/hurl/src/main/java/com/commonsware/android/http/MainActivity.java](#))

The `onConnected()` method then just uses the fully-configured `URLConnection`

object:

```
@Override
public void onConnected(final HttpURLConnection conn) {
    new Thread() {
        @Override
        public void run() {
            try {
                InputStream in=conn.getInputStream();
                BufferedReader reader=
                    new BufferedReader(new InputStreamReader(in));

                final SOQuestions result=
                    new Gson().fromJson(reader, SOQuestions.class);

                runOnUiThread(new Runnable() {
                    @Override
                    public void run() {
                        setListAdapter(new ItemsAdapter(result.items));
                    }
                });

                reader.close();
            }
            catch (IOException e) {
                onConnectionException(e);
            }
            finally {
                conn.disconnect();
            }
        }
    }.start();
}
```

(from [Internet/HTTPStacks/hurl/src/main/java/com/commonsware/android/http/MainActivity.java](http://Internet/HTTPStacks/hurl/src/main/java/com/commonsware/android/http/MainActivity.java))

To help make this a bit easier, StrongConnectionBuilder supports the copy constructor. You can create a master StrongConnectionBuilder with your base configuration, then make a copy, call `connectTo()` on the copy, then call `build()` on the copy, throwing away the copy when you are done.

### **StrongHttpClientBuilder**

The builder for Apache's independent packaging of HttpClient for Android extends Apache's own HttpClientBuilder. As a result, you can call all the normal HttpClientBuilder methods in addition to calling the StrongBuilder methods. The

noteworthy exception is that the standard zero-parameter `build()` offered by `HttpClientBuilder` is not supported.

The `httpClient` module's `MainActivity` does not need any `HttpClient`-specific configuration:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongHttpClientBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .build(this);
    }
    catch (Exception e) {
        Toast
            .makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception loading SO questions", e);
        finish();
    }
}
```

(from [Internet/HTTPStacks/httpclient/src/main/java/com/commonsware/android/http/MainActivity.java](https://github.com/Internet/HTTPStacks/httpclient/src/main/java/com/commonsware/android/http/MainActivity.java))

The `onConnected()` method then just uses the configured `HttpClient` object:

```
@Override
public void onConnected(final HttpClient client) {
    new Thread() {
        @Override
        public void run() {
            try {
                HttpGet get=new HttpGet(SO_URL);
                String json=client.execute(get, new BasicResponseHandler());

                final SOQuestions result=
                    new Gson().fromJson(new StringReader(json),
                        SOQuestions.class);

                runOnUiThread(new Runnable() {
                    @Override
                    public void run() {
                        setListAdapter(new ItemsAdapter(result.items));
                    }
                });
            }
        }
    }.start();
}
```

```
    }
    });
}
catch (IOException e) {
    onConnectionException(e);
}
}
}.start();
}
```

(from [Internet/HTTPStacks/httpclient/src/main/java/com/commonsware/android/http/MainActivity.java](https://Internet/HTTPStacks/httpclient/src/main/java/com/commonsware/android/http/MainActivity.java))

### StrongVolleyQueueBuilder

This builder class adheres to the StrongBuilder API without any changes, making its use fairly straightforward:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    try {
        StrongVolleyQueueBuilder
            .forMaxSecurity(this)
            .withTorValidation()
            .build(this);
    }
    catch (Exception e) {
        Toast
            .makeText(this, R.string.msg_crash, Toast.LENGTH_LONG)
            .show();
        Log.e(getClass().getSimpleName(),
            "Exception loading SO questions", e);
        finish();
    }
}
```

(from [Internet/HTTPStacks/volley/src/main/java/com/commonsware/android/http/MainActivity.java](https://Internet/HTTPStacks/volley/src/main/java/com/commonsware/android/http/MainActivity.java))

The onConnected() method then just uses the configured RequestQueue object:

```
@Override
public void onConnected(final RequestQueue rq) {
    new Thread() {
        @Override
        public void run() {
            final StringRequest stringRequest=
```

```
new StringRequest(StringRequest.Method.GET, SO_URL,
new Response.Listener<String>() {
    @Override
    public void onResponse(String response) {
        final SOQuestions result=
            new Gson().fromJson(new StringReader(response),
                SOQuestions.class);

        runOnUiThread(new Runnable() {
            @Override
            public void run() {
                setListAdapter(new ItemsAdapter(result.items));
            }
        });
    }
},
new Response.ErrorListener() {
    @Override
    public void onErrorResponse(VolleyError error) {
        Log.e(getClass().getSimpleName(),
            "Exception making Volley request", error);
    }
});

rq.add(stringRequest);
}
}.start();
}
```

(from [Internet/HTTPStacks/volley/src/main/java/com/commonsware/android/http/MainActivity.java](https://github.com/martinkravaric/volley/blob/master/src/main/java/com/commonsware/android/http/MainActivity.java))

### StrongOkHttpClientBuilder

Note that OkHttp3 [does not support SOCKS proxies](#). Hence, `supportsSocksProxy()` returns false, causing `withBestProxy()` to fall back to the HTTP proxy. This is handled for you automatically.

# Miscellaneous Network Topics

---

This chapter is a catch-all for various Android capabilities related to network I/O and the Internet, beyond what is covered elsewhere in the book.

(yes, this chapter could have a more exciting rationale for existing, but the author is subject to “Truth in Advertising” laws...)

## Prerequisites

Readers of this chapter should have read the core chapters of the book.

## Downloading Files

Android 2.3 introduced a `DownloadManager`, designed to handle a lot of the complexities of downloading larger files, such as:

1. Determining whether the user is on WiFi or mobile data, and if so, whether the download should occur
2. Handling when the user, previously on WiFi, moves out of range of the access point and “fails over” to mobile data
3. Ensuring the device stays awake while the download proceeds

`DownloadManager` itself is less complicated than the alternative of writing all of that stuff yourself. However, it does present a few challenges. In this section, we will examine the [Internet/Download](#) sample project, one that uses `DownloadManager`.

## The Permissions

To use DownloadManager, you will need to hold the INTERNET permission. You will also need the WRITE\_EXTERNAL\_STORAGE permission, as DownloadManager can only download to external storage. Note that you need to hold WRITE\_EXTERNAL\_STORAGE even if you are trying to have DownloadManager write to some location where that permission might not be needed (e.g., getExternalFilesDir() on an Android 4.4+ device). DownloadManager is requiring you to hold that permission, more so than the Android framework, and DownloadManager requires that permission for all API levels at the present time.

For example, here is the manifest for the Internet/Download application, where we request these two permissions:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.downmgr"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:anyDensity="true"
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true" />

  <uses-permission android:name="android.permission.INTERNET" />
  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".DownloadDemo"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
</manifest>
```

---

## MISCELLANEOUS NETWORK TOPICS

---

(from [Internet/Download/app/src/main/AndroidManifest.xml](#))

WRITE\_EXTERNAL\_STORAGE is a dangerous permission. With a targetSdkVersion of 23 or higher, we need to handle that in our app. This app uses the same AbstractPermissionActivity seen in [the chapter on permissions](#), so we can request WRITE\_EXTERNAL\_STORAGE from the user on the first run of our app from the DownloadDemo activity:

```
package com.commonware.android.downmgr;

import android.Manifest;
import android.app.Activity;
import android.app.DownloadManager;
import android.content.Intent;
import android.os.Bundle;
import android.os.StrictMode;
import android.widget.Toast;

public class DownloadDemo extends AbstractPermissionActivity {

    @Override
    protected String[] getDesiredPermissions() {
        return(new String[] {Manifest.permission.WRITE_EXTERNAL_STORAGE});
    }

    @Override
    protected void onPermissionDenied() {
        Toast
            .makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG)
            .show();
        finish();
    }

    @Override
    public void onReady(Bundle savedInstanceState) {
        StrictMode.setThreadPolicy(new StrictMode.ThreadPolicy.Builder()
            .detectNetwork()
            .penaltyDeath()
            .build());

        if (getSupportFragmentManager().findFragmentById(android.R.id.content)==null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new DownloadFragment()).commit();
        }
    }

    public void viewLog() {
        startActivity(new Intent(DownloadManager.ACTION_VIEW_DOWNLOADS));
    }
}
```

(from [Internet/Download/app/src/main/java/com/commonware/android/downmgr/DownloadDemo.java](#))

That activity then goes on to display a DownloadFragment, where most of our code resides.

## The Layout

Our sample application has a simple layout, consisting of three buttons:

1. One to kick off a download
2. One to query the status of a download
3. One to display a system-supplied activity containing the roster of downloaded files

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:orientation="vertical"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  >
  <Button
    android:id="@+id/start"
    android:text="@string/start_download"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
  <Button
    android:id="@+id/query"
    android:text="@string/query_status"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
    android:enabled="false"
  />
  <Button android:id="@+id/view"
    android:text="@string/view_log"
    android:layout_width="match_parent"
    android:layout_height="0dip"
    android:layout_weight="1"
  />
</LinearLayout>
```

(from [Internet/Download/app/src/main/res/layout/main.xml](#))

## Requesting the Download

To kick off a download, we first need to get access to the DownloadManager. This is a so-called “system service”. You can call `getSystemService()` on any activity (or other

## MISCELLANEOUS NETWORK TOPICS

---

Context), provide it the identifier of the system service you want, and receive the system service object back. However, since `getSystemService()` supports a wide range of these objects, you need to cast it to the proper type for the service you requested.

So, for example, here is the `onCreateView()` method of the `DownloadFragment`, in which we get the `DownloadManager`:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup parent,
    Bundle savedInstanceState) {
    mgr=
        (DownloadManager) getActivity().getSystemService(Context.DOWNLOAD_SERVICE);

    View result=inflater.inflate(R.layout.main, parent, false);

    query=result.findViewById(R.id.query);
    query.setOnClickListener(this);
    start=result.findViewById(R.id.start);
    start.setOnClickListener(this);

    result.findViewById(R.id.view).setOnClickListener(this);

    return(result);
}
```

(from [Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java](#))

Most of these managers have no `close()` or `release()` or `goAwayPlease()` sort of methods — you can just use them and let garbage collection take care of cleaning them up.

Given the manager, we can now call an `enqueue()` method to request a download. The name is relevant — do not assume that your download will begin immediately, though often times it will. The `enqueue()` method takes a `DownloadManager.Request` object as a parameter. The `Request` object uses the builder pattern, in that most methods return the `Request` itself, so you can chain a series of calls together with less typing.

For example, the top-most button in our layout is tied to a `startDownload()` method in `DownloadFragment`, shown below:

```
private void startDownload(View v) {
    Uri uri=Uri.parse("https://commonsware.com/misc/test.mp4");

    Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS)
        .mkdirs();

    DownloadManager.Request req=new DownloadManager.Request(uri);
```

---

## MISCELLANEOUS NETWORK TOPICS

---

```
req.setAllowedNetworkTypes(DownloadManager.Request.NETWORK_WIFI
    | DownloadManager.Request.NETWORK_MOBILE)
    .setAllowedOverRoaming(false)
    .setTitle("Demo")
    .setDescription("Something useful. No, really.")
    .setDestinationInExternalPublicDir(Environment.DIRECTORY_DOWNLOADS,
        "test.mp4");

lastDownload=mgr.enqueue(req);

v.setEnabled(false);
query.setEnabled(true);
}
```

(from [Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java](#))

We are downloading a sample MP4 file, and we want to download it to the external storage area. To do the latter, we are using `getExternalStoragePublicDirectory()` on `Environment`, which gives us a directory suitable for storing a certain class of content. In this case, we are going to store the download in the `Environment.DIRECTORY_DOWNLOADS`, though we could just as easily have chosen `Environment.DIRECTORY_MOVIES`, since we are downloading a video clip. Note that the `File` object returned by `getExternalStoragePublicDirectory()` may point to a not-yet-created directory, which is why we call `mkdirs()` on it, to ensure the directory exists.

We then create the `DownloadManager.Request` object, with the following attributes:

1. We are downloading the specific URL we want, courtesy of the `Uri` supplied to the `Request` constructor
2. We are willing to use either mobile data or WiFi for the download (`setAllowedNetworkTypes()`), but we do not want the download to incur roaming charges (`setAllowedOverRoaming()`)
3. We want the file downloaded as `test.mp4` in the downloads area on the external storage (`setDestinationInExternalPublicDir()`)

We also provide a name (`setTitle()`) and description (`setDescription()`), which are used as part of the notification drawer entry for this download. The user will see these when they slide down the drawer while the download is progressing.

The `enqueue()` method returns an ID of this download, which we hold onto for use in querying the download status.

### Keeping Track of Download Status

If the user presses the Query Status button, we want to find out the details of how

---

## MISCELLANEOUS NETWORK TOPICS

---

the download is progressing. To do that, we can call `query()` on the `DownloadManager`. The `query()` method takes a `DownloadManager.Query` object, describing what download(s) you are interested in. In our case, we use the value we got from the `enqueue()` method when the user requested the download:

```
private void queryStatus(View v) {
    Cursor c=
        mgr.query(new DownloadManager.Query().setFilterById(lastDownload));

    if (c == null) {
        Toast.makeText(getActivity(), R.string.download_not_found,
            Toast.LENGTH_LONG).show();
    }
    else {
        c.moveToFirst();

        Log.d(getClass().getName(),
            "COLUMN_ID: "
            + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_ID)));
        Log.d(getClass().getName(),
            "COLUMN_BYTES_DOWNLOADED_SO_FAR: "
            + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_BYTES_DOWNLOADED_SO_FAR)));
        Log.d(getClass().getName(),
            "COLUMN_LAST_MODIFIED_TIMESTAMP: "
            + c.getLong(c.getColumnIndex(DownloadManager.COLUMN_LAST_MODIFIED_TIMESTAMP)));
        Log.d(getClass().getName(),
            "COLUMN_LOCAL_URI: "
            + c.getString(c.getColumnIndex(DownloadManager.COLUMN_LOCAL_URI)));
        Log.d(getClass().getName(),
            "COLUMN_STATUS: "
            + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_STATUS)));
        Log.d(getClass().getName(),
            "COLUMN_REASON: "
            + c.getInt(c.getColumnIndex(DownloadManager.COLUMN_REASON)));

        Toast.makeText(getActivity(), statusMessage(c), Toast.LENGTH_LONG)
            .show();

        c.close();
    }
}
```

(from [Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java](#))

The `query()` method returns a `Cursor`, containing a series of columns representing the details about our download. There is a series of constants on the `DownloadManager` class outlining what is possible. In our case, we retrieve (and dump to Logcat):

1. The ID of the download (`COLUMN_ID`)
2. The amount of data that has been downloaded to date (`COLUMN_BYTES_DOWNLOADED_SO_FAR`)
3. What the last-modified timestamp is on the download

## MISCELLANEOUS NETWORK TOPICS

---

- (COLUMN\_LAST\_MODIFIED\_TIMESTAMP)
- 4. Where the file is being saved to locally (COLUMN\_LOCAL\_URI)
- 5. What the actual status is (COLUMN\_STATUS)
- 6. What the reason is for that status (COLUMN\_REASON)

Note that COLUMN\_LOCAL\_URI may be unavailable, if the user has deleted the downloaded file between when the download completed and the time you try to access the column.

There are a number of possible status codes (e.g., STATUS\_FAILED, STATUS\_SUCCESSFUL, STATUS\_RUNNING). Some, like STATUS\_FAILED, may have an accompanying reason to provide more details.

Note that you really should close this Cursor when you are done with it. StrictMode, for example, will complain if you do not.

### Download Broadcasts

To find out about the results of the download, we need to register a BroadcastReceiver, to watch for two actions used by DownloadManager:

1. ACTION\_DOWNLOAD\_COMPLETE, to let us know when the download is done
2. ACTION\_NOTIFICATION\_CLICKED, to let us know if the user taps on the Notification displayed on the user's device related to our download

So, in onResume() of our fragment, we register a single BroadcastReceiver for both of those events:

```
@Override
public void onResume() {
    super.onResume();

    IntentFilter f=
        new IntentFilter(DownloadManager.ACTION_DOWNLOAD_COMPLETE);

    f.addAction(DownloadManager.ACTION_NOTIFICATION_CLICKED);

    getActivity().registerReceiver(onEvent, f);
}
```

(from [Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java](https://commonsware.com/android/downmgr/DownloadFragment.java))

That BroadcastReceiver is unregistered in onPause():

## MISCELLANEOUS NETWORK TOPICS

---

```
@Override
public void onPause() {
    getActivity().unregisterReceiver(onEvent);

    super.onPause();
}
```

(from [Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java](#))

The BroadcastReceiver implementation examines the action string of the incoming Intent (via a call to `getAction()`) and either displays a Toast (for `ACTION_NOTIFICATION_CLICKED`) or enables the start-download Button:

```
public void onReceive(Context ctxt, Intent i) {
    if (DownloadManager.ACTION_NOTIFICATION_CLICKED.equals(i.getAction())) {
        Toast.makeText(ctxt, R.string.hi, Toast.LENGTH_LONG).show();
    }
    else {
        start.setEnabled(true);
    }
}
};
}
```

(from [Internet/Download/app/src/main/java/com/commonsware/android/downmgr/DownloadFragment.java](#))

## What the User Sees

The user, upon launching the application, sees our three pretty buttons:

*Figure 777: The Download Demo Sample, As Initially Launched*

## MISCELLANEOUS NETWORK TOPICS

---

Clicking the first disables the button while the download is going on, and a download icon appears in the status bar (though it is a bit difficult to see, given the poor contrast between Android's icon and Android's status bar):

*Figure 778: The Download Demo Sample, Downloading*

## MISCELLANEOUS NETWORK TOPICS

---

Sliding down the notification drawer shows the user the progress in the form of a ProgressBar widget:

*Figure 779: The DownloadManager Notification*

Tapping on the entry in the notification drawer returns control to our original activity, where they see a Toast, raised by our BroadcastReceiver.

If they tap the middle button during the download, a different Toast will appear indicating that the download is in progress:

*Figure 780: The Download Demo, Showing Download Status*

Additional details are also dumped to Logcat:

```
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_ID: 12  
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_BYTES_DOWNLOADED_SO_FAR: 615400  
12-10 08:45:01.289: DEBUG/com.commonware.android.download.DownloadDemo(372):  
COLUMN_LAST_MODIFIED_TIMESTAMP: 1291988696232

```

Tapping the bottom button brings up the activity displaying all downloads, including both successes and failures:

*Figure 781: The DownloadManager Results*

And, of course, the file is downloaded.

### Limitations

While `DownloadManager` nowadays supports HTTPS (SSL) URLs, that was not the case when it was introduced back in Android 2.3. You will want to test any HTTPS URLs you intend to use with `DownloadManager` if you are supporting older versions of Android.

If you display the list of all downloads, and your download is among them, it is a really good idea to make sure that some activity (perhaps one of yours) is able to respond to an `ACTION_VIEW` Intent on that download's MIME type. Otherwise, when the user taps on the entry in the list, they will get a Toast indicating that there is nothing available to view the download. This may confuse users. Alternatively, use `setVisibleInDownloadsUi()` on your request, passing in `false`, to suppress it from this list.

Also, starting with Android 5.0, the Downloads app that provides the core implementation of `DownloadManager` keeps track of when other apps get uninstalled. At that point, the Downloads app deletes the files downloaded by `DownloadManager` on behalf of that app. This includes files stored in common locations (e.g., `DIRECTORY_DOWNLOADS`) that would ordinarily survive an uninstall. For example, if you run the `Internet/Download` sample app on an Android 5.0+ device, then uninstall the app, the downloaded file vanishes from the Downloads app. If you elect to use `DownloadManager`, you should either:

- Download the file to a temporary spot, then move it to a long-term location yourself, or
- Advise the user that the file will be deleted if the user uninstalls your app, suggesting that the user might want to make a safe copy of the file

## Data Saver

Android has had a per-app “data saver” mode for some time, with an eye towards reducing bandwidth consumption when the device is using a known metered data plan. Android 7.0+ extended this to a device-wide setting,

Apps can be in one of three states as a result:

- The device is normal
- The device is in data-saver mode
- The device is in data-saver mode, but your app is whitelisted by the user

The idea is that if the device is in normal mode, you can do what you want. If the device is in data-saver mode, you should restrict your bandwidth, even if the user whitelists you. Apps that are not whitelisted have no network access while in the background.

To that end, `ConnectivityManager` has three things for you.

## MISCELLANEOUS NETWORK TOPICS

---

First, `isActiveNetworkMetered()` will return `true` if the device is on a metered data connection, `false` otherwise. This has been around for years (API Level 16+), but has not been all that popular, apparently.

Second, Android 7.0 has a `getRestrictBackgroundStatus()` method on `ConnectivityManager`. This returns an `int` that resolves to one of three values:

- `RESTRICT_BACKGROUND_STATUS_DISABLED`
- `RESTRICT_BACKGROUND_STATUS_ENABLED`
- `RESTRICT_BACKGROUND_STATUS_WHITELISTED`

If `isActiveNetworkMetered()` is `true`, and `getRestrictBackgroundStatus()` returns `RESTRICT_BACKGROUND_STATUS_ENABLED`, any attempts to use the network may fail, and so your app should plan accordingly.

If you want to try to react in real-time to changes in the data-saver configuration, you can register a receiver for `ACTION_RESTRICT_BACKGROUND_CHANGED` (defined on `ConnectivityManager`). This will be broadcast for any change in data-saver settings, which means that *your* app's state may not have changed. You will need to call `getRestrictBackgroundStatus()` to find out your current state. Also note that this broadcast is only sent to receivers registered dynamically, via `registerReceiver()`. You cannot register for this broadcast in the manifest.

To try to get on the whitelist, you might be tempted to try using `ACTION_IGNORE_BACKGROUND_DATA_RESTRICTIONS_SETTINGS` to lead the user to add your app to the Data Saver whitelist, so you have normal background network access. However, bear in mind that Google has a similar feature for the battery saver whitelist... and trying to use *that* action [got apps banned from the Play Store](#). At the moment, there is no similar language around the use of the data saver whitelist... but, then again, they did not tell you they were going to ban you for asking to be on the battery saver whitelist until after Android 6.0 shipped.

**Trail: Media**

---

# Audio Playback

---

Whether it comes in the form of simple beeps or in the form of symphonies (or gangster rap or whatever), Android applications often need to play audio. A few things in Android can play audio automatically, such as [a Notification](#). However, once you get past those, you are on your own.

Fortunately for you, Android offers support for audio playback, and we will examine some of the options in this chapter.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Get Your Media On

In Android, you have a few different places you can pull media clips from — one of these will hopefully fit your needs:

- You can package audio clips as raw resources (`res/raw/` in your project), so they are bundled with your application. The benefit is that you're guaranteed the clips will be there; the downside is that they cannot be replaced without upgrading the application.
- You can package audio clips as assets (`assets/` in your project) and reference them via `file:///android_asset/` URLs in a `Uri`. The benefit over raw resources is that this location works with APIs that expect `Uri` parameters instead of resource IDs. The downside — assets are only replaceable when the application is upgraded — remains. On the whole, the audio APIs tend

to favor raw resources over assets.

- You can download and store media in internal storage, external storage, or possibly on removable storage.
- You can, in some cases, stream media off the Internet, bypassing any local storage.

## MediaPlayer for Audio

If you want to play back music, particularly material in MP3 format, you will want to use the `MediaPlayer` class. With it, you can feed it an audio clip, start/stop/pause playback, and get notified on key events, such as when the clip is ready to be played or is done playing.

You have three ways to set up a `MediaPlayer` and tell it what audio clip to play:

- If the clip is a raw resource, use `MediaPlayer.create()` and provide the resource ID of the clip.
- If you have a `Uri` to the clip, use the `Uri`-flavored version of `MediaPlayer.create()`.
- If you have a string path to the clip, just create a `MediaPlayer` using the default constructor, then call `setDataSource()` with the path to the clip. However, in this case, you also need to call `prepare()` or `prepareAsync()`. Both will set up the clip to be ready to play, such as fetching the first few seconds off the file or stream. The `prepare()` method is synchronous; as soon as it returns, the clip is ready to play. The `prepareAsync()` method is asynchronous.

Once the clip is prepared, `start()` begins playback, `pause()` pauses playback (with `start()` picking up playback where `pause()` paused), and `stop()` ends playback. One caveat: you cannot simply call `start()` again on the `MediaPlayer` once you have called `stop()` — we'll cover a workaround a bit later in this section.

To see this in action, take a look at the [Media/Audio](#) sample project. It contains a single activity — `MainActivity` — that offers playback of a Creative Commons-licensed audio clip, stored as an Ogg Vorbis file as a raw resource (`R.raw.clip`).

In `onCreate()`, we use the static `create()` factory method on `MediaPlayer` to set up a `MediaPlayer` for our audio clip:

```
@Override
public void onCreate(Bundle state) {
```

## AUDIO PLAYBACK

---

```
super.onCreate(state);

try {
    mp=MediaPlayer.create(this, R.raw.clip);
    mp.setOnCompletionListener(this);
}
catch (Exception e) {
    goBlooney(e);
}
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

We also register the activity itself as the `OnCompletionListener`, to find out if the audio clip is played through to the end.

Under the covers, `create()` not only creates an instance of `MediaPlayer` and sets up the data source, but it also calls `prepare()`, so the `MediaPlayer` is ready for use once `create()` returns. However, this also means that there might be an exception, such as providing an invalid resource ID (e.g., one pointing to a Photoshop file instead of an audio file). `goBlooney()` simply logs the exception and shows a `Toast` as a crude form of error handling:

```
private void goBlooney(Exception e) {
    Log.e(getClass().getSimpleName(), getString(R.string.msg_error),
        e);
    Toast
        .makeText(this, R.string.msg_error_toast, Toast.LENGTH_LONG)
        .show();
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

Our UI is purely a set of action bar items:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">
    <item
        android:id="@+id/play"
        android:icon="@drawable/ic_play_arrow"
        android:showAsAction="ifRoom"
        android:title="@string/menu_play" />
    <item
        android:id="@+id/pause"
        android:icon="@drawable/ic_pause"
        android:showAsAction="ifRoom">
```

## AUDIO PLAYBACK

---

```
        android:title="@string/menu_pause"
        android:visible="false" />
    <item
        android:id="@+id/stop"
        android:icon="@drawable/ic_stop"
        android:showAsAction="ifRoom"
        android:title="@string/menu_stop"
        android:visible="false" />
</menu>
```

(from [Media/Audio/app/src/main/res/menu/actions.xml](#))

Note that only the play action bar item is visible at the outset. We will toggle the visibility of the action bar items based on the status of the playback of the clip.

We populate the action bar in `onCreateOptionsMenu()`, also retrieving the three `MenuItem` objects for our three action bar items:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    play=menu.findItem(R.id.play);
    pause=menu.findItem(R.id.pause);
    stop=menu.findItem(R.id.stop);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

`onOptionsItemSelected()` merely delegates the three action items to three similarly-named methods: `play()`, `pause()`, and `stop()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.play:
            play();
            return (true);

        case R.id.pause:
            pause();
            return (true);

        case R.id.stop:
            stop();
            return (true);
    }
}
```

## AUDIO PLAYBACK

---

```
}  
  
return(super.onOptionsItemSelected(item));  
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

The `play()` method calls `start()` to cause the `MediaPlayer` to begin playing back the audio clip. It also toggles the visibility of the action bar items, so the pause and stop ones are now visible:

```
private void play() {  
    mp.start();  
  
    play.setVisible(false);  
    pause.setVisible(true);  
    stop.setVisible(true);  
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

`play()` is asynchronous, as the audio clip plays back on another system-supplied thread. We are not tying up the main application thread by playing back this clip.

`pause()` is similar: it calls `pause()` to cause the `MediaPlayer` to pause playback of the audio clip. It also toggles the visibility of the action bar items, so the play and stop ones are now visible:

```
private void pause() {  
    mp.pause();  
  
    play.setVisible(true);  
    pause.setVisible(false);  
    stop.setVisible(true);  
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

Where things get a bit complicated is in the `stop()` method. There, we not only want to stop playback, but also set up the `MediaPlayer` to be able to play back from the beginning of the clip:

```
private void stop() {  
    mp.stop();  
    pause.setVisible(false);  
    stop.setVisible(false);  
}
```

## AUDIO PLAYBACK

---

```
findViewById(android.R.id.content).postDelayed(new Runnable() {
    @Override
    public void run() {
        try {
            mp.prepare();
            mp.seekTo(0);
            play.setVisible(true);
        }
        catch (Exception e) {
            goBlooney(e);
        }
    }
}, 100);
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

Stopping the playback is merely a matter of calling `stop()` on the `MediaPlayer`. After that, we hide all the action bar items.

To reset the `MediaPlayer` to play the clip again, you need to re-prepare the player, via `prepare()` or `prepareAsync()`. You also need to call `seekTo(0)`. `seekTo()` positions playback at a certain number of milliseconds from the beginning of the audio, so `seekTo(0)` repositions the player back to the beginning.

However, if we try doing this work right away, we get odd results, owing to the asynchronous nature of the media playback. We need to let the `stop()` complete its work before we `prepare()` and `seekTo()`. Unfortunately, there is no listener interface for the stop-completed event. So, we fake it, delaying the “rewind” of the clip by 100 milliseconds.

Also, once the `MediaPlayer` is ready again, we enable the play action bar item, allowing playback to commence from start, if the user wants.

Finally, in `onDestroy()`, we `stop()` the `MediaPlayer` if it returns `true` from `isPlaying()`, so the playback does not continue after the activity is destroyed:

```
@Override
public void onDestroy() {
    super.onDestroy();

    if (mp.isPlaying()) {
        mp.stop();
    }
}
```

```
}
```

(from [Media/Audio/app/src/main/java/com/commonsware/android/audio/MainActivity.java](#))

## Other Ways to Make Noise

While `MediaPlayer` is the primary audio playback option, particularly for content along the lines of MP3 files, there are other alternatives if you are looking to build other sorts of applications, notably games and custom forms of streaming audio.

### SoundPool

The `SoundPool` class's claim to fame is the ability to overlay multiple sounds, and do so in a prioritized fashion, so your application can just ask for sounds to be played and `SoundPool` deals with each sound starting, stopping, and blending while playing.

This may make more sense with an example.

Suppose you are creating a first-person shooter. Such a game may have several sounds going on at any one time:

1. The sound of the wind whistling amongst the trees on the battlefield
2. The sound of the surf crashing against the beach in the landing zone
3. The sound of booted feet crunching on the sand
4. The sound of the character's own panting as the character runs on the beach
5. The sound of orders being barked by a sergeant positioned behind the character
6. The sound of machine gun fire aimed at the character and the character's squad mates
7. The sound of explosions from the gun batteries of the battleship providing suppression fire

And so on.

In principle, `SoundPool` can blend all of those together into a single audio stream for output. Your game might set up the wind and surf as constant background sounds, toggle the feet and panting on and off based on the character's movement, randomly add the barked orders, and tie the gunfire based on actual game play.

In reality, your average smartphone will lack the CPU power to handle all of that audio without harming the frame rate of the game. So, to keep the frame rate up,

you tell `SoundPool` to play at most two streams at once. This means that when nothing else is happening in the game, you will hear the wind and surf, but during the actual battle, those sounds get dropped out — the user might never even miss them — so the game speed remains good.

### AudioTrack

The lowest-level Java API for playing back audio is `AudioTrack`. It has two main roles:

1. Its primary role is to support streaming audio, where the streams come in some format other than what `MediaPlayer` handles. While `MediaPlayer` can handle RTSP, for example, it does not offer SIP. If you want to create a SIP client (perhaps for a VOIP or Web conferencing application), you will need to convert the incoming data stream to PCM format, then hand the stream off to an `AudioTrack` instance for playback.
2. It can also be used for “static” (versus streamed) bits of sound that you have pre-decoded to PCM format and want to play back with as little latency as possible. For example, you might use this for a game for in-game sounds (beeps, bullets, or “boing”s). By pre-decoding the data to PCM and caching that result, then using `AudioTrack` for playback, you will use the least amount of overhead, minimizing CPU impact on game play and on battery life.

### ToneGenerator

If you want your phone to sound like... well... a phone, you can use `ToneGenerator` to have it play back [dual-tone multi-frequency](#) (DTMF) tones. In other words, you can simulate the sounds played by a regular “touch-tone” phone in response to button presses. This is used by the Android dialer, for example, to play back the tones when users dial the phone using the on-screen keypad, as an audio reinforcement.

Note that these will play through the phone’s earpiece, speaker, or attached headset. They do not play through the outbound call stream. In principle, you might be able to get `ToneGenerator` to play tones through the speaker loud enough to be picked up by the microphone, but this probably is not a recommended practice.

You can create a `ToneGenerator` through its constructor. This takes two parameters:

- the audio stream associated with this audio
- the volume level to apply to the audio

## AUDIO PLAYBACK

---

```
final private ToneGenerator beeper=  
    new ToneGenerator(AudioManager.STREAM_NOTIFICATION, 100);
```

The stream indication helps with muting; if the user has muted this particular stream, then `ToneGenerator` will wind up not generating a tone.

Then, when you need a beep, you can call `startTone()`, with the identifier of one of the many DTMF tones listed on the `ToneGenerator` class:

```
beeper.startTone(ToneGenerator.TONE_PROP_NACK);
```

Many of the tones have a fixed duration. In that case, `startTone()` will play that tone to completion, or until you call `stopTone()` to interrupt it.

Some tones will repeat indefinitely. There is a second `startTone()` variant that takes a duration in milliseconds that you can use to automatically stop the tone after a particular period of time. Or, you can use `stopTone()` to stop the one.

# Audio Recording

---

Most Android devices have microphones. On such devices, it might be nice to get audio input from those microphones, whether to record locally, process locally (e.g., speech recognition), or to stream out over the Internet (e.g., voice over IP).

Not surprisingly, Android has some capabilities in this area. Also, not surprisingly, there are multiple APIs, with varying mixes of power and complexity, to allow you to capture microphone input. In this chapter, we will examine `MediaRecorder` for recording audio files and `AudioRecord` for raw microphone input.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on [audio playback](#) is probably also a good idea. And, for the section on playing back local streams, you will want to have read up on content providers, particularly [the chapter on provider patterns](#).

## Recording by Intent

Just as the easiest way to take a picture with the camera is [to use the device's built-in camera app](#), the easiest way to record some audio is to use a built-in activity for it. And, as with using the built-in camera app, the built-in audio recording activity has some significant limitations.

Requesting the built-in audio recording activity is a matter of calling `startActivityForResult()` for a `MediaStore.Audio.Media.RECORD_SOUND_ACTION` action. You can see this in the [Media/SoundRecordIntent](#) sample project, specifically the `MainActivity`:

## AUDIO RECORDING

---

```
package com.commonware.android.soundrecord;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.provider.MediaStore;
import android.widget.Toast;

public class MainActivity extends Activity {
    private static final int REQUEST_ID=1337;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        Intent i=new Intent(MediaStore.Audio.Media.RECORD_SOUND_ACTION);

        startActivityForResult(i, REQUEST_ID);
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode,
        Intent data) {
        if (requestCode == REQUEST_ID && resultCode == RESULT_OK) {
            Toast.makeText(this, "Recording finished!", Toast.LENGTH_LONG)
                .show();
        }

        finish();
    }
}
```

(from [Media/SoundRecordIntent/app/src/main/java/com/commonware/android/soundrecord/MainActivity.java](#))

## AUDIO RECORDING

---

As with a few other sample apps in this book, the `Media/SoundRecordIntent` uses a `Theme.Translucent.NoTitleBar` activity, [avoiding its own UI](#). Instead, in `onCreate()`, we immediately call `startActivityForResult()` for `MediaStore.Audio.Media.RECORD_SOUND_ACTION`. That will bring up a recording activity:

If the user records some audio via the “record” `ImageButton` (one with the circle icon) and the “stop” `ImageButton` (one with the square icon), you will get control back in `onActivityResult()`, where you are passed an `Intent` whose `Uri` (via `getData()`) will point to this audio recording in the `MediaStore`.

However:

- You have no control over where the file is stored or what it is named. It appears that, by default, these files are dumped unceremoniously in the root of external storage.
- You have no control over anything about the way the audio is recorded, such as codecs or bitrates. For example, it appears that, by default, the files are recorded in AMR format.
- `ACTION_VIEW` may not be able to play back this audio (leastways, it failed to

in testing on a few devices). Whether that is due to codecs, the way the data is put in `MediaStore`, or the limits of the default audio player on Android, is unclear.

Hence, in many cases, while this works, it may not work well enough — or controlled enough — to meet your needs. In that case, you will want to handle the recording yourself, as will be described in the next couple of sections.

## Recording to Files

If your objective is to record a voice note, a presentation, or something along those lines, then `MediaRecorder` is probably the class that you want. It will let you specify what sort of media you wish to record, in what format, and to what location. It then handles the actual act of recording.

To illustrate this, let us review the [Media/AudioRecording](#) sample project.

Our activity's layout consists of a single `ToggleButton` widget named `record`:

```
<ToggleButton xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:id="@+id/record"
  android:layout_width="match_parent"
  android:layout_height="match_parent"
  android:textAppearance="?android:attr/textAppearanceLarge"/>
```

(from [Media/AudioRecording/app/src/main/res/layout/activity\\_main.xml](#))

Our project is set up to record the output to the `Environment.DIRECTORY_DOWNLOADS` location on external storage. And, if we have a `targetSdkVersion` of 23 or higher (which we do), we need runtime permissions. We also need runtime permissions for `RECORD_AUDIO`, since, well, we are recording audio. So our manifest requests both of those permissions:

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.audiorecord"
  android:versionCode="1"
  android:versionName="1.0">

  <supports-screens
    android:largeScreens="true"
    android:normalScreens="true"
    android:smallScreens="true"/>
```

## AUDIO RECORDING

---

```
<uses-permission android:name="android.permission.RECORD_AUDIO"/>
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>

<uses-feature
    android:name="android.hardware.microphone"
    android:required="true"/>

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
        android:name=".MainActivity"
        android:label="@string/title_activity_main">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>
</manifest>
```

(from [Media/AudioRecording/app/src/main/AndroidManifest.xml](#))

And, following in the pattern demonstrated in [the chapter on permissions](#), we use `AbstractPermissionsActivity` to handle all the details of obtaining our runtime. Our launcher activity — `MainActivity` — inherits from `AbstractPermissionsActivity`, which requests our permissions when the app starts up. `MainActivity` simply overrides the necessary methods. Two of these, `getDesiredPermissions()` and `onPermissionDenied()`, are specifically for the permission logic:

```
@Override
protected String[] getDesiredPermissions() {
    return(new String[]{RECORD_AUDIO, WRITE_EXTERNAL_STORAGE});
}

@Override
protected void onPermissionDenied() {
    Toast
        .makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG)
        .show();
    finish();
}
```

## AUDIO RECORDING

---

(from [Media/AudioRecording/app/src/main/java/com/commonsware/android/audiorecord/MainActivity.java](#))

`onReady()` serves as our `onCreate()` replacement, and it will be invoked when we have our runtime permissions. There, we load the layout and set the activity itself up as the `OnCheckedChangeListener`, to find out when the user toggles the button:

```
@Override
public void onReady(Bundle savedInstanceState) {
    setContentView(R.layout.activity_main);

    ((ToggleButton)findViewById(R.id.record)).setOnCheckedChangeListener(this);
}
```

(from [Media/AudioRecording/app/src/main/java/com/commonsware/android/audiorecord/MainActivity.java](#))

Also, in `onStart()`, we initialize a `MediaRecorder`, setting the activity up as being the one to handle info and error events about the recording. Similarly, we `release()` the `MediaRecorder` in `onStop()`, to reduce our overhead when we are not in the foreground:

```
@Override
public void onStart() {
    super.onStart();

    recorder=new MediaRecorder();
    recorder.setOnErrorListener(this);
    recorder.setOnInfoListener(this);
}

@Override
public void onStop() {
    recorder.release();
    recorder=null;

    super.onStop();
}
```

(from [Media/AudioRecording/app/src/main/java/com/commonsware/android/audiorecord/MainActivity.java](#))

Most of the work occurs in `onCheckedChanged()`, where we get control when the user toggles the button. If we are now checked, we begin recording; if not, we stop the previous recording:

```
@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {
    if (isChecked) {
```

## AUDIO RECORDING

---

```
output=
    new File(Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS),
        BASENAME);

recorder.setAudioSource(MediaRecorder.AudioSource.MIC);
recorder.setOutputFormat(MediaRecorder.OutputFormat.THREE_GPP);
recorder.setOutputFile(output.getAbsolutePath());

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD_MR1) {
    recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AAC);
    recorder.setAudioEncodingBitRate(160 * 1024);
}
else {
    recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AMR_NB);
}

recorder.setAudioChannels(2);

try {
    recorder.prepare();
    recorder.start();
}
catch (Exception e) {
    Log.e(getClass().getSimpleName(),
        "Exception in preparing recorder", e);
    Toast.makeText(this, e.getMessage(), Toast.LENGTH_LONG).show();
}
}
else {
    try {
        recorder.stop();

        MediaScannerConnection
            .scanFile(this, new String[] {output.getAbsolutePath()}, null, null);
    }
    catch (Exception e) {
        Log.w(getClass().getSimpleName(),
            "Exception in stopping recorder", e);
        // can fail if start() failed for some reason
    }
}

recorder.reset();
}
}
```

(from [Media/AudioRecording/app/src/main/java/com/commonsware/android/audiorecord/MainActivity.java](#))

To record audio, we:

- Create a File object representing where the recording should be stored, in this case using Environment.getExternalStoragePublicDirectory() to find a location on external storage
- Tell the MediaRecorder that we wish to record from the microphone, through a call to setAudioSource(), that we wish to record a 3GP file via a call to setOutputFormat(), and that we wish to record the results to our

## AUDIO RECORDING

---

- File via a call to `setOutputFile()`
- If we are running on Android 2.3.3 or higher, we can also configure our encoder to be AAC via `setAudioEncoder()` and set our requested bitrate to 160Kbps via `setAudioEncodingBitRate()` — otherwise, we use `setAudioEncoder()` to request AMR narrowband
- Indicate how many audio channels we want via `setAudioChannels()`, such as 2 to attempt to record in stereo
- Kick off the actual recording via calls to `prepare()` (to set up the output file) and `record()`

Stopping the recording, when the user toggles off the button, is merely a matter of calling `stop()` on the `MediaRecorder`, then using `MediaScannerConnection` to get the resulting file indexed by the `MediaStore`, so it shows up for desktop users, media apps, etc.

Because we told the `MediaRecorder` that our activity was our `OnErrorListener` and `OnInfoListener`, we have to implement those interfaces on the activity and implement their required methods (`onError()` and `onInfo()`, respectively). In the normal course of events, neither of these should be triggered. If they are, we are passed an `int` value (typically named `what`) that indicates what happened:

```
@Override
public void onInfo(MediaRecorder mr, int what, int extra) {
    String msg=getString(R.string.strange);

    switch (what) {
        case MediaRecorder.MEDIA_RECORDER_INFO_MAX_DURATION_REACHED:
            msg=getString(R.string.max_duration);
            break;

        case MediaRecorder.MEDIA_RECORDER_INFO_MAX_FILESIZE_REACHED:
            msg=getString(R.string.max_size);
            break;
    }

    Toast.makeText(this, msg, Toast.LENGTH_LONG).show();
}

@Override
public void onError(MediaRecorder mr, int what, int extra) {
    Toast.makeText(this, R.string.strange, Toast.LENGTH_LONG).show();
}
```

(from [Media/AudioRecording/app/src/main/java/com/commonsware/android/audiorecord/MainActivity.java](#))

Here, we just raise a `Toast` in either case, with either a generic message or a specific message for the cases where the maximum time duration or the maximum file size for our recording has been reached.

The results are that we get a recording on external storage (typically in a `Downloads` directory) after we toggle the button on, record some audio, then toggle the button off.

`MediaRecorder` is rather fussy about the order of method calls for its configuration. For example, you must call `setAudioEncoder()` *after* the call to `setOutputFormat()`.

Also, the available codecs and file types are rather limited. Notably, Android lacks the ability to record to MP3 format, perhaps due to patent licensing issues.

## Recording to Streams

The nice thing about recording to files is that Android handles all of the actual file I/O for us. The downside is that because Android handles all of the actual file I/O for us, it can only write files that are accessible to it and our process, meaning external storage. This may not be suitable in all cases, such as wanting to record to some form of private encrypted storage.

The good news is that Android does support recording to streams, in the form of a pipe created by `ParcelFileDescriptor` and `createPipe()`. This follows the same basic pattern that we saw in [the chapter on content provider patterns](#), where we [served a stream via a pipe](#). However, as you will see, there are some limits on how well we can do this.

To demonstrate and explain, let us examine the [Media/AudioRecordStream](#) sample project. This is nearly a complete clone of the previous sample, so we will only focus on the changes in this section.

The author would like to thank Lucio Maciel for his assistance in [getting this example to work](#).

## Setting Up the Stream

The biggest change, by far, is in our `setOutputFile()` call. Before, we supplied a path to external storage. Now, we supply the write end of a pipe:

## AUDIO RECORDING

---

```
recorder.setOutputFile(getStreamFd());
```

(from [Media/AudioRecordStream/app/src/main/java/com/commonsware/android/audiorecstream/MainActivity.java](#))

Our `getStreamFd()` method looks a lot like the `openFile()` method of our pipe-providing provider:

```
private FileDescriptor getStreamFd() {
    ParcelFileDescriptor[] pipe=null;

    try {
        pipe=ParcelFileDescriptor.createPipe();

        new TransferThread(new AutoCloseInputStream(pipe[0]),
            new FileOutputStream(getOutputFile())).start();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);
    }

    return(pipe[1].getFileDescriptor());
}
```

(from [Media/AudioRecordStream/app/src/main/java/com/commonsware/android/audiorecstream/MainActivity.java](#))

We create our pipe with `createPipe()`, spawn a `TransferThread` to copy the recording from an `InputStream` to a `FileOutputStream`, and return the write end of the pipe. However, `setOutputFile()` on `MediaRecorder` takes the actual integer file descriptor, not a `ParcelFileDescriptor`, so we use `getFileDescriptor()` to retrieve the file descriptor and return that.

Our `TransferThread` is similar to the one from the content provider sample, except that we pass over a `FileOutputStream`, so we can not only `flush()` but also `sync()` when we are done writing:

```
static class TransferThread extends Thread {
    InputStream in;
    FileOutputStream out;

    TransferThread(InputStream in, FileOutputStream out) {
        this.in=in;
        this.out=out;
    }

    @Override
    public void run() {
```

```
byte[] buf=new byte[8192];
int len;

try {
    while ((len=in.read(buf)) >= 0) {
        out.write(buf, 0, len);
    }

    in.close();

    out.flush();
    out.getFD().sync();
    out.close();
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(),
        "Exception transferring file", e);
}
}
```

(from [Media/AudioRecordStream/app/src/main/java/com/commonsware/android/audiorecstream/MainActivity.java](#))

### Changes in Recording Configuration

The biggest limitation of a pipe's stream is that it is *purely* a stream. You cannot rewind re-read earlier bits of data. In other words, the stream is not seekable.

That is a problem with `MediaRecorder` in some configurations. For example, a 3GP file contains a header with information about the overall file, information that `MediaRecorder` does not know until the recording is complete. In the case of a file, `MediaRecorder` can simply rewind and update the header with the final data when everything is done. However, that is not possible with a pipe-based stream.

However, some configurations will work, notably “raw” ones that just have the recorded audio, with no type of header. That is what we use in this sample.

Specifically, we now write to a `.amr` file:

```
private static final String BASENAME="recording-stream.amr";
```

(from [Media/AudioRecordStream/app/src/main/java/com/commonsware/android/audiorecstream/MainActivity.java](#))

We also set our output format to `RAW_AMR`, and our encoder to `AMR_NB`:

---

## AUDIO RECORDING

---

```
recorder.setAudioSource(MediaRecorder.AudioSource.MIC);
recorder.setOutputFormat(MediaRecorder.OutputFormat.RAW_AMR);
recorder.setOutputFile(getStreamFd());
recorder.setAudioEncoder(MediaRecorder.AudioEncoder.AMR_NB);
recorder.setAudioChannels(2);
```

(from [Media/AudioRecordStream/app/src/main/java/com/commonsware/android/audiorecstream/MainActivity.java](#))

This combination works. Other combinations might also work. But our approach of writing the 3GP file, as in the file-based example, will not work.

## Raw Audio Input

Just as `AudioTrack` allows you to play audio supplied as raw 8- or 16-bit PCM input, `AudioRecord` allows you to record audio from the microphone, supplied to you in PCM format. It is then up to you to actually do something with the raw byte PCM data, including converting it to some other format and container as needed.

Note that you need the `RECORD_AUDIO` permission to work with `AudioRecord`, just as you need it to work with `MediaRecorder`.

## Requesting the Microphone

As noted in the opening paragraph of this chapter, most Android devices have microphones. The key word there is *most*. Not all Android devices will have microphones, as only some tablets (and fewer Android TV devices) will support microphone input.

As with most of this optional hardware, the solution is to use `<uses-feature>`. In that case, you would request the `android.hardware.microphone` feature, with `android:required="false"` if you felt that you do not absolutely *need* a microphone. In that case, you would use `hasSystemFeature()` on `PackageManager` to determine at runtime if you do indeed have a microphone.

Note that the `RECORD_AUDIO` permission implies that you need a microphone. Hence, even if you skip the `<uses-feature>` element, your app will still only ship to devices that have a microphone. If the microphone is optional, be sure to include `android:required="false"`, so your app will be available to devices that lack a microphone.

# Video Playback

---

Just as Android supports audio playback, it also supports video playback of local and streaming content. Unlike audio playback – which supports a mix of high-level and low-level APIs – video playback offers a purely high-level interface, in the form of the same `MediaPlayer` class you used for audio playback. To keep things a bit simpler, though, Android does offer a `VideoView` widget you can drop in an activity or fragment to play back video.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, along with [the chapter on audio playback](#).

## Moving Pictures

Video clips get their own widget, the `VideoView`. Put it in a layout, feed it an MP4 video clip, and you get playback!

For example, take a look at this layout, from the [Media/Video](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <VideoView
        android:id="@+id/video"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
    >
```

## VIDEO PLAYBACK

---

```
 />  
</LinearLayout>
```

(from [Media/Video/app/src/main/res/layout/main.xml](#))

The layout is simply a full-screen video player. Whether it will use the full screen will be dependent on the video clip, its aspect ratio, and whether you have the device (or emulator) in portrait or landscape mode.

Wiring up the Java is almost as simple:

```
package com.commonware.android.video;  
  
import java.io.File;  
import android.Manifest;  
import android.app.Activity;  
import android.graphics.PixelFormat;  
import android.os.Bundle;  
import android.os.Environment;  
import android.widget.MediaController;  
import android.widget.Toast;  
import android.widget.VideoView;  
  
public class VideoDemo extends AbstractPermissionActivity {  
    private VideoView video;  
    private MediaController ctrlr;  
  
    @Override  
    protected String[] getDesiredPermissions() {  
        return(new String[] {Manifest.permission.WRITE_EXTERNAL_STORAGE});  
    }  
  
    @Override  
    protected void onPermissionDenied() {  
        Toast  
            .makeText(this, R.string.msg_sorry, Toast.LENGTH_LONG)  
            .show();  
        finish();  
    }  
  
    @Override  
    public void onReady(Bundle state) {  
        getWindow().setFormat(PixelFormat.TRANSLUCENT);  
        setContentView(R.layout.main);  
  
        File clip=new File(Environment.getExternalStorageDirectory(),  
            "test.mp4");
```

## VIDEO PLAYBACK

---

```
if (clip.exists()) {
    video=(VideoView)findViewById(R.id.video);
    video.setVideoPath(clip.getAbsolutePath());

    ctrl=new MediaController(this);
    ctrl.setMediaPlayer(video);
    video.setMediaController(ctrl);
    video.requestFocus();
    video.start();
}
}
```

(from [Media/Video/app/src/main/java/com/commonsware/android/video/VideoDemo.java](#))

We use the `AbstractPermissionActivity` profiled [earlier in the book](#), as we need `READ_EXTERNAL_STORAGE` rights to be able to read a test .mp4 video from the root of external storage.

Beyond that, we:

1. Confirm that our video file exists on external storage
2. Tell the `VideoView` which file to play
3. Create a `MediaController` pop-up panel and cross-connect it to the `VideoView`
4. Give the `VideoView` the focus and start playback

The biggest trick with `VideoView` is getting a video clip onto the device. While `VideoView` does support some streaming video, the requirements on the MP4 file are fairly stringent. If you want to be able to play a wider array of video clips, you need to have them on the device, preferably on an SD card.

## VIDEO PLAYBACK

---

The crude `VideoDemo` class assumes there is an MP4 file named `test.mp4` in the root of external storage on your device or emulator. Once there, the Java code shown above will give you a working video player:

*Figure 783: VideoDemo, Showing a Creative Commons-Licensed Video*

## VIDEO PLAYBACK

---

Tapping on the video will pop up the playback controls:

*Figure 784: VideoDemo, Showing Media Controls*

The video will scale based on space as well:

# **Using the Camera via 3rd-Party Apps**

Most Android devices will have a camera, since they are fairly commonplace on mobile devices these days. You, as an Android developer, can take advantage of the camera, for everything from snapping tourist photos to scanning barcodes. If you wish to let other apps do the “heavy lifting” for you, working with the camera can be fairly straightforward. If you want more control, you can work with the camera directly, though this control comes with greater complexity.

You can also record videos using the camera. Once again, you have the option of either using a third-party activity, or doing it yourself.

## **Prerequisites**

Understanding this chapter requires that you have read the core chapters, particularly the material on [implicit Intents](#). You also need to read the chapters on the ContentProvider component, particularly [the coverage of FileProvider](#).

## **Being Specific About Features**

If your app needs a camera — by any of the means cited in this chapter – you should include a `<uses-feature>` element in the manifest indicating your requirements. However, you need to be fairly specific about your requirements here.

For example, the Nexus 7 (2012) has a camera... but only a front-facing camera. This facilitates apps like video chat. However, the `android.hardware.camera` implies that you need a high-resolution rear-facing camera. Hence, to work with the Nexus 7’s camera, you need to:

## USING THE CAMERA VIA 3RD-PARTY APPS

---

- Require the CAMERA permission (if you are using the Camera directly)
- Not require the android.hardware.camera feature (android:required="false")
- Optionally require the android.hardware.camera.front feature (if your app definitely needs a front-facing camera)

At runtime, you would use `hasSystemFeature()` on `PackageManager`, or interrogate the `Camera` class for available cameras, to determine what you have access to.

Note that if you want to record audio when recording videos, you should also consider the `android.hardware.microphone` feature.

## Still Photos: Letting the Camera App Do It

The easiest way to take a picture is to not take the picture yourself, but let somebody else do it. The most common implementation of this approach is to use an `ACTION_IMAGE_CAPTURE` Intent to bring up the user's default camera application, and let it take a picture on your behalf.

In theory, this is fairly simple:

- You call `startActivityForResult()` on an `ACTION_IMAGE_CAPTURE` Intent
- You either get a thumbnail photo back or — if you provided `EXTRA_OUTPUT` as an extra on the `ACTION_IMAGE_CAPTURE` Intent — a full-sized photo should be written to where you designated in `EXTRA_OUTPUT`

In practice, this gets complicated, in part because Android 7.0 is trying to get rid of file schemes on `Uri` values. As a result, `EXTRA_OUTPUT` cannot point to a file. Instead, it has to point to a `ContentProvider`, such as `FileProvider`.

To see this in use, take a look at the [Camera/FileProvider](#) sample project. This app will use system-supplied activities to take a picture, then view the result, without actually implementing any of its own UI.

## Setting the Theme

Of course, we still need an activity, so our code can be launched by the user. We just set it up with `Theme.Translucent.NoTitleBar`, so [no UI will be created for it](#):

```
<activity
    android:name=".MainActivity"
```

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
android:label="@string/app_name"
android:theme="@android:style/Theme.Translucent.NoTitleBar">
<intent-filter>
  <action android:name="android.intent.action.MAIN" />

  <category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
</activity>
```

(from [Camera/FileProvider/app/src/main/AndroidManifest.xml](#))

### Requesting the Feature

Since our app is useless without a camera, we have the `<uses-feature>` element in the manifest stating that we need some sort of camera:

```
<uses-feature android:name="android.hardware.camera.any" />
```

(from [Camera/FileProvider/app/src/main/AndroidManifest.xml](#))

This will prevent our app from being installed on a device that lacks a camera.

### Adding the FileProvider

As noted earlier, Android 7.0 has a ban on `file: Uri` values, if your `targetSdkVersion` is 24 or higher. In particular, you cannot use a `file: Uri` in an Intent, whether as the “data” aspect of the Intent or as the value of an extra.

The proper way to implement this is to use a ContentProvider, such as a FileProvider, as is covered in [one of the chapters on providers](#). This is a fair bit more complicated, and not all camera apps will work well with a `content: Uri`, but our options are limited.

Our `res/xml/provider_paths.xml` metadata for the FileProvider indicate that we want to serve up the contents of the `photos/` directory inside of `getFilesDir()`, with a `Uri` segment of `/p/` mapping to that location:

```
<?xml version="1.0" encoding="utf-8"?>
<paths>
  <files-path
    name="p"
    path="photos" />
</paths>
```

(from [Camera/FileProvider/app/src/main/res/xml/provider\\_paths.xml](#))

## USING THE CAMERA VIA 3RD-PARTY APPS

---

Our manifest now has a <provider> element for our FileProvider subclass, named LegacyCompatFileProvider:

```
<provider
  android:name="LegacyCompatFileProvider"
  android:authorities="${applicationId}.provider"
  android:exported="false"
  android:grantUriPermissions="true">
  <meta-data
    android:name="android.support.FILE_PROVIDER_PATHS"
    android:resource="@xml/provider_paths" />
</provider>
```

(from [Camera/FileProvider/app/src/main/AndroidManifest.xml](#))

That element:

- Provides a pointer to that metadata resource, to configure FileProvider
- Uses the applicationId of this app as the basis of our authorities value, using a [manifest placeholder](#)
- Blocks access to third parties (android:exported="false") except where we explicitly grant permission in our Java code (android:grantUriPermissions="true")

LegacyCompatFileProvider is the same implementation as from [the original discussion of FileProvider](#), using LegacyCompatCursorWrapper to help increase the odds that clients of this ContentProvider will behave properly:

```
package com.commonware.android.camcon;

import android.database.Cursor;
import android.net.Uri;
import android.support.v4.content.FileProvider;
import com.commonware.cwac.provider.LegacyCompatCursorWrapper;

public class LegacyCompatFileProvider extends FileProvider {
    @Override
    public Cursor query(Uri uri, String[] projection, String selection, String[] selectionArgs, String sortOrder) {
        return(new LegacyCompatCursorWrapper(super.query(uri, projection, selection, selectionArgs, sortOrder)));
    }
}
```

(from [Camera/FileProvider/app/src/main/java/com/commonware/android/camcon/LegacyCompatFileProvider.java](#))

Now we can start the work of taking pictures.

### Taking a Picture

At this point, we can start using the provider, to give us a Uri that we can use with EXTRA\_OUTPUT and an ACTION\_IMAGE\_CAPTURE Intent.

Our onCreate() method spends a lot of lines to eventually make that startActivityForResult() call:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (savedInstanceState==null) {
        output=new File(new File(getFilesDir(), PHOTOS), FILENAME);

        if (output.exists()) {
            output.delete();
        }
        else {
            output.getParentFile().mkdirs();
        }

        Intent i=new Intent(MediaStore.ACTION_IMAGE_CAPTURE);
        Uri outputUri=FileProvider.getUriForFile(this, AUTHORITY, output);

        i.putExtra(MediaStore.EXTRA_OUTPUT, outputUri);

        if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
            i.addFlags(Intent.FLAG_GRANT_WRITE_URI_PERMISSION);
        }
        else if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.JELLY_BEAN) {
            ClipData clip=
                ClipData.newUri(getContentResolver(), "A photo", outputUri);

            i.setClipData(clip);
            i.addFlags(Intent.FLAG_GRANT_WRITE_URI_PERMISSION);
        }
        else {
            List<ResolveInfo> resInfoList=
                getPackageManager()
                    .queryIntentActivities(i, PackageManager.MATCH_DEFAULT_ONLY);

            for (ResolveInfo resolveInfo : resInfoList) {
                String packageName = resolveInfo.activityInfo.packageName;
                grantUriPermission(packageName, outputUri,
                    Intent.FLAG_GRANT_WRITE_URI_PERMISSION);
            }
        }
    }
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
    }  
  }  
  
  try {  
    startActivityForResult(i, CONTENT_REQUEST);  
  }  
  catch (ActivityNotFoundException e) {  
    Toast.makeText(this, R.string.msg_no_camera, Toast.LENGTH_LONG).show();  
    finish();  
  }  
}  
else {  
  output=(File)savedInstanceState.getSerializable(EXTRA_FILENAME);  
}  
}
```

(from [Camera/FileProvider/app/src/main/java/com/commonsware/android/camcon/MainActivity.java](#))

When we are first run, our `savedInstanceState Bundle` will be `null`. If it is not `null`, we know that we are coming back from some prior invocation of this activity, and so we do not need to call `startActivityForResult()` to take a picture.

First, we need a `File` pointing to where we want the photo to be stored. We create a directory inside of `getFilesDir()` (named `photos` via the `PHOTOS` constant), and in there identify a file (named `CameraContentDemo.jpeg` via the `FILENAME` constant).

Then, we create the `ACTION_IMAGE_CAPTURE` Intent, use `FileProvider.getUriForFile()` to get a `Uri` pointing to our desired `File`, then put that `Uri` in the `EXTRA_OUTPUT` extra of the Intent.

Now, though, we have to grant permissions to be able to write to that `Uri`.

If we are on Android 5.0+, calling `addFlags(FLAG_GRANT_WRITE_URI_PERMISSION)` not only affects the “data” aspect of the Intent, but also `EXTRA_OUTPUT`, due to a bit of a hack that Google added to the Intent class. So, that scenario is simple. The problem comes in with Android 4.4 and older devices, where `addFlags(FLAG_GRANT_WRITE_URI_PERMISSION)` does not affect `Uri` values passed in extras.

For Android 4.2 through 4.4, we can use a trick: while flags skip over Intent extras, flags *do* apply to a `ClipData` that you attach to the Intent via `setClipData()`. Even though the camera app will never use this `ClipData`, by wrapping our `Uri` in a `ClipData` and attaching that to the Intent, our `addFlags(FLAG_GRANT_WRITE_URI_PERMISSION)` will affect that `Uri`. The fact that the

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

camera app gets the `Uri` from `EXTRA_OUTPUT`, instead of from the `ClipData`, makes no difference.

For Android 4.1 and older devices, though, there is no means for us to simply indicate on the `Intent` itself that it is fine for the app handling our request to write to our `Uri`. Instead, we:

- Find all activities that support `ACTION_IMAGE_CAPTURE`, using `PackageManager` and `queryIntentActivities()`
- Iterate over all of them and call `grantUriPermission()`, inherited from `Context`, to allow the app to read and write from our `Uri`

This allows our `Intent` to succeed for any camera app... at least those that properly handle content: `Uri` values.

Finally, after all of that, we can call `startActivityForResult()`. However, in case the user does not have a camera app, we wrap that call in a `try/catch` block, watching for an `ActivityNotFoundException`.

### Saving the State

In order to be able to save the `File` across configuration changes, we stuff it in the saved instance state `Bundle` in `onSaveInstanceState()`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putSerializable(EXTRA_FILENAME, output);
}
```

(from [Camera/FileProvider/app/src/main/java/com/commonsware/android/camcon/MainActivity.java](#))

This is what allows us to pull that value back out in `onReady()`.

### Viewing the Photo

Our `onActivityResult()` method then uses the same `File`, creating an `ACTION_VIEW` `Intent`, pointing at our output `Uri`, granting read permission on that `Uri`, indicating the MIME type is `image/jpeg`, and starting up an activity for that.

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
```

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
        Intent data) {
    if (requestCode == CONTENT_REQUEST) {
        if (resultCode == RESULT_OK) {
            Intent i=new Intent(Intent.ACTION_VIEW);
            Uri outputUri=FileProvider.getUriForFile(this, AUTHORITY, output);

            i.setDataAndType(outputUri, "image/jpeg");
            i.addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

            try {
                startActivity(i);
            }
            catch (ActivityNotFoundException e) {
                Toast.makeText(this, R.string.msg_no_viewer, Toast.LENGTH_LONG).show();
            }

            finish();
        }
    }
}
```

(from [Camera/FileProvider/app/src/main/java/com/commonsware/android/camcon/MainActivity.java](#))

We do not have to fuss with the `grantUriPermissions()` loop, as `addFlags()` has always granted permission to the “data” aspect of the Intent (our Uri).

We wrap the `startActivity()` call in another try/catch block, watching for `ActivityNotFoundException`. Not all devices will have an image viewing app that supports a content Uri. For example, stock Android 5.1 (e.g., on a Nexus 4) will not have such an image viewer.

### The Caveats

There are several downsides to this approach.

First, you have no control over the camera app itself. You do not even really know what app it is. You cannot dictate certain features that you would like (e.g., resolution, color effects). You simply blindly ask for a photo and get the result.

Also, since you do not know what the camera app is or behaves like, you cannot document that portion of your application’s flow very well. You can say things like “at this point, you can take a picture using your chosen camera app”, but that is about as specific as you can get.

As noted above, it is possible that your app’s process will be terminated while your app is not in the foreground, because the user is taking a picture using the third-party camera app. Whether or not this happens depends on how much system RAM the camera app uses and what else is all going on with the device. But, it does

happen. Your app should be able to cope with such things, just as we are doing with the saved instance state `Bundle`. However, many developers do not expect their process to be replaced between a call to `startActivityForResult()` and the corresponding `onActivityResult()` callback.

Not every camera app will support a content `Uri` for the `EXTRA_OUTPUT` value. In fact, Google's own camera app did not do this until the summer of 2016. With `ACTION_VIEW`, since the content `Uri` is in the "data" facet of the `Intent`, the `<intent-filter>` elements in the manifest will ensure that our `Intent` only goes to an activity that advertises support for content. However, there is no equivalent of this for `Uri` values in extras. And so we will launch the camera app, which then may crash because it does not like our `Uri`, and our app does not really find out about the problem, other than not getting `RESULT_OK` in `onActivityResult()`.

Finally, some camera apps misbehave, returning odd results, such as a thumbnail-sized image rather than a max-resolution image. There is little you can do about this.

## Permissions and Third-Party Camera Apps

The sample app shown above does not request any permissions — there are no `<uses-permission>` elements in the manifest. While there is a `CAMERA` permission to use the camera, we do not need it. The camera app that we are starting needs it.

However, you might need the `CAMERA` permission elsewhere in your app. For example, you might be embedding some third-party scanning library, where it will use the camera directly in your app.

In this case, on Android 6.0+, for apps with a `targetSdkVersion` of 23 or higher, even though `ACTION_IMAGE_CAPTURE` itself does not normally need the `CAMERA` permission, you cannot use `ACTION_IMAGE_CAPTURE` if the user has not granted the `CAMERA` permission at runtime.

In other words:

## USING THE CAMERA VIA 3RD-PARTY APPS

---

If you do this...	...can you use ACTION_IMAGE_CAPTURE?
If you do not request the CAMERA permission	Yes
If you request the CAMERA permission, and your <code>targetSdkVersion</code> is below 23	Yes
If you request the CAMERA permission, and the user grants the runtime permission	Yes
If you request the CAMERA permission, and you have not yet asked the user for the runtime permission	No
If you request the CAMERA permission, and the user <b>denies</b> the runtime permission	No

## A Matter of Orientation

When you take a picture using an Android device — whether using ACTION\_IMAGE\_CAPTURE or [working with the camera APIs directly](#), you may find that your picture turns out strange. For example, you might take a picture in portrait mode, then find that some image viewers will show you a portrait picture, while others show you a landscape picture with its contents rotated.

That is due to the way Android camera hardware encodes the JPEG images that it takes. The orientation that you take the picture in may not be the orientation of the result.

## EXIF Tags

JPEG images can have [EXIF tags](#). These represent metadata about the image itself. For example, if you hear that an image has been “geotagged”, that means that the image has EXIF tags that contain the latitude and longitude of where the picture was taken.

These tags are contained in the JPEG file but are in a separate section from the actual image data itself. Tools can read in the EXIF tags and use them for additional information for the user (e.g., an image viewer with an integrated map to show where the picture was taken).

### EXIF Tags and Camera Images

One EXIF tag is the “orientation” tag. In effect, this tag is a message from whatever created the image (e.g., camera hardware) to whatever is showing the camera image, saying “could you please rotate this image for me? #kthxbye”.

In other words, the camera hardware is being lazy.

A lot of camera hardware is designed to take landscape images, particularly when using a rear-facing camera, as that is the traditional way that cameras were held by default, going back decades. In an ideal world, if the user took a portrait photo, the camera hardware would take a portrait picture. Or, at least, the camera hardware would take a landscape picture, but then rotate the image to be portrait before delivering the JPEG to whatever app requested the image.

Some camera hardware does just that.

However, other camera hardware leaves the image as a landscape image, regardless of how the device was held when the image was taken. Instead, the camera hardware will set the orientation tag to indicate how image viewers should rotate the image, to reflect what the image really should look like.

### EXIF Tags and Android

Of course, this would not be a problem if all image viewers paid attention to the orientation tag. However, many do not, particularly on Android... because `BitmapFactory` ignores all EXIF tags. As a result, you get the unmodified image, instead of one rotated as the camera hardware requested.

And so, if you blindly load the image, it will show up without taking the orientation tag into account.

If *you* want to take the orientation tag into account, you need to find out the value of that tag. `BitmapFactory` will not help you here. However, `ExifInterface` can... though *which* `ExifInterface` you use is important.

`android.media.ExifInterface` that Android used for years has security flaws. Android 7.0+ devices should all ship with a patched version. Some Android 6.0 devices might get a patch. Everything else will go unpatched, and if your app uses `android.media.ExifInterface`, your app may expose the user to security risks.

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

Fortunately, alternative ExifInterface implementations exist, that not only avoid the security flaw, but also support InputStream as well as File. That is only available on android.media.ExifInterface starting with Android 7.0; older versions only supported a File, which is awkward in modern Android development.

The simplest solution for most developers would be to use the exifinterface artifact from the Android Support Library

```
dependencies {  
    implementation 'com.android.support:exifinterface:25.1.0'  
}
```

This has the same API as does the Android 7.0+ edition of ExifInterface, including InputStream support.

However, for whatever reason, the API that Google has elected to expose through both of their supplied ExifInterface classes pales in comparison to the EXIF classes that they have elsewhere, such as the AOSP editions of the camera and gallery apps. A version of this code is available [as an artifact](#) published by Alessandro Crugnola and is demonstrated in the next section. If your EXIF needs are fairly limited, using the Google-supplied ExifInterface classes is simple. But even for something as seemingly simple as rotating an image, you need a more robust EXIF API.

### You Spin (Photos) Right Round

The [Camera/EXIFRotater](#) sample project contains three images in assets/, culled from [this GitHub repository](#) that supplements [this article on the problems with EXIF orientation handling](#). Specifically, we have images with orientation tag values of 3, 6, and 8, which are the most common ones that you will encounter.

## USING THE CAMERA VIA 3RD-PARTY APPS

---

The objective of this app is to show one of those images in its original form and rotated in accordance with the EXIF orientation tag:

Figure 785: EXIF Rotater Sample App, with Original and Rotated Images

However, there are two product flavors in this project, reflecting two different ways of getting that visual output: rotating the `ImageView` and rotating the image itself. These are controlled via a `ROTATE_BITMAP` value added to `BuildConfig`:

```
productFlavors {
    image {
        dimension "default"
        buildConfigField "boolean", "ROTATE_BITMAP", "false"
    }
    matrix {
        dimension "default"
        buildConfigField "boolean", "ROTATE_BITMAP", "true"
    }
}
```

(from [Camera/EXIFRotater/app/build.gradle](#))

The `MainActivity` kicks off an `ImageLoadThread` in `onCreate()`. That thread is responsible for loading (and, if appropriate, rotating) the image. When that is done,

## USING THE CAMERA VIA 3RD-PARTY APPS

---

the thread will post an `ImageLoadedEvent` to an event bus (using greenrobot's `EventBus`) to have the UI display the image (and, if needed, rotate a copy of it):

```
private static class ImageLoadThread extends Thread {
    private final Context ctxt;

    ImageLoadThread(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
        AssetManager assets=ctxt.getAssets();

        try {
            InputStream is=assets.open(ASSET_NAME);
            ExifInterface exif=new ExifInterface();

            exif.readExif(is, ExifInterface.Options.OPTION_ALL);

            ExifTag tag=exif.getTag(ExifInterface.TAG_ORIENTATION);
            int orientation=(tag==null ? -1 : tag.getValueAsInt(-1));

            if (orientation==8 || orientation==3 || orientation==6) {
                is=assets.open(ASSET_NAME);

                Bitmap original=BitmapFactory.decodeStream(is);
                Bitmap rotated=null;

                if (BuildConfig.ROTATE_BITMAP) {
                    rotated=rotateViaMatrix(original, orientation);

                    exif.setTagValue(ExifInterface.TAG_ORIENTATION, 1);
                    exif.removeCompressedThumbnail();

                    File output=
                        new File(ctxt.getExternalFilesDir(null), "rotated.jpg");

                    exif.writeExif(rotated, output.getAbsolutePath(), 100);

                    MediaScannerConnection.scanFile(ctxt,
                        new String[]{output.getAbsolutePath()}, null, null);
                }

                EventBus
                    .getDefault()
                    .postSticky(new ImageLoadedEvent(original, rotated, orientation));
            }
        }
    }
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
    }  
  }  
  catch (Exception e) {  
    Log.e(getClass().getSimpleName(), "Exception processing image", e);  
  }  
}  
}
```

(from [Camera/EXIFRotater/app/src/main/java/com/commonsware/android/exif/MainActivity.java](#))

We first get an `InputStream` on the particular image from `assets/` that we are to show (hard-coded as the `ASSET_NAME` constant).

We then create an `ExifInterface`, using the richer implementation from the aforementioned artifact. This `ExifInterface` has a few versions of `readExif()`, including one that can take our `InputStream` as input. We can then get the orientation tag value via calls to `getTag()` (to get an `ExifTag` for `TAG_ORIENTATION`), then `getValueAsInt()`. The latter method retrieves an integer tag value, with a supplied default value if the tag exists but does not have an integer value.

However, it is also possible that the tag does not exist. In fact, many JPEG images will lack this header, implying that the image is already in the correct orientation. So, we use the ternary operator and the default value to `getValueAsInt()` to get either the actual orientation tag numeric value or `-1` if, for any reason, we cannot get that value.

If the orientation is 3, 6, or 8, we will want to show the image. So, we use `BitmapFactory` to load the image, via `decodeStream()`. If `ROTATE_BITMAP` is true, we do five things:

1. We rotate the `Bitmap` itself using a `Matrix`, in the `rotateViaMatrix()` method:

```
static private Bitmap rotateViaMatrix(Bitmap original, int orientation) {  
    Matrix matrix=new Matrix();  
  
    matrix.setRotate(degreesForRotation(orientation));  
  
    return(Bitmap.createBitmap(original, 0, 0, original.getWidth(),  
        original.getHeight(), matrix, true));  
}
```

(from [Camera/EXIFRotater/app/src/main/java/com/commonsware/android/exif/MainActivity.java](#))

## USING THE CAMERA VIA 3RD-PARTY APPS

---

1. We set the orientation tag to normal (1), reflecting the fact that we have oriented the image properly.
2. We remove any thumbnail from our EXIF metadata read from the original image
3. We write the revised EXIF data and the rotated Bitmap to a file on external storage, so we have a JPEG showing the rotated results yet including all of the original EXIF tags (excluding the orientation tag and thumbnail)
4. We tell MediaScannerConnection to scan this newly-created file, so it shows up in file managers, both on-device and on-desktop

If `ROTATE_BITMAP` is false, we instead handle the rotation in our `onImageLoaded()` method that is called when the `ImageLoadedEvent` is posted:

```
@Subscribe(sticky=true, threadMode=ThreadMode.MAIN)
public void onImageLoaded(ImageLoadedEvent event) {
    original.setImageBitmap(event.original);

    if (BuildConfig.ROTATE_BITMAP) {
        oriented.setImageBitmap(event.rotated);
    }
    else {
        oriented.setImageBitmap(event.original);
        oriented.setRotation(degreesForRotation(event.orientation));
    }
}
```

(from [Camera/EXIFRotater/app/src/main/java/com/commonsware/android/exif/MainActivity.java](#))

Rather than show the rotated image in the lower `ImageView`, we show the original image, then rotate the `ImageView`.

Which of these two approaches — rotate the `ImageView` or rotate the image — is appropriate for you depends on your app. If all you need to do is show the image properly to the user, rotating the `ImageView` should be less memory-intensive. If, on the other hand, you need to save the corrected image somewhere for later use, you will need to rotate the image itself to make that correction.

## And Then, There Are the Bugs

Some devices have buggy firmware, where they do not rotate the image themselves *nor* set the orientation tag in the image. Instead, they just ignore the whole issue. For these devices, we have no way of distinguishing between “images that need to be rotated, but we do not know the orientation” and “images that are fine and do not

need to be rotated”.

Your best option is to let the user manually request that the image be rotated (e.g., action bar “rotate” item).

## Scanning with ZXing

If your objective is to scan a barcode, it is *much* simpler for you to integrate Barcode Scanner into your app than to roll it yourself.

[Barcode Scanner](#) – one of the most popular Android apps of all time — can scan a wide range of 1D and 2D barcode types. They offer an integration library that you can add to your app to initiate a scan and get the results. The library will even lead the user to the Play Store to install Barcode Scanner if they do not already have the app.

One limitation is that while the ZXing team (the authors and maintainers of Barcode Scanner) make the integration library available, they only do so in [source form](#).

That sample project — [Camera/ZXing](#) – has a UI dominated by a “Scan!” button. Clicking the button invokes a `doScan()` method in our sample activity:

This passes control to Barcode Scanner by means of the integration JAR and the `IntentIntegrator` class. `initiateScan()` will validate that Barcode Scanner is installed, then will start up the camera and scan for a barcode.

Once Barcode Scanner detects a barcode and decodes it, the activity invoked by `initiateScan()` finishes, and control returns to you in `onActivityResult()` (as the Barcode Scanner scanning activity was invoked via `startActivityForResult()`). There, you can once again use `IntentIntegrator` to find out details of the scan, notably the type of barcode and the encoded contents:

```
public void onActivityResult(int request, int result, Intent i) {
    IntentResult scan=IntentIntegrator.parseActivityResult(request,
                                                         result,
                                                         i);

    if (scan!=null) {
        format.setText(scan.getFormatName());
        contents.setText(scan.getContents());
    }
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
}
```

(from [Camera/ZXing/app/src/main/java/com/commonsware/android/zxing/ZXingDemo.java](#))

To use `IntentIntegrator` and `IntentResult`, the sample project has two modules: the `app/` module for the app, and a `zxing/` module containing those two classes (and a rump `AndroidManifest.xml` to make the build tools happy). The `app/` module depends upon the `zxing` module via a `implementation project(':zxing')` dependency directive.

Some notes:

- Barcode Scanner's scanning activity only works in landscape
- Even though you are not using the camera directly yourself, you should consider including the `<uses-feature>` element declaring that you need a camera, if your app cannot function without barcodes
- If you wish to add Barcode Scanner logic directly to your app, and avoid the dependency on the third-party APK, that is possible, but the process for doing it is not well documented or supported

## Videos: Letting the Camera App Do It

Just as `ACTION_IMAGE_CAPTURE` can be used to have a third-party app supply you with still images, there is an `ACTION_VIDEO_CAPTURE` on `MediaStore` that can be used as an Intent action for asking a third-party app capture a video for you. As with `ACTION_IMAGE_CAPTURE`, you use `startActivityForResult()` with `ACTION_VIDEO_CAPTURE` to find out when the video has been recorded.

There are two extras of note for `ACTION_VIDEO_CAPTURE`:

- `MediaStore.EXTRA_OUTPUT`, which indicates where the video should be written, and
- `MediaStore.EXTRA_VIDEO_QUALITY`, which should be an integer, either 0 for low quality/low size videos or 1 for high quality

If you elect to skip `EXTRA_OUTPUT`, the video will be written to the default directory for videos on the device (typically a "Movies" directory in the root of external storage), and the `Uri` you receive on the Intent in `onActivityResult()` will point to this file.

The impacts of skipping `EXTRA_VIDEO_QUALITY` are undocumented.

## USING THE CAMERA VIA 3RD-PARTY APPS

---

The [Media/VideoRecordIntent](#) sample project is a near-clone of the Camera/FileProvider sample from earlier in this chapter. Instead of requesting a third-party app take a still image, though, this sample requests that a third-party app record a video:

```
package com.commonware.android.videorecord;

import android.app.Activity;
import android.content.Intent;
import android.content.pm.PackageManager;
import android.content.pm.ResolveInfo;
import android.net.Uri;
import android.os.Build;
import android.os.Bundle;
import android.provider.MediaStore;
import android.support.v4.content.FileProvider;
import java.io.File;
import java.util.List;

public class MainActivity extends Activity {
    private static final String EXTRA_FILENAME=
        BuildConfig.APPLICATION_ID+".EXTRA_FILENAME";
    private static final String AUTHORITY=
        BuildConfig.APPLICATION_ID+".provider";
    private static final String VIDEOS="videos";
    private static final String FILENAME="sample.mp4";
    private static final int REQUEST_ID=1337;
    private File output=null;
    private Uri outputUri=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (savedInstanceState==null) {
            output=new File(new File(getFilesDir(), VIDEOS), FILENAME);

            if (output.exists()) {
                output.delete();
            }
            else {
                output.getParentFile().mkdirs();
            }
        }
        else {
            output=(File)savedInstanceState.getSerializable(EXTRA_FILENAME);
        }
    }
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
outputUri=FileProvider.getUriForFile(this, AUTHORITY, output);

if (savedInstanceState==null) {
    Intent i=new Intent(MediaStore.ACTION_VIDEO_CAPTURE);

    i.putExtra(MediaStore.EXTRA_OUTPUT, outputUri);
    i.putExtra(MediaStore.EXTRA_VIDEO_QUALITY, 1);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
        i.addFlags(Intent.FLAG_GRANT_WRITE_URI_PERMISSION |
            Intent.FLAG_GRANT_READ_URI_PERMISSION);
    }
    else {
        List<ResolveInfo> resInfoList=
            getPackageManager()
                .queryIntentActivities(i, PackageManager.MATCH_DEFAULT_ONLY);

        for (ResolveInfo resolveInfo : resInfoList) {
            String packageName = resolveInfo.activityInfo.packageName;

            grantUriPermission(packageName, outputUri,
                Intent.FLAG_GRANT_WRITE_URI_PERMISSION |
                Intent.FLAG_GRANT_READ_URI_PERMISSION);
        }
    }

    startActivityForResult(i, REQUEST_ID);
}

@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putSerializable(EXTRA_FILENAME, output);
}

@Override
protected void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (requestCode==REQUEST_ID && resultCode==RESULT_OK) {
        Intent view=
            new Intent(Intent.ACTION_VIEW)
                .setDataAndType(outputUri, "video/mp4")
                .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

        startActivity(view);
    }
}
```

```
        finish();
    }
}
}
```

(from [Media/VideoRecordIntent/app/src/main/java/com/commonsware/android/videorecord/MainActivity.java](#))

`onCreate()` of `MainActivity` starts by setting up a `File` object pointing to a `sample.mp4` file in internal storage. If the file already exists, `onCreate()` deletes it; otherwise it ensures that the directory already exists. We then go through much of the same headache that we did in the `ACTION_IMAGE_CAPTURE` scenario, creating a `Uri` for our `FileProvider` that points to our designated `File`, ensures that the video-recording app has read/write access to our `Uri`, before finally calling `startActivityForResult()`.

The call to `startActivityForResult()` will trigger the third-party app to record the video. When control returns to `MainActivity`, `onActivityResult()` creates an `ACTION_VIEW` Intent for the same `Uri`, then calls `startActivity()` to request that some app play back the video.

And, as before, we hold onto the `File` object via the saved instance state `Bundle`, and we only record the video if there is no such saved instance state `Bundle`, in case there is a configuration change causing our activity to be destroyed and recreated.

There is only one problem: this app is less likely to work on your device that did the `ACTION_IMAGE_CAPTURE` sample.

Camera apps need to be able to support content `Uri` values for `EXTRA_OUTPUT` for both still images and video. However, [Google did not support this in their own camera app](#), decreasing the likelihood that anyone else supports it.

You can elect to use a `file Uri`, pointing to a location on external storage. However, that will require you to keep your `targetSdkVersion` at 23 or lower, as once you go above that, `file Uri` values are banned in Intent objects on Android 7.0.

## Using a Camera Library

Relying upon third-party applications for taking pictures does introduce some challenges:

- Not all camera apps are created equal. Some implement `ACTION_IMAGE_CAPTURE` and `ACTION_VIDEO_CAPTURE` well... and others do not.

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

- Some might only ever give you a thumbnail, or some might not support all valid `Uri` values for writing out the output, and so on.
- Even within “valid” output, there can be variances. One common variation is how portrait images are handled. Some camera apps will write out an image that is actually in portrait mode. Some camera apps will write out an image that is set up for landscape, but with an “EXIF header” in the JPEG data that tells image viewers to rotate the image to portrait. Unfortunately, not everything honors those headers, such as Android’s own `BitmapFactory`.
  - If the camera app uses a lot of system RAM, your app may be kicked out of RAM while the user is taking a picture. This should not be a problem, as your app’s process is eligible to be terminated at any point when you are not in the foreground. However, it is a bit unexpected to think that taking a picture may cause you to have to switch to a fresh process.

The alternative to relying upon a third-party app is to implement camera functionality within your own app. For that, you have three major options:

1. Use the `android.hardware.Camera` API, added to Android way back in API Level 1, but marked as deprecated in API Level 21
2. Use the `android.hardware.camera2` API, added to Android in API Level 21 as a replacement for `android.hardware.Camera`, but therefore is only useful on its own if your `minSdkVersion` is 21 or higher
3. Use some third-party library that wraps around one or both of those APIs

Using the native camera APIs is possible [but difficult](#). However, there are a few libraries that simplify the process. Here, we will look at two of them: `CameraKit-Android` and `Fotoapparat`.

### CameraKit-Android

Debuting in 2017, [CameraKit-Android](#) is an MIT-licensed library, making it convenient for both open source and proprietary development. It offers a fair bit of flexibility in a simple API. It supports both taking photos and recording videos. However:

- The library was handed off from previous maintainers to a new team, leaving many outstanding issues in limbo
- The documentation is incorrect for several features

The [Camera/CameraKit](#) sample project demonstrates using `CameraKit-Android`. It has a two-button UI in its `MainActivity`, where one button will trigger taking a

picture, while the other button triggers recording a video.

### Adding the Dependency

CameraKit-Android is published as the `com.wonderkiln:camerakit-core` artifact on JCenter. However:

- The library depends upon `appcompat-v7`, despite [not using classes from there](#)
- The library depends upon Google Play Services, though only for one particular method

Hence, the sample app uses Gradle to exclude those two transitive dependencies and instead depend upon `support-compat`, since the sample app it not using `appcompat-v7` itself:

```
dependencies {
    implementation 'com.github.clans:fab:1.6.4'
    implementation 'com.githang:com-phillipcalvin-iconbutton:1.0.1@aar'
    implementation 'com.android.support:support-compat:27.0.2'
    implementation('com.wonderkiln:camerakit-core:0.13.1') {
        exclude group: 'com.android.support', module: 'appcompat-v7'
        exclude group: 'com.google.android.gms', module: 'play-services-vision'
    }
}
```

(from [Camera/CameraKit/app/build.gradle](#))

The other two dependencies are for:

- An implementation of a floating action button (FAB), profiled in [the chapter on the Design Support Library](#)
- An icon button library, for use by the MainActivity

### Adding the Preview Display

The actual photo- or video-taking activity is `CameraActivity`. It uses a `camera.xml` layout resource, which in our case contains a custom `CameraView` from `CameraKit-Android`, along with a FAB:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
android:layout_width="match_parent"
android:layout_height="match_parent">

<com.wonderkiln.camerakit.CameraView android:id="@+id/camera"
    xmlns:camerakit="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:adjustViewBounds="true"
    camerakit:ckFlash="on" />

<com.github.clans.fab.FloatingActionButton
    android:id="@+id/fab"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:layout_alignParentBottom="true"
    android:layout_alignParentEnd="true"
    android:layout_alignParentRight="true"
    android:layout_marginBottom="@dimen/fab_margin"
    android:layout_marginEnd="@dimen/fab_margin"
    android:layout_marginRight="@dimen/fab_margin"
    android:src="@drawable/ic_camera_black_24dp"
    app:fab_colorNormal="@color/ready" />
</RelativeLayout>
```

(from [Camera/CameraKit/app/src/main/res/layout/camera.xml](#))

CameraKit-Android puts most of its configuration on its `CameraView`, whether via custom attributes or via corresponding getter/setter methods on the Java class. In this case, we are using the `ckFlash` attribute, indicating that we want flash mode to be enabled.

Other available attributes include:

- `ckFacing`, to indicate if you want the rear-facing (default) or front-facing camera
- `ckFocus`, to indicate what focus mode you want (defaults to continuous focus)
- `ckJpegQuality`, to indicate the quality factor to use when saving a photo as JPEG (defaults to 100, indicating maximum quality/maximum size)
- `ckVideoQuality`, to indicate the resolution of the video to capture, or to choose the highest-available or lowest-available resolution (defaults to a maximum of 480p, or 640x480)
- `ckZoom`, indicating that we want a pinch-to-zoom implementation, so pinch gestures control the camera's zoom level

### Permissions

If you do not request runtime permissions, CameraKit-Android will do that for you as part of displaying that CameraView. In the case of this sample app, MainActivity extends the AbstractPermissionActivity seen elsewhere in this book, and it requests three permissions:

- CAMERA, for using the camera
- WRITE\_EXTERNAL\_STORAGE, as this is where videos are recorded by default
- RECORD\_AUDIO, needed for recording videos, as they also capture audio off of a microphone

### Integrating with the Lifecycle

MainActivity invokes CameraActivity by means of two static methods on CameraActivity: takePhoto() and recordVideo(). These simply start up CameraActivity with EXTRA\_IS\_PHOTO indicating which mode the camera should use:

```
public static void takePhoto(Activity requester, int requestCode) {
    Intent i=new Intent(requester, CameraActivity.class)
        .putExtra(EXTRA_IS_PHOTO, true);

    requester.startActivityForResult(i, requestCode);
}

public static void recordVideo(Activity requester, int requestCode) {
    Intent i=new Intent(requester, CameraActivity.class)
        .putExtra(EXTRA_IS_PHOTO, false);

    requester.startActivityForResult(i, requestCode);
}
```

(from [Camera/CameraKit/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

In onCreate(), we load up our layout and retrieve the CameraView, holding onto it in a camera field:

```
@Override
protected void onCreate(@Nullable Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.camera);

    isPhoto=getIntent().getBooleanExtra(EXTRA_IS_PHOTO, true);
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
camera=findViewById(R.id.camera);
fab=findViewById(R.id.fab);

fab.setOnClickListener(new View.OnClickListener() {
    @Override
    public void onClick(View view) {
        if (isPhoto) {
            takePhoto();
        }
        else {
            recordVideo();
        }
    }
});

if (!isPhoto) {
    fab.setImageResource(R.drawable.ic_videocam_black_24dp);
}

camera.addCameraKitListener(new CameraKitEventListenerAdapter() {
    @Override
    public void onImage(CameraKitImage image) {
        // TODO: do something with picture

        setResult(RESULT_OK);
        finish();
    }

    @Override
    public void onVideo(CameraKitVideo video) {
        // TODO: do something with video file

        setResult(RESULT_OK);
        finish();
    }
});
}
```

(from [Camera/CameraKit/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

In addition, we:

- Set up the FAB with the proper icon and action, depending upon whether we are taking a picture or recording a video
- Add a listener to the CameraView, as will be discussed shortly

We need to forward `onPause()` and `onResume()` events from the hosting activity or

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

fragment along to the CameraView, so the custom view knows when it should be releasing the camera:

### Taking a Picture

Taking a picture with CameraKit-Android is merely a matter of calling `captureImage()`:

```
private void takePhoto() {
    camera.captureImage();
    fab.setEnabled(false);
}
```

(from [Camera/CameraKit/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

When the picture is taken, the `CameraKitEventListenerAdapter` instance that we registered via `addCameraKitListener()` on the `CameraView` will be called with `onImage()`. We are handed a `CameraKitImage` object, which has `getBitmap()` and `getJpeg()` methods to give us the photo in memory. The latter is the original data off of the camera; the former returns a `Bitmap` created from that JPEG. Note that for a high-resolution image, you may not be able to create the `Bitmap` without running out of memory. In a real app, we would do something with the photo, such as saving it to disk on a background thread.

### Recording a Video

To start recording a video, call `start()`; to stop recording a video, call `stopVideo()`:

```
private void recordVideo() {
    if (isRecording) {
        camera.stopVideo();
        finish();
    }
    else {
        fab.setColorNormalResId(R.color.recording);
        fab.setImageResource(R.drawable.ic_stop_black_24dp);
        isRecording=true;
        camera.start();
    }
}
```

(from [Camera/CameraKit/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

When the video is taken, our listener will be called with `onVideo()`, where we are

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

given a `CameraKitVideo` object. That has a `getFile()` method, which contains a `File` object pointing to wherever the library elected to save the video. By default, this will be in your app's `getExternalFilesDir()` location, so if your `minSdkVersion` is 19 or higher, you will not need the `WRITE_EXTERNAL_STORAGE` permission. A production app would do something with this file.

### Fotoapparat

Also debuting in 2017, the Apache-licensed [Fotoapparat](#) has a similar flow to `CameraKit-Android`: add a custom `View` for the preview and call methods to take pictures. However:

- `Fotoapparat` puts most of the configuration on a `Fotoapparat` object
- The `Fotoapparat` API offers a few more features than does `CameraKit-Android`'s API, though with a somewhat funky fluent API
- As of January 2019, `Fotoapparat` only supports taking photos, not recording videos

The [Camera/Fotoapparat](#) sample project is a clone of the `CameraKit-Android` sample, with `Fotoapparat` as the camera library. Since `Fotoapparat` does not support recording videos, the code related to that was removed, and its button in the UI is disabled.

### Adding the Dependency

The `io.fotoapparat:fotoapparat:2.5.0` dependency used in this project supports the Android Support Library:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.github.clans:fab:1.6.4'
    implementation 'com.githubang:com-phillipcalvin-iconbutton:1.0.1@aar'
    implementation 'com.android.support:support-compat:28.0.0'
    implementation 'io.fotoapparat:fotoapparat:2.5.0'
}

android {
    compileSdkVersion 28

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 28
    }
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
    applicationId 'com.commonware.android.camera.fotoapparat'
  }

  compileOptions {
    sourceCompatibility JavaVersion.VERSION_1_8
    targetCompatibility JavaVersion.VERSION_1_8
  }
}
```

(from [Camera/Fotoapparat/app/build.gradle](#))

Starting with 2.6.0, Fotoapparat has moved to using AndroidX dependencies.

Also note that Fotoapparat nowadays is implemented in Kotlin. A side effect of this is that you will wind up pulling in the Kotlin runtime library, even if your app otherwise is implemented in Java, not Kotlin.

### Permissions

Fotoapparat will merge in the `<uses-permission>` element for the CAMERA permission to your manifest, but it does not attempt to request that permission at runtime. Apps using Fotoapparat have to handle that themselves, before attempting to use the camera.

The sample app uses the same `AbstractPermissionsActivity` as before, albeit only with the CAMERA permission, since that is the only one needed here.

### Adding the Preview Display

Fotoapparat has its own `CameraView`. However, whereas `CameraKit-Android` puts its configuration on the `CameraView`, Fotoapparat does not. As a result, other than sizing and positioning the `CameraView` where you want it, little else is needed:

```
<?xml version="1.0" encoding="utf-8"?>
<RelativeLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <io.fotoapparat.view.CameraView android:id="@+id/camera"
        android:layout_width="match_parent"
        android:layout_height="wrap_content" />

    <com.github.clans.fab.FloatingActionButton
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

```
android:id="@+id/fab"
android:layout_width="wrap_content"
android:layout_height="wrap_content"
android:layout_alignParentBottom="true"
android:layout_alignParentEnd="true"
android:layout_alignParentRight="true"
android:layout_marginBottom="@dimen/fab_margin"
android:layout_marginEnd="@dimen/fab_margin"
android:layout_marginRight="@dimen/fab_margin"
android:src="@drawable/ic_camera_black_24dp"
app:fab_colorNormal="@color/ready" />
</RelativeLayout>
```

(from [Camera/Fotoapparat/app/src/main/res/layout/camera.xml](#))

### Configuring the Fotoapparat

However, what we remove from the layout goes into Java code. Specifically, Fotoapparat has a Fotoapparat class. We need to build an instance of a Fotoapparat and connect it to the CameraView.

CameraActivity handles this in onCreate():

```
@Override
protected void onCreate(@Nullable Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.camera);

    CameraView camera = findViewById(R.id.camera);

    fab = findViewById(R.id.fab);
    fab.setOnClickListener(view -> takePhoto());

    fotoapparat = Fotoapparat
        .with(this)
        .into(camera)
        .previewScaleType(ScaleType.CenterCrop)
        .photoResolution(ResolutionSelectorsKt.highestResolution())
        .lensPosition(LensPositionSelectorsKt.back())
        .focusMode(SelectorsKt.firstAvailable(
            FocusModeSelectorsKt.continuousFocusPicture(),
            FocusModeSelectorsKt.autoFocus(), FocusModeSelectorsKt.fixed()))
        .flash(SelectorsKt.firstAvailable(FlashSelectorsKt.autoRedEye(),
            FlashSelectorsKt.autoFlash()))
        .build();
}
```

## USING THE CAMERA VIA 3RD-PARTY APPS

---

(from [Camera/Fotoapparat/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

The Fotoapparat API is designed for significant use of statically imported methods. This is akin to how libraries like JUnit and Espresso work, reducing the visual clutter of the main Java code at the cost of a bunch of additional import statements. In Fotoapparat's case, these methods are actually Kotlin global functions, which Kotlin/JVM maps to static methods on generated classes based on the Kotlin filename.

Fotoapparat is also significantly more configurable than is CameraKit-Android. There are many more options, and more complex options, for controlling how the camera is used.

So, in `onCreate()`, we:

- Create a `FotoapparatBuilder` via `with()`, which takes a `Context`
- Tie it to the `CameraView` via `into()`
- Indicate that we want the camera preview to fill the available space, at the cost of cropping portions that do not match our `CameraView` aspect ratio, via `previewScaleType(ScaleType.CenterCrop)`
- Indicate that we want to take the highest resolution photo possible, via `photoResolution(ResolutionSelectorsKt.highestResolution())`
- Indicate that we want the rear-facing camera via `lensPosition(LensPositionSelectorsKt.back())`
- Request either continuous focus, auto-focus, or fixed focus, whichever one is available, via the `focusMode()` call
- Request either auto-redeye or auto flash, whichever one is available, via the `flash()` call

Then, we `build()` the `Fotoapparat` from the `FotoapparatBuilder`.

Methods like `photoResolution()`, `focusMode()`, and `flashMode()` take a “selector” object. Sometimes, that might be a specific setting (e.g., `highestResolution()` for `photoResolution()`). Sometimes, that might be more of a “functor” object, one that makes a decision of other selectors to use based upon availability (e.g., `firstAvailable()`). This leads to a very expressive API, at the cost of a fairly convoluted set of objects and methods — writing an API like this can get complicated rather quickly.

### Integrating with the Lifecycle

As with CameraKit-Android, we need to forward lifecycle events along to the

---

## USING THE CAMERA VIA 3RD-PARTY APPS

---

Fotoapparat object. In this case, though, we need to forward `onStart()` and `onStop()`, not `onPause()` and `onResume()`:

```
@Override
protected void onStart() {
    super.onStart();
    fotoapparat.start();
}

@Override
protected void onStop() {
    fotoapparat.stop();
    super.onStop();
}
```

(from [Camera/Fotoapparat/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

### Taking a Picture

The Fotoapparat object has a `takePicture()` method which, as you might expect, takes a picture. It gives you back a `PhotoResult` object, which you can use to work with the resulting photo. In the sample app, we call `toBitmap()` on it, then use `whenAvailable()` to get a callback when the image is ready. This gives us a `BitmapPhoto` object, from which we can get the JPEG bytes, akin to the `CameraKit-Android` example:

```
private void takePhoto() {
    fab.setEnabled(false);

    PhotoResult result = fotoapparat.takePicture();

    result.toBitmap().whenAvailable(bitmapPhoto -> {
        // TODO: do something with picture

        setResult(RESULT_OK);
        finish();

        return Unit.INSTANCE;
    });
}
```

(from [Camera/Fotoapparat/app/src/main/java/com/commonsware/android/camera/CameraActivity.java](#))

(note: the `return Unit.INSTANCE;` in the lambda expression is there because this really is a Kotlin-defined function set to return `Unit`, so in Java we have to explicitly

have the return to specify the object to return)

If, however, your objective is to save the photo to a file, simply call `saveToFile()` on the `PhotoResult` object. This will asynchronously write your JPEG to the supplied File location, and it returns a `PendingResult`, as `toBitmap()` does, for you to attach a callback to find out when the save operation is complete.

## Directly Working with the Camera

Of course, you can bypass these third-party apps and libraries, electing instead to work directly with the camera if you so choose. This is very painful, as will be illustrated in the [next chapter](#).

# Working Directly with the Camera

---

Letting third-party apps take the pictures and videos for you is all well and good, but there will be times where you need more control than that. It is possible for you to work directly with the device cameras. However, doing is exceptionally complicated.

Part of that complexity is because Android presently has three separate APIs for working with the camera:

- `android.hardware.Camera` for taking still photos
- `android.hardware.camera2` for taking still photos on Android 5.0+ devices
- `MediaRecorder` for recording videos

This chapter will attempt to outline the basic steps for using these APIs.

## Prerequisites

This chapter assumes that you have read [the previous chapter](#) covering Intent-based uses of the camera and [the chapter on audio recording](#).

## Notes About the Code Snippets

The code snippets shown in this chapter are here purely to illustrate how to call certain APIs. They are not from any particular sample project, as a sample project small enough to fit in a book would be riddled with bugs and limitations.

## A Tale of Two APIs

As noted in the introduction to this chapter, there are three APIs for working with

the camera. One — `MediaRecorder` — is focused purely on recording videos. It relies on you using one of the other two APIs for setting up the camera preview, so the user can see what will be recorded. Those other two APIs exist for taking still photos, where one (`android.hardware.camera2`) is substantially newer.

### **android.hardware.Camera**

The original camera API is based around the `android.hardware.Camera` class.

(NOTE: there is another `Camera` class, in `android.graphics`, that is not directly related to taking pictures)

Instances of this class represent an open camera, where you call methods on the `Camera` to do things like take pictures. You also work extensively with a `Camera.Parameters` object, where you can determine a number of key characteristics about the camera (e.g., what the available resolutions are for pictures) and set up the particular results that you want.

This API works on all Android devices.

### **android.hardware.camera2**

The original camera API worked, albeit with some difficulty. However, it was fairly limited, as it was designed primarily around the smartphone camera capabilities of 2005-2010. Nowadays, device manufacturers have access to much more powerful camera modules from chipset manufacturers like Qualcomm. Android needed a more powerful API to accommodate the current hardware, and a more flexible API to be able to adjust to changes over time.

Hence, Android 5.0 brought a new API, based on a series of classes in the `android.hardware.camera2` package. On the plus side, these offer much greater capability. They are also designed with asynchronous work in mind, off-loading slow or complex operations onto background threads for you. However, on the whole, the API is more complicated, much less documented, and substantially different than the original API.

It is also only available on Android 5.0 devices. If your `minSdkVersion` is 21 or higher, that is not a problem. If, however, you are aiming to support older devices than that, you have two choices:

1. Stick with the original API for all devices

2. Use the original API for older devices and the newer API for newer devices

The latter might allow you to offer more features to users of those newer devices, but it does roughly double the work required to implement camera logic in your app.

### MediaRecorder

MediaRecorder is responsible for both [audio recording](#) and video recording. MediaRecorder has a fairly limited API, one that has not changed substantially since 2011. However, if you use it carefully, it works. It works in tandem with either camera API — you use the camera APIs to show the user what will be recorded, and you use MediaRecorder to actually do the recording.

However, MediaRecorder has a number of issues, such as a fair bit of delay between when you ask it to begin recording and when it actually *does* begin recording. This makes it a poor choice for fast-twitch video recording purposes. Some apps, notably Vine, have elected to skip using MediaRecorder. Instead, they use the regular camera APIs. These APIs, among other things, give you access to the preview frames that are used to show the user what is visible through the camera lens. With a fair amount of work, you can stitch those together into a video. Needless to say, this is a beyond-advanced topic that is well outside the scope of this book.

### The APIs That You (Probably) Can't Use

The aforementioned APIs are all part of the Android SDK. For camera apps that ship with devices, those apps are not limited to these APIs. Device manufacturers are welcome to create apps that use internal proprietary APIs for their devices.

Hence, when it comes to determining what is and is not possible through the camera APIs, it is important to compare to other third-party camera apps, more so than manufacturer-supplied apps. Manufacturers can “cheat”; you cannot.

## Performing Basic Camera Operations

Cameras have some key functionality:

- Showing a preview to the user, so the user can see in real time what the camera lens sees, so the user can frame a picture
- Take a still picture
- Record a video

In the following sections, we will outline what is required to perform these operations using the various APIs.

### Permissions

First, you need permission to use the camera. That way, when end users install your application, they will be notified that you intend to use the camera, so they can determine if they deem that appropriate for your application.

You simply need the `CAMERA` permission in your `AndroidManifest.xml` file, along with whatever other permissions your application logic might require.

If you plan to record video, using `MediaRecorder`, you will also want to request the `RECORD_AUDIO` permission.

And, if you were planning on storing pictures or videos out on external storage, you probably need the `WRITE_EXTERNAL_STORAGE` permission. The exception would be if your `minSdkVersion` is 19 or higher and you are only storing those files in locations that are automatically read/write for your app, such as `getExternalFilesDir()` or `getExternalCacheDir()`.

Note that all three of these permissions (`CAMERA`, `RECORD_AUDIO`, and `WRITE_EXTERNAL_STORAGE`) are part of the Android 6.0 runtime permission system. If your app has a `targetSdkVersion` of 23 or higher, you will need to request those permissions at runtime. If your app has a lower `targetSdkVersion`, while you will not have to do anything special for your app, bear in mind that the user can still revoke your access to those capabilities, and so you may find lots of devices that claim to support a camera but just do not seem to have any cameras available when you try to use one.

### Features

Your manifest also should contain one or more `<uses-feature>` elements, declaring what you need in terms of camera hardware. By default, asking for the `CAMERA` permission indicates that you *need* a camera. More specifically, asking for the `CAMERA` permission indicates that you need an *auto-focus* camera.

The following sections outline some common scenarios and how to handle them.

### A Camera is Optional

If you would like a camera, but having one is not essential for the use of your app, put the following `<uses-feature>` element in your manifest:

```
<uses-feature android:name="android.hardware.camera" android:required="false" />
```

This indicates that you would like a camera, but it is not required. This reverses the default established by the CAMERA permission.

### A Camera is Required

Technically, you would not need any `<uses-feature>` element in your manifest to indicate that you need a camera, as the CAMERA permission would handle that for you. However, it is good form to explicitly declare it anyway:

```
<uses-feature android:name="android.hardware.camera" android:required="true" />
```

Not only does that make your manifest more self-documenting, but it also helps protect you in case the default behavior of the CAMERA permission changes.

### Other Camera Features

There are three other camera features that you could consider having `<uses-feature>` elements for:

1. `android.hardware.camera.autofocus`, to indicate whether or not the device needs a camera with auto-focus capability.
2. `android.hardware.camera.flash`, to indicate whether or not the device must support a camera flash
3. `android.hardware.camera.front`, to indicate whether or not the app needs a front-facing camera specifically (`android.hardware.camera` requests a rear-facing camera)

Of these, the only one you should definitely include in your app is `android.hardware.camera.autofocus`, once again because of the default effects of requesting the CAMERA permission. In particular, if you do not absolutely need auto-focus capabilities, you can use `android:required="false"` to reverse the CAMERA default requirement.

## Finding Out What Cameras Exist

Some devices will have just a rear-facing camera. Some will have just a front-facing camera. Some will have both cameras. Some will have no cameras. And, in theory at least, some could have yet more camera options.

At some point, you are likely to need to find out what cameras exist on the device that you are running on. Perhaps you need a particular camera (e.g., a front-facing camera for your “selfie”-focused app). Or, perhaps you want to allow your users to switch between cameras on the fly.

### **android.hardware.Camera**

The simplest way to choose a camera is to not choose at all, and arrange to open the default camera. That default camera is the first rear-facing camera on the device. However, devices that have *no* rear-facing cameras effectively have no default camera, and so going with the default is rarely the correct choice. Instead, you should iterate over the available cameras, to find the one that you want.

To find out how many cameras there are for the current device, you can call the static `getNumberOfCameras()` method on the `Camera` class.

To find out details about a particular camera, you can call the static `getCameraInfo()` method on `Camera`. This takes two parameters:

- the ID of the camera to open, which will be a number from 0 to the number of available camera minus 1
- a `Camera.CameraInfo` object, into which `getCameraInfo()` will pour details about the camera

The most notable field on `Camera.CameraInfo` is `facing`, which tells you if this is a rear-facing (`Camera.CameraInfo.CAMERA_FACING_BACK`) or front-facing (`Camera.CameraInfo.CAMERA_FACING_FRONT`) camera.

For example, the following code snippet could be used to identify the first front-facing camera:

```
int chosen=-1;
int count=Camera.getNumberOfCameras();
Camera.CameraInfo info=new Camera.CameraInfo();
```

---

## WORKING DIRECTLY WITH THE CAMERA

---

```
for (int cameraId=0; cameraId < count; cameraId++) {
    Camera.getCameraInfo(cameraId, info);

    if (info.facing==Camera.CameraInfo.CAMERA_FACING_FRONT) {
        chosen=cameraId;
        break;
    }
}
```

If chosen remains at a value of -1, you know that there is no front-facing camera available to you, and you would need to decide how you wish to proceed, if you really wanted such a camera.

### **android.hardware.camera2**

With the original camera API, your main entry point is the Camera class. With the Android 5.0+ camera API, your main entry point is a CameraManager. This is another system service, one you can retrieve by calling `getSystemService()` on a Context, asking for the `CAMERA_SERVICE`:

```
CameraManager mgr=
    (CameraManager)ctxt.
        getApplicationContext().
            getSystemService(Context.CAMERA_SERVICE);
```

You will notice here that we are specifically calling `getSystemService()` on the Application context. That is because there is a bug in Android 5.0 where CameraManager leaks the Context that creates it. This bug has been fixed in Android 5.1. However, to be safe, you are better off retrieving this system service via the singleton Application object, as there is no risk of a memory leak (singletons are “pre-leaked”, as it were).

Given a CameraManager, you can call `getCameraIdList()` to get a list of camera IDs. These are strings, not integers as they were with the original camera API.

To learn more about the camera, you can ask the CameraManager to give you a CameraCharacteristics object for a given camera ID. The CameraCharacteristics object has all sorts of information about the camera, including what direction it is facing. CameraCharacteristics behaves a lot like a HashMap, in that you use `get()` and a key to retrieve a value, such as `CameraCharacteristics.LENS_FACING` to determine the camera’s facing direction.

---

## WORKING DIRECTLY WITH THE CAMERA

---

So, the code snippet for the first front-facing camera using a `CameraManager` named `mgr`, would be something like:

```
String chosen=null;

for (String cameraId : mgr.getCameraIdList()) {
    CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);

    if
(cc.get(CameraCharacteristics.LENS_FACING)==CameraCharacteristics.LENS_FACING_FRONT) {
        chosen=cameraId;
        break;
    }
}
```

Here, a value of `null` would indicate that there is no available front-facing camera.

### Opening and Closing a Camera

Once you decide which camera you wish to use, you will eventually need to “open” it. This gives your app access to that camera, and blocks other app’s access while you have it open. You need to open a camera before you can use that camera to take pictures, record video, etc.

Eventually, when you are done with the camera, you should close it, to allow other apps to have access to the camera again. If you fail to close it, until your process is terminated, the camera is inaccessible.

#### **android.hardware.Camera**

Old code samples would open the camera by calling a zero-parameter static `open()` method on the `Camera` class. This opens the default camera, and as noted above, this is rarely a good idea. However, it is your only option on API Level 8 and below, if you are still supporting such devices, as those devices only supported a single camera.

Instead, if you have the ID of the camera that you wish to open, call the one-parameter static `open()` method, passing in the ID of the camera.

Both flavors of `open()` return an instance of `Camera`, which you can hold onto in your activity or fragment that is working with the camera.

While you have access to this camera, no other process can. Hence, it is important to

## WORKING DIRECTLY WITH THE CAMERA

---

release the camera when you are no longer needing it. To release the camera, call `release()` on your `Camera` instance, after which it is no longer safe to use the camera. A common pattern is to `open()` the camera in `onStart()` or `onResume()` and `release()` it in `onPause()` or `onStop()`, so you tie up the camera only while you are in the foreground.

### **android.hardware.camera2**

Opening and closing a camera is a *lot* more complicated with the Android 5.0+ camera API.

Partly, that complexity seems to be due to a threading limitation with `CameraManager` — while we want to do long tasks related to the camera on background threads, `CameraManager` itself is not free-threaded when it comes to opening and closing cameras. Hence, we need to use some form of thread synchronization to make sure that we are not trying to open and close cameras simultaneously.

Partly, that complexity is that the way that `CameraManager` deals with background operations is via a `Handler` tied to a `HandlerThread`. `HandlerThread`, as the name suggests, is a `Thread` which has all the associated bits to support a `Handler`. The main application thread itself is a `HandlerThread` (or, close enough), but we specifically want to use a background thread, so we do not tie up the main application thread. So, we need to create and manage our own `HandlerThread` and `Handler`.

So, the first thing you will need to do is set up a `HandlerThread`, such as in a data member of some class:

```
final private HandlerThread handlerThread=new HandlerThread(NAME,  
    android.os.Process.THREAD_PRIORITY_BACKGROUND);
```

Here, `NAME` is some string to identify this thread (used in places like the list of running threads in DDMS). The second parameter is the thread priority; in general, you want your own `HandlerThread` instances to have background priority.

Creating the `HandlerThread` instance does not actually start the thread, any more than creating a `Thread` object starts the thread. Instead, you need to call `start()` when you want the thread to begin working its message loop. Any time after this point, it is safe to create a `Handler` for that `HandlerThread`, by getting the `Looper` from the `HandlerThread` and passing it to the `Handler` constructor:

## WORKING DIRECTLY WITH THE CAMERA

---

```
handlerThread.start();  
handler=new Handler(handlerThread.getLooper());
```

(You might wonder why a class named `HandlerThread`, designed to work with a `Handler`, lacks any methods to give you such a `Handler`. Lots of people wonder this, so you are not alone.)

Next, to actually open the camera, you will need to call `openCamera()` on your `CameraManager`, supplying:

- the ID of the camera that you wish to open
- a `CameraDevice.StateCallback` instance
- the `Handler` that you created for your `HandlerThread`

But, we want to make sure that we are not trying to open or close another camera while all of this is going on, so we need to use some sort of Java thread synchronization for that, such as a `Semaphore`:

```
final private Semaphore lock=new Semaphore(1);
```

Then, we can consider opening the camera, once we obtain the lock:

```
if (!lock.tryAcquire(2500, TimeUnit.MILLISECONDS)) {  
    throw new RuntimeException("Time out waiting to lock camera opening.");  
}  
  
mgr.openCamera(cameraId, new DeviceCallback(), handler);
```

You will notice that we do not release the lock here, as we need to keep the lock until the camera has completed opening.

`CameraDevice.StateCallback` is an abstract class, so we usually have to create some dedicated subclass for it. There are three abstract methods that we will need to implement: `onOpened()`, `onError()`, and `onDisconnected()`. Plus, we will typically want to implement `onClosed()`, even though there is a default implementation of this callback.

`onOpened()` will be called when the camera is open and is ours to use. We are passed a `CameraDevice` object representing our open camera, and it is our job to hold onto this device while we have the camera open. The big thing that we need to do in `onOpened()` is release that lock that we obtained when we tried opening the camera. This is also a fine time to consider starting to show camera previews to the user, and

we will see how to do that in upcoming sections of the book.

`onError()` will be called if there is some serious error when trying to open or use the camera. We are passed an error code to indicate what sort of problem we encountered. It could be that the camera is already in use (`ERROR_CAMERA_IN_USE`), or that while the camera exists, we do not have access to it due to device policy (`ERROR_CAMERA_DISABLED`), or that there was a general problem with this specific camera (`ERROR_CAMERA_DEVICE`) or with the overall camera engine (`ERROR_CAMERA_SERVICE`).

`onDisconnected()` will be called if we no longer can use the camera, for reasons other than our closing it ourselves. We are supposed to close the `CameraDevice`, if we have one, as the camera is no longer usable.

To close the camera, whether in response to `onDisconnected()` or because you are simply done with the camera, call `close()` on the `CameraDevice`, inside of the lock:

```
try {
    lock.acquire();
    cameraDevice.close();
    cameraDevice=null;
}
finally {
    lock.release();
}
```

Note that `close()` is a synchronous call, and so we can `release()` our lock in a `finally` block.

Our `CameraDevice.StateCallback` will be called with `onClosed()`, to let us know that the close operation has completed.

### Setting Up a Preview Surface

The camera preview is basically a stream of images, taken by the camera, usually at less than full resolution. Mostly, that stream is to be presented to the user on the screen, to help them “see what the camera sees”, so they can line up the right picture.

For presenting the preview stream to the user, there are two typical solutions: `SurfaceView` and `TextureView`.

### SurfaceView for the Camera

SurfaceView is used as a raw canvas for displaying all sorts of graphics outside of the realm of your ordinary widgets. In this case, Android knows how to display a live look at what the camera sees on a SurfaceView, to serve as a preview pane. A SurfaceView is also used for [video playback](#), and a variation of SurfaceView called GLSurfaceView is used for OpenGL animations.

That being said, SurfaceView is a subclass of View, and so it can be added to your UI the same as any other widget:

- Include it in a layout
- Return it as the View from onCreateView() of a Fragment
- Instantiate it in Java and add it to some container via addView()
- Etc.

If your app will support API Level 10 and older, you will want to call `getSurfaceHolder().getType(SurfaceHolder.SURFACE_TYPE_PUSH_BUFFERS)` on the SurfaceView. A “push buffers” SurfaceView is one designed to have images pushed to the surface, usually from video playback or camera previews. A SurfaceHolder is a quasi-controller object for the SurfaceView — most interactions with the SurfaceView come by way of the SurfaceHolder. This bit of configuration is not needed on API Level 11 and higher, as Android handles it for us automatically as the SurfaceView is put to use.

### TextureView for the Camera

SurfaceView, however, has some limitations. This is mostly tied back to the way it works, by “punching a hole” in the UI to allow some lower-level component (like the camera) to render stuff into it. While there is a transparent layer on top of this “hole”, for use in alpha-compositing in any overlapping widgets, the SurfaceView *content* is not rendered as part of the normal view hierarchy. The net effect is that you cannot readily move, animate, or otherwise transform a SurfaceView.

TextureView was added in API Level 14 and works for camera previews as of API Level 15. TextureView serves much the same role as does SurfaceView, for showing camera previews, playing videos, or rendering OpenGL scenes. However, TextureView behaves as a regular View and so therefore can be animated and such without issue.

However, the cost is in performance. TextureView relies upon the GPU to do more

work, and therefore `TextureView` is a bit less performant than is a `SurfaceView`. Most camera apps will not show a difference.

### Showing the Previews

To show previews, you need to create your surface (`SurfaceView` or `TextureView`) and have it be part of your UI. Then, you can teach your opened camera to show previews on that surface.

#### **`android.hardware.Camera`**

The biggest thing that we need to do in the original camera API to configure the preview is determine what size of preview images should be used. Devices cannot support arbitrary-sized previews. Instead, we need to ask the camera what preview sizes it supports, choose one, then configure the camera to use that specific preview size.

To do any of this, we need the `Camera.Parameters` associated with our chosen and open `Camera`. `Camera.Parameters` serves two roles:

- It tells us what is possible, in terms of camera capabilities, above and beyond the limited information reported by `Camera.Info`
- It is where we stipulate what behavior we want, by updating the parameters and associating the updated parameters with the `Camera`

Getting the `Camera.Parameters` object from a `Camera` is a simple matter of calling `getParameters()`.

To find out what the valid preview sizes are, we can call `getSupportedPreviewSizes()` on the `Camera.Parameters` object. This will return a `List` of `Camera.Size` objects, with each `Camera.Size` holding a width and a height as integers.

Choosing a preview size is a bit of an art form. Too big of a preview size is wasteful from a performance standpoint. Too small of a preview size results in a grainy preview. And, as will be seen [later in this chapter](#), the difference in aspect ratio between your surface and your preview size will need to be taken into account. We will explore choosing preview sizes a bit more [later in this chapter](#). For the moment, assume that we have sifted through the available preview sizes and have chosen something suitable. Whatever size you choose, you can pass to `setPreviewSize()` on the `Camera.Parameters`.

---

## WORKING DIRECTLY WITH THE CAMERA

---

Then, you can call `setParameters()` on the Camera, passing in your modified `Camera.Parameters` object, to affect this change.

You will wind up with a block of code resembling:

```
Camera.Parameters parameters=camera.getParameters();
Camera.Size previewSize=chooseSomePreviewSize(parameters.getSupportedPreviewSizes());

parameters.setPreviewSize(previewSize.width, previewSize.height);

camera.setParameters(parameters);
```

(where `chooseSomePreviewSize()` is a method of your own design)

Given that, in principle, there are just three more steps:

1. Attach your preview surface to the Camera by calling `setPreviewDisplay()` (if you are using a `SurfaceView`) or `setPreviewTexture()` (if you are using a `SurfaceTexture`)
2. Show the preview on-screen by calling `startPreview()` on the Camera
3. Stop showing the preview by calling `stopPreview()` on the Camera

However, timing is important.

You also cannot call `setPreviewDisplay()` or `startPreview()` before your preview surface is ready. To know when *that* is, you will need to register a listener with your surface:

- You can register a `SurfaceHolder.Callback` with the `SurfaceHolder` of your `SurfaceView` by calling `addCallback()` on the `SurfaceHolder`. Your `SurfaceHolder.Callback` will be called with `surfaceChanged()` when the surface is ready for use, at which point it is safe to call `setPreviewDisplay()` and `startPreview()`.
- You can register a `TextureView.SurfaceTextureListener` with your `TextureView` by means of the `setSurfaceTextureListener()` call. Your `TextureView.SurfaceTextureListener` will be called with `onSurfaceTextureAvailable()` at the point in time when it is safe to call `setPreviewTexture()` and `startPreview()`.

You also need to stop the preview before you `release()` the Camera. And, as we will see [later in this chapter](#), you also need to restart your preview after taking a photo.

### android.hardware.camera2

Once the camera is opened — even right from within the `onOpened()` method of your `CameraDevice.StateCallback` — you can request to have preview frames be pushed to your desired preview surface.

First, strangely enough, you are going to need to choose the resolution of the picture that you wish to take. You might think that this would be delayed until a later point, such as when we actually go to take a picture, but the API seems to want it right away.

To find out the possible resolutions, you need to request a `StreamConfigurationMap` from the `CameraCharacteristics`:

```
CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map=
    cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
```

(where `cameraId` is the ID of the camera that you are working with)

From there, you can get an array of `Size` objects via a call to `getOutputSizes()`. Curiously, `getOutputSizes()` takes a Java class object, identifying the use case for the frames to be generated by the camera. So, passing `SurfaceTexture.class` would give you preview frame resolutions, but passing `ImageFormat.JPEG` would give you picture resolutions (at least, for images to be encoded in JPEG format).

So, you can get your roster of available picture sizes via:

```
CameraCharacteristics cc=mgr.getCameraCharacteristics(cameraId);
StreamConfigurationMap map=
    cc.get(CameraCharacteristics.SCALER_STREAM_CONFIGURATION_MAP);
Size[] rawSizes=map.getOutputSizes(ImageFormat.JPEG);
```

From there, you will need to choose a size. This process can be a bit interesting; some notes about it appear [later in this chapter](#). But, for example, you might choose the size that is the highest resolution, as determined by the total area (width times height).

Next, you are going to need to set up an `ImageReader`. Typically this is done via the `newInstance()` factory method, which takes four parameters:

- The width and height of the desired resolution of the *picture* that you wish

## WORKING DIRECTLY WITH THE CAMERA

---

to later take with the camera

- The image format to use (e.g., `ImageFormat.JPEG`) for those pictures
- How many simultaneous frames will be needed (typical value: 2)

```
ImageReader reader=ImageReader.newInstance(pictureSize.getWidth(),  
    pictureSize.getHeight(), pictureFormat, 2);
```

Then, you need a `Surface` associated with your preview surface. For example, you can call `getSurfaceTexture()` on a `TextureView` to get a `SurfaceTexture`, then pass it to the `Surface` constructor to get the associated `Surface` object.

Next, you can call `createCaptureSession()` on the `CameraDevice` representing the opened camera. This takes three parameters:

- An `ArrayList` of `Surface` objects, for every places that the camera driver needs to route frames towards. Typically, you will have two elements in this list: the `Surface` for your preview surface and the `Surface` that you get from your `ImageReader` by calling `getSurface()` on it.
- A `CameraCaptureSession.StateCallback` instance, to be notified about state changes in the frame-capturing process
- The `Handler` tied to your `HandlerThread`

```
cameraDevice  
    .createCaptureSession(Arrays.asList(surface, reader.getSurface()),  
        new PreviewCaptureSession(), handler);
```

(where `PreviewCaptureSession` is some subclass of `CameraCaptureSession.StateCallback`)

That actually does not begin the previews. Instead, it configures the camera to indicate that it is possible to do previews.

To continue the work for getting the previews rolling, in the `onConfigured()` callback method on your `CameraCaptureSession.StateCallback`, you can create a `CaptureRequest.Builder` that you can use for configuring the camera to capture preview frames. You get one of those by calling `createCaptureRequest()` on the `CameraDevice`, passing in an `int` indicating the general type of request that you are creating, such as `TEMPLATE_PREVIEW` for preview frames:

```
CaptureRequest.Builder b=  
    cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);
```

## WORKING DIRECTLY WITH THE CAMERA

---

You then call `addTarget()` on the Builder, supplying the Surface onto which the captured frames will be written. For previews, that target is the Surface associated with your preview surface.

You can also call `set()` on the Builder to configure various options that you would like for the camera, such as auto-focus modes, flash modes, and the like. The code snippet shown below demonstrates setting up “continuous picture” auto-focus mode and having the auto-exposure mode engage the flash as needed.

Eventually, you ask the `CaptureRequest.Builder` to `build()` you a `CaptureRequest`, and you pass that to `setRepeatingRequest()` on the `CameraCaptureSession` that is passed into `onConfigure()` of your `CameraCaptureSession.StateCallback`:

```
@Override
public void onConfigured(CameraCaptureSession session) {
    try {
        CaptureRequest.Builder b=
            cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_PREVIEW);

        b.addTarget(surface);
        b.set(CaptureRequest.CONTROL_AF_MODE,
            CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
        b.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

        // other Builder configuration goes here

        CaptureRequest previewRequest=b.build();

        session.setRepeatingRequest(previewRequest, null, handler);
    }
    catch (CameraAccessException e) {
        // do something
    }
    catch (IllegalStateException e) {
        // do something
    }
}
```

`setRepeatingRequest()` takes three parameters:

- the `CaptureRequest` created by the Builder
- an optional `CameraCaptureSession.CaptureCallback` object to be notified about frame captures
- the Handler associated with your `HandlerThread`

Note that you will want to hold onto the `CaptureRequest.Builder` that you created here, as you will want it again when it comes time to take a picture.

When you go to `close()` the `CameraDevice`, before you do so, you must also close up the previews. You do this by calling `close()` on the `CameraCaptureSession` and `close()` on your `ImageReader`.

### Taking a Picture

At some point, you will want to take a picture. Typically, this is based on user input, though it would not have to be. Taking a picture not only involves telling the camera to capture a picture (typically at a different resolution than the previews), but also to arrange to get that written out to disk somewhere as a JPEG file.

#### **android.hardware.Camera**

Taking a photo with a `Camera` is a matter of calling `takePicture()` on the `Camera` object. There are two flavors of `takePicture()`, for which three parameters are in common:

- a `Camera.ShutterCallback`, which will be called the moment the picture is taken, so that you can customize the “shutter” sound
- two `Camera.PictureCallback` objects, for raw (uncompressed) and JPEG photo data, where relatively few devices support raw images using the original camera API

The four-parameter version of `takePicture()` also takes a third `Camera.PictureCallback`, to be called when “a scaled, fully processed postview image is available”. This explanation probably means something to somebody, but the author of this book has no idea what it means.

You cannot call `takePicture()` until *after* `startPreview()` has been called to set up a preview pane. `takePicture()` will automatically stop the preview. At some point, if you want to be able to take another photo, you will need to call `startPreview()` again. Note, though, that you *cannot* call `startPreview()` until after the final compressed photo has been delivered to your `Camera.PictureCallback` object.

Before you call `takePicture()`, you are going to want to adjust the `Camera.Parameters` to configure how the photo should be taken. The primary setting to adjust is the size of the picture to take. Just as you ask `Camera.Parameters` for available preview sizes and choose one, you can call

## WORKING DIRECTLY WITH THE CAMERA

---

`getSupportedPictureSizes()`, which returns a List of `Camera.Size` objects. You can then choose a size and pass its width and height to `setPictureSize()` on the `Camera.Parameters`. Other things to potentially adjust include:

- flash mode (`getSupportedFlashModes()` and `setFlashMode()`)
- focus mode (`getSupportedFocusModes()` and `setFocusMode()`)
- white balance (`getSupportedWhiteBalance()` and `setWhiteBalance()`)
- geo-tagging (`setGpsLatitude()`, `setGpsLongitude()`, `setGpsAltitude()`, etc.)
- JPEG image quality (`setJpegQuality()`)
- and so on

Note that calling `setParameters()` multiple times seems to lead to camera instability. Ideally, you collect all your desired settings from the user up front, then call `setParameters()` once when you set up your preview size. If you need to change parameters, you may wish to consider closing and re-opening the camera.

The `Camera.PictureCallback` will be called with `onPictureTaken()` and will be handed a byte array representing the picture. Typically, you will supply a `PictureCallback` for JPEG images, and so the byte array will represent the photo encoded in JPEG. At this point, you can hand that byte array off to a background thread to write it to disk, upload it to some server, or whatever else you planned to do with the picture.

Note that one thing you cannot readily do with the picture is hand it to another activity. There is a 1MB limit on the size of an Intent used with `startActivity()`, and usually the JPEG will be bigger than that. Hence, you cannot readily pass the picture via an Intent extra to another activity. If at all possible, use fragments or something else to keep all your relevant bits of UI together in a single activity, rather than try to get the images from activity to activity.

### **android.hardware.camera2**

First, you should attach an `ImageReader.OnImageAvailableListener` instance to your `ImageReader`, using `setOnImageAvailableListener()`.

`ImageReader.OnImageAvailableListener` is an interface; you will be called with `onImageAvailable()` when a new image is delivered to the `ImageReader`. We will come back to that `onImageAvailable()` method after quite a bit of additional coding.

Next, given the `CaptureRequest.Builder` you created when you set up the previews,

## WORKING DIRECTLY WITH THE CAMERA

---

you need to adjust the builder to lock the auto-focus (assuming that auto-focus is enabled):

```
b.set(CaptureRequest.CONTROL_AF_TRIGGER,  
    CameraMetadata.CONTROL_AF_TRIGGER_START);
```

At that point, you can build() a fresh CaptureRequest and call setRepeatingRequest() on the CameraCaptureSession, to change the previews to switch to a locked focus:

```
captureSession.setRepeatingRequest(b.build(),  
    new RequestCaptureTransaction(),  
    handler);
```

Here, RequestCaptureTransaction is a subclass of CameraCaptureSession.CaptureCallback, so you can be notified of how the auto-focus locking is proceeding. You wind up having to implement a fairly convoluted state machine to eventually find out it is time to take a picture... or possibly to ask for a “precapture trigger” to start on the auto-exposure system:

```
private class RequestCaptureTransaction extends CameraCaptureSession.CaptureCallback {  
    private final Session s;  
    boolean isWaitingForFocus=true;  
    boolean isWaitingForPrecapture=false;  
    boolean haveWeStartedCapture=false;  
  
    RequestCaptureTransaction(CameraSession session) {  
        this.s=(Session)session;  
    }  
  
    @Override  
    public void onCaptureProgressed(CameraCaptureSession session,  
        CaptureRequest request, CaptureResult  
partialResult) {  
        capture(partialResult);  
    }  
  
    @Override  
    public void onCaptureFailed(CameraCaptureSession session, CaptureRequest request,  
        CaptureFailure failure) {  
        // TODO: raise event  
    }  
  
    @Override  
    public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest
```

## WORKING DIRECTLY WITH THE CAMERA

---

```
request, TotalCaptureResult result) {
    capture(result);
}

private void capture(CaptureResult result) {
    if (isWaitingForFocus) {
        isWaitingForFocus=false;

        int autoFocusState=result.get(CaptureResult.CONTROL_AF_STATE);

        if (CaptureResult.CONTROL_AF_STATE_FOCUSED_LOCKED == autoFocusState ||
            CaptureResult.CONTROL_AF_STATE_NOT_FOCUSED_LOCKED == autoFocusState) {
            Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

            if (state == null ||
                state == CaptureResult.CONTROL_AE_STATE_CONVERGED) {
                isWaitingForPrecapture=false;
                haveWeStartedCapture=true;
                capture(s);
            }
            else {
                isWaitingForPrecapture=true;
                precapture();
            }
        }
    }
    else if (isWaitingForPrecapture) {
        Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

        if (state == null ||
            state == CaptureResult.CONTROL_AE_STATE_PRECAPTURE ||
            state == CaptureRequest.CONTROL_AE_STATE_FLASH_REQUIRED) {
            isWaitingForPrecapture=false;
        }
    }
    else if (!haveWeStartedCapture) {
        Integer state=result.get(CaptureResult.CONTROL_AE_STATE);

        if (state == null ||
            state != CaptureResult.CONTROL_AE_STATE_PRECAPTURE) {
            haveWeStartedCapture=true;
            capture();
        }
    }
}

private void precapture() {
    try {
```

## WORKING DIRECTLY WITH THE CAMERA

---

```
b.set(CaptureRequest.CONTROL_AE_PRECAPTURE_TRIGGER,
      CaptureRequest.CONTROL_AE_PRECAPTURE_TRIGGER_START);
s.captureSession.capture(b.build(), this, handler);
}
catch (Exception e) {
    // do something
}
}

private void capture() {
    try {
        CaptureRequest.Builder captureBuilder=
            cameraDevice.createCaptureRequest(CameraDevice.TEMPLATE_STILL_CAPTURE);

        captureBuilder.addTarget(reader.getSurface());
        captureBuilder.set(CaptureRequest.CONTROL_AF_MODE,
            CaptureRequest.CONTROL_AF_MODE_CONTINUOUS_PICTURE);
        captureBuilder.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);

        captureSession.stopRepeating();
        captureSession.capture(captureBuilder.build(),
            new CapturePictureTransaction(), null);
    }
    catch (Exception e) {
        // do something
    }
}
}
```

The author of this book wishes he understood what all this stuff is for.

But, eventually, it will be time to take the picture, represented by the `capture()` method in the above code dump. Here, we create a new `CaptureRequest.Builder`, this time using `TEMPLATE_STILL_CAPTURE` to indicate that we are trying to take a picture. We set up our target (via `addTarget()`) to be the `Surface` from the `ImageReader`. We re-establish our desired auto-focus and auto-exposure modes. Then, we stop the previews, by calling `stopRepeating()` on the `CameraCaptureSession`, undoing the prior `setRepeatingRequest()` call where we asked for previews. Then, we call `capture()` on the `CameraCaptureSession`, requesting a single-frame capture rather than a repeating request. This, like `setRepeatingRequest()`, takes our `CaptureRequest` from the `Builder`, a `CameraCaptureSession.CaptureCallback` to find out the results of the capture work, and our `Handler`.

---

## WORKING DIRECTLY WITH THE CAMERA

---

The primary job of this `CameraCaptureSession.CaptureCallback` is to restart the previews, in `onCaptureCompleted()`. First, we use the preview edition of the `CaptureRequest.Builder` to undo some of the changes made during the camera capture process. Then, given the original preview `CaptureRequest`, we call `setRepeatingRequest()` again, to get the previews showing once more:

```
@Override
public void onCaptureCompleted(CameraCaptureSession session, CaptureRequest request,
    TotalCaptureResult result) {
    try {
        b.set(CaptureRequest.CONTROL_AF_TRIGGER,
            CameraMetadata.CONTROL_AF_TRIGGER_CANCEL);
        b.set(CaptureRequest.CONTROL_AE_MODE,
            CaptureRequest.CONTROL_AE_MODE_ON_AUTO_FLASH);
        s.captureSession.capture(b.build(), null, handler);
        s.captureSession.setRepeatingRequest(previewRequest, null, handler);
    }
    catch (CameraAccessException e) {
        // do something
    }
    catch (IllegalStateException e) {
        // do something
    }
}
```

As part of all of this work, your `onImageAvailable()` method on your `ImageReader.OnImageAvailableListener` will be called when the picture is ready. The recipe for getting your JPEG image looks like this:

```
@Override
public void onImageAvailable(ImageReader imageReader) {
    Image image=imageReader.acquireNextImage();
    ByteBuffer buffer=image.getPlanes()[0].getBuffer();
    byte[] bytes=new byte[buffer.remaining()];

    buffer.get(bytes);
    image.close();

    // do something with the byte[] of JPEG data
}
```

Here, you are subject to the same sorts of limitations as were described in the section on taking pictures with the original camera API. Notably, that byte array may be large, too large to put into an `Intent` extra and pass to another activity.

### Recording a Video

Traditional Android video recording is handled via `MediaRecorder`. This means that we need to hand control over the camera from the regular camera API that we are using to `MediaRecorder`, record the video, and then return control back to the camera API (e.g., for previews).

`MediaRecorder` itself then has its own API for configuring the recorder, starting the recording, and stopping the recording.

#### `android.hardware.Camera`

To retain the camera access for your app, but allow `MediaRecorder` to take over the camera, call `stopPreview()`, then `unlock()`, on the `Camera` object:

```
camera.stopPreview();
camera.unlock();
```

When the recording is complete, you reverse the process, by calling `reconnect()` and `startPreview()`:

```
camera.reconnect();
camera.startPreview();
```

In between the `unlock()` and `reconnect()` calls is when you use the `MediaRecorder` API.

#### `android.hardware.camera2`

This particular combination (video recording with the Android 5.0+ camera API) will be covered in a future edition of this chapter.

### Using `MediaRecorder`

Creating a `MediaRecorder` instance is simple enough: just use the zero-argument constructor.

You then need to tell it what camera to use. With the original camera API, that is a matter of calling `setCamera()` on the `MediaRecorder`, passing in your `Camera` object.

```
MediaRecorder recorder=new MediaRecorder();
```

## WORKING DIRECTLY WITH THE CAMERA

---

```
recorder.setCamera(camera);
```

Next, call `setAudioSource()` and `setVideoSource()` to indicate where the audio and video to be recorded are coming from. The typical value to use for the audio source is `CAMCORDER`. For the original camera API, you will need to use `CAMERA` as the video source:

```
recorder.setAudioSource(MediaRecorder.AudioSource.CAMCORDER);
recorder.setVideoSource(MediaRecorder.VideoSource.CAMERA);
```

Next, you need to configure how the video should be recorded, in terms of things like resolution. The typical approach using the original camera API is to use `setProfile()`, passing in a `CamcorderProfile` to the `MediaRecorder`. You can find out what profiles are supported by calling methods like `hasProfile()` on `CamcorderProfile`. There are some fairly generic profiles, like `QUALITY_HIGH` and `QUALITY_LOW`, and some fairly specific profiles, like `QUALITY_2160P` for 2K video. Not all devices will support all profiles, based on Android version and camera driver capabilities. So, you will need to be responsive to varying cameras and gracefully degrade from the profile you want to a profile that you can get. For example, the following code snippet tries `QUALITY_HIGH`, falls back to `QUALITY_LOW` if `QUALITY_HIGH` is not available, and bails out if neither of those profiles exist:

```
boolean canGoHigh=CamcorderProfile.hasProfile(cameraId,
    CamcorderProfile.QUALITY_HIGH);
boolean canGoLow=CamcorderProfile.hasProfile(cameraId,
    CamcorderProfile.QUALITY_LOW);

if (canGoHigh) {
    recorder.setProfile(CamcorderProfile.get(cameraId,
        CamcorderProfile.QUALITY_HIGH));
}
else if (canGoLow) {
    recorder.setProfile(CamcorderProfile.get(cameraId,
        CamcorderProfile.QUALITY_LOW));
}
else {
    throw new IllegalStateException(
        "cannot find valid CamcorderProfile");
}
```

Here, `cameraId` is the `int` identifying your open camera.

Then, you can configure:

## WORKING DIRECTLY WITH THE CAMERA

---

- the file path to which the resulting video should be written
- the maximum file size you want, after which recording will automatically stop (optional)
- the maximum duration that you want, after which recording will automatically stop (optional)
- a hint for what orientation the video should be recorded in (optional)

```
recorder.  
    setOutputFile(new File(getExternalFilesDir(null), FILENAME).getAbsolutePath());  
recorder.setMaxFileSize(5000000); // ~5MB max  
recorder.setMaxDuration(10000); // ~10 seconds max  
recorder.setOrientationHint(90); // rotate output 90 degrees
```

Optionally, you can call `setInfoListener()` and `setErrorListener()`, supplying objects that will be invoked when certain events occur. Notably, if you use `setMaxFileSize()` or `setMaxDuration()`, the `OnInfoListener` object will be notified when recording automatically stops due to reaching one of those limits.

You then call `prepare()`, followed by `start()`, and your video recording will commence:

```
recorder.prepare();  
recorder.start();
```

When it comes time to stop the recording manually (e.g., user taps a “stop” button), just call `stop()`, then `release()`, on the `MediaRecorder`.

## Configuring the Still Camera

In general, when using the camera classes in Android, you get reasonable defaults for things like focus mode and flash mode. However, what might be reasonable defaults may not be what the user wants in any given circumstance. Other bits of configuration, like zoom, cannot really be defaulted (other than to “no zoom”).

For these, you will need to provide some sort of UI to allow the user to request settings, then apply them as part of your camera implementation. Here, we will focus on applying the configuration.

(and, yes, that was a pun)

### Focus Mode

Frequently, a user will want simple autofocus behavior, where the camera attempts to focus on the content centered within the preview. However, in some situations, the user may want autofocus to be disabled, turning the camera into a fixed-focus camera. And there are some specialty focus modes that may be available to you as well, depending upon device and camera API.

Here is how you can set up the camera to use one of those focus modes, for each of the camera APIs.

#### **android.hardware.Camera**

The `Camera.Parameters` object has a `getSupportedFocusModes()` method. This returns a `List` of `String` objects, where each value corresponds to a focus mode that is available on this camera (front-facing, rear-facing) on this device. The possible strings are defined as constants on `Camera.Parameters`:

- `FOCUS_MODE_AUTO`
- `FOCUS_MODE_CONTINUOUS_PICTURE`
- `FOCUS_MODE_CONTINUOUS_VIDEO`
- `FOCUS_MODE_EDOF` (“extended depth of field”)
- `FOCUS_MODE_FIXED`
- `FOCUS_MODE_INFINITY`
- `FOCUS_MODE_MACRO`

In truth, few devices support all of these. However, every device will support at least one; `getSupportedFocusModes()` is guaranteed to not return `null` and not return an empty `List`.

To choose a focus mode, call `setFocusMode()` on the `Camera.Parameters`, supplying the string of the desired mode. And, of course, you will eventually need to call `setParameters()` on the `Camera`, supplying your modified `Camera.Parameters`.

#### **android.hardware.camera2**

Similarly, you can get a list of supported auto-focus modes by calling `get(CameraCharacteristics.CONTROL_AF_AVAILABLE_MODES)` on a `CameraCharacteristics` object tied to your chosen camera. This returns an array of `int` values, instead of a `List` of strings. The possible values are defined as constants

on `CameraMetadata`:

- `CONTROL_AF_MODE_AUTO`
- `CONTROL_AF_MODE_CONTINUOUS_PICTURE`
- `CONTROL_AF_MODE_CONTINUOUS_VIDEO`
- `CONTROL_AF_MODE_EDOF` (“extended depth of field”)
- `CONTROL_AF_MODE_MACRO`
- `CONTROL_AF_MODE_OFF`

After the user chooses a value, you will need to call `set(CaptureRequest.CONTROL_AF_MODE, ...)` on your `CaptureRequest.Builder`, where `...` is the `int` of the desired focus mode. Note that you will need to do this both for the `CaptureRequest.Builder` for preview frames and for the `CaptureRequest.Builder` used when you take an actual picture. If the user is changing this value while you are already showing the preview, you will need to update the preview behavior, by calling `build()` on the `Builder` to create the `CameraRequest`, then calling `setRepeatingRequest()` to override your previous `CameraRequest` with the new one with the new focus mode. As a result, you tend to want to hang onto your `CameraRequest.Builder` for previews, so you can make these sorts of incremental changes in behavior, without having to create a fresh `Builder` from scratch with all of the desired settings.

### Flash Mode

Typically, users want flash when they need flash, due to insufficient ambient lighting. However, once again, they may want specific flash modes instead (definitely flash, definitely *not* flash, etc.).

As with focus modes, you can ask the camera APIs what flash modes are available for a given camera. In this case, though, there is no guarantee of any flash mode configurability, since not all cameras have flash (and Android considers “off” and “flash does not exist” to be different things). And, once the user has chosen a flash mode, you can configure the camera APIs to use that particular mode.

Of course, the details vary by camera API.

#### **android.hardware.Camera**

`Camera.Parameters` has `getSupportedFlashModes()`, which returns a `List` of strings representing the supported flash modes, or `null` if flash modes cannot be configured

for this camera. The string values map to constants defined on `Camera.Parameters`:

- `FLASH_MODE_AUTO`
- `FLASH_MODE_OFF`
- `FLASH_MODE_ON`
- `FLASH_MODE_RED_EYE` (“red-eye reduction mode”)

There is an additional flash mode, `FLASH_MODE_TORCH`, that will keep the flash during the preview as well as flashing it during the actual act of taking the picture. In truth, this setting is more often used for flashlight apps.

Once the user has chosen a flash mode, you can call `setFlashMode()` on the `Camera.Parameters`, then eventually call `setParameters()` on the `Camera`.

### **android.hardware.camera2**

To find out what flash modes are available for a camera2 camera, you can call `get(CameraCharacteristics.CONTROL_AE_AVAILABLE_MODES)` on the `CameraCharacteristics` for the camera in question. This returns an array of `int` values, mapping to constants defined on `CameraCharacteristics`:

- `CONTROL_AE_MODE_ON` (which really means “off”)
- `CONTROL_AE_MODE_ON_ALWAYS_FLASH`
- `CONTROL_AE_MODE_ON_AUTO_FLASH`
- `CONTROL_AE_MODE_ON_AUTO_FLASH_REDEYE`

Here, AE is short for “auto-exposure”. `CONTROL_AE_MODE_ON` says that auto-exposure is enabled, just without any flash. There is a separate `CONTROL_AE_MODE_OFF` which totally disables the auto-exposure capability. However, that will screw up auto-focus and auto-white balance, and so rarely will camera apps want to use `CONTROL_AE_MODE_OFF`.

Once the user chooses the desired flash mode, you can call `set(CaptureRequest.CONTROL_AE_MODE, ...)` on your `CaptureRequest.Builder` object, where `...` is the desired flash mode `int`. You will need to do this both for the preview `Builder` and the `Builder` used when actually taking the picture. If the user is changing this value on the fly, you will need to update the preview behavior, by calling `build()` on the `Builder` to create the `CameraRequest`, then calling `setRepeatingRequest()` to override your previous `CameraRequest` with the new flash-enabled one.

### Zoom

Flash and focus modes might be the sort of thing that the user could choose before you start up your camera preview, let alone take a picture. Zoom, on the other hand, is the sort of thing that the user will want to adjust on the fly, based on what they see in the preview.

Hence, your first challenge with implementing a zoom feature is deciding how you want users to indicate that they want to zoom in or out, given that probably most of your screen space is taken up by the preview itself. Options include:

- Float a `SeekBar` over the preview along an edge, where the user can slide the thumb or tap on the bar to move the thumb to indicate an increase or decrease in the zoom
- Use a pinch-zoom gesture, via `ScaleGestureDetector`
- Use some other gesture, such as a vertical swipe, using a `GestureDetector`
- Have a pair of buttons to increase or decrease the zoom

Both Android camera APIs have the notion of a numeric zoom level. The bottom end of the zoom range is either 0 (for the classic camera API) or 1 (for the camera2 API). The top end is found by from the camera APIs. Your job will be to convert whatever input signals you get from the user into a zoom level, then update the camera settings to zoom to that setting.

The code segments shown in this section assume that your input is giving you a zoom level in the 0-100 range, such as via a `SeekBar` with the default maximum value.

#### **`android.hardware.Camera`**

`Camera.Parameters` offers several methods related to zoom.

The big one is `isZoomSupported()`. `false` means that the camera does not offer any sort of zoom (digital or optical). You might use that to disable your zoom input option, so as not to offer something to the user that will not work. Few devices will return `false`, though.

Assuming `isZoomSupported()` is true, then `getMaxZoom()` will tell you the highest possible zoom value. Your overall range of zoom values will be from 0 to this maximum.

## WORKING DIRECTLY WITH THE CAMERA

---

If you are using some form of user input that only indicates incremental changes in zoom (e.g., buttons for zoom in and zoom out), you can use `getZoom()` to find out the current zoom value. You can then increment or decrement that value and check your new value against the ends of the range (0 and `getMaxZoom()`) to ensure that it is valid.

Given a new zoom value, you have two choices for applying it:

- `setZoom()` on `CameraParameters` does a “smash cut”, jumping to the new zoom value immediately upon applying those parameters to the camera via `setParameters()`.
- `startSmoothZoom()` on `Camera` will “animate” the zoom change from the current to the new value over a period of a second or two. However, not all devices support this. Call `isSmoothZoomSupported()` on the `Camera.Parameters` to see if smooth zoom is available to you.

The following code snippet takes a zoom level from 0 to 100 and zooms the camera, assuming zoom is supported:

```
@Override
public boolean zoomTo(Camera camera, int zoomLevel) {
    Camera camera=descriptor.getCamera();
    Camera.Parameters params=camera.getParameters();
    int zoom=zoomLevel*params.getMaxZoom()/100;
    boolean result=false;

    if (params.isSmoothZoomSupported()) {
        camera.setZoomChangeListener(this);
        camera.startSmoothZoom(zoom);
        result=true;
    }
    else if (params.isZoomSupported()) {
        params.setZoom(zoom);
        camera.setParameters(params);
    }

    return(result);
}
```

You will notice that if `isSmoothZoomSupported()` returns true, we not only call `startSmoothZoom()`, but we also call `setZoomChangeListener()`. This registers a listener to find out about how the smooth zoom is progressing. In particular, you should disable further changes to the zoom until the smooth zoom process completes. Your `OnZoomChangeListener` will be called with `onZoomChange()` for each

## WORKING DIRECTLY WITH THE CAMERA

---

incremental change in the zoom from start to finish, with `stopped` set to `true` when we are done with the smooth zoom operation:

```
@Override
public void onZoomChange(int zoomValue, boolean stopped,
                        Camera camera) {
    if (stopped) {
        // do something
    }
}
```

If you need to stop the smooth zoom before completion, there is a `stopSmoothZoom()` method on `Camera` that you can call. For example, instead of disabling zoom controls, you might stop the current smooth zoom operation if the user chooses a new zoom level, then start a fresh smooth zoom operation to the newly-requested level.

### **android.hardware.camera2**

(the author would like to thank Daniel Albert for [helping](#) with this section)

On the surface, the `camera2` API works much the same: you find out the maximum zoom value, translate your user input into the valid zoom value range (this time, from `1.0f` to the maximum), and then update the camera for that zoom value.

However, that last step is substantially different than before.

For digital zoom, rather than saying “zoom in to this value”, we say “crop the camera inputs to this rectangle, and expand that rectangle to fill the preview or the picture”. This is rather more complex, albeit with potentially more power.

To find out the maximum digital zoom value, call `get(CameraCharacteristics.SCALER_AVAILABLE_MAX_DIGITAL_ZOOM)` on the `CameraCharacteristics` for the camera in question. That will be a float value. `1.0f` would indicate that the camera cannot perform digital zoom. The range of possible digital zoom values is from `1.0f` to whatever the maximum is.

So, the first part of this edition of `zoomTo()` normalizes a 0-100 integer into a float representing the zoom value:

```
@Override
public boolean zoomTo(String cameraId,
```

## WORKING DIRECTLY WITH THE CAMERA

---

```
        CaptureRequest.Builder previewRequestBuilder,
        CameraCaptureSession captureSession,
        int zoomLevel) {
    try {
        final CameraCharacteristics cc=
            mgr.getCameraCharacteristics(cameraId);
        final float maxZoom=
            cc.get(
                CameraCharacteristics.SCALER_AVAILABLE_MAX_DIGITAL_ZOOM);

        // if <=1, zoom not possible, so eat the event
        if (maxZoom>1.0f) {
            float zoomTo=1.0f+((float)zoomLevel*(maxZoom-1.0f)/100.0f);

            zoomRect=cropRegionForZoom(cc, zoomTo);

            previewRequestBuilder
                .set(CaptureRequest.SCALER_CROP_REGION, zoomRect);
            previewRequest=previewRequestBuilder.build();
            captureSession.setRepeatingRequest(previewRequest,
                null, handler);
        }
    }
    catch (CameraAccessException e) {
        // ummm... do something
    }

    return(false);
}
```

Given a zoom value, we need to determine the Rect that represents the subset of the field of vision that we want to zoom into. The following algorithm zooms into the center of the field:

```
private static Rect cropRegionForZoom(CameraCharacteristics cc,
                                       float zoomTo) {
    Rect sensor=
        cc.get(CameraCharacteristics.SENSOR_INFO_ACTIVE_ARRAY_SIZE);
    int sensorCenterX=sensor.width()/2;
    int sensorCenterY=sensor.height()/2;
    int deltaX=(int)(0.5f*sensor.width()/zoomTo);
    int deltaY=(int)(0.5f*sensor.height()/zoomTo);

    return(new Rect(
        sensorCenterX-deltaX,
        sensorCenterY-deltaY,
        sensorCenterX+deltaX,
```

```
sensorCenterY+deltaY));  
}
```

That Rect then gets used:

- Immediately, via a call to `set()` on the `CaptureRequest.Builder`, to set the `SCALER_CROP_REGION`. That Builder then is used to re-establish the preview repeating capture request.
- At the point in time when the user requests to take a picture. We will need to call `set()` on *that* `CaptureRequest.Builder`, to reproduce the same zoom.
- Later, if we have to set up the preview capture request again and we still want this zoom value taken into account.

Note that this does not cover optical zoom. On Android 5.0, that is handled as available focal lengths. You can get the list of available focal lengths by requesting `LENS_INFO_AVAILABLE_FOCAL_LENGTHS` from the `CameraCharacteristics`. Setting `LENS_FOCAL_LENGTH` on a `CaptureRequest.Builder` will shift the camera's focal length as requested. This may take a moment, as optical zoom usually requires mechanical changes in the camera configuration. The `LENS_STATE` (on `CaptureResult`) will be reported as `MOVING` while the focal length is changing, or `STATIONARY` once the focal length has reached the requested value.

## And Now, The Problems

Of course, taking pictures is not nearly this simple. The preceding sections glossed over all sorts of problems that you will run into in practice when trying to implement these APIs. The following sections outline a few of those problems, particularly ones that will affect both camera APIs.

### Choosing a Preview Size

Camera drivers are capable of delivering preview images to your preview surface in one of several resolutions. You have to sift through a roster of resolutions and choose one.

Your gut instinct might be to choose the highest-available resolution. After all, that should result in the highest-quality previews. However, this can be wasteful, if the preview images are significantly bigger than your preview surface. Plus, the larger the preview frames, the slower the camera driver will be to deliver them, reducing your possible frames-per-second (fps) for the previews. You might instead elect to

choose the largest preview that is smaller than the surface, or some algorithm like that.

### Previews and Aspect Ratios

Compounding the problem of choosing preview sizes is that the resolutions of available preview sizes bear no relationship at all to the size of your preview surface. After all, you might have a `TextureView` that fills the screen, or you might have a `TextureView` that is rather tiny. That is up to you from a UI design standpoint; the camera driver is oblivious to such considerations.

In particular, the aspect ratios (width divided by height) of the preview frames do not necessarily have to match the aspect ratio of your preview surface. For example, few camera drivers support square previews, yet for aesthetic reasons you might be aiming for a square preview surface.

You have two main approaches for dealing with this: letterboxing and cropping.

Letterboxing is where your preview frames retain their aspect ratio, but do not fill up all the available space in the preview surface. Instead, part of the preview surface is unused. For example, if your preview surface is square, and your preview frames have a landscape aspect ratio (width is greater than the height), letterboxing would show the landscape aspect ratio within the square box of the preview surface, with black bars for the unused portion of the square's height. Typically, using gravity, you try to have the preview frames be centered and the unused portion of the surface be split to either side of the frames.

If you want to fill the preview surface, then letterboxing is not a viable option. However, if you just take the preview frames and try to put them into the surface, the surface will stretch the frames to fit the surface. If the aspect ratio of the frames is significantly different than is the aspect ratio of the surface, the subject matter in the preview will seem significantly stretched, either vertically or horizontally.

The trick to deal with this, on API Level 14+ (with graphics acceleration enabled, as is the default), is to have the surface be *bigger* than what you really want, but then to have something overlapping the surface and causing it to be visually cropped. You have your new, larger surface match the aspect ratio of the preview frames, so there is no stretching. However, now what the user sees in your preview surface may differ substantially from what winds up in the picture or video, as you are cropping off portions that do not fit your preview surface, where those cropped areas might well show up in final output.

### Choosing a Picture or Video Size

Choosing a picture or video size is reminiscent of choosing a preview size. While many cases will call for as high of a resolution as you can muster, some use cases will lead you towards choosing a lower resolution. For example, situations requiring a rapid upload of the resulting media might select a lower resolution, as that will reduce the file size and make the upload process that much faster.

Also, bear in mind that the aspect ratio of the available picture or video sizes do not necessarily match the aspect ratio of *either* the preview frames *or* your preview surface. Emphasize to your users that the preview surface is for *aiming* the camera; what actually gets recorded may be somewhat different in scope but should be centered on the same spot.

### Picture Orientation

Your app may wish to take pictures in both landscape and portrait modes. However, the camera drivers are designed around taking pictures in landscape, particularly for rear-facing cameras.

You can hint to the camera driver what orientation you think the resulting picture should have, such as via `setRotation()` on the `Camera.Parameters` in the original camera API. However, as the documentation for that method states:

The camera driver may set orientation in the EXIF header without rotating the picture. Or the driver may rotate the picture and the EXIF thumbnail. If the Jpeg picture is rotated, the orientation in the EXIF header will be missing or 1 (row #0 is top and column #0 is left side).

Many camera drivers take the approach of leaving the image alone and setting the `Orientation` EXIF header. That header tells image viewers to rotate the image. Unfortunately, not all image viewers or image decoding libraries pay attention to this. Notably, *Android* usually does not pay attention to this, as `BitmapFactory` ignores this EXIF header. As a result, when you go to load in your own picture that you took, your result may come out mis-oriented.

You have two major choices:

1. Put more smarts in any logic that you are using to display images that you take with the camera, where you read the EXIF headers yourself and you arrange to rotate the image as needed, perhaps by rotating the `ImageView`

- you are using to show the image.
2. As part of post-processing the image before saving it, you rotate the image based upon what is in the EXIF header, and save the image with the proper rotation and no EXIF header. This has the advantage of making the image “correct” for all image viewers. However, rotating full-resolution photos is rather memory-intensive and slow. Using NDK code, such as [this library](#), may be able to help.

### Storage Considerations

Bear in mind that if you wish to save pictures or videos in common locations on external storage, such as the standard location for digital camera output (`Environment.DIRECTORY_DCIM`), you will need the `WRITE_EXTERNAL_STORAGE` permission on all relevant API levels. As of Android M, this is a dangerous permission handled via the runtime permission system, so you will need to have the `<uses-permission>` element in the manifest *and* ask the user for that permission at runtime.

Also, files written out to external storage will not be picked up immediately by MediaStore, and so “gallery” and related apps that rely upon the MediaStore will not see your pictures or videos. You can use `MediaScannerConnection` to proactively have the MediaStore add your newly-created files to the index, as was covered [earlier in the book](#).

### Configuration Changes

Opening and closing a camera each takes a fair amount of time. As a result, if your app wants to support taking pictures and videos in either portrait or landscape, this is a case where you will want to strongly consider using a retained fragment to hold onto your Camera (or combination of `CameraManager` and `CameraDevice`) across a configuration change. That way, Android will not destroy and recreate the fragment, and you can keep the camera open during the change.

### Camera Peeking Attacks

(NOTE: this section is based upon [a blog post](#) from the author)

A [research paper](#) points out an interesting Android attack vector, resulting in a possible leak of private information. The paper’s authors refer to it as the “camera peeking” attack.

## WORKING DIRECTLY WITH THE CAMERA

---

An Android camera driver can only be used by one app at a time. The attack is simple:

- monitor for when an app that might use the camera for something important comes to the foreground
- at that point, start watching for the camera to become unavailable
- once the camera is unavailable, then available again, grab the camera and take a picture, in hopes that the camera is still pointing at the private information

The example cited by the paper's authors is to watch for a banking app taking a photo of a check, to try to take another photo of the check to send to those who might use the information for various types of fraud.

Polling for camera availability is slow, simply because the primary way to see if the camera is available is to open it, and that takes hundreds of milliseconds. The paper's specific technique helped to minimize the polling, by knowing when the right activity was in the foreground and therefore the camera was probably already in use. Then, it would be a matter of polling until the camera is available again and taking a picture. Even without the paper's specific attack techniques, this general attack is possible, and there may be more efficient ways to see if the camera is in use.

On the other hand, the defense is simple: if your app is taking pictures, and those pictures may be of sensitive documents, ask the user to point the camera somewhere else before you release the camera. So long as you have exclusive control over the camera, nothing else can use it, including any attackers.

A sophisticated implementation of this might use image-recognition techniques to see, based upon preview frames plus the taken picture, if the camera is pointing somewhere else. For example, a banking app offering check-scanning might determine if the dominant color in the camera field significantly changes, as that would suggest that the camera is no longer pointed at a check, since checks are typically fairly monochromatic.

Or, just ask the user to point the camera somewhere else, then close the camera after some random number of seconds.

General-purpose camera apps might offer an "enhanced security" mode that does this sort of thing, but having that on by default might annoy the user trying to take pictures at the zoo, or at a sporting event. However, document-scanning apps might want to have this mode on by default, and check-scanning apps might simply always

## WORKING DIRECTLY WITH THE CAMERA

---

use this mode.

# Media Routes

---

Android can send audio and video to a variety of places, such as:

- Bluetooth headsets or headphones
- External displays, like a TV or monitor
- External devices that themselves play back media, such as a Chromecast

There is a common API for determining which of these “places” are available and allowing the user to choose which of these “places” should be used for a given bit of media. This common API centers around a `MediaRouter`, which is the focus of this chapter.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of the book. In addition, you should read the chapters on [advanced action bar techniques](#) and [the appcompat-v7 action bar backport](#).

## Terminology

First, we need to establish some common ground in terms of..., well, terms.

### Media

In this chapter, “media” refers to audio or video. This includes both media that may be stored on the device as well as media that may be streamed from some other source, frequently over the Internet.

### Route

A route indicates where media should be played. There are three categories of routes that concern us:

- Where should we be playing live audio, in terms of speakers or headphones or other things connected to the device?
- Where should we be playing live video: on the device's own screen or on some other screen connected via a cable?
- Is there any sort of “remote playback” device available, such as a Chromecast, that can play back media on its own under our direction, rather than requiring our own app to play back the media itself?

### MediaRouter

MediaRouter is the name of a class (actually, two classes) that know what routes are possible given the current environment and what routes are selected for the different categories (by default or by user choice).

## A Tale of Two MediaRouters

MediaRouter and its related classes represent a curious API. There are two versions of the MediaRouter class related support classes that will concern you as a developer.

### **android.media**

MediaRouter debuted in Android in API Level 16, through classes added to the `android.media` package. This version of MediaRouter can work with live audio and live video routes, but not the Chromecast-style remote playback routes.

`android.media` also contains other classes that pertain to routes, such as `MediaRouteActionProvider`, a way to allow the user to choose media routes via an action bar item. The version of these classes in `android.media` work with native API Level 11 versions of the action bar and fragments.

### **android.support.v7.media**

In 2013, an update to the Android Support package was released that contained another version of MediaRouter and kin, in `android.support.v7` packages. These are contained in a dedicated Android library project that you can add to your app, found

## MEDIA ROUTES

---

in the `extras/android/support/v7/mediarouter` directory of your Android SDK installation, if you have a current Android Support package installed.

While the native version of `MediaRouter` is a system service — obtained via `getSystemService()` — the v7 version of `MediaRouter` is a singleton, obtained from a static `getInstance()` method on the `MediaRouter` class.

The good news is that this updated version of `MediaRouter` can work with all three categories of routes, including the Chromecast-style remote playback routes.

However, the bad news is that the v7 version of `MediaRouter`'s support classes only support the Android Support backports of fragments and the action bar. This requires you to inherit from `ActionBarActivity` and use the v4 version of `Fragment` and kin. This is a rather annoying limitation, considering that many developers have specifically started dropping support for older API levels to be able to *avoid* using this backport.

## Attaching to MediaRouter

To be able to take advantage of all that `MediaRouter` has to offer, we need to obtain an instance of it and connect to that instance, via method calls and registering callbacks.

### Getting a MediaRouter Instance

To get an instance of the `android.support.v7.media.MediaRouter` flavor of `MediaRouter`, call `getInstance()` on `MediaRouter`.

This is in contrast to the `android.media.MediaRouter` variant, which is a system service, obtained by calling `getSystemService()`.

Note that the `android.support.v7.media.MediaRouter` flavor is global for your process, but weakly held from a garbage collection standpoint. You need to ensure that you hold onto your instance of `MediaRouter` as long as you need it. Once your application code lets go of the `MediaRouter` instance, it becomes eligible for garbage collection, disposing of any registered callbacks and such along the way.

### Working with Routes

`MediaRouter` has a `getSelectedRoute()` method that returns the media route

chosen by the user, or the overall default if the user has not yet had a chance in your app to choose a route. This method returns a `MediaRouter.RouteInfo` object, containing details about the route. In particular, you can call `supportsControlCategory()` to determine if the route is a live audio route, a live video route, or a remote playback route, so you can take advantage of it accordingly.

There is also `getDefaultRoute()`, which, as the name suggests, returns the `MediaRouter.RouteInfo` instance that is the overall default for your app.

You can call `getRoutes()` to obtain a list of all routes known at the present time. You might use this to allow the user to choose a route, though `MediaRouteActionProvider` is generally a better choice, as will be seen [later in this chapter](#).

Given that you have a `MediaRouter.RouteInfo` instance from somewhere, you can call `selectRoute()` to make this route the active one, replacing whatever the previously-selected route was.

### Registering a Callback

You can also call `addCallback()` to provide a `MediaRouter.Callback` instance that will be invoked at various points in time based on the changes in media routes. `addCallback()` also takes a `MediaRouteSelector`, which describes what sorts of routes you are interested in. We will examine `MediaRouteSelector` in greater detail in the coverage of `MediaRouteActionProvider` [later in this chapter](#).

There are two flavors of `addCallback()`. Both take the `MediaRouteSelector` and the `MediaRouter.Callback`, but one also takes an `int` supplying flags to control the behavior of `addCallback()`. One flag of particular importance is `CALLBACK_FLAG_REQUEST_DISCOVERY`. This tells `MediaRouter` to not only set up the callback, but to attempt to find new routes previously unknown to it. Mostly, this is for remote playback routes, which require network I/O to find and are not necessarily known if not specifically scanned for.

`MediaRouter.Callback` is a class, not an interface. You create your own subclass of `MediaRouter.Callback` and override the callback methods that interest you. Some noteworthy callback methods include:

- `onRouteAdded()` and `onRouteRemoved()`, which are called when routes are newly detected or have been lost, such as when a user plugs in or unplugs an HDMI cable from the device

## MEDIA ROUTES

---

- `onRouteSelected()` is called when a new route is selected, either by the user (e.g., via `MediaRouteActionProvider`) or by you (e.g., via `selectRoute()`)
- `onRouteUnselected()` is also called when a new route is selected, but in this case, you are notified about the *old* route being unselected

When you are done with the callback, call `removeCallback()` on the `MediaRouter`, passing in the same `MediaRouter.Callback` instance you supplied to `addCallback()`.

We will see examples of using `MediaRouter.Callback` [in the next section](#).

## User Route Selection with `MediaRouteActionProvider`

To give the user some measure of control over where media is played, you can add a `MediaRouteActionProvider` to your action bar. This will add a button that, when tapped, will allow the user to choose routes of relevance to your app (live audio, live video, remote playback).

However, this does not really work the way you (or the user) might expect, simply because some routes are automatically applied by the OS. Depending upon what the Android device is connected to will determine what routes are automatically applied and which ones the user can choose via `MediaRouteActionProvider`. For example, while Android will route live video to an HDMI-connected external display automatically, the user must opt into connecting to a Chromecast for remote playback capability.

This section outlines how to use `MediaRouteActionProvider` and what the user will see for various circumstances. Most of the sections will be focusing on the [MediaRouter/ActionProvider](#) sample project.

### The Basic Project and Dependencies

The project has dependency on the `mediarouter` Android library project. Projects that need `mediarouter` will need to have access to the Android Support library from the SDK Manager and follow [the instructions to add it to your project](#). Since `mediarouter-v7` depends upon `appcompat-v7`, you will need both library projects.

The `appcompat-v7` backport of the action bar requires that your activities use a theme extending from `Theme.AppCompat`. Hence, we have a `res/values/styles.xml` resource that defines `AppTheme` in the context of

## MEDIA ROUTES

---

Theme.AppCompat.Light.DarkActionBar:

```
<resources>

  <style name="AppBaseTheme" parent="@style/Theme.AppCompat.Light.DarkActionBar"></style>

  <style name="AppTheme" parent="AppBaseTheme">
    <!-- All customizations that are NOT specific to a particular API-level can go here. -->
  </style>

</resources>
```

(from [MediaRouter/ActionProvider/app/src/main/res/values/styles.xml](#))

And our <activity> in the manifest, pointing to MainActivity, refers to that theme:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.mrap"
  android:versionCode="1"
  android:versionName="1.0">

  <application
    android:allowBackup="true"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name="com.commonware.android.mrap.MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>

</manifest>
```

(from [MediaRouter/ActionProvider/app/src/main/AndroidManifest.xml](#))

## The Menu Resource

Since `MediaRouteActionProvider` is an action provider, we can add it to our action bar via an `actionProviderClass` attribute in a menu resource. And, since the Google implementation of `MediaRouteActionProvider` works with the `appcompat-v7` action bar backport, we specifically need to use the `appcompat-v7` approach to adding

## MEDIA ROUTES

---

actionProviderClass, putting it in our app's custom XML namespace:

```
<menu xmlns:android="http://schemas.android.com/apk/res/android"
      xmlns:app="http://schemas.android.com/apk/res-auto">

    <item
        android:id="@+id/route_provider"
        android:title="@string/route_provider_title"
        app:actionProviderClass="android.support.v7.app.MediaRouteActionProvider"
        app:showAsAction="always"/>

</menu>
```

(from [MediaRouter/ActionProvider/app/src/main/res/menu/main.xml](#))

## Initializing the MediaRouter and Selector

Our activity (MainActivity) is an AppCompatActivity subclass, following the rules for using the appcompat-v7 action bar backport:

```
package com.commonware.android.mrap;

import android.os.Bundle;
import android.support.v4.view.MenuItemCompat;
import android.support.v7.app.AppCompatActivity;
import android.support.v7.app.MediaRouteActionProvider;
import android.support.v7.media.MediaControlIntent;
import android.support.v7.media.MediaRouteSelector;
import android.support.v7.media.MediaRouter;
import android.view.Menu;
import android.view.MenuItem;
import android.widget.TextView;

public class MainActivity extends AppCompatActivity {
    private MediaRouteSelector selector=null;
    private MediaRouter router=null;
    private TextView selectedRoute=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);
        selectedRoute=(TextView)findViewById(R.id.selected_route);

        router=MediaRouter.getInstance(this);
        selector=
            new MediaRouteSelector.Builder().addControlCategory(MediaControlIntent.CATEGORY_LIVE_AUDIO)
                .addControlCategory(MediaControlIntent.CATEGORY_LIVE_VIDEO)
                .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
                .build();
    }
}
```

## MEDIA ROUTES

---

```
@Override
public void onStart() {
    super.onStart();

    router.addCallback(selector, cb,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
}

@Override
public void onStop() {
    router.removeCallback(cb);

    super.onStop();
}

@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.main, menu);

    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

    provider.setRouteSelector(selector);

    return(true);
}

private MediaRouter.Callback cb=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
        MediaRouter.RouteInfo route) {
        selectedRoute.setText(route.toString());
    }
};
}
```

(from [MediaRouter/ActionProvider/app/src/main/java/com/commonsware/android/mrap/MainActivity.java](#))

In `onCreate()` we obtain an instance of `MediaRouter`. More specifically, we obtain an instance of `android.support.v7.media.MediaRouter`.

We also will need a `MediaRouteSelector` instance. `MediaRouteSelector` expresses rules for what sorts of media routes we are interested in. The simplest way to set up a `MediaRouteSelector` is to use the `MediaRouteSelector.Builder` inner class, which follows the fluent API style of other Android Builder classes (e.g., `Notification.Builder`, `AlertDialog.Builder`). Here, we call `addControlCategory()` three times, indicating three categories of routes that we are interested in:

- `MediaControlIntent.CATEGORY_LIVE_AUDIO`
- `MediaControlIntent.CATEGORY_LIVE_VIDEO`
- `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK`

Calling `build()` on the resulting `Builder` gives us our `MediaRouteSelector`, which we will use elsewhere in the activity.

### Configuring the ActionProvider

In `onCreateOptionsMenu()` of `MainActivity`, we inflate our menu resource and pull out the `MediaRouteActionProvider`. To obtain an action provider from the `appcompat-v7` action bar, the simplest solution is to use the `MenuItemCompat` helper class from the Android Support package, calling its static `getActionProvider()` method. This will work both with the `appcompat-v7` backport of the action bar *and* with the native API Level 11+ action bar, though you do not need to use `MenuItemCompat` for the latter if you do not want.

We then call the `setRouteSelector()` method on our `MediaRouteActionProvider` instance, passing in the `MediaRouteSelector` we configured back in `onCreate()`. This tells the action provider what routes the user should be able to configure. In our case, that is all three major categories of routes (live audio, live video, and remote playback).

### Registering for Route Changes

Interestingly enough, that is insufficient to make the `MediaRouteActionProvider` work. We *also* need to register a `MediaRouter.Callback` with the `MediaRouter`, to be informed about events related to media routes. Our `cb` private data member is an instance of an anonymous inner class extending `MediaRouter.Callback`, overriding the `onRouteSelected()` method. This method will be called whenever a new route is selected, telling us the `MediaRouter.RouteInfo` of the newly-selected route. In our case, we just update a `TextView` that is our activity's UI with the details of that route, courtesy of calling `toString()` on the `RouteInfo` object.

To inform `MediaRouter` about our desire for such callbacks, we need to call `addCallback()` on the `MediaRouter`, and later on call `removeCallback()` when we no longer need to know about such events. In `MainActivity`, these steps are done in `onStart()` and `onStop()`, respectively.

Note that we provide the `CALLBACK_FLAG_REQUEST_DISCOVERY` flag in the `addCallback()` method, to trigger a search for any Chromecast or other remote playback-capable devices that can serve as media routes.

### The Results

Running this on an emulator is largely pointless, as emulators do not emulate media routes.

Running this on a device will give varying results, depending upon what other media-related accessories are available to that device. If there are no user-selectable media routes available, the `MediaRouteActionProvider` is marked as invisible, so the user does not see the icon and perhaps get confused by why tapping on it has no effect.

However, our `TextView` will show some initial route that was chosen by the device:

*Figure 786: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route*

### Live Audio Routes

If you launch the demo with some form of external headset or speakers attached, such as via Bluetooth, you will see the route for that is automatically selected:

*Figure 787: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Audio Route*

## MEDIA ROUTES

---

The `MediaRouteActionProvider` appears, with a blue highlight, indicating an active selected route. More importantly, the blue highlight indicates that the route is configurable by tapping on it to bring up a dialog:

*Figure 788: MediaRouter ActionProvider Demo, on a Nexus 4, Live Audio Route Configuration*

## MEDIA ROUTES

---

Here, we can adjust the volume, plus disconnect from the route. Disconnecting shows our `MediaRouteActionProvider` with the default white highlight:

*Figure 789: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Default Route and Provider*

## MEDIA ROUTES

---

The white highlight means that there are possible routes, though none in use. Tapping the icon brings up a connection dialog:

*Figure 790: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Routes*

### Live Video Routes

If you launch the demo with some form of external display attached — HDMI, MHL, SlimPort, etc. — you still will not see the `MediaRouteActionProvider`, as live video routes are automatically selected, at least if there is only one such route.

## MEDIA ROUTES

---

However, `onRouteSelected()` will still be called as part of starting up the activity, so the `TextView` will reflect the live video route:

*Figure 791: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Live Video Route*

### Remote Playback Routes

Since the user has to opt into remote playback media routes, the `MediaRouteActionProvider` *will* appear if you configure it to show such routes and a route is available:

*Figure 792: MediaRouter ActionProvider Demo, on a Nexus 4, Showing ActionProvider*

## MEDIA ROUTES

---

The `MediaRouteActionProvider`, when tapped, will pop up a dialog of available routes that the user can select:

*Figure 793: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Available Chromecast Route*

## MEDIA ROUTES

---

Note that if the device has both a Bluetooth audio connection *and* access to a remote playback route (like a Chromecast), and you requested both live audio and remote playback routes, then the route selection dialog could have multiple choices:

*Figure 794: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Multiple Available Routes*

## MEDIA ROUTES

---

If the user chooses a route from the dialog, our `onRouteSelected()` method will be called to reflect the new selection:

*Figure 795: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Selected Chromecast Route*

Also note that the `MediaRouteActionProvider` color changes from white to blue, indicating an altered route.

## MEDIA ROUTES

---

Tapping the action provider again pops up a dialog to control the volume of the route, plus a “Disconnect” button:

Figure 796: MediaRouter ActionProvider Demo, on a Nexus 4, Showing Route Dialog

Tapping that “Disconnect” button returns everything to its original state.

## Using Live Video Routes

A live video route is designed to be used with Presentation, a class that enables you to render your own content on the external display, much like how you would render your own content in a Dialog.

The use of Presentation is covered [in an upcoming chapter](#).

## Using Remote Playback Routes

In principle, RemotePlaybackClient allows you to work with remote playback routes, to specify Uri values to play back.

In practice, not even Google’s own sample code for RemotePlaybackClient works

reliably, let alone as documented.

That being said, let's take a look at the [MediaRouter/RemotePlayback](#) sample project, to see how `RemotePlaybackClient` works and where the current problems lie.

### Setting Up `MediaRouteActionProvider`

Much of the basic setup of this application mirrors the `MediaRouteActionProvider` sample shown [earlier in this chapter](#). One difference is that the UI is now encapsulated in a `PlaybackFragment`, with `MainActivity` simply setting up that fragment when needed:

```
package com.commonware.android.remoteplayback;

import android.os.Bundle;
import android.support.v7.app.AppCompatActivity;

public class MainActivity extends AppCompatActivity {
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new PlaybackFragment()).commit();
        }
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonware/android/remoteplayback/MainActivity.java](#))

`PlaybackFragment`, when it is created, opts into being retained on configuration changes, tells Android that it wishes to add items to the action bar, and sets up a `MediaRouteSelector` for `CATEGORY_REMOTE_PLAYBACK` routes:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);
    setHasOptionsMenu(true);
    selector =
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK).build();
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonware/android/remoteplayback/PlaybackFragment.java](#))

Then, in `onAttach()` — called when the `PlaybackFragment` is attached to the hosting activity — we obtain a `MediaRouter` instance:

## MEDIA ROUTES

---

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    router=MediaRouter.getInstance(host);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

In `onStart()`, we hook a `cb` data member — an instance of `MediaRouter.Callback` up to the `MediaRouter`, also requesting that the `MediaRouter` initiate discovery of available routes. We remove our callback in `onStop()`:

```
@Override
public void onStart() {
    super.onStart();

    router.addCallback(selector, cb,
        MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
}

@Override
public void onStop() {
    router.removeCallback(cb);

    super.onStop();
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

We will examine `cb`'s declaration later in this section.

Later on, as part of our `onCreateOptionsMenu()` processing, we configure the `MediaRouteActionProvider` as before:

```
MenuItem item=menu.findItem(R.id.route_provider);
MediaRouteActionProvider provider=
    (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

provider.setRouteSelector(selector);
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

All of this is very similar to the earlier examples. From here, though, we will actually use the route once the user selects it, to play back some media.

### The Rest of the User Interface

The UI of the PlaybackFragment — other than the action bar — consists of a “transcript”. This is a TextView inside of a ScrollView:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/transcript"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="20sp"/>

</ScrollView>
```

(from [MediaRouter/RemotePlayback/app/src/main/res/layout/activity\\_main.xml](#))

As with most fragments, we inflate this layout in `onCreateView()`, holding onto the TextView and ScrollView widgets:

```
@Override
public View onCreateView(LayoutInflater inflater,
    ViewGroup container,
    Bundle savedInstanceState) {
    scroll=
        (ScrollView)inflater.inflate(R.layout.activity_main, container,
            false);

    transcript=(TextView)scroll.findViewById(R.id.transcript);

    logToTranscript("Started");

    return(scroll);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `logToTranscript()` method will append a String to the TextView contents on a new line, plus scroll to the bottom to ensure that the new text is visible:

```
private void logToTranscript(String msg) {
    if (client != null) {
        String sessionId=client.getSessionId();
```

## MEDIA ROUTES

---

```
    if (sessionId != null) {
        msg="(" + sessionId + ") " + msg;
    }
}

transcript.setText(transcript.getText().toString() + msg + "\n");
scroll.fullScroll(View.FOCUS_DOWN);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The client data member referred to in `logToTranscript()` is our `RemotePlaybackClient` instance, which will be covered in the next section.

What the user sees when first running the sample is the action bar (with our `MediaRouteActionProvider`) and the transcript, with a simple “Started” message:

*Figure 797: RemotePlaybackClient Demo, on a Nexus 4, As Initially Launched*

## MEDIA ROUTES

---

As before, tapping on the “cast” action bar item pops up our dialog of available routes:

Figure 798: RemotePlaybackClient Demo, on a Nexus 4, Showing Available Routes

### Connecting and Session Management

When the user selects a route, our `MediaRouter.Callback (cb)` is called with `onRouteSelected()`. Similarly, if the user elects to disconnect via the `MediaRouteActionProvider`, our `Callback` is called with `onRouteUnselected()`. In the `MediaRouter.Callback` implementation inside `PlaybackFragment`, those events route to `connect()` and `disconnect()` methods, respectively, after logging a message to the transcript:

```
private MediaRouter.Callback cb=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
                               MediaRouter.RouteInfo route) {
        logToTranscript(getActivity().getString(R.string.route_selected));
        connect(route);
    }

    @Override
```

## MEDIA ROUTES

---

```
public void onRouteUnselected(MediaRouter router,
                             MediaRouter.RouteInfo route) {
    logToTranscript(getActivity().getString(R.string.route_unselected));
    disconnect();
}
};
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `connect()` method handles connecting to the remote playback device and starting a session:

```
private void connect(MediaRouter.RouteInfo route) {
    client=
        new RemotePlaybackClient(getActivity().getApplication(), route);

    if (client.isRemotePlaybackSupported()) {
        logToTranscript(getActivity().getString(R.string.connected));

        if (client.isSessionManagementSupported()) {
            client.startSession(null, new SessionActionCallback() {
                @Override
                public void onResult(Bundle data, String sessionId,
                                     MediaSessionStatus sessionStatus) {
                    logToTranscript(getActivity().getString(R.string.session_started));
                    updateMenu();
                }

                @Override
                public void onError(String error, int code, Bundle data) {
                    logToTranscript(getActivity().getString(R.string.session_failed));
                }
            });
        }
        else {
            getActivity().supportInvalidateOptionsMenu();
        }
    }
    else {
        logToTranscript(getActivity().getString(R.string.remote_playback_not_supported));
        client=null;
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

All of that, though, requires a bit more explanation.

### What's a Session?

The objective of the `connect()` method is to establish a “session” with the `RemotePlaybackClient`. In Android’s terms, a “session” is the state associated with an application’s interactions with the remote playback client. In principle, the

session could be shared among several instances of the app, such as several people contributing tracks to a dynamic playlist for audio playback at a party. Here, though, we are simply focused on having this one application instance have a session.

In principle, not all remote playback clients may support session management. In those cases, everybody is considered to be part of the same session. The test device for this sample (Chromecast) does support session management, however.

### Connecting the Client

Connecting to the remote playback device is simply a matter of creating an instance of `RemotePlaybackClient`, specifying the route to connect to:

```
client=  
    new RemotePlaybackClient(getActivity().getApplication(), route);
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

Here, we use `getActivity().getApplication()` in the `RemotePlaybackClient` constructor. That is because we want to hold onto this `RemotePlaybackClient` instance across configuration changes, so we can easily maintain our session. Since we do not know what `RemotePlaybackClient` may hold onto given the supplied `Context`, and since we do not want to leak our activity by retaining a reference to it, we use the global `Application` instance, for a “leak-resistant” `Context`.

We also call `isRemotePlaybackSupported()` to confirm that, indeed, the `RemotePlaybackClient` is connected to something that supports remote playback. This should always return `true` in this case, as we are only interested in remote playback routes. But, a little defensive programming never hurts.

Assuming that is all OK, we log a “connected” message to the transcript and continue on to start our session.

### Starting a Session

`isSessionManagementSupported()` on `RemotePlaybackClient` will indicate if the device supports explicit session management or not. If not, we will use the default implicit session and just continue on.

Otherwise, we call `startSession()` to explicitly start a session. This takes an optional `Bundle` of additional information to send in the start-session request to the

## MEDIA ROUTES

---

device (or null if unused), plus a `SessionActionCallback`. The `SessionActionCallback` is supposed to be called when the session is ready for use. Surprisingly enough, this actually works... for `startSession()`.

The `SessionActionCallback` will be called with `onResult()` for success and `onError()` for failure. In either case, we log a message to the transcript indicating the status.

In addition, if we have a session — either explicitly created via `startSession()` or implicitly created for devices without explicit session management — we call an `updateMenu()` method to update the action bar items.

### About the Action Bar

The fragment maintains two boolean values representing key states in the operation of the playback:

1. `isPlaying` indicates if playback was started and not yet stopped
2. `isPaused` indicates if playback was paused and not yet resumed

The aforementioned `updateMenu()` implementation uses those, plus the existence of a non-null `client`, to configure the action bar items:

```
private void updateMenu() {
    if (menu != null) {
        menu.findItem(R.id.stop).setVisible(client != null && isPlaying);
        menu.findItem(R.id.pause).setVisible(client != null && isPlaying
            && !isPaused);

        menu.findItem(R.id.play)
            .setVisible(client != null && (!isPlaying || isPaused));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

Specifically:

- When we are not playing, the play item is visible; when we *are* playing, the stop item is visible
- When we are not paused, the pause item is visible (play serves “double duty”, handling starting playback from a stopped state and resuming playback from a paused state)

## MEDIA ROUTES

---

This is based on a cached copy of the Menu object, saved in `onCreateOptionsMenu()` as part of setting up the action bar:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    this.menu=menu;
    inflater.inflate(R.menu.main, menu);

    updateMenu();

    MenuItem item=menu.findItem(R.id.route_provider);
    MediaRouteActionProvider provider=
        (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

    provider.setRouteSelector(selector);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

This is also where the logic shown previously for configuring the `MediaRouteActionProvider` resides.

### Session IDs

A session has a `String` identifier. In principle, this can be shared with other instances of your application, to allow for shared management of the session.

In the case of this sample, the session ID is merely logged to the transcript for all messages that are tied to an active session.

## MEDIA ROUTES

---

Hence, when the user chooses a remote playback route from the `MediaRouteActionProvider`, the resulting UI should resemble:

*Figure 799: RemotePlaybackClient Demo, on a Nexus 4, Showing an Active Session*

We see that we have connected to the client and started our session, and the play action bar item is now available to start playback of some media.

### Playing

The play action bar item is tied to a `play()` method via `onOptionsItemSelected()`, if we are not paused:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.play:
            if (isPlaying && isPaused) {
                resume();
            }
            else {
                play();
            }
    }
}
```

## MEDIA ROUTES

---

```
        return(true);

    case R.id.stop:
        stop();
        return(true);

    case R.id.pause:
        pause();
        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

play(), in turn, uses the play() method on RemotePlaybackClient to play back a copy of “[Elephants Dream](#)”, a Creative Commons-licensed video, hosted on CommonsWare’s corner of the Amazon S3 service:

```
private void play() {
    logToTranscript(getActivity().getString(R.string.play_requested));

    ItemActionCallback playCB=new ItemActionCallback() {
        @Override
        public void onResult(Bundle data, String sessionId,
            MediaSessionStatus sessionStatus,
            String itemId, MediaItemStatus itemStatus) {
            logToTranscript(getActivity().getString(R.string.playing));
            isPlaying=true;
            updateMenu();
        }

        @Override
        public void onError(String error, int code, Bundle data) {
            logToTranscript(getActivity().getString(R.string.play_error)
                + error);
        }
    };

    client.play(Uri.parse("http://misc.commonsware.com/ed_hd_512kb.mp4"),
        "video/mp4", null, 0, null, playCB);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The play() method on RemotePlaybackClient takes a few parameters:

## MEDIA ROUTES

---

- The `Uri` of the media to be played back
- The MIME type of that media (or `null` if you do not know the MIME type)
- An optional `Bundle` of metadata about the media to be played, where the `Bundle` keys come from `MediaItemMetadata` class (or `null` if none)
- The starting offset in the media to begin playback from (use 0 to start from the beginning)
- An optional `Bundle` of additional data to pass to the device
- An instance of `ItemActionCallback` to be notified when playback has started or has failed

`ItemActionCallback` is reminiscent of `SessionActionCallback`, in that `onResult()` will be called when playback begins and `onError()` will return when playback ends. The method signature of `onResult()` is slightly different, offering an ID and status of this particular media item.

In our case, we log a message to the transcript before requesting playback, then again on success or failure. On success, we also update `isPlaying` to be true and refresh the action bar.

## MEDIA ROUTES

---

Hence, once the user begins playback by tapping the play action bar item, the UI will look like this:

*Figure 800: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Started*

And, of course, the movie should be showing up on your remote playback device.

### Stopping, and a Bug

The `stop()` action bar item is tied to a `stop()` method in `PlaybackFragment`. You would think that this would be very similar to starting playback — call some `stop()` method on `RemotePlaybackClient` and update the UI after playback has stopped.

And, indeed, that is what we do... except that we have to deal with a bug:

```
private void stop() {
    logToTranscript(getActivity().getString(R.string.stop_requested));

    StopCallback stopCB=new StopCallback();

    client.stop(null, stopCB);
    transcript.postDelayed(stopCB, 1000);
}
```

## MEDIA ROUTES

---

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

### The stop() Call, and the Bug

stop() on RemotePlaybackClient takes an optional Bundle (here, null) and a SessionActionCallback. The SessionActionCallback is supposed to be called when playback has stopped (onResult()) or if there was some error in processing the request (onError()).

In practice, [neither happen when testing this on a Chromecast](#). This same behavior can be seen with [Google's own sample code](#), so it would not appear to be a problem with the author's own sample.

What actually happens is that playback is indeed stopped, but the SessionActionCallback is not called with onResult() or onError().

### The Workaround: RunnableSessionActionCallback

Since we cannot rely upon onResult() to be called for us, if we have work that we need to do in that case, we have to have some sort of fallback mechanism. One crude fallback is to assume that the request succeeded if we have not received a specific response after a period of time (say, 1000 milliseconds).

To that end, this sample has RunnableSessionActionCallback, a SessionActionCallback that implements Runnable:

```
abstract class RunnableSessionActionCallback extends
    SessionActionCallback implements Runnable {
    abstract protected void doWork();

    private boolean hasRun=false;

    @Override
    public void onResult(Bundle data, String sessionId,
        MediaSessionStatus sessionStatus) {
        transcript.removeCallbacks(this);
        run();
    }

    @Override
    public void run() {
        if (!hasRun) {
            hasRun=true;
        }
    }
}
```

## MEDIA ROUTES

---

```
doWork();
    }
}
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

The `run()` method sees whether or not the callback has already been run from a previous `run()` call. If not, it does the work specified by the abstract `doWork()` method, to be implemented in subclasses.

`StopCallback`, as seen in the `stop()` method above, extends `RunnableSessionActionCallback` and overrides `doWork()`:

```
private class StopCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPlaying=false;
        isPaused=false;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.stopped));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

`stop()` then not only passes the `StopCallback` to the `stop()` implementation on `RemotePlaybackClient`, but also schedules it as a `Runnable` to be invoked in 1000 milliseconds, via a call to `postDelayed()` on the `TextView` portion of the transcript. The `onResult()` implementation in `RunnableSessionActionCallback` calls `removeCallbacks()`, so we do not bother invoking the posted `Runnable` if that is not needed.

## MEDIA ROUTES

The `doWork()` implementation in `StopCallback` updates our flags, refreshes the action bar, and logs a message to the transcript. The result will look like:

*Figure 801: RemotePlaybackClient Demo, on a Nexus 4, After Playback Has Stopped*

This sample also does not handle the case where the media completes playback on its own, insofar as this event is not detected, to update the action bar. This will be added in a future version of this sample, if further bugs allow such support to actually work.

### Pausing and Resuming

Similarly, the pause action bar item forwards to a `pause()` method that calls `pause()` on the `RemotePlaybackClient`:

```
private void pause() {
    logToTranscript(getActivity().getString(R.string.pause_requested));

    PauseCallback pauseCB=new PauseCallback();

    client.pause(null, pauseCB);
    transcript.postDelayed(pauseCB, 1000);
}
```

## MEDIA ROUTES

---

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

That, in turn, uses `PauseCallback`:

```
private class PauseCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPaused=true;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.paused));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

This updates the action bar and logs messages to the transcript, similar to the `stop()` behavior. It also should successfully pause playback on the remote device.

The play action bar item routes to `resume()` if playback is paused:

```
private void resume() {
    logToTranscript(getActivity().getString(R.string.resume_requested));

    ResumeCallback resumeCB=new ResumeCallback();

    client.resume(null, resumeCB);
    transcript.postDelayed(resumeCB, 1000);
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

That, in turn, uses `ResumeCallback`:

```
private class ResumeCallback extends RunnableSessionActionCallback {
    @Override
    protected void doWork() {
        isPaused=false;
        updateMenu();
        logToTranscript(getActivity().getString(R.string.resumed));
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

This too updates the action bar and logs messages to the transcript, in addition to resuming playback on the remote device.

### Disconnecting

A call to `disconnect()` on `PlaybackFragment` is triggered from two locations:

- `onRouteUnselected()` in our `MediaRouter.Callback`, such as when the user uses the `MediaRouteActionProvider` to disconnect from the route
- `onDestroy()`, as part of general cleanup of the fragment

`disconnect()` should reverse the work done in `connect()`, ending our session and releasing the client:

```
private void disconnect() {
    isPlaying=false;
    isPaused=false;

    if (client != null) {
        logToTranscript(getActivity().getString(R.string.session_ending));
        EndSessionCallback endCB=new EndSessionCallback();

        if (client.isSessionManagementSupported()) {
            client.endSession(null, endCB);
        }

        transcript.postDelayed(endCB, 1000);
    }
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remoteplayback/PlaybackFragment.java](#))

This simply calls the `endSession()` method on the `RemotePlaybackClient`, supplying an `EndSessionCallback` to be notified (theoretically) of when the session has been torn down. But it only calls `endSession()` if session management is supported; otherwise, we would get a runtime error.

To be sure we complete the disconnection, though, we schedule the `EndSessionCallback` as seen in the `stop()`, `pause()`, and `resume()` methods. `EndSessionCallback` calls `release()` on the `RemotePlaybackClient`, to indicate that we are done with it, before setting `client` to `null`, refreshing the action bar, and logging something to the transcript:

```
private class EndSessionCallback extends
    RunnableSessionActionCallback {
    @Override
    protected void doWork() {
```

## MEDIA ROUTES

---

```
client.release();
client=null;

if (getActivity() != null) {
    updateMenu();
    logToTranscript(getActivity().getString(R.string.session_ended));
}
}
}
```

(from [MediaRouter/RemotePlayback/app/src/main/java/com/commonsware/android/remotep playback/PlaybackFragment.java](#))

### Other Remote Playback Features

There are other things that `RemotePlaybackClient` offers that are not shown in this sample:

- `enqueue()` allows you to build up a queue of media to be played back in the current session. This could be used by an individual or, in principle, by several people using the same app with a shared session ID. `remove()` allows you to remove specific items from the playback queue. These methods only work if `isQueueingSupported()` returns true.
- `getStatus()` will return information about the currently-playing piece of media, while `getSessionStatus()` will return information about the overall session. You can also find out about these changes on the fly by registering with `setStatusCallback()`.
- `seek()` allows you to move the playback to a new offset within the media, for “rewind” and “fast-forward” functionality. The status APIs (above) can tell you where you are in the playback, so you can determine the appropriate offset to seek to.

# Supporting External Displays

---

Android 4.2 inaugurated support for applications to control what appears on an external or “secondary” display (e.g., TV connected via HDMI), replacing the default screen mirroring. This is largely handled through a `Presentation` object, where you declare the UI that goes onto the external display, in parallel with whatever your activity might be displaying on the primary screen.

In this chapter, we will review how Android supports these external displays, how you can find out if an external display is attached, and how you can use `Presentation` objects to control what is shown on that external display.

The author would like to thank Mark Allison, whose “Multiple Screens” blog post series helped to blaze the trail for everyone in this space.

## Prerequisites

In addition to the core chapters, you should read [the chapter on dialogs](#) and [the chapter on `MediaRouter`](#) before reading this chapter.

## A History of External Displays

In this chapter, “external displays” refers to a screen that is temporarily associated with an Android device, in contrast with a “primary screen” that is where the Android device normally presents its user interface. So, most Android devices connected to a television via HDMI would consider the television to be a “external display”, with the touchscreen of the device itself as the “primary screen”. However, a [Android TV](#) box or a [Fire TV](#) connected to a television via HDMI would consider the television to be the “primary screen”, simply because there is no other screen. Some

devices themselves may have multiple screens, such as the [Sony Tablet P](#) — what those devices do with those screens will be up to the device.

Historically, support for external displays was manufacturer-dependent. Early Android devices had no ability to be displayed on an external display except through so-called “software projectors” like Jens Riboe’s [Droid@Screen](#). Some Android 2.x devices had ports that allowed for HDMI or composite connections to a television or projector. However, control for what would be displayed resided purely in the hands of the manufacturer. Some manufacturers would display whatever was on the touchscreen (a.k.a., “mirroring”). Some manufacturers would do that, but only for select apps, like a built-in video player.

Android 3.0 marked the beginning of Android’s formal support for external displays, as the Motorola XOOM supported mirroring of the LCD’s display via an micro-HDMI port. This mirroring was supplied by the core OS, not via device-dependent means. Any Android 3.0+ device with some sort of HDMI connection (e.g., micro-HDMI port) should support this same sort of mirroring capability.

However, mirroring was all that was possible. There was no means for an application to have something on the external display (e.g., a video) and something *else* on the primary screen (e.g., playback controls plus IMDB content about the movie being watched).

Android 4.2 changed that, with the introduction of Presentation.

## What is a Presentation?

A Presentation is a container for displaying a UI, in the form of a View hierarchy (like that of an activity), on an external display.

You can think of a Presentation as being a bit like a Dialog in that regard. Just as a Dialog shows its UI separate from its associated activity, so does a Presentation. In fact, as it turns out, Presentation *inherits from* Dialog.

The biggest difference between a Presentation and an ordinary Dialog, of course, is where the UI is displayed. A Presentation displays on an external display; a Dialog displays on the primary screen, overlaying the activity. However, this difference has a profound implication: the *characteristics* of the external display, in terms of size and density, are likely to be different than those of a primary screen.

Hence, the resources used by the UI on an external display may be different than the resources used by the primary screen. As a result, **the Context of the Presentation is not the Activity**. Rather, it is a separate Context, one whose Resources object will use the proper resources based upon the external display characteristics.

This seemingly minor bit of bookkeeping has some rippling effects on setting up your Presentation, as we will see as this chapter unfolds.

## Playing with External Displays

To write an app that uses an external display via a Presentation, you will need Android 4.2 or higher.

Beyond that, though, you will also need an external display of some form. Presently, you have three major options: emulate it, use a screen connected via some sort of cable, or use Miracast for wireless external displays (on Android 6.0 and older devices).

### Emulated

Even without an actual external display, you can lightly test your Presentation-enabled app via the Developer Options area of Settings on your Android 4.2 device. There, in the Drawing category, you will see the “Simulate secondary displays” preference:

*Figure 802: Nexus 10 “Simulate secondary displays” Preference*

## SUPPORTING EXTERNAL DISPLAYS

Tapping that will give you various options for what secondary display to emulate:

Figure 803: Nexus 10 “Simulate secondary displays” Options

## SUPPORTING EXTERNAL DISPLAYS

---

Tapping one of those will give you a small window in the upper-left corner, showing the contents of the external display, overlaid on top of your regular screen:

*Figure 804: Nexus 10, Simulating a 720p external display*

Normally, that will show a mirrored version of the primary screen, but with a Presentation-enabled app, it will show what is theoretically shown on the real external display.

However, there are limits with this technology:

- You will see this option on an Android emulator, but it may not work, particularly if you are not capable of using the “Host GPU Support” option. At the time of this writing, it works on the x86 Android 4.2 emulator image, but not the x86 Android 4.3 or 4.4 emulator image, and the ARM emulators are likely to be far too slow.
- The external display is rather tiny, making it difficult for you to accurately determine if everything is sized appropriately.
- The external display occludes part of the screen, overlaying your activities, though you can at least drag it around the screen to move it out of your way as needed.

In practice, before you ship a Presentation-capable app, you will want to test it with an actual physical external display.

### HDMI

If you have a device with HDMI-out capability, and you have the appropriate cable, you can simply plug that cable between your device and the display. “Tuning” the display to use that specific HDMI input port should cause your device’s screen contents to be mirrored to that display. Once this is working, you should be able to control the contents of that display using `Presentation`.

### MHL

Mobile High-Definition Link, or MHL for short, is a relatively new option for connections to displays. On many modern Android devices, the micro USB port supports MHL as well. Some external displays have MHL ports, in which case a male-to-male MHL direct cable will connect the device to the display. Otherwise, MHL can be converted to HDMI via adapters, so an MHL-capable device can attach to any HDMI-compliant display.

### SlimPort

SlimPort is another take on the overload-the-micro-USB-port-for-video approach. MHL is used on substantially more devices, but SlimPort appears on several of the Nexus-series devices (Nexus 4, Nexus 5, and the 2013 generation of the Nexus 7). Hence, while users will be more likely to have an MHL device, *developers* may be somewhat more likely to have a SlimPort device, given the popularity of Nexus devices among Android app developers.

From the standpoint of your programming work, MHL and SlimPort are largely equivalent — there is nothing that you need to do with your `Presentation` to address either of those protocols, let alone anything else like native HDMI.

### USB 3.1 Type C

The new USB 3.1 Type C specification has enough hooks for video display that we may see Android devices starting to use it (along with USB->HDMI adapters) for supporting external displays.

## Miracast

There are a few wireless display standards available. Android 4.2-6.0 supports Miracast, based upon WiFiDirect. This is also supported by some devices running earlier versions of Android, such as some Samsung devices (where Miracast is sometimes referred to as “AllShare Cast”). However, unless and until those devices get upgraded to Android 4.2, you cannot control what they display, except perhaps through some manufacturer-specific APIs.

On a Miracast-capable device, going into Settings > Displays > Wireless display will give you the ability to toggle on wireless display support and scan for available displays:

*Figure 805: Nexus 4 Wireless Display Settings*

You can then elect to attach to one of the available wireless displays and get your screen mirrored, and later use this with your Presentation-enabled app.

Of course, you also need some sort of Miracast-capable display, typically via some form of add-on box that connect to normal displays via HDMI and make them available via Miracast. One such box is the [Netgear PTV3000](#), whose current firmware supports Miracast along with other wireless display protocols.

Note that Miracast uses a compressed protocol, to minimize the bandwidth needed to transmit the video. This, in turn, can cause some lag.

Note that Intel's WiDi is an extended version of Miracast.

### WirelessHD

An up-and-coming competitor to Miracast is WirelessHD. WirelessHD has greater bandwidth requirements. On the other hand, it avoids compression, and therefore the lag that you experience with Miracast. At the time of this writing, though, no WirelessHD-native Android devices are available.

## Detecting Displays

Of course, we can only present a Presentation on an external display if there is, indeed, such a screen available. There are two approaches for doing this: using `DisplayManager` and using `MediaRouter`. We examined `MediaRouter` for detecting live video routes [in a preceding chapter](#), so let's focus here on `DisplayManager`.

`DisplayManager` is a system service, obtained by calling `getSystemService()` and asking for the `DISPLAY_SERVICE`.

Once you have a `DisplayManager`, you can ask it to give you a list of all available displays (`getDisplay()` with zero arguments) or all available displays in a certain category (`getDisplay()` with a single `String` parameter). As of API Level 17, the only available display category is `DISPLAY_CATEGORY_PRESENTATION`. The difference between the two flavors of `getDisplay()` is just the sort order:

- The zero-argument `getDisplay()` returns the `Display` array in arbitrary order
- The one-argument `getDisplay()` will put the `Display` objects matching the identified category earlier in the array

These would be useful if you wanted to pop up a list of available displays to ask the user which `Display` to use.

You can also register a `DisplayManager.DisplayListener` with the `DisplayManager` via `registerDisplayListener()`. This listener will be called when displays are added (e.g., HDMI cable was connected), removed (e.g., HDMI cable was disconnected), or changed. It is not completely clear what would trigger a "changed" call, though

possibly an orientation-aware display might report back the revised height and width.

Note that while `DisplayManager` was added in API Level 17, `Display` itself has been around since API Level 1, though some additions have been made in more recent Android releases. But, this may mean that you can pass the `Display` object around to code supporting older devices without needing to constantly check for SDK level or add the `@TargetApi()` annotation.

Also note that the `support-v4` library contains a `DisplayManagerCompat`, allowing you to call `DisplayManager`-like methods going all the way back to API Level 4. This does not give older devices the ability to work with external displays — that would require a time machine — but it can make it incrementally easier for you to write your app, without having to worry about API level. `DisplayManagerCompat` just gracefully degrades to returning information only about the device's standard touchscreen.

## A Simple Presentation

Let's take a look at a small sample app that demonstrates how we can display custom content on an external display using a `Presentation`. The app in question can be found in the [Presentation/Simple](#) sample project.

### The Presentation Itself

Since `Presentation` extends from `Dialog`, we provide the UI to be displayed on the external display via a call to `setContentView()`, much like we would do in an activity. Here, we just create a `WebView` widget in Java, point it to some Web page, and use it:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private class SimplePresentation extends Presentation {
    SimplePresentation(Context ctxt, Display display) {
        super(ctxt, display);
    }

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        WebView wv=new WebView(getContext());
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
wv.loadUrl("https://commonsware.com");

setContentView(wv);
}
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

However, there are two distinctive elements of our implementation:

- Our constructor takes a Context (typically the Activity), along with a Display object indicating where the UI should be presented.
- Our call to the WebView constructor uses `getContext()`, instead of the Activity object. In this case, that may have no real-world effect, as WebView is not going to be using any of our resources. But, had we used a LayoutInflater for inflating our UI, we would need to use one created from `getContext()`, not from the activity itself.

### Detecting the Displays

We need to determine whether there is a suitable external display when our activity comes into the foreground. We also need to determine if an external display was added or removed while we are in the foreground.

So, in `onStart()`, if we are on an Android 4.2 or higher device, we will get connected to the MediaRouter to handle those chores:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onStart() {
    super.onStart();

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        if (cb==null) {
            cb=new RouteCallback();
            router=(MediaRouter)getSystemService(MEDIA_ROUTER_SERVICE);
        }

        handleRoute(router.getSelectedRoute(MediaRouter.ROUTE_TYPE_LIVE_VIDEO));
        router.addCallback(MediaRouter.ROUTE_TYPE_LIVE_VIDEO, cb);
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

---

## SUPPORTING EXTERNAL DISPLAYS

---

Specifically, we:

- Create an instance of `RouteCallback`, an inner class of our activity that extends `SimpleCallback`
- Use `getSystemService()` to obtain a `MediaRouter`
- Call a `handleRoute()` method on our activity that will update our UI based upon the current video route, obtained by calling `getSelectedRoute()` on the `MediaRouter`
- Register the `RouteCallback` object with the `MediaRouter` via `addCallback()`

The `RouteCallback` object simply overrides `onRoutePresentationDisplayChanged()`, which will be called whenever there is a change in what screens are available and considered to be the preferred modes for video. There, we just call that same `handleRoute()` method that we called in `onStart()`:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN)
private class RouteCallback extends SimpleCallback {
    @Override
    public void onRoutePresentationDisplayChanged(MediaRouter router,
                                                RouteInfo route) {
        handleRoute(route);
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

Hence, our business logic for showing the presentation is isolated in one method, `handleRoute()`.

Our `onStop()` method will undo some of the work done by `onStart()`, notably removing our `RouteCallback`. We will examine that more closely in the next section.

### Showing and Hiding the Presentation

Our `handleRoute()` method will be called with one of two parameter values:

- The `RouteInfo` of the active route we should use for displaying the Presentation
- `null`, indicating that there is no route for such content, other than the primary screen

If we are passed the `RouteInfo`, it may represent the route we are already using, or

## SUPPORTING EXTERNAL DISPLAYS

---

possibly it may represent a different route entirely.

We need to handle all of those cases, even if some (switching directly from one route to another) may not necessarily be readily testable.

Hence, our `handleRoute()` method does its best:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void handleRoute(RouteInfo route) {
    if (route == null) {
        clearPreso();
    }
    else {
        Display display=route.getPresentationDisplay();

        if (route.isEnabled() && display != null) {
            if (preso == null) {
                showPreso(route);
                Log.d(getClass().getSimpleName(), "enabled route");
            }
            else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
                clearPreso();
                showPreso(route);
                Log.d(getClass().getSimpleName(), "switched route");
            }
            else {
                // no-op: should already be set
            }
        }
        else {
            clearPreso();
            Log.d(getClass().getSimpleName(), "disabled route");
        }
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

There are five possibilities handled by this method:

- If the route is null, then we should no longer be displaying the Presentation, so we call a `clearPreso()` method that will handle that
- If the route exists, but is disabled or is not giving us a `Display` object, we also assume that we should no longer be displaying the Presentation, so we call `clearPreso()`
- If the route exists and seems ready for use, and we are not already showing a

## SUPPORTING EXTERNAL DISPLAYS

---

Presentation (our `preso` data member is `null`), we need to show the Presentation, which we delegate to a `showPreso()` method

- If the route exists, seems ready for use, but we are already showing a Presentation, and the ID of the new Display is different than the ID of the Display our Presentation had been using, we use *both* `clearPreso()` and `showPreso()` to switch our Presentation to the new Display
- If the route exists, seems ready for use, but we are already showing a Presentation on this Display, we do nothing and wonder why `handleRoute()` got called

Showing the Presentation is merely a matter of creating an instance of our `SimplePresentation` and calling `show()` on it, like we would a regular `Dialog`:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void showPreso(RouteInfo route) {
    preso=new SimplePresentation(this, route.getPresentationDisplay());
    preso.show();
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

Clearing the Presentation calls `dismiss()` on the Presentation, then sets the `preso` data member to `null` to indicate that we are not showing a Presentation:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
private void clearPreso() {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

Our `onPause()` uses `clearPreso()` and `removeCallback()` to unwind everything:

```
@TargetApi(Build.VERSION_CODES.JELLY_BEAN_MR1)
@Override
protected void onStop() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        clearPreso();

        if (router != null) {
            router.removeCallback(cb);
        }
    }
}
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
}  
  
    super.onStop();  
}
```

(from [Presentation/Simple/app/src/main/java/com/commonsware/android/preso/simple/MainActivity.java](#))

### The Results

If you run this with no external display, you will just see a plain `TextView` that is the UI for our primary screen:

*Figure 8o6: Nexus 10, No Emulated Secondary Display, Showing Sample App*

If you run this *with* an external display, the external display will show our WebView:

*Figure 807: Nexus 10, With Emulated Secondary Display, Showing Sample App*

## A Simpler Presentation

There was a fair bit of code in the previous sample for messing around with `MediaRouter` and finding out about changes in the available displays.

To help simplify apps using Presentation, the author of this book maintains a library, [CWAC-Presentation](#), with various reusable bits of code for managing Presentations.

One piece of this is `PresentationHelper`, which isolates all of the display management logic in a single reusable object. In this section, we will examine how to use `PresentationHelper`, then how `PresentationHelper` itself works, using `DisplayManager` under the covers.

## Getting a Little Help

Our [Presentation/Simpler](#) sample project uses the CWAC-Presentation artifact:

## SUPPORTING EXTERNAL DISPLAYS

---

```
apply plugin: 'com.android.application'

repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonware.com"
    }
}

dependencies {
    implementation 'com.commonware.cwac:presentation:0.5.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 17
        targetSdkVersion 27
    }
}
```

(from [Presentation/Simpler/app/build.gradle](#))

This gives us access to `PresentationHelper`. Our `MainActivity` in the sample creates an instance of `PresentationHelper` in `onCreate()`, stashing the object in a data member:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setContentView(R.layout.activity_main);
    helper=new PresentationHelper(this, this);
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonware/android/preso/simpler/MainActivity.java](#))

The constructor for `PresentationHelper` takes two parameters:

- a `Context` object, one that should be valid for the life of the helper, typically the `Activity` that creates the helper, and
- a implementation of `PresentationHelper.Listener` — in this case, the interface is implemented on `MainActivity` itself

The activity that creates the helper must forward `onPause()` and `onResume()`

## SUPPORTING EXTERNAL DISPLAYS

---

lifecycle methods to the equivalent methods on the helper:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

The implementer of `PresentationHelper.Listener` also needs to have `showPreso()` and `clearPreso()` methods, much like the ones from the original `Presentation` sample in this chapter. `showPreso()` will be passed a `Display` object and should arrange to display a `Presentation` on that `Display`:

```
@Override
public void showPreso(Display display) {
    preso=new SimplerPresentation(this, display);
    preso.show();
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

`clearPreso()` should get rid of any outstanding `Presentation`. It is passed a boolean value, which will be true if we simply lost the `Display` we were using (and so the activity might want to display the `Presentation` contents elsewhere, such as in the activity itself), or false if the activity is moving to the background (triggered via `onPause()`):

```
@Override
public void clearPreso(boolean showInline) {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Simpler/app/src/main/java/com/commonsware/android/preso/simpler/MainActivity.java](#))

The implementations here are pretty much the same as the ones used in the

---

previous example. PresentationHelper has handled all of the Display-management events – our activity can simply focus on showing or hiding the Presentation on demand.

### Help When You Need It

In many respects, the PresentationHelper from the CWAC-Presentation project works a lot like the logic in the original Presentation sample's MainActivity, detecting various states and calling showPreso() and clearPreso() accordingly. However, PresentationHelper uses a different mechanism for this — DisplayManager.

The PresentationHelper constructor just stashes the parameters it is passed in data members and obtains a DisplayManager via getSystemService(), putting it in another data member:

```
/**
 * Basic constructor.
 *
 * @param ctxt a Context, typically the activity that is planning on showing
 *           the Presentation
 * @param listener the callback for show/hide events
 */
public PresentationHelper(Context ctxt, Listener listener) {
    this.listener=listener;

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        mgr=
            (DisplayManager)ctxt.getSystemService(Context.DISPLAY_SERVICE);
    }
}
```

onResume() calls out to a private handlePreso() method to initialize our state, and tells the DisplayManager to let it know as displays are attached and detached from the device, by means of registerDisplayListener():

```
/**
 * Call this from onResume() of your activity, so we can determine what
 * changes need to be made to the Presentation, if any
 */
public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        handleRoute();
        mgr.registerDisplayListener(this, null);
    }
}
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
}  
}
```

The `PresentationHelper` itself implements the `DisplayListener` interface, which requires three callback methods:

- `onDisplayAdded()` is called when a new output display is available
- `onDisplayChanged()` is called when an existing attached display changes its characteristics
- `onDisplayRemoved()` is called whenever a previously-attached output display has been detached

In our case, all three methods route to the same `handleRoute()` method, to update our state:

```
/**  
 * {@inheritDoc}  
 */  
@Override  
public void onDisplayAdded(int displayId) {  
    handleRoute();  
}  
  
/**  
 * {@inheritDoc}  
 */  
@Override  
public void onDisplayChanged(int displayId) {  
    handleRoute();  
}  
  
/**  
 * {@inheritDoc}  
 */  
@Override  
public void onDisplayRemoved(int displayId) {  
    handleRoute();  
}
```

`handleRoute()` is where the bulk of the “business logic” of `PresentationHelper` resides:

```
private void handleRoute() {  
    if (isEnabled()) {  
        Display[] displays=  

```

## SUPPORTING EXTERNAL DISPLAYS

---

```
mgr.getDisplays(DisplayManager.DISPLAY_CATEGORY_PRESENTATION);

if (displays.length == 0) {
    if (current != null || isFirstRun) {
        listener.clearPreso(true);
        current=null;
    }
}
else {
    Display display=displays[0];

    if (display != null && display.isValid()) {
        if (current == null) {
            listener.showPreso(display);
            current=display;
        }
        else if (current.getDisplayId() != display.getDisplayId()) {
            listener.clearPreso(true);
            listener.showPreso(display);
            current=display;
        }
        else {
            // no-op: should already be set
        }
    }
    else if (current != null) {
        listener.clearPreso(true);
        current=null;
    }
}

isFirstRun=false;
}
```

We get the list of attached displays from the DisplayManager by calling `getDisplays()`. By passing in `DISPLAY_CATEGORY_PRESENTATION`, we are asking for returned array of Display objects to be ordered such that the preferred display for presentations is the first element.

If the array is empty, and we already had a current Display from before (or if this is the first time `handlePreso()` has run), we call `clearPreso()` to inform the listener that there is no Display for presentation purposes.

If we do have a valid Display:

- If we were not displaying anything before, we call `showPreso()` to inform the listener to start displaying things, plus keep track of the current `Display` in a data member
- If we were displaying something before, but now the preferred `Display` for a `Presentation` is different (the ID value of the `Display` objects differ), we call `clearPreso()` and `showPreso()` to get the listener to switch to the new `Display`
- Otherwise, this was a spurious call to `handlePreso()`, so we do not do anything of note

If, for whatever reason, the best `Display` is not valid, we do the same thing as if we had no `Display` at all: call `clearPreso()`.

Finally, in `onPause()`, we call `clearPreso()` to ensure that we are no longer attempting to display anything, plus call `unregisterDisplayListener()` so we are no longer informed about changes to the mix of `Display` objects that might be available:

```
/**
 * Call this from onPause() of your activity, so we can determine what
 * changes need to be made to the Presentation, if any
 */
public void onPause() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR1) {
        listener.clearPreso(false);
        current=null;

        mgr.unregisterDisplayListener(this);
    }
}
```

## Presentations and Configuration Changes

One headache when using `Presentation` comes from the fact that it is a `Dialog`, which is owned by an `Activity`. If the device undergoes a configuration change, the activity will be destroyed and recreated by default, forcing you to destroy and recreate your `Dialog`. This, in turn, causes flicker on the external display, as the display briefly reverts to mirroring while this goes on.

Devices that support external displays may be orientation-locked to landscape when an external display is attached (e.g., an HDMI cable is plugged in). This reduces the odds of a configuration change considerably, as the #1 configuration change is an

orientation change. However, that is not a guaranteed “feature” of Android external display support, and there are other configuration changes that could go on (e.g., devices gets plugged into a keyboard dock).

You can either just live with the flicker, or use `android:configChanges` to try to avoid the destroy/re-create cycle for the configuration change. As was noted back in [the chapter on configuration changes](#), this is a risky approach, as it requires you to remember all your resources that might change on the configuration change and reset them to reflect the configuration change.

A “middle ground” approach is to ensure that your activity running the Presentation is orientation-locked to landscape mode, by adding `android:orientation="landscape"` to your `<activity>` in the manifest, then use `android:configChanges` to handle the configuration changes related to orientation:

- `orientation`
- `keyboardHidden`
- `screenSize`
- `screenLayout`

For those configuration changes, nothing should be needed to be modified in your activity, since you want to be displaying in landscape all of the time, and so you will not need to modify your use of resources. This leaves open the possibility of other configuration changes that would cause flicker on the external display, but those are relatively unlikely to occur while your activity is in the foreground, and so it may not be worth trying to address the flicker in all those cases.

Yet another possibility is to have your presentation be delivered by a service, as we will discuss [later in this chapter](#).

## Presentations as Fragments

Curiously, the support for Presentation is focused on View. There is nothing built into Android 4.2 that ties a Presentation to a Fragment. However, this can be a useful technique, one we can roll ourselves... with a bit of difficulty.

### The Reuse Reality

There will be a few apps that will only want to deliver content if there is a external display on which to deliver it. However, the vast majority of apps supporting external

displays will do so optionally, still supporting regular Android devices with only primary screens.

In this case, though, we have a problem: we need to show that UI *somewhere* if there is no external display to show it on. Our only likely answer is to have it be part of our primary UI.

Fragments would seem to be tailor-made for this. We could “throw” a fragment to the external display if it exists, or incorporate it into our main UI (e.g., as another page in a `ViewPager`) if the external display does not exist, or even have it be shown by some separate activity on smaller-screen devices like phones. Our business logic will already have been partitioned between the fragments — it is merely a question of where the fragment shows up.

### Presentations as Dialogs

The nice thing is that `Presentation` extends `Dialog`. We already have a `DialogFragment` as part of Android that knows how to display a `Dialog` populated by a `Fragment` implementation of `onCreateView()`. `DialogFragment` even knows how to handle either being part of the main UI *or* as a separate dialog.

Hence, one could imagine a `PresentationFragment` that extends `DialogFragment` and adds the ability to either be part of the main UI on the primary screen *or* shown on an external display, should one be available.

And, in truth, it is possible to create such a `PresentationFragment`, though there are some limitations.

### The Context Conundrum

The biggest limitation comes back to the `Context` used for our UI. Normally, there is only one `Context` of relevance: the `Activity`. In the case of `Presentation`, though, there is a separate `Context` that is tied to the display characteristics of the external display.

This means that `PresentationFragment` must manipulate *two* `Context` values:

- The `Activity`, if the fragment should be part of our main UI
- Some other `Context` supplied by the `Presentation`, if the fragment should be displayed in the `Presentation` on the external display

This makes creating a `PresentationFragment` class a bit tricky... though not impossible. After all, if it *were* impossible, these past several paragraphs would not be very useful.

### A `PresentationFragment` (and Subclasses)

The [Presentation/Fragment](#) sample project has the same UI as the `Presentation/Simple` project, if there is an external display. If there is only the primary screen, though, we will elect to display the `WebView` side-by-side with our `TextView` in the main UI of our activity. And, to pull this off, we will create a `PresentationFragment` based on `DialogFragment`.

Note that this sample project has its `android:minSdkVersion` set to 17, mostly to cut down on all of the “only do this if we are on API Level 17” checks and `@TargetApi()` annotations. Getting this code to work on earlier versions of Android is left as an exercise for the reader.

In a simple `DialogFragment`, we might just override `onCreateView()` to provide the contents of the dialog. The default implementation of `onCreateDialog()` would create an empty `Dialog`, to be populated with the `View` returned by `onCreateView()`.

In our `PresentationFragment` subclass of `DialogFragment`, though, we need to override `onCreateDialog()` to use a `Presentation` instead of a `Dialog`... if we have a `Presentation` to work with:

```
package com.commonware.android.preso.fragment;

import android.app.Dialog;
import android.app.Presentation;
import android.content.Context;
import android.os.Bundle;
import android.support.v4.app.DialogFragment;
import android.view.Display;

abstract public class PresentationFragment extends DialogFragment {
    private Display display=null;
    private Presentation preso=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        if (preso == null) {
            return(super.onCreateDialog(savedInstanceState));
        }
    }
}
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
        return(preso);
    }

    public void setDisplay(Context ctxt, Display display) {
        if (display == null) {
            preso=null;
        }
        else {
            preso=new Presentation(ctxt, display, getTheme());
        }
    }

    this.display=display;
}

public Display getDisplay() {
    return(display);
}

public Context getContext() {
    if (preso != null) {
        return(preso.getContext());
    }

    return(getActivity());
}
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/PresentationFragment.java](#))

We also expose `getDisplay()` and `setDisplay()` accessors, to supply the `Display` object to be used if this fragment will be thrown onto an external display. `setDisplay()` also creates the `Presentation` object wrapped around the display, using the three-parameter `Presentation` constructor that supplies the theme to be used (in this case, using the `getTheme()` method, which a subclass could override if desired).

`PresentationFragment` also implements a `getContext()` method. If this fragment will be used with a `Display` and `Presentation`, this will return the `Context` from the `Presentation`. If not, it returns the `Activity` associated with this `Fragment`.

This project contains a `WebPresentationFragment`, that pours the same basic Android source code used elsewhere in this book for a `WebViewFragment` into a subclass of `PresentationFragment`:

```
package com.commonsware.android.preso.fragment;
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
import android.annotation.TargetApi;
import android.os.Build;
import android.os.Bundle;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.webkit.WebView;

public class WebPresentationFragment extends PresentationFragment {
    private WebView mWebView;
    private boolean mIsWebViewAvailable;

    /**
     * Called to instantiate the view. Creates and returns the
     * WebView.
     */
    @Override
    public View onCreateView(LayoutInflater inflater,
                            ViewGroup container,
                            Bundle savedInstanceState) {
        if (mWebView != null) {
            mWebView.destroy();
        }

        mWebView=new WebView(getContext());
        mIsWebViewAvailable=true;
        return mWebView;
    }

    /**
     * Called when the fragment is visible to the user and
     * actively running. Resumes the WebView.
     */
    @TargetApi(11)
    @Override
    public void onPause() {
        super.onPause();

        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
            mWebView.onPause();
        }
    }

    /**
     * Called when the fragment is no longer resumed. Pauses
     * the WebView.
     */
    @TargetApi(11)
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
@Override
public void onResume() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.HONEYCOMB) {
        mWebView.onResume();
    }

    super.onResume();
}

/**
 * Called when the WebView has been detached from the
 * fragment. The WebView is no longer available after this
 * time.
 */
@Override
public void onDestroyView() {
    mIsWebViewAvailable=false;
    super.onDestroyView();
}

/**
 * Called when the fragment is no longer in use. Destroys
 * the internal state of the WebView.
 */
@Override
public void onDestroy() {
    if (mWebView != null) {
        mWebView.destroy();
        mWebView=null;
    }
    super.onDestroy();
}

/**
 * Gets the WebView.
 */
public WebView getWebView() {
    return mIsWebViewAvailable ? mWebView : null;
}
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/WebPresentationFragment.java](#))

(note: the flawed comments came from the original Android open source code from which this fragment was derived)

The only significant difference, besides the superclass, is that the onCreateView()

## SUPPORTING EXTERNAL DISPLAYS

---

method uses `getContext()`, not `getActivity()`, as the `Context` to use when creating the `WebView`.

And, the project has a `SamplePresentationFragment` subclass of `WebPresentationFragment`, where we use the factory-method-and-arguments pattern to pass a URL into the fragment to use for populating the `WebView`:

```
package com.commonware.android.preso.fragment;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class SamplePresentationFragment extends WebPresentationFragment {
    private static final String ARG_URL="url";

    public static SamplePresentationFragment newInstance(Context ctxt,
                                                         Display display,
                                                         String url) {
        SamplePresentationFragment frag=new SamplePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();

        b.putString(ARG_URL, url);
        frag.setArguments(b);

        return(frag);
    }

    @Override
    public View onCreateView(LayoutInflater inflater,
                             ViewGroup container,
                             Bundle savedInstanceState) {
        View result=
            super.onCreateView(inflater, container, savedInstanceState);

        getWebView().loadUrl(getArguments().getString(ARG_URL));

        return(result);
    }
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/SamplePresentationFragment.java](#))

### Using PresentationFragment

Our activity's layout now contains not only a `TextView`, but also a `FrameLayout` into which we will slot the `PresentationFragment` if there is no external display:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="horizontal"
    tools:context=".MainActivity">

    <TextView
        android:id="@+id/prose"
        android:layout_width="0px"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:layout_weight="1"
        android:gravity="center"
        android:text="@string/secondary"
        android:textSize="40sp"/>

    <FrameLayout
        android:id="@+id/preso"
        android:layout_width="0px"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:visibility="gone"/>

</LinearLayout>
```

(from [Presentation/Fragment/app/src/main/res/layout/activity\\_main.xml](#))

Note that the `FrameLayout` is initially set to have gone as its visibility, meaning that only the `TextView` will appear. Based on the widths and weights, the `TextView` will take up the full screen when the `FrameLayout` is gone, or they will split the screen in half otherwise.

In the `onCreate()` implementation of our activity (`MainActivity`), we inflate that layout and grab both the `TextView` and the `FrameLayout`, putting them into data members:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
super.onCreate(savedInstanceState);

setContentView(R.layout.activity_main);

inline=findViewById(R.id.preso);
prose=findViewById(R.id.prose);
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

Our `onStart()` method, and our `RouteCallback`, are identical to those from the previous sample. Our `handleRoute()` method is *nearly* identical to the original, as is our `onStop()` method. The difference is that we need to distinguish whether we have lost an external display (and therefore want to move the Web page into the main UI) or if we are going away entirely (and therefore just wish to clean up the external display, if any). Hence, `clearPreso()` takes a boolean parameter (`switchToInline`), `true` if we want to show the fragment in the main UI, `false` otherwise. And, our `onStop()` and `handleRoute()` methods pass the appropriate value to `clearPreso()`:

```
@Override
protected void onStop() {
    clearPreso(false);

    if (router != null) {
        router.removeCallback(cb);
    }

    super.onStop();
}

private void handleRoute(RouteInfo route) {
    if (route == null) {
        clearPreso(true);
    }
    else {
        Display display=route.getPresentationDisplay();

        if (route.isEnabled() && display != null) {
            if (preso == null) {
                showPreso(route);
                Log.d(getClass().getSimpleName(), "enabled route");
            }
            else if (preso.getDisplay().getDisplayId() != display.getDisplayId()) {
                clearPreso(true);
                showPreso(route);
                Log.d(getClass().getSimpleName(), "switched route");
            }
        }
    }
}
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
    }
    else {
        // no-op: should already be set
    }
}
else {
    clearPreso(true);
    Log.d(getClass().getSimpleName(), "disabled route");
}
}
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

`showPreso()` is called when we want to display the Presentation on the external display. Hence, we need to remove the `WebPresentationFragment` from the main UI if it is there:

```
private void showPreso(RouteInfo route) {
    if (inline.getVisibility() == View.VISIBLE) {
        inline.setVisibility(View.GONE);
        prose.setText(R.string.secondary);

        Fragment f=getSupportFragmentManager().findFragmentById(R.id.preso);

        getSupportFragmentManager().beginTransaction().remove(f).commit();
    }

    preso=buildPreso(route.getPresentationDisplay());
    preso.show(getSupportFragmentManager(), "preso");
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

Creating the actual `PresentationFragment` is delegated to a `buildPreso()` method, which employs the `newInstance()` method on the `SamplePresentationFragment`:

```
private PresentationFragment buildPreso(Display display) {
    return(SamplePresentationFragment.newInstance(this, display,
        "https://commonsware.com"));
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonsware/android/preso/fragment/MainActivity.java](#))

`clearPreso()` is responsible for *adding* the `PresentationFragment` to the main UI, if `switchToInline` is true:

## SUPPORTING EXTERNAL DISPLAYS

```
private void clearPreso(boolean switchToInline) {
    if (switchToInline) {
        inline.setVisibility(View.VISIBLE);
        prose.setText(R.string.primary);
        getSupportFragmentManager().beginTransaction()
            .add(R.id.preso, buildPreso(null)).commit();
    }

    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Fragment/app/src/main/java/com/commonware/android/preso/fragment/MainActivity.java](#))

With an external display, the results are visually identical to the original sample. Without an external display, though, our UI is presented side-by-side:

Figure 8o8: Nexus 10, With Inline PresentationFragment

### Limits

This implementation of PresentationFragment has its limitations, though.

First, we cannot reuse the same fragment *instance* for both the inline UI and the Presentation UI, as they use different Context objects. Hence, production code will need to arrange to get data out of the old fragment instance and into the new instance when the screen mix changes. You might be able to leverage `onSaveInstanceState()` for that purpose, with a more-sophisticated implementation of `PresentationFragment`.

Also, depending upon the device and the external display, you *may* see multiple calls to `handleRoute()`. For example, attaching an external display may trigger three calls to your `RouteCallback`, for an attach, a detach, and another attach event. It is unclear why this occurs. However, it may require some additional logic in your app to deal with these events, if you encounter them.

### Another Sample Project: Slides

At the 2013 Samsung Developer Conference, the author of this book delivered [a presentation on using Presentation](#). Rather than use a traditional presentation package driven from a notebook, the author used [the Presentation/Slides sample app](#). This sample app shows how to show slides on an external display, controlled by a `ViewPager` on a device's touchscreen.

What the audience saw, through most of the presentation, were simple slides. What the presenter saw was a ViewPager, with tabs, along with action bar items for various actions:

*Figure 809: PresentationSlidesDemo, Showing Overflow*

### The Slides

The slides themselves are a series of 20 drawable resources (img0, img1, etc.), put into the `res/drawable-nodpi/` resource directory, as there is no intrinsic “density” that the slides were prepared for. As we use the slides in `ImageView` widgets, their images will be resized to fit the available `ImageView` space alone, not taking screen density into account.

There is a matching set of 20 string resources (title0, title1, etc.) containing a string representation of the slide titles, for use with `getPageTitle()` of a `PagerAdapter`.

### The PagerAdapter

That `PagerAdapter`, named `SlidesAdapter`, has each slide be visually represented by an `ImageView` widget. In this case, `SlidesAdapter` extends `PagerAdapter` directly, skipping fragments:

```
package com.commonware.android.preso.slides;
```

## SUPPORTING EXTERNAL DISPLAYS

---

```
import android.content.Context;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;

class SlidesAdapter extends PagerAdapter {
    private static final int[] SLIDES= { R.drawable.img0,
        R.drawable.img1, R.drawable.img2, R.drawable.img3,
        R.drawable.img4, R.drawable.img5, R.drawable.img6,
        R.drawable.img7, R.drawable.img8, R.drawable.img9,
        R.drawable.img10, R.drawable.img11, R.drawable.img12,
        R.drawable.img13, R.drawable.img14, R.drawable.img15,
        R.drawable.img16, R.drawable.img17, R.drawable.img18,
        R.drawable.img19 };
    private static final int[] TITLES= { R.string.title0,
        R.string.title1, R.string.title2, R.string.title3,
        R.string.title4, R.string.title5, R.string.title6,
        R.string.title7, R.string.title8, R.string.title9,
        R.string.title10, R.string.title11, R.string.title12,
        R.string.title13, R.string.title14, R.string.title15,
        R.string.title16, R.string.title17, R.string.title18,
        R.string.title19 };
    private Context ctxt=null;

    SlidesAdapter(Context ctxt) {
        this.ctxt=ctxt;
    }

    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        ImageView page=new ImageView(ctxt);

        page.setImageResource(getPageResource(position));
        container.addView(page,
            new ViewGroup.LayoutParams(
                ViewGroup.LayoutParams.MATCH_PARENT,
                ViewGroup.LayoutParams.MATCH_PARENT));

        return(page);
    }

    @Override
    public void destroyItem(ViewGroup container, int position,
        Object object) {
        container.removeView((View)object);
    }

    @Override
    public int getCount() {
        return(SLIDES.length);
    }

    @Override
    public boolean isViewFromObject(View view, Object object) {
        return(view == object);
    }

    @Override
```

---

## SUPPORTING EXTERNAL DISPLAYS

---

```
public String getPageTitle(int position) {
    return(ctxt.getString(TITLES[position]));
}

int getPageResource(int position) {
    return(SLIDES[position]);
}
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/SlidesAdapter.java](#))

The data for the SlidesAdapter consists of a pair of static int arrays, one holding the drawable resource IDs, one holding the string resource IDs.

Of note, SlidesAdapter has a getPageResource() method, to return the drawable resource ID for a given page position, which is used by instantiateItem() for populating the position's ImageView.

### The PresentationFragment

We also want to be able to show the slide on an external display via a Presentation. As with the preceding sample app, this one uses a PresentationFragment, here named SlidePresentationFragment:

```
package com.commonsware.android.preso.slides;

import android.content.Context;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.commonsware.cwac.preso.PresentationFragment;

public class SlidePresentationFragment extends PresentationFragment {
    private static final String KEY_RESOURCE="r";
    private ImageView slide=null;

    public static SlidePresentationFragment newInstance(Context ctxt,
                                                       Display display,
                                                       int initialResource) {
        SlidePresentationFragment frag=new SlidePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();
```

```
b.putInt(KEY_RESOURCE, initialResource);
frag.setArguments(b);

return(frag);
}

@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    slide=new ImageView(getContext());

    setSlideContent(getArguments().getInt(KEY_RESOURCE));

    return(slide);
}

void setSlideContent(int resourceId) {
    slide.setImageResource(resourceId);
}
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/SlidePresentationFragment.java](#))

Here, in addition to the sort of logic seen in the preceding sample app, we also need to teach the fragment which image it should be showing at any point in time. We do this in two ways:

1. We pass in an int named `initialResource` to the factory method, where `initialResource` represents the image to show when the fragment is first displayed. That value is packaged into the arguments Bundle, and `onCreateView()` uses that value.
2. Actually putting the drawable resource into the `ImageView` for this Presentation is handled by `setSlideContent()`. This is called by `onCreateView()`, passing in the `initialResource` value.

### The Activity

The rest of the business logic for this application can be found in its overall entry point, `MainActivity`.

### Setting Up the Pager

`onCreate()` of `MainActivity` is mostly focused on setting up the `ViewPager`:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    ViewPagerIndicator tabs=(ViewPagerIndicator)findViewById(R.id.titles);

    pager=(ViewPager)findViewById(R.id.pager);
    adapter=new SlidesAdapter(this);
    pager.setAdapter(adapter);
    tabs.setViewPager(pager);
    tabs.setOnPageChangeListener(this);

    helper=new PresentationHelper(this, this);
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

The `ViewPager` and our `SlidesAdapter` are saved in data members of the activity, for later reference. We also wire in a `ViewPagerIndicator`, from the `ViewPagerIndicator` library, and arrange to get control in our `OnPageChangeListener` methods when the page changes (whether via the tabs or via a swipe on the `ViewPager` itself).

`onCreate()` also hooks up a `PresentationHelper`, following the recipe used elsewhere in this chapter. And, as `PresentationHelper` requires, we forward along the `onResume()` and `onPause()` events to it:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

### Setting Up the Presentation

In the `showPreso()` method, required by the `PresentationHelper.Listener` interface, we create an instance of `SlidePresentationFragment`, passing in the resource ID of the current slide, as determined by the `ViewPager`:

```
@Override
public void showPreso(Display display) {
    int drawable=adapter.getPageResource(pager.getCurrentItem());

    preso=
        SlidePresentationFragment.newInstance(this, display, drawable);
    preso.show(getFragmentManager(), "preso");
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

We then `show()` the `PresentationFragment`, causing it to appear on the attached `Display`.

The corresponding `clearPreso()` method follows the typical recipe of calling `dismiss()` on the `PresentationFragment`, if one exists:

```
@Override
public void clearPreso(boolean showInline) {
    if (preso != null) {
        preso.dismiss();
        preso=null;
    }
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

### Controlling the Presentation

However, the `SlidesPresentationFragment` now is showing the slide that was current when the `Display` was discovered or attached. What happens if the user changes the slide, using the `ViewPager`?

In that case, our `OnPageChangeListener` `onPageSelected()` method will be called, and we can update the `SlidesPresentationFragment` to show the new slide:

```
@Override
public void onPageSelected(int position) {
```

---

## SUPPORTING EXTERNAL DISPLAYS

---

```
if (preso != null) {
    preso.setSlideContent(adapter.getPageResource(position));
}
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

### Offering an Action Bar

The activity also sets up the action bar with three items:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:android="http://schemas.android.com/apk/res/android">

    <item
        android:id="@+id/first"
        android:icon="@android:drawable/ic_media_previous"
        android:showAsAction="always"
        android:title="@string/first">
    </item>
    <item
        android:id="@+id/last"
        android:icon="@android:drawable/ic_media_next"
        android:showAsAction="always"
        android:title="@string/last">
    </item>
    <item
        android:id="@+id/present"
        android:checkable="true"
        android:checked="true"
        android:showAsAction="never"
        android:title="@string/show_presentation">
    </item>
</menu>
```

(from [Presentation/Slides/app/src/main/res/menu/activity\\_actions.xml](#))

Two, first and last, simply set the ViewPager position to be the first or last slide, respectively. This will also update the SlidesPresentationFragment, as onPageSelected() is called when we call setCurrentItem() on the ViewPager.

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    return(super.onCreateOptionsMenu(menu));
}
```

```
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.present:
            boolean original=item.isChecked();

            item.setChecked(!original);

            if (original) {
                helper.disable();
            }
            else {
                helper.enable();
            }

            break;

        case R.id.first:
            pager.setCurrentItem(0);
            break;

        case R.id.last:
            pager.setCurrentItem(adapter.getCount() - 1);
            break;
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Presentation/Slides/app/src/main/java/com/commonsware/android/preso/slides/MainActivity.java](#))

The other action bar item, `present`, is a checkable action bar item, initially set to be checked. This item controls what we are showing on the external display:

- If it is checked, we want to show our Presentation
- If it is unchecked, we want to revert to default mirroring

The theory here is that, in a presentation, we could switch from showing the slides to showing the audience what the presenter has been seeing all along.

Switching between Presentation and default mirroring is a matter of calling `enable()` (to show a Presentation) or `disable()` (to revert to mirroring) on the `PresentationHelper`.

## Device Support for Presentation

Alas, there is a problem: not all Android 4.2 devices support Presentation, even though they support displaying content on external displays. Non-Presentation devices simply support classic mirroring.

Generally speaking, it appears that devices that *shipped* with Android 4.2 and higher will support Presentation, assuming that they have some sort of external display support (e.g., MHL). Devices that were *upgraded* to Android 4.2 are less likely to support Presentation.

Unfortunately, at the present time, there is no known way to detect whether or not Presentation will work, let alone any means of filtering on this capability in the Play Store via `<uses-feature>`. With luck, [this issue](#) will be addressed in the future.

## Presentations from a Service

Since Presentation inherits from Dialog, it also “inherits” one of the limitations of Dialog: you can only show one from an Activity. In many cases, that is not a big problem. If you are using the external display as an adjunct to your own app’s use of the primary touchscreen, you would be using an activity anyway. However, it does prevent one from using Presentation to, say, implement a video player app that plays on an external display but does not tie up the touchscreen, so the user can use other apps while the video plays.

However, as it turns out, it *is* possible to drive the content of an external display from a background app... just not by using a Presentation.

The details of this are a bit tricky, derived from [one Stack Overflow answer](#) and another [Stack Overflow question](#).

However, you do not need to deal with all of the details, courtesy of PresentationService.

PresentationService is a class in the [CWAC-Presentation library](#). PresentationService clones some of the logic from Presentation and Dialog, enough to allow you to define a View that will be shown on external display, driven by a Service. PresentationService is an abstract base class for you to extend, where PresentationService handles showing your content on an external display, and you simply manage that content.

The CWAC-Presentation library has [a demoService/ directory](#) containing a sample use of PresentationService. The recipe is fairly simple and is outlined in the following sections.

### Step #1: Attach the Libraries

The [CWAC-Presentation README](#) contains instructions for attaching the libraries to your project, whether via Gradle dependencies, downloading a pair of JARs, or using the source form of the Android library project.

### Step #2: Create a Stub PresentationService

As is noted above, PresentationService is an abstract class, so you will need to create your own concrete subclass of it, under whatever name you wish. And, as with any service, you will need a <service> element in the manifest. None of this is especially unusual.

The sample app is a service-based rendition of [the Presentation/Slides sample app](#) described earlier in this chapter. It has a SlideshowService that will display the slideshow on an external display from the background, switching slides every five seconds.

### Step #3: Return the Theme

One of the abstract methods that you will need to implement is `getThemeId()`. This should return the value of the style resource that represents the theme that you wish to use for the widgets you are going to show on the external display.

For example, if your project uses the `@style/AppTheme` approach that is code-generated for you, you can simply return `R.style.AppTheme` from `getThemeId()`, as the sample app does:

```
@Override
protected int getThemeId() {
    return(R.style.AppTheme);
}
```

### Step #4: Build the View

The other abstract method you need to implement is `buildPresoView()`. You are passed a `Context` and a `LayoutInflater`, and your job is to use those to build your

## SUPPORTING EXTERNAL DISPLAYS

---

UI for the external display, returning the root view. The `LayoutInflater` is already set up to use the theme you provided via `getThemeId()`.

Since this will be called shortly before showing the result on the external display, you can also take this time to initialize other aspects of your presentation. For example, the `SlideshowService` implements `Runnable` and has a `Handler` for the main application thread, initialized in `onCreate()`:

```
@Override
public void onCreate() {
    handler=new Handler(Looper.getMainLooper());
    super.onCreate();

    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
        mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
        mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
            "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    startForeground(1338, buildForegroundNotification());
}
```

`buildPresoView()` not only returns an `ImageView` for the slides, but also calls `run()`, which populates the `ImageView` and calls `postDelayed()` on the `Handler` to schedule `run()` to be called again in five seconds, thereby arranging to update the slide every five seconds:

```
@Override
protected View buildPresoView(Context ctxt, LayoutInflater inflater) {
    iv=new ImageView(ctxt);
    run();

    return(iv);
}

@Override
public void run() {
    iv.setImageResource(SLIDES[iteration % SLIDES.length]);
    iteration+=1;

    handler.postDelayed(this, 5000);
}
```

onDestroy() calls removeCallbacks() to break the Handler postDelayed() loop:

```
@Override
public void onDestroy() {
    handler.removeCallbacks(this);

    super.onDestroy();
}
```

### Step #5: Start and Stop the Service

Calling startService() on your service will then trigger the presentation. Or, more accurately, it will trigger PresentationService to work with a PresentationHelper to determine when a presentation should be shown. PresentationService will then use buildPresoView() to populate the external display. Conversely, calling stopService() will stop the presentation.

It is up to you to determine what is the trigger for these calls. The sample app simply starts the service immediately when run and stops the service in response to an action bar item click.

While the service is running, you are welcome to use an [event bus](#) or other means to control the contents of the presentation, by manipulating the widgets you created in buildPresoView().

Note that it is safe to call startService() on the service multiple times, if you do not know whether the service is already running and need to ensure that it is running now.

## Hey, What About Chromecast?

In February 2014, Google released a long-awaited SDK to allow anyone to write an app that connects to [Chromecast](#), Google's streaming-media HDMI stick. This Cast SDK also works with other Google Cast-capable devices, like some Android TV models. A natural question coming out of that is whether Presentation and DisplayManager work with Chromecast.

The answer is: that depends on how you look at the problem.

While Chromecast may physically resemble a wireless display adapter, in truth it is its own device, running a customized mashup of Android and ChromeOS.

Chromecast's strength is in playing streaming media from any source, primarily directly off of the Internet.

The classic approach for the Google Cast SDK is that apps are telling the Chromecast what to stream from, not streaming to the Chromecast itself. As such, the Cast API is distinctly different from that of Presentation, and while the two both deal with what the Android device would consider an external display, they are not equivalent solutions.

However:

- A Chromecast can also serve as a Miracast endpoint; if a user sets that up, then your app can use Presentation with a Chromecast
- In 2015, the Cast SDK added a Presentation-workalike API, one that presumably works with Chromecast without having to go through the Miracast setup

More coverage of Chromecast can be found in [the next chapter](#).

# Google Cast and Chromecast

---

A popular target for MediaRouter, in some countries, is Chromecast, Google's lightweight streaming media player for televisions and other HDMI displays. Originally, Chromecast was a "closed box", with no official support for third-party apps (and active work to block unofficial support). In early 2014, though, Google finally opened up Chromecast to developers.

This chapter covers what it takes to enable an Android app to "cast" content to a Chromecast, possibly as part of a broader external display strategy.

## Prerequisites

In addition to the core chapters, you should read [the chapter on MediaRouter](#) before reading this chapter.

## Here a Cast, There a Cast

You will see two terms used in this chapter and in the online literature regarding all of this: Chromecast and "Google Cast". Despite the similarities in their names, these are fairly distinct items.

### What is Chromecast?

Chromecast, as noted earlier in this chapter, is a streaming media receiver, sold by Google under their own brand.

*Figure 810: Google Chromecast*

It plugs into an HDMI port of a television or similar display, plus uses micro USB for supplying power.

However, rather than other streaming media receivers, that use Bluetooth or IR (infrared) peripherals for controlling the playback, Chromecast appears to use WiFi, designed to be controlled by a smartphone, tablet, or Chrome Web browser.

Chromecast itself runs its own OS, apparently a hybrid of Android and ChromeOS.

### What is Google Cast?

Google Cast can be thought of as a control protocol for Google Cast-enabled receivers. Through a Google-supplied SDK (or other means), Google Cast client apps (“senders”) can direct a Google Cast-enabled receiver to play, pause, rewind, fast-forward, etc. a stream.

Google Cast could, in theory, be “baked into” displays (such as a television), in addition to being supported by dedicated media receivers like the Chromecast.

Google Cast does assume that, in general, the media receiver runs its own OS and is capable of playing streaming media without ongoing assistance from the Google Cast client. Hence, the client is not “locked into” having to keep feeding content to the Google Cast client, allowing the user to go off and do other things with that client while playback is going on.

## Common Chromecast Development Notes

Chromecast goes to sleep if it detects that it is plugged into a television or monitor that is turned off (or perhaps even not accepting input from the HDMI port the Chromecast is using). While it is in this sleep mode, it may not appear as an available route. You may need to keep the display active to allow Chromecast to work properly. A 720p-capable pico projector, such as [the Vivitek Qumi series](#), can be a handy way to have a test display for Chromecast (or for live video media routes) at your development station, without the bulk of another monitor, if you have a handy surface to project upon.

Also, note that a Chromecast “uses Google’s DNS regardless of what you have defined locally”, according to [a Google engineer](#). That will preclude you from using any local domains on an organization’s own DNS server, without some tricky firewall configuration to route Google DNS requests to the in-house DNS server. Similarly, you cannot use machine names as pseudo-domain names, the way you might be able to using a regular Web browser.

## Your API Choices

Chromecast offers up remote playback media routes and works with `RemotePlaybackClient`, as is discussed in [the chapter on `MediaRouter`](#). The sample app for `RemotePlaybackClient` was tested on a Chromecast.

If you want greater control than is offered via `RemotePlaybackClient`, though, you can use [the Cast SDK](#). This SDK is part of the Play Services framework, not part of Android itself. It also works solely with Google Cast devices, of which Chromecast is the only known example, whereas other sorts of devices are able to publish remote playback media routes. Hence, using the Cast SDK will tie you to Google Cast — and some of its restrictions, both technical and legal — but will give you greater developer control over the behavior of both the Google Cast device and your app.

This chapter will focus on the Cast SDK. See [the chapter on MediaRouter](#) for coverage of `RemotePlaybackClient`.

## Senders and Receivers

There are three major components to the Google Cast environment:

- The sources of streaming media, usually out on the Internet
- The software on the playback device that plays that streaming media (“receiver”)
- The software on the control device (phone, tablet, Chrome Web browser) that directs the receiver about what to play and when (“sender”)

### The Sender App

The sender app is responsible for allowing the user to choose some media to play, then to control the actual playback (pause, start, stop, rewind, fast-forward, etc.).

The details of how to choose some media will depend heavily on the nature of the sender app. For example, a subscription-based streaming video service, such as Netflix, would allow the user to browse and search eligible content hosted by Netflix itself. Netflix presumably has its own Web service APIs that its own sender app would use for this purpose, and it is up to Netflix to offer a sensible UI for choosing a piece of media to watch.

Passing a reference (e.g., URL) to the receiver, and issuing control commands, will either be handled by `RemotePlaybackClient` (on Android) or via a Google-supplied SDK (for Android, iOS, or Chrome Web apps).

### The Receiver

The details of how a receiver is implemented is up to the manufacturer of the Google Cast-enabled device. In the case of Chromecast, it is a version of the Chrome Web browser. In principle, the implementation could be anything; in practice, it is likely that the same basic software stack will be used, courtesy of licensing Google Cast technology from Google for streaming media devices.

Official Google Cast receiver software comes in three flavors: default, styled, and custom.

### Default Receiver

The default receiver is what you get by default, as you might have guessed. If you do nothing else, your sender will be communicating with the default receiver. In effect, the default receiver is a specific Chrome Web app, running on the Chrome browser inside of the Chromecast, that is responsible for playback of your chosen media.

Other than providing the URLs to the media, plus requests to pause, start, stop, etc. the playback, you have no control over the default receiver, particularly from a look-and-feel standpoint.

### Styled Receiver

A styled receiver is one where you, the developer, supply light branding information that is applied to what otherwise is the default receiver, such as a logo.

Whereas using the default receiver requires no explicit registration with Google, using the styled receiver does require you to register your sender app with Google, at which point you will be able to provide a URL pointing to a CSS file that contains the custom styles.

### Custom Receiver

If you would rather replace the default receiver functionality with your own, either to offer more functionality, or to consume media types that may require additional configuration (e.g., DRM), you can create a custom receiver. This, in effect, is a Chrome Web app, where you provide not only CSS, but the HTML and JavaScript as well. This is substantially more complicated, and it requires registration with Google (as with the styled receiver). However, you have far greater control over what appears on the television.

## Supported Media Types

The [list of supported media types](#) is likely to change over time. At present, Google Cast-enabled devices are supposed to support major media types, such as:

- MP4 and VP8 for video
- MP3, AAC, and Ogg Vorbis for audio
- PNG, JPEG, GIF, BMP, and WEBP for still images (e.g., photos)
- HLS and MPEG-DASH for streaming

## Cast SDK Dependencies

Using the Cast SDK to develop for Google Cast devices has a fair number of dependencies... and not just dependencies on particular libraries.

### Developer Registration

If you are going to be using the default receiver, *and* you do not need to have debugging access to the device (e.g., to examine JavaScript logs from the Web rendering engine on the Google Cast device), you are welcome to develop your apps independently.

However, if you will use a styled or custom receiver, or you wish to gain debugging access to the device, you will need to [register with Google](#).

This process will involve you agreeing to some terms of service (see below), along with paying a \$5 registration fee.

### The Terms of Service

The Google Cast SDK has separate [Developer Terms of Service](#) from anything else. If you are going to use the Google Cast SDK, you will be expected to agree to these terms as part of the registration processes. You are strongly encouraged to review these terms with qualified legal counsel. Failure to comply with the terms may cause your app (or, more accurately, your styled or custom receivers) to “be de-registered”, presumably meaning that it will no longer work.

These terms contain some curious clauses, worth discussing with your attorney, including a requirement to adhere to a massive [design checklist](#), controlling the look-and-feel of your sender and receiver. This includes a specific requirement for the precise icon to be used for initiating communications with the Google Cast receiver. Those agreeing to these terms are also barred from doing things that might allow others to display content on a Google Cast receiver without using the SDK or breaking through any access controls on the Google Cast device (e.g., creating an exploit that roots it).

### Device Registration and Development Setup

While registering your device is optional, it may be handy for custom receivers, so that you can debug your custom HTML and JavaScript that is being rendered by the

Google Cast device.

First, you should configure your device to publish its serial number to Google when it checks for Google Cast software updates. For the Chromecast, this involves using whatever means you used to configure the Chromecast in the first place for your network (e.g., [the Chromecast Android app](#)). There should be an option for “Send this Chromecast’s serial number when checking for updates” — in the Chromecast Android app, this will be in the “Share Data” section of the device’s settings screen.

Once you have registered as a Cast SDK developer, the [Google Cast SDK Developer Console](#) will have an option for you to “Add New Device”. You will need the Google Cast device’s serial number — in the case of the Chromecast, this is etched on the underside of the device.

Note that it may take some time before your device registration will be complete, as the device will not find out about the registration until it checks for another update, and there does not appear to be a way to trigger this. Hence, you may need to wait a few hours. You will know that you have access once you can successfully connect, via a Web browser, to port 9222 on the IP address of the Google Cast device. For the Chromecast, the easiest way to get that IP address is through your Chromecast configuration tool (e.g., the Chromecast Android app). Note that the Web page may not be much (e.g., “Inspectable WebContents”), but it will not return a 404 or similar error code.

If you wish to use a styled or custom receiver, you will also need to register your application, in the same Cast SDK Console area. This will be covered in a future edition of this book.

### **The Official Libraries**

You will need the Google Play Services SDK, which you may have used already for other portions of the Play Services framework, such as [GCM](#), [Maps V2](#), and so on.

You will also need the same mediarouter Android library project covered in [the chapter on MediaRouter](#), along with its dependencies (e.g., the support-v4 library and the appcompat library).

### **The CastCompanionLibrary... Or Not**

The Play Services SDK (and its dependencies) is all that you need to write Cast SDK applications. However, Google has also published [the Cast Companion Library](#)

[\(CCL\)](#), containing a lot of helper code to make it a bit easier for you to write apps that adhere to the [design checklist](#)

## Developing Google Cast Apps

Coverage of the Cast SDK, including sample apps, will be added to this chapter in a future edition of this book.

# The “Ten-Foot UI”

---

Increasingly, Android devices are being used to drive screens that are somewhat larger than those found on your average phone or tablet:

- Many Android phones and tablets [can directly deliver content to TVs, monitors, and projectors](#) via HDMI, MHL, SlimPort, Miracast, and similar technologies
- Android devices can control the behavior of non-Android presentation engines, like [Chromecast](#)
- Some Android devices themselves use a TV or other display as their primary screen, from big names ([Google](#) and [Amazon](#)), mid-range firms (OUYA), and firms you have never heard of (various Android “HDMI sticks” available on eBay, Alibaba, etc.)

Technically, writing for these displays is a bit different than you would do for a phone or tablet. In some cases, such as with Google Cast, writing for these displays is more substantially different.

However, in all cases, the design of the UI needs to be different, owing to different physical and usage characteristics of large screens. This chapter will focus on this so-called “ten-foot UI” and help you understand what sorts of changes will need to be considered.

## Prerequisites

Understanding this chapter requires that you have read the chapter on [focus management](#).

The sample of the “leanback” UI is a revised version of a sample app profiled in [the](#)

[chapter on the MediaStore ContentProvider.](#)

### What is the “Ten-Foot UI”?

The “ten-foot UI” is not referring to a UI that is 3.048 meters high or 9.87789527 by  $10^{-17}$  parsecs wide.

Rather, the distance referred to by the “ten-foot UI” indicates the approximate distance between the viewer and the screen. People usually sit farther from TVs, monitors, and projectors than they do phones or tablets when using them. Partly, that is because the screens are a lot bigger, so they do not need to sit as closely. Partly, that is because often times the screens are being “used” by more than one person (e.g., an audience watching a presentation on a projector), and everybody needs to be able to see the screen.

The expression “ten-foot UI” refers to the design constraints inherent in developing user interfaces to be used across such a distance. Even though the screen may be bigger, the *apparent* screen size (or “[visual angle](#)” may be no bigger than phones or tablets, or sometimes even less. That, plus user input differences, technical differences between TVs and other displays, and so on all go into the “ten-foot UI” design guidance that UI experts give us.

### Overscan

Television standards have been with us for several decades. Television sets from the dawn of television had significantly lower and more variable quality than today’s devices. The delivery of the signal at the outset had significantly lower and more variable quality than today’s over-the-air HDTV or cable connections. As a result of these two characteristics, the engineers devising television standards made some decisions that, while necessary at the time, add some complexity to delivering apps to televisions, in the form of overscan.

Simply put, not all televisions show exactly the same picture. Depending on device and signal, a television may show up to 12% less of the picture, as measured horizontally and vertically. Hence, the theoretical ideal screen size (e.g., 720p = 1280 x 720 pixels) may be achieved in some cases, but you may get less (e.g., 1128 x 634 pixels) in other cases.

Android TV and Fire TV ignore overscan, relying upon developers to take it into account. As a result, the reported screen resolution is *not* necessarily available to

you. Instead, you need to avoid putting anything important in the outer ~10% of the screen, centering the important stuff within the available space.

So, for example, you might have a background for your game (e.g., a starfield). Make sure that there is nothing essential on the background image that the user must see that is along the outside edge. Then, if part of the background is lost due to overscan, there is no particular problem.

The bigger issue, of course, is standard foreground widgets and containers. Android developers are used to being able to have layouts that work edge-to-edge, with just a minor amount of margin so text, icons, and the like do not run right into the edge of the screen. Now, you need more than a “minor amount” of margin. Google and Amazon recommend a 27dp margin on the top and bottom sides of your activities, and a 48dp margin on the left and right sides of your activities.

For activity and fragment layouts that are dedicated for TV presentation, you could elect to put those margins in those layouts, or add them via a theme. However, for activity and fragment layouts that may be used both for a touchscreen device (phone or tablet) and a television, adding the margin on the touchscreen device may be unsuitable.

For that, you could use dimension resources in different resource sets. Define `overscan_horizontal` and `overscan_vertical` to be both 0dp (or whatever) in `res/values/dimens.xml`. Define them to be 48dp and 27dp, respectively, in `res/values-television/dimens.xml`, where `-television` is a resource set qualifier that will be used in Android TV and other TV-based Android devices. Then, you can refer to `@dimen/overscan_horizontal` and `@dimen/overscan_vertical` in activity/fragment layouts, to take overscan into account conditionally.

## Navigation

Most televisions, monitors, and projectors are not touchscreens. Users will be changing what is shown either by using some sort of remote control (e.g., Fire TV, Android TV) or by using an app that runs on a touchscreen device (e.g., direct monitor connection, Chromecast).

In the remote control scenarios, in-screen navigation becomes important. Those remote controls usually focus on some sort of D-pad or arrow keys for moving focus and clicking on widgets. This forces users into a sequential-access model (e.g., click “left” three times then “enter” once) rather than the random-access model that

touchscreens offer.

The chapter on [focus management](#) covers these sorts of concerns. Bear in mind that getting focus management implemented properly in your app not only helps with the “ten-foot UI”, but also can help other sorts of users, such as the visually impaired or motion impaired who cannot readily use touchscreens.

Also note that text input is a significant chore when you try to do it using a remote control. Hence, even to the extent it is possible, try to limit the number of places that users *have* to type into `EditText` widgets and the like in your UI. If possible, offer a way for users to do that sort of thing via a separate app on their phone or tablet, or perhaps through a Web browser that pushes the information to the TV set-top box.

## Stylistic Considerations

In addition to structural issues like overscan and focus management, there are some stylistic issues that you will need to take into account when designing your ten-foot UI.

### Fonts

With phones and tablets, if the user has some difficulty reading a bit of text, they can usually fix the problem just by moving their hand a bit, to bring the screen closer.

That becomes less likely of a solution as you get into larger screens. People get annoyed if they have to get up off of their sofa to squint and try to read text on a television. In a presentation setting, people may be unable to move into a better viewing position.

To combat this:

- Err on the side of larger fonts, with a medium weight (i.e., not too light or too heavy of strokes that make up the letters)
- Aim to use simpler fonts, particularly sans-serif fonts, as those tend to be more readable at a distance
- Where practical, give the user control over font size within your application, or allow some other sort of “zoom” mechanism, to help see details that they might otherwise be unable to see

## THE “TEN-FOOT UI”

---

- Light text on a dark background tends to be easier to read on televisions, so consider using a theme that supports this (e.g., `Theme.Holo` as opposed to `Theme.Holo.Light`)
- Use fewer words
- Use more line spacing (e.g., via `android:lineSpacingMultiplier` on a `TextView`), so descenders from one line are clearly distinguished from the tops of characters on the next line

### Padding and Margins

In addition to adding more line spacing, consider adding more padding and margins to your ten-foot UIs.

Bear in mind that screen density calculations start to go astray as the user moves further away from the screen. We are used to making those calculations based on actual pixels on phones and tablets (a.k.a., “two-foot UI”). The *apparent* size of a television may be no bigger than that of a tablet, once the user’s distance from the screen is taken into account. However, screen density has no good way to take that distance into account, other than by effectively hard-coding the density (e.g., Fire TV considering everything to be `-xhdpi`). Hence, particularly for padding and margins, you may need to “finesse” your values a bit on televisions and the like.

In cases where Android is directly talking to the television (e.g., HDMI/MHL from a phone or tablet, Fire TV, Android TV, Android HDMI sticks), you can use `-notouch` qualifiers on resource sets to provide different values for dimension resources.

### Colors

Usually, with the ten-foot UI, we treat televisions, monitors, and projectors equally. They do differ in one key area: color management.

Televisions, for historical reasons, tend to have different color responses than do monitors or projectors. As [Google puts it](#):

TV screens have higher contrast and saturation levels than computer monitors

Even to the extent that those settings could be adjusted, if the television will be used *as a television*, the factory settings may be the proper ones. Beyond that, few television owners think about changing such things.

## THE “TEN-FOOT UI”

---

As a result, you need to be careful with your color choices:

- Pure white (#FFFFFF) can cause problems, such as “ghosting”, so use a very light gray (e.g., #F1F1F1, #E8E8E8) instead. Pure black (#000000) is not a problem.
- Aim for more muted colors, particularly in the blue/green/violet end of the color spectrum, as opposed to bright red or orange. Warm colors tend to bleed more than cool colors.

### Aspect Ratio

Bear in mind that different TVs (or other displays) may have different aspect ratios. While many will be 16:9, also consider 4:3 and 21:9 (also known as 2.35:1).

## The Leanback UI

In 2014, Google added the `leanback-v17` library to the Android Support package. This contains code to help you create TV-focused user interfaces. While the intention is for this library to help you create UIs for Android TV, there is nothing strictly tied to the Android TV platform in `leanback-v17`. Your user interfaces can work just fine on other TV environments (e.g., Amazon Fire TV). And they still support touchscreen events, and so they can be used on phones and tablets as well, though perhaps not optimally.

### Where to Get Leanback

Android Studio users can add a dependency on the `leanback-v17` artifact from the Android Support Repository:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.android.support:leanback-v17:27.1.1'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 17
    }
}
```

## THE “TEN-FOOT UI”

---

```
targetSdkVersion 27
applicationId "com.commonware.android.video.browse"
}
}
```

(from [Leanback/VideoBrowse/app/build.gradle](#))

This particular bit of Gradle configuration comes from the [Leanback/VideoBrowse](#) sample application, which will be the focus of this “leanback” UI section. This project depends not only upon `leanback-v17`, but also upon the Picasso image loading library, profiled in [the chapter on Internet access](#).

If you read through [the chapter on MediaStore](#), this sample app will seem familiar. In the `MediaStore` chapter, we created a sample app that would present a list of videos available on the device in a `ListView`, using Picasso for handling the video thumbnails. The `VideoBrowse` “leanback” sample app is the same app, adjusted to use a “leanback” UI instead of a `ListView`.

### **BrowseSupportFragment**

The primary UI element that we get from `leanback-v17` is `BrowseSupportFragment`. `BrowseSupportFragment` is a fragment designed to allow browsing of a roster of content through a two-dimensional scrolling interface. There is a list of “headers” (e.g., categories of videos), and within each header is a horizontal scrolling list of items within that header.

## THE “TEN-FOOT UI”

---

This sort of UI pattern is fairly commonplace in TV-centric apps, as it works well with TV-style remotes:

*Figure 811: VideoBrowse Sample App, As Initially Launched*

The VideoBrowse sample application consists of one activity, hosting a `BrowseSupportFragment`, that will display the roster of available videos on the device. Clicking on an individual video will bring up the device’s default video player app, just as the `VideoList` sample did in the chapter on the `MediaStore`.

### Theme and Activity

There is very little specifically required of an activity that hosts a `BrowseSupportFragment`, particularly on the Java side. So long as the activity gets the `BrowseSupportFragment` onto the screen, the key work is done.

In the case of our `MainActivity`, it uses a `res/layout/main.xml` file, pointing to our `VideosFragment`, which is a subclass of `BrowseSupportFragment`:

```
<?xml version="1.0" encoding="utf-8"?>
<fragment xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/videos"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

## THE “TEN-FOOT UI”

---

```
android:name="com.commonware.android.video.browse.VideosFragment"  
</>
```

(from [Leanback/VideoBrowse/app/src/main/res/layout/main.xml](#))

The Java code simply loads up the layout containing that static fragment, plus has an `onVideoSelected()` method that will be called if the user clicks on a video:

```
package com.commonware.android.video.browse;  
  
import android.content.Intent;  
import android.net.Uri;  
import android.widget.Toast;  
import java.io.File;  
import static android.Manifest.permission.READ_EXTERNAL_STORAGE;  
  
public class MainActivity extends AbstractPermissionActivity {  
    private static final String[] PERMS={READ_EXTERNAL_STORAGE};  
  
    @Override  
    protected String[] getDesiredPermissions() {  
        return PERMS;  
    }  
  
    @Override  
    protected void onPermissionDenied() {  
        Toast  
            .makeText(this, R.string.msg_no_perm, Toast.LENGTH_LONG)  
            .show();  
        finish();  
    }  
  
    @Override  
    public void onReady() {  
        setContentView(R.layout.main);  
    }  
  
    public void onVideoSelected(String uri, String mimeType) {  
        Uri video=Uri.fromFile(new File(uri));  
        Intent i=new Intent(Intent.ACTION_VIEW);  
  
        i.setDataAndType(video, mimeType);  
        startActivity(i);  
    }  
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonware/android/video/browse/MainActivity.java](#))

---

## THE “TEN-FOOT UI”

---

However, there are two other requirements of the activity.

For this particular sample app, we want to show the videos that are available locally on the device. That requires us to have the `READ_EXTERNAL_STORAGE` permission, which in turn requires us to use runtime permissions. So, this sample app uses the same sort of `AbstractPermissionActivity` seen elsewhere in the book to handle the up-front permission request. Assuming that the user grants the permission, `onReady()` loads the aforementioned layout, which loads our fragment.

In terms of what goes in the manifest:

- The activity needs to use a theme that is, or inherits from, `Theme.Leanback`
- To show up as the “launcher activity” for an Android TV device, the activity needs to have an `<action>` of `MAIN` and a `<category>` of `LEANBACK_LAUNCHER`:

```
<application
  android:allowBackup="false"
  android:hardwareAccelerated="true"
  android:icon="@drawable/ic_launcher"
  android:banner="@drawable/banner"
  android:label="@string/app_name">
  <activity
    android:name="MainActivity"
    android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
    android:label="@string/app_name"
    android:screenOrientation="sensorLandscape"
    android:theme="@style/Theme.Leanback">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
      <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
    </intent-filter>
  </activity>
</application>
```

(from [Leanback/VideoBrowse/app/src/main/AndroidManifest.xml](#))

In our case, we match on either the `LAUNCHER` or the `LEANBACK_LAUNCHER` category, as this particular activity can work on either form factor family (touchscreens or TVs). However, other apps might have separate “launcher activity” implementations for phones/tablets versus televisions, and so having a separate `LEANBACK_LAUNCHER` category allows us to indicate which activities serve which role.

This activity also sets its `screenOrientation` to `sensorLandscape`, indicating that it will always present itself in landscape mode, no matter how the device is held. It also uses a `configChanges` attribute to opt out of configuration changes due to orientation changes, as the UI is not changing in those cases.

## THE “TEN-FOOT UI”

---

Android TV wants a “banner” graphic as well, identified in the `android:banner` attribute of either the `<application>` element or the `LEANBACK_LAUNCHER <activity>` element. This graphic should be 320px by 180px, saved as an `xhdpi` drawable. This will be used for the entry in the Android TV launcher, in lieu of our regular launcher icon:

*Figure 812: Android TV Launcher, Showing VideoBrowse App Banner, Selected*

We also have two `<uses-feature>` elements:

- `android.software.leanback`, saying that we would love to run on a leanback-style device (e.g., Android TV), but it is not required
- `android.hardware.touchscreen`, saying that we would love to run on a device with a touchscreen, but it is not required

The latter element is particularly important for Android TV and similar devices. By default, Android apps expect a touchscreen; this element opts out of that requirement, so the app can be installed on a device that lacks a touchscreen.

### Loading the Videos

`VideosFragment` is responsible for showing the roster of available videos on the device, using a `BrowseSupportFragment` two-dimensional structure. This means,

---

## THE “TEN-FOOT UI”

---

though, that VideosFragment needs to be able to find out what videos are available. As with the VideoList sample in [the MediaStore chapter](#), VideosFragment will query the MediaStore ContentProvider to find out about the videos, by means of a CursorLoader.

In onCreateView(), VideosFragment calls initLoader() to start loading the videos, in addition to indicating that the fragment itself will serve as the controller handling clicks on individual videos, via the setOnItemClickListener() interface:

```
@Override
public void onCreateView(View view, Bundle savedInstanceState) {
    super.onCreateView(view, savedInstanceState);

    getLoaderManager().initLoader(0, null, this);
    setOnItemClickListener(this);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

For those calls to work, VideosFragment needs to implement the LoaderManager.LoaderCallbacks<Cursor> interface (for initLoader()) and the OnItemClickListener (for setOnItemClickListener()).

The initLoader() call triggers a call to our onCreateLoader() method, which queries the MediaStore roster of videos for all videos, ordered by title:

```
@Override
public Loader<Cursor> onCreateLoader(int arg0, Bundle arg1) {
    return(new CursorLoader(
        getActivity(),
        MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
        null, null, null,
        MediaStore.Video.Media.TITLE));
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

That, in turn, will eventually trigger a call to onLoadFinished():

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    mapCursorToModels(c);

    setHeadersState(BrowseSupportFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));
}
```

## THE “TEN-FOOT UI”

---

```
ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
ArrayObjectAdapter listRowAdapter=
    new ArrayObjectAdapter(new VideoPresenter(getActivity()));

for (Video v : videos) {
    listRowAdapter.add(v);
}

HeaderItem header=new HeaderItem(0, "Videos");

rows.add(new ListRow(header, listRowAdapter));
setAdapter(rows);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

We will get to much of the code in `onLoadFinished()` a bit later in this chapter. However, the first thing that `onLoadFinished()` does is call a `mapCursorToModels()` method. This method will be responsible for taking the data from the `Cursor` we get back from `MediaStore` and using it to populate some model objects that will drive what the `BrowseSupportFragment` displays to the user. `BrowseSupportFragment`'s API is not especially well-suited for working with a `Cursor` directly; it is simpler to have a separate collection of model objects representing the results of the database query.

In our case, the model object will be a `Video`:

```
package com.commonsware.android.video.browse;

class Video {
    int id;
    String uri;
    String mimeType;
    String title;

    Video(int id, String uri, String mimeType, String title) {
        this.id=id;
        this.uri=uri;
        this.mimeType=mimeType;
        this.title=title;
    }

    @Override
    public String toString() {
        return(title);
    }
}
```

## THE “TEN-FOOT UI”

---

```
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/Video.java](#))

There are four pieces of data we need to track for the video:

- Its unique id, so we can get a thumbnail of the video later on
- Its Uri (here, held in a string representation), to be used to play back the video
- Its MIME type, also to be used to play back the video
- Its title, which will be used along with its thumbnail when rendering the video as part of the BrowseSupportFragment roster of content

VideosFragment holds onto a collection of these Video objects in a data member named videos:

```
private ArrayList<Video> videos=new ArrayList<Video>();
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

mapCursorToModels() iterates over the Cursor rows and creates a Video object for each row, adding the Video to the videos, and closing the Cursor when done:

```
private void mapCursorToModels(Cursor c) {
    videos.clear();

    int idColumn=c.getColumnIndex(MediaStore.Video.Media._ID);
    int uriColumn=c.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        c.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
    int titleColumn=
        c.getColumnIndex(MediaStore.Video.Media.TITLE);

    for (c.moveToFirst(); !c.isAfterLast(); c.moveToNext()) {
        videos.add(new Video(c.getInt(idColumn),
            c.getString(uriColumn),
            c.getString(mimeTypeColumn),
            c.getString(titleColumn)));
    }

    c.close();
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

### Headers and Contents

So, let’s look at the full `onLoadFinished()` method, called when we have our `Cursor` of videos:

```
@Override
public void onLoadFinished(Loader<Cursor> loader, Cursor c) {
    mapCursorToModels(c);

    setHeadersState(BrowseSupportFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));

    ArrayObjectAdapter rows=new ArrayObjectAdapter(new ListRowPresenter());
    ArrayObjectAdapter listRowAdapter=
        new ArrayObjectAdapter(new VideoPresenter(getActivity()));

    for (Video v : videos) {
        listRowAdapter.add(v);
    }

    HeaderItem header=new HeaderItem(0, "Videos");

    rows.add(new ListRow(header, listRowAdapter));
    setAdapter(rows);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](https://github.com/commonsware/android-video/browse/VideosFragment.java))

As mentioned, the first thing that we do is map the `Cursor` contents to `Video` objects.

We then make two general changes to the look of the `BrowseSupportFragment`:

- We enable the headers. In truth, that would not make sense for this particular application, as we only have one header. However, we are enabling the headers to show what that looks like, as many uses of `BrowseSupportFragment` will need the full two-dimensional browsing experience.
- We set the title to be the `app_name` string resource. This title goes in the upper-right corner and is used to remind the user of what app they are in, much like the title in an action bar would on a phone or tablet.

We then build up the two-dimensional data model and rendering rules for the browsing experience. This involves creating instances of an `ObjectAdapter` base

## THE “TEN-FOOT UI”

---

class, supplied by `leanback-v17`. `ObjectAdapter` fills a role reminiscent of `Adapter` with `AdapterView`, insofar as it organizes model data and helps with the rendering. However, whereas `Adapter` does that all itself, `ObjectAdapter` splits the roles out: it handles the model data and delegates to `Presenter` implementations for rendering individual items from the model data.

In the two-dimensional browsing model, we need an `ObjectAdapter` that represents our rows, where each row has a header and a nested `ObjectAdapter` for the items to appear in that row.

Just as `ArrayAdapter` is the easiest `Adapter` class to use, `ArrayObjectAdapter` is the easiest `ObjectAdapter` to use. `ArrayObjectAdapter` adapts arrays of objects, where in this case, “array” really means `ArrayList`.

Unlike `ArrayAdapter`, where we primarily build up our array and hand it to the adapter, `ArrayObjectAdapter` has us populate the “array” via methods like `add()` on the `ArrayObjectAdapter`.

So, after calling `setHeadersState()` and `setTitle()` as described above, we:

- Create an `ArrayObjectAdapter`, named `rows`, that uses the `ListRowPresenter` supplied by `leanback-v17` to render the row
- Create another `ArrayObjectAdapter`, named `listRowAdapter`, that uses a custom `VideoPresenter` that we will examine later in this chapter
- Iterate over the `Video` roster and add each to the `listRowAdapter`
- Create an instance of a `HeaderItem`, supplied by `leanback-v17`, that represents the header entry itself, with a title for that header
- Create an instance of a `ListRow`, supplied by `leanback-v17`, that wraps around the `HeaderItem` and the `listRowAdapter` for the items to show in that row
- Put the `ListRow` in the `rows` `ArrayObjectAdapter`, and pass `rows` to `setAdapter()` to tell the `BrowseSupportFragment` what to display

A more complex app might have several `ListRow` objects in `rows`, one per header. For example, you might group videos by some sort of categorization scheme, where each `HeaderItem` names the category and the `ListRow` also contains the videos specific to that category.

Of the classes cited here, all are stock implementations from `leanback-v17`, with the exception of `VideoPresenter`, which is responsible for rendering a `Video` as an item in the horizontal list of videos.

### Presenting the Presenters

A Presenter, in the leanback-v17 system, is an object responsible for converting some model object (e.g., a Video) into a visual representation that will be used for an ObjectAdapter.

The Presenter abstract class enforces a “view holder” approach. A view holder is simply a data structure holding onto a basket of widgets. The idea is that the view holder represents all the widgets for a particular instance of the Presenter. So, we now have two levels of indirection over the Adapter approach used by ListView and kin: not only does ObjectAdapter not do the rendering, but Presenter alone does not do the rendering, but instead involves a view holder.

As a result, a Presenter implementation will tend to be artificially complex.

First, let’s look at the view holder, implemented as a static class inside VideoPresenter, named Holder, that extends the stock Presenter.ViewHolder class:

```
static class Holder extends Presenter.ViewHolder {
    private final ImageCardView cardView;
    private int targetWidth, targetHeight;

    public Holder(View view) {
        super(view);

        cardView=(ImageCardView)view;

        Resources res=view.getContext().getResources();

        targetWidth=(int)res.getDimension(R.dimen.card_width);
        targetHeight=(int)res.getDimension(R.dimen.card_height);
    }

    protected void updateCardViewImage(Uri uri) {
        Picasso.with(cardView.getContext())
            .load(uri)
            .resize(targetWidth, targetHeight)
            .centerCrop()
            .onlyScaleDown()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(new Target() {
                @Override
                public void onBitmapLoaded(Bitmap bitmap,
                    Picasso.LoadedFrom from) {
                    Drawable bmpDrawable=
```

## THE “TEN-FOOT UI”

---

```
        new BitmapDrawable(
            cardView.getContext().getResources(),
            bitmap);

        cardView.setMainImage bmpDrawable);
    }

    @Override
    public void onBitmapFailed(Drawable errorDrawable) {
        cardView.setMainImage(errorDrawable);
    }

    @Override
    public void onPreparesLoad(Drawable placeholderDrawable) {
        cardView.setMainImage(placeholderDrawable);
    }
}
});
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

The Presenter will set up the UI, in the form of an `ImageCardView` – another stock class provided by `leanback-v17` that is an `ImageView` with an associated caption. As we will want to pour video thumbnails into the `ImageView`, this sample app uses Picasso, the same way the `VideoList` sample does.

We also determine how big the thumbnail should be, based on a pair of dimension resources, `card_width` and `card_height`:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
  <dimen name="card_width">400dp</dimen>
  <dimen name="card_height">300dp</dimen>
</resources>
```

(from [Leanback/VideoBrowse/app/src/main/res/values/dimens.xml](#))

The `updateCardViewImage()` will be called when we are ready to use this `ViewHolder` to present the contents of some particular `Video`. We receive the `Uri` to the video and set up Picasso to:

- Load the image from that `Uri` (`load()`)
- Resize it to the target dimensions (`resize()`), but only if the image is larger (`onlyScaleDown()`), and then crop to get the image centered in the desired size (`centerCrop()`)

## THE “TEN-FOOT UI”

---

- Use the supplied `ic_media_video_poster` as a placeholder

Then, since Picasso has no knowledge of how to work with an `ImageCardView` from `leanback-v17`, we have to use a different version of `into()`, one that takes a `Target` as parameter. Here, we use an anonymous inner class implementation of a `Target`. The key method is `onBitmapLoaded()`, where we wrap the `Bitmap` in a `BitmapDrawable` and call `setMainImage` on the `ImageCardView` to populate it. Similarly, there are `onBitmapFailed()` and `onPrepareLoad()` methods for handling errors and the placeholder, respectively.

Now, given the `Holder`, we can set up the rest of `VideoPresenter`, starting with its constructor:

```
VideoPresenter(Context ctxt) {  
    super();  
  
    this.ctxt=ctxt;  
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

Here, mostly, we are holding onto a supplied `Context` for eventually creating our `ImageCardView`.

At the point in time that the `VideoPresenter` needs to create a view holder to use for rendering an item, `onCreateViewHolder()` will be called:

```
@Override  
public ViewHolder onCreateViewHolder(ViewGroup parent) {  
    ImageCardView cardView=new ImageCardView(ctxt);  
  
    cardView.setFocusable(true);  
    cardView.setFocusableInTouchMode(true);  
  
    return(new Holder(cardView));  
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

Here, we set up an `ImageCardView`, marking it as focusable both for the D-pad and for touchscreens, and wrap that in our custom `Holder`.

At the point in time when we are ready to show a `Video` using the widgets managed by the `Holder`, `onBindViewHolder()` is called:

---

## THE “TEN-FOOT UI”

---

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
    Object item) {
    Video video=(Video)item;
    Holder h=(Holder)viewHolder;
    Resources res=ctxt.getResources();

    h.cardView.setTitleText(video.toString());
    h.cardView.setMainImageDimensions((int)res.getDimension(R.dimen.card_width),
        (int)res.getDimension(R.dimen.card_height));

    Uri thumbnailUri=
        ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
            video.id);

    h.updateCardViewImage(thumbnailUri);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

We are passed in a generic Object that is the model data from our ObjectAdapter — in this case, it will be a Video, as we are using VideoPresenter with an ArrayObjectAdapter that holds the Video instances. We update the ImageCardView caption based on the title of the Video, then set the size of the ImageView based upon the same dimension resources as we used with UIL’s ImageSize. We construct a Uri pointing to the video as known to MediaStore (given the video’s id), and pass the String representation of that into the Holder, which will handle the UIL work.

There is one other abstract method that we need to override to satisfy Presenter: onUnbindViewHolder():

```
@Override
public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideoPresenter.java](#))

onUnbindViewHolder() can often be skipped. However, if you have memory-intensive stuff in the view holder — like the bitmap in an ImageView — this is a fine time to take steps to release that memory. In our case, we null out the image in the ImageCardView. Ideally, we would somehow work with UIL to arrange to recycle this Bitmap object, since all of our Bitmap objects should be the same size.

### Handling Clicks

BrowseSupportFragment automatically handles a lot of input events, such as:

## THE “TEN-FOOT UI”

---

- arrow key events in the list of headers, to move a selection bar up and down the list
- click events on a header, to allow navigation into the row of items for that header
- arrow key events on an item, to navigate to the next or previous item
- BACK button events on an item, to return to the list of headers

It also captures the click event on an item and routes that to the `onItemClicked()` method of the `BrowseSupportFragment`, which we override in `VideosFragment`:

```
@Override
public void onItemClicked(Presenter.ViewHolder viewHolder,
    Object o,
    RowPresenter.ViewHolder rowViewHolder,
    Row row) {
    Video video=(Video)o;
    ((MainActivity) getActivity()).onVideoSelected(video.uri,
                                                video.mimeType);
}
```

(from [Leanback/VideoBrowse/app/src/main/java/com/commonsware/android/video/browse/VideosFragment.java](#))

The `Object` passed as the second parameter to `onItemClicked()` is the `Object` in our `ObjectAdapter` for the clicked-upon item. In our case, the `ObjectAdapter` is our `ArrayObjectAdapter` wrapped around our `Video` objects, and so the `Object` passed into `onItemClicked()` is a `Video`. Given that, we can call out to the hosting activity and its `onVideoSelected()` to go play back the selected video.

## THE “TEN-FOOT UI”

---

### The Results

Launching the app shows our list of headers (with just the one header), thumbnails of videos in that header, and the “Video Browse Demo” title:

*Figure 813: VideoBrowse Sample App, As Initially Launched*

## THE “TEN-FOOT UI”

---

Selecting a video slides the headers out of the way and shows the full card for the video, including the video’s title:

*Figure 814: VideoBrowse Sample App, With First Video Selected*

Clicking on the selected video brings up the default video player for the device.

Note that this UI is not tied strictly to TV-style displays. For example, the screenshots shown in this section came from an Android tablet, as you can tell by the status bar and navigation bar. The `BrowseSupportFragment` UI is not completely out of place on a tablet, and it works with touch events as well as the key events that would be emitted by a TV-style remote control. On a phone, the `BrowseSupportFragment` UI gets a bit cramped, particularly in portrait, though it still works.

## Testing Your Theories

Ideally, you test your ten-foot UI in a ten-foot experience, using something connected to a television.

This does not have to be expensive:

- If you have a phone or tablet that can connect to a TV via HDMI, MHL, or

## THE “TEN-FOOT UI”

---

- Miracast, at most you might need a cable or a Miracast adapter
- Android “HDMI sticks” or other Android set-top boxes can be found on eBay, Alibaba, or elsewhere
- The Fire TV line of devices are available in some markets fairly inexpensively
- Some Android TV devices are not especially expensive

If you need to develop using more traditional hardware (phone or a tablet) or an emulator, the big thing will be to make sure that you are estimating the screen size properly. For example, a 10“ tablet, held fully at arm’s length, will have the same visual angle as a modest television (~26”) at a comfortable seating distance. While this will not help with color saturation, using remote controls, or other aspects of the ten-foot UI, you can at least get a sense of whether your text and UI controls will be large enough to be usable.

# Putting the TVs All Together: Decktastic

---

This book profiles many ways of getting content to a TV:

- By means of `Presentation` and related classes, for touchscreen-enabled devices that also happen to presently have a connection to an external display
- By means of `RemotePlaybackClient`, for use with devices like the Chromecast
- By means of directly displaying output on a TV, for devices where the TV is the primary display (e.g., Android TV devices, Amazon's Fire TV and Fire TV Stick)

It is entirely possible to create one app that can support all of these modes from one code base, though you are constrained by the most limited option. In this case, `RemotePlaybackClient` is the most limited option, as its API is designed to tell some external device to play some media, whereas the other options can support comparatively arbitrary user interfaces rendered through normal Android widgets.

In this chapter, we will review the [Presentation/Decktastic](#) sample application. This app is designed to give the user a roster of slide-based presentations to choose from, then deliver one of those presentations. The presentation will appear on the external display (e.g., TV or projector), while the presenter will be able to control the presentation either from a touchscreen-equipped Android device or a remote control.

## Prerequisites

You should read the following chapters before this one:

- [Supporting External Displays](#)
- [Media Routes](#)
- [The “10 Foot UI”](#)

Reading up on specific hardware, like the [Amazon Fire TV](#), is a good idea but not as critical.

## Introducing Decktastic

Before we get into discussing the implementation of Decktastic, we should first review what the app looks like and how it functions.

## Launcher UI

If you were to set up Decktastic on some test device and run it, the first thing that you would see is a media browsing UI built from the Leanback-v17 support library, showing you a roster of the available presentations to choose from:

*Figure 815: Decktastic Media Browser*

This UI works fine on TVs and on tablets. On phones... it gets a bit cramped.

Tapping on a presentation selects it:

*Figure 816: Decktastic Media Browser, With Selected Presentation*

## Presentation UI

Tapping on the presentation again opens it up into a ViewPager-based UI for the presenter:

Figure 817: Decktastic Main UI, Showing Presentation and Open Overflow

However, who sees what depends a bit upon the available hardware:

- If you are running this standalone on a phone or tablet, you will see the ViewPager-based UI
- If you are running this on a phone or tablet with a connection to an external display, you will see the ViewPager-based UI, but the *audience* (those looking at the external display) will, by default, just see the slides
- If you are running this on a phone or tablet with a connection to a Chromecast or similar remote playback device, we get the same results as with the external display (you see the full UI, the audience sees the slides)
- If you are running this on an Android TV, Fire TV, or similar device, both you and the audience only see the slides

To move through the slides, you can:

- Swipe the ViewPager

- Use the ViewPager tabs
- Use right or down keys to move forward, or left or up keys to move backward, whether on a QWERTY keyboard (e.g., Bluetooth) or via the D-pad on some form of remote (for TV-centric scenarios, like Android TV or Fire TV)

## Implementing Decktastic

Decktastic is a pair of activities that “stand upon the shoulders of giants”, in the form of using seven third-party libraries that provide a lot of the utility code.

### The Gradle Dependencies

The project’s build.gradle file specifies a fair number of dependencies:

```
dependencies {
    implementation 'com.android.support:leanback-v17:24.1.1'
    implementation 'com.android.support:mediarouter-v7:24.1.1'
    implementation 'com.android.support:design:24.1.1'
    implementation 'com.google.code.gson:gson:2.7'
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.commonware.cwac:presentation:0.4.5'
}
```

(from [Presentation/Decktastic/app/build.gradle](#))

The project uses:

- cwac-presentation for PresentationHelper
- design, for [its TabLayout](#); this library also pulls in appcompat-v7 (for [AppCompatActivity and kin](#)) and support-v4 (for [ViewPager and kin](#))
- Google’s Gson
- greenrobot’s EventBus
- Google’s leanback-v17 library, for [“ten-foot UI” elements](#) used in our launcher activity
- Square’s Picasso, for asynchronously loading images

### The Presentation Format

A Decktastic presentation consists of a JSON file and a series of image files. The

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

image files are the slides, perhaps exported from a traditional presentation package like LibreOffice Impress. The JSON file spells out what the image files are and their order of appearance.

For example, here is a JSON file from one of the presentations:

```
{
  "title": "Notifications, Front to Back",
  "duration": 70,
  "baseUrl": "http://misc.commonsware.com/andevcon2014/preso2/",
  "slides": [
    {
      "title": "(title slide)",
      "image": "img0.png"
    },
    {
      "title": "Order of Battle",
      "image": "img1.png"
    }
  ]
}
```

The title is used on the initial “leanback” activity as part of displaying the available presentations.

The duration is how long the presentation should run, in minutes. This will be used for a countdown timer to help the presenter know how much time remains in the presentation.

The baseUrl is a URL to a directory on a Web server somewhere that contains the same slide images as are available locally. This is needed to support RemotePlaybackClient, as Chromecast and similar devices need to be able to download their content over the network. We do not have an easy way to deliver that content from the phone or tablet that runs Decktastic and so we need a network-hosted copy of the slides as well. If you were willing to dispense with Chromecast support, you would not need this baseUrl property.

The slides array contains JSON objects, each of which provides the title for a slide and the image associated with that slide. The title will be used for the ViewPager tabs, so the presenter knows the upcoming slides and can rapidly switch to a specific slide. The images, of course, are what the presenter and the audience see. Of particular importance is the first slide in the array, as this will be used as the “title slide”, shown on the initial “leanback” activity.

The JSON and slides are stored as assets. One full presentation (“Your Android App. On TV.”) is stored in `assets/preso1/`, while a stub presentation (“Notifications, Front to Back”) is stored in `assets/preso2/`.

### The Model Classes

Given that JSON, we need a model class that will represent it, caching the parsed JSON so that we can use that information to render the presentation. We also need a model class that represents the collection of parsed presentations, so that we have the information necessary to render the “leanback” activity that allows the user to find the presentation to display.

There are two model classes in the book that handle this: `PresoContents` and `PresoRoster`.

### PresoContents

`PresoContents` represents the parsed JSON, along with a few other bits of information about the presentation:

```
package com.commonware.android.preso.decktastic;

import java.util.List;

public class PresoContents {
    String title;
    List<Slide> slides;
    int duration;
    String baseUrl;
    String baseDir;
    int id=-1;

    static class Slide {
        String image;
        String title;
    }

    @Override
    public String toString() {
        return(title);
    }

    String getSlideImage(int position) {
        return(baseDir+slides.get(position).image);
    }
}
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
}

String getSlideTitle(int position) {
    return(slides.get(position).title);
}

String getSlideURL(int position) {
    return(baseUrl+slides.get(position).image);
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoContents.java](#))

The title, slides, duration, and baseUrl fields come straight from the JSON. The baseDir field represents the directory in which the presentation was loaded; all images will be assumed to be relative to this directory. Finally, each presentation is given an id, so we can distinguish one presentation from another in our collection of presentations.

PresoContents also has getter methods to retrieve the local image file (getSlideImage()), title (getSlideTitle()), and remote image URL (getSlideURL()) for a slide given its position in the array of slides.

### PresoRoster

PresoRoster is a singleton collection of the available presentations. It also contains the model logic for loading the collection of presentations and parsing the JSON to create an individual PresoContents object for a single presentation:

```
package com.commonsware.android.preso.decktastic;

import android.content.Context;
import android.content.res.AssetManager;
import android.util.Log;
import com.google.gson.Gson;
import java.io.BufferedReader;
import java.io.IOException;
import java.io.InputStream;
import java.io.InputStreamReader;
import java.util.ArrayList;
import java.util.List;

class PresoRoster {
    private static final PresoRoster INSTANCE=new PresoRoster();
    private static String[] PRESO_ASSET_DIRS={"preso1/", "preso2/"};
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
private List<PresoContents> presos=new ArrayList<PresoContents>();

static PresoRoster getInstance() {
    return(INSTANCE);
}

private PresoRoster() {}

int getPresoCount() {
    return(presos.size());
}

PresoContents getPreso(int position) {
    return(presos.get(position));
}

PresoContents getPresoById(int id) {
    return(getPreso(id));
}

void load(Context ctxt) {
    Gson gson=new Gson();
    AssetManager assets=ctxt.getAssets();

    for (String presoDir : PRESO_ASSET_DIRS) {
        PresoContents c=loadPreso(gson, assets, presoDir);

        if (c!=null) {
            c.id=presos.size();
            presos.add(c);
        }
    }
}

private PresoContents loadPreso(Gson gson, AssetManager assets,
    String presoDir) {
    PresoContents result=null;

    try {
        InputStream is=assets.open(presoDir+"preso.json");
        BufferedReader reader=
            new BufferedReader(new InputStreamReader(is));

        result=gson.fromJson(reader, PresoContents.class);
        result.baseDir=presoDir;
        is.close();
    }
    catch (IOException e) {
```

## PUTTING THE TVS ALL TOGETHER: DECKTASTIC

---

```
    Log.e(getClass().getSimpleName(), "Exception parsing JSON", e);
  }

  return(result);
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoRoster.java](#))

The class includes:

- Getters to retrieve a presentation by index in the array of presentations (`getPreso()`) and to retrieve a presentation by the ID of the presentation (`getPresoById()`)
- A `getPresoCount()` method that indicates how many presentations were found
- A `load()` method that will iterate over known presentation asset directories (defined in `PRESO_ASSET_DIRS`), then attempt to parse a `preso.json` file in the asset directory for a presentation (via a private `loadPreso()` method) using Gson

The result of `load()` is that the `PresoRoster` should be populated with all known presentations in assets. Note, though, that this work is done on the current thread, and therefore `load()` needs to be called on a background thread. Also note that `PresoRoster` makes no attempt at thread synchronization, and so `load()` should be called before anything attempts to use the `PresoRoster` getter methods like `getPresoCount()`.

### The Launcher Activity: `LeanbackActivity`

As noted previously, our launcher activity is one that implements Google's "[leanback](#)" user interface, specifically a `BrowseFragment` for browsing media content. In this case, that content consists of the roster of available presentations.

The `LeanbackActivity` itself is fairly short:

```
package com.commonsware.android.preso.decktastic;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;

public class LeanbackActivity extends Activity {
```

---

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
        getFragmentManager()
            .beginTransaction()
            .add(android.R.id.content, new RosterFragment()).commit();
    }
}

public void showPreso(PresoContents preso) {
    startActivity(new Intent(this, MainActivity.class)
        .putExtra(MainActivity.EXTRA_PRESO_ID,
            preso.id));
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/LeanbackActivity.java](#))

All it does is add a `RosterFragment` to the UI managed by the activity, plus add a `showPreso()` method that will be called by that `RosterFragment` when a presentation is selected. `showPreso()`, in turn, will start a separate activity (`MainActivity`), supplying `EXTRA_PRESO_ID` with the ID of the selected presentation, so `MainActivity` knows what presentation to show.

### Manifest Entry

To work properly with the `leanback-v17` classes like `BrowseFragment`, `LeanbackActivity` needs to use `Theme.Leanback`, supplied by `leanback-v17`:

```
<activity
    android:name="com.commonsware.android.preso.decktastic.LeanbackActivity"
    android:configChanges="keyboard|keyboardHidden|orientation|screenSize|smallestScreenSize"
    android:label="@string/app_name"
    android:screenOrientation="sensorLandscape"
    android:theme="@style/Theme.Leanback">
    <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
        <category android:name="android.intent.category.LEANBACK_LAUNCHER" />
    </intent-filter>
</activity>
```

(from [Presentation/Decktastic/app/src/main/AndroidManifest.xml](#))

Other noteworthy items in the `<activity>` element in the manifest include:

- Locking the screen orientation to `sensorLandscape`, as we want to stick with a landscape-style orientation, but it could either be “regular” or “reverse” landscape without issue
- Handling orientation-related configuration changes, which are not needed since we are locking the screen orientation to `sensorLandscape`, and therefore the UI does not change on an orientation change
- Having the `LEANBACK_LAUNCHER` category as an option in the `<intent-filter>`, as this will cause this activity to appear on Android TV’s home screen launcher (as opposed to the `LAUNCHER` category used by normal Android devices)

### RosterFragment

`RosterFragment` is a `BrowseFragment`, designed to provide the two-dimensional navigation of headers and items in a header. In this case, we will have just one header, “Presentations”, containing all of the presentations found by `PresoRoster`.

In `onAttach()`, we check to see how many presentations are known about. If there are none, we make two assumptions:

1. That this is the first time we have needed to look for presentations, and
2. That there are presentations to be found

So, we fork a `LoadThread` to go load those presentations:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    if (PresoRoster.getInstance().getPresoCount()==0) {
        new LoadThread(host).start();
    }
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

Of course, those assumptions are a gross simplification. It could be that the user launched our `LeanbackActivity`, pressed `BACK`, then launched it again for some reason, and therefore the first `LoadThread` did not yet finish before we go and fork a second one. Or, it could be that there are no presentations to be found, in which case we scan unnecessarily. A production-grade version of this app should have a more sophisticated means of ensuring a one- (and only one-) time initialization.

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

LoadThread drops our thread priority to background levels, then tells the PresoRoster to load presentations from our app's standard spot on external storage. Then, we raise a RosterLoadedEvent on greenrobot's EventBus:

```
private static class LoadThread extends Thread {
    private Context ctxt=null;

    LoadThread(Context ctxt) {
        super();

        this.ctxt=ctxt.getApplicationContext();
    }

    @Override
    public void run() {
        android.os.Process.setThreadPriority(android.os.Process.THREAD_PRIORITY_BACKGROUND);
        PresoRoster.getInstance().load(ctxt);

        EventBus.getDefault().postSticky(new RosterLoadedEvent());
    }
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

You will notice that we call `postSticky()`, not `post()` on the EventBus instance. This says that we not only want to deliver this event to any current registrants, but that the EventBus should cache this event and hand it to future registrants.

To respond to the RosterLoadedEvent, we register the RosterFragment on the bus in `onResume()` and unregister in `onPause()`:

```
@Override
public void onResume() {
    super.onResume();

    EventBus.getDefault().register(this);
}

@Override
public void onPause() {
    EventBus.getDefault().unregister(this);

    super.onPause();
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

We then have `onRosterLoaded()` set up with the `@Subscribe` annotation to watch for the RosterLoadedEvent:

---

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
@Subscribe(sticky=true, threadMode=ThreadMode.MAIN)
public void onRosterLoaded(RosterLoadedEvent event) {
    setHeadersState(BrowseFragment.HEADERS_ENABLED);
    setTitle(getString(R.string.app_name));

    ArrayAdapter rows=new ArrayAdapter(new ListRowPresenter());
    PresoRoster roster=PresoRoster.getInstance();
    ArrayAdapter listRowAdapter=new ArrayAdapter(new PresoPresenter());

    for (int i=0; i < roster.getPresoCount(); ++i) {
        listRowAdapter.add(roster.getPreso(i));
    }

    HeaderItem header=new HeaderItem(0, "Presentations");
    rows.add(new ListRow(header, listRowAdapter));

    setAdapter(rows);
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

The `sticky=true` part of the annotation, in conjunction with `postSticky()`, means that if events were sticky-posted in the past, we are delivered those immediately, in addition to future events. This will allow us to handle configuration changes — even though our activity and fragment might be destroyed on a locale change, or if our device is put into some sort of desk dock, we will get the `RosterLoadedEvent` when our fragment is created anew.

The `threadMode=ThreadMode.MAIN` portion of the annotation indicates that we want the event to be received on the main application thread, even though it was raised via a background thread.

In `onRosterLoaded()`, we:

- Indicate that we do want headers (though, in reality, since this app only has one header, you could easily skip the headers)
- Set the title to appear in the upper-right corner
- Create an `ArrayAdapter` for the rows that make up the entirety of the `BrowseFragment` contents, using the standard `ListRowPresenter` for our headers and rows
- Create another `ArrayAdapter`, wrapped around a `PresoPresenter`, that will manage the presentations in our one-and-only row
- Pour our `PresoContents` instances into the `ArrayAdapter` for our row
- Attach the “Presentations” title to the row via a standard `ListRow` object
- Tell the `RosterFragment` that the rows represents what it should render

This is all covered in greater detail in the chapter on [the “ten-foot” UI](#).

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

In `onViewCreated()` of `RosterFragment`, we indicate that the `RosterFragment` itself should be the listener for click events on items (in our case, presentations):

```
@Override
public void onViewCreated(View view, Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    setOnItemClickListener(this);
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

This works because `RosterFragment` implements the `OnItemClickListener` interface and therefore implements the `onItemClick()` method:

```
@Override
public void onItemClick(Presenter.ViewHolder viewHolder,
    Object o,
    RowPresenter.ViewHolder rowViewHolder,
    Row row) {
    ((LeanbackActivity) getActivity()).showPreso((PresoContents) o);
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/RosterFragment.java](#))

Here, we ask the hosting `LeanbackActivity` to show the clicked-upon presentation, which causes `LeanbackActivity` to launch a `MainActivity` to do just that.

### PresoPresenter

The role of `PresoPresenter` is to render the individual items shown in the `BrowseFragment`. In this case, the items are `PresoContents` model objects; `PresoPresenter` will pour the presentation information into `ImageCardView` widgets. `ImageCardView` is supplied by the `leanback-v17` library and is designed to be used for rendering items in a `BrowseFragment`.

The `Presenter` abstract class — which `PresoPresenter` extends — enforces the view holder pattern. A `Presenter` is really responsible for creating and updating `Presenter.ViewHolder` instances, which in turn are responsible for updating the actual widgets themselves. To that end, the `PresoPresenter.Holder` static class is a subclass of `Presenter.ViewHolder`, one that is responsible for pouring a `PresoContents` into an `ImageCardView`:

```
static class Holder extends Presenter.ViewHolder {
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
private ImageCardView cardView;
private PicassoImageCardViewTarget viewTarget;

public Holder(View view) {
    super(view);

    cardView=(ImageCardView)view;
    viewTarget=new PicassoImageCardViewTarget(cardView);
}

protected void updateCardViewImage(String path) {
    Picasso.with(cardView.getContext())
        .load("file:///android_asset/" + path)
        .resize(convertDpToPixel(cardView.getContext(), CARD_WIDTH),
            convertDpToPixel(cardView.getContext(), CARD_HEIGHT))
        .into(viewTarget);
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

Here, we are going to use Picasso to load the initial slide off of disk and put it in the ImageCardView. However, Picasso has no built-in knowledge of ImageCardView, the way it has built-in knowledge of ImageView. We need to teach Picasso how to populate an ImageCardView. Picasso's mechanism for this is to define a Target implementation (PicassoImageCardViewTarget in this case) that is responsible for taking a loaded bitmap and updating the UI with it:

```
private static class PicassoImageCardViewTarget implements Target {
    private ImageCardView imageCardView;

    public PicassoImageCardViewTarget(ImageCardView imageCardView) {
        this.imageCardView=imageCardView;
    }

    @Override
    public void onBitmapLoaded(Bitmap bmp, Picasso.LoadedFrom lf) {
        Drawable bmpDrawable=
            new BitmapDrawable(imageCardView.getContext().getResources(),
                bmp);

        imageCardView.setMainImage(bmpDrawable);
    }

    @Override
    public void onBitmapFailed(Drawable d) {
        imageCardView.setMainImage(d);
    }
}
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
}  
  
@Override  
public void onPrepareLoad(Drawable d) {  
    imageView.setMainImage(d);  
}  
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

Target requires implementations of:

- `onBitmapLoaded()`, where we take the image and put it as the “main image” of the `ImageCardView` by means of `setMainImage()`
- `onBitmapFailed()`, where we are given a failure `Drawable` and need to use it, once again by setting it as the `ImageCardView` main image
- `onPrepareLoad()`, where we are given a “loading” `Drawable` and need to use it, once more by setting it as the `ImageCardView` main image

The `PresoPresenter.Holder` class creates an instance of a `PicassoImageCardViewTarget` and uses that for the `into()` method of the `PicassoRequestBuilder` (created via the `with()` static method on the `Picasso` class).

The other thing interesting about our use of Picasso is in the `resize()` call. Particularly since Picasso does not know about `ImageCardView` and how big the image should be, we need to manually tell Picasso what size to make the image. Here, we hard-code the sizes of the card width and height in density-independent pixels:

```
private static final int CARD_WIDTH=400;  
private static final int CARD_HEIGHT=300;
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

We then use a static `convertDpToPixel()` method to get the actual number of hardware pixels to use, based upon the current screen density:

```
static int convertDpToPixel(Context ctxt, int dp) {  
    float density=ctxt.getResources().getDisplayMetrics().density;  
  
    return(Math.round((float)dp*density));  
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

Back up in `PresoPresenter` itself, the `Presenter` abstract class requires us to override `onCreateViewHolder()`, where we are responsible for creating a `Presenter.ViewHolder`. In the case of `PresoPresenter`, that comes in the form of the aforementioned `PresoPresenter.Holder`:

```
@Override
public ViewHolder onCreateViewHolder(ViewGroup parent) {
    ImageView cardView=new ImageView(parent.getContext());

    cardView.setFocusable(true);
    cardView.setFocusableInTouchMode(true);

    return(new Holder(cardView));
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

We also have to override `onBindViewHolder()`, where we are given an eligible `Presenter.ViewHolder` and need to populate its widgets from a supplied item:

```
@Override
public void onBindViewHolder(Presenter.ViewHolder viewHolder,
                             Object item) {
    PresoContents preso=(PresoContents)item;
    Holder h=(Holder)viewHolder;

    h.cardView.setTitleText(preso.toString());
    h.cardView.setMainImageDimensions(CARD_WIDTH, CARD_HEIGHT);
    h.updateCardViewImage(preso.getSlideImage(0));
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

Here, the item is a `PresoContents` and the `Presenter.ViewHolder` is a `PresoPresenter.Holder`. We update the `ImageView` title and image size based on the presentation, plus tell the `Holder` to update the image itself, calling the `updateCardViewImage()` method that contained our Picasso request.

Note that we are passing the density-independent pixels values (`CARD_WIDTH`, `CARD_HEIGHT`) to `setMainImageDimensions()`. Unfortunately, this method is undocumented, and so what the units of measure should be are not disclosed.

The `Presenter` abstract class also requires implementations of `onUnbindViewHolder()` (called when we should no longer be populating those widgets) and `onViewAttachedToWindow()` (called when the widgets associated with a

Presenter.ViewHolder are now “live”):

```
@Override
public void onUnbindViewHolder(Presenter.ViewHolder viewHolder) {
    ((Holder)viewHolder).cardView.setMainImage(null);
}

@Override
public void onViewAttachedToWindow(Presenter.ViewHolder viewHolder) {
    // no-op
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresoPresenter.java](#))

## The Guts: MainActivity

All of the above was just to handle the launcher activity, to allow the user to choose a presentation. MainActivity is where we actually show the presentation itself. This is based upon [the Presentation/Slides sample app](#), profiled in [the chapter on Presentation](#), with a replacement implementation of the tabs, and additional logic to handle RemotePlaybackClient-compatible devices (e.g., Chromecast) and TV-centric devices (e.g., Fire TV).

## Basic Setup

onCreate() of MainActivity is responsible for basic setup.

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    preso=
        PresoRoster
            .getInstance()
            .getPresoById(getIntent().getIntExtra(EXTRA_PRESO_ID, 0));

    setContentView(R.layout.activity_main);

    pager=(ViewPager)findViewById(R.id.pager);
    helper=new PresentationHelper(this, this);

    selector=
        new MediaRouteSelector.Builder()
            .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
            .build();
}
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
router=MediaRouter.getInstance(this);
router.addCallback(selector, routeCB,
    MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);

if (isDirectToTV()) {
    getSupportActionBar().hide();
}

setupPager();
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

First, we take the EXTRA\_PRESO\_ID value received via an Intent extra and uses that to find the PresoContents object representing the presentation to be shown. That PresoContents object is then referenced by a data member named preso.

Next, we load up the activity\_main layout resource, containing our ViewPager and a TabLayout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:keepScreenOn="true"
    android:orientation="vertical">

    <android.support.v4.view.ViewPager
        android:id="@+id/pager"
        android:layout_width="match_parent"
        android:layout_height="match_parent">

        <android.support.design.widget.TabLayout
            android:id="@+id/tabs"
            android:layout_width="match_parent"
            android:layout_height="wrap_content"
            android:layout_gravity="top"
            android:visibility="gone"
            app:tabMode="scrollable" />
    </android.support.v4.view.ViewPager>

</LinearLayout>
```

(from [Presentation/Decktastic/app/src/main/res/layout/activity\\_main.xml](#))

Then, we create a PresentationHelper, so that we find out when we should and

---

should not be displaying a Presentation. As before, MainActivity itself is the PresentationHelper.Listener for finding out about these events. We will explore that more [later in this chapter](#).

We then go through some logic for setting up remote playback device support (MediaRouteSelector.Builder and kin) and direct-to-TV device support (calling isDirectToTV()). Those will be explored later in this chapter, in sections on [remote playback device support](#) and [direct-to-TV device support](#).

Finally, we call setupPager(), to populate our ViewPager.

### The ViewPager

The setupPager() method is responsible for putting a SlidesAdapter into the ViewPager and otherwise setting things up to allow the presenter to control what slide is shown and for us to find out what slide the presenter selects:

```
private void setupPager() {
    durationInSeconds=preso.duration * 60;

    if (rc!=null) {
        rc.setOverallDuration(durationInSeconds);
    }

    adapter=new SlidesAdapter(this, preso);
    pager.setAdapter(adapter);

    if (!isDirectToTV()) {
        TabLayout tabs=(TabLayout)findViewById(R.id.tabs);

        tabs.setVisibility(View.VISIBLE);
        tabs.setupWithViewPager(pager);
        tabs.addOnTabSelectedListener(this);
    }
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Some of this — specifically the SlidesAdapter logic — is standard ViewPager setup work, with TabLayout being a popular implementation of tabs for activities that, like this one, extend from AppCompatActivity. The durationInSeconds stuff at the top is for setting up a ReverseChronometer, as will be discussed [later in this chapter](#). The isDirectToTV() call and if block will be explained more in the section on [direct-to-TV device support](#) later in this chapter.

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

SlidesAdapter is a fragment-free edition of a PagerAdapter, as the slides are purely ImageView widgets:

```
package com.commonware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.support.v4.view.PagerAdapter;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

class SlidesAdapter extends PagerAdapter {
    private PresoContents preso;
    private Context ctxt;

    SlidesAdapter(Context ctxt, PresoContents preso) {
        this.ctxt=ctxt;
        this.preso=preso;
    }

    @Override
    public Object instantiateItem(ViewGroup container, int position) {
        ImageView page=new ImageView(ctxt);
        ViewGroup.LayoutParams p=
            new ViewGroup.LayoutParams(ViewGroup.LayoutParams.MATCH_PARENT,
                ViewGroup.LayoutParams.MATCH_PARENT);

        container.addView(page, p);

        Picasso.with(ctxt).load(getSlideImageUri(position)).into(page);

        return(page);
    }

    @Override
    public void destroyItem(ViewGroup container, int position,
        Object object) {
        container.removeView((View)object);
    }

    @Override
    public int getCount() {
        return(preso.slides.size());
    }
}
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
@Override
public boolean isViewFromObject(View view, Object object) {
    return(view == object);
}

@Override
public String getPageTitle(int position) {
    return(preso.getSlideTitle(position));
}

Uri getSlideImageUri(int position) {
    return(Uri.parse("file:///android_asset/"+preso.getSlideImage(position)));
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/SlidesAdapter.java](#))

Of note:

- `instantiateItem()` creates the `ImageView`, adds it to the supplied container (set to fill that container), and tells Picasso to go load the image asynchronously into the `ImageView`
- `destroyItem()` removes the `ImageView` from the container
- `getCount()` returns the number of pages, based on the number of slides in the `PresoContents` supplied to the `SlidesAdapter` via its constructor
- `getPageTitle()` returns the page title, obtained from the `PresoContents` object
- `getSlideImageUri()` gets a `Uri` pointing to a local file from the `PresoContents`, for use both by `instantiateItem()` and by the `Presentation` object that we will use for external display support (as will be covered [later in this chapter](#))

### Supporting the Direct-to-TV Scenario

To determine whether or not our activity is natively displaying on a TV-style screen, we check to see whether the device has either `FEATURE_TELEVISION` or `FEATURE_LEANBACK`, in the private `isDirectToTV()` method on `MainActivity`:

```
private boolean isDirectToTV() {
    return(getPackageManager().hasSystemFeature(PackageManager.FEATURE_TELEVISION)
        || getPackageManager().hasSystemFeature(PackageManager.FEATURE_LEANBACK));
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

Admittedly, not all Android direct-to-TV devices may advertise that they have one of these features. In particular, minor-brand Android HDMI sticks might just be using a fairly vanilla Android device profile, culled from a tablet. There is no good way of detecting such a scenario, though Decktastic could provide some manual option (e.g., checkable action item) to go into direct-to-TV mode if this proved to be important.

We use `isDirectToTV()` in two places. First, in `onCreate()`, we hide the action bar if we are going direct to a TV:

```
if (isDirectToTV()) {
    getSupportActionBar().hide();
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Second, in `setupPager()`, we hide the `TabLayout` if we are going direct to a TV:

```
if (!isDirectToTV()) {
    TabLayout tabs=(TabLayout)findViewById(R.id.tabs);

    tabs.setVisibility(View.VISIBLE);
    tabs.setupWithViewPager(pager);
    tabs.addTabSelectedListener(this);
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

This eliminates the “chrome” from our activity, leaving us with just the contents of the `ViewPager` itself, in the form of our slides. On the plus side, this gives us the visual output we want. However, it comes at a cost: there is no means for the presenter to change slides. After all, there is no touchscreen in this scenario, and so even though the `ViewPager` could be swiped, that is not possible without a touchscreen.

To support standard presentation remotes and similar mechanisms, `MainActivity` overrides `onKeyDown()`:

```
@Override
public boolean onKeyDown(int keyCode, KeyEvent event) {
    switch(keyCode) {
        case KeyEvent.KEYCODE_SPACE:
        case KeyEvent.KEYCODE_DPAD_RIGHT:
        case KeyEvent.KEYCODE_DPAD_DOWN:
        case KeyEvent.KEYCODE_PAGE_DOWN:
```

```
case KeyEvent.KEYCODE_MEDIA_NEXT:
    if (pager.canScrollHorizontally(1)) {
        pager.setCurrentItem(pager.getCurrentItem()+1, true);
    }

    return(true);

case KeyEvent.KEYCODE_DPAD_LEFT:
case KeyEvent.KEYCODE_DPAD_UP:
case KeyEvent.KEYCODE_PAGE_UP:
case KeyEvent.KEYCODE_MEDIA_PREVIOUS:
    if (pager.canScrollHorizontally(-1)) {
        pager.setCurrentItem(pager.getCurrentItem()-1, true);
    }

    return(true);
}

return(super.onKeyDown(keyCode, event));
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here, we will advance to the next slide if the user presses:

- the space bar or the Page Down key on a QWERTY keyboard
- right or down arrow keys, D-pad buttons, or the like
- a “next” media button on a media remote

Conversely, we will return to the preceding slide if the user presses:

- the Page Up key on a QWERTY keyboard
- left or up arrow keys, D-pad buttons, or the like
- a “previous” media button on a media remote

This should allow most remotes for direct-to-TV devices to control our slides. Note that we are passing `true` as the second parameter to the `setCurrentItem()` method, and therefore the audience will see an animated transition to the next slide. That may or may not be desirable; an enhanced edition of Decktastic might allow that to be configured (e.g., via a checkable action item).

Note that this is still a bit limited compared to having touchscreen access, as our `onKeyDown()` method only moves a slide at a time. There is no facility to jump to an arbitrary spot, the way you could by swiping and tapping upon `ViewPager` tabs on a

touchscreen.

### Supporting External Displays

As noted earlier, in `onCreate()` of `MainActivity`, we create an instance of `PresentationHelper`, supplying the activity itself as both the `Context` and the `PresentationHelper.Listener` for presentation-related events:

```
helper=new PresentationHelper(this, this);
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

That, in turn, requires us to forward along `onPause()` and `onResume()` events from our activity to the `PresentationHelper`:

```
@Override
public void onResume() {
    super.onResume();
    helper.onResume();
}

@Override
public void onPause() {
    helper.onPause();
    super.onPause();
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

We also have to implement `showPreso()` and `clearPreso()` methods to satisfy the `PresentationHelper.Listener` interface:

```
@Override
public void clearPreso(boolean showInline) {
    if (presoFrag != null) {
        presoFrag.dismiss();
        presoFrag=null;
    }
}

@Override
public void showPreso(Display display) {
    Uri slide=adapter.getSlideImageUri(pager.getCurrentItem());

    presoFrag=
        SlidePresentationFragment.newInstance(this, display, slide);
}
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
presoSfrag.show(getSupportFragmentManager(), "presoSfrag");
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

In `showPreso()`, we obtain the `Uri` for the current slide by calling the `getSlideImageUri()` method we conveniently implemented on the `SlidesAdapter`. Then, we create an instance of a `SlidePresentationFragment`, handing it the slide `Uri`, and we `show()` that fragment. We only `dismiss()` the fragment in `clearPreso()`.

The fragment itself is a `PresentationFragment`, with an `ImageView` as the fragment's UI, populated using `Picasso`, with the `Uri` being transferred from the `newInstance()` factory method to the fragment itself via the arguments `Bundle`:

```
package com.commonsware.android.preso.decktastic;

import android.content.Context;
import android.net.Uri;
import android.os.Bundle;
import android.view.Display;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ImageView;
import com.squareup.picasso.Picasso;

public class SlidePresentationFragment extends PresentationFragment {
    private static final String KEY_URI="u";
    private ImageView slide=null;

    public static SlidePresentationFragment newInstance(Context ctxt,
                                                       Display display,
                                                       Uri slideUri) {
        SlidePresentationFragment frag=new SlidePresentationFragment();

        frag.setDisplay(ctxt, display);

        Bundle b=new Bundle();

        b.putParcelable(KEY_URI, slideUri);
        frag.setArguments(b);

        return(frag);
    }
}
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {
    slide=new ImageView(getContext());

    setSlideContent((Uri) getArguments().getParcelable(KEY_URI));

    return(slide);
}

void setSlideContent(Uri slideUri) {
    Picasso.with(getContext()).load(slideUri).into(slide);
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/SlidePresentationFragment.java](#))

While the cwac-presentation library contains a PresentationFragment, it is set up for the native API Level 11 implementation of fragments. Hence, Decktastic contains its own PresentationFragment, cloned from the cwac-presentation implementation, that uses the fragment backport, for use with our AppCompatActivity:

```
package com.commonsware.android.preso.decktastic;

import android.app.Dialog;
import android.app.Presentation;
import android.content.Context;
import android.os.Bundle;
import android.support.v4.app.DialogFragment;
import android.view.Display;

abstract public class PresentationFragment extends DialogFragment {
    private Display display=null;
    private Presentation preso=null;

    @Override
    public Dialog onCreateDialog(Bundle savedInstanceState) {
        if (preso == null) {
            return(super.onCreateDialog(savedInstanceState));
        }

        return(preso);
    }

    public void setDisplay(Context ctxt, Display display) {
```

## PUTTING THE TVS ALL TOGETHER: DECKTASTIC

---

```
    if (display == null) {
        preso=null;
    }
    else {
        preso=new Presentation(ctxt, display, getTheme());
    }

    this.display=display;
}

public Display getDisplay() {
    return(display);
}

@Override
public Context getContext() {
    if (preso != null) {
        return(preso.getContext());
    }

    return(getActivity());
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/PresentationFragment.java](#))

This arranges to show the *current* slide, for whatever the current slide is at the time showPreso() is called on MainActivity. However, we need to update this fragment to reflect changes in the current slide. To accomplish this, we set up MainActivity to implement the OnTabSelectedListener interface, then call addOnTabSelectedListener() on the TabLayout in setupPager() to have it forward tab-change events to the activity. Of those events, we pay particular attention to onTabSelected(), updating the SlidePresentationFragment if there is one around:

```
@Override
public void onTabReselected(TabLayout.Tab tab) {
    // unused
}

@Override
public void onTabUnselected(TabLayout.Tab tab) {
    // unused
}

@Override
public void onTabSelected(TabLayout.Tab tab) {
    if (presoFrag != null) {
```

---

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
presoSfrag
    .setSlideContent(adapter.getSlideImageUri(tab.getPosition()));
}

if (client!=null) {
    String url=preso.getSlideURL(tab.getPosition());

    client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
}
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

We will get into the `client` stuff from `onTabSelected()` in the next section, as that pertains to supporting remote playback devices.

### Supporting Chromecast and Remote Playback Devices

The key limitation of Chromecast and other remote playback devices is that they can only play back media that they can access. While Chromecast supports mirroring, that is handled via the Presentation API discussed previously; devices limited to the `RemotePlaybackClient` API need URLs to media files. That is why our JSON for the presentation contains a URL pointing to a copy of each slide up on some public Web server. To push those URLs over to the Chromecast at the appropriate points, we need to set up the `RemotePlaybackClient` system.

First, in `onCreate()`, we define a `MediaRouteSelector` for remote playback devices, set up a `MediaRouter`, and add a callback to find out about selected route changes, asking `MediaRouter` to scan for possible routes along the way:

```
selector=
    new MediaRouteSelector.Builder()
        .addControlCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)
        .build();
router=MediaRouter.getInstance(this);
router.addCallback(selector, routeCB,
    MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY);
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

All of this is using the `mediarouter-v7` portion of the Android Support package, as the native `MediaRouter` and `kin` do not support remote playback devices.

Our menu resource for our action bar contains, among other things, a

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

MediaRouteActionProvider from mediarouter-v7:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
      xmlns:android="http://schemas.android.com/apk/res/android"
      xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/countdown"
    app:actionViewClass="com.commonsware.android.preso.decktastic.ReverseChronometer"
    app:showAsAction="always"
    tools:ignore="AlwaysShowAction,MenuTitle" />

  <item
    android:id="@+id/route_provider"
    android:title="@string/media_route_provider"
    app:actionProviderClass="android.support.v7.app.MediaRouteActionProvider"
    app:showAsAction="always" />

  <item
    android:id="@+id/first"
    android:icon="@android:drawable/ic_media_previous"
    android:title="@string/first"
    app:showAsAction="ifRoom" />

  <item
    android:id="@+id/last"
    android:icon="@android:drawable/ic_media_next"
    android:title="@string/last"
    app:showAsAction="ifRoom" />

  <item
    android:id="@+id/present"
    android:checkable="true"
    android:checked="true"
    android:title="@string/show_presentation"
    app:showAsAction="never" />

</menu>
```

(from [Presentation/Decktastic/app/src/main/res/menu/activity\\_actions.xml](#))

As part of our work in setting up the action bar in `onCreateOptionsMenu()`, we retrieve the `MediaRouteActionProvider` and configure it with the same `MediaRouteSelector` that we used for the `MediaRouter` callback:

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_actions, menu);

    rc=(ReverseChronometer)menu.findItem(R.id.countdown)
        .getActionView();

    rc.setWarningDuration(5 * 60);
    rc.setOnClickListener(this);
    rc.setOnLongClickListener(this);
    rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
    rc.setTextColor(Color.WHITE);
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
if (durationInSeconds>0) {
    rc.setOverallDuration(durationInSeconds);
}

MenuItem item=menu.findItem(R.id.route_provider);
MediaRouteActionProvider provider=
    (MediaRouteActionProvider)MenuItemCompat.getActionProvider(item);

provider.setRouteSelector(selector);

return(super.onCreateOptionsMenu(menu));
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

(the lines in `onCreateOptionsMenu()` pertaining to the `ReverseChronometer` will be explained [later in this chapter](#))

If the user interacts with the `MediaRouteActionProvider` and elects to connect to a remote playback device, our `MediaRouter.Callback` will be notified about the change of route:

```
private MediaRouter.Callback routeCB=new MediaRouter.Callback() {
    @Override
    public void onRouteSelected(MediaRouter router,
                               MediaRouter.RouteInfo route) {
        connect(route);
    }

    @Override
    public void onRouteUnselected(MediaRouter router,
                                  MediaRouter.RouteInfo route) {
        disconnect();
    }
};
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here, we just delegate the `onRouteSelected()` and `onRouteUnselected()` callbacks to `connect()` and `disconnect()` methods on `MainActivity`. `MediaRouter.Callback` is an abstract class, not an interface — otherwise, we would simply have implemented the interface on `MainActivity` and bypassed this anonymous inner class instance.

The `connect()` method on `MainActivity` is responsible for sending over the current

slide to the remote playback device:

```
private void connect(MediaRouter.RouteInfo route) {
    client=
        new RemotePlaybackClient(getApplicationContext(), route);

    if (client.isRemotePlaybackSupported()) {
        String url=preso.getSlideURL(pager.getCurrentItem());

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
    else {
        client=null;
    }
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here, we:

- Create an instance of `RemotePlaybackClient`
- Confirm that the remote playback device supports the remote playback protocol (`isRemotePlaybackSupported()`)
- Call `play()`, passing over a URL pointing to the same slide that the `ViewPager` is showing from a local file

The `play()` call requires an `ItemActionCallback` as the last parameter. We really do not need the callback, but passing `null` does not work. So, we have a do-nothing `ItemActionCallback` named `playCB` that we use:

```
RemotePlaybackClient.ItemActionCallback playCB=
    new RemotePlaybackClient.ItemActionCallback() {
        @Override
        public void onResult(Bundle data, String sessionId,
            MediaSessionStatus sessionStatus,
            String itemId, MediaItemStatus itemStatus) {
        }

        @Override
        public void onError(String error, int code, Bundle data) {
        }
    };
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

That will show the slide that was current as of the time the user connected to the

---

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

remote playback device. We need to show a new slide when the presenter switches to a new slide, just as we did in the Presentation scenario. This too is handled in `onTabSelected()`, where we make the same sort of `play()` call that we did in `connect()`:

```
@Override
public void onTabSelected(TabLayout.Tab tab) {
    if (presoFrag != null) {
        presoFrag
            .setSlideContent(adapter.getSlideImageUri(tab.getPosition()));
    }

    if (client!=null) {
        String url=preso.getSlideURL(tab.getPosition());

        client.play(Uri.parse(url), "image/png", null, 0, null, playCB);
    }
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Not only is `disconnect()` called from `MediaRouter.Callback`, but it is also called from `onDestroy()` of `MainActivity`, where we also remove that callback from the `MediaRouter`:

```
@Override
public void onDestroy() {
    disconnect();
    router.removeCallback(routeCB);
    super.onDestroy();
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

`disconnect()` releases the `RemotePlaybackClient` and ensures that we are back on our default route:

```
private void disconnect() {
    if (client != null) {
        client.release();
        client=null;
    }

    router.getDefaultRoute().select();
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

The net effect of all of this is that the slides will update on the remote playback device as the presenter switches slides, in addition to when the presenter connects to the remote playback device originally. We are not in control of any transition effects — we simply provide the slides, and it is up to the remote playback device to download and show them, however that device wishes.

### The Rest of the Story

One common need of a presenter is to know how much time is remaining in which to deliver the presentation. Presentations are usually time-limited, to fit conference agendas and the like. The JSON structure for a presentation contains the duration of the presentation, and it would be useful to let the presenter know how much of that duration is remaining.

The chapter on custom views has a section outlining the implementation of [a ReverseChronometer widget](#). Chronometer is a standard Android SDK class for counting up time (e.g., a stopwatch). ReverseChronometer is for counting *down* time.

Decktastic puts a ReverseChronometer in the action bar as a custom view, courtesy of our menu XML:

```
<?xml version="1.0" encoding="utf-8"?>
<menu xmlns:tools="http://schemas.android.com/tools"
      xmlns:android="http://schemas.android.com/apk/res/android"
      xmlns:app="http://schemas.android.com/apk/res-auto">

  <item
    android:id="@+id/countdown"
    app:actionViewClass="com.commonware.android.preso.decktastic.ReverseChronometer"
    app:showAsAction="always"
    tools:ignore="AlwaysShowAction,MenuTitle" />
  <item
    android:id="@+id/route_provider"
    android:title="@string/media_route_provider"
    app:actionProviderClass="android.support.v7.app.MediaRouteActionProvider"
    app:showAsAction="always" />
  <item
    android:id="@+id/first"
    android:icon="@android:drawable/ic_media_previous"
    android:title="@string/first"
    app:showAsAction="ifRoom" />
  <item
    android:id="@+id/last"
    android:icon="@android:drawable/ic_media_next"
    android:title="@string/last"
    app:showAsAction="ifRoom" />
  <item
    android:id="@+id/present"
```

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

```
android:checkable="true"
android:checked="true"
android:title="@string/show_presentation"
app:showAsAction="never" />
</menu>
```

(from [Presentation/Decktastic/app/src/main/res/menu/activity\\_actions.xml](#))

We customize the `ReverseChronometer` through a handful of lines in the `onCreateOptionsMenu()` method:

```
rc=(ReverseChronometer)menu.findViewById(R.id.countdown)
    .getActionView();

rc.setWarningDuration(5 * 60);
rc.setOnClickListener(this);
rc.setOnLongClickListener(this);
rc.setTextSize(TypedValue.COMPLEX_UNIT_SP, 24);
rc.setTextColor(Color.WHITE);

if (durationInSeconds>0) {
    rc.setOverallDuration(durationInSeconds);
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Here we:

- Retrieve the `ReverseChronometer` from the action item
- Have it change to a “warning” presentation with five minutes remaining
- Set up the activity to respond to click and long-click events
- Set the appearance to be 24sp white text

And, if we already know the presentation’s overall duration, via the `durationInSeconds` data member, we pour that into the `ReverseChronometer` as well.

`durationInSeconds` is populated via a few lines at the top of `setupPager()`:

```
private void setupPager() {
    durationInSeconds=preso.duration * 60;

    if (rc!=null) {
        rc.setOverallDuration(durationInSeconds);
    }
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

This way, no matter whether `setUpPager()` or `onCreateOptionsMenu()` is called first, we pour the duration into the `ReverseChronometer`.

By default, that `ReverseChronometer` does nothing other than show the remaining time... which remains fixed by default. That is where the click and long-click event handlers come into play:

```
@Override
public void onClick(View v) {
    ReverseChronometer rc=(ReverseChronometer)v;

    if (rc.isRunning()) {
        rc.stop();
    }
    else {
        if (isFirstRCClick) {
            isFirstRCClick=false;
            rc.reset();
        }

        rc.run();
    }
}

@Override
public boolean onLongClick(View v) {
    ReverseChronometer rc=(ReverseChronometer)v;

    rc.reset();

    return(true);
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

There are three possibilities when the user taps on the `ReverseChronometer`:

- It was never clicked before (`isFirstRCClick` is `true`), in which case we ensure that the `ReverseChronometer` is reset to the overall duration before calling `run()` to start the countdown
- It is already running, in which case we call `stop()` to pause the countdown
- It was not already running (but was clicked before), in which case we call `run()` again to resume the countdown

This gives us what from a media standpoint would be play, pause, and resume logic.

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

A long-click will `reset()` the `ReverseChronometer`, returning the time remaining to the overall duration.

Our action bar also has a few other action items, handled in `onOptionsItemSelected()`:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.present:
            boolean original=item.isChecked();

            item.setChecked(!original);

            if (original) {
                helper.disable();
            }
            else {
                helper.enable();
            }

            break;

        case R.id.first:
            pager.setCurrentItem(0);
            break;

        case R.id.last:
            pager.setCurrentItem(adapter.getCount() - 1);
            break;
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Presentation/Decktastic/app/src/main/java/com/commonsware/android/preso/decktastic/MainActivity.java](#))

Specifically:

- There is a checkable action item to determine whether or not we should be showing a `Presentation`. If this is unchecked, and an external display is attached, we still disable the `PresentationHelper`. This will cause normal display mirroring to begin, and the audience will see the same UI that the presenter does, complete with the `ViewPager`, action bar, and so on. Checking it re-enables the `PresentationHelper`, so if an external display is available, we start showing the slides again.

## PUTTING THE TVs ALL TOGETHER: DECKTASTIC

---

- The first and last action bar items are “fast-forward” and “rewind” options, allowing the presenter to quickly jump to the first or the last slide in the presentation. This happens via calls to `setCurrentItem()` on the `ViewPager`, which will in turn invoke `onPageSelected()`, causing us to update our `PresentationFragment` or remote playback device, if needed.

Note that since the direct-to-TV mode hides the action bar, none of these options are available to the presenter on a device like Android TV or a Fire TV. This will require the presenter to use something else to track the remaining time in a presentation, such as a countdown timer app running on a separate Android device.

# Creating a MediaRouteProvider

---

As was noted [earlier in the book](#), you can use `MediaRouter` to identify media routes, such as those published by devices like Google’s Chromecast. Specifically, remote playback routes let you write apps that tell other devices, like the Chromecast, to play back media on your behalf.

However, not only can you write *clients* for remote playback routes, you can write *providers* of those routes. Perhaps you are working with a hardware manufacturer that is creating a Chromecast-like device. Perhaps you want to allow your app, running on a [Fire TV](#) or an Android HDMI stick, to be controlled by a user’s phone or tablet. Or perhaps you are trying to tie Android into specialized media hardware that does not communicate by conventional means (e.g., wireless speakers that do not use normal Bluetooth profiles).

This chapter will outline how you can create code that will publish media routes to users of `MediaRouter`, so that you can then take those requests and forward them to a remote device.

## Prerequisites

This chapter assumes that you have read [the chapter on MediaRouter](#).

## Terminology

For the purposes of this chapter:

- The “client device” refers to a phone or tablet that runs an app that should be able to direct what is shown on a streaming media player

- The “player device” refers to the streaming media player itself, which may or may not be running Android
- The “player app” refers to an Android app running on an Android-powered player device

## DIY Chromecast

Google’s Chromecast is a nice little device. However, it has issues:

- The device itself is not especially open.
- The Cast SDK that Google encourages for writing Chromecast-enabled apps is not especially open.
- The [terms and conditions](#) for using the Cast SDK may be troublesome for many developers.
- Chromecast is not available globally.
- Chromecast is only one device, and there are plenty of other streaming media devices available that need to be considered.

Some of these issues can be mitigated by the use of `MediaRouter` and `RemotePlaybackClient` instead of the proprietary Cast SDK. You are not bound by any particular license terms (beyond the norm for Android development) and the implementation of the media framework is open.

However, to make this work, the client device needs to know how to talk to the player device.

The good news is that the media routing framework in Android supports plug-in media route providers for just this purpose. The OS ships with such a provider for the Chromecast, and you can create your own providers to talk to whatever else you would like to talk to. The user can then install a small app on their client device that implements this media route provider, and *any* apps already on their client device that use classes like `RemotePlaybackClient` will automatically be able to cast their desired content to the player device.

## MediaRouteProvider

The guts of this come in the form of a `MediaRouteProvider`. Your custom subclass of `MediaRouteProvider` will:

- Tell Android what general capabilities you support, such as remote playback,

- session management, and the like
- Advertise what sorts of content your player device is capable of playing (e.g., certain video MIME types, certain URL schemes like `http` and `rtsp`)
- Serve as the recipient of commands from `MediaRouter`, `RemotePlaybackClient`, and the like, for you to forward along asynchronously to the player device

Depending upon your use case, you could elect to keep the `MediaRouteProvider` private to your application. That way, your app can cast to the player device, but no other apps can. Or, you can make your `MediaRouteProvider` available to all apps on the device, with the media routing framework taking care of the IPC details to have those apps tell your `MediaRouteProvider` what the player device should do.

### Player Device... and Maybe a Player App

Of course, this assumes the existence of some player device that is not supported by Android out of the box. Since Android only really supports Chromecast, external displays (e.g., HDMI, MHL, Miracast), and some Bluetooth options (e.g., external speakers) for media routes, there are countless player devices that need additional help. These will run the gamut from devices from major players (e.g., Amazon's Fire TV) to no-name devices (e.g., Android HDMI "sticks").

Some player devices will run Android. In that case, you would be writing a player app that would run on the player device that would be the recipient of commands sent to it from your `MediaRouteProvider` on the client device. For example, if you write a video player app, you could augment it with remote control capability driven by a `MediaRouteProvider` on a client device, turning your player app and anything it can run on (e.g., Fire TV, OUYA game console) into a Chromecast-like environment.

Some player devices will not run Android. If they offer some existing remote control over-the-air protocol, you could create a `MediaRouteProvider` that speaks that protocol. Or, perhaps the player devices are programmable, just not via Android (e.g., a Linux program for XMBC), in which case you might be able to write both ends of the communications channel.

### Communications Protocol

Somehow, the data from the `MediaRouteProvider` needs to get to the player device (and, where relevant, the player app). Likely candidates include Bluetooth, regular WiFi (if both devices are on the same network), and WiFi Direct.

However, in principle, anything is possible. For example, there is nothing stopping you from sending `MediaRouteProvider` commands to some Web server out on the Internet, which forwards them to some distant location for use. That would be a bit unusual – normally, the user of the client device is controlling something she can see — but it certainly could be done.

The biggest thing to watch out for is the addressability of the media to be played back. There is little point in connecting a `MediaRouteProvider` to some player device, then not have the ability for the player device to access the media that the client device is requesting. The expected pattern is that the media is hosted in some (relatively) central location, like a Web server. However, once again, anything is possible. If you want to have some sort of server on the client device, to allow the player device to play back media from it, and you believe that you can adequately secure this, you are welcome to do so.

## Creating the `MediaRouteProvider`

As noted earlier, the core of all of this is a custom `MediaRouteProvider`. Google supplies a [sample application](#) for creating such a `MediaRouteProvider`. However, it is overly complex, and it is undocumented.

This chapter will focus instead on the [MediaRouter/RouteProvider](#) sample project. This is a clone of the `MediaRouter/RemotePlayback` sample project covered [earlier in this book](#), with the addition of a custom `MediaRouteProvider`.

## Defining the Supported Actions

A `MediaRouteProvider` advertises — whether to its own app's `MediaRouter` or to the entire device — what sorts of actions it can perform. For example, a remote playback route provider needs to support actions like play, pause, resume, and stop of some piece of media.

The way this is handled in the media routing framework is via a series of `IntentFilter` objects.

Since `IntentFilter` objects do not need a `Context` to be created, it is safe to define them statically, if desired. That's what we do in `DemoRouteProvider`, a custom subclass of `MediaRouteProvider`. It declares a pair of static final `IntentFilter` objects, `ifPlay` and `ifControl`, which are then configured in a static initialization block:

## CREATING A MEDIAROUTEPROVIDER

---

```
private static final IntentFilter ifPlay=new IntentFilter();
private static final IntentFilter ifControl=new IntentFilter();

static {
    ifPlay.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
    ifPlay.addAction(MediaControlIntent.ACTION_PLAY);
    ifPlay.addDataScheme("http");
    ifPlay.addDataScheme("https");
    ifPlay.addDataScheme("rtsp");

    try {
        ifPlay.addDataType("video/*");
    }
    catch (MalformedMimeTypeException e) {
        throw new RuntimeException("Exception setting MIME type", e);
    }

    ifControl.addCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK);
    ifControl.addAction(MediaControlIntent.ACTION_PAUSE);
    ifControl.addAction(MediaControlIntent.ACTION_RESUME);
    ifControl.addAction(MediaControlIntent.ACTION_STOP);
    ifControl.addAction(MediaControlIntent.ACTION_GET_STATUS);
    ifControl.addAction(MediaControlIntent.ACTION_SEEK);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProvider.java](#))

Both stipulate that they are looking for Intent objects in the `MediaControlIntent.CATEGORY_REMOTE_PLAYBACK` category. This category is used for all media routing Intents that form the foundation of the routing framework.

`ifPlay` is defined as supporting `MediaControlIntent.ACTION_PLAY`, stating that we know how to play back some content. The qualifications for “some content” are handled via scheme and type constraints placed on the `IntentFilter`. Here, we limit the content to be URLs that might be reachable by a playback device (http, https, rtsp) and have a MIME type matching `video/*`. Hence, we are stating that we can play back streaming video.

`ifControl` sets up the remaining actions that we support:

- `MediaControlIntent.ACTION_PAUSE`
- `MediaControlIntent.ACTION_RESUME`
- `MediaControlIntent.ACTION_STOP`
- `MediaControlIntent.ACTION_GET_STATUS`
- `MediaControlIntent.ACTION_SEEK`

---

## CREATING A MEDIAROUTEPROVIDER

---

These are placed on an independent `IntentFilter` because, technically, we can support these actions on any type of media. In the case of this specific example, the only media we support is streaming video. But, we could configure other `IntentFilter` objects, like `ifPlay` was, stating yet other media types that we handle.

To fully comply with the `RemotePlaybackClient` API, we must advertise that we handle all of those actions... even if our intended client will not use all of them.

We could also:

- Advertise that we support session management actions, like `MediaControlIntent.ACTION_START_SESSION`
- Advertise that we support the “enqueue” operation for stacking up media to be played (e.g., `MediaControlIntent.ACTION_ENQUEUE`) and manipulating that queue (e.g., `MediaControlIntent.ACTION_REMOVE`)
- Define a custom category for other actions that we support that are “out of band” with respect to the standard media routing actions

All of those are demonstrated in Google’s sample app.

### Creating the Descriptors

Just because we have some static `IntentFilter` objects does not mean that anything will pay attention to them. We need to actually register them with the media routing framework, wrapped in a pair of “descriptor” objects.

`DemoRouteProvider` calls a private `handleDiscovery()` method from the constructor, where `handleDiscovery()` sets up the descriptors:

```
private void handleDiscovery() {
    MediaRouteDescriptor.Builder mrdBuilder=
        new MediaRouteDescriptor.Builder(DEMO_ROUTE_ID, "Demo Route");

    mrdBuilder.setDescription("The description of a demo route")
        .addControlFilter(ifPlay)
        .addControlFilter(ifControl)
        .setPlaybackStream(AudioManager.STREAM_MUSIC)
        .setPlaybackType(MediaRouter.RouteInfo.PLAYBACK_TYPE_REMOTE)
        .setVolumeHandling(MediaRouter.RouteInfo.PLAYBACK_VOLUME_FIXED);

    MediaRouteProviderDescriptor.Builder mrpdBuilder=
        new MediaRouteProviderDescriptor.Builder();

    mrpdBuilder.addRoute(mrdBuilder.build());
}
```

## CREATING A MEDIAROUTEPROVIDER

---

```
setDescriptor(mrpdBuilder.build());  
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProvider.java](#))

In the end, we need to provide a `MediaRouteProviderDescriptor` to the `MediaRouteProvider` by means of a `setDescriptor()` method. `MediaRouteProviderDescriptor` is, in effect, metadata about the `MediaRouteProvider` itself. At the present time, the only thing this holds is a set of `MediaRouteDescriptor` objects, one for each media route that the `MediaRouteProvider` claims to support.

A `MediaRouteProvider` is made up of several pieces of information, including:

- The `IntentFilter`(s) representing the supported actions and, where relevant, MIME types and schemes
- A locally-unique ID of the route, to distinguish it from any other one that we might configure
- A name and description, which the user will see when they try to connect to this route (e.g., via a `MediaRouteActionProvider`)
- What audio stream is being used for the playback, from the standpoint of volume management, audio ducking, and the like
- Whether the playback is occurring locally on the device to some peripheral (e.g., speaker) or if the playback is occurring remotely on a player device (e.g., Chromecast)
- Whether playback volume is controlled here on the client device or on the player device
- Etc.

These are all configured on a `MediaRouteProvider` by creating a `MediaRouteProvider.Builder` and supplying the values either in the `Builder` constructor or via fluent setter methods. In the particular case of our simple demo provider, we:

- Use various strings for the ID, name, and description
- Use the two `IntentFilter` objects defined earlier to indicate what actions we can perform
- Indicate that the playback stream is `STREAM_MUSIC`, that the playback type is `PLAYBACK_TYPE_REMOTE`, and that the volume handling is `PLAYBACK_VOLUME_FIXED` (i.e., volume should be managed on the TV or whatever the media is being played upon)

---

## CREATING A MEDIAROUTEPROVIDER

---

It is very likely that you will elect to have several `MediaRouteDescriptor` objects for different client application scenarios. Google's sample app uses a total of four `MediaRouteDescriptor` objects:

- One set up largely like the one in this sample
- One set up with `PLAYBACK_VOLUME_VARIABLE` (so volume is controllable by a client app)
- One set up with variable volume plus queuing actions
- One set up with variable volume plus queuing and session management actions

### Receiving the Actions

Now, we have told the media routing framework what actions we support. Some app will then try to use `RemotePlaybackClient` and ask us to perform those actions. Hence, we need to find out when this happens, so we can do the actual work of having the playback device actually play back the media, pause the media, etc.

To do this, we need to create a custom subclass of `MediaRouteProvider.RouteController`. This contains a series of callback methods which we can override to find out when various events occur.

There are four such callback methods that the `DemoRouteController` subclass of `MediaRouteProvider.RouteController` implements:

- `onSelect()`, which will be called when a client app has selected our `MediaRouteProvider` to handle some media on behalf of that client app
- `onUnselect()` and `onRelease()`, which will be called when the client app disconnects from our `MediaRouteProvider`
- `onControlRequest()`, which will be called when some specific action that we advertised is requested, such as playing back a piece of media

The `DemoRouteController` just logs a message to Logcat for the first three callbacks:

```
@Override
public void onRelease() {
    Log.d(getClass().getSimpleName(), "released");
}

@Override
public void onSelect() {
    Log.d(getClass().getSimpleName(), "selected");
}
```

## CREATING A MEDIAROUTEPROVIDER

---

```
}

@Override
public void onUnselect() {
    Log.d(getClass().getSimpleName(), "unselected");
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

The `onControlRequest()` method is a bit more complex, as *all* control requests route through here: play, pause, resume, stop, etc. `onControlRequest()` is passed the Intent identifying the particular action that should be performed, and we can examine the Intent action string to determine what needs to be done. In this case, `onControlRequest()` delegates the real work to action-specific methods like `onPlayRequest()`:

```
@Override
public boolean onControlRequest(Intent i, ControlRequestCallback cb) {
    if (i.hasCategory(MediaControlIntent.CATEGORY_REMOTE_PLAYBACK)) {
        if (MediaControlIntent.ACTION_PLAY.equals(i.getAction())) {
            return(onPlayRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_PAUSE.equals(i.getAction())) {
            return(onPauseRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_RESUME.equals(i.getAction())) {
            return(onResumeRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_STOP.equals(i.getAction())) {
            return(onStopRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_GET_STATUS.equals(i.getAction())) {
            return(onGetStatusRequest(i, cb));
        }
        else if (MediaControlIntent.ACTION_SEEK.equals(i.getAction())) {
            return(onSeekRequest(i, cb));
        }
    }

    Log.w(getClass().getSimpleName(), "unexpected control request"
        + i.toString());

    return(false);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

`onControlRequest()` should return `true` if we agree to perform the action and will use the supplied `ControlRequestCallback` object to asynchronously deliver our results. If `onControlRequest()` returns `false`, that means that we are rejecting the action for some reason, such as it being one that is unrecognized. In `DemoRouteController`, that will occur if the category or the action on the `Intent` is not one of the supported options.

Note that if you opted into variable volume, there are `onSetVolume()` and `onUpdateVolume()` callback methods that will give you access to those events.

### Handling the Actions

For those actions that you advertise and receive in `onControlRequest()`, you need to actually do the work for those actions. The details of this will vary widely depending upon your playback device and playback app that you are supporting. For example, you might establish a WiFi Direct connection in `onSelect()`, then use that connection in handling play, pause, etc. actions.

However, a few aspects of handling these actions will be in common across all implementations:

- `onControlRequest()` must return `true` or `false` as was described in the preceding section
- You must call `onResult()` or `onError()` on the `ControlRequestCallback` object to indicate if the action succeeded or failed
- You must supply an appropriate `Bundle` to those methods, particularly to `onResult()`, containing the right set of values to provide more details about the results of the action

The details of what that `Bundle` must contain are documented on the `MediaControlIntent` class, on the definition of each action string (e.g., `ACTION_PLAY`).

With that in mind, let's look at the six actions supported by `DemoRouteController`.

#### Play

The `Bundle` passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_PLAY`, needs three values:

- `EXTRA_SESSION_ID`: if you are implementing session management, this will

---

## CREATING A MEDIAROUTEPROVIDER

---

be the unique session ID (String) for the session you are playing the media in. If you are not implementing session management, then what you are supposed to return is undocumented and (hopefully) unused

- EXTRA\_ITEM\_ID: if you are implementing “enqueue” support, this will be the item ID (String) for managing this item in the queue of available items. If you are not supporting a playback queue, then what you are supposed to return is undocumented and (hopefully) unused
- EXTRA\_ITEM\_STATUS: this should point to a Bundle created from a MediaItemStatus object where you indicate what the status is of the playback of this item

You create a MediaItemStatus object via a MediaItemStatus.Builder, where you can pass into the constructor a value indicating the overall status (e.g., MediaItemStatus.PLAYBACK\_STATE\_PLAYING), plus use fluent setter methods to define additional characteristics of the status, such as the current seek position.

The DemoRouteController logic for ACTION\_PLAY, in the onPlayRequest() method, logs the event to Logcat and crafts a valid-but-meaningless result Bundle for use with onResult():

```
private boolean onPlayRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "play: "
        + i.getData().toString());

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putString(MediaControlIntent.EXTRA_SESSION_ID, DemoRouteProvider.DEMO_SESSION_ID);
    b.putString(MediaControlIntent.EXTRA_ITEM_ID, DemoRouteProvider.DEMO_ITEM_ID);
    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
        statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

### Pause, Resume, and Stop

The Bundle passed to onResult() of the ControlRequestCallback, when the action is ACTION\_PAUSE, ACTION\_RESUME, or ACTION\_STOP, does not need any particular values at the present time. Hence, the DemoRouteController methods for those

## CREATING A MEDIAROUTEPROVIDER

---

actions just log the event to Logcat and pass an empty Bundle to `onResult()`:

```
private boolean onPauseRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "pause");

    cb.onResult(new Bundle());

    return(true);
}

private boolean onResumeRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "resume");

    cb.onResult(new Bundle());

    return(true);
}

private boolean onStopRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "stop");

    cb.onResult(new Bundle());

    return(true);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

### Get Status and Seek

The Bundle passed to `onResult()` of the `ControlRequestCallback`, when the action is `ACTION_GET_STATUS` or `ACTION_SEEK`, must contain the same sort of `MediaItemStatus`-built nested Bundle representing the current status. For `ACTION_GET_STATUS`, the only “work” to be done is to pass back the status; for `ACTION_SEEK`, you should move the playback position to the location indicated by an extra on the Intent, then return the revised status.

In the case of `DemoRouteController`, both just log a message to Logcat and return a fairly pointless status:

```
private boolean onGetStatusRequest(Intent i,
                                   ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "get-status");

    MediaItemStatus.Builder statusBuilder=
```

---

## CREATING A MEDIAROUTEPROVIDER

---

```
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
        statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}

private boolean onSeekRequest(Intent i, ControlRequestCallback cb) {
    Log.d(getClass().getSimpleName(), "seek");

    MediaItemStatus.Builder statusBuilder=
        new MediaItemStatus.Builder(
            MediaItemStatus.PLAYBACK_STATE_PLAYING);

    Bundle b=new Bundle();

    b.putBundle(MediaControlIntent.EXTRA_ITEM_STATUS,
        statusBuilder.build().asBundle());

    cb.onResult(b);

    return(true);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteController.java](#))

## Publishing the Controller

While we have defined our RouteController, we still need to teach our MediaRouteProvider about it. That is through overriding the onCreateRouteController() method and returning an instance of RouteController:

```
@Override
public RouteController onCreateRouteController(String routeId) {
    return(new DemoRouteController());
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProvider.java](#))

onCreateRouteController() is passed the route ID String used in the

`MediaRouteDescriptor`. You can either use that to instantiate a different `RouteProvider`, pass the `String` into a common `RouteProvider` so it knows what to do, or ignore it entirely if you have only one published route. In the case of `DemoRouteProvider`, we ignore the route ID and always return a `DemoRouteController`.

### Handling Discovery Requests

`DemoRouteProvider` is always available, largely because it does not do much of anything.

In the real world, your `MediaRouteProvider` may not always be relevant. For example, the TV you are set up to talk to may be powered down. Or, the user may not be at home where the TV is, so the client device and the TV are not on the same network.

Rather than constantly polling the outside world to see if a route is possible, we only do this when a client app requests “route discovery”, such as by providing the `MediaRouter.CALLBACK_FLAG_REQUEST_DISCOVERY` flag on an `addCallback()` call to a `MediaRouter`. That in turn triggers an `onDiscoveryRequestChanged()` call on our `MediaRouteProvider`.

There, and in our constructor-triggered setup, we should do work to determine if a route is currently possible and set up our descriptors. This work should be done in a background thread if it involves network I/O.

Note that `onDiscoveryRequestChanged()` is passed a `MediaRouteDiscoveryRequest` object, describing what the consuming app is looking for. If the request is irrelevant for your provider (e.g., the app wants a local audio route, and you provide remote playback routes), simply ignore it.

The `onDiscoveryRequestChanged()` implementation in `DemoRouteProvider` just calls the same `handleDiscovery()` method that the constructor does.

### Consuming the MediaRouteProvider

Having a `MediaRouteProvider` is nice, but it is useless if apps are not going to know about it.

You have two main options for consuming the `MediaRouteProvider`: use it only

within your own app, or publish it to all apps on the device.

### Private Provider

Using a `MediaRouteProvider` for your own app is very simple. Just add a single call to `addProvider()` on your `MediaRouter`, supplying an instance of your `MediaRouteProvider`.

Since our sample project is a fork of the original `RemotePlaybackClient` sample, we still have a `PlaybackFragment` that sets up the `MediaRouter` and `MediaRouteActionProvider`. In `onAttach()` of that `PlaybackFragment`, we can configure our `MediaRouterProvider` after obtaining the `MediaRouter` instance:

```
@Override
public void onAttach(Activity host) {
    super.onAttach(host);

    router=MediaRouter.getInstance(host);
    provider=new DemoRouteProvider(getActivity());
    router.addProvider(provider);
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/PlaybackFragment.java](#))

## CREATING A MEDIAROUTEPROVIDER

---

At this point, our DemoRouteProvider will be available as an option for the user, along with any other eligible media routes:

*Figure 818: MediaRouteProvider Demo, on a Nexus 4, Showing Available Routes*

## CREATING A MEDIAROUTEPROVIDER

Choosing the `DemoRouteProvider` (“Demo Route” in the screenshot) will allow you to use it just like you do a Chromecast... if you do not mind the fact that nothing shows up on your television:

*Figure 819: MediaRouteProvider Demo, on a Nexus 4, After Several Commands*

As it turns out, the `DemoRouteProvider` works better than Google’s own `MediaRouteProvider` for the Chromecast, insofar as more of the callbacks work. Specifically, we actually receive callbacks for pause, resume, and stop events, as opposed to having to just assume that those events completed.

Also, we remove the demo provider in `onDetach()`:

```
@Override
public void onDetach() {
    router.removeProvider(provider);

    super.onDetach();
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/PlaybackFragment.java](#))

Among other things, this allows us to correctly handle configuration changes — if we fail to call `removeProvider()` and blindly add another provider in `onAttach()`, we

---

## CREATING A MEDIAROUTEPROVIDER

---

wind up with multiple providers, because our `MediaRouter` is a framework-provided singleton and is not re-created with the new fragment.

### Public Provider

If you want your `MediaRouteProvider` to be used by other apps, you will need to create one more Java class: a subclass of `MediaRouteProviderService`. This requires only one method, `onCreateMediaRouteProvider()`, where you return an instance of your `MediaRouteProvider`:

```
package com.commonsware.android.mrp;

import android.support.v7.media.MediaRouteProvider;
import android.support.v7.media.MediaRouteProviderService;

public class DemoRouteProviderService extends MediaRouteProviderService {
    @Override
    public MediaRouteProvider onCreateMediaRouteProvider() {
        return(new DemoRouteProvider(this));
    }
}
```

(from [MediaRouter/RouteProvider/app/src/main/java/com/commonsware/android/mrp/DemoRouteProviderService.java](#))

This also needs to be added to your manifest, like any other `Service`. Give it an `<intent-filter>` looking for the `android.media.MediaRouteProviderService` action, so the media routing framework knows that it can obtain a `MediaRouteProvider` from it:

```
<service
    android:name="DemoRouteProviderService"
    tools:ignore="ExportedService">
    <intent-filter>
        <action android:name="android.media.MediaRouteProviderService"/>
    </intent-filter>
</service>
```

However, do *not* do both `addProvider()` *and* have the `<service>` element. If you use the `<service>` element, your app can use the `MediaRouteProvider`, just as can any other app on the device. Hence, in the published source code for this sample, the `<service>` element is commented out — you will need to uncomment it, and comment out the `addProvider()` call, to test the `DemoRouteProvider` with other apps.

## Implementing This “For Realz”

Of course, `DemoRouteProvider` is just a demo and does not actually play any media anywhere. It is here to give you the basic steps for responding to `RemotePlaybackClient` requests. For a production `MediaRouteProvider`, in addition to the usual tightening-up of the code (e.g., better exception handling), you will need to work on other areas as well, ones that are beyond the scope of the sample app.

### Communicating with the Playback Device

Of course, the big one is passing the actions over to the playback device, so you actually *do* play back media.

If you are the developer of the playback device and its protocols (e.g., it is an Android device, and you are writing the playback app for it), then you can choose how you wish to handle the communications. You can work with low-level socket protocols directly, or you can leverage libraries like [AllJoyn](#) or [ZeroMQ](#).

If the playback device “is what it is”, and you cannot change it, then you will need to determine what protocols it offers and how best to map the `MediaControlIntent` actions to that protocol.

Also note that `onControlRequest()` is designed for asynchronous operation. The sample app just invoked the `ControlRequestCallback` during the `onControlRequest()` processing. Usually, though, your communications with the playback device will not be as fast as a call to `Log.d()`. You should arrange to do those communications in a background thread, perhaps via a single-thread thread pool as an `ExecutorService`. Simply pass the `ControlRequestCallback` to that thread along with the rest of the action’s data (e.g., the URL of the media to load), and the thread can call `onResult()` or `onError()` as needed.

### Handling Other Actions/Protocols

As was noted in the description of the sample app, that app avoids:

- volume control
- session management
- queue management

Any of those may be of interest to your users, and so you may need to consider offering them at some point. Also note that some potential client apps might need those capabilities and therefore will not see or use your published media routes without them.

### Custom Actions

When setting up the `MediaRouteProvider`, we create one or more `MediaRouteDescriptor` objects wrapped around one or more `IntentFilter` objects. Those `IntentFilter` objects indicate what actions we support. The `DemoRouteProvider` uses standard actions (e.g., `ACTION_PLAY`) in a standard category (`CATEGORY_REMOTE_PLAYBACK`).

However, you are not limited to that.

You are welcome to also support custom actions in a custom category, to represent other things that your particular `MediaRouteProvider` offers. You can then use those actions from your own client app, or document them for use by third-party apps.

The client app can use `supportsControlRequest()` and `sendControlRequest()` to determine whether a particular media route supports a particular `Intent` that represents an action to be performed by that route's `MediaRouteProvider`. This way, a client app can work both with your custom `MediaRouteProvider` (taking advantage of your custom actions) and with regular providers that lack such support, assuming that the client can gracefully degrade its functionality.

Google's sample app defines a custom `ACTION_GET_STATISTICS` action that their sample client requests where available and their sample provider implements.

# The Media Projection APIs

---

Android 5.0 debuted the ability for Android apps to take screenshots of whatever is in the foreground. It further allows apps to record full-resolution video of whatever is in the foreground, for screencasts, product demo videos, and the like. For whatever reason, this is called “media projection”, and is based around classes like `MediaProjectionManager`.

In this chapter, we will explore how to use the media projection APIs to record screenshots and screencast-style videos.

## Prerequisites

Understanding this chapter requires that you have read the core chapters.

Having read the chapter on [using the camera APIs](#) would not be a bad idea, particularly for video recording, though it is not essential.

## Requesting Screenshots

Here, “screenshot” (or “screen capture”) refers to generating an ordinary image file (e.g., PNG) of the contents of the screen. Most likely, you have created such screenshots yourself for a desktop OS (e.g., using the `PrtSc` key on Windows or Linux). Android’s development tools allow you to take screenshots of devices and emulators, and there is a cumbersome way for users to take screenshots using the volume and power keys.

The media projection APIs allow you to take a screenshot of whatever is in the foreground... which does not necessarily have to be your own app. Indeed, you can

## THE MEDIA PROJECTION APIS

---

take screenshots of any app, plus of system-supplied UI, such as the pull-down notification shade.

Not surprisingly, this has privacy and security issues. As such, in order to be able to take screenshots, the user must agree to allow it. In particular, instead of a durable permission that the user might grant once and forget about, the user has to agree to allow your app to take screenshots every time you want to do so.

The [MediaProjection/andshooter](#) sample project allows you to take screenshots on demand, whether from a Notification or from a broadcast, such as one triggered from the command line.

### Asking for Permission

To get permission from the user, we get an instance of the `MediaProjectionManager` system service and call `createScreenCaptureIntent()`:

```
package com.commonware.android.andshooter;

import android.app.Activity;
import android.content.Intent;
import android.media.projection.MediaProjectionManager;
import android.os.Bundle;

public class MainActivity extends Activity {
    private static final int REQUEST_SCREENSHOT=59706;
    private MediaProjectionManager mgr;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        mgr=(MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);

        startActivityForResult(mgr.createScreenCaptureIntent(),
            REQUEST_SCREENSHOT);
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode, Intent data) {
        if (requestCode==REQUEST_SCREENSHOT) {
            if (resultCode==RESULT_OK) {
                Intent i=
                    new Intent(this, ScreenshotService.class)
                        .putExtra(ScreenshotService.EXTRA_RESULT_CODE, resultCode)
                        .putExtra(ScreenshotService.EXTRA_RESULT_INTENT, data);

                startService(i);
            }
        }
    }

    finish();
}
```

```
}  
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/MainActivity.java](#))

This is designed for use with `startActivityForResult()`. Starting that activity brings up a dialog for the user to confirm that we should be allowed to take screenshots and record screencasts:

*Figure 820: andshooter Permission Dialog*

In `onActivityResult()`, if our request for permission was granted, we pass the details along via `Intent` extras to a `ScreenshotService` that we start using `startService()`.

`MainActivity` uses `Theme.Translucent.NoTitleBar` to have no UI, so once we get our result, we `finish()` the activity.

### Setting Up the Notification

The `onCreate()` method of the `ScreenshotService` simply obtains access to the `WindowManager` and `MediaProjectionManager` system services, plus sets up a `HandlerThread` that the `MediaProjectionManager` will want:

```
@Override  
public void onCreate() {  
    super.onCreate();  
}
```

## THE MEDIA PROJECTION APIS

---

```
mgr=(MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);
wmgr=(WindowManager) getSystemService(WINDOW_SERVICE);

handlerThread.start();
handler=new Handler(handlerThread.getLooper());
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](#))

`onStartCommand()` performs different work based upon the Intent action used to start this service:

```
@Override
public int onStartCommand(Intent i, int flags, int startId) {
    if (i.getAction()==null) {
        resultCode=i.getIntExtra(EXTRA_RESULT_CODE, 1337);
        resultData=i.getParcelableExtra(EXTRA_RESULT_INTENT);
        foregroundify();
    }
    else if (ACTION_RECORD.equals(i.getAction())) {
        if (resultData!=null) {
            startCapture();
        }
        else {
            Intent ui=
                new Intent(this, MainActivity.class)
                    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK);

            startActivity(ui);
        }
    }
    else if (ACTION_SHUTDOWN.equals(i.getAction())) {
        beeper.startTone(ToneGenerator.TONE_PROP_NACK);
        stopForeground(true);
        stopSelf();
    }

    return(START_NOT_STICKY);
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](#))

In the case where there is no action string, this must be the Intent from the `startService()` call in `MainActivity`. So, we grab and hold onto that result code and result Intent passed in via extras, then call `foregroundify()` to set up a the service as a foreground service with an associated Notification:

## THE MEDIA PROJECTION APIS

---

```
private void foregroundify() {
    NotificationManager mgr=
        (NotificationManager)getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
        mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
        mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
            "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL);

    b.setTitle(getString(R.string.app_name))
        .setSmallIcon(R.mipmap.ic_launcher)
        .setTicker(getString(R.string.app_name));

    b.addAction(R.drawable.ic_record_white_24dp,
        getString(R.string.notify_record),
        buildPendingIntent(ACTION_RECORD));

    b.addAction(R.drawable.ic_eject_white_24dp,
        getString(R.string.notify_shutdown),
        buildPendingIntent(ACTION_SHUTDOWN));

    startForeground(NOTIFY_ID, b.build());
}

private PendingIntent buildPendingIntent(String action) {
    Intent i=new Intent(this, getClass());

    i.setAction(action);

    return(PendingIntent.getService(this, 0, i, 0));
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](https://github.com/CommonsWare/android-andshooter/blob/master/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java))

That Notification, in turn, has “record” and “shutdown” actions that will trigger ScreenshotService with custom action strings, to trigger other branches within onStartCommand().

The downside of relying upon a foreground Notification is that the user has to interact with that Notification to request the screenshot. As a result, that

## THE MEDIA PROJECTION APIS

---

Notification — and the rest of the notification tray — will be visible in the screenshot. While this could be addressed by delaying the screenshot, we do not know how long to wait. It would be nice to be able to operate andshooter without affecting the screen.

Fortunately, we can, courtesy of `adb`.

As is covered in [the chapter on ADB](#), it is possible to use the `adb shell am` command to start an activity, start a service, and send a broadcast. In this case, since we are using a service for managing the recording process, we can use `adb shell am` to trigger the same actions that the Notification does.

This, however, requires that our `ScreenshotService` be exported. For the `PendingIntent` objects used in the Notification, we would not need to export the service. Invoking the service from the command line, however, does require an exported service, since the command line is not the app itself and therefore is considered to be a third-party client of the app. Moreover, there is no obvious way to validate that the commands were sent from `adb shell am`, which means that when `andshooter` is installed, any app could send commands to `ScreenshotService`.

From a security standpoint, this is not great. The user still has to be involved to grant permission to record the screen, which limits the security risk a little bit. However, in general, **you should not run andshooter on your own personal device**, due to this security hole. Or, at minimum, run `andshooter`, then uninstall it immediately when you are done with it, so it does not linger where malware might try to use it.

The `andshooter` project contains a `bash` script to invoke the `ScreenshotService`. This should be able to be trivially converted to Windows command file; the proof of this is left as an exercise for the reader:

```
#!/bin/bash

adb shell am startservice -n com.commonware.android.andshooter/.ScreenshotService \
-a com.commonware.android.andshooter.RECORD
sleep 2s

adb pull /storage/emulated/0/Android/data/com.commonware.android.andshooter/files/
screenshot.png $1
adb shell rm /storage/emulated/0/Android/data/com.commonware.android.andshooter/
files/screenshot.png
```

**NOTE:** the backslashes indicate where a line break was added to allow these lines to fit on the width of the page

### Capturing a Screenshot

If the user asks to record a screenshot — via the Notification or the shell script — `startCapture()` is called:

```
private void startCapture() {
    projection=mgr.getMediaProjection(resultCode, resultData);
    it=new ImageTransmogriifier(this);

    MediaProjection.Callback cb=new MediaProjection.Callback() {
        @Override
        public void onStop() {
            vdisplay.release();
        }
    };

    vdisplay=projection.createVirtualDisplay("andshooter",
        it.getWidth(), it.getHeight(),
        getResources().getDisplayMetrics().densityDpi,
        VIRT_DISPLAY_FLAGS, it.getSurface(), null, handler);
    projection.registerCallback(cb, handler);
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](#))

We start by asking our `MediaProjectionManager` to give us a `MediaProjection` object, using the permission that we obtained from `createScreenCaptureIntent()`, as embodied in the result code and result `Intent` we were given in `onActivityResult()`.

We then ask the `MediaProjection` to create a `VirtualDisplay`, tied to an `ImageTransmogriifier` and its `ImageReader`. We will see more about the `ImageTransmogriifier` shortly. The `VirtualDisplay` basically is a fake screen which is used for collecting screenshots and screencasts.

To create a `VirtualDisplay` need to provide:

- a name for this virtual display, primarily for logging purposes
- the size of the virtual display, in terms of width and height, where we use the scaled width and height computed by the `ImageTransmogriifier`
- the density of the virtual display, which we set to match the density of the

## THE MEDIA PROJECTION APIS

---

actual device screen

- a set of flags (VIRT\_DISPLAY\_FLAGS), where the magic values that seem to work are VIRTUAL\_DISPLAY\_FLAG\_OWN\_CONTENT\_ONLY and VIRTUAL\_DISPLAY\_FLAG\_PUBLIC:

```
static final int VIRT_DISPLAY_FLAGS=  
    DisplayManager.VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY |  
    DisplayManager.VIRTUAL_DISPLAY_FLAG_PUBLIC;
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](#))

- a Surface representing the virtual display, in this case retrieved from the ImageReader inside the ImageTransmogriifier
- an optional VirtualDisplay.Callback to be notified about events in the lifecycle of the VirtualDisplay (unused here, so we pass null)
- a Handler from a HandlerThread, to be used for that callback (presumably unused here, but since we have the right Handler anyway, we use it)

We also need to know about events surrounding the MediaProjection itself, so we create and register a MediaProjection.Callback.

### The ImageTransmogriifier

ImageTransmogriifier, in its constructor, sets about determining the screen size (using WindowManager and getDefaultDisplay()). Since high-resolution displays will wind up with *very* large bitmaps, and therefore slow down the data transfer, we scale the width and height until such time as each screenshot will contain no more than 512K pixels.

```
ImageTransmogriifier(ScreenshotService svc) {  
    this.svc=svc;  
  
    Display display=svc.getWindowManager().getDefaultDisplay();  
    Point size=new Point();  
  
    display.getRealSize(size);  
  
    int width=size.x;  
    int height=size.y;  
  
    while (width*height > (2<<19)) {  
        width=width>>1;  
        height=height>>1;  
    }  
}
```

## THE MEDIA PROJECTION APIS

---

```
this.width=width;
this.height=height;

imageReader=ImageReader.newInstance(width, height,
    PixelFormat.RGBA_8888, 2);
imageReader.setOnImageAvailableListener(this, svc.getHandler());
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ImageTransmogriker.java](#))

Then we create a new `ImageReader`, which boils down to a class that manages a bitmap Surface that can be written to, using our specified width, height, and bit depth. In particular, we are saying that there are two possible outstanding bitmaps at a time, courtesy of the 2 final parameter, and that we should be notified when a new image is ready, by registering the `ImageTransmogriker` as the listener. The `Handler` is used so that we are informed about image availability on our designated background `HandlerThread`.

We find out when a screenshot is available via the `ImageReader.Callback` we set up in `ImageTransmogriker`, specifically its `onImageAvailable()` callback. Since `ImageTransmogriker` itself is implementing the `ImageReader.Callback` interface, `ImageTransmogriker` has the `onImageAvailable()` implementation:

```
@Override
public void onImageAvailable(ImageReader reader) {
    final Image image=imageReader.acquireLatestImage();

    if (image!=null) {
        Image.Plane[] planes=image.getPlanes();
        ByteBuffer buffer=planes[0].getBuffer();
        int pixelStride=planes[0].getPixelStride();
        int rowStride=planes[0].getRowStride();
        int rowPadding=rowStride - pixelStride * width;
        int bitmapWidth=width + rowPadding / pixelStride;

        if (latestBitmap == null ||
            latestBitmap.getWidth() != bitmapWidth ||
            latestBitmap.getHeight() != height) {
            if (latestBitmap != null) {
                latestBitmap.recycle();
            }

            latestBitmap=Bitmap.createBitmap(bitmapWidth,
                height, Bitmap.Config.ARGB_8888);
        }
    }
}
```

## THE MEDIA PROJECTION APIS

---

```
latestBitmap.copyPixelsFromBuffer(buffer);
image.close();

ByteArrayOutputStream baos=new ByteArrayOutputStream();
Bitmap cropped=Bitmap.createBitmap(latestBitmap, 0, 0,
    width, height);

cropped.compress(Bitmap.CompressFormat.PNG, 100, baos);

byte[] newPng=baos.toByteArray();

svc.processImage(newPng);
}
}

Surface getSurface() {
    return(imageReader.getSurface());
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ImageTransmogriker.java](#))

This is complex.

First, we ask the ImageReader for the latest image, via `acquireLatestImage()`. If, for some reason, there is no image, there is nothing for us to do, so we skip all the work.

Otherwise, we have to go through some gyrations to get the actual bitmap itself from Image object. The recipe for that probably makes sense to somebody, but that “somebody” is not the author of this book. Suffice it to say, the first six lines of the main if block in `onImageAvailable()` get access to the bytes of the bitmap (as a `ByteBuffer` named `buffer`) and determine the width of the bitmap that was handed to us (as an `int` named `bitmapWidth`).

Because `Bitmap` objects are large and therefore troublesome to allocate, we try to reuse one where possible. If we do not have a `Bitmap` (`latestBitmap`), or if the one we have is not the right size, we create a new `Bitmap` of the appropriate size. Otherwise, we use the `Bitmap` that we already have. Regardless of where the `Bitmap` came from, we use `copyPixelsFromBuffer()` to populate it from the `ByteBuffer` we got from the `Image.Plane` that we got from the `Image` that we got from the `ImageReader`.

You might think that this `Bitmap` would be the proper size. However, it is not. For inexplicable reasons, on some devices, it will be a bit larger, with excess unused pixels on each row on the end. This is why we need to use `Bitmap.createBitmap()`

to create a cropped edition of the original Bitmap, for our actual desired width.

We then `compress()` the cropped Bitmap into a PNG file, get the byte array of pixel data from the compressed result, and hand that off to the `ProjectorService` via `processImage()`.

### Saving the Screenshot

In `processImage()`, we write the PNG to a file, update the `MediaStore` so it knows about the image, play an acknowledgment tone to let the user know the screenshot is ready, and call `stopCapture()`:

```
void processImage(final byte[] png) {
    new Thread() {
        @Override
        public void run() {
            File output=new File(getExternalFilesDir(null),
                "screenshot.png");

            try {
                FileOutputStream fos=new FileOutputStream(output);

                fos.write(png);
                fos.flush();
                fos.getFD().sync();
                fos.close();

                MediaScannerConnection.scanFile(ScreenshotService.this,
                    new String[] {output.getAbsolutePath()},
                    new String[] {"image/png"},
                    null);
            }
            catch (Exception e) {
                Log.e(getClass().getSimpleName(), "Exception writing out screenshot", e);
            }
        }
    }.start();

    beeper.startTone(ToneGenerator.TONE_PROP_ACK);
    stopCapture();
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](https://github.com/CommonWare/android-andshooter/blob/master/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java))

All `stopCapture()` does is close down the `MediaProjection` and associated virtual display, to clean things up in preparation for the next screenshot:

```
private void stopCapture() {
    if (projection!=null) {
        projection.stop();
        vdisplay.release();
    }
}
```

```
projection=null;
    }
}
```

(from [MediaProjection/andshooter/app/src/main/java/com/commonsware/android/andshooter/ScreenshotService.java](#))

## Recording the Screen

Here, a “screencast” refers to a full-motion video of what goes on the screen. You can think of it as a series of screenshots all written to one video file (e.g., an MP4). Many apps on the Play Store have screencasts as part of their product profile, so you can see what the app looks like when it is run.

Android’s media projection APIs allow you to capture screencasts, using a mechanism similar to the one used to take screenshots. You have to ask permission from the user to be able to record the screen, and that permission will last for the duration of one screen recording. During that period of time, you can direct Android to make a duplicate copy of what goes on the screen to a video file. This winds up using the `MediaRecorder` API along with dedicated media projection APIs, which is a bit awkward, since `MediaRecorder` is really aimed at using the device camera to record videos of the world outside the device.

Jake Wharton, with his open source [Telecine app](#), helped blaze the trail in how these APIs are supposed to work, since the documentation, as usual, is limited.

The [MediaProjection/andcorder](#) sample project offers screen recording through the media projection APIs. In the end, `andcorder` does the same basic stuff as does `Telecine`, with fewer bells and whistles. Also, the control channel is different: `Telecine` uses a screen overlay, while `andcorder` uses a foreground Notification or the command line.

## Requesting Media Projection... Without a GUI

As with `andshooter`, `andcorder` has a `MainActivity` that uses `MediaProjectionManager` and `createScreenCaptureIntent()` to get permission from the user to record the screen, passing the results along to a `RecorderService`:

```
package com.commonsware.android.andcorder;

import android.app.Activity;
import android.content.Intent;
import android.media.projection.MediaProjectionManager;
import android.os.Bundle;
```

## THE MEDIA PROJECTION APIS

---

```
public class MainActivity extends Activity {
    private static final int REQUEST_SCREENCAST=59706;
    private MediaProjectionManager mgr;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        mgr=(MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);

        startActivityForResult(mgr.createScreenCaptureIntent(),
            REQUEST_SCREENCAST);
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode, Intent data) {
        if (requestCode==REQUEST_SCREENCAST) {
            if (resultCode==RESULT_OK) {
                Intent i=
                    new Intent(this, RecorderService.class)
                        .putExtra(RecorderService.EXTRA_RESULT_CODE, resultCode)
                        .putExtra(RecorderService.EXTRA_RESULT_INTENT, data);

                startService(i);
            }
        }

        finish();
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/MainActivity.java](#))

### Implementing a Control Channel... Without a GUI

And, as with andshooter, andcorder uses a Notification tied to a foreground service that manages the actual screen recording, to allow the user to request to start and stop the screen recording.

We will use action strings, in the Intent used to start the RecorderService, to indicate what is to be done. Those action strings will be the application ID plus a segment at the end that is the specific operation we want:

```
static final String ACTION_RECORD=
    BuildConfig.APPLICATION_ID+".RECORD";
static final String ACTION_STOP=
    BuildConfig.APPLICATION_ID+".STOP";
static final String ACTION_SHUTDOWN=
    BuildConfig.APPLICATION_ID+".SHUTDOWN";
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

## THE MEDIA PROJECTION APIS

---

Here, we use `BuildConfig.APPLICATION_ID`, a faster, no-Context way to get our application ID, as part of building up these strings. We have three actions: to start recording (RECORD), to stop recording (STOP), and to shut down the `RecorderService` (SHUTDOWN). An Intent with *no* action string will be used on the initial launch of the service, from `MainActivity`.

`onStartCommand()` is where all of these commands, triggered by `startService()` calls, will come in:

```
@Override
public int onStartCommand(Intent i, int flags, int startId) {
    if (i.getAction()==null) {
        resultCode=i.getIntExtra(EXTRA_RESULT_CODE, 1337);
        resultData=i.getParcelableExtra(EXTRA_RESULT_INTENT);

        if (recordOnNextStart) {
            startRecorder();
        }

        foregroundify(!recordOnNextStart);
        recordOnNextStart=false;
    }
    else if (ACTION_RECORD.equals(i.getAction())) {
        if (resultData!=null) {
            foregroundify(false);
            startRecorder();
        }
        else {
            Intent ui=
                new Intent(this, MainActivity.class)
                    .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK);

            startActivity(ui);
            recordOnNextStart=true;
        }
    }
    else if (ACTION_STOP.equals(i.getAction())) {
        foregroundify(true);
        stopRecorder();
    }
    else if (ACTION_SHUTDOWN.equals(i.getAction())) {
        stopSelf();
    }

    return(START_NOT_STICKY);
}
```

## THE MEDIA PROJECTION APIS

---

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

If we have no action string, this should be the command from MainActivity, so we grab the resultCode and resultData out of the Intent and stash them in simple fields on the service:

```
private int resultCode;
private Intent resultData;
private boolean recordOnNextStart=false;
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

We also:

- Call startRecorder() if recordOnNextStart is set to true
- Call foregroundify(), with a boolean that indicates whether we should give the user the option to begin recording (true) or to stop existing recording (false)
- Clear the recordOnNextStart flag

We will discuss more about that recordOnNextStart, its role, and why it exists, later in this chapter.

If, instead, a RECORD action string was on the Intent, then ideally we should begin recording the screen contents. The “ideally” part is because there will be scenarios in which the RECORD action is invoked before we actually have permission from the user to record the screen (more on this later).

So, if a RECORD action comes in, *and* we have permission from the user to record the screen (resultData is not null), we call startRecorder() to start recording, plus call foregroundify() to put up a Notification with an action for STOP. If, on the other hand, we do not presently have permission from the user (resultData is null), we start up MainActivity to get that permission, plus set recordOnNextStart to true.

The other two cases are simpler:

- If we get a STOP Intent, we call stopRecorder(), plus call foregroundify() to change the foreground service Notification to one that has an action for RECORD
- If we get a SHUTDOWN Intent, we call stopSelf() to go away entirely

foregroundify() is invoked for most of those cases, to put the service in the

## THE MEDIA PROJECTION APIS

---

foreground (if it is not in the foreground already) and show a Notification with the appropriate mix of actions:

```
private void foregroundify(boolean showRecord) {
    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.O &&
        mgr.getNotificationChannel(CHANNEL_WHATEVER) == null) {
        mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
            "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL);

    b.setTitle(getString(R.string.app_name))
        .setSmallIcon(R.mipmap.ic_launcher)
        .setTicker(getString(R.string.app_name));

    if (showRecord) {
        b.addAction(R.drawable.ic_videocam_white_24dp,
            getString(R.string.notify_record), buildPendingIntent(ACTION_RECORD));
    }
    else {
        b.addAction(R.drawable.ic_stop_white_24dp,
            getString(R.string.notify_stop), buildPendingIntent(ACTION_STOP));
    }

    b.addAction(R.drawable.ic_eject_white_24dp,
        getString(R.string.notify_shutdown), buildPendingIntent(ACTION_SHUTDOWN));

    if (isForeground) {
        mgr.notify(NOTIFY_ID, b.build());
    }
    else {
        startForeground(NOTIFY_ID, b.build());
        isForeground=true;
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

In addition to generic NotificationCompat.Builder configuration, we:

- add an action to shut down the service, tied to the SHUTDOWN action string
- either add an action to RECORD or STOP the recording, based upon the boolean passed into foregroundify()
- either use startForeground() to move the service into the foreground and show the Notification or use NotificationManager to update the existing Notification (if we are already in the foreground)

## THE MEDIA PROJECTION APIS

---

The latter distinction may not be necessary. Calling `startForeground()` multiple times does not seem to have any harm, and it also updates the foreground Notification. Using `NotificationManager` directly for the already-in-the-foreground scenario, though, may be superfluous.

The `addAction()` calls delegate to a `buildPendingIntent()` method, to create the `PendingIntent` to be triggered when the action is tapped:

```
private PendingIntent buildPendingIntent(String action) {
    Intent i=new Intent(this, getClass());

    i.setAction(action);

    return(PendingIntent.getService(this, 0, i, 0));
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

This creates an explicit Intent, tied to `RecorderService` itself, but also adds the action string. This Intent will always resolve to our `RecorderService`; the action string is just part of the payload.

## THE MEDIA PROJECTION APIS

---

That foreground Notification provides the visual way of starting recording:

*Figure 821: andcorder Notification, Showing Record and Shutdown Actions*

...and stopping recording once started:

*Figure 822: andcorder Notification, Showing Stop and Shutdown Actions*

In addition, `onDestroy()` stops the recording and removes us from the foreground, plus we have the obligatory `onBind()` implementation:

```
@Override
public void onDestroy() {
    stopRecorder();
    stopForeground(true);

    super.onDestroy();
}

@Override
public IBinder onBind(Intent intent) {
    throw new IllegalStateException("go away");
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

## Using the Control Channel... From the Command Line

As with `andshooter`, `andcorder` is designed to use command-line scripts to start and stop recording.

The `andcorder` project contains three `bash` scripts to invoke the `RecorderService`. These should be able to be converted to Windows command files for those that need them.

All three scripts use `adb shell am startservice`, and all point to the same component (`-n com.commonware.android.andcorder/.RecorderService`). What varies is the action string supplied to the `-a` switch.

**NOTE:** the shell script code listings are word-wrapped due to line length limitations in the books; the files themselves have the `adb shell` commands all on one line.

So, the `record` script, for example, passes `com.commonware.android.andcorder.RECORD` as the action string:

```
#!/bin/bash
adb shell am startservice -n com.commonware.android.andcorder/.RecorderService
-a com.commonware.android.andcorder.RECORD
```

The `stop` script passes the `STOP` action string; the `shutdown` script passes the `SHUTDOWN` action string.

These, therefore, replicate the `Intent` structures used in the `PendingIntent` objects for the `Notification` actions.

However, there is one key usage difference: it would be nice to be able to run the `record` script without having to think about whether or not you ran `andcorder` from the home screen launcher or not. The `RECORD` action cannot actually do the recording without the result data from the `startActivityForResult()` call in `MainActivity`.

This is why the `RECORD` action logic detects this case and starts up `MainActivity` — so we can just run the `record` script and, if we do not presently have screen-recording permission, request it from the user.

The `recordOnNextStart` flag indicates whether or not `RECORD` started up `MainActivity`. If it did, when we get the result data in the no-action

onStartCommand() call, we should go ahead and begin recording. This prevents the user from having to run the record script twice, once to pop up the permission dialog and once to actually begin recording.

### Starting the Recording

The startRecorder() method on RecorderService is called when it is time to begin screen recording, either because the user asked us to record just now or the user asked us to record (via the command-line script) and we just now got permission from the user to do that.

```
synchronized private void startRecorder() {
    if (session==null) {
        MediaProjectionManager mgr=
            (MediaProjectionManager) getSystemService(MEDIA_PROJECTION_SERVICE);
        MediaProjection projection=
            mgr.getMediaProjection(resultCode, resultData);

        session=
            new RecordingSession(this, new RecordingConfig(this),
                projection);
        session.start();
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

Here, as with the andshooter sample, we use a MediaProjectionManager to turn the resultCode int and resultData Intent into a MediaProjection. Then, we create a RecordingSession, wrapped around a RecordingConfig and the MediaProjection, and call start() on the RecordingSession.

Both RecordingSession and RecordingConfig are classes that are part of the app, not the Android SDK. RecordingConfig holds onto information about the nature of what is being recorded (notably, the video resolution) to capture. RecordingSession handles the stateful work of actually recording the video.

Of the two, you might expect RecordingSession to be far more complex. In truth, it is decidedly more straightforward than is RecordingConfig. Determining the resolution and other information about our screen recording is annoyingly complicated.

### Deciding How Big Our Recording Is

The job of `RecordingConfig` is to derive and hold onto five pieces of data regarding the screen recording that we are about to initiate:

- The width and height of the video, in pixels
- The bit rate at which the video should be recorded
- The frame rate (frames per second) at which the video should be recorded
- The screen density

These are held in five `final int` fields, as `RecordingConfig` is designed to be immutable:

```
final int width;
final int height;
final int frameRate;
final int bitRate;
final int density;
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

All five of these values will be initialized in the constructor (since they are `final`). In fact, all the business logic for `RecordingSession` is just in the constructor, to derive these five values.

That constructor starts off simple enough:

```
RecordingConfig(Context ctxt) {
    DisplayMetrics metrics=new DisplayMetrics();
    WindowManager wm=(WindowManager)ctxt.getSystemService(Context.WINDOW_SERVICE);

    wm.getDefaultDisplay().getRealMetrics(metrics);

    density=metrics.densityDpi;

    Configuration cfg=ctxt.getResources().getConfiguration();

    boolean isLandscape=
        (cfg.orientation==Configuration.ORIENTATION_LANDSCAPE);
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

Here, we:

- Populate a `DisplayMetrics` data structure, given a `WindowManager`
- Save the screen density in its `final` field
- Get the current `Configuration` and determine if we are in landscape mode

or not

Where things start to get messy is with the other four fields, as they need to be populated based on the device's video recording capabilities. For various reasons, screen recording is actually handled mostly by `MediaRecorder`, the same class used to [record videos from a device camera](#). Hence, we are limited by not only the actual resolution of the screen but by the capabilities of the video recording engine.

The classic way to handle this is by using `CamcorderProfile` objects. These standardize video recording support for various resolutions. We can find out which of these profiles the device supports and use that to help determine our video resolution, frame rate, and bitrate.

However, we also have to take into account the resolution of the screen itself. If `MediaRecorder` is capable of 1080p (1920 x 1080) video recording, but the device has a low-end WXGA (1280 x 800) screen, we will waste a lot of space recording that screen at 1080p. What we want is the smallest resolution that is bigger than the screen, to minimize wasted space while not losing data. If, for some reason, we do not have a `CamcorderProfile` that is bigger than the screen, we will have to settle for one that is as big as we can manage.

To that end, the `CAMCORDER_PROFILES` static field on `RecordingConfig` lists the major `CamcorderProfile` IDs, in descending order based on resolution:

```
private static final int[] CAMCORDER_PROFILES={
    CamcorderProfile.QUALITY_2160P,
    CamcorderProfile.QUALITY_1080P,
    CamcorderProfile.QUALITY_720P,
    CamcorderProfile.QUALITY_480P,
    CamcorderProfile.QUALITY_CIF,
    CamcorderProfile.QUALITY_QVGA,
    CamcorderProfile.QUALITY_QCIF
};
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

If we simply iterate over this list and choose either the first one we find, or one that is smaller yet is bigger than the screen, we will get the right `CamcorderProfile` for our use case:

```
CamcorderProfile selectedProfile=null;

for (int profileId : CAMCORDER_PROFILES) {
    CamcorderProfile profile=null;
```

## THE MEDIA PROJECTION APIS

---

```
try {
    profile=CamcorderProfile.get(profileId);
}
catch (Exception e) {
    // not documented to throw anything, but does
}

if (profile!=null) {
    if (selectedProfile==null) {
        selectedProfile=profile;
    }
    else if (profile.videoFrameWidth>=metrics.widthPixels &&
        profile.videoFrameHeight>=metrics.heightPixels) {
        selectedProfile=profile;
    }
}
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

To get a `CamcorderProfile` given its ID, you call the static `get()` method on `CamcorderProfile`. This is supposed to return the `CamcorderProfile` if it is supported or `null` if it is not. In actuality, it may throw an exception if the profile is not supported, which is why we have to wrap the `get()` call in a `try/catch` block. Then, if `profile` exists, we hold onto it as the `selectedProfile` if either:

- `selectedProfile` is `null`, meaning this is the largest available profile, or
- the profile has a resolution bigger than the screen on both axes

If, after all that is done, we have a `null` `selectedProfile`, that means that *none* of the `CamcorderProfile` values were available. That is very strange, and rather than take a random guess as to what will work, we just blow up with an `IllegalStateException`. Obviously, a production-grade app would need to blow up more nicely.

Otherwise, we can collect our remaining data... which once again is more complex than you might expect:

```
if (selectedProfile==null) {
    throw new IllegalStateException("No CamcorderProfile available!");
}
else {
    frameRate=selectedProfile.videoFrameRate;
    bitRate=selectedProfile.videoBitRate;
}
```

```
int targetWidth, targetHeight;

if (isLandscape) {
    targetWidth=selectedProfile.videoFrameWidth;
    targetHeight=selectedProfile.videoFrameHeight;
}
else {
    targetWidth=selectedProfile.videoFrameHeight;
    targetHeight=selectedProfile.videoFrameWidth;
}

if (targetWidth>=metrics.widthPixels &&
    targetHeight>=metrics.heightPixels) {
    width=metrics.widthPixels;
    height=metrics.heightPixels;
}
else {
    if (isLandscape) {
        width=targetHeight*metrics.widthPixels/metrics.heightPixels;
        height=targetHeight;
    }
    else {
        width=targetWidth;
        height=targetWidth*metrics.heightPixels/metrics.widthPixels;
    }
}
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingConfig.java](#))

Getting the frame rate and the bitrate are easy enough, as they are just fields on the CamcorderProfile. Where things start to get strange is in determining what we should tell the MediaRecorder that we want recorded in terms of resolution.

Partly, this is a problem of orientation. MediaRecorder thinks that everything is recorded in landscape, but we may well want to record the screen held in portrait mode.

Partly, this is a problem of aspect ratios. There is no requirement that the MediaRecorder advertise support for resolutions that match the screen size, or even match the screen's aspect ratio. So, if the MediaRecorder is capable of recording our full screen, we ask it to record the full screen (as determined from the DisplayMetrics). If, however, we are on some odd device whose MediaRecorder is not capable of recording video at the screen's own resolution, we try to at least

maintain the aspect ratio of the screen when deriving the resolution to use for recording.

The net of all that work is that we have the details of how we want the screen recording to be done, encapsulated in the `RecordingConfig` object, ready for use by the `RecordingSession`.

### Actually Recording Stuff

None of that actually records the screen, though. That is the responsibility of the `RecordingSession`.

In the `RecordingSession` constructor, we:

- Hold onto the `RecordingConfig` and `MediaProjection`
- Hold onto the application `Context`, as we will need a `Context` later on
- Create an instance of a `ToneGenerator` to use for audible feedback about the state of the recording
- Create a `File` object pointing at our desired output: an `andcorder.mp4` file in our app's portion of external storage

```
RecordingSession(Context ctxt, RecordingConfig config,
                 MediaProjection projection) {
    this.ctxt=ctxt.getApplicationContext();
    this.config=config;
    this.projection=projection;
    this.beeper=new ToneGenerator(
        AudioManager.STREAM_NOTIFICATION, 100);

    output=new File(ctxt.getExternalFilesDir(null), "andcorder.mp4");
    output.getParentFile().mkdirs();
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

The actual work to record the video is handled in the `start()` method on `RecordingSession`, where we set up the `MediaRecorder` and a `VirtualDisplay`, the latter being the same thing that we used in the `andshooter` sample:

```
void start() {
    recorder=new MediaRecorder();
    recorder.setVideoSource(MediaRecorder.VideoSource.SURFACE);
    recorder.setOutputFormat(MediaRecorder.OutputFormat.MPEG_4);
    recorder.setVideoFrameRate(config.frameRate);
```

## THE MEDIA PROJECTION APIS

---

```
recorder.setVideoEncoder(MediaRecorder.VideoEncoder.H264);
recorder.setVideoSize(config.width, config.height);
recorder.setVideoEncodingBitRate(config.bitRate);
recorder.setOutputFile(output.getAbsolutePath());

try {
    recorder.prepare();
    vdisplay=projection.createVirtualDisplay("andcorder",
        config.width, config.height, config.density,
        VIRT_DISPLAY_FLAGS, recorder.getSurface(), null, null);
    beeper.startTone(ToneGenerator.TONE_PROP_ACK);
    recorder.start();
}
catch (IOException e) {
    throw new RuntimeException("Exception preparing recorder", e);
}
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

First, we create an instance of `MediaRecorder` and configure it. As is discussed in [the chapter on working with the camera](#), `MediaRecorder` is a *very* fussy class, requiring a fairly specific order of method calls to configure it without messing things up too bad. The values for the configuration come from:

- the `RecordingConfig`, notably the requested resolution, frame rate, and bitrate
- the output `File` created in the `RecordingSession` constructor
- hardcoded values for the video source, output format, and encoder format

Of particular interest is the call to `setVideoSource()`. Usually, you would set this to `CAMERA`, to record from a device-supplied camera. Here, though, we set it to `SURFACE`, indicating that `MediaRecorder` should supply a `Surface` onto which we can render what should get recorded.

We then:

- Prepare the `MediaRecorder`, which might throw an `IOException` if there is some problem with the output file
- Create a `VirtualDisplay`, as we did in `andshooter`, tied to the details of the display we got from `DisplayMetrics` by way of the `RecordingConfig`
- Play a tone using `ToneGenerator` to let the user know that recording has begun
- Actually begin the recording, via a call to `start()` on the `MediaRecorder`

## THE MEDIA PROJECTION APIS

---

The `VIRT_DISPLAY_FLAGS` used here are the same ones used for `andshooter`:

```
static final int VIRT_DISPLAY_FLAGS=
    DisplayManager.VIRTUAL_DISPLAY_FLAG_OWN_CONTENT_ONLY |
    DisplayManager.VIRTUAL_DISPLAY_FLAG_PUBLIC;
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

And, at this point, the screen is being recorded.

### Stopping the Recording

Eventually, we will want to stop that recording, whether triggered via the Notification or the command-line script. That eventually results in a call to `stopRecorder()` on the `RecorderService`, which just calls `stop` on the `RecordingSession` before setting the field to `null`:

```
synchronized private void stopRecorder() {
    if (session!=null) {
        session.stop();
        session=null;
    }
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecorderService.java](#))

The `stop()` method on `RecordingSession` unwinds everything we set up, via `stop()` and `release()` calls on the `MediaProjection`, `MediaRecorder`, and `VirtualDisplay`. `stop()` also calls `scanFile()` on `MediaScannerConnection`, so that our video gets indexed by the `MediaStore` and therefore can be seen in on-device video players and via the MTP connection to your developer machine:

```
void stop() {
    projection.stop();
    recorder.stop();
    recorder.release();
    vdisplay.release();

    MediaScannerConnection.scanFile(ctxt,
        new String[]{output.getAbsolutePath()}, null, this);
}

@Override
public void onScanCompleted(String path, Uri uri) {
    beeper.startTone(ToneGenerator.TONE_PROP_NACK);
}
```

## THE MEDIA PROJECTION APIS

---

```
}
```

(from [MediaProjection/andcorder/app/src/main/java/com/commonsware/android/andcorder/RecordingSession.java](#))

When the scan is complete, another beep signals to the user that the screen recording is finished.

### Usage Notes

On the plus side, andcorder has no built-in duration limitation, the way that [adb shell screenrecord](#) does.

However, it does not optimize configuration changes. If you rotate the device during the recording, the recording will continue, but the screen will be shrunk to fit within the original dimensions. So, for example, if you start recording in landscape, then rotate the device to portrait, the video will still be landscape, with part of the video showing a small portrait rendition of the screen.

# AlarmManager and the Scheduled Service Pattern

---

Many applications have the need to get control every so often to do a bit of work. And, many times, those applications need to get control in the background, regardless of what the user may be doing (or not doing) at the time.

The solution, in some cases, is to use AlarmManager, which is roughly akin to cron on Linux and macOS and Scheduled Tasks in Windows. You teach AlarmManager when you want to get control back, and AlarmManager will give you control at that time.

Android 5.0 added a separate JobScheduler. Like AlarmManager, JobScheduler is designed for background work. JobScheduler is more sophisticated than is AlarmManager. For example, if you need an Internet connection to do your work, JobScheduler will only give you control if there is an Internet connection. If your app's minSdkVersion is 21 or higher, you might consider using JobScheduler instead of AlarmManager. JobScheduler is covered in [an upcoming chapter](#).

## Prerequisites

This chapter requires you to have read the core chapters of the book, in particular [the chapter on services](#).

## Scenarios

The two main axes to consider with scheduled work are frequency and foreground (vs. background).

If you have an activity that needs to get control every second, the simplest approach is to use a `postDelayed()` loop, scheduling a `Runnable` to be invoked after a certain delay, where the `Runnable` reschedules itself to be invoked after the delay in addition to doing some work. We saw this in [the chapter on threads](#). This has the advantages of giving you control back on the main application thread and avoiding the need for any background threads.

On the far other end of the spectrum, you may need to get control on a somewhat slower frequency (e.g., every 15 minutes), and do so in the background, even if nothing of your app is presently running. You might need to poll some Web server for new information, such as downloading updates to an RSS feed. This is the scenario that `AlarmManager` excels at. While `postDelayed()` works *inside* your process (and therefore does not work if you no longer have a process), `AlarmManager` maintains its schedule *outside* of your process. Hence, it can arrange to give you control, even if it has to start up a new process for you along the way.

## Options

There are a variety of things you will be able to configure about your scheduled alarms with `AlarmManager`.

### Wake Up... Or Not?

The biggest one is whether or not the scheduled event should wake up the device.

A device goes into a sleep mode shortly after the screen goes dark. During this time, nothing at the application layer will run, until something wakes up the device. Waking up the device does not necessarily turn on the screen — it may just be that the CPU starts running your process again.

If you choose a “wakeup”-style alarm, Android will wake up the device to give you control. This would be appropriate if you need this work to occur even if the user is not actively using the device, such as your app checking for critical email messages in the middle of the night. However, it does drain the battery some.

Alternatively, you can choose an alarm that will not wake up the device. If your desired time arrives and the device is asleep, you will not get control until something else wakes up the device.

### Repeating... Or Not?

You can create a “one-shot” alarm, to get control once at a particular time in the future. Or, you can create an alarm that will give you control periodically, at a fixed period of your choice (e.g., every 15 minutes).

If you need to get control at multiple times, but the schedule is irregular, use a “one-shot” alarm for the nearest time, where you do your work *and* schedule a “one-shot” alarm for the next-nearest time. This would be appropriate for scenarios like a calendar application, where you need to let the user know about upcoming appointments, but the times for those appointments may not have any fixed schedule.

However, for most polling operations (e.g., checking for new messages every NN minutes), a repeating alarm will typically be the better answer.

### Inexact... Or Not?

If you do choose a repeating alarm, you will have your choice over having (relatively) precise control over the timing of event or not.

If you choose an “inexact” alarm, while you will provide Android with a suggested time for the first event and a period for subsequent events, Android reserves the right to shift your schedule somewhat, so it can process your events and others around the same time. This is particularly important for “wakeup”-style alarms, as it is more power-efficient to wake up the device fewer times, so Android will try to combine multiple apps’ events to be around the same time to minimize the frequency of waking up the device.

However, inexact alarms are annoying to test and debug, simply because you do not have control over when they will be invoked. Hence, during development, you might start with an exact alarm, then switch to inexact alarms once most of your business logic is debugged.

Note that Android 4.4 changes the behavior of AlarmManager, such that it is more difficult to actually create an exact-repeating alarm schedule. This will be examined in greater detail shortly, as we review the various methods and flags for scheduling AlarmManager events.

### Absolute Time... Or Not?

As part of the alarm configuration, you will tell Android when the event is to occur (for one-shot alarms) or when the event is to *first* occur (for repeating alarms). You can provide that time in one of two ways:

- An absolute “real-time clock” time (e.g., 4am tomorrow), or
- A time relative to now

For most polling operations, particularly for periods more frequent than once per day, specifying the time relative to now is easiest. However, some alarms may need to tie into “real world time”, such as alarm clocks and calendar alerts — for those, you will need to use the real-time clock (typically by means of a Java Calendar object) to indicate when the event should occur.

### What Happens (Or Not???)

And, of course, you will need to tell Android what to do when each of these timer events occurs. You will do that in the form of supplying a PendingIntent. First mentioned in [the chapter on services](#), a PendingIntent is [a Parcelable object](#), one that indicates an operation to be performed upon an Intent:

- start an activity
- start a service
- send a broadcast
- call `onActivityResult()` of an existing activity (created via `createPendingResult()`)

## A Simple Example

A trivial sample app using AlarmManager can be found in [AlarmManager/Simple](#).

This application consists of a single activity, SimpleAlarmDemoActivity, that will both set up an alarm schedule and respond to alarms:

```
package com.commonsware.android.alarm;

import android.app.Activity;
import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.Intent;
```

## ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

---

```
import android.os.Bundle;
import android.os.SystemClock;
import android.util.Log;
import android.widget.Toast;

public class SimpleAlarmDemoActivity extends Activity {
    private static final int ALARM_ID=1337;
    private static final int PERIOD=5000;
    private PendingIntent pi=null;
    private AlarmManager mgr=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        mgr=(AlarmManager) getSystemService(ALARM_SERVICE);
        pi=createPendingResult(ALARM_ID, new Intent(), 0);
        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME,
            SystemClock.elapsedRealtime() + PERIOD, PERIOD, pi);
    }

    @Override
    public void onDestroy() {
        mgr.cancel(pi);

        super.onDestroy();
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode,
        Intent data) {
        if (requestCode == ALARM_ID) {
            Toast.makeText(this, R.string.toast, Toast.LENGTH_SHORT).show();
            Log.d(getClass().getSimpleName(), "I ran!");
        }
    }
}
```

(from [AlarmManager/Simple/app/src/main/java/com/commonsware/android/alarm/SimpleAlarmDemoActivity.java](#))

In `onCreate()`, in addition to setting up the “hello, world”-ish UI, we:

- Obtain an instance of `AlarmManager`, by calling `getSystemService()`, asking for the `ALARM_SERVICE`, and casting the result to be an `AlarmManager`
- Create a `PendingIntent` by calling `createPendingResult()`, supplying an empty `Intent` as our “result” (since we do not really need it here)

- Calling `setRepeating()` on `AlarmManager`

The call to `setRepeating()` is a bit complex, taking four parameters:

1. The type of alarm we want, in this case `ELAPSED_REALTIME`, indicating that we want to use a relative time base for when the first event should occur (i.e., relative to now) and that we do not need to wake up the device out of any sleep mode
2. The time when we want the first event to occur, in this case specified as a time delta in milliseconds (`PERIOD`) added to “now” as determined by `SystemClock.elapsedRealtime()` (the number of milliseconds since the device was last rebooted)
3. The number of milliseconds to occur between events
4. The `PendingIntent` to invoke for each of these events

When the event occurs, since we used `createPendingResult()` to create the `PendingIntent`, our activity gets control in `onActivityResult()`, where we simply display a `Toast` (if the event is for our alarm’s request ID). This continues until the activity is destroyed (e.g., pressing the `BACK` button), at which time we `cancel()` the alarm, supplying a `PendingIntent` to indicate which alarm to cancel. While here we use the same `PendingIntent` object as we used for scheduling the alarm, that is not required — it merely has to be an *equivalent* `PendingIntent`, meaning:

- The `Intent` inside the `PendingIntent` matches the scheduled alarm’s `Intent`, in terms of component, action, data (`Uri`), `MIME` type, and categories
- The ID of the `PendingIntent` (here, `ALARM_ID`) must also match

Running this simply brings up a `Toast` every five seconds until you `BACK` out of the activity... except on Android 5.1 and higher, where it will appear every minute. That is due to a limitation of `setRepeating()` that we will see in the next section.

## The Five `set...()` Varieties

There are five methods that you can call on `AlarmManager` to establish an alarm, including the `setRepeating()` demonstrated above.

On Android 4.4 (API Level 19) and higher, `setExact()` is used for a one-shot alarm, where you want to get control at one specific time in the future. This would be used for specific events or for irregular alarm schedules.

On Android 4.3 and below, and for apps whose `targetSdkVersion` is set to 18 or lower, `set()` has the same behavior as `setExact()`. However, on Android 4.4 and above, apps with their `targetSdkVersion` set to be 19 or higher will have different, *inexact* behavior for `set()`. The time of the event is considered a minimum — your `PendingIntent` will not be invoked before your desired time, but it can occur any time thereafter... and you do not have control over how long that delay will be. As with all “inexact” schedules, the objective is for Android to be able to “batch” these events, to do several around the same time, for greater efficiency, particularly when waking up the device.

On Android 4.4 and higher, you have a `setWindow()` option that is a bit of a hybrid between the new-style `set()` and `setExact()`. Here, you specify the time you want the event to occur and an amount of time that Android can “flex” the actual event. So, for example, you might set up an event to occur every hour, with a “window” of five minutes, to allow Android the flexibility to invoke your `PendingIntent` within that five-minute window. This allows for better battery optimization than with `setExact()`, while still giving you some control over how far “off the mark” the event can occur.

On Android 4.3 and below, and for apps whose `targetSdkVersion` is set to 18 or lower, `setRepeating()` is used for an alarm that should occur at specific points in time at a specific frequency. In addition to specifying the time of the first event, you also specify the period for future events. Android will endeavor to give you control at precisely those times, though since Android is not a real-time operating system (RTOS), microsecond-level accuracy is certainly not guaranteed. However, note that as of Android 5.1, your minimum period is one minute (60000ms) — values less than that will be rounded up to one minute. This minimum period is enforced regardless of your `targetSdkVersion` value.

`setInexactRepeating()` is used for an alarm that should occur on a general frequency, such as every 15 minutes. In addition to specifying the time of the first event, you also specify a general frequency, as one of the following public static data members on `AlarmManager`:

- `INTERVAL_FIFTEEN_MINUTES`
- `INTERVAL_HALF_HOUR`
- `INTERVAL_HOUR`
- `INTERVAL_HALF_DAY`
- `INTERVAL_DAY`

Android guarantees that it will give your app control somewhere during that time

window, but precisely *when* within that window is up to Android.

Note that on Android 4.4 and above, for apps with their `targetSdkVersion` set to be 19 or higher, `setRepeating()` behaves identically to `setInexactRepeating()` – in other words, all repeating alarms are inexact. The only way to get exact repeating would be to use `setExact()` and to re-schedule the event yourself, rather than relying upon Android doing that for you automatically. Ideally, you use `setInexactRepeating()`, to help extend battery life.

And, note that on Android 5.1 and higher, alarms must be set to occur at least 5 seconds in the future from now. You cannot trigger an alarm to occur in the future sooner than 5 seconds.

## The Four Types of Alarms

In the above sample, we used `ELAPSED_REALTIME` as the type of alarm. There are three others:

- `ELAPSED_REALTIME_WAKEUP`
- `RTC`
- `RTC_WAKEUP`

Those with `_WAKEUP` at the end will wake up a device out of sleep mode to execute the `PendingIntent` — otherwise, the alarm will wait until the device is awake for other means.

Those that begin with `ELAPSED_REALTIME` expect the second parameter to `setRepeating()` to be a timestamp based upon `SystemClock.elapsedRealtime()`. Those that begin with `RTC`, however, expect the second parameter to be based upon `System.currentTimeMillis()`, the classic Java “what is the current time in milliseconds since the Unix epoch” method.

## When to Schedule Alarms

The sample, though, begs a bit of a question: when are we supposed to set up these alarms? The sample just does so in `onCreate()`, but is that sufficient?

For most apps, the answer is “no”. Here are the three times that you will need to ensure that your alarms get scheduled:

### When User First Runs Your App

When your app is first installed, none of your alarms are set up, because your code has not yet run to schedule them. There is no means of setting up alarm information in the manifest or something that might automatically kick in.

Hence, you will need to schedule your alarms when the user first runs your app.

As a simplifying measure — and to cover another scenario outlined below — you might be able to simply get away with scheduling your alarms *every* time the user runs your app, as the sample app shown above does. This works for one-shot alarms (using `set()`) and for alarms with short polling periods, and it works because setting up a new alarm schedule for an equivalent `PendingIntent` will replace the old schedule. However, for repeating alarms with slower polling periods, it may excessively delay your events. For example, suppose you have an alarm set to go off every 24 hours, and the user happens to run your app 5 minutes before the next event was to occur — if you blindly reschedule the alarm, instead of going off in 5 minutes, it might not go off for another 24 hours.

There are more sophisticated approaches for this (e.g., using a `SharedPreferences` value to determine if your app has run before or not).

### On Boot

The alarm schedule for alarm manager is wiped clean on a reboot, unlike `cron` or Windows Scheduled Tasks. Hence, you will need to get control at boot time to re-establish your alarms, if you want them to start up again after a reboot. We saw how to get control at boot time, via an `ACTION_BOOT_COMPLETED` `BroadcastReceiver`, back in [the chapter on broadcasts](#).

### After a Force-Stop

There are other events that could cause your alarms to become unscheduled. The best example of this is if the user goes into the Settings app and presses “Force Stop” for your app. At this point, on Android 3.1+, nothing of your code will run again, until the user manually launches some activity of yours.

If you are rescheduling your alarms every time your app runs, this will be corrected the next time the user launches your app. And, by definition, you cannot do anything until the user runs one of your activities, anyway.

If you are trying to avoid rescheduling your alarms on each run, though, you have a couple of options.

One is to record the time when your alarm-triggered events occur, each time they occur, such as by updating a `SharedPreferences`. When the user launches one of your activities, you check the last-event time — if it was too long ago (e.g., well over your polling period), you assume that the alarm had been canceled, and you reschedule it.

Another is to rely on `FLAG_NO_CREATE`. You can pass this as a parameter to any of the `PendingIntent` factory methods, to indicate that Android should only return an *existing* `PendingIntent` if there is one, and not create one if there is not:

```
PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, PendingIntent.FLAG_NO_CREATE);
```

If the `PendingIntent` is null, your alarm has been canceled — otherwise, Android would already have such a `PendingIntent` and would have returned it to you. This feels a bit like a side-effect, so we cannot rule out the possibility that, in future versions of Android, this technique could result in false positives (null `PendingIntent` despite the scheduled alarm) or false negatives (non-null `PendingIntent` despite a canceled alarm).

## Archetype: Scheduled Service Polling

The classic `AlarmManager` scenario is where you want to do a chunk of work, in the background, on a periodic basis. This is fairly simple to set up in Android, though perhaps not quite as simple as you might think.

### Back to the Main Application Thread

When an `AlarmManager`-triggered event occurs, it is very likely that your application is not running. This means that the `PendingIntent` is going to have to start up your process to have you do some work. Since everything that a `PendingIntent` can do intrinsically gives you control on your main application thread, you are going to have to determine how you want to move your work to a background thread.

One approach is to use a `PendingIntent` created by `getService()`, and have it send a command to an `IntentService` that you write. Since `IntentService` does its work on a background thread, you can take whatever time you need, without interfering with the behavior of the main application thread. This is particularly important

when:

- The AlarmManager-triggered event happens to occur when the user happens to have one of your activities in the foreground, so you do not freeze the UI, or
- You want the same business logic to be executed on demand by the user, such as via an action bar item, as once again you do not want to freeze the UI

### Problem: Keeping the Device Awake

However, this approach has a flaw: the device might fall asleep before our service can complete its work, if we woke it up out of sleep mode to process the event.

For a `_WAKEUP`-style alarm, Android makes precisely one guarantee: *if* the `PendingIntent` supplied to `AlarmManager` for the alarm is one created by `getBroadcast()` to send a broadcast `Intent`, Android will ensure that the device will stay awake long enough for `onReceive()` to be completed. Anything beyond that is not guaranteed.

While sending the command directly to the service via a `getService()` `PendingIntent` is straightforward, Android makes no guarantees about what happens after `AlarmManager` wakes up the device, and the device could fall back asleep before our `IntentService` completes processing of `onHandleIntent()`.

So, we have two problems:

1. How do we ensure that the service itself keeps the device awake while it is doing its work?
2. How do we ensure that we can actually get that service started, without the device falling asleep after we return from `onReceive()`?

### Return of the JobIntentService

`JobIntentService` neatly solves both of those problems. It takes responsibility for keeping the device awake, both to set up the work, and to process the work.

So, what we need to do is put our business logic in a `JobIntentService`, then use a broadcast `PendingIntent` to trigger enqueuing work to that `JobIntentService`. `JobIntentService` will take it from there.

### Examining a Sample

An incrementally-less-trivial sample app using AlarmManager for the scheduled service pattern can be found in [AlarmManager/Scheduled](#).

This application consists of three components: a BroadcastReceiver, a JobIntentService, and an Activity.

This sample demonstrates scheduling your alarms at two points in your app:

- At boot time
- When the user runs the activity

For the boot-time scenario, we need a BroadcastReceiver set up to receive the ACTION\_BOOT\_COMPLETED broadcast, with the appropriate permission. So, we set that up, along with our other components, in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.android.wakesvc"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.WAKE_LOCK" />
  <uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name">
    <activity
      android:name="ScheduledServiceDemoActivity"
      android:label="@string/app_name"
      android:theme="@android:style/Theme.Translucent.NoTitleBar">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>

    <receiver android:name="PollReceiver">
      <intent-filter>
        <action android:name="android.intent.action.BOOT_COMPLETED" />
      </intent-filter>
    </receiver>
```

## ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

---

```
<service
    android:name="ScheduledService"
    android:permission="android.permission.BIND_JOB_SERVICE" />
</application>

</manifest>
```

(from [AlarmManager/Scheduled/app/src/main/AndroidManifest.xml](#))

The PollReceiver has its onReceive() method, to be called at boot time, which delegates its work to a scheduleAlarms() static method, so that logic can also be used by our activity:

```
package com.commonware.android.wakesvc;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
    private static final int PERIOD=900000; // 15 minutes
    private static final int INITIAL_DELAY=5000; // 5 seconds

    @Override
    public void onReceive(Context ctxt, Intent i) {
        if (i.getAction() == null) {
            ScheduledService.enqueueWork(ctxt);
        }
        else {
            scheduleAlarms(ctxt);
        }
    }

    static void scheduleAlarms(Context ctxt) {
        AlarmManager mgr=
            (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
        Intent i=new Intent(ctxt, PollReceiver.class);
        PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

        mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
            SystemClock.elapsedRealtime() + INITIAL_DELAY,
            PERIOD, pi);
    }
}
```

## ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN

---

```
}  
}
```

(from [AlarmManager/Scheduled/app/src/main/java/com/commonsware/android/wakesvc/PollReceiver.java](#))

The `scheduleAlarms()` method retrieves our `AlarmManager`, creates a `PendingIntent` designed to call `startService()` on our `ScheduledService`, and schedules an exact repeating alarm to have that command be sent every five seconds.

The `ScheduledService` itself is the epitome of “trivial”, simply logging a message to Logcat on each command:

```
package com.commonsware.android.wakesvc;  
  
import android.content.Context;  
import android.content.Intent;  
import android.support.v4.app.JobIntentService;  
import android.util.Log;  
  
public class ScheduledService extends JobIntentService {  
    private static final int UNIQUE_JOB_ID=1337;  
  
    static void enqueueWork(Context ctxt) {  
        enqueueWork(ctxt, ScheduledService.class, UNIQUE_JOB_ID,  
            new Intent(ctxt, ScheduledService.class));  
    }  
  
    @Override  
    public void onHandleWork(Intent i) {  
        Log.d(getClass().getSimpleName(), "I ran!");  
    }  
}
```

(from [AlarmManager/Scheduled/app/src/main/java/com/commonsware/android/wakesvc/ScheduledService.java](#))

That being said, because this is an `JobIntentService`, we could do much more in `onHandleWork()` and not worry about tying up the main application thread.

Our activity — `ScheduledServiceDemoActivity` — is set up with `Theme.Translucent.NoTitleBar` in the manifest, never calls `setContentView()`, and calls `finish()` right from `onCreate()`. As a result, [it has no UI](#). It simply calls `scheduleAlarms()` and raises a `Toast` to indicate that the alarms are indeed scheduled:

```
package com.commonsware.android.wakesvc;
```

## ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

---

```
import android.app.Activity;
import android.os.Bundle;
import android.widget.Toast;

public class ScheduledServiceDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        PollReceiver.scheduleAlarms(this);

        Toast.makeText(this, R.string.alarms_scheduled, Toast.LENGTH_LONG)
            .show();
        finish();
    }
}
```

(from [AlarmManager/Scheduled/app/src/main/java/com/commonsware/android/wakesvc/ScheduledServiceDemoActivity.java](#))

On Android 3.1+, we also need this activity to move our application out of the stopped state and allow that boot-time BroadcastReceiver to work.

If you run this app on a device or emulator, after seeing the initial Toast, messages will appear in Logcat every 15 minutes, even though you have no activity running.

### How the Magic Works

A `JobIntentService` keeps the device awake by using a `WakeLock`. A `WakeLock` allows a “userland” (e.g., Android SDK) app to tell the Linux kernel at the heart of Android to keep the device awake, with the CPU powered on, indefinitely, until the `WakeLock` is released.

This can be a wee bit dangerous, as you can accidentally keep the device awake much longer than you need to. That is why using existing code like `JobIntentService` can be useful — to use more-tested code rather than rolling your own.

Also note that to request a `WakeLock` — from your code or code from a library — you need to request the `WAKE_LOCK` permission, as we saw in the manifest:

```
<uses-permission android:name="android.permission.WAKE_LOCK" />
```

(from [AlarmManager/Scheduled/app/src/main/AndroidManifest.xml](#))

## Warning: Not All Android Devices Play Nice

Some Android devices take liberties with the way AlarmManager works, in ways that may affect your applications.

One example of this today is the SONY Xperia Z. It has a [“STAMINA mode”](#) that the user can toggle on via the “Power Management” screen in Settings. This mode will be entered when the device’s screen turns off, if the device is not plugged in and charging. The user can add apps to a whitelist (“Apps active in standby”), where STAMINA mode does not affect those apps’ behavior.

`_WAKEUP` style alarms do not wake up the device when it is in STAMINA mode. The behavior is a bit reminiscent of non-`_WAKEUP` alarms. Alarms that occur while the device is asleep are suppressed, and you get one invocation of your `PendingIntent` at the point the device wakes back up. At that point, the schedule continues as though the alarms had been going off all along. Apps on the whitelist are unaffected.

Mostly, you need to be aware of this from a support standpoint. If Xperia Z owners complain that your app behaves oddly, and you determine that your alarms are not going off, see if they have STAMINA mode on, and if they do, ask them to add your app to the whitelist.

If you are using “if my alarm has not gone off in X amount of time, the user perhaps force-stopped me, so let me reschedule my alarms” logic, you should be OK. Before one of your activities gets a chance to make that check, your post-wakeup alarm should have been invoked, so you can update your event log and last-run timestamp. Hence, you should not be tripped up by STAMINA and accidentally reschedule your alarms (potentially causing duplicates, depending upon your alarm-scheduling logic).

Other devices with similar characteristics include Sony’s Xperia P, Xperia U, Xperia sola, and Xperia go.

## Debugging Alarms

If you are encountering issues with your alarms, the first thing to do is to ensure that the alarm schedule in AlarmManager is what you expect it to be. To do that, run `adb shell dumpsys alarm` from a command prompt. This will dump a report of all the scheduled alarms, including when they are set to be invoked next (with portions replaced by vertical ellipses to keep this listing from being too long):

## ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

---

Current Alarm Manager state:

```
Realtime wakeup (now=2013-03-09 07:49:51):
RTC_WAKEUP #11: Alarm{429c6028 type 0 com.android.providers.calendar}
  type=0 when=+21h40m9s528ms repeatInterval=0 count=0
  operation=PendingIntent{42ec2f40: PendingIntentRecord{434fb2f8
com.android.providers.calendar broadcastIntent}}
RTC_WAKEUP #10: Alarm{42e17e28 type 0 com.google.android.gms}
  type=0 when=+18h10m8s480ms repeatInterval=86400000 count=1

You are given details of each outstanding alarm, including the all-important `when` value indicating the time the alarm should be invoked next, if it is not canceled first (e.g., `when=+5d15h10m7s782ms`), along with the package requesting the alarm. You can use this to identify your app's alarms and see when they should be invoked next.

You are also given:

- Per-app details about how frequently their alarms have gone off, which can be useful for battery impact analysis
- A list of “top alarms” by number of occurrences, also for device performance analysis

Note, though, that for inexact alarms, the `when` value may not indicate when the event will actually occur.

## Android 6.0 and the War on Background Processing

Android 6.0 introduced some changes to the behavior of `AlarmManager` that significantly affect its use on Android 6.0+ devices. These changes also affect `JobScheduler`, and so this topic is covered in grand detail [at the end of the `JobScheduler` chapter](#).

## Android 7.0 and `OnAlarmListener`

Android 7.0 introduced a curious variant of the existing `set()`, `setExact()`, and `setWindow()` methods. Rather than taking a `PendingIntent`, they take an implementation of `OnAlarmListener`. That listener's `onAlarm()` method then gets called when the alarm is scheduled to go off.

These methods are only useful if the app has a process running and that process is likely to *be* running when the time for the alarm is to occur. If the app's process is

## ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

---

terminated after the `OnAlarmListener` is registered, the alarms are canceled, as the `OnAlarmListener` no longer exists.

For `RTC` and `ELAPSED_REALTIME` alarms, it is unclear what value there is in these `AlarmManager` methods over using some other in-process timing mechanism, such as Java's `ScheduledExecutorService`.

However, for `RTC_WAKEUP` and `ELAPSED_REALTIME_WAKEUP` alarms, the new `OnAlarmListener` methods may be useful, if you expect the device to be asleep but the process still running, and you want to get control to go do something. However, they still only make sense if you only want to get control *if* you already have a process running, and if your process goes away you do not mind the alarms going away.

There may be a set of apps that could use this. The author cannot quite figure out what such an app would be.

To illustrate the use of `OnAlarmListener`, we can turn to the [AlarmManager/Listener](#) sample app. This is reminiscent of the `AlarmManager/Simple` app shown in the beginning of this chapter, where we want an activity to get control every five seconds to show a `Toast`. However, in this case, rather than use `setRepeating()` and `createPendingResult()`, we will use `setWindow()` and `OnAlarmListener`:

```
package com.commonsware.android.alarm;

import android.app.Activity;
import android.app.AlarmManager;
import android.os.Bundle;
import android.os.SystemClock;
import android.util.Log;
import android.widget.Toast;

public class SimpleAlarmDemoActivity extends Activity
    implements AlarmManager.OnAlarmListener {
    private static final int PERIOD=5000;
    private static final int WINDOW=10000;
    private AlarmManager mgr=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        mgr=getSystemService(AlarmManager.class);
```

## ALARMMANAGER AND THE SCHEDULED SERVICE PATTERN

---

```
    schedule();
}

@Override
public void onDestroy() {
    mgr.cancel(this);

    super.onDestroy();
}

@Override
public void onAlarm() {
    Toast.makeText(this, R.string.toast, Toast.LENGTH_SHORT).show();
    Log.d(getClass().getSimpleName(), "I ran!");
    schedule();
}

private void schedule() {
    mgr.setWindow(AlarmManager.ELAPSED_REALTIME,
        SystemClock.elapsedRealtime()+PERIOD, WINDOW,
        getClass().getSimpleName(), this, null);
}
}
```

(from [AlarmManager/Listener/app/src/main/java/com/commonsware/android/alarm/SimpleAlarmDemoActivity.java](#))

`onCreate()` gets an `AlarmManager` as before. However, since this version of the app has a `minSdkVersion` of 24, we can use the version of `getSystemService()` that takes the desired system service `Class` object as a parameter and returns the system service instance in the proper data type.

Then, `onCreate()` calls `schedule()`, which in turn calls `setWindow()`. The version of `setWindow()` that we are using takes:

- the type of alarm (`ELAPSED_REALTIME`)
- the time the alarm event should fire first (`PERIOD` milliseconds from now)
- the window in which we are willing to allow Android to “flex” the actual time of the event, to perhaps save battery
- a `String` representing some tag to be used for battery usage logging purposes
- our `OnAlarmListener` implementation, which in this case happens to be the activity itself
- `null`, indicating that we want `onAlarm()` of the `OnAlarmListener` to be called on the main application thread

## **ALARM MANAGER AND THE SCHEDULED SERVICE PATTERN**

---

The alternative to null for the latter parameter would be a Handler from a HandlerThread, indicating that onAlarm() should be called on that thread.

Eventually, onAlarm() is called, where we show a Toast, log a message to Logcat,... and call schedule() again, so our alarm repeats.

Later, when the activity is destroyed, we call cancel(), passing in our OnAlarmListener, so all alarms tied to that listener will be discontinued.

# PowerManager and WakeLocks

---

There are going to be times when you want the device to keep running, even though it ordinarily would go into a sleep mode, with the CPU powered down and the screen turned off. Sometimes, that will be based upon user interactions, or the lack thereof, such as keeping the screen on while playing back a video. Sometimes, that will be to allow background scheduled work to run to completion, as was introduced in the chapter on `AlarmManager`.

This chapter looks a bit more at the details of this sort of power management, including coverage of how `AlarmManager` works.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on `AlarmManager`](#).

## Keeping the Screen On, UI-Style

If your objective is to keep the screen (and CPU) on while your activity is in the foreground, the simplest solution is to add `android:keepScreenOn="true"` to something in the activity's layout. So long as that widget or container is visible, the screen will stay on.

If you wish to do this conditionally, `setKeepScreenOn()` allows you to toggle this setting at runtime.

Once your activity is no longer in the foreground, or the widget or container is no longer visible, the effect lapses, and screen operation returns to normal.

## The Role of the WakeLock

Most of the time in Android, you are developing code that will run while the user is actually using the device. Activities, for example, only really make sense when the device is fully awake and the user is tapping on the screen or keyboard.

Particularly with scheduled background tasks, though, you need to bear in mind that the device will eventually “go to sleep”. In full sleep mode, the display, main CPU, and keyboard are all powered off, to maximize battery life. Only on a low-level system event, like an incoming phone call, will anything wake up the device.

Another thing that will partially wake up the phone is an Intent raised by the AlarmManager. So long as broadcast receivers are processing that Intent, the AlarmManager ensures the CPU will be running (though the screen and keyboard are still off). Once the broadcast receivers are done, the AlarmManager lets the device go back to sleep.

You can achieve the same effect in your code via a WakeLock.

One of the changes that the core Android team made to the Linux kernel was to introduce the concept of the “wakelock”. In simple terms, a wakelock allows a Linux userland application — such as our Android SDK apps — to control whether or not the CPU can be powered down as part of a sleep mode. While a wakelock is in force, the CPU will remain on and processing instructions from the processes and threads that are on the device.

From the SDK, to access a wakelock, you use a WakeLock object, obtained from the PowerManager system service. When you call `acquire()` on that WakeLock, the CPU will remain on; when you call `release()` on that WakeLock, the CPU can fall back asleep, if there are no other outstanding WakeLocks from SDK apps or the operating system itself.

There are four types of WakeLock objects. All will keep the CPU on. They vary in their effects on the screen (leave it off, have it display with dim backlight, have it display with normal backlight) and any physical keys (ignore or accept). You will pass a flag into `newWakeLock()` on the PowerManager system service to indicate what type of WakeLock you want. The most common is the `PARTIAL_WAKE_LOCK`, which keeps the CPU on but leaves the screen and keyboard off — ideal for periodic background work triggered by an AlarmManager event.

## What WakefulIntentService Does

For a `_WAKEUP` alarm, the `AlarmManager` will arrange for the device to stay awake, via a `WakeLock`, for as long as the `BroadcastReceiver`'s `onReceive()` method is executing. For some situations, that may be all that is needed. However, `onReceive()` is called on the main application thread, and Android will kill off the receiver if it takes too long.

Your natural inclination in this case is to have the `BroadcastReceiver` arrange for a `Service` to do the long-running work on a background thread, since `BroadcastReceiver` objects should not be starting their own threads. Perhaps you would use an `IntentService`, which packages up this “start a `Service` to do some work in the background” pattern. And, given the preceding section, you might try acquiring a partial `WakeLock` at the beginning of the work and release it at the end of the work, so the CPU will keep running while your `IntentService` does its thing.

This strategy will work... some of the time.

The problem is that there is a gap in `WakeLock` coverage, as depicted in the following diagram:

The `BroadcastReceiver` will call `startService()` to send work to the `IntentService`, but that service will not start up until after `onReceive()` ends. As a result, there is a window of time between the end of `onReceive()` and when your `IntentService` can acquire its own `WakeLock`. During that window, the device might fall back asleep. Sometimes it will, sometimes it will not.

What you need to do, instead, is arrange for overlapping `WakeLock` instances. You need to acquire a `WakeLock` in your `BroadcastReceiver`, during the `onReceive()` execution, and hold onto that `WakeLock` until the work is completed by the

## POWERMANAGER AND WAKELOCKS

---

IntentService:

Then you are assured that the device will stay awake as long as the work remains to be done.

The `WakefulIntentService` recipe described in [its chapter](#) does not have you manage your own `WakeLock`. That is because `WakefulIntentService` handles it for you. One reason why `WakefulIntentService` exists is to manage that `WakeLock`, because `WakeLocks` suffer from one major problem: they are [not Parcelable](#), and therefore cannot be passed in an `Intent` extra. Hence, for our `BroadcastReceiver` and our `WakefulIntentService` to use the same `WakeLock`, they have to be shared via a static data member... which is icky. `WakefulIntentService` is designed to hide this icky part from you, so you do not have to worry about it.

`WakefulIntentService` also handles various edge and corner cases, such as:

- What happens if Android elects to get rid of your process due to low memory conditions?
- What happens if your `doWakefulWork()` crashes, so we do not leak the acquired `WakeLock`?
- What if your UI also sends commands to the `WakefulIntentService`, or your processing takes longer than your polling period in `AlarmManager`, so that we have more than one piece of work outstanding at a point in time?

The one requirement related to a `WakeLock` that `WakefulIntentService` imposes upon you is the `WAKE_LOCK` permission. Any code in your process that is directly manipulating `WakeLock` objects needs this permission, even if that code is from a third-party JAR like `WakefulIntentService`.

# JobScheduler

---

AlarmManager was our original solution for doing work on a periodic basis. However, AlarmManager can readily be misused, in ways that impact the battery — this is why API Level 19 put renewed emphasis on “inexact” alarm schedules. Worse, AlarmManager will give us control at points in time that may be useless to us, such as giving us control when there is no Internet access, when the point of the scheduled work is to transfer some data over the Internet.

Android 5.0 introduced JobScheduler, which offers a more sophisticated API for handling these sorts of scenarios. This chapter will explore how to set up JobScheduler and use it for one-off and periodic work.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly [the chapter on AlarmManager](#). Also, you should have read [the chapter on PowerManager and wakelocks](#).

## The Limitations of AlarmManager

AlarmManager does its job, and frequently does it well. However, it is far from perfect:

- It does not persist its alarm schedule across reboots, forcing us to implement an ACTION\_BOOT\_COMPLETED BroadcastReceiver to re-establish our alarms
- It does not keep the device awake after waking it up with a \_WAKEUP alarm, forcing us to use tools like WakefulBroadcastReceiver to make sure that we can get our work done without the device falling back asleep

- It gives us control even if the work we want to do is not possible, such as wanting to download material from the Internet but being woken up at points in time when we lack a working Internet connection (e.g., a WiFi-only tablet in a location for which it does not recognize any access points)
- In cases where the criteria we want cannot be met, we cannot readily implement any sort of back-off policy, except by doing the calculations ourselves and perhaps abandoning the convenient “repeating” API outright

And so on. `AlarmManager` is nice, but it would be better to have another solution.

## Enter the JobScheduler

`JobScheduler` was designed to handle those four problems outlined above:

- It persists its roster of jobs and will re-establish them automatically after a reboot. Note, though, that you still have to hold the `RECEIVE_BOOT_COMPLETED` permission for this to work. Also note that you do not *have* to have jobs be persisted — this is an opt-in capability of `JobScheduler`.
- It handles “wakefulness” for us, via its own `WakeLock`, so we do not have to worry about it ourselves.
- It offers an API where we can specify criteria to be satisfied before we should be given control, notably a criteria indicating that we need a working network connection.
- If our criteria cannot be met, `JobScheduler` implements a configurable back-off policy, so we can slow down our attempts to get control when those attempts are regularly failing.

## Employing JobScheduler

The [JobScheduler/PowerHungry](#) sample project demonstrates the use of `JobScheduler`, by way of comparing its use to that of `AlarmManager`.

## JOB SCHEDULER

---

The UI for JobScheduler allows you to pick from three types of event schedules: exact alarm, inexact alarm, and JobScheduler. You can also choose from one of four polling periods: 1 minute, 15 minutes, 30 minutes, and 60 minutes:

*Figure 825: PowerHungry Demo, As Initially Launched*

A Switch allows you to determine whether you are simply getting control at those points in time to just log to Logcat, or whether you are going to try to do some work at those points in time. Specifically, the “work” is to download a file, using `URLConnection`.

The bottom Switch toggles on and off the event schedules. When the event schedules are toggled on, you cannot manipulate the rest of the UI — you need to turn off the events in order to change the event configuration.

Note that none of this information is persisted. This is a lightweight demo; it is expected that you are keeping this UI in the foreground while a test is running.

### Defining and Scheduling the Job

The “job” is defined as an instance of `JobInfo`, typically created using an instance of `JobInfo.Builder` to configure a `JobInfo` using a fluent builder-style API. We teach

## JOB SCHEDULER

---

the `JobInfo` the work to do and when to do it, then use a `JobScheduler` to actually schedule the job.

In the sample app, this work is mostly accomplished via a `manageJobScheduler()` method on the `MainActivity` class:

```
private void manageJobScheduler(boolean start) {
    if (start) {
        JobInfo.Builder b=new JobInfo.Builder(JOB_ID,
            new ComponentName(this, DemoJobService.class));
        PersistableBundle pb=new PersistableBundle();

        if (download.isChecked()) {
            pb.putBoolean(KEY_DOWNLOAD, true);
            b.setExtras(pb).setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY);
        } else {
            b.setRequiredNetworkType(JobInfo.NETWORK_TYPE_NONE);
        }

        b.setPeriodic(getPeriod()).setPersisted(false)
            .setRequiresCharging(false).setRequiresDeviceIdle(true);

        jobs.schedule(b.build());
    }
    else {
        jobs.cancel(JOB_ID);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

The `start` parameter to `manageJobScheduler()` is driven by the bottom `Switch` widget. A `start` value of `true` means that we should start up the job; a value of `false` means that we should cancel any existing job.

If `start` is `true`, we begin by creating a `JobInfo.Builder`, supplying two key pieces of data:

- an `int` that will serve as the job ID, which needs to be unique to our app but does not have to be unique for the whole device
- a `ComponentName` identifying the `JobService` that will actually implement the work of the job itself

The primary way of passing data from the scheduling code (our activity) and the job-implementing code (`JobService`) is by means of a `PersistableBundle` – a

## JOB\_SCHEDULER

---

Bundle-like object that can be persisted to disk. `PersistableBundle` was introduced in API Level 21, but at that time it inexplicably lacked support for boolean values. API Level 22 added `getBoolean()` and `putBoolean()` to `PersistableBundle`, and this sample project has `minSdkVersion` of 22 to be able to take advantage of it. If you wanted to use this sample on API Level 21, you would need to convert the boolean into something else, such as 0 and 1 int values.

Our `PersistableBundle` can have more data than just this one extra, though that is all we need in this case. We attach the `PersistableBundle` to the `JobInfo` via the `setExtras()` method on the `JobInfo.Builder`.

We can also call methods on the `JobInfo.Builder` to configure the criteria that should be satisfied before giving us control. In our case, one criterion that we need is to have a network connection, but only if we are supposed to be downloading a file. So, we call `setRequiredNetworkType()` in either case, indicating that we either want ANY type of network connection (metered or unmetered) or NONE.

Other criteria-defining methods that we invoke include `setRequiresCharging()` (set to false to indicate we want control even if we are on battery) and `setRequiresDeviceIdle()` (set to true to indicate that we want control only if the user is not using it).

In the case of this sample, we want to do this work every so often, based upon the period chosen by the user in the bottom Spinner and retrieved via the `getPeriod()` method. So, we call `setPeriodic()` on the `JobInfo.Builder` to request getting control with that frequency, bearing in mind that this is merely a hint, not a requirement, and we may get control more or less frequently than this.

We also call `setPersisted(false)` to indicate that we do not need for this job to be persisted, so it will be lost on a reboot. If we instead called `setPersisted(true)`, the manifest would need to request the `RECEIVE_BOOT_COMPLETED` permission to have the job be re-created at boot time.

Finally, we call `schedule()` on a `JobScheduler` instance named `jobs` to schedule the job.

The `jobs` data member is populated up in `onReady()` of the activity, where `onReady()` is a callback from the `AbstractPermissionActivity`:

```
jobs=(JobScheduler) getSystemService(JOB_SCHEDULER_SERVICE);
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

## JOB SCHEDULER

---

`AbstractPermissionActivity`, seen elsewhere in this book, handles requesting the runtime permission for external storage that we are going to need later on.

If the `start` parameter to `manageJobScheduler()` is `false`, we call `cancel()` on the `JobScheduler`, passing in our unique job ID (`JOB_ID`) to indicate what job to cancel. Or, we could have called `cancelAll()`, which would cancel all jobs scheduled by our application.

### Implementing the Job

The work for the job itself is handled by a `JobService`. This is a subclass of `Service` that we, in turn, extend ourselves, overriding two job-specific callback methods to actually do the work: `onStartJob()` and `onStopJob()`.

The `JobService` in our sample app is `DemoJobService`:

```
package com.commonware.android.job;

import android.app.job.JobParameters;
import android.app.job.JobService;
import android.os.PersistableBundle;
import android.util.Log;

public class DemoJobService extends JobService {
    private volatile Thread job=null;

    @Override
    public boolean onStartJob(JobParameters params) {
        PersistableBundle pb=params.getExtras();

        if (pb.getBoolean(MainActivity.KEY_DOWNLOAD, false)) {
            job=new DownloadThread(params);
            job.start();

            return(true);
        }

        Log.d(getClass().getSimpleName(), "job invoked");

        return(false);
    }

    @Override
    synchronized public boolean onStopJob(JobParameters params) {
        if (job!=null) {
```

## JOB SCHEDULER

---

```
        Log.d(getClass().getSimpleName(), "job interrupted");
        job.interrupt();
    }

    return(false);
}

synchronized private void clearJob() {
    job=null;
}

private class DownloadThread extends Thread {
    private final JobParameters params;

    DownloadThread(JobParameters params) {
        this.params=params;
    }

    @Override
    public void run() {
        Log.d(getClass().getSimpleName(), "job begins");
        new DownloadJob().run();
        Log.d(getClass().getSimpleName(), "job ends");
        clearJob();
        jobFinished(params, false);
    }
}
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/DemoJobService.java](#))

`onStartJob()` is passed a `JobParameters`. This serves both as a “handle” identifying a particular job invocation and giving us access to the job ID (`getJobId()`) and `PersistableBundle` of extras (`getExtras()`) that were set up by our `JobInfo` when we scheduled the job.

`onStartJob()` needs to return `true` if we have successfully forked a background thread to do the work, or `false` if no work needs to be done. In our case, this is determined by whether or not we want to try to download a file. In a production-grade app, this may be determined by whether there is any work to be done (e.g., “do we have entries in the upload queue?”).

In `onStartJob()`, we check the `PersistableBundle` to see if we are supposed to download a file. If we are, we fork a `DownloadThread` to do that work, then return `true`. Otherwise, we return `false`.

## JOB SCHEDULER

---

Because this sample app illustrates the difference in behavior between `JobScheduler` and `AlarmService`, we want to isolate the actual download-the-file logic into a common implementation that can be used from either code path. That takes the form of a `DownloadJob`, which implements `Runnable` and does the download work when it is `run()`:

```
package com.commonware.android.job;

import android.net.Uri;
import android.os.Environment;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

class DownloadJob implements Runnable {
    static final Uri TO_DOWNLOAD=
        Uri.parse("https://commonware.com/Android/excerpt.pdf");

    @Override
    public void run() {
        try {
            File root=Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

            root.mkdirs();

            File output=new File(root, TO_DOWNLOAD.getLastPathSegment());

            if (output.exists()) {
                output.delete();
            }

            URL url=new URL(TO_DOWNLOAD.toString());
            HttpURLConnection c=(HttpURLConnection)url.openConnection();

            FileOutputStream fos=new FileOutputStream(output.getPath());
            BufferedOutputStream out=new BufferedOutputStream(fos);

            try {
                InputStream in=c.getInputStream();
                byte[] buffer=new byte[8192];
                int len=0;

                while ((len=in.read(buffer)) >= 0) {
                    out.write(buffer, 0, len);
                }

                out.flush();
            }
            finally {
                fos.getFD().sync();
                out.close();
                c.disconnect();
            }
        }
    }
}
```

## JOB SCHEDULER

---

```
    }  
  }  
  catch (IOException e2) {  
    Log.e("DownloadJob", "Exception in download", e2);  
  }  
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/DownloadJob.java](#))

DownloadThread delegates to DownloadJob to do the actual work. However, when the work is complete, it then calls `jobFinished()` on the DemoJobService.

`jobFinished()`, as the name suggests, tells the framework that we are finished doing the work associated with this job. If the job succeeded, we pass `false` as the second parameter, to indicate that this job does not need to be rescheduled. If, on the other hand, we were unable to actually do the work (e.g., we cannot connect to the desired server, perhaps due to server maintenance), we would pass `true` as the second parameter, to request that this job be rescheduled to be invoked again shortly, so that we can retry the operation.

Our `onStopJob()` method will be called by Android if environmental conditions have changed and we should stop the background work that we are doing. For example, we asked to do this work when the device was idle — if the user picks up the device and starts using it, we should stop our background work. In this case, if the job thread is still outstanding, we `interrupt()` it. `onStopJob()` should return `true` if this job is still needed and should be retried, or `false` otherwise. Most short-period periodic jobs should return `false`, to just worry about the next job in the next period, and that is what `onStopJob()` does here. One-time jobs, or jobs with long periods (e.g., a day), may wish to return `true` to ensure that they will get another chance to do the desired work. We will cover more about this issue [later in this chapter](#).

### Wiring in the Job Service

Since a JobService is a Service, we need the corresponding `<service>` element in the manifest. For a JobService, the `<service>` element is perfectly normal... with one exception:

```
<service  
  android:name=".DemoJobService"  
  android:permission="android.permission.BIND_JOB_SERVICE" />
```

(from [JobScheduler/PowerHungry/app/src/main/AndroidManifest.xml](#))

You need to defend the service with the `BIND_JOB_SERVICE` permission. This only

allows code that holds the `BIND_JOB_SERVICE` permission to start or bind to this service, which should limit it to the OS itself.

### The Rest of the Sample

As noted earlier, the UI for our activity is a pair of Spinner widgets, along with a pair of Switch widgets:

```
<?xml version="1.0" encoding="utf-8"?>

<GridLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:padding="8dp"
    android:useDefaultMargins="true">

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/type_label"
        android:layout_row="0"
        android:layout_column="0" />

    <Spinner
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/type"
        android:layout_row="0"
        android:layout_column="1" />

    <TextView
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/period_label"
        android:layout_row="1"
        android:layout_column="0" />

    <Spinner
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:id="@+id/period"
        android:layout_row="1"
        android:layout_column="1" />

    <TextView
```

## JOB SCHEDULER

---

```
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="@string/download_label"
        android:layout_row="2"
        android:layout_column="0" />

<Switch
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/download"
    android:layout_row="2"
    android:layout_column="1" />

<TextView
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:text="@string/scheduled_label"
    android:layout_row="3"
    android:layout_column="0" />

<Switch
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:id="@+id/scheduled"
    android:layout_row="3"
    android:layout_column="1" />
</GridLayout>
```

(from [JobScheduler/PowerHungry/app/src/main/res/layout/main.xml](#))

`onReady()` of `MainActivity` sets up the UI, including populating the two `Spinner` widgets based on `<string-array>` resources and hooking up the activity to respond to changes in the checked state of the scheduled `Switch` widget:

```
@SuppressWarnings("ResourceType")
@Override
public void onReady(Bundle savedInstanceState) {
    setContentView(R.layout.main);
    type=findViewById(R.id.type);

    ArrayAdapter<String> types=
        new ArrayAdapter<String>(this,
            android.R.layout.simple_spinner_item,
            getResources().getStringArray(R.array.types));

    types.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
    type.setAdapter(types);

    period=findViewById(R.id.period);

    ArrayAdapter<String> periods=
```

## JOB SCHEDULER

---

```
new ArrayAdapter<String>(this,
    android.R.layout.simple_spinner_item,
    getResources().getStringArray(R.array.periods));

periods.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
period.setAdapter(periods);

download=findViewById(R.id.download);
scheduled=findViewById(R.id.scheduled);
scheduled.setOnCheckedChangeListener(this);

alarms=(AlarmManager) getSystemService(ALARM_SERVICE);
jobs=(JobScheduler) getSystemService(JOB_SCHEDULER_SERVICE);
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

When the user toggles the scheduled Switch widget, we examine the type Spinner and route control to a method dedicated for handling that particular type of periodic request, such as the `manageJobScheduler()` method we saw earlier in this chapter:

```
private void manageJobScheduler(boolean start) {
    if (start) {
        JobInfo.Builder b=new JobInfo.Builder(JOB_ID,
            new ComponentName(this, DemoJobService.class));
        PersistableBundle pb=new PersistableBundle();

        if (download.isChecked()) {
            pb.putBoolean(KEY_DOWNLOAD, true);
            b.setExtras(pb).setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY);
        } else {
            b.setRequiredNetworkType(JobInfo.NETWORK_TYPE_NONE);
        }

        b.setPeriodic(getPeriod()).setPersisted(false)
            .setRequiresCharging(false).setRequiresDeviceIdle(true);

        jobs.schedule(b.build());
    }
    else {
        jobs.cancel(JOB_ID);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

Our `onCheckedChanged()` for the schedule Switch also calls a `toggleWidgets()` method that enables or disables the other widgets, depending upon whether the schedule Switch is checked or unchecked:

## JOB SCHEDULER

---

```
private void toggleWidgets(boolean enable) {
    type.setEnabled(enable);
    period.setEnabled(enable);
    download.setEnabled(enable);
}

private void manageExact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleExactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}

private void manageInexact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleInexactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}

private void manageJobScheduler(boolean start) {
    if (start) {
        JobInfo.Builder b=new JobInfo.Builder(JOB_ID,
            new ComponentName(this, DemoJobService.class));
        PersistableBundle pb=new PersistableBundle();

        if (download.isChecked()) {
            pb.putBoolean(KEY_DOWNLOAD, true);
            b.setExtras(pb).setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY);
        } else {
            b.setRequiredNetworkType(JobInfo.NETWORK_TYPE_NONE);
        }

        b.setPeriodic(getPeriod()).setPersisted(false)
            .setRequiresCharging(false).setRequiresDeviceIdle(true);

        jobs.schedule(b.build());
    }
}
```

## JOB SCHEDULER

---

```
    else {
        jobs.cancel(JOB_ID);
    }
}

private long getPeriod() {
    return(PERIODS[period.getSelectedItemPosition()]);
}
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

If the user had chosen an exact alarm, `onCheckedChanged()` routes control to `manageExact()`:

```
private void manageExact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleExactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

It, in turn, routes control over to a `PollReceiver`, a `BroadcastReceiver` that is set up for handling our alarms:

```
package com.commonsware.android.job;

import android.app.AlarmManager;
import android.app.PendingIntent;
import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class PollReceiver extends BroadcastReceiver {
    static final String EXTRA_PERIOD="period";
    static final String EXTRA_IS_DOWNLOAD="isDownload";

    @Override
    public void onReceive(Context ctxt, Intent i) {
```

## JOB SCHEDULER

---

```
boolean isDownload=i.getBooleanExtra(EXTRA_IS_DOWNLOAD, false);

DemoScheduledService.enqueueWork(ctxt,
    new Intent(ctxt, DemoScheduledService.class)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload));

long period=i.getLongExtra(EXTRA_PERIOD, -1);

if (period>0) {
    scheduleExactAlarm(ctxt,
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE),
        period, isDownload);
}
}

static void scheduleExactAlarm(Context ctxt, AlarmManager alarms,
    long period, boolean isDownload) {
    Intent i=new Intent(ctxt, PollReceiver.class)
        .putExtra(EXTRA_PERIOD, period)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.setExact(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+period, pi);
}

static void scheduleInexactAlarm(Context ctxt, AlarmManager alarms,
    long period, boolean isDownload) {
    Intent i=new Intent(ctxt, PollReceiver.class)
        .putExtra(EXTRA_IS_DOWNLOAD, isDownload);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.setInexactRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
        SystemClock.elapsedRealtime()+period, period, pi);
}

static void cancelAlarm(Context ctxt, AlarmManager alarms) {
    Intent i=new Intent(ctxt, PollReceiver.class);
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);

    alarms.cancel(pi);
}
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/PollReceiver.java](#))

This sample app has a targetSdkVersion of 21. Hence, on Android 5.0 devices — the ones that have JobScheduler, we cannot set up exact repeating alarms. Our only

---

option is to handle the repeating work ourselves.

Hence, `scheduleExactAlarm()` creates a broadcast `PendingIntent`, on an `Intent` pointing at our `PollReceiver`, with a pair of extras indicating the polling period and whether or not we should be downloading a file. It then uses `setExact()` on an `AlarmManager` to schedule a *one-off* event to occur one polling period from now.

That, in turn, will trigger `onReceive()` of the `PollReceiver`. Here, we call `startWakefulService()` to have our work be done by a `DemoScheduledService`. In addition, if we have a polling period, that means that this is an exact alarm, and we call `scheduleExactAlarm()` to set up the next occurrence of this “repeating” event.

`DemoScheduledService` is simply a `JobIntentService` wrapper around the `DownloadJob` that we used with `DemoJobService`.

`cancelAlarm()` on `PollReceiver` — called by `manageExact()` when we are stopping the repeating event — creates an equivalent `PendingIntent` to the ones used for the `AlarmManager` events, and uses that with `cancel()` on `AlarmManager` to cancel those events.

If the user had chosen an inexact alarm, `onCheckedChanged()` routes control to `manageInexact()`:

```
private void manageInexact(boolean start) {
    if (start) {
        long period=getPeriod();

        PollReceiver.scheduleInexactAlarm(this, alarms, period,
            download.isChecked());
    }
    else {
        PollReceiver.cancelAlarm(this, alarms);
    }
}
```

(from [JobScheduler/PowerHungry/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

It uses the same recipe as `manageExact()`, except that it calls `scheduleInexactAlarm()` on `PollReceiver`. `scheduleInexactAlarm()`, in turn, uses `setInexactRepeating()` on `AlarmManager` to arrange to get control every so often.

## Pondering Backoff Criteria

Sometimes, even with the Internet-availability checks offered by `JobScheduler`, you find that you cannot actually do the job you scheduled. Perhaps the server is down for maintenance, or has been replaced by [a honeycomb frame](#), or something. In this case, while you failed to do the job now, you may want to try again later.

Sometimes, “later” can just be handled by your existing `JobScheduler` setup. If the job in question is a periodic job, and missing a whole period is not a big problem, you might just continue on normally.

However, sometimes you will want the job to be retried, either because:

- it was a one-shot job, not a periodic one, or
- the period of the job is fairly long (e.g., once per day) and you want to retry well before the job is scheduled to happen again

Requesting that a job be retried is handled by the boolean parameter to `jobFinished()` or the boolean return value from `onStopJob()`. `true` means that you want the job to be rescheduled; `false` means that it is OK to skip the job entirely.

Given that you use `true` for either `jobFinished()` or `onStopJob()`, there are three possible options for how to request and retry a failed job:

- What happens for a job which you requested only run when the device is idle
- What happens for other jobs by default
- How you can influence the timing of when the job is retried, known as the “backoff criteria”

## Idle Jobs

If you requested idle-only jobs, if the user wakes up the device while the job is going on, you will be called with `onStopJob()`. Ideally, you then stop the background work and return `true` or `false` from `onStopJob()` to determine if the job should be rescheduled.

If you request a job be rescheduled, when that job is set up to only run when the device is idle, the job is simply “put back in the queue” to be tried again during the next idle window.

### Default Behavior

If, for a non-idle-only job, you use `true` for `jobFinished()` or `onStopJob()`, the next time to try will be calculated using the default backoff criteria, which has a time of 30 seconds and a policy of `BACKOFF_POLICY_EXPONENTIAL`.

What this means is that the first time you use `true`, your job will be tried again 30 seconds later. If you use `true` again for that job, it will be tried again 60 seconds later. If you use `true` again, it would be tried 120 seconds later — in other words, each job failure will reschedule using the formula  $2^{n-1}t$ , where  $n$  is the number of failures and  $t$  is 30 seconds.

However, there is a cap of 18,000,000 milliseconds, or what normal people would refer to as “5 hours”. That is the most your job will be delayed, regardless of how many failures you have.

### Custom Backoff Criteria

You can change the backoff criteria for non-idle-only jobs via a call to `setBackoffCriteria()` on your `JobInfo.Builder`, where you provide your own time (measured in milliseconds) and policy (`BACKOFF_POLICY_EXPONENTIAL` or `BACKOFF_POLICY_LINEAR`).

As noted above, the formula for exponential backoff rescheduling is  $2^{n-1}t$ , where  $n$  is the number of failures and  $t$  is your chosen time.

The formula for linear backoff rescheduling is  $n*t$ , where  $n$  is the number of failures and  $t$  is your chosen time.

### Other JobScheduler Features

There are a few other options for scheduling jobs that may be of use to you in select circumstances:

- `JobInfo.Builder` has `setOverrideDeadline()`, which indicates a maximum delay for this job before it will be executed even if other criteria (e.g., idleness) have not been met. Note that this is only available on one-shot jobs, not periodic jobs.
- The `JobParameters` passed to `onStartJob()` has an `isOverrideDeadlineExpired()` method. This will return `true` if the job was

executed early due to a `setOverrideDeadline()` value being met. This will indicate to you that your requirements may not be met (e.g., Internet access) and you will need to double-check those things yourself.

- `JobInfo.Builder` has `setMinimumLatency()` which sets a minimum delay time; the job will not be considered until at least this amount of time has elapsed. Note that this is only available on one-shot jobs, not periodic jobs.

Also, `JobScheduler` has a `getAllPendingJobs()` method, that returns a `List` of `JobInfo` objects representing “the jobs registered by this package that have not yet been executed”. Presumably, this includes the next occurrence of any periodic jobs and any jobs that are blocked pending a backoff delay, though the documentation is unclear on this point.

## JobScheduler Period Limits

[As of Android 7.0](#), `JobScheduler` does not support jobs running more frequently than once every 15 minutes.

## GcmNetworkManager

As noted earlier in this chapter, Android 5.0 added `JobScheduler`. However, Google did not release any sort of backport of this, as that would be difficult to do on a whole-device basis. They did not even implement a `JobSchedulerCompat`, hampering adoption.

Firebase now has a [GcmNetworkManager](#) that, despite the name, is basically a backport of `JobScheduler`. In fact, it will delegate to `JobScheduler` on Android 5.0+ devices. It is unclear how old of an Android OS version `GcmNetworkManager` supports, but it is likely to work on more devices than does `JobScheduler`.

However, it does introduce a tie to Google Play Services, which will not be appropriate for all apps.

## Periodic Work, Across Device Versions

Of course, all of this is a pain. And, where there is pain, somebody eventually creates a library to try to ease that pain.

Evernote — the NSaaS (note storage as a service) provider — has released android-

job, a library that offers a single API that uses `GcmNetworkManager` (if you opt into it), `JobScheduler` (on API Level 21+, for inexact jobs), or `AlarmManager` (for API Level 19 and below, plus for exact jobs). This library can simplify your code, by handling the version-specific logic for you.

The [JobScheduler/Dispatcher](#) sample project demonstrates the use of `android-job`. It is based upon the `PowerHungry` sample app, adding in a new option for using this new library.

### The Dependency

Evernote publishes `android-job` as an artifact, so adding it to your project is as simple as a single line in your `build.gradle` file:

```
dependencies {  
    implementation 'com.android.support:support-v13:27.0.2'  
    implementation 'com.evernote:android-job:1.2.1'  
}
```

(from [JobScheduler/Dispatcher/app/build.gradle](#))

### The Job

With `AlarmManager`, usually your periodic work is handled by a combination of a `WakefulBroadcastReceiver` and an `IntentService`. With `JobScheduler`, your work is handled by a `JobService`. With `android-job`, your work is handled by custom subclasses of a library-supplied `Job` class.

Your `Job` subclass needs to override `onRunJob()`. Akin to `onStartJob()` of a `JobService`, you get a `Params` object that you can use to identify the details of this specific job. Based on the library's implementation and `JavaDocs`, you should do the work for your job directly in `onRunJob()`, returning one of three values:

- `Result.SUCCESS`, meaning that life is good
- `Result.RECHEDULE`, meaning that you did not do the work, and it should be rescheduled to be tried again shortly
- `Result.FAILURE`, meaning that you did not do the work, but there is no reason to reschedule the job

The sample app has a `DemoUnifiedJob` that handles all of this:

```
package com.commonware.android.job;
```

## JOB SCHEDULER

---

```
import android.support.annotation.NonNull;
import android.util.Log;
import com.evernote.android.job.Job;

public class DemoUnifiedJob extends Job {
    static final String JOB_TAG=
        DemoUnifiedJob.class.getCanonicalName();

    @NonNull
    @Override
    protected Result onRunJob(Params params) {
        Log.d(getClass().getSimpleName(), "scheduled unified work begins");

        if (getParams()
            .getExtras()
            .getBoolean(PollReceiver.EXTRA_IS_DOWNLOAD, false)) {
            new DownloadJob().run(); // do synchronously, as we are on
                                    // a background thread already
        }

        Log.d(getClass().getSimpleName(), "scheduled unified work ends");

        return(Result.SUCCESS);
    }
}
```

(from [JobScheduler/Dispatcher/app/src/main/java/com/commonsware/android/job/DemoUnifiedJob.java](#))

As will be seen later when we schedule this work, we add in our EXTRA\_IS\_DOWNLOAD boolean value, akin to how we handled this with JobScheduler, to know whether or not we are supposed to download the file or not.

## The JobCreator

While executing jobs is similar to JobScheduler (just simpler), actually setting up jobs is quite a bit more cumbersome.

The first step towards setting up jobs is to create a JobCreator. This class is simply a way to tie a String to a Job subclass. In the create() method, given a String, you return an instance of the associated Job subclass, as is done in the sample app's DemoUnifiedJobCreator:

```
package com.commonsware.android.job;

import com.evernote.android.job.Job;
```

## JOB SCHEDULER

---

```
import com.evernote.android.job.JobCreator;

public class DemoUnifiedJobCreator implements JobCreator {
    @Override
    public Job create(String tag) {
        if (DemoUnifiedJob.JOB_TAG.equals(tag)) {
            return(new DemoUnifiedJob());
        }

        throw new IllegalArgumentException("Job tag not recognized: "+tag);
    }
}
```

(from [JobScheduler/Dispatcher/app/src/main/java/com/commonsware/android/job/DemoUnifiedJobCreator.java](#))

### The Application

The recommended pattern for setting up android-job is to use a custom Application subclass. It needs to set up a JobManager singleton and register any JobCreator classes that you might have.

The sample app does this in DemoUnifiedApplication:

```
package com.commonsware.android.job;

import android.app.Application;
import com.evernote.android.job.JobManager;

public class DemoUnifiedApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        JobManager
            .create(this)
            .addJobCreator(new DemoUnifiedJobCreator());
    }
}
```

(from [JobScheduler/Dispatcher/app/src/main/java/com/commonsware/android/job/DemoUnifiedApplication.java](#))

That, in turn, is set up as our app's Application subclass via the android:name attribute on the <application> element in the manifest:

```
<application
    android:name=".DemoUnifiedApplication"
```

```
android:icon="@drawable/ic_launcher"  
android:label="@string/app_name">
```

(from [JobScheduler/Dispatcher/app/src/main/AndroidManifest.xml](#))

### Scheduling Jobs

Given all of that prep work, we can now actually schedule jobs to be executed. The flow is very similar to that of `JobScheduler`:

- Create and populate a `JobRequest.Builder` with the details of the job, notably the `String` to identify which `Job` subclass to use (by way of the `JobCreator`)
- `build()` the `JobRequest` using that `Builder`, and call `schedule()` on it to schedule the job
- Hold onto the `int` returned by `schedule()` and use that to `cancel()` the job later on, if needed

```
private void manageUnified(boolean start) {  
    if (start) {  
        final JobRequest.Builder b=  
            new JobRequest.Builder(DemoUnifiedJob.JOB_TAG);  
        PersistableBundleCompat extras=new PersistableBundleCompat();  
  
        if (download.isChecked()) {  
            extras.putBoolean(KEY_DOWNLOAD, true);  
            b  
                .setExtras(extras)  
                .setRequiredNetworkType(JobRequest.NetworkType.CONNECTED);  
        }  
        else {  
            b.setRequiredNetworkType(JobRequest.NetworkType.ANY);  
        }  
  
        b  
            .setPeriodic(getPeriod())  
            .setRequiresCharging(false)  
            .setRequiresDeviceIdle(true);  
  
        unifiedJobId=b.build().schedule();  
    }  
    else {  
        JobManager.getInstance().cancel(unifiedJobId);  
    }  
}
```

(from [JobScheduler/Dispatcher/app/src/main/java/com/commonsware/android/job/MainActivity.java](#))

### Enabling GcmNetworkManager Support

By default, android-job will use JobScheduler and/or AlarmManager. However, if you add the play-services-gcm dependency to your project (version 9.4.0 or higher), and configure a specific <service> element in your manifest, then android-job will also consider using GcmNetworkManager. Details for this are available in [the project documentation](#).

## Android 6.0 and “the War on Background Processing”

Google has been increasingly aggressive about trying to prevent background work, particularly while the device is deemed to be idle, in an effort to improve battery life. In Android 4.4 (API Level 19), we were given a strong “nudge” to use inexact alarms. In Android 5.0 (API Level 21), we were given JobScheduler as a smarter AlarmManager, but one that also emphasizes inexact schedules.

In Android 6.0, Google broke out more serious weaponry in the war against background work, in ways that are going to cause a fair bit of pain and confusion for users.

### Doze Mode

If the device’s screen is off, the device is not being charged, and the device does not appear to be moving (as determined via sensors, like the accelerometer), an Android 6.0+ device will go into “Doze mode”. This mode is reminiscent of similar modes used by specific device manufacturers, such as [SONY’s STAMINA mode](#).

While in “Doze mode”, your scheduled alarms (with AlarmManager), jobs (with JobScheduler), and syncs (with SyncManager) will be ignored by default, except during occasional “idle maintenance windows”. In short, much of what your user thinks will happen in the background will not happen.

### App Standby Mode

Further compounding the problem from “Doze mode” is “app standby”.

After some undefined period of time, an app that has not been in the foreground (or

is showing a Notification) will be put into “standby” state. While the app is in “standby”:

- If the device is unplugged, the app behaves as though the device is in “Doze mode”, with background access degrading over time to a point where the app will only get network access in the background around once per day
- If the device is plugged in, the app behaves normally

### How to Win the War

The vision behind “the war on background processing” is to improve battery life, particularly while the device is not being used (Doze mode) or for apps that are not being used (app standby). However, any number of apps will have their behavior severely compromised by these changes.

Here are some techniques for helping your app behave better on Android 6.0+.

### GCM

If you are using [Google Cloud Messaging](#) (GCM), and you send a “high-priority tinkle” to the app on a device, that may allow you to run then, despite being in Doze mode or app standby mode. However, this implies that you have all the plumbing set up for GCM, that the device has an active network connection, etc. Also, this requires you to adopt GCM, which has its issues (no service-level agreement, Google has access to all of the messages, etc.).

### ...`AndAllowWhileIdle()`

`AlarmManager` now has two additional methods:

- `setAndAllowWhileIdle()`
- `setExactAndAllowWhileIdle()`

These work better in Doze mode and app standby mode, allowing you to get control briefly even if otherwise you would not. However:

- While in those modes, these alarms will occur at most once every 15 minutes, except during the aforementioned “idle maintenance windows”
- There is no guarantee of how long you will be able to keep the device awake
- There is no guarantee that you can access the Internet

## Use a Foreground Service

While not officially documented, Dianne Hackborn (a core Android developer) wrote in a comment on [a Google+ post](#):

Apps that have been running foreground services (with the associated notification) are not restricted by doze.

## The Whitelist

Users have the ability to disable these “battery optimizations” for an individual app, allowing it to run closer to normally. On the “Apps” screen in Settings, there is now a gear icon in the action bar:

## JOB SCHEDULER

---

Tapping that brings up a “Configure apps” screen. On there is a “Battery optimization” entry. Tapping on that will initially show the apps for which battery optimizations will be ignored (a.k.a., “Not optimized”):

*Figure 827: Android 6.0, Settings App, Battery Optimization Screen*

If the user toggles the “Not optimized” drop-down to “All apps” and taps on one of those apps, the user can elect to decide whether to “optimize” the app (and cause app standby to trigger) or not:

*Figure 828: Android 6.0, Settings App, Battery Optimization Options Dialog*

This “whitelist” of apps allows you to hold wakelocks and access the network. It does *not* change the behavior of `AlarmManager`, `JobScheduler`, or `SyncManager` — those things will still fire far less frequently in Doze mode or in app standby.

To determine if your app is already on the whitelist, you can call `isIgnoringBatteryOptimizations()` on a `PowerManager` instance.

If you would like to lead the user over to the screen where they can generally configure the whitelist, use an `ACTION_IGNORE_BATTERY_OPTIMIZATION_SETTINGS` Intent with `startActivity()`:

```
startActivity(new Intent(Settings.ACTION_IGNORE_BATTERY_OPTIMIZATION_SETTINGS));
```

If you would like to drive the user straight to the screen where they can add your specific app to the whitelist:

- Request the `REQUEST_IGNORE_BATTERY_OPTIMIZATIONS` permission via a `<uses-permission>` element in the manifest

## JOB SCHEDULER

---

- Create a package: Uri pointing to your app
- Wrap that Uri in an ACTION\_REQUEST\_IGNORE\_BATTERY\_OPTIMIZATIONS Intent
- Call startActivity() with that Intent

```
Intent i=new Intent(Settings.ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS,
    Uri.parse("package:" + getPackageName()));

startActivity(intent);
```

Note, though, that using this [may cause your app to be banned on the Play Store](#), even though it is a legitimate part of the Android SDK.

While the whitelist existed in the first developer preview of Android 6.0, its role was expanded very late in the process, as originally it did not affect Doze mode. The rationale appears to be for apps that cannot use GCM as the trigger mechanism to do background work, particularly if they need something else network-based as the trigger. For example, SIP clients, XMPP clients, MQTT clients, and so on are idle until a message comes in on an open network connection, yet none of those can be readily converted to use GCM. The whitelist allows apps to behave as they did prior to Android 6.0, though it requires user involvement.

However, any app can use this whitelist approach to return to more-normal behavior. The biggest limitation is for apps that relied upon AlarmManager, JobScheduler, or SyncAdapter as their triggers, as those are still crippled, regardless of whitelist status. The best you can get is ~15 minute periods, via setExactAndAllowWhileIdle().

If you are sure that you need polling more frequently than that, and you are sure that the user will value that polling, your primary option is to use a foreground Service (or whitelisted app) and Java's ScheduledExecutorService to get control every so often, using a partial wakelock to keep the CPU powered on *all the time*. From a battery standpoint, this is horrible, far worse than the behavior you would get on Android 5.1 and earlier using AlarmManager. But, it's the ultimate workaround, which is why it is demonstrated in the [AlarmManager/AntiDoze](#) sample application.

The AntiDoze sample is based off of the greenrobot's EventBus sample from [the chapter on event bus alternatives](#). In that app, we used AlarmManager to get control every 15 seconds to either update a fragment (if the UI was in the foreground) or show a Notification (if not). AntiDoze gets rid of the every-event Notification, replacing it with appending an entry to a log file. And, it replaces AlarmManager with

## JOB SCHEDULER

---

ScheduledExecutorService inside of a foreground Service, trying to run forever and get control every 15 seconds along the way.

This app has two product flavors defined in its app/build.gradle file, normal and foreground:

```
apply plugin: 'com.android.application'

dependencies {
    implementation 'org.greenrobot:eventbus:3.0.0'
    implementation "com.android.support:support-v13:27.0.2"
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
    }

    flavorDimensions "default"

    productFlavors {
        foreground {
            dimension "default"
            buildConfigField "boolean", "IS_FOREGROUND", "true"
        }

        normal {
            dimension "default"
            buildConfigField "boolean", "IS_FOREGROUND", "false"
        }
    }
}
```

(from [AlarmManager/AntiDoze/app/build.gradle](#))

A normal build will use a regular Service; a foreground build will use a foreground Service.

The launcher activity is EventDemoActivity. Its onCreate() method will do three things:

1. If we are on Android 6.0 or higher, it will use

## JOB SCHEDULER

---

isIgnoringBatteryOptimizations() on PowerManager to see if we are already on the battery optimization whitelist, and if not, display a system-supplied dialog-themed activity to ask the user to add our app to the whitelist

2. If we do not already have the EventLogFragment, add it
3. If we do not already have the EventLogFragment, also start up the ScheduledService, as probably it is not already running

```
package com.commonware.android.antidoze;

import android.support.v4.app.FragmentActivity;
import android.content.Intent;
import android.net.Uri;
import android.os.Build;
import android.os.Bundle;
import android.os.PowerManager;
import android.provider.Settings;

public class EventDemoActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (Build.VERSION.SDK_INT > Build.VERSION_CODES.LOLLIPOP_MR1) {
            String pkg = getPackageName();
            PowerManager pm = getSystemService(PowerManager.class);

            if (!pm.isIgnoringBatteryOptimizations(pkg)) {
                Intent i =
                    new Intent(Settings.ACTION_REQUEST_IGNORE_BATTERY_OPTIMIZATIONS)
                        .setData(Uri.parse("package:" + pkg));

                startActivity(i);
            }
        }

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new EventLogFragment()).commit();
            startService(new Intent(this, ScheduledService.class));
        }
    }
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonware/android/antidoze/EventDemoActivity.java](#))

To be able to use ACTION\_REQUEST\_IGNORE\_BATTERY\_OPTIMIZATIONS, we need to request and hold the REQUEST\_IGNORE\_BATTERY\_OPTIMIZATIONS permission, which we handle in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest
    package="com.commonware.android.antidoze"
```

## JOB SCHEDULER

---

```
xmlns:android="http://schemas.android.com/apk/res/android"
android:versionCode="1"
android:versionName="1.0">

<uses-permission android:name="android.permission.WAKE_LOCK"/>
<uses-permission android:name="android.permission.RECEIVE_BOOT_COMPLETED"/>
<uses-permission android:name="android.permission.REQUEST_IGNORE_BATTERY_OPTIMIZATIONS" />

<application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <activity
        android:name="EventDemoActivity"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>

    <receiver android:name="PollReceiver">
        <intent-filter>
            <action android:name="android.intent.action.BOOT_COMPLETED"/>
        </intent-filter>
    </receiver>

    <receiver android:name="StopReceiver"/>

    <service android:name="ScheduledService"/>
</application>
</manifest>
```

(from [AlarmManager/AntiDoze/app/src/main/AndroidManifest.xml](#))

The rest of the UI layer is unchanged. Where the differences really creep in is with `ScheduledService`. This used to be a `WakefulIntentService`, triggered by an alarm event. Now, it is a regular service, designed to run all the time.

As part of initializing the `ScheduledService` class, we create an instance of `ScheduledExecutorService`, through the `newSingleThreadScheduledExecutor()` static method on the `Executors` utility class:

```
private ScheduledExecutorService sched=
    Executors.newSingleThreadScheduledExecutor();
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

In `onCreate()`, we:

- Acquire a partial wakelock

## JOB SCHEDULER

---

- Call a private `foregroundify()` method to make our service be a foreground service with a suitable Notification, if our `IS_FOREGROUND` value is true based upon our product flavor
- Set up a File for use with logging (named `log`), including creating the directory for it if needed
- Call `scheduleAtFixedRate()` on the `ScheduledExecutorService` to get control every 15 seconds

```
@Override
public void onCreate() {
    super.onCreate();

    PowerManager mgr=(PowerManager)getSystemService(POWER_SERVICE);

    wakeLock=mgr.newWakeLock(PowerManager.PARTIAL_WAKE_LOCK,
        getClass().getSimpleName());
    wakeLock.acquire();

    if (BuildConfig.IS_FOREGROUND) {
        foregroundify();
    }

    log=new File(getExternalFilesDir(null), "antidoze-log.txt");
    log.getParentFile().mkdirs();
    sched.scheduleAtFixedRate(this, 0, 15, TimeUnit.SECONDS);
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

We can pass the service itself to `scheduleAtFixedRate()` because it implements the `Runnable` interface. Its `run()` method uses greenrobot's `EventBus` to tell the UI layer about our event, plus it calls an `append()` method to log that event to our log file:

```
@Override
public void run() {
    RandomEvent event=new RandomEvent(rng.nextInt());

    EventBus.getDefault().post(event);
    append(log, event);
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

`append()` simply uses Java file I/O to append a line to the log file:

```
private void append(File f, RandomEvent event) {
```

## JOB SCHEDULER

---

```
try {
    FileOutputStream fos=new FileOutputStream(f, true);
    Writer osw=new OutputStreamWriter(fos);

    osw.write(event.when.toString());
    osw.write(" : ");
    osw.write(Integer.toHexString(event.value));
    osw.write('\n');
    osw.flush();
    fos.flush();
    fos.getFD().sync();
    fos.close();

    Log.d(getClass().getSimpleName(),
        "logged to "+f.getAbsolutePath());
}
catch (IOException e) {
    Log.e(getClass().getSimpleName(),
        "Exception writing to file", e);
}
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

The `foregroundify()` method, called from `onCreate()`, creates a Notification and calls `startForeground()` to make the service be a foreground service:

```
private void foregroundify() {
    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.O &&
        mgr.getNotificationChannel(CHANNEL_WHATEVER) == null) {
        mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
            "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this, CHANNEL_WHATEVER);
    Intent iActivity=new Intent(this, EventDemoActivity.class);
    PendingIntent piActivity=
        PendingIntent.getActivity(this, 0, iActivity, 0);
    Intent iReceiver=new Intent(this, StopReceiver.class);
    PendingIntent piReceiver=
        PendingIntent.getBroadcast(this, 0, iReceiver, 0);

    b.setAutoCancel(true)
        .setDefaults(Notification.DEFAULT_ALL)
```

## JOB SCHEDULER

---

```
.setTitle(getString(R.string.app_name))
.setContentIntent(piActivity)
.setSmallIcon(R.drawable.ic_launcher)
.setTicker(getString(R.string.app_name))
.addAction(R.drawable.ic_stop_white_24dp,
    getString(R.string.notif_stop),
    piReceiver);

startForeground(NOTIFY_ID, b.build());
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

The Notification includes a “stop” action, pointing to a StopReceiver, which just uses stopService() to stop the service. This allows the user to shut down our background service at any point, just via the Notification.

When the service is stopped, onDestroy() tidies things up, notably releasing the wakelock:

```
@Override
public void onDestroy() {
    sched.shutdownNow();
    wakeLock.release();
    stopForeground(true);

    super.onDestroy();
}
```

(from [AlarmManager/AntiDoze/app/src/main/java/com/commonsware/android/antidoze/ScheduledService.java](#))

Running this overnight on an Android 6.0 device shows that, indeed, we get control every 15 seconds, as desired. The device’s battery drains commensurately, considering that we are keeping the CPU powered on all of the time. Either the whitelist keeps us going (normal flavor) or the foreground service keeps us going (foreground flavor).

### setAlarmClock()

AlarmManager also has a setAlarmClock() method, added in API Level 21. This works a bit like setExact() (and, hence, setExactAndAllowWhileIdle()), in that you provide a time to get control and a PendingIntent to be invoked at that time. From the standpoint of power management, Doze mode leaves setAlarmClock() events alone, and so they are executed at the appropriate time regardless of device

state. However, at the same time, `setAlarmClock()` has some user-visible impacts that make it suitable for certain apps (e.g., calendar reminders) and unsuitable for others (e.g., polling).

### Hope Somebody Else Does Something

Doze mode is for the entire device. Hence, your app may wind up getting control more frequently than you might expect, even without any code changes, simply because *somebody else* is doing something to get control more frequently.

## Scheduling Content Monitoring

One long-standing challenge in Android is finding out when content changes in other apps. While `ContentObserver` is great for this purpose, you have to have a running process for it to work. As a result, some apps try desperately to keep a process running all the time to find out about changes to foreign `ContentProviders`, tying up system RAM as a result.

`JobScheduler`, as of Android 7.0, has an option to effectively register a `ContentObserver` for you. You indicate the `Uri` to monitor, and it invokes your `JobService` when the data at that `Uri` changes. This way, you do not need to keep a process around.

To do that, you create a `JobInfo.TriggerContentUri` object, identifying what to monitor. You pass that to `addTriggerContentUri()` on your `JobInfo.Builder`, and schedule the resulting `JobInfo` with the `JobScheduler` as before.

For example, the [JobScheduler/Content](#) sample project asks `JobScheduler` to monitor the `ContactsContract` provider for new contacts.

`MainActivity` has virtually nothing to do with any of this, but instead goes through all the work to set up runtime permission access to the `READ_CONTACTS` permission:

```
package com.commonware.android.jobsched.content;

import android.app.Activity;
import android.content.pm.PackageManager;
import android.os.Bundle;
import android.support.v4.app.ActivityCompat;
import android.support.v4.content.ContextCompat;
import android.view.View;
```

## JOBSCHEULER

---

```
import android.widget.Toast;
import static android.Manifest.permission.READ_CONTACTS;

public class MainActivity extends Activity {
    private static final String[] PERMS_ALL={
        READ_CONTACTS
    };
    private static final int RESULT_PERMS_INITIAL=1339;
    private static final String STATE_IN_PERMISSION=
        "com.commonware.android.jobsched.content.inPermission";
    private boolean isInPermission=false;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (savedInstanceState!=null) {
            isInPermission=
                savedInstanceState.getBoolean(STATE_IN_PERMISSION, false);
        }

        if (!isInPermission) {
            if (hasPermission(READ_CONTACTS)) {
                configureJob();
            }
            else {
                isInPermission=true;
                ActivityCompat.requestPermissions(this, PERMS_ALL,
                    RESULT_PERMS_INITIAL);
            }
        }
    }

    @Override
    protected void onSaveInstanceState(Bundle outState) {
        super.onSaveInstanceState(outState);

        outState.putBoolean(STATE_IN_PERMISSION, isInPermission);
    }

    @Override
    public void onRequestPermissionsResult(int requestCode,
                                           String[] permissions,
                                           int[] grantResults) {

        boolean sadTrombone=true;

        isInPermission=false;
    }
}
```

## JOB SCHEDULER

---

```
if (requestCode==RESULT_PERMS_INITIAL) {
    if (hasPermission(READ_CONTACTS)) {
        configureJob();
        sadTrombone=false;
    }
}

if (sadTrombone) {
    Toast.makeText(this, R.string.msg_no_perm,
        Toast.LENGTH_LONG).show();
}

private void configureJob() {
    Toast.makeText(this, R.string.msg_add,
        Toast.LENGTH_LONG).show();
    DemoJobService.schedule(this);
    finish();
}

private boolean hasPermission(String perm) {
    return(ContextCompat.checkSelfPermission(this, perm)==
        PackageManager.PERMISSION_GRANTED);
}
```

(from [JobScheduler/Content/app/src/main/java/com/commonsware/android/jobsched/content/MainActivity.java](#))

Eventually, though, if the user agrees to the permission, MainActivity calls a static `schedule()` method on `DemoJobService`, to set up the content monitor:

```
static void schedule(Context ctxt) {
    ComponentName cn=
        new ComponentName(ctxt, DemoJobService.class);
    JobInfo.TriggerContentUri trigger=
        new JobInfo.TriggerContentUri(CONTENT_URI,
            JobInfo.TriggerContentUri.FLAG_NOTIFY_FOR_DESCENDANTS);
    JobInfo.Builder b=
        new JobInfo.Builder(ME_MYSELF_AND_I, cn)
            .addTriggerContentUri(trigger);
    JobScheduler jobScheduler=
        (JobScheduler)ctxt.getSystemService(Context.JOB_SCHEDULER_SERVICE);

    jobScheduler.schedule(b.build());
}
```

(from [JobScheduler/Content/app/src/main/java/com/commonsware/android/jobsched/content/DemoJobService.java](#))

## JOB SCHEDULER

---

Here, we:

- Create a `ComponentName` identifying our `JobService`
- Create a `TriggerContentUri`, asking for `ContactsContract.Contacts.CONTENT_URI` (imported via `import static`), and asking to be notified about changes in any “descendants” (i.e., already-existing contacts)
- Pass those two values, plus a job ID, to `JobInfo.Builder`
- Get a `JobScheduler` via `getSystemService()`
- Build the `JobInfo` and `schedule()` it with the `JobScheduler`

The rest of `DemoJobService` handles the results, in this case just raising a `Notification`:

```
@Override
public boolean onStartJob(JobParameters params) {
    NotificationManager mgr=
        (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.O &&
        mgr.getNotificationChannel(CHANNEL_WHATEVER) == null) {
        mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
            "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
    }

    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this, CHANNEL_WHATEVER)
            .setAutoCancel(true)
            .setDefaults(Notification.DEFAULT_ALL)
            .setContentTitle("You added a contact!")
            .setSmallIcon(android.R.drawable.stat_notify_more);

    mgr.notify(NOTIFY_ID, b.build());

    return(false);
}

@Override
synchronized public boolean onStopJob(JobParameters params) {
    return(false);
}
```

(from `JobScheduler/Content/app/src/main/java/com/commonsware/android/jobsched/content/DemoJobService.java`)

However, if we wanted, the `JobParameters` passed into `onStartJob()` contains

information about what changed.

`getTriggeredContentAuthorities()` returns a `String` array of the names of the authorities whose changes triggered this job, if any. It will return `null` if the job triggered for some other reason, such as a deadline.

If `getTriggeredContentAuthorities()` returns a non-`null` value, then you can try calling `getTriggeredContentUris()` to find out the specific `Uri` values that changed. However, this may be `null`, if there were too many changes to report (the limit is ~50).

Note that there are limitations on these content-monitoring jobs:

- They cannot be persisted, and so you need to re-request them after a reboot
- They cannot be periodic, though other job restrictions may still work (e.g., must be on a charger, must have a network connection)
- The job is a one-shot event — if you want continuous updates, you need to schedule a fresh job after this one is invoked (either with matches or due to hitting the deadline)

One problem with monitoring content for changes is that those changes may occur too frequently. In Android 7.0, you have two new `JobInfo.Builder` methods that you can use to manage this:

- `setTriggerContentUpdateDelay()` indicates how long after the last content change before the job will be invoked. For example, suppose that through some sort of sync operation, a provider that you are monitoring is updated 10 times within a second, then is quiet. By default, your job would be invoked 10 times. But, if you pass something like 3000 to `setTriggerContentUpdateDelay()`, your job would be invoked once, 3000 milliseconds after the last of that burst of updates.
- `setTriggerContentMaxDelay()` puts an upper bound for how long you are willing to wait before the job is invoked. If the provider is very busy, and your `setTriggerContentUpdateDelay()` counter keeps getting reset due to updates, it may be quite some time after the burst began before you finally have your job run. `setTriggerContentMaxDelay()` sets a limit for how long we will wait; if this time elapses, your job will be run even if updates are ongoing.

### JobScheduler as Work Queue

Android 8.0 adds a work queue mode to `JobScheduler`. `IntentService` had such a queue, after a fashion, in that it would process one `Intent` at a time through `onHandleIntent()`, queuing up other `Intent` objects that arrive while `onHandleIntent()` is busy. `JobScheduler` now offers a similar capability for your `JobService`, where you can post jobs and have your `JobService` end when the work is completed.

The [JobScheduler/WorkQueue](#) sample project illustrates this. We have a `JobService` that will download files as its “work”, posting the results on an event bus. Our client is an instrumentation test that will confirm that the downloads work as expected.

### Defining Some “Work”

The “work” to be enqueued comes in the form of a `JobWorkItem`, which is a thin wrapper around an `Intent`. That `Intent` is used for payload, such as filling in extras. That `Intent` is *not* used for actually starting or binding to a service.

The sample project has a `WorkService` which is the `JobService` for handling these jobs. It has a static `buildWorkItem()` method that will help create a `JobWorkItem` from the two pieces of data that we want as our “work”:

- A URL identifying something to download
- An `int` identifying which piece of work this is

```
public static JobWorkItem buildWorkItem(int workIndex, String url) {
    Intent i=new Intent();

    i.setData(Uri.parse(url));
    i.putExtra(EXTRA_WORK_INDEX, workIndex);

    return(new JobWorkItem(i));
}
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

### Enqueuing the Work

`JobScheduler` in Android 8.0 has an `enqueue()` method. It takes a `JobInfo`, the way you normally schedule jobs, along with a `JobWorkItem`. It arranges to start the `JobService` if it is not already running and adds the `JobWorkItem` to its work queue.

## JOB SCHEDULER

---

One strong recommendation outlined in the documentation is to try to use the same (or an equivalent) `JobInfo` object for each `enqueue()` call. Changing the job characteristics — in particular, tightening constraints, like now needing to be on a charger — will cause Android to have to stop your running `JobService` (if it is running) and restart it, perhaps later.

`WorkService` has a static `enqueueWork()` method that handles all of the details:

```
public static JobInfo enqueueWork(Context ctxt, JobInfo jobInfo, List<JobWorkItem> work) {
    JobScheduler jobScheduler=ctxt.getSystemService(JobScheduler.class);

    if (jobInfo==null) {
        ComponentName cn=new ComponentName(ctxt, WorkService.class);

        jobInfo=new JobInfo.Builder(JOB_ID, cn)
            .setRequiredNetworkType(JobInfo.NETWORK_TYPE_ANY)
            .build();
    }

    for (JobWorkItem item : work) {
        jobScheduler.enqueue(jobInfo, item);
    }

    return(jobInfo);
}
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

`enqueueWork()` takes three parameters:

- A `Context`
- A `JobInfo` returned from a previous `enqueueWork()` call, or `null` if we do not have one
- The instances of `JobWorkItem` to enqueue, in this case in the form of a `List`

`enqueueWork()` will create a `JobInfo` object if needed, but otherwise it will reuse the passed-in `JobInfo`. That `JobInfo` requires a network connection, as we will be downloading a file, but otherwise sets no constraints. Then, `enqueueWork()` simply iterates over the `JobWorkItem` objects and calls `enqueue()` to register each of them. `enqueueWork()` returns the `JobInfo` object that we created or used, for later reuse.

## Working Off the Queue

As with any `JobService`, `onStartJob()` is our entry point for doing the work requested by whoever scheduled the job. In this case, it delegates the real work to a `scheduleWork()` method, then returns `true` to indicate that the work is ongoing.

## JOB SCHEDULER

---

```
@Override
public boolean onStartJob(JobParameters params) {
    scheduleWork(params);

    return(true);
}
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

`scheduleWork()`, in turn, calls `dequeueWork()` on the `JobParameters`, until it returns null to indicate that there is no more queued work:

```
private void scheduleWork(final JobParameters params) {
    if (!threadPool.isShutdown()) {
        JobWorkItem item;

        while ((item=params.dequeueWork())!=null) {
            final int workIndex=item.getIntent().getIntExtra(EXTRA_WORK_INDEX, -1);
            final String url=item.getIntent().getData().toString();
            final JobWorkItem itemToDo=item;

            threadPool.execute(new Runnable() {
                @Override
                public void run() {
                    download(workIndex, url);
                    params.completeWork(itemToDo);
                    scheduleWork(params);
                }
            });
        }
    }
}
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

`dequeueWork()` returns a `JobWorkItem` object if there is one. We can retrieve values out of it and arrange for a `ThreadPoolExecutor` to perform the actual work. Remember: `onStartJob()` is called on the main application thread, so you cannot process the work directly in most cases.

That `ThreadPoolExecutor` is a simple field on the `WorkService`, initialized via `Executors.newFixedThreadPool()`:

```
private ExecutorService threadPool=Executors.newFixedThreadPool(3);
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

## JOB SCHEDULER

---

For each `JobWorkItem`, the `ThreadPoolExecutor` does three things on a background thread:

1. It calls a `download()` method to download the file identified by the supplied URL
2. It calls `completeWork()` on the `JobParameters`, to indicate that this work item is complete and can be removed from the queue
3. It calls `scheduleWork()` again, in case more jobs arrived while we were busy downloading the file

The result is that we keep calling `scheduleWork()` until we are out of `JobWorkItem` instances to process. At that point, the final `dequeueWork()` call will not only return `null` but also arrange to shut down our `JobService`. In particular, we do *not* call `jobFinished()` to do that ourselves.

`download()` uses `OkHttp` to download the content identified by the URL, then uses Okio's `HashingSource` to compute the SHA-256 hash of the content:

```
private void download(int workIndex, String url) {
    try {
        Response response=ok.newCall(new Request.Builder().url(url).build()).execute();
        HashingSource hashingSource=HashingSource.sha256(response.body().source());

        EventBus.getDefault().post(new Result(hashingSource.hash(), workIndex, null));
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception from OkHttp", e);
        EventBus.getDefault().post(new Result(null, workIndex, e));
    }
}
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

`download()` posts the results — either the hash or an `Exception`, along with the `int` identifying this piece of work — on an event bus, wrapped in a `Result` object:

```
public static class Result {
    public final ByteString hash;
    public final int workIndex;
    public final Exception e;

    Result(ByteString hash, int workIndex, Exception e) {
        this.hash=hash;
        this.workIndex=workIndex;
        this.e=e;
    }
}
```

## JOB SCHEDULER

---

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

However, it is possible that while our downloads are going on, that we lose connectivity. Not only will OkHttp start throwing errors, but JobScheduler will trigger a call to `onStopJob()` on our `WorkService`. There, we just `shutdown()` the thread pool, as we do when all of the work is done:

```
@Override
public boolean onStopJob(JobParameters params) {
    threadPool.shutdown();

    return(true);
}
```

(from [JobScheduler/WorkQueue/app/src/main/java/com/commonsware/android/job/work/WorkService.java](#))

## Testing the Service

The sample project has no significant UI — the `MainActivity` just shows a `Toast` telling you to run the instrumentation tests. There, you will find a `WorkTests` class that:

- Schedules two batches of work items, one second apart, to download the URL contents a random number of times
- Waits for all of the events to be received on the event bus
- Fails if either we get an exception or we missed a work item (based on its index)

```
@RunWith(AndroidJUnit4.class)
public class WorkTests {
    private static final String URL=
        "https://commonsware.com/Android/Android-1_0-CC.pdf";
    private static final String EXPECTED_HASH_HEX=
        "e3b0c44298fc1c149afb4c8996fb92427ae41e4649b934ca495991b7852b855";
    private CountdownLatch latch;
    private Exception e=null;
    private HashSet<Integer> workIndices=new HashSet<>();

    @Test
    public void testWork() throws Exception {
        Random r=new Random();
        int firstBatchCount=4+r.nextInt(4);
        int secondBatchCount=4+r.nextInt(4);

        latch=new CountdownLatch(firstBatchCount+secondBatchCount);

        EventSink sink=new EventSink();

        EventBus.getDefault().register(sink);
    }
}
```

## JOB SCHEDULER

---

```
try {
    JobInfo jobInfo=null;
    ArrayList<JobWorkItem> items=new ArrayList<>();

    for (int i=0;i<firstBatchCount;i++) {
        items.add(WorkService.buildWorkItem(i, URL));
    }

    jobInfo=WorkService.enqueueWork(InstrumentationRegistry.getTargetContext(),
        jobInfo, items);

    SystemClock.sleep(1000);

    items.clear();

    for (int i=0;i<secondBatchCount;i++) {
        items.add(WorkService.buildWorkItem(i+firstBatchCount, URL));
    }

    WorkService.enqueueWork(InstrumentationRegistry.getTargetContext(),
        jobInfo, items);

    latch.await(firstBatchCount+secondBatchCount, TimeUnit.SECONDS);

    if (e!=null) {
        throw e;
    }
}
finally {
    EventBus.getDefault().unregister(sink);
}

assertEquals(firstBatchCount+secondBatchCount, workIndices.size());
}

private class EventSink {
    @Subscribe(threadMode =ThreadMode.ASYNC)
    public void onWorkResult(WorkService.Result result) {
        workIndices.add(result.workIndex);

        if (result.e!=null) {
            WorkTests.this.e=result.e;
        }
        else {
            String hash=result.hash.hex();

            if (!EXPECTED_HASH_HEX.equals(hash)) {
                WorkTests.this.e=
                    new IllegalStateException(String.format("Expected hash of %s, received %s",
                        EXPECTED_HASH_HEX, hash));
            }
        }

        latch.countDown();
    }
}
}
```

(from [JobScheduler/WorkQueue/app/src/androidTest/java/com/commonsware/android/job/work/test/WorkTests.java](#))

### Work Limits

As noted previously, the work queue system with JobScheduler relies on your using the same or an equivalent JobInfo for each piece of work. Otherwise, our JobService needs to stop processing jobs and restart them, perhaps after some delay.

---

## **Trail: Hardware and System Services**

---

# **Accessing Location-Based Services**

---

A popular feature on current-era mobile devices is GPS capability, so the device can tell you where you are at any point in time. While the most popular use of GPS service is mapping and directions, there are other things you can do if you know your location. For example, you might set up a dynamic chat application where the people you can chat with are based on physical location, so you are chatting with those you are nearest. Or, you could automatically “geotag” posts to Twitter or similar services.

GPS is not the only way a mobile device can identify your location. Alternatives include:

1. Cell tower triangulation, where your position is determined based on signal strength to nearby cell towers
2. Proximity to public WiFi “hotspots” that have known geographic locations
3. GPS alternatives, such as [GLONASS](#) (Russia), [Galileo](#) (European Union, still under development), and [Compass](#) (China, still under development)

Android devices may have one or more of these services available to them. You, as a developer, can ask the device for your location, plus details on what providers are available. There are even ways for you to simulate your location in the emulator, for use in testing your location-enabled applications.

## **Prerequisites**

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on threads](#).

## Location Providers: They Know Where You're Hiding

Android devices can have access to several different means of determining your location. Some will have better accuracy than others. Some may be free, while others may have a cost associated with them. Some may be able to tell you more than just your current position, such as your elevation over sea level, or your current speed.

Android, therefore, has abstracted all this out into a set of `LocationProvider` objects. Your Android environment will have zero or more `LocationProvider` instances, one for each distinct locating service that is available on the device. Providers know not only your location, but also their own characteristics, in terms of accuracy, cost, etc. There are two main providers: `GPS_PROVIDER` (which uses GPS) and `NETWORK_PROVIDER` (which uses cell tower triangulation and WiFi hotspot proximity).

You, as a developer, will use a `LocationManager`, which holds the `LocationProvider` set, to figure out which `LocationProvider` is right for your particular circumstance. You will also need a permission in your application, or the various location APIs will fail due to a security violation.

Depending on which location providers you wish to use, you may need `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. Note that `ACCESS_COARSE_LOCATION` may intentionally “fuzz” or filter out location fixes that are “too good” (i.e., more accurate than a city block), such as those obtained from being near a known WiFi hotspot. The `GPS_PROVIDER` specifically requires `ACCESS_FINE_LOCATION` to work, at least on modern versions of Android. Also note that these permissions are dangerous, and therefore if your `targetSdkVersion` is 23 or higher, you need to ask for these permissions at runtime.

## Finding Yourself

The obvious thing to do with a location service is to figure out where you are right now.

To do that, you need to get a `LocationManager` — call `getSystemService(LOCATION_SERVICE)` from your activity or service and cast it to be a `LocationManager`.

## ACCESSING LOCATION-BASED SERVICES

---

The next step to find out where you are is to get the name of the `LocationProvider` you want to use. Here, you have two main options:

- Ask the user to pick a provider
- Find the best-match provider based on a set of criteria

If you want the user to pick a provider, calling `getProviders()` on the `LocationManager` will give you a `List` of providers, which you can then present to the user for selection.

Or, you can create and populate a `Criteria` object, stating the particulars of what you want out of a `LocationProvider`, such as:

1. `setAltitudeRequired()` to indicate if you need the current altitude or not
2. `setAccuracy()` to set a minimum level of accuracy, in meters, for the position
3. `setCostAllowed()` to control if the provider must be free or if it can incur a cost on behalf of the device user

Given a filled-in `Criteria` object, call `getBestProvider()` on your `LocationManager`, and Android will sift through the criteria and give you the best answer. Note that not all of your criteria may be met – all but the monetary cost criterion might be relaxed if nothing matches.

You are also welcome to hard-wire in a `LocationProvider` name (e.g., `GPS_PROVIDER`), perhaps just for testing purposes.

Once you know the name of the `LocationProvider`, you can call `getLastKnownLocation()` to find out where you were recently. However, unless something else is causing the desired provider to collect fixes (e.g., unless the GPS radio is on), `getLastKnownLocation()` will return `null`, indicating that there is no known position. On the other hand, `getLastKnownLocation()` incurs no monetary or power cost, since the provider does not need to be activated to get the value.

This method returns a `Location` object, which can give you the latitude and longitude of the device in degrees as a Java `double`. If the particular location provider offers other data, you can get at that as well:

1. For altitude, `hasAltitude()` will tell you if there is an altitude value, and `getAltitude()` will return the altitude in meters.
2. For bearing (i.e., compass-style direction), `hasBearing()` will tell you if there

- is a bearing available, and `getBearing()` will return it as degrees east of true north.
3. For speed, `hasSpeed()` will tell you if the speed is known and `getSpeed()` will return the speed in meters per second.

A more likely approach to getting the `Location` from a `LocationProvider`, though, is to register for updates, as described in the next section.

## On the Move

Not all location providers are necessarily immediately responsive. GPS, for example, requires activating a radio and getting a fix from the satellites before you get a location. That is why Android does not offer a `getMeMyCurrentLocationNow()` method. Combine that with the fact that your users may well want their movements to be reflected in your application, and you are probably best off registering for location updates and using that as your means of getting the current location.

The [Location/Classic](#) sample application shows how to register for updates and use them when they arrive. It also shows how to deal with the runtime permissions that we need for locations.

## Getting Permission

Our UI is implemented in `MainActivity` and its associated `WeatherFragment`. However, `MainActivity` extends `AbstractPermissionActivity`, which handles the basics of ensuring that we have the `ACCESS_FINE_LOCATION` permission that our app needs in order to get a location fix. This is a variation on the `AbstractPermissionActivity` covered in [the material on runtime permissions](#) earlier in the book.

Subclasses of `AbstractPermissionActivity` need to implement three methods:

- `getDesiredPermissions()`, returning the array of permission names that the activity needs in order to proceed
- `onReady()`, called by `AbstractPermissionActivity` once we get all of the requested permissions
- `onPermissionDenied()`, called by `AbstractPermissionActivity` if the user did not grant us all of the requested permissions when we asked for them

In the case of `MainActivity`, `getDesiredPermissions()` asks for

## ACCESSING LOCATION-BASED SERVICES

---

ACCESS\_FINE\_LOCATION, onReady() displays the WeatherFragment, and onPermissionDenied() shows a Toast and finishes the activity:

```
package com.commonware.android.weather2;

import android.Manifest;
import android.widget.Toast;

public class MainActivity extends AbstractPermissionActivity {
    private static final String[] PERMS=
        {Manifest.permission.ACCESS_FINE_LOCATION};

    @Override
    protected String[] getDesiredPermissions() {
        return(PERMS);
    }

    @Override
    protected void onPermissionDenied() {
        Toast
            .makeText(this, R.string.msg_no_perm, Toast.LENGTH_LONG)
            .show();
        finish();
    }

    @Override
    protected void onReady() {
        if (getFragmentManager().findFragmentById(android.R.id.content) == null) {
            getFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new WeatherFragment()).commit();
        }
    }
}
```

(from [Location/Classic/app/src/main/java/com/commonware/android/weather2/MainActivity.java](#))

The result is that by the time WeatherFragment is displayed, we now have ACCESS\_FINE\_LOCATION, and it is safe for us to use LocationManager.

## Modelling the Weather

This app will use the US National Weather Service (NWS) to get weather details for a given location. This may not work outside the US. And even inside the US, the National Weather Service's servers seem to have issues sometimes. But, it is free, with no registration or API keys required, at least at the present time.

## ACCESSING LOCATION-BASED SERVICES

---

The [NWS REST Web service](#) serves data in a variety of formats, including JSON. The WeatherResponse POJO models the subset of that JSON that we need for displaying basic weather details to the user:

```
package com.commonware.android.weather2;

import java.util.List;

public class WeatherResponse {
    public final Properties properties=null;

    public static class Properties {
        public final List<Period> periods=null;
    }

    public static class Period {
        public final String startTime=null;
        public final int temperature;
        public final String temperatureUnit=null;
        public final String icon=null;

        public Period() {
            temperature=0;
        }
    }
}
```

(from [Location/Classic/app/src/main/java/com/commonware/android/weather2/WeatherResponse.java](#))

The JSON object that gets returned has a `properties` field, which in turn has a `periods` field. The `periods` are a `List` of `Period` objects, each of which has the time for the forecast, the projected temperature (and unit of measure, such as “F” for Fahrenheit), and a URL to an icon representing the type of weather (sunny, cloudy, rain, snow, zombie invasion, etc.).

### Requesting Updates

In `onCreate()` of `WeatherFragment`, we get our hands on a `LocationManager` via a call to `getSystemService()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setRetainInstance(true);
}
```

## ACCESSING LOCATION-BASED SERVICES

---

```
mgr=(LocationManager) getActivity()
    .getSystemService(Context.LOCATION_SERVICE);

Retrofit retrofit=
    new Retrofit.Builder()
        .baseUrl("https://api.weather.gov")
        .addConverterFactory(GsonConverterFactory.create())
        .build();

nws=retrofit.create(NWSInterface.class);
}
```

(from [Location/Classic/app/src/main/java/com/commonsware/android/weather2/WeatherFragment.java](#))

We also create a Retrofit instance, pointing to the API endpoint of the NWS. Retrofit is a library for accessing REST-style Web services, and it is profiled [earlier in the book](#).

We then use the Retrofit instance to create an instance of NWSInterface. This interface is augmented with Retrofit annotations to describe how we should request a weather forecast:

```
package com.commonsware.android.weather2;

import retrofit2.Call;
import retrofit2.http.GET;
import retrofit2.http.Headers;
import retrofit2.http.Path;

public interface NWSInterface {
    @Headers("Accept: application/geo+json")
    @GET("/points/{lat},{lon}/forecast")
    Call<WeatherResponse> getForecast(@Path("lat") double latitude,
                                     @Path("lon") double longitude);
}
```

(from [Location/Classic/app/src/main/java/com/commonsware/android/weather2/NWSInterface.java](#))

Here, we have a `getForecast()` method that takes a latitude and longitude and pours them into the path portion of the URL for our REST request. We also indicate that we want a GeoJSON response (`application/geo+json`); `WeatherResponse` models a small bit of what a GeoJSON response might contain.

In `onStart()`, we request location updates:

```
@Override
```

## ACCESSING LOCATION-BASED SERVICES

---

```
@SuppressWarnings({"MissingPermission"})
public void onStart() {
    super.onStart();

    mgr.requestLocationUpdates(LocationManager.GPS_PROVIDER, 3600000,
        1000, this);
}
```

(from [Location/Classic/app/src/main/java/com/commonsware/android/weather2/WeatherFragment.java](#))

`requestLocationUpdates()` on `LocationManager` takes four parameters:

- The name of the location provider you wish to use
- How long, in milliseconds, *should* have elapsed before we might get a location update
- How far, in meters, must the device have moved before we might get a location update
- An implementation of the `LocationListener` interface that will be notified of key location-related events

In our case, we are asking for updates from the `GPS_PROVIDER` once an hour, where the device has moved a least 1 kilometer, with our fragment serving as the `LocationListener` implementation.

Bear in mind that the time parameter is only a guide to help steer Android from a power consumption standpoint. You may get many more location updates than this. To get the maximum number of location updates, supply 0 for both the time and distance constraints.

In `onStop()`, we call `removeUpdates()`, so we only get location updates while we are visible:

```
@Override
@SuppressWarnings({"MissingPermission"})
public void onStop() {
    mgr.removeUpdates(this);

    super.onStop();
}
```

(from [Location/Classic/app/src/main/java/com/commonsware/android/weather2/WeatherFragment.java](#))

The `@SuppressWarnings({"MissingPermission"})` annotation on `onStart()` and `onStop()` are because Android Studio cannot determine for certain that we have

---

## ACCESSING LOCATION-BASED SERVICES

---

implemented runtime permissions properly. Since the IDE does not know if we hold `ACCESS_FINE_LOCATION`, it complains. However, we *have* implemented runtime permissions — this fragment will not exist until we have that permission. So, we suppress the Lint warning.

### Implementing the Listener

`LocationListener` requires four methods, the big one being `onLocationChanged()`, where you will receive your `Location` object when an update is ready:

```
@Override
public void onLocationChanged(Location location) {
    double roundedLat=(double)Math.round(location.getLatitude()*10000d)/10000d;
    double roundedLon=(double)Math.round(location.getLongitude()*10000d)/10000d;

    nws.getForecast(roundedLat, roundedLon)
        .enqueue(new Callback<WeatherResponse>() {
            @Override
            public void onResponse(Call<WeatherResponse> call,
                                   Response<WeatherResponse> response) {
                if (response.code()==200) {
                    adapter=new ForecastAdapter(response.body().properties.periods);
                    setListAdapter(adapter);
                }
                else {
                    Toast.makeText(getActivity(), R.string.msg_nws,
                                   Toast.LENGTH_LONG).show();
                }
            }
        });

    @Override
    public void onFailure(Call<WeatherResponse> call, Throwable t) {
        Toast.makeText(getActivity(), t.getMessage(),
                       Toast.LENGTH_LONG).show();
        Log.e(getClass().getSimpleName(),
              "Exception from Retrofit request to National Weather Service", t);
    }
});
}
```

(from [Location/Classic/app/src/main/java/com/commonsware/android/weather2/WeatherFragment.java](#))

Here, we:

- Round the location to four decimal places, as the NWS REST Web service will not accept more precise values than this and fails with an HTTP 500 response if you provide more decimal places
- Call the `getForecast()` on our Retrofit-supplied `NWSInterface` and `enqueue()` the resulting `Call`, so the network I/O is done on a background thread
- In `onResponse()`, if we got an HTTP 200 response from the Web service, we

pass that List of Period objects to a ForecastAdapter and attach it to the ListView

- In onResponse() shows that we got some error from the Web service, or if there was a problem that triggered onFailure() (e.g., no Internet connection), we show a Toast

### Displaying the Results

ForecastAdapter shows the time and temperature directly, by updating the associated TextView widgets. It delegates the icon-loading process to Picasso, discussed back in [the chapter on Internet access](#).

```
private class ForecastAdapter extends ArrayAdapter<WeatherResponse.Period> {
    private int size;
    private java.text.DateFormat dateFormat;
    private java.text.DateFormat timeFormat;

    ForecastAdapter(List<WeatherResponse.Period> items) {
        super(getActivity(), R.layout.row, R.id.date, items);

        size=getActivity()
            .getResources()
            .getDimensionPixelSize(R.dimen.icon);
        dateFormat=DateFormat.getDateFormat(getActivity());
        timeFormat=DateFormat.getTimeFormat(getActivity());
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        WeatherResponse.Period item=getItem(position);

        if (!TextUtils.isEmpty(item.icon)) {
            ImageView icon=row.findViewById(R.id.icon);

            Picasso.with(getActivity()).load(item.icon)
                .resize(size, size).centerCrop().into(icon);
        }

        TextView title=row.findViewById(R.id.date);

        try {
            Date parsedStartTime=ISO8601.parse(item.startTime);
            String date=dateFormat.format(parsedStartTime);
            String time=timeFormat.format(parsedStartTime);
        }
```

## ACCESSING LOCATION-BASED SERVICES

```
        title.setText(date+" "+time);
    }
    catch (ParseException e) {
        title.setText(item.startTime);
    }

    TextView temp=row.findViewById(R.id.temp);

    temp.setText(getString(R.string.temp, item.temperature,
        item.temperatureUnit));

    return(row);
}
}
```

(from [Location/Classic/app/src/main/java/com/commonsware/android/weather2/WeatherFragment.java](#))

The result is a `ListView` showing the weather forecast... at least if your location is somewhere covered by the US National Weather Service:

*Figure 829: Weather in Eastern Pennsylvania*

## Getting Locations via PendingIntent

There is another version of `requestLocationUpdates()` that takes a `PendingIntent` rather than a `LocationListener`. This is useful if you want to be notified of changes in your position even when your code is not running. For example, if you are logging movements, you could use a `PendingIntent` that triggers a `BroadcastReceiver` (`getBroadcast()`) and have the `BroadcastReceiver` add the entry to the log. This way, your code is only in memory when the position changes, so you do not tie up system resources while the device is not moving.

## Are We There Yet? Are We There Yet? Are We There Yet?

Sometimes, you want to know not where you are now, or even when you move, but when you get to where you are going. This could be an end destination, or it could be getting to the next step on a set of directions, so you can give the user the next turn.

To accomplish this, `LocationManager` offers `addProximityAlert()`. This registers a `PendingIntent`, which will be fired off when the device gets within a certain distance of a certain location. The `addProximityAlert()` method takes, as parameters:

1. The latitude and longitude of the position that you are interested in
2. A radius, specifying how close you should be to that position for the Intent to be raised
3. A duration for the registration, in milliseconds — after this period, the registration automatically lapses. A value of -1 means the registration lasts until you manually remove it via `removeProximityAlert()`.
4. The `PendingIntent` to be raised when the device is within the “target zone” expressed by the position and radius

Note that it is not guaranteed that you will actually receive an Intent, if there is an interruption in location services, or if the device is not in the target zone during the period of time the proximity alert is active. For example, if the position is off by a bit, and the radius is a little too tight, the device might only skirt the edge of the target zone, or go by so quickly that the device’s location isn’t sampled while in the target zone.

It is up to you to arrange for an activity or receiver to respond to the Intent you

register with the proximity alert. What you then do when the Intent arrives is up to you: set up a notification (e.g., vibrate the device), log the information to a content provider, post a message to a Web site, etc. Note that you will receive the Intent whenever the position is sampled and you are within the target zone – not just upon entering the zone. Hence, you will get the Intent several times, perhaps quite a few times depending on the size of the target zone and the speed of the device’s movement.

## Testing... Testing...

The Android emulator does not have the ability to get a fix from GPS, triangulate your position from cell towers, or identify your location by some nearby WiFi signal. So, if you want to simulate a moving device, you will need to have some means of providing mock location data to the emulator.

You can send location fixes via `telnet` to an emulator. The port number is in your emulator’s title bar (usually 5554 for the first running emulator instance). You can then run:

```
telnet localhost 5554
```

to access the Android Console within the emulator. Running the `geo fix NNN NNN` command, where `NNN NNN` is your latitude and longitude, will have the emulator respond as if those coordinates came from GPS.

## Alternative Flavors of Updates

There are more ways to get updates from `LocationManager` than the versions of `requestLocationUpdates()` we have seen so far. There are four major axes of difference:

1. Some versions of `requestLocationUpdates()` take a `Criteria` object, having Android give you fixes based on the best-available provider given the requirements stipulated in the `Criteria`
2. Some versions of `requestLocationUpdates()` take a `Looper` as a parameter, allowing you to receive updates on a background `HandlerThread` instead of the main application thread
3. Some versions of `requestLocationUpdates()` take a `PendingIntent` which will be executed, instead of calling your `LocationListener`
4. There are a few flavors of `requestSingleUpdate()`, which, as the name

## ACCESSING LOCATION-BASED SERVICES

---

suggests, gives you just one location fix, rather than a stream until you remove the request for updates

For the Criteria-flavored versions of `requestLocationUpdates()` and `requestSingleUpdate()`, bear in mind that your code will still crash if there are no possible providers for your Criteria. For example, even if you use an empty Criteria object (for maximum possible matches), but GPS is disabled and the device lacks telephony (e.g., a tablet), you can get a crash like this one:

```
02-09 13:29:21.549: E/AndroidRuntime(2236): FATAL EXCEPTION: main

com.android.internal.os.ZygoteInit.main(ZygoteInit.java:554)
02-09 13:29:21.549: E/AndroidRuntime(2236): at
dalvik.system.NativeStart.main(Native Method)
02-09 13:29:21.549: E/AndroidRuntime(2236): Caused by:
java.lang.IllegalArgumentException: no providers found for criteria
02-09 13:29:21.549: E/AndroidRuntime(2236): at
android.os.Parcel.readException(Parcel.java:1331)
02-09 13:29:21.549: E/AndroidRuntime(2236): at
android.os.Parcel.readException(Parcel.java:1281)
```

02-09 13:29:21.549: E/AndroidRuntime(2236): ... 19 more

Hence, you will still want to use `getProviders()` or `getBestProvider()` to ensure that your Criteria will resolve to *something* before you try using the Criteria to actually request fixes.

## The Fused Option

Google Play Services — the proprietary API set supported by many Android devices — offers a fused location provider that simplifies location tracking. This capability is covered in [the next chapter](#).

## Locations and Features

Sometimes, requesting a permission implies that your app requires a certain hardware feature. For example, having a `<uses-permission>` element for the CAMERA permission implies that your app requires a camera. To undo that requirement, you use a `<uses-feature>` element, with `android:required="false"` to stipulate that you do not necessarily *need* the hardware, though you may use it if it is available:

```
<uses-feature android:name="android.hardware.camera" android:required="false" />
```

When it comes to the location permissions, the behavior depends on your `targetSdkVersion`:

Permission	targetSdkVersion	Implied Feature Requirement
ACCESS_FINE_LOCATION	<=20	android.hardware.location and android.hardware.location.gps
ACCESS_FINE_LOCATION	>=21	android.hardware.location
ACCESS_COARSE_LOCATION	<=20	android.hardware.location and android.hardware.location.network
ACCESS_COARSE_LOCATION	>=21	android.hardware.location

In other words, a device with any sort of location technology will be able to install your app if you request `ACCESS_FINE_LOCATION`, not necessarily one with GPS

## ACCESSING LOCATION-BASED SERVICES

---

capability.

This leads to two directions for applying `<uses-feature>` elements to control this behavior:

- If you can live without location technology, consider having a `<uses-feature>` element to say that `android.hardware.location` is not required
- If you want to ensure that the device has GPS capability, add a `<uses-feature>` element to say that `android.hardware.location.gps` is required

# The Fused Location Provider

---

At the 2013 Google I/O conference, Google announced an update to Google Play Services that offers a “fused location provider”, one that seamlessly uses all available location data to give you as accurate of a location as possible, as quickly as possible, with as little power consumption as possible. This serves as an adjunct to the traditional `LocationManager` approach for finding one’s position. The fused location provider has a different API, though one that is similar in some respects to the `LocationManager` API. However, this provider is part of the Play Services SDK, not part of Android itself.

In this chapter, we will examine how to use the fused location provider, in its latest incarnation, sporting a new API that debuted in 2017.

## Prerequisites

This chapter assumes that you have read the preceding chapter on [location-based services](#), along with that chapter’s prerequisites.

## Why Use the Fused Location Provider?

The traditional recipes for using location providers are a bit complicated, if you want to maximize results. Simply asking for a GPS fix is not that hard, but:

- What if GPS is disabled?
- What if GPS signals are unavailable (e.g., the device is indoors)?
- What about the GPS power drain?

The fused location provider is designed to address these sorts of concerns. Its

---

## THE FUSED LOCATION PROVIDER

---

implementation will blend data from GPS, cell tower triangulation, and WiFi hotspot proximity to determine the device's location, without your having to manually set all of that up. The fused location provider will also take advantage of sensor data, so it does not try to update your location as frequently if the accelerometer indicates that you are not moving.

The net result is better location data, delivered more quickly, with (reportedly) less power consumption.

### Why Not Use the Fused Location Provider?

The fused location provider is part of Google Play Services. Google Play Services is available on hundreds of millions of Android devices. However:

- It is closed source, and so we do not know what the Play Services all do, and whether anything that it does might be detrimental.
- Play Services is only available on devices that have the Play Store, as opposed to devices like the Kindle Fire series and many devices in China

If you are aiming to distribute your app solely through the Play Store, relying upon the Play Services framework is reasonable. If, however, you are distributing through other channels, you will either need to *conditionally* use the fused location provider on devices that offer it, or *avoid* the fused location provider entirely, falling back to the traditional `LocationManager` solution.

### Finding Our Location, Once

This section will review the [Location/LocationServices](#) sample application, which is akin to the `Location/Classic` sample application from [the previous chapter](#), revised to use the fused location provider to get a one-off weather forecast.

### Adding Dependencies

Currently, the Play Services SDK is distributed through Google's Maven repository, the same as with the Support Library. Most likely, your Android Studio project is already set up to use that, so all you need is to add an entry in your dependencies closure that pulls in the `com.google.android.gms:play-services-location` artifact:

```
apply plugin: 'com.android.application'
```

---

## THE FUSED LOCATION PROVIDER

---

```
dependencies {
    implementation 'com.google.android.gms:play-services-location:11.8.0'
    implementation 'com.android.support:support-v4:27.1.0'
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.squareup.okhttp3:okhttp:3.9.1'
}

android {
    compileSdkVersion 27

    defaultConfig {
        minSdkVersion 15
        targetSdkVersion 27
        applicationId 'com.commonware.android.weather2.fused'
    }
    compileOptions {
        sourceCompatibility JavaVersion.VERSION_1_8
        targetCompatibility JavaVersion.VERSION_1_8
    }
}
```

(from [Location/LocationServices/app/build.gradle](#))

### Deal With Runtime Permissions

As with the `Location/Classic` sample, we need to handle runtime permissions. And, as with the `Location/Classic` sample, we use an `AbstractPermissionActivity` to handle all of the permission-related bits, so we can focus on the task at hand.

### Confirm Locations Are Available

It is entirely possible that the user has disabled location access on the device. If so, we are doomed.

Hence, it would be nice to know if we are doomed. Even better would be to ask the user if they would enable location access, so our app can be moderately less doomed.

This is possible, but it works a bit like how runtime permissions works, which means that it is a pain.

---

## THE FUSED LOCATION PROVIDER

---

As part of our work in `onReady()` — after we have obtained the location runtime permission from the user — we create a `LocationSettingsRequest` via a `Builder`:

```
LocationSettingsRequest request=new LocationSettingsRequest.Builder()
    .addLocationRequest(LocationRequest.create())
    .build();
LocationServices.getSettingsClient(this)
    .checkLocationSettings(request)
    .addOnCompleteListener(this::handleSettingsResponse);
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

A `LocationSettingsRequest` makes a request of Play Services to find out if the location settings on the device matches the requirements of a supplied `LocationRequest`. As it turns, we do not have a `LocationRequest` elsewhere — we will see that coming up later in this chapter, when we start requesting periodic location updates. So, we create a fairly basic `LocationRequest` via `LocationRequest.create()` and supply that to the `Builder` as part of building the `LocationSettingsRequest`.

Then, we call `LocationServices.getSettingsClient()` and ask it to `checkLocationSettings()`. We arrange to have a `handleSettingsResponse()` method on our activity be called when the settings request has completed, via `addOnCompleteListener()` and a Java 8 method reference.

The job of the `handleSettingsResponse()` method is to either proceed with requesting the location or asking the user to enable locations:

```
private void handleSettingsResponse(Task<LocationSettingsResponse> task) {
    try {
        LocationSettingsResponse response=task.getResult(ApiException.class);
        LocationSettingsStates states=response.getLocationSettingsStates();

        if (states.isLocationPresent() && states.isLocationUsable()) {
            findLocation();
        }
        else {
            unavailable();
        }
    }
    catch (ApiException e) {
        copeWithFailure(e);
    }
}
```

---

## THE FUSED LOCATION PROVIDER

---

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

The somewhat strange API that Play Services offers here has us call `getResult()` on the supplied `Task` object, and from there call `getLocationSettingsStates()` to get a `LocationSettingsStates` object. There are three basic possibilities at this point.

First, we could find out that locations seem to be usable, via checks of `isLocationPresent()` and `isLocationUsable()`. In that case, we can request our location, which is handled by a `findLocation()` method that we will examine shortly.

Second, we could find out that locations are not usable at this point. In that case, we call an `unavailable()` method, which just shows a `Toast` and exits the activity:

```
private void unavailable() {
    Toast.makeText(this, R.string.msg_not_avail, Toast.LENGTH_LONG)
        .show();
    finish();
}
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

The third possibility is that our call to `getResult()` throws an `ApiException`. In that case, we call `copeWithFailure()` to examine that exception:

```
private void copeWithFailure(Exception e) {
    if (e instanceof ResolvableApiException) {
        try {
            ((ResolvableApiException)e).startResolutionForResult(this, REQUEST_RESOLUTION);
            return;
        }
        catch (IntentSender.SendIntentException e1) {
            e=e1;
        }
    }

    Toast.makeText(this, e.getMessage(), Toast.LENGTH_LONG).show();
    Log.e(getClass().getSimpleName(), "Exception getting location", e);
    finish();
}
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

If the exception is a `ResolvableApiException`, then while there is a problem, it is something that the user can address. Typically, this will be if locations are not enabled in Settings, as the user can fix that. If that is what we receive, we call `startResolutionForResult()` on the `ResolvableApiException`. Under the covers, this calls `startActivityForResult()` to display a Play Services-supplied activity,

typically to ask the user to enable location settings:

*Figure 830: Location Settings Dialog*

If the exception is not a `ResolvableApiException`, or we run into a problem calling `startResolutionForResult()`, we show a `Toast` and bail out of the activity.

So, at this point, if our activity is still around, either we can `findLocation()` or we will be called with `onActivityResult()`, to find out the results of the problem-resolution process that we triggered with `startResolutionForResult()`.

`onActivityResult()` looks at the result code and calls `findLocation()` or `unavailable()` depending on what we got:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode==REQUEST_RESOLUTION) {
        isInResolution=false;

        if (resultCode==RESULT_OK) {
            findLocation();
        }
        else {
            unavailable();
        }
    }
}
```

## THE FUSED LOCATION PROVIDER

---

```
else {
    super.onActivityResult(requestCode, resultCode, data);
}
}
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

You will notice, though, that we set an `isInResolution` field to `false`. `startResolutionForResult()` behaves much like `requestPermissions()` in the runtime permission system: it displays a dialog-themed activity from another app. If we undergo a configuration change while that activity is in the foreground, since our activity is still visible, our activity will be destroyed and recreated. In that case, we do not want to start this whole process again, as we will wind up with a second dialog.

So, we use a similar recipe to the one that `AbstractPermissionActivity` uses for dealing with requesting permissions when the activity starts up:

- Keep track of whether we are in the process of resolving a problem via an `isInResolution` field, initially set to `false`
- Hold onto that value in the saved instance state `Bundle`:

```
@Override
protected void onSaveInstanceState(Bundle outState) {
    super.onSaveInstanceState(outState);

    outState.putBoolean(STATE_IN_RESOLUTION, isInResolution);
}
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

- Restore that value from the `Bundle` in `onCreate()`, and only make the `LocationSettingsRequest` if we are not already handling one from a configuration change:

```
@Override
protected void onReady(Bundle state) {
    if (state!=null) {
        isInResolution=state.getBoolean(STATE_IN_RESOLUTION, false);
    }

    fragment=
        (WeatherFragment)getSupportFragmentManager().findFragmentById(android.R.id.content);

    if (fragment==null) {
        fragment=new WeatherFragment();
        getSupportFragmentManager().beginTransaction()
            .add(android.R.id.content, fragment).commit();
    }
}
```

---

## THE FUSED LOCATION PROVIDER

---

```
}

if (!isInResolution) {
    isInResolution=true;
    LocationSettingsRequest request=new LocationSettingsRequest.Builder()
        .addLocationRequest(LocationRequest.create())
        .build();
    LocationServices.getSettingsClient(this)
        .checkLocationSettings(request)
        .addOnCompleteListener(this::handleSettingsResponse);
}
}
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

- Flip `isInResolution` back to `false` when we handle the resolution in `onActivityResult()`

And, after all of that, either we will call `findLocation()` or our activity will be finished.

### Request the Location

So, eventually, we wind up at `findLocation()`:

```
private void findLocation() {
    FusedLocationProviderClient client=
        LocationServices.getFusedLocationProviderClient(this);

    client.getLastLocation()
        .addOnCompleteListener(this, this::useResult)
        .addOnFailureListener(this, this::copeWithFailure);
}
```

(from [Location/LocationServices/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

The Play Services SDK offers a `LocationServices` class, which has a `getFusedLocationProviderClient()` method. This gives us a `FusedLocationProviderClient` instance that we can use to find out the current location.

However, calling `getLastLocation()` on the `FusedLocationProviderClient` does not hand over the current location. The Play Services SDK talks to a separate Play Services Framework app, which in turn handles all of the Play Services work. That app may or may not be running, and even if it is, there may or may not be a current location. So, `getLastLocation()` returns a `Task` object instead.

---

## THE FUSED LOCATION PROVIDER

---

The two big things that you can do with a Task is call `addOnCompleteListener()` and `addOnFailureListener()`. The former is called if your request succeeds, and in this case it gives us a `Location` via `getResult()` on the passed-in Task that we can hand over to the fragment. The latter is called if there is some unrecoverable problem, where we are handed an `Exception` to use to inform the user about what went wrong. In this case, we are using lambda expressions to replace the `OnCompleteListener` and `OnFailureListener` interfaces.

You will notice that we did not use `addOnFailureListener()` with the previous Task usage: the `checkLocationSettings()` call. There, we just used `addOnCompleteListener()`. There is nothing stopping you from adding a failure listener there. However, due to what may be bugs in Play Services, for a recoverable problem (e.g., locations not enabled), *both* the completion listener *and* the failure listener get called. You might accidentally wind up calling `startResolutionForResult()` in both cases, which will give you two dialogs. Since we have to catch the `ApiException` in the completion listener anyway, in the `checkLocationSettings()` scenario we only use the completion listener.

Both `addOnCompleteListener()` and `addOnFailureListener()` have a few different flavors; in this case, we are using ones that take an `Activity` as the first parameter. This causes the Play Services SDK to pay attention to the activity lifecycle, and if the activity is stopped before the request is completed, the Play Services SDK will abandon the request.

### Using the Location

`WeatherFragment` has a subset of the original sample's logic, mostly focused on `fetchForecast()` and the work to display the weather forecast. `WeatherFragment` itself no longer has any logic to get the location itself – it relies on the activity to push over the location when it is ready.

Similarly, `WeatherFragment` is no longer retained. On a configuration change, the activity and fragment start over from scratch. That is simple but not the most efficient option. A production app probably has both the location retrieval and the forecast Web service call be managed by some sort of “repository” object that is independent of the activity/fragment lifecycle. Coverage of the repository pattern can be found in the companion volume, [Android's Architecture Components](#).

## Getting Periodic Locations

Getting periodic location data is only incrementally more complex than is getting a single update. While this particular sample app does not need periodic updates, we can still use it to experiment with the API. The [Location/LocationPeriodic](#) sample application is a clone of the `Location/LocationServices` sample, modified to request “periodic” updates... though we will only use the first one.

### Defining a Location Request

Core to both finding out whether we can use the fused location provider, and later getting location fixes, will be to define a `LocationRequest` object. This is a pure POJO, without any ties to any `Context` or other existing `Play Services SDK` objects:

```
private LocationRequest buildLocationRequest() {
    return new LocationRequest()
        .setNumUpdates(1)
        .setExpirationDuration(60000)
        .setInterval(5000)
        .setPriority(LocationRequest.PRIORITY_LOW_POWER);
}
```

(from [Location/LocationPeriodic/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

Here, we indicate that the `LocationRequest`:

- Only needs to provide us with a single location fix (`setNumUpdates(1)`)
- Can give up automatically if we do not get a location fix within the first minute (`setExpirationDuration(60000)`)
- Should start working fairly quickly to get us our fix (`setInterval(5000)`)
- Can optimize for power over accuracy (`setPriority(LocationRequest.PRIORITY_LOW_POWER)`)

The `setInterval()` call may seem odd, given that we are only seeking one fix. Leaving this out, though, means that you may *never* get a fix, for unclear reasons.

Also, while we are requesting `PRIORITY_LOW_POWER`, and we do not need a particularly accurate fix just to get a weather forecast, we still request `ACCESS_FINE_LOCATION` in the manifest. Without this, once again we seem to never get a fix.

Another issue comes with the expiration value. `setExpirationDuration()` calculates

---

## THE FUSED LOCATION PROVIDER

---

the expiration time based on when the `LocationRequest` object is *created*, not when it is *used*. If we declared this as a constant with a static initializer, our `LocationRequest` would be created when the `WeatherDemo` class is loaded. However, if we do not hold the runtime permissions, we cannot request location updates without user interaction, and that may take some time, which eats into our requested duration. So, instead, we wait to create the `LocationRequest` until we can use it, as we will see shortly.

### Requesting Location Updates

We use `buildLocationRequest()` in the new `findLocation()` method:

```
private void findLocation() {
    request=buildLocationRequest();

    client.requestLocationUpdates(request, cb, Looper.getMainLooper())
        .addOnFailureListener(this, e -> {
            Toast.makeText(this, e.getMessage(), Toast.LENGTH_LONG).show();
            Log.e(getClass().getSimpleName(), "Exception getting location", e);
        });
}
```

(from [Location/LocationPeriodic/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

We use the same `FusedLocationProviderClient` object as before. This time, we call a `requestLocationUpdates()` method on the `FusedLocationProviderClient`. There are two flavors of this method, both taking the `LocationRequest` as the first parameter. The flavor that we are using here takes a `LocationCallback` and a `Looper` as the other parameters. The other flavor takes a `PendingIntent` and is designed for background use, where your process might not be around at the time the location request is ready and timely.

The `LocationCallback` is defined here as a `cb` field:

```
private final LocationCallback cb=new LocationCallback() {
    @Override
    public void onLocationResult(LocationResult locationResult) {
        if (fragment!=null && locationResult.getLastLocation()!=null) {
            fragment.fetchForecast(locationResult.getLastLocation());
        }
    }
}

@Override
public void onLocationAvailability(LocationAvailability avail) {
```

## THE FUSED LOCATION PROVIDER

---

```
super.onLocationAvailability(avail);

    // unused
}
};
```

(from [Location/LocationPeriodic/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

In `onLocationResult()`, we get a `LocationResult`, rather than a simple `Location` object as we did before. Regardless, we can get that `Location` via `getLastLocation()`. If we have our fragment and we have our location, we tell the fragment to fetch the forecast for that location. The `onLocationAvailability()` method would let us know if our ability to obtain locations changes (e.g., user disables GPS); for this sample, we ignore that.

The `Looper` indicates the thread on which we want to receive the `onLocationResult()` call. In this case, we want to get that call on the main application thread, so we use `Looper.getMainLooper()` to get the `Looper` tied to that thread. Otherwise, we could fork a separate `HandlerThread` and use its `Looper` to get calls delivered on that particular thread.

If you call `requestLocationUpdates()`, you also need to call `removeLocationUpdates()` passing in the same `LocationCallback` object (or an equivalent `PendingIntent` to the original one, if you used that flavor of `requestLocationUpdates()`). In this case, we do that in `onStop()`, and we re-request location updates in `onStart()` if we have our `FusedLocationProviderClient` object already:

```
@Override
protected void onStart() {
    super.onStart();

    if (client!=null && request==null) {
        findLocation();
    }
}

@Override
protected void onStop() {
    client.removeLocationUpdates(cb);
    request=null;

    super.onStop();
}
```

## THE FUSED LOCATION PROVIDER

---

(from [Location/LocationPeriodic/app/src/main/java/com/commonsware/android/weather2/WeatherDemo.java](#))

We use the request object as a flag to indicate whether or not we need to request the updates. For example, if `onReady()` is triggered as a part of `onCreate()`, we will have requested location updates already by the time `onStart()` is called.

As before, this sample app is less-than-optimal in its handling of configuration changes. Everything works, but we wind up re-requesting location updates on each configuration change.

# Working with the Clipboard

---

Being able to copy and paste is something that mobile device users seem to want almost as much as their desktop brethren. Most of the time, we think of this as copying and pasting text, but one could copy and paste other things, such as `Uri` values pointing to more elaborate forms of content.

In this chapter, we will explore how to work with the modern clipboard APIs. Here, “modern” refers to `android.content.ClipboardManager`. Android 1.x and 2.x used `android.text.ClipboardManager`, which still exists in the Android SDK for backwards-compatibility reasons. However, most modern development should use `android.content.ClipboardManager`.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Working with the Clipboard

`ClipboardManager` can be obtained via a call to `getSystemService()` on any handy `Context`.

The old Android 1.x/2.x API was dominated by three methods, all focused on plain text:

- `setText()`, to put text on the clipboard
- `hasText()`, to indicate if the clipboard has something on it
- `getText()`, to retrieve the text on the clipboard

## WORKING WITH THE CLIPBOARD

---

Those methods still exist, but they have been deprecated as of API Level 11.

Their replacements are:

- `setPrimaryClip()`, to put something on the clipboard
- `hasPrimaryClip()`, to indicate if the clipboard has something on it
- `getPrimaryClip()`, to retrieve something from the clipboard

Here, the “something” winds up being in the form of `ClipData` objects, which can hold:

1. plain text
2. a `Uri` (e.g., to a piece of music)
3. an `Intent`

The `Uri` means that you can put anything on the clipboard that can be referenced by a `Uri`... and if there is nothing in Android that lets you reference some data via a `Uri`, you can invent your own content provider to handle that chore for you.

Furthermore, a single `ClipData` can actually hold as many of these as you want, each represented as individual `ClipData.Item` objects. As such, the possibilities are endless.

There are static factory methods on `ClipData`, such as `newUri()`, that you can use to create your `ClipData` objects. In fact, that is what we use in the [SystemServices/ClipMusic](#) sample project and the `MusicClipper` activity.

`MusicClipper` has the classic two-big-button layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="horizontal"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <Button android:id="@+id/pick"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:layout_weight="1"
        android:text="Pick"
        android:onClick="pickMusic"
    />
    <Button android:id="@+id/view"
        android:layout_width="match_parent"
```

## WORKING WITH THE CLIPBOARD

---

```
    android:layout_height="match_parent"
    android:layout_weight="1"
    android:text="Play"
    android:onClick="playMusic"
  />
</LinearLayout>
```

(from [SystemServices/ClipMusic/app/src/main/res/layout-land/main.xml](#))

*Figure 831: The Music Clipper main screen*

In `onCreate()`, we get our hands on our `ClipboardManager` system service:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    clipboard=(ClipboardManager) getSystemService(CLIPBOARD_SERVICE);
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonware/android/clip/music/MusicClipper.java](#))

Tapping the “Pick” button will let you pick a piece of music, courtesy of the `pickMusic()` method wired to that `Button` object:

## WORKING WITH THE CLIPBOARD

```
public void pickMusic(View v) {
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);

    i.setType("audio/*");
    startActivityForResult(i, PICK_REQUEST);
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

Here, we tell Android to let us pick a piece of music from any available audio MIME type (audio/\*). Fortunately, Android has an activity that lets us do that:

Figure 832: The XOOM tablet's music track picker

We get the result in `onActivityResult()`, since we used `startActivityForResult()` to pick the music. There, we package up the `content://Uri` to the music into a `ClipData` object and put it on the clipboard:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode == PICK_REQUEST) {
        if (resultCode == RESULT_OK) {
            ClipData clip=
```

## WORKING WITH THE CLIPBOARD

---

```
        ClipData.newUri(getContentResolver(), "Some music",
                        data.getData());

    try {
        clipboard.setPrimaryClip(clip);
    }
    catch (Exception e) {
        Log.e(getClass().getSimpleName(), "Exception clipping Uri", e);
        Toast.makeText(this, "Exception: " + e.getMessage(),
                       Toast.LENGTH_SHORT).show();
    }
}
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

Note that there is a significant bug in Android 4.3 that, until it is fixed, will require you to do a bit more error-handling with your clipboard operations. That is why we have our `setPrimaryClip()` call wrapped in a try/catch block, even though `setPrimaryClip()` does not throw a checked exception. The rationale for this will be discussed [later in this chapter](#).

The catch with rich data on the clipboard is that somebody has to know about the sort of information you are placing on the clipboard. Eventually, the Android development community will work out common practices in this area. Right now, though, you can certainly use it within your own application (e.g., clipping a note and pasting it into another folder).

Since putting `ClipData` onto the clipboard involves a call to `setPrimaryClip()`, it should not be surprising that the reverse operation — getting a `ClipData` from the clipboard — uses `getPrimaryClip()`. However, since you do not know where this clip came from, you need to validate that it has what you expect and to let the user know when the clipboard contents are not something you can leverage.

The “Play” button in our UI is wired to a `playMusic()` method. This will only work when we have pasted a `Uri ClipData` to the clipboard pointing to a piece of music. Since we cannot be sure that the user has done that, we have to sniff around:

```
public void playMusic(View v) {
    ClipData clip=clipboard.getPrimaryClip();

    if (clip == null) {
        Toast.makeText(this, "There is no clip!", Toast.LENGTH_LONG)
    }
}
```

```
        .show();
    }
    else {
        ClipData.Item item=clip.getItemAt(0);
        Uri song=item.getUri();

        if (song != null
            && getContentResolver().getType(song).startsWith("audio/")) {
            startActivity(new Intent(Intent.ACTION_VIEW, song));
        }
        else {
            Toast.makeText(this, "There is no song!", Toast.LENGTH_LONG)
                .show();
        }
    }
}
```

(from [SystemServices/ClipMusic/app/src/main/java/com/commonsware/android/clip/music/MusicClipper.java](#))

First, there may be nothing on the clipboard, in which case the `ClipData` returned by `getPrimaryClip()` would be `null`. Or, there may be stuff on the clipboard, but it may not have a `Uri` associated with it (`getUri()` on `ClipData`). Even then, the `Uri` may point to something other than music, so even if we get a `Uri`, we need to use a `ContentResolver` to check the MIME type (`getContentResolver().getType()`) and make sure it seems like it is music (e.g., starts with `audio/`). Then, and only then, does it make sense to try to start an `ACTION_VIEW` activity on that `Uri` and hope that something useful happens. Assuming you clipped a piece of music with the “Pick” button, “Play” will kick off playback of that song.

## ClipData and Drag-and-Drop

API Level 11 also introduced Android’s first built-in drag-and-drop framework. One might expect that this would be related entirely to `View` and `ViewGroup` objects and have nothing to do with the clipboard. In reality, the drag-and-drop framework leverages `ClipData` to say what it is that is being dragged and dropped. You call `startDrag()` on a `View`, supplying a `ClipData` object, along with some objects to help render the “shadow” that is the visual representation of this drag operation. A `View` that can receive objects “dropped” via drag-and-drop needs to register an `OnDragListener` to receive drag events as the user slides the shadow over the top of the `View` in question. If the user lifts their finger, thereby dropping the shadow, the recipient `View` will get an `ACTION_DROP` drag event, and can get the `ClipData` out of the event.

[The chapter on drag-and-drop](#) goes into this in much greater detail.

## Monitoring the Clipboard

API Level 11 added the capability for an app to monitor what is put on the clipboard, including things put on the clipboard by other apps.

This is a somewhat esoteric feature, but one that perhaps has some valid use cases. Mostly, it would be used by something *not* in the foreground, since the foreground activity is probably what is adding material to the clipboard. A service, or perhaps an activity that has moved to the background, could use this feature to find out about new clipboard entries.

To monitor the clipboard, you simply call `addPrimaryClipChangedListener()` on `ClipboardMonitor`, passing an implementation of an `OnPrimaryClipChangedListener` interface. That object, in turn, will be called with `onPrimaryClipChanged()` whenever there is a new clipboard entry. Later on, you can call `removePrimaryClipChangedListener()` to stop being notified about new clipboard entries.

For example, here is `MainActivity` from the [SystemServices/ClipboardMonitor](#) sample project:

```
package com.commonware.android.clipmon;

import android.app.Activity;
import android.content.ClipboardManager;
import android.content.ClipboardManager.OnPrimaryClipChangedListener;
import android.os.Bundle;
import android.widget.TextView;

public class MainActivity extends Activity implements
    OnPrimaryClipChangedListener {
    private ClipboardManager cm=null;
    private TextView lastClip=null;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        lastClip=(TextView)findViewById(R.id.last_clip);
        cm=(ClipboardManager) getSystemService(CLIPBOARD_SERVICE);
```

## WORKING WITH THE CLIPBOARD

---

```
}

@Override
public void onStart() {
    super.onStart();
    cm.addPrimaryClipChangedListener(this);
}

@Override
public void onStop() {
    cm.removePrimaryClipChangedListener(this);
    super.onStop();
}

@Override
public void onPrimaryClipChanged() {
    lastClip.setText(cm.getPrimaryClip().getItemAt(0)
        .coerceToText(this));
}
}
```

(from [SystemServices/ClipboardMonitor/app/src/main/java/com/commonsware/android/clipmon/MainActivity.java](#))

Here, we:

- Retrieve the ClipboardManager in onCreate()
- Register for clipboard events via addPrimaryClipChangedListener() in onStart()
- Unregister from clipboard events via removePrimaryClipChangedListener() in onStop()
- Convert the first item (getItemAt(0)) of the primary clip (getPrimaryClip()) to text (coerceToText(this)), and stuff the results into a TextView

In theory, this activity will display new clipboard entries as they arrive. In practice, it will only do so while it is in the foreground, and so it would require something in the background to add something to the clipboard. That is not a particularly useful example... except to test the bug outlined in the next section.

## The Android 4.3 Clipboard Bug

[AndroidPolice](#) reported on [a fairly unpleasant bug in Android 4.3](#). While this bug was fixed in Android 4.4, there is little evidence that Google will be releasing a fix for Android 4.3 devices, which means that this problem will plague developers into 2015

and perhaps beyond.

The bug stems from [the clipboard monitoring facility](#). If an app has used `addPrimaryClipChangedListener()`, *any other app* that tries to paste to the clipboard will crash.

The first crash will be a `SecurityException`:

```
java.lang.SecurityException: uid ... does not have
android.permission.UPDATE_APP_OPS_STATS
```

The second and subsequent times this occurs on the device, it will be an `IllegalStateException`:

```
java.lang.IllegalStateException: beginBroadcast() called while already
in a broadcast
```

The only resolution is to unregister the clipboard listener... and hope that the first crash has not occurred. If it has, a **full reboot of the device is required** to fix the broken system.

### If Your App Monitors the Clipboard...

If you have a component, such as a long-running service, that is monitoring the clipboard, please ensure that the users have an easy way to stop that behavior, even if it means stopping your whole service. While this may mean that your app has seriously degraded functionality, the alternative is that the user has to keep rebooting their device while your app is installed.

### If Your App Pastes to the Clipboard...

If you are pasting to the clipboard, with `setPrimaryClip()` or the older `setText()`, you will want to throw a try/catch block around those calls, so you catch the `RuntimeExceptions` that will be thrown.

However, you will need to tell your users that they are now fairly well screwed, needing to both find the clipboard-monitoring app and learn how to control it (or uninstall/disable it, if needed), plus reboot their device, in order to paste to the clipboard again.

# Telephony

---

Many, if not most, Android devices will be phones. As such, not only will users be expecting to place and receive calls using Android, but you will have the opportunity to help them place calls, if you wish.

Why might you want to?

1. Maybe you are writing an Android interface to a sales management application (a la Salesforce.com) and you want to offer users the ability to call prospects with a single button click, and without them having to keep those contacts both in your application and in the phone's contacts application
2. Maybe you are writing a social networking application, and the roster of phone numbers that you can access shifts constantly, so rather than try to "sync" the social network contacts with the phone's contact database, you let people place calls directly from your application
3. Maybe you are creating an alternative interface to the existing contacts system, perhaps for users with reduced motor control (e.g., the elderly), sporting big buttons and the like to make it easier for them to place calls

Whatever the reason, Android has the means to let you manipulate the phone just like any other piece of the Android system.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on working with multiple activities](#).

## Report To The Manager

To get at much of the phone API, you use the `TelephonyManager`. That class lets you do things like:

1. Determine if the phone is in use via `getCallState()`, with return values of `CALL_STATE_IDLE` (phone not in use), `CALL_STATE_RINGING` (call requested but still being connected), and `CALL_STATE_OFFHOOK` (call in progress)
2. Find out the SIM ID (IMSI) via `getSubscriberId()`
3. Find out the phone type (e.g., GSM) via `getPhoneType()` or find out the data connection type (e.g., GPRS, EDGE) via `getNetworkType()`

## You Make the Call!

You can also initiate a call from your application, such as from a phone number you obtained through your own Web service. To do this, simply craft an `ACTION_DIAL` Intent with a `Uri` of the form `tel:NNNNN` (where `NNNNN` is the phone number to dial) and use that Intent with `startActivity()`. This will not actually dial the phone; rather, it activates the dialer activity, from which the user can then press a button to place the call.

For example, let's look at the [Phone/Dialer](#) sample application. Here's the crude-but-effective layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <LinearLayout
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        >
        <TextView
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Number to dial:"
            />
        <EditText android:id="@+id/number"
            android:layout_width="match_parent"
```

## TELEPHONY

---

```
        android:layout_height="wrap_content"
        android:cursorVisible="true"
        android:editable="true"
        android:singleLine="true"
    />
</LinearLayout>
<Button android:id="@+id/dial"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_weight="1"
        android:text="Dial It!"
        android:onClick="dial"
    />
</LinearLayout>
```

(from [Phone/Dialer/app/src/main/res/layout/main.xml](#))

We have a labeled field for typing in a phone number, plus a button for dialing said number.

The Java code simply launches the dialer using the phone number from the field:

```
package com.commonware.android.dialer;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.view.View;
import android.widget.EditText;

public class DialerDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);
    }

    public void dial(View v) {
        EditText number=(EditText)findViewById(R.id.number);
        String toDial="tel:"+number.getText().toString();

        startActivity(new Intent(Intent.ACTION_DIAL, Uri.parse(toDial)));
    }
}
```

(from [Phone/Dialer/app/src/main/java/com/commonware/android/dialer/DialerDemo.java](#))

The activity's own UI is not that impressive:

*Figure 833: The DialerDemo sample application, as initially launched*

However, the dialer you get from clicking the dial button is better, showing you the number you are about to dial:

Figure 834: The Android Dialer activity, as launched from DialerDemo

## No, Really, You Make the Call!

The good news is that `ACTION_DIAL` works without any special permissions. The bad news is that it only takes the user to the Dialer – the user still has to take action (pressing the green call button) to actually place the phone call.

An alternative approach is to use `ACTION_CALL` instead of `ACTION_DIAL`. Calling `startActivity()` on an `ACTION_CALL` Intent will immediately place the phone call, without any other UI steps required. However, you need the `CALL_PHONE` [permission](#) in order to use `ACTION_CALL`.

# Working With SMS

---

Oh, what a tangled web we weave

When first we practice to work with SMS on Android, Eve

(with apologies to [Sir Walter Scott](#))

Android devices have had SMS capability since Android 1.0. However, from a programming standpoint, for years, SMS and Android were intensely frustrating. When the Android SDK was developed, some aspects of working with SMS were put into the SDK, while others were held back. This, of course, did not stop many an intrepid developer from working with the undocumented, unsupported SMS APIs, with varying degrees of success.

After much wailing and gnashing of teeth by developers, Google finally formalized a more complete SMS API in Android 4.4. However, this too has its issues, where some apps that worked fine with the undocumented API will now fail outright, in irreparable fashion, on Android 4.4+.

This chapter starts with the one thing you can do reasonably reliably across Android device versions – [send an SMS](#), either directly or by invoking the user's choice of SMS client. The chapter then examines how to monitor or receive SMS messages (both pre-4.4 and 4.4+) and the SMS-related ContentProvider (both pre-4.4 and 4.4+).

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on [broadcast Intents](#). One of the samples uses [the](#)

[ContactsContract provider](#), so reading that chapter will help you understand that particular sample.

## Sending Out an SOS, Give or Take a Letter

While much of Android's SMS capabilities are not in the SDK, sending an SMS is. You have two major choices for doing this:

- Invoke the user's choice of SMS client application, so they can compose a message, track its progress, and so forth using that tool
- Send the SMS directly yourself, bypassing any existing client

Which of these is best for you depends on what your desired user experience is. If you are composing the message totally within your application, you may want to just send it. However, as we will see, that comes at a price: an extra permission.

### Sending Via the SMS Client

Sending an SMS via the user's choice of SMS client is very similar to the use of ACTION\_SEND described [elsewhere in this book](#). You craft an appropriate Intent, then call startActivity() on that Intent to bring up an SMS client (or allow the user to choose between clients).

The Intent differs a bit from the ACTION\_SEND example:

1. You use ACTION\_SENDTO, rather than ACTION\_SEND
2. Your Uri needs to begin with smsto:, followed by the mobile number you want to send the message to
3. Your text message goes in an sms\_body extra on the Intent

For example, here is a snippet of code from the [SMS/Sender](#) sample project:

```
Intent sms=new Intent(Intent.ACTION_SENDTO,
                    Uri.parse("smsto:"+c.getString(2)));

sms.putExtra("sms_body", msg.getText().toString());

startActivity(sms);
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/Sender.java](#))

Here, our phone number is coming out of the third column of a Cursor, and the text

message is coming from an `EditText` — more on how this works later in this section, when we review the `Sender` sample more closely.

### Sending SMS Directly

If you wish to bypass the UI and send an SMS directly, you can do so through the `SmsManager` class, in the `android.telephony` package. Unlike most Android classes ending in `Manager`, you obtain an `SmsManager` via a static `getDefault()` method on the `SmsManager` class. You can then call `sendTextMessage()`, supplying:

1. The phone number to send the text message to
2. The “service center” address — leave this `null` unless you know what you are doing
3. The actual text message
4. A pair of `PendingIntent` objects to be executed when the SMS has been sent and delivered, respectively

If you are concerned that your message may be too long, use `divideMessage()` on `SmsManager` to take your message and split it into individual pieces. Then, you can use `sendMultipartTextMessage()` to send the entire `ArrayList` of message pieces.

For this to work, your application needs to hold the `SEND_SMS` permission, via a child element of your `<manifest>` element in your `AndroidManifest.xml` file.

For example, here is code from `Sender` that uses `SmsManager` to send the same message that the previous section sent via the user’s choice of SMS client:

```
SmsManager
    .getDefault()
    .sendTextMessage(c.getString(2), null,
                    msg.getText().toString(),
                    null, null);
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/Sender.java](#))

### Inside the Sender Sample

The `Sender` example application is fairly straightforward, given the aforementioned techniques.

The manifest has both the `SEND_SMS` and `READ_CONTACTS` permissions, because we want to allow the user to pick a mobile phone number from their list of contacts,

rather than type one in by hand:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.sender"
    android:installLocation="preferExternal"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission android:name="android.permission.READ_CONTACTS"/>
    <uses-permission android:name="android.permission.SEND_SMS"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name">
        <activity
            android:name="Sender"
            android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [SMS/Sender/app/src/main/AndroidManifest.xml](#))

If you noticed the `android:installLocation` attribute in the root element, that is to allow this application to be installed onto external storage, such as an SD card.

The layout has a `Spinner` (for a drop-down of available mobile phone numbers), a pair of `RadioButton` widgets (to indicate which way to send the message), an `EditText` (for the text message), and a “Send” Button:

```
<?xml version="1.0" encoding="utf-8"?>
```

---

## WORKING WITH SMS

---

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
>
    <Spinner android:id="@+id/spinner"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:drawSelectorOnTop="true"
    />
    <RadioGroup android:id="@+id/means"
        android:orientation="horizontal"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
    >
        <RadioButton android:id="@+id/client"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:checked="true"
            android:text="Via Client" />
        <RadioButton android:id="@+id/direct"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Direct" />
    </RadioGroup>
    <EditText
        android:id="@+id/msg"
        android:layout_width="match_parent"
        android:layout_height="0px"
        android:layout_weight="1"
        android:singleLine="false"
        android:gravity="top|left"
    />
    <Button
        android:id="@+id/send"
        android:text="Send!"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:onClick="sendMessage"
    />
</LinearLayout>
```

(from [SMS/Sender/app/src/main/res/layout/main.xml](#))

Sender uses the same technique for obtaining mobile phone numbers from our contacts as is seen in the [chapter on contacts](#). To support Android 1.x and Android 2.x devices, we implement an abstract class and two concrete implementations, one

## WORKING WITH SMS

---

for the old API and one for the new. The abstract class then has a static method to get at an instance suitable for the device the code is running on:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.os.Build;
import android.widget.SpinnerAdapter;

abstract class ContactsAdapterBridge {
    abstract SpinnerAdapter buildPhonesAdapter(Activity a);

    public static final ContactsAdapterBridge INSTANCE=buildBridge();

    private static ContactsAdapterBridge buildBridge() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();

        if (sdk<5) {
            return(new OldContactsAdapterBridge());
        }

        return(new NewContactsAdapterBridge());
    }
}
```

(from [SMS/Sender/app/src/main/java/com/commonware/android/sms/sender/ContactsAdapterBridge.java](#))

The Android 2.x edition uses ContactsContract to find just the mobile numbers:

```
package com.commonware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.ContactsContract.Contacts;
import android.provider.ContactsContract.CommonDataKinds.Phone;
import android.widget.SpinnerAdapter;
import android.widget.SimpleCursorAdapter;

class NewContactsAdapterBridge extends ContactsAdapterBridge {
    SpinnerAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts._ID,
                                           Contacts.DISPLAY_NAME,
                                           Phone.NUMBER
                                           };
        String[] ARGS={String.valueOf(Phone.TYPE_MOBILE)};
        Cursor c=a.managedQuery(Phone.CONTENT_URI,
                               PROJECTION, Phone.TYPE+"=?",
```

## WORKING WITH SMS

---

```
        ARGS, Contacts.DISPLAY_NAME);

SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
        android.R.layout.simple_spinner_item,
        c,
        new String[] {
            Contacts.DISPLAY_NAME
        },
        new int[] {
            android.R.id.text1
        });

adapter.setDropDownViewResource(
        android.R.layout.simple_spinner_dropdown_item);

return(adapter);
}
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/NewContactsAdapterBridge.java](#))

... while the Android 1.x edition uses the older Contacts provider to find the mobile numbers:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.database.Cursor;
import android.provider.Contacts;
import android.widget.SimpleCursorAdapter;
import android.widget.SpinnerAdapter;

@SuppressWarnings("deprecation")
class OldContactsAdapterBridge extends ContactsAdapterBridge {
    SpinnerAdapter buildPhonesAdapter(Activity a) {
        String[] PROJECTION=new String[] { Contacts.Phones._ID,
            Contacts.Phones.NAME,
            Contacts.Phones.NUMBER
        };

        String[] ARGS={String.valueOf(Contacts.Phones.TYPE_MOBILE)};
        Cursor c=a.managedQuery(Contacts.Phones.CONTENT_URI,
            PROJECTION,
            Contacts.Phones.TYPE+"=?", ARGS,
            Contacts.Phones.NAME);

        SimpleCursorAdapter adapter=new SimpleCursorAdapter(a,
            android.R.layout.simple_spinner_item,
            c,
```

## WORKING WITH SMS

---

```
        new String[] {
            Contacts.Phones.NAME
        },
        new int[] {
            android.R.id.text1
        });

adapter.setDropDownViewResource(
    android.R.layout.simple_spinner_dropdown_item);

return(adapter);
}
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/OldContactsAdapterBridge.java](#))

For more details on how those providers work, please see the [chapter on contacts](#).

The activity then loads up the Spinner with the appropriate list of contacts. When the user taps the Send button, the `sendMessage()` method is invoked (courtesy of the `android:onClick` attribute in the layout). That method looks at the radio buttons, sees which one is selected, and routes the text message accordingly:

```
package com.commonsware.android.sms.sender;

import android.app.Activity;
import android.content.Intent;
import android.database.Cursor;
import android.net.Uri;
import android.os.Bundle;
import android.telephony.SmsManager;
import android.view.View;
import android.widget.EditText;
import android.widget.RadioGroup;
import android.widget.Spinner;

public class Sender extends Activity {
    Spinner contacts=null;
    RadioGroup means=null;
    EditText msg=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        contacts=(Spinner)findViewById(R.id.spinner);
```

```
contacts.setAdapter(ContactsAdapterBridge
    .INSTANCE
    .buildPhonesAdapter(this));

means=(RadioGroup)findViewById(R.id.means);
msg=(EditText)findViewById(R.id.msg);
}

public void sendTheMessage(View v) {
    Cursor c=(Cursor)contacts.getSelectedItemAt();

    if (means.isCheckedRadioButtonId()==R.id.client) {
        Intent sms=new Intent(Intent.ACTION_SENDTO,
            Uri.parse("smsto:"+c.getString(2)));

        sms.putExtra("sms_body", msg.getText().toString());

        startActivity(sms);
    }
    else {
        SmsManager
            .getDefault()
            .sendTextMessage(c.getString(2), null,
                msg.getText().toString(),
                null, null);
    }
}
}
```

(from [SMS/Sender/app/src/main/java/com/commonsware/android/sms/sender/Sender.java](#))

### SMS Sending Limitations

Apps running on Android 1.x and 2.x devices are limited to sending 100 SMS messages an hour, before the user starts getting prompted with each SMS message request to confirm that they do indeed wish to send it.

Apps running on Android 4.x devices, the limits are now 30 SMS messages in 30 minutes, [according to some source code analysis by Al Sutton](#).

### Monitoring and Receiving SMS

For the purposes of this section, “monitoring” refers to the ability to inspect incoming SMS messages, including reading their contents. In contrast, “receiving”

SMS messages is actually consuming the message and storing it somewhere for the user to use.

As it turns out, “monitoring” and “receiving” are much the same thing prior to Android 4.4, but are significantly different in the new API made available in Android 4.4

### **The Undocumented, Unsupported, Pre-Android 4.4 Way**

It is possible for an application to monitor or receive an incoming SMS message... if you are willing to listen on the undocumented `android.provider.Telephony.SMS_RECEIVED` broadcast Intent. That is sent by Android whenever an SMS arrives, and it is up to an application to implement a `BroadcastReceiver` to respond to that Intent and do something with the message. The Android open source project has such an application — `Messaging` — and device manufacturers can replace it with something else.

Note that to listen for this broadcast, your app must hold the `RECEIVE_SMS` permission.

The `BroadcastReceiver` can then turn around and use the `SmsMessage` class, in the `android.telephony` package, to get at the message itself, through the following undocumented recipe:

1. Given the received Intent (`intent`), call `intent.getExtras().get("pdus")` to get an `Object` array representing the raw portions of the message
2. For each of those “pdus” objects, call `SmsMessage.createFromPdu()` to convert the `Object` into an `SmsMessage` — though to make this work, you need to cast the `Object` to a byte array as part of passing it to the `createFromPdu()` static method

The resulting `SmsMessage` object gets you access to the text of the message, the sending phone number, etc.

The `SMS_RECEIVED` broadcast Intent is broadcast a bit differently than most others in Android. It is an “ordered broadcast”, meaning the Intent will be delivered to one `BroadcastReceiver` at a time. This has two impacts of note:

- In your receiver’s `<intent-filter>` element, you can have an `android:priority` attribute. Higher priority values get access to the broadcast Intent earlier than will lower priority values. The standard

## WORKING WITH SMS

---

Messaging application has the default priority (undocumented, appears to be 0 or 1), so you can arrange to get access to the SMS before the application does.

- Your `BroadcastReceiver` can call `abortBroadcast()` on itself to prevent the Intent from being broadcast to other receivers of lower priority. In effect, this causes your receiver to consume the SMS — the Messaging application will not receive it. So, aborting the broadcast means that your app chose to “receive” the SMS; not aborting the broadcast means that your app is merely “monitoring” the SMS messages that come in.

However, just because the Messaging application has the default priority does not mean all SMS clients will, and so you cannot reliably intercept SMS messages this way. That, plus the undocumented nature of all of this, means that applications you write to receive SMS messages are likely to be fragile in production, breaking on various devices due to device manufacturer-installed apps, third-party apps, or changes to Android itself... such as the changes that came about in Android 4.4.

### The Android 4.4+ Way: Monitoring SMS

The code described above still works on Android 4.4, though the formerly-hidden `android.provider.Telephony` class is now part of the SDK.

The biggest difference, though, is that even if you call `abortBroadcast()`, the user’s chosen SMS messaging client will still receive the message. It is not possible for an app listening for `SMS_RECEIVED` broadcasts to prevent the user’s chosen SMS messaging client from receiving those same messages. This is a substantial change, one that will break or make obsolete many Android applications.

Regardless, if monitoring SMS fits your needs, `SMS_RECEIVED` can do it.

So, for example, the [SMS/Monitor](#) sample project implements a `BroadcastReceiver` for `SMS_RECEIVED`, one with slightly elevated priority:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
package="com.commonware.android.sms.monitor" android:versionCode="1" android:versionName="1.0">

  <supports-screens android:largeScreens="true" android:normalScreens="true" android:smallScreens="false"/>

  <uses-permission android:name="android.permission.RECEIVE_SMS"/>

  <uses-sdk android:minSdkVersion="4" android:targetSdkVersion="19"/>

  <application android:icon="@drawable/ic_launcher" android:label="@string/app_name">
    <receiver android:name="Monitor" android:permission="android.permission.BROADCAST_SMS">
```

## WORKING WITH SMS

---

```
<intent-filter android:priority="2">
  <action android:name="android.provider.Telephony.SMS_RECEIVED"/>
</intent-filter>
</receiver>

<activity android:name="BootstrapActivity" android:theme="@android:style/Theme.Translucent.NoTitleBar">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity>
</application>
</manifest>
```

(from [SMS/Monitor/app/src/main/AndroidManifest.xml](#))

You will notice that the `BroadcastReceiver` not only has the slightly-elevated priority (`android:priority="2"`), but also a required permission (`android:permission="android.permission.BROADCAST_SMS"`). Only apps that hold this permission can send this broadcast in a way that will be picked up by the receiver. Since this permission can only be held by the device firmware, you are protected from “spoof” SMS messages from rogue apps on the device, sending the `SMS_RECEIVED` themselves.

The app also has a do-nothing activity, solely there to activate the manifest-registered `BroadcastReceiver`, which will not work until some component of the app is manually started.

The bulk of the business logic — what little there is of it — lies in the `Monitor` class that is the `BroadcastReceiver`:

```
package com.commonsware.android.sms.monitor;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.telephony.SmsMessage;
import android.util.Log;

public class Monitor extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Object[] rawMsgs=(Object[])intent.getExtras().get("pdu");

        for (Object raw : rawMsgs) {
            SmsMessage msg=SmsMessage.createFromPdu((byte[])raw);
```

---

## WORKING WITH SMS

---

```
    if (msg.getMessageBody().toUpperCase().contains("SEKRIT")) {
        Log.w("SMS:" + msg.getOriginatingAddress(),
            msg.getMessageBody());

        abortBroadcast();
    }
}
```

(from [SMS/Monitor/app/src/main/java/com/commonsware/android/sms/monitor/Monitor.java](#))

Here, we retrieve the raw messages from the Intent extra, iterate over them, and convert each to an `SmsMessage`. Those that have the magic word in their message body will result in the message being dumped to Logcat, plus the broadcast is aborted. On Android 4.3 and below, this will prevent lower-priority receivers from receiving the SMS. On Android 4.4, the abort request is ignored.

### The Android 4.4+ Way: Receiving SMS

Receiving SMS messages, on Android 4.4+, means that you are implementing an SMS client application, one the user might be willing to set as their default SMS client application in Settings. There are other sorts of apps that may temporarily want to be the default SMS client, such as a backup/restore utility, as only the default SMS client will be able to work with the SMS ContentProvider suite, such as the inbox.

#### Receiving the Broadcasts

The default SMS client should be able to handle both SMS and MMS. This is a problem, as while supporting SMS is poorly documented, supporting MMS has almost no documentation whatsoever. However, unless the default SMS client handles MMS, nobody else can (at least, while saving MMS details to the ContentProvider suite).

Hence, Google is expecting you to have two `BroadcastReceivers` registered in the manifest: one for SMS and one for MMS. Unfortunately, these cannot readily be combined into a single receiver, because each has its own permission requirement:

- the SMS receiver should require senders to hold `BROADCAST_SMS`
- the MMS receiver should require senders to hold `BROADCAST_WAP_PUSH`

---

## WORKING WITH SMS

---

In practice, probably both are held by the OS component that is sending these broadcasts in response to incoming messages of either type. In principle, though, they could be separate, and an individual `<receiver>` can only specify one such permission.

[The Android documentation](#) illustrates the `<receiver>` elements that Google expects your SMS client application to have:

```
<!-- BroadcastReceiver that listens for incoming SMS messages -->
<receiver android:name=".SmsReceiver"
    android:permission="android.permission.BROADCAST_SMS">
    <intent-filter>
        <action android:name="android.provider.Telephony.SMS_DELIVER" />
    </intent-filter>
</receiver>

<!-- BroadcastReceiver that listens for incoming MMS messages -->
<receiver android:name=".MmsReceiver"
    android:permission="android.permission.BROADCAST_WAP_PUSH">
    <intent-filter>
        <action android:name="android.provider.Telephony.WAP_PUSH_DELIVER" />
        <data android:mimeType="application/vnd.wap.mms-message" />
    </intent-filter>
</receiver>
```

Notice that the MMS receiver has both an `<action>` and a `<data>` element in its `<intent-filter>`, which is rather unusual.

On the SMS side, the Intent you receive should be the same as the Intent you would receive for the `SMS_RECEIVED` broadcast, where you can decode the message(s) and deal with them as you see fit. On the MMS side... there is little documentation.

### Other Expectations

Google expects the default SMS client to be able to handle `ACTION_SEND` and `ACTION_SENDTO` for relevant schemes:

```
<!-- Activity that allows the user to send new SMS/MMS messages -->
<activity android:name=".ComposeSmsActivity" >
    <intent-filter>
        <action android:name="android.intent.action.SEND" />
        <action android:name="android.intent.action.SENDTO" />
        <category android:name="android.intent.category.DEFAULT" />
        <category android:name="android.intent.category.BROWSABLE" />
    </intent-filter>
</activity>
```

## WORKING WITH SMS

---

```
<data android:scheme="sms" />
<data android:scheme="smsto" />
<data android:scheme="mms" />
<data android:scheme="mmsto" />
</intent-filter>
</activity>
```

That may not be terribly surprising. What *is* surprising is that Google also expects you to have an exported *service* for handling “quick response” requests. These requests come when the user receives a phone call and taps on an icon to reply with a text message, rather than accept the call. In those cases, Android will invoke a service in the default SMS client, with an action of `android.intent.action.RESPOND_VIA_MESSAGE`. The Intent that you receive in `onStartCommand()` (or `onHandleIntent()`, if you elect to use an `IntentService`) will have an `EXTRA_TEXT` and optionally an `EXTRA_SUBJECT` as extras, representing the message to be sent. The `Uri` in the Intent will indicate the intended recipient of the message. Your job is to use `SmsManager` to actually send the message.

The Android documentation cites this as the relevant `<service>` element:

```
<!-- Service that delivers messages from the phone "quick response" -->
<service android:name=".HeadlessSmsSendService"
    android:permission="android.permission.SEND_RESPOND_VIA_MESSAGE"
    android:exported="true" >
    <intent-filter>
        <action android:name="android.intent.action.RESPOND_VIA_MESSAGE" />
        <category android:name="android.intent.category.DEFAULT" />
        <data android:scheme="sms" />
        <data android:scheme="smsto" />
        <data android:scheme="mms" />
        <data android:scheme="mmsto" />
    </intent-filter>
</service>
```

Note:

- The `<service>` requires that the sender have the `SEND_RESPOND_VIA_MESSAGE` permission, to reduce spoofing
- The `android:exported="true"` shown in the sample should be superfluous, as since the `<service>` has an `<intent-filter>`, it should be exported by default
- The `<category>`, and possibly the `<data>`, elements may be erroneous... and since the author cannot find anything in the OS that uses `RESPOND_VIA_MESSAGE`, the author cannot validate that these elements

should be here or represent copy-and-paste errors in the documentation

### Handling Both Receive Options

If you want to support receiving SMS using both the legacy approach and the Android 4.4+ approach, you can have two `BroadcastReceiver` implementations, one for `android.provider.Telephony.SMS_RECEIVED` and one for `android.provider.Telephony.SMS_DELIVER`. However, you will only need the latter one on Android 4.4, and by default you would receive both broadcasts.

To handle that, you can define a boolean resource in the `res/values-v19/` directory (e.g., `isPreKitKat`) to be `false`, with a default definition in `res/values/` of `true` for the same resource. Then, in your manifest, you can have `android:enabled="@bool/isPreKitKat"` on your `SMS_RECEIVED <receiver>` element. This will only enable this component on API Level 18 and below, disabling it on API Level 19+.

You can also define a counterpart resource for the positive case (e.g., `@bool/isKitKat`), and use that to selectively enable the SMS and MMS receivers, if desired.

### The SMS Inbox

Many users keep their text messages around, at least for a while. These are stored in an “inbox”, represented by a `ContentProvider`. How you work with this `ContentProvider` — or if you can work with it at all, varies upon whether you are running on Android 4.4+ or not.

### The Undocumented, Unsupported, Pre-Android 4.4 Way

When perusing the Internet, you will find various blog posts and such referring to the SMS inbox `ContentProvider`, represented by the `content://sms/inbox` `Uri`.

This `ContentProvider` is undocumented and is not part of the Android SDK, because it is not part of the Android OS.

Rather, this `ContentProvider` is used by the aforementioned Messaging application, for storing saved SMS messages. And, as noted, this application may or may not exist on any given Android device. If a device manufacturer replaces Messaging with their own application, there may be nothing on that device that responds to that `Uri`, or the schemas may be totally different. Plus, Android may well change or even remove this `ContentProvider` in future editions of Android.

For all those reasons, developers should not be relying upon this `ContentProvider`.

### The Android 4.4+ Way

Android 4.4 has exposed a series of `ContentProviders`, in the `android.provider.Telephony` namespace, for storing SMS and MMS messages. These include:

- the `Inbox` for received messages
- the `Outbox` for a log of sent messages
- the `Draft` for messages that were written but have not yet been sent
- etc.

Some are duplicated, such as separate providers for the SMS inbox versus the MMS inbox. Some are distinct, such as `Sms.Conversations` and `Mms.Rate`.

All are largely undocumented.

The user's chosen default SMS client can write to these providers. Apps with `READ_SMS` permission should be able to read from them.

### Asking to Change the Default

There are many areas in Android where the user must do two things to use an app:

1. Install the app (from the Play Store or elsewhere)
2. Go into Settings (or sometimes elsewhere) and indicate that a certain capability of the newly-installed app should become active

You see this with app widgets, input method editors, device administrators, and many others.

On Android 4.4+, you also see this with SMS/MMS clients. Devices usually ship with one. If the user wants a replacement, the user must indicate in Settings that this new SMS/MMS client should be the default, so it can write to the SMS/MMS `ContentProvider` suite.

Your app can determine what the default client is by calling `getDefaultSmsPackage()` on the `Telephony.Sms` class. This will return the package name of the current default client.

---

## WORKING WITH SMS

---

If this is not your package, and you would like the user to make you the default, you can start an activity to request this change:

```
Intent i = new Intent(Sms.Intents.ACTION_CHANGE_DEFAULT);
i.putExtra(Sms.Intents.EXTRA_PACKAGE_NAME, getPackageName());
startActivity(i);
```

The EXTRA\_PACKAGE\_NAME will trigger the UI to ask the user if the user wishes to change the current default to your package (versus anything else on the device that might also be a possible SMS/MMS client).

Hence, the recommended flow for a backup/restore app is to:

- Make note of the current default, via getDefaultSmsPackage()
- Request to the user to make you the default, via ACTION\_CHANGE\_DEFAULT
- Confirm that they did this, via getDefaultSmsPackage()
- If they did, do your backup or restore work
- Request to the user to restore the original default, via ACTION\_CHANGE\_DEFAULT

## SMS and the Emulator

The “Emulator Control” view in DDMS allows you to send fake SMS messages to a running emulator. This is very useful for light testing.

You can also send fake SMS messages to an emulator via the emulator console. This can be accessed via `telnet`, where the console is available on localhost on your development machine, via the port number that appears in the title bar of your emulator window (e.g., 5554). In the `telnet` session, you can enter `sms send [sendingNumber> <txt>`, replacing `<sendingNumber>` with the phone number of the pretend sender of the SMS, and replacing `<txt>` with the text message itself.

## SMS Tokens

The changes that Android made in 4.4 to limit who can delete SMS messages all but eliminated one common bit of app functionality: sending an SMS from the server to a user’s device to validate that the user’s phone number is what was expected. This is still possible, but the app can no longer delete that SMS message, meaning that it will clutter up the user’s SMS inbox.

## WORKING WITH SMS

---

Android 8.0+ provides “app-specific SMS tokens”, via a `createAppSpecificSmsToken()` method on `SmsManager`. You supply a `PendingIntent`, and you get a unique string back. If an SMS is received by the device containing that string, the `PendingIntent` is invoked, instead of the message being delivered to the user’s SMS client.

Hence, phone number validation flow is once again possible:

- Call `createAppSpecificSmsToken()` on the `SmsManager`
- Send that token, along with the phone number, to your server
- Have your server trigger an SMS message containing that token, sent to the device

Your `PendingIntent` that you gave to `createAppSpecificSmsToken()` will get triggered as a result, invoking whatever component that you identified in the underlying `Intent`.

The [SMS/Token](#) sample project demonstrates this flow. It consists of two activities: one to show you a generated token, and one that will be displayed when that token is received in an SMS message.

`MainActivity` is responsible for showing you the token:

```
package com.commonware.android.sms.token;

import android.app.Activity;
import android.app.PendingIntent;
import android.content.Intent;
import android.os.Bundle;
import android.telephony.SmsManager;
import android.widget.TextView;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        SmsManager mgr=SmsManager.getDefault();
        String token=mgr.createAppSpecificSmsToken(buildPendingIntent());
        TextView tv=(TextView)findViewById(R.id.text);

        tv.setText(getString(R.string.msg, token));
    }
}
```

## WORKING WITH SMS

---

```
private PendingIntent buildPendingIntent() {  
    return(PendingIntent.getActivity(this, 1337,  
        new Intent(this, ResultActivity.class), 0));  
}  
}
```

(from [SMS/Token/app/src/main/java/com/commonsware/android/sms/token/MainActivity.java](#))

Here, we:

- Get the SmsManager by calling the getDefault() static method
- Build an activity PendingIntent identifying ResultActivity
- Generate an SMS token associated with that PendingIntent
- Display that token as part of a message on the screen

The token itself is not really designed for manual user entry:

*Figure 835: Token Sample App, Showing a Token*

If another device sends an SMS message containing that token (along with perhaps other information), ResultActivity will be displayed:

```
package com.commonsware.android.sms.token;
```

## WORKING WITH SMS

---

```
import android.app.Activity;
import android.app.PendingIntent;
import android.os.Bundle;
import android.provider.Telephony;
import android.telephony.SmsManager;
import android.telephony.SmsMessage;
import android.widget.TextView;

public class ResultActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.activity_main);

        TextView tv=(TextView)findViewById(R.id.text);

        for (SmsMessage pdu :
            Telephony.Sms.Intents.getMessagesFromIntent(getIntent())) {
            tv.append(pdu.getDisplayMessageBody());
        }
    }
}
```

(from [SMS/Token/app/src/main/java/com/commonsware/android/sms/token/ResultActivity.java](https://github.com/CommonWare/android-sms-token/blob/master/app/src/main/java/com/commonsware/android/sms/token/ResultActivity.java))

## WORKING WITH SMS

---

The actual SMS message is included in the Intent extras, filled into a copy of the Intent that you supplied in the PendingIntent. The `getMessagesFromIntent()` method on `Telephony.Sms.Intents` offers a convenient way to get the actual `SmsMessage` objects. Here, we assume that they represent a text message, and we concatenate their messages together to display in a `TextView`:

*Figure 836: Token Sample App, Showing a Received Message with the Token*

Usually, rather than show the token to the user, you will send it programmatically where it needs to go (e.g., a Web service call). Since the SMS message containing the token does not wind up in the user's SMS client, the message containing the token does not need to be human-readable. It does need to contain the token verbatim, without any compression, encryption, or other conversions placed upon it.

Also:

- There can only be one outstanding token per app per device. If you call `createAppSpecificSmsToken()` twice in succession, the first token will be invalidated and ignored.
- A token is only good for one message. If you try sending messages to the device twice with the same token, the second message will be delivered to the user's SMS client, rather than invoke your `PendingIntent`.

## WORKING WITH SMS

---

- For a demo like this sample app, hardware is not required. You can use the emulator's extended controls to send a fake SMS message to the emulator, and that will go through normal SMS processing, including token analysis.

NFC, courtesy of high-profile boosters like Google Wallet, is poised to be a significant new capability in Android devices. While at the time of this writing, only a handful of Android devices have NFC built in, other handsets are slated to be NFC-capable in the coming months. Google is hoping that developers will write NFC-aware applications to help further drive adoption of this technology by device manufacturers.

This, of course, raises the question: what is NFC? Besides being where the Green Bay Packers play, that is?

(For those of you from outside of the United States, that was an American football joke. We now return you to your regularly-scheduled chapter.)

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapters on [broadcast Intents](#) and [services](#).

## What Is NFC?

NFC stands for Near-Field Communications. It is a wireless standard for data exchange, aimed at very short range transmissions — on the order of a couple of centimeters. NFC is in wide use today, for everything from credit cards to passports. Typically, the NFC data exchange is for simple data — contact information, URLs, and the like.

In particular, NFC tends to be widely used where one side of the communications

channel is “passive”, or unpowered. The other side (the “initiator”) broadcasts a signal, which the passive side converts into power enough to send back its response. As such, NFC “tags” containing such passive targets can be made fairly small and can be embedded in a wide range of containers, from stickers to cards to hats.

The objective is “low friction” interaction — no pairing like with Bluetooth, no IP address shenanigans as with WiFi. The user just taps and goes.

### ... Compared to RFID?

NFC is often confused with or compared to RFID. It is simplest to think of RFID as being an umbrella term, under which NFC falls. Not every RFID technology is NFC, but many things that you hear of being “RFID” may actually be NFC-compliant devices or tags.

### ... Compared to QR Codes?

In many places, NFC will be used in ways you might consider using QR codes. For example, a restaurant could use either technology, or both, on a sign to lead patrons to the restaurant’s [Yelp](#) page, as a way of soliciting reviews. Somebody with a capable device could either tap the NFC tag on the sign to bring up Yelp or take a picture of the QR code and use that to bring up Yelp.

NFC’s primary advantage over QR codes is that it requires no user intervention beyond physically moving their device in close proximity to the tag. QR codes, on the other hand, require the user to launch a barcode scanning application, center the barcode in the viewfinder, and then get the results. The net effect is that NFC will be faster.

QR’s advantages include:

1. No need for any special hardware to generate the code, as opposed to needing a tag and something to write information into the tag for NFC
2. The ability to display QR codes in distant locations (e.g., via Web sites), whereas NFC requires physical proximity

## To NDEF, Or Not to NDEF

RFID is a concept, not a standard. As such, different vendors created their own ways of structuring data on these tags or chips, making one vendor’s tags incompatible

with another vendor's readers or writers. While various standards bodies, like ISO, have gotten involved, it's still a bit of a rat's nest of conflicting formats and approaches.

The NFC offshoot of RFID has had somewhat greater success in establishing standards. NFC itself is an ISO and ECMA standard, covering things like transport protocols and transfer speeds. And a consortium called the NFC Forum created NDEF — the NFC Data Exchange Format — for specifying the content of tags.

However, not all NFC tags necessarily support NDEF. NDEF is much newer than NFC, and so lots of NFC tags are out in the wild that were distributed before NDEF even existed.

You can roughly divide NFC tags into three buckets:

- Those that support NDEF “out of the box”
- Those that can be “formatted” as NDEF
- Those that use other content schemes

Android has some support for non-NDEF tags, such as the MIFARE Classic. However, the hope and expectation going forward is that NFC tags will coalesce around NDEF.

NDEF, as it turns out, maps neatly to Android's Intent system, as you will see as we proceed through this chapter.

## NDEF Modalities

Most developers interested in NFC will be interested in reading NFC tags and retrieving the NDEF data off of them. In Android, tapping an NDEF tag with an NFC-capable device will trigger an activity to be started, based on a certain `IntentFilter`.

Some developers will be interested in writing to NFC tags, putting URLs, vCards, or other information on them. This may or may not be possible for any given tag.

And while the “traditional” thinking around NFC has been that one side of the communication is a passive tag, Android will help promote the “peer-to-peer” approach — having two Android devices exchange data via NFC and NDEF. Basically, putting the two devices back-to-back will cause each to detect the other

device's "tag", and each can read and write to the other via this means. This is referred to as "Android Beam" and will be discussed [later in this chapter](#).

Of course, all of these are only available on hardware. At the present time, there is no emulator for NFC, nor any means of accessing a USB NFC reader or writer from the emulator.

## NDEF Structure and Android's Translation

NDEF is made up of messages, themselves made up of a series of records. From Android's standpoint, each tag consists of one such message.

Each record consists of a binary (byte array) payload plus metadata to describe the nature of the payload. The metadata primarily consists of a type and a subtype. There are quite a few combinations of these, but the big three for new Android NFC uses are:

- A type of `TNF_WELL_KNOWN` and a subtype of `RTD_TEXT`, indicating that the payload is simply plain text
- A type of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, indicating that the payload is a URI, such as a URL to a Web page
- A type of `TNF_MIME_MEDIA`, where the subtype is a standard MIME type, indicating that the payload is of that MIME type

When Android scans an NDEF tag, it will use this information to construct a suitable Intent to use with `startActivity()`. The action will be `android.nfc.action.NDEF_DISCOVERED`, to distinguish the scanned-tag case from, say, something simply asking to view some content. The MIME type in the Intent will be `text/plain` for the first scenario above or the supplied MIME type for the third scenario above. The data (`Uri`) in the Intent will be the supplied URI for the second scenario above. Once constructed, Android will invoke `startActivity()` on that Intent, bringing up an activity or an activity chooser, as appropriate.

NFC-capable Android devices have a Tags application pre-installed that will handle any NFC tag not handled by some other app. So, for example, an NDEF tag with an HTTP URL will fire up the Tags application, which in turn will allow the user to open up a Web browser on that URL.

## The Reality of NDEF

The enthusiasm that some have with regards to Android and NFC technology needs to be tempered by the reality of NDEF, NFC tags in general, and Android's support for NFC. It is easy to imagine all sorts of possibilities that may or may not be practical when current limitations are reached.

### Some Tags are Read-Only

Some tags come “from the factory” read-only. Either you arrange for the distributor to write data onto them (e.g., blast a certain URL onto a bunch of NFC stickers to paste onto signs), or they come with some other pre-established data. Touchatag, for example, distributes NFC tags that have Touchatag URLs on them — they then help you set up redirects from their supplied URL to ones you supply.

While these tags will be of interest to consumers and businesses, they are unlikely to be of interest to Android developers, since their use cases are already established and typically do not need custom Android application support. Android developers seeking customizable tags will want ones that are read-write, or at least write-once.

### Some Tags Can't Be Read-Only

Conversely, some tags lack any sort of read-only flag. An ideal tag for developers is one that is write-once: putting an NDEF message on the tag and flagging it read-only in one operation. Some tags do not support this, or making the tag read-only at any later point. The MIFARE Classic 1K tag is an example — while technically it can be made read-only, it requires a key known only to the tag manufacturer.

### Some Tags Need to be Formatted

The MIFARE Classic 1K NFC tag is NDEF-capable, but must be “formatted” first, supplying the initial NDEF message contents. You have the option of formatting it read-write or read-only (turning the Classic 1K a write-once tag).

This is not a problem — in fact, the write-once option may be compelling. However, it is something to keep in mind.

Also, note that the MIFARE Classic 1K, while it can be formatted as NDEF, uses a proprietary protocol “under the covers”. Not all Android devices will support the Classic 1K, as the device manufacturers elect not to pay the licensing fee. Where

possible, try to stick to tags that are natively NDEF-compliant (so-called “NFC Forum Tag Types 1-4”).

### Tags Have Limited Storage

The “1K” in the name “MIFARE Classic 1K” refers to the amount of storage on the tag: 1 kilobyte of information.

And that’s far larger than other tags, such as the MIFARE Ultralight C, some of which have ~64 bytes of storage.

Clearly, you will not be writing an MP3 file or JPEG photo to these tags. Rather, the tags will tend to either be a “launcher” into something with richer communications (e.g., URL to a Web site) or will use the sorts of data you may be used to from QR codes, such as a vCard or iCalendar for contact and event data, respectively.

### NDEF Data Structures Are Documented Elsewhere

The Android developer documentation is focused on the [Android classes](#) related to NFC and on [the Intent mechanism used for scanned tags](#). It does not focus on the actual structure of the payloads.

For TNF\_MIME\_MEDIA and RTD\_TEXT, the payload is whatever you want. For RTD\_URI, however, the byte array has a bit more structure to it, as the NDEF specification calls for a single byte to represent the URI prefix (e.g., `http://www.` versus `http://` versus `https://www.`). The objective, presumably, is to support incrementally longer URLs on tags with minuscule storage. Hence, you will need to convert your URLs into this sort of byte array if you are writing them out to a tag.

Generally speaking, the rules surrounding the structure of NDEF messages and records is found at the [NFC Forum site](#).

### Tag and Device Compatibility

Different devices will have different NFC chipsets. Not all NFC chipsets can read and write all tags. The expectation is that NDEF-formatted tags will work on all devices, but if you wander away from that, things get dicier. For example, NXP’s Mifare Classic tag can only be read and written by NXP’s NFC chip.

This is increasingly a challenge for Android developers, as a Broadcom NFC chip is becoming significantly more popular. Many new major Android devices, such as the

Samsung Galaxy S4, the Nexus 4, the Nexus 10, and the 2013/2nd generation version of the Nexus 7, all use the Broadcom chip. Those devices are incompatible with the Mifare tags, such as the popular Mifare Classic 1K.

That is because NXP is the maker of the Mifare Classic series, and those tags broke the NFC Forum's standards to create a tag that was NXP-specific.

Right now, NTAG203 and Topaz tags (like the Topaz 512), are likely candidate tags that will work across all NFC-capable Android devices, due to their adherence to NFC standard protocols.

## Sources of Tags

NFC tags are not the sort of thing you will find on your grocer's shelves. In fact, few, if any, mainstream firms sell them today.

Here are some online sites from which you can order rewritable NFC tags, listed here in alphabetical order:

1. [Andytags](#)
2. [Buy NFC Tags](#)
3. [Smartcard Focus](#)
4. [tagstand](#)

Note that not all may ship to your locale.

## Writing to a Tag

So, let's see what it takes to write an NDEF message to a tag, formatting it if needed. The code samples shown in this chapter are from the [NFC/URLTagger](#) sample application. This application will set up an activity to respond to ACTION\_SEND activity Intents, with an eye towards receiving a URL from a browser, then waiting for a tag and writing the URL to that tag. The idea is that this sort of application could be used by non-technical people to populate tags containing URLs to their company's Web site, etc.

## Getting a URL

First, we need to get a URL from the browser. As we saw in the chapter on integration, the standard Android browser uses ACTION\_SEND of text/plain contents

---

## NFC

---

when the user chooses the “Share Page” menu. So, we have one activity, `URLTagger`, that will respond to such an Intent:

```
<activity
  android:name="URLTagger"
  android:label="@string/app_name">
  <intent-filter android:label="@string/app_name">
    <action android:name="android.intent.action.SEND"/>

    <data android:mimeType="text/plain"/>

    <category android:name="android.intent.category.DEFAULT"/>
  </intent-filter>
</activity>
```

(from [NFC/URLTagger/app/src/main/AndroidManifest.xml](#))

Of course, lots of other applications support `ACTION_SEND` of `text/plain` contents that are not URLs. A production-grade version of this application would want to validate the `EXTRA_TEXT` Intent extra to confirm that, indeed, this is a URL, before putting in an NDEF message claiming that it is a URL.

### Detecting a Tag

When the user shares a URL with our application, our activity is launched. At that point, we need to go into “detect a tag” mode – the user should then tap their device to a tag, so we can write out the URL.

First, in `onCreate()`, we get access to the `NfcAdapter`, which is our gateway to much of the NFC functionality in Android:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    nfc=NfcAdapter.getDefaultAdapter(this);
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

We use a boolean data member — `inWriteMode` — to keep track of whether or not we are set up to write to a tag. Initially, of course, that is set to be `false`. Hence, when we are first launched, by the time we get to `onResume()`, we can go ahead and register our interest in future tags:

## NFC

---

```
@Override
public void onResume() {
    super.onResume();

    if (!inWriteMode) {
        IntentFilter discovery=new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
        IntentFilter[] tagFilters=new IntentFilter[] { discovery };
        Intent i=new Intent(this, getClass())
            .addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP|
                Intent.FLAG_ACTIVITY_CLEAR_TOP);
        PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

        inWriteMode=true;
        nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

When an NDEF-capable tag is within signal range of the device, Android will invoke `startActivity()` for the `NfcAdapter.ACTION_TAG_DISCOVERED` Intent action. However, it can do this in one of two ways:

- Normally, it will use a chooser (via `Intent.createChooser()`) to allow the user to pick from any activities that claim to support this action.
- The foreground application can request via `enableForegroundDispatch()` for it to handle all tag events while it is in the foreground, superseding the normal `startActivity()` flow. In this case, while Android still will invoke an activity, it will be our activity, not any other one.

We want the second approach right now, so the next tag brought in range is the one we will try writing to.

To do that, we need to create an array of `IntentFilter` objects, identifying the NFC-related actions that we want to capture in the foreground. In this case, we only care about `ACTION_TAG_DISCOVERED` – if we were supporting non-NDEF NFC tags, we might also need to watch for `ACTION_TECH_DISCOVERED`.

We also need a `PendingIntent` identifying the activity that should be invoked when such a tag is encountered while we are in the foreground. Typically, this will be the current activity. By adding `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to the `Intent` as flags, we ensure that our current specific instance of the activity will be given control again via `onNewIntent()`.

Armed with those two values, we can call `enableForegroundDispatch()` on the `NfcAdapter` to register our request to process tags via the current activity instance.

## NFC

---

In `onPause()`, if the activity is finishing, we call `disableForegroundDispatch()` to undo the work done in `onResume()`:

```
@Override
public void onPause() {
    if (isFinishing()) {
        nfc.disableForegroundDispatch(this);
        inWriteMode=false;
    }

    super.onPause();
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

We have to see if we are finishing, because even though our activity never leaves the screen, Android still calls `onPause()` and `onResume()` as part of delivering the Intent to `onNewIntent()`. Our approach, though, has flaws — if the user presses HOME, for example, we never disable the NFC dispatch logic. A production-grade application would need to handle this better.

For any of this code to work, we need to hold the NFC permission via an appropriate line in the manifest:

```
<uses-permission android:name="android.permission.NFC" />
```

Also note that if you have several activities that the user can reach while you are trying to also capture NFC tag events, you will need to call `enableForegroundDispatch()` in each activity — it's a per-activity request, not a per-application request.

## Reacting to a Tag

Once the user brings a tag in range, `onNewIntent()` will be invoked with the `ACTION_TAG_DISCOVERED` Intent action:

```
@Override
protected void onNewIntent(Intent intent) {
    if (inWriteMode &&
        NfcAdapter.ACTION_TAG_DISCOVERED.equals(intent.getAction())) {
        Tag tag=intent.getParcelableExtra(NfcAdapter.EXTRA_TAG);
        byte[] url=buildUrlBytes(getIntent().getStringExtra(Intent.EXTRA_TEXT));
        NdefRecord record=new NdefRecord(NdefRecord.TNF_WELL_KNOWN,
            NdefRecord.RTD_URI,
```

## NFC

---

```
        new byte[] {}, url);
    NdefMessage msg=new NdefMessage(new NdefRecord[] {record});

    new WriteTask(this, msg, tag).execute();
}
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

If we are in write mode and the delivered Intent is indeed an ACTION\_TAG\_DISCOVERED one, we can get at the Tag object associated with the user's NFC tag via the `NfcAdapter.EXTRA_TAG` [Parcelable extra on the Intent](#).

Writing an NDEF message to the tag, therefore, is a matter of crafting the message and actually writing it. An NDEF message consists of one or more records (though, typically, only one record is used), with each record wrapping around a byte array of payload data.

### Getting the Shared URL

We did not do anything to get the URL out of the Intent back in `onCreate()`, when our activity was first started up. Now, of course, we need that URL. You might think it is too late to get it, since our activity was effectively started again due to the tag and `onNewIntent()`.

However, `getIntent()` on an Activity always returns the Intent used to create the activity in the first place. The `getIntent()` value is not replaced when `onNewIntent()` is called.

Hence, as part of the `buildUrlBytes()` method to create the binary payload, we can go and call `getIntent().getStringExtra(Intent.EXTRA_TEXT)` to retrieve the URL.

### Creating the Byte Array

Given the URL, we need to convert it into a byte array suitable for use in a TNF\_WELL\_KNOWN, RTD\_URI NDEF record. Ordinarily, you would just call `toArray()` on the String and be done with it. However, the byte array we need uses a single byte to indicate the URL prefix, with the rest of the byte array for the characters after this prefix.

This is efficient. This is understandable. This is annoying.

## NFC

---

First, we need the roster of prefixes, defined in URLTagger as a static data member cunningly named PREFIXES:

```
static private final String[] PREFIXES={"http://www.", "https://www.",
    "http://", "https://",
    "tel:", "mailto:",
    "ftp://anonymous:anonymous@",
    "ftp://ftp.", "ftps://",
    "sftp://", "smb://",
    "nfs://", "ftp://",
    "dav://", "news:",
    "telnet://", "imap:",
    "rtsp://", "urn:",
    "pop:", "sip:", "sips:",
    "tftp:", "btsp://",
    "bt12cap://", "btgoep://",
    "tcpobex://",
    "irdaobex://",
    "file://", "urn:epc:id:",
    "urn:epc:tag:",
    "urn:epc:pat:",
    "urn:epc:raw:",
    "urn:epc:", "urn:nfc:"};
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

Then, in buildUrlBytes(), we need to find the prefix (if any) and use it:

```
private byte[] buildUrlBytes(String url) {
    byte prefixByte=0;
    String subset=url;
    int bestPrefixLength=0;

    for (int i=0;i<PREFIXES.length;i++) {
        String prefix = PREFIXES[i];

        if (url.startsWith(prefix) && prefix.length() > bestPrefixLength) {
            prefixByte=(byte)(i+1);
            bestPrefixLength=prefix.length();
            subset=url.substring(bestPrefixLength);
        }
    }

    final byte[] subsetBytes = subset.getBytes();
    final byte[] result = new byte[subsetBytes.length+1];

    result[0]=prefixByte;
```

## NFC

---

```
System.arraycopy(subsetBytes, 0, result, 1, subsetBytes.length);

return(result);
}
```

(from [NFC/URLTagger/app/src/main/java/com/commonsware/android/nfc/url/URLTagger.java](#))

We iterate over the PREFIXES array and find a match, if any, and the best possible match if there is more than one. If there is a match, we record the NDEF value for the first byte (our PREFIXES index plus one) and create a subset string containing the characters after the prefix. If there is no matching prefix, the prefix byte is 0 and we will include the full URL.

Given that, we construct a byte array containing our prefix byte in the first slot, and the rest taken up by the byte array of the subset of our URL.

### Creating the NDEF Record and Message

Given the result of `buildUrlBytes()`, our `onNewIntent()` implementation creates a `TNF_WELL_KNOWN, RTD_URI NdefRecord` object, and pours that into an `NdefMessage` object.

The third parameter to the `NdefRecord` constructor is a byte array representing the optional “ID” of this record, which is not necessary here.

Finally, we delegate the actual writing to a `WriteTask` subclass of `AsyncTask`, as writing the `NdefMessage` to the Tag is... interesting.

### Writing to a Tag

Here is the aforementioned `WriteTask` static inner class:

```
static class WriteTask extends AsyncTask<Void, Void, Void> {
    Activity host=null;
    NdefMessage msg=null;
    Tag tag=null;
    String text=null;

    WriteTask(Activity host, NdefMessage msg, Tag tag) {
        this.host=host;
        this.msg=msg;
        this.tag=tag;
    }
}
```

```
@Override
protected Void doInBackground(Void... arg0) {
    int size=msg.toByteArray().length;

    try {
        Ndef ndef=Ndef.get(tag);

        if (ndef==null) {
            NdefFormatable formatable=NdefFormatable.get(tag);

            if (formatable!=null) {
                try {
                    formatable.connect();

                    try {
                        formatable.format(msg);
                    }
                    catch (Exception e) {
                        text="Tag refused to format";
                    }
                }
                catch (Exception e) {
                    text="Tag refused to connect";
                }
                finally {
                    formatable.close();
                }
            }
            else {
                text="Tag does not support NDEF";
            }
        }
        else {
            ndef.connect();

            try {
                if (!ndef.isWritable()) {
                    text="Tag is read-only";
                }
                else if (ndef.getMaxSize()<size) {
                    text="Message is too big for tag";
                }
                else {
                    ndef.writeNdefMessage(msg);
                }
            }
            catch (Exception e) {
```

on the tag (if any). If the tag supported it, a call to `makeReadOnly()` would block further updates to the tag. Again, when we are done, we `close()` the connection.

All of the actual NFC I/O is performed in `doInBackground()`, because this I/O may take some time, and we do not want to block the main application thread while doing it.

## Responding to a Tag

Writing to a tag is a bit complicated. Responding to an NDEF message on a tag is significantly easier.

If the foreground activity is not consuming NFC events — as `URLTagger` does in write mode — then Android will use normal Intent resolution with `startActivity()` to handle the tag. To respond to the tag, all you need to do is have an activity set up to watch for an `android.nfc.action.NDEF_DISCOVERED` Intent. To get control ahead of the built-in Tags application, also have a `<data>` element that describes the sort of content or URL you are expecting to find on the tag.

For example, suppose you used the Android browser to visit [some page on the CommonsWare Web site](#), and you wrote that to a tag using `URLTagger`. The `URLTagger` application has another activity, `URLHandler`, that will respond when you tap the newly-written tag from the home screen or anywhere else. It accomplishes this via a suitable `<intent-filter>`:

```
<activity
  android:name="URLHandler"
  android:label="@string/app_name">
  <intent-filter android:label="@string/app_name">
    <action android:name="android.nfc.action.NDEF_DISCOVERED" />

    <data
      android:host="commonsware.com"
      android:scheme="http" />

    <category android:name="android.intent.category.DEFAULT" />
  </intent-filter>
</activity>
```

(from [NFC/URLTagger/app/src/main/AndroidManifest.xml](#))

The `URLHandler` activity can then use `getIntent()` to retrieve the key pieces of data from the tag itself, if needed. In particular, the `EXTRA_NDEF_MESSAGES` Parcelable

array extra will return an array of `NdefMessage` objects. Typically, there will only be one of these. You can call `getRecords()` on the `NdefMessage` to get at the array of `NdefRecord` objects (again, typically only one). Methods like `getPayload()` will allow you to get at the individual portions of the record.

The nice thing is that the URL still works, even if `URLTagger` is not on the device. In that case, the Tags application would react to the tag, and the user could tap on it to bring up a browser on this URL. A production application might create a Web page that tells the user about this great and wonderful app she can install, and provide links to the Play Store (or elsewhere) to go get the app.

## Expected Pattern: Bootstrap

Tags tend to have limited capacity. Even in peer-to-peer settings, the effective bandwidth of NFC is paltry compared to anything outside of dial-up Internet access.

As a result, NFC will be used infrequently as the complete communications solution between a publisher and a device. Sometimes it will, when the content is specifically small, such as a contact (vCard) or event (iCalendar). But, for anything bigger than that, NFC will serve more as a convenient bootstrap for more conventional communications options:

1. Embedding a URL in a tag, as the previous sample showed, allows an installed application to run or a Web site to be browsed
2. Embedding a Play Store URL in a tag allows for easy access to some specialized app (e.g., menu for a restaurant)
3. A multi-player game might use peer-to-peer NFC to allow local participants to rapidly connect into the same shared game area, where the game is played over the Internet or Bluetooth
4. And so on.

## Mobile Devices are Mobile

Reading and writing NFC tags is a relatively slow process, mostly due to low bandwidth. It may take a second or two to actually complete the operation.

Users, however, are not known for their patience.

If a user moves their device out of range of the tag while Android is attempting to read it, Android simply will skip the dispatch. If, however, the tag leaves the signal

area of the device while you are writing to it, you will get an `IOException`. At this point, the state of the tag is unknown.

You may wish to incorporate something into your UI to let the user know that you are working with the tag, encouraging them to leave the phone in place until you are done.

## Enabled and Disabled

There are two separate system settings that control NFC behavior:

- The user could have NFC disabled outright, which you would detect by calling `isEnabled()` on your `NfcAdapter`
- The user could have NFC enabled but have Android Beam disabled, which you would detect by calling `isNdefPushEnabled()` on your `NfcAdapter`

As with most enabled/disabled settings, you cannot change these values yourself. On newer Android SDK versions, though, you can try to bring up the relevant Settings screens for the user to enable these features, by using the following activity action strings from the `android.provider.Settings` class:

- `ACTION_NFC_SETTINGS` for the main NFC settings screen (added in API Level 16)
- `ACTION_NFCSHARING_SETTINGS` for the Android Beam settings screen (added in API Level 14)

## Android Beam

Android Beam is Google's moniker for peer-to-peer NFC messaging, with an emphasis — obviously — on Android apps. Rather than you tapping your NFC-capable Android device on a smart tag, you put it back-to-back with another NFC-capable Android device, and romance ensues.

Partially, this is simply one side of the exchange “pushing” an NDEF record, in a fashion that makes the other side of the exchange think that it is picking up a smart tag.

Partially, this is the concept of the “Android Application Record” (AAR), another NDEF record you can place in the NDEF message being pushed. This will identify the app you are trying to push the message to. If nothing on the device can handle

## NFC

---

the rest of the NDEF message, the AAR will lead Android to start up an app, or even lead the user to the Play Store to go download said app.

As the basis for explaining further how this all works, let's take a look at the [NFC/WebBeam](#) sample application. The UI consists of a `WebViewFragment`, in which we can browse to some Web page. Then, running this app on two NFC-capable devices, one app can “push” the URL of the currently-viewed Web page to the other app, which will respond by displaying that page. In this fashion, we are “sharing” a URL, without one side having to type it in by hand. And, while we are using this to share a URL, you could use Android Beam to share any sort of bootstrapping data, such as the user IDs of each person, for use in connecting to some common game server.

### The Fragment

The fragment that implements our UI, `BeamFragment`, extends from `WebViewFragment`. In `onViewCreated()`, we configure the `WebView` and load up Google's home page:

```
@SuppressWarnings("SetJavaScriptEnabled")
@Override
public void onViewCreated(@NonNull View view,
                          @Nullable Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    getWebView().setWebViewClient(new BeamClient());
    getWebView().getSettings().setJavaScriptEnabled(true);
    loadUrl("https://google.com");
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/BeamFragment.java](#))

To keep all links within the `WebView`, we attached a `WebViewClient` implementation, named `BeamClient`, that just loads all requested URLs back into the `WebView`:

```
class BeamClient extends WebViewClient {
    @Override
    public boolean shouldOverrideUrlLoading(WebView wv, String url) {
        wv.loadUrl(url);

        return true;
    }
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/BeamFragment.java](#))

## NFC

---

We add one item to the action bar: a toolbar button (`R.id.beam`) that will be used to indicate we wish to beam the URL in our WebView to another copy of this application running on another NFC-capable Android device:

```
@Override
public void onCreateOptionsMenu(Menu menu, MenuInflater inflater) {
    if (getContract().hasNFC()) {
        inflater.inflate(R.menu.actions, menu);
    }

    super.onCreateOptionsMenu(menu, inflater);
}

@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId() == R.id.beam) {
        getContract().enablePush();

        return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/BeamFragment.java](#))

So, when the app is initially launched, it will look something like this:

*Figure 837: The WebBeam UI*

The user can use Google to find a Web page worth beaming.

### Requesting the Beam

Our hosting activity, `WebBeamActivity`, gets access to our `NfcAdapter`, as we did in the previous example:

```
adapter=NfcAdapter.getDefaultAdapter(this);
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

When the user taps on our action bar item, the fragment calls `enablePush()` on the activity. `WebBeamActivity`, in turn, calls `setNdefPushMessageCallback()` on the `NfcAdapter`, supplying two parameters:

1. An implementation of the `NfcAdapter.CreateNdefMessageCallback` interface, used to let us know when another device is in range for us to beam to (in our case, `WebBeamActivity` implements this interface)
2. Our activity that is participating in this push

## NFC

---

If something else comes to the foreground, `onStop()` will call a corresponding `disablePush()`, which also calls `setNdefPushMessageCallback()`, specifying a null first parameter, to turn off our request to beam:

```
void enablePush() {
    adapter.setNdefPushMessageCallback(this, this);
}

void disablePush() {
    adapter.setNdefPushMessageCallback(null, this);
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

In between the calls to `enablePush()` and `disablePush()`, if another NFC device comes in range that supports the NDEF push protocols, we're beamin'.

## Sending the Beam

When our beam-enabled device encounters another beam-capable device, our `NfcAdapter.CreateNdefMessageCallback` is called with `createNdefMessage()`, where we need to prepare the `NfcMessage` to beam to the other party:

```
@Override
public NdefMessage createNdefMessage(NfcEvent arg0) {
    NdefRecord uriRecord=
        new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
            MIME_TYPE.getBytes(Charset.forName("US-ASCII")),
            new byte[0],
            beamFragment.getUrl()
                .getBytes(Charset.forName("US-ASCII")));
    NdefMessage msg=
        new NdefMessage(
            new NdefRecord[] {
                uriRecord,
                NdefRecord.createApplicationRecord("com.commonsware.android.webbeam") });
    return(msg);
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

We first create a typical `NfcRecord`, in this case of `TNF_MIME_MEDIA`, with a MIME type defined in a static data member and payload consisting of the URL from our `WebView`:

```
private static final String MIME_TYPE=
    "application/vnd.commonsware.sample.webbeam";
```

## NFC

---

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

You might wonder why we are using `TNF_MIME_MEDIA`, instead of `TNF_WELL_KNOWN` and a subtype of `RTD_URI`, since our payload is a URL. The reason is that we need to have a unique MIME type for our message for the whole beam process to work properly, and `TNF_WELL_KNOWN` does not support MIME types. This is also why the MIME type is something distinctive, and not just `text/plain` — it has to be something only we will pick up.

Our `NfcMessage` then consists of two `NfcRecord` objects: the one we just created, and one created via the static `createApplicationRecord()` method on `NfcRecord`. This helper method creates an AAR record, identifying our application by its Android package name. This record must go last – Android will try to find an app to work with based on the other records first, before “failing over” to use the AAR.

### Receiving the Beam

To receive our beam, our `WebBeamActivity` must be configured in the manifest to respond to `NDEF_DISCOVERED` actions with our unique MIME type:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonsware.android.webbeam"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-sdk
        android:minSdkVersion="14"
        android:targetSdkVersion="14"/>

    <uses-permission android:name="android.permission.INTERNET"/>
    <uses-permission android:name="android.permission.NFC"/>

    <application
        android:icon="@drawable/ic_launcher"
        android:label="@string/app_name"
        android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
        <activity
            android:name=".WebBeamActivity"
            android:label="@string/app_name"
            android:launchMode="singleTask"
            android:screenOrientation="landscape">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

## NFC

---

```
<category android:name="android.intent.category.LAUNCHER" />
</intent-filter>
<intent-filter>
  <action android:name="android.nfc.action.NDEF_DISCOVERED" />

  <category android:name="android.intent.category.DEFAULT" />

  <data android:mimeType="application/vnd.commonware.sample.webbeam" />
</intent-filter>
</activity>
</application>

</manifest>
```

(from [NFC/WebBeam/app/src/main/AndroidManifest.xml](#))

You will also notice that we set `android:launchMode="singleTask"` on this activity. That is so we will only have one instance of this activity, regardless of whether it is in the foreground or not. Otherwise, if we already have an instance of this activity, and we receive a beam, Android will create a *second* instance of this activity — when the user later presses BACK, they return to our first instance, and wonder why our app is broken.

If we receive the beam, we will get the Intent for the NDEF\_DISCOVERED action *either* in `onCreate()` (if we were not already running) or `onNewIntent()` (if we were). In either case, we want to handle it the same way: pass the URL from the first record's payload to our `BeamFragment`. However, we cannot do that from `onCreate()` — the fragment will not have created the `WebView` yet. So, we use a trick: calling `post()` with a `Runnable` puts that `Runnable` on the *end* of the work queue for the main application thread. We can delay our processing of the Intent by this mechanism, so we can safely assume the `WebView` exists.

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    beamFragment=
        (BeamFragment)getSupportFragmentManager().findFragmentById(android.R.id.content);

    if (beamFragment == null) {
        beamFragment=new BeamFragment();

        getSupportFragmentManager().beginTransaction()
            .add(android.R.id.content, beamFragment)
            .commit();
    }

    adapter=NfcAdapter.getDefaultAdapter(this);
```

## NFC

---

```
findViewById(android.R.id.content).post(new Runnable() {
    public void run() {
        handleIntent(getIntent());
    }
});
}

@Override
public void onNewIntent(Intent i) {
    handleIntent(i);
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

```
private void handleIntent(Intent i) {
    if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
        Parcelable[] rawMsgs=
            i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);
        NdefMessage msg=(NdefMessage)rawMsgs[0];
        String url=new String(msg.getRecords()[0].getPayload());

        beamFragment.loadUrl(url);
    }
}
```

(from [NFC/WebBeam/app/src/main/java/com/commonsware/android/webbeam/WebBeamActivity.java](#))

## The Scenarios

There are three possible scenarios, when we try beaming from one device to another:

1. The other device has our application installed, and it is running. In that case, our activity is brought to the foreground and the Intent is delivered to it, courtesy of our NDEF\_DISCOVERED <intent-filter> with our unique MIME type.
2. The other device has our application installed, but it is not running. Android's Intent system handles this in the same general fashion as the first scenario, though it starts up a process for us and creates our activity instance anew in this case.
3. The other device does not have our application installed. Since nothing (hopefully) claims to support our unique MIME type, the AAR takes effect, and the user is led to the Play Store to go download our app (or, in this case, display an error message, as WebBeam is not in the Play Store).

## Beaming Files

Android 4.1 (a.k.a., Jelly Bean) added in a far simpler facility for an app to beam a file to another device using the Android Beam system. You can use `setBeamPushUri()` or `setBeamPushUriCallback()` on an `NfcAdapter` to hand Android one or more `Uri` objects representing files to be transferred. While the initial connection will be made via NFC and Android Beam, the actual data transfer will be via Bluetooth or WiFi, much more suitable than NFC for bulk data.

The difference between the two approaches is mostly when you provide the array of `Uri` objects. With `setBeamPushUri()`, you initiate the beam operation and supply the `Uri` values immediately. With `setBeamPushUriCallback()`, you initiate the beam but do not supply the `Uri` values until the beam connection is established with the peer app.

The [NFC/FileBeam](#) sample application shows file-based beaming in action.

In our activity (`MainActivity`), in `onCreate()`, we check to make sure that Android Beam is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`. If it is, then we use `ACTION_GET_CONTENT` to retrieve some file from the user (MIME type wildcard of `*/*`):

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    adapter=NfcAdapter.getDefaultAdapter(this);

    if (!adapter.isNdefPushEnabled()) {
        Toast.makeText(this, R.string.sorry, Toast.LENGTH_LONG).show();
        finish();
    }
    else {
        Intent i=new Intent(Intent.ACTION_GET_CONTENT);

        i.setType("*/*").addCategory(Intent.CATEGORY_OPENABLE);
        startActivityForResult(i, 0);
    }
}
```

(from [NFC/FileBeam/app/src/main/java/com/commonsware/android/filebeam/MainActivity.java](#))

In `onActivityResult()`, if we actually got a file (e.g., the result is `ACTION_OK`), we turn around and call `setBeamPushUri()` to pass that file to some peer device. We

---

## NFC

---

also set up a Button as our UI — clicking the Button will finish() the activity:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode==0 && resultCode==RESULT_OK) {
        adapter.setBeamPushUri(new Uri[] {data.getData()}, this);

        Button btn=new Button(this);

        btn.setText(R.string.over);
        btn.setOnClickListener(this);
        setContentView(btn);
    }
}
```

(from [NFC/FileBeam/app/src/main/java/com/commonsware/android/filebeam/MainActivity.java](#))

That is all there is to it. If you run this app and pick a file, then hold the device up to another Android 4.1+ device, you will be prompted to “Touch to Beam” — doing so will kick off the transfer. Once the transfer is shown on the receiving device, you can pull the devices apart a bit, as the transfer will be proceeding over Bluetooth or WiFi. However, while Bluetooth ranges are much longer than NFC, you still need to keep the devices within a handful of meters of one another.

Note that the receiving device is not running our app. The OS handles the receipt of the transferred file, not our code. Similarly, the OS on the sending device is really the one responsible for the file transfer, so our app does not need the INTERNET or BLUETOOTH permissions. The downside is that we have no control over anything on the receiving side — the file is stored wherever the OS elects to put it, and the Notification it displays when complete will simply launch ACTION\_VIEW on the pushed file.

## Another Sample: SecretAgentMan

To provide another take on using these features of NfcAdapter, let’s examine the [NFC/SecretAgentMan](#) sample application, originally written for a presentation at the 2012 droidcon UK conference. This combines writing to tags, directly beaming text to another device, and using Uri-based beaming, all in one app.

## NFC

---

The UI of the app is a large EditText widget with an action bar:

*Figure 838: The SecretAgentMan UI*

There are three action bar items, one each for the three operations: writing to a tag, directly beaming to another device, and beaming a file (represented via a Uri).

### Configuration and Initialization

Our app is comprised of a single activity, named MainActivity. As part of our manifest setup, we request the NFC permission. And, since the app needs NFC to be useful, we also have a <uses-feature> element, stipulating that the device needs to have NFC, otherwise the app should not be shown in the Play Store:

```
<uses-permission android:name="android.permission.NFC"/>

<uses-feature
    android:name="android.hardware.nfc"
    android:required="true"/>
```

(from [NFC/SecretAgentMan/app/src/main/AndroidManifest.xml](#))

In onCreate() of MainActivity, we can then safely get access to an NfcAdapter, since the NFC hardware should exist and we have rights to use NFC:

---

## NFC

---

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    nfc=NfcAdapter.getDefaultAdapter(this);
    secretMessage=(EditText)findViewById(R.id.secretMessage);

    nfc.setOnNdefPushCompleteCallback(this, this);

    if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(getIntent().getAction())) {
        readFromTag(getIntent());
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

We also get our hands on the EditText widget, storing a reference to it in a data member named secretMessage. We will cover the rest of the initialization work in onCreate() later in this section, as we cover the code that needs that initialization.

### Writing to the Tag

If the user chooses the “Write to Tag” action bar item, we call a setUpWriteMode() method from onOptionsItemSelected() of MainActivity. We maintain an inWriteMode boolean data member to track whether or not we are already trying to write to an NFC tag. If inWriteMode is false, we go ahead and take control over the NFC hardware to attempt to write to the next tag we see:

```
void setUpWriteMode() {
    if (!inWriteMode) {
        IntentFilter discovery=
            new IntentFilter(NfcAdapter.ACTION_TAG_DISCOVERED);
        IntentFilter[] tagFilters=new IntentFilter[] { discovery };
        Intent i=
            new Intent(this, getClass()).addFlags(Intent.FLAG_ACTIVITY_SINGLE_TOP
                | Intent.FLAG_ACTIVITY_CLEAR_TOP);
        PendingIntent pi=PendingIntent.getActivity(this, 0, i, 0);

        inWriteMode=true;
        nfc.enableForegroundDispatch(this, pi, tagFilters, null);
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

## NFC

---

To do that, we:

- Create an `IntentFilter` for `ACTION_TAG_DISCOVERED`
- Create a `PendingIntent` for an `Intent` pointing back to this same activity instance (using `getClass()` to identify the instance, plus `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to route control back to our running instance)
- Call `enableForegroundDispatch()` on our `NfcAdapter`, to route newly-discovered tags to us, with the `IntentFilter` identifying the tag-related events we are interested in, and the `PendingIntent` identifying what to do when such a tag is encountered

Once our activity is finishing (e.g., the user presses `BACK`), we need to clean up our write-to-tag logic. This is kicked off in `onPause()` of `MainActivity`:

```
@Override
public void onPause() {
    if (isFinishing()) {
        cleanUpWritingToTag();
    }

    super.onPause();
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

All we do in `cleanUpWritingToTag()` is discontinue our foreground control over the NFC hardware:

```
void cleanUpWritingToTag() {
    nfc.disableForegroundDispatch(this);
    inWriteMode=false;
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

If, before that occurs, the device is tapped on a tag, our activity should regain control in `onNewIntent()` as a result of our `PendingIntent` having been executed:

```
@Override
protected void onNewIntent(Intent i) {
    if (inWriteMode
        && NfcAdapter.ACTION_TAG_DISCOVERED.equals(i.getAction())) {
        writeToTag(i);
    }
    else if (NfcAdapter.ACTION_NDEF_DISCOVERED.equals(i.getAction())) {
```

## NFC

---

```
        readFromTag(i);
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

If we are in write mode, and if the Intent that was just used with `startActivity()` was `ACTION_TAG_DISCOVERED`, we call our `writeToTag()` method to actually start writing information to the tag:

```
void writeToTag(Intent i) {
    Tag tag=i.getParcelableExtra(NfcAdapter.EXTRA_TAG);
    NdefMessage msg=
        new NdefMessage(new NdefRecord[] { buildNdefRecord() });

    new WriteTagTask(this, msg, tag).execute();
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

To write to the tag, we get our Tag out of its Intent extra (keyed by `EXTRA_TAG`). Then, we build an `NfcMessage` to write to the tag, getting its `NfcRecord` from `buildNdefRecord()`:

```
NdefRecord buildNdefRecord() {
    return(new NdefRecord(NdefRecord.TNF_MIME_MEDIA,
        MIME_TYPE.getBytes(), new byte[] {},
        secretMessage.getText().toString().getBytes()));
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

Our NDEF record will be of a specific MIME type, represented by a static data member named `MIME_TYPE`:

```
private static final String MIME_TYPE="vnd.secret/agent.man";
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

The payload of the NDEF record is our “secret message” from the `secretMessage EditText` widget.

The `writeToTag()` method then kicks off the same `WriteTagTask` that we used earlier in this chapter:

```
package com.commonsware.android.jimmyb;
```

## NFC

---

```
import android.nfc.NdefMessage;
import android.nfc.Tag;
import android.nfc.tech.Ndef;
import android.nfc.tech.NdefFormatable;
import android.os.AsyncTask;
import android.util.Log;
import android.widget.Toast;

class WriteTagTask extends AsyncTask<Void, Void, Void> {
    MainActivity host=null;
    NdefMessage msg=null;
    Tag tag=null;
    String text=null;

    WriteTagTask(MainActivity host, NdefMessage msg, Tag tag) {
        this.host=host;
        this.msg=msg;
        this.tag=tag;
    }

    @Override
    protected Void doInBackground(Void... arg0) {
        int size=msg.toByteArray().length;

        try {
            Ndef ndef=Ndef.get(tag);

            if (ndef == null) {
                NdefFormatable formatable=NdefFormatable.get(tag);

                if (formatable != null) {
                    try {
                        formatable.connect();

                        try {
                            formatable.format(msg);
                        }
                        catch (Exception e) {
                            text=host.getString(R.string.tag_refused_to_format);
                        }
                    }
                    catch (Exception e) {
                        text=host.getString(R.string.tag_refused_to_connect);
                    }
                    finally {
                        formatable.close();
                    }
                }
            }
        }
    }
}
```

## NFC

---

```
    }
    else {
        text=host.getString(R.string.tag_does_not_support_ndef);
    }
}
else {
    ndef.connect();

    try {
        if (!ndef.isWritable()) {
            text=host.getString(R.string.tag_is_read_only);
        }
        else if (ndef.getMaxSize() < size) {
            text=host.getString(R.string.message_is_too_big_for_tag);
        }
        else {
            ndef.writeNdefMessage(msg);
            text=host.getString(R.string.success);
        }
    }
    catch (Exception e) {
        text=host.getString(R.string.tag_refused_to_connect);
    }
    finally {
        ndef.close();
    }
}
}
catch (Exception e) {
    Log.e("URLTagger", "Exception when writing tag", e);
    text=host.getString(R.string.general_exception) + e.getMessage();
}

return(null);
}

@Override
protected void onPostExecute(Void unused) {
    host.cleanupWritingToTag();

    if (text != null) {
        Toast.makeText(host, text, Toast.LENGTH_SHORT).show();
    }
}
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/WriteTagTask.java](https://github.com/jimmyb/SecretAgentMan/blob/master/app/src/main/java/com/commonsware/android/jimmyb/WriteTagTask.java))

The net result is that if the user taps the “Write to Tag” action bar item, then taps and holds the device to a tag, we will write a message to the tag and display a Toast when we are done.

And, yes, this is a surprising amount of code for what really should be a simple operation...

### Reading from the Tag

We can set up MainActivity to respond to tags similar to the one we wrote — ones that have the desired MIME Type — via an `android.nfc.action.NDEF_DISCOVERED` `<intent-filter>`:

```
<intent-filter android:label="@string/app_name">
  <action android:name="android.nfc.action.NDEF_DISCOVERED"/>

  <data android:mimeType="vnd.secret/agent.man"/>

  <category android:name="android.intent.category.DEFAULT"/>
</intent-filter>
```

(from [NFC/SecretAgentMan/app/src/main/AndroidManifest.xml](#))

In both `onCreate()` and `onNewIntent()`, if the Intent that started our activity is an `NDEF_DISCOVERED` Intent, we route control to a `readFromTag()` method:

```
void readFromTag(Intent i) {
    Parcelable[] msgs=
        (Parcelable[])i.getParcelableArrayExtra(NfcAdapter.EXTRA_NDEF_MESSAGES);

    if (msgs.length > 0) {
        NdefMessage msg=(NdefMessage)msgs[0];

        if (msg.getRecords().length > 0) {
            NdefRecord rec=msg.getRecords()[0];

            secretMessage.setText(new String(rec.getPayload(), US_ASCII));
        }
    }
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

In principle, there could be several NDEF messages on the tag, but we only pay attention to the first element, if any, of the `EXTRA_NDEF_MESSAGES` array of `Parcelable` objects on the Intent. Similarly, in principle, there could be several NDEF records in the first message, but we only examine the first element out of the array of `NdefRecord` objects contained in the `NdefMessage`. From there, we extract

our secret message and display it by means of putting it in the EditText widget.

### Beaming the Text

This sample only supports beaming — whether of NDEF messages directly or of a file — if we are on API Level 16 or higher. Hence, in `onCreateOptionsMenu()`, we check our version and only enable our default-disabled beam action bar items if:

- We are on API Level 16 or higher, and
- NDEF push mode is enabled, via a call to `isNdefPushEnabled()` on our `NfcAdapter`:

```
@TargetApi(16)
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.activity_main, menu);

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN) {
        menu.findItem(R.id.simple_beam)
            .setEnabled(nfc.isNdefPushEnabled());
        menu.findItem(R.id.file_beam).setEnabled(nfc.isNdefPushEnabled());
    }

    return(super.onCreateOptionsMenu(menu));
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

If the user taps on the “Beam” action bar item, we call an `enablePush()` method from `onOptionsItemSelected()`, which simply enables push mode:

```
void enablePush() {
    nfc.setNdefPushMessageCallback(this, this);
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonsware/android/jimmyb/MainActivity.java](#))

We arrange for the activity itself to be the `CreateNdefMessageCallback` necessary for push mode. That requires us to implement `createNdefMessage()`, which will be called if we are in push mode and a push-compliant device comes within range:

```
@Override
public NdefMessage createNdefMessage(NfcEvent event) {
    return(new NdefMessage(
        new NdefRecord[] {
            buildNdefRecord(),
        }
    ));
}
```

## NFC

---

```
        NdefRecord.createApplicationRecord("com.commonware.android.jimmyb") }));  
    }
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonware/android/jimmyb/MainActivity.java](#))

Here, we create an `NdefMessage` similar to the one we wrote to the tag earlier in this sample. However, we also attach an Android Application Record (AAR), by means of the static `createApplicationRecord()` method on `NdefRecord`. This, in theory, will help route the push to our app on the other device, including downloading it from the Play Store if needed (and, of course, if it actually existed on the Play Store, which it does not).

Back up in `onCreate()`, we call `setOnNdefPushCompleteCallback()`, to be notified of when a push operation is completed. Once again, we set up `MainActivity` to be the callback, this time by implementing the `OnNdefPushCompleteCallback` interface. That, in turn, requires us to implement `onNdefPushComplete()`, where we disable push mode via a call to `setNdefPushMessageCallback()` with a null listener:

```
@Override  
public void onNdefPushComplete(NfcEvent event) {  
    nfc.setNdefPushMessageCallback(null, this);  
}
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonware/android/jimmyb/MainActivity.java](#))

To receive the beam, we only need our existing logic to read from the tag, as on the receiving side, a push is indistinguishable from reading a tag, and we are using the same MIME type for both the message written to the tag and the message we are pushing.

## Beaming the File

If the user taps the “Beam File” action bar item, we find some file to beam, by means of an `ACTION_GET_CONTENT` request and `startActivityForResult()`:

```
case R.id.file_beam:  
    Intent i=new Intent(Intent.ACTION_GET_CONTENT);  
  
    i.setType("*/*").addCategory(Intent.CATEGORY_OPENABLE);  
    startActivityForResult(i, 0);  
    return(true);
```

(from [NFC/SecretAgentMan/app/src/main/java/com/commonware/android/jimmyb/MainActivity.java](#))

In `onActivityResult()`, if the request succeeded, we use `setBeamPushUris()` to tell

## NFC

---

Android to beam the selected file to another device. Nothing more is needed on our side, and the receipt of the file is handled entirely by the OS, not our application code, so there is nothing to be written for that.

This code assumes the NFC adapter is enabled. We could check that via a call to `isEnabled()` on our `NfcAdapter`. If it is not enabled, we could — on user request — bring up the Settings activity for configuring NFC, via `startActivity(new Intent(Settings.ACTION_NFC_SETTINGS))`. However, oddly, this Intent action is only available on Android 4.1 (API Level 16) and higher, despite NFC having been available for some time previously.

This code ignores the possibility of doing the simple beam (not the file-based beam) on Android 4.0.x devices. That is because the `isNdefPushEnabled()` method was not added until Android 4.1, and therefore we do not know whether or not we can actually do a beam.

If `isNdefPushEnabled()` returns `false`, we simply disable some action bar items. Alternatively, we could use `startActivity(new Intent(Settings.ACTION_NFC_SHARING_SETTINGS))`, on API Level 14 and higher, to bring up the beam screen in Settings, to allow the user to toggle beam support on.

## Additional Resources

To help make sense of the tags that you are trying to use with your app, you may wish to grab the [NFC TagInfo](#) application off of the Google Play Store. This application simply scans a tag and allows you to peruse all the details of that tag, including the supported technologies (e.g., does it support NDEF? is it `NdefFormatable?`), the NDEF records, and so on.

To learn more about NFC on Android — beyond this chapter or the Android developer documentation — [this Google I/O 2011 presentation](#) is recommended.

# Device Administration

---

Balding authors of Android books often point out that enterprises and malware authors have the same interests: they want to take control of a device away from the person that is holding it and give that control to some other party. Android, being a consumer operating system, is designed to defend against malware, and so enterprises can run into issues.

However, Android does have a growing area of device administration APIs, that allow carefully-constructed and installed applications to exert some degree of control over the device, how it is configured, and how it operates.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the chapter on [broadcast Intents](#).

## Objectives and Scope

One might read the phrase “device administration” and assume that somebody, using these APIs, could do anything they want on the device.

That’s not quite what “device administration” means in this case.

Rather, the device administration APIs serve three main roles:

1. They allow an application to dictate how well a device is secured, from the password required in the OS lock screen to whether the device should have full-disk encryption

2. They allow an application to find out when security issues might arise, notably failed password attempts
3. They allow an application to lock the device, disable its cameras, or even perform a “wipe” (i.e., factory reset)

The user, however, has to agree to enable a device administration app. It does not magically get all these powers simply by being installed. What the user gets from agreeing to this is access to something that otherwise would be denied (e.g., to use Enterprise App X, you must agree to allow it to be a device administrator).

## Defining and Registering an Admin Component

There are four pieces for defining and registering a device administration app: creating the metadata, adding the `<receiver>` to the manifest, implementing that `BroadcastReceiver`, and telling Android to ask the user to agree to allow the app to a device administrator.

Here, we will take a peek at the [DeviceAdmin/LockMeNow](#) sample application.

### The Feature

Apps implementing device administrators should add a `<uses-feature>` element with a name of `android.software.device_admin`, indicating whether or not they require this device feature to exist. This can be used by the Play Store to filter your app from being available on devices that, for one reason or another, do not offer this capability.

### The Metadata

As with [app widgets](#) and other Android facilities, you will need to define a metadata file as an XML resource, describing in greater detail what your device administration app wishes to do. This information will determine what you will be allowed to do once the user approves your app, and what you list here will be displayed to the user when you request such approval.

The `DeviceAdminInfo` class has a series of static data members (e.g., `USES_ENCRYPTED_STORAGE`) that represent specific policies that your device administrator app could use. The documentation for each of those static data members lists the corresponding element that goes in this XML metadata file (e.g., `<encrypted-storage>`). These elements are wrapped in a `<uses-policies>` element,

## DEVICE ADMINISTRATION

---

which itself is wrapped in a `<device-admin>` element. The range of possible policies is shown in the following sample XML metadata file:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-camera />
    <encrypted-storage />
    <expire-password />
    <force-lock />
    <limit-password />
    <reset-password />
    <watch-login />
    <wipe-data />
  </uses-policies>
</device-admin>
```

Here, we:

- Intend to disable the cameras, if needed
- Will ask the user to encrypt their device storage, if it has not been done already
- Will set an expiration time for the user's password, after which they will need to set up a new one
- Intend to lock the device, if needed
- Will set criteria for password quality, such as minimum length
- Intend to forcibly reset the user's password, if needed
- Intend to monitor for failed and successful login attempts
- Intend to wipe the device, if needed

Choose which of those policies you need — the fewer you request, the more likely it is the user will not wonder about your intentions. In your project's `res/xml/` directory, create a file that looks like the above with the policies you wish. You can name this file whatever you want (e.g., `device_admin.xml`), within standard Android resource naming rules.

## The Manifest

In the manifest, you will need to declare a `<receiver>` element for the `DeviceAdminReceiver` component that you will write. This component not only is the embodiment of the device admin capabilities of your app, but it will be the one notified of failed logins and other events.

For example, here is the `<receiver>` element from the `LockMeNow` sample app:

## DEVICE ADMINISTRATION

---

```
<receiver
  android:name="AdminReceiver"
  android:permission="android.permission.BIND_DEVICE_ADMIN">
  <meta-data
    android:name="android.app.device_admin"
    android:resource="@xml/device_admin"/>

  <intent-filter>
    <action android:name="android.app.action.DEVICE_ADMIN_ENABLED"/>
  </intent-filter>
</receiver>
```

(from [DeviceAdmin/LockMeNow/app/src/main/AndroidManifest.xml](#))

There are three things distinctive about this element compared to your usual `<receiver>` element:

1. It requires that whoever sends broadcasts to it hold the `BIND_DEVICE_ADMIN` permission. Since that permission is protected and can only be held by apps signed with the firmware's signing key, you can be reasonably assured that any events sent to you are real.
2. It has the `<meta-data>` child element pointing to our device administration metadata from the previous section.
3. It registers for `android.app.action.DEVICE_ADMIN_ENABLED` broadcasts via its `<intent-filter>` — this is the broadcast that will be used to notify you when your app gains device administration privileges

## The Receiver

The `DeviceAdminReceiver` itself needs to exist as a component in your app, registered in the manifest as shown above. At minimum, though, it does not need to override any methods, such as the implementation from the `LockMeNow` sample app:

```
package com.commonware.android.lockme;

import android.app.admin.DeviceAdminReceiver;

public class AdminReceiver extends DeviceAdminReceiver {
}
```

(from [DeviceAdmin/LockMeNow/app/src/main/java/com/commonware/android/lockme/AdminReceiver.java](#))

By requesting the `DEVICE_ADMIN_ENABLED` broadcasts, we could get control when we are enabled by overriding an `onEnabled()` method. We could also register for other

broadcasts (e.g., ACTION\_PASSWORD\_FAILED) and implement the corresponding callback method on our DeviceAdminReceiver (e.g., onPasswordFailed()).

### The Demand for Device Domination

Simply having this component in our manifest, though, is insufficient. The user must proactively agree to allow us to administer their device. And, since this is potentially very dangerous, a simple permission was deemed to also be insufficient. Instead, we need to ask the user to approve us as a device administrator from our app, typically from an activity.

In the case of LockMeNow, the UI is just a really big button, tied to a lockMeNow() method on our LockMeNowActivity:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical">

    <Button
        android:id="@+id/Button1"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:onClick="lockMeNow"
        android:text="@string/lock_me"
        android:textColor="#FFFF0000"
        android:textSize="40sp"
        android:textStyle="bold"/>

</LinearLayout>
```

(from [DeviceAdmin/LockMeNow/app/src/main/res/layout/main.xml](#))

In onCreate() of the activity, in addition to loading up the UI via setContentView(), we create a ComponentName object identifying our AdminReceiver component. We also request access to the DevicePolicyManager, via a call to getSystemService(). DevicePolicyManager is our gateway for making direct requests for device administration operations, such as locking the device:

```
package com.commonware.android.lockme;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
```

## DEVICE ADMINISTRATION

---

```
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class LockMeNowActivity extends Activity {
    private DevicePolicyManager mgr=null;
    private ComponentName cn=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        setContentView(R.layout.main);
        cn=new ComponentName(this, AdminReceiver.class);
        mgr=(DevicePolicyManager) getSystemService(DEVICE_POLICY_SERVICE);
    }

    public void lockMeNow(View v) {
        if (mgr.isAdminActive(cn)) {
            mgr.lockNow();
        }
        else {
            Intent intent=
                new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
            intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
            intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
                getString(R.string.device_admin_explanation));
            startActivity(intent);
        }
    }
}
```

(from [DeviceAdmin/LockMeNow/app/src/main/java/com/commonsware/android/lockme/LockMeNowActivity.java](#))

In `lockMeNow()`, we ask the `DevicePolicyManager` if we have already been registered as a device administrator, by calling `isAdminActive()`, supplying the `ComponentName` of our `DeviceAdminReceiver` that should be so registered. If that returns false, then the user has not approved us as a device administrator yet, so we need to ask them to do so. To do that, you:

- Create an Intent for the `DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN` action
- Add the `ComponentName` of our `DeviceAdminReceiver` as an extra, keyed as `DevicePolicyManager.EXTRA_DEVICE_ADMIN`
- Add another extra, `DevicePolicyManager.EXTRA_ADD_EXPLANATION`, which is some text to show the user as part of the authorization screen, to explain

## DEVICE ADMINISTRATION

---

why we need to be a device admin

- Start up an activity using that Intent, via `startActivity()`

If you run this on a device, then tap the button, the first time you do so the user will be prompted to agree to making the app be a device administrator:

*Figure 839: The Activate Device Administrator Screen*

The “For experimentation purposes only” is the value of our `DevicePolicyManager.EXTRA_ADD_EXPLANATION` extra, loaded from a string resource.

## DEVICE ADMINISTRATION

---

If the user clicks “Activate”, and you override `onEnabled()` in your `DeviceAdminReceiver`, that will be called to let you know that you have been approved and can perform device administration functions. Your component will also appear in the list of device administrators in the Settings app:

*Figure 840: The Device Administrator List*

The user can, at any time, uncheck you in this list and disable you. You can find out about this by having your `DeviceAdminReceiver` listen for `ACTION_DEVICE_ADMIN_DISABLE_REQUESTED` broadcasts and overriding the `onDisableRequested()` method, where you can return the text of a message to be displayed to the user confirming that they do indeed wish to go ahead with the disable operation. To find out if they go through with it, your `DeviceAdminReceiver` can listen for `ACTION_DEVICE_ADMIN_DISABLED` broadcasts and override `onDisabled()`.

## Going Into Lockdown

Given that the user has approved your device administration request, and given that you requested `<force-lock>` in your metadata, you can call `lockNow()` on a `DevicePolicyManager`. That will immediately lock the device and (generally) turn off

the screen. It is as if the user pressed the POWER button on the device. If anything, `lockNow()` will offer tighter security.

The `LockItNow` sample app does this if, when the user clicks the really big button, it detects that it is already a device administrator. If you test this on a device, it will behave as though the user pressed POWER; on an emulator, you will need to press the HOME button to “power on” the screen and be able to re-enter your emulator.

You can also call:

- `setCameraDisabled()` to disable all cameras, if you requested `<disable-camera>` in the metadata. Note that this disables all cameras; there is no provision at this time to disable individual cameras separately.
- `wipeData()`, which performs what amounts to a factory reset — it leaves external storage alone but wipes the contents of internal storage as part of a reboot. This requires the `<wipe-data>` policy in the metadata.
- `setKeyguardDisabledFeatures()`, to control whether or not the lockscreen allows direct access to the camera and/or app widgets (lockscreen app widgets are described in [the chapter on app widgets](#))

For example, the latter feature, while available in the Android SDK, is not built into the Settings app of Android 4.2. As a result, users need a third-party app to toggle on or off lockscreen access to the camera and app widgets. One such third-party app is [LockscreenLocker](#), released as open source by the author of this book.

## DEVICE ADMINISTRATION

---

Basically, the app presents you with two Switch widgets to control the camera and app widgets on the lock screen. First, though, it shows you a message and a Button, if the app is not set up as a device administrator:

*Figure 841: LockscreenLocker, On Initial Run*

## DEVICE ADMINISTRATION

---

Once that is complete, the Switch widgets become enabled and usable:

*Figure 842: LockscreenLocker, After Being Made a Device Admin*

The device admin metadata for this app specifies that we want to control keyguard features:

```
<device-admin xmlns:android="http://schemas.android.com/apk/res/android">
  <uses-policies>
    <disable-keyguard-features/>
  </uses-policies>
</device-admin>
```

Note that, at the time of this writing, there is a flaw in the Android developer documentation — the correct element to have in the metadata is [disable-keyguard-features/>, not <disable-keyguard-widgets>]. You can track [this issue](#) to see when this documentation bug has been repaired.

Our device admin component, `LockscreenAdminReceiver`, is empty, because there are no events that we are trying to listen to:

## DEVICE ADMINISTRATION

---

```
public class LockscreenAdminReceiver extends DeviceAdminReceiver {  
}
```

However, we still need the `LockscreenAdminReceiver`, as it is the component that is tied to our device admin metadata and indicates to the system that we should be an option in Settings for available device administrators.

Our activity layout contains all the requisite widgets: a `TextView` for the message, a `Button` to jump to the Settings app, a `View` to serve as a divider, and a pair of `Switch` widgets to manage the lockscreen settings:

```
<?xml version="1.0" encoding="utf-8"?>  
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:orientation="vertical">  
  
    <TextView  
        android:id="@+id/setupMessage"  
        android:layout_width="match_parent"  
        android:layout_height="wrap_content"  
        android:text="@string/setup_message"  
        android:textAppearance="?android:attr/textAppearanceMedium"  
        android:visibility="gone"/>  
  
    <Button  
        android:id="@+id/setup"  
        android:layout_width="match_parent"  
        android:layout_height="wrap_content"  
        android:onClick="showSettings"  
        android:text="@string/visit_settings"  
        android:visibility="gone"/>  
  
    <View  
        android:id="@+id/divider"  
        android:layout_width="match_parent"  
        android:layout_height="2dip"  
        android:layout_marginBottom="4dip"  
        android:layout_marginTop="4dip"  
        android:background="#FF000000"  
        android:visibility="gone"/>  
  
    <Switch  
        android:id="@+id/camera"  
        android:layout_width="match_parent"  
        android:layout_height="wrap_content"
```

## DEVICE ADMINISTRATION

---

```
        android:text="@string/allow_camera"/>

<Switch
    android:id="@+id/widgets"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_marginTop="4dip"
    android:text="@string/allow_widgets"/>

</LinearLayout>
```

In `onCreate()` of our activity (`MainActivity`), we request a `DevicePolicyManager`, set up a `ComponentName` identifying our `DeviceAdminReceiver` implementation (`LockscreenAdminReceiver`), and hook up the activity to know about changes in the state of the `Switch` widgets:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);

    mgr=(DevicePolicyManager) getSystemService(DEVICE_POLICY_SERVICE);
    cn=new ComponentName(this, LockscreenAdminReceiver.class);

    camera=(CompoundButton) findViewById(R.id.camera);
    camera.setOnCheckedChangeListener(this);

    widgets=(CompoundButton) findViewById(R.id.widgets);
    widgets.setOnCheckedChangeListener(this);
}
```

In `onResume()`, we check to see if our `DeviceAdminReceiver` is active — in other words, whether the user has set us up as being a device administrator or not:

```
@Override
public void onResume() {
    super.onResume();

    if (mgr.isAdminActive(cn)) {
        toggleWidgets(true);

        int status=mgr.getKeyguardDisabledFeatures(cn);

        camera.setChecked(!((status & DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA) ==
DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA));
        widgets.setChecked(!((status & DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL) ==
DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL));
    }
    else {
```

## DEVICE ADMINISTRATION

---

```
toggleWidgets(false);
}
}
```

We toggle the visibility and enabled settings of our widgets based upon whether we are a device administrator or not, in a `toggleWidgets()` private method:

```
private void toggleWidgets(boolean enable) {
    int visibility=(enable ? View.GONE : View.VISIBLE);

    camera.setEnabled(enable);
    widgets.setEnabled(enable);

    findViewById(R.id.divider).setVisibility(visibility);
    findViewById(R.id.setup).setVisibility(visibility);
    findViewById(R.id.setupMessage).setVisibility(visibility);
}
```

`onResume()` also sets the state of our Switch widgets based upon the current state of the keyguard features, by calling `getKeyguardDisabledFeatures()` on the `DevicePolicyManager`. This returns a bit set of which features are disabled, with `DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA` and/or `DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL` possibly being set.

At the outset, after being installed, we will not be a device administrator, so the Switch widgets will be disabled and the Button will be visible. We simply send the user to the security screen in the Settings app if they click that button:

```
public void showSettings(View v) {
    startActivity(new Intent(Settings.ACTION_SECURITY_SETTINGS));
}
```

When the user toggles a Switch, our activity will be called with `onCheckedChanged()`. There, we need to call `setKeyguardDisabledFeatures()` with a new bit set, toggling on or off a bit based on the user's chosen values in the UI:

```
@Override
public void onCheckedChanged(CompoundButton buttonView,
                             boolean isChecked) {
    int status=mgr.getKeyguardDisabledFeatures(cn);

    if (buttonView == camera) {
        if (isChecked) {
            mgr.setKeyguardDisabledFeatures(cn, status
                & ~DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
        }
    }
}
```

```
    }
    else {
        mgr.setKeyguardDisabledFeatures(cn, status
            | DevicePolicyManager.KEYGUARD_DISABLE_SECURE_CAMERA);
    }
}
else {
    if (isChecked) {
        mgr.setKeyguardDisabledFeatures(cn, status
            & ~DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
    }
    else {
        mgr.setKeyguardDisabledFeatures(cn, status
            | DevicePolicyManager.KEYGUARD_DISABLE_WIDGETS_ALL);
    }
}
}
```

Note that we have the Switch widgets set up for positive statements (e.g., “enable the camera”), while the bit set uses negative statements (e.g., “disable the camera”). That makes toggling the bit set a “bit” more complicated, to ensure that we are applying the user’s choices correctly.

## Passwords and Device Administration

One popular facet of the device administration APIs is for an app to mandate a certain degree of password quality. The app might then fail to operate if the current password does not meet the requested quality standard.

### Mandating Quality of Security

You can call various setters on `DevicePolicyManager` to dictate your minimum requirements for the password that the user uses to get past the lock screen.

Examples include:

- `setPasswordMinimumLength()`
- `setPasswordQuality()` (with an integer flag describing the type of “quality” you seek, such as `PASSWORD_QUALITY_NUMERIC` if a PIN is OK, or `PASSWORD_QUALITY_COMPLEX` if you require mixed case and numbers and such)
- `setPasswordMinimumLowerCase()` (indicating how many lowercase letters are required at minimum in the user’s password)

All of these require the <limit-password> policy be requested in the metadata.

Then, you can call `isActivePasswordSufficient()` to determine if the current password meets your requirements. If it does not, you might elect to disable certain functionality. Or, if you requested the <reset-password> policy in the metadata, you can call `resetPassword()` to force the user to come up with a password meeting your requirements.

Similarly, you can also call `getStorageEncryptionStatus()` on `DevicePolicyManager` to find out whether full-disk encryption is active, inactive, or unavailable on this particular device. If it is inactive, and you requested the <encrypted-storage> policy in your metadata, you can call `setStorageEncryption()` to demand it, and start the encryption process via starting the `ACTION_START_ENCRYPTION` activity.

### Establishing Password Requirements

To see password quality enforcement in action, let us examine the [DeviceAdmin/PasswordEnforcer](#) sample application.

The activity (`MainActivity`) is fairly short, and much of its code is based on the earlier `LockMeNow` sample:

```
package com.commonware.android.pwenforce;

import android.app.Activity;
import android.app.admin.DevicePolicyManager;
import android.content.ComponentName;
import android.content.Intent;
import android.os.Bundle;
import android.widget.Toast;

public class MainActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        ComponentName cn=new ComponentName(this, AdminReceiver.class);
        DevicePolicyManager mgr=
            (DevicePolicyManager) getSystemService(DEVICE_POLICY_SERVICE);

        if (mgr.isAdminActive(cn)) {
            int msgId;
```

## DEVICE ADMINISTRATION

---

```
    if (mgr.isActivePasswordSufficient()) {
        msgId=R.string.compliant;
    }
    else {
        msgId=R.string.not_compliant;
    }

    Toast.makeText(this, msgId, Toast.LENGTH_LONG).show();
}
else {
    Intent intent=
        new Intent(DevicePolicyManager.ACTION_ADD_DEVICE_ADMIN);
    intent.putExtra(DevicePolicyManager.EXTRA_DEVICE_ADMIN, cn);
    intent.putExtra(DevicePolicyManager.EXTRA_ADD_EXPLANATION,
        getString(R.string.device_admin_explanation));
    startActivity(intent);
}

finish();
}
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/java/com/commonsware/android/pwenforce/MainActivity.java](#))

In `onCreate()`, after obtaining a `DevicePolicyManager`, we see if our app has been designated by the user as a device administrator. If not — which will be the case when the app is first installed — we use an `ACTION_ADD_DEVICE_ADMIN` Intent and `startActivity()` to steer the user towards making our app be a device administrator.

If the user does make our app be a device administrator, our `AdminReceiver` will get control in `onEnabled()`, as we have registered it for `DEVICE_ADMIN_ENABLED` broadcasts in the manifest. In `onEnabled()`, we mandate that the password for the device must be alphanumeric, via a call to `setPasswordQuality()` on the `DevicePolicyManager`:

```
@Override
public void onEnabled(Context ctxt, Intent intent) {
    ComponentName cn=new ComponentName(ctxt, AdminReceiver.class);
    DevicePolicyManager mgr=
        (DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);

    mgr.setPasswordQuality(cn,
        DevicePolicyManager.PASSWORD_QUALITY_ALPHANUMERIC);

    onPasswordChanged(ctxt, intent);
}
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/java/com/commonsware/android/pwenforce/AdminReceiver.java](#))

We will see the role of the `onPasswordChanged()` method, called late in `onEnabled()`, later in this chapter.

Back in `onCreate()` of our `MainActivity`, if we *are* a device administrator, then we know that the `setPasswordQuality()` call has been made, and so we can check to see if the current password meets our standards via a call to `isActivePasswordSufficient()` on the `DevicePolicyManager`. The app displays a `Toast` showing whether the password is or is not currently “sufficient”.

### Password-Related Events

Via appropriate actions in our `<intent-filter>` for our `DeviceAdminReceiver`, and associated callback methods, we can find out other things that go on with respect to the password:

- `ACTION_PASSWORD_CHANGED` informs us when the user has changed her password
- `ACTION_PASSWORD_FAILED` informs us when somebody tries to enter a password, and the password was incorrect
- `ACTION_PASSWORD_SUCCEEDED` informs us when the user has successfully entered the password and unlocked the device... after an attempt had previously failed

The `PasswordEnforcer` sample registers for all of these in the manifest:

```
<receiver
  android:name="AdminReceiver"
  android:permission="android.permission.BIND_DEVICE_ADMIN">
  <meta-data
    android:name="android.app.device_admin"
    android:resource="@xml/device_admin" />

  <intent-filter>
    <action android:name="android.app.action.DEVICE_ADMIN_ENABLED" />
    <action android:name="android.app.action.ACTION_PASSWORD_CHANGED" />
    <action android:name="android.app.action.ACTION_PASSWORD_FAILED" />
    <action android:name="android.app.action.ACTION_PASSWORD_SUCCEEDED" />
  </intent-filter>
</receiver>
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/AndroidManifest.xml](#))

The implementations of the corresponding `onPasswordChanged()`,

## DEVICE ADMINISTRATION

---

`onPasswordFailed()`, and `onPasswordSucceeded()` methods simply display Toast messages about those events:

```
@Override
public void onPasswordChanged(Context ctxt, Intent intent) {
    DevicePolicyManager mgr=
        (DevicePolicyManager)ctxt.getSystemService(Context.DEVICE_POLICY_SERVICE);
    int msgId;

    if (mgr.isActivePasswordSufficient()) {
        msgId=R.string.compliant;
    }
    else {
        msgId=R.string.not_compliant;
    }

    Toast.makeText(ctxt, msgId, Toast.LENGTH_LONG).show();
}

@Override
public void onPasswordFailed(Context ctxt, Intent intent) {
    Toast.makeText(ctxt, R.string.password_failed, Toast.LENGTH_LONG)
        .show();
}

@Override
public void onPasswordSucceeded(Context ctxt, Intent intent) {
    Toast.makeText(ctxt, R.string.password_success, Toast.LENGTH_LONG)
        .show();
}
```

(from [DeviceAdmin/PasswordEnforcer/app/src/main/java/com/commonsware/android/pwenforce/AdminReceiver.java](#))

However, these will illustrate some quirks in the behavior of the device administration APIs:

- `onPasswordSucceeded()` is not called on *every* successful password entry, only those that come after a prior `onPasswordFailed()` call. One imagines that perhaps `onPasswordSucceededAfterItHadFailedBefore()` was deemed to be too wordy.
- `isActivePasswordSufficient()` will return a value based on the *previous* password in `onPasswordChanged()`, not the newly-changed password. Since the system will prevent the user from entering a new password that is insufficient, you should not need to call `isActivePasswordSufficient()` from `onPasswordChanged()`.
- A Toast cannot display over the lockscreen, and so the `onPasswordFailed()` Toast will never be seen.

## Getting Along with Others

Bear in mind that you might not be the only device administrator on any given device. If there are multiple administrators, the most secure requirements are in force. So, for example, if Admin A requests a minimum password length of 7, and Admin B requests a minimum password length of 10, the user will have to supply a password that is at least 10 characters long, to meet both device administrators' requirements.

This also means that certain requests you make may fail. For example, if you decide to say that you do *not* need encryption (`setStorageEncryption()` with a value of `false`), if something *else* needs encryption, the user will still need to encrypt their device.

# Basic Use of Sensors

---

“Sensors” is Android’s overall term for ways that Android can detect elements of the physical world around it, from magnetic flux to the movement of the device. Not all devices will have all possible sensors, and other sensors are likely to be added over time. In this chapter, we will explore the general concept of Android sensors and how to receive data from them.

Note, however, that this chapter will not get into details of detecting movement via the accelerometer, etc.

## Prerequisites

Understanding this chapter requires that you have read the core chapters, particularly the [chapter on threads](#). Having experience with other system-service-and-listener patterns, such as [fetching locations with LocationManager](#), is helpful but not strictly required.

## The Sensor Abstraction Model

When fetching locations from `LocationManager`, you do not have dedicated APIs per location-finding technology (e.g., GPS vs. WiFi hotspot proximity vs. cell-tower triangulation vs. ...). Instead, you work with a `LocationManager` system service, asking for locations using a single API, where location technologies are identified by name (e.g., `GPS_PROVIDER`).

Similarly, when working with sensors, you do not have dedicated APIs to get sensor readings from each sensor. Instead, you work with a `SensorManager` system service, asking for sensor events using a single API, where sensors are identified by name

(e.g., TYPE\_LINEAR\_ACCELERATION).

Note, though, that there are some dedicated methods on `SensorManager` to help you *interpret* some of the sensors, particularly the accelerometer. However, those are merely helper methods; getting at the actual accelerometer data uses the same APIs that you would use to, say, access the barometer for atmospheric pressure.

## Considering Rates

Usually, when working with sensors, you want to find out about changes in the sensor reading over a period of time. For example, in a driving game, where the user holds their device like a steering wheel and uses it to “turn” their virtual car, you need to know information about acceleration and positioning so long as game play is going on.

Hence, when you request a feed of sensor readings from `SensorManager`, you will specify a desired rate at which you should receive those readings. You do that by specifying an amount of delay in between readings; Android will drop sensor readings that arrive before the delay period has elapsed.

There are four standard delay periods, defined as constants on the `SensorManager` class:

1. `SENSOR_DELAY_NORMAL`, which is what most apps would use for broad changes, such as detecting a screen rotating from portrait to landscape
2. `SENSOR_DELAY_UI`, for non-game cases where you want to update the UI continuously based upon sensor readings
3. `SENSOR_DELAY_GAME`, which is faster (less delay) than `SENSOR_DELAY_UI`, to try to drive a higher frame rate
4. `SENSOR_DELAY_FASTEST`, which is the “firehose” of sensor readings, without delay

The more sensor readings you get, the faster your code has to be for using those readings, lest you take too long and starve your thread of time to do anything else. This is particularly important given that you receive these sensor events on the main application thread, and therefore the time you spend processing these events is time unavailable for screen updates. Hence, choose the slowest rate that you can that will give you acceptable granularity of output.

## Reading Sensors

Sensors are event-driven. You cannot ask Android for the value of a sensor at a point in time. Rather, you register a listener for a sensor, then process the sensor events as they come in. You can unregister the listener when you are done, either because you have the reading that you need, or the user has done something (like move to another activity) that indicates that you no longer need the sensor events.

To demonstrate this, we will examine the [Sensor/Monitor](#) sample application, which will list all of the available sensors, plus show the incoming readings from a selected sensor.

This app uses a pair of fragments: `SensorsFragment` for showing the list, and `SensorLogFragment` for showing the log of sensor readings. These are wrapped in a [SlidingPaneLayout](#), so both fragments will appear side-by-side if there is enough room, otherwise the list of sensors will be in a sliding pane that overlaps the list of log events:

```
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <fragment
        android:id="@+id/sensors"
        android:name="com.commonware.android.sensor.monitor.SensorsFragment"
        android:layout_width="300sp"
        android:layout_height="match_parent" />

    <fragment
        android:id="@+id/log"
        android:name="com.commonware.android.sensor.monitor.SensorLogFragment"
        android:layout_width="400dp"
        android:layout_height="match_parent"
        android:layout_weight="1" />

</android.support.v4.widget.SlidingPaneLayout>
```

(from [Sensor/Monitor/app/src/main/res/layout/activity\\_main.xml](#))

## Obtaining a SensorManager

The gateway to the sensor roster on the device is the `SensorManager` system service. You obtain one of these by calling `getSystemService()` on any `Context`, asking for the `SENSOR_SERVICE`, and casting the result to be a `SensorManager`, as seen in the `onCreate()` method of our `MainActivity`:

---

## BASIC USE OF SENSORS

---

```
mgr=(SensorManager) getSystemService(Context.SENSOR_SERVICE);
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

We do this before the `setContentView()` call, as in some situations, `setContentView()` with static fragments will inflate the fragments and call `onViewCreated()` on them before `setContentView()` returns. As you will see, `SensorsFragment` calls back into `MainActivity` to get the list of sensors. Since that needs the `SensorManager`, we need to get our hands on the `SensorManager` before it is safe to load our layout.

### Identifying a Sensor of Interest

There are sensor types, and then there are sensors.

You might think that there would be a one-to-one mapping between these. In truth, there might be more than one sensor for a given type, the way the `SensorManager` API is set up. Regardless, somewhere along the line, you will need to identify the `Sensor` that you want to work with.

The most common pattern, if you know the type of sensor that you want, is to call `getDefaultSensor()` on `SensorManager`, supplying the type of the sensor (e.g., `TYPE_ACCELEROMETER`, `TYPE_GYROSCOPE`), where the type names are constants defined on the `Sensor` class. If there is more than one possible `Sensor` for that type, Android will give you the “default” one, which is usually a reasonable choice.

Another approach, and the one used by this sample application, is to call `getSensorList()` on `SensorManager`, which returns a `List` of all `Sensor` objects available on this device. The sample’s `MainActivity` has a `getSensorList()` that returns this list, after a bit of manipulation:

```
@Override
public List<Sensor> getSensorList() {
    List<Sensor> unfiltered=
        new ArrayList<>(mgr.getSensorList(Sensor.TYPE_ALL));
    List<Sensor> result=new ArrayList<>();

    for (Sensor s : unfiltered) {
        if (Build.VERSION.SDK_INT < Build.VERSION_CODES.KITKAT
            || !isTriggerSensor(s)) {
            result.add(s);
        }
    }
}
```

## BASIC USE OF SENSORS

---

```
Collections.sort(result, new Comparator<Sensor>() {
    @Override
    public int compare(final Sensor a, final Sensor b) {
        return(a.toString().compareTo(b.toString()));
    }
});

return(result);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

Android 4.4 started introducing some “trigger sensors”, ones that are designed to deliver a single reading, then automatically become unregistered. This sample app is designed to display results from more traditional sensors that provide ongoing readings. So, `getSensorList()` calls an `isTriggerSensor()` method on API Level 19+ devices, and throws out sensors that are trigger sensors. The `isTriggerSensor()` method simply checks the sensor type against a list of trigger sensors:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isTriggerSensor(Sensor s) {
    int[] triggers=
        { Sensor.TYPE_SIGNIFICANT_MOTION, Sensor.TYPE_STEP_DETECTOR,
          Sensor.TYPE_STEP_COUNTER };

    return(Arrays.binarySearch(triggers, s.getType()) >= 0);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

The reason for isolating `isTriggerSensor()` into a separate method, and not having the array of sensor types as a static `final` array, is because these sensor types are not available in all Android versions. Having the array of sensor types as a static `final` data member would require putting the `@TargetApi` annotation on the entire class, which is unwise if the class will be used on older devices. This way, we can isolate the new-target code into a dedicated method, with a more locally-scoped `@TargetApi` annotation.

## Getting Sensor Events

To get sensor events, you need a `SensorEventListener`. This is an interface, calling for two method implementations:

1. `onAccuracyChanged()`, where you are informed about a significant change in

## BASIC USE OF SENSORS

---

- the accuracy of the readings that you are going to get from the sensor
2. `onSensorChanged()`, where you are passed a `SensorEvent` representing one of those readings

To receive events for a given `Sensor`, you call `registerListener()` on the `SensorManager`, supplying the `Sensor`, the `SensorEventListener`, and one of the `SENSOR_DELAY_*` values to control the rate of events. Later on, you need to call `unregisterListener()`, supplying the same `SensorEventListener`, to break the connection. **Failing to unregister the listener is bad.** The sensor subsystem is oblivious to things like activity lifecycles, and so if you leak a listener, not only will you perhaps leak the component that registered the listener, but you will continue to get sensor events until the process is terminated. As active sensors do consume power, users will not appreciate the battery drain your leaked listener will incur.

The List of `Sensor` objects from that `getSensorList()` method shown previously will be used to populate a `ListView`. When the user taps on a `Sensor` in the list, an `onSensorSelected()` method is called on the `MainActivity`. Here, we unregister our listener (a `SensorLogFragment` that we will discuss more in a bit), in case we were registered for a prior `Sensor` choice, before registering for the newly-selected `Sensor`:

```
@Override
public void onSensorSelected(Sensor s) {
    mgr.unregisterListener(log);
    mgr.registerListener(log, s, SensorManager.SENSOR_DELAY_NORMAL);
    log.init(isXYZ(s));
    panes.closePane();
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

We will discuss the remainder of the `onSensorSelected()` method a bit later in this chapter.

Since `SensorLogFragment` implements `SensorEventListener` — so we can use it with `registerListener()` — we need to implement `onAccuracyChanged()` and `onSensorChanged()`:

```
@Override
public void onAccuracyChanged(Sensor sensor, int accuracy) {
    // unused
}

@Override
public void onSensorChanged(SensorEvent e) {
```

## BASIC USE OF SENSORS

---

```
Float[] values=new Float[3];

values[0]=e.values[0];
values[1]=e.values.length>1 ? e.values[1] : 0.0f;
values[2]=e.values.length>2 ? e.values[2] : 0.0f;

adapter.add(values);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

Once again, we will get into the implementation of `onSensorChanged()` a bit later in this chapter.

The big thing to note now about `onSensorChanged()`, though, is that **the `SensorEvent` object comes from an object pool and gets recycled**. It is not safe for you to hold onto this `SensorEvent` object past the call to `onSensorChanged()`. Hence, you need to do something with the data in the `SensorEvent`, then let go of the `SensorEvent` itself, so that instance can be used again later. This is to help prevent excessive garbage collection, particularly for low-delay requests for sensor readings (e.g., `SENSOR_DELAY_FASTEST`).

### Interpreting Sensor Events

The key piece of data in the `SensorEvent` object is `values`. This is a six-element float array containing the actual sensor reading. What those values *mean* will vary by sensor. For example:

- For accelerometer readings (e.g., `TYPE_ACCELEROMETER`), the first three elements of the array represent the reported acceleration, in  $m/s^2$ , along the X, Y, and Z axes respectively (X = out the right side of the device, Y = out the top edge of the device, Z = out the screen towards the user's eyes)
- `TYPE_PRESSURE` uses the first element of the `values` array to report the barometric pressure in millibars
- `TYPE_LIGHT` uses the first element of the `values` array to report the light level in lux

And so on.

The `SensorEvent` documentation contains instructions on how to interpret these events on a per-sensor-type basis.

## BASIC USE OF SENSORS

---

That being said, sensors can be roughly divided into two groups:

1. Sensors whose readings take into account three axes (X/Y/Z). These include TYPE\_ACCELEROMETER, TYPE\_GRAVITY, TYPE\_GYROSCOPE, TYPE\_LINEAR\_ACCELERATION, and TYPE\_MAGNETIC\_FIELD.
2. Sensors that have simple single-value readings, such as TYPE\_PRESSURE and TYPE\_LIGHT

The `isXYZ()` method on `MainActivity` simply returns a boolean indicating whether or not this particular `Sensor` is one that uses all three axes (`true`) or not (`false`). As the roster of sensors has changed over the years, it also does some checks based on API level:

```
@TargetApi(Build.VERSION_CODES.KITKAT)
private boolean isXYZ(Sensor s) {
    switch (s.getType()) {
        case Sensor.TYPE_ACCELEROMETER:
        case Sensor.TYPE_GRAVITY:
        case Sensor.TYPE_GYROSCOPE:
        case Sensor.TYPE_LINEAR_ACCELERATION:
        case Sensor.TYPE_MAGNETIC_FIELD:
        case Sensor.TYPE_ROTATION_VECTOR:
            return(true);
    }

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.JELLY_BEAN_MR2) {
        if (s.getType() == Sensor.TYPE_GAME_ROTATION_VECTOR
            || s.getType() == Sensor.TYPE_GYROSCOPE_UNCALIBRATED
            || s.getType() == Sensor.TYPE_MAGNETIC_FIELD_UNCALIBRATED) {
            return(true);
        }
    }

    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.KITKAT) {
        if (s.getType() == Sensor.TYPE_GEOMAGNETIC_ROTATION_VECTOR) {
            return(true);
        }
    }

    return(false);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

### Wiring Together the Sample

Overall, this sample app uses the `SlidingPaneLayout` first seen back in the chapter on large-screen support. We have two fragments, in a master-detail pattern, where the “master” will be a list of all available sensors, and the “detail” will be a log of sensor readings from a selected sensor.

Our layout (`res/layout/activity_main.xml`) wires in a `SensorsFragment` (master) and `SensorLogFragment` (detail) in a `SlidingPaneLayout`:

```
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <fragment
        android:id="@+id/sensors"
        android:name="com.commonware.android.sensor.monitor.SensorsFragment"
        android:layout_width="300sp"
        android:layout_height="match_parent"/>

    <fragment
        android:id="@+id/log"
        android:name="com.commonware.android.sensor.monitor.SensorLogFragment"
        android:layout_width="400dp"
        android:layout_height="match_parent"
        android:layout_weight="1"/>

</android.support.v4.widget.SlidingPaneLayout>
```

(from [Sensor/Monitor/app/src/main/res/layout/activity\\_main.xml](#))

The `SensorsFragment` is reminiscent of `CountriesFragment` from the `SlidingPaneLayout` variant of the `EU4You` sample. The biggest differences are that we use a `SensorListAdapter` for representing the list of sensors, that we use `getSensorList()` on our `SensorsFragment.Contract` class to retrieve the model data, and that we call `onSensorSelected()` on the contract to report of selections:

```
package com.commonware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Bundle;
import android.view.View;
import android.widget.ListView;
import java.util.List;

public class SensorsFragment extends
    ContractListFragment<SensorsFragment.Contract> {
    static private final String STATE_CHECKED=
```

## BASIC USE OF SENSORS

---

```
    "com.commonware.android.sensor.monitor.STATE_CHECKED";
private SensorListAdapter adapter=null;

@Override
public void onCreateView(View view, Bundle state) {
    super.onCreateView(view, state);

    adapter=new SensorListAdapter(this);
    listView().setChoiceMode(ListView.CHOICE_MODE_SINGLE);
    setListAdapter(adapter);

    if (state != null) {
        int position=state.getInt(STATE_CHECKED, -1);

        if (position > -1) {
            listView().setItemChecked(position, true);
            getContract().onSensorSelected(adapter.getItem(position));
        }
    }
}

@Override
public void onItemClick(ListView l, View v, int position, long id) {
    l.setItemChecked(position, true);

    getContract().onSensorSelected(adapter.getItem(position));
}

@Override
public void onSaveInstanceState(Bundle state) {
    super.onSaveInstanceState(state);

    state.putInt(STATE_CHECKED, listView().getCheckedItemPosition());
}

interface Contract {
    void onSensorSelected(Sensor s);

    List<Sensor> getSensorList();
}
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonware/android/sensor/monitor/SensorsFragment.java](#))

SensorListAdapter illustrates another approach for handling the difference in “activated” row support. The EU4You samples used an activated style to apply the “activated” support on Android 3.0 and higher. Here, our custom ArrayAdapter

## BASIC USE OF SENSORS

---

subclass dynamically chooses between `android.R.layout.simple_list_item_activated_1` (an activated-capable built-in row layout) and the classic `android.R.layout.simple_list_item_1` based upon API level:

```
package com.commonware.android.sensor.monitor;

import android.hardware.Sensor;
import android.os.Build;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.TextView;

class SensorListAdapter extends ArrayAdapter<Sensor> {
    SensorListAdapter(SensorsFragment sensorsFragment) {
        super(sensorsFragment.getActivity(), getRowResourceId(),
            sensorsFragment.getContract().getSensorList());
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        ((TextView)result).setText(getItem(position).getName());

        return(result);
    }

    private static int getRowResourceId() {
        if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.GINGERBREAD) {
            return(android.R.layout.simple_list_item_activated_1);
        }

        return(android.R.layout.simple_list_item_1);
    }
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonware/android/sensor/monitor/SensorListAdapter.java](#))

We also have to override `getView()`, as our model is `Sensor`, whose `toString()` is not what we want, so we have to manually populate the list row with `getName()` instead.

`SensorLogFragment` is another `ListFragment`. In particular, though, we set it up for `TRANSCRIPT_MODE_NORMAL`, which means that Android will automatically scroll the

## BASIC USE OF SENSORS

---

ListView to the bottom if we add new rows to the list *and* the user has not scrolled up in the list to view past data:

```
@Override
public void onCreateView(View view, Bundle state) {
    super.onCreateView(view, state);

    getListView().setTranscriptMode(ListView.TRANSCRIPT_MODE_NORMAL);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

However, we do not initialize our ListAdapter in onCreateView(), as we might normally do. Instead, we have a dedicated init() method, to be called by MainActivity, where we set up the SensorLogAdapter and keep track of whether the Sensor that we are logging is designed to report three-dimensional values (isXYZ is true) or not:

```
void init(boolean isXYZ) {
    this.isXYZ=isXYZ;
    adapter=new SensorLogAdapter(this);
    setListAdapter(adapter);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

The init() method, in turn, was called by onSensorSelected() of MainActivity. Hence, whenever the user taps on a sensor, we set up a fresh log. init() can do this because MainActivity retrieved our SensorLogFragment up in onCreate(), stashing it in a log data member:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    mgr=(SensorManager)getSystemService(Context.SENSOR_SERVICE);

    setContentView(R.layout.activity_main);

    log=
        (SensorLogFragment)getSupportFragmentManager().findFragmentById(R.id.log);

    panes=findViewById(R.id.panes);
    panes.openPane();
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/MainActivity.java](#))

Our onSensorChanged() method in SensorLogFragment copies the values from the

## BASIC USE OF SENSORS

---

SensorEvent into a separate Float array that is our list's model data:

```
@Override
public void onSensorChanged(SensorEvent e) {
    Float[] values=new Float[3];

    values[0]=e.values[0];
    values[1]=e.values.length>1 ? e.values[1] : 0.0f;
    values[2]=e.values.length>2 ? e.values[2] : 0.0f;

    adapter.add(values);
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

Most of the sensors will have three readings in the values array, but not all will. We are guaranteed at least one element in values. So, we normalize our Float array to use up to three values from values, substituting in 0.0f for missing elements.

SensorLogAdapter uses the isXYZ value to determine how it should format the rows:

- For single-value sensors, we just show the first Float from the array
- For three-dimensional sensors, we show all three dimensions, plus the “net” (square root of the sum of the squares), separated by slashes

```
private class SensorLogAdapter extends ArrayAdapter<Float[]> {
    SensorLogAdapter(SensorLogFragment sensorLogFragment) {
        super(sensorLogFragment.getActivity(),
            android.R.layout.simple_list_item_1,
            new ArrayList<Float[]>());
    }

    @SuppressWarnings("DefaultLocale")
    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        TextView row=
            (TextView)super.getView(position, convertView, parent);
        String content=null;
        Float[] values=getItem(position);

        if (isXYZ) {
            content=
                String.format("%7.3f / %7.3f / %7.3f / %7.3f",
                    values[0],
                    values[1],
                    values[2],
```

## BASIC USE OF SENSORS

```
        Math.sqrt(values[0] * values[0] + values[1]
            * values[1] + values[2] * values[2]));
    }
    else {
        content=String.format("%7.3f", values[0]);
    }

    row.setText(content);

    return(row);
}
}
```

(from [Sensor/Monitor/app/src/main/java/com/commonsware/android/sensor/monitor/SensorLogFragment.java](#))

The rest of MainActivity simply manages the SlidingPaneLayout, much like the EU4YouSlidingPane sample did.

## The Results

When the user taps on a sensor in the list, we get a log of readings:

## Batching Sensor Readings

API Level 19 (Android 4.4) added a new feature to the sensor subsystem: batched sensor events. Now, `registerListener()` can take a batch period in microseconds, and Android may elect to deliver events to you delayed by up to that amount of time. The objective will be to reduce the power draw of the sensors, for sensor hardware that supports this sort of batching behavior. Not all hardware will, in which case your requested batch latency will be ignored.

# Printing and Document Generation

---

Mobile devices are continuing to close the gap on capabilities that had formerly been the sole province of desktop systems or servers. After all, if the vision is that people should be able to use phones and tablets *instead of* desktops and notebooks, phones and tablets need to do whatever it is that those people need to have done.

One such capability is the ability to print to networked printers. While various third-party printing options had been available for some time, it is only starting with the Android 4.4 release that the OS and framework itself has support for printing. Hence, at this time, a significant majority of Android devices will be natively capable of printing, and so users will be more likely to expect that your app supports such printing.

As it turns out, the print engine in Android is centered upon the PDF document format, and Android supports converting HTML into PDF, albeit on a somewhat limited basis.

The API seems simple and clean. It actually *is* simple and clean... so long as you are printing very simple contents (bitmaps or HTML). Once you get into anything more complicated than that, the threading alone starts to make things rather messy.

This chapter describes how to use the Android 4.4 print system, including how to print HTML and PDF files. It will also cover how to generate HTML and PDF files, whether for printing or for other purposes (e.g., reports to be emailed or uploaded somewhere).

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this

book. Also, you should read the chapter on [advanced uses of WebView](#).

## The Android Print System

Writing programs that print on desktop operating systems historically has been tedious. The fine-grained control that is needed for high-quality output makes the APIs complicated, and these tend to be only partially masked by high-level wrappers to simplify common scenarios.

Android's print system is no different.

Starting with Android 4.4, you can request access to a `PrintManager` system service (via `getSystemService()`, called on any `Context`). It offers a `print()` method that lets you describe what should be printed, in the form of a `PrintAttributes` (e.g., what size paper are you looking for?) and a `PrintDocumentAdapter`. The latter is responsible for working with Android to actually create the content to be printed.

`print()` returns a `PrintJob`, which you can use to examine the status of the print request. `PrintManager` also offers a `getPrintJobs()` method that returns all of *your* outstanding print requests. Note that you cannot access print jobs from other applications.

Hence, the real complexity of printing lies in the `PrintDocumentAdapter` implementation. This class is responsible for generating a PDF that represents the content to be printed. This leads to four basic ways of working with a `PrintDocumentAdapter`:

1. Have one created for you, such as via a `WebView` for printing HTML content
2. Create one that takes a PDF generated elsewhere and uses it for the output
3. Create one that uses Android's Canvas-based PDF generation class, called `PrintedPdfDocument`
4. Use APIs that avoid all of this entirely, such as `printBitmap()` on `PrintHelper`

## About the Sample App

The [Printing/PrintManager](#) sample project demonstrates all but the Canvas option.

The UI is just a large `EditText`, designed for you to type in a message.

The action bar overflow contains four options:

- “Bitmap”, to print an image from your device or emulator
- “Web Page”, to print [the Web page for this book](#)
- “TPS Report”, which prints a report containing the message from the EditText
- “PDF”, which prints a copy of the cover of Version 5.8 of this book, which is packaged in the app as an asset

*Figure 844: Print Demo App, Showing Overflow*

## Printing a Bitmap

Google helpfully supplies a `PrintHelper` class in the Android Support package that makes it trivially easy to print a bitmap. Just call `printBitmap()` on the `PrintHelper`, after some minor configuration, and it takes over from there.

In `onOptionsItemSelected()` of the sample app's `MainActivity`, when the user chooses the “Bitmap” item, we call `startActivityForResult()` on an `ACTION_GET_CONTENT` Intent, to allow the user to pick an image from the device or emulator:

## PRINTING AND DOCUMENT GENERATION

---

```
case R.id.bitmap:
    Intent i=
        new Intent(Intent.ACTION_GET_CONTENT)
            .addCategory(Intent.CATEGORY_OPENABLE)
            .setType("image/*");

    startActivityForResult(i, IMAGE_REQUEST_ID);
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

This, in turn, will trigger a call to `onActivityResult()`, once the user has (presumably) chosen an image:

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
                                Intent data) {
    if (requestCode == IMAGE_REQUEST_ID
        && resultCode == Activity.RESULT_OK) {
        try {
            PrintHelper help=new PrintHelper(this);

            help.setScaleMode(PrintHelper.SCALE_MODE_FIT);
            help.printBitmap("Photo!", data.getData());
        }
        catch (FileNotFoundException e) {
            Log.e(getClass().getSimpleName(), "Exception printing bitmap",
                e);
        }
    }
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

If the user did indeed choose an image, we create an instance of `PrintHelper`, call `setScaleMode()` to tell it fit the image to the page, and then call `printBitmap()` to print the image.

`setScaleMode()` takes one of two values:

1. `SCALE_MODE_FIT` will show the entire image, blown up as big as possible
2. `SCALE_MODE_FILL` will fill the entire page, at the cost of cropping the image along one axis, if the image's aspect ratio does not match the paper's aspect ratio

`printBitmap()` takes the name of the print job (so the user, when reviewing the outstanding print jobs, knows what it is) and either a `Uri` or a `Bitmap` for the image

## PRINTING AND DOCUMENT GENERATION

---

itself. In the case of a `Uri`, the `Uri` could be malformed, in which case the `FileNotFoundException` may be thrown, which is why we catch it.

What the user sees, after choosing an image to print (and a printer, if the user has more than one available), is a print configuration dialog appear, much like those you might see in a desktop OS:

*Figure 845: HP Print Configuration Dialog*

The dialog itself is provided by Android; the contents of the dialog is provided by a `PrintService` that is responsible for taking our print job and actually dispatching it to the printer.

Here, the user can make typical changes, like portrait/landscape printing and the number of copies, before pressing the “Print” button. At that point, the user’s chosen image will be printed.

Note that, in Android 4.4, the print dialog does not work especially well in landscape on smaller screen sizes, forcing the user to scroll to get to all of the widgets, including the “Print” button.

## Printing an HTML Document

Printing a bitmap is nice. It is not especially useful, as it implies that we have a bitmap worth printing by itself. That is certainly possible, but it is unlikely. Even in the case where we want to print a photo, there is a very good chance that we will need to print some additional information along with the photo (caption, date when photo was taken, etc.).

Being able to print something over which we have greater control of the rendering would be more useful. The easiest way to do that is to print some HTML. [Later in this chapter](#) we will cover how to generate some dynamic HTML representing what you want to print. For the moment, though, let's focus on the printing itself.

### Printing and WebView

Starting in API Level 19, `WebView` is capable of participating in the print process. You can load up a `WebView` with your desired content, then print that content.

Some apps will already be using a `WebView` as part of the UI, and that `WebView` will contain what needs to be printed. For example, a Web browser can easily add a “Print” action bar overflow item that would print the contents of the active `WebView` in the browser.

For cases where you want to print something, but you are not using the `WebView` for anything but printing, you do *not* need to add the `WebView` to the UI. You can create a `WebView` instance via its constructor, passing in your `Activity` as the `Context` required by that constructor. You can then populate that `WebView` with what needs to be printed, then print it. That is the technique that the sample application demonstrates, in part because it is likely to be the more common scenario — only so many apps use a `WebView` in the UI, and more are likely to need to print.

### Printing a URL

The sample app's “Web Page” action bar overflow item is tied to an `R.id.web MenuItem`. When that is tapped by the user, `onOptionsItemSelected()` calls `printWebPage()` to print a Web page loaded from a URL:

```
private void printWebPage() {
    WebView print=prepPrintWebView(getString(R.string.web_page));

    print.loadUrl("https://commonsware.com/Android");
}
```

## PRINTING AND DOCUMENT GENERATION

---

```
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

Here, `getString(R.string.web_page)` is returning a string resource that will be used for the name of a print job. `prepPrintWebView()` returns the `WebView` that will be used for printing. `loadUrl()` is the standard `WebView` method for populating the `WebView` from a URL. Note that this causes the sample app to need the `INTERNET` permission, since we are downloading a Web page and its related assets (CSS, images) from the Internet.

You will notice that we are not actually printing anything directly in `printWebPage()`, which may seem a bit odd given the name of the method. That is because we cannot print anything until the page is loaded — after all, it is only then that we have what we want to print.

The job of `prepPrintWebView()` is to arrange to get control when the page is loaded and actually print the desired page:

```
private WebView prepPrintWebView(final String name) {
    WebView result=getWebView();

    result.setWebViewClient(new WebViewClient() {
        @Override
        public void onPageFinished(WebView view, String url) {
            print(name, view.createPrintDocumentAdapter(),
                new PrintAttributes.Builder().build());
        }
    });

    return(result);
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

`getWebView()` is just a lazy-initialization method, populating a `wv` data member of the activity with a `WebView`. This way, we avoid creating the `WebView` up front, as if the user does not elect to print any HTML, we do not need the `WebView`, and a `WebView` is expensive to initialize:

```
private WebView getWebView() {
    if (wv == null) {
        wv=new WebView(this);
    }
}
```

## PRINTING AND DOCUMENT GENERATION

---

```
return(wv);  
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

We are holding onto the `WebView` in a data member to ensure that it will not be garbage-collected. A `WebView` that is part of our UI is being strongly held by its parent in the View hierarchy, so we do not normally need to worry about this. However, in this case, we are creating a `WebView` dynamically and are *not* adding it to the UI, so we are responsible for holding onto it, at least as long as is needed. In this sample, we just hold onto it for the rest of the life of the activity.

Back in `prepPrintWebView()`, we call `setWebViewClient()`, to attach an anonymous inner class extending `WebViewClient` to the `WebView`. Back in [the chapter introducing `WebView`](#), we saw `WebViewClient` in the context of `shouldOverrideUrlLoading()`. Another popular method to override on a `WebViewClient` is `onPageFinished()`. This is called when the HTML and related assets (CSS, images, etc.) have been loaded and rendered within the `WebView`. At this point, for the particular URL we are loading, it is safe to print the page.

In `onPageFinished()`, we call a `print()` method on `MainActivity` itself:

```
private PrintJob print(String name, PrintDocumentAdapter adapter,  
    PrintAttributes attrs) {  
    startService(new Intent(this, PrintJobMonitorService.class));  
  
    return(mgr.print(name, adapter, attrs));  
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The first line of `print()` calls `startService()` to start a `PrintJobMonitorService`. We will see more about why we are doing that [later in this chapter](#). For the moment, take it on faith that this service will help ensure that our process stays around long enough for our print job to finish.

The second line of `print()` calls a `print()` method on a `mgr` data member. Here, `mgr` is a `PrintManager`, initialized up in `onCreate()` of the activity, by calling `getSystemService()`, asking for the `PRINT_SERVICE`, and casting the result to be a `PrintManager`.

```
@Override  
protected void onCreate(Bundle savedInstanceState) {  
    super.onCreate(savedInstanceState);  
}
```

```
setContentView(R.layout.main);
prose=findViewById(R.id.prose);
mgr=(PrintManager)getSystemService(PRINT_SERVICE);
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The `print()` method tells the `PrintManager` to go print something. `print()` takes three parameters:

1. The name of the print job, which is kept along with the print job itself in case something (e.g., the print driver) wishes to show the user a roster of print jobs. In our case, this is that string resource passed in as the name parameter to `prepPrintWebView()`. That parameter is marked `final`, so the call to `setWebViewClient()` will include the value of that parameter in the anonymous inner class' implementation of `onPageFinished()`.
2. A `PrintDocumentAdapter`. For the case of printing HTML, we get one of those by calling `createPrintDocumentAdapter()` on our populated `WebView`.
3. A `PrintAttributes` object, describing any particular requirements that you have for the printed output (e.g., media size, margins, color/monochrome). If you will let the user control all of that via the print dialog, an empty `PrintAttributes` is fine to use with `print()`. You typically create a `PrintAttributes` by creating a `PrintAttributes.Builder`, calling setters on the `Builder` to configure the `PrintAttributes`, and getting the resulting `PrintAttributes` via a call to `build()`.

And that's it. Android — in particular, `WebView` and its `PrintDocumentAdapter` — takes over from here and prints the Web page.

### Limitations and Concerns

Alas, we do not have infinite flexibility with printing HTML from a `WebView`. Here are some limitations and potential problem areas that you will encounter:

- While you can use JavaScript in the loaded HTML, it cannot trigger the print itself using any standard DOM methods.
- Also, if your JavaScript is going to fire off some asynchronous operations, like an AJAX request, bear in mind that `onPageFinished()` does *not* take those operations into account. You will need to use `addJavascriptInterface()` to inject a Java object into the JavaScript realm, then have your asynchronous work arrange to call some method on that Java object, to signal to you that the document is ready for printing.

- Print CSS rules, like headers, footers, page numbers, landscape properties, and the like are ignored at present.
- A WebView can only do one print job at a time. Printing occurs asynchronously, and so you have to be careful that you do not accidentally start off a second print job while an earlier one is in process. The `print()` method returns a `PrintJob` that you can use to monitor the print job status, and this object will be covered in a bit more detail [later in this chapter](#). You may wish to set up a WebView pool, where you reuse an existing WebView only if its associated `PrintJob` is completed, creating a new WebView instance if there is no available WebView at the moment. Or, you might disable printing options in the UI until the `PrintJob` is done, so you can reuse the WebView. The sample app does none of this, to keep things simpler.
- Printing HTML is “an all-or-nothing affair”. You cannot print a subset of the HTML, whether denoted by HTML constructs (e.g., `<div>` IDs) or by page numbers. Hence, you need to load into the WebView *exactly* what you want to print, no more, no less.

Also, any direct use of `PrintManager` will only work on API Level 19. You will need to ensure that you only try using it on API Level 19+ devices, using Java version guard blocks. You will also need to set your build target (i.e., `compileSdkVersion` in Android Studio) to at least API Level 19 to be able to reference the `PrintManager` and related classes.

Finally, while loading and printing HTML are both intrinsically asynchronous, *generating* HTML locally is not. We will discuss this issue a bit more [later in this chapter](#).

## Printing a PDF File

As will be seen in [the next section](#), even if we “hand-roll” our printed output using a Canvas, the result seems to be a PDF file. Hence, you would think that the printing framework would provide convenience code to print a PDF file that we obtained by other means.

Alas, that is not the case.

The sample app contains some code demonstrating how this is possible, inspired by [this Stack Overflow answer](#), though it may cut a few corners that Google would prefer not be cut. However, it also illustrates how to create your own `PrintDocumentHandler`, which you will need for any print job not involving a bitmap

or HTML.

### The PrintDocumentAdapter Protocol

We supply a `PrintDocumentAdapter` to the `print()` method on `PrintManager`. In the HTML case, we got a `PrintDocumentAdapter` from the `WebView`, and so it is Google's job to implement that adapter. Similarly, `PrintHelper` has its own internal implementation of a `PrintDocumentAdapter` that it uses for printing the bitmap.

For anything else, you need to create your own `PrintDocumentAdapter`, or find a third-party implementation that you can perhaps reuse.

`PrintDocumentAdapter`'s job is to supply the `PrintManager` with the content to be printed, in the form of a PDF file. To do that, there are four callback methods that `PrintManager` (and related classes) will call on the `PrintDocumentAdapter`:

1. `onStart()` is called first. If you are planning on using the same `PrintDocumentAdapter` instance for multiple print jobs, this would be a spot to initialize the work for a new job. Otherwise, if you were only planning on using a `PrintDocumentAdapter` instance once, you may as well just put your initialization logic in the constructor.
2. `onLayout()` is called next. Here is where you do enough work to determine what the resulting output will be later on as printing continues. In particular, if you want to provide an accurate page count, this is where you will need to perform the necessary calculations to determine that.
3. `onWrite()` is called next, asking you to write one or more PDF pages out to a supplied `ParcelFileDescriptor` (on which you can create an `OutputStream`).
4. `onFinish()` is called last, when the printing request is completed, so you can free up any necessary resources.

### Introducing ThreadedPrintDocumentAdapter

All four of those callback methods are called on the main application thread. Your `onStart()` and `onFinish()` methods need to be fast enough to complete their work on that thread, and that may not be a problem. The work that `onLayout()` and `onWrite()` do may take a while, though, and so the protocol is designed to allow you to do that work on a background thread. Both methods are passed a callback object that you use to pass along the results of your work, and both are passed a `CancellationSignal` to indicate if the user cancels the print job while you are doing the work.

## PRINTING AND DOCUMENT GENERATION

---

What PrintDocumentAdapter does *not* do is actually give you a thread to use.

So, the sample app contains a ThreadedPrintDocumentAdapter that moves the onLayout() and onFinish() work to a background thread:

```
package com.commonware.android.print;

import android.content.Context;
import android.os.Bundle;
import android.os.CancellationSignal;
import android.os.ParcelFileDescriptor;
import android.print.PageRange;
import android.print.PrintAttributes;
import android.print.PrintDocumentAdapter;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;

abstract class ThreadedPrintDocumentAdapter extends
    PrintDocumentAdapter {
    abstract LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
        PrintAttributes newAttributes,
        CancellationSignal cancellationSignal,
        LayoutResultCallback callback,
        Bundle extras);

    abstract WriteJob buildWriteJob(PageRange[] pages,
        ParcelFileDescriptor destination,
        CancellationSignal cancellationSignal,
        WriteResultCallback callback,
        Context ctxt);

    private Context ctxt=null;
    private ExecutorService threadPool=Executors.newFixedThreadPool(1);

    ThreadedPrintDocumentAdapter(Context ctxt) {
        this.ctxt=ctxt;
    }

    @Override
    public void onLayout(PrintAttributes oldAttributes,
        PrintAttributes newAttributes,
        CancellationSignal cancellationSignal,
        LayoutResultCallback callback, Bundle extras) {
        threadPool.submit(buildLayoutJob(oldAttributes, newAttributes,
            cancellationSignal, callback,
            extras));
    }
}
```

## PRINTING AND DOCUMENT GENERATION

---

```
@Override
public void onWrite(PageRange[] pages,
                    ParcelFileDescriptor destination,
                    CancellationSignal cancellationSignal,
                    WriteResultCallback callback) {
    threadPool.submit(buildWriteJob(pages, destination,
                                    cancellationSignal, callback, ctxt));
}

@Override
public void onFinish() {
    threadPool.shutdown();

    super.onFinish();
}

protected abstract static class LayoutJob implements Runnable {
    PrintAttributes oldAttributes;
    PrintAttributes newAttributes;
    CancellationSignal cancellationSignal;
    LayoutResultCallback callback;
    Bundle extras;

    LayoutJob(PrintAttributes oldAttributes,
              PrintAttributes newAttributes,
              CancellationSignal cancellationSignal,
              LayoutResultCallback callback, Bundle extras) {
        this.oldAttributes=oldAttributes;
        this.newAttributes=newAttributes;
        this.cancellationSignal=cancellationSignal;
        this.callback=callback;
        this.extras=extras;
    }
}

protected abstract static class WriteJob implements Runnable {
    PageRange[] pages;
    ParcelFileDescriptor destination;
    CancellationSignal cancellationSignal;
    WriteResultCallback callback;
    Context ctxt;

    WriteJob(PageRange[] pages, ParcelFileDescriptor destination,
             CancellationSignal cancellationSignal,
             WriteResultCallback callback, Context ctxt) {
        this.pages=pages;
        this.destination=destination;
    }
}
```

## PRINTING AND DOCUMENT GENERATION

---

```
    this.cancellationSignal=cancellationSignal;
    this.callback=callback;
    this.ctxt=ctxt;
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/ThreadedPrintDocumentAdapter.java](#))

This class uses a single-thread thread pool, managed by an `ExecutorService`. In principle, a well-written `PrintDocumentAdapter` could handle multiple print jobs in parallel — if you attempt this and are using `ThreadedPrintDocumentAdapter` for inspiration, simply increase the size of the thread pool.

The `onLayout()` and `onWrite()` methods package up their parameters (described in [the next section](#)) into job objects. Those objects implement `Runnable`, and they are then handed to the `ExecutorService` to be run on the next-available thread. `onFinish()` shuts down the `ExecutorService`, though if you wanted to use the `ThreadedPrintDocumentAdapter` for multiple print jobs, you would come up with some other logic to clean up the `ExecutorService` when you were done with *all* of the jobs.

Subclasses of `ThreadedPrintDocumentAdapter` need to:

- Create subclasses of the `LayoutJob` and `WriteJob` static inner classes, implementing their respective `run()` methods, to do the work required of `onLayout()` and `onWrite()`
- Implement `buildLayoutJob()` and `buildWriteJob()` methods that return instances of those custom subclasses

(fans of dependency injection no doubt can find better solutions for wiring up a `ThreadedPrintDocumentAdapter`)

### A PdfDocumentAdapter

However, we still need to actually be able to print a PDF, which `ThreadedPrintDocumentAdapter` does not do on its own. The sample app also has a `PdfDocumentAdapter`, which extends `ThreadedPrintDocumentAdapter` and demonstrates a crude way of printing a PDF through the `PrintDocumentAdapter` protocol.

`PdfDocumentAdapter` does not use `onStart()` or `onFinish()`. And, since the

## PRINTING AND DOCUMENT GENERATION

---

`onLayout()` and `onWrite()` methods are handled by `ThreadedPrintDocumentAdapter`, `PdfDocumentAdapter` does not have those either.

It does, however, have the `buildLayoutJob()` and `buildWriteJob()` methods required by `ThreadedPrintDocumentAdapter`. These return instances of a `PdfLayoutJob` and `PdfWriteJob`, respectively:

```
@Override
LayoutJob buildLayoutJob(PrintAttributes oldAttributes,
                        PrintAttributes newAttributes,
                        CancellationSignal cancellationSignal,
                        LayoutResultCallback callback, Bundle extras) {
    return(new PdfLayoutJob(oldAttributes, newAttributes,
                           cancellationSignal, callback, extras));
}

@Override
WriteJob buildWriteJob(PageRange[] pages,
                      ParcelFileDescriptor destination,
                      CancellationSignal cancellationSignal,
                      WriteResultCallback callback, Context ctxt) {
    return(new PdfWriteJob(pages, destination, cancellationSignal,
                           callback, ctxt));
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PdfDocumentAdapter.java](#))

`PdfLayoutJob` needs to fulfill the bulk of the `onLayout()` contract:

- Monitor the `CancellationSignal` and call `onLayoutCancelled()` on the supplied `LayoutResultCallback` if the job has been canceled
- Populate a `PrintDocumentInfo` object to provide metadata about the document to be printed, and pass that to `onLayoutFinished()` on the `LayoutResultCallback`

```
private static class PdfLayoutJob extends LayoutJob {
    PdfLayoutJob(PrintAttributes oldAttributes,
                PrintAttributes newAttributes,
                CancellationSignal cancellationSignal,
                LayoutResultCallback callback, Bundle extras) {
        super(oldAttributes, newAttributes, cancellationSignal, callback,
              extras);
    }

    @Override
    public void run() {
```

## PRINTING AND DOCUMENT GENERATION

---

```
if (cancellationSignal.isCanceled()) {
    callback.onLayoutCancelled();
}
else {
    PrintDocumentInfo.Builder builder=
        new PrintDocumentInfo.Builder("CHANGE ME PLEASE");

    builder.setContentType(PrintDocumentInfo.CONTENT_TYPE_DOCUMENT)
        .setPageCount(PrintDocumentInfo.PAGE_COUNT_UNKNOWN)
        .build();

    callback.onLayoutFinished(builder.build(),
        !newAttributes.equals(oldAttributes));
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PdfDocumentAdapter.java](#))

`PdfLayoutJob` also has access to two `PrintAttributes` objects, the “old” attributes and the “new” attributes. In principle, `onLayout()` could be called a couple of times, perhaps based upon changes the user makes in the print dialog. These `PrintAttributes` objects describe the nature of the output, including things like page size and margins. `PdfLayoutJob` totally ignores these, because the PDF is a packaged asset in this case and cannot be changed. If you are dynamically generating a PDF file, you may wish to pay attention to the new `PrintAttributes` and take them into account.

`PdfLayoutJob` also has access to a `Bundle` of “extras”, not unlike the “extras” associated with an `Intent`. At the present time, there is only one semi-documented “extra”, `EXTRA_PRINT_PREVIEW`, which will be true if `onLayout()` is being called to generate a print preview of the printed output, false otherwise.

What `PdfLayoutJob` does do is create a `PrintDocumentInfo.Builder` to set up a `PrintDocumentInfo` object indicating that:

- The output is a “document” (`CONTENT_TYPE_DOCUMENT`) versus a “photo” (`CONTENT_TYPE_PHOTO`) or “unknown” (`CONTENT_TYPE_UNKNOWN`). This information is passed to the `PrintService` that functions as a bridge between `PrintManager` and the printer, and the `PrintService` might optimize output based upon this setting (e.g., lower quality print output for a “document” instead of a “photo”).
- The page count of the output is unknown (`PAGE_COUNT_UNKNOWN`). In principle, the page count is known, insofar as the PDF that will be printed is

---

## PRINTING AND DOCUMENT GENERATION

---

an asset baked into the app, and so we could hard-code the page count in addition to hard-coding other details (like the asset's filename).

The boolean second parameter to `onLayoutFinished()` is supposed to be true if the layout changed, false otherwise. In practice, the value does not seem to matter on the first `onLayout()` call. The implementation here compares the two `PrintAttributes` objects using `equals()`.

The last piece is the `PdfWriteJob`, which performs the work required of the `onWrite()` callback:

```
private static class PdfWriteJob extends WriteJob {
    PdfWriteJob(PageRange[] pages, ParcelFileDescriptor destination,
                CancellationSignal cancellationSignal,
                WriteResultCallback callback, Context ctxt) {
        super(pages, destination, cancellationSignal, callback, ctxt);
    }

    @Override
    public void run() {
        InputStream in=null;
        OutputStream out=null;

        try {
            in=ctxt.getAssets().open("cover.pdf");
            out=new FileOutputStream(destination.getFileDescriptor());

            byte[] buf=new byte[16384];
            int size;

            while ((size=in.read(buf)) >= 0
                && !cancellationSignal.isCanceled()) {
                out.write(buf, 0, size);
            }

            if (cancellationSignal.isCanceled()) {
                callback.onWriteCancelled();
            }
            else {
                callback.onWriteFinished(new PageRange[] { PageRange.ALL_PAGES });
            }
        }
        catch (Exception e) {
            callback.onWriteFailed(e.getMessage());
            Log.e(getClass().getSimpleName(), "Exception printing PDF", e);
        }
    }
}
```

```
finally {
    try {
        in.close();
        out.close();
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(),
            "Exception cleaning up from printing PDF", e);
    }
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PdfDocumentAdapter.java](#))

At its core, PdfWriteJob simply writes our PDF (culled from a cover.pdf asset) to an OutputStream. The OutputStream is built from the ParcelFileDescriptor, indicating where the PDF content should be written to.

The InputStream-to-OutputStream “bucket brigade” is augmented with checks on the CancellationSignal, to abandon the loop if the print job was canceled by the user. At the end, we call one of three methods on the WriteResultCallback:

- onWriteCancelled() if the CancellationSignal indicates that the job was canceled
- onWriteFinished() if everything succeeded
- onWriteFailed() (with an error message) if there was some problem, such as failed I/O

PdfWriteJob has access to a PageRange array, representing the particular pages out of a larger document to be printed. The parameter to onWriteFinished() is another PageRange array that should indicate what pages were printed. Once again, since the PDF is fixed, PdfWriteJob ignores the input PageRange array, and it indicates that we wrote all pages (PageRange.ALL\_PAGES) in the output. In principle, if you have more control over your environment, you should only print the requested pages, in which case the output parameter to onWriteFinished() might be the same array as was passed into onWrite().

### Using PdfDocumentAdapter

Back in MainActivity, the “PDF” action bar overflow item triggers a call to print() on the PrintManager, supplying our PdfDocumentAdapter and another empty PrintAttributes:

```
case R.id.pdf:
    print("Test PDF",
        new PdfDocumentAdapter(getApplicationContext()),
        new PrintAttributes.Builder().build());
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The PdfDocumentAdapter needs a Context, in order to access the cover .pdf asset. If your PDF file is being generated, or is saved as a file on external storage, you would not need this. Since it is theoretically possible that our activity could be destroyed while the printing is going on in background threads, rather than briefly leak an Activity, we provide the Application Context to PdfDocumentAdapter, as that is a singleton and cannot be leaked.

The result of all of this is that when the user chooses the “PDF” action bar overflow item, the book cover copy is printed.

## Printing Using a Canvas

What Google *really* wants you to do — if bitmaps and HTML are insufficient — is to create PDF documents using PrintedPdfDocument and a Canvas.

The concept is simple:

- Create a PrintedPdfDocument instance, given a PrintAttributes that describes the page size, margins, etc.
- Call startPage() to add a page to the document, which returns a PdfDocument.Page
- Call getCanvas() on the Page and use the standard Android 2D drawing APIs to draw lines, text, shaded areas, and so forth
- Call finishPage() on the PdfPrintedDocument when you are done rendering that page
- Repeat the preceding three steps for all needed pages
- Call writeTo() on the PrintedPdfDocument to write the PDF to an OutputStream, such as the one you get from the ParcelFileDescriptor in the onWrite() callback of your PrintDocumentAdapter
- Call close() on the PrintedPdfDocument when you are done

For example, let’s look at the onWrite() implementation used by PrintHelper to print a bitmap:

```
@Override
```

---

## PRINTING AND DOCUMENT GENERATION

---

```
public void onWrite(PageRange[] pageRanges, ParcelFileDescriptor fileDescriptor,
    CancellationSignal cancellationSignal,
    WriteResultCallback writeResultCallback) {
    PrintedPdfDocument pdfDocument = new PrintedPdfDocument(mContext,
        mAttributes);
    try {

        Page page = pdfDocument.startPage(1);
        RectF content = new RectF(page.getInfo().getContentRect());

        // Compute and apply scale to fill the page.
        Matrix matrix = getMatrix(mBitmap.getWidth(), mBitmap.getHeight(),
            content, fittingMode);

        // Draw the bitmap.
        page.getCanvas().drawBitmap(mBitmap, matrix, null);

        // Finish the page.
        pdfDocument.finishPage(page);

        try {
            // Write the document.
            pdfDocument.writeTo(new FileOutputStream(
                fileDescriptor.getFileDescriptor()));
            // Done.
            writeResultCallback.onWriteFinished(
                new PageRange[]{PageRange.ALL_PAGES});
        } catch (IOException ioe) {
            // Failed.
            Log.e(LOG_TAG, "Error writing printed content", ioe);
            writeResultCallback.onWriteFailed(null);
        }
    } finally {
        if (pdfDocument != null) {
            pdfDocument.close();
        }
        if (fileDescriptor != null) {
            try {
                fileDescriptor.close();
            } catch (IOException ioe) {
                /* ignore */
            }
        }
    }
}
```

(note: the preceding code snippet is Copyright (C) 2013 The Android Open Source

Project)

Here, they:

- Create the `PrintedPdfDocument`
- Add a page using `startPage()`
- Calculate a scaling `Matrix` based upon the image size, the page size, and the scale type (`FIT` or `FILL`)
- Draw the bitmap on the `Canvas` using that `Matrix`
- Finish the page
- Write the result to an `OutputStream` for the supplied `ParcelFileDescriptor`
- Close the document

Curiously, they do not do this work in a background thread, though the `onLayout()` implementation does use a background thread (since the image `Uri` may require an Internet download).

If you are comfortable with the `Canvas` API, writing PDF pages is much the same as drawing to your custom `View`. On the other hand, Android's `Canvas` API is not the same as any other drawing system's API, so there will be distinct differences from any other 2D drawing API that you might have used previously.

## Print Jobs

The `print()` method that we have been calling on `PrintManager` returns a `PrintJob`, representing the print job. This object has a number of status inquiry methods, including (in rough order of when the events occur):

- `isStarted()`
- `isQueued()` (i.e., waiting for the print system to process it)
- `isBlocked()` (i.e., permanently stuck, but needs to be canceled)
- `isCompleted()`
- `isFailed()`
- `isCancelled()`

It also has a `cancel()` method that you can call to cancel the print job (e.g., based on user request). `PrintJob` also offers a `restart()` method that you can use to re-try a failed (but not canceled) print job.

What `PrintJob` does not have is a listener interface to be proactively notified when

the job changes state.

PrintManager also has `getPrintJobs()`, which will return a list of the `PrintJob` objects representing the jobs you have requested in this process, rather than having to keep track of all of those yourself.

## Printing, Threads, and Services

If you are going to create a report in HTML, you will want to consider doing that work in an `AsyncTask`'s `doInBackground()` method, so the I/O involved in creating the report happens in the background. However, `PrintManager` requires that `print()` be called on the main application thread, so you would call `print()` from `onPostExecute()` of the `AsyncTask`.

Similarly, if you are creating your own `PrintDocumentAdapter`, you will want to consider moving the `onLayout()` and `onWrite()` work into background threads, such as is illustrated in the sample app via `ThreadedPrintDocumentAdapter`.

The problem with bare threads or an `AsyncTask` is that they do not indicate to Android that your process is still doing some work. It is possible that the user could request that you print something, then switch to another app (e.g., HOME, recent-tasks list). Android might consider your process to be relatively low priority and could terminate it before your print job completes.

The obvious solution is to involve a service, perhaps even a foreground service, to indicate to Android that your process is doing work that the user will notice if it does not complete. You could start the service when you do the print job, and then stop the service when the print job is completed, to return your process to normal priority.

However, actually having a service do the printing is a serious pain:

- `WebView`'s `PrintDocumentAdapter` really wants the `Context` that created the `WebView` to be an `Activity`
- The key parameters to `onLayout()` and `onWrite()` are [not Parcelable](#) and so cannot be passed in `Intent` extras via `startService()` to the service

One possibility would be to create a `PrintJobMonitorService`, which is what the sample app does. `PrintJobMonitorService` takes advantage of that `listPrintJobs()` method on `PrintManager` to keep tabs on all of our requested

## PRINTING AND DOCUMENT GENERATION

---

print jobs. So long as there is one or more print jobs in an active state, the service keeps running. Otherwise, the service stops. Hence, while the service is not actually doing the printing, it is running while the printing is going on, flagging to the OS to leave our process alone during this critical juncture.

```
package com.commonware.android.print;

import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.os.SystemClock;
import android.print.PrintJob;
import android.print.PrintJobInfo;
import android.print.PrintManager;
import java.util.concurrent.Executors;
import java.util.concurrent.ScheduledExecutorService;
import java.util.concurrent.TimeUnit;

public class PrintJobMonitorService extends Service implements Runnable {
    private static final int POLL_PERIOD=3;
    private PrintManager mgr=null;
    private ScheduledExecutorService executor=
        Executors.newSingleThreadScheduledExecutor();
    private long lastPrintJobTime=SystemClock.elapsedRealtime();

    @Override
    public void onCreate() {
        super.onCreate();

        mgr=(PrintManager) getSystemService(PRINT_SERVICE);
        executor.scheduleAtFixedRate(this, POLL_PERIOD, POLL_PERIOD,
            TimeUnit.SECONDS);
    }

    @Override
    public int onStartCommand(Intent intent, int flags, int startId) {
        return(super.onStartCommand(intent, flags, startId));
    }

    @Override
    public void onDestroy() {
        executor.shutdown();

        super.onDestroy();
    }

    @Override
```

## PRINTING AND DOCUMENT GENERATION

---

```
public void run() {
    for (PrintJob job : mgr.getPrintJobs()) {
        if (job.getInfo().getState() == PrintJobInfo.STATE_CREATED
            || job.isQueued() || job.isStarted()) {
            lastPrintJobTime=SystemClock.elapsedRealtime();
        }
    }

    long delta=SystemClock.elapsedRealtime() - lastPrintJobTime;

    if (delta > POLL_PERIOD * 2) {
        stopSelf();
    }
}

@Override
public IBinder onBind(Intent intent) {
    return(null);
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/PrintJobMonitorService.java](#))

PrintJobMonitorService uses a single-thread ScheduledExecutorService, to get control every three seconds in its run() method. The run() method iterates over the PrintJob objects associated with our app and looks for any that are in one of three states:

- “started”, meaning that printing has begun
- “queued”, meaning that the user has accepted the print dialog values, but printing has not yet started
- “created”, meaning that the job has been created, but it is not yet considered queued, such as when the print dialog is up on the screen

The first two states have simple test methods on PrintJob (isStarted() and isQueued()). The “created” state does not, for some reason, so we have to get the underlying PrintJobInfo object and manually check its state (getState()) to see if it is started (PrintJobInfo.STATE\_STARTED).

PrintJobMonitorService tracks the last time we saw an in-progress print job. If we have gone through two three-second polling periods without any in-progress print jobs, the service assumes that it is no longer needed and calls stopSelf().

## Printing Prior to Android 4.4

Before Android 4.4, printing in Android was limited and clunky.

The primary approach was to use Google Cloud Print. In effect, Google Cloud Print is a Web-managed print server. You would teach Google how to talk to your printers, and then any authorized device could print to those printers. By sharing your content (particularly PDFs) via `ACTION_SEND`, the user could choose Google Cloud Print as an option if they had Google Cloud Print set up for their device and printer. Note that the Android 4.4 printing framework includes a `PrintService` that works with Google Cloud Print, so users who have set up Google Cloud Print can still use it even with the new printing framework.

Various printer manufacturers or third parties also created their own apps that would fill a similar role, albeit perhaps working with printers on the local network. Or, you could write your own low-level code to talk to a network printer via relevant printing protocols like IPP, though this would be unpleasant at best.

## HTML Generation

[Earlier in this chapter](#), we saw how to print HTML. However, the HTML we printed was loaded from a URL. That is fine, but, as with printing bitmaps, it may not be a very popular scenario. What will be more likely is that you want to print some sort of report, generated on the device. And, since printing using the Canvas is a bit complicated, creating the report via HTML may be an easier route to take.

The typical approach for this involves creating an HTML template that sets up the basic page (e.g., references to CSS), then uses some sort of “macros” in the template to indicate portions that should be replaced dynamically with something from outside of the template.

This approach has been used since the early days of the original “dot-com revolution” of the 1990’s, pioneered by tools like Cold Fusion. In Java, there are any number of [available template engines](#).

However, for HTML, it is reasonably likely that a Web designer is going to want to get involved, to style the report. Ideally, you choose a template engine that is either something the designer is already using, or is one that is something the designer might wish to use elsewhere in the future. Forcing the designer to learn some new template syntax, just for the purposes of creating these reports, may not be the best

use of the designer's time (or your time, for answering all of the designer's questions).

One of the more popular template structures used today use braces (a.k.a., curly brackets) as the macro delimiters (e.g., `{{ something }}`). In particular, the macro syntax popularized by [mustache](#) is used by many template engine implementations. There is a very good chance that your Web designer already has used mustache-style templates, or at least has heard about them.

And, conveniently enough, there is a Java implementation – [jmustache](#) — that is Android-friendly. The sample app in this chapter implements a [“TPS Report”](#) that is generated from a mustache template using `jmustache`.

### Adding `jmustache` To Your App

[The “Get It” section of the `jmustache` documentation](#) contains up-to-date instructions for adding it to a project.

Developers using the Android Gradle Plugin — including Android Studio users — should reference the Maven Central artifact (`com.samskivert:jmustache`) from `build.gradle`.

### Writing the Report Template

A report template for `jmustache` can be a `String` or a `Reader`, with the latter allowing you to pull in files, assets, or raw resources (the latter two via an `InputStreamReader`).

In the case of the sample app, the template is small, and is packaged as a string resource. However, since the template involves HTML tags, we have to use CDATA notation to allow those tags to be left alone within the XML of the string resource:

```
<string name="report_body">
<![CDATA[
<html>
<body>
<h1>TPS Report for: {{reportDate}}</h1>
<p>Here are the contents of this week\'s TPS report:</p>
<p>{{message}}</p>
<p>If you have any questions regarding this report, please
do <b>not</b> ask Mark Murphy.</p>
</body>
</html>
]]>
```

*Figure 846: TPS Report Mustache Template*

The template contains `{{reportDate}}` and `{{message}}` variables to be replaced at runtime with dynamic data from our app. Also note that, despite the CDATA, we still need to escape the apostrophe with a leading backslash (`\'`).

### Creating a Report Context

What will fill in the `{{reportDate}}` and `{{message}}` variables will be values from a “context”. Here, “context” is not referring to `Context`, but rather an object that we pass to `jmustache` to serve as the source of data to blend into the report.

`jmustache` has fairly flexible rules for how it can resolve template variables, including calling Java getter methods based on the variable names. Hence, we can create a “context” that has `getReportDate()` and `getMessage()` methods, such as the `TpsReportContext` class in the sample app:

```
private static class TpsReportContext {
    private static final SimpleDateFormat fmt=
        new SimpleDateFormat("yyyy-MM-dd", Locale.US);
    String msg;

    TpsReportContext(String msg) {
        this.msg=msg;
    }

    @SuppressWarnings("unused")
```

```
String getReportDate() {
    return(fmt.format(new Date()));
}

@SuppressWarnings("unused")
String getMessage() {
    return(msg);
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

### Printing the Report

The “TPS Report” action bar overflow item eventually routes to a `printReport()` method on `MainActivity`:

```
private void printReport() {
    Template tpl=
        Mustache.compiler().compile(getString(R.string.report_body));
    WebView print=prepPrintWebView(getString(R.string.tps_report));

    print.loadData(tpl.execute(new TpsReportContext(prose.getText()
                                                    .toString())),
                  "text/html; charset=UTF-8", null);
}
}
```

(from [Printing/PrintManager/app/src/main/java/com/commonsware/android/print/MainActivity.java](#))

The first statement creates a `jmustache` `Template` object representing the report template. This is created by getting the singleton `compiler()` from `Mustache`, and calling `compile()` on it to interpret the string resource. Note that since this `Template` only depends upon the string resource, we could cache the `Template`, rebuilding it only on configuration changes, if desired.

Note that we load the template on the main application thread, as `printReport()` is called from `onOptionsItemSelected()`. For a small string resource, that is OK. If you are loading a more complex report template, you will want to do that in a background thread.

The second statement mirrors one from printing the Web page from before, where we call `prepPrintWebView()` to lazy-create our `WebView` and set it up to print when the page is loaded. Here, we use a different print job name than before, one reflecting the fact that this is a TPS report.

Finally, we use `execute()` on the `Template` to generate our HTML for printing, then pass that HTML to the `loadData()` method on `WebView`. `execute()` takes our “context” Object, which in this case is an instance of our `TpsReportContext` class, with the value typed into the `EditText` widget in our UI as the “message” to go into the report.

Note that we `execute()` the `Template` on the main application thread as well as having loaded it on that thread in the first place. Once again, the more complex the report, the more likely it is that you will want to move this logic into a background thread. However, remember that `print()` needs to be called on the main application thread.

The result is that the user gets a printed TPS report, containing today’s date and whatever message they typed into the `EditText`.

## PDF Generation Options

Perhaps you feel that generating HTML does not give you enough control, yet using the Canvas options directly was *too* much control. Perhaps you then think that generating a PDF to print, using something other than `PdfDocument`, is the right answer. Or perhaps you are generating a PDF for other reasons, such as to use with `ACTION_SEND` as output from your app.

You have two basic options for getting this PDF: generate it on the device, or offload the generation to a server.

There are various [open source and commercial libraries](#) for generating PDF on Android. The best-known open source Java PDF library – `iText` — has as dedicated Android version ([iTextG](#)), though the AGPL license may make it unsuitable for your use case. The commercial libraries range from fixed-price to per-device licenses. How much advantage these have over using `PrintedPdfDocument` from the Android SDK depends upon your needs.

If the bulk of the data needed for generating the PDF resides on a server, rather than downloading that data and using an underpowered Android device to create the PDF, you could upload the device-specific data to the server, have it create the PDF, and download the result from the server. There are plenty of server-side PDF generation tools, ranging from open source (e.g., [wkhtmltopdf](#), [unoconv](#), [prawn](#)) to commercial (e.g., [Prince](#), used to generate the PDF edition of this book). You also get to work in your preferred programming language, in case that is not Java, and

## PRINTING AND DOCUMENT GENERATION

---

perhaps leverage the PDF generation logic for other uses (e.g., generate reports from your Web app).

# Basic Bluetooth RFCOMM

---

For short-range communications, Bluetooth is fairly popular. It is widespread, available on mobile devices, notebooks, and many Internet of Things platforms. It performs reasonably well, at least for moderate amounts of data. Android has a variety of classes in the Android SDK for adding Bluetooth communications to an app.

However, Bluetooth overall is a *vast* topic. The documentation for the Android SDK classes is spotty. And it can be fairly difficult to make sense of how all the different pieces are supposed to plug in together.

In this chapter, we will explore a sample app that demonstrates Bluetooth communications between two Android devices and use that to see how to work with Bluetooth on Android. For extra fun, we will also peek a bit at how things differ when you try to use Bluetooth on an Android Things device, such as a Raspberry Pi.

## Prerequisites

This chapter makes use of [RxJava](#), [foreground services](#), [RecyclerView](#), and [data binding](#).

If you want to run the sample app, you will need two Android 5.0+ devices, each with working Bluetooth.

## A Quick Bit of Scope

As mentioned, Bluetooth is vast, much more than can be covered in a single chapter.

This chapter will focus on Bluetooth, not Bluetooth Low Energy (BLE). When most people think of Bluetooth, they are thinking of “full” Bluetooth. BLE is designed for low-power environments and lower data throughput.

This chapter will focus on RFCOMM. Bluetooth is based around “profiles”, which describe particular standards of data exchange between parties. If you think of Bluetooth as being HTTPS, a Bluetooth profile is a particular Web service API. RFCOMM is a general-purpose mechanism designed for communications that fall outside any standard profile.

And, this chapter will focus on one particular recipe for using Bluetooth. As with many of the book examples, the code shown here is not bulletproof, but is here to illustrate the use of various APIs and concepts. A production-grade app will need to handle concerns that lie outside the scope of the chapter, such as:

- What if we try sending significant amounts of data, not just short strings, between the devices?
- What if the devices that had been in communication move out of range of one another?
- What if Bluetooth is turned off on one of the devices, or if that device goes into airplane mode?
- How many simultaneous Bluetooth connections can an app manage, and how do we handle cases where we hit the limit?

## About the Sample App

The sample app – [Bluetooth/RxEcho](#) – is somewhat more complex than are many in this book. The explanation of how the app works may be somewhat clearer if we take a look at the app overall first, before diving in the details.

## The User Experience

When you launch the app, Android will prompt you to allow the app to detect the device’s location. As we will see [later in the chapter](#), Bluetooth has some interesting permission requirements.

If you agree to the permission, you then may get a dialog asking you if you want to enable Bluetooth, if it is not already enabled. If you decline, the app shuts down, as it cannot really do anything useful.

## BASIC BLUETOOTH RFCOMM

---

If you grant the location permission and enable Bluetooth, the app will present a largely empty UI. The fun begins with the action bar overflow menu, where there is a “Server” checkable item, a “Discover” item, and an “Allow Discovery” item.

Designate one of your two test devices as the “client” and the other as the “server”. Both will need the app up and running.

On the server, click the “Server” action bar item. This will spawn a Notification letting you know that something is running... a bit loudly:

Later, when you are done with the sample app, you can stop the server either through the action bar overflow item (unchecking it) or by clicking the “Stop Server” action in the Notification.

Then, on the server, from the action bar overflow menu, choose “Allow Discovery”. This will pop up a dialog box asking you if you are willing to allow other devices to discover this one, for 120 seconds. If you accept the dialog... nothing visible happens, but your device will now be discoverable by other Bluetooth devices.

## BASIC BLUETOOTH RFCOMM

---

During those 120 seconds, on the client, choose “Discover” from the action bar overflow menu. You should see an entry pop up with the Bluetooth MAC address of the server device:

*Figure 848: RxEcho Client, Showing Discovered Device*

You have no good way of knowing that this is the Bluetooth MAC address of your other device, but most likely there is nothing else discoverable right now that matches what the app is looking for, and so most likely what you find will be your server device.

## BASIC BLUETOOTH RFCOMM

---

Then, tap on that MAC address, to bring up a screen dedicated to that device:

*Figure 849: RxEcho Client, Showing the Selected Device*

## BASIC BLUETOOTH RFCOMM

---

Click the “Connected” switch. After a short delay, you should see a pairing dialog appear on *both* devices:

*Figure 850: RxEcho Client, Showing the Pairing Dialog*

Click “Pair” on both devices, though you do not need to grant rights for accessing contacts via the checkbox on the dialog.

## BASIC BLUETOOTH RFCOMM

---

At this point, the “Connected” switch should be in the “on” state. More importantly, the field at the bottom of the screen should be enabled. Tap on the field, type in a short message, and click the “send” action button. You should see an entry appear on the screen with your message echoed back to you in all caps:

*Figure 851: RxEcho Client, Showing the Echoed Response From the Server*

Your message was sent via Bluetooth RFCOMM to the server, which sent back the all-caps echo.

If you type in other messages, they will be added to the list. You can disconnect at any time, either by clicking the “Connected” switch again to toggle it off, or by pressing BACK to return to the list of device MAC addresses.

Once you have paired a device, you no longer need to discover it. So, for example, if you exit the sample app on the client and terminate its process (e.g., press the square “stop” toolbar button in Android Studio), then start it again, your server device should appear in the list immediately, even though the 120-second discoverability window may have elapsed and you have not asked the client to discover devices in any case. Your devices are paired, and you will see that pairing not only in the app on both devices, but in the Bluetooth screen in Settings as well.

### The Code

The app consists of a single activity, called `MainActivity`. It uses two fragments:

1. `RosterFragment` for showing the paired and discovered devices in a `RecyclerView`
2. `DeviceFragment` for showing the “Connected” Switch, `EditText` for message entry, and `RecyclerView` for the responses

There is also `ShoutingEchoService`, which is a foreground Service that handles our incoming requests and their associated responses.

The Bluetooth logic is wrapped up in [RxBluetooth](#). As the name suggests, this puts an RxJava wrapper around many of the Bluetooth APIs, to make it easier for us to handle thread management. The prose in this chapter will cover both the Android SDK classes and methods plus `RxBluetooth`; the sample just uses `RxBluetooth`.

### Bluetooth and Permissions

A Bluetooth app usually will need three permissions:

- `BLUETOOTH`, for general Bluetooth operations
- `BLUETOOTH_ADMIN`, for Bluetooth discovery operations... which nearly every Bluetooth app will need
- either `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`, in order to be able to get the Bluetooth MAC addresses of discovered or paired devices

The latter requirement is for privacy:

- Apps cannot use Bluetooth discovery and MAC addresses to determine that two users are nearby without user permission
- Apps cannot build a database of MAC addresses and physical locations, then use such a database to guess the user’s location given a nearby MAC address, without user permission

`BLUETOOTH` and `BLUETOOTH_ADMIN` permissions have a `protectionLevel` of `normal`, and so all you need to do is request them in the manifest. The location permissions are dangerous, though, and so on Android 6.0+ devices, with a `targetSdkVersion` of 23 or higher, you need to request those at runtime. The `RxBluetooth` library has the `<uses-permission>` elements for `BLUETOOTH`, `BLUETOOTH_ADMIN`, and

---

## BASIC BLUETOOTH RFCOMM

---

ACCESS\_COARSE\_LOCATION, which is all that we need, and therefore we do not need our own manifest entries for those.

However, we do need to request ACCESS\_COARSE\_LOCATION at runtime. Hence, this app uses the same AbstractPermissionActivity seen elsewhere in the book, to manage our permission request on first run of the app. MainActivity declares that it needs ACCESS\_COARSE\_LOCATION and exits with a Toast if the user declines to grant the permission.

## The Rx for Your Bluetooth

RxBluetooth is available as a `com.github.ivbaranov:rxbluetooth2` artifact, which we pull in using our dependencies closure:

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 27

    defaultConfig {
        applicationId "com.commonware.android.bluetooth.rxecho"
        minSdkVersion 21
        targetSdkVersion 27
        versionCode 1
        versionName "1.0"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }

    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'), 'proguard-rules.pro'
        }
    }

    compileOptions {
        sourceCompatibility JavaVersion.VERSION_1_8
        targetCompatibility JavaVersion.VERSION_1_8
    }

    dataBinding {
        enabled = true
    }
}

def supportVer="27.1.1"

dependencies {
    implementation("com.android.support:support-v4:$supportVer") {
        exclude group: 'com.android.support', module: 'support-media-compat'
    } // for https://issuetracker.google.com/issues/64909326
    implementation "com.android.support:recyclerview-v7:$supportVer"
    implementation "com.android.support.constraint:constraint-layout:1.1.0"
```

---

## BASIC BLUETOOTH RFCOMM

---

```
implementation "com.github.ivbaranov:rxbluetooth2:2.0.1"
implementation "io.reactivex.rxjava2:rxjava:2.1.7"
implementation "io.reactivex.rxjava2:rxandroid:2.0.1"
implementation "com.github.davidmoten:rxjava2-extras:0.1.18"
implementation "android.arch.lifecycle:extensions:1.1.1"
}
```

(from [Bluetooth/RxEcho/app/build.gradle](#))

We will discuss some of those other dependencies later in this chapter.

The entry point to the RxBluetooth library is an RxBluetooth class. Its constructor takes a Context, which RxBluetooth holds onto directly. As a result, it is safest to pass in the Application singleton, so we do not wind up with memory leaks. Both fragments and the ShoutingEchoService need to use Bluetooth, so each have their own RxBluetooth instances, held in rxBluetooth fields, initialized as those fragments and service are created, such as:

```
rxBluetooth=new RxBluetooth(getActivity().getApplicationContext());
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

## I Can Haz Bluetooth?

Roughly speaking, there are three possibilities with respect to Bluetooth on the device:

- The device lacks Bluetooth hardware
- The device has Bluetooth hardware, but it is disabled by the user
- The device has Bluetooth hardware that is ready for us to use

The first scenario should not happen. Our request of Bluetooth permissions triggers an implicit requirement of Bluetooth hardware. We would have to have `[uses-feature android:name="android.hardware.bluetooth" android:required="false" /]` in our manifest to say that Bluetooth is *not* required, if we were willing to work without it. As it stands, our app should not be installable on devices that lack Bluetooth.

That being said, for illustration purposes, the sample code checks to see whether we have Bluetooth hardware, by calling `isBluetoothAvailable()` on the RxBluetooth object:

```
if (!rxBluetooth.isBluetoothAvailable()) {
    Toast.makeText(getActivity(), R.string.msg_no_bt, Toast.LENGTH_LONG).show();
}
```

## BASIC BLUETOOTH RFCOMM

---

```
else {
    enableBluetooth(false);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

Under the covers, RxBluetooth works with BluetoothAdapter, the entry point into the Bluetooth APIs in the Android SDK. BluetoothAdapter has a getDefaultAdapter() method that returns its singleton instance. If that returns null or has an empty address, then we do not have Bluetooth hardware.

If isBluetoothAvailable() returns true, we then go and see if Bluetooth is enabled, via an enableBluetooth() method. There are three possibilities that this method needs to handle:

1. Bluetooth is enabled, in which case we can start using it
2. Bluetooth is not enabled, and so we want to ask the user to enable it
3. Bluetooth is not enabled, we asked the user to enable it, and the user declined to do so

We need to handle that latter case so that we can exit gracefully, rather than continuously popping up demands that the user enable Bluetooth.

The boolean parameter to enableBluetooth() indicates whether this is the first call (as we are starting up) or the second call (after we asked the user to enable Bluetooth). The code snippet shown above — from the onCreateView() method of RosterFragment — has the first call. enableBluetooth(), then, takes over:

```
void enableBluetooth(boolean didWeAskAlready) {
    if (rxBluetooth.isBluetoothEnabled()) {
        bluetoothReady();
    }
    else if (isThing()) {
        rxBluetooth.enable();

        subs.add(rxBluetooth.observeBluetoothState()
            .subscribeOn(Schedulers.io())
            .observeOn(AndroidSchedulers.mainThread())
            .filter(state -> (BluetoothAdapter.STATE_CONNECTED==state))
            .subscribe(state -> bluetoothReady()));
    }
    else if (didWeAskAlready) {
        Toast.makeText(getActivity(), R.string.msg_away, Toast.LENGTH_LONG).show();
        getActivity().finish();
    }
    else {
        rxBluetooth.enableBluetooth(getActivity(), MainActivity.REQUEST_ENABLE_BLUETOOTH);
    }
}
```

## BASIC BLUETOOTH RFCOMM

---

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

We first call `isBluetoothEnabled()` on the `RxBluetooth` instance. That just calls `isEnabled()` on the `BluetoothAdapter`, and returns a simple boolean status. If Bluetooth is enabled, we call a `bluetoothReady()` method to get things started — we will examine this method in detail shortly.

If Bluetooth is not enabled, and we are running on an Android Things device, we will handle Bluetooth a bit differently, which we will examine [later in this chapter](#).

If Bluetooth is not enabled, and we are not on an Android Things devices, *and* this is the first call (`didWeAskAlready` is `false`), we call `enableBluetooth()` on the `RxBluetooth` instance. This, in turn, will call `startActivityForResult()`, for an Intent with the `BluetoothAdapter.ACTION_REQUEST_ENABLE` action string. This will cause the system to display a dialog-themed activity prompting the user to enable Bluetooth. So, we pass an Activity and a request code into `enableBluetooth()`, and those are used to make the `startActivityForResult()` call.

The catch is that `enableBluetooth()` takes an Activity as a parameter and calls `startActivityForResult()` on it. Hence, the result goes to the Activity. This code is in `RosterFragment`, and so we cannot implement `onActivityResult()` here, as that will not be used. Instead, `onActivityResult()` goes on `MainActivity`, which then turns around and calls `enableBluetooth()` again, this time with a `true` parameter:

```
@Override
public void onActivityResult(int requestCode, int resultCode, Intent data) {
    if (requestCode==REQUEST_ENABLE_BLUETOOTH && roster!=null) {
        roster.enableBluetooth(true);
    }
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/MainActivity.java](#))

Here, `roster` is the `RosterFragment` instance, set up in `onCreate()`.

Back in `enableBluetooth()` in `RosterFragment`, if Bluetooth is not available, and we already asked the user — we are being called again by that `onActivityResult()` from `MainActivity` — we show a `Toast` and exit, since the user does not want to enable Bluetooth.

Ideally, eventually, the user enables Bluetooth, so our app can work.

# I Feel a Bond Between Us

Next, we need to provide the user with a list of devices that might be running our app. This list comes from two sources:

1. The list of Bluetooth devices paired with this one
2. The list of Bluetooth devices discovered by our app

However, this list will also need to be filtered, so we do not present clearly silly options to the user, such as suggesting that our app is running on a Bluetooth-connected speaker.

## Getting the Paired Devices

BluetoothAdapter has a `getBondedDevices()` method; RxBluetooth wraps that in its own `getBondedDevices()` method. This returns the list of “bonded” devices, which pretty much everyone else would refer to as the “paired” devices.

Specifically, we get back a list of `BluetoothDevice` objects. We will need those objects later on for connecting to and communicating with the other device, so we will maintain a model collection of these objects.

The `bluetoothReady()` method is called when we know that Bluetooth is ready for use. There, part of its work is to call `initAdapter()`:

```
private void initAdapter() {
    adapter.setItems(rxBluetooth.getBondedDevices());
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

Here, we call `getBondedDevices()` and pass that to a `setItems()` method on an adapter. `adapter` is a `DevicesAdapter` instance that we set up when we create the fragment. `DevicesAdapter` is a `RecyclerView.Adapter`, tied to a `RowHolder` for our list rows:

```
private class DevicesAdapter extends RecyclerView.Adapter<RowHolder> {
    private final ArrayList<BluetoothDevice> devices=new ArrayList<>();

    @Override
    public RowHolder onCreateViewHolder(ViewGroup parent, int viewType) {
        return(new RowHolder(RosterRowBinding.inflate(getLayoutInflater(), parent, false)));
    }
}
```

## BASIC BLUETOOTH RFCOMM

---

```
@Override
public void onBindViewHolder(RowHolder holder, int position) {
    holder.bind(devices.get(position));
}

@Override
public int getItemCount() {
    return(devices.size());
}

void setItems(Collection<BluetoothDevice> devices) {
    this.devices.clear();

    for (BluetoothDevice device : devices) {
        if (isCandidateDevice(device)) {
            this.devices.add(device);
        }
    }

    notifyDataSetChanged();
}

void addDevice(BluetoothDevice device) {
    if (isCandidateDevice(device) && !devices.contains(device)) {
        devices.add(device);
        notifyItemInserted(devices.size()-1);
    }
}

boolean isCandidateDevice(BluetoothDevice device) {
    int deviceClass=device.getBluetoothClass().getDeviceClass();

    return(((deviceClass & BluetoothClass.Device.Major.COMPUTER)==
BluetoothClass.Device.Major.COMPUTER) ||
((deviceClass & BluetoothClass.Device.Major.PHONE)==
BluetoothClass.Device.Major.PHONE) ||
((deviceClass & BluetoothClass.Device.Major.AUDIO_VIDEO)==
BluetoothClass.Device.Major.AUDIO_VIDEO));
}

public class RowHolder extends RecyclerView.ViewHolder {
    private final RosterRowBinding binding;

    RowHolder(RosterRowBinding binding) {
        super(binding.getRoot());

        this.binding=binding;
    }

    void bind(BluetoothDevice device) {
        binding.setDevice(device);
        binding.setController(this);
        binding.executePendingBindings();
    }

    public void onClick(BluetoothDevice device) {
        ((Contract)(getActivity())).showDevice(device);
    }
}
```

```
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

### Filtering the Devices

Most of the above code follows from what we saw with [RecyclerView](#) and [the data binding framework](#) elsewhere in the book. What's a little strange is the filtering going on in methods like the `setItems()` that `initAdapter()` calls.

Bluetooth devices have classes. Computers are a different class than are audio devices, which are in a different class than are toys, and so on. An Android device might discover, or be paired with, other devices from a variety of classes. Rather than present all possible devices, it makes sense to limit the devices to things that are reasonably likely to have our app.

`BluetoothDevice` has a `getBluetoothClass()` method, which returns a `BluetoothClass` object. That, in turn, has a `getDeviceClass()` method, which returns an `int` that represents the device class.

There are three classes (at least) that Android devices can fall in, identified by constants defined on the `BluetoothClass.Device.Major` class:

- Some phones and tablets report themselves as being a `COMPUTER`
- Some phones report themselves as being a `PHONE`
- An Android Things device [inexplicably reports itself as being `AUDIO\_VIDEO`](#)

So, `isCandidateDevice()` does some bit-checking to see if the device we are bonded to is in one of those three major classes, rejecting any others.

### Listing the Devices

The `onViewCreated()` method of `RosterFragment` sets up that `RecyclerView`, as well as creating the `RxBluetooth` instance, seeing if we have Bluetooth hardware, and triggering the initial call to `enableBluetooth()`:

```
@Override
public void onViewCreated(View view, @Nullable Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    rv=view.findViewById(R.id.devices);

    rv.setLayoutManager(new LinearLayoutManager(getActivity()));
    rv.addItemDecoration(new DividerItemDecoration(getActivity(),
        LinearLayoutManager.VERTICAL));
}
```

```
rv.setAdapter(adapter);

rxBluetooth=new RxBluetooth(getActivity().getApplicationContext());

if (!rxBluetooth.isBluetoothAvailable()) {
    Toast.makeText(getActivity(), R.string.msg_no_bt, Toast.LENGTH_LONG).show();
}
else {
    enableBluetooth(false);
}
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

## A Voyage of Discovery

Before we can connect to a Bluetooth device, we need to pair with it. And before we can pair with it, we need to discover it. So, while the preceding section outlined how we can show the user already-paired devices, we also have to allow the user to discover devices to pair with.

This is a three-part process:

1. One device — the server — has to become discoverable, as devices are not discoverable by default, for security reasons
2. The other device — the client — has to scan for discoverable devices
3. If and when any devices are discovered, we need to add them to our list of devices to potentially connect to

## Enabling Discoverability

In the Android SDK, to allow other devices to discover the one your app is running on, you use `startActivityForResult()` on a `BluetoothAdapter.ACTION_REQUEST_DISCOVERABLE` Intent. This will pop up a system-supplied dialog-themed activity to confirm that the user really wants the device to be discoverable. If the user agrees, then the device will be discoverable... for a short while.

The default discoverability duration is 120 seconds. You can add a `BluetoothAdapter.EXTRA_DISCOVERABLE_DURATION` extra to the Intent, with a value in seconds (up to 300) of how long you would like the device to be discoverable.

`RxBluetooth` hides all of this behind a pair of `enableDiscoverability()` methods. Both take an Activity and a request code, for use with the

---

## BASIC BLUETOOTH RFCOMM

---

`startActivityForResult()` call. One of the `enableDiscoverability()` methods also takes a duration, to pass along via `EXTRA_DISCOVERABLE_DURATION`.

As with `enableBluetooth()`, the `startActivityForResult()` call is made on the supplied Activity, not any fragment. If you want the result, you will need to implement `onActivityResult()` on the same Activity that you supplied to the `enableDiscoverability()` call. Here, the result is contained entirely in the result code, which will be `RESULT_CANCELED` if the user declined to enable discoverability... or the duration in seconds that the device will be discoverable. `RESULT_OK` is *not* the value indicating success in this case.

In `RosterFragment`, if the user taps on the “Allow Discovery” action bar item, we just call `enableDiscoverability()`:

```
rxBluetooth.enableDiscoverability(getActivity(), REQUEST_ENABLE_DISCOVERY);
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

In our case, we are ignoring the result, as we have no behavior to invoke based upon that result.

There is no way to cancel discoverability — it will simply time out on its own.

## Discovering Other Devices

In the Android SDK, `BluetoothAdapter` has three methods tied to discovery (the act of discovering discoverable devices):

- `startDiscovery()`
- `isDiscovering()`
- `cancelDiscovery()`

`RxBluetooth` has its own versions of those methods, which just call the corresponding method on the wrapped `BluetoothAdapter`.

The three methods do pretty much what you would expect from their names: start searching for discoverable devices, report if a discovery search is ongoing, and stop the search.

In `RosterFragment`, if the user taps the “Discover” action bar item, we just call `startDiscovery()`:

---

## BASIC BLUETOOTH RFCOMM

---

```
rxBluetooth.startDiscovery();
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

As part of cleanup, we call `cancelDiscovery()` in `onDestroy()`, so a discovery operation will not continue past the lifetime of the fragment instance.

### Reacting to Discovery Results

However, somewhere along the line, it would be very useful if we actually found out about the discovery results. If the scan finds devices, we need to know about them. We also need to know when the discovery scan stops of its own accord, as it will not run forever.

To that end, as part of our work in `bluetoothReady()` in `RosterFragment`, we set up two RxJava chains. One will use `observeDevices()` on `RxBluetooth` to find out about discovered devices. The other will use `observeDiscovery()` on `RxBluetooth` to find out about the status of the discovery scan itself:

```
subs.add(rxBluetooth.observeDevices()
    .subscribeOn(Schedulers.io())
    .observeOn(AndroidSchedulers.mainThread())
    .subscribe(this::addDevice));

subs.add(rxBluetooth.observeDiscovery()
    .subscribeOn(Schedulers.io())
    .observeOn(AndroidSchedulers.mainThread())
    .subscribe(s ->
        discover.setEnabled(!BluetoothAdapter.ACTION_DISCOVERY_STARTED.equals(s)));
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

`observeDiscovery()`, under the covers, uses a `BroadcastReceiver` to listen for `BluetoothAdapter.ACTION_DISCOVERY_STARTED` and `BluetoothAdapter.ACTION_DISCOVERY_FINISHED` broadcasts, forwarding them along to our chain. We simply enable and disable the “Discovery” `MenuItem` depending upon the scan state.

Similarly, `observeDevices()` uses a `BroadcastReceiver` for `BluetoothDevice.ACTION_FOUND` devices, forwarding the `BluetoothDevice` extra (`EXTRA_DEVICE`) along to our chain. We call `addDevice()`, which will add the device to our `RecyclerView`, if that device is not already in the list. It might already be in the list because:

- We were paired to it, but it happened to be discoverable during our scan, or

- We had it in the list from a previous scan

## Serving and Shouting

Given all of that, our client device can find our server device. Now, we need to set up the actual communications between them.

First, let's look at how our server listens for incoming connections from clients. That is managed by the `ShoutingEchoService`, so that we can listen for connections and respond to requests from the background, if desired.

## Service Scaffolding

`ShoutingEchoService` is a foreground service, partly so the user can stop the service from the Notification, and partly so that the service can run for an extended period of time. So, in `onCreate()`, among other things, we set up our notification channel and call `startForeground()`:

```
NotificationManager mgr=
    (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER) == null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
}

startForeground(1338, buildForegroundNotification());
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

`startForeground()` relies on a `buildForegroundNotification()` method to create the Notification:

```
private Notification buildForegroundNotification() {
    NotificationCompat.Builder b=
        new NotificationCompat.Builder(this, CHANNEL_WHATEVER);

    b.setOngoing(true)
        .setTitle(getString(R.string.msg_foreground))
        .setSmallIcon(R.drawable.ic_stat_ping)
        .addAction(android.R.drawable.ic_media_pause, getString(R.string.msg_stop),
            buildStopPendingIntent());

    return b.build();
}
```

---

## BASIC BLUETOOTH RFCOMM

---

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

`buildForegroundNotification()`, in turn, calls `buildStopPendingIntent()`, to craft a `PendingIntent` to be tied to the “stop” action added to the `Notification`. `buildStopPendingIntent()` uses a service `PendingIntent`, wrapped around an explicit `Intent` (identifying our service) to which we also happen to attach a custom action string (`ACTION_STOP`):

```
private PendingIntent buildStopPendingIntent() {
    Intent i=new Intent(this, getClass()).setAction(ACTION_STOP);

    return(PendingIntent.getService(this, 0, i, 0));
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

`onStartCommand()` then examines the `Intent` used to start the service, sees if it is `ACTION_STOP`, and calls `stopSelf()` if so:

```
@Override
public int onStartCommand(Intent intent, int flags, int startId) {
    if (ACTION_STOP.equals(intent.getAction())) {
        stopSelf();
    }

    return(START_NOT_STICKY);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

As a result, if the user taps the “Stop Server” notification action, the service will stop itself.

## A Quick Word About `MutableLiveData`

The `RosterFragment` has a checkable action bar item, “Server”, used to start and stop the `ShoutingEchoService`. To make that work, the `RosterFragment` needs to know about the status of the service, and *changes* to the status of the service. For example, if the user stops the service through the notification action, we need to uncheck the `MenuItem` if our UI is still around.

We could use an event bus, such as greenrobot’s `EventBus`. In this case, we are using `MutableLiveData`.

---

## BASIC BLUETOOTH RFCOMM

---

`MutableLiveData` is from the Architecture Components family of libraries. `LiveData` is a bit like a very tiny subset of `RxJava`, allowing you to observe on a stream of data. `MutableLiveData` is a subclass of `LiveData` that allows external parties to post events to observers. As a result, `MutableLiveData` can be used a bit like an event bus. The main “claim to fame” for `LiveData` — beyond it coming from Google — is that its mechanism for observing changes is lifecycle-aware, so we do not need to register and unregister from activity or fragment lifecycle methods.

You can learn a lot more about `MutableLiveData`, `LiveData`, and the rest of the Architecture Components in the companion volume, [Android’s Architecture Components](#).

### Keeping the UI in the Loop

To keep the UI layer informed about the status of the service, `ShoutingEchoService` has a `MutableLiveData` that publishes `Status` objects:

```
static final MutableLiveData<Status> STATUS=new MutableLiveData<>();
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

Here, `Status` is a simple wrapper around a `boolean`:

```
static class Status {
    static final Status IS_RUNNING=new Status(true);
    static final Status NOT_RUNNING=new Status(false);
    final boolean isRunning;

    private Status(boolean isRunning) {
        this.isRunning=isRunning;
    }
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

This could be replaced by an `enum` or `Boolean`, but you might have more complex data that you want to publish as part of the status.

Then, in `onCreate()`, we use `postValue()` on `MutableLiveData` to publish that the service is running:

```
@Override
public void onCreate() {
    super.onCreate();
```

## BASIC BLUETOOTH RFCOMM

---

```
rxBluetooth=new RxBluetooth(getApplicationContext());
acceptConnections();

NotificationManager mgr=
    (NotificationManager) getSystemService(NOTIFICATION_SERVICE);

if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.O &&
    mgr.getNotificationChannel(CHANNEL_WHATEVER)==null) {
    mgr.createNotificationChannel(new NotificationChannel(CHANNEL_WHATEVER,
        "Whatever", NotificationManager.IMPORTANCE_DEFAULT));
}

startForeground(1338, buildForegroundNotification());

STATUS.postValue(Status.IS_RUNNING);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

In `onDestroy()`, among other things, we publish that the service is no longer running:

```
STATUS.postValue(Status.NOT_RUNNING);
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

RosterFragment sets up a lambda expression to observe these status changes and update the checked state of a server MenuItem:

```
ShoutingEchoService.STATUS.observe(this,
    status -> {
        if (server!=null && status!=null) server.setChecked(status.isRunning);
    });
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

That informs us in real time about status *changes*. To find out the current status, we have to call `getValue()` on the `MutableLiveData`, which RosterFragment wraps in an `isServerRunning()` method:

```
private boolean isServerRunning() {
    ShoutingEchoService.Status status=ShoutingEchoService.STATUS.getValue();

    return(status!=null && status.isRunning);
}
```

---

## BASIC BLUETOOTH RFCOMM

---

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

That can then be used to control what happens when the user taps that “Server” action bar item:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    switch (item.getItemId()) {
        case R.id.server:
            if (isServerRunning()) {
                getActivity().stopService(new Intent(getActivity(),
                    ShoutingEchoService.class));
            }
            else {
                getActivity().startService(new Intent(getActivity(),
                    ShoutingEchoService.class));
            }

            return(true);

        case R.id.discover:
            rxBluetooth.startDiscovery();
            return(true);

        case R.id.allow_disco:
            rxBluetooth.enableDiscoverability(getActivity(), REQUEST_ENABLE_DISCOVERY);
            return(true);
    }

    return(super.onOptionsItemSelected(item));
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

## Services with Services

Of course, none of this has anything much to do with Bluetooth. It would be nice if our server actually used Bluetooth somewhere.

Up in `onCreate()`, in addition to initializing our `RxBluetooth` instance, we call `acceptConnections()`. That is where the Bluetooth fun starts with our service:

```
private void acceptConnections() {
    connectionSub=rxBluetooth
        .observeBluetoothSocket(getString(R.string.app_name), SERVICE_ID)
        .subscribeOn(Schedulers.io())
        .observeOn(Schedulers.computation())
        .subscribe(this::operateServer,
            throwable -> Log.e(getClass().getSimpleName(),
                "Exception from Bluetooth", throwable));
}
```

## BASIC BLUETOOTH RFCOMM

---

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

In the Android SDK, a server can start listening for RFCOMM connection requests by calling `listenUsingRfcommWithServiceRecord()` on the `BluetoothAdapter` instance. That is wrapped by `observeBluetoothSocket()` on `RxBluetooth`, so we can observe the results of that work.

`listenUsingRfcommWithServiceRecord()` takes two parameters:

- Some sort of display name, for unknown reasons
- A UUID identifying the Bluetooth service that we are publishing

Clients that try to connect to us will need to use that same UUID, to distinguish our Bluetooth service from other ones. In our case, the UUID is `SERVICE_ID`:

```
static final UUID SERVICE_ID=  
    UUID.fromString("20c6de08-2cf5-4ca2-96af-cb0a45055d37");
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

`listenUsingRfcommWithServiceRecord()` returns a `BluetoothServerSocket`. Calling `accept()` on it blocks until a connection is made, at which time `accept()` returns a `BluetoothSocket` that can be used for communicating with that connected client. At this point, you `close()` the `BluetoothServerSocket`, as a given instance of `BluetoothServerSocket` is used for establishing just one connection. All of that work is wrapped up inside of `RxBluetooth`, so we can just set up an RxJava chain, using background threads both for listening for incoming connections and consuming the resulting `BluetoothSocket`.

Once we get a `BluetoothSocket`, we call `operateServer()`. Among other things, `operateServer()` turns around and calls `acceptConnections()` again, so we can accept the next incoming client connection request. So that we do not wind up with a bunch of RxJava subscriptions piling up, we keep track of the outstanding one in a `connectionSub` field, disposing of it both in `onDestroy()` (as we no longer need it then) and in `acceptConnections()` (as we no longer need the previous subscription, since we already received our `BluetoothSocket`).

## Reach Out and Touch Someone

Given that our server has its service to respond to connections, our client has to make those connections.

## BASIC BLUETOOTH RFCOMM

---

On the client side, this is managed by the DeviceFragment. We create and show one of these when the user clicks on a device in the list displayed in the RosterFragment. As it turns out, BluetoothDevice is Parcelable, so we can pass that over to the DeviceFragment using the arguments Bundle:

```
public static Fragment newInstance(BluetoothDevice device) {
    DeviceFragment result=new DeviceFragment();
    Bundle args=new Bundle();

    args.putParcelable(ARG_DEVICE, device);
    result.setArguments(args);

    return(result);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

```
private BluetoothDevice getDevice() {
    return(getArguments().getParcelable(ARG_DEVICE));
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

## Finding Out When We Should Connect

The DeviceFragment UI is mediated by the data binding framework. The fragment's layout — `res/layout/device.xml` — injects the fragment itself as a controller and has the Switch invoke `onConnectionChange()` on the fragment when the Switch state changes:

```
<?xml version="1.0" encoding="utf-8"?>
<layout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto">

    <data>

        <variable
            name="controller"
            type="com.commonsware.android.bluetooth.rxecho.DeviceFragment" />
    </data>

    <android.support.constraint.ConstraintLayout
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:padding="@dimen/padding_main">
```

## BASIC BLUETOOTH RFCOMM

---

```
<Switch
    android:id="@+id/connected"
    android:layout_width="wrap_content"
    android:layout_height="wrap_content"
    android:checkedChanged="@{() -> controller.onConnectionChange()}"
    android:text="@string/switch_connected"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toTopOf="parent" />

<android.support.v7.widget.RecyclerView
    android:id="@+id/transcript"
    android:layout_width="0dp"
    android:layout_height="0dp"
    app:layoutManager="LinearLayoutManager"
    app:layout_constraintBottom_toTopOf="@+id/entry"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintStart_toStartOf="parent"
    app:layout_constraintTop_toBottomOf="@+id/connected"
    app:stackFromEnd="true" />

<EditText
    android:id="@+id/entry"
    android:layout_width="0dp"
    android:layout_height="wrap_content"
    android:ems="10"
    android:enabled="false"
    android:hint="@string/hint_entry"
    android:inputType="text"
    android:imeOptions="actionSend"
    app:layout_constraintBottom_toBottomOf="parent"
    app:layout_constraintEnd_toEndOf="parent"
    app:layout_constraintHorizontal_bias="0.627"
    app:layout_constraintStart_toStartOf="parent" />
</android.support.constraint.ConstraintLayout>
</layout>
```

(from [Bluetooth/RxEcho/app/src/main/res/layout/device.xml](#))

`onCreateView()` then sets up the `DeviceBinding`, holding onto it in a binding field:

```
@Nullable
@Override
public View onCreateView(LayoutInflater inflater,
                        @Nullable ViewGroup container,
                        @Nullable Bundle savedInstanceState) {
    binding=DeviceBinding.inflate(inflater, container, false);
    binding.setController(this);
}
```

```
return(binding.getRoot());  
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

### Connecting and Disconnecting

That `onConnectionChange()` method then checks to see if the Switch is checked. If it is, we disable the Switch, so the disabled state indicates that we are in a “connecting” state, as opposed to a “disconnected” or “connected” state:

```
public void onConnectionChange() {  
    if (binding.connected.isChecked()) {  
        binding.connected.setEnabled(false);  
        connectionSub=rxBluetooth.observeConnectDevice(getDevice(), ShoutingEchoService.SERVICE_ID)  
            .subscribeOn(Schedulers.io())  
            .observeOn(AndroidSchedulers.mainThread())  
            .subscribe(this::onConnected, this::onConnectionError);  
    }  
    else {  
        disconnect();  
    }  
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

More importantly, we set up an RxJava chain based on `observeConnectDevice()` on our `RxBluetooth` object. This will try to connect to our service, given the `BluetoothDevice` of the server’s device and the UUID of the service.

`observeConnectDevice()` wraps a call to `createRfcommSocketToServiceRecord()` on `BluetoothDevice`. This creates a `BluetoothSocket` representing the client side of the connection to the UUID-identified service running on the designated device. A call to `connect()` will block until we successfully connect to that service or it throws some form of `IOException` indicating that we could not connect.

Our RxJava chain routes successful connections to an `onConnected()` method. Among other things, it enables the Switch (to show that we are connected) and the `EditText` (initially disabled, since we cannot send messages until we are connected). The rest has to do with data exchange, which we will look at in the next section.

Our RxJava chain routes exceptions to `onConnectionError()`, which unchecks the Switch (since we are not connected), logs the details to `LogCat` (in case this error was unexpected), and shows a `Toast`.

The fact that we uncheck the Switch triggers a fresh call to `onConnectionChange()`.

If the `Switch` is unchecked, we call a `disconnect()` method, which, among other things, will `dispose()` the `connectionSub` subscription, as we no longer need that RxJava chain for our failed connection attempt.

There is nothing in this code specific to pairing. That happens automatically when we try to connect to the service on the other device. If we are already paired, getting our `BluetoothSocket` is relatively quick. If we are not paired, we need to wait for the user to agree to pair the devices, which may take some time or possibly never happen (e.g., user declines, user fails to notice the dialog and it times out).

## Ping and Pong

Once our client has connected to the server, we can start exchanging messages.

Technically, there is nothing in Bluetooth that requires a request/response protocol. Both sides can communicate as needed to the other. However, a request/response pattern is easy to write, which is why we use it here.

## Getting Our Client Streams

A `BluetoothSocket` has `getInputStream()` and `getOutputStream()` methods for receiving and sending data to the other party, respectively. RxBluetooth does not add anything for these — you are on your own for determining when and how to use those streams.

The `onConnected()` method, in addition to adjusting the state of some widgets:

- Holds onto our `BluetoothSocket`
- Create a `PrintWriter` tied to the output stream from the `BluetoothSocket`
- Arranges to process the data arriving on the input stream using an RxJava chain

```
private void onConnected(BluetoothSocket socket) throws IOException {
    binding.connected.setEnabled(true);
    binding.entry.setEnabled(true);
    this.socket=socket;
    out=new PrintWriter(new OutputStreamWriter(socket.getOutputStream()));
    responseSub=Bytes.from(socket.getInputStream())
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .subscribe(bytes -> post(new String(bytes)),
            throwable -> out.close());
}
```

```
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

We will examine that RxJava chain in greater detail a bit later in this chapter.

### Sending the Message

The DeviceFragment layout, shown above, has `android:imeOptions="actionSend"`, to ask for a “send” button on any soft keyboard. In `onViewCreated()`, we tie the `EditText` to a `send()` method by means of a lambda expression supplied to `setOnEditorActionListener()`, to find out when the user taps that “send” button:

```
@Override
public void onViewCreated(View view, @Nullable Bundle savedInstanceState) {
    super.onViewCreated(view, savedInstanceState);

    binding.entry.setOnEditorActionListener((v, actionId, event) -> (send()));
    binding.entry.setEnabled(socket!=null);

    RecyclerView rv=view.findViewById(R.id.transcript);

    rv.setAdapter(adapter);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

`send()`, in turn, uses the `PrintWriter` to send the entered text to the server:

```
public boolean send() {
    Single.just(binding.entry.getText().toString())
        .observeOn(Schedulers.io())
        .subscribe(message -> {
            out.print(message);
            out.flush();
        });

    return(true);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

We want to do that work on a background thread, as we always want to do I/O on a background thread. To stick to a single thread pool, we wrap the text that the user types in into a `Single` (a “one-shot” RxJava type otherwise reminiscent of `Observable`), observe the data on the `io()` thread, and in there `print()` the text to

the `PrintWriter` and `flush()` it to make sure that it goes out.

### Processing the Request

Back in `ShoutingEchoService`, the `operateServer()` method gets the `BluetoothSocket` representing the server side of the connection and sets up its own `RxJava` chain to work with it:

```
private void operateServer(BluetoothSocket socket) throws IOException {
    disconnect();
    this.socket=socket;
    acceptConnections();

    final PrintWriter out=
        new PrintWriter(new OutputStreamWriter(socket.getOutputStream()));

    Bytes.from(socket.getInputStream())
        .subscribeOn(Schedulers.io())
        .observeOn(Schedulers.computation())
        .subscribe(bytes -> {
            out.print(new String(bytes).toUpperCase());
            out.flush();
        }, throwable -> out.close());
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

First, though, we call `disconnect()`, which closes any existing `BluetoothSocket` that we might have:

```
private void disconnect() {
    if (socket!=null) {
        try {
            socket.close();
        }
        catch (IOException e) {
            Log.e(TAG, "Exception from Bluetooth", e);
        }
    }
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/ShoutingEchoService.java](#))

As noted above, we also call `acceptConnections()`, so we can accept a connection from the next client. We only support one client at a time, closing the `BluetoothSocket` from the previous client as part of accepting the next one here.

## BASIC BLUETOOTH RFCOMM

---

That's mostly a limitation of the sample app, to try to keep this sample from being excessively complex.

RxJava does not provide anything that works directly with Java's stream classes, like `InputStream` or `OutputStream`. However, David Moten offers [the rxjava2-extras library](#) which adds more Java-specific bridges to RxJava. Here, we use the `Bytes` class, which sets up RxJava chains for data coming in from an `InputStream`.

We want to receive the message on a background thread, and we also want to send the response on a background thread. To prevent sending the response from blocking future input, we use separate threads, with the `io()` thread for reading the data off of the `InputStream` and the `computation()` thread for sending the response.

Actually sending the response then is simply a matter of:

- Converting the bytes into a `String`
- Capitalizing the `String` using `toUpperCase()`, so the service appears to be shouting
- Using `print()` and `flush()` on our `PrintWriter` to send the response back to the client

If there is an `IOException`, we just close the `PrintWriter`, which closes the associated `OutputStream`. `Bytes` automatically closes our `InputStream` when the stream is closed from the sending side.

### Receiving the Response

In `DeviceFragment`, part of what `onConnected()` does is set up a similar Bytes-based RxJava chain to listen for the responses from the server:

```
private void onConnected(BluetoothSocket socket) throws IOException {
    binding.connected.setEnabled(true);
    binding.entry.setEnabled(true);
    this.socket=socket;
    out=new PrintWriter(new OutputStreamWriter(socket.getOutputStream()));
    responseSub=Bytes.from(socket.getInputStream())
        .subscribeOn(Schedulers.io())
        .observeOn(AndroidSchedulers.mainThread())
        .subscribe(bytes -> post(new String(bytes)),
            throwable -> out.close());
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

---

## BASIC BLUETOOTH RFCOMM

---

Here, we get the data on the main application thread, using `AndroidSchedulers.mainThread()`, so we can take the bytes, convert them into a `String`, and call a `post()` method. `post()`, in turn, clears out the `EditText` (to prepare for the next message) and adds the response message to a `TranscriptAdapter` that populates the `RecyclerView` that dominates this fragment's UI:

```
private void post(String message) {
    binding.entry.setText("");
    adapter.add(message);
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/DeviceFragment.java](#))

The result is that when we get the response, it appears in the list of responses, reminiscent of a chat client.

## Differences with Android Things

There are a couple of differences in how the `RxEcho` app runs on an Android Things platform.

First, we need to know that we *are* on an Android Things platform. To determine that, we have an `isThing()` method that checks to see if we have the `FEATURE_EMBEDDED` system feature or not:

```
private boolean isThing() {
    return(Build.VERSION.SDK_INT >= Build.VERSION_CODES.O &&
        (getActivity().getPackageManager().hasSystemFeature(PackageManager.FEATURE_EMBEDDED)));
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

In `enableBluetooth()`, if we are on an Android Thing, and we do not already have Bluetooth enabled, we can enable it directly ourselves, by calling `enable()` on the `RxBluetooth` instance (which, in turn, calls `enable()` on the `BluetoothAdapter`). This is frowned upon in conventional Android apps, where we should ask the user if it is OK to enable Bluetooth. In the case of an Android Thing, we have no way to ask the user — not only might the Thing not have a screen, but the system-supplied confirmation activity does not even exist.

However, `enable()` is asynchronous. We get control right away, and Bluetooth will not yet be powered on. We need to find out when it is ready, so we can continue. `RxBluetooth` offers an `observeBluetoothState()` method to allow us to set up an

---

## BASIC BLUETOOTH RFCOMM

---

RxJava chain to find out about state changes in Bluetooth itself. As with some of the other `observe...()` methods, this wraps around a `BroadcastReceiver`, in this case one that watches for `BluetoothAdapter.ACTION_STATE_CHANGED` events, passing to us the state as an `Integer`. There are a few constants out on `BluetoothAdapter` for different possible states; the one that we want is `STATE_CONNECTED`. We use an RxJava `filter()` operator to only pass along `STATE_CONNECTED` to our subscriber, which then calls `bluetoothReady()` to set up the rest of the Bluetooth support.

`bluetoothReady()` itself behaves substantially differently depending on whether we are on a `Thing` or not:

```
private void bluetoothReady() {
    isReady=true;

    if (isThing()) {
        getActivity().startService(new Intent(getActivity(),
            ShoutingEchoService.class));
        rxBluetooth.enableDiscoverability(getActivity(), REQUEST_ENABLE_DISCOVERY,
            300);
        Toast.makeText(getActivity(), R.string.msg_disco, Toast.LENGTH_LONG).show();
    }
    else {
        updateMenu();
        initAdapter();

        subs.add(rxBluetooth.observeDevices()
            .subscribeOn(Schedulers.io())
            .observeOn(AndroidSchedulers.mainThread())
            .subscribe(this::addDevice));

        subs.add(rxBluetooth.observeDiscovery()
            .subscribeOn(Schedulers.io())
            .observeOn(AndroidSchedulers.mainThread())
            .subscribe(s ->
                discover.setEnabled(!BluetoothAdapter.ACTION_DISCOVERY_STARTED.equals(s))));
    }
}
```

(from [Bluetooth/RxEcho/app/src/main/java/com/commonsware/android/bluetooth/rxecho/RosterFragment.java](#))

If we are not on a `Thing`, we:

- Make sure our action bar overflow items are enabled as appropriate
- Populate our `RecyclerView` with paired devices
- Set up the RxJava chain to add discovered devices to the list as well

On a `Thing`, we do not need any of that, as we do not necessarily have a screen to work with. Instead, we:

- Start the `ShoutingEchoService` directly

## BASIC BLUETOOTH RFCOMM

---

- Enable discoverability for 300 seconds, so there is a five-minute window in which clients can find our Thing
- Show a Toast about the discoverability, in case we *do* happen to have a screen (as might be the case on a Raspberry Pi)

The net is that on a Thing, we immediately set up the echo server and make it possible for clients to pair with it, since we cannot rely on the user to request those things from the action bar.

# Dealing with Different Hardware

---

While a lot of focus is placed on screen sizes, there are many other possible hardware differences among different Android devices. For example, some have telephony features, while others do not.

There is a three-phase plan for dealing with these variations:

1. **Filter** out devices that cannot possibly run your app successfully, so your app will not appear to them in the Play Store and they will be unable to install your app if obtained by other means
2. **React** to varying hardware that you can support, but perhaps might support differently (e.g., choosing a particular flash mode for a device having a camera with a flash)
3. **Cope** with device bugs or regressions that impact your application

This chapter will go through each of these topics.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Filtering Out Devices

There are a few manifest entries that will serve to filter out devices that cannot run your app:

- [android:minSdkVersion in the <uses-sdk> element](#), to stipulate that devices

- must run a certain version of Android (or higher)
- `<supports-screens>` and `<compatible-screens>`, which indicate which screens sizes and densities you are capable of supporting

This section outlines other “advertisements” that you can put in the manifest to restrict which devices run your app.

### uses-feature

The `<uses-feature>` element restricts your app to devices that have certain hardware features. For each element, you supply the name of a feature (e.g., `android.hardware.telephony`) and whether or not it is required:

```
<uses-feature
  android:name="android.hardware.camera"
  android:required="false" />
```

By default, `android:required` is set to `true`, so typically you will only see it in a manifest when it is set to `false`.

You might wonder why we would bother ever setting `android:required` to `false`. After all, that should have the same effect as not listing it at all. In practice, though, it has two major uses.

First, markets like the Play Store might highlight the fact that you *can* use a particular hardware capability, even though you do not strictly require it.

More importantly, you can use `android:required="false"` to *undo* a *requirement* that Android infers from your permissions. Requesting some permissions causes Android to assume — for backwards-compatibility reasons — that your app needs the affiliated hardware. For example, requesting the `CAMERA` permission causes Android to assume that you need a camera (`android.hardware.camera`) *and* that the camera support auto-focus (`android.hardware.camera.autofocus`). If, however, you are requesting the permission because you would like to use the hardware if available, but can live without it, you need to expressly add a `<uses-feature>` element declaring that the hardware feature is not required.

For example, in February 2010, the Motorola XOOM tablet was released. This was the first Android device that had the Play Store on it and truly had no telephony capability. As such, the XOOM would be filtered out of the then-Android Market (now Play Store) for any app that required permissions like `SEND_SMS`. Many

developers requested this permission, even though their apps could survive without SMS-sending capability. However, their apps were still filtered out if they did not have the `<uses-feature>` element declaring that telephony was not required.

You can find a table listing Android permissions and assumed hardware feature requirements in [the Android developer documentation](#).

### uses-configuration

The `<uses-configuration>` element is very reminiscent of `<uses-feature>`: it dictates hardware requirements. The difference is two-fold:

1. It focuses on hardware elements that represent different device configurations, meaning that you might use different resources for them
2. It allows you to specify *combinations* of capabilities that you need

There are three capabilities that you can require via `<uses-configuration>`:

1. The existence of a five-way navigation control, whether a specific type (D-pad, trackball, etc.) or any such control
2. The existence of a physical keyboard, whether a specific type (QWERTY, 12-key numeric keypad, etc.) or any such keyboard
3. A touchscreen

You can have as many `<uses-configuration>` elements as you need – any device that matches at least one such configuration will be eligible to install your app.

For example, the following `<uses-configuration>` element restricts your app to devices that have some sort of navigation control but do not necessarily have a touchscreen, such as an Android TV device:

```
<uses-configuration
  android:reqFiveWayNav="true"
  android:reqTouchScreen="notouch" />
```

### uses-library

The `<uses-library>` element tells Android that your application wishes to use a particular *firmware*-supplied library. The most common case for this was Maps V1, which is shipped in the form of an SDK add-on and firmware library. This, however, has been deprecated for quite some time.

However, there are other firmware libraries that you might need. These will typically be manufacturer-specific libraries, allowing your application to take advantage of particular beyond-the-Android-SDK capabilities of a particular device. This is very uncommon nowadays.

The Google Play Store will filter out your application from devices that lack a firmware library that you require via `<uses-library>`. If the user tries installing your app by some other means (e.g., download from a Web site), your app will fail to install on devices that lack the firmware library.

If you conditionally want the firmware library — you will use it if available but can cope if it is not — you can add `android:required="false"` to your `<uses-library>` element. That will allow your app to install and run on devices missing the library in question. Detecting whether or not the library exists in your process at runtime is a matter of using `Class.forName()` to see if you have access to some class from that library, where a `ClassNotFoundException` means that you do not have the library.

## Runtime Capability Detection

Reacting to device capabilities is the second phase of dealing with different devices. Some features you might want (e.g., telephony for sending SMSes) but can live without. Other features may have subtle variations that you cannot filter against and therefore need to adapt to at runtime (e.g., possible picture resolutions off of a camera).

This section will cover various techniques for determining what a device can do, at runtime, so you can react accordingly.

### Features

Any feature you do not make required via `<uses-feature>` can be detected at runtime by calling `hasSystemFeature()` on `PackageManager`. For example, if you would like to send SMS messages, but only on telephony-capable devices, you could have the following `<uses-feature>` element:

```
<uses-feature  
  android:name="android.hardware.telephony"  
  android:required="false" />
```

Then, at runtime, you can call `hasSystemFeature(PackageManager.FEATURE_TELEPHONY)` on a `PackageManager`

instance to find out if, indeed, the device has telephony capability and sending SMSes should work.

### Other Capabilities

Various subsystems have their own means of helping you determine what is possible or not:

- The [camera APIs](#) can let you know the capabilities of a camera (e.g., whether or not it has a flash, and what specific flash modes are supported).
- The [LocationManager](#) will help you determine what location providers are available that meet your Criteria.
- The sensor subsystem lets you find out what sensors are installed, either overall or for a particular type (e.g., accelerometer).

### Dealing with Device Bugs

Alas, devices are not perfect. Even though [the Compatibility Test Suite](#) attempts to ensure that all Android devices legitimately running the Play Store faithfully implement the Android SDK, some device manufacturers make changes that introduce bugs.

Just as Web developers can “sniff” on the User-Agent HTTP header to determine what sort of browser is requesting a page, you can use the `Build` class to determine what sort of device is running your app. If you encounter problems with a specific device, you may be able to use `Build` to identify that device at runtime and “route around the damage”.

---

## **Trail: Integration and Introspection**

---

# Writing and Using Parcelables

---

Parcelable is a marker interface, reminiscent of `Serializable`, that shows up in many places in the Android SDK. Parcelable objects can be put into Intent extras or Bundle objects, for example. Making your own custom classes implement Parcelable greatly increases their flexibility.

At the same time, Parcelable is something that can be overused. In most Android apps, few if any custom classes really need to have Parcelable capabilities.

In this chapter, we will review how to modify classes to implement Parcelable and what the limitations are on using Parcelable.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## The Role of Parcelable

A Parcelable object is one that can be placed into a Parcel. A Parcel is the primary vehicle for passing data between processes in Android's inter-process communication (IPC) framework.

IPC abounds in Android, even in places where you may not expect it. Every time you call `startActivity()`, for example, IPC occurs, even if the activity that calls `startActivity()` and the activity to be started are in the same process. A core OS process is the one that is responsible for identifying the activity to be started and routing control to it, so `startActivity()` performs IPC from the original activity's

process to a core OS process. The core OS process then eventually performs IPC to the target process for the activity to be started.

If you see an `Intent` or a `Bundle` in the Android SDK, odds are that those objects are involved in IPC. That is not always the case — `LocalBroadcastManager`, for example, uses `Intent` objects purely in-process — but it is a reasonable rule of thumb. Hence, there is keen interest in being able to implement `Parcelable` on specific classes, either to pass to other components via `Intent` extras, or to become part of the saved instance state `Bundle`.

`Parcelable` objects are also important for use with [remote services via the binding pattern](#).

## Writing a Parcelable

You have three major approaches for adding `Parcelable` capabilities to your classes in Android:

1. Use an annotation processor that will add in the appropriate bits of magic for you
2. Use a code generator site or tool that will take your existing class as input and give you the `Parcelable`-enabled rendition as output
3. Just do it yourself

### By Annotations

Enterprising developers have created annotation processing libraries that can be used to add `Parcelable` capabilities to a Java class in an Android app.

One approach is used by [Parceler](#). Here, you just add a `@Parcel` annotation to the Java class, and it code generates what is needed. However, it does *not* actually make the Java class `Parcelable`. Rather, it creates a runtime wrapper class that *is* `Parcelable` and that knows how to convert instances of your own Java class to and from the wrapper. You wind up calling static `wrap()` and `unwrap()` methods on a `Parcels` class to handle the conversion between your class and the generated `Parcelable` class.

[AutoParcel](#) takes a slightly different approach. In this case, you need to:

- Add the `@AutoParcel` annotation to the class

## WRITING AND USING PARCELABLES

---

- Make the class abstract and have it implement `Parcelable`
- Write abstract method signatures for getters for the data members

`AutoParcel` then code-generates a Java class that implements the getters, data members, and `Parcelable` logic, along with other niceties like `equals()` and `hashCode()`. That Java class will be named `AutoParcel_`, followed by the name of the class with the `@AutoParcel` annotation (e.g., annotating a `Foo` class gives you an `AutoParcel_Foo` class). The `AutoParcel`-generated class is a concrete subclass of the abstract base class, and so you can just work with the abstract class' public API and let `AutoParcel` handle the details.

However, neither of these give you classes that play well with the other children. Other code that expects to work with your classes — whether that is passing a `Parceler`-defined `Parcelable` to a third-party app or using something like `Gson` to handle JSON parsing — will not like either `Parceler` or `AutoParcel` that much.

### By Code Generator Sites and Tools

[The Parcelabler Web site](#) is a code generator. You paste in a simple Java class, with the class declaration and data members:

```
class Book {
    String isbn;
    String title;
    int pubYear;
}
```

and it gives you an output class that adds the `Parcelable` logic:

```
class Book implements Parcelable {
    String isbn;
    String title;
    int pubYear;

    protected Book(Parcel in) {
        isbn = in.readString();
        title = in.readString();
        pubYear = in.readInt();
    }

    @Override
    public int describeContents() {
        return 0;
    }
}
```

```
@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeString(isbn);
    dest.writeString(title);
    dest.writeInt(pubYear);
}

@SuppressWarnings("unused")
public static final Parcelable.Creator<Book> CREATOR = new
Parcelable.Creator<Book>() {
    @Override
    public Book createFromParcel(Parcel in) {
        return new Book(in);
    }

    @Override
    public Book[] newArray(int size) {
        return new Book[size];
    }
};
}
```

We will see in the next section what all of that code does for us, as part of understanding how to build it by hand.

However, the Parcelabler Web site has some limitations in its Java parsing, and so the more complex your Java class, the more likely it is that the Parcelabler site will have difficulty understanding it and blending in the Parcelable logic.

[The ParcelableCodeGenerator project](#) implements a command-line code generator that takes a JSON schema and gives you a Java class that, among other things, has the Parcelable implementation.

### By Hand

Adding Parcelable support yourself is not especially difficult, though it is a bit tedious.

### The Parcelable Interface

The first step is to add implements Parcelable to the class. Immediately, your IDE should start complaining that you need to implement two methods to satisfy the Parcelable interface.

## WRITING AND USING PARCELABLES

---

The easier of the two methods is `describeContents()`, where you will return 0, most likely.

The other method you will need to implement is `writeToParcel()`. You are passed in two parameters: a very important `Parcel`, and a usually-ignored `int` named `flags`.

Your job, in `writeToParcel()`, is to call a series of `write...()` methods on the `Parcel` to write out all data members of this object that should be considered part of the object as it is passed across process boundaries. There are dozens of type-safe methods for writing data into the `Parcel`:

- methods that write individual primitives (e.g., `writeInt()`) or Java arrays of primitives (e.g., `writeStringArray()`)
- `writeBundle()`, for writing out a `Bundle`
- `writeParcelable()` and `writeParcelableArray()`, for writing out other objects that implement `Parcelable`
- `writeFileDescriptor()`, for putting a `FileDescriptor` into the `Parcel`, with an eye towards allowing whoever reconstitutes the `Parcelable` to be able to read or write a stream based on that `FileDescriptor`
- methods to write other “active objects”, such as `IBinder` objects from [a remote service binding](#)
- various specialized methods for particular data types (e.g., `writeSizeF()`) or interfaces (e.g., `writeSerializable()`)

If, in `writeToParcel()`, you called `writeFileDescriptor()`, you will want to have `describeContents()` return `CONTENTS_FILE_DESCRIPTOR` instead of 0, as apparently the `Parcelable` support logic needs to know that a file descriptor is in the `Parcel`.

In the case of the generated `Book` code shown earlier in this chapter, `writeToParcel()` writes out the two `String` and one `int` data member:

```
@Override
public int describeContents() {
    return 0;
}

@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeString(isbn);
    dest.writeString(title);
    dest.writeInt(pubYear);
}
```

### The CREATOR

When Android tries reading objects in from a `Parcel`, and it encounters an instance of your `Parcelable` class, it will retrieve a static `CREATOR` object that must be defined on that class. The `CREATOR` is an instance of `Parcelable.Creator`, using generics to tie it to the type of your class:

```
@SuppressWarnings("unused")
public static final Parcelable.Creator<Book> CREATOR = new Parcelable.Creator<Book>()
{
    @Override
    public Book createFromParcel(Parcel in) {
        return new Book(in);
    }

    @Override
    public Book[] newArray(int size) {
        return new Book[size];
    }
};
```

The `@SuppressWarnings("unused")` annotation is because the IDE will think that this `CREATOR` instance is not referred to anywhere. That is because it will only be used via Java reflection.

The `CREATOR` will need two methods. `createFromParcel()`, given a `Parcel`, needs to return an instance of your class populated from that `Parcel`. `newArray()`, given a size, needs to return a type-safe array of your class.

The typical implementation of `createFromParcel()` will delegate the actual work to a protected or private constructor on your class that takes the `Parcel` as input:

```
protected Book(Parcel in) {
    isbn = in.readString();
    title = in.readString();
    pubYear = in.readInt();
}
```

You need to read in the *same* values that you wrote out to the `Parcel`, and in the same order.

### By Hand, With a Little Bit of Help

Android Studio 1.3 and higher have a template for a new Parcelable class. Right-click over your desired Java package and choose New > Other > New Parcelable Type from the context menu. Fill in your class and the template will create a new standalone Java class, akin to this one:

```
import android.os.Parcel;
import android.os.Parcelable;

public class Item implements Parcelable {

    // TODO declare your real class members
    // Members must be either primitives, primitive arrays or parcelables
    private int mFoo;
    private String mBar;

    // TODO implement your constructors, getters & setters, methods

    private Item(Parcel in) {
        // TODO read your class members from the parcel
        // Note: order is important - you must read in the same order
        // you write in writeToParcel!
        mFoo=in.readInt();
        mBar=in.readString();
    }

    @Override
    public void writeToParcel(Parcel out, int flags) {
        // TODO write your class members to the parcel
        // Note: order is important - you must write in the same order
        // you read in your private parcelable constructor!
        out.writeInt(mFoo);
        out.writeString(mBar);
    }

    @Override
    public int describeContents() {
        // TODO return Parcelable.CONTENTS_FILE_DESCRIPTOR if your class members
        // include a FileDescriptor, otherwise you can simply return 0
        return 0;
    }

    public static final Parcelable.Creator<Item> CREATOR=new Parcelable.Creator<Item>()
    {
        public Item createFromParcel(Parcel in) {
```

```
        return new Item(in);
    }

    public Item[] newArray(int size) {
        return new Item[size];
    }
};
}
```

You would have to adjust the stock fields (`mFoo`, `mBar`) to be what you need, and adjust the `writeToParcel()` and private constructor to match.

However, this template is designed for starting from scratch; it is not that useful when you have an existing class and wish to now make it be `Parcelable`.

The [ParcelablePlease](#) library saves you from having to do all of the reading and writing to and from the `Parcel` yourself. Putting the `@ParcelablePlease` annotation on the class generates a class for you (your class name followed by `ParcelablePlease`, so `FooParcelablePlease` for a `Foo` class). This class *only* marshals your data members to and from a `Parcel`, via static `readFromParcel()` and `writeToParcel()` methods. You still have to have the rest of the `Parcelable` boilerplate. Hence, this library is not as powerful as the annotation processors mentioned earlier in this chapter, but you wind up with a “real” complete Java class that can work better with other annotation-based libraries like `Gson`. On the other hand, it still makes it difficult for you to distribute your code to third parties, as they will need to also have this annotation processing library in their project builds.

## The Limitations of Parcelable

While the mechanics of writing a `Parcelable` are not hard, this does not mean that every model object or other POJO in your app should be made `Parcelable`. Overuse of `Parcelable` is a bit of a code smell, as it suggests that the developer is not necessarily considering all of the limitations and effects of the use of `Parcelable`.

### The 1MB Limit

The biggest one (pun lightly intended) is the size limitation. A `Parcel` – the IPC structure that is used to pass `Parcelable` objects across process boundaries — has a 1MB size limit. If you get over this limit, you will likely crash with a “Failed Binder Transaction” message as part of the exception’s stack trace.

There are two main ways you can reach this limit:

1. Have a Parcelable that individually is too large. A common case for this is wrapping a Bitmap or other large byte array in some Parcelable object.
2. Have too many Parcelable objects. For example, you might have performed a database query, converted the results into a collection of model objects, then tried to pass that collection to another activity via an Intent extra. Syntactically, this can work fine, if the collection and its model objects are all Parcelable. But now your risk of hitting the 1MB limit is determined by how many rows there are in the query's result set, and that can vary by user.

Large data like this need to be managed by singletons or other static data members and shared among your application components, rather than passed via Parcelable objects.

### Pass-By-Value

Suppose we have two activities, A and B. Activity A calls `startActivity()`, identifying activity B in the Intent. The Intent also includes a custom Parcelable object, one that takes up 1KB of space.

**Question:** how much system RAM is taken up by that Parcelable?

**Wrong Answer:** 1KB.

**Right Answer:** At least 3KB, as there are at least three copies of the Parcelable data:

- One copy is the original Parcelable object, the one that is stored as an extra in the Intent
- Another copy is the one in the Parcel that is held by a core OS process, for handling things like configuration changes and the recent-tasks list, where that Intent (and its extras, including your Parcelable) are needed
- A third copy is the one in the Intent that Activity B receives

Parcelable is, in effect “pass-by-value”, as the Parcelable object is copied as part of getting it across the process boundary twice, once from your process to the core OS, and once from the core OS back to your process.

This means that modifications that Activity B makes to the Parcelable object will not be seen by Activity A, as they are working on separate copies of the object.

Similarly, changes that Activity B makes to the Parcelable will not affect the copy held by the core OS process and re-delivered to Activity B on a configuration change.

The safest way to help defend against mistakes related to this is to consider a Parcelable object to be an immutable object. Only configure it through a constructor (possibly with the assistance of some Builder if you want a cleaner API). Offer getters for the values in the Parcelable, but do not offer any setters, so once the instance is created, it cannot be changed.

Also note that these copies magnify the effects of having a large Parcelable object, or too many Parcelable objects in a Parcel. A 900KB Parcel might fit within the 1MB size limit, but it would consume at least 2.7MB if the Parcel is part of some IPC.

Conversely, there are cases where Intent objects are not passed across process boundaries, such as LocalBroadcastManager. In those cases, neither the 1MB limit nor the pass-by-value effect are an issue. Only if the Intent is “flattened” into a Parcel, and later converted back into an Intent, do these extra copies and the 1MB limit come into play.

### The ClassLoader Conundrum

Sometimes, weird stuff happens, particularly when trying to read in other Parcelable objects that you wrote to the Parcel. In this case, the Parcel system needs to use Java reflection to find the Java class associated with the Parcelable objects, and sometimes it gets a bit lost.

When you use `readParcelable()` to read in the Parcelable objects out of the Parcel, you may need to supply the ClassLoader that you know has those Parcelable classes:

```
Foo(Parcel in) {
    this.someField=in.readParcelable(getClass().getClassLoader());
    this.anotherField=in.readParcelable(getClass().getClassLoader());
}
```

Here, we are using the same ClassLoader that has this Foo class.

### Sharing Between Apps

Parcelable objects need to read and write the same values to and from the Parcel.

This sounds simple, but it gets into some nasty issues when multiple code bases need to work with the Parcelable.

For example, suppose your app offers an SDK, such as a remote service. You have some custom Parcelable objects that you can either give to third-party clients of your app or get as input from those clients. Now, your SDK needs to ship implementations of the Parcelable classes; without them, clients cannot use your exposed service API.

What happens now, if you change the definition of the Parcelable? Bear in mind that:

- You may not be able to control when third-party developers take on some new version of your SDK
- You may not be able to control when end users update your app
- You may not be able to control when end users update third-party client apps

As a result, it is reasonably likely that your Parcelable implementations will be out of sync on a user's device, with your app having one implementation and a third-party app having another implementation. The results of this may not be pretty.

This is not a problem for purely internal uses of Parcelable, such as for holding onto data across a configuration change.

## Beware the PendingIntent

Custom Parcelable objects are fine for use as extras in Intent objects used with LocalBroadcastManager or otherwise limited to your own process. Custom Parcelable objects *should* work when placed in the saved instance state Bundle.

The further you get from these scenarios, though, the more likely it is that you will run into cases where your custom Parcelable will cause problems. That is because other apps — and core OS processes — have no access to your Parcelable class. Any attempt to work with Intent extras will result in a crash in that other process, probably interrupting whatever it was that you were trying to do.

One example of this is using a custom Parcelable in an extra for an Intent, wrapped in a PendingIntent. The party that executes the PendingIntent has the ability to add extras to the Intent inside the PendingIntent. That, in turn, causes

## WRITING AND USING PARCELABLES

---

problems, as Android does not have access to your Parcelable class. You get a stack trace like this one:

```
E/Parcel: Class not found when unmarshalling:
com.commonware.android.parcelable.marshall.Thingy
  java.lang.ClassNotFoundException:
com.commonware.android.parcelable.marshall.Thingy
  at java.lang.Class.classForName(Native Method)
  at java.lang.Class.forName(Class.java:400)

  at android.os.Parcel.readArrayMapInternal(Parcel.java:2717)
  at android.os.BaseBundle.unparcel(BaseBundle.java:269)
  at android.os.Bundle.putAll(Bundle.java:226)
  at android.content.Intent.fillIn(Intent.java:8171)
  at
com.android.server.am.PendingIntentRecord.sendInner(PendingIntentRecord.java:255)
  at
com.android.server.am.PendingIntentRecord.sendWithResult(PendingIntentRecord.java:216)
  at
com.android.server.am.ActivityManagerService.sendIntentSender(ActivityManagerService.java:7151)
  at android.app.PendingIntent.send(PendingIntent.java:836)
  at
com.android.server.AlarmManagerService$DeliveryTracker.deliverLocked(AlarmManagerService.java:2984)
  at
com.android.server.AlarmManagerService.deliverAlarmsLocked(AlarmManagerService.java:2424)
  at
com.android.server.AlarmManagerService$AlarmThread.run(AlarmManagerService.java:2543)
```

One workaround for cases like this is to still use a custom Parcelable, but instead of putting it directly as an Intent extra, use the Parcel system to convert it into a byte array, and store *that* as the extra. Foreign processes have no idea what the byte array is for and will not try to convert it into anything. When you get the byte array, you can then use the Parcel system to get your Parcelable back.

The [Parcelable/Marshall](#) sample project demonstrates this technique. It is a clone of the EventBus/GreenRobot3 sample app, discussed in [the chapter on event buses](#). The app uses AlarmManager to get control every minute, posting an event on a greenrobot EventBus. That event adds a row in a ListView if the UI is in the foreground; otherwise, the WakefulIntentService triggered by the alarm event will show a Notification.

This sample app does not really need a custom Parcelable. However, lots of programs have lots of things that they do not really need. So, the Parcelable/

## WRITING AND USING PARCELABLES

---

Marshall project adds a custom Parcelable class, named Thingy:

```
package com.commonware.android.parcelable.marshall;

import android.os.Parcel;
import android.os.Parcelable;

public class Thingy implements Parcelable {
    final String something;
    final int anotherThing;

    public Thingy(String something, int anotherThing) {
        this.something=something;
        this.anotherThing=anotherThing;
    }

    protected Thingy(Parcel in) {
        something=in.readString();
        anotherThing=in.readInt();
    }

    @Override
    public int describeContents() {
        return(0);
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeString(something);
        dest.writeInt(anotherThing);
    }

    @SuppressWarnings("unused")
    public static final Parcelable.Creator<Thingy> CREATOR=
        new Parcelable.Creator<Thingy>() {
            @Override
            public Thingy createFromParcel(Parcel in) {
                return(new Thingy(in));
            }

            @Override
            public Thingy[] newArray(int size) {
                return(new Thingy[size]);
            }
        };
}
```

(from [Parcelable/Marshall/app/src/main/java/com/commonware/android/parcelable/marshall/Thingy.java](#))

## WRITING AND USING PARCELABLES

---

It is fairly vanilla Parcelable class, wrapped around a string and an integer.

In theory, we could put a Thingy into the Intent used with AlarmManager via a PendingIntent. However, that will run into the problem outlined in this section, as Android does not have a Thingy. In fact, the stack trace shown above comes from this sample project, if you try putting a Thingy into the Intent.

The revised version of the project instead puts a byte array in the Intent as an extra, by way of the Parcelables utility class:

```
package com.commonware.android.parcelable.marshall;

import android.os.Parcel;
import android.os.Parcelable;

// inspired by http://stackoverflow.com/a/18000094/115145

public class Parcelables {
    public static byte[] toByteArray(Parcelable parcelable) {
        Parcel parcel=Parcel.obtain();

        parcelable.writeToParcel(parcel, 0);

        byte[] result=parcel.marshall();

        parcel.recycle();

        return(result);
    }

    public static <T> T toParcelable(byte[] bytes,
                                   Parcelable.Creator<T> creator) {
        Parcel parcel=Parcel.obtain();

        parcel.unmarshall(bytes, 0, bytes.length);
        parcel.setDataPosition(0);

        T result=creator.createFromParcel(parcel);

        parcel.recycle();

        return(result);
    }
}
```

(from [Parcelable/Marshall/app/src/main/java/com/commonware/android/parcelable/marshall/Parcelables.java](https://github.com/CommonWare/android-parcelable-marshall/blob/master/Parcelables.java))

## WRITING AND USING PARCELABLES

---

Parcelables mirrors standard Java utility classes like Arrays (static utility methods for Java arrays) and Collections (static utility methods for subclasses of Collection). Parcelables has two static utility methods for working with Parcelable objects:

- `toByteArray()` converts the Parcelable to a byte array
- `toParcelable()` converts the byte array back into a Parcelable

Both work by way of a Parcel object. You can get one of these from an instance pool by calling the static `obtain()` method on Parcel.

`toByteArray()` gets a Parcel, uses `writeToParcel()` to put your Parcelable into the Parcel, then uses `marshall()` to get a byte array representation of the Parcel contents. Before returning that result, though, we `recycle()` the Parcel, returning it to the instance pool for later use.

`toParcelable()` needs not only the byte array representing your object, but also your `Parcelable.Creator`, which knows how to convert a Parcel back into your Parcelable. So, `toParcelable()`:

- gets a Parcel via `obtain()`
- calls `unmarshall()` to populate the Parcel with the byte array contents
- calls `setDataPosition(0)` to effectively “rewind” the Parcel back to the beginning
- calls `createFromParcel()` on your `Parcelable.Creator` to get the Parcelable out of the Parcel
- recycles the Parcel
- and returns your Parcelable

The `scheduleAlarms()` method on `PollReceiver` is responsible for creating the Intent to schedule some alarm events. It adds a `Thingy` to the Intent, but uses `toByteArray()` to add the extra, rather than putting the raw `Thingy` in as the extra:

```
static void scheduleAlarms(Context ctxt) {
    AlarmManager mgr=
        (AlarmManager)ctxt.getSystemService(Context.ALARM_SERVICE);
    Thingy thingy=
        new Thingy(mgr.getClass().getCanonicalName(), mgr.hashCode());
    Intent i=
        new Intent(ctxt, PollReceiver.class)
            .putExtra(EXTRA_THINGY, Parcelables.toByteArray(thingy));
    PendingIntent pi=PendingIntent.getBroadcast(ctxt, 0, i, 0);
}
```

## WRITING AND USING PARCELABLES

---

```
mgr.setRepeating(AlarmManager.ELAPSED_REALTIME_WAKEUP,
                SystemClock.elapsedRealtime() + INITIAL_DELAY,
                PERIOD, pi);
}
```

(from [Parcelable/Marshall/app/src/main/java/com/commonsware/android/parcelable/marshall/PollReceiver.java](#))

When the alarm event occurs, `PollReceiver` can get the `Thingy` back by retrieving the byte array extra and using `toParcelable()`:

```
@Override
public void onReceive(Context ctxt, Intent i) {
    Thingy thingy=
        Parcelables.toParcelable(i.getByteArrayExtra(EXTRA_THINGY),
            Thingy.CREATOR);

    if (i.getAction() == null) {
        ScheduledService.enqueueWork(ctxt);
    }
    else {
        scheduleAlarms(ctxt);
    }
}
```

(from [Parcelable/Marshall/app/src/main/java/com/commonsware/android/parcelable/marshall/PollReceiver.java](#))

While this approach will add a few lines of code to your project, it should not incur significant additional overhead. All the work that is being done here is part and, um, parcel of passing a `Parcelable` between processes anyway. We are just doing it proactively, to eliminate any references in the `Parcel` to our custom `Parcelable` class.

# Responding to URLs

---

You may have noticed that Android supports a `market:` URL scheme. Web pages can use such URLs so that, if they are viewed on an Android device's browser, the user can be transported to a Play Store page, perhaps for a specific app or a list of apps for a publisher.

Fortunately, that mechanism is not limited to Android's code — you can get control for various other types of links as well. You do this by adding certain entries to an activity's `<intent-filter>` for an `ACTION_VIEW` Intent.

However, be forewarned that this capability is browser-specific. What works on the original Android “Browser” app and Google's Chrome may not necessarily work on Firefox for Android or other browsers.

## Prerequisites

Understanding this chapter requires that you have read the chapter on [Intent filters](#).

## Manifest Modifications

First, any `<intent-filter>` designed to respond to browser links will need to have a `<category>` element with a name of `android.intent.category.BROWSABLE`. Just as the `LAUNCHER` category indicates an activity that should get an icon in the launcher, the `BROWSABLE` category indicates an activity that wishes to respond to browser links.

You will then need to further refine which links you wish to respond to, via a `<data>` element. This lets you describe the URL and/or MIME type that you wish to respond

## RESPONDING TO URLS

---

to. For example, here is the `AndroidManifest.xml` file from the [Introspection/URLHandler](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
package="com.commonware.android.urlhandler" android:versionCode="1" android:versionName="1.0">

    <uses-sdk android:minSdkVersion="14" android:targetSdkVersion="19"/>

    <supports-screens android:largeScreens="true" android:normalScreens="true" android:smallScreens="false"/>

    <application android:icon="@drawable/ic_launcher" android:label="@string/app_name">
        <activity android:name="URLHandler" android:label="@string/app_name">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>

                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.intent.action.VIEW"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>

                <data android:mimeType="application/pdf"/>
            </intent-filter>
            <intent-filter>
                <action android:name="android.intent.action.VIEW"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>

                <data android:host="www.this-so-does-not-exist.com" android:path="/something"
android:scheme="http"/>
            </intent-filter>
            <intent-filter>
                <action android:name="com.commonware.android.MY_ACTION"/>

                <category android:name="android.intent.category.DEFAULT"/>
                <category android:name="android.intent.category.BROWSABLE"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

(from [Introspection/URLHandler/app/src/main/AndroidManifest.xml](#))

Here, we have four `<intent-filter>` elements for our one activity:

- The first is a standard “put an icon for me in the launcher, please” filter, with the LAUNCHER category
- The second claims that we handle PDF files (MIME type of `application/pdf`), and that we will respond to browser links (BROWSABLE category)
- The third claims that we will handle any HTTP request (scheme of “http”)

## RESPONDING TO URLS

---

for a certain Web site (host of "www.this-so-does-not-exist.com" and path of /something), and that we will respond to browser links (BROWSABLE category)

- The last is a custom action, for which we will generate a URL that Android will honor, and that we will respond to browser links (BROWSABLE category) — we will examine this more closely in [the next section](#)

What happens for the first two links varies based on browser.

The original Android “Browser” app, and Google Chrome, will do the following:

- Tapping the link to the PDF, on Android 2.3+, will trigger a download of the PDF. When the user taps on the downloaded file (e.g., from the Notification in the status bar), the user will have URLHandler as one of the options in the chooser to view the PDF file.
- Tapping the link to `http://www.this-so-does-not-exist.com/something` will bring up a chooser showing all available Web browser, plus URLHandler, as expected

Firefox for Android will treat the PDF link the same way. However, Firefox for Android does not check the URL for the second link to see if there is anything else supporting ACTION\_VIEW for the URL, and so it always loads up the Web page.

## Creating a Custom URL

Responding to MIME types makes complete sense... if we implement something designed to handle such a MIME type.

Responding to certain schemes, hosts, paths, or file extensions is certainly usable, but other than perhaps the file extension approach, it makes your application a bit fragile. If the site changes domain names (even a sub-domain) or reorganizes its site with different URL structures, your code will break.

If the goal is simply for you to be able to trigger your own application from your own Web pages, though, the safest approach is to use an `intent: URL`. These can be generated from an Intent object by calling `toUri(Intent.URI_INTENT_SCHEME)` on a properly-configured Intent, then calling `toString()` on the resulting Uri.

For example, the `intent: URL` for the fourth `<intent-filter>` from above is:

```
intent:#Intent;action=com.commonware.android.MY_ACTION;end
```

This is not an official URL scheme, any more than `market:` is, but it works for Android devices. When the Android built-in Browser encounters this URL, it will create an Intent out of the URL-serialized form and call `startActivity()` on it, thereby starting your activity. Chrome also supports this URL structure. Firefox for Android does not, indicating instead that it cannot recognize the URL.

## Reacting to the Link

Your activity can then examine the Intent that launched it to determine what to do. In particular, you will probably be interested in the `Uri` corresponding to the link — this is available via the `getData()` method. For example, here is the `URLHandler` activity for this sample project:

```
package com.commonware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        TextView uri=(TextView)findViewById(R.id.uri);

        if (Intent.ACTION_MAIN.equals(getIntent().getAction())) {
            String intentUri=(new Intent("com.commonware.android.MY_ACTION"))
                .toUri(Intent.URI_INTENT_SCHEME)
                .toString();

            uri.setText(intentUri);
            Log.w("URLHandler", intentUri);
        }
        else {
            Uri data=getIntent().getData();

            if (data==null) {
                uri.setText("Got com.commonware.android.MY_ACTION Intent");
            }
        }
    }
}
```

## RESPONDING TO URLS

---

```
        else {
            uri.setText(getIntent().getData().toString());
        }
    }
}

public void visitSample(View v) {
    startActivity(new Intent(Intent.ACTION_VIEW,
        Uri.parse("https://commonsware.com/sample")));
}
}
```

(from [Introspection/URLHandler/app/src/main/java/com/commonsware/android/urlhandler/URLHandler.java](#))

This activity's layout has a `TextView` (`uri`) for showing a `Uri` and a `Button` to launch a page of links, found on the CommonsWare site (<https://commonsware.com/sample>). The `Button` is wired to call `visitSample()`, which just calls `startActivity()` using the aforementioned URL to display it in the user's chosen Web browser.

When the activity starts up, though, it first loads up the `TextView`. What goes in there depends on how the activity was launched:

1. If it was launched via the launcher (e.g., the action is `MAIN`), then we display in the `TextView` the `intent: URL` shown in the previous section, generated from an `Intent` object designed to trigger our fourth `<intent-filter>`. This also gets dumped to `Logcat`, and is how the author got this URL in the first place to put on the sample Web page of links.
2. If it was not launched via the launcher, it was launched from a Web link. If the `Uri` from the launching `Intent` is `null`, though, that means the activity was launched via the custom `intent: URL` (which only has an action string), so we put a message in the `TextView` to match.
3. Otherwise, the `Uri` from the launching `Intent` will have something we can use to process the link request. For the PDF file, it will be the local path to the downloaded PDF, so we can open it. For the `www.this-so-does-not-exist.com` URL, it will be the URL itself, so we can process it our own way.

Note that for the PDF case, clicking the PDF link in the Browser will download the file in the background, with a `Notification` indicating when it is complete. Tapping on the entry in the notification drawer will then trigger the `URLHandler` activity.

Also, bear in mind that the device may have multiple handlers for some URLs. For example, a device with a real PDF viewer will give the user a choice of whether to launch the downloaded PDF in the real view or `URLHandler`.

## App Links

We have had the ability to have activities with `<intent-filter>` elements that support custom schemes (e.g., `myapp://`) since Android 1.0. The benefit that this offers over using a custom scheme is that, if it is unique on the device, an Intent for that custom scheme will go straight to the desired activity. However, this approach had a lot of flaws:

- There is no guarantee of uniqueness
- Few apps would recognize the custom scheme and issue an `ACTION_VIEW` Intent on the desired `Uri`
- If the user *did* encounter a link that would try to issue the `ACTION_VIEW` Intent, and the app handling that custom scheme was not installed, the request would simply fail

Using an `<intent-filter>` advertising support for some `http` or `https` URL would improve the results for the latter two issues, as many more apps would recognize the URL as being a URL, and usually the fallback would be to have a browser open up on that URL. However, now it is guaranteed that the scheme is *not* unique. Users would initially get a chooser, to determine what activity should handle the request. This can be confusing, particularly since the chooser does not really indicate the scope of the choice (would I be saying that XYZ app is now handling all Web links?).

Android 6.0 added an interesting solution for this. If you use a `<intent-filter>` for a domain that you control, you can publish a bit of metadata, as a JSON file, on the Web server. Android can be taught to sniff for that metadata and use it to validate that the app was developed by the same person or group that runs the server for the identified domain. In that case, Android will bypass the chooser and go straight to the activity with the domain-specific `<intent-filter>`. The cited example would be Twitter doing this, so any link click on a `twitter.com` URL would bring up the Twitter app, not a Web browser.

Of course, these links are only so useful. They are fine for when a link appears in an ordinary app. Web browsers, however, tend not to actually see whether a URL they encounter is handled by some on-device app. Android 6.0 does not change this behavior. So, links on Web pages viewed in 2015 versions of Firefox will not honor your desired `<intent-filter>` regardless of whether you are using this new app link system or not. Chrome's behavior varies by version.

That being said, app links still have their uses (e.g., responding to links from social

media posts).

### Setting Up the IntentFilter

Supporting an `<intent-filter>` for some http or https URL has been possible since Android 1.0. The only thing that is different is that now you can add an `android:autoVerify="true"` to the `<intent-filter>` element, to tell Android that you would like it to verify the connection between the app and the domain used in the `<intent-filter>`, to skip the chooser when URLs for that domain trigger your `<intent-filter>`.

For example, the [Introspection/URLHandlerMNC](#) sample project is a revised version of the URLHandler sample, one that switches its http `<intent-filter>` to look for `https://commonsware.com` URLs, and it incorporates `android:autoVerify="true"`:

```
<intent-filter android:autoVerify="true">
  <action android:name="android.intent.action.VIEW" />

  <category android:name="android.intent.category.DEFAULT" />
  <category android:name="android.intent.category.BROWSABLE" />

  <data
    android:host="commonsware.com"
    android:scheme="https" />
</intent-filter>
```

(from [Introspection/URLHandlerMNC/app/src/main/AndroidManifest.xml](#))

On pre-Marshmallow versions of Android, this attribute will be ignored, as it will not be recognized. But, on Android 6.0+, this attribute will be used to attempt to validate that your app was written by somebody who owns the specified domain.

The author of this book owns the `commonsware.com` domain. To actually run this project and have the updated app linking work, you would need to switch this to be some domain that *you* control.

Note that while `android:autoVerify="true"` is written at the scope of a single `<intent-filter>`, it affects *all* activities and *all* `<intent-filter>` structures. *All* of them that use http or https as the `android:scheme` must support the app links protocol described in this chapter. You cannot have some filters supporting app links and others not — either they *all* support app links, or none will.

### Setting Up the JSON

When Android installs an app that has one or more `<intent-filter>` elements with `android:autoVerify="true"`, it will attempt to find a JSON file on the identified server. Specifically, for the sample app, Android will create a URL of the form:

```
https://commonsware.com/.well-known/assetlinks.json
```

In your app, `commonsware.com` would be replaced with the domain you have in your `<intent-filter>`.

This URL is part of a [proposed IETF standard](#) that unfortunately does not appear to be formally documented.

Android 6.0+ will use HTTPS to retrieve your `assetlinks.json` file, regardless of the scheme that you use in the `<intent-filter>`. Also, the JSON needs to be publicly accessible, without any forms of authentication. And, the JSON needs to be served with a MIME type of `application/json`.

The JSON content itself is an array of JSON objects, one object per application ID that you publish as an app:

```
[
  {
    "relation": ["delegate_permission/common.handle_all_urls"],
    "target": {
      "namespace": "android_app",
      "package_name": "com.commonsware.android.urlhandler",
      "sha256_cert_fingerprints": ["A9:99:84:D8:...:60:5B:CB:E3"]
    }
  }
]
```

(the `sha256_cert_fingerprints` value is shown truncated for easier reading)

Here, the only two variable bits are:

1. The `package_name`, which will be your application ID, and
2. The `sha256_cert_fingerprints` array, which will list the SHA256 hashes of your public signing keys, for whatever keystores you might be using for this app (e.g., your debug keystore and your production keystore)

To get the SHA256 hash of your public signing key, you will need to use the `keytool`

## RESPONDING TO URLS

---

command from your Java SDK (Java 7 or higher required):

```
keytool -list -v -keystore ...
```

where ... is the path to your keystore (e.g., ~/.android/debug.keystore for your debug keystore on macOS and Linux).

You will need to provide the password to the keystore. For the debug keystore, this is android.

As part of the output, you will get the SHA256 hash:

```
Keystore type: JKS
Keystore provider: SUN

Your keystore contains 1 entry

Alias name: androiddebugkey
Creation date: Aug 7, 2011
Entry type: PrivateKeyEntry
Certificate chain length: 1
Certificate<1>:
Owner: CN=Android Debug, O=Android, C=US
Issuer: CN=Android Debug, O=Android, C=US
Serial number: 4e3f2684
Valid from: Sun Aug 07 19:57:56 EDT 2011 until: Tue Jul 30 19:57:56 EDT 2041
Certificate fingerprints:
  MD5:  98:84:0E:36:F0:B3:48:9C:CD:13:EB:C6:D8:7F:F3:B1
  SHA1: E6:C5:81:EB:8A:F4:35:B0:04:84:3E:6E:C3:88:BD:B2:66:52:E7:09
  SHA256: A9:99:84:D8:....:60:5B:CB:E3
  Signature algorithm name: SHA1withRSA
  Version: 3

*****
*****
```

(the SHA256 value is shown truncated for easier reading)

That long set of hex digits will need to go in the sha256\_cert\_fingerprints JSON array.

The rest of the JSON is fixed. Try not to introduce other JSON properties and such into this file, as they may cause your file to fail validation. However, you can have multiple JSON objects for multiple apps, each providing the relation and target

properties.

### Results

Our URLHandler activity not only responds to `http://misc.commonsware.com` URLs, but it uses one if the user taps the “view-sample” button:

```
package com.commonsware.android.urlhandler;

import android.app.Activity;
import android.content.Intent;
import android.net.Uri;
import android.os.Bundle;
import android.util.Log;
import android.view.View;
import android.widget.TextView;

public class URLHandler extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        if (Intent.ACTION_VIEW.equals(getIntent().getAction())) {
            findViewById(R.id.visit).setEnabled(false);
        }
    }

    public void visitSample(View v) {
        startActivity(new Intent(Intent.ACTION_VIEW,
            Uri.parse("https://commonsware.com/Android/")));
    }
}
```

(from [Introspection/URLHandlerMNC/app/src/main/java/com/commonsware/android/urlhandler/URLHandler.java](#))

There, we launch an `ACTION_VIEW` Intent on a `http://commonsware.com/Android` URL via `startActivity()`.

On a pre-Marshmallow device, this `startActivity()` request will normally bring up a chooser, offering the URLHandler activity along with Web browsers and potentially other apps.

On an Android 6.0+ device, in the normal case, if the server is configured properly with the above JSON, and if the app was compiled by the author of this book, the

## RESPONDING TO URLS

---

chooser is bypassed, and the user gets another instance of `URLHandler`. The “another instance” part can be controlled via Intent flags or manifest entries, as is covered in [the chapter on tasks](#).

However, this is not assured:

- If *you* compile and run the app, your signing key should not match the JSON-published fingerprint, and so the validation will fail and normal chooser behavior will return. You would have to substitute some URL of your own with a corresponding JSON file on that server that contains your hash.
- If the server is mis-configured (e.g., JSON not available via HTTPS), the validation will fail and normal chooser behavior will return.
- If the app is not signed with the correct signing key — such as the user is really running a copy of your app with injected malware and somebody else’s signing key — the validation will fail and normal chooser behavior will return.
- If there is no connectivity at the time the user installs the app (e.g., they are side-loading it), the validation will fail and normal chooser behavior will return. The device may try to validate again in the future, though.

## User Intervention

Another thing that can change the behavior to return is if the user revokes the app link. Users can do this by going to the app's screen in the Settings app and clicking the "Open by default" option:

*Figure 852: URLHandlerMNC in Settings, "Open by default" Visible*

## RESPONDING TO URLS

---

If the user taps that entry, one section of the next screen is entitled “App links” and gives the user the option to toggle the app link behavior off:

## RESPONDING TO URLS

Unfortunately, the labeling here does not seem to work properly. The “Ask every time” choice shown selected here actually bypasses the chooser. The available choices are “open in this app”, “ask every time”, and “don’t open in this app”:

### Testing Your Setup

You can confirm that other parties can see your `assetlinks.json` file by visiting the following URL:

```
https://digitalassetlinks.googleapis.com/v1/statements:list?  
source.web.site=https://DDDDD&  
relation=delegate_permission/common.handle_all_urls
```

(NOTE: the URL shown above is split across several lines for readability but should be all on one line when actually using the URL)

Replace DDDDD with the domain name for your site, and you should get a JSON document back that, among other things, contains the details from your `assetlinks.json` file:

```
{  
  "statements": [  
    ...  
  ]  
}
```

## RESPONDING TO URLS

---

```
{
  "source": {
    "web": {
      "site": "https://commonsware.com."
    }
  },
  "relation": "delegate_permission/common.handle_all_urls",
  "target": {
    "androidApp": {
      "packageName": "com.commonsware.android.urlhandler",
      "certificate": {
        "sha256Fingerprint": "A9:99:84:D8:....:60:5B:CB:E3"
      }
    }
  }
},
"maxAge": "3213.779933024s"
}
```

(sha256Fingerprint truncated for readability)

If you try visiting that URL, and there is no `assetlinks.json` file available for that domain, you will get a JSON response back containing a `debugString` indicating the nature of the problem.

You can see if an Android device in your lab has successfully performed the app link validation by running the `adb shell dumpsys package domain-preferred-apps` command. This will list all of the apps that have app links, and your app should appear among them, in a stanza like this one:

```
Package: com.commonsware.android.urlhandler
Domains: commonsware.com
Status: never
```

The status will reflect the user's choice of how to handle your app link inside of Settings (the `never` shown above indicates that the user decided to ignore your app link and have your app never handle such URLs).

# App Shortcuts

---

Your app probably has a single activity that appears in the user’s home screen launcher. It is the activity that has the `<intent-filter>` for the `MAIN` action and the `LAUNCHER` category.

For years, many home screens for Android have allowed the user to make “shortcuts” to that activity, typically by long-pressing the icon in the launcher, then dragging it to the desired spot on the home screen. This is reminiscent of similar capabilities in many desktop operating systems.

However, some desktops have gone beyond that. For example, with the Unity desktop in Linux, right-clicking a launcher icon in the Unity dock may bring up specific ways to get into the app identified by that icon. For example, an email client might offer “Compose New Message” from the icon’s context menu, so whereas a simple click on the icon would bring up the inbox, right-clicking and choosing “Compose New Message” would bring up a message composer.

Android 7.1 adds the awkwardly-named “app shortcuts” to mimic this sort of feature. There are two ways of adding these shortcuts: via a resource tied into the manifest, and via Java code. The former approach has no particular ties to Android 7.1, and third-party home screen implementations are already adopting it.

In this chapter, we will explore what app shortcuts are, how to add them to the manifest, and how to offer “dynamic” app shortcuts from Java.

## Prerequisites

Understanding this chapter requires that you have read the chapter on [Intent filters](#).

## Enabling Deep Dives

Google has been steadily increasing the ways in which users can drive directly into specific portions of your app, as opposed to always getting into it via a home screen launcher or perhaps the overview screen, such as:

- Notifications allow you to offer several actions in addition to the “main” action of tapping on your tile in the notification shade, to let the user go directly to where they want to go (or take action straight from the notification, bypassing your activity-based UI)
- [App links](#) allow specific URLs to drive directly into whatever portion of your app makes sense, perhaps even bypassing the normal chooser
- [Direct share targets](#) allow you to drive the user to some specific portion of your app when they elect to “share” some content via ACTION\_SEND

All of these are designed to make it a bit easier for power users to get where they want to go quickly, saving some taps, swipes, or other forms of input.

The app shortcuts added by Android 7.1 work much the same way.

## App Shortcuts, from the User’s POV

It will help to understand what you are supposed to be adding to your app if you see what the user experience is for apps with app shortcuts.

However, technically, a home screen can do whatever it wants with app shortcuts, from a presentation standpoint. So, let’s focus on the Pixel Launcher first, which is the launcher that Google shipped with their 2016 Pixel phones and offers app shortcut support. The Android 7.1 emulator has a similar launcher.

## Ad-Hoc Requests

The user can long-press on an app icon and pull up a list of available app shortcuts:

*Figure 855: App Shortcuts for Settings App*

If the icon does not support app shortcuts, the long-press simply does whatever it ordinarily would have done prior to app shortcuts. For example, long-pressing an icon in the launcher would allow the user to drag it to be a shortcut on the main home screen. To do those sorts of things with an icon that *does* support app shortcuts, you not only need to long-press but also start dragging the icon somewhere.

### Pinning

Each of those app shortcuts has a small “grab handle” (looks like =). The user can drag that and use it to create a shortcut on the home screen for that particular app shortcut:

Tapping that icon directly launches whatever the app shortcut has specified.

### Alternatives

However, developers are limited only by their imaginations in terms of presentation of app shortcuts. Home screens have easy access to app shortcut information via the `LauncherApps` utility class, and there is little stopping other apps from doing the same. So, you can imagine:

- An app widget that makes app shortcuts available for a particular app, without having to manually pin them
- A launcher for a mouse-centric device offering a floating panel of app shortcuts when the user hovers a mouse over a launcher icon
- A launcher for a keyboard-centric device offering users the ability to “pin” app shortcuts to key combinations
- An app that converts an app shortcut into [a notification shade tile](#)

And so on.

## Offering Manifest App Shortcuts

The “low-hanging fruit” of app shortcuts is to offer some static options via the manifest. This takes very little time to implement, including no mandatory Java code changes. Furthermore, while the Android 7.1 APIs for working with app shortcuts may not exist on older devices, home screens and other apps could still support manifest app shortcuts with a bit of additional code. Hence, the app shortcuts that you offer via the manifest will become available to the users of many popular alternative home screen implementations, in addition to users of Android 7.1+ devices.

The [AppShortcuts/WeakBrowser](#) sample project demonstrates the use of both manifest and dynamic app shortcuts. This app implements a silly little Web browser, allowing the user to visit a handful of hard-coded sites.

### Identify the Destinations

First, you need to decide where these app shortcuts should send users.

From a navigation flow standpoint, an app shortcut:

- Should improve efficiency of power users, saving them clicks elsewhere
- Should *not* be uniquely accessible via app shortcuts, for users who lack them or do not know about them

For example, suppose that a common bit of existing navigation in your app is:

- User taps on launcher icon
- User taps on a tab in the activity, which leads them to a particular destination

Adding an app shortcut to that same destination is easy but not that useful, as it will be no faster — and perhaps slower — to activate the app shortcut than it would to be to just go into the activity and tap on the desired tab.

But, the navigation might be more complex, where getting to the destination:

- Requires opening a navigation drawer
- Requires scrolling through a list or grid, which might be lengthy
- Requires executing some sort of search

Now offering rapid access to the destination via an app shortcut may be useful, as it may be faster than the ordinary navigation options.

Of course, WeakBrowser, being weak, has one manifest app shortcut: to allow the user to visit a search engine. This same page is available by tapping a “search” action bar item. This is not an especially effective use of manifest app shortcuts, but it helps to simplify the example.

### Ensure the Destination is “Evergreen”

App shortcuts offered via the manifest are static. You cannot modify them at runtime, the way that you can with [dynamic app shortcuts](#). Hence, they cannot really be personalized.

Also, if the user pins one of these app shortcuts, and some future version of your app eliminates the app shortcut, the pinned app shortcut may remain on the user’s home screen. Tapping it would display some sort of “you cannot do this anymore” message. From a user experience standpoint, this will not be popular.

So, try to have your manifest app shortcuts be “evergreen”, ones that are unlikely to need to be changed or removed in the future.

### Add Entry Points for Destination in Manifest

An app shortcut triggers a call to `startActivity()` on some Intent. With manifest app shortcuts, you describe the Intent in XML, and some other process creates that Intent and passes it to `startActivity()`.

This means that any destination that you want to offer needs to be able to be reached by some `startActivity()` call, with an Intent that can be built out of [some combination of the following](#):

- action string
- a `Uri` (the data facet of an Intent)
- a MIME type
- a target class and package name of the desired activity

Notably, it appears that you cannot use extras or categories to distinguish this Intent from any other that starts up the same activity.

Also, this activity will need to be exported, as third-party apps will need to be able to

start up the activity. If the activity has an `<intent-filter>`, it will be exported. Otherwise, you will need to add `android:exported="true"` to the `<activity>` in the manifest.

### Write the XML

The manifest app shortcuts are defined via an XML resource, usually residing in `res/xml/` within your module's `main/` source set. This will contain a root `<shortcuts>` element, which itself contains one or more `<shortcut>` elements:

```
<?xml version="1.0" encoding="utf-8"?>
<shortcuts xmlns:android="http://schemas.android.com/apk/res/android">
  <shortcut
    android:icon="@drawable/ic_search_black_24dp"
    android:shortcutId="search"
    android:shortcutLongLabel="@string/search_long_desc"
    android:shortcutShortLabel="@string/search">
    <intent
      android:action="android.intent.action.SEARCH"
      android:targetClass="com.commonware.android.appshortcuts.MainActivity"
      android:targetPackage="com.commonware.android.appshortcuts" />
    </shortcut>
  </shortcuts>
```

(from [AppShortcuts/WeakBrowser/app/src/main/res/xml/shortcuts.xml](#))

Here, we have a single app shortcut. The required attributes are:

- `android:shortcutId`, for a unique identifier for this app shortcut
- `android:icon`, for a launcher-style icon for this app shortcut
- `android:shortcutShortLabel`, which will be the caption for the app shortcut icon

`android:shortcutLongLabel` is optional. In theory, it will be used in places where a longer description of the app shortcut may be useful. In practice, it is unclear where this would be used.

The other required piece of a shortcut definition is the nested `<intent>` element. This describes what Intent should be used with `startActivity()` to take the user to where this app shortcut advertises as its destination. Typically, you will use the three attributes shown in the above sample:

- `android:action`, for an action string, as this is required, even if it is totally

---

## APP SHORTCUTS

---

useless

- `android:targetClass` and `android:targetPackage`, to provide the pieces of the `ComponentName` to identify the activity to be started

A shortcut can have several `<intent>` elements, which will cause Android to create a fake back stack for the user (i.e., pressing `BACK` from the last `<intent>` will take the user to whatever activity was identified in the preceding `<intent>`). And, a `<shortcuts>` element can have one or several `<shortcut>` elements. However, bear in mind that a launcher may not use many app shortcuts — for example, the Pixel Launcher seems to cap the presentation at three app shortcuts. These results will vary by launcher (or other app shortcuts client) but you should assume that you only have so many app shortcut “slots” to display to the user.

### Add to the Manifest

Then, you need to add a `<meta-data>` element to your `<activity>` element for your launcher activity in the manifest, pointing Android to your XML resource:

```
<activity android:name=".MainActivity">
  <intent-filter>
    <action android:name="android.intent.action.MAIN" />

    <category android:name="android.intent.category.LAUNCHER" />
  </intent-filter>
  <meta-data
    android:name="android.app.shortcuts"
    android:resource="@xml/shortcuts" />
</activity>
```

(from [AppShortcuts/WeakBrowser/app/src/main/AndroidManifest.xml](#))

Only app shortcuts declared on launcher activities will be honored. If you try putting this `<meta-data>` element on other activities, it will be ignored. If your app is one of the few with multiple launcher icons, each could have its own app shortcuts. Or, you might take this opportunity to consolidate those launcher icons into a single one, with the secondary launcher icons turning into app shortcuts.

The fact that this is just a `<meta-data>` element and an XML resource is why existing home screens could adopt manifest app shortcuts. All of this information is available via `PackageManager`, going back to the earliest Android versions.

## Results

If you install this app on a device with a compatible home screen implementation, the manifest app shortcut should be available, such as what you get on the Pixel:

*Figure 857: Manifest App Shortcut for WeakBrowser*

The biggest problem comes with the icons. There are no instructions at all as what these icons should look like, or what size they should be. The author's assumption is that they should be launcher-style icons is made in part by the behavior of when you use *other* types of icons, such as the simple action bar-style search icon:

*Figure 858: Pinned Manifest App Shortcut for WeakBrowser*

Here, the app shortcut was pinned to the home screen, and the icon looks... unpleasant.

Also note that while the Pixel Launcher superimposes your app's icon over the app shortcut icon, it is unclear if that is something that is required by the framework or merely a Pixel Launcher convention.

### **Disabling Manifest App Shortcuts**

So, you ship an update to your app, where you declare some manifest app shortcuts. Some time later, you revamp the UI of your app, and one of those app shortcuts no longer makes sense. It might not even work anymore — for example, you might have removed support for the activity that the app shortcut pointed to.

You might think that whatever shortcut XML you use in the new app version is what the device will use, once the user upgrades to the new app version. That is true, with one noteworthy exception: pinned app shortcuts. Google does not want these to vanish into thin air based on an app update, as that might confuse the user.

You have two main options for how to handle this gracefully:

1. Your revised shortcut XML might *repurpose* the existing app shortcut. Have a `<shortcut>` with the same `android:shortcutId` attribute, but give it whatever icon, labels, and `<intent>` are appropriate. Users who upgrade your app will have their pinned shortcut updated to reflect the new settings. This works well in cases where the app shortcut has changed a bit but still closely resembles its original role.
2. Your revised shortcut XML might *disable* the existing app shortcut. This would happen if your shortcut XML lacked any `<shortcut>` for the old ID. Preferably, though, you have a `<shortcut>` for the to-be-disabled ID. On that element, you can have `android:enabled="false"` to indicate that the app shortcut is now disabled, and you can have `android:shortcutDisabledMessage` pointing to a string resource where you explain why that app shortcut has been disabled. If the user taps on the app shortcut, this message should appear.

## Offering Dynamic App Shortcuts

Truly personalized app shortcuts usually cannot be specified in the manifest. For example, you may want to allow the user to have an app shortcut to their favorite “friend” in your social network client. The identity of that friend varies by user and time. While you could offer a manifest-registered app shortcut for “Favorite Friend”, the user will not know necessarily who that friend is. With dynamic shortcuts, you can craft one that uses the name and avatar of that specific friend.

Offering dynamic app shortcuts is more powerful and correspondingly more complex.

## APP SHORTCUTS

---

Our WeakBrowser sample app, on initial install, only has the one manifest app shortcut. However, the user can visit a Settings activity within the app and elect to enable “bookmarks”:

*Figure 859: WeakBrowser Settings Activity*

## APP SHORTCUTS

---

The user can choose which bookmarks to use from a multi-selection preference:

*Figure 860: WeakBrowser Settings Activity, Showing Bookmarks*

## APP SHORTCUTS

---

If the user checks some bookmarks, they get added as dynamic app shortcuts, to go along with the existing manifest app shortcut:

*Figure 861: WeakBrowser Manifest and Dynamic App Shortcuts*

### Grok the Adjectives

An app shortcut is “pinned” if, by one means or another, the user has indicated that they want long-term direct access to whatever that app shortcut represents. In the Pixel Launcher, an app shortcut is pinned if the user grabs the grab handle and drags it as a shortcut onto the home screens. Different home screens will have different visual metaphors for “pinned”.

An app shortcut is “immutable” if it cannot be changed by the app that provided (“published”) the app shortcut. Manifest app shortcuts are immutable. Conversely, an app shortcut is “mutable” if its contents can be changed. Dynamic app shortcuts are mutable.

### Ponder the IDs

Each app shortcut has a unique ID. For manifest app shortcuts, that is set via the `android:shortcutId` attribute in the `<shortcut>` element. Dynamic app shortcuts

have an equivalent means of establishing their ID.

As you manipulate dynamic app shortcuts, what happens depends upon:

- What operation are you doing (setting? adding? updating? removing?)
- Whether the app shortcut ID(s) associated with the operation matches existing app shortcut ID(s) from your app
- Whether those app shortcuts are mutable or immutable
- Whether the user has pinned any of those app shortcuts

### Identify the Destinations

As with manifest app shortcuts, you need to know where you are going to send the user within your app when the user chooses one of your dynamic app shortcuts. However, in this case, you will be able to provide a full Intent associated with the app shortcut. In principle, you could use things like extras, whereas that is not documented to be supported for manifest app shortcuts.

### Craft the Intent

As with manifest app shortcuts, the destination for your dynamic app shortcuts needs to be identifiable by an Intent that will be used with `startActivity()` to take the user to that destination. However, unlike with manifest app shortcuts, you have full control over the setup of the Intent that is used for dynamic app shortcuts.

In particular, you may want to consider what Intent flags to use. A manifest app shortcut will have `FLAG_ACTIVITY_NEW_TASK` and `FLAG_ACTIVITY_CLEAR_TASK` added to the Intent constructed from the shortcut XML. This will send the user to your destination, wiping out the back stack from that task. You might elect to use other flags, or control things using `<activity>` manifest attributes like `android:taskAffinity`, to get the flow that you want.

For the bookmarks, our sample app has a model class, named `Bookmark`, much to nobody's surprise:

```
package com.commonware.android.appshortcuts;

import java.util.HashMap;

class Bookmark implements Comparable<Bookmark> {
    static final HashMap<String, Bookmark> MODEL=new HashMap<>();
    final String url;
```

## APP SHORTCUTS

---

```
final String title;
final String id;

static {
    add(new Bookmark("Android Developer Home",
        "https://developer.android.com",
        "687a9ea6-f0c0-448c-9cc9-a4aa6e10a1af"));
    add(new Bookmark("Android Open Source Project",
        "https://source.android.com",
        "0ee37e25-2dac-4602-8aa2-3709ac4037c8"));
    add(new Bookmark("AOSP Source Search",
        "http://xref.opersys.com/",
        "405ba533-337e-40be-abe0-fb86cd04bf7d"));
    add(new Bookmark("Stack Overflow Android Questions",
        "https://stackoverflow.com/questions/tagged/android",
        "c9599794-cb9f-46a1-ad61-971ff2a8a172"));
    add(new Bookmark("The CommonsBlog",
        "https://commonsware.com/blog/",
        "948fe25a-44d4-49d0-a23f-2783f786040d"));
    add(new Bookmark("CWAC Community",
        "https://community.commonsware.com/c/cwac",
        "4c7fac0f-fc86-4c68-8ad8-99198fc3d433"));
}

private static void add(Bookmark b) {
    MODEL.put(b.id, b);
}

Bookmark(String title, String url, String id) {
    this.url=url;
    this.title=title;
    this.id=id;
}

@Override
public int compareTo(Bookmark bookmark) {
    return(title.compareTo(bookmark.title));
}
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/Bookmark.java](#))

Here, to keep the example simple, the “database” of bookmarks is merely hardcoded roster, stored in a HashMap, keyed by a UUID serving as a unique identifier. In addition to its id, each Bookmark has a title and a url.

When it comes time to build an Intent for a given Bookmark, we use that url as the

“data” facet of the Intent, to deliver it to our MainActivity:

```
private Intent buildIntent(Bookmark item) {
    return(new Intent(getActivity(), MainActivity.class)
        .setAction("i.can.haz.reason.why.this.is.REQUIRED")
        .setData(Uri.parse(item.url))
        .putExtra(MainActivity.EXTRA_BOOKMARK_ID, item.id)
        .addFlags(Intent.FLAG_ACTIVITY_NEW_TASK|Intent.FLAG_ACTIVITY_CLEAR_TASK));
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/SettingsFragment.java](#))

We also:

- Set the component to identify our MainActivity
- Set the action string because, if we do not, our app shortcut will not work
- Add the same flags to the Intent that are used by manifest app shortcuts, to synchronize the behavior between our one manifest app shortcut and any dynamic app shortcuts that we create
- Save the bookmark’s ID in an extra

## Define the Shortcuts

Android 7.1’s SDK offers a `ShortcutInfo.Builder`, which lets you create `ShortcutInfo` objects, each of which represents one dynamic app shortcut.

Given a Set of Bookmark IDs, we can craft the corresponding `ShortcutInfo` objects via builders:

```
private List<ShortcutInfo> buildShortcuts(Set<String> ids) {
    List<Bookmark> items=new ArrayList<>();

    for (String id: ids) {
        items.add(Bookmark.MODEL.get(id));
    }

    if (items.size(>0) Collections.sort(items);

    List<ShortcutInfo> shortcuts=new ArrayList<>();

    for (Bookmark item : items) {
        shortcuts.add(new ShortcutInfo.Builder(getActivity(), item.id)
            .setShortLabel(item.title)
            .setIcon(buildIcon(item))
            .setIntent(buildIntent(item))
        );
    }
}
```

## APP SHORTCUTS

---

```
        .build());
    }

    return(shortcuts);
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/SettingsFragment.java](#))

The `ShortcutInfo.Builder` constructor takes a `Context` for resource resolution, plus a unique ID of the app shortcut. In our case, we just use the unique ID of the `Bookmark`, since a `Bookmark` corresponds 1:1 with our dynamic app shortcuts.

The builder methods that we use here mirror the XML that we used in the manifest app widget:

Manifest App Widget XML	Builder Method
<code>android:shortcutShortLabel</code>	<code>setShortLabel()</code>
<code>android:icon</code>	<code>setIcon()</code>
<code>&lt;intent&gt;</code>	<code>setIntent()</code>

Our `setIntent()` call uses the `buildIntent()` method shown in the preceding section. In theory, our corresponding `buildIcon()` method would craft an icon for each bookmark, perhaps using the favicon of the site. Here, we just use a simple resource image, the same one for each bookmark:

```
private Icon buildIcon(Bookmark item) {
    return(Icon.createWithResource(getActivity(),
        R.drawable.ic_bookmark_border_black_24dp));
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/SettingsFragment.java](#))

This `buildShortcuts()` method simply creates the `ShortcutInfo` objects. To apply them, we need to get our hands on a `ShortcutManager`, via `getSystemService()`:

```
shortcuts=getActivity().getSystemService(ShortcutManager.class);
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/SettingsFragment.java](#))

Then, we can call `setDynamicShortcuts()` on the `ShortcutManager`, supplying our list of `ShortcutInfo` objects, to specify that this list of `ShortcutInfo` objects

---

## APP SHORTCUTS

---

represents the current roster of dynamic app shortcuts to offer to the user:

```
private void showBookmarks() {
    updateBookmarks(bookmarks.getValues());
}

private void updateBookmarks(Set<String> ids) {
    shortcuts.setDynamicShortcuts(buildShortcuts(ids));
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/SettingsFragment.java](#))

All of this code is appearing in a `SettingsFragment` that shows the `SwitchPreference` and `MultiSelectListPreference` for manipulating the bookmarks. `showBookmarks()` is called if the user toggles on the `SwitchPreference`, and `updateBookmarks()` is called when the user changes which items are checked in the `MultiSelectListPreference` (held in the `bookmarks` field).

### Remove the Shortcuts

It is possible that you will want to remove some existing dynamic app shortcuts. In the case of the sample app, there are two possibilities:

1. The user changes the mix of bookmarks to be something other than it was before, including perhaps unchecking some previously-checked bookmarks
2. The user turns off the `SwitchPreference`, meaning that no dynamic app shortcuts should be offered

Scenario #1 is handled just by calling `setDynamicShortcuts()` on the `ShortcutManager`, as this removes any existing app shortcuts.

Scenario #2 is handled by `removeAllDynamicShortcuts()` on the `ShortcutManager`, which does pretty much what the method name suggests and removes all dynamic app shortcuts:

```
private void hideBookmarks() {
    shortcuts.removeAllDynamicShortcuts();
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/SettingsFragment.java](#))

Another option is the `removeShortcuts()` method on the `ShortcutManager`. This takes a `List` of ID values and removes those app shortcuts.

## APP SHORTCUTS

---

However, bear in mind that:

- You cannot remove immutable app shortcuts, so you cannot use this to remove a manifest app shortcut
- This does not affect any pinned app shortcuts, which will remain even after you have “removed” the app shortcut

What these methods are doing is changing the roster of dynamic app shortcuts that are available to the user from the launcher icon. They do not affect any existing pinned app shortcuts.

### Grok the Other Verbs

`ShortcutManager` has a handful of other methods that allow you to manipulate the roster of dynamic app shortcuts that your app produces.

`addDynamicShortcuts()` will update any dynamic app shortcuts with the same IDs as the ones that you supply, and any new dynamic app shortcuts will be added. Where `setDynamicShortcuts()` says “replace the existing roster with this one”, `addDynamicShortcuts()` says “update or augment the existing roster with these, and leave everything else alone”.

`updateShortcuts()` is like `addDynamicShortcuts()`, except that it will only update existing dynamic app shortcuts, not add new ones.

`reportShortcutUsed()` should be called, with the ID of a shortcut, whenever that app shortcut gets used by the app. In theory, this information might help Android optimize the presentation of app shortcuts to the user, though it is unclear if this is being used at the moment. This is why we put the bookmark ID in the `EXTRA_BOOKMARK_ID` extra: so `MainActivity` can report the usage of this app shortcut.

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.N_MR1) {
    String id = i.getStringExtra(EXTRA_BOOKMARK_ID);

    if (id != null) {
        getSystemService(ShortcutManager.class)
            .reportShortcutUsed(id);
    }
}
```

(from [AppShortcuts/WeakBrowser/app/src/main/java/com/commonsware/android/appshortcuts/MainActivity.java](#))

(here, `i` is the `Intent` used to display this activity)

`disableShortcuts()` — where you supply it with a list of dynamic app shortcut IDs — allows you to stop pinned dynamic app shortcuts from working. While `setDynamicShortcuts()`, `removeDynamicShortcuts()`, and `removeAllDynamicShortcuts()` affect the roster of available dynamic app shortcuts, they do not affect any pinned dynamic app shortcuts. Those will still work. If the reason why you are removing some dynamic app shortcuts is that the user is no longer eligible for those things (e.g., the user failed to renew a subscription), `disableShortcuts()` allows you to block those dynamic app shortcuts from working. The user will be shown a message instead of having the pinned dynamic app shortcut launch an activity, and you can tailor that message if desired.

### Contemplate Update vs. Replace

`setDynamicShortcuts()`, `updateShortcuts()`, and `addDynamicShortcuts()` all do the same thing if there is an existing dynamic app shortcut with the same ID: update its contents to reflect whatever you passed in to those methods. This includes “updating” it to have the same information as it already has, if you have not changed anything. These not only update the roster that will be shown to the user, but they also update any pinned editions of those dynamic app shortcuts.

This introduces a potential area of confusion for the user.

For example, a Web browser that is more sophisticated than is `WeakBrowser` could keep track of which sites the user visits most often. Then, the browser could offer a dynamic app shortcut to visit that specific site. Let’s pretend for a moment that, at some point in time, the user’s most-visited site is [the CommonsWare site](#). The browser would have a dynamic app shortcut for “CommonsWare”, which the user could pin.

Some time later, as the user continues using the browser, the browser realizes that some new site has supplanted the CommonsWare site as the one that the user has visited the most. So, the browser will want its dynamic app shortcut roster to reflect this change.

There are two ways of going about this:

1. The browser could reuse the existing app shortcut ID (e.g., `mostPopular`) and change its label and `Intent` to reflect the new most-popular site. However, this will not only change what the user sees when looking at the

available app shortcuts, but it also *changes the pinned app shortcut*. Now that home screen shortcut would bring up some other site, while the user had pinned the CommonsWare site.

2. The browser could use app shortcut IDs that are unique not for the role, but for the site (e.g., use the actual URL). If the browser uses `setDynamicShortcuts()` now, the list of shortcuts would contain one with the new app shortcut ID and would not contain one with the old app shortcut ID. The list of dynamic app shortcuts that the user sees will reflect this change. But, since the browser did not change any data with the old app shortcut ID, *the pinned one remains as it was*, still pointing to the CommonsWare site.

If this sort of thing sounds like it might be plausible for your planned use of dynamic app shortcuts, you probably want to consider the app shortcut ID to be tied to the content (e.g., the site URL), not the role the content is being applied to (e.g., the most-popular site URL).

### Get the Existing Shortcuts

There are three getter methods that allow you to find out what app shortcuts are outstanding and are related to your app:

- `getDynamicShortcuts()`
- `getManifestShortcuts()`
- `getPinnedShortcuts()`

The latter, as the name suggests, lets you know which app shortcuts (manifest or dynamic) have been pinned by the user.

Note that the `ShortcutInfo` objects that you get back from these methods may not have all of their details filled in (e.g., may be missing the icon). Mostly, you will be looking for the shortcut IDs, so you can make determinations of how to manipulate the app shortcut roster (e.g., do you need to disable anything?).

### Deal with Reality

Unfortunately, there are some aspects of dynamic app shortcuts which will require additional work.

If your labels for the dynamic app shortcuts have translations for other languages, you need to replace the dynamic app shortcuts when the user switches the device to

a different locale. For example, you could have a manifest-registered `BroadcastReceiver`, listening for the `ACTION_LOCALE_CHANGED` system broadcast. There, you could call `setDynamicShortcuts()` or `updateShortcuts()` to reflect the new labels.

However, outside of locale changes, you need to be careful about updating dynamic app shortcut information when your app is in the background. There is a “rate limit” established that will prevent you from changing those shortcuts too frequently. `addDynamicShortcuts()`, `setDynamicShortcuts()`, and `updateShortcuts()` each return a boolean; `false` indicates that your request failed due to rate-limiting. You can also call `isRateLimitingActive()` on the `ShortcutManager` to find out in advance whether your app is being rate-limited and would not be able to affect dynamic app shortcut changes.

Also, there is a limit of how many app shortcuts you can have at any one time. `getMaxShortcutCountPerActivity()` on `ShortcutManager` reports this limit. Attempting to go past that will result in an exception. Android 7.1 appears to have a limit of five; if you try enabling all six bookmarks in the sample app, you will crash.

## Privacy, Security, and App Shortcuts

Bear in mind that information contained in app shortcuts will be visible to home screens and anything else using `LauncherApps` to get at the possible app shortcuts. As such, please be careful to avoid putting sensitive information in app shortcuts (e.g., labels).

# PackageManager Tricks

---

`PackageManager` is your primary means of introspection at the component level, to determine what else is installed on the device and what components they export (activities, etc.). As such, there are many ways you can use `PackageManager` to determine if something you want is possible or not, so you can modify your behavior accordingly (e.g., disable action bar items that are not possible).

This chapter will outline some ways you can use `PackageManager` to find out what components are available to you on a device.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Asking Around

The ways to find out whether there is an activity that will respond to a given `Intent` are by means of `queryIntentActivityOptions()` and the somewhat simpler `queryIntentActivities()`.

The `queryIntentActivityOptions()` method takes the caller `ComponentName`, the “specifics” array of `Intent` instances, the overall `Intent` representing the actions you are seeking, and the set of flags. It returns a `List` of `Intent` instances matching the stated criteria, with the “specifics” ones first.

If you would like to offer alternative actions to users, but by means other than `addIntentOptions()`, you could call `queryIntentActivityOptions()`, get the `Intent`

## PACKAGEMANAGER TRICKS

---

```
        setListAdapter(adapter);
    }

    @Override
    protected void onItemClick(ListView l, View v,
                               int position, long id) {
        ResolveInfo launchable=adapter.getItem(position);
        ActivityInfo activity=launchable.activityInfo;
        ComponentName name=new ComponentName(activity.applicationInfo.packageName,
                                             activity.name);

        Intent i=new Intent(Intent.ACTION_MAIN);

        i.addCategory(Intent.CATEGORY_LAUNCHER);
        i.setFlags(Intent.FLAG_ACTIVITY_NEW_TASK |
                  Intent.FLAG_ACTIVITY_RESET_TASK_IF_NEEDED);
        i.setComponent(name);

        startActivity(i);
    }

    class AppAdapter extends ArrayAdapter<ResolveInfo> {
        private PackageManager pm=null;

        AppAdapter(PackageManager pm, List<ResolveInfo> apps) {
            super(Launchalot.this, R.layout.row, apps);
            this.pm=pm;
        }

        @Override
        public View getView(int position, View convertView,
                           ViewGroup parent) {
            if (convertView==null) {
                convertView=newView(parent);
            }

            bindView(position, convertView);

            return(convertView);
        }

        private View newView(ViewGroup parent) {
            return(getLayoutInflater().inflate(R.layout.row, parent, false));
        }

        private void bindView(int position, View row) {
            TextView label=(TextView)row.findViewById(R.id.label);

            label.setText(getItem(position).loadLabel(pm));
        }
    }
}
```

## PACKAGEMANAGER TRICKS

---

```
    ImageView icon=(ImageView)row.findViewById(R.id.icon);

    icon.setImageDrawable(getItem(position).loadIcon(pm));
}
}
```

(from [Introspection/Launchalot/app/src/main/java/com/commonsware/android/lauchalot/Launchalot.java](https://github.com/Introspection/lauchalot/blob/master/app/src/main/java/com/commonsware/android/lauchalot/Launchalot.java))

In onCreate(), we:

1. Get a PackageManager object via `getPackageManager()`
2. Create an Intent for ACTION\_MAIN in CATEGORY\_LAUNCHER, which identifies activities that wish to be considered “launchable”
3. Call `queryIntentActivities()` to get a List of ResolveInfo objects, each one representing one launchable activity
4. Sort those ResolveInfo objects via a `ResolveInfo.DisplayNameComparator` instance
5. Pour them into a custom AppAdapter and set that to be the contents of our ListView

AppAdapter is an ArrayAdapter subclass that maps the icon and name of the launchable Activity to a row in the ListView, using a custom row layout.

Finally, in `onListItemClick()`, we construct an Intent that will launch the clicked-upon Activity, given the information from the corresponding ResolveInfo object. Not only do we need to populate the Intent with ACTION\_MAIN and CATEGORY\_LAUNCHER, but we also need to set the component to be the desired Activity. We also set FLAG\_ACTIVITY\_NEW\_TASK and FLAG\_ACTIVITY\_RESET\_TASK\_IF\_NEEDED flags, following Android’s own launcher implementation from the Home sample project. Finally, we call `startActivity()` with that Intent, which opens up the activity selected by the user.

The result is a simple list of launchable activities:

*Figure 862: The Launchalot sample application*

There is also a `resolveActivity()` method that takes a template `Intent`, as do `queryIntentActivities()` and `queryIntentActivityOptions()`. However, `resolveActivity()` returns the single best match, rather than a list.

**NOTE:** On modern versions of Android, there is a `LauncherApps` class that simplifies a lot of this and takes things like Android Work profiles into account. For really implementing a home screen-style launcher, you will probably want to use `LauncherApps`. However, using `PackageManager` to find what can handle certain `Intent` structures is used for other purposes beyond home screen launchers.

## Preferred Activities

Users, when presented with a default activity chooser, usually have the option to make their next choice be the default for this action for now on. The next time they do whatever they did to bring up the chooser, it should go straight to this default. This is known in the system as the “preferred activity” for an `Intent` structure, and is stored in the system as a set of pairs of `IntentFilter` objects and the corresponding

## PACKAGEMANAGER TRICKS

---

ComponentName of the preferred activity.

To find out what the preferred activities are on a given device, you can ask PackageManager to `getPreferredActivities()`. You pass in a `List<IntentFilter>` and a `List<ComponentName>`, and Android fills in those lists with the preferred activity information.

To see this in action, take a look at the [Introspection/PrefActivities](#) sample application. This simply loads all of the information into a `ListView`, using `android.R.layout.simple_list_item_2` as a row layout for a title-and-description pattern.

The PackageManager logic is confined to `onCreate()`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    PackageManager mgr=getPackageManager();

    mgr.getPreferredActivities(filters, names, null);
    setListAdapter(new IntentFilterAdapter());
}
```

(from [Introspection/PrefActivities/app/src/main/java/com/commonsware/android/prefact/PreferredActivitiesDemoActivity.java](#))

In this case, the two lists are data members of the activity:

```
ArrayList<IntentFilter> filters=new ArrayList<IntentFilter>();
ArrayList<ComponentName> names=new ArrayList<ComponentName>();
```

(from [Introspection/PrefActivities/app/src/main/java/com/commonsware/android/prefact/PreferredActivitiesDemoActivity.java](#))

Most of the logic is in formatting the `ListView` contents. `IntentFilter`, unfortunately, does not come with a method that gives us a human-readable dump of its definition. As a result, we need to roll that ourselves. Compounding the problem is that `IntentFilter` tends to return `Iterator` objects for its collections (e.g., roster of actions), rather than something `Iterable`. The activity leverages an `Iterator-to-Iterable` wrapper culled from [a Stack Overflow answer](#) to help with this. The `IntentFilterAdapter` and helper code looks like this:

```
// from http://stackoverflow.com/a/8555153/115145
public static <T> Iterable<T> in(final Iterator<T> iterator) {
```

## PACKAGEMANAGER TRICKS

---

```
class SingleUseIterable implements Iterable<T> {
    private boolean used=false;

    @Override
    public Iterator<T> iterator() {
        if (used) {
            throw new IllegalStateException("Already invoked");
        }
        used=true;
        return iterator();
    }
}

return new SingleUseIterable();
}

class IntentFilterAdapter extends ArrayAdapter<IntentFilter> {
    IntentFilterAdapter() {
        super(PreferredActivitiesDemoActivity.this,
            android.R.layout.simple_list_item_2, android.R.id.text1,
            filters);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View row=super.getView(position, convertView, parent);
        TextView filter=(TextView)row.findViewById(android.R.id.text1);
        TextView name=(TextView)row.findViewById(android.R.id.text2);

        filter.setText(buildTitle(getItem(position)));
        name.setText(names.get(position).getClassName());

        return(row);
    }

    String buildTitle(IntentFilter filter) {
        StringBuilder buf=new StringBuilder();
        boolean first=true;

        if (filter.countActions() > 0) {
            for (String action : in(filter.actionsIterator())) {
                if (first) {
                    first=false;
                }
                else {
                    buf.append('/');
                }
            }

            buf.append(action.replaceAll("android.intent.action.", ""));
        }
    }
}
```

## PACKAGEMANAGER TRICKS

---

```
    }
}

if (filter.countDataTypes() > 0) {
    first=true;

    for (String type : in(filter.typesIterator())) {
        if (first) {
            buf.append(" : ");
            first=false;
        }
        else {
            buf.append('|');
        }

        buf.append(type);
    }
}

if (filter.countDataSchemes() > 0) {
    buf.append(" : ");
    buf.append(filter.getDataScheme(0));

    if (filter.countDataSchemes() > 1) {
        buf.append(" (other schemes)");
    }
}

if (filter.countDataPaths() > 0) {
    buf.append(" : ");
    buf.append(filter.getDataPath(0));

    if (filter.countDataPaths() > 1) {
        buf.append(" (other paths)");
    }
}

return(buf.toString());
}
}
```

(from [Introspection/PrefActivities/app/src/main/java/com/commonsware/android/prefact/PreferredActivitiesDemoActivity.java](#))

## PACKAGEMANAGER TRICKS

---

The resulting activity shows a simple description of the `IntentFilter` along with the class name of the corresponding activity in each row:

Figure 863: Preferred Activities on a Stock HTC One S

Another way to think about preferred activities is to determine what specific activity will handle a `startActivity()` call on some `Intent`. If there is only one alternative, or the user chose a preferred activity, that activity should handle the `Intent`. Otherwise, the activity handling the `Intent` *should* be one implementing a chooser. The `resolveActivity()` method on `PackageManager` can let us know what will handle the `Intent`.

To examine what `resolveActivity()` returns, take a look at the [Introspection/Resolver](#) sample application.

The activity — which uses `Theme.Translucent.NoTitleBar` and so has no UI of its own — is fairly short:

```
package com.commonware.android.resolver;

import android.app.Activity;
import android.content.Intent;
import android.content.pm.PackageManager;
```

## PACKAGEMANAGER TRICKS

---

```
import android.content.pm.ResolveInfo;
import android.net.Uri;
import android.os.Bundle;
import android.widget.Toast;

public class ResolveActivityDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        PackageManager mgr=getPackageManager();
        Intent i=
            new Intent(Intent.ACTION_VIEW,
                Uri.parse("https://commonsware.com"));
        ResolveInfo ri=
            mgr.resolveActivity(i, PackageManager.MATCH_DEFAULT_ONLY);

        Toast.makeText(this, ri.loadLabel(mgr), Toast.LENGTH_LONG).show();

        startActivity(i);
        finish();
    }
}
```

(from [Introspection/Resolver/app/src/main/java/com/commonsware/android/resolver/ResolveActivityDemoActivity.java](#))

We get a `PackageManager`, create an `Intent` to test, and pass the `Intent` to `resolveActivity()`. We include `MATCH_DEFAULT_ONLY` so we only get activities that have `CATEGORY_DEFAULT` in their `<intent-filter>` elements. We then use `loadLabel()` on the resulting `ResolveInfo` object to get the display name of the activity, toss that in a `Toast`, and invoke `startActivity()` on the `Intent` to confirm the results.

On a device with only one option, or with a default chosen, the `Toast` will show the name of the preferred activity (e.g., `Browser`). On most devices with more than one option, the `startActivity()` call will display a chooser, and the `Toast` will show the display name of the chooser (e.g., `“Android System”`).

However, on some devices — notably newer models from HTC distributed in the US — `resolveActivity()` indicates that `HTCLinkifyDispatcher` is the one that will handle `ACTION_VIEW` on a URL... even if there is more than one browser installed and no default has been specified. This is part of a workaround that HTC added in 2012 to help deal with a patent dispute with Apple.

## Middle Management

The `PackageManager` class offers much more than merely `queryIntentActivities()` and `queryIntentActivityOptions()`. It is your gateway to all sorts of analysis of what is installed and available on the device where your application is installed and available. If you want to be able to intelligently connect to third-party applications based on whether or not they are around, `PackageManager` is what you will want.

### Finding Applications and Packages

Packages are what get installed on the device — a package is the in-device representation of an APK. An application is defined within a package's manifest. Between the two, you can find out all sorts of things about existing software installed on the device.

Specifically, `getInstalledPackages()` returns a `List` of `PackageInfo` objects, each of which describes a single package. Here, you can find out:

1. The version of the package, in terms of a monotonically increasing number (`versionCode`) and the display name (`versionName`)
2. Details about all of the components — activities, services, etc. — offered by this package
3. Details about the permissions the package requires

Similarly, `getInstalledApplications()` returns a `List` of `ApplicationInfo` objects, each providing data like:

1. The user ID that the application will run as
2. The path to the application's private data directory
3. Whether or not the application is enabled

In addition to those methods, you can call:

1. `getApplicationIcon()` and `getApplicationLabel()` to get the icon and display name for an application
2. `getLaunchIntentForPackage()` to get an `Intent` for something launchable within a named package
3. `setApplicationEnabledSetting()` to enable or disable an application

## Finding Resources

You can access resources from another application, apparently without any security restrictions. This may be useful if you have multiple applications and wish to share resources for one reason or another.

The `getResourcesForActivity()` and `getResourcesForApplication()` methods on `PackageManager` return a `Resources` object. This is just like the one you get for your own application via `getResources()` on any `Context` (e.g., `Activity`). However, in this case, you identify what activity or application you wish to get the `Resources` from (e.g., supply the application's package name as a `String`).

There are also `getText()` and `getXml()` methods that dive into the `Resources` object for an application and pull out specific `String` or `XmlPullParser` objects. However, these require you to know the resource ID of the resource to be retrieved, and that may be difficult to manage between disparate applications.

## Finding Components

Not only does Android offer “query” and “resolve” methods to find activities, but it offers similar methods to find other sorts of Android components:

1. `queryBroadcastReceivers()`
2. `queryContentProviders()`
3. `queryIntentServices()`
4. `resolveContentProvider()`
5. `resolveService()`

For example, you could use `resolveService()` to determine if a certain remote service is available, so you can disable certain UI elements if the service is not on the device. You could achieve the same end by calling `bindService()` and watching for a failure, but that may be later in the application flow than you would like.

There is also a `setComponentEnabledSetting()` to toggle a component (activity, service, etc.) on and off. While this may seem esoteric, there are a number of possible uses for this method, such as:

1. Flagging a launchable activity as disabled in your manifest, then enabling it programmatically after the user has entered a license key, achieved some level or standing in a game, or any other criteria
2. Controlling whether a `BroadcastReceiver` registered in the manifest is

## PACKAGEMANAGER TRICKS

---

hooked into the system or not, replicating the level of control you have with `registerReceiver()` while still taking advantage of the fact that a manifest-registered `BroadcastReceiver` can be started even if no other component of your application is running

# Remote Services and the Binding Pattern

---

Earlier in this book, we covered using services by sending commands to them to be processed. That “command pattern” is one of two primary means of interacting with a service — the binding pattern is the other. With the binding pattern, your service exposes a more traditional API, in the form of a “binder” object with methods of your choosing. On the plus side, you get a richer interface. However, it more tightly ties your activity to your service, which may cause you problems with configuration changes.

Either the command pattern or the binding pattern can be used, if desired, across process boundaries, with the client being some third-party application. In either case, you will need to export your service via an `<intent-filter>`. And, in the case of the binding pattern, your “binder” implementation will have some restrictions.

This chapter covers the binding pattern for local services, plus inter-process commands and binding (a.k.a., remote services).

## Prerequisites

Understanding this chapter requires that you have read the chapters on:

- [broadcast Intents](#)
- [service theory](#)

## The Binding Pattern

Implementing the binding pattern requires work on both the service side and the client side. The service will need to have a full implementation of the `onBind()` method, which typically just returns `null` or throws some sort of runtime exception for a service solely implementing the command pattern. And, the client (e.g., an activity) will need to ask to bind to the service, instead of (or perhaps in addition to) starting the service.

### What the Service Does

The service implements a subclass of `Binder` that represents the service's exposed API. For a local service, your `Binder` can have pretty much whatever methods you want: method names, parameters, return types, and exceptions thrown are up to you. When you get into remote services, your `Binder` implementation will be substantially more constrained, to support inter-process communication.

Then, your `onBind()` method returns an instance of the `Binder`.

### What the Client Does

Clients call `bindService()`, supplying the `Intent` that identifies the service, a `ServiceConnection` object representing the client side of the binding, and an optional `BIND_AUTO_CREATE` flag. As with `startService()`, `bindService()` is asynchronous. The client will not know anything about the status of the binding until the `ServiceConnection` object is called with `onServiceConnected()`. This not only indicates the binding has been established, but for local services it provides the `Binder` object that the service returned via `onBind()`. At this point, the client can use the `Binder` to ask the service to do work on its behalf.

Note that if the service is not already running, and if you provide `BIND_AUTO_CREATE`, then the service will be created first before being bound to the client. If you skip `BIND_AUTO_CREATE`, and the service is not already running, `bindService()` is supposed to return `false`, indicating there was no existing service to bind to. However, in actuality, Android returns `true`, due to [an apparent bug](#).

Eventually, the client will need to call `unbindService()`, to indicate it no longer needs to communicate with the service. For example, an activity might call `bindService()` in its `onCreate()` method, then call `unbindService()` in its `onDestroy()` method. Once you call `unbindService()`, your `Binder` object is no

longer safe to be used by the client. If there are no other bound clients to the service, Android will shut down the service as well, releasing its memory. Hence, we do not need to call `stopService()` ourselves — Android handles that, if needed, as a side effect of unbinding.

Your `ServiceConnection` object will also need an `onServiceDisconnected()` method. This will be called only if there is an unexpected disconnection, such as the service crashing with an unhandled exception.

### A Binding Sample

In the chapter introducing services, we saw a sample app that would [download a file off of a Web server](#). That sample used the command pattern, telling the service what to download via an Intent extra. In this chapter, we will review a few variations of that sample, all of which use the binding pattern instead of the command pattern.

Right now, we are focused on local services, and so the [Binding/Local](#) sample project does the download via a local bound service.

We start by defining an interface that will serve as the “contract” between the client (fragment) and service. This interface, `IDownload`, contains a single `download()` method:

```
package com.commonware.android.advservice.binding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

(from [Binding/Local/app/src/main/java/com/commonware/android/advservice/binding/IDownload.java](#))

Our service, `DownloadService`, implements just one method, `onBind()`, which returns an instance of a `DownloadBinder`:

```
package com.commonware.android.advservice.binding;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Binder;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import java.io.BufferedOutputStream;
import java.io.File;
```

## REMOTE SERVICES AND THE BINDING PATTERN

---

```
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
    @Override
    public IBinder onBind(Intent intent) {
        return(new DownloadBinder());
    }

    private static class DownloadBinder extends Binder implements IDownload {
        @Override
        public void download(String url) {
            new DownloadThread(url).start();
        }
    }

    private static class DownloadThread extends Thread {
        String url=null;

        DownloadThread(String url) {
            this.url=url;
        }

        @Override
        public void run() {
            try {
                File root=
                    Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

                root.mkdirs();

                File output=new File(root, Uri.parse(url).getLastPathSegment());

                if (output.exists()) {
                    output.delete();
                }

                HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

                FileOutputStream fos=new FileOutputStream(output.getPath());
                BufferedOutputStream out=new BufferedOutputStream(fos);

                try {
                    InputStream in=c.getInputStream();
                    byte[] buffer=new byte[8192];
                    int len=0;

                    while ((len=in.read(buffer)) >= 0) {
                        out.write(buffer, 0, len);
                    }

                    out.flush();
                }
                finally {
                    fos.getFD().sync();
                    out.close();
                    c.disconnect();
                }
            }
        }
    }
}
```

## REMOTE SERVICES AND THE BINDING PATTERN

---

```
    }  
  }  
  catch (IOException e2) {  
    Log.e("DownloadJob", "Exception in download", e2);  
  }  
}  
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadService.java](#))

DownloadBinder implements the IDownload interface. Its download() method, in turn, forks a DownloadThread to perform the download in the background — remember, for local services, the methods you invoke on the Binder are executed on whatever thread you call them on.

Our fragment, DownloadFragment, loads our layout, res/layout/main.xml, containing a Button to trigger the download:

```
<?xml version="1.0" encoding="utf-8"?>  
<Button xmlns:android="http://schemas.android.com/apk/res/android"  
    android:id="@+id/go"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent"  
    android:text="@string/go"/>
```

(from [Binding/Local/app/src/main/res/layout/main.xml](#))

The implementation of onCreateView() simply loads that layout, gets the Button, sets up the fragment as being the click listener for the Button, and disables the Button:

```
@Override  
public View onCreateView(LayoutInflater inflater,  
    ViewGroup container,  
    Bundle savedInstanceState) {  
    View result=inflater.inflate(R.layout.main, container, false);  
  
    btn=(Button)result.findViewById(R.id.go);  
    btn.setOnClickListener(this);  
    btn.setEnabled(binding!=null);  
  
    return(result);  
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

The reason why we disable the Button is because we are not connected to our

## REMOTE SERVICES AND THE BINDING PATTERN

---

service at this point, and until we are, we cannot allow the user to try to download a file.

In `onCreate()` of our fragment, we mark the fragment as retained and bind to the service:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();
    appContext.bindService(new Intent(getActivity(),
        DownloadService.class),
        this, Context.BIND_AUTO_CREATE);
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

You will notice something curious here: `getApplicationContext()`. Technically, we could bind to the service directly from the Activity, by calling `bindService()` on it, as `bindService()` is a method on `Context`. However, our service binding represents some state, and it is possible that this state will hold a reference to the `Context` that created the binding. In that case, we run the risk of leaking our original activity during a configuration change. The `getApplicationContext()` method returns the global `Application` singleton, which is a `Context` suitable for binding, but one that cannot be leaked, since it is already in a global scope. In effect, it is “pre-leaked”.

The call to `setRetainInstance()` allows the fragment – serving as our `ServiceConnection` — to survive a configuration change, so we can cleanly unbind from the service later on, when `onDestroy()` is called.

Some time after `onCreate()` is called and we call `bindService()`, our `onServiceConnected()` method will be called, as we designated our fragment to be the `ServiceConnection`. Here, we can cast the `IBinder` object we receive to be our `IDownload` interface to the service, and we can enable the Button:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
    binding=(IDownload)binder;
    btn.setEnabled(true);
}
```

---

## REMOTE SERVICES AND THE BINDING PATTERN

---

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

Since we are implementing the `ServiceConnection` interface, our fragment also needs to implement the `onServiceDisconnected()` method, invoked if our service crashes. Here, we delegate responsibility to a `disconnect()` private method, which removes our link to the `IDownload` object and disables our `Button`:

```
@Override
public void onServiceDisconnected(ComponentName className) {
    disconnect();
}

private void disconnect() {
    binding=null;
    btn.setEnabled(false);
}
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

And, when our fragment is destroyed, we unbind from the service (using the same `Context` as before, from `getApplicationContext()`) and `disconnect()`:

```
@Override
public void onDestroy() {
    appContext.unbindService(this);
    disconnect();

    super.onDestroy();
}
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

However, in between `onServiceConnected()` and either `onServiceDisconnected()` or `onDestroy()`, the user can click the `Button`, which will trigger the download via a call to `download()` on our `IDownload` instance:

```
@Override
public void onClick(View view) {
    binding.download(TO_DOWNLOAD);
}
}
```

(from [Binding/Local/app/src/main/java/com/commonsware/android/advservice/binding/DownloadFragment.java](#))

The `DownloadBindingDemo` activity adds our `DownloadFragment` via a `FragmentManager`:

---

## REMOTE SERVICES AND THE BINDING PATTERN

---

```
package com.commonware.android.advservice.binding;

import android.os.Bundle;
import android.support.v4.app.FragmentActivity;

public class DownloadBindingDemo extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);

        if (getSupportFragmentManager().findFragmentById(android.R.id.content) == null) {
            getSupportFragmentManager().beginTransaction()
                .add(android.R.id.content,
                    new DownloadFragment()).commit();
        }
    }
}
```

(from [Binding/Local/app/src/main/java/com/commonware/android/advservice/binding/DownloadBindingDemo.java](#))

### Starting and Binding

Some developers will use *both* `startService()` and `bindService()` at the same time. The typical argument is that they need frequent updates from the service (e.g., percentage of progress, for updating a `ProgressBar`) in the client and are concerned about the overhead of sending broadcasts.

With the advent of [LocalBroadcastManager and other event bus implementations](#), binding to a service you are using with `startService()` should no longer be necessary.

### When IPC Attacks!

If you wish to extend the binding pattern to serve in the role of IPC, whereby other processes can get at your Binder and call its methods, you will need to use AIDL: the Android Interface Description Language. If you have used IPC mechanisms like SOAP, XML-RPC, DCOM, CORBA, or the like, you will recognize the notion of IDL. AIDL describes the public IPC interface, and Android supplies tools to build the client and server side of that interface.

With that in mind, let's take a look at AIDL and IPC.

### Write the AIDL

IDLs are frequently written in a "language-neutral" syntax. AIDL, on the other hand, looks a lot like a Java interface file. For example, here is some AIDL:

## REMOTE SERVICES AND THE BINDING PATTERN

---

```
package com.commonware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

(from [Binding/Remote/Service/app/src/main/aidl/com/commonware/android/advservice/remotebinding/IDownload.aidl](#))

As you will notice, this looks suspiciously like the regular Java interface we used in the simple binding example earlier in this chapter.

As with a Java interface, you declare a package at the top. As with a Java interface, the methods are wrapped in an interface declaration (`interface IDownload { ... }`). And, as with a Java interface, you list the methods you are making available.

The differences, though, are critical.

First, not every Java type can be used as a parameter. Your choices are:

1. Primitive values (int, float, double, boolean, etc.)
2. String and CharSequence
3. List and Map (from `java.util`)
4. Any other AIDL-defined interfaces
5. Any Java classes that implement the `Parcelable` or `Serializable` interface

In the case of the latter two categories, you need to include `import` statements referencing the names of the classes or interfaces that you are using (e.g., `import com.commonware.android.ISomething`). This is true even if these classes are in your own package — you have to import them anyway.

Next, parameters can be classified as `in`, `out`, or `inout`. Values that are `out` or `inout` can be changed by the service and those changes will be propagated back to the client. Primitives (e.g., `int`) can only be `in`.

Also, you cannot throw any exceptions. You will need to catch all exceptions in your code, deal with them, and return failure indications some other way (e.g., error code return values).

Name your AIDL files with the `.aidl` extension and place them in the proper directory based on the package name:

- For native Android Studio projects, this will be an `aidl/` directory in your

src/ source set, as a peer of your java/ directory, with the same sort of subdirectories-based-on-the-Java-package approach as you use for regular Java source code

- For Eclipse-compatible projects, the .aidl files will go alongside your .java files in the src/ directory tree

When you build your project, either via an IDE or via command-line build tools, the aidl utility from the Android SDK will translate your AIDL into a server stub and a client proxy.

### Implement the Interface

Given the AIDL-created server stub, now you need to implement the service, either directly in the stub, or by routing the stub implementation to other methods you have already written.

The mechanics of this are fairly straightforward:

1. Create a subclass of the AIDL-generated .Stub class (e.g., IDownload.Stub)
2. Implement methods matching up with each of the methods you placed in the AIDL
3. Return an instance of this subclass from your onBind() method in the Service subclass

Note that AIDL IPC calls are synchronous, and so the caller is blocked until the IPC method returns. Hence, your services need to be quick about their work.

We will see examples of service stubs later in this chapter.

## Service From Afar

So, given our AIDL description, let us examine a sample implementation, using AIDL for a remote service.

Our sample applications — shown in the [Binding/Remote/Service](#) and [Binding/Remote/Client](#) sample projects — simply move the service logic into a separate project from the client logic.

### Service Names

To bind to a service's AIDL-defined API, you need to craft an Intent that can identify the service in question. In the case of a local service, that Intent can use the local approach of directly referencing the service class.

Obviously, that is not possible in a remote service case, where the service class is not in the same process, and may not even be known by name to the client.

When you define a service to be used by remote, you need to add an `<intent-filter>` element to your service declaration in the manifest, indicating how you want that service to be referred to by clients. The manifest for RemoteService is shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.advservice.remotebinding.svc"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-sdk
    android:minSdkVersion="14"
    android:targetSdkVersion="14" />

  <uses-permission android:name="android.permission.INTERNET" />
  <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE" />

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
    <service android:name=".DownloadService">
      <intent-filter>
        <action android:name="com.commonware.android.advservice.remotebinding.IDownload" />
      </intent-filter>
    </service>
  </application>
</manifest>
```

(from [Binding/Remote/Service/app/src/main/AndroidManifest.xml](#))

Here, we say that the service can be identified by the name `com.commonware.android.advservice.remotebinding.IDownload`. So long as the client uses this name to identify the service, it can bind to that service's API.

In this case, the name is not an implementation, but the AIDL API, as you will see below. In effect, this means that so long as some service exists on the device that implements this API, the client will be able to bind to something.

### Remote Services and Implicit Intents

We are used to a device having multiple activities that can respond to the same `<intent-filter>`. In that case, by default, the user will see a chooser if we try to start one of those activities.

We are used to a device having multiple `BroadcastReceiver` components that can respond to the same `<intent-filter>` (or `IntentFilter`). In that case, in a regular broadcast, all eligible receivers will receive it.

We are used to it being impossible to have multiple `ContentProvider` components with the same authority, as the second one fails on install with an `INSTALL_FAILED_CONFLICTING_PROVIDER` error.

What happens if there are *two* (or more) services installed on the device that claim to support the same `<intent-filter>`, but have different package names? You might think that this would fail on install, as happens with providers with duplicate authorities. Alas, it does not... prior to Android 5.0. Instead, the higher-priority `<intent-filter>` gets it (set via the `android:priority` attribute). If 2+ implementations have the same priority, the first one installed wins.

So, if we have `BadService` and `GoodService`, both responding to the same `<intent-filter>`, and a client app tries to communicate to `GoodService` via the implicit Intent matching that `<intent-filter>`, it might *actually* be communicating with `BadService`, simply because `BadService` was installed first. The user is oblivious to this.

Android 5.0 solves this by preventing binding using an implicit Intent. This, however, presents a conundrum:

- We cannot bind using an implicit Intent
- We do not know how to construct an explicit Intent identifying the desired service, as that might be from a third-party app

As you will see, when we examine the client side of this sample, we have to use `PackageManager` to convert an implicit Intent into a valid explicit Intent for our service. This not only allows us to comply with the Android 5.0 binding restriction, but it gives us an opportunity to detect and handle the cases where there is no matching service (e.g., the service app has not yet been installed) or when there is more than one matching service (e.g., `BadService` and `GoodService`). And the techniques that all of this uses works on pretty much any version of Android, so

while we *need* them for Android 5.0 and higher, we can *use* them anywhere.

### The Service

Beyond the manifest, the service implementation is not too unusual. There is the AIDL interface, IDownload:

```
package com.commonware.android.advservice.remotebinding;

// Declare the interface.
interface IDownload {
    void download(String url);
}
```

(from [Binding/Remote/Service/app/src/main/aidl/com/commonware/android/advservice/remotebinding/IDownload.aidl](#))

And there is the actual service class itself, DownloadService:

```
package com.commonware.android.advservice.remotebinding.svc;

import android.app.Service;
import android.content.Intent;
import android.net.Uri;
import android.os.Environment;
import android.os.IBinder;
import android.util.Log;
import com.commonware.android.advservice.remotebinding.IDownload;
import java.io.BufferedOutputStream;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.InputStream;
import java.net.HttpURLConnection;
import java.net.URL;

public class DownloadService extends Service {
    @Override
    public IBinder onBind(Intent intent) {
        return(new DownloadBinder());
    }

    private static class DownloadBinder extends IDownload.Stub {
        @Override
        public void download(String url) {
            new DownloadThread(url).start();
        }
    }

    private static class DownloadThread extends Thread {
        String url=null;

        DownloadThread(String url) {
            this.url=url;
        }
    }
}
```

```
@Override
public void run() {
    try {
        File root=
            Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

        root.mkdirs();

        File output=new File(root, Uri.parse(url).getLastPathSegment());

        if (output.exists()) {
            output.delete();
        }

        HttpURLConnection c=(HttpURLConnection)new URL(url).openConnection();

        FileOutputStream fos=new FileOutputStream(output.getPath());
        BufferedOutputStream out=new BufferedOutputStream(fos);

        try {
            InputStream in=c.getInputStream();
            byte[] buffer=new byte[8192];
            int len=0;

            while ((len=in.read(buffer)) >= 0) {
                out.write(buffer, 0, len);
            }

            out.flush();
        }
        finally {
            fos.getFD().sync();
            out.close();
            c.disconnect();
        }
    }
    catch (IOException e2) {
        Log.e("DownloadJob", "Exception in download", e2);
    }
}
}
```

(from [Binding/Remote/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/svc/DownloadService.java](#))

This is identical to the local binding example, with one key difference: DownloadBinder now extends `IDownload.Stub` rather than the generic Binder class.

### The Client

The client — a revised version of `DownloadFragment` — connects to the remote service to ask it to download the file on the user's behalf. This has three changes of note over our original local implementation.

## REMOTE SERVICES AND THE BINDING PATTERN

---

First, when we call `download()` on the `IDownload` object, we need to catch a `RemoteException`. This will be thrown if the service crashes during our request or otherwise is unable to return properly:

```
@Override
public void onClick(View view) {
    try {
        binding.download(TO_DOWNLOAD);
    }
    catch (RemoteException e) {
        Log.e(getClass().getSimpleName(), "Exception requesting download", e);
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
    }
}
```

(from [Binding/Remote/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/client/DownloadFragment.java](#))

Second, our `onServiceConnected()` uses `IDownload.Stub.asInterface()` to convert the raw `IBinder` into an `IDownload` object for use:

```
@Override
public void onServiceConnected(ComponentName className, IBinder binder) {
    binding=IDownload.Stub.asInterface(binder);
    btn.setEnabled(true);
}
```

(from [Binding/Remote/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/client/DownloadFragment.java](#))

Third, our binding logic in `onCreate()` is significantly more complicated:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();

    Intent implicit=new Intent(IDownload.class.getName());
    List<ResolveInfo> matches=getActivity().getPackageManager()
        .queryIntentServices(implicit, 0);

    if (matches.size() == 0) {
        Toast.makeText(getActivity(), "Cannot find a matching service!",
            Toast.LENGTH_LONG).show();
    }
}
```

## REMOTE SERVICES AND THE BINDING PATTERN

---

```
}
else if (matches.size() > 1) {
    Toast.makeText(getActivity(), "Found multiple matching services!",
        Toast.LENGTH_LONG).show();
}
else {
    Intent explicit=new Intent(implicit);
    ServiceInfo svcInfo=matches.get(0).serviceInfo;
    ComponentName cn=new ComponentName(svcInfo.applicationInfo.packageName,
        svcInfo.name);

    explicit.setComponent(cn);
    appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
}
}
```

(from [Binding/Remote/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/client/DownloadFragment.java](#))

Here, we:

- Get the Application singleton Context as before
- Craft an implicit Intent for the service, using the appropriate action string (which, in this case, happens to be the fully-qualified name of the IDownload interface)
- Use PackageManager and queryIntentServices() to find out all services that implement a matching <intent-filter> for that implicit Intent
- Fail with a Toast if there is not exactly one such service
- Use the ServiceInfo object from our queryIntentServices() call to craft an explicit Intent, with the same structure as the implicit Intent had, but also with the actual matched component (via setComponent())
- Use the explicit Intent to bind to the service

Note that the client needs its own copy of IDownload.aidl. After all, it is a totally separate application, and therefore does not share source code with the service.

If you compile both applications and upload them to the device, then start up the client, you can have the service download the file.

## Tightening Up the Security

The previous sample confirms that there is exactly one service that matches the desired Intent. This catches the zero-service scenario (requiring the user to install

the other app) and catches the multiple-service scenario (where one service is an attacker, presumably).

However, what happens if there is only one service installed, and it is not the desired service, but rather is an attacker? The preceding binding code will still go ahead and bind with that service.

You might consider just examining the package name/application ID of the other service, to see if it matches an expected value. However, that will not help you if the attacker is a modified version of the real service, one that kept its original package name but changed the service to do evil things.

Checking the digital signature of the other service is a more robust check, as that cannot readily be forged. Even if somebody modifies and repackages the app with the service, that app would wind up being signed by a different signing key, which you can detect.

Moreover, this approach can be used in both directions: the client can validate the service, and the service can validate the client. For example, perhaps as part of a licensing scheme, your service can only be used by apps developed by certain firms, based upon their signing keys.

The [Binding/SigCheck/Client](#) sample project illustrates a client that will perform this signature check on the client side. The corresponding service project – [Binding/SigCheck/Service](#) – will perform a signature check on the service side.

### Adding the Dependency

Both projects use the CWAC-Security library, described [elsewhere in this book](#), to do the signature checking. Hence, their Gradle build files have a dependency on that library:

```
repositories {
    maven {
        url "https://s3.amazonaws.com/repo.commonsware.com"
    }
}

dependencies {
    implementation 'com.android.support:support-fragment:27.1.1'
    implementation 'com.commonsware.cwac:security:0.8.0'
}
```

### Adding the Signature Check: Client

The client's `DownloadFragment` is nearly the same as before, with an adjustment to `onCreate()` to check the signature if there is exactly one service that matches the `Intent`:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    setRetainInstance(true);

    appContext=(Application)getActivity().getApplicationContext();

    Intent implicit=new Intent(IDownload.class.getName());
    List<ResolveInfo> matches=getActivity().getPackageManager()
        .queryIntentServices(implicit, 0);

    if (matches.size() == 0) {
        Toast.makeText(getActivity(), "Cannot find a matching service!",
            Toast.LENGTH_LONG).show();
    }
    else if (matches.size() > 1) {
        Toast.makeText(getActivity(), "Found multiple matching services!",
            Toast.LENGTH_LONG).show();
    }
    else {
        ServiceInfo svcInfo=matches.get(0).serviceInfo;

        try {
            String otherHash=SignatureUtils.getSignatureHash(getActivity(),
                svcInfo.applicationInfo.packageName);
            String expected=getActivity().getString(R.string.expected_sig_hash);

            if (expected.equals(otherHash)) {
                Intent explicit=new Intent(implicit);
                ComponentName cn=new ComponentName(svcInfo.applicationInfo.packageName,
                    svcInfo.name);

                explicit.setComponent(cn);
                appContext.bindService(explicit, this, Context.BIND_AUTO_CREATE);
            }
            else {
                Toast.makeText(getActivity(), "Unexpected signature found!",
                    Toast.LENGTH_LONG).show();
            }
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(), "Exception trying to get signature hash", e);
        }
    }
}
```

(from [Binding/SigCheck/Client/app/src/main/java/com/commonsware/android/advservice/remotebinding/sigcheck/DownloadFragment.java](#))

In the one-match scenario, we get the signature of the other app, by using `getSignatureHash()` on `SignatureUtils`, passing in the package name of the other app. We then compare that with a hard-coded expected hash, pulled from a string resource, one that is unfortunately too long to represent in this book.

Only if those two match do we go ahead with the binding.

### Adding the Signature Check: Service

This gets a bit more complicated, as we first need to figure out who the client is, before we can validate the signature. In the case of the client connecting to the service, we know the application ID of the service courtesy of the `queryIntentServices()` call. On the service side, we need to use a different approach to identify who the client is.

To do this work, `DownloadBinder` now needs a `Context` with which to work, so `onBind()` passes one to a revised `DownloadBinder` constructor:

```
@Override
public IBinder onBind(Intent intent) {
    return(new DownloadBinder(this));
}
```

(from [Binding/SigCheck/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/sig/DownloadService.java](#))

The constructor holds on to three things:

- a `Context`, in this case the `Application` obtained from the `Service`
- a `PackageManager`, as we will need this for the signature lookup
- the expected hash of the client's signing key, pulled once again from a string resource

```
private static class DownloadBinder extends IDownload.Stub {
    private final PackageManager pm;
    private final String expectedHash;
    private final Context ctxt;

    public DownloadBinder(Context ctxt) {
        this.ctxt=ctxt.getApplicationContext();
        this.pm=this.ctxt.getPackageManager();
        this.expectedHash=this.ctxt.getString(
            R.string.expected_sig_hash);
    }
}
```

## REMOTE SERVICES AND THE BINDING PATTERN

---

(from [Binding/SigCheck/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/sig/DownloadService.java](#))

A Binder can find out who is invoking one of its exposed methods via `Binder.getCallingUid()`. This returns the Linux user ID (uid) that the client uses.

Normally, this will be tied to one application ID. However, it is possible for a suite of apps to share a Linux user ID, via the `android:sharedUserId` option in the manifest. Hence, the call to map the user ID to an application ID is `getPackagesForUid()` on `PackageManager`, which returns a *list* of application IDs.

So, the revised `download()` method iterates over those application IDs to see if any of them have the expected signature:

```
@Override
public void download(String url) {
    boolean ok=false;

    for (String pkg :
        pm.getPackagesForUid(Binder.getCallingUid())) {
        try {
            String otherHash=
                SignatureUtils.getSignatureHash(ctxt, pkg);

            if (expectedHash.equals(otherHash)) {
                ok=true;
                break;
            }
        }
        catch (Exception e) {
            Log.e(getClass().getSimpleName(),
                "Exception finding signature hash", e);
        }
    }

    if (ok) {
        new DownloadThread(url).start();
    }
    else {
        Log.e(getClass().getSimpleName(),
            "Could not validate client signature");
    }
}
```

(from [Binding/SigCheck/Service/app/src/main/java/com/commonsware/android/advservice/remotebinding/sig/DownloadService.java](#))

In practice, Android itself will ensure that if there are several application IDs sharing

a Linux user ID, they will all be signed by the same signing key.

If and only if we find a signature match do we actually do the download; otherwise, we log an error.

This happens to be a very simple service with a single-method Binder. In a more complicated service, where there are several methods exposed by the Binder, the signature-check logic could be refactored into a common private method that the AIDL-defined Binder methods could all use to validate the client.

### So, Where Do We Get the Expected Hash From?

Today, there are two main ways you can get the expected hash:

- Since this is really a hash of the public part of the app's signing key, the author of the other app might publish it as part of integration documentation, where the hash is generated via `keytool`
- You might call `getSignatureHash()` from your app and log the results, running it against a known good copy of the other app

## Servicing the Service

However, we do not get any result back from the service to know if the download succeeded or failed. That is likely to be rather important information for the user.

In principle, `download()` could return some success-or-failure indication... but then we would have a blocking call. Neither the client nor the service could proceed until the download is completed. That would require the client to manage its own background thread, which is a minor hassle. It also means that the service ties up one of a limited number of "Binder threads", which is not a good idea.

Another approach would be to pass some sort of callback object with `download()`, such that the server could run the script asynchronously and invoke the callback on success or failure. This, though, implies that there is some way to have the client export an API to the service.

Fortunately, this is eminently doable, as you will see in this section, and the accompanying samples ( [Binding/Callback/Service](#) and [Binding/Callback/Client](#) ).

## Callbacks via AIDL

AIDL does not have any concept of direction. It just knows interfaces, proxies, and stub implementations. In the preceding example, we used AIDL to have the service flesh out the stub implementation and have the client access the service via the AIDL-defined interface. However, there is nothing magic about services implementing interfaces and clients accessing them — it is equally possible to reverse matters and have the client implement something the service uses via an interface.

So, for example, we could create an `IDownloadCallback.aidl` file:

```
package com.commonware.android.advservice.callbackbinding;

// Declare the interface.
interface IDownloadCallback {
    void onSuccess();
    void onFailure(String msg);
}
```

(from [Binding/Callback/Service/app/src/main/aidl/com/commonware/android/advservice/callbackbinding/IDownloadCallback.aidl](#))

Then, we can augment `IDownload` itself, to pass an `IDownloadCallback` with `download()`:

```
package com.commonware.android.advservice.callbackbinding;

import com.commonware.android.advservice.callbackbinding.IDownloadCallback;

// Declare the interface.
interface IDownload {
    void download(String url, IDownloadCallback cb);
}
```

(from [Binding/Callback/Service/app/src/main/aidl/com/commonware/android/advservice/callbackbinding/IDownload.aidl](#))

Notice that we need to specifically import `IDownloadCallback`, just like we might import some “regular” Java interface. And, as before, we need to make sure the client and the server are working off of the same AIDL definitions, so these two AIDL files need to be replicated across each project.

But other than that one little twist, this is all that is required, at the AIDL level, to have the client pass a callback object to the service: define the AIDL for the callback and add it as a parameter to some service API call.

Of course, there is a little more work to do on the client and server side to make use of this callback object.

### Revising the Client

On the client, we need to implement an `IDownloadCallback`. In `onSuccess()` and `onFailure()` we can do something like raise a `Toast`.

The catch is that we cannot be certain we are being called on the UI thread in our callback object. In fact, it is almost assured that we are not. So, we need to get our work moved over to the main application thread. To do that, this sample uses `runOnUiThread()`:

```
IDownloadCallback.Stub cb=new IDownloadCallback.Stub() {
    @Override
    public void onSuccess() throws RemoteException {
        getActivity().runOnUiThread(new Runnable() {
            @Override
            public void run() {
                Toast.makeText(getActivity(), "Download successful!", Toast.LENGTH_LONG).show();
            }
        });
    }

    @Override
    public void onFailure(final String msg) throws RemoteException {
        getActivity().runOnUiThread(new Runnable() {
            @Override
            public void run() {
                Toast.makeText(getActivity(), msg, Toast.LENGTH_LONG).show();
            }
        });
    }
};
```

(from [Binding/Callback/Client/app/src/main/java/com/commonsware/android/advservice/callbackbinding/client/DownloadFragment.java](#))

And, of course, we need to pass the `IDownloadCallback` object in our `download()` call:

```
@Override
public void onClick(View view) {
    try {
        binding.download(TO_DOWNLOAD, cb);
    }
    catch (RemoteException e) {
        Log.e(getClass().getSimpleName(), "Exception requesting download", e);
        Toast.makeText(getActivity(), e.getMessage(), Toast.LENGTH_LONG).show();
    }
}
```

```
}
```

(from [Binding/Callback/Client/app/src/main/java/com/commonsware/android/advservice/callbackbinding/client/DownloadFragment.java](#))

### Revising the Service

The service also needs changing, to use the supplied callback object for the end results of the download.

DownloadBinder now receives an IDownloadCallback proxy in its download() method, which it passes along to the DownloadThread:

```
private static class DownloadBinder extends IDownload.Stub {
    @Override
    public void download(String url, IDownloadCallback cb) {
        new DownloadThread(url, cb).start();
    }
}
```

(from [Binding/Callback/Service/app/src/main/java/com/commonsware/android/advservice/callbackbinding/svc/DownloadService.java](#))

Notice that the service's own API just needs the IDownloadCallback parameter, which can be passed around and used like any other Java object. The fact that it happens to cause calls to be made synchronously back to the remote client is invisible to the service.

DownloadThread, in turn, invokes onSuccess() or onFailure() as appropriate:

```
private static class DownloadThread extends Thread {
    String url=null;
    IDownloadCallback cb=null;

    DownloadThread(String url, IDownloadCallback cb) {
        this.url=url;
        this.cb=cb;
    }

    @Override
    public void run() {
        boolean succeeded=false;

        try {
            File root=
                Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY_DOWNLOADS);

            root.mkdirs();

            File output=new File(root, Uri.parse(url).getLastPathSegment());
```

## REMOTE SERVICES AND THE BINDING PATTERN

---

```
if (output.exists()) {
    output.delete();
}

URLConnection c=(URLConnection)new URL(url).openConnection();

FileOutputStream fos=new FileOutputStream(output.getPath());
BufferedOutputStream out=new BufferedOutputStream(fos);

try {
    InputStream in=c.getInputStream();
    byte[] buffer=new byte[8192];
    int len=0;

    while ((len=in.read(buffer)) >= 0) {
        out.write(buffer, 0, len);
    }

    out.flush();
    succeeded=true;
}
finally {
    fos.getFD().sync();
    out.close();
    c.disconnect();
}
}
catch (IOException e2) {
    Log.e("DownloadJob", "Exception in download", e2);

    try {
        cb.onFailure(e2.getMessage());
    }
    catch (RemoteException e) {
        Log.e("DownloadJob", "Exception when calling onFailure()", e2);
    }
}

if (succeeded) {
    try {
        cb.onSuccess();
    }
    catch (RemoteException e) {
        Log.e("DownloadJob", "Exception when calling onSuccess()", e);
    }
}
}
```

(from [Binding/Callback/Service/app/src/main/java/com/commonsware/android/advservice/callbackbinding/svc/DownloadService.java](#))

## Thinking About Security

Remote services, by definition, are available for anyone to connect to. This may or may not be a good idea.

If the only client of your remote service is some other app of yours, you could protect the service using [a custom signature-level permission](#).

If you anticipate third-party apps communicating with your service, you should strongly consider protecting the service with [an ordinary custom permission](#), so the *user* can vote on whether the communication is allowed.

For local services, the simplest way to secure the service is to not export it, typically by not having an `<intent-filter>` element for the `<service>` in the manifest. Then, your app is the only app that can work with the service.

## The “Everlasting Service” Anti-Pattern

One anti-pattern that is all too prevalent in Android is the “everlasting service”. Such a service is started via `startService()` and never stops — the component starting it does not stop it and it does not stop itself via `stopSelf()`.

Why is this an anti-pattern?

1. The service takes up memory all of the time. This is bad in its own right if the service is not continuously delivering sufficient value to be worth the memory.
2. Users, fearing services that sap their device’s CPU or RAM, may attack the service with so-called “task killer” applications or may terminate the service via the Settings app, thereby defeating your original goal.
3. Android itself, due to user frustration with sloppy developers, will terminate services it deems ill-used, particularly ones that have run for quite some time.

Occasionally, an everlasting service is the right solution. Take a VOIP client, for example. A VOIP client usually needs to hold an open socket with the VOIP server to know about incoming calls. The only way to continuously watch for incoming calls is to continuously hold open the socket. The only component capable of doing that would be a service, so the service would have to continuously run.

However, in the case of a VOIP client, or a music player, the user is the one specifically requesting the service to run forever. By using `startForeground()`, a service can ensure it will not be stopped due to old age for cases like this.

As a counter-example, imagine an email client. The client wishes to check for new

## REMOTE SERVICES AND THE BINDING PATTERN

---

email messages periodically. The right solution for this is the `AlarmManager` pattern described [elsewhere in this book](#). The anti-pattern would have a service running constantly, spending most of its time waiting for the polling period to elapse (e.g., via `Thread.sleep()`). There is no value to the user in taking up RAM to watch the clock tick. Such services should be rewritten to use `AlarmManager`.

Most of the time, though, it appears that services are simply leaked. That is one advantage of using `AlarmManager` and an `IntentService` – it is difficult to leak the service, causing it to run indefinitely. In fact, `IntentService` in general is a great implementation to use whenever you use the command pattern, as it ensures that the service will shut down eventually. If you use a regular service, be sure to shut it down when it is no longer actively delivering value to the user.

# Advanced Manifest Tips

---

If you have been diligent about reading this book (versus having randomly jumped to this chapter), you will already have done a fair number of things with your project's `AndroidManifest.xml` file:

1. Used it to define components, like activities, services, content providers, and manifest-registered broadcast receivers
2. Used it to declare permissions your application requires, or possibly to define permissions that other applications need in order to integrate with your application
3. Used it to define what SDK level, screen sizes, and other device capabilities your application requires

In this chapter, we continue looking at things the manifest offers you, starting with a discussion of controlling where your [application gets installed](#) on a device, and wrapping up with a bit of information about [activity aliases](#).

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Just Looking For Some Elbow Room

On October 22, 2008, the [HTC Dream](#) was released, under the moniker of “T-Mobile G1”, as the first production Android device.

Complaints about the lack of available storage space for applications probably

started on October 23rd.

The Dream, while a solid first Android device, offered only 70MB of on-board flash for application storage. This storage had to include:

1. The Android application (APK) file
2. Any local files or databases the application created, particularly those deemed unsafe to put on the SD card (e.g., privacy)
3. Extra copies of some portions of the APK file, such as the compiled Dalvik bytecode, which get unpacked on installation for speed of access

It would not take long for a user to fill up 70MB of space, then have to start removing some applications to be able to try others.

Users and developers alike could not quite understand why the Dream had so little space compared to the available iPhone models, and they begged to at least allow applications to install to the SD card, where there would be more room. This, however, was not easy to implement in a secure fashion, and it took until Android 2.2 for the feature to become officially available.

If your app's `android:minSdkVersion` is 11 or higher, you can probably ignore all of this. At that time, what the Android SDK refers to as “internal storage” and “external storage” were moved to be part of one filesystem partition, and so there is no artificial division of space between the two.

But, if you are still supporting Android 2.2 and 2.3, you may wish to consider supporting having your app be installed to, or moved to, external storage.

### Configuring Your App to Reside on External Storage

Indicating to Android that your application can reside on the SD card is easy... and necessary, if you want the feature. If you do not tell Android this is allowed, Android will *not* install your application to the SD card, nor allow the user to move the application to the SD card.

All you need to do is add an `android:installLocation` attribute to the root `<manifest>` element of your `AndroidManifest.xml` file. There are three possible values for this attribute:

- `internalOnly`, the default, meaning that the application cannot be installed to the SD card

## ADVANCED MANIFEST TIPS

---

- `preferExternal`, meaning the application would like to be installed on the SD card
- `auto`, meaning the application can be installed in either location

If you use `preferExternal`, then your application will be initially installed on the SD card in most cases. Android reserves the right to still install your application on internal storage in cases where that makes too much sense, such as there not being an SD card installed at the time.

If you use `auto`, then Android will make the decision as to the installation location, based on a variety of factors. In effect, this means that `auto` and `preferExternal` are functionally very similar – all you are doing with `preferExternal` is giving Android a hint as to your desired installation destination.

Because Android decides where your application is initially installed, and because the user has the option to move your application between the SD card and on-board flash, you cannot assume any given installation spot. The exception is if you choose `internalOnly`, in which case Android will honor your request, at the potential cost of not allowing the installation at all if there is no more room in on-board flash.

For example, here is the manifest from the [SMS/Sender](#) sample project, profiled in [another chapter](#), showing the use of `preferExternal`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.commonware.android.sms.sender"
    android:installLocation="preferExternal"
    android:versionCode="1"
    android:versionName="1.0">

    <uses-permission android:name="android.permission.READ_CONTACTS"/>
    <uses-permission android:name="android.permission.SEND_SMS"/>

    <uses-sdk
        android:minSdkVersion="7"
        android:targetSdkVersion="11"/>

    <supports-screens
        android:largeScreens="true"
        android:normalScreens="true"
        android:smallScreens="false"/>

    <application
        android:icon="@drawable/ic_launcher"
```

## ADVANCED MANIFEST TIPS

---

```
    android:label="@string/app_name">
    <activity
        android:name="Sender"
        android:label="@string/app_name">
        <intent-filter>
            <action android:name="android.intent.action.MAIN"/>

            <category android:name="android.intent.category.LAUNCHER"/>
        </intent-filter>
    </activity>
</application>

</manifest>
```

(from [SMS/Sender/app/src/main/AndroidManifest.xml](#))

Since this feature only became available in Android 2.2, to support older versions of Android, just have your build tools target API level 8 (e.g., `compileSdkVersion` of 8 or higher in `build.gradle` for Android Studio users) while having your `minSdkVersion` attribute in the manifest state the lowest Android version your application supports overall. Older versions of Android will ignore the `android:installLocation` attribute. So, for example, in the above manifest, the Sender application supports API level 4 and above (Android 1.6 and newer), but still can use `android:installLocation="preferExternal"`, because the build tools are targeting API level 8.

### What the User Sees

On newer devices, such as those running Android 4.2, the user will see nothing different. That is because internal and external storage share a common pool of space, and therefore there is no advantage in having your application installed to external storage.

However, on, say, Android 2.3, you will see a difference in behavior.

For an application that wound up on external storage, courtesy of your choice of `preferExternal` or `auto`, the user will have an option to move it to the phone's internal storage. This can be done by choosing the application in the Manage Applications list in the Settings application, then clicking the "Move to phone" button.

Conversely, if your application is installed in on-board flash, and it is movable to external storage, they will be given that option with a "Move to SD card" button.

## What the Pirate Sees

Ideally, the pirate sees nothing at all.

One of the major concerns with installing applications to the SD card is that the SD card is usually formatted FAT<sub>32</sub> (vfat), offering no protection from prying eyes. The concern was that pirates could then just pluck the APK file off external storage and distribute it, even for paid apps from the Play Store.

Apparently, they solved this problem.

To quote the [Android developer documentation](#):

The unique container in which your application is stored is encrypted with a randomly generated key that can be decrypted only by the device that originally installed it. Thus, an application installed on an SD card works for only one device.

Moreover, this “unique container” is not normally mounted when the user mounts external storage on their host machine. The user mounts /mnt/sdcard; the “unique container” is /mnt/asec.

## What Your App Sees... When External Storage is Inaccessible

So far, this has all seemed great for users and developers. Developers need to add a single attribute to the manifest, and Android 2.2+ users gain the flexibility of where the app gets stored.

Alas, there is a problem, and it is a big one: on Android 1.x and 2.x, either the host PC or the device can have access to the SD card, but not both. As a result, if the user makes the SD card available to the host PC, by plugging in the USB cable and mounting the SD card as a drive via a Notification or other means, that SD card becomes unavailable for running applications.

So, what happens?

1. First, your application is terminated forcibly, as if your process was being closed due to low memory. Notably, your activities and services will not be called with `onDestroy()`, and instance state saved via `onSaveInstanceState()` is lost.
2. Second, your application is unhooked from the system. Users will not see

## ADVANCED MANIFEST TIPS

---

- your application in the launcher, your AlarmManager alarms will be canceled, and so on.
3. When the user makes external storage available to the phone again, your application will be hooked back into the system and will be once again available to the user (for example, your icon will reappear in the launcher)

The upshot: if your application is simply a collection of activities, otherwise not terribly connected to Android, the impact on your application is no different than if the user reboots the phone, kills your process via a so-called “task killer” application, etc. If, however, you are doing more than that, the impacts may be more dramatic.

Perhaps the most dramatic impact, from a user’s standpoint, will be if your application implements app widgets. If the user has your app widget on her home screen, that app widget will be removed when the SD card becomes unavailable to the phone. Worse, your app widget cannot be re-added to the home screen until the phone is rebooted (a limitation that hopefully will be lifted sometime after Android 2.2).

The user is warned about this happening, at least in general:

*Figure 864: Warning when unmounting the SD card*

## ADVANCED MANIFEST TIPS

---

Two broadcast Intents are sent out related to this:

- ACTION\_EXTERNAL\_APPLICATIONS\_UNAVAILABLE, when the SD card (and applications installed upon it) become unavailable
- ACTION\_EXTERNAL\_APPLICATIONS\_AVAILABLE, when the SD card and its applications return to normal

Note that the documentation is unclear as to whether your own application, that had been on the SD card, can receive ACTION\_EXTERNAL\_APPLICATIONS\_AVAILABLE once the SD card is back in action.

Also note that all of these problems hold true for longer if the user physically removes the SD card from the device. If, for example, they replace the card with a different one — such as one with more space — your application will be largely lost. They will see a note in their applications list for your application, but the icon will indicate it is on external storage, and the only thing they can do is uninstall it:

*Figure 865: The Manage Applications list, with an application shown from a removed SD card*

## Choosing Whether to Support External Storage

Given the huge problem from the previous section, the question of whether or not your application should support external storage is far from clear.

As the [Android developer documentation](#) states:

Large games are more commonly the types of applications that should allow installation on external storage, because games don't typically provide additional services when inactive. When external storage becomes unavailable and a game process is killed, there should be no visible effect when the storage becomes available again and the user restarts the game (assuming that the game properly saved its state during the normal Activity lifecycle).

Conversely, if your application implements any of the following features, it may be best to not support external storage:

1. Polling of Web services or other Internet resources via a scheduled alarm
2. Account managers and their corresponding sync adapters, for custom sources of contact data
3. App widgets, as noted in the previous section
4. Device administration extensions
5. Live folders
6. Custom soft keyboards ("input method engines")
7. Live wallpapers
8. Custom search providers

But, as noted earlier, this is not even usually necessary on API Level 11+ devices. Hence, even if your app would otherwise qualify for being installed to external storage, you may not wish to bother. If few devices (Android 2.2 and Android 2.3) might need the capability, it may not be worth the extra testing burden.

## Android 6.0 and "Adoption" of Removable Storage

When Android 3.0 did away with the required separate partitions for internal storage and external storage, the `android:installLocation` option fell out of use, as there was no particular value in having the apps on external storage. For single-partition devices — meaning, for most devices — users did not even have the option for moving their apps to external storage.

## ADVANCED MANIFEST TIPS

---

However, `android:installLocation` is returning to relevance, once again courtesy of removable media.

On Android 6.0+, users with removable storage options, such as micro SD card slots, have the option of “adopting” those as an extension of the device’s internal storage. Once done, apps set with `auto` or `preferExternal` for `android:installLocation` can be moved to the removable media. However, there appears to be one key difference: not only is the APK on the removable media, but so is all of that app’s portion of internal storage. The removable media is encrypted, so the material copied to the removable media should remain fairly inaccessible.

From the user’s standpoint, for low-end devices with minimal on-board flash, they have additional storage space that they can use for apps.

However:

## ADVANCED MANIFEST TIPS

---

- Removable media tends to be slow, and some cards will be slower than others. For developers, this makes it all that much more important for you to move disk I/O off of the main application thread.
- Removable media tends to be removable. If the user removes the removable media, while your app is installed on that removable media, your app will no longer work.
- All the [old rules](#) for apps that allow themselves to be installed on external storage will still hold true. Basically, any app that does periodic work, or will respond to incoming GCM messages, or has an app widget, or is always possibly needed (e.g., custom soft keyboard), should not allow itself to be moved to removable media. If the user *does* eject the media, they will get a permanent Notification telling them to put it back:

*Figure 866: Android 6.0, Ejected Adopted Removable Media Notification*

The user does have an “Erase & Format” option that will reformat the removable media and allow it to be permanently removed from the device. It does not appear that this will automatically move any apps back to internal storage. The users would need to move those apps back to internal storage by means of the Apps list in Settings.

Normally, it appears this system will be limited to internal card slots for things like

micro SD cards. While USB On-The-Go (OTG) allows Android devices to access thumb drives, those are likely to be accidentally removed by the user (not to mention they usually tie up the charging port). However, for development testing purposes, you can run the `adb shell sm set-force-adoptable true` command to allow the device to adopt USB OTG drives. Note though that once you do this, the drive is more or less owned by that Android device until you “Erase & Format” it, and you will lose everything on the drive as part of this whole process.

## Using an Alias

As was mentioned in the [chapter on integration](#), you can use the `PackageManager` class to enable and disable components in your application. This works at the component level, meaning you can enable and disable activities, services, content providers, and broadcast receivers. It does not support enabling or disabling individual `<intent-filter>` stanzas from a given component, though.

Why might you want to do this?

1. Perhaps you have an activity you want to be available for use, but not necessarily available in the launcher, depending on user configuration or unlocking “pro” features or something
2. Perhaps you want to add browser support for certain MIME types, but only if other third-party applications are not already installed on the device

While you cannot control individual `<intent-filter>` stanzas directly, you can have a similar effect via an activity alias.

An activity alias is another manifest element — `<activity-alias>` – that provides an alternative set of filters or other component settings for an already-defined activity. For example, here is the `AndroidManifest.xml` file from the [Manifest/Alias](#) sample project:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android" android:versionCode="1"
android:versionName="1.0" package="com.commonware.android.alias">

    <supports-screens android:largeScreens="true" android:normalScreens="true" android:smallScreens="false"/>
    <application android:icon="@drawable/ic_launcher" android:label="@string/app_name">
        <activity android:label="@string/app_name" android:name="AliasActivity">
            <intent-filter>
                <action android:name="android.intent.action.MAIN"/>
                <category android:name="android.intent.category.LAUNCHER"/>
            </intent-filter>
        </activity>
    </application>
</manifest>
```

---

## ADVANCED MANIFEST TIPS

---

```
<activity-alias android:label="@string/app_name2" android:name="ThisIsTheAlias"
android:targetActivity="AliasActivity">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>
    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
</activity-alias>
</application>
</manifest>
```

(from [Manifest/Alias/app/src/main/AndroidManifest.xml](#))

Here, we have one `<activity>` element, with an `<intent-filter>` to put the activity in the launcher. We also have an `<activity-alias>` element... which puts a second icon in the launcher for the same activity implementation.

An activity alias can be enabled and disabled independently of its underlying activity. Hence, you can have one activity class have several independent sets of intent filters and can choose which of those sets are enabled at any point in time.

For testing purposes, you can also enable and disable these from the command line. Use the `adb shell pm disable` command to disable a component:

```
adb shell pm disable
com.commonware.android.alias/com.commonware.android.alias.ThisIsTheAlias
```

... and the corresponding `adb shell pm enable` command to enable a component:

```
adb shell pm enable
com.commonware.android.alias/com.commonware.android.alias.ThisIsTheAlias
```

In each case, you supply the package of the application (`com.commonware.android.alias`) and the class of the component to enable or disable (`com.commonware.android.alias.ThisIsTheAlias`), separated by a slash.

## Getting Meta (Data)

Sometimes, you may want to put more data in the manifest, associated with your components. You will frequently see this for use with libraries or plugin distribution models, where sharing some configuration data between parties could eliminate a bunch of API code that a reuser might need to implement.

To support this, Android offers a `<meta-data>` element as a child of `<activity>`, `<activity-alias>`, `<receiver>`, or `<service>`. Each `<meta-data>` element has an `android:name` attribute plus an associated value, supplied by either an

## ADVANCED MANIFEST TIPS

---

`android:value` attribute (typically for literals) or an `android:resource` attribute (for references to resources).

Other parties can then get at this information via `PackageManager`. So, for example, the implementer of a plugin could have `<meta-data>` elements indicating details of how the plugin should be used (e.g., desired polling frequency), and the host of the plugin could then get that configuration data without the plugin author having to mess around with implementing some Java API for it.

For example, Roman Nurik's [DashClock](#) is a [lockscreen app widget](#) designed to serve as a replacement for the clock app widget that ships with many Android 4.2+ devices. Not only does it display the time, but it is a plugin host, allowing third party developers to supply "extensions" that can also display data in the app widget. This way, users can set up a single lockscreen app widget and get at a bunch of useful information.

DashClock's extension API makes use of `<meta-data>` to pass configuration data from the extension to DashClock itself. The implementation of a DashClock extension is a service, and so the extension's `<service>` element will have a batch of `<meta-data>` elements with this configuration data:

```
<service android:name=".ExampleExtension"
    android:icon="@drawable/ic_extension_example"
    android:label="@string/extension_title"
    android:permission="com.google.android.apps.dashclock.permission.READ_EXTENSION_DATA">
    <intent-filter>
        <action android:name="com.google.android.apps.dashclock.Extension" />
    </intent-filter>
    <meta-data android:name="protocolVersion" android:value="1" />
    <meta-data android:name="description"
        android:value="@string/extension_description" />
    <!-- A settings activity is optional -->
    <meta-data android:name="settingsActivity"
        android:value=".ExampleSettingsActivity" />
</service>
```

(sample from [the DashClock documentation](#))

Here, the developer can specify:

- What version of the communications protocol is supported, so DashClock can update its protocol over time yet remain backwards-compatible with

## ADVANCED MANIFEST TIPS

---

- older extensions, via the `protocolVersion` entry
- What the description is for the extension, used in DashClock's configuration screens to let the user know what available extensions there are, via the `description` entry
- What activity, if any, does the extension supply that allows the user to configure that extension, that DashClock should provide access to from its own settings activity, via the `settingsActivity` entry

In all three cases, DashClock uses `android:value`. Note that `android:value` *does* support the use of resources — the value of `description` is a reference to the `extension_description` string resource, for example.

To retrieve that metadata, an app can ask for `PackageManager.GET_META_DATA` as a flag on `PackageManager` [methods for introspection](#), like `queryIntentActivities()`. In the case of DashClock, it retrieves all implementations of its plugin by asking Android what *services* have an `<intent-filter>` with an `<action>` of `com.google.android.apps.dashclock.Extension`, via `queryIntentServices()`, asking for `PackageManager` to also supply each service's metadata:

```
List<ResolveInfo> resolveInfos = pm.queryIntentServices(  
    new Intent(DashClockExtension.ACTION_EXTENSION),  
    PackageManager.GET_META_DATA);
```

(from [the `ExtensionManager.java` file](#) in the DashClock source code)

Each `ResolveInfo` object that comes back in the list will have a `serviceInfo` field containing details of the service. Because `GET_META_DATA` was passed in as a flag, the `serviceInfo` will have a `Bundle` named `metaData` which will contain the key/value pairs specified by the `<meta-data>` elements. DashClock can then grab that data and use it to populate its own object model:

```
for (ResolveInfo resolveInfo : resolveInfos) {  
    ExtensionListing listing = new ExtensionListing();  
    listing.componentName = new ComponentName(resolveInfo.serviceInfo.packageName,  
        resolveInfo.serviceInfo.name);  
    listing.title = resolveInfo.loadLabel(pm).toString();  
    Bundle metaData = resolveInfo.serviceInfo.metaData;  
    if (metaData != null) {  
        listing.protocolVersion = metaData.getInt("protocolVersion");  
        listing.description = metaData.getString("description");  
        String settingsActivity = metaData.getString("settingsActivity");  
        if (!TextUtils.isEmpty(settingsActivity)) {  
            listing.settingsActivity = ComponentName.unflattenFromString(  

```

## ADVANCED MANIFEST TIPS

---

```
        resolveInfo.serviceInfo.packageName + "/" + settingsActivity);  
    }  
}
```

(from [the ExtensionManager.java file](#) in the DashClock source code)

The <meta-data> element supports five data types for android:value:

- String
- Integer
- Boolean (specified as true or false in the android:value attribute)
- Float

It also supports colors, specified in #AARRGGBB and similar formats, which, according to [the documentation](#), is returned as a string.

In this fashion, extension developers can supply enough information for DashClock to allow the user to see the list of installed extensions, choose which one(s) they want, and configure those (where applicable). Actually getting the *content* to display will need to be done at runtime, in this case via making requests of the service to supply a ExtensionData structure with the messages, icon, and so forth to be displayed.

# Miscellaneous Integration Tips

---

This chapter is a collection of other miscellaneous integration and introspection tips and techniques that you might find useful in your Android apps.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Direct Share

The classic means of “sharing” content between apps is via `ACTION_SEND`. You create an `ACTION_SEND` Intent, identifying the content to share, and use it with `startActivity()`. The decision of what the candidates are to share with is based solely on the MIME type of the content in question.

Sometimes, sharing of content with another app really means sharing that content with some other person, folder, or finer-grained context within the other app. `ACTION_SEND`, on its own, does not do anything for this. The user chooses the other app, then inside that app chooses the finer-grained context. While `ACTION_SENDTO` supports the sender indicating who to share the content with, that only works for select Uri schemes (`mailto` and `smsto`, mostly), and it requires that the sender have a suitable Uri to identify the recipient. As a result, few apps support `ACTION_SENDTO`.

Android 6.0 introduced “direct share targets”. Now, the recipients of sharing operations can elect to serve up specific share targets, pointing not only to the app but to the finer-grained context within the app. The user will then see these targets listed in the “chooser” window, alongside other standard share targets.

---

## MISCELLANEOUS INTEGRATION TIPS

---

This involves creating a subclass of `ChooserTargetService` and tying it via some `<meta-data>` to your activity supporting the `ACTION_SEND <intent-filter>`. That service will then be called with `onGetChooserTargets()`, where it is told what activity and `<intent-filter>` was matched, and the service can return a list of `ChooserTarget` objects. Those `ChooserTarget` objects each represent a single direct share target, where the `ChooserTarget` wraps up a dedicated caption, icon, and `PendingIntent` for each. Those may be presented to the user in the chooser; if the user chooses one, the `PendingIntent` is invoked.

The [Intents/FauxSenderMNC](#) sample project is a revised version of the `FauxSender` sample. `FauxSender` has an implementation of an `ACTION_SEND` activity, plus a `LAUNCHER` activity that just uses `startActivity()` to trigger an `ACTION_SEND` Intent. `FauxSenderMNC` augments the original sample with direct-share functionality.

### The `ChooserTargetService`

The bulk of the business logic goes in your subclass of `ChooserTargetService`, here named `CTService`:

```
package com.commonware.android.fsendermnc;

import android.app.PendingIntent;
import android.content.ComponentName;
import android.content.Intent;
import android.content.IntentFilter;
import android.graphics.drawable.Icon;
import android.os.Bundle;
import android.service.chooser.ChooserTarget;
import android.service.chooser.ChooserTargetService;
import java.util.ArrayList;
import java.util.List;

public class CTService extends ChooserTargetService {
    private String titleTemplate;

    @Override
    public void onCreate() {
        super.onCreate();

        titleTemplate=getString(R.string.title_template);
    }

    @Override
    public List<ChooserTarget> onGetChooserTargets(ComponentName sendTarget,
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
IntentFilter matchedFilter) {
    ArrayList<ChooserTarget> result=new ArrayList<ChooserTarget>();

    for (int i=1;i<=6;i++) {
        result.add(buildTarget(i));
    }

    return(result);
}

private ChooserTarget buildTarget(int targetId) {
    String title=String.format(titleTemplate, targetId);
    int iconId=getResources().getIdentifier("ic_share" + targetId,
        "drawable", getPackageName());
    Icon icon=Icon.createWithResource(this, iconId);
    float score=1.0f-((float)targetId/40);
    ComponentName cn=new ComponentName(this, FauxSender.class);
    Bundle extras=new Bundle();

    extras.putInt(FauxSender.EXTRA_TARGET_ID, targetId);

    return(new ChooserTarget(title, icon, score, cn, extras));
}
}
```

(from [Intents/FauxSenderMNC/app/src/main/java/com/commonsware/android/fsendermnc/CTService.java](#))

You are welcome to override the `onCreate()` and `onDestroy()` lifecycle methods in your `ChooserTargetService` if you want, though it is not required. Here, we override `onCreate()` just to grab a string resource value that will be used as a template, stashing it in a data member.

The one method that you have to implement is `onGetChooserTargets()`. This will be called when direct-share is triggered, as directed by some manifest entries that we will examine in a bit. Your job is to return a `List` of `ChooserTarget` objects that represent specific ways to share the content into your app, such as sharing to particular contacts or folders or something.

Note that whatever you return from `onGetChooserTargets()` is included *along with your regular ACTION\_SEND activity itself*. Hence, you only want to return `ChooserTarget` objects that improve the user flow beyond your base `ACTION_SEND` activity — you do not need to have a `ChooserTarget` that simply replicates what the user would get from the `ACTION_SEND` activity itself.

In this case, `onGetChooserTargets()` returns a six-element `ArrayList` of

ChooserTarget objects, each built using a private buildTarget() method.

A ChooserTarget is a simple wrapper around five pieces of data:

- A String to use as a caption for your direct-share icon
- An Icon that represents the icon itself
- A float “score” that represents the relative importance of this direct-share target over any others that you return, where 1.0f means “the user is really going to like this one”, 0.0f means “the user could conceivably want this, but probably not”, and values in between 0 and 1 represent shades of gray in the realm of importance
- A ComponentName identifying either an activity in your app (the typical answer) or an exported activity in another app (rather unusual)
- A Bundle of extras to go into the Intent that the framework will create, using that ComponentName, to trigger the activity in question

Note that the ComponentName does *not* have to start the same activity that is your ACTION\_SEND activity. In this sample, it happens to use the same activity. But that is not a requirement, and frequently you will use some other activity. For example, if your normal ACTION\_SEND flow would first have the user choose a folder, then provide additional information about the shared item (e.g., confirm the title, add tags), if you create direct-share targets that specify particular folders, you would want to bypass the folder-selection step in your own UI. If the ACTION\_SEND activity implements the folder-selection logic and forwarded the user along to some other activity to handle the rest, your ChooserTarget ComponentName objects might just drive straight to the second activity, skipping the folder-selection UI.

Also note that you may be creating several ChooserTarget objects, probably having each pointing to the same activity. You will need to ensure that the extras Bundle contains what you need to distinguish one request from the next. However, do not put custom Parcelable objects in this Bundle, as Android will attempt to un-parcel them as part of its work, and it will fail to do so since Android does not have your custom Parcelable class.

An Icon is a new construct in Android 6.0, serving as a wrapper around multiple possible image sources. You can create an Icon from a drawable resource (as the sample app does), from a Bitmap, from a byte array representing PNG or JPEG data, from a file path pointing to a PNG or JPEG file, or from a Uri to a ContentProvider pointing to an image.

## The Manifest Entries

Your ChooserTargetService will have a typical `<service>` manifest entry, with two special bits:

- An `android:permission="android.permission.BIND_CHOOSER_TARGET_SERVICE"` attribute, to limit access to your service to the framework, rather than being spoofed by other clients, and
- An `<intent-filter>` for the `android.service.chooser.ChooserTargetService` action

```
<service
  android:name=".CTService"
  android:permission="android.permission.BIND_CHOOSER_TARGET_SERVICE">
  <intent-filter>
    <action android:name="android.service.chooser.ChooserTargetService"/>
  </intent-filter>
</service>
```

(from [Intents/FauxSenderMNC/app/src/main/AndroidManifest.xml](#))

Your ACTION\_SEND activity will have its normal `<activity>` element, with just one change: a `<meta-data>` element pointing to your ChooserTargetService:

```
<activity
  android:name="FauxSender"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.Translucent.NoTitleBar">
  <intent-filter android:label="@string/app_name">
    <action android:name="android.intent.action.SEND"/>

    <data android:mimeType="text/plain"/>

    <category android:name="android.intent.category.DEFAULT"/>
  </intent-filter>
  <meta-data
    android:name="android.service.chooser.chooser_target_service"
    android:value=".CTService"/>
</activity>
```

(from [Intents/FauxSenderMNC/app/src/main/AndroidManifest.xml](#))

It is possible that your app has multiple ACTION\_SEND activities. In that case, each could have its own ChooserTargetService. However, you could elect to have all of

## MISCELLANEOUS INTEGRATION TIPS

---

your ACTION\_SEND activities route to the same ChooserTargetService if you prefer. onGetChooserTargets() is passed two parameters to help identify where the direct-share request is coming from:

- the ComponentName of the ACTION\_SEND activity that was tied to your service, and
- the IntentFilter that triggered that activity in the first place, so you can determine things like the MIME type of the to-be-shared content

Note that you are *not* given the content itself, in the form of the Intent that will eventually be delivered to your ACTION\_SEND activity or to your direct-share target via its ComponentName. This is for privacy reasons; otherwise, an app could ask to share anything and be able to peek at anything the user tried sharing with any app.

## The Results

The FauxSender activity — the one handling the ACTION\_SEND Intent and the direct-share Intent — now looks for the EXTRA\_TARGET\_ID that the CTService put in its Intent and includes it in the Toast:

```
package com.commonware.android.fsendermnc;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.widget.Toast;

public class FauxSender extends Activity {
    public static final String EXTRA_TARGET_ID="targetId";

    @Override
    public void onCreate(Bundle savedInstanceState) {
        String epilogue="";

        super.onCreate(savedInstanceState);

        int targetId=getIntent().getIntExtra(EXTRA_TARGET_ID, -1);

        if (targetId>0) {
            epilogue=" for target ID #"+targetId;
        }

        String msg=getIntent().getStringExtra(Intent.EXTRA_TEXT);
```

## MISCELLANEOUS INTEGRATION TIPS

```
if (TextUtils.isEmpty(msg)) {  
    msg=getIntent().getStringExtra(Intent.EXTRA_SUBJECT);  
}  
  
if (TextUtils.isEmpty(msg)) {  
    msg=getString(R.string.no_message_supplied);  
}  
  
Toast.makeText(this, msg+epilogue, Toast.LENGTH_LONG).show();  
  
finish();  
}  
}
```

(from [Intents/FauxSenderMNC/app/src/main/java/com/commonware/android/fsendermnc/FauxSender.java](https://github.com/Commonware/android-fsendermnc/blob/master/app/src/main/java/com/commonware/android/fsendermnc/FauxSender.java))

If you run the sample app from Android Studio, the launcher activity will trigger an ACTION\_SEND of some text. That, in turn, will bring up the chooser panel... but on an Android 6.0 device, that panel will start off with our six direct-share targets:

Figure 867: Chooser, Showing Direct-Share Targets

## MISCELLANEOUS INTEGRATION TIPS

---

Expanding the panel shows that our original ACTION\_SEND activity is also there, after the direct-share targets:

*Figure 868: Chooser, Showing More Share Targets*

---

## MISCELLANEOUS INTEGRATION TIPS

---

If the user taps on the regular ACTION\_SEND activity icon, the sample works as it did originally, showing a Toast with the text supplied by the launcher activity. If, however, the user taps on one of the direct-share targets, the Toast also shows which target was chosen:

*Figure 869: Toast from a Direct-Share Target*

Now, our Bundle for the direct-share target did not include the shared text, because we did not have it. Instead, the regular ACTION\_SEND extras are merged in with our own extras, so our activity gets all of the relevant extras.

### **But... I Got Nothin'!**

If you do not have any direct-share targets for a particular request, returning an empty list is perfectly fine.

If you know in advance that you will not have any direct-share targets — for example, the user has not really worked with your app yet after installation — you can disable the service (`android:enabled="false"`). Even though the `<meta-data>` will point to the service, the framework seems to detect the disabled service and continues on unabated.

Even if you elect to leave the service enabled at the outset for Android 6.0, you should consider disabling the service for earlier versions of Android, since it is useless on those devices. You could do this using boolean resources:

- Have a `res/values/bools.xml` file with a `bool` resource (e.g., `offer_direct_share`) set to `false`
- Have a `res/values-v23/bools.xml` file redefining that resource to `true`
- Have `android:enabled="@bool/offer_direct_share"` on your service, to have it be enabled only on Android 6.0 and higher

### Best Practices

At the moment, it appears that Android 6.0 is limiting the number of share targets, only showing 8 of them. If you provide more than 8, Android will choose the ones with the highest score.

Since returning the list of direct-share targets should be involving IPC, there may be capacity limitations, for the number and size of the direct-share targets. Do not be surprised if you get a “FAILED BINDER TRANSACTION” exception if your roster of direct-share targets exceeds 1MB.

Hence, between those two limitations, you will want to constrain how many share targets you try returning from your `ChooserTargetService`.

As with other places in Android 5.0+ (e.g., large icons in notifications), your app’s icon will be applied as a badge over the icons that you use for direct-share targets. Make sure that your app’s icon will work both as a launcher icon and as a direct-share target badge.

### Take the Shortcut

Another way to integrate with Android is to offer custom shortcuts. Shortcuts are available from the home screen. Whereas app widgets allow you to draw on the home screen, shortcuts allow you to wrap a custom `Intent` with an icon and caption and put that on the home screen. You can use this to drive users not just to your application’s “front door”, like the launcher icon, but to some specific capability within your application, like a bookmark.

In our case, in the [Introspection/QuickSender](#) sample project, we will allow users to create shortcuts that use `ACTION_SEND` to send a pre-defined message, either to a

specific address or anywhere, as we have seen [before in this chapter](#).

Once again, the key is in the intent filter.

### Registering a Shortcut Provider

Here is the manifest for QuickSender:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
package="com.commonware.android.qsender" android:versionCode="1" android:versionName="1.0">

  <uses-sdk android:minSdkVersion="15" android:targetSdkVersion="15"/>
  <application android:icon="@drawable/ic_launcher" android:label="@string/app_name">
    <activity android:name="QuickSender" android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.CREATE_SHORTCUT"/>
        <category android:name="android.intent.category.DEFAULT"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

(from [Introspection/QuickSender/app/src/main/AndroidManifest.xml](#))

Our single activity does not implement a traditional launcher `<intent-filter>`. Rather, it has one that watches for a `CREATE_SHORTCUT` action. This does two things:

- It means that our activity will show up in the list of possible shortcuts a user can configure
- It means this activity will be the recipient of a `CREATE_SHORTCUT` Intent if the user chooses this application from the shortcuts list

### Implementing a Shortcut Provider

The job of a shortcut-providing activity is to:

1. Create an Intent that will be what the shortcut launches
2. Return that Intent and other data to the activity that started the shortcut provider
3. Finally, `finish()`, so the caller gets control

You can see all of that in the QuickSender implementation:

```
package com.commonware.android.qsender;
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.text.TextUtils;
import android.view.View;
import android.widget.TextView;

public class QuickSender extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void save(View v) {
        Intent shortcut=new Intent(Intent.ACTION_SEND);
        TextView addr=(TextView)findViewById(R.id.addr);
        TextView subject=(TextView)findViewById(R.id.subject);
        TextView body=(TextView)findViewById(R.id.body);
        TextView name=(TextView)findViewById(R.id.name);

        if (!TextUtils.isEmpty(addr.getText())) {
            shortcut.putExtra(Intent.EXTRA_EMAIL,
                new String[] { addr.getText().toString() });
        }

        if (!TextUtils.isEmpty(subject.getText())) {
            shortcut.putExtra(Intent.EXTRA_SUBJECT, subject.getText()
                .toString());
        }

        if (!TextUtils.isEmpty(body.getText())) {
            shortcut.putExtra(Intent.EXTRA_TEXT, body.getText().toString());
        }

        shortcut.setType("text/plain");

        Intent result=new Intent();

        result.putExtra(Intent.EXTRA_SHORTCUT_INTENT, shortcut);
        result.putExtra(Intent.EXTRA_SHORTCUT_NAME, name.getText()
            .toString());
        result.putExtra(Intent.EXTRA_SHORTCUT_ICON_RESOURCE,
            Intent.ShortcutIconResource.fromContext(this,
                R.drawable.icon));

        setResult(RESULT_OK, result);
        finish();
    }
}
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
}  
}
```

(from [Introspection/QuickSender/app/src/main/java/com/commonsware/android/qsender/QuickSender.java](#))

The shortcut Intent is the one that will be launched when the user taps the shortcut icon on the home screen. The result Intent packages up shortcut plus the icon and caption, where the icon is converted into an `Intent.ShortcutIconResource` object. That result Intent is then used with the `setResult()` call, to pass that back to whatever called `startActivityForResult()` to open up QuickSender. Then, we `finish()`.

At this point, all the information about the shortcut is in the hands of Android (or, more accurately, the home screen application), which can add the icon to the home screen.

### Using the Shortcuts

Exactly how `CREATE_SHORTCUT` implementations like this are handled depends on the home screen implementation. Some might not offer them at all. Other home screens might have dedicated options for shortcuts.

## MISCELLANEOUS INTEGRATION TIPS

---

The Nexus series devices, running Android 6.0, lump `CREATE_SHORTCUT` implementations in with the app widgets. You can add one to your home screen by long-tapping on the home screen, choosing “Widgets”, and scrolling down to the shortcut that you want:

*Figure 870: Android 6.0, Widgets List, Showing Sample App*

## MISCELLANEOUS INTEGRATION TIPS

---

Tap-and-hold on the “widget”, and you will be able to place it on the screen. Once that is done, our activity will appear, with the form to define what to send:

*Figure 871: QuickSender Configuration Activity*

## MISCELLANEOUS INTEGRATION TIPS

---

Fill in the name, either the subject or body, and optionally the address. Then, click the Create Shortcut button, and you will find your shortcut sitting on your home screen, with your chosen shortcut name as the label:

*Figure 872: Home Screen, Showing QuickSender-Defined Shortcut*

---

## MISCELLANEOUS INTEGRATION TIPS

---

If you launch that shortcut, and if there is more than one application on the device set up to handle `ACTION_SEND`, Android will bring up a special chooser, to allow you to not only pick how to send the message, but optionally make that method the default for all future requests:

*Figure 873: ACTION\_SEND Request, As Triggered by Shortcut*

Depending on what you choose, of course, will dictate how the message actually gets sent.

## Homing Beacons for Intents

If you are encountering problems with Intent resolution — you create an Intent for something and try starting an Activity or Service with it, and it does not work — you can add the `FLAG_DEBUG_LOG_RESOLUTION` flag to the Intent. This will dump information to Logcat about how the Intent resolution occurred, so you can better diagnose what might be going wrong.

## Integrating with Text Selection

On Android 6.0+, if you highlight text, you will see a new floating action mode,

## MISCELLANEOUS INTEGRATION TIPS

---

where cut, copy, and paste operations reside:

*Figure 874: Floating Action Mode*

## MISCELLANEOUS INTEGRATION TIPS

---

If you tap that overflow indicator on the action mode, a fly-out menu will appear... one that contains arbitrary apps, in addition to system-supplied options:

*Figure 875: Floating Action Mode, Showing Overflow with Custom Apps*

## MISCELLANEOUS INTEGRATION TIPS

---

In this case, the Android 6.0 “API Demos” app appears as an option. Choosing it pops up an activity *that has access to the highlighted text from the preceding activity*:

*Figure 876: API Demos Application, Showing Text Selection*

Replacing the value in the field and clicking the button puts your replacement text in as a replacement for whatever you had highlighted.

This is accomplished via the `ACTION_PROCESS_TEXT` Intent action. Apps can advertise activities that support this action, and they will be added (sometimes) to the floating action mode. Apps that have `EditText` widgets just automatically get these options in the floating action mode, with no additional required code.

**NOTE:** `ACTION_PROCESS_TEXT` support [is broken on Android 8.0 and 8.1](#), though it is working again in Android 9.0

### Supporting `ACTION_PROCESS_TEXT`

Your app can offer an `ACTION_PROCESS_TEXT` activity, in which case you will appear in Android 6.0+ text-selection floating action modes. This is illustrated in the [Introspection/ProcessText](#) sample application.

### The Manifest

To be visible to these text-selection action modes, you need an activity with an `<intent-filter>` calling for `ACTION_PROCESS_TEXT` and a MIME type of `text/plain`:

```
<activity
  android:name="MainActivity"
  android:label="@string/app_name">
  <intent-filter>
    <action android:name="android.intent.action.MAIN"/>

    <category android:name="android.intent.category.LAUNCHER"/>
  </intent-filter>
  <intent-filter>
    <action android:name="android.intent.action.PROCESS_TEXT"/>
    <category android:name="android.intent.category.DEFAULT" />
    <data android:mimeType="text/plain" />
  </intent-filter>
</activity>
```

(from [Introspection/ProcessText/app/src/main/AndroidManifest.xml](#))

Exactly which MIME types are supported is not documented. At the time of this writing, the only examples showed `text/plain`. It is possible that other formats (e.g., `text/html`) might also be supported.

### The Extras

You will get one of two extras attached to the `ACTION_PROCESS_TEXT` Intent:

- `EXTRA_PROCESS_TEXT` is the text to be processed, and also indicates that you can supply replacement text, if you wish
- `EXTRA_PROCESS_TEXT_READONLY` will be set if `EXTRA_PROCESS_TEXT` is not, and provides the text to be processed and an indication that you cannot supply replacement text

It is up to you to check for those string extras, grab the right value, and do something useful with it.

In the sample app, in `onCreate()` of the `MainActivity`, if we are starting fresh (i.e., there is no `QuestionsFragment` already), we get the search string and provide it to `QuestionsFragment` via a `newInstance()` factory method:

```
implements QuestionsFragment.Contract {
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);

    if (getSupportFragmentManager().findFragmentById(android.R.id.content)==null) {
        String search=null;

        if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
            if (Intent.ACTION_PROCESS_TEXT.equals(getIntent().getAction())) {
                search=getIntent().getStringExtra(Intent.EXTRA_PROCESS_TEXT);

                if (search==null) {
                    search=getIntent()
                        .getStringExtra(Intent.EXTRA_PROCESS_TEXT_READONLY);
                }
            }
        }

        getSupportFragmentManager()
            .beginTransaction()
            .add(android.R.id.content,
                QuestionsFragment.newInstance(search))
            .commit();
    }
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/processtext/MainActivity.java](#))

QuestionsFragment, in turn, stuffs that value into the arguments Bundle in newInstance():

```
static QuestionsFragment newInstance(String search) {
    QuestionsFragment result=new QuestionsFragment();
    Bundle args=new Bundle();

    args.putString(ARG_SEARCH, search);
    result.setArguments(args);

    return(result);
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/processtext/QuestionsFragment.java](#))

An expanded version of StackOverflowInterface offers not only the original questions() method, but also a search() method, the latter of which searches Stack Overflow for questions in the android tag that have a search term in the title:

```
package com.commonsware.android.processtext;

import retrofit.Callback;
import retrofit.http.GET;
import retrofit.http.Query;

public interface StackOverflowInterface {
    @GET("/2.1/questions?order=desc&sort=creation&site=stackoverflow")
```

---

## MISCELLANEOUS INTEGRATION TIPS

---

```
void questions(@Query("tagged") String tags, Callback<SOQuestions> cb);
@GET("/2.2/questions?order=desc&sort=creation&site=stackoverflow&tagged=android")
void search(@Query("intitle") String search, Callback<SOQuestions> cb);
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/processtext/StackOverflowInterface.java](#))

onCreateView() in QuestionsFragment then calls either questions() or search(), depending on whether or not we have a search string from ACTION\_PROCESS\_TEXT:

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {

    View result=
        super.onCreateView(inflater, container, savedInstanceState);

    setRetainInstance(true);

    RestAdapter restAdapter=
        new RestAdapter.Builder().setEndpoint("https://api.stackexchange.com")
                                .build();

    StackOverflowInterface so=
        restAdapter.create(StackOverflowInterface.class);
    String search=getArguments().getString(ARG_SEARCH);

    if (search==null) {
        so.questions("android", this);
    }
    else {
        so.search(search, this);
    }

    return(result);
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/processtext/QuestionsFragment.java](#))

### The Results (If Any)

If you got a value for EXTRA\_PROCESS\_TEXT and you wish to return a replacement string, you need to create an Intent with your own EXTRA\_PROCESS\_TEXT value that is the replacement text, then use that Intent with setResult(). MainActivity does this when the user taps on a list item in QuestionsFragment:

```
@Override
public void onQuestion(Item question) {
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.M &&
    Intent.ACTION_PROCESS_TEXT.equals(getIntent().getAction()) &&
    getIntent().getStringExtra(Intent.EXTRA_PROCESS_TEXT) != null) {
    setResult(Activity.RESULT_OK,
        new Intent().putExtra(Intent.EXTRA_PROCESS_TEXT, question.link));
    finish();
}
else {
    startActivity(new Intent(Intent.ACTION_VIEW,
        Uri.parse(question.link)));
}
}
```

(from [Introspection/ProcessText/app/src/main/java/com/commonsware/android/process/text/MainActivity.java](#))

If the activity was started due to a replaceable bit of text to be processed, we return the URL to the question the user tapped on. In all other cases, we just start up some browser or other app to view that URL.

If you install this app on an Android 6.0+ device, then run some other app that has an `EditText`, type in some term in portrait mode, highlight it, and choose “PROCESS TEXT DEMO” from the floating action mode, you will be presented with a list of Stack Overflow questions in the android tag that refer to your search term in the title. If you tap on one, your search term will be replaced in the `EditText` widget by the URL of the question.

### Limitations of ACTION\_PROCESS\_TEXT

Alas, `ACTION_PROCESS_TEXT` is “not all unicorns and rainbows”. There are a few issues that you will need to take into account.

#### Security

There is no documented `android:permission` attribute to place on the `<activity>` that is offering `ACTION_PROCESS_TEXT`, to limit callers. Ideally, we could limit invocations of `ACTION_PROCESS_TEXT` only to the firmware itself. As it stands, any app can call `startActivity()` (or, worse, `startActivityForResult()`) for your `ACTION_PROCESS_TEXT` activity and have your code process the text (with user intervention). Please be sure that if you return data via `EXTRA_PROCESS_TEXT` that the data not include any private information or anything that needs to be secured.

With luck, [this will be improved in a future version of Android](#).

## Supporting ACTION\_PROCESS\_TEXT in Custom Views

TextView and its subclasses are already capable of offering the user ACTION\_PROCESS\_TEXT options. However, you may have custom View classes that have the notion of text selection, but where you are rendering the available actions to take upon that selection yourself. In that case, you will need to do the reverse: find the implementers of ACTION\_PROCESS\_TEXT and add them to your UI.

To do this:

- Create an Intent for ACTION\_PROCESS\_TEXT and a MIME type of text/plain
- Use queryIntentActivities() on PackageManager to find out the activities that handle that Intent structure
- Organize the results, such as sorting them alphabetically by label using ResolveInfo.DisplayNameComparator
- Create Intent objects for each resolved activity, also with ACTION\_PROCESS\_TEXT and text/plain, but also with EXTRA\_PROCESS\_TEXT or EXTRA\_PROCESS\_TEXT\_READONLY filled in with your selection, and also call setClassName() to provide the package name and activity class name to make the Intent explicit
- Add appropriate elements to your UI for each of those Intent objects
- If the user chooses one, call startActivity() (for EXTRA\_PROCESS\_TEXT\_READONLY) or startActivityForResult() (for EXTRA\_PROCESS\_TEXT) to invoke the other activity
- In the case of EXTRA\_PROCESS\_TEXT, watch for your result in onActivityResult() and use the replacement text supplied in the result Intent and its EXTRA\_PROCESS\_TEXT string extra

The [Android Developers Blog](#) has a post that provides some code for this, assuming that you want to put items in an action bar or action mode for the various resolved activities.

## Blocking ACTION\_PROCESS\_TEXT

There will be cases where you do not want ACTION\_PROCESS\_TEXT to be offered to your users. For example, perhaps the text contains sensitive information that should not be passed outside of your app.

The best solution, particularly for a TextView, is to mark the text as not being selectable. This is accomplished via android:textIsSelectable="false" in a layout file, or via setTextIsSelectable(false) in Java. false is the default value for

## MISCELLANEOUS INTEGRATION TIPS

---

TextView.

However, for an EditText widget, true is the default is-selectable state, and you cannot seem to override that with `setTextIsSelectable(false)`.

There is no officially supported option for handling this case, though [perhaps there will be one in the future](#).

One unsupported hack of a workaround relies upon the fact that EditText blocks the floating action mode for password fields. In the source code to EditText, TextView, and related classes, this is handled by seeing if the TransformationMethod associated with the widget is PasswordTransformationMethod. A TransformationMethod is responsible for on-the-fly adjustments between what the user types and what the user sees, such as PasswordTransformationMethod replacing typed-in characters with dots.

Making your EditText widget use PasswordTransformationMethod itself is fine for actual password fields. But suppose you have an EditText whose contents should be kept private but should not have the input-shrouding effect of PasswordTransformationMethod. To offer this, you would need to create a *subclass* of PasswordTransformationMethod (so the block-the-floating-action-mode logic works) that does not actually transform the text (to block the changes that PasswordTransformationMethod would ordinarily apply).

A proof-of-concept implementation of this can be found in the [Introspection/ProcessTextBlocker](#) sample application. This is a clone of the FilesEditor sample app from [the chapter on files](#), with one change: the use of DummyTransformationMethod:

```
private static class DummyTransformationMethod
    extends PasswordTransformationMethod {
    @Override
    public CharSequence getTransformation(CharSequence source,
                                         View view) {
        return(source);
    }

    @Override
    public void onTextChanged(CharSequence s, int start,
                              int before, int count) {
        // no-op
    }
}
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
@Override
public void onFocusChanged(View view,
                           CharSequence sourceText,
                           boolean focused, int direction,
                           Rect previouslyFocusedRect) {

    // no-op
}

@Override
public void afterTextChanged(Editable s) {
    // no-op
}

@Override
public void beforeTextChanged(CharSequence s, int start,
                               int count, int after) {

    // no-op
}
}
```

(from [Introspection/ProcessTextBlocker/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java](#))

This is a do-nothing TransformationMethod. Ordinarily, this would be completely useless. However, it inherits from PasswordTransformationMethod, which is what we need to block the floating action mode.

In onCreateView() of the EditorFragment, we apply a DummyTransformationMethod via setTransformationMethod():

```
@Override
public View onCreateView(LayoutInflater inflater,
                        ViewGroup container,
                        Bundle savedInstanceState) {

    View result=inflater.inflate(R.layout.editor, container, false);

    editor=result.findViewById(R.id.editor);
    editor.setTransformationMethod(new DummyTransformationMethod());

    return(result);
}
```

(from [Introspection/ProcessTextBlocker/app/src/main/java/com/commonsware/android/fileseditor/EditorFragment.java](#))

However, this approach has limitations:

- It only works in portrait, not landscape, for unclear reasons. Since ACTION\_PROCESS\_TEXT *also* only works in portrait, not landscape, we still

succeed in blocking ACTION\_PROCESS\_TEXT options.

- It blocks the entire floating action mode (in portrait), clobbering the existing cut/copy/paste/select-all options that might ordinarily be there.
- Since it is tied to internal implementation (that the floating action mode is suppressed when using an instance of a PasswordTransformationMethod), not only is this subject to change across Android versions, but also it is subject to change based on device manufacturer or custom ROM tweaks to the Android source code.

## Quick Settings and TileService

Android 5.0 added “quick settings” tiles to the notification shade. Android 7.0 allows developers to define their own tiles.

However, to paraphrase Marvel Comics, “with great power comes great need to actually think this through”.

Such tiles are only needed in cases where:

- You are doing background work that the user might need to configure
- You do not have a Notification tied to that background work, such as through a foreground service (as, in that case, they can and should interact with the Notification)

So, if your work is driven by things like AlarmManager, JobScheduler, or GCM, having your own custom tile may be reasonable. Similarly, if your app is serving as a bridge to some external hardware, via USB, Bluetooth, or other protocols, offering a tile may be useful.

However, [Google seems concerned](#) about the scenarios where this gets used:

Quick Settings tiles are reserved for controls or actions that are either urgently required or frequently used, and should not be used as shortcuts to launching an app.

Hence, be *very* judicious about where you use this capability, lest Google decide to start banning apps for having tiles that do not meet their intended use cases.

Assuming that you feel that your use case is valid, you can implement a TileService and publish a Tile. The Tile contains the icon and caption that will be shown to the

---

## MISCELLANEOUS INTEGRATION TIPS

---

user. You can find out when the tile is tapped (e.g., to start an activity to manage whatever the tile is showing) and arrange to update the tile if needed (e.g., reflecting changes in the state of the external hardware or your connection to it).

To see this in action, let's examine part of the [Introspection/SAWMonitor](#) sample project. This app monitors for installations of apps and updates of apps. If an app is installed or updated, and that app has requested the `SYSTEM_ALERT_WINDOW` permission (and the app is not on a user-maintained whitelist), the app raises a Notification. On Android 7.1 and older devices, SAWMonitor monitors for app installs and updates via a manifest-registered receiver; on Android 8.0+, it uses a `JobService` to poll for changes periodically.

Other aspects of the SAWMonitor sample app can be found in [the chapter on advanced preferences](#).

On Android 7.0+ devices, SAWMonitor offers a notification shade tile via a `TileService`. This `TileService` enables and disables the monitoring. The user can also accomplish this through the `MainActivity` and its “enabled” `SwitchPreference`. However, since this app does not need an always-on Notification, offering the tile to the user gives the user flexibility to use the tile for rapidly enabling or disabling the monitor.

### The Manifest Entry

Your app's manifest will need to have a `<service>` element pointing to your `TileService` subclass. That `<service>` element has some specific requirements, if you want your tile to work:

```
<service
  android:name=".ToggleTileService"
  android:icon="@drawable/ic_new_releases_24dp"
  android:label="@string/app_name"
  android:enabled="@bool/is_n"
  android:permission="android.permission.BIND_QUICK_SETTINGS_TILE">
  <intent-filter>
    <action android:name="android.service.quicksettings.action.QS_TILE" />
  </intent-filter>
  <meta-data
    android:name="android.service.quicksettings.ACTIVE_TILE"
    android:value="false" />
</service>
```

(from [Introspection/SAWMonitor/app/src/main/AndroidManifest.xml](#))

Specifically:

- It needs the `android.service.quicksettings.action.QS_TILE` `<intent-filter>`, so Android knows that you are publishing a tile
- It needs `android:permission="android.permission.BIND_QUICK_SETTINGS_TILE"`, so that only the system can bind to your service
- It needs the `android:label` and `android:icon` attributes, pointing to resources that will make up the default content of your tile
- Optionally, it can have the `<meta-data>` element, with a name of `android.service.quicksettings.ACTIVE_TILE`, and a boolean value indicating whether this tile is an “active tile” or not (more on this later)

Ordinarily, you could skip the label and icon, inheriting the values from the `<application>`. In this case, the tile’s icon needs to more closely resemble a modern Notification icon: an alpha channel mask, not a full-color icon. Hence, most likely you would be overriding these attributes here anyway.

### Active and Passive Tiles

Your tile can be considered “active” or “passive”. The default is “passive”, where you will be told to update the tile’s contents when the user slides open the notification shade. For most situations, this will be fine. But, it may be that you need to show real-time updates while that shade is open. In that case, you need an “active” update model. To opt into that, your `<service>` also needs the following child element:

```
<meta-data
  android:name="android.service.quicksettings.ACTIVE_TILE"
  android:value="true" />
```

Then, elsewhere in your code, when the tile content needs to be updated, you can call the static `requestListeningState()` method on `TileService`, to tell Android that you want it to poll your active `TileService` for an update.

### And, Of Course, Bugs

Note that if you change your icon or caption after shipping your app, the user will not see the changes if they already have your tile in their notification shade. They would have to remove and re-add the tile to pick up the new icon and/or caption. This is due to [this bug](#) on Android 7.x and [this bug](#) on Android 8.x and [this bug](#) for

the Android 9.0.

### Only Enabling on Android 7.0+

On Android 6.0 and older devices, our `TileService` is useless. There is no value in having it be enabled, and there is always a chance that some security flaw might exploit it. So, it is best to disable this service on older devices. That is what the `android:enabled="@bool/is_n"` attribute is for in the `<service>` element. This is set to `false` in `res/values/bools.xml` and `true` in `res/values-v24/bools.xml`. Hence, on Android 6.0 and older devices, the service will be disabled.

### The Service

`ToggleTileService` extends `TileService` and is responsible for dynamically changing the tile and responding to clicks on the tile:

```
package com.commonware.android.sawmonitor;

import android.annotation.TargetApi;
import android.content.SharedPreferences;
import android.graphics.drawable.Icon;
import android.os.Build;
import android.preference.PreferenceManager;
import android.service.quicksettings.Tile;
import android.service.quicksettings.TileService;

@TargetApi(Build.VERSION_CODES.N)
public class ToggleTileService extends TileService {
    private SharedPreferences prefs;

    @Override
    public void onStartListening() {
        super.onStartListening();

        updateTile();
    }

    @Override
    public void onClick() {
        super.onClick();

        boolean isEnabled=getPrefs().getBoolean(MonitorApp.PREF_ENABLED, false);

        getPrefs()
            .edit()
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
.putBoolean(MonitorApp.PREF_ENABLED, !isEnabled)
    .apply();
updateTile();
}

private void updateTile() {
    Tile tile=getQsTile();

    if (tile!=null) {
        boolean isEnabled=getPrefs().getBoolean(MonitorApp.PREF_ENABLED, false);
        int state=isEnabled ? Tile.STATE_ACTIVE : Tile.STATE_INACTIVE;

        tile.setIcon(Icon.createWithResource(this,
            R.drawable.ic_new_releases_24dp));
        tile.setLabel(getString(R.string.app_name));
        tile.setState(state);
        tile.updateTile();
    }
}

private SharedPreferences getPrefs() {
    if (prefs==null) {
        prefs=PreferenceManager.getDefaultSharedPreferences(this);
    }

    return(prefs);
}
}
```

(from [Introspection/SAWMonitor/app/src/main/java/com/commonsware/android/sawmonitor/ToggleTileService.java](#))

As with many specialized Service subclasses, the API that you need to implement and consume for a TileService does not bear much resemblance to the regular Service API. You are welcome to override onCreate() and onDestroy() if needed, though ToggleTileService did not really need either of those.

If and when the user adds your tile to their notification shade, by default, you will be called with onStartListening(). There is also a corresponding onStopListening(). In between those two events, the user has the notification shade open, and so if you have changes that you need to publish to the tile, you should do so. For example, you might register some sort of event listener in onStartListening() (e.g., for WiFi signal strength changes) and unregister that listener in onStopListening(). While the listener is registered, if there is an event that needs to be reflected in the tile, your TileService might update that tile.

In this case, `onStartListening()` just updates the tile with the current state, in the private `updateTile()` method. `getQsTile()` returns a `Tile` object representing the current tile state, which you can examine and modify as needed. `getQsTile()` will return `null` if you cannot update the tile right now, for whatever reason.

In the case of `ToggleTileService`, we want the tile to reflect the state of the enabled boolean value in `SharedPreferences`. So, we lazy-load the `SharedPreferences` and see what `enabled` is. From there, we derive a state value, choosing between `STATE_ACTIVE` and `STATE_INACTIVE`. There are three possible states to choose from:

- `STATE_ACTIVE` is the normal state, indicating that the tile should be displayed normally and should support click events
- `STATE_INACTIVE` is the same, except that the tile should be displayed in an “inactive” style (e.g., dimmed)
- `STATE_UNAVAILABLE` — the default state until you indicate otherwise — indicates that the tile is disabled and will not respond to click events

`ToggleTileService` then updates the `Tile` with that state, along with setting the icon and label. Those happen to be set to the same values as are defined in the manifest, so this work is superfluous and here only for illustration. Note that `setIcon()` takes an `Icon` object, which can be created from a wide range of sources, including resources and local files.

Once you have the `Tile` configured to your liking, call `updateTile()` to push the changes over to the system, which will update the tile in the notification shade to match.

If the user clicks on the tile, you will be called with `onClick()`, where you can take whatever action makes sense. In this case, we just want to update the `SharedPreferences` to toggle the `enabled` value, then update the tile to match.

### The User Experience

When the user installs an app that has a `TileService`, the tile is not automatically put in the user’s notification shade. Instead, it *allows* the user to add the tile if the user wants to.

## MISCELLANEOUS INTEGRATION TIPS

---

If the user opens the notification shade, an “Edit” button should appear:

*Figure 877: Notification Shade on Nexus 9 Running Android 7.0*

## MISCELLANEOUS INTEGRATION TIPS

---

Tapping “Edit” brings up the tile roster editor:

*Figure 878: Android 7.0 Tile Roster Editor*

The tile for the newly-installed app will appear. Since the `TileService` has never been invoked, the tile will display the icon and label from the `<service>` element.

## MISCELLANEOUS INTEGRATION TIPS

---

The user can drag and drop from the “Drag to add tiles” area into the mock notification shade itself. Upon closing the editor, the new tile will appear in the notification shade

*Figure 879: Notification Shade with SAW Monitor Tile*

At this point, the tile should have been updated by the `TileService`. If the user later returns to the notification shade, the `TileService` will get another shot to update the tile via `onStartListening()`, and so forth.

If the user wants to, the user can return to the editor and drag the existing tile out of the mock notification shade back into the “Drag to add tiles” area, thereby removing it.

## The Other Features and Limitations

Here are some other items of note related to tiles and `TileService`:

- You can determine if the device is locked by calling `isLocked()` on the `TileService`.
- You can respond to a tap on the tile by showing a dialog (`showDialog()`), launching an activity (`startActivityAndCollapse()`), or asking the user to

- unlock the device first (`unlockAndRun()`).
- If your tile may show sensitive data, `isSecure()` will tell you if your tile is visible in some “secure state” and therefore whether it is safe to show that sensitive data.
- Each `TileService` has only one tile. For most apps, this will be plenty. But, if for some reason your app needs multiple tiles, you will need multiple `TileService` implementations, one per tile.

## Installing Packages

To install an app from an APK, you can use `ACTION_INSTALL_PACKAGE` on API Level 14+, and `ACTION_VIEW` on older devices. An `Intent` with one of those actions, and a `Uri` pointing to an APK, will lead the user to install the app... if the user grants our app the ability to install apps.

Prior to Android 8.0, the user would grant the ability to install “non-market apps” globally. This was simple but not especially secure, as any app could then ask to install other apps. While the user would be involved in the installation process — via confirmation dialogs and such — this still was not ideal.

On Android 8.0+, the user flow is a bit different, as now rather than enabling app-installation rights to all apps via Settings, the user grants it on a per-installer basis.

We can determine whether or not we have app-installation rights by calling `canRequestPackageInstalls()` on a `PackageManager`. However:

- This method is only available on Android 8.0+
- Apps need to hold the `REQUEST_INSTALL_PACKAGES` permission to make this call
- This value does you little good, other than to perhaps warn the user as to what is coming, as there is no way to request app-installation rights other than to try installing an app

The [Introspection/AppWrangler](#) sample project has an overflow menu with an “Install...” item in it. Tapping that will bring up an `ACTION_OPEN_DOCUMENT` screen, for you to find an APK on your device or emulator. When we get the `Uri` in `onActivityResult()`, we:

- Call `canRequestPackageInstalls()` and show a `Toast` if we do not already have app-installation rights

## MISCELLANEOUS INTEGRATION TIPS

---

- Start the ACTION\_INSTALL\_PACKAGE activity regardless of the canRequestPackageInstalls() state

```
@Override
protected void onActivityResult(int requestCode, int resultCode,
    Intent data) {
    if (requestCode==REQUEST_OPEN && resultCode==RESULT_OK) {
        if (getPackageManager().canRequestPackageInstalls()) {
            Toast.makeText(this, R.string.msg_install_perm, Toast.LENGTH_LONG).show();
        }

        Intent i=new Intent(Intent.ACTION_INSTALL_PACKAGE)
            .setData(data.getData())
            .addFlags(Intent.FLAG_GRANT_READ_URI_PERMISSION);

        startActivity(i);
    }
}
```

(from [Introspection/AppWrangler/app/src/main/java/com/commonsware/android/appwrangler/MainActivity.java](#))

What the user sees — other than the Toast — is a dialog confirming whether or not installing an app is what the user has in mind:

Figure 88o: Android 8.0 Emulator, Initial App Installation Dialog

## MISCELLANEOUS INTEGRATION TIPS

---

If the user taps “External Sources”, a screen dedicated to your app appears:

*Figure 881: Android 8.0 Emulator, Trust Screen in Settings*

(the dark gray background on the top banner appears on the emulator, but not on hardware)

## MISCELLANEOUS INTEGRATION TIPS

---

If the user checks the “Trust apps from this source” switch and presses BACK, ideally the user is then taken to the normal app installation flow:

*Figure 882: Android 8.0 Emulator, Installing F-Droid*

## Deleting Packages

Similarly, to install an app from an APK, you can use `ACTION_UNINSTALL_PACKAGE` on API Level 14+, and `ACTION_DELETE` on older devices. An Intent with one of those actions, and a `Uri` pointing to an APK, will ask the user if they want to uninstall the app.

None of that has changed.

There is an `REQUEST_DELETE_PACKAGES` permission, and its documentation indicates that you need this to use `ACTION_UNINSTALL_PACKAGE`. [This is not the case](#) for Android 8.x, but it is the case starting with Android 9.0 (if you have a `targetSdkVersion` of 28 or higher). This is a normal permission, so you do not need to go through the runtime permissions request path for it.

## Detecting Changes in Packages

Sometimes, your app might need to know if apps are installed or removed.

On Android 7.1 and older, if we want to find out about changes in the mix of installed packages, we would listen for `ACTION_PACKAGE_ADDED` and `ACTION_PACKAGE_REMOVED`.

However, those are implicit broadcasts, and we cannot register for those in the manifest on Android 8.0+. As a result, we can only listen to those broadcasts when we already have a process running for other reasons and can use `registerReceiver()`. That is fine as far as it goes, but it means that we may not find out about every package change.

The workaround for this is to call `getChangedPackages()` on `PackageManager` on Android 8.0+. This returns a `ChangedPackages` object, listing the packages that have changed.

The scope of the change is based on a sequence number. This starts at zero, when the device is booted. Every change to the mix of installed packages should trigger a new sequence number. You pass in the sequence number of the last `getChangedPackages()` call that you made, or 0 if you have not called it before. The `ChangedPackages` will give you the list of packages changed between your passed-in sequence number and the current state. The `ChangedPackages` also has the current sequence number. The idea is that you can persist that sequence number, so when your app runs, you can find out about package changes that went on while your process was not around.

The AppWrangler sample app demonstrates this, though not using persistence, as it is not needed here.

The AppWrangler UI is dominated by a list of installed apps. That list is populated at the outset by a call to `refresh()` from `onResume()`:

```
private void refresh(boolean toast) {
    if (lastPackageSequenceNumber== -1) {
        ChangedPackages delta=pm.getChangedPackages(0);

        lastPackageSequenceNumber=(delta==null) ? 0 : delta.getSequenceNumber();
        populateList();
    }
    else {
```

## MISCELLANEOUS INTEGRATION TIPS

---

```
ChangedPackages delta=pm.getChangedPackages(lastPackageSequenceNumber);

if (delta!=null && delta.getSequenceNumber(>lastPackageSequenceNumber) {
    populateList();

    if (toast) {
        Toast.makeText(this, R.string.msg_refresh_ack,
            Toast.LENGTH_SHORT).show();
    }
}
else if (toast) {
    Toast.makeText(this, R.string.msg_refresh_nack,
        Toast.LENGTH_LONG).show();
}
}
```

(from [Introspection/AppWrangler/app/src/main/java/com/commonsware/android/appwrangler/MainActivity.java](https://github.com/commonsware/android-appwrangler/blob/master/src/main/java/com/commonsware/android/appwrangler/MainActivity.java))

`lastPackageSequenceNumber` is initialized to `-1`, meaning that we have never tried getting our packages yet. In that case, we call `getChangedPackages()` to get the now-current sequence number, passing in `0` as the starting sequence number. Since `getChangedPackages()` might return `null`, we either read the sequence number out of the `ChangedPackages` or use `0` for the new `lastPackageSequenceNumber` value. Then, we call `populateList()`, which uses `PackageManager` and `getInstalledApplications()` to populate the `ListView`.

There is a “refresh” action bar item, which also triggers a call to `refresh()`. In this case, `lastPackageSequenceNumber` should be something other than `-1`, courtesy of our original `refresh()` call triggered by `onResume()`. If `lastPackageSequenceNumber` is not `-1`, we call `getChangedPackages()`, supplying `lastPackageSequenceNumber` as the starting point. If we get a `ChangedPackages` back, and the new sequence number is higher, we know that there was a package change that went on “behind our backs”, so we update the list. If we were using `RecyclerView`, we might use the list of packages in the `ChangedPackages` to make the specific modifications to our list that are required — since that is not really an option with `ListView`, we just reload the whole list.

If, with the `AppWrangler` app in the foreground, you install an app from the command line using `adb install`, then click the “refresh” action bar item, you should see a `Toast` indicating that there were changes in the packages, and the list should update to show the newly-installed app.

# **Android Studio Editors and Dialogs**

---

Eclipse, with the ADT plugin, had many structured editors and specialized dialogs for modifying Android project files and otherwise configuring Android project behavior.

Android Studio has fewer of those, and they are generally less critical. The editors and dialogs presented in this chapter can be useful, at least in some cases, but you do not need to use any of them to be able to create your Android projects. However, some may speed up your Android development a bit over working with bare resource and Gradle files.

## **Prerequisites**

Understanding this chapter requires that you have read the core chapters of this book, along with the chapter on [Gradle and build variants](#).

## **Project Structure**

The Project Structure dialog allows you to configure many aspects of your `build.gradle` files from a tabbed property-style dialog, as opposed to having to work with the Gradle scripts directly. On the plus side, this can be easier. However, since Gradle is built on the Groovy scripting language, `build.gradle` files are not simple XML or JSON data structures. It remains to be seen how well the Project Structure dialog will be able to handle complex Gradle scripts.

To access the Project Structure dialog, choose File > Project Structure from the main IDE menu.

The left-hand side lists major areas of the dialog; choosing one of those switches to that area's form on the right.

The sections that follow outline each of the major areas and what you can configure in them.

### SDK Location

The Project Structure dialog opens up on the SDK Location area, where you can configure where your Android SDK is located, where your JDK is located, and where your NDK is located:

*Figure 883: Project Structure Dialog, SDK Location Category*

For new Android Studio 2.2+ installations, the default is for Android Studio to use a version of the Java JDK that ships with the IDE itself, in which case “Use embedded JDK (recommended)” will be checked.

Adjusting these in Project Settings affects this specific project. There is also File > Other Settings > Default Project Structure, where you can edit the default values to be used for new projects and projects that you import in the future.

## Project Settings

The second entry in the Project Structure dialog category list is “Project”. This allows you to configure four items found by default in the `build.gradle` file in your project root or in the `gradle-wrapper.properties` file:

- What version of Gradle you wish to use for the Gradle Wrapper
- What version of the Android Gradle Plugin you wish to use
- What artifact repository should be used for pulling in the Gradle for Android plugin (and any other plugins you may be using)
- What artifact repository should be used by default for standard module artifacts (e.g., those you request via `implementation` directives in your module’s `build.gradle` file)

Figure 884: Project Structure Dialog, Project Settings Category

## Developer Services

If you are using select portions of the Play Services SDK, the items under the “Developer Services” divider allow you to configure those portions. By default, they amount to checkboxes, to enable certain features:

Figure 885: Project Structure Dialog, Notifications Category

## Module Settings

Below the “Modules” divider in the category list on the left will come all of your modules. If you are not using modules, there will be a single entry in the category list with the same name as your project, as a quasi-module.

Clicking on a module will bring up a set of tabs on the right to edit various properties of that module, independently of any other module in your project. The following sections outline the contents of those tabs.

### Properties

The first tab is labeled “Properties” and allows you to adjust various top-level

settings in your module's `build.gradle` file.

*Figure 886: Project Structure Dialog, Module Category, Properties Tab*

These include:

- Your `compileSdkVersion` (“Compile Sdk Version” drop-down)
- Your `buildToolsVersion` (“Build Tools Version” drop-down)
- Another artifact repository to use for this module, added to your module’s repositories closure (“Library Repository”)
- The `ignoreAssetsPattern` property in `aaptOptions` (“Ignore Assets Pattern”)
- The `incremental` property in `dexOptions` (“Incremental Dex”)
- The `sourceCompatibility` in `compileOptions` (“Source Compatibility”)
- The `targetCompatibility` in `compileOptions` (“Target Compatibility”)

## Signing

If your module's `build.gradle` file has a `signingConfigs` closure, the "Signing" tab will let you edit those signing configurations:

Figure 887: Project Structure Dialog, Module Category, Signing Tab

Each signing configuration that you have defined will appear in the list on the left side of the tab. On the right are fields for you to fill in the signing configuration name, the keystore file and key alias to use, and the passwords to use for accessing that file and alias.

The green plus (“+”) icon on the right side of the list lets you define a new signing configuration, while the red minus (“-”) icon lets you delete an existing signing configuration.

## Flavors

The “Flavors” tab starts off with a single “flavor”, representing your `build.gradle` file's `defaultConfig` settings. The green plus icon next to the list of flavors lets you define a new flavor, while the red minus icon lets you remove an existing flavor. Note that you cannot remove `defaultConfig`, as it is defined by the Gradle for Android

plugin.

Figure 888: Project Structure Dialog, Module Category, Flavors Tab

On the right side of the tab, you can set or change the name of the flavor, plus you can adjust various flavor (or defaultConfig) settings, including:

- the `minSdkVersion` value (“Min Sdk Version” drop-down)
- the `applicationId` (“Application Id”)
- the ProGuard rules file to use for builds (“Proguard File”)
- which of your defined signing configurations to use (“Signing Config” drop-down)
- the `targetSdkVersion` value (“Target Sdk Version” drop-down )
- [the `testInstrumentationRunner` to use for instrumentation testing](#) (“Test Instrumentation Runner”)
- [the `testApplicationId` value for instrumentation testing](#) (“Test Application Id”)
- the `versionCode` and `versionName` to use (“Version Code” and “Version Name”), along with the suffix to apply to the version name (unique to this product flavor)

## Build Types

The “Build Types” tab allows you to adjust settings for the debug and release build types. The green plus icon next to the list of build types lets you define a new build type, while the red minus icon lets you remove an existing build type. Note that you cannot remove debug or release, as they are defined by Gradle.

Figure 889: Project Structure Dialog, Module Category, Build Types Tab

On the right side of the tab, you can set or change the name of the build type, plus you can adjust various settings in your `buildTypes` closure, including:

- the value of `debuggable`, to control if the app is considered to be debuggable on production hardware (“Debuggable” drop-down)
- the value of the undocumented `jniDebuggable` flag (“Jni Debuggable”)
- which signing configuration to use (“Signing Config” drop-down)
- the value of the undocumented `renderscriptDebuggable` flag (“Renderscript Debuggable”)
- the value of the undocumented `renderscriptOptimLevel` property (“Renderscript Optim Level”)
- the value of `minifyEnabled`, to control whether the build process should attempt to strip out unused code (“Minify Enabled” drop-down)

## ANDROID STUDIO EDITORS AND DIALOGS

- the value of the undocumented `pseudoLocalesEnabled` flag (“Pseudo Locales Enabled”)
- the ProGuard rules file to use for builds (“Proguard File”)
- the suffix to append to the `applicationId` (“Application Id Suffix”)
- the suffix to append to the `versionName` (“Version Name Suffix”)
- whether the resulting APK should be processed by `zipalign` (“Zip Align Enabled”)

### Dependencies

If your project has any defined dependencies in a dependencies closure, these will appear in the “Dependencies” tab:

Figure 890: Project Structure Dialog, Module Category, Dependencies Tab

## ANDROID STUDIO EDITORS AND DIALOGS

The tab is dominated by a two-column table, where the left column is the dependency itself. The right column is the “scope”, where the cell shows the current scope, and if you click on it, you get a drop-down list of available scopes:

Figure 891: Dependencies Tab, Showing Scope Drop-Down

Those scopes include:

- “Implementation”, for an implementation dependency
- “Test implementation” for an androidTestImplementation dependency (i.e., one to be used only for instrumentation testing)
- “Unit test implementation” for a testImplementation dependency (i.e., one to be used only for unit testing)
- Other “compile” scopes for your build variants (e.g., “Debug compile” for a debugCompile dependency)
- “Compile only”, for a compileOnly dependency (where the dependency is used only at compile time and its contents are not packaged into the APK file)
- “Runtime only” for a runtimeOnly dependency (where the dependency is not used at compile time, but its contents are packaged into the APK file)

The latter two scopes will be used infrequently.

---

## ANDROID STUDIO EDITORS AND DIALOGS

---

If you click the green + button, you will be able to add a new dependency. A drop-down menu will let you choose between a library dependency (i.e., for an artifact in a repository), a file dependency, and a module dependency (i.e., to depend upon another module in your project).

Typically, you will be adding library dependencies. When you choose that option, another dialog appears to allow you to search for likely dependencies or type in the full dependency identifier (group ID:artifact ID:version).

Figure 892: Choose Library Dependency Dialog, As Initially Launched

Figure 893: Choose Library Dependency Dialog, With Search Results for “greenrobot”

The red - icon in the same toolbar as the green + will remove a dependency, while the up and down arrows allow you to reorder the dependencies.

## Translations Editor

On Android Studio, if you open a file containing string resources, you will find a notification banner atop the editor, offering a way for you to “Edit translations for all locales in the translations editor”:

Figure 894: Notification Banner for Translations Editor

Clicking the “Open editor” link will open the Translations Editor. You can also get to this editor by right-clicking over the resource file in the Project or Android view on the left and choosing “Open Translation Editor” from the context menu.

For an un-translated project — such as one newly-created from the new-project wizard — when you open the Translations Editor, you will just see all of the existing strings:

Figure 895: Translations Editor, As Initially Opened

These are labeled as “default value” because, in this case, the values are coming from the default resource set (res/values/strings.xml), not some specific language translation.

You can edit an existing default value either by clicking on the cell containing the default value (e.g., clicking the “My Application” cell), or by clicking anywhere on the row and then editing the value in the “Default Value” field towards the bottom of

the editor. Note that you cannot edit keys via this editor.

The right-hand column of the table has checkboxes, with a column heading of “Untranslatable”. Checking one of those adds a `translatable="false"` attribute to the `<string>` element in the XML. The IDE and related tools can use this to not warn you that this string lacks translations. This would be good for strings that you elected to put in string resources yet are not user-facing and therefore do not need translation.

The + icon in the toolbar, when clicked, pops up a dialog where you can define a new string:

Figure 896: Translations Editor, New-String Dialog

Where the fun begins, though, is if you click the globe icon in the toolbar. This displays a drop-down list of languages:

Figure 897: Translations Editor, Showing Languages Drop-Down List

## ANDROID STUDIO EDITORS AND DIALOGS

Choosing a language has two main effects. First, it creates a corresponding `res/values-*/` directory for your chosen language. Second, it adds a column to the Translations Editor for that language:

*Figure 898: Spanish Strings in Resource File and Translations Editor*

You can then click on a cell representing a word and its language, and fill in the translation in the form:

*Figure 899: Translations Editor, Showing Spanish Translation*

## ANDROID STUDIO EDITORS AND DIALOGS

---

The icons to the right of the “Default Value” and “Translation” fields in the form simply pop up a dialog giving you a bit more room to type:

*Figure 900: Translations Editor, Values Edit Dialog*

## **Trail: Other Tools**

---

# Advanced Emulator Capabilities

---

The Android emulator, at its core, is not that complex. Once you have one or more Android virtual devices (AVDs) defined, using them is a matter of launching the emulator and installing your app upon it. With Android Studio, those two steps can even be combined — the IDE will automatically start an emulator instance if one is needed.

However, there is much more to the Android emulator. This chapter will explore various advanced features of the emulator and how you can use them.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## Other Notable Configuration Options

When defining an AVD, or editing an existing AVD definition, there are many other configuration options at your disposal.

### Hardware Graphics Acceleration

Another way to speed up the emulator is to have it use the graphic card or GPU of your development machine to accelerate the graphics rendering of the emulator window. By default, the emulator will use software-based rendering, without the GPU, which is slow in general and worse when running an ARM-based image.

Whether this will work or not for you will depend in part upon your graphics drivers

---

## ADVANCED EMULATOR CAPABILITIES

---

of your development machine. Also, their use might conflict with other things you might want to do — on Linux, using hardware GPU mode might break your ability to take screenshots, for example.

This setting is toggled within the AVD Manager, for new and existing AVDs, via the “Graphics” drop-down list in the “Emulated Performance” group:

Figure 901: Virtual Device Configuration, Showing “Use Host GPU” Checkbox

There are three options:

- “Software” says to render the graphics purely within the emulator software
- “Hardware” says to render the graphics using the GPU of your development machine
- “Auto” (the default) delegates the decision to the emulator itself, based on its own heuristics of what will work well

## Keyboard Behavior

The Android emulator can emulate devices that have, or do not have, a physical keyboard. Most Android devices do not have a physical keyboard, and so the emulator is set up to behave the same. However, this means that typing on your

---

## ADVANCED EMULATOR CAPABILITIES

---

development machine’s keyboard will not work in EditText widgets and the like — you have to tap out what you want to type on the on-screen keyboard.

If you wish to switch your emulator to emulate a device with a physical keyboard – either “for realz” or just to simplify working with the emulator on your development machine — you can do so.

In the Android Studio AVD Manager, in the “Advanced Settings” area, there is an “Enable keyboard input” checkbox that determines whether hardware keyboard input is honored in the AVD or not:

Figure 902: Virtual Device Configuration, Showing “Enable keyboard input” Checkbox

## Startup Settings

You can also control whether the device starts up in portrait or landscape mode at the outside, by the toggle buttons labeled “Startup orientation”:

Figure 903: Virtual Device Configuration, Showing “Startup orientation” Options

## Camera Options

In the “Advanced Settings” area, you can control whether or not the emulator emulates a device with a camera:

Figure 904: Virtual Device Configuration, Showing Camera Options

Whether you can configure both front and back cameras, or just one, is indeterminate. If you can configure a camera, your options are:

- “None”, to emulate a device without a camera
- “Emulated”, which emulates a device with a camera, but where the camera images themselves are emulated
- some hardware indicator (e.g., “Webcam”), which emulates a device with a camera, where the camera images are pulled from some camera hardware on

your development machine (e.g., a notebook webcam)

The back camera also will have a “VirtualScene” option, where the camera will appear to be looking at the interior of a home, in the form of a 3D rendering of that interior.

However, the emulator’s ability to truly emulate the way Android cameras behave is very limited. Serious camera testing needs to be done using Android hardware, not the emulator.

### Memory and Storage Configuration

In the “Advanced Settings” area, you can control how much RAM and storage is used by the emulator:

Figure 905: Virtual Device Configuration, Showing Memory and Storage Options

Specifically:

- “RAM” controls how much system RAM the emulator emulates. This will be a subset of the overall RAM of your development machine that the emulator consumes.
- “VM heap” appears to control the Dalvik/ART heap limit assigned to applications.
- “Internal Storage” indicates how much space is allocated for the main device partitions in the emulated device.
- “SD card” is still the misnomer for external storage. Your options are either to have Android Studio manage this for you, or for you to use tools like `mksdcard` to create your own disk image that you attach to the emulator.

Usually, the defaults are fine.

### Frames and Skins

By default, the emulator appears in a bare window, showing the contents of the “touchscreen”. Of course, an actual Android device will have more around it, such as bezels, optional hardware buttons, and so on.

In the “Device Frame” group in the “Advanced Settings” area, you can check “Enable Device Frame” and choose a skin to wrap around the touchscreen and make your emulator look a bit more like a real device:

Figure 906: Virtual Device Configuration, Showing Device Frame Options

## The Emulator Sidebar

Starting with Android Studio 2.0, the emulator sports a “sidebar” that runs alongside the main emulator window:

*Figure 907: Android Emulator, with Sidebar on the Right*

This provides you with rapid access to a number of emulator features and controls. Some of those are hidden behind the “More” button, at the bottom of the sidebar (looks like an ellipsis, “...”).

Note that the sidebar buttons have tooltips that will tell both the button’s purpose and the keyboard shortcut, if any, for that button.

## Power and Navigation Controls

The top icon in the sidebar is a power button. A quick click on it will close your emulator. A long-click will behave like the POWER button on an Android device, bringing up the power menu:

*Figure 908: Android Emulator, Showing Power Menu*

## ADVANCED EMULATOR CAPABILITIES

---

Towards the bottom of the sidebar are BACK, HOME, and RECENTS buttons for navigation:

*Figure 909: Android Emulator Sidebar Navigation Buttons*

## ADVANCED EMULATOR CAPABILITIES

If you click the “More” button, you will open up the “Extended Controls” window:

Figure 910: Android Emulator with Extended Controls

## ADVANCED EMULATOR CAPABILITIES

---

Clicking the “Directional pad” category on the left of the “Extended Controls” gives you D-pad and media buttons for in-app navigation:

*Figure 911: Emulator Extended Controls, Showing Directional Pad*

## Screen Orientation and Zoom

Two buttons on the sidebar allow you to rotate the device clockwise or counter-clockwise:

*Figure 912: Android Emulator Sidebar Rotation Buttons*

The magnifying glass icon allows you to zoom and out of the emulator screen contents:

*Figure 913: Android Emulator Sidebar Zoom Button*

When in zoom mode, the mouse cursor changes to a magnifying glass, and left-mouse clicks will zoom in at the clicked-upon point. Right-mouse clicks will zoom out. To return the mouse to normal behavior, tap the zoom sidebar button again. However, note that you will remain zoomed in on the last-selected zoom state; to return the emulator fully to normal, zoom out all the way first.

## Screenshots

The camera button on the sidebar allows you to rapidly take screenshots of the

---

## ADVANCED EMULATOR CAPABILITIES

---

emulator window:

*Figure 914: Android Emulator Sidebar Screenshot Button*

These will be stored in a directory controlled by the “Settings” category in the “Extended controls” window:

*Figure 915: Emulator Extended Controls, Showing Settings*

## Faking the Real World

The “Extended controls” panel also allows you to fake real world behavior in your emulator.

### Location

The “Location” category lets you fake GPS fixes:

*Figure 916: Emulator Extended Controls, Showing Location*

The upper half allows you to specify a single GPS fix and “send” that to the emulator, which should respond the same way as if an actual Android device received a GPS fix.

The bottom half allows you to load a GPX or KML file containing a series of waypoints and the time between them, then play those back, either at normal speed or at an accelerated pace (if you get bored easily).

### Network Status

The “Cellular” category controls how the emulator emulates its cellular network connection:

### Battery

The “Battery” category allows you to simulate changes in the power status of the emulator:

*Figure 918: Emulator Extended Controls, Showing Battery*

Not only will your code be able to receive events like `ACTION_BATTERY_CHANGED`, but you can see the changes in the status bar of the emulator, such as the battery icon showing charging status and current charge level.

### Telephony

The “Phone” category allows you to simulate incoming phone calls and text messages:

*Figure 919: Emulator Extended Controls, Showing Phone*

## Emulator Window Operations

Dragging a window edge of the emulator window will change the scale used by the emulator. The entire emulator window is still there, just smaller or larger than before. The resulting window will have the proper aspect ratio, so if you drag the left or right side and shrink the window, it will shrink both vertically and horizontally.

Using your development machine’s native file manager (e.g., Nautilus on Ubuntu Linux), you can drag-and-drop files into the emulator window. If the file is an APK, it will be installed automatically, as if you had installed it through the `adb install` command. If the file is anything else, it will be uploaded into the emulator’s `Download/` directory on external storage. If your app has permission to work with external storage, it can read the file from there.

## Headless Operation

Sometimes, you want an emulator without a GUI. Typically, this is used for continuous integration or some other server-based testing solution — you use the “headless” emulator to run tests, even on a machine that lacks any GUI capability.

To do this, you will need to run the emulator from the command-line. Run `emulator -no-window -avd ...`, where ... is the name of your AVD (e.g., the value in the left column of the list of AVDs in the AVD Manager). To test this first in normal mode, run the command without the `-no-window` switch.

The simplest solution to get rid of the emulator instance is to kill its process.

There are many other [command-line switches for the emulator](#) that you may wish to investigate. While most of these have UI analogues in the AVD Manager, the switches would be necessary to replicate some of those for headless operation.

# Lint and the Support Annotations

---

As C/C++ developers are well aware, lint is not merely something that collects in pockets and belly buttons.

Lint is a long-standing C/C++ utility that points out issues in a code base that are not errors or warnings, but are still indicative of a likely flaw in the code. After all, what might be legal from a syntax standpoint may still be a bug when used.

Android Studio and the Android Plugin for Gradle have their own equivalent Lint tool, for reporting similar sorts of issues with an Android project's Java code, resources, and manifest. You can also get Lint reports from the command line, such as via the Android Gradle Plugin, perhaps as part of integrating your builds into a continuous integration server.

To help Lint catch problems stemming from your own code, Google has released the support-annotations library, to help catch things like passing a widget ID, instead of a layout ID, into `setContentView()`. You can also use these annotations to help those using your code – whether in the same project or in consumers of a library that you publish – make sure that they do not make similar mistakes.

This chapter will explore how you use Lint to detect problems and how you can add annotations to your code to help Lint catch even more problems.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## What It Is

Lint can be best described as “a pest, but a good pest”.

Normally, what stops you from building your app are compiler errors: bad Java syntax, malformed XML resource files, and the like. At the command line, these stop an in-progress build and dump error messages to the console. In Android Studio, these are noted in a log and also by notations in the source code, frequently as red squiggle lines underneath the offending Java or XML when viewed in an editor. You also may get yellow squiggle lines for warnings — things the compiler will allow but the compiler thinks may be a problem.

However, there are many things that might be syntactically valid but are not a good idea from an Android standpoint. For example, if you specify a minimum SDK version of API Level 8, and you try using a class that only exists on API Level 11, that’s a problem if you are not handling it correctly and avoiding this class on the older-yet-supported devices. Yet, if your build target (i.e., `compileSdkVersion` in Android Studio) is API Level 11 or higher, it is perfectly valid syntax and would compile just fine.

Lint is designed to encapsulate rules that transcend syntax, to add more errors and warnings that reflect good Android practices beyond simple validity.

## When It Runs

Running Lint sometimes happens automatically (e.g., from your IDE) or sometimes happens manually. The following sections outline the various possibilities.

### Android Studio

By default, in Android Studio, Lint will run when you save a file, giving you error (red) or warning (yellow) squiggles for things that run afoul of Lint rules:

```
finishAffinity();
```

*Figure 920: Android Studio Lint Error*

## LINT AND THE SUPPORT ANNOTATIONS

---

You can manually invoke it via Analyze > Inspect Code... from the main menu, though this also performs other analyses that are not necessarily relevant for you as an Android developer, such as “J2ME issues”.

Figure 921: Android Studio Inspection Results

### Command Line

You can also invoke Lint via `gradle lint` or a per-variant edition (e.g., `gradle lintRelease`). This will write results to an XML file in `build/outputs/` based upon product variant (e.g., `build/outputs/lint-results-release.xml` for a `gradle lintRelease` run). It will also emit an HTML file with the same base name in the same directory. These contain the same basic information as you get from the command-line output, with the XML in particular designed to be consumed by other tools, such as a continuous integration server.

### What to Fix

In Android Studio, clicking on a red or yellow squiggle will pop up an adjacent “lightbulb” drop-down offering ways to fix the problem:

Figure 922: Android Studio Lint Fix Suggestions

You can also bring up this “quick fixes” list via `Alt-Enter`. For example:

---

## LINT AND THE SUPPORT ANNOTATIONS

---

- Errors related to accessing classes or methods higher than your `minSdkVersion` have “quick fixes” to add the `@TargetApi` annotation to the class or method containing your code
- Warnings related to hard-coded strings in layouts or the manifest have “quick fixes” to convert those strings into string resources

All warnings and errors will have “quick fixes” to suppress that warning or error in the future, by adding notations to the file to that effect.

## What to Configure

You have some measure of control over Lint’s behavior, though the mechanics of doing this varies by tool.

## Android Studio

In Android Studio, you can configure Lint’s behavior via the Project Settings dialog, accessible via `File > Settings`:

*Figure 923: Android Studio Lint Error Checking Preferences*

You can change some details about the specific checks that Lint makes:

- the severity of the issue, usually set to Warning or Error
- whether the specific issue should be ignored rather than executed

To do this, you may wish to create your own inspection profile, rather than

modifying the stock “Project Default” profile. To do this, just click the “Copy” button in the Inspections page of the Settings dialog and supply a name for the new profile.

The above recipe changes the inspections for the individual project. To change them for new projects, go into File > Other Settings > Default Settings, and make your changes there.

### Command Line

To block certain Lint checks in Gradle, you can create a `lint.xml` file, in the root directory of your project, containing information about which particular issues should be suppressed for that project. The benefit here is that you can configure suppression at a finer granularity, blocking issues for certain files or directories and allowing them for others. The sample `lint.xml` from [the Lint documentation](#) looks like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<lint>
  <!-- Disable the given check in this project -->
  <issue id="IconMissingDensityFolder" severity="ignore" />

  <!-- Ignore the ObsoleteLayoutParam issue in the given files -->
  <issue id="ObsoleteLayoutParam">
    <ignore path="res/layout/activation.xml" />
    <ignore path="res/layout-xlarge/activation.xml" />
  </issue>

  <!-- Ignore the UselessLeaf issue in the given file -->
  <issue id="UselessLeaf">
    <ignore path="res/layout/main.xml" />
  </issue>

  <!-- Change the severity of hardcoded strings to "error" -->
  <issue id="HardcodedText" severity="error" />
</lint>
```

You can also configure lint via a `lintOptions` closure inside the `android` closure of your `build.gradle` file. In particular, you can have a `disable` statement to list the Lint checks that you would like to block:

```
android {
  lintOptions {
    disable 'IconMissingDensityFolder', 'InefficientWeight'
    ...
  }
}
```

## LINT AND THE SUPPORT ANNOTATIONS

---

```
}  
}
```

The names used in `lint.xml` or `lintOptions` are the “issue IDs”. You can get a roster of these by running `lint --list` for brief summaries:

```
Valid issue categories:  
  Correctness  
  Correctness:Messages  
  Security  
  Performance  
  Usability:Typography  
  Usability:Icons  
  Usability  
  Accessibility  
  Internationalization  
  Bi-directional Text
```

Valid issue id's:

```
"ContentDescription": Image without contentDescription  
"AddJavascriptInterface": addJavascriptInterface Called  
"ShortAlarm": Short or Frequent Alarm  
"AlwaysShowAction": Usage of showAsAction=always  
"ShiftFlags": Dangerous Flag Constant Declaration  
"LocalSuppress": @SuppressWarnings on invalid element  
"UniqueConstants": Overlapping Enumeration Constants  
"InlinedApi": Using inlined constants on older versions  
"Override": Method conflicts with new inherited method  
"NewApi": Calling new methods on older versions  
...
```

...or `lint --show` for a set of more elaborate descriptions:

Available issues:

```
Correctness  
=====
```

```
AdapterViewChildren  
-----
```

```
Summary: AdapterViews cannot have children in XML
```

```
Priority: 10 / 10
```

```
Severity: Warning
```

```
Category: Correctness
```

```
AdapterViews such as ListViews must be configured with data from Java code,
```

## LINT AND THE SUPPORT ANNOTATIONS

---

such as a `ListAdapter`.

More information:

<http://developer.android.com/reference/android/widget/AdapterView.html>

`OnClick`

-----

Summary: `onClick` method does not exist

Priority: 10 / 10

Severity: Error

Category: Correctness

The `onClick` attribute value should be the name of a method in this View's context to invoke when the view is clicked. This name must correspond to a public method that takes exactly one parameter of type `View`.

Must be a string value, using `'\;'` to escape characters such as `'\n'` or `'\uxxxx'` for a unicode character.

`StopShip`

-----

Summary: Code contains `STOPSHIP` marker

Priority: 10 / 10

Severity: Warning

Category: Correctness

NOTE: This issue is disabled by default!

You can enable it by adding `--enable StopShip`

Using the comment `// STOPSHIP` can be used to flag code that is incomplete but checked in. This comment marker can be used to indicate that the code should not be shipped until the issue is addressed, and lint will look for these.

`MissingPermission`

-----

Summary: Missing Permissions

Priority: 9 / 10

Severity: Error

Category: Correctness

This check scans through your code and libraries and looks at the APIs being used, and checks this against the set of permissions required to access those APIs. If the code using those APIs is called at runtime, then the program will crash.

...

The `lint` command can be found in the `tools/` directory of your Android SDK installation.

## Support Annotations

The `support-annotations` library, from the Android Support set of libraries, offers a series of annotations that you can add to methods, method parameters, and the like to teach Lint certain types of bugs to check for. Some of the Android Support libraries use these annotations, so Lint can help catch problems when you use those public APIs. You, in turn, can add these annotations to *your* code, to catch certain problems at compile time that otherwise might be missed.

However, the important thing is that these are compile-time checks, not assertions at runtime. Lint will see if there is a likely bug at compile time and point it out to the developer, but there are many places where Lint simply has no way to know if everything is OK or not. These annotations are not a replacement for defensive programming. In fact, they not only help *users* of some API you publish to use it correctly, they help *you* by serving as a reminder that these should be checked at runtime as well.

Pretty much all of the Android Support libraries pull in `support-annotations`, courtesy of Gradle and transitive dependencies. If you do not seem to have `support-annotations` in your project, just add it to your dependencies closure, as you would any other of the Android Support libraries:

```
dependencies {  
    implementation 'com.android.support:support-annotations:23.1.0'  
}
```

You may occasionally run into version conflicts over this library, where Library A wants one version and Library B wants another version. In those cases, you may need to teach Gradle to not try to load the `support-annotations` version that a particular library might want, so you can use a different version:

```
dependencies {  
    implementation 'com.android.support:support-annotations:23.1.0'  
    compile('com.davemorrissey.labs:subsampling-scale-image-view:3.4.0') {  
        exclude module: 'support-annotations'  
    }  
}
```

In this case, `com.davemorrissey.labs:subsampling-scale-image-view:3.4.0` wants version 20.0.0 of the `support-annotations`, which is rather old. Hence, we block that dependency and substitute our own, for version 23.1.0. In general, newer versions of this library should be backwards-compatible with older versions of this library, so in case of conflict, use the newer version.

### Permissions, Again

You can indicate that certain bits of your app require callers to hold certain permissions, using the `@RequiresPermission` annotation. This is mostly for libraries, where other projects might use the library.

### Methods

The most common place to put this annotation will be on a method, to indicate that the method requires that callers hold a certain permission.

The simplest scenario is where the method requires that callers hold a single permission, in which case you just list the permission as a parameter to the annotation:

```
@RequiresPermission(Manifest.permission.CAMERA)
public void takeSelfie() {
    // do work here
}
```

If the caller does not have a `<uses-permission>` element for the `CAMERA` permission, Lint will complain at the point where the app calls `takeSelfie()`.

Sometimes, you may need callers to hold more than one permission. In that case, you can use `allOf` to list permissions; callers have to have requested all of them in the manifest:

```
@RequiresPermission(
    allOf = {
        Manifest.permission.CAMERA,
        Manifest.permission.WRITE_EXTERNAL_STORAGE
    }
)
public void takeSelfie() {
    // do work here
}
```

## LINT AND THE SUPPORT ANNOTATIONS

---

On occasion, you may need the caller to hold one of a set of possible permissions. The quintessential example here is location, where your code might dynamically adapt based upon whether the app has `ACCESS_COARSE_LOCATION` or `ACCESS_FINE_LOCATION`. In that case, you can use `anyOf` to list the possibilities; if the app has any of those permissions requested in the manifest, Lint will be happy:

```
@RequiresPermission(  
    anyOf = {  
        Manifest.permission.ACCESS_COARSE_LOCATION,  
        Manifest.permission.ACCESS_FINE_LOCATION  
    }  
)  
public void makeNoteOfWhereWeAt() {  
    // do work here  
}
```

It is unclear if there is a way to combine `anyOf` and `allOf` in a single annotation (e.g., a `takeSelfie()` method that wants to geotag the photo with the user's current location).

### Intent Actions

If you have a custom Intent action string, and the operation tied to that action string requires a permission, you can teach Lint about that by putting a `@RequiresPermission` annotation on a static String for that action string:

```
@RequiresPermission(Manifest.permission.CAMERA)  
public static final String ACTION_TAKE_SELFIE="com.commonsware.intent.action.SELFIE";
```

Basically, Lint keeps track of such strings, and if any Intent in the app is created using those strings as actions, Lint will check to see if the permission was requested.

### ContentProviders

Similarly, you can annotate a static `Uri` that serves as the base `Uri` for a `ContentProvider`. Any calls to `ContentObserver` that have a `Uri` based on the static base will trigger Lint to check to see if permissions were requested.

Frequently, though, a `ContentProvider` will have separate read and write permissions. To handle that, you have to use some fairly clunky syntax, wrapping the `@RequiresPermission` annotation in `@RequiresPermission.Read` or `@RequiresPermission.Write` annotations. For example, the `ContactsContract` class

could, in theory, have:

```
public static final String AUTHORITY = "com.android.contacts";
public static final Uri AUTHORITY_URI = Uri.parse("content://" + AUTHORITY);

@RequiresPermission.Read(@RequiresPermission(Manifest.permission.READ_CONTACTS))
@RequiresPermission.Write(@RequiresPermission(Manifest.permission.WRITE_CONTACTS))
public static final Uri CONTENT_URI = Uri.withAppendedPath(AUTHORITY_URI, "contacts");
```

(it actually does not have these; any Lint checks for this CONTENT\_URI are being handled through rules internal to the tools, not through the support annotations)

### What Permissions Should I Annotate?

If the method (or whatever) absolutely needs the permission, in all significant cases, then having the annotation will be useful.

However, there will be scenarios in which a permission may or may not be needed, depending upon circumstances.

For example, let's go back to:

```
@RequiresPermission(
    allOf = {
        Manifest.permission.CAMERA,
        Manifest.permission.WRITE_EXTERNAL_STORAGE
    }
)
public void takeSelfie() {
    // do work here
}
```

Here, we are implying that takeSelfie() will need both of those permissions, and probably all of the time. For example, perhaps the method is set up to write to Environment.getExternalStoragePublicDirectory(Environment.DIRECTORY\_DCIM). That directory requires WRITE\_EXTERNAL\_STORAGE all of the time.

But, suppose the method were implemented where the destination was a Uri, instead? You would have:

```
@RequiresPermission(
    allOf = {
        Manifest.permission.CAMERA,
        Manifest.permission.WRITE_EXTERNAL_STORAGE
    }
)
```

```
    }  
  )  
  public void takeSelfie(Uri dest) {  
    // do work here  
  }  
}
```

That `Uri` could point to any number of locations, only some of which might require `WRITE_EXTERNAL_STORAGE`. For example, the caller could provide a file: `Uri` pointing to `getExternalFilesDir()`, which does not need `WRITE_EXTERNAL_STORAGE` on API Level 19+.

There are two major strategies here, with respect to these annotations:

- Be conservative, and annotate for both permissions, as shown in the example above. The caller can always suppress the warning, if the caller is sure that `WRITE_EXTERNAL_STORAGE` is not required. However, this may confuse people not familiar with your API or with Android overall.
- Be liberal, and only annotate for the `CAMERA` permission (which `takeSelfies()` always needs). Here, you are relying on the caller to read the documentation for your library, use common sense, or perform adequate testing to ensure that `WRITE_EXTERNAL_STORAGE` is requested in cases where it is needed.

A “middle ground” approach would be to be conservative in cases where the permission might require significant work, and liberal otherwise. For example, `WRITE_EXTERNAL_STORAGE` is a dangerous permission on Android 6.0+, and so the caller has to go through all of the runtime permission request stuff for that if the app’s `targetSdkVersion` is 23 or higher. But, if `takeSelfie()` really needed `CAMERA` and `VIBRATE` (to shake the device once the selfie is taken, perhaps based on user preferences), requesting `VIBRATE` is merely a single line in the manifest, and so demanding it via the annotation when it might not be needed would be excessive.

## Type Roles, and the War on Enums

In 2015, a [kerfuffle](#) erupted in the world of Android development, one that quickly got tagged with the label, “the War on Enums”.

Google developer advocates started promoting the idea that using the Java enum construct was bad, and that you should use `int` constants instead, the way the Android SDK does. Core Android engineers slowly backed away from those developer advocates, but explained the reason why all through the Android SDK we

are passing around int values.

In a nutshell, an enum reference will consume more heap space than will an int. If every place we passed around int flags or int resource IDs, we passed around enum objects, we would put greater pressure on our available heap space.

For most Android developers, for their own code, this particular concern is unimportant, compared to the type safety one gets from using an enum properly. However, the Android SDK team decided that, in general, they should use int values rather than enum values, so they would not be the ones to blame for consuming too much heap space.

However, this does bring us back to the core problem of passing the *wrong* int values into the *wrong* methods, such as:

- passing a widget ID or a string resource ID into `setContentView()`
- passing in Intent flags (e.g., `FLAG_ACTIVITY_NEW_TASK`) to `PendingIntent` methods like `getActivity()`
- passing in a color resource ID to a method that takes an actual ARGB color value

Instead, we get a convoluted set of annotations to try to help developers using public APIs to provide the smarts that ordinarily would be handled simply by enum.

### Resources

Ideally, resource IDs would use Java's enum, so that you could not pass a string resource ID to a method that is expecting a menu resource ID. Alas, that is not the case.

Instead, if you accept resource IDs as parameters on methods or as return values from those methods, you can use a set of annotations to indicate what specific role the int values play.

- `@AnimatorRes`
- `@AnimRes`
- `@ArrayRes`
- `@AttrRes`
- `@BoolRes`
- `@ColorRes` (i.e., the int should be a color resource ID)
- `@DimenRes`

## LINT AND THE SUPPORT ANNOTATIONS

---

- @DrawableRes (i.e., the int should be a drawable resource ID)
- @FractionRes
- @IdRes
- @InterpolatorRes
- @LayoutRes
- @MenuRes
- @PluralsRes
- @RawRes
- @StringRes (i.e., the int should be a string resource ID)
- @StyleableRes
- @StyleRes
- @TransitionRes
- @XmlRes

Documentation for these, such as it is, can be found in [the JavaDocs for the android.support.annotation package](#).

There is also @AnyRes, which indicates that the int needs to be a resource, but does not imply a particular type of resource.

So, for example, you could have:

```
public void loadConfig(@XmlRes int xmlResId) {  
    // do work here  
}
```

If Lint is uncertain whether the parameter passed to loadConfig() is really an R.xml value, it can warn the caller.

### Custom Enum Replacement

Sometimes, the int values are replacing what would have been a custom Java enum.

For example, [the CWAC-Cam2 library](#) has a FlashMode enum:

```
public enum FlashMode {  
    OFF,  
    ALWAYS,  
    AUTO,  
    REDEYE  
}
```

## LINT AND THE SUPPORT ANNOTATIONS

---

Apparently, the author of that library is evil and therefore supports the use of an enum.

(note: the author of that library is also the author of this book)

An alternative would be to define those as a series of int flags:

```
public class FlashMode {
    public static final int OFF=0x0;
    public static final int ALWAYS=0x1;
    public static final int AUTO=0x2;
    public static final int REDEYE=0x3;
}
```

However, we are then back in the state where we do not know if some arbitrary int that we are passed as a parameter really is a FlashMode, as a method might expect. With the enum, we can have methods like:

```
public void setFlashMode(FlashMode mode) {
    // do work
}
```

The support-annotations library makes it possible to write a setFlashMode() that warns developers if they pass in the wrong int, but it takes a bit of work.

The [documented recipe](#) is:

```
public class FlashMode {
    @IntDef({OFF, ALWAYS, AUTO, REDEYE})
    @Retention(RetentionPolicy.SOURCE)
    public @interface FlashModeInt {}

    public static final int OFF=0x0;
    public static final int ALWAYS=0x1;
    public static final int AUTO=0x2;
    public static final int REDEYE=0x3;
}
```

Then, elsewhere, we could reference that custom FlashModeInt annotation:

```
public void setFlashMode(@FlashMode.FlashModeInt int mode) {
    // do work
}
```

Then, if Lint cannot confirm that the supplied mode is one of those constants, Lint

can warn the caller.

### Flags

One benefit of `int` over `enum` is that it is easier to implement parameters and return values that represent a combination of values rather than single values.

For example, there are a wide range of flags that you can put on an `Intent`, like `FLAG_ACTIVITY_CLEAR_TOP` and `FLAG_ACTIVITY_SINGLE_TOP`. An `Intent` can have zero, one, or several of these flags.

With an `enum` for those flags, you would need to be passing around a `Set` of `enum` instances. With `int` values, though, you can use bitfields, where each flag is assigned a bit within the `int`. For example, `FLAG_ACTIVITY_CLEAR_TOP` is `0x04000000` and `FLAG_ACTIVITY_SINGLE_TOP` is `0x20000000`. Having both of those on a single `Intent` is merely a matter of using a `OR` bit operation:

```
yourIntent.setFlags(Intent.FLAG_ACTIVITY_CLEAR_TOP|FLAG_ACTIVITY_SINGLE_TOP)
```

This takes up a lot less space, and is more efficient from a CPU standpoint, than a `Set` of `enum` values. However, once again, type safety becomes a problem.

`@IntDef` also supports a “flag” mode, where `Lint` will validate that the value passed in is comprised of the designated constants, either used individually or in combination using boolean bit operators. For example, perhaps we can support several possible flash modes in a camera API, and the caller can indicate the various modes of interest using flags:

```
@IntDef(flag=true, value={
    FLAG_OFF,
    FLAG_ALWAYS,
    FLAG_ON,
    FLAG_REDEYE
})
@Retention(RetentionPolicy.SOURCE)
public @interface FlashModeOptions {}
```

Now, methods and parameters annotated with `@FlashModeOptions` will be validated to ensure they are passing valid flags and combinations of flags.

### Does It Null?

The `@NonNull` annotation can be used for parameters that are not allowed to be `null`. If, at compile time, the caller is clearly passing a `null` value, the caller will be warned.

```
public void doSomethingContextual(@NonNull Context ctxt) {  
    // do work here  
}
```

This could also be used on methods where you are sure that the return value cannot be `null`. This is particularly important with abstract methods, methods you expect other developers to override, callbacks, and the like — putting `@NotNull` on return values for those methods indicate that *you* are requiring that the implementer not hand you back a `null` value.

Conversely, the `@Nullable` annotation can be used on methods that explicitly *can* return `null` as valid value:

```
@Nullable  
public Context getContextIfWeHaveOne() {  
    // do work here  
  
    return(result);  
}
```

Any caller of `getContextIfWeHaveOne()` will get a Lint warning, pointing out that they need to check for `null` results. That warning will remain there until the developer suppresses it or, in Lint's estimation, appears to check the result for a `null` value and handle that case.

This can be used to help find `@NonNull` violations elsewhere, by helping Lint see where things might be `null`.

### Data Validation

A variety of other annotations can be used for checking parameter values at compile time, to perhaps catch bugs earlier.

### Size

For parameters and return values that implement `java.util.Collection` – such as

## LINT AND THE SUPPORT ANNOTATIONS

---

`ArrayList`, you can use the `@Size` annotation to provide some compile-time guidance with regards to your expectations for that collection. This also works for ordinary Java arrays.

A simple number in the `@Size` annotation means you are expecting exactly that number of items in the collection, no more, no less:

```
public void growPair(@Size(2) ArrayList<String> values) {  
    // do something  
}
```

You can use `min` and `max` to constrain the size, without tying it down to a particular value:

```
public void sortInPlace(@Size(min=1) List<Comparable> unsorted) {  
    // do a sort  
}  
  
public @Size(min=1, max=6) float[] getReading(SensorEvent e) {  
    return(e.values);  
}
```

Occasionally, you might have a collection that does not have a specific size, but the size it *does* have has to be evenly divisible by some number. For that, there is the `multiple` option:

```
@RequiresPermission(Manifest.permission.VIBRATE)  
public void shakeItOff(@Size(multiple=2) long[] vibrationPattern) {  
    // use Vibrator system service  
}
```

### Ranges

`@IntRange` and `@FloatRange` help validate that the annotated value lies within a particular range of values. The range is inclusive: values equal to the ends of the range are assumed to be valid.

These work somewhat like `@Size`, except they directly examine a value, instead of examining the length of a collection or string.

```
public void howManyRoadsMustAManWalkDown(@IntRange(from=0,to=42) int roads) {  
    // do something involving a towel  
}
```

### Colors

If you have a method that expects a color resource ID as a parameter or return value, use the `@ColorRes` annotation, as noted previously.

However, more often than not, you will be expecting *colors*, not color resource IDs, to give the other developers flexibility about where the colors come from. In that case, `@ColorInt` will help identify parameters and return values that are expected to be actual ARGB colors, not just arbitrary integers. In particular, this will catch when somebody tries using a color resource ID where you expect an actual color.

### Thread Validation

If a method needs to be invoked on a certain type of thread (e.g., a background thread), you can use annotations to try to catch that sort of bug.

The simple one is `@WorkerThread`, which indicates that the method needs to be called on a background thread. If Lint thinks that the method is being invoked from something else (e.g., the main application thread), it will flag the caller with a warning.

```
@WorkerThread
public void thisIsGoingToTakeLikeForEVER() {
    // do something tedious
}
```

There are two possible converse annotations: `@MainThread` and `@UiThread`. In one bit of documentation, [Google says they are interchangeable](#). In another bit of documentation, [Google tries to point out a disparity between them](#)

There is one and only one main thread in the process. That's the `@MainThread`. That thread is also a `@UiThread`. This thread is what the main window of an activity runs on, for example. However it is also possible for applications to create other threads on which they run different windows. This will be very rare; really the main place this distinction matters is the system process. Generally you'll want to annotate methods associated with the life cycle with `@MainThread`, and methods associated with the view hierarchy with `@UiThread`. Since the `@MainThread` is a `@UiThread`, and since it's usually the case that a `@UiThread` is the `@MainThread`, the tools (lint, Android Studio, etc) treat these threads as interchangeable, so you can call `@UiThread` methods from `@MainThread`

methods and vice versa.

Roughly speaking, if the method has to be run on the main application thread for lifecycle reasons, use `@MainThread`. If the method has to be run on a UI thread to avoid “cannot modify views from a non-UI thread” sorts of errors, use `@UiThread`. And, if you’re not sure, flip a coin.

### Other Annotations

If you have a protected or public method in a class that might be subclassed, and you want to help ensure that if the method is overridden that the developer calls through to your superclass implementation, use `@CallSuper`.

(note: this annotation will not call a building superintendent; it will only be honored by Superman if your name is on the whitelist, e.g., Lois Lane)

```
@CallSuper
protected int heyDontForgetAboutMe() {
    // do something

    return(somethingToo);
}
```

`@CheckResult` allows you to nag any caller of your method, to ensure that they actually look at the value you return, rather than ignore it.

# Inspecting Layouts

---

Layouts get complicated. Not only might you be pulling in from several sources (via fragments or `<include>` or whatever), but you make changes to the contents of the UI at runtime. What you have in your layout resources is a starting point, but only that. Sometimes, it would be helpful to see exactly what is in the UI of your app *right now*, based on what you have done inside that app.

## Launching the Layout Inspector

First, get a debuggable build of your app running on your chosen device or emulator, with the desired activity in the foreground, in the state that you are interested in. Layout Inspector captures a snapshot of the state; it does not continuously update as the UI changes. Hence, you need to get the UI into the state that you want to inspect first.

Then, choose Tools > Layout Inspector from the Android Studio main menu.

## Viewing the View Hierarchy

When you inspect a layout, a tab is opened in Android Studio with a tree of widgets on the left, a wireframe-enhanced screenshot in the center, and a properties pane on the right:

Figure 924: Layout Inspector, As Initially Launched

Hovering over a widget in the tree or the wireframe will outline it in red. Selecting that widget in the tree or the wireframe, by clicking on it, outlines it in blue and updates the properties pane with the properties for that particular widget or container.

The properties pane shows a tree of fields, getter methods, and XML-style attributes. You can use these to view the state of the widget or container. However, these properties are read-only; you cannot modify the UI from the Layout Inspector.

## Inspections and Captures

Layout Inspector is not purely a tab in the IDE. The data collected by Android Studio to populate the Layout Inspector is saved in your project's captures/ directory. This allows you to view that same data again in the future. This may be useful for comparing different captures from different times, such as “before-and-

## INSPECTING LAYOUTS

---

after” captures to see what effects a code change had on your layout contents.

# Screenshots and Screencasts

---

They say that [a picture is worth a thousand words](#).

If that were really true, this book would be a lot shorter, mostly consisting of a bunch of screenshots.

That being said, having screenshots of your app is essential for documentation, marketing, and other uses. You are going to want to collect screenshots from your app by one means or another.

Screencasts — videos recording the user's interaction with a device — are also very useful for the same purposes, even if their nature precludes their practical use in various mediums (e.g., PDFs). These are also a bit more complex to collect, though you have plenty of options for that.

This chapter will outline various ways to get screenshots and screencasts of your app.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## Collecting from Android Studio

The Logcat tool has buttons to take a screenshot and record a screencast, in the toolbar:

*Figure 925: Android Studio Screenshot and Screencast Toolbar Buttons*

Note that these toolbar buttons may be hidden, as they are fairly far down the toolbar. You may need to expand the Logcat pane to show more of the toolbar to get to these buttons. Or, there is a “>>” affordance that shows the hidden toolbar buttons that you can click.

### Screenshots

The top one takes a screenshot, giving you a dialog to control what gets captured:

The main area shows the screen at the time you clicked the screenshot toolbar button. Clicking the “Reload” button on the top of the dialog will update the dialog to show the now-current device (or emulator) contents.

Depending on Android Studio version and device characteristics, the dialog may open with the correct orientation. If not, click the “Rotate” button until the image is oriented as you would like it to be.

---

## SCREENSHOTS AND SCREENCASTS

---

The “Frame Screenshot” checkbox, if checked, will wrap your screenshot in an image that resembles the hardware from the drop-down list:

*Figure 927: Android Studio Screenshot Dialog, Framing as Nexus 5*

The “chessboard” on the outside edges of the image represent transparent areas in the PNG that will be created when you save the image.

Checking the “Drop Shadow” checkbox updates the fake device frame to make it seem like the device is sitting on its edge on some horizontal surface, with a drop-shadow effect. Similarly, checking the “Screen Glare” checkbox adds a fake bit of lighting to the screenshot, as if a light from the upper right side is causing a glare on the fake glass of the fake device frame. Suffice it to say, none of this looks especially realistic.

When you have the screenshot set to your liking, click the “Save” button on the bottom of the dialog, to get a platform-specific “Save As” dialog for you to save your screenshot to wherever you like.

The resulting screenshot will then open in a tab in your IDE. This tab does not let you edit the picture, but it does have an “eyedropper” toolbar button that allows you to examine the image and identify the exact colors of various pixels.

### Screencasts

Clicking the second of the two toolbar icons mentioned above brings up a dialog for configuring a screencast:

The particular technique that Android Studio uses to record the screencast is capped at three minutes, which is one of the reasons why there are other alternatives that this chapter will explore.

The bit rate will determine the size of the resulting MP4 file, where a higher bit rate will give you a larger file. However, too low of a bit rate will degrade the quality of the recording, particularly if there is a lot of motion. You will need to experiment for yourself to see what bit rate value works best for you; 4Mbps is the default.

Similarly, normally, the screencast will be at the resolution of the device screen. However, there will be some low-end devices that are incapable of recording a video at that resolution, due to weak video recording support. For those devices, the screencast will be downgraded to 720p. Or, you can attempt to specify the resolution, though you get odd results from the IDE if you try to specify a resolution that is not supported.

Clicking the “Start Recording” button will then start the screencast recording. The dialog that appears has a corresponding “Stop Recording” button. After clicking that, you will be given a “Save As” dialog to save the video wherever you like.

### Collecting from the Command Line

The same capabilities that Android Studio taps into to collect screenshots and screencasts graphically are also available to you from the command line, via `adb`. Since `adb` is in the `platform-tools/` directory of your Android SDK installation, if

that directory is in your PATH, you can run `adb` from any likely directory on your development machine.

### Screenshots

`adb shell screencap` captures a screenshot. This sounds easy enough.

The difficulty is that the screenshot is stored directly on the device or emulator, not on your development machine. This means that taking a screenshot is really a two-step process:

1. Capturing the screen to a PNG on the device
2. Moving that PNG from the device to your development machine

`adb shell screencap` takes the path for where the PNG should be saved on the device. Since we want to move that PNG to the development machine, it will be simplest if that path is pointing to external storage. What path you use will be tied to what version of Android you are running the `screencap` command on:

- Android 4.x/5.x: Use `/mnt/shell/emulated/0` as the base, which points to the root of external storage
- Android 6.0+: Use `/storage/emulated/0` as the base, which points to the root of external storage

You can then use `adb pull` to copy that PNG to your development machine, followed by `adb shell rm` to delete the copy that is on the device (to save space, remove clutter, etc.).

For example, the following script would take a screenshot on an Android 6.0 device or emulator and move it to your development machine into whatever the current working directory is:

```
adb shell screencap /storage/emulated/0/screenshot.png
adb pull /storage/emulated/0/screenshot.png .
adb shell rm /storage/emulated/0/screenshot.png
```

Note that the other effects handled by Android Studio, such as rotating the image, are not offered by the command-line interface. Instead, you would use your available image editing tools on your development machine to handle that.

### Screencasts

Similarly, `adb shell screenrecord` will record a screencast, saving it as a MP4 file on your device or emulator. And, once again, you will need to use something like `adb pull` to copy that MP4 to your development machine, perhaps followed by `adb shell rm` to remove the copy from the device.

`adb shell screenrecord` is a bit more configurable, though. In addition to the device path to the MP4 file, you can use command-line switches to change the nature of the recording:

- `--size` sets your desired resolution, overriding the default of 1280x720 if your resolution is supported. For example, use `--size 1920x1080` for a 1080p recording.
- `--bit-rate` sets the bit rate, as discussed in the earlier section about screencasts in Android Studio. This is expressed in *bits per second*, so `--bit-rate 8000000` would save at ~8Mbps.
- `--time-limit` will automatically stop the recording after the stipulated number of seconds, capped at a maximum value of three minutes (the equivalent of `--time-limit 180`). Alternatively, while the screencast is recording, press `Ctrl-C` to stop the recording.

For example, the following script would record a 30-second 1080p screencast on an Android 6.0 device or emulator and move it to your development machine into whatever the current working directory is:

```
adb shell screenrecord --size 1920x1080 --time-limit 30 /storage/emulated/0/
screencast.mp4
adb pull /storage/emulated/0/screencast.mp4 .
adb shell rm /storage/emulated/0/screencast.mp4
```

### Collecting from Another App

The three-minute limitation on screencasts, imposed by Android Studio and `adb shell screenrecord`, can be troublesome in some situations.

On Android 5.0 and higher devices, the media projection APIs allow authorized apps to take screenshots and record screencasts. These screencasts do not have an arbitrary time limitation. However, do bear in mind that the videos are stored on the device itself, so disk space can become an issue.

Various apps on the Play Store and elsewhere are available for “out of the box” screencast recording. On the open source front, Jake Wharton wrote and released Telecine, both in [a GitHub repository](#) and as [an app on the Play Store](#).

[Another chapter in this book](#) shows how you can use the media projection APIs, and one of the sample apps (andcorder) can be used akin to how you would use Telecine or `adb shell screenrecorder`.

## Tips and Tricks

Note that none of these approaches will record audio along with the video for the screencasts. You will need to use video editing software to add an audio track to the video, whether that comes in the form of a spoken-word voiceover, a soundtrack, or whatever.

While all of the techniques described here will work with devices and emulators, emulators need “Use Host GPU” enabled, at least for API Level 15+ emulators on Linux. Otherwise, your screenshots and screencasts turn out blank.

For screencasts designed to show users how to use an app, you may wish to enable “Show touches” in the Developer Options area of Settings. This will display a white dot where your finger touches the screen, to help illustrate where you are tapping, sliding, etc. Otherwise, the user may or may not be able to follow exactly what you are doing to cause the app to behave as shown.

# ADB Tips and Tricks

---

Several chapters in this book offer `adb` recipes for doing certain things at the command line. Having the `adb` binary in the `PATH` environment variable for your development machine is very handy, so you can run such commands from anywhere.

However, those other chapters only skim the surface of what sorts of `adb` commands there are and what they can be used for. Several others are presented here.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book, and that you know how to work on the command line.

## This is the Droid That You Are Looking For

`adb` works well, except when there is more than one visible Android environment, such as two devices, or a device and an emulator. Some commands — notably `adb devices` — work normally. Most other commands will complain that `adb` does not know which of the Android environments the command is supposed to act upon.

There are three switches you can include after `adb` and before the command that control what `adb` will use:

- `-d` says “use the device, there should only be one” (and if there is more than one, you get an error)
- `-e` says “use the emulator, there should only be one” (and if there is more than one, you get an error)
- `-s ...` says “use the environment whose serial number is ...”

That serial number is the value given in the `adb devices` command. For an actual device, the serial number usually is the real serial number. For an emulator, the serial number is `emulator-NNNN`, where `NNNN` is the value before the AVD name in the title bar of the emulator window. Frequently, that value starts with 5554 and increments by two for each subsequent running emulator. Hence, `-e` is roughly equivalent to `-s emulator-5554`.

## Installing and Uninstalling Apps

If you have an APK file that you wish to install — such as the APK edition of this book — you can do that at the command line via `adb install /path/to/the.apk`, where `/path/to/the.apk` is where the APK can be found on your development machine.

If the app already exists on the device or emulator, and you wish to replace it with this new APK, you will have to include the `-r` switch: `adb install -r /path/to/the.apk`. This indicates that you wish to reinstall the app.

`adb install` works if the APK in question was created with an eye towards this sort of manual installation, such as:

- Built using the “Build APK(s)” menu choice in Android Studio
- Built using the `assembleDebug` or `assembleRelease` tasks in Gradle

Starting with Android Studio 3.0, when you run your app from the IDE, while a copy of the APK will be left in your module’s `build/` directory, that copy [has a flag set that blocks it from being installed manually](#). While `adb install -t` can overcome this block, it is not particularly safe to assume that what Android Studio builds when you run the app from the IDE is safe to be manually installed, let alone distributed anywhere. Use the Gradle tasks or the “Build APK(s)” menu option to create safe APKs instead.

Conversely, `adb uninstall your.application.id` will uninstall the app identified by the application ID (`your.application.id`).

## Playing with Permissions

In an `adb install` command, you can include the `-g` switch to proactively grant all of the Android 6.0+ runtime permissions that ordinarily you would need to grant manually.

## ADB TIPS AND TRICKS

---

You can manually grant permissions via the `adb shell pm grant` command. This takes the application ID of your app and the fully-qualified name of the permission:

```
adb shell pm grant com.commonware.android.perm.tutorial android.permission.CAMERA
```

Similarly, you can use `adb shell pm revoke` to revoke a permission that was already granted to the app:

```
adb shell pm revoke com.commonware.android.perm.tutorial android.permission.CAMERA
```

These can be useful for testing purposes, either to save you some steps when testing manually, or to blend into automated tests. However, do not become overly reliant upon programmatic permission grants — you need to be sure that your permission flow works for the user, and the user is not going to be using `-g` switches or `adb shell pm grant` commands when using your app.

## Starting and Stopping Components

Given an installed app, you can trigger its activities, services, and broadcast receivers from the command line, using `adb shell` to run commands on the device or emulator.

The actual commands are simple:

- `adb shell am start ...` to start an activity
- `adb shell am startservice ...` to start a service
- `adb shell am broadcast ...` to send a broadcast

The challenge is in the `...` part, where you provide command-line switches to construct an Intent that will be used for those operations. Here are some common patterns:

- Simple implicit Intent with just an action string, use `-a` (e.g., `adb shell am start -a android.intent.action.VOICE_COMMAND`)
- Implicit Intent with a Uri, use `-a` and `-d` (e.g., `adb shell am start -a android.intent.action.VIEW -d https://commonware.com`)
- Implicit Intent with a different category, use `-a` and `-c` (e.g., `adb shell am start -a android.intent.action.MAIN -c android.intent.category.HOME`)
- Explicit Intent: use `-n` (e.g., `adb shell am start -n your.app.id/.YourActivity`)

There are [all sorts of command-line switches](#), for everything from flags to extras, that you can use to build up the Intent.

The [chapter on the media projection APIs](#) covers a sample screencast recorder, one that can be controlled using these sorts of commands. For example, to start the recording, the record shell script from the sample project uses:

```
adb shell am startservice -n
com.commonware.android.andcorder/.RecorderService -a
com.commonware.android.andcorder.RECORD
```

This starts the RecorderService, using an explicit Intent (-n) but also providing an action string (-a) to state what sort of command we are sending to the service.

## Killing Processes and Clearing Data

`adb shell am kill ...` will kill all processes associated with the application ID (...).

`adb shell am force-stop ...` will force-stop the app associated with the application ID (...), as if the user went into Settings and clicked the “Force Stop” button for the identified app.

`adb shell pm clear ...` will clear the data associated with the application ID (...), as if the user went into Settings and clicked the “Clear Data” button for the identified app. This will erase that app’s portion of internal storage, plus app-specific directories on external storage (e.g., `getExternalFilesDir()`).

## Changing Display Metrics

One reason why developers use emulators is because they lack hardware for device scenarios that they wish to test. Two such scenarios are screen size and density. Many developers have only a device or two to test against, and they may need to try out screen sizes and densities that their hardware does not offer directly.

However, if you have a device with a *higher* resolution or density, you can use `adb` to have the device fake operating as a lower-resolution or lower-density device.

Specifically, on Android 4.3 and higher, `adb shell wm size 1280x800` would tell an

## ADB TIPS AND TRICKS

---

Android device to pretend to have a WXGA800 display. You will see the smaller area centered within the overall device screen.

Note, though, that the device may no longer honor orientation changes by rotating the device. You will need to stipulate your size based upon the orientation that you are holding the device and the default orientation of the device itself.

For example, running the above command on a Nexus 9 gives you the following, regardless of whether the Nexus 9 is in portrait or landscape:

*Figure 929: 1280x800 Display Size, On a Nexus 9, Held in Landscape*

---

## ADB TIPS AND TRICKS

---

If you were planning on testing the Nexus 9 in portrait mode and wanted a landscape WXGA800 display, this is fine. More likely, you will need to change the order of your dimensions in the command. So, running `adb shell wm size 800x1280` gives you:

*Figure 930: 800x1280 Display Size, On a Nexus 9, Held in Landscape*

Here, at least, the device orientation matches the reduced-size screen orientation, if you were to hold the device in portrait mode.

If you prefer, you can use `dp` units instead, by appending `dp` after the values. Using `reset` instead of a resolution will return the device to its native resolution.

Similarly, `adb shell wm density 160` will have the device behave as though it has 160dpi screen density. This, however, starts to look a little strange, and you may find it difficult to completely understand what is going on, at least with third-party apps like the home screen. `adb shell wm density reset` returns the device to its natural screen density.

In 2015, Facebook announced [Stetho](#), “a new debugging platform for Android”. That description is more apt than you might think, in that Stetho allows you to examine your view hierarchy, see network requests, and otherwise analyze your project... using Chrome.

## Wait, Wut? Chrome?

Many modern Web browsers have Web client debugging tools, either built into the browser itself or available as an extension or other add-on. These tools can let you browse the content of the Web page, see network requests, and otherwise analyze the content of a browser tab.

Stetho leverages the Chrome Developer Tools, available in Chrome and Chromium, to have those tools examine an Android app, rather than a browser tab.

This works by way of Chrome Developer Tools’ support for remote debugging. Stetho basically embeds a small server in your app that speaks the same protocol that Chrome Developer Tools uses for remote debugging. From Chrome’s perspective, your Android app is just another Web browser. In reality, Stetho translates Chrome Developer Tools’ requests (e.g., “give me your DOM”) into things that would help an Android developer (e.g., “give me your view hierarchy”).

## Basic Stetho Integration

Stetho is not that hard to integrate, though Facebook’s documentation for it would have you ship Stetho in production in a release build, which is not an especially good idea.

## STETHO

---

The [Diagnostics/Stetho](#) sample project will show you how to hook Stetho up to your app, in a way that allows you to ship Stetho only in your debug builds. Overall, this app is yet another variant on the “show the latest android questions from Stack Overflow” introduced originally in [the chapter on Internet access](#). This particular one uses Retrofit 2.x and Picasso for the network requests... though as you will see, we have both of those libraries delegate the actual network I/O to OkHttp 3.x.

### Adding the Stetho Dependency

The official Stetho dependency is `com.facebook.stetho:stetho`, for some version (e.g., 1.5.0). However, if you want to allow Stetho to help you debug your network requests, you will need a different dependency, based on which HTTP client API you are using for those network requests:

HTTP Client API	Stetho Dependency
OkHttp	<code>com.facebook.stetho:stetho-okhttp</code>
OkHttp 3.x	<code>com.facebook.stetho:stetho-okhttp3</code>
HttpURLConnection	<code>com.facebook.stetho:stetho-urlconnection</code>

Those each have `com.facebook.stetho:stetho` as a transitive dependency, so you only need one Stetho dependency, based on your HTTP client API.

Specifically, we are using the `stetho-okhttp3` dependency, so we get Stetho plus its OkHttp 3.x support:

```
apply plugin: 'com.android.application'

dependencies {
    implementation "com.android.support:support-fragment:27.1.0"
    implementation 'com.squareup.picasso:picasso:2.5.2'
    implementation 'com.squareup.retrofit2:converter-gson:2.3.0'
    implementation 'com.squareup.okhttp3:okhttp:3.9.1'
    implementation 'com.jakewharton.picasso:picasso2-okhttp3-downloader:1.0.2'
    debugImplementation 'com.facebook.stetho:stetho-okhttp3:1.5.0'
}

android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'
```

```
defaultConfig {
    minSdkVersion 15
    targetSdkVersion 27
    applicationId "com.commonware.android.stetho"
}
}
```

(from [Diagnostics/Stetho/app/build.gradle](#))

We use `debugImplementation` so that these libraries are only used in debug builds, not release builds.

### Creating a Debug Sourceset

Ideally, as much of our Stetho-specific stuff as possible should *not* be in the main source set, as that is what ships to customers. Using `debugImplementation` keeps the Stetho dependencies out of a release build, but we are going to need some code to initialize and configure Stetho. That code, ideally, goes somewhere other than main.

As was covered in [the chapter on the Gradle project structure](#), we can have a debug source set, as a peer of main. Everything in debug will be merged into our project for a debug build but will be ignored with a release build. So, other than the `debugImplementation` statements in `app/build.gradle`, the rest of our Stetho stuff will go into debug.

### Adding the Stetho Application

Stetho requires some initialization work, and Facebook recommends that this be done in a custom `Application` object. This is a process-wide singleton, initialized when our process is forked, and so it is good for one-time, process-scope initialization work.

However, we really want this to be in the debug source set, and that requires a little bit of work.

### The Main Application

Over in the main source set, we have an `App` class that extends `Application` and provides initialization for all build types:

```
package com.commonware.android.stetho;
```

## STETHO

---

```
import android.app.Application;
import okhttp3.OkHttpClient;

public class App extends Application {
    private OkHttpClient ok;

    @Override
    public void onCreate() {
        super.onCreate();

        ok=buildOkBuilder().build();
    }

    OkHttpClient getOk() {
        return(ok);
    }

    protected OkHttpClient.Builder buildOkBuilder() {
        return(new OkHttpClient.Builder());
    }
}
```

(from [Diagnostics/Stetho/app/src/main/java/com/commonsware/android/stetho/App.java](#))

Here, we are initializing an app-wide instance of `OkHttpClient`, to be used for our network requests. In other incarnations of this sample app, we either create the `OkHttpClient` directly in `QuestionsFragment` (where the network I/O is triggered) or are not using `OkHttp` at all. Here, we are doing this at the process level, for two reasons:

1. For a more complex app, where you are doing network I/O in several places, you may want a single `OkHttpClient` instance with all of your configuration.
2. Stetho needs access to the `OkHttpClient`, if we want it to report on network access. And, we need to use that same Stetho-configured `OkHttpClient` for all our network access that we want Stetho to report.

Note that we have a protected method, `buildOkBuilder()`, that sets up the `OkHttpClient.Builder` that we use to create the `OkHttpClient` instance. We will see that method again shortly... in a Stetho-specific subclass.

The main edition of the manifest then says that we should use `App` by setting `android:name` on `<application>`:

```
<?xml version="1.0" encoding="utf-8"?>
```

## STETHO

---

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.commonware.android.stetho"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.INTERNET" />

  <application
    android:allowBackup="false"
    android:name="com.commonware.android.stetho.App"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/Theme.Apptheme">
    <activity
      android:name="com.commonware.android.stetho.MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
</manifest>
```

(from [Diagnostics/Stetho/app/src/main/AndroidManifest.xml](#))

This causes Android to create an instance of App, instead of the standard Application class, as the process-wide singleton.

### The Debug Application

Over in the debug source set, we have a StethoApp class that extends the App class from the main source set:

```
package com.commonware.android.stetho;

import com.facebook.stetho.Stetho;
import com.facebook.stetho.okhttp3.StethoInterceptor;
import okhttp3.OkHttpClient;

public class StethoApp extends App {
    @Override
    public void onCreate() {
        super.onCreate();

        Stetho.initializeWithDefaults(this);
    }
}
```

## STETHO

---

```
@Override
protected OkHttpClient.Builder buildOkBuilder() {
    return(super.buildOkBuilder().addNetworkInterceptor(new StethoInterceptor()));
}
}
```

(from [Diagnostics/Stetho/app/src/debug/java/com/commonsware/android/stetho/StethoApp.java](#))

debug source set classes can “see” those in main, which is why we can successfully subclass App.

Here, in `onCreate()`, we initialize Stetho with a default configuration, using `initializeWithDefaults()`. If all we wanted was basic Stetho integration, without network call tracking, this would be all that we need.

To integrate network tracking, you need some additional code, based on the particular HTTP client API that you are using. We pulled in the `stetho-okhttp3` dependency and are using `OkHttp3`, so we need to add an `OkHttp` network interceptor. Such an interceptor is called on each network request, for cross-cutting concerns like logging.

So, we override `buildOkBuilder()`, call `addNetworkInterceptor()` to add a `StethoInterceptor` to the interceptor chain, and return the modified `OkHttpClient.Builder`. Now, when App uses `buildOkBuilder()`, it will pull in our subclass override... if the Application singleton for our process is a `StethoApp`, instead of an `App`.

### Overriding the Application

That requires us to teach a manifest to use `StethoApp`, in the same way that we modified the main source set’s manifest to use `App`. The debug source set can have its own manifest, and that manifest can override certain settings from main:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:tools="http://schemas.android.com/tools"
    package="com.commonsware.android.stetho"
    android:versionCode="1"
    android:versionName="1.0">

    <application
        android:name="com.commonsware.android.stetho.StethoApp"
        tools:replace="android:name">
    </application>
```

## STETHO

---

```
</manifest>
```

(from [Diagnostics/Stetho/app/src/debug/AndroidManifest.xml](#))

Here we tell Android to use StethoApp for the singleton (via the same `android:name` attribute on the `<application>` element). And, via `tools:replace`, we tell the build tools to use *our* definition for `android:name`. Otherwise, the build will fail, as there is a conflict between what the main manifest has (App) and what the debug manifest has (StethoApp).

The “Merged Manifest” tab in Android Studio shows that our resulting `android:name` attribute for a debug build uses StethoApp:

*Figure 931: Merged Manifest for Debug Build, Showing StethoApp*

## STETHO

If we use Android Studio's Build Variants view to switch to the release build, now the merged manifest shows that the regular App class will be used:

*Figure 932: Merged Manifest for Release Build, Showing No StethoApp*

So, we have achieved our objective: use Stetho in debug builds but not in release builds.

So, with all that, let's see what Stetho actually gives us.

## Connecting Chrome to Your App

With your app running on an emulator, or on a device connected to your development machine, open up Chrome or Chromium and visit `chrome://inspect/#devices`. This should bring up a page that shows you the available “remote targets”, which should include your Stetho-enabled app:

Figure 933: Chrome Developer Tools, Showing Remote Targets

While a square that resembles an unchecked checkbox appears next to your app, that seems to have no use. Instead, click the “inspect” link below your app to bring up the Chrome Developer Tools on your Stetho-enabled app.

## What You Get In Chrome Dev Tools

Not every tool in Chrome Developer Tools is populated by Stetho. So, for example, the “Sources” and “Timeline” tools will remain empty. However, some of the other tools will give you insights into your app, courtesy of Stetho:

### Elements: View Hierarchy

The “Elements” tool is roughly comparable to Android Studio’s Layout Inspector or the `uiautomator` tool. It allows you to examine the view hierarchy of your UI.

## STETHO

However, since the Elements tool is designed for examining HTML and Web pages, the view hierarchy is represented in the form of pseudo-HTML elements:

Figure 934: Elements Tool, Showing Stetho Sample UI Elements

The rules for HTML elements are akin to the rules for layout XML resources:

- If the view is from a well-known package, like `android.widget`, the HTML element uses the bare class name
- Otherwise, the HTML element uses the fully-qualified class name

However, these are converted into all lowercase, since HTML elements are not case-sensitive. This takes a bit of getting used to.

## STETHO

The Styles tab on the right will show common properties of the highlighted view, represented as if they were CSS styles (e.g., is-enabled). The rightward-pointing caret in tabs on the right has a “Properties” option. Selecting will give you a dump of all of the fields inside of the highlighted view, presumably obtained via Java reflection APIs:

Figure 935: Elements Tool, Showing Properties of a Stetho Sample UI Element

Also, on your Android device or emulator, the view that you select in the Elements tool gets a tint applied to it, akin to how the Layout Inspector and `uiautomatorviewer` tint the regions of the screenshot shown in each of those tools. This helps you to identify exactly what widget or container the highlighted element refers to.

## Network: HTTP Requests

The “Network” tool, for a standard Web page, shows all of the HTTP requests that were made in support of rendering that Web page. With Stetho, that tool shows the HTTP requests made by your app... that went through whatever API you configured when you set up Stetho. In the sample app, we configured a particular `OkHttpClient` to use a Stetho-supplied network interceptor. So, if we click the refresh action bar item — forcing a fresh set of network calls – we will see those in the network tool:

Figure 936: Network Tool, Showing HTTP Requests from Sample App Refresh

some key details (e.g., size):

Figure 939: Network Tool, Showing Image Response

## Screencast: Your UI, Mostly

The button in the upper-right of the Dev Tools window, that looks like a phone, will open up the “Screencast” pane:

Figure 940: Stetho Screencast

This shows a semi-live edition of your UI. It has occasional hiccups, particularly with scrollable content, but generally works.

## Resources: In-Place Database CLI

The Resources tool gives you access to your SQLite databases, assuming that they are stored in the default location used by SQLiteOpenHelper.

Alas, our earlier sample app has no database.

The [Diagnostics/StethoDB](#) sample project is a clone of one of [the database samples](#), where we are storing some gravity constants culled from SensorManager in a database table as starter data, and we allow the user to add more constants.

This time, though, we add the same basic debug/ source set as was used in the Diagnostics/Stetho sample. In this case, the StethoApplication extends Application (as the main app has no custom Application class) and only initializes Stetho itself:

```
package com.commonware.android.stetho;

import android.app.Application;
import com.facebook.stetho.Stetho;

public class StethoApp extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        Stetho.initializeWithDefaults(this);
    }
}
```

(from [Diagnostics/StethoDB/app/src/debug/java/com/commonware/android/stetho/StethoApp.java](#))

We also have two different Stetho dependencies. One is just `com.facebook.stetho:stetho`, which is the base Stetho artifact. We also load in `com.facebook.stetho:stetho-js-rhino`, which enables the JavaScript console, as we will see [later in this chapter](#). Since this sample app is not doing any network I/O — let alone with OkHttp3 — we do not need the `com.facebook.stetho:stetho-okhttp3` artifact.

## STETHO

In the Resources tool, you can expand the “Web SQL” tree to see all of your databases. Expanding a database brings up the tables in that database, and clicking on a table shows you its current contents:

Figure 941: Resources Tool, Showing Constants Table Content

Clicking on the database name itself (e.g., constants.db) in the tree brings up an interactive SQL utility, akin to the `sqlite3` command-line tool. You can execute arbitrary SQL statements and see their results:

Figure 942: Resources Tool, Showing Interactive SQL

This is all using your live database on the device or emulator. This is much more

## STETHO

---

convenient than using `adb shell run-as` commands to pull a SQLite database off of production hardware and then opening it in some other SQLite utility.

### Console: Example Environment via JavaScript

The `com.facebook.stetho:stetho-js-rhino` is completely optional. And, if you add it, it will expand your APK by a fair bit (around 1MB and over 6,000 methods). However, it adds an interesting feature: JavaScript access to your Application object, via the Dev Tools' Console.

The context synthetic JavaScript global object is your custom Application, and you can interact with it using the Rhino JavaScript-on-Java interpreter. The return value of any JavaScript expression will be whatever the Java code returns, or "undefined" for void methods.

Just typing in context allows you to inspect the contents of your custom Application:

*Figure 943: Console Tool, Inspecting the Application Context*

`importPackage()` works akin to how `import` does in traditional Java code, to allow you to reference classes from other packages. Anything that can be reached via your custom Application, or via some static field, can be done, such as sending a broadcast:

Note: use `Shift-Enter` to write multiple lines of JavaScript code without executing them, until you press `Enter` after the last line.

## Getting Help with Stetho

The [Stetho Web site](#) and [its corresponding GitHub repository](#) appear to be your primary places for getting assistance with Stetho.

## Hey, What About Sonar?

In 2018, Facebook debuted their next generation of this sort of debugging tool, called [Sonar](#). Sonar has a few advantages over Stetho:

- It works with iOS and Android
- It has a dedicated desktop client, rather than having to try to cram everything into Chrome Dev Tools' UI
- It has a richer plugin mechanism

However, as of its debut, it had significant limitations:

- The desktop client only works with macOS (though, since it is based on Electron, there is hope for Windows and Linux clients in the future)
- It offers a subset of Stetho's debugging tools, as it slowly builds out its functionality
- Creating a plugin requires implementing both the mobile side and the Electron UI for the tool side

## STETHO

---

In the long term, Sonar is likely to supplant Stetho.

---

## **Trail: Tuning Android Applications**

---

# Issues with Speed

---

Mobile devices are never fast enough. Either they are slow in general (e.g., slow CPU) or they are slow for particular operations (e.g., advanced game graphics).

What you do not want is for your application to be unnecessarily slow, where the user determines what is and is not “necessary”. Your opinion of what is “necessary”, alas, is of secondary importance.

This part of the book will focus on speed, including how you can measure and reduce lag in your applications. First, though, let’s take a look at some of the specific issues surrounding speed.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## Getting Things Done

In some cases, you simply cannot seem to get the work done that you want to accomplish. Your database query seems slow. Your encryption algorithm seems slow. Your image processing logic seems slow. And so on.

The limits of the device will certainly make this more of a problem than it might otherwise be. Even a current-era multi-core device will be slow compared to your average notebook or desktop, as mobile CPUs cannot readily be directly compared to desktop and notebook CPUs. Also, this sort of speed issue is pervasive throughout computing, with decades of experience to help developers learn how to write leaner

code.

This part of the book will aim to help you identify where the problem spots are, so you know what needs optimization, and then some Android-specific techniques for trying to improve matters.

## Your UI Seems... Janky

Sometimes, the speed would be less of an issue for the user, if it was not freezing the UI or otherwise making it appear sluggish and “[janky](#)”.

The Android widget framework operates in a single-threaded mode. All UI changes — from setting the text of a `TextView` to handling scrolling of a `GridView` — are processed as events on an event queue by the main application thread. That same thread is used for most UI callbacks, including activity lifecycle methods (e.g., `onCreate()`) and UI event methods (e.g., `onClick()` of a `Button`, `getView()` of an `Adapter`). Any time you take in those methods on the main application thread tie up that thread, preventing it from processing other GUI events or dispatching user input. For example, if your `getView()` processing in an `Adapter` takes too long, scrolling a `ListView` may appear slow compared to other `ListView` widgets in other applications.

Your objective is to identify where things are slow and move them into background operations. Some of this has been advised since the early days of Android, such as moving all network I/O to background threads. Lots of work has gone into providing libraries for you to be able to easily move common tasks, like loading images, onto background threads.

This part of the book will point out ways for you to find out where you may be doing unfortunate things on the main application thread and techniques for getting that work handled by a background thread, or possibly eliminated outright.

## Not Far Enough in the Background

Sometimes, even work you are trying to do in the background will seem to impact the foreground.

For example, you might think that your `Service` is automatically in the background. An `IntentService` does indeed use a background thread for processing commands via `onHandleIntent()`. However, all lifecycle methods of any `Service`, including

`onStartCommand()`, are called on the main application thread. Hence, any time you take in those lifecycle methods will steal time away from GUI processing for the main application thread. The same holds true for `onReceive()` of a `BroadcastReceiver` and all the main methods of a `ContentProvider` (e.g., `query()`).

Even your background threads may not be sufficiently in the background. A process runs with a certain priority, using Linux process management APIs, based upon its state (e.g., if there is an activity in the foreground, it runs at a higher priority than if the process solely hosts some service). This will help to cap the CPU utilization of the background work, but only to a point. Similarly, threads that you fork — directly or via something like `IntentService` — may run at default priority rather than a lower priority. Even with lower priorities for the thread or process, every CPU instruction executed in the background is one clock tick that cannot be utilized by the foreground.

This part of the book will help you identify where you are taking lots of time on various threads and will help you manually manage priorities to help minimize the foreground impact of those threads, in addition to helping you reduce the amount of work those threads have to do.

## Playing with Speed

Games, more so than most other applications, are highly speed-dependent. Everyone is seeking the “holy grail” of 60 frames per second (FPS) necessary for smooth animated effects. Not achieving that frame rate overall may mean the application will not appear quite as smooth; sporadically falling below that frame rate will result in jerky animation effects, much like the “janky” UIs in a non-game Android application.

For example, a classic problem with Android game development is garbage collection (GC). The original Android garbage collector was a “stop the world” implementation, that would freeze the game long enough for a bit of GC work to be done before the game could continue. This behavior pretty much guaranteed sporadic failures to maintain a consistent frame rate. This caused game developers to have to take particular steps to avoid generating any garbage, such as maintaining its own object pools, to minimize or eliminate garbage collection pauses. While Android 2.3 and beyond have taken steps to have garbage collection be more concurrent, there are still short pauses (1-2ms, typically), where all threads have to be suspended to wrap up the GC run.

## **ISSUES WITH SPEED**

---

This book does not focus much on specific issues related to game development, though many of the techniques outlined here will be relevant for game developers.

# Finding CPU Bottlenecks

---

CPU issues tend to manifest themselves in three ways:

- The user has a bad experience when using your app directly — scrolling is sluggish, activities take too long to display, etc.
- The user has a bad experience when your app is running in the background, such as having slower frame rates on their favorite game because you are doing something complex in a service
- The user has poor battery performance, driven by your excessive CPU utilization

Regardless of how the issue appears to the user, in the end, it is a matter of you using too much CPU time. That could be simply because your application is written to be constantly active (e.g., you have an everlasting service that uses `TimerTask` to wake up every second and do something). There is little anyone can do to help that short of totally rethinking the app's architecture (e.g., switch to `AlarmManager` and allow the user to configure the polling period).

However, in many cases, the problem is that you are using algorithms – yours or ones built into Android — that simply take too long when used improperly. This chapter will help you identify these bottlenecks, so you know what portions of your code need to be optimized in general or apply the techniques described in later chapters of this part of the book.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

## Android Studio's Profiler

In Android Studio, the Android Profiler tool allows you to examine the real-time behavior of your app with respect to various system resources, such as the CPU.

### Opening the Profiler

If one or more debuggable processes are running on an attached device or an emulator, the Android Profiler tool will appear as an option on the bottom dock:

Figure 945: Android Studio Bottom Tool Dock, Showing Android Profiler

Opening the profiler will give you a real-time look at the consumption of CPU, heap space, and network associated with your process:

Figure 946: Android Profiler

The top area will show a green bar when your UI is in the foreground, with a note as to what activity of yours is in the foreground. Purple dots show when you have received user input, such as taps on buttons.

### Manipulating the Profiler

Across the top, there are:

- Drop-downs to choose the device and process that you are profiling
- A close button to close this tool
- Buttons to zoom in, zoom out, or reset the zoom to its default level
- A “Live” button that serves to pause the results or, from a paused state, resume normal real-time output

Hovering your mouse over a portion of the graph will show you the specific value at that point in time for the particular metric you are hovering over:

---

## FINDING CPU BOTTLENECKS

---

Clicking on the CPU graph at any point shows you more details about the per-thread CPU utilization:

Figure 948: Android Profiler, Showing Per-Thread CPU Usage

## Hey, Why Is My App Running So Slow Now?

Depending on the nature of your app, you may find that the profiler dramatically slows down your app.

Use the “End Session” button to close the profiler, and your app should return to normal.

## Method Tracing

The #1 tool in your toolbox for finding out where bottlenecks are occurring in your application is method tracing. This will record your code and how long it takes your various methods to do their work. You can use this to look for outliers:

- Methods that are called way too frequently
- Methods that call other methods way too frequently

- Methods that take a lot of time in their own statements, including things like blocking on I/O

### OK, What Is Method Tracing, Really?

Technically, the method tracing in Android is performed by the virtual machine, under the direction of either your IDE or requests from your application code. Dalvik or ART will write the “trace data” (call graphs showing methods, what they call, and the amount of time in each) to a file on external storage of the device or emulator. Your IDE then views these trace files in a GUI, allowing you to visualize “hot spots”, drill down to find where the time is being taken, and so forth.

### Collecting Trace Data

Hence, the first step for finding where your CPU bottlenecks lie comes in the form of collecting trace data for analysis. As mentioned, there are two approaches for requesting trace data be logged: using the `Debug` class, and using your IDE.

#### Debug Class

If you know what chunk of code you want to profile, one way to arrange for the profile is to call `startMethodTracing()` on the `Debug` class. This takes the name of a trace file as a parameter and will begin recording all activity to that file, stored in the root of your external storage. You need to call `stopMethodTracing()` at some point to stop the trace — failing to do so will leave you with a corrupt trace file in the end.

Note that your application will need the `WRITE_EXTERNAL_STORAGE` permission for this to work. If your application does not normally need this permission, make yourself a note to remove it before you ship the production edition of your product, as there is no sense asking for any more permissions than you absolutely need. Or, put this permission in a debug source set’s manifest in Android Studio, and then it will only be included in debug builds.

Also, your device or emulator will need enough external storage to hold the file, which can get very large for long traces — 100MB a minute is well within reason.

#### Android Studio

On the per-thread details view of the Android Profiler’s CPU graph, there is a red dot with a drop-down list to the left of it. This allows you to start method tracing

## FINDING CPU BOTTLENECKS

took compared to the other tiny boxes. Method calls are denoted by tiny boxes beneath a method's tiny box.

The “flame chart” is more or less the same perspective, just upside-down:

Figure 950: Method Tracing, Flame Chart, As Initially Launched

In both cases, your mouse scroll wheel can expand those tiny boxes to make them somewhat wider, but the font is extremely small, and there is no search facility to find anything in it.

Instead, switch over to the “Top Down” tab, which starts to become a bit more useful:

Figure 951: Method Tracing, “Top Down” Table, As Initially Launched

Here, you see the tree of method calls represented as a more classic tree, with an actually readable font.

The “Bottom Up” tab is even more useful, showing a simple table of all the distinct

## FINDING CPU BOTTLENECKS

methods that were called:

Name	Self (µs)	%	Children (µs)	%	Total (µs)	%
nativePollOnce() (android.os.MessageQueue)	109,775	11.48%	119,027	12.45%	228,802	23.93%

Figure 952: Method Tracing, “Bottom Up” Table, As Initially Launched

The two tables not only show methods and their classes, but also:

- How much time was taken directly in the method body for that method (“Self”)
- How much time was taken by methods called by the method (“Children”)
- How much total time was taken by the method, which is the sum of the first two columns (“Total”)

The values are shown in microseconds and as a percentage of the total.

What you are looking for are:

- References to your own classes and methods
- References to classes and methods from libraries that you are using
- Odd stuff that you do not recognize from previous examinations of this sort of method trace

If those sorts of things are taking significant time, as a percentage of the total, those are areas to investigate further:

- Are they being called too frequently?
- Are they intrinsically expensive?

## Other General CPU Measurement Techniques

While method tracing can be useful for narrowing down a general performance issue

to a specific portion of code, it does assume that you know approximately where the problem is, or that you even have a problem in the first place. There are other approaches to help you identify if and (roughly) where you have problems, which you can then attack with method tracing to try to refine.

### Logging

Method tracing can be useful, if you have a rough idea of where your performance problem lies and need to narrow it down further. If you have a large and complicated application, though, trying to sift through all of it in method tracing may be difficult.

However, there is nothing stopping you from using good old-fashioned logging to get a rough idea of where your problems lie, for further analysis via method tracing. Just sprinkle your code with `Log.d()` calls, logging `SystemClock.uptimeMillis()` with an appropriate label to identify where you were at that moment in time. “Eyeballing” the Logcat output can illustrate areas where unexpected delays are occurring — the areas in which you can focus more time using method tracing.

A useful utility class for this is `TimingLogger`, in the `android.util` package. It will collect a series of “splits” and can dump them to Logcat along with the overall time between the creation of the `TimingLogger` object and the corresponding `dumpToLog()` method call. Note, though, that this will only log to Logcat when you call `dumpToLog()` — all of the calls to `split()` to record intermediate times have their results buffered until `dumpToLog()` is called. Also note that logging needs to be set to `VERBOSE` for this information to actually be logged — use the command `adb shell setprop log.tag.LOG_TAG VERBOSE`, substituting your log tag (supplied to the `TimingLogger` constructor) for `LOG_TAG`.

### FPS Calculations

Sometimes, it may not even be strictly obvious how bad the problem is. For example, consider scrolling a `ListView`. Some performance issues, like sporadic “hiccups” in the scrolling, will be visually apparent. However, absent those, it may be difficult to determine whether your particular `ListView` is behaving more slowly than you would expect.

A classic measurement for games is frames per second (FPS). Game developers aim for a high FPS value — 60 FPS is considered to be fairly smooth, for example. However, this sort of calculation can only really be done for applications that are

continuously drawing – such as [Romain Guy's WindowBackground sample application](#). Ordinary Android widget-based UIs are only drawing based upon user interaction or, possibly, upon background updates to data. In other words, if the UI will not even be trying to draw 60 times in a second, trying to measure FPS to get 60 FPS is pointless.

You may be able to achieve similar results, though, simply by logging how long it takes to, say, fling a list (use `setOnScrollListener()` and watch for `SCROLL_STATE_FLING` and other events).

## UI “Jank” Measurement

A user interface is considered “janky” if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Sometimes, janky behavior is obvious to all. Sometimes, janky behavior is only noticeable to those sensitive to small hiccups in the UI.

This section will outline what “jank” is and how to determine, concretely, if your UI suffers from it.

### What, Exactly, is Jank?

Prior to Android 4.0, it was difficult to come up with a concrete definition of jank. In effect, we were stuck with [“I know it when I see it”](#) ad-hoc analysis, rather than being able to rely on concrete measurements.

Project Butter changed that.

Android 4.0 ties all graphic operations to a 60 frames-per-second “vsync” frequency. If everything is working smoothly, your UI will update 60 times per second, uniformly (versus varying amounts of times between changes).

The converse is also true: if everything is not working smoothly, your UI will not update 60 times per second. This is the source of the term “dropped frames”: when the time came around for an update, you were not ready, and that frame was skipped.

There are two main ways in which you will drop a frame:

1. You spend too much time on the main application thread, preventing

## FINDING CPU BOTTLENECKS

---

- Android from processing your requested UI updates in a timely fashion
2. Your UI changes are too complex to be rendered before time runs out for the current frame, causing your changes to spill over into the next frame

Each frame is ~16ms in duration on-screen (1/60th of a second). Hence, if we cause per-frame work to exceed 16ms, we will skip, or “drop”, a frame.

So, what we need is some way to determine if our code is actually delivering frames on time.

### Using gfxinfo

To determine if our problem is in the actual rendering of our UI updates, we can use the GPU profiling feature added in Android 4.2.

### Enabling Developer Options

To toggle on GPU profiling, you will need to be able to get to the Developer Options portion of your Settings app. If you see this — typically towards the bottom of the list on the initial Settings screen — just tap on the entry.

If, however, Developer Options is missing, then you will need to use the super-secret trick for enabling Developer Options:

1. Tap on “About Phone”, “About Tablet”, or the equivalent at the bottom of your Settings list
2. Tap on the “Build Number” entry seven times in succession
3. Press BACK, and “Developer Options” should now be in the list

### Toggling on GPU Profiling

There are two checkboxes in Developer Options that need to be checked for GPU profiling to be enabled.

The first is “Force GPU rendering”, in the Drawing section. As the name suggests, this will force your application to use the GPU for drawing, even if your application may have requested that hardware acceleration be disabled. Since most applications do not force hardware acceleration to be disabled, this checkbox probably will have no real effect on your app. Note that if you disabled hardware acceleration due to specific rendering problems, this checkbox will probably cause those rendering

## FINDING CPU BOTTLENECKS

---

artifacts to re-appear during your testing.

The second is “Profile GPU rendering”, in the Monitoring section. This will cause the device to keep track of graphics performance on a per-process basis, in a way that we can dump later on.

*Figure 953: Developer Options, Showing “Force GPU rendering” and “Profile GPU rendering”*

If your app was already running, you will need to get rid of its process (e.g., via swiping it off the recent-tasks list) after you check the “Profile GPU rendering” checkbox. At the present time, whether or not this profiling takes effect is determined at process startup time and is not changed on the fly when you toggle the checkbox. Besides, starting with a fresh process should give you more accurate results.

### Collecting Data

At this point, you can run your app and conduct your specific test, whether manually or via instrumentation (e.g., a targeted [JUnit test suite](#)).

When complete, run `adb shell dumpsys gfxinfo ...` in a terminal window, where

## FINDING CPU BOTTLENECKS

---

... is replaced by the package name of your app (e.g., `com.commonware.android.anim.threepane`). This will dump a fair amount of information to the terminal display:

We will discuss what this means in just a bit.

### Disabling GPU Profiling

When you are done with your test, it is a good idea to undo the settings changes you made, at least “Profile GPU rendering”. That way, the act of collecting this data does not itself add overhead to unrelated tests in the future.

### Analyzing the Results

The key bit for our performance analysis is that long table labeled “Profile data in ms:”. This reports, for a series of UI requests, how much time is spent:

- drawing your UI changes (e.g., `onDraw()` calls to various widgets and containers)
- processing the low-level drawing commands created via the draw phase, to create the contents of the frame
- executing the frame, sending it to the compositor to display on the screen

One way to interpret this table is to paste it into your favorite spreadsheet program, then use that program to draw a stacked column chart of the data. You can

## FINDING CPU BOTTLENECKS

---

[download a spreadsheet](#) in ODS format (for use with LibreOffice, OpenOffice, or other tools that can handle that format) that contains the above table along with a stacked column chart:

What you are looking for are columns that come close to, or exceed, the 16ms mark, with milliseconds on the Y axis. As you can see, many operations towards the end of the table are near or above 16ms, indicating that we are probably dropping some frames.

### Using systrace

Another way we could determine whether or not we are dropping frames is to use systrace to collect system-level tracing information about the entire device, including our app.

systrace is a very powerful tool, one that few people truly understand, due to cryptic output and limited documentation. Using gfxinfo for detecting dropped frames is simple by comparison.

Using systrace involves collecting a trace, which is saved in the form of an HTML file. The HTML file is then used to determine what went on during the period of the trace itself.

### Enabling and Collecting a Trace: Command-Line

The original means of using `systrace` was from the command line. There is a `systrace.py` Python script located in the `platform-tools/systrace/` directory of your SDK installation. If you have a Python interpreter (e.g., your development machine does not run Windows), you can use this approach.

To indicate what specific bits of information to collect, on Android 4.2 and higher, you can tap the “Enable traces” entry in the Monitoring section of the Developer Options page in Settings. This displays a multi-select dialog of the possible major categories of information that `systrace` should collect:

Figure 955: “Enable traces” In Settings

Alternatively, when you run the `systrace.py` script, you can include the `--set-tags` switch, with a comma-delimited list of specific traces (“tags”) that you want to collect. The list of available tag names can be found in [the developer documentation](#).

To actually collect the trace, you run the `systrace.py` script, optionally with `--set-tags` or other command-line switches.

## FINDING CPU BOTTLENECKS

---

On Android 4.1 and 4.2, this would look like:

```
python systrace.py --set-tags gfx,view,wm
adb shell stop
adb shell start
python systrace.py --time=10 -o trace.html
```

The first `python` command runs `systrace.py` just to set the tags to collect. If you set them using Developer Options in Settings, this would not be required. Restarting `adb shell` is apparently needed, for unclear reasons. The second `systrace.py` run will actually collect the trace, for 10 seconds (`--time=10`), resulting in report written to `trace.html` in the current working directory (`-o trace.html`).

The syntax changed for Android 4.3 and higher to simplify matters, combining the two `systrace.py` commands into one:

```
python systrace.py --time=10 -o trace.html gfx view sched wm
```

Note that `--set-tags` is no longer used. Instead, all values not identified by a switch are considered to be tags.

Once you run the script, quickly go to your device and run your test scenario, as the trace starts immediately upon running the script.

### Collecting Traces on Android 9.0 Devices

On Android 9.0 devices, collecting systrace traces is a bit easier, courtesy of some on-device options. If you go into Settings > Developer Options > Debugging, you will find a “System Tracing” option that is your gateway to systrace, as a replacement for the “Enable traces” option on prior Android versions:

*Figure 956: System Tracing in Developer Options*

## FINDING CPU BOTTLENECKS

---

Tapping that item brings up a dedicated screen for configuring systrace:

*Figure 957: System Tracing Settings in Developer Options*

Principally, you will want to toggle the “Record trace” switch to be on when you want to start collecting a trace. This will also bring up a notification to allow you to stop the trace collection. Tapping that notification not only stops the trace collection, but it also raises another notification, which you can tap to use `ACTION_SEND` to transfer the `.ctrace` file off of the device using your preferred app. Alternatively, to get the trace file off of the device, use `adb pull`. Ideally, you would be able to get it via Android Studio’s Device File Explorer, but there is [a bug](#) that prevents this.

Then, to convert the `.ctrace` file that you get into an HTML report, use `systrace.py` akin to above:

```
python systrace.py --from-file /path/to/your.ctrace
```

(where `/path/to/your.ctrace` is the path to the `.ctrace` file that you obtained from the device)

If you plan on collecting traces frequently this way, you might consider toggling the “Show Quick Settings Tile” switch in the “System Tracing” screen in the Developer

---

## FINDING CPU BOTTLENECKS

---

Options. This will add a tile to your notification shade, for one-tap starting and stopping of trace collection:

Figure 958: System Tracing Quick Settings Tile

### Choosing the Trace Tags

All of these instructions have been telling you to specify what systrace tags to collect when you collect the trace data. So, what should you collect?

The big four are:

- sched for CPU scheduling
- gfx for graphics
- view for widget rendering
- wm for window management

Apps using WebView might consider the webview tag. There are [a variety of other tags](#) as well that you might find useful for one analysis or another. However, be careful not to request “everything but the kitchen sink”, as it may make your reports difficult to interpret.

---

## FINDING CPU BOTTLENECKS

---

Also note that not all devices support all tags. `python systrace.py --list-categories` should tell you what is possible for your connected device.

Android 9.0 users can choose these options via the “Categories” item in the “System Tracing” screen in the Developer Options:

*Figure 959: System Tracing Categories/Tags in Settings*

### Augmenting the Trace from Java

You can effectively add your own tag to the output in Java code, to flag key sections of application processing and see where they fall in the report’s timeline. To do this:

- Add calls to `Trace.beginSection()` and `Trace.endSection()` in your API Level 18+ app. Here, `Trace` is `android.os.Trace`, and `beginSection()` takes a `String` parameter that you would like to have logged. Note that these calls can nest, so you can have one section inside of another, but `endSection()` closes the last-begun section. Hence, make sure that your `beginSection()` and `endSection()` calls match up, typically by using `try/finally` exception handling. Also, your `beginSection()` and `endSection()` calls must match up in terms of threads — you cannot begin a section on one thread and end it on another.

## FINDING CPU BOTTLENECKS

---

- Add the `--app` switch to name your application's package if you are running `systrace` from the command line.

### Viewing and Interpreting the Results

What you get as output is an HTML file that can be viewed in the Chrome browser, though you will tend to want to use a development machine for this instead of, say, an Android tablet. That is because the navigation of the Web page is designed for use with a hardware QWERTY keyboard, which most Android devices lack.

You can find [a sample trace](#) from a Nexus 7 online, though note that the HTML is a bit large and may take a few seconds to download. Initially, you will see something like this:

*Figure 960: Systrace Output, As Initially Viewed*

The left-hand sidebar represents various categories (or “slices” or “tags” or whatever) of data collected by `systrace`. The main area shows a timeline for the test, with rows corresponding to the sidebar entries for what was occurring at the various times for that particular category. The bottom pane will hold details that will appear when you click on various little blocks within that timeline.

## FINDING CPU BOTTLENECKS

Mostly, your navigation will use the W, A, S, and D keys, presumably chosen to make it appear as though you are playing a video game. Specifically:

- W will zoom in the timeline, while S will zoom out
- A and D will pane the timeline left and right

Jank will show up as gaps in the SurfaceFlinger:

*Figure 961: Systrace Output, Zoomed In on 0.7 Seconds of Profiling*

Each of the major ticks across the timeline represents 0.1 seconds. There should be six frames in those seconds. However, we can see that in the 3.4-3.5 second range, there is a dropped frame, which shows up as a gap where there should be a pulse of SurfaceFlinger activity.

## FINDING CPU BOTTLENECKS

Zooming in further starts to bring up some detail for the threads in our process, showing methods within the view processing hierarchy that we were working on during this period of time:

*Figure 962: Systrace Output, Zoomed In on 40 Milliseconds of Profiling*

In our gfx/view slice, we will see various blocks for different major operations in the rendering of our UI. Notably, you will see blocks labeled “performTraversals”, referring to the private `performTraversals()` method on `ViewRootImpl`. It turns out that `performTraversals()` wraps around all of the work shown in the three columns of our `gfxinfo` output: `draw`, `process`, and `execute`. The widths of the “performTraversals” blocks in the systrace output shows us how long each of those takes. What we want are nice, short blocks. Instead, panning through our trace, you will see several that are too long. [The chapter on “jank busting”](#) will go into further analysis of where this particular sample application went wrong that caused this behavior.

# Focus On: NDK

---

When Android was first released, many a developer wanted to run C/C++ code on it. There was little support for this, other than by distributing a binary executable and running it via a forked process. While this works, it is a bit cumbersome, and the process-based interface limits how cleanly your C/C++ code could interact with a Java-based UI. On top of all of that, the use of such binary executables is not well supported.

In June 2009, the core Android team released the Native Development Kit (NDK). This allows developers to write C/C++ for Android applications in a supported fashion, in the form of libraries linked to a hosting Java-based application via the Java Native Interface (JNI). This offers a wealth of opportunities for Android development, and this part of the book will explore how you can take advantage of the NDK to exploit those opportunities.

This chapter explains how to set up the NDK and apply it to your project. What it does not do is attempt to cover all possible uses of the NDK — game applications in particular have access to many frameworks, like OpenGL and OpenSL, that are beyond the scope of this book.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

This chapter also assumes that you know C/C++ programming.

## The Role of the NDK

We start by examining Dalvik's primary limitation — speed. Next, we look at the reasons one might choose the NDK, speed among them. We wrap up with some reasons why the NDK may not be the right solution for every Android problem, despite its benefits.

### Dalvik: Secure, Yes; Speedy, Not So Much

Dalvik was written with security as a high priority. Android's security architecture is built around Linux's user model, with each application getting its own user ID. With each application's process running under its own user ID, one process cannot readily affect other processes, helping to contain any single security flaw in an Android application or subsystem. This requires a fair number of processes. However, phones have limited RAM, and the Android project wanted to offer Java-based development. Multiple processes hosting their own Java virtual machines simply could not fit in a phone. Dalvik's virtual machine is designed to address this, maximizing the amount of the virtual machine that can be shared securely between processes (e.g., via “copy-on-write”).

Of course, it is wonderful that Android has security so woven into the fabric of its implementation. However, inventing a new virtual machine required tradeoffs, and most of those are related to speed.

A fair amount of work has gone into making Java fast. Standard Java virtual machines do a remarkable job of optimizing applications on the fly, such that Java applications can perform at speeds near their C/C++ counterparts. This borders on the amazing and is a testament to the many engineers who put countless years into Java.

Dalvik, by comparison, is very young. Many of Java's performance optimization techniques — such as advanced garbage collection algorithms — simply have not been implemented to nearly the same level in Dalvik. This is not to say they will never exist, but it will take some time. Even then, though, there may be limits as to how fast Dalvik can operate, considering that it cannot “throw memory at the problem” to the extent Java can on the desktop or server.

ART has significantly improved matters, with ahead-of-time compilation (AOT) replacing just-in-time compilation (JIT) for getting native opcodes from the Dalvik bytecodes. However, that code may still be inefficient when compared with writing

C/C++ by hand.

## **Going Native**

Java-based Android development via Dalvik and the Android SDK is far and away the option with the best support from the core Android team. HTML5 application development is another option that was brought to you by the core Android development team. The third leg of the official Android development triad is the NDK, provided to developers to address some specific problems, outlined below.

### **Speed**

Far and away the biggest reason for using the NDK is speed, pure and simple. Writing in C/C++ for the device's CPU will be a major speed improvement over writing the same algorithms in Java, despite Android's JIT compiler (Dalvik) and AOT compiler (ART).

There is overhead in reaching out to the C/C++ code from a hosting Java application, and so for the best performance, you will want a coarse interface, without a lot of calls back and forth between Java and the native opcodes. This may require some redesign of what might otherwise be the “natural” way of writing the C/C++ code, or you may just have to settle for less of a speed improvement. Regardless, for many types of algorithms — from cryptography to game AI to video format conversions — using C/C++ with the NDK will make your application perform much better, to the point where it can enable applications to be successful that would be entirely too slow if written solely in Java.

Bear in mind, though, that much of what you think is Java code in your app really is native “under the covers”. Many of the built-in Android classes are thin shims over native implementations. Again, focus on applying the NDK where you are performing lots of work yourself in Java code that might benefit from the performance gains.

### **Porting**

You may already have some C/C++ code, written for another environment, that you would like to use with Android. That might be for a desktop application. That might be for another mobile platform, such as iOS, where C/C++ is an option. That might be for mobile platform, such as Symbian, where C/C++ is the conventional solution, rather than some other language. Regardless, so long as that code is itself relatively

platform-independent, it should be usable on Android.

This may significantly streamline your ability to support multiple platforms for your application, even if down-to-the-metal speed is not really something you necessarily need. This may also allow you to reuse existing C/C++ code written by others, for image processing or scripting languages or anything else.

### Knowing Your Limits

Developers love silver bullets. Developers are forevermore seeking The One True Approach to development that will be problem-free. Sisyphus would approve, of course, as development always involves tradeoffs. So while the NDK's speed may make it tantalizing, it is not a solution for general Android application development, for several reasons, explored in this section.

### Android APIs

The biggest issue with the NDK is that you have very limited access to Android itself. There are a few libraries bundled with Android that you can leverage, and a few other APIs offered specifically to the NDK, such as the ability to render OpenGL 3D graphics. But, generally speaking, the NDK has no access to the Android SDK, except by way of objects made available to it from the hosting application via JNI.

As such, it is best to view the NDK as a way of speeding up particular pieces of an SDK application — game physics, audio processing, OCR, and the like. All of those are algorithms that need to run on Android devices with data obtained from Android, but otherwise are independent of Android itself.

### Cross-Platform Compatibility

While C/C++ *can* be written for cross-platform use, often it is not.

Sometimes, the disparity is one of APIs. Any time you use an API from a platform (e.g., iPhone) or a library (e.g., Qt) not available on Android, you introduce an incompatibility. This means that while a lot of your code — measured in terms of lines — may be fine for Android, there may be enough platform-specific bits woven throughout it that you would have a significant rewrite ahead of you to make it truly cross-platform.

Android itself, though, has a compatibility issue, in terms of CPUs. Android mostly

runs on ARM devices today, since Android's initial focus was on smartphones, and ARM-powered smartphones at that. However, the focus on ARM will continue to waver, particularly as Android moves into other devices where other CPU architectures are more prevalent, such as Atom or MIPS for set-top boxes. While your code may be written in a fashion that works on all those architectures, the binaries that code produces will be specific to one architecture. The NDK gives you additional assistance in managing that, so that your application can simultaneously support multiple architectures.

Right now, the NDK supports ARM, x86, and MIPS CPU architectures. Of these, ARM CPUs power the *vast* majority of Android devices. The first generation of Google TV boxes, and a few other devices, use Intel x86 CPUs (usually Atom-based). MIPS is a relative newcomer to Android, with few devices using such CPUs at this time.

## Introducing CWAC-AndDown

[CWAC-AndDown](#) is mentioned in passing in [the chapter on rich text handling](#). It is an Android library that wraps [hoedown](#), a C-based Markdown-to-HTML converter. The hoedown project itself is a fork of sundown, which itself was used by many sites, like GitHub, for their Markdown processing. CWAC-AndDown is great for projects that take in Markdown and want to render the results in a WebView.

Because CWAC-AndDown uses hoedown, and since hoedown is in C, CWAC-AndDown needs the NDK. We will examine how the NDK works using CWAC-AndDown as an example.

## Installing the NDK

You can now use the NDK from Android Studio, which was not the case for quite some time.

---

## FOCUS ON: NDK

---

In the Android Studio SDK Manager, you will need the CMake and NDK items from the SDK Tools tab:

Figure 963: NDK-Related Items from SDK Manager

Also note that when you create a new project, you will have the option of choosing to add C++ code support, which implies the NDK. This may cause the new-project wizard and later steps to install pieces of the NDK that you may be missing.

## The Contents of an NDK Project

At its core, an NDK-enhanced Android project is a regular Android project. You still need a manifest, layouts, Java source code, and all the other trappings of a regular Android application. The NDK simply enables you to add C/C++ code to that project and have it included in your builds, referenced from your Java code via the Java Native Interface (JNI).

### Your C/C++ Code

Android Studio tends to organize its code based on language. Hence, in your main/ source set, in addition to java/, you can have a cpp/ directory. Despite the name,

---

## FOCUS ON: NDK

---

both C and C++ code can reside in there, along with associated header files. These can be organized into whatever directory structure you want.

On the whole, your C/C++ code will be made up of two facets:

- The code doing the real work
- The code implementing your JNI interface

In the case of CWAC-AndDown, the hoedown source code is in a hoedown/ directory off of the cpp/ directory, while the JNI interface code is directly off of the cpp/ directory:

## Your Makefile

The recommended build engine for the NDK in Android Studio is CMake, which is why that is an option available in the SDK Manager. CMake in Android Studio works off of a CMakeLists.txt file, which is a variation on the “makefile” sort of build instructions that has been used for C/C++ code for decades. This file goes in your module’s directory (e.g., in app/, or in the case of CWAC-AndDown, in anddown/). It provides the details of what you want built in terms of native code:

## FOCUS ON: NDK

---

```
# For more information about using CMake with Android Studio, read the
# documentation: https://d.android.com/studio/projects/add-native-code.html

# Sets the minimum version of CMake required to build the native library.

cmake_minimum_required(VERSION 3.4.1)

# Creates and names a library, sets it as either STATIC
# or SHARED, and provides the relative paths to its source code.
# You can define multiple libraries, and CMake builds them for you.
# Gradle automatically packages shared libraries with your APK.

add_library( # Sets the name of the library.
            anddown

            # Sets the library as a shared library.
            SHARED

            # Provides a relative path to your source file(s).
            src/main/cpp/anddown.c
            src/main/cpp/hoedown/autolink.c
            src/main/cpp/hoedown/buffer.c
            src/main/cpp/hoedown/document.c
            src/main/cpp/hoedown/escape.c
            src/main/cpp/hoedown/html.c
            src/main/cpp/hoedown/html_blocks.c
            src/main/cpp/hoedown/html_smartypants.c
            src/main/cpp/hoedown/stack.c
            src/main/cpp/hoedown/version.c)

include_directories(src/main/cpp src/main/cpp/hoedown)

set(CMAKE_CXX_FLAGS
    "${CMAKE_CXX_FLAGS} -std=c++0x -O2 -D_FORTIFY_SOURCE=2 -fstack-protector-all -fPIE")
set(CMAKE_SHARED_LINKER_FLAGS "${CMAKE_SHARED_LINKER_FLAGS} -pie")
```

Here, we have four major configuration items.

- `cmake_minimum_required()` indicates the minimum required version of CMake that is likely to understand this `CMakeLists.txt` file and be able to compile your code
- `add_library()` indicates the name of the library (here, `anddown`), `SHARED` to indicate that we are building a shared library, then the paths to each of the individual C or C++ files that should be compiled into this library
- `include_directories()` provides the directories in which the C compiler (`gcc`) will be told to use to resolve any `#include` directives in the C/C++ code for pulling in headers
- `set()` sets environment variables used in the forked process for the C compiler (in this case, setting some compile and link flags)

Presumably, CMake supports much more than this, but this should be sufficient for many simple uses of the NDK.

## Your Gradle Changes

Your module's `build.gradle` file can have `externalNativeBuild` closures to configure CMake:

```
android {
    compileSdkVersion 27
    buildToolsVersion '27.0.3'

    defaultConfig {
        minSdkVersion 9
        targetSdkVersion 27

        testApplicationId "com.commonware.cwac.anddown.test"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }

    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'), 'proguard-rules.pro'

            externalNativeBuild {
                cmake { cppFlags "" }
            }
        }
        debug {
            jniDebuggable true

            externalNativeBuild {
                cmake { cppFlags "-DDEBUG" }
            }
        }
    }

    externalNativeBuild {
        cmake { path "CMakeLists.txt" }
    }
}
```

Here, we:

- Tell CMake that our `CMakeLists.txt` file is in the designated file, for all build variants
- Tell CMake to make our debug builds debuggable, via the `-DDEBUG` flag and via the `jniDebuggable` Gradle setting

## Building Your Library

Given all of the above, Android Studio will happily compile your NDK code as part of a build. Or, at the very least, it will try to. Unfortunately, at least as of Android

---

## FOCUS ON: NDK

---

Studio 2.3.3, the integration between gcc and Android Studio is weak in terms of compile errors. If you have a syntax error in your native code — or, worse, have something wrong in `CMakeLists.txt` — you may have some challenges in understanding exactly what is wrong.

The compiled code will show up in `build/intermediates/cmake/` and, eventually, in the APK or AAR being assembled by this module. By default, Android Studio will build your native code for the following CPU architectures:

- arm64-v8a
- armeabi
- armeabi-v7a
- mips
- mips64
- x86
- x86\_64

However, that means that you will wind up with a bigger APK than is necessary for any given user: they have an APK with N CPU architectures, installed on a device with only 1 CPU architecture. You can use [“ABI splits”](#) to arrange to also generate separate APKs for each CPU architecture. Some distribution channels, like the Play Store, support distributing separate APKs per CPU architecture for a single application ID.

Splits are configured using a `splits` closure inside the `android` closure:

```
android {
    splits {
        abi {
            enable true
            universalApk true
        }
    }
}
```

By default, ABI splits are disabled; the `enabled true` statement says that you want APKs split by CPU architecture. The `universalApk true` statement indicates that you want a “fat APK” supporting all CPU architectures in addition to a per-architecture APK. The “fat APK” would be useful for distribution channels that do not support per-architecture APKs.

By default, you get one APK for every CPU architecture. That is fine for cases where

---

## FOCUS ON: NDK

---

you are in control over the NDK code. If you are using a third-party library that has the NDK code, it may be that the library developers are supporting CPU architectures that you are not. In that case, you have two options:

1. Add an `exclude` statement to blacklist certain CPU architectures that you specifically do not want to support
2. Use `reset()` and `include` to whitelist certain CPU architectures that you specifically *do* want to support

```
android {
    splits {
        abi {
            enable true
            reset()
            include "x86", "armeabi-v7a", "x86", "x86_64", "arm64-v8a"
            universalApk true
        }
    }
}
```

Note that the Play Store will be requiring that you ship 64-bit architecture support in 2019. You are welcome to *also* support 32-bit architectures, but 64-bit architectures will be required.

## Your Java and JNI Code

Now that you have your base C/C++ code being successfully compiled by the NDK, you need to turn your attention towards crafting the bridge between the Dalvik VM and the C/C++ code, following in the conventions of the Java Native Interface (JNI).

This section, while explaining the various steps involved in using the JNI, is far from a complete treatise on the subject. If you are going to spend a lot of time working with JNI, you are encouraged to seek additional resources on this topic, such as [Core Java: Volume II](#), which has a chapter on JNI.

We want Android apps to be able to easily generate HTML from Markdown. To that end, we have an `AndDown` Java class containing two public methods:

- A one-parameter `markdownToHtml()`, which performs a basic conversion of Markdown to HTML, returning the `String` of HTML-formatted content
- A three-parameter `markdownToHtml()` method that also takes a pair of `int` bitfields for hoedown “extensions” and flags

## FOCUS ON: NDK

---

The catch is that the three-parameter method has the native keyword, meaning that it is implemented in C/C++:

```
package com.commonware.cwac.anddown;

/**
 * Java entry point to convert Markdown to HTML. Call the static markdownToHtml()
 * method for this.
 */
public class AndDown {
    static {
        System.loadLibrary("anddown");
    }

    /* block-level extensions */
    public static final int HOEDOWN_EXT_TABLES = (1 << 0);
    public static final int HOEDOWN_EXT_FENCED_CODE = (1 << 1);
    public static final int HOEDOWN_EXT_FOOTNOTES = (1 << 2);

    /* span-level extensions */
    public static final int HOEDOWN_EXT_AUTOLINK = (1 << 3);
    public static final int HOEDOWN_EXT_STRIKETHROUGH = (1 << 4);
    public static final int HOEDOWN_EXT_UNDERLINE = (1 << 5);
    public static final int HOEDOWN_EXT_HIGHLIGHT = (1 << 6);
    public static final int HOEDOWN_EXT_QUOTE = (1 << 7);
    public static final int HOEDOWN_EXT_SUPERSCRIPT = (1 << 8);
    public static final int HOEDOWN_EXT_MATH = (1 << 9);

    /* other flags */
    public static final int HOEDOWN_EXT_NO_INTRA_EMPHASIS = (1 << 11);
    public static final int HOEDOWN_EXT_SPACE_HEADERS = (1 << 12);
    public static final int HOEDOWN_EXT_MATH_EXPLICIT = (1 << 13);

    /* negative flags */
    public static final int HOEDOWN_EXT_DISABLE_INDENTED_CODE = (1 << 14);

    public static final int HOEDOWN_HTML_SKIP_HTML = (1 << 0);
    public static final int HOEDOWN_HTML_ESCAPE = (1 << 1);
    public static final int HOEDOWN_HTML_HARD_WRAP = (1 << 2);
    public static final int HOEDOWN_HTML_USE_XHTML = (1 << 3);

    /**
     * Given Markdown, returns HTML. 'Nuff said.
     *
     * @param raw Markdown-formatted string
     * @return HTML-formatted string
     */
    public String markdownToHtml(String raw) {
        return(markdownToHtml(raw, 0, 0));
    }

    public native String markdownToHtml(String raw, int extensions, int flags);
}
```

AndDown also has a static block with a `System.loadLibrary()` call, which teaches the virtual machine what native library to load and look for the native methods. In this case, the library is `anddown`, which is the name that we gave it in

## FOCUS ON: NDK

---

CMakeLists.txt.

The Java JDK comes with a `javah` utility. Given a Java class like `AndDown`, `javah` will generate the appropriate C header file for all native methods. That gives us the awkwardly-named `com_commonsware_cwac_anddown_AndDown.h` file, with the equally-awkward `Java_com_commonsware_cwac_anddown_AndDown_markdownToHtml()` function declaration:

```
/* DO NOT EDIT THIS FILE - it is machine generated */
#include <jni.h>
/* Header for class com_commonsware_cwac_anddown_AndDown */

#ifdef _Included_com_commonsware_cwac_anddown_AndDown
#define _Included_com_commonsware_cwac_anddown_AndDown
#ifdef __cplusplus
extern "C" {
#endif
/*
 * Class:      com_commonsware_cwac_anddown_AndDown
 * Method:     markdown
 * Signature:  (Ljava/lang/String;)Ljava/lang/String;
 */
JNIEXPORT jstring JNICALL Java_com_commonsware_cwac_anddown_AndDown_markdownToHtml
    (JNIEnv *, jobject, jstring, unsigned int, unsigned int);
#ifdef __cplusplus
}
#endif
#endif
```

We do not really use this file much, other than to get the C function prototype that we need to implement. The JNI bridge code will look for that function when our Java code calls the native implementation of `markdownToHtml()`. Our implementation of that C function delegates to a series of `hoedown` functions for actually performing the Markdown-to-HTML conversion:

```
/**
 * Copyright (c) 2010 CommonsWare, LLC
 * Portions (c) somebody else who didn't bother to indicate who they were
 *
 * Licensed under the Apache License, Version 2.0 (the "License"); you may
 * not use this file except in compliance with the License. You may obtain
 * a copy of the License at
 *     http://www.apache.org/licenses/LICENSE-2.0
 * Unless required by applicable law or agreed to in writing, software
 * distributed under the License is distributed on an "AS IS" BASIS,
 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */

#include "com_commonsware_cwac_anddown_AndDown.h"
#include "document.h"
```

## FOCUS ON: NDK

---

```
#include "html.h"
#include "buffer.h"

#define INPUT_UNIT 64
#define OUTPUT_UNIT 64

JNIEXPORT jstring JNICALL Java_com_commonsware_cwac_anddown_AndDown_markdownToHtml
(JNIEnv *env, jobject o, jstring raw, unsigned int extensions, unsigned int flags) {
    struct hoedown_buffer *ib, *ob;
    jstring result;
    hoedown_renderer *renderer;
    hoedown_document *document;
    const char* str;

    str = (*env)->GetStringUTFChars(env, raw, NULL);

    ib = hoedown_buffer_new(INPUT_UNIT);
    hoedown_buffer_puts(ib, str);
    ob = hoedown_buffer_new(OUTPUT_UNIT);

    (*env)->ReleaseStringUTFChars(env, raw, str);

    renderer = hoedown_html_renderer_new(flags, 0);
    document = hoedown_document_new(renderer, extensions, 16);

    hoedown_document_render(document, ob, ib->data, ib->size);
    hoedown_document_free(document);

    result=(*env)->NewStringUTF(env, hoedown_buffer_cstr(ob));

    /* cleanup */
    hoedown_buffer_free(ib);
    hoedown_buffer_free(ob);

    return(result);
}
```

However, our Java code is largely oblivious to this. It can simply call the `markdownToHtml()` methods on `AndDown`, such as in a trivial instrumentation test case for confirming that the build works:

```
package com.commonsware.cwac.anddown.test;

import android.support.test.runner.AndroidJUnit4;
import com.commonsware.cwac.anddown.AndDown;
import junit.framework.Assert;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(AndroidJUnit4.class)
public class MarkdownTest {
    @Test
    public void testSimple() {
```

```
AndDown andDown=new AndDown();

Assert.assertEquals("<p>Hello, world</p>",
    andDown.markdownToHtml("Hello, world").trim());
Assert.assertEquals("<p>This <q>contains</q> a quote</p>",
    andDown.markdownToHtml("This \"contains\" a quote",
        AndDown.HOEDOWN_EXT_QUOTE, 0).trim());
}
}
```

## libhoudini and the NDK

libhoudini is a proprietary ARM translation layer for x86-powered Android devices. It allows an app that has NDK binaries for ARM, but not x86, to still run on x86 hardware, albeit not as quickly as it would with native x86 binaries. The advantage is that you can ship an APK without x86 binaries (so the APK is smaller) yet still be able to run on x86 devices.

Given ARM's current dominance in the Android ecosystem, libhoudini is hugely useful for Intel and hardware vendors interested in using Intel's mobile CPUs. Without it, only apps that ship x86 NDK binaries would be compatible with x86-powered devices like the Samsung Galaxy Tab 3 10.1" tablet. Some developers probably skip x86 NDK binaries, because they are not aware of popular x86-powered devices, or lack one for testing, or are concerned over APK size. The Play Store for x86 would shrink substantially from the million-plus apps available to ARM devices, to those that do not use the NDK or happen to ship x86 binaries. libhoudini makes ARM-only NDK binaries usable on x86, giving x86-powered Android devices access to more of the Play Store catalog.

However, it is slower. A test suite for [SQLCipher for Android](#), run on an ASUS MeMO Pad FHD 10, ran about three times as long when using the ARM binaries and libhoudini, when compared to the same test run using x86 binaries. On the other hand, supporting x86 in addition to ARM adds another 5MB to the app, on top of the 6.5MB spent for ARM and the platform-neutral pieces. Being able to use SQLCipher for Android without the x86 binaries might be useful, particularly for apps bumping up against APK size limits, like the 50MB limit on the Play Store.

You may wish to do your own testing. Testing is easy enough: just temporarily move the x86/ directory from libs/ somewhere else, then recompile and test on libhoudini-equipped hardware. If you do not have your own libhoudini-equipped hardware, you may be able to take advantage of services like [Samsung's Remote Test](#)

## FOCUS ON: NDK

---

[Lab](#), which recently added the Galaxy Tab 3 10.1 to its lineup.

If you have the space for it, include the x86 binaries for your NDK-compiled libraries. This will give you maximum speed for little incremental engineering cost. However, if space is at a premium, libhoudini may allow you to reach many of the same x86 devices, but be sure that your app will run acceptably given the performance overhead.

# **Improving CPU Performance in Java**

---

Knowing that you have CPU-related issues in your app is one thing — doing something about it is the next challenge. In some respects, tuning an Android application is a “one-off” job, tied to the particulars of the application and what it is trying to accomplish. That being said, this chapter will outline some general-purpose ways of boosting performance that may counter issues that you are running into.

## **Prerequisites**

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Reading [the introductory chapter to this trail](#) is also a good idea.

## **Reduce CPU Utilization**

One class of CPU-related problems come from purely sluggish code. These are the sorts of things you will see in Traceview, for example – methods or branches of code that seem to take an inordinately long time. These are also some of the most difficult to have general solutions for, as often times it comes down to what the application is trying to accomplish. However, the following sections provide suggestions for consuming fewer CPU instructions while getting the same work done.

These are presented in no particular order.

### Standard Java Optimizations

Most of your algorithm fixes will be standard Java optimizations, no different than have been used by Java projects over the past decade and change. This section outlines a few of them. For more, consider reading *Effective Java* by Joshua Bloch or *Java Performance Tuning* by Jack Shirazi.

### Avoid Excessive Synchronization

Few objects in `java.*` namespaces are intrinsically thread-safe, outside of `java.util.concurrent`. Typically, you need to perform your own synchronization if multiple threads will be accessing non-thread-safe objects. However, sometimes, Java classes have synchronization that you neither expect nor need. Synchronization adds unnecessary overhead.

The classic example here is `StringBuffer` and `StringBuilder`. `StringBuffer` was part of Java from early on, and, for whatever reason, was written to be thread-safe — two threads that append to the buffer will not cause any problems. However, most of the time, you are only using the `StringBuffer` from one thread, meaning all that synchronization overhead is a waste. Later on, Java added `StringBuilder`, with the same basic set of methods as has `StringBuffer`, but without the synchronization.

Similarly, in your own code, only synchronize where it is really needed. Do not toss the synchronized keyword around randomly, or use concurrent collections that will only be used by one thread, etc.

### Avoid Floating-Point Math

The first generation of Android devices lacked a floating-point coprocessor on the ARM CPU package. As a result, floating-point math speed was atrocious. That is why the Google Maps add-on for Android uses `GeoPoint`, with latitude and longitude in integer microdegrees, rather than the standard Android `Location` class, which uses Java double variables holding decimal degrees.

While later Android devices do have floating-point coprocessor support, that does not mean that floating-point math is now as fast as integer math. If you find that your code is spending lots of time on floating-point calculations, consider whether a change in units would allow you to replace the floating-point calculations with integer equivalents. For example, microdegrees for latitude and longitude provide adequate granularity for most maps, yet allow Google Maps to do all of its

calculations in integers.

Similarly, consider whether the full decimal accuracy of floating-point values is really needed. While it may be physically possible to perform distance calculations in meters with accuracy to a few decimal points, for example, in many cases the user will not need that degree of accuracy. If so, perhaps changing to fixed-point (integer) math can boost your performance.

### **Don't Assume Built-In Algorithms are Best**

Years upon years of work has gone into the implementation of various algorithms that underlie Java methods, like searching for substrings inside of strings.

Somewhat less work has gone into the implementation of the Apache Harmony versions of those methods, simply because the project is younger, and it is a modified version of the Harmony implementation that you will find in Android. While the core Android team has made many improvements to the original Harmony implementation, those improvements may be for optimizations that do not fit your needs (e.g., optimizing to reduce memory consumption at the expense of CPU time).

But beyond that, there are [dozens of string-matching algorithms](#), some of which may be better for you depending on the string being searched and the string being searched for. Hence, you may wish to consider applying your own searching algorithm rather than relying on the built-in one, to boost performance. And, this same concept may hold for other algorithms as well (e.g., sorting).

Of course, this will also increase the complexity of your application, with long-term impacts in terms of maintenance cost. Hence, do not assume the built-in algorithms are the worst, either — optimize those algorithms that Traceview or logging suggest are where you are spending too much time.

### **Support Hardware-Accelerated Graphics**

An easy “win” is to add `android:hardwareAccelerated="true"` to your `<application>` element in the manifest. This toggles on hardware acceleration for 2D graphics, including much of the stock widget framework. For maximum backwards compatibility, this hardware acceleration is off, but adding the aforementioned attribute will enable it for all activities in your application.

Note that this is only available starting with Android 3.0. It is safe to have the

attribute in the manifest for older Android devices, as they simply will ignore your request.

You also should test your application thoroughly after enabling hardware acceleration, to make sure there are no unexpected issues. For ordinary widget-based applications, you should encounter no problems. Games or other applications that do their own drawing might have issues. If you find that some of your code runs into problems, you can override hardware acceleration on a per-activity basis by putting the `android:hardwareAccelerated` attribute on `<activity>` elements in the manifest.

### Minimize IPC

Calling a method on an object in your own process is fairly inexpensive. The overhead of the method invocation is fairly minuscule, and so the time involved is simply however long it takes for that method to do its work.

Invoking behaviors in another process, via inter-process communication (IPC), is considerably more expensive. Your request has to be converted into a byte array (e.g., via [the Parcelable interface](#)), made available to the other process, converted back into a regular request, then executed. This adds substantial CPU overhead.

There are three basic flavors of IPC in Android:

1. “Directly” invoking a third-party application’s service’s AIDL-published interface, to which you bound with `bindService()`
2. Performing operations on a content provider that is not part of your application (i.e., supplied by the OS or a third-party application)
3. Performing other operations that, under the covers, trigger IPC

### Remote Bound Service

Using a remote service is fairly obvious when you do it — it is difficult to mistake copying the AIDL into your project and such. The proxy object generated from the AIDL converts all your method calls on the interface into IPC operations, and this is relatively expensive.

If you are exposing a service via AIDL, design your API to be coarse-grained. Do not require the client to make 1,000 method invocations to accomplish something that can be done in 1 via slightly more complex arguments and return values.

## IMPROVING CPU PERFORMANCE IN JAVA

---

If you are consuming a remote service, try not to get into situations where you have to make lots of calls in a tight loop, or per row of a scrolled `AdapterView`, or anything else where the overhead may become troublesome.

For example, in the [CPU-Java/AIDLOverhead](#) sample project, you will find a pair of projects implementing the same do-nothing method in equivalent services. One uses AIDL and is bound to remotely from a separate client application; the other is a local service in the client application itself. The client then calls the do-nothing method 1 million times for each of the two services. On average, on a Samsung Galaxy Tab 10.1, 1 million calls takes around 170 seconds for the remote service, while it takes around 170 *milliseconds* for the local service. Hence, the overhead of an individual remote method invocation is small (~170 microseconds), but doing lots of them in a loop, or as the user flings a `ListView`, might become noticeable.

### Remote Content Provider

Using a content provider can be somewhat less obvious of a problem. Using `ContentResolver` or a `CursorLoader` looks the same whether it is your own content provider or someone else's. However, you know what content providers you wrote; anything else is probably running in another process.

As with remote services, try to aggregate operations with remote content providers, such as:

1. Use `bulkInsert()` rather than lots of individual `insert()` calls
2. Try to avoid calling `update()` or `delete()` in a tight loop – instead, if the content provider supports it, use a more complex “WHERE clause” to update or delete everything at once
3. Try to get all your data back in few queries, rather than lots of little ones... though this can then cause you issues in terms of memory consumption

### Remote OS Operation

The content provider scenario is really a subset of the broader case where you request that Android do something for you and winds up performing IPC as part of that.

Sometimes, this is going to be obvious. If you are sending commands to a third-party service via `startService()`, by definition, this will involve IPC, since the third-party service will run in a third-party process. Try to avoid calling `startService()` lots of

times in close succession.

However, there are plenty of cases that are less obvious:

1. All requests to `startActivity()`, `startService()`, and `sendBroadcast()` involve IPC, as it is a separate OS process that does the real work
2. Registering and unregistering a `BroadcastReceiver` (e.g., `registerReceiver()`) involves IPC
3. All of the “system services”, such as `LocationManager`, are really rich interfaces to an AIDL-defined remote service, and so most operations on these system services require IPC

Once again, your objective should be to minimize calls that involve IPC, particularly where you are making those calls frequently in close succession, such as in a loop. For example, frequently calling `getLastKnownLocation()` will be expensive, as that involves IPC to a system process.

### Android-Specific Java Optimizations

The way that the Dalvik VM was implemented and operates is subtly different than a traditional Java VM. Therefore, there are some optimizations that are more important on Android than you might find in regular desktop or server Java.

The Android developer documentation has [a roster of such optimizations](#). Some of the highlights include:

1. Getters and setters, while perhaps useful for encapsulation, are significantly slower than direct field access. For simpler cases, such as `ViewHolder` objects for optimizing an `Adapter`, consider skipping the accessor methods and just use the fields directly.
2. Some popular method calls are replaced by hand-created assembler instructions rather than code generated via the JIT compiler. `indexOf()` on `String` and `arraycopy()` on `System` are two cited examples. These will run much faster than anything you might create yourself in Java.

### Reduce Time on the Main Application Thread

Another class of CPU-related problem is when your code may be efficient, but it is occurring on the main application thread, causing your UI to react sluggishly. You might have tuned your decryption algorithm as best as is mathematically possible,

but it may be that decrypting data on the main application thread simply takes too much time. Or, perhaps `StrictMode` complained about some disk or network I/O that you are performing on the main application thread.

The following sections recap some commonly-seen patterns for moving work off the main application thread, plus a few newer options that you may have missed.

### Generate Less Garbage

Most developers think of having too many allocations as being solely an issue of heap space. That certainly has an impact, and depending on the nature of the allocations (e.g., bitmaps), it may be the dominant issue.

However, garbage has impacts from a CPU standpoint as well. Every object you create causes its constructor to be executed. Every object that is garbage-collected requires CPU time both to find the object in the heap and to actually clean it up (e.g., execute the finalizer, if any).

Worse still, on older versions of Android (e.g., Android 2.2 and down), the garbage collector interrupts the entire process to do its work, so the more garbage you generate, the more times you “stop the world”. Game developers have had to deal with this since Android’s inception. To maintain a 60 FPS refresh rate, you cannot afford *any* garbage collections on older devices, as a single GC run could easily take more than the ~16ms you have per drawing pass.

As a result of all of this, game developers have had to carefully manage their own object pools, pre-allocating a bunch of objects before game play begins, then using and recycling those objects themselves, only allowing them to become garbage after game play ends.

Most non-game Android applications may not have to go to quite that extreme across the board. However, there are cases where excessive allocation may cause you difficulty. For example, avoiding creating too much garbage is one aspect of view recycling with `AdapterView`, which is covered in greater detail [in the next section](#).

If Traceview indicates that you are spending a lot of time in garbage collection, pay attention to your loops or things that may be invoked many times in rapid succession (e.g., accessing data from a custom `Cursor` implementation that is tied to a `CursorAdapter`). These are the most likely places where your own code might be creating lots of extra objects that are not needed. Examining the heap to see what is all being created (and eventually garbage collected) will be covered in [an upcoming](#)

[chapter of the book.](#)

## View Recycling

Perhaps the best-covered Android-specific optimization is view recycling with `AdapterView`.

In a nutshell, if you are extending `BaseAdapter`, or if you are overriding `getView()` in another adapter, please make use of the `View` parameter supplied to `getView()` (referred to here as `convertView`). If `convertView` is not null, it is one of your previous `View` objects you returned from `getView()` before, being offered to you for recycling purposes. Using `convertView` saves you from inflating or manually constructing a fresh `View` every time the user scrolls, and both of those operations are relatively expensive.

If you have been ignoring `convertView` because you have more than one type of `View` that `getView()` returns, your `Adapter` should be overriding `getViewTypeCount()` and `getItemViewType()`. These will allow Android to maintain separate object pools for each type of row from your `Adapter`, so `getView()` is guaranteed to be passed a `convertView` that matches the row type you are trying to create.

A somewhat more advanced optimization — caching all those `findViewById()` lookups — is also possible once your row recycling is in place. Often referred to as “the holder pattern”, you do the `findViewById()` calls when you inflate a new row, then attach the `findViewById()` results to the row itself via some custom “holder” object and the `setTag()` method on `View`. When you recycle the row, you can get your “holder” back via `getTag()` and skip having to do the `findViewById()` calls again.

## Background Threads

Of course, the backbone of any strategy to move work off the main application thread is to use background threads, in one form or fashion. You will want to apply these in places where `StrictMode` complains about network or disk I/O, or places where `Traceview` or logging indicate that you are taking too much time on the main application thread during GUI processing (e.g., converting downloaded bitmap images into `Bitmap` objects via `BitmapFactory`).

Sometimes, you will manually dictate where work should be done in the background, either by forking threads yourself or by using `AsyncTask`. `AsyncTask` is a nice framework, handling all of the inter-thread communication for you and neatly

packaging up the work to be done in readily understood methods. However, `AsyncTask` does not fit every scenario — it is mostly designed for “transactional” work that is known to take a modest amount of time (milliseconds to seconds) then end. For cases where you need unbounded background processing, such as monitoring a socket for incoming data, forking your own thread will be the better approach.

Sometimes, you will use facilities supplied by Android to move work to the background. For example, many activities are backed by a `Cursor` obtained from a database or content provider. Classically, you would manage the cursor (via `startManagingCursor()`) or otherwise arrange to refresh that `Cursor` in `onResume()`, so when your activity returns to the foreground after having been gone for a while, you would have fresh data. However, this pattern tends to lead to database I/O on the main application thread, triggering complaints from `StrictMode`. Android 3.0 and the Android Compatibility Library offer a `Loader` framework designed to try to solve the core pattern of refreshing the data, while arranging for the work to be done asynchronously.

### Asynchronous BroadcastReceiver Operations

99.44% of the time (approximately) that Android calls your code in some sort of event handler, you are being called on the main application thread. This includes manifest-registered `BroadcastReceiver` components — `onReceive()` is called on the main application thread. So any work you do in `onReceive()` ties up that thread (possibly impacting an activity of yours in the foreground), and if you take more than 10 seconds, Android will terminate your `BroadcastReceiver` with extreme prejudice.

Classically, manifest-registered `BroadcastReceiver` components only live as long as the `onReceive()` call does, meaning you can do very little work in the `BroadcastReceiver` itself. The typical pattern is to have it send a command to a service via `startService()`, where the service “does the heavy lifting”.

Android 3.0 added a `goAsync()` method on `BroadcastReceiver` that can help a bit here. While under-documented, it tells Android that you need more time to complete the broadcast work, but that you can do that work on a background thread. This does not eliminate the 10-second rule, but it does mean that the `BroadcastReceiver` can do some amount of I/O without having to send a command to a service to do it while still not tying up the main application thread.

The [CPU- Java/GoAsync](#) sample project demonstrates `goAsync()` in use, as the project

name might suggest.

Our activity's layout consists of two Button widgets and an EditText widget:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical" android:layout_width="match_parent"
    android:layout_height="match_parent">
    <EditText android:id="@+id/editText1" android:layout_width="match_parent"
        android:layout_height="wrap_content">
    </EditText>
    <Button android:layout_width="match_parent" android:id="@+id/button1"
        android:layout_height="wrap_content" android:text="@string/nonasync"
        android:onClick="sendNonAsync"></Button>
    <Button android:layout_width="match_parent" android:id="@+id/button2"
        android:layout_height="wrap_content" android:text="@string/async"
        android:onClick="sendAsync"></Button>
</LinearLayout>
```

(from [CPU-Java/GoAsync/app/src/main/res/layout/main.xml](#))

The activity itself simply has `sendAsync()` and `sendNonAsync()` methods, each invoking `sendBroadcast()` to a different `BroadcastReceiver` implementation:

```
package com.commonware.android.tuning.goasync;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;

public class GoAsyncActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void sendAsync(View v) {
        sendBroadcast(new Intent(this, AsyncReceiver.class));
    }

    public void sendNonAsync(View v) {
        sendBroadcast(new Intent(this, NonAsyncReceiver.class));
    }
}
```

## IMPROVING CPU PERFORMANCE IN JAVA

---

(from [CPU-Java/GoAsync/app/src/main/java/com/commonsware/android/tuning/goasync/GoAsyncActivity.java](#))

The NonAsyncReceiver simulates doing time-consuming work in onReceive() itself:

```
package com.commonsware.android.tuning.goasync;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class NonAsyncReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context arg0, Intent arg1) {
        SystemClock.sleep(7000);
    }
}
```

(from [CPU-Java/GoAsync/app/src/main/java/com/commonsware/android/tuning/goasync/NonAsyncReceiver.java](#))

Hence, if you click the “Send Non-Async Broadcast” button, not only will the button fail to return to its normal state for seven seconds, but the EditText will not respond to user input either.

The AsyncReceiver, though, uses goAsync():

```
package com.commonsware.android.tuning.goasync;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.os.SystemClock;

public class AsyncReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        final BroadcastReceiver.PendingResult result=goAsync();

        (new Thread() {
            public void run() {
                SystemClock.sleep(7000);
                result.finish();
            }
        }).start();
    }
}
```

---

## IMPROVING CPU PERFORMANCE IN JAVA

---

(from [CPU-Java/GoAsync/app/src/main/java/com/commonsware/android/tuning/goasync/AsyncReceiver.java](#))

The `goAsync()` method returns a `PendingResult`, which supports a series of methods that you might ordinarily fire on the `BroadcastReceiver` itself (e.g., `abortBroadcast()`) but want to do on a background thread. You need your background thread to have access to the `PendingResult` — in this case, via a `final` local variable. When you are done with your work, call `finish()` on the `PendingResult`.

If you click the “Send Async Broadcast” button, even though we are still sleeping for 7 seconds, we are doing so on a background thread, and so our user interface is still responsive.

### Saving SharedPreferences

The classic way to save `SharedPreferences.Editor` changes was via a call to `commit()`. This writes the preference information to an XML file on whatever thread you are on — another hidden source of disk I/O you might be doing on the main application thread.

If you are on API Level 9, and you are willing to blindly try saving the changes, use the new `apply()` method on `SharedPreferences.Editor`, which works asynchronously.

If you need to support older versions of Android, or you really want the boolean return value from `commit()`, consider doing the `commit()` call in an `AsyncTask` or background thread.

And, of course, to support both of these, you will need to employ tricks like conditional class loading. You can see that used for saving `SharedPreferences` in the [CPU-Java/PrefsPersist](#) sample project. The activity reads in a preference, puts the current value on the screen, then updates the preference with the help of an `AbstractPrefsPersistStrategy` class and its `persist()` method:

```
package com.commonsware.android.tuning.prefs;

import android.app.Activity;
import android.content.SharedPreferences;
import android.os.Bundle;
import android.preference.PreferenceManager;
import android.widget.TextView;

public class PrefsPersistActivity extends Activity {
```

## IMPROVING CPU PERFORMANCE IN JAVA

---

```
private static final String KEY="counter";

@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    SharedPreferences prefs=
        PreferenceManager.getDefaultSharedPreferences(this);
    int counter=prefs.getInt(KEY, 0);

    ((TextView)findViewById(R.id.value)).setText(String.valueOf(counter));

    AbstractPrefsPersistStrategy.persist(prefs.edit().putInt(KEY, counter+1));
}
}
```

(from [CPU-Java/PrefsPersist/app/src/main/java/com/commonsware/android/tuning/prefs/PrefsPersistActivity.java](#))

AbstractPrefsPersistStrategy is an abstract base class that will hold a strategy implementation, depending on Android version. On pre-Honeycomb builds, it uses an implementation that forks a background thread to perform the commit():

```
package com.commonsware.android.tuning.prefs;

import android.content.SharedPreferences;
import android.os.Build;

abstract public class AbstractPrefsPersistStrategy {
    abstract void persistAsync(SharedPreferences.Editor editor);

    private static final AbstractPrefsPersistStrategy INSTANCE=initImpl();

    public static void persist(SharedPreferences.Editor editor) {
        INSTANCE.persistAsync(editor);
    }

    private static AbstractPrefsPersistStrategy initImpl() {
        int sdk=new Integer(Build.VERSION.SDK).intValue();

        if (sdk<Build.VERSION_CODES.HONEYCOMB) {
            return(new CommitAsyncStrategy());
        }

        return(new ApplyStrategy());
    }
}
```

---

## IMPROVING CPU PERFORMANCE IN JAVA

---

```
static class CommitAsyncStrategy extends AbstractPrefsPersistStrategy {
    @Override
    void persistAsync(final SharedPreferences.Editor editor) {
        (new Thread() {
            @Override
            public void run() {
                editor.commit();
            }
        }).start();
    }
}
```

(from [CPU-Java/PrefsPersist/app/src/main/java/com/commonsware/android/tuning/prefs/AbstractPrefsPersistStrategy.java](#))

On Honeycomb and higher, it uses a separate strategy class that uses the new `apply()` method:

```
package com.commonsware.android.tuning.prefs;

import android.content.SharedPreferences.Editor;

public class ApplyStrategy extends AbstractPrefsPersistStrategy {

    @Override
    void persistAsync(Editor editor) {
        editor.apply();
    }
}
```

(from [CPU-Java/PrefsPersist/app/src/main/java/com/commonsware/android/tuning/prefs/ApplyStrategy.java](#))

By separating the Honeycomb-specific code out into a separate class, we can avoid loading it on older devices and encountering the dreaded `VerifyError`.

Whether using the built-in `apply()` method is worth dealing with multiple strategies, versus simply calling `commit()` on a background thread, is up to you.

## Improve Throughput and Responsiveness

Being efficient and doing work on the proper thread may still not be enough. It could be that your work is not consuming excessive CPU time, but is taking too long in “wall clock time” (e.g., the user sits waiting too long at a `ProgressDialog`). Or, it could be that your work, while efficient and in the background, is causing difficulty for foreground operations.

The following sections outline some common problems and solutions in this area.

### **Minimize Disk Writes**

Earlier in this book, we emphasized moving disk writes off to background threads.

Even better is to get rid of some of the disk writes entirely.

A big culprit here comes in the form of database operations. By default, each `insert()`, `update()`, or `delete()`, or any `execSQL()` invocation that modifies data, will occur in its own transaction. Each transaction involves a set of disk writes. Many times, this is not a problem. But, if you are doing a lot of these – such as importing records from a CSV file — hundreds or thousands of transactions will mean thousands of individual disk writes, and that can take some time. You may wish to wrap those operations in your own transaction, using methods like `beginTransaction()`, simply to reduce the number of transactions and, therefore, disk writes.

If you are doing your own disk I/O beyond databases, you may encounter similar sorts of issues. Overall, it is better to do a few larger writes than lots of little ones.

### **Set Thread Priority**

Threads you fork, by default, run at a default priority: `THREAD_PRIORITY_DEFAULT` as defined on the `Process` class. This is a lower priority than the main application thread (`THREAD_PRIORITY_DISPLAY`).

Threads you use via `AsyncTask` run at a lower priority (`THREAD_PRIORITY_BACKGROUND`). If you fork your own threads, then, you might wish to consider moving them to a lower priority as well, to affect how much time they get compared to the main application thread. You can do this via `setThreadPriority()` on the `Process` class.

The lowest possible priority, `THREAD_PRIORITY_LOWEST`, is described as “only for those who really, really don’t want to run if anything else is happening”. You might use this for “idle-time processing”, but bear in mind that the thread will be paused a lot to allow other threads to run.

Lower-priority threads will help ensure that your background work does not affect your foreground UI. Processes themselves are put in a lower-priority class as they move to the background (e.g., you have no activities visible), which further reduces

the amount of CPU time you will be using at any given moment.

Also, note that `IntentService` uses a thread at default (*not* background) priority — you may wish to drop the priority of this thread to something that will be lower than your main application thread, to minimize how much CPU time the `IntentService` steals from your UI.

### Do the Work Some Other Time

Just because you could do the work now does not mean you should do the work now. Perhaps a better answer is to do the work later, or do part of the work now and part of the work later.

For example, suppose that you have your own database of points of interest for your custom map application. Periodically, you publish a new database on your Web site, which your Android app should download. Odds are decent that the user is not in desperate need for this new database right away. In fact, the CPU time and disk I/O time to download and save the database might incrementally interfere with the foreground application, despite your best efforts.

In this case, not only should you check for and download the database when the user is unlikely to be using the device (e.g., before dawn), but you should check whether the screen is on via `isScreenOn()` on `PowerManager`, and delay the work to sometime when the screen is off. For example, you could have `AlarmManager` set up to have your code check for updates every 24 hours at 4am. If, at 4am, the screen is on, your code could skip the download and wait until tomorrow, or skip the download and add a one-shot alarm to wake you up in 30 minutes, in hopes that the user will no longer be using the device.

At the same time, you may wish to consider having a “refresh” menu choice somewhere, for when the user specifically wants you to go get the update (if available) *now*, for whatever reason.

# Finding and Eliminating Jank

---

A user interface is considered “janky” if it stutters or otherwise fails to operate smoothly, particularly during animated effects like scrolling. Finding and eliminating the causes of janky behavior (“jank”) is part science, part art, and part throwing darts at a dartboard.

This chapter will outline some techniques for identifying and removing jank from a user interface. The steps shown here originated in [a blog post by Google’s Romain Guy](#), with a few additional twists and turns due to the different nature of the particular case being studied. Mr. Guy’s blog post is essential reading for all advanced Android developers, and the author is deeply indebted to Mr. Guy for his work in this area.

## Prerequisites

The only hard prerequisite for this chapter is having read the core chapters and [the chapter on finding CPU bottlenecks](#).

That being said, having read [the chapter on animators](#) would help understand portions of this chapter a bit better.

## The Case: ThreePaneDemoBC

In [the chapter on animators](#), we examined an implementation of the Gmail-style three-pane layout with animated transitions (a.k.a., “[The Three-Fragment Problem](#)”). The implementation shown there originated with [a Stack Overflow question](#) with the solution presented in this book offered as [an answer](#).

[A commenter on that answer](#) pointed out that he detected some stutter, even on decent hardware.

This chapter reviews the steps that were taken to determine if we really are doing things incorrectly, what specifically we are doing wrong, and what can be done to fix it.

### Are We Janky?

In the eyes of this book's author, the three-pane implementation presented in the chapter on animators was perfectly reasonable on good hardware.

There are two lessons to take from this:

1. It is better to come up with an objective definition for “jank” and test to see if your code meets that definition at various points
2. The author of this book is very tolerant of janky user interfaces

The results shown in [the chapter on CPU measurement](#) for the `gfxinfo` and `systrace` tools come from the three-pane demo code. The `gfxinfo` and the `systrace` results both point to the three-pane demo spending too much time doing work and therefore dropping some number of frames. This lines up with the visual report, and indicates that we have some work to do to try to improve matters.

### Finding the Source of the Jank

Just because we know that we are janky does not mean that we have any idea what to do about it. We need to conduct some further analysis to determine where, exactly, our jank is coming from.

#### Traceview

One thing that we can do to help further refine the source of our trouble is to use Traceview. As outlined in [the section on Traceview](#), Traceview reports how many calls were made of various methods in our code (and in the framework code) and how much time was spent there.

## FINDING AND ELIMINATING JANK

Here are some of the results from a Traceview run on the three-pane demo on a Nexus 7:

Figure 965: Traceview of Three-Pane Demo

We see that 88.9% of our CPU time is spent in `doFrame()` on `Choreographer` and the calls triggered from it. `doFrame()` is a private method which, as the name suggests, performs the drawing, processing, and executing of a single frame's worth of rendering. More importantly, we see that `doFrame()` was called 68 times during our test run, meaning that our UI changed 68 times during the ~3 seconds of activity during our trace.

Further down the table, we see that `layout()` on `ViewGroup` was called 26 times directly (and 248 more times via recursion), contributing about 25% of the time consumed by `doFrame()`. Since `layout()` is called on less than half of the `doFrame()` calls, the time consumed by `layout()` makes up a fairly significant portion of the `doFrame()` time during those 26 frames.

More importantly, `layout()` is something that we trigger. It implies that we have made some change to our UI content that requires a layout pass of some `ViewGroup`.

Having a layout pass on occasion is perfectly normal, particularly in response to user

input. A `layout()` might be triggered by the user tapping on a row in one of our `ListView`s, for example. But we are not doing 26 user input events in our test — all we are doing is tapping one time each on a pair of `ListView` rows, then pressing the `BACK` button. This implies that something else in our code is causing `layout()` to be needed.

Unfortunately, at this point, `Traceview` does not help much, because the calls to `layout()` are asynchronous with respect to our own code, so it will not be all that obvious where the extra calls are coming from. This is where we need some expert help, as we will see [later in this chapter](#).

### Overdraw

Another common source of jank is overdraw. Overdraw refers to the act of painting the same pixel several times, due to overlapping components. For example:

- The activity window itself has a background
- You have a container that fills the activity's content, such as a `ListView`, which has a background
- You have children in that container with backgrounds (row), who have their own children with backgrounds and, eventually, content (widgets like `ImageView` and `TextView`)

Places where there is overlap, the OS might set the color of a pixel several times per frame, wasting time.

---

## FINDING AND ELIMINATING JANK

---

The easiest way to track down overdraw is to use the “Show GPU overdraw” option in the Developer Options portion of the Settings app:

This option is only available on Android 4.2 and higher.

When you enable this option, then restart your app’s process (if it was already running), Android will shade pixels that are overdrawn:

- Blue for pixels that are drawn twice
- Green for pixels that are drawn three times
- Pink for pixels that are drawn four times
- Red for pixels that are drawn five or more times

In short: pink and red are bad. Green and blue are OK, though if you have large patches of either shade, you might consider trying to see if there’s a way to get rid of the overdraw.

Of course, the fact that these are shades applied to existing pixel colors may make it a bit difficult to tell exactly where the overdraw is occurring. For example, a red portion of your UI might be red from overdraw... or it might be red because you

## FINDING AND ELIMINATING JANK

---

made it red. Temporarily changing your color scheme to something else (e.g., yellow) will help distinguish what is overdraw and what is just the natural UI coloration.

## FINDING AND ELIMINATING JANK

---

If you enable this option on a Nexus 7 and run the three-pane demo, you will see very little blue or green (beyond the normal blue of the activated state of our ListView rows), and virtually no red:

*Figure 967: Three-Pane Demo, As Initially Launched, Showing Overdraw*

## FINDING AND ELIMINATING JANK

Figure 968: Three-Pane Demo, Left and Middle Panes, Showing Overdraw

Figure 969: Three-Pane Demo, Middle and Right Panes, Showing Overdraw

## FINDING AND ELIMINATING JANK

Figure 970: Three-Pane Demo, Left and Middle Panes Via BACK, Showing Overdraw

## FINDING AND ELIMINATING JANK

---

On the other hand, bringing up the Contacts app on the same Nexus 7 shows significantly more overdraw:

*Figure 971: Contacts App, Showing Overdraw*

The good news is that our app is not suffering performance problems due to overdraw.

The bad news is that the Contacts app is.

The good news is that if you are reading this, you are probably not responsible for maintaining the Contacts app.

The Contacts app's major problems come from the contact photos, or placeholders as seen here. Either the `ImageView` has a background, or the `ImageView` fills some container with a background. For example, the `ImageView` might be in some container with a background to provide a bevel effect around the image. Making the portion of the background that is behind the `ImageView` be transparent will eliminate the overdraw.

Note: some GPU architectures can automatically fix overdraw in select places, while others cannot. Notably, the Tegra 3 cannot. Hence, the Tegra 3 is a good test

platform for using this overdraw-detection feature of Android.

### Extraneous Views

Another related source of jank is having too many extraneous views. Each widget and container contributes to the cost of drawing the overall UI, so having extraneous views adds overhead.

Perhaps the most common scenario for extraneous views is the single-child container. If a container will only ever hold one child, perhaps you can get rid of that container. Not only will this speed up execution at runtime, but it can help avoid running out of stack space.

One way to find these extraneous views is to bring up your user interface [in the Android Studio Layout Inspector](#), or in the older [Hierarchy View tool](#).

*Figure 972: Three-Pane Demo, As Initially Launched, in Layout Inspector*

## FINDING AND ELIMINATING JANK

---

The root DecorView has only one child. This is a framework-supplied container, and so we have no control over it.

*Figure 973: Three-Pane Demo in Layout Inspector, Showing More Hierarchy*

value by getting rid of the unnecessary calls in the first place, if indeed they are unnecessary.

## Where Things Went Wrong

Of course, it doesn't hurt to call in an expert, to try to confirm exactly what is going on.

Chet Haase — Google engineer on Android, [celebrated book author](#), and part-time comedian – [chimed in with an answer](#) to a Stack Overflow question about this three-pane animation, asked by the person who commented about the dropped frames on the original Stack Overflow question.

The key statement from his answer was:

Sliding things around is fine (translationX/Y), fading things in/out is good (alpha), but actually laying things out on every frame? Just say no.

Specifically, he is referring to our use of `ObjectAnimator` to change the width of the middle pane as we show and hide the right pane. Each time we change the width of the middle pane, we trigger a `layout()` call, to reposition the child widgets within that pane as needed. Our animations are adding ~20 `layout()` calls, introducing overhead that is pushing us over the per-frame limit on the Nexus 7.

## Removing the Jank

To remove the jank, we need to remove the `ObjectAnimator` changing the width of the middle pane on the fly. You can see the results of this in the [Jank/ThreePaneBC](#) sample app.

Now, our `showLeft()` and `hideLeft()` methods immediately change the width of the middle pane, rather than arranging its animation:

```
public void hideLeft() {
    if (leftWidth == -1) {
        leftWidth=left.getWidth();
        middleWidthNormal=middle.getWidth();
        resetWidget(left, leftWidth);
        resetWidget(middle, middleWidthNormal);
        resetWidget(right, middleWidthNormal);
        requestLayout();
    }
}
```

## FINDING AND ELIMINATING JANK

---

```
}

translateWidgets(-1 * leftWidth, left, middle, right);
setMiddleWidth(leftWidth);
}

public void showLeft() {
    translateWidgets(leftWidth, left, middle, right);
    setMiddleWidth(middleWidthNormal);
}

private void setMiddleWidth(int value) {
    middle.getLayoutParams().width=value;
    requestLayout();
}
}
```

(from [Jank/ThreePaneBC/app/src/main/java/com/commonsware/android/anim/threepane/ThreePaneLayout.java](#))

This does not provide nearly as good of a UI as the original. However, the revised solution does reduce the jank, as seen in this `gfxinfo` output:

Figure 975: `gfxinfo` Output of Revised `ThreePaneDemoBC`

There are probably ways to improve upon the revised jank-free implementation. Lacking that, it is up to you to decide if the amount of jank found in the original implementation is worth the improved animation or not.

## Frame Metrics API

Above, we looked at `gfxtrace`, which gives you a dump of information related to the rendering of your UI, including how much time is spent in different aspects of that work. However, `gfxtrace` is a device-wide data collection, and so there may be a bit of noise in the results due to other things being updated (Notification icons, other status bar icons, status bar clock, third-party app overlay views, etc.). Plus, `gfxtrace` itself represents a chunk of overhead, slowing down the device.

Android 7.0+ gives us a frame metrics API. We can register a listener to find out the same sorts of information that `gfxtrace` reports, but only to our app, and in Java code. We can log that to Logcat, or do our own [diagnostic overlay](#), or cache it and later send it to a server for analysis. We can also elect to collect this data in our [instrumentation tests](#), to help detect a significant shift in our UI rendering performance.

### What Data You Get

Unfortunately, there is virtually no documentation on the data that we get.

We will receive `FrameMetrics` objects, on which we can call `getMetric()` and provide the identifier of one of the specific metrics that we can retrieve. Note that `FrameMetrics` objects get recycled, so when your listener is handed one, you should copy the data you want out of it and save it somewhere else, rather than attempt to hold onto the `FrameMetrics` object itself. This pattern is used elsewhere in Android, such as with [sensors](#).

Most of the metrics represent amounts of time, measured in nanoseconds, returned as `long` values:

## FINDING AND ELIMINATING JANK

Metric ID	Role
ANIMATION_DURATION	Time spent in animation callbacks
COMMAND_ISSUE_DURATION	Time spent issuing draw commands to the GPU
DRAW_DURATION	Time spent building display lists of commands
INPUT_HANDLING_DURATION	Time spent in input-handling callbacks
LAYOUT_MEASURE_DURATION	Time spent in <code>measure()</code> and <code>layout()</code> work for your view hierarchy
SWAP_BUFFERS_DURATION	Time spent sending the frame buffer for this frame to the display
SYNC_DURATION	Time spent synchronizing the display lists with the render thread
UNKNOWN_DELAY_DURATION	Time spent waiting for the UI thread to process the frame

There is also `TOTAL_DURATION`, which should match the sum of the above values. And, there is `FIRST_DRAW_FRAME`, which returns a boolean value encoded as a long (0 for false, 1 for true), indicating whether this frame was the first to draw in a new window layout.

Developers with deep understanding of the graphics rendering pipeline in Android may recognize these values. For everybody else, the objective is for them to be as low as possible, and for the sum to be well under the 16ms (16,000,000ns) we have for a frame.

### How You Get That Data

The [Jank/FrameMetrics](#) sample project is another variation on the “show a list of videos in a RecyclerView” sample that was profiled in [the chapter on RecyclerView](#) and elsewhere.

This time, though, we have a menu resource:

```
<?xml version="1.0" encoding="utf-8"?>
```

## FINDING AND ELIMINATING JANK

---

```
<menu xmlns:android="http://schemas.android.com/apk/res/android">
  <item
    android:id="@+id/record"
    android:icon="@drawable/ic_record_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_record" />
  <item
    android:id="@+id/stop"
    android:icon="@drawable/ic_stop_white_24dp"
    android:showAsAction="always"
    android:title="@string/menu_stop"
    android:visible="false" />
</menu>
```

(from [Jank/FrameMetrics/app/src/main/res/menu/actions.xml](#))

It defines two action bar items: one to record frame metrics, and one to stop the recording, whether the latter is initially invisible.

In MainActivity, we inflate that menu resource, find those two action items, and hold onto them in fields, via onCreateOptionsMenu():

```
@Override
public boolean onCreateOptionsMenu(Menu menu) {
    getMenuInflater().inflate(R.menu.actions, menu);
    record=menu.findItem(R.id.record);
    stop=menu.findItem(R.id.stop);

    return(super.onCreateOptionsMenu(menu));
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameetrics/MainActivity.java](#))

In onOptionsItemSelected(), when one of those two is tapped, we invert their visibilities, so when the user taps record, the stop item appears, and vice versa:

```
@Override
public boolean onOptionsItemSelected(MenuItem item) {
    if (item.getItemId()==R.id.record) {
        record.setVisible(false);
        stop.setVisible(true);
        afm=new AggregateFrameMetrics();
        getWindow()
            .addOnFrameMetricsAvailableListener(this,
                new Handler(handlerThread.getLooper()));

        return(true);
    }
}
```

## FINDING AND ELIMINATING JANK

---

```
else if (item.getItemId()==R.id.stop) {
    record.setVisible(true);
    stop.setVisible(false);
    getWindow().removeOnFrameMetricsAvailableListener(this);
    afm.log(getClass().getSimpleName());
    afm=null;

    return(true);
}

return(super.onOptionsItemSelected(item));
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameMetrics/MainActivity.java](#))

However, in addition, when the user taps record, we:

- Create an instance of an `AggregateFrameMetrics` class and hold onto it in a field (`afm`)
- Call `addOnFrameMetricsAvailableListener()` on the activity's `Window`, passing in a `Window.OnFrameMetricsAvailableListener` implementation (here, our `MainActivity` itself) and a `Handler` on which we want to have that listener's callback method be invoked (here, a `Handler` tied to a `HandlerThread` created when the activity is created)

The result is that when the user taps record, our activity's `onFrameMetricsAvailable()` method will be called on that `HandlerThread`, providing us with metrics on the just-completed frame:

```
@Override
public void onFrameMetricsAvailable(Window window,
                                     FrameMetrics frameMetrics,
                                     int droppedEvents) {
    afm.add(frameMetrics, droppedEvents);
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameMetrics/MainActivity.java](#))

`onFrameMetricsAvailable()` is passed three parameters:

- the `Window` which we registered for metrics on
- the `FrameMetrics` for that frame
- an `int` indicating how many `onFrameMetricsAvailable()` calls were missed because we took too long in the last `onFrameMetricsAvailable()` call processing the previous results (ideally, this is always 0)

## FINDING AND ELIMINATING JANK

---

Here, we pass the metrics and dropped-events values to the `AggregateFrameMetrics` object.

Back up in `onOptionsItemSelected()`, if the user taps on stop, we remove our activity as a listener via `removeOnFrameMetricsAvailableListener()` and call `log()` on the `AggregateFrameMetrics` object.

`AggregateFrameMetrics`, in turn, is responsible for maintaining a running total of the various individual metrics and dumping them to Logcat when `log()` is called:

```
package com.commonware.android.jank.frameMetrics;

import android.util.Log;
import android.view.FrameMetrics;

public class AggregateFrameMetrics {
    int droppedReports;
    long animationDuration;
    long commandIssueDuration;
    long drawDuration;
    long inputHandlingDuration;
    long layoutMeasureDuration;
    long swapBuffersDuration;
    long syncDuration;
    long unknownDelayDuration;
    long totalDuration;

    void add(FrameMetrics metrics, int droppedReports) {
        this.droppedReports+=droppedReports;

        animationDuration+=
            metrics.getMetric(FrameMetrics.ANIMATION_DURATION);
        commandIssueDuration+=
            metrics.getMetric(FrameMetrics.COMMAND_ISSUE_DURATION);
        drawDuration+=metrics.getMetric(FrameMetrics.DRAW_DURATION);
        inputHandlingDuration+=
            metrics.getMetric(FrameMetrics.INPUT_HANDLING_DURATION);
        layoutMeasureDuration+=
            metrics.getMetric(FrameMetrics.LAYOUT_MEASURE_DURATION);
        swapBuffersDuration+=
            metrics.getMetric(FrameMetrics.SWAP_BUFFERS_DURATION);
        syncDuration+=metrics.getMetric(FrameMetrics.SYNC_DURATION);
        unknownDelayDuration+=
            metrics.getMetric(FrameMetrics.UNKNOWN_DELAY_DURATION);
        totalDuration+=metrics.getMetric(FrameMetrics.TOTAL_DURATION);
    }
}
```

## FINDING AND ELIMINATING JANK

---

```
void log(String tag) {
    Log.d(tag, String.format("animation: %dns", animationDuration));
    Log.d(tag, String.format("command issue: %dns", commandIssueDuration));
    Log.d(tag, String.format("draw: %dns", drawDuration));
    Log.d(tag, String.format("input handling: %dns", inputHandlingDuration));
    Log.d(tag, String.format("layout measure: %dns", layoutMeasureDuration));
    Log.d(tag, String.format("swap buffers: %dns", swapBuffersDuration));
    Log.d(tag, String.format("sync: %dns", syncDuration));
    Log.d(tag, String.format("unknown: %dns", unknownDelayDuration));
    Log.d(tag, String.format("total: %dns", totalDuration));
    Log.d(tag, String.format("%d dropped reports", droppedReports));
}
}
```

(from [Jank/FrameMetrics/app/src/main/java/com/commonsware/android/jank/frameetrics/AggregateFrameMetrics.java](#))

The net effect is that between taps on record and stop, we collect information about the UI rendering performance. If you try this on a device that has a bunch of videos on it, scroll through the list while the collection is ongoing. Once you click stop to end the collection, the aggregated results are printed to Logcat.

# Issues with Bandwidth

---

As anyone who owned an Apple Newton or Palm V PDA back in the 1990's knows, handheld devices have been around for quite some time. For a very long time, they were a niche product, associated with geeks, nerds, and the occasional business executive.

Internet access changed all of that.

Blackberry for enterprise messaging — an outgrowth of its original two-way paging approach — blazed part of the trail, but the concept “crossed the chasm” to ordinary people with the advent of the iPhone, Android devices, and similar equipment.

Therefore, it is not terribly surprising when Android developers want to add Internet capabilities to their apps. To the contrary, it is almost unusual when you encounter an app that does *not* want to use the Internet for something or another.

However, mobile Internet access inherits all of the classic problems of Internet access (e.g., “server not found”) and adds new and exciting challenges, all of which can leave a developer with an app that has performance issues.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## You're Using Too Much of the Slow Stuff

To paraphrase America's Founding Fathers, “all Internet connections are not created

equal”.

One form of inequality is speed. Different classes of connection have different theoretical upper bounds. WiMAX and other 4G connections are theoretically faster than 3G connections, which are theoretically faster than 2G or EDGE connections. WiFi is theoretically ridiculously fast though it is typically limited by the ISP connection, and ISP connections can run the gamut from really fast to merely good.

However, “theoretical” bounds tend to run afoul of reality. There are plenty of places where high-speed mobile data connections are non-existent, despite what the carriers’ coverage maps claim. 2G mobile data works, but is not especially speedy. This layers on top of the typical Internet congestion issues, along with typically transitory problems (e.g., trying to get connectivity while attending a technology conference keynote presentation).

Beyond that, there are financial issues. While WiFi is usually unmetered (no incremental cost per MB/GB), many mobile data connections are metered. Those mobile data connections that are not metered in theory – advertised as “unlimited” — have usage caps that, once exceeded, impose costs or impose speed limits.

Hence, what runs quickly in the lab may run much more slowly in users’ hands.

If you followed the instructions in previous chapters on CPU bottlenecks, the limited bandwidth will not cause your UI to become “janky”, in that it will be responsive to touches and taps. However, poor connectivity will mean that you are simply slow to respond to user requests. For example, clicking the “check for new email” menu button has no immediate effect. If you feel that you need a splash screen or progress indicator to tell the user that “we are really checking for new email, honest”, then you know that your Internet access is slower than is ideal.

Obviously, some of this is unavoidable. However, the objective of the chapters in this part of the book is to give you an idea of ways to reduce your bandwidth consumption, making those delays be that much less annoying for your users.

## **You’re Using Too Much of the Expensive Stuff**

Mobile data tends to come with more strings attached than does WiFi.

In the US, it used to be that mobile data connections included unlimited usage. Now, at best, a mobile data plan has “unlimited” usage for a curious definition of the

term “unlimited”. More and more carriers are moving towards a hard cap — go above the cap, and you either cannot use more bandwidth, have your speeds curtailed, or pay significantly for additional bandwidth.

Outside of the US, the “pay significantly for bandwidth” approach is fairly typical. So-called “metered” data plans simply charge you such-and-so per MB or GB of bandwidth.

And, to top it off, roaming almost always is a metered plan. So, a US resident traveling overseas, even with a SIM and phone that supports international usage, would pay a ridiculous sum for bandwidth. Stories of phone bills in the tens of thousands of dollars abound, where people simply used their phone as they normally would when they were outside of their home network.

Hence, if you use a fair bit of bandwidth, it would be really nice if you offered users means to consume less of it when they are on mobile data compared to WiFi (which is typically unmetered). You could elect to poll your server less frequently, for example, giving the users the ability to specify separate polling periods depending on which type of connection they have.

And, of course, there are other “costs” for using bandwidth besides direct monetary costs. For example, downloading data over a slower mobile data connection may consume more power than downloading the same data over WiFi — while the WiFi radio might consume additional power, the time difference might account for more power consumption, if the CPU could be powered down for the rest of that time.

These chapters will show you how you can react to changes in connectivity and approaches for how to use that information to reduce costs for the user.

## **You’re Using Too Much of Somebody Else’s Stuff**

It is easy for developers to think that they alone are using a user’s device. Alas, this is infrequently the case, particularly when it comes to background Internet access.

While your application is busily downloading stuff, some other application might be busily downloading stuff. In principle, this should not be an issue, as multiple applications can access the Internet simultaneously. However, bandwidth can become an issue. If you are in the background, and the other application is in the foreground, the user might notice that bandwidth is an issue. For example, users might be unhappy if your downloads are impeding their ability to watch streaming

video, or play their favorite Android-based MMORPG, or whatever.

A polite Android application will test to see whether the foreground application is heavily using the Internet and will curtail its own Internet use while that is going on. This chapter will help you learn how to make that determination and how to respond.

## You're Using Too Much... And There Is None

Not only might location dictate how much bandwidth you have, but whether you have any bandwidth at all.

While some people think that the entire planet has connectivity, reality once again dictates otherwise. Major metropolitan areas have connectivity. Outlying areas are much more hit-or-miss. Voice is sometimes a challenge, let alone data. And it only *seems* as though there is a Starbucks every 100 meters in the US, which might actually provide blanket WiFi coverage.

Then, of course, there are planes (many still do not offer in-flight WiFi at this time), international travel without an international-capable phone plan, and so on.

Some Android applications have the potential to still offer near-complete functionality despite this, with a bit of user assistance. For example, Google Maps for Android has an offline caching feature, which will download data for a 10-mile radius from a given point, for use while the device is otherwise offline.

Here, the issue becomes less one of bandwidth (other than detecting that you have no connection) and more one of caching and storage. The space-related issues that these techniques can raise will be covered elsewhere in this book.

# Focus On: TrafficStats

---

To be able to have more intelligent code — code that can adapt to Internet activity on the device — Android offers the `TrafficStats` class. This class really is a gateway to a block of native code that reports on traffic usage for the entire device and per-application, for both received and transmitted data. This chapter will examine how you can access `TrafficStats` and interpret its data.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## TrafficStats Basics

The `TrafficStats` class is not designed to be instantiated — you will not be invoking a constructor by calling `new TrafficStats()` or something like that. Rather, `TrafficStats` is merely a collection of static methods, mapped to native code, that provide access to point-in-time traffic values. No special permissions are needed to use any of these methods. Most of the methods were added in API Level 8 and therefore should be callable on most Android devices in use today.

## Device Statistics

If you are interested in overall traffic, you will probably care most about the `getTotalRxBytes()` and `getTotalTxBytes()` on `TrafficStats`. These methods return received and transmitted traffic, respectively, measured in bytes.

You also have:

1. `getTotalRxPackets()` and `getTotalTxPackets()`, if for your case measuring IP packets is a better measure than bytes
2. `getMobileRxBytes()` and `getMobileTxBytes()`, which return the traffic going over mobile data (also included in the total)
3. `getMobileRxPackets()` and `getMobileTxPackets()`, which are the packet counts for the mobile data connection

### Per-Application Statistics

Technically, `TrafficStats` does not provide per-application traffic statistics. Rather, it provides per-UID traffic statistics. In most cases, the UID (user ID) of an application is unique, and therefore per-UID statistics map to per-application statistics. However, it is possible for multiple applications to share a single UID (e.g., via the `android:sharedUserId` manifest attribute) — in this case, `TrafficStats` would appear to provide traffic data for all applications sharing that UID.

There are per-UID equivalents of the first four methods listed in the previous section, replacing “Total” with “Uid”. So, to find out overall traffic for an application, you could use `getUidRxBytes()` and `getUidTxBytes()`. However, these are the only two UID-specific methods that were implemented in API Level 8. Equivalents of the others (e.g., `getUidRxPackets()`) were added in API Level 12. API Level 12 also added some TCP-specific methods (e.g., `getUidTcpTxBytes()`). Note, though, that the mobile-only methods are only available at the device level; there are no UID-specific versions of those methods.

### Interpreting the Results

You will get one of two types of return value from these methods.

In theory, you will get the value the method calls for (e.g., number of bytes, number of packets). The documentation does not state the time period for that value, so while it is possible that it is really “number of bytes since the device was booted”, we do not know that for certain. Hence, `TrafficStats` results should be used for comparison purposes, either comparing the same value over time or comparing multiple values at the same time. For example, to measure bandwidth consumption, you will need to record the `TrafficStats` values at one point in time, then again later — the difference between them represents the consumed bandwidth during that period of time.

In practice, while the “total” methods seem reliable, the per-UID methods may return -1. Three possible meanings are:

1. The device is old and is not set up to measure per-UID values
2. There has been no traffic of that type on that UID since boot, or
3. You do not have permission to know the traffic of that type on that UID

Hence, the per-UID values are a bit “hit or miss”, which you will need to take into account.

## Example: TrafficMonitor

To illustrate the use of `TrafficStats` methods and analysis, let us walk through the code associated with the [Bandwidth/TrafficMonitor](#) sample application. This is a simple activity that records a snapshot of the current traffic levels on startup, then again whenever you tap a button. On-screen, it will display the current value, previous value, and difference (“delta”) between them. In Logcat, it will dump the same information on a per-UID basis.

### TrafficRecord

It would have been nice if `TrafficStats` were indeed an object that you would instantiate, that captured the traffic values at that moment in time. Alas, that is not how it was written, so we need to do that ourselves. In the `TrafficMonitor` project, this job is delegated to a `TrafficRecord` class:

```
package com.commonware.android.tuning.traffic;

import android.net.TrafficStats;

class TrafficRecord {
    long tx=0;
    long rx=0;
    String tag=null;

    TrafficRecord() {
        tx=TrafficStats.getTotalTxBytes();
        rx=TrafficStats.getTotalRxBytes();
    }

    TrafficRecord(int uid, String tag) {
        tx=TrafficStats.getUidTxBytes(uid);
        rx=TrafficStats.getUidRxBytes(uid);
    }
}
```

## FOCUS ON: TRAFFICSTATS

---

```
    this.tag=tag;
  }
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficRecord.java](#))

There are two separate constructors, one for the total case and one for the per-UID case. The total case just logs `getTotalRxBytes()` and `getTotalTxBytes()`, while the per-UID case uses `getUidRxBytes()` and `getUidTxBytes()`. The per-UID case also stores a “tag”, which is simply a `String` identifying the UID for this record — as you will see, `TrafficMonitor` uses this for a package name.

### TrafficSnapshot

An individual `TrafficRecord`, though, is insufficient to completely capture the traffic figures at a moment in time. We need a collection of `TrafficRecord` objects, one for the device (“total”) and one per running UID. The work to collect all of that is handled by a `TrafficSnapshot` class:

```
package com.commonsware.android.tuning.traffic;

import java.util.HashMap;
import android.content.Context;
import android.content.pm.ApplicationInfo;

class TrafficSnapshot {
    TrafficRecord device=null;
    HashMap<Integer, TrafficRecord> apps=
        new HashMap<Integer, TrafficRecord>();

    TrafficSnapshot(Context ctxt) {
        device=new TrafficRecord();

        HashMap<Integer, String> appNames=new HashMap<Integer, String>();

        for (ApplicationInfo app :
            ctxt.getPackageManager().getInstalledApplications(0)) {
            appNames.put(app.uid, app.packageName);
        }

        for (Integer uid : appNames.keySet()) {
            apps.put(uid, new TrafficRecord(uid, appNames.get(uid)));
        }
    }
}
```

## FOCUS ON: TRAFFICSTATS

---

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficSnapshot.java](#))

The constructor uses `PackageManager` to iterate over all installed applications and builds up a `HashMap`, mapping the UID to a `TrafficRecord` for that UID, tagged with the application package name (e.g., `com.commonsware.android.tuning.traffic`). It also creates one `TrafficRecord` for the device as a whole.

### TrafficMonitorActivity

`TrafficMonitorActivity` is what creates and uses `TrafficSnapshot` objects. This is a fairly conventional activity with a `TableLayout`-based UI:

```
<?xml version="1.0" encoding="utf-8"?>
<TableLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/table"
    android:layout_width="match_parent"
    android:layout_height="wrap_content">

    <Button
        android:onClick="takeSnapshot"
        android:text="Take Snapshot"/>

    <TableRow>

        <TextView
            android:layout_column="1"
            android:layout_gravity="right"
            android:text="@string/received"
            android:textSize="20sp"/>

        <TextView
            android:layout_gravity="right"
            android:text="@string/sent"
            android:textSize="20sp"/>
    </TableRow>

    <TableRow>

        <TextView
            android:layout_marginRight="@dimen/margin_right"
            android:gravity="right"
            android:text="@string/latest"
            android:textSize="20sp"
            android:textStyle="bold"/>

        <TextView
```

## FOCUS ON: TRAFFICSTATS

---

```
        android:id="@+id/latest_rx"
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:textSize="20sp"/>

    <TextView
        android:id="@+id/latest_tx"
        android:gravity="right"
        android:textSize="20sp"/>
</TableRow>

<TableRow>

    <TextView
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:text="@string/previous"
        android:textSize="20sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/previous_rx"
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:textSize="20sp"/>

    <TextView
        android:id="@+id/previous_tx"
        android:gravity="right"
        android:textSize="20sp"/>
</TableRow>

<TableRow>

    <TextView
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:text="@string/delta"
        android:textSize="20sp"
        android:textStyle="bold"/>

    <TextView
        android:id="@+id/delta_rx"
        android:layout_marginRight="@dimen/margin_right"
        android:gravity="right"
        android:textSize="20sp"/>

<TextView
```

## FOCUS ON: TRAFFICSTATS

---

```
        android:id="@+id/delta_tx"
        android:gravity="right"
        android:textSize="20sp"/>
    </TableRow>
</TableLayout>
```

(from [Bandwidth/TrafficMonitor/app/src/main/res/layout/main.xml](#))

The activity implementation consists of three methods. There is your typical `onCreate()` implementation, where we initialize the UI, get our hands on the `TextView` widgets for output, and take the initial snapshot:

```
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.main);

    latest_rx=(TextView)findViewById(R.id.latest_rx);
    latest_tx=(TextView)findViewById(R.id.latest_tx);
    previous_rx=(TextView)findViewById(R.id.previous_rx);
    previous_tx=(TextView)findViewById(R.id.previous_tx);
    delta_rx=(TextView)findViewById(R.id.delta_rx);
    delta_tx=(TextView)findViewById(R.id.delta_tx);

    takeSnapshot(null);
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficMonitorActivity.java](#))

The `takeSnapshot()` method creates a new `TrafficSnapshot` (held in a latest data member) after moving the last `TrafficSnapshot` to a previous data member. It then updates the `TextView` widgets for the latest data and, if the previous data member is not null, also for the previous snapshot and the difference between them. This alone is sufficient to update the UI, but we also want to log per-UID data to Logcat:

```
public void takeSnapshot(View v) {
    previous=latest;
    latest=new TrafficSnapshot(this);

    latest_rx.setText(String.valueOf(latest.device.rx));
    latest_tx.setText(String.valueOf(latest.device.tx));

    if (previous!=null) {
        previous_rx.setText(String.valueOf(previous.device.rx));
        previous_tx.setText(String.valueOf(previous.device.tx));
    }
}
```

## FOCUS ON: TRAFFICSTATS

---

```
delta_rx.setText(String.valueOf(latest.device.rx-previous.device.rx));
delta_tx.setText(String.valueOf(latest.device.tx-previous.device.tx));
}

ArrayList<String> log=new ArrayList<String>();
HashSet<Integer> intersection=new HashSet<Integer>(latest.apps.keySet());

if (previous!=null) {
    intersection.retainAll(previous.apps.keySet());
}

for (Integer uid : intersection) {
    TrafficRecord latest_rec=latest.apps.get(uid);
    TrafficRecord previous_rec=
        (previous==null ? null : previous.apps.get(uid));

    emitLog(latest_rec.tag, latest_rec, previous_rec, log);
}

Collections.sort(log);

for (String row : log) {
    Log.d("TrafficMonitor", row);
}
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficMonitorActivity.java](#))

One possible problem with the snapshot system is that the process list may change between snapshots. One simple way to address this is to only log to Logcat data where the application's UID exists in both the previous and latest snapshots. Hence, `takeSnapshot()` uses a `HashSet` and `retainAll()` to determine which UIDs exist in both snapshots. For each of those, we call an `emitLog()` method to record the data to an `ArrayList`, which is then sorted and dumped to Logcat.

The `emitLog()` method builds up a line with the package name and bandwidth consumption information, assuming that there is bandwidth to report (i.e., we have a value other than -1):

```
private void emitLog(CharSequence name, TrafficRecord latest_rec,
                    TrafficRecord previous_rec,
                    ArrayList<String> rows) {
    if (latest_rec.rx>-1 || latest_rec.tx>-1) {
        StringBuilder buf=new StringBuilder(name);

        buf.append("=");
```

## FOCUS ON: TRAFFICSTATS

---

```
buf.append(String.valueOf/latest_rec.rx));
buf.append(" received");

if (previous_rec!=null) {
    buf.append(" (delta=");
    buf.append(String.valueOf/latest_rec.rx-previous_rec.rx));
    buf.append(")");
}

buf.append(", ");
buf.append(String.valueOf/latest_rec.tx));
buf.append(" sent");

if (previous_rec!=null) {
    buf.append(" (delta=");
    buf.append(String.valueOf/latest_rec.tx-previous_rec.tx));
    buf.append(")");
}

rows.add(buf.toString());
}
}
```

(from [Bandwidth/TrafficMonitor/app/src/main/java/com/commonsware/android/tuning/traffic/TrafficMonitorActivity.java](#))

Since the lines created by `emitLog()` start with the package name, and since we are sorting those before dumping them to Logcat, they appear in Logcat in sorted order by package name.

## Using TrafficMonitor

Running the activity gives you the initial received and sent counts (in bytes):

*Figure 976: The TrafficMonitor sample application, as initially launched*

## FOCUS ON: TRAFFICSTATS

---

Tapping Take Snapshot grabs a second snapshot and compares the two:

*Figure 977: The TrafficMonitor sample application, after Take Snapshot was clicked*

Also, Logcat will show how much was used by various apps:

```
08-15 14:05:10.128: DEBUG/TrafficMonitor(10283): com.amblingbooks.bookplayerpro=880
received (delta=0), 3200 sent (delta=0)

```

## Other Ways to Employ TrafficStats

Of course, there are more ways you could use TrafficStats than simply having an activity to report them on a button click. TrafficMonitor is merely a demonstration of using the class and providing a lightweight way to get value out of that data. Depending upon your application's operations, though, you may wish to consider using TrafficStats in other ways, in your production code or in your test suites.

### In Production

If your app is a bandwidth monitor, the need to use TrafficStats is obvious. However, even if your app does something else, you may wish to use TrafficStats to understand what is going on in terms of Internet access within your app or on the device as a whole.

For example, you might want to consider bandwidth consumption to be a metric worthy of including in the rest of the “analytics” you generate from your app. If you are using services like [Flurry](#) to monitor which activities get used and so on, you

might consider also logging the amount of bandwidth your application consumes. This not only gives you much more “real world” data than you will be able to collect on your own, but it may give you ideas of how users are using your application beyond what the rest of your metrics are reporting.

Another possibility would be to include your app’s bandwidth consumption in error logs reported via libraries like [ACRA](#). Just as device particulars can help identify certain bug report patterns, perhaps certain crashes of your app only occur when users are using a lot of bandwidth in your app, or using a lot of bandwidth elsewhere and perhaps choking your own app’s Internet access.

The [chapter on bandwidth mitigation strategies](#) will also cover a number of uses of TrafficStats for real-time adjustment of your application logic.

### During Testing

You might consider adding TrafficStats-based bandwidth logging for your application in your test suites. While individual tests may or may not give you useful data, you may be able to draw trendlines over time to see if you are consuming more or less bandwidth than you used to. Take care to factor in that you may have changed the tests, in addition to changing the code that is being tested.

From a JUnit-based unit test suite, measuring bandwidth consumption is not especially hard. You can bake it into the `setUp()` and `tearDown()` methods of your test cases, either via inheritance or composition, and log the output to a file or Logcat.

From an external test engine, like [monkeyrunner](#) or [NativeDriver](#), recording bandwidth usage is more tricky, because your test code is not running on the device or emulator. You may have to include a `BroadcastReceiver` in your production code that will log bandwidth usage and trigger that code via the `am broadcast shell` command.

# Measuring Bandwidth Consumption

---

The first step towards addressing bandwidth concerns is to get a better picture of how much bandwidth you are actually consuming, when, and under what conditions. Only then will you be able to determine where your efforts need to be applied and whether those efforts are actually giving you positive results. This chapter will examine a handful of ways you can determine how much bandwidth you are really using in your application.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## On-Device Measurement

Many times, you are best served by measuring your bandwidth consumption right on the device itself:

1. This is your only option for gathering bandwidth metrics from copies of your app in end users' hands, unless they invite you to their home or office and have you sniff on their personal network, which seems unlikely
2. This is your only option for gathering bandwidth metrics when you are using mobile data plans (e.g., 3G) instead of WiFi, since you probably do not control the wireless telecommunications infrastructure in your area
3. This is your simplest option for tying bandwidth metrics to events within your app or occurring on the device
4. This is your only option for using bandwidth metrics to adjust your application behavior in real time, in addition to using the metrics to learn

how best to adjust your code in future updates to the app

Hence, in addition to perhaps other off-device techniques, you really should consider one of the on-device approaches outlined in the following sections.

### **Yourself, via TrafficStats**

The [preceding chapter](#) outlined how to use the `TrafficStats` class to collect metrics on the bandwidth consumed by applications (including yours) and for the device as a whole. This gives you the most flexibility, because you can write your own code to collect whatever portion of this data you need. It can address all of the bullets shown above, for example.

It is not perfect, though:

1. It requires you to write your own code, adding yet more work to your plate
2. Per-UID traffic data may or may not be available, depending upon the device

## Data Usage Screen in Settings

For more casual use, the Settings app in most Android devices offers a “Data Usage” screen that shows how much bandwidth has been consumed over a period of time:

## MEASURING BANDWIDTH CONSUMPTION

Scrolling further down will give you details of what apps were involved in that data usage:

## MEASURING BANDWIDTH CONSUMPTION

---

Tapping on any one of those list items will give you a bit more detail, specifically how much of that bandwidth was consumed while the app was in the foreground or the background:

*Figure 980: Settings, App, Data Usage Screen, Data Usage App Details*

## Off-Device Measurement

The biggest limitation of `TrafficStats` is that it only gives you gross metrics: numbers of bytes, packets, and so on. Sometimes, that is not enough to help you understand why those bytes, packets, and so on are actually being sent or received. Sometimes, it would be nice to understand the traffic in more detail, from the ports and IP addresses to perhaps the actual data being transmitted. For obvious security reasons, this is not something an ordinary Android SDK application can do. However, there are techniques for accomplishing this, mostly for use over WiFi in your own home or office network. Some of these are outlined in the following sections.

### Wireshark

[Wireshark](#), formerly known as `Ethereal`, is perhaps the world's leading open source network traffic analyzer and packet inspector. Using it, you can learn in great detail

## MEASURING BANDWIDTH CONSUMPTION

what is going on with your local network. And, Android provides additional options for you to leverage Wireshark to make sense of application behavior. Wireshark is available for Linux, macOS, and Windows.

There is a lightly-documented `-tcpdump` switch available on the Android emulator. If you launch the emulator from the command line with that switch (plus `-avd` to identify the AVD file you want to use), all network access is dumped to your specified log file. You can then load that data into Wireshark for analysis, via File|Open from the main menu.

For example, here is a screenshot of Wireshark examining data from such an emulator dump file, in which the emulator was used to conduct a Google search:

Figure 981: Wireshark examining captured emulator packets

This screenshot shows an HTTP request in the highlighted line in the list, with the hex and ASCII contents of the request shown in the bottom pane.

In terms of using Wireshark to monitor traffic from actual hardware, that is indubitably possible. However, WiFi packet collection is a tricky process with Wireshark, being very dependent upon operating system and possibly even the WiFi adapter chipset. You also get much lower-level information, making it a bit more challenging to figure out what is going on. Attempting to cover all of this is well

beyond the scope of this book and the author's Wireshark expertise.

### Networking Hardware

Sophisticated firewalls sometimes have packet tracing/sniffing capability. In this case, “sophisticated” does not necessarily mean “expensive”, as open source router/firewall distributions, like OpenWrt, can be used for this sort of work. In this case, the router captures the packets and, in many cases, routes them to Wireshark for analysis. Some might offer on-board analysis (e.g., Web interface to packet capture logs).

This is particularly useful on a Windows wireless network. Wireshark has limits, imposed by Windows, that cause some problems when trying to capture WiFi packets. By offloading the packet capture to networking hardware, those limits can be bypassed.

### Android Studio Profiler

TrafficStats is great for measuring gross bandwidth consumption over some period of time. However, it requires coding, logging, and your own analysis mechanism.

In Android Studio, the Android Profiler tool allows you to examine the real-time behavior of your app with respect to various system resources, such as bandwidth consumption:

*Figure 982: Android Studio, Android Profiler, Network Graph*

## MEASURING BANDWIDTH CONSUMPTION

Clicking on the graph gives you a bit more detail, including the state of various radios and the number of connections that were in use:

*Figure 983: Android Studio, Android Profiler, Detailed Network Graph*

This graph comes from a Picasso demo application from earlier in the book, which retrieves the latest 25 android questions on Stack Overflow and shows them in a `ListView`, along with the avatar for the person asking the question. The graph shows the initial load of data from the Stack Exchange JSON API, followed about 15 seconds later by some scrolling in the app, forcing Picasso to go load more avatars.

As this responds in near-real-time to things you do in your app, you can see if the graph shows network accesses at unexpected times, or more bandwidth consumed than you might expect. For example, once all the avatars were loaded, no more bandwidth should be consumed by the Picasso sample app, assuming all the avatars could fit in Picasso's memory cache.

# Being Smarter About Bandwidth

---

Given that you are [collecting metrics about bandwidth consumption](#), you can now start to determine ways to reduce that consumption. You may be able to permanently reduce that consumption (at least on a per-operation basis). You may be able to shunt that consumption to times or networks that the user prefers. This chapter reviews a variety of means of accomplishing these ends.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Internet access](#).

## Bandwidth Savings

The best way to reduce bandwidth consumption is to consume less bandwidth.

(in other breaking news, water is wet)

In recent years, developers have been able to be relatively profligate in their use of bandwidth, pretty much assuming everyone has an unlimited high-speed Internet connection to their desktop or notebook and the desktop or Web apps in use on them. However, those of us who lived through the early days of the Internet remember far too well the challenges that dial-up modem accounts would present to users (and perhaps ourselves). Even today, as Web apps try to “scale to the Moon and back”, bandwidth savings becomes important not so much for the end user, but for the Web app host, so its own bandwidth is not swamped as its user base grows.

Fortunately, widespread development problems tend to bring rise to a variety of solutions — a variant on the “many eyes make bugs shallow” collaborative development phenomenon. Hence, there are any number of tried-and-true techniques for reducing bandwidth consumption that have had use in Web apps and elsewhere. Many of these are valid for native Android apps as well, and a few of them are profiled in the following sections.

### Classic HTTP Solutions

Trying to get lots of data to fit on a narrow pipe — whether that pipe is on the user’s end or the provider’s end — has long been a struggle in Web development. Fortunately, there are a number of ways you can leverage HTTP intelligently to reduce your bandwidth consumption.

#### GZip Encoding

By default, HTTP requests and response are uncompressed. However, you can enable GZip encoding and thereby request that the server compress its response, which is then decompressed on the client. This trades off CPU for bandwidth savings and therefore needs to be done judiciously.

Enabling GZip compression is a two-step process:

- Adding the `Accept-Encoding: gzip` header to the HTTP request
- Determine if the response was compressed and, if so, decompressing it

Bear in mind that the Web server may or may not honor your GZip request, for whatever reason (e.g., response is too small to make it worthwhile).

#### If-Modified-Since / If-None-Match

Of course, avoiding a download offers near-100% compression. If you are caching data, you can take advantage of HTTP headers to try to skip downloads that are the same content as what you already have, specifically `If-Modified-Since` and `If-None-Match`.

An HTTP response can contain either a `Last-Modified` header or an `ETag` header. The former will contain a timestamp and the latter will contain some opaque value. You can store this information with the cached copy of the data (e.g., in a database table). Later on, when you want to ensure you have the latest version of that file,

your HTTP GET request can include an `If-Modified-Since` header (with the cached Last-Modified value) or an `If-None-Match` header (with the cached ETag value). In either case, the server should return either a 304 response, indicating that your cached copy is up to date, or a 200 response with the updated data. As a result, you avoid the download entirely (other than HTTP headers) when you do not need the updated data.

### Binary Payloads

While XML and JSON are relatively easy for humans to read, that very characteristic means they tend to be bloated in terms of bandwidth consumption. There are a variety of tools, such as Google's [Protocol Buffers](#) and Apache's [Thrift](#), that allow you to create and parse binary data structures in a cross-platform fashion. These might allow you to transfer the same data that you would in XML or JSON in less space. As a side benefit, parsing the binary responses is likely to be faster than parsing XML or JSON. Both of these tools involve the creation of an IDL-type file to describe the data structure, then offer code generators to create Java classes (or equivalents for other languages) that can read and write such structures, converting them into platform-neutral on-the-wire byte arrays as needed.

### Minification

If you are loading JavaScript or CSS into a `WebView`, you should consider standard tricks for compressing those scripts, collectively referred to as "[minification](#)". These techniques eliminate all unnecessary whitespace and such from the files, rename variables to be short, and otherwise create a syntactically-identical script that takes up a fraction of the space.

### Keep-Alive Semantics

A chunk of the overhead involved in HTTP operations is simply establishing the socket connection with the Web server. Advertising that you want the socket to be kept alive, in anticipation of upcoming follow-on requests, can reduce this overhead.

Using higher-level HTTP clients, like `OkHttp`, helps here, because usually they handle all the details of keeping the socket open.

With SSL, though, keep-alive was not an option, until Google released the SPDY specification. SPDY in turn formed the basis of HTTP/2, the new standard for Web communications (replacing the venerable HTTP/1.1). `OkHttp` supports SPDY and

HTTP/2.

### Push versus Poll

Another way to consume less bandwidth is to only make the requests when it is needed. For example, if you are writing an email client, the way to use the least bandwidth is to download new messages only when they exist, rather than frequently polling for messages.

Off the cuff, this may seem counter-intuitive. After all, how can we know whether or not there are any messages if we are not polling for them?

The answer is to use a low-bandwidth push mechanism. The quintessential example of this is [GCM](#), the Google Cloud Messaging system, available for Android 2.2 and newer. This service from Google allows your application to subscribe to push notifications sent out by your server. Those notifications are delivered asynchronously to the device by way of Google's own servers, using a long-lived socket connection. All you do is register a `BroadcastReceiver` to receive the notifications and do something with them.

For example, Remember the Milk — a task management Web site and set of mobile apps — uses GCM to alert the device of task changes you make through the Web site. Rather than the Remember the Milk app having to constantly poll to see if tasks were added, changed, or deleted, the app simply waits for GCM events.

You could create your own push mechanism, perhaps using a `WebSocket` or [MQTT](#). The downside is that you will need a service in memory all of the time to manage the socket and thread that monitors it. If you only need this while your service is in memory for other reasons, that is fine. However, keeping a service in memory 24x7 has its own set of issues, not the least of which is that users will tend to smack it down using a “task killer” or the Manage Services screen in the Settings app. Doze mode on Android 6.0+ will also cause problems with this approach.

### Thumbnails and Tiles

A general rule of thumb is: don't download it until you really need it.

Sometimes, you do not know if you really need a particular item until something happens in the UI. Take a `ListView` displaying thumbnails of album covers for a music app. Assuming the album covers are not stored locally, you will need to download them for display. However, which covers you need varies based upon

scrolling. Downloading a high-resolution album cover that might get tossed in a matter of milliseconds (after an expensive rescale to fit a thumbnail-sized space) is a waste of bandwidth.

In this case, either the album covers are something you control on the server side, or they are not. If they are, you can have the server prepare thumbnails of the covers, stored at a spot that the app can know about (e.g., `.../cover.jpg` it is `.../thumbnail.jpg`). The app can then download thumbnails on the fly and only grab the full-resolution cover if needed (e.g., user clicks on the album to bring up a detail screen). If you do not control the album covers, this option might still be available to you if you can run your own server for the purposes of generating such thumbnails.

You can see a similar effect with the map tiles in Google Maps. When zooming out, the existing map tiles are scaled down, with placeholders (the gridlines) for the remaining spots, until the tiles for those spots are downloaded. When zooming in, the existing map tiles are scaled up with a slight blurring effect, to give the user some immediate feedback while the full set of more-detailed tiles is downloaded. And, if the user pans, you once again get placeholders while the tiles for the newly uncovered areas are downloaded. In this fashion, Google Maps is able to minimize bandwidth consumption by giving users partial results immediately and back-filling in the final results only when needed. This same sort of approach may be useful with your own imagery.

## Bandwidth Shaping

Sometimes, you have no ability to reduce the bandwidth itself. Perhaps you do not control both ends of the communications pipeline. Perhaps the data you are trying to exchange is already compressed (e.g., downloading an MP4 video). Perhaps some of the techniques in the preceding section were unavailable to you (e.g., cannot route data through third-party servers like Google's for [GCM](#)).

There still may be ways for you to help your users, by shaping your bandwidth use. Rather than just blindly doing whatever you want whenever you want, you learn what the *user* wants and what *other applications* want and tailor your bandwidth use on the fly to match those needs. The following sections outline some ways of achieving this.

## Driven by Preferences

If you are consuming enough bandwidth that this chapter is relevant to you, you probably are consuming enough bandwidth that you should be asking the user how best to consume that bandwidth. After all, they are the one paying the price — in time as well as money — for that consumption.

The following sections present some possible strategies for preference-based bandwidth shaping.

### Budgets

One strategy is for the user to give you a budget (e.g., 20MB/day) and for you to stick within that budget.

Collecting the budget is fairly easy — just use `SharedPreferences`. Either use a `ListPreference` with likely budget value or an `EditTextPreference` and a bit of validation for a free-form budget amount.

Next, you will need to have some idea how much bandwidth any given network operation will consume. For some things, this might be an estimate based on your experiments as a developer, or perhaps it is based on historical averages for this user and type of operation. For example, a “podcatcher” (feed reader designed to download podcast episodes) should have some idea how big a given RSS or Atom feed download should be. In some cases, it might be worthwhile to get a better estimate — for example, the podcatcher might use an HTTP HEAD request to determine the size of the MP3 or OGG file before deciding whether to download it.

Then, you need to be keeping track of your budget. This could be a simple flat file with the initial `TrafficStats` bandwidth values for your process. Re-initialize that file on the first network operation of the day (or whatever period you chose for your budget). Before doing another network operation, compare the current `TrafficStats` values with the initial ones and see how close you are to the budget. If the new network operation will exceed the budget, skip the operation, perhaps putting it in a work queue to perform in the next budget. You might even hold a reserve for certain types of operations. For example, the podcatcher might ensure there is at least 10% of the budget available for downloading the feeds, even if it means putting a podcast on the queue for download tomorrow. That way, you can present to the user the latest podcast information, with icons indicating which are downloaded and which are queued for download — the user might be able to then

request to override the budget and download something on demand.

For devices that lack per-UID `TrafficStats` support, you will have to “fake it” a bit. Use your own calculations of how much bandwidth each operation consumes and track that information, even if you wind up missing out on some bytes here or there.

### Connectivity

If the user might not care how much bandwidth you consume, so long as it is unmetered bandwidth, you might include a `CheckBoxPreference` to indicate if large network operations should be limited to WiFi and avoid mobile data.

You could then use `ConnectivityManager` and `getActiveNetworkInfo()` to see what connection you have before performing a network operation. If it is a background operation (e.g., the podcatcher checking for new podcasts every hour), if the network is not the desired one, you can skip the operation or put it on a work queue for re-trying later. If it is a foreground operation (e.g., the user clicked a “refresh” menu choice), you could pop up a confirmation `AlertDialog` to warn the user that they are on mobile data — perhaps this time they are interested in doing the operation anyway.

Another approach for handling the background operations is to register a `BroadcastReceiver` for the `CONNECTIVITY_ACTION` broadcast (defined on `ConnectivityManager`). If the connectivity switches to mobile data, cancel your outstanding `AlarmManager` alarms; if connectivity switches to WiFi, re-enable those alarms.

Of course, you should also consider monitoring the background data setting — the global `Settings` checkbox indicating whether background network operations are allowed. On `ConnectivityManager`, `getBackgroundDataSetting()` tells you the state of this checkbox, and `ACTION_BACKGROUND_DATA_SETTING_CHANGED` allows you to set up a `BroadcastReceiver` to watch for changes in its state.

### Windows

If your user is less concerned about the bandwidth or the network, but does care about the time of day (e.g., does not want your application consuming significant bandwidth when they might be getting a VOIP call), you could offer preferences for that as well. Cook up a `TimePreference` and use that to collect start and stop times for the high-bandwidth window. Then, set up alarms with `AlarmManager` for those

points in time. The alarm for the start time of the window sets up a third alarm with your regular polling interval. The alarm for the stop time of the window cancels the polling interval alarm.

### Driven by Other Usage

If your network I/O is part of a foreground application, one presumes that you are the most important thing in the user's life right now. Or, at least, the most important thing on the user's phone right now. Hence, what other applications might want to do with the Internet connection is not a major concern.

If, however, your network I/O is part of a background operation, it might be nice to try to avoid doing things that might upset the user. If the user is watching streaming video or is on a VOIP call or otherwise is aware of bandwidth changes, the bandwidth you use might impact the user in ways that the user will not appreciate very much. This is unlikely to be a big problem for small operations (e.g., downloading a 1KB JSON file), but larger operations (e.g., downloading a 5MB podcast) might be more noticeable.

You can use `TrafficStats` to help here. Before doing the actual network I/O, grab the current traffic data, wait a couple of seconds, and compare the latest to the previous values. If little to no bandwidth was consumed during that period, assume it is safe and go ahead and do your work. If, however, a bunch of bandwidth was consumed, you might want to consider:

1. Skipping this polling cycle and trying again later, or
2. Adding a one-off alarm using `set()` on `AlarmManager` to give you control again in a minute, with the current traffic data packaged as an extra on the `Intent`, so you can make a decision after a bigger sample size of bandwidth consumption, or
3. Adding an entry in a persistent work queue, so you know later on to try again if bandwidth contention has improved

You could try to get more sophisticated, by using `ActivityManager` and the per-UID values from `TrafficStats` to see if it is a foreground application that is the one consuming the bandwidth. It is unclear how reliable this will be, both in determining who is consuming the bandwidth (again, per-UID traffic is not available on many devices) and in avoid user angst. It may be simpler just to assume the worst and side-step your I/O until the other apps have quieted down.

## Avoiding Metered Connections

Android 4.1 added `isActiveNetworkMetered()` as a method on `ConnectivityManager`. In principle, this will return `true` if Android thinks that the current data connection may involve bandwidth charges. You can examine this value and steer your bandwidth consumption accordingly.

Android 5.0 added `JobScheduler`, as an alternative to `AlarmManager` for arranging periodic work. One feature of `JobScheduler` is that you can indicate that certain jobs require Internet access, in which case Android will not bother giving you control unless such access is available. A further refinement is that you can state that a job requires an unmetered Internet connection, so you avoid doing bandwidth-hogging work on an expensive connection.

## Data Saver

Android has had a per-app “data saver” mode for some time, with an eye towards reducing bandwidth consumption when the device is using a known metered data plan. Android 7.0 extends this to a device-wide setting,

Apps can be in one of three states as a result:

- The device is normal
- The device is in data-saver mode
- The device is in data-saver mode, but your app is whitelisted by the user

The idea is that if the device is in normal mode, you can do what you want. If the device is in data-saver mode, you should restrict your bandwidth, even if the user whitelists you. Apps that are not whitelisted have no network access while in the background.

To that end, `ConnectivityManager` has three things for you.

First, `isActiveNetworkMetered()` will return `true` if the device is on a metered data connection, `false` otherwise. This has been around for years (API Level 16+), but has not been all that popular, apparently.

Second, Android 7.0 has a `getRestrictBackgroundStatus()` method on `ConnectivityManager`. This returns an `int` that resolves to one of three values:

## BEING SMARTER ABOUT BANDWIDTH

---

- `RESTRICT_BACKGROUND_STATUS_DISABLED`
- `RESTRICT_BACKGROUND_STATUS_ENABLED`
- `RESTRICT_BACKGROUND_STATUS_WHITELISTED`

If `isActiveNetworkMetered()` is true, and `getRestrictBackgroundStatus()` returns `RESTRICT_BACKGROUND_STATUS_ENABLED`, any attempts to use the network may fail, and so your app should plan accordingly.

If you want to try to react in real-time to changes in the data-saver configuration, you can register a receiver for `ACTION_RESTRICT_BACKGROUND_CHANGED` (defined on `ConnectivityManager`). This will be broadcast for any change in data-saver settings, which means that *your* app's state may not have changed. You will need to call `getRestrictBackgroundStatus()` to find out your current state. Also note that this broadcast is only sent to receivers registered dynamically, via `registerReceiver()`. You cannot register for this broadcast in the manifest.

To try to get on the whitelist, you might be tempted to try using `ACTION_IGNORE_BACKGROUND_DATA_RESTRICTIONS_SETTINGS` to lead the user to add your app to the Data Saver whitelist, so you have normal background network access. However, bear in mind that Google has a similar feature for the battery saver whitelist... and trying to use *that* action [got apps banned from the Play Store](#). At the moment, there is no similar language around the use of the data saver whitelist... but, then again, they did not tell you they were going to ban you for asking to be on the battery saver whitelist until after Android 6.0 shipped.

# Issues with Application Heap

---

RAM. Developers nowadays are used to having lots of it, and a virtual machine capable of using as much of it as exists (and more, given swap files and page files).

“Graybeards” — like the author of this book — distinctly remember a time when we had 16KB of RAM and were happy for it. Such graybeards would also appreciate it if you would get off their respective lawns.

Android comes somewhere in the middle. We have orders of magnitude more RAM than, say, the TRS-80 Model III. We do not have as much RAM as does the modern notebook, let alone a Web server. As such, it is easy to run out of RAM if you do not take sufficient care.

There are two facets of memory issues with Android:

- What are the problems we encounter inside our own app, in terms of our application heap?
- What problems can we encounter with system RAM overall, and how can we resolve them?

This part of the book examines memory-related issues, with this chapter focusing on the application heap. Another chapter will deal with [system RAM issues](#). These are not to be confused with any memory-related issues inherent to graybeards.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#).

# You Are in a Heap of Trouble

When we think of “memory” and Java-style programming, the primary form of memory is the heap. The heap holds all of our Java objects – from an Activity to a widget to a String.

Traditional Java applications have an initial heap size determined by the virtual machine, possibly configured via command-line options when the program was run. Traditional Java applications can also request additional memory from the OS, up to some maximum, also configurable.

Android applications have the same basic structure, with very limited configurability and much lower maximums than you might expect.

The original Android devices had a heap limit of 16MB. As screens increase in resolution, the heap limit tends to rise, but only to a point. 32MB to 64MB of heap space is fairly typical, but less-expensive devices, such as Android One models, will tend towards the lower end of that range.

This heap limit can be problematic. For example, each widget or layout manager instance takes around 1KB of heap space. This is why AdapterView provides the hooks for view recycling — we cannot have a ListView with literally thousands of row views without potentially running out of heap.

API Level 11+ supports applications requesting a “large heap”. This is for applications that specifically need tons of RAM, such as an image editor to be used on a tablet. This is not for applications that run out of heap due to leaks or sloppy programming. Bear in mind that users will feel effects from large-heap applications, in that their other applications will be kicked out of memory more quickly, possibly irritating them. Also, garbage collection on large-heap applications runs more slowly, consuming more CPU time. To enable the large heap, add `android:largeHeap="true"` to the `<application>` element of your manifest. Finally, bear in mind that your “large heap” may not be any bigger than your regular heap would have been, as the “large heap” size is determined by the device manufacturer and takes into account things like available system RAM.

## Determining Your Heap Size At Runtime

To get a sense for how much heap you will be able to potentially grow to, you can call `getMemoryClass()` on an `ActivityManager`. This will return your per-process

heap limit in megabytes.

If you requested `android:largeHeap="true"` in the manifest, use `getLargeMemoryClass()` on `ActivityManager` to learn how large your “large heap” actually is. Note that it is entirely possible that the “large heap” is not all that large, or potentially is no bigger than the standard heap, depending upon how much RAM is physically present on the device.

## Fragments of Memory

The Dalvik garbage collector is a non-compacting implementation, which makes `OutOfMemoryError` messages somewhat more likely than you would find on traditional Java environments.

Here, “non-compacting” means that Dalvik does not try to move objects around in physical memory to “compact” the use of physical memory, leaving a large contiguous block of free physical memory for future allocations.

For example, suppose that we allocate three 1K byte arrays, named A, B, and C. As it turns out, they were allocated using adjacent portions of physical memory, so that the last byte of A immediately precedes the first byte of B, and so on. Hence, we consumed 3K of available heap space to create these three 1K blocks.

If we release all references to A and B, they can be garbage-collected. Dalvik, like Java, will see that A and B are adjacent and will free up their physical memory, such that the memory is available as one contiguous 2K block for future allocations.

If, however, we release all references to A and C instead of A and B, Dalvik would be unable to make their blocks be contiguous, and so our heap would have two free 1K blocks, in addition to whatever other free memory that the heap already had.

Hence, allocating memory not only ties up that memory while it is in use, but it may *fragment* the memory even when it is released, such that our formerly pristine heap is now comprised of lots of little free blocks of space, separated from other such blocks by in-use objects. When we try to make a large allocation, such as setting up a byte array for a large image, it may be that while we have enough *total* heap available for the request, there is no single block that would meet our request, and so we get an `OutOfMemoryError`.

One technique to help address this is to pre-allocate any large buffers that you know

you need, up front when your process starts up, such as via a custom `Application` subclass. Then, use an “object pool” approach to obtain, use, and reuse these pre-allocated buffers, rather than having them be garbage-collected and have to be re-allocated later.

ART — the runtime engine used on Android 5.0+ — has a compacting garbage collector. However, it only compacts the heap when the app is in the background. So long as your application is in the foreground, ART behaves like Dalvik does, and your heap will continue to fragment.

## Getting a Trim

It would be nice if we knew when a good time would be to cut back on our heap usage. For example, if we are caching a lot of data in our process, to save on future disk I/O, we could free up those caches at some point to help minimize our heap usage.

Fortunately, Android has some hooks for doing just that.

### **`onTrimMemory()` Callbacks**

Starting in API Level 14, your activities, services, content providers, and custom `Application` classes all offer an `onTrimMemory()` method that you can override. This will be called from time to time to let you know about changes in the state of your app that might indicate it is time to free up some caches or otherwise cut back on memory consumption.

`onTrimMemory()` is passed a “level”, indicating how serious the memory crunch is. At the present time, there are seven such levels, but others may be added in future versions of Android. However, these levels are in priority order, and the documentation indicates that Google will ensure that future levels are slotted into the order as appropriate. Hence, you can watch for levels of a certain severity *or higher* and take appropriate action at those points in time.

The seven levels are all defined as constants on the `ComponentCallbacks2` interface that defines `onTrimMemory()`. Four were defined in API Level 14, while the remaining three were defined in API Level 16. They are (in order of increasing severity):

- `TRIM_MEMORY_RUNNING_MODERATE` (added in API Level 16)
- `TRIM_MEMORY_RUNNING_LOW` (added in API Level 16)

## ISSUES WITH APPLICATION HEAP

---

- TRIM\_MEMORY\_RUNNING\_CRITICAL (added in API Level 16)
- TRIM\_MEMORY\_UI\_HIDDEN (added in API Level 14)
- TRIM\_MEMORY\_BACKGROUND (added in API Level 14)
- TRIM\_MEMORY\_MODERATE (added in API Level 14)
- TRIM\_MEMORY\_COMPLETE (added in API Level 14)

In particular, TRIM\_MEMORY\_BACKGROUND (or higher) indicates that your process is now on the list of processes to terminate to free up memory, and so the more memory you can free up, the less likely it is that your process will be terminated. Also, at TRIM\_MEMORY\_UI\_HIDDEN or higher, your UI is no longer visible to the user, and so this is a fine time to free up UI-related memory that is safe to release, such as perhaps widget hierarchies that you would be rebuilding in `onResume()` later on anyway.

Note that while the focus tends to be on activities implementing `onTrimMemory()` to clean up UI-related resources, you are welcome to implement `onTrimMemory()` in services, content providers, and any custom `Application` subclass, so that you can free up memory that those may be managing as caches.

In the chapter on system RAM, we will get into why freeing up memory may help keep your process around, as we discuss [the relationship between your application heap and available system RAM](#).

## Warning: Contains Graphic Images

However, the most likely culprit for `OutOfMemoryError` messages are bitmaps. Bitmaps take up a remarkable amount of heap space. Developers often look at the size of a JPEG file and think that “oh, well, that’s only a handful of KB”, without taking into account:

1. the fact that most image formats, like JPEG and PNG, are compressed, and Android needs the uncompressed image to know what to draw
2. the fact that each pixel may take up several bytes (2 bytes per pixel for RGB\_565, 3 bytes per pixel for RGB\_888)
3. what matters is the resolution of the bitmap in its original form, as much (if not more) than the size in which it will be rendered – an 800x480 image displayed in an 80x48 `ImageView` still consumes 800x480 worth of pixel data
4. there are an awful lot of pixels in an image — 800 times 480 is 384,000

Android can make some optimizations, such as only loading in one copy of a

Drawable resource no matter how many times you render it. However, in general, each bitmap you load takes a decent sized chunk of your heap, and too many bitmaps means not enough heap. It is not unheard of for an application to have more than half of its heap space tied up in various bitmap images.

Compounding this problem is that bitmap memory, before Android 3.0, was difficult to measure. In the actual Dalvik heap, a `Bitmap` would need ~80 bytes or so, regardless of image size. The actual pixel data was held in “native heap”, the space that a C/C++ program would obtain via calls to `malloc()`. While this space was still subtracted from the available heap space, many diagnostic programs — such as MAT, to be examined in the next chapter — will not know about it. Android 3.0 moved the pixel data into the Dalvik heap, which will improve our ability to find and deal with memory leaks or overuse of bitmaps.

### Bitmap Caching

Many Android libraries, like [Picasso](#), offer bitmap caching. Using an existing caching implementation is a lot easier than is rolling your own.

However:

- Make sure that the library is intelligently sizing the cache based upon possible heap space, such as via `getMemoryClass()` as is noted earlier in this chapter.
- Where possible, tie your cache to `onTrimMemory()` so that you can flush that cache when appropriate.
- Be careful about using *multiple* libraries, each of which might implement its own cache, that you do not wind up caching too much overall. Each library tends to think that it is The One True Cache for your app and will be oblivious to any other caches — bitmap or otherwise — that you may have in your app. Ideally, the library will have a way for you to set the maximum cache size.

### Bitmap Sizing

Sometimes, you do not need a full-size image. For example, if you are showing thumbnails of images in a `ListView`, but only expect to show the full-size image for a few (e.g., rows that the user clicks upon), it is wasteful to load the full-size image for everything in the list.

`BitmapFactory.Options` offers `inSampleSize`, which tells the framework to sample

## ISSUES WITH APPLICATION HEAP

---

the image as it is loaded, to result in a smaller image. `inSampleSize` of 2 will result in an image that is half the width and half the height; `inSampleSize` of 4 will result in an image that is a quarter the width and a quarter the height; etc. Note that `inSampleSize` is limited to powers of 2 and will round as needed.

If you know ahead of time the size of the image, you can calculate an appropriate `inSampleSize` to use. Otherwise, for local content, you can use `BitmapFactory` twice:

- Once with a `BitmapFactory.Options` set with `inJustDecodeBounds` set to true, which will merely tell you how big the image is via `outHeight` and `outWidth` on the `BitmapFactory.Options` itself
- Once with a `BitmapFactory.Options` set with `inSampleSize` set to your desired value and `inJustDecodeBounds` set to false, to really load the image, but downsampled to consume less memory

This approach does not work well for images being downloaded directly from the Internet, as you do not want to download the image twice, once just to figure out how big it is. Instead, download the image *without* using `BitmapFactory` to a local file, then use `BitmapFactory` to load in the image. If you are electing to use a two-level cache (memory plus disk), you might download the image to the disk cache, for example.

For example, let's look at the [Bitmaps/InSampleSize](#) sample project, which demonstrates the memory impact (and visual impact) of loading bitmaps at varying sample sizes.

In the `assets/` directory, we have a ~70KB JPEG file of a flower (courtesy of [the Wikimedia Project](#)) and a ~50KB PNG of the CommonsWare logo. Both images are 672 pixels square, which makes them relatively large images. These are in `assets` to ensure that Android will not attempt any sort of density-based conversion of the images, if they were to be in a `drawable` resource directory.

The `MainActivity` of the project simply loads up a `ViewPager` and attaches it to a `SampleAdapter`:

```
package com.commonware.android.bitmap.iss;

import android.app.Activity;
import android.os.Bundle;
import android.support.v4.app.FragmentActivity;
import android.support.v4.view.PagerAdapter;
import android.support.v4.view.ViewPager;
```

## ISSUES WITH APPLICATION HEAP

---

```
public class MainActivity extends FragmentActivity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        ViewPager pager=findViewById(R.id.pager);

        pager.setAdapter(buildAdapter());
    }

    private PagerAdapter buildAdapter() {
        return(new SampleAdapter(this, getSupportFragmentManager()));
    }
}
```

(from [Bitmaps/InSampleSize/app/src/main/java/com/commonsware/android/bitmap/iss/MainActivity.java](#))

SampleAdapter, in turn, populates the ViewPager with four instances of a BitmapFragment, where we supply the newInstance() factory method of BitmapFragment with a value of 1, 2, 4, or 8 (1 << position), indicating the inSampleSize value we want to use for that fragment instance:

```
package com.commonsware.android.bitmap.iss;

import android.content.Context;
import android.support.v4.app.Fragment;
import android.support.v4.app.FragmentManager;
import android.support.v4.app.FragmentPagerAdapter;

public class SampleAdapter extends FragmentPagerAdapter {
    Context ctxt=null;

    public SampleAdapter(Context ctxt, FragmentManager mgr) {
        super(mgr);
        this.ctxt=ctxt;
    }

    @Override
    public int getCount() {
        return(4);
    }

    @Override
    public Fragment getItem(int position) {
        return(BitmapFragment.newInstance(1 << position));
    }
}
```

## ISSUES WITH APPLICATION HEAP

---

```
}  
  
@Override  
public String getPageTitle(int position) {  
    return(BitmapFragment.getTitle(ctxt, 1 << position));  
}  
}
```

(from [Bitmaps/InSampleSize/app/src/main/java/com/commonsware/android/bitmap/iss/SampleAdapter.java](#))

BitmapFragment then:

- Inflates a layout consisting of four ImageView widgets, two at 672dp square for the “natural” size (scaling only for density), and two at 128dp square to illustrate how the images appear when constrained to a smaller space:

```
<ScrollView xmlns:android="http://schemas.android.com/apk/res/android"  
    android:layout_width="match_parent"  
    android:layout_height="match_parent">

If you run this on a device, you will see the images at the various sample sizes, one sample size per page of the ViewPager. While the quality of the loaded images decreases as `inSampleSize` increases, the smaller `ImageView` widgets are still usable for the flower JPEG, though the line-art PNG suffers.

## ISSUES WITH APPLICATION HEAP

---

**NOTE:** The following screenshots will themselves be modified as part of the publishing process of the book and are here only for illustration purposes. You will want to run the demo and see the results first-hand.

*Figure 984: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 1, Flower JPEG, Full Size*

## ISSUES WITH APPLICATION HEAP

---

## ISSUES WITH APPLICATION HEAP

---

*Figure 986: InSampleSize Demo, on an LG Pad 8.3, inSampleSize = 8, Flower JPEG, Full Size*

The key, though, is the reduced memory footprint. The images loaded without sampling (*inSampleSize* of 1) take up 1,806,336 bytes of heap space (672 x 672 x 4 bytes per pixel). The *inSampleSize* of 8, by contrast, take up 28,244 bytes of heap space, less than 2% of the original.

You should consider experimenting with *inSampleSize* and determine an appropriate sampling level for the types of images you will receive (photos work better than line art) and the sizes you intend to use them in.

### Bitmap Color Space

*BitmapFactory* will load images as *ARGB\_8888* by default. That means that each pixel takes up four bytes, one each for the red, green, and blue color channels, plus a byte for the alpha channel (transparency).

However, particularly for thumbnails of photographs, where transparency probably does not exist and the image is small when viewed by the user, four bytes per pixel may be overkill.

Instead, you can set `inPreferredConfig` of the `BitmapFactory.Options` to `RGB_565`, which uses only two bytes (five bits for red, six bits for green, five bits for blue, and no transparency). This will cut your memory consumption for the bitmap in half, with no loss of resolution (as you get with `inSampleSize`).

### Bitmap Reuse

If you will be doing a lot of work with bitmaps, particularly bitmaps of the same size, an object pool can be of tremendous help to minimize heap fragmentation. You can reuse the same `Bitmap` over and over again, by supplying it via `inBitmap` in the `BitmapFactory.Options` object. If the `Bitmap` is compatible with what you are looking to decode, it will be reused, rather than have a new `Bitmap` (backed by a new hunk of heap space) be created.

Here, “compatible” means:

- The image is the same bit depth configuration (`ARGB_8888` versus `RGB_565`)
- For API Level 18 and below, the resolution is identical; for API Level 19+, the `inBitmap` resolution is the same as or higher than the bitmap to be loaded

### Releasing SQLite Memory

SQLite maintains a “page cache” of loaded pages from your database files. Curiously, it does so on a static basis, not on a per-`SQLiteDatabase` basis. Hence, even after you have closed your databases, you might still be consuming more memory than you need to, due to this cache.

From `onTrimMemory()`, you can call the static `releaseMemory()` method on `SQLite`, to try to free up some of this memory. This should not cause any database errors, but it may slow down the next few database accesses, as the necessary pages may no longer be cached and may have to be loaded again from disk.

### Cheating

All your efforts at improving memory management may be merely “rearranging deck chairs on the Titanic”. Certain scenarios simply require a lot of system RAM, such as complex image manipulations.

`android:largeHeap="true"` is one example of “cheating”: working around the heap

limits. However, as noted above, you may or may not get a particularly “large” heap, depending upon device capabilities.

The NDK is another option for cheating. The heap limits are for the Dalvik and ART runtime engines. Anything you do in native C/C++ code does not count against that heap limit. Hence, you might consider migrating complex logic into NDK code not only to get a possible boost in execution speed but also to avoid impacting your heap limit.

However, even with the NDK, you may not have enough RAM, because the *system* may not have enough RAM. Android One and similar low-spec devices might have as little as 512MB for the entire *device*, and your app would only be able to use a fraction of that, even from native code. Note that Android devices do not use “swap space” or similar memory paging techniques, and so once system RAM is exhausted, the device is likely to crash.

You can use `isLowRamDevice()` on `ActivityManager` to determine whether the device that your app is running on is considered to have low RAM. Nowadays, that means 512MB or lower of system RAM with a low screen resolution (e.g., 800x480). Before trying to use the NDK to cheat, check whether the device is a low-RAM device. If it is, you may need to disable certain features, rather than potentially crash the system by consuming all available system RAM.

## The 1MB IPC Transaction Limit

Sometimes, even cheating cannot help you.

One example of this is a `FAILED BINDER TRANSACTION` error message, sans stack trace, that may show up in Logcat associated with a subsequent crash of yours. Alternatively, it sometimes appears as a `TransactionTooLargeException`. This message arises because there is a 1MB limit on the amount of memory used in IPC transactions. This includes:

- Starting activities or services, where the limit is imposed on the Intent and its extras
- Sending a broadcast, again measured in terms of the Intent and its extras
- the saved instance state Bundle
- responses from bound services (return values, out parameters)
- responses from `startActivityForResult()` calls
- and so on

## ISSUES WITH APPLICATION HEAP

---

Worse, this is not a per-transaction limit, but rather a per-process limit. *Usually*, you will only have one IPC request going at a time, but that is not always the case (e.g., you try starting an activity at the same time that you happen to be receiving a broadcast). Hence, coming anywhere close to the 1MB limit is risky, lest your transaction combine with others to have you exceed the 1MB limit.

This limit is baked into the operating system and cannot be altered by developers.

Worse, you do not actually know if the transaction totally failed (it could not be sent) or partially failed (the transaction was sent, but the response failed).

Overall, try to keep your transaction sizes low:

- Do not put bitmaps into transactions wherever possible
- Do not transfer large arrays, huge strings, and the like
- Do not use IPC when in-process communications (e.g., [event buses](#)) can work

# Finding Memory Leaks

---

Android Studio's heap analyzer is your #1 tool for identifying memory leaks and the culprits behind running out of heap space. Particularly when used with Android 3.0+ versions of Android, the heap analyzer can tell you:

1. Who are the major sources of memory consumption, both directly (e.g., bitmaps) or indirectly (e.g., leaked activities holding onto lots of widgets)
2. What is keeping objects in memory unexpectedly, defying standard garbage collection — the way that you leak memory in a managed runtime environment like Dalvik or ART

Android Studio's heap analyzer builds on the earlier Memory Analysis Tool (MAT), used by Java developers, and by Android developers prior to Android Studio.

However, Android Studio's heap analysis leaves a lot to be desired. Not only do you have to manually examine and check heap dumps, but you get a lot of false positives due to bugs in Android. A library that helps with both of these issues is LeakCanary, and we will examine it in this chapter as well.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#). Reading [the introductory chapter to this trail](#) might be nice.

## Android Studio Profiler

The first question is: when do we bother looking for leaks? Complex apps are complex, and so we might spend a lot of time looking for leaks that either do not exist or do not matter much.

In Android Studio, the Android Profiler tool will allow you to examine the real-time behavior of your app with respect to various system resources, such as heap space in your app:

Figure 988: Android Profiler

## FINDING MEMORY LEAKS

Clicking on the memory portion of the graphs will bring up details for the memory consumption:

Figure 989: Android Profiler, Showing Memory Details

The color coding shows the different types of memory being consumed. For example, the largest area in this graph is the tan “Graphics” area. The sample app being tested here happens to be a Picasso sample app from [the chapter on Internet access](#). However, “Graphics” does not refer to bitmaps, but rather is “used for graphics buffer queues to display pixels to the screen, including GL surfaces, GL textures, and so on”, according to [the documentation](#). Generally speaking, you will be most interested in:

- The light blue portion of the graph, representing memory consumed by your Java objects
- The dashed line, which represents the number of allocated Java objects
- The garbage can icons, representing garbage collection events

## FINDING MEMORY LEAKS

On Android 5.0+ devices, the memory usage can also fall... while your app is no longer in the foreground:

Figure 990: Android Studio, Android Monitor, Memory Tab, Showing Shrunken Heap

The major drop in the memory usage came with the release of some of those GL buffers and textures, some of which are no longer necessary when the app no longer is in the foreground from a UI standpoint.

The major drop in the number of allocated Java objects presumably came from ART. Once your app is no longer in the foreground, ART will do a more aggressive garbage collection run, including moving objects in heap space to coalesce free blocks. If this frees up some of the allocated pages from the OS, ART can then free those pages, returning the memory to the OS and reducing our app's overall memory footprint.

You can also perform a manual garbage collection run by tapping the “garbage can” icon in the toolbar. Other toolbar buttons include:

- A button to dump the heap (discussed later in this chapter)
- A close button to close this tool
- Buttons to zoom in, zoom out, or reset the zoom to its default level
- A “Live” button that serves to pause the results or, from a paused state,

resume normal real-time output

## Getting Heap Dumps

The first step to analyzing what is in your heap is to actually get your hands on what is in your heap. This is referred to as creating a “heap dump” — what amounts to a log file containing all your objects and who points to what.

### In Android Studio

In the memory details view of the Android Profiler tool in Android Studio, you can create a heap dump by clicking the toolbar button that looks like an open square with a downwards-pointing arrow in it, adjacent to the “garbage can” icon for forcing garbage collection:

*Figure 991: “Dump Java Heap” Toolbar Button in Android Profiler*

Tap that, then go get a cup of coffee (or another preferred beverage). Generating a heap dump used to take a few seconds. With Android Studio 3.0, it takes much longer than that.

Eventually the bottom portion of the Android Profiler pane will show the results of the heap dump.

### From Code

Another possibility is to trigger the heap dump yourself from code. The `dumpHprofData()` static method on the `Debug` class (in the `android.os` package) will write out a heap dump to the file you indicate. Since you will need to transfer them off the device or emulator, it will be simplest to specify a path to a file on external

storage, which means that your project will need the `WRITE_EXTERNAL_STORAGE` permission.

To view the results in Android Studio, you will need to transfer the file from wherever you saved it on the device or emulator to your development machine. For example, you can double-click on it in the Device File Explorer.

The UI that you get has the same basic functionality as does the UI from a manually-requested heap dump from the Android Profiler, though they look somewhat different.

## Analyzing Heap Dumps in Android Studio

Having a heap dump is nice, but we need tools to determine exactly what is in there and what that means for our app. Android Studio lets us examine a heap dump to see what is going on and perhaps identify leaks.

### Navigating the Heap Dump UI

There are several pieces to the UI that we use to examine a heap dump.

## FINDING MEMORY LEAKS

### Class List

We start off with a class list table:

Class Name	Alloc Count	Native Size	Shallow Size	Retained Size
app heap	12526	2540563	598264	11473776
Bitmap (android.graphics)	51	2452388	2193	2457001
LinkedHashMap\$LinkedHashMapEntry (java.util)	103	0	3296	1123710
LinkedHashMap (java.util)	17	0	833	1109150
LruCache (com.squareup.picasso)	1	0	36	1085736
View[] (android.view)	31	0	1540	465233
LinearLayout (android.widget)	16	0	10688	426305
BitmapDrawable\$BitmapState (android.graphics.drawable)	18	0	1044	423857
LayerDrawable\$ChildDrawable[] (android.graphics.drawable)	7	0	88	324860
LayerDrawable\$ChildDrawable (android.graphics.drawable)	14	0	840	324772
ProgressBar (android.widget)	1	0	564	323983
LayerDrawable (android.graphics.drawable)	1	0	76	321728
LayerDrawable\$LayerState (android.graphics.drawable)	1	0	72	321500
RotateDrawable (android.graphics.drawable)	2	0	104	321268
byte[]	2128	0	206267	206267
Class (java.lang)	476	0	61620	199628
ActionBarView (com.android.internal.widget)	1	0	798	154716
NinePatch (android.graphics)	16	0	512	130984
ListView (android.widget)	1	0	1124	122320
BitmapDrawable (android.graphics.drawable)	6	0	432	93216
NinePatchDrawable\$NinePatchState (android.graphics.drawable)	31	0	1302	89990
RenderNode (android.view)	71	72704	1704	74408

*Figure 992: Android Studio Heap Dump, Class List Table*

This table comes filled in with a list of classes and primitive arrays, sorted by “retained size”. This indicates how much memory those objects, and everything that they point to, consume. So, for example, this heap dump contains 51 `Bitmap` objects with a retained size of 2,457,001 bytes.

The other columns are:

- **Alloc Count:** the number of instances of this class found in your app’s heap
- **Native Size:** the amount of “native memory” used by these objects (generally zero, but non-zero for some classes like `Bitmap`)
- **Shallow Size:** how much memory these instances consume in their own primitives, not including any other objects that they point to

Roughly speaking, the sum of the “Native Size” and the “Shallow Size” equals the amount of space that the objects are taking up directly themselves, not counting references to other objects.

### Heap Selector

The drop-down above the table that defaults to “App heap” will have other options on Android 5.0+ devices. Specifically, you can switch between the app heap, the undocumented “default heap”, the similarly-undocumented “image heap”, and the equally-undocumented “zygote heap”. The zygote is a core OS process, started when the device boots; all Android SDK apps are forked off of the zygote. Given that and other announced ART tidbits suggests that:

- the “image heap” may be the large object space, mostly set aside for bitmaps
- the “zygote heap” may be the objects in the heap that were instantiated by the zygote and its initialization of the Android framework classes, as opposed to your code

In general, you want the app heap, which is what appears by default.

## FINDING MEMORY LEAKS

### Package Tree View

The drop-down above the table that defaults to “Arrange by class” can be toggled to “Arrange by package”, which turns the table into a tree-table, for navigation by Java package name, plus primitive arrays:

Heap Dump @ 14m44s15ms | app heap | Arrange by package

*Figure 995: Android Studio Heap Dump, Instance List*

The “shallow size” refers to the number of bytes consumed directly by that particular instance, such as by primitive fields. The “retained size” roughly equates to “how much memory can this object be blamed for”. In other words, if that object could be garbage-collected, how much would we recover, not only from the “shallow size” but from other objects uniquely referenced by this object?

The “depth” refers to how many hops away from a garbage collection root (“GC root”) this object is.

## FINDING MEMORY LEAKS

This table initially appears as a simple table. In reality, though, it is a tree table. You can expand nodes in the tree to drill down into all the objects referenced by a particular instance, and all objects that reference the instance in question:

The screenshot shows the 'Instance View' window in Android Studio. It displays a tree view of memory instances. The top table lists instances with columns for Instance, Depth, Native Size, Shallow Size, and Retained Size. The instance 'QuestionsFragment@316219160' is expanded to show its fields: mProgressContainer, mList, mAdapter, mStandardEmptyView, mView, mListContainer, mContainer, shadow\$\_klass\_, mFragmentManager, mChildFragmentManager, mSavedViewState, mLayoutInflater, and mHost. Below this is the 'References' section, which shows a list of references to the selected instance, including 'this\$0' in various adapters and managers, and 'Index 0' in object arrays.

Instance	Depth	Native Size	Shallow Size	Retained Size
QuestionsFragment@316219160 (0x12d91f18)	7	0	161	523
mProgressContainer = {LinearLayout}	7	0	668	328362
mList = {ListView}	5	0	1124	122320
mAdapter = {QuestionsFragment\$ItemsAdapter}	6	0	64	9777
mStandardEmptyView = {TextView}	8	0	786	2335
mView = {FrameLayout}	5	0	632	2061
mListContainer = {FrameLayout}	6	0	632	1876
mContainer = {FrameLayout}	3	0	632	1869
shadow\$_klass_ = {Class}	0	0	124	1624
mFragmentManager = {FragmentManagerImpl}	6	0	110	680
mChildFragmentManager = {FragmentManagerImpl}	8	0	110	218
mSavedViewState = {SparseArray}	8	0	21	181
mLayoutInflater = {PhoneLayoutInflater}	8	0	41	73
mHost = {Activity\$HostCallbacks}	5	0	44	69

Reference	Depth	Native S...	Shallow ...	Retaine...
QuestionsFragment@316219160 (0x12d91f18)	7	0	161	523

Index 0 in Object[]@316298288 (0x12da5430)	8	0	40	40
mParent in FragmentManagerImpl@316222680 (0x12d92cd8)	8	0	110	218
Index 0 in Object[]@316219104 (0x12d91ee0)	9	0	40	40
this\$0 in Fragment\$1@316224216 (0x12d932d8)	9	0	12	12

Figure 996: Android Studio Heap Dump, Instance Tree

You can further expand the References tree to see who references some of those references, and so on.

### Identifying Leak Candidates

All of that is just great, but you still need to determine if you have a memory leak and, if so, where is it coming from.

Basically, you rummage through the class list or package tree, looking for classes that either:

- you would not expect to be there (e.g., all instances should have been garbage-collected)
- you would not expect to be so numerous
- you would not expect to retain so much heap space

## FINDING MEMORY LEAKS

---

Bear in mind that the act of generating a heap dump only logs objects that are reachable from other objects, or themselves are considered “garbage collection roots” (a.k.a., “GC roots”). Any objects that are actual garbage, but perhaps have not yet been collected by the garbage collector, do not appear in the dump. Hence, if you see it in the heap snapshot tab, the objects are “real”, not uncollected garbage.

Conversely, just because you find an object in the heap does not mean that it is truly “leaked”. For example:

- Activities that have not been destroyed are not leaked, strictly speaking, though you may wish to consider whether changes to your app’s navigation can allow you to reuse existing activity instances better.
- Objects that are part of a cache, such as Picasso’s memory caching of downloaded images, are intentionally “leaked”. You may use what you see in the heap snapshot tab to elect to reduce the size of those caches, or perhaps better consolidate multiple disparate caches, where possible.
- Objects in use by a running thread are not leaked... unless the thread itself is effectively leaked (i.e., exists, and refers to objects, but you do not know why that thread is still outstanding).

## Common Leak Scenarios

With all that in mind, let’s look at a few common scenarios of leaking objects, to see what those leaks look like when we do a heap dump and analyze that dump in Android Studio.

### The Static Widget

The [Leaks/StaticWidget](#) sample project does something naughty:

```
package com.commonware.android.button;

import android.app.Activity;
import android.os.Bundle;
import android.widget.Button;

public class ButtonDemoActivity extends Activity {
    private static Button pleaseDoNotDoThis;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
```

## FINDING MEMORY LEAKS

```
setContentView(R.layout.main);

pleaseDoNotDoThis=(Button)findViewById(R.id.button1);
}
}
```

(from [Leaks/StaticWidget/app/src/main/java/com/commonsware/android/button/ButtonDemoActivity.java](#))

We take a widget (specifically a Button) and put it in a static data member, and never replace it with null.

As a result, even if the user presses BACK to get out of the activity, the static data member holds onto Button, which itself has a reference back to our Activity.

If you run the app, press BACK to exit the activity, and generate a heap dump of this process, you will see that ButtonDemoActivity appears in the dump:

Package Name	Alloc Count	Native Size	Shallow Size	Retained Size
float[]	24	0	1096	1096
boolean[]	9	0	43	43
android	1502	445646	66431	1226175
java	3319	400	81708	361053
com	77	0	5847	136660
android	76	0	5624	135821
commonsware	1	0	223	839
android	1	0	223	839
button	1	0	223	839
ButtonDemoActivity	1	0	223	839
sun	138	0	4567	11787
libcore	147	0	2708	2836
dalvik	10	0	207	1486

Figure 997: Heap Dump UI, Showing Leaked Activity

## FINDING MEMORY LEAKS

If you click on `ButtonDemoActivity` and poke around the References tab, you will find where our static field shows up:

Reference	Depth	Native Size	Shallow Si...	Retained S...
ButtonDemoActivity@314903232 (0x12c50ac0)	2	0	223	839
mContext in Button@314973648 (0x12c61dd0)	1	0	786	182683
<b>pleaseDoNotDoThis in Class@314899240 (0x12c4fb28)</b>	<b>0</b>	<b>0</b>	<b>128</b>	<b>187208</b>
mOwningView in RenderNode@315066896 (0x12c78a10)	2	1024	24	1048
mOwningView in RenderNode@314974440 (0x12c620e8)	2	1024	24	1048
Index 0 in View[]@314973248 (0x12c61c40)	3	0	48	48
referent in WeakReference@314994576 (0x12c66f90)	3	0	24	24
referent in WeakReference@314994504 (0x12c66f48)	3	0	24	24
referent in WeakReference@315017896 (0x12c6caa8)		0	24	24
referent in WeakReference@315017872 (0x12c6ca90)		0	24	24
mContext in LinearLayout@314972456 (0x12c61928)	2	0	668	1888

*Figure 998: Heap Dump UI, Showing Static Field*

The leaked object (`ButtonDemoActivity`) is referenced by an `mContext` field in a static `pleaseDoNotDoThis` field in `ButtonDemoActivity` itself. The latter item has a depth of 0, so we know that it is a GC root. The hope is that you will recognize some of the items shown here (e.g., field names like `pleaseDoNotDoThis`) and can see how those items affect the ability for Android to garbage collect the leaked object.

## Thread References

The [Leaks/LeakedThread](#) sample project does something else naughty:

```
package com.commonware.android.leak.thread;

import android.app.Activity;
import android.os.Bundle;
import android.os.SystemClock;

public class LeakedThreadActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        new Thread() {
            public void run() {
                while(true) {
                    SystemClock.sleep(100);
                }
            }
        }
    }
}
```

## FINDING MEMORY LEAKS

```
    }.start();  
  }  
}
```

(from [Leaks/LeakedThread/app/src/main/java/com/commonsware/android/leak/thread/LeakedThreadActivity.java](#))

Here, we kick off a Thread from onCreate() of our activity and have it enter a pseudo-polling loop, sleeping for 100ms per pass through the loop.

This is naughty for all sorts of reasons:

- Fast polling loops like this are bad for the battery
- We start a thread and never stop it
- We are using an anonymous inner class for our Thread

The latter two flaws combine to cause a memory leak.

So, we can go through the package tree view, find the Java packages for the code, and see what objects from those packages are outstanding:

Package Name	Alloc Count	Native Size	Shallow Size	Retained Size
android	975	222501	45995	918613
com	65	0	7988	793680
commonsware	2	0	359	556392
android	2	0	359	556392
leak	2	0	359	556392
thread	2	0	359	556392
LeakedThreadActivity\$1	1	0	136	278284
LeakedThreadActivity	1	0	223	278108
android	63	0	7629	237288
java	1209	0	37414	115342
sun	87	0	3074	10630
libcore	98	0	2452	2868
dalvik	9	0	195	1492

Figure 999: Heap Dump UI, Showing Classes In App Package

Here, we see that we have leaked two objects. One is LeakedThreadActivity. The other is an anonymous inner class of LeakedThreadActivity (assigned the name LeakedThreadActivity\$1 by the Java compiler).

## FINDING MEMORY LEAKS

Clicking on the activity and examining the first child in the reference tree once again discloses the leak:

Figure 1000: Heap Dump UI, Showing Another Leak and Its Path to a GC Root

Our zero-depth entry is threads, which is basically the collection of all Java Thread objects that are still alive in this process. One of those is our anonymous inner class (this\$0 in LeakedThreadActivity\$1), which holds onto the activity instance.

To avoid this sort of leak:

- Do not have everlasting threads — whatever component creates a thread needs to stop the thread when the component is being destroyed
- Do not use anonymous inner classes when creating threads, as an anonymous inner class has an implicit reference back to the outer class instance that created it (in this case, our activity), and that outer class instance cannot be garbage-collected until the thread terminates

## Retaining Too Much

In [the chapter on threads](#), we had an AsyncTask demo app that used a retained fragment to manage the task. That fragment was a ListFragment, and it was

## FINDING MEMORY LEAKS

---

responsible for displaying the Latin words as those words were “downloaded” in the background by the task. Google is not a fan of retained fragments having widgets... and the [Leaks/ConfigChange](#) sample project demonstrates why.

The change in this project versus the original mostly comes down to a humble Button, which we will use to restart the download from the beginning once it has completed:

```
<Button
  android:id="@+id/again"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
  android:text="@string/btn_again"/>
</LinearLayout>
```

(from [Leaks/ConfigChange/app/src/main/res/layout/main.xml](#))

The Button itself is stored as a field in the fragment, named btnAgain. This already raises some concerns, if we are retaining the fragment. However, this approach is safe, if and only if we clear out or refresh that field on a configuration change. For example, if you used `findViewById()` to get the Button and assign it to btnAgain in `onViewCreated()`, you would not have a problem, as `onViewCreated()` is called as part of the configuration change, even for retained fragments.

However, this sample app instead lazy-initializes that data member, via a `getAgain()` getter method:

```
private Button getAgain() {
    if (btnAgain==null) {
        btnAgain=(Button)getView().findViewById(R.id.again);
    }

    return(btnAgain);
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

That getter method is used in the rest of the fragment to retrieve the Button, such as in `onViewCreated()`:

```
@Override
public void onViewCreated(View v, Bundle savedInstanceState) {
    super.onViewCreated(v, savedInstanceState);

    getListView().setScrollbarFadingEnabled(false);
}
```

## FINDING MEMORY LEAKS

---

```
setListAdapter(adapter);

getAgain().setOnClickListener(this);

if (task!=null) {
    getAgain().setEnabled(false);
}
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

...onClick() (as the fragment now implements the View.OnClickListener interface):

```
@Override
public void onClick(View v) {
    getAgain().setEnabled(false);
    adapter.clear();
    task=new AddStringTask();
    task.execute();
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

...and onPostExecute() of the AsyncTask:

```
@Override
protected void onPostExecute(Void unused) {
    task=null;
    getAgain().setEnabled(true);
}
```

(from [Leaks/ConfigChange/app/src/main/java/com/commonsware/android/leak/configchange/AsyncDemoFragment.java](#))

Nowhere do we set btnAgain to null, including after a configuration change. So, when the activity starts up, everything is fine. However, when we rotate the screen or otherwise undergo a configuration change, the fragment misbehaves. getAgain() says “hey, btnAgain is already initialized, so I can skip the findViewById() call”. But we have a *different* Button now after the configuration change, and btnAgain is pointing to the original Button. That original Button is tied to the original, pre-configuration change Activity instance, and we have a leak, until the *second* Activity is destroyed.

## FINDING MEMORY LEAKS

If you run the app, rotate the screen, and then capture a heap dump, the snapshot will show two outstanding instances of AsyncDemo:

Package Name	Alloc Count	Native Size	Shallow Size	Retained Size
app heap	12100	581122	493167	2998528
byte[]	1977	0	79969	79969
long[]	328	0	67264	67264
int[]	570	0	21932	21932
char[]	233	0	16790	16790
int[][]	61	0	3356	3432
float[]	50	0	2184	2184
boolean[]	27	0	116	116
android	3114	580722	152929	2060557
com	128	0	11026	453712
android	124	0	10364	256991
commonsware	4	0	662	196721
android	4	0	662	196721
leak	4	0	662	196721
configchange	4	0	662	196721
AsyncDemo	2	0	446	145555
AsyncDemoFragment	1	0	180	51130
AsyncDemoFragment\$AddStringTas	1	0	36	36

Figure 1001: Heap Snapshot Tab, Showing Two Activities Instead of One

However, this leak will be difficult to diagnose, for two reasons:

1. Android Studio's heap analyzer does a poor job of illustrating what is holding onto the activities
2. Not only are *you* leaking the activities, but so is Android itself, as will be explored in the next section

## A Canary in a Leaky Coal Mine

When the author of this book was testing the previous section's demo, he was trying to use Android Studio to confirm that the leak was caused by the Button. As part of that analysis, he went back to the original [Threads/AsyncDemo](#) sample project... and Android Studio said that *it* was leaking the activity.

At this point, a long series of expletives could be heard emanating from the author's office.

To help try to suss out exactly what was going on, the author turned to a library that you may wish to consider: [LeakCanary](#). And, as it turns out, LeakCanary indicates that the Android Studio-reported leak is a false positive, and that there is no serious

memory leak.

### Introducing LeakCanary

LeakCanary is another library from the indefatigable developers at Square. It allows you to monitor certain objects to see if they get leaked. In particular, if you use the standard setup, it will automatically watch for activities that get leaked. When it detects a leak, it will dump the heap, then read in the heap dump *on the device* and try to determine where the leak is coming from. To help with that, it has a roster of known false positives that it can filter out, and the authors encourage the community to provide more false positives where possible.

If a leak is detected, but it is a false positive, a message will be dumped to Logcat with the details. If a leak is detected that appears to be genuine, a Notification will appear, leading to an activity that will show you the source of the leak.

### Adding LeakCanary to a Project

Adding LeakCanary to a project is fairly easy, courtesy of some well-designed defaults and a tricky use of build type-specific dependencies.

#### Adding the Dependencies

We only want LeakCanary to be used in debug builds, not release builds. Even if we are leaking memory, the effects of LeakCanary (including slow heap dumps) are not the sort of thing that we should be putting users through.

Yet, at the same time, we will need a bit of Java code to hook up LeakCanary itself. Ordinarily, this would require setting up `src/debug/` and `src/release/` source sets and trying to isolate the LeakCanary-specific code to the debug build.

LeakCanary addresses this by publishing two versions of the artifact: the real one (for debug) and a no-op one (for release). The public API for each is identical, so your application code can build in either case. It just so happens that the no-op artifact does nothing in response to the API, as it merely contains stubs necessary to satisfy the API. This is *much* simpler, and for coarse-grained APIs is a technique worth emulating.

The [Leaks/AsyncTask](#) sample project is akin to the `Threads/AsyncDemo` sample project, but uses LeakCanary (and a `ListView` rather than a `RecyclerView`). In its

## FINDING MEMORY LEAKS

---

app module's `build.gradle` file, we have the twin dependencies, scoped for the appropriate build types:

```
dependencies {
    implementation 'com.android.support:support-fragment:27.1.1'
    debugImplementation 'com.squareup.leakcanary:leakcanary-android:1.6.1'
    releaseImplementation 'com.squareup.leakcanary:leakcanary-android-no-op:1.6.1'
}
```

(from [Leaks/AsyncTask/app/build.gradle](#))

If you have your own custom build types, you would need to adjust the conditional dependencies to match, using the no-op one for any build that should not have the real LeakCanary in it.

### Adding the Application

Usually, if you are going to use LeakCanary, it is with the intent of availing yourself of its mostly-automatic detection of leaked activities. The recipe for doing that involves calling `install()` on the LeakCanary class when your process starts, such as in `onCreate()` of a custom Application subclass.

The sample app has such a class, `CanaryApplication`:

```
package com.commonware.android.async;

import android.app.Application;
import com.squareup.leakcanary.LeakCanary;

public class CanaryApplication extends Application {
    @Override
    public void onCreate() {
        super.onCreate();

        if (LeakCanary.isInAnalyzerProcess(this)) {
            // LeakCanary is processing a heap dump here; please do not disturb!
            return;
        }

        LeakCanary.install(this);

        // do your normal initialization work here
    }
}
```

(from [Leaks/AsyncTask/app/src/main/java/com/commonware/android/async/CanaryApplication.java](#))

---

## FINDING MEMORY LEAKS

---

When LeakCanary detects a possible leak, it collects and analyzes a heap dump. The analysis is performed in a separate process, so its own memory usage does not affect your main process' heap limit. However, the same custom Application is used for every one of your app's processes. `LeakCanary.isInAnalyzerProcess()` returns true if your Application code is running in this analysis process, so you can skip any initialization work that you might already have in a custom Application. In the "real" app process, you use `LeakCanary.install()` to set up LeakCanary for automatic analysis.

This Application subclass is registered in the manifest, via `android:name` on the `<application>` element:

```
<application
  android:name=".CanaryApplication"
  android:icon="@drawable/ic_launcher"
  android:label="@string/app_name"
  android:theme="@android:style/Theme.Holo.Light.DarkActionBar">
  <activity
    android:name=".AsyncDemo"
    android:label="@string/app_name">
    <intent-filter>
      <action android:name="android.intent.action.MAIN"/>

      <category android:name="android.intent.category.LAUNCHER"/>
    </intent-filter>
  </activity>
</application>
```

(from [Leaks/AsyncTask/app/src/main/AndroidManifest.xml](#))

And that is all that you need for basic integration.

### Adding Manual Leak Checks

`LeakCanary.install()` returns a `RefWatcher` object. If all you want to do is use the semi-automatic activity leak detection, you can safely ignore this return value.

However, if you would like to watch for other objects leaking — fragments, domain model objects, threads, etc. — you can hang onto that `RefWatcher` and, where needed, call `watch()` on it to add an object to watch for leaks. Watching for leaks is not terribly expensive but not free, so be judicious in what you are watching.

### Testing with LeakCanary

Once you have LeakCanary integrated, you can try out your app and see if it leaks.

Note that the quasi-automatic activity leak detection is based upon the activity lifecycle. LeakCanary considers an activity to be leaked if it is destroyed and there are still unknown strong references to it. This assumes that your activity is destroyed in an ordinary fashion. Hence, how you use your app influences what leaks you find. For example, if you terminate the app process (e.g., swipe away the associated task in the overview screen), you will not find out if any live activities were leaked. Where possible, try to use the BACK button to step your way out of the app when testing, to ensure everything gets destroyed and the most leaks can be found.

### The Notifications

If LeakCanary detects a possible leak, it will start displaying notifications to let you know about this and what is going on:

Figure 1002: LeakCanary Notifications

LeakCanary wants `WRITE_EXTERNAL_STORAGE` rights, and so the first time you use it with an app that does not request that permission on its own, you will get a

---

## FINDING MEMORY LEAKS

---

notification that leads you to grant the permission.

Note that it may take a few moments after the activity is destroyed before the message appears, and that it may take a long time after the message disappears before you get final results.

Eventually, though, if there is a leak detected, you will get a notification advising you of that fact:

*Figure 1003: LeakCanary Confirmation Notification*

### Activity Output

The [Leaks/StaticWidgetLC](#) sample project is a clone of the static widget leak scenario from earlier in this chapter. This version has LeakCanary integrated in, though, and LeakCanary catches this leak.

## FINDING MEMORY LEAKS

---

So, after running the app, pressing BACK to destroy the activity, and waiting a bit for the heap analysis to finish, you will eventually get a “ButtonDemoActivity leaked” notification. Tapping that shows a “timeline”-style list of objects, starting with a GC root and ending in the leaked object:

*Figure 1004: LeakCanary Diagnostic Activity, As Launched From the Notification*

Here, we see that `pleaseDoNotDoThis` holds a reference to the `Button`, which holds a reference to the `Activity`.

This has two advantages over using Android Studio’s own leak analysis:

1. It is automatic: we do not have to go and check for leaks ourselves proactively
2. The output can be much easier to read

The overflow menu has an option to “Share info”, which sends a complicated report to your favorite `ACTION_SEND` implementation (e.g., an email client). “Share heap dump”, also in the overflow, forwards the heap dump itself via `ACTION_SEND`, for you to perhaps get over to Android Studio for deeper analysis if that proves necessary.

Pressing the up navigation arrow in the action bar brings up a list of the saved leak

## FINDING MEMORY LEAKS

---

reports:

*Figure 1005: LeakCanary Report Roster*

The “DELETE” button on the diagnostic activity deletes that report; the “DELETE ALL” button on the roster activity deletes all saved reports.

The [LeakCanary project documentation](#) outlines many other possibilities for tailoring LeakCanary’s behavior, including:

- “Whitelisting” certain objects or activity classes, so they do not show up in leak reports
- Sending reports to a server
- Automatically running LeakCanary after instrumented tests

# Issues with System RAM

---

Your application heap is your little corner of the system RAM on the device that you focus on in your Java development. However, there are other things that you might do that consume system RAM, such as use the NDK to add C/C++ code to your app. How much system RAM you consume overall will have an impact on user acceptance of your app, as the more RAM you use, the more frequently the user's other apps are terminated to make room for you. And, as a result, the more system RAM you use, the more likely it is that *your* process will be terminated when you are not in the foreground, to free up RAM for other apps. Hence, while system RAM is not something you necessarily think about as often as you do your application heap, it is something that you should pay attention to, at least a little bit.

This chapter will explain a bit more about the relationship between your app and system RAM, how you can measure how much system RAM your app is consuming, and how you can reduce that consumption.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate, particularly the [chapter on Android's process model](#). Reading the chapter on [issues with the application heap](#) is also a good idea.

## Can't We All Just Get Along?

Alas, we have not invented the device with infinite RAM, nor the application that takes zero memory. In fact, our devices have fairly limited RAM (e.g., 1GB), and our apps therefore fight over that memory. That includes both apps that the user runs

explicitly (e.g., via the home screen launcher) and apps that run based upon external factors (e.g., the app that receives a [GCM push event](#) and uses that trigger to update some data).

The good news is that the user tends to be a bit oblivious to all of the comings and goings of apps. Android keeps process around while it can and terminates them as needed to free up system RAM for other processes, without the user's explicit involvement. Of course, power users might try to employ "task managers" and the like to be more involved in decision-making, but that's something they opted into, not something that was forced upon them, the way that older mobile operating systems like Windows Mobile required.

However, there is a fundamental assumption in Android that apps play fair. The per-process heap limits — and the fact that apps do not necessarily have to use all the way up to those limits — means that a given Android device can power many processes at once. That starts to break down when apps do various things to consume an excessive amount of system RAM, more than what the per-process heap limit would normally constrain them to. Hence, it is a good idea to keep tabs on how much you use of system RAM, so that you can be a "good citizen" and not cause the user undue angst or force them to employ task managers to try to keep you in line.

## Contributors to System RAM Consumption

There are many factors that contribute towards your system RAM consumption, including:

- Your heap usage, up to the per-process heap limit, for each process that you are running
- Your native libraries (.so files) from the NDK
- The system RAM allocated by that native code, which does not count against your per-process heap usage

In addition, the reporting tools usually allocate a portion of shared RAM to your app. Your app's process is forked from the zygote process, which contains the Dalvik runtime environment, framework JAR (for all those `android.*` classes), and related libraries. Your app shares that memory with all other processes forked from the zygote. However, to reflect the fact that there is this overhead, your app's share of it (roughly calculated as the amount of shared RAM divided by the number of processes) tends to get added to your memory consumption totals.

## Measuring System RAM Consumption: Tools

Figuring out how much RAM your application is using is not easy. Or, as [Dianne Hackborn](#) put it:

Note that memory usage on modern operating systems like Linux is an extremely complicated and difficult to understand area. In fact the chances of you actually correctly interpreting whatever numbers you get is extremely low. (Pretty much every time I look at memory usage numbers with other engineers, there is always a long discussion about what they actually mean that only results in a vague conclusion.)

Fortunately, particularly in Android 4.4, a fair bit of work has gone into trying to help us determine how much our apps impact system RAM.

### Process Stats in Settings

On Android 4.4, in Settings > Developer Options, you will find:

Process Stats: Geeky stats about running processes

## ISSUES WITH SYSTEM RAM

---

(here, “geeky” is presumably used as a term of endearment)

*Figure 1006: Developer Options in Android 4.4, Showing “Process Stats”*

## ISSUES WITH SYSTEM RAM

---

Tapping on that entry brings up a screen that describes the current state of the system, with respect to RAM:

Figure 1007: Process Stats in Android 4.4

While it may look simple, this screen, and its child screens, are remarkably complex, particularly once you start playing around with various options from the action bar overflow.

### The Summary

At the top, you will see:

- How much history is being reported in this screen (“1h 47m”)
- What the current status of the system is with respect to RAM (“currently normal”)
- What the status of the system has been over that range of time, as illustrated by the bar, where green is “normal”

The bar is not so much a timeline as a stacked bar chart, where the mix of red and yellow indicates the amount of time the device was in a low-memory state, contrasted with the green “normal” state.

Usually, your device should be “normal” with a mostly-green or completely-green bar.

### The Roster

The list beneath the summary shows some running processes. What is included in this list depends on what mode Process Stats is running in. The summary indicates that our mode is “Background apps”. There are three major categories for apps:

1. Foreground, which includes whatever app is truly in the visible foreground, plus any apps that have a foreground service
2. Background, which is pretty much everything else with a service
3. Cached, which are all apps that still have running processes but do not have a service

By default, Process Stats will show background processes.

Each row in the list shows details for a specific process:

- the application label for the app that owns the process (e.g., “K-9 Mail”)
- the percentage of time, for the time period Process Stats is reporting, that this process was running (e.g., “100%”)
- the “relative computed memory load” of that process, as is indicated by the blue bar, with longer blue bars indicating greater load

The list is sorted in order of “relative computed memory load”.

Many background apps will have a running percentage of 100%, indicating that they have an always-running service. Those with a percentage less than 100% indicate an app that had a service running at the point in time of the Process Stats snapshot that you are examining, but did not necessarily have a service running for the entire timeframe (e.g., periodic IntentService doing background work)

### Refresh and Duration

There is a “refresh” icon in the action bar that will update the current view to reflect changes since you last opened or refreshed the screen.

---

## ISSUES WITH SYSTEM RAM

---

How long the timeframe is depends a bit upon device operation and also on the “Duration” entry in the overflow menu:

*Figure 1008: Process Stats Overflow in Android 4.4*

Tapping that gives you a roster of available timeframes:

*Figure 1009: Process Stats Duration Options in Android 4.4*

Even though these items render with checkboxes, they function as radio buttons, so whatever you tap on becomes the new duration. Upon making a change, the summary area will reflect the newly-chosen duration. Note that this choice is not persistent, as exiting Process Stats via the BACK button and re-entering it returns you to a three-hour duration.

### **Controlling What is Shown**

If your application is not showing up in the background roster, it may be classified as “foreground” (e.g., if you have a foreground service) or “cached” (if not). The “Stats type” overflow option will let you toggle between these categories, to see what processes are reported in each.

Note that an app can appear in more than one roster, since the roster is by *process*. For example, at the time of this writing, Evernote appears in the author’s Nexus 4 both in “foreground” and in “cached”, for separate processes.

As with the duration, the choice of category is not persistent, and you will be returned to the background process roster if you exit Process Stats via the BACK button and later return to it.

### Drilling Down Into an App

Tapping on an item in the list will bring up details about that particular app and process:

Figure 1010: Process Stats Details for K-9 Mail

The “Average RAM use” value shows how much system RAM is attributed to your app. This will include:

- All system RAM used uniquely by your app (e.g., your heap)
- A portion of system RAM shared by your app and others (e.g., the Dalvik runtime)

This is known as “Proportional Set Size” or “PSS” in Linux, and is a common way of coming up with a simple number for the amount of RAM that a particular process is responsible for.

The blue bar is based on this average RAM use (or PSS) value, multiplied by the percentage of the time that the process was running.

The “Maximum RAM use” value is the highest PSS associated with your process

## ISSUES WITH SYSTEM RAM

---

during the period under examination.

Also listed are the services of your app and the percentage of time that they were in a running state. Everlasting services will show up as 100%, while transient services (e.g., IntentService) will show up with a much smaller percentage.

### How You Want Your App to Appear

Ideally:

- Your app spends most of its time in the “cached” process list, not the “background” or “foreground” list
- Your app has a low percentage of time spent running
- Your app has a low “relative computed memory load” and, ideally, a low “Average RAM use” value

The better you are in these areas, the more likely it is that you are not seriously impacting system RAM.

### procstats

The data that powers the Process Stats screen in Settings is also available as human-readable text output, using the `adb shell dumpsys procstats` command, against your Android 4.4 device or emulator.

Running that command will give you three blocks of information:

- Process memory usage, aggregated over the last 24 hours
- Process memory usage, aggregated over the last 3 hours
- A snapshot of the current memory usage, at the time you ran the command

This can be a long report, even for just one of those blocks. For example, here is the last-3-hours block, run on the author’s personal Nexus 4:

```
AGGREGATED OVER LAST 3 HOURS:
```

```

```

Unfortunately, it is rather cryptic and rather long.

There are various command-line switches you can add to help manage the output. Use the `-h` switch to see the full roster. Some notable options:

- `-csv` switches the output to be in CSV format, for importing into a spreadsheet or running through an analysis tool, with other switches (e.g., `-csv-proc`) to control what is included in the CSV output
- `--current` will only report the current snapshot
- `--hours NNN` will only report the aggregate over the stated number of hours
- `--full-details` provides a somewhat more documented report, at the cost of greatly increasing its verbosity

## ISSUES WITH SYSTEM RAM

---

Also, including a package name (e.g., `com.commonware.android.sample`) at the end of the command line will constrain the output to solely that package, which is useful if you are only looking to examine your own app's data.

The numbers in parentheses (e.g., (4.7MB-4.7MB-4.7MB/3.8MB-3.8MB-3.8MB over 2)) report:

- the minimum proportional set size (PSS) seen
- the average PSS seen
- the maximum PSS seen
- the minimum unique set size (USS) seen, where this is the amount of memory consumed by your app that is *not* shared with other processes (i.e., it is how much memory that would be freed if your process were terminated)
- the average USS seen
- the maximum USS seen
- the number of samples taken of the memory during the timeframe being analyzed

The listing also shows the percentage of time your process was in various states (e.g., cached vs. service vs. “important foreground”)

### meminfo

Older devices that do not support `procrank` can support `meminfo`, accessed via `adb shell dumpsys meminfo`. Run as-is, it will generate a report of all processes and their PSS, plus the same roster broken down into various process categories (e.g., foreground, cached), and other summary data. The report for the same Nexus 4 that generated the `procrank` shown earlier in this chapter is:

```
Applications Memory Usage (kB):
Uptime: 95955008 Realtime: 788076654
```

```
Total PSS by process:
```

com.commonsware.books.android/databases/booksearch.db
```

This can show you:

- How much memory is being consumed by your Dalvik bytecode (.dex mmap), native libraries used directly by you or by framework components (.so mmap), etc.
- How many objects of various types are in the Dalvik heap, such as views and activities
- How much memory is used by SQLite for its page cache and related process-level buffers, plus which databases you have open that are contributing to memory consumption

Note that the combination of the `Private Dirty` and `Private Clean` columns is roughly analogous to the `USS` reported by `procstats`, in that it represents the amount of memory private to your process and that would be released should your process be terminated.

## Measuring System RAM Consumption: Runtime

Some of the same information that the aforementioned reports contain is available at runtime via `ActivityManager` and other framework classes.

### `getMemoryInfo()`

`getMemoryInfo()` on `ActivityManager` will fill in a supplied `ActivityManager.MemoryInfo` object. This will report to you:

- The total memory on the device (`totalMem`)
- The “available memory” (whose definition is a bit unclear) (`availMem`)
- What level of “available memory” is considered “low” and should trigger Android to start terminating processes beyond those that are cached, such as ones with running services (`threshold`)

- Whether we are presently in such a low-memory state (`lowMemory`)

### **getMyMemoryState()**

`ActivityManager` also has a `getMyMemoryState()` method, on API Level 16+, that will populate an `ActivityManager.RunningAppProcessInfo` object with information about your process. While not everything in this object will be filled in, you will be able to get:

- The last trim level reported to your activities and `Application` via `onTrimMemory()` (`lastTrimLevel`)
- What importance level the OS considers your process to be in (`importance`), such as `IMPORTANCE_FOREGROUND` and `IMPORTANCE_EMPTY`
- For processes in the `IMPORTANCE_BACKGROUND` category — meaning the process has outstanding activities but is not in the foreground and has no service — the relative standing of the process compared to other background processes from a least-recently-used standpoint (`lru`), where lower numbers mean more recent usage

### **getProcessMemoryInfo()**

The `getProcessMemoryInfo()` method on `ActivityManager` returns an array of `Debug.MemoryInfo` objects corresponding to the array of `int` process IDs (`pids`) that you pass in. The `Debug.MemoryInfo` objects report how much memory those identified processes are consuming. Of particular note, `getTotalPss()` returns the PSS for that process.

To get the `Debug.MemoryInfo` for your own process, you can use `getMemoryInfo()` on the `Debug` class, rather than find your own process ID and use `getProcessMemoryInfo()`. Or, on API Level 14+, you can simply call `getPss()` on `Debug` directly to find out your PSS.

## **Learn To Let Go (Of Your Heap)**

Part of the reason for worrying a bit about your system RAM consumption is simply to “play nice” with the other apps that the user wants to use. However, since part of Android’s decision-making about what processes to terminate tie into how much RAM those processes take up, the lower your system RAM footprint, the more likely it is that you can hang around for a while.

## ISSUES WITH SYSTEM RAM

---

Part of reducing your system RAM consumption involves cleaning up your heap.

The reason the framework calls callback methods like `onTrimMemory()` is to help you reduce your heap usage to avoid `OutOfMemoryError` exceptions. However, allowing objects to be garbage-collected not only gives you more heap space, but it *also may reduce your system RAM footprint*.

To limit your system RAM usage, your process is not allocated all of its possible heap when the process is started up. Instead, the heap starts small and expands as you allocate more and more memory. However, the reverse is also true: if you release memory, the heap can shrink, returning RAM to the system. Android expands the heap on a “paged” basis, allocating more system RAM to add more pages to the heap. If, as a result of garbage collection, Dalvik sees that there are too many totally empty pages, Dalvik can free up those pages, returning them to the OS for use by other processes.

As noted in [the chapter on the application heap](#), Dalvik’s garbage collector is **non-compacting**, meaning that it does not move objects around to try to clean up pages or otherwise coalesce free memory blocks. Hence, a fragmented heap not only limits how well you can allocate new memory, but it also inhibits Dalvik’s ability to reduce your system RAM usage.

# Issues with Battery Life

---

Most Android devices are powered by batteries — Android TV is the biggest class of device that is not. Batteries are wonderful gizmos with one major problem: they are *always* running out of power.

Hence, users are very sensitive to battery consumption. Their ability to use their phones as actual *phones*, let alone for Android apps, depends on having enough battery power. The more apps drain the battery, the more frequently the user has to find a way to recharge the phone, and the more frequently the user fails and their phone shuts down.

The catch is that you may not notice the battery issues in your day-to-day development. The Android emulator's emulated battery does not drain based on you running your app. Your devices are often connected to your development machine via USB for testing and debugging, meaning they are perpetually being charged. Unless you are a regular user of your own app, you might not notice any increased power drain.

This part of the book is focused on helping you understand what is draining power and what you can do to be kinder and gentler on your users' batteries.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## You're Getting Blamed

Users, for better or worse, have limited ability to determine what is responsible for draining the battery of their phone. Their #1 tool for this is the “Power Usage Summary” screen in the Settings app, sometimes referred to as the “battery blame screen”.

*Figure 1011: Battery Screen from Settings App*

This lists both device features (e.g., the display) and applications. Android incrementally improves the accuracy of this screen with each passing release, trying to make sure the user understands what specifically is consuming the power.

If your application starts appearing on this screen, and the user does not feel that it is justified, the user is likely to become irritated with you.

Now, your appearance on this list might be perfectly reasonable. If you have written a video player app, and the user has just watched a few hours' worth of video, it is very likely that you will appear on this list and will be justified in your battery consumption.

However, anything that you can do to not appear on this screen, or appear lower in the list, will help with user acceptance of your app.

This part of the book will show you how to measure your power usage and ways of trying to use less of it.

### **Not All Batteries Are Created Equal**

Roughly speaking, battery capacity is proportional to screen size. Larger screens mean physically larger devices, and since the rest of the components (e.g., CPU) tend to be the same size, a larger device offers more room for a larger battery. This is good, as the screen is one of the major power draws on a device, and bigger screens draw more power.

Conversely, the battery on a “wearable” — whether eyewear like Google Glass, a smartwatch, or other form factors — tends to be much smaller than average, just because the wearables are physically smaller. A wearable is likely to have a battery with less than a third of the capacity of a phone, which in turn may have a battery with less than a third of the capacity of a large tablet.

Hence, depending upon where your app will be running, the amount of battery available in total will vary widely. What might be considered acceptable battery consumption on a tablet would be considered excessive on a wearable.

### **Stretching Out the Last mWh**

Sometimes, what the user wants your app to do in one case is not what the user wants your app to do in other cases. Serious power-draining might be reserved for when the device is plugged in, or when the device has at least such-and-so power remaining. The user may value the last milliwatt-hours (mWh) more than others and want your application to use less power in those circumstances.

Hence, if your application polls the Internet, you might offer a feature to poll less frequently, or perhaps not at all, when power is low. If your application uses GPS to find a location (e.g., automatic “check-ins” to social networks like Foursquare), you might offer to skip such actions when the battery is low. You might want to signal to the user when the battery gets low during playback of a video, or during the game they are in. And so on.

This part of the book will help you identify when the battery is low and strategies for

## ISSUES WITH BATTERY LIFE

---

making use of that information.

# Power Measurement Options

---

As with any situation where you are trying to reduce your use of some system resource, you need to be able to accurately measure how much you are using that resource. Otherwise, you will have no idea whether your attempts to reduce usage are helping. It is possible that what you think will consume less of the resource actually consumes *more*, because of unanticipated side-effects. And, if nothing else, if the change makes your code more complicated and does not help much with resource consumption, you may be better served sticking with the original, simpler implementation.

So, when it comes to power usage, it helps to know how much power you are consuming, to determine if your attempts to use less power actually do help.

Unfortunately, compared to things like RAM and bandwidth, power measurement is a significant challenge. You really need to have hardware specifically instrumented to report power consumption for pieces of that hardware (CPU versus screen versus GPS versus mobile data radio versus ...). Even if you cannot get power usage per component, just having accurate power consumption overall is not something you can necessarily get from any Android device. Alas, getting that level of power usage knowledge can be troublesome in its own right, for a variety of reasons.

This chapter will explore a few ways of measuring power usage, along with the pros and cons of that approach.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

## batterystats and the Battery Historian

Android 5.0 brought us “Project Volta”, an initiative to reduce the amount of power consumed by apps, the framework classes, and the OS itself.

Part of what we got from Project Volta is `batterystats`, a dump of data pertaining to power consumption. Since that data dump can be large and inscrutable, we also have the Battery Historian, a tool that can convert key `batterystats` output into a timeline of events.

However, none of this is especially well-documented at this time, and so the usefulness of these utilities is limited at present. The following sections provide some basic guidance for trying to use these tools.

### Running a Test

First, since `batterystats` is obtained via `adb shell dumpsys`, you will want `adb` to be in your `PATH`, by adding your SDK installation’s `platform-tools/` directory to your `PATH` environment variable.

Then, in a terminal, run:

```
adb shell dumpsys batterystats --enable full-wake-history
adb shell dumpsys batterystats --reset
```

This will ensure that `batterystats` captures all relevant information about `WakeLock` behavior, and it resets all of the logs.

At this point, run your tests. Ideally, you would do so in a fairly power-neutral environment, such as not using a USB cable for an `adb` connection (as that charges the device).

When your test scenario is complete, run `adb shell dumpsys batterystats`, redirecting the output to some file:

```
adb shell dumpsys batterystats > /tmp/bs.txt
```

You can optionally supply your `applicationId` as part of the `batterystats` command, which will restrict the output to events pertaining to your app. However, some events that are from other processes, like the Play Services Framework, may be of interest to you. You will need to experiment to determine which mode (full or

## POWER MEASUREMENT OPTIONS

---

filtered for your app) will work best for you.

### Interpreting the Text Output

Depending on how long your test runs, the information included in the batterystats output can be anywhere from tens of KB to tens of MB in size. The output will also vary by Android OS release.

### Battery History

The file will lead off with the “Battery History” section:

```
Battery History (13% used, 35KB used of 256KB, 68 strings using 4232):

. . .
```

This contains information about how much the battery was drained during the test run, along with a detailed roster of the power-related events that occurred during the test run. The timestamps on those roster entries are relative to the first entry in the roster. Beyond that, there is little explanation of what the roster entries mean.

### Per-PID Stats

Next, there will be a short stanza labeled “Per-PID Stats” and, possibly, “Discharge step durations”:

```
Per-PID Stats:  
PID 0 wake time: +134ms  
PID 536 wake time: +1m35s993ms  
PID 0 wake time: +10s842ms  
PID 881 wake time: +301ms  
PID 536 wake time: +70ms  
PID 989 wake time: +23s167ms  
PID 1136 wake time: +2s974ms  
PID 1193 wake time: +230ms  
PID 0 wake time: +1s123ms  
PID 617 wake time: +187ms
```

## POWER MEASUREMENT OPTIONS

---

```
PID 536 wake time: +18ms
PID 536 wake time: +13ms
PID 627 wake time: +586ms
PID 536 wake time: +184ms
PID 3690 wake time: +9m42s965ms
```

Discharge step durations:

```
#0: +4h8m36s976ms to 97 (screen-off, power-save-off)
#1: +3h7m47s132ms to 98 (screen-off, power-save-off)
```

If you determine your process' PID, you will see how long the process' "wake time" was. The precise definition of "wake time" is undocumented.

### Daily Stats

Next may be a section entitled "Daily stats":

Daily stats:

```
Current start time: 2015-12-12-05-27-33
Next min deadline: 2015-12-13-01-00-00
Next max deadline: 2015-12-13-03-00-00
Package changes:
  Update com.google.android.dialer vers=20312
  Update com.google.android.apps.cloudprint vers=113
  Update com.android.chrome vers=252608301
  Update com.google.android.marvin.talkback vers=40400003
  Update com.google.android.contacts vers=10307
  Update com.commonware.empublite vers=1
  Update com.commonware.android.picasso vers=1
Daily from 2015-12-11-05-55-34 to 2015-12-12-05-27-33:
Discharge step durations:
  #0: +4h49m4s38ms to 93 (screen-off, power-save-off, device-idle-on)
  #1: +3h53m22s969ms to 94 (screen-off, power-save-off)
  #2: +5h8m4s10ms to 95 (screen-off, power-save-off, device-idle-on)
  #3: +3h33m53s102ms to 96 (screen-off, power-save-off, device-idle-on)
  Discharge total time: 18d 3h 10m 2s 900ms (from 4 steps)
  Discharge screen off time: 18d 3h 10m 2s 900ms (from 4 steps)
  Discharge screen off device idle time: 18d 18h 33m 58s 300ms (from 3 steps)
Package changes:
  Update com.commonware.empublite vers=1
Daily from 2015-12-10-04-55-48 to 2015-12-11-05-55-34:
Discharge step durations:
  #0: +5h1m15s618ms to 98 (screen-off, power-save-off, device-idle-on)
  #1: +42m34s7ms to 98 (screen-off, power-save-off, device-idle-off)
  Discharge total time: 11d 22h 31m 21s 200ms (from 2 steps)
  Discharge screen off time: 11d 22h 31m 21s 200ms (from 2 steps)
```

## POWER MEASUREMENT OPTIONS

---

```
Discharge screen off device idle time: 20d 22h 6m 1s 800ms (from 1 steps)
Package changes:
  Update com.commonware.ct3 vers=1
  Update com.commonware.android.fsendermnc vers=1
...
```

This indicates, for various time slices, what apps were updated and what the “discharge step durations” are (which is undocumented).

### “Statistics since last charge” Summary

Next up will be a “Statistics since last charge” header, with a few summary blocks of data:

```
Statistics since last charge:
  System starts: 0, currently on battery: false
  Time on battery: 11h 30m 29s 177ms (99.9%) realtime, 16m 13s 306ms (2.3%) uptime
  Time on battery screen off: 11h 30m 7s 940ms (99.9%) realtime, 15m 52s 69ms (2.3%)
uptime
  Total run time: 11h 30m 55s 300ms realtime, 16m 39s 430ms uptime
  Start clock time: 2014-10-25-19-54-07
  Screen on: 21s 237ms (0.1%) 2x, Interactive: 20s 191ms (0.0%)
  Screen brightnesses:
    dark 21s 237ms (100.0%)
  Total partial wakelock time: 10m 22s 877ms
  Mobile total received: 0B, sent: 0B (packets received 0, sent 0)
  Phone signal levels:
    none 11h 30m 29s 177ms (100.0%) 0x
  Signal scanning time: 9s 0ms
  Radio types:
    none 11h 30m 29s 177ms (100.0%) 0x
  Mobile radio active time: 0ms (0.0%) 0x
  Wi-Fi total received: 0B, sent: 0B (packets received 0, sent 0)
  Wifi on: 11h 30m 29s 177ms (100.0%), Wifi running: 11h 30m 29s 177ms (100.0%)
  Wifi states: (no activity)
  Wifi supplicant states:
    group-handshake 16ms (0.0%) 12x
    completed 11h 30m 29s 161ms (100.0%) 12x
  Wifi signal levels:
    level(4) 11h 30m 29s 177ms (100.0%) 1x
  Bluetooth on: 0ms (0.0%)
```

## POWER MEASUREMENT OPTIONS

---

```
Bluetooth states: (no activity)
```

```
Device battery use since last full charge
```

```
Amount discharged (lower bound): 2  
Amount discharged (upper bound): 3  
Amount discharged while screen on: 0  
Amount discharged while screen off: 3
```

```
Estimated power use (mAh):
```

```
Capacity: 3448, Computed drain: 107, actual drain: 69.0-103  
Idle: 40.3  
Wifi: 36.4  
Uid u0a58: 14.8  
Uid 0: 12.8  
Uid 1000: 1.75  
Uid u0a20: 0.521  
Uid u0a7: 0.389  
Screen: 0.375  
Uid 1013: 0.0775  
Uid 1001: 0.0219  
Uid u0a42: 0.0168  
Uid u0a12: 0.0138  
Uid 1027: 0.0110  
Uid u0a5: 0.00866  
Uid u0a33: 0.00253  
Uid u0a16: 0.000867  
Uid u0a3: 0.000815  
Uid u0a29: 0.000523  
Uid u0a2: 0.000474  
Over-counted: 4.04
```

The first block has useful data about how much various radios were on, how much data they transmitted, how long the screen was on, how long the device had an outstanding partial WakeLock, etc.

Also, the “Estimated power use (mAh)” block is basically the data that underlies the “battery blame screen” in Settings. You will see how many milliamp-hours (mAh) were attributed to your process.

### WakeLock Summary

Next up may a summary of WakeLock events:

```
All kernel wake locks:
```

```
Kernel Wake lock PowerManagerService.WakeLocks: 10m 23s 46ms (717 times) realtime
```

## POWER MEASUREMENT OPTIONS

---

```
Kernel Wake lock qcom_rx_wakelock: 9m 9s 836ms (1537 times) realtime
Kernel Wake lock alarm_rtc: 55s 327ms (717 times) realtime
Kernel Wake lock sns_async_ev_wakelock: 16s 525ms (9 times) realtime
Kernel Wake lock power-supply: 15s 730ms (1448 times) realtime
Kernel Wake lock event0-536: 11s 822ms (1484 times) realtime
Kernel Wake lock event2-536: 10s 686ms (1509 times) realtime
Kernel Wake lock event4-536: 10s 234ms (1509 times) realtime
Kernel Wake lock alarm: 7s 972ms (1239 times) realtime
Kernel Wake lock wlan: 1s 608ms (2 times) realtime
Kernel Wake lock PowerManagerService.Display: 611ms (2 times) realtime
Kernel Wake lock main: 608ms (0 times) realtime
Kernel Wake lock KeyEvents: 136ms (1548 times) realtime
Kernel Wake lock mmc0_detect: 38ms (1507 times) realtime
Kernel Wake lock deleted_wake_locks: 28ms (170 times) realtime
Kernel Wake lock event5-536: 20ms (2 times) realtime
```

All partial wake locks:

```
Wake lock u0a58 wake:com.commonsware.android.job/.DemoScheduledService: 9m 0s 153ms
(671 times) realtime
Wake lock 1000 *alarm*: 44s 114ms (683 times) realtime
Wake lock u0a7 Checkin Service: 16s 572ms (4 times) realtime
Wake lock 1000 NetworkStats: 7s 347ms (338 times) realtime
Wake lock 1013 AudioMix: 5s 833ms (2 times) realtime
Wake lock 1000 DHCP: 4s 953ms (12 times) realtime
Wake lock u0a7 *net_scheduler*: 1s 504ms (82 times) realtime
Wake lock u0a7 Event Log Service: 1s 98ms (18 times) realtime
Wake lock u0a42 DownloadManager: 322ms (1 times) realtime
Wake lock u0a7 Config Service fetch: 235ms (1 times) realtime
Wake lock u0a7 Icing: 197ms (5 times) realtime
Wake lock u0a7 Event Log Handoff: 143ms (18 times) realtime
Wake lock u0a58 *alarm*: 120ms (24 times) realtime
Wake lock u0a7 GCM_CONN: 61ms (36 times) realtime
Wake lock u0a7 GmsDownloadService: 47ms (1 times) realtime
Wake lock u0a7 *alarm*: 42ms (10 times) realtime
Wake lock u0a7 Wakeful StateMachine: GeofencerStateMachine: 35ms (8 times) realtime
Wake lock 1000 SyncManagerHandleSyncAlarm: 34ms (6 times) realtime
Wake lock u0a7 GCM_HB_ALARM: 34ms (36 times) realtime
Wake lock u0a7 Checkin Handoff: 12ms (4 times) realtime
Wake lock 1000 SyncLoopWakeLock: 8ms (4 times) realtime
Wake lock u0a33 *alarm*: 7ms (4 times) realtime
Wake lock u0a42 *alarm*: 4ms (3 times) realtime
Wake lock u0a7 GCoreFlp: 2ms (5 times) realtime
```

If you do not have a separate section for these, they may be interleaved in the “Statistics since last charge:” data.

Your code will tend to show up in the “All partial wake locks” section, showing how

## POWER MEASUREMENT OPTIONS

---

many WakeLocks you acquired and for how long overall.

And, if you show up here, you can definitely find out your app's PID — for example, u0a58 is associated with the com.commonware.android.job package.

### Per PID Summary

Next up may be summaries of information per process; otherwise, this information is interleaved in the “Statistics since last charge:” section. Your process will show up somewhere in the list:

```
.
.
.
u0a58:
  Wake lock wake:com.commonware.android.job/.DemoScheduledService: 9m 0s 153ms
partial (671 times) realtime
  Wake lock *alarm*: 120ms partial (24 times) realtime
  TOTAL wake: 9m 0s 273ms partial realtime
  Foreground activities: 7s 817ms realtime (1 times)
  Foreground for: 12s 959ms
  Active for: 3h 58m 47s 853ms
  Running for: 11h 30m 29s 177ms
  Proc com.commonware.android.job:
    CPU: 1m 4s 370ms usr + 21s 140ms krn ; 400ms fg
  Proc *wakelock*:
    CPU: 43s 690ms usr + 1m 19s 590ms krn ; 0ms fg
  Apk com.commonware.android.job:
    672 wakeup alarms
  Service com.commonware.android.job.DemoScheduledService:
    Created for: 11m 14s 174ms uptime
    Starts: 647, launches: 647
.
.
.
```

As usual, the exact definitions of the information here is largely undocumented.

### Installing the Battery Historian

While batterystats is part of the Android 5.0+ runtime environment, and tools like adb are part of the Android SDK, the Battery Historian is neither. Instead, it is a separate project that you have to download to your development machine from [its GitHub project](#).

## POWER MEASUREMENT OPTIONS

---

The original implementation of the Battery Historian was a Python script. This is still available as the `historian.py` file in that GitHub repository, until such time as Google elects to delete it.

Battery Historian 2.0 is now a server written in the Go programming language. This requires a fair bit more work to set up, as you need to:

- install a Go compiler
- download Go dependencies manually
- modify your `PATH` environment variable, plus add new environment variables
- deal with the intrinsic hassles and risks of running an unnecessary server

This chapter focuses on the original Python script.

### Running the Battery Historian

Once you have downloaded that Python script, and assuming that you have a Python interpreter installed, you can run the script, supplying it with the output of your `batterystats` run, and redirecting the script's output to an HTML file:

```
python historian.py /tmp/bs.txt > /tmp/bs-report.html
```

## POWER MEASUREMENT OPTIONS

Figure 1013: Battery Historian Timeline, Additional

## POWER MEASUREMENT OPTIONS

The length of the bar shows the approximate duration of the event, though really short events have a *de minimus* length to give you something to see. Hovering your mouse over one of the bars brings up a pop-up with more details about that event:

Figure 1014: Battery Historian Timeline, Partial View, with Pop-Up

If the bar is really long, you may need to scroll your browser horizontally to see the pop-up, as the rendering of the pop-up location does not seem to pay attention to the browser viewport very well.

---

## POWER MEASUREMENT OPTIONS

---

Below the main chart is a “Zoom” field that you can use to change the scale of the horizontal axis, along with an “Event summary”:

Again, this is largely undocumented.

## PowerTutor

Perhaps the best-known third-party power analyzer is [PowerTutor](#). PowerTutor is the outcome of a research project from the University of Michigan, with a bit of assistance from Google. In principle, PowerTutor is capable of letting you know power consumption on a device, much along the lines of what Trepn can record on a Qualcomm MDP. In practice, PowerTutor is significantly less powerful and sophisticated.

PowerTutor was created with the HTC Dream (T-Mobile G1), HTC Magic (T-Mobile G2), and Nexus One in mind. Its power output values will be as accurate as they could make it for those devices. If you run PowerTutor on other hardware, the results will be less accurate.

You can obtain PowerTutor from the Play Store, or from the PowerTutor Web site, or you can [compile it from source](#).

PowerTutor is not tied to testing a particular application. As such, you can simply

## POWER MEASUREMENT OPTIONS

---

run PowerTutor whenever you want from its launcher icon, then press “Start Power Profiler” in the main activity:

*Figure 1016: The PowerTutor main activity*

## POWER MEASUREMENT OPTIONS

---

At this point, you can start playing with your application, or running your unit test suite, or whatever. When you want to get an idea of how much power you have been consuming, you can switch back to the PowerTutor activity and choose “View Application Power Usage”. This brings up a list of processes and toggle buttons to show various power consumption values for each:

*Figure 1017: The PowerTutor application roster*

## POWER MEASUREMENT OPTIONS

---

Tapping the list entry brings up a graph for that particular process, though since this information is only available while PowerTutor is recording new data, the graph is usually empty unless you have logic running in the background:

*Figure 1018: The PowerTutor live charts for a single process current power consumption*

## POWER MEASUREMENT OPTIONS

---

You can also bring up a chart showing what portion of your power consumption came from various sources for the whole device, such as a pie chart of current consumption:

Given that the source code is available, one might augment PowerTutor to:

1. Saving results, both as data files for offline analysis (akin to Trepn's CSV files) or for viewing charts and tables on the device when data is not being actively collected
2. Allowing one to record application states, akin to Trepn, to better correlate application functionality to saved power results

## Battery Screen in Settings Application

Of course, what developers tend to focus on most with power is the battery consumption screen in the Settings application, as shown in [a previous chapter](#):

*Figure 1020: Battery Screen from Settings App*

After all, this is what users will tend to focus on — anything showing up in here is a source of blame for whatever power woes the user believes she is experiencing. Conversely, if your application does not show up in this screen during normal operation, then there is no compelling reason for you to do further analysis, as users will tend to be oblivious to your actual power consumption.

## POWER MEASUREMENT OPTIONS

---

If you do show up in the list, tapping on your entry can give you some more details of what power you consumed and why:

*Figure 1021: Battery Details Screen from Settings App*

However, the information contained in here is mostly guesswork, using a more refined version of the same approach that PowerTutor uses. Ordinary Android hardware simply lacks enough fine-grained power measurement instrumentation to do an accurate job of apportioning power usage among different processes. So, the details of how long you kept the CPU powered on may be accurate, but the percentage of battery consumption associated with your app is just an estimate.

## BatteryInfo Dump

Yet another possibility on older Android devices is to use the `adb shell dumpsys batteryinfo` command from your command prompt or terminal on your development workstation. This will emit a fair amount of data that probably means something to somebody, such as general device information:

```
Battery History:
-1h00m56s463ms 096 20030002 status=discharging health=good
plug=none temp=191 volt=4060 +screen +wake_lock +sensor
```

## POWER MEASUREMENT OPTIONS

---

```
brightness=medium
-1h00m52s490ms 096 22030302 +wifi phone_state=off
-1h00m51s844ms 096 2703d102 +phone_scanning +wifi_running
phone_state=out data_conn=other

Kernel Wake lock "radio-interface": 3s 1ms (3 times) realtime
Kernel Wake lock "ApmCommandThread": 4ms (10 times) realtime
Kernel Wake lock "ds2784-battery": 2s 6ms (21 times) realtime
Kernel Wake lock "msmfb_idle_lock": 14ms (2273 times) realtime
Kernel Wake lock "kgsl": 51s 482ms (613 times) realtime
Kernel Wake lock "rpc_read": 164ms (272 times) realtime
Kernel Wake lock "main": 7m 39s 708ms (0 times) realtime
Total received: 0B, Total sent: 0B
Total full wakelock time: 149ms , Total partial wakelock time: 31s
14ms
Signal levels: none 59m 57s 63ms (99.9%) 1x
Signal scanning time: 59m 57s 63ms
```

## POWER MEASUREMENT OPTIONS

---

```
Radio types: none 641ms (0.0%) 1x, other 59m 56s 973ms (99.9%) 1x
Radio data uptime when unplugged: 0 ms
Wifi on: 59m 57s 709ms (99.9%), Wifi running: 22m 35s 424ms
(37.6%), Bluetooth on: 0ms (0.0%)
```

```
Device battery use since last full charge
Amount discharged (lower bound): 0
Amount discharged (upper bound): 1
Amount discharged while screen on: 1
Amount discharged while screen off: 0
```

(... and lots more...)

and per-process information (here, showing power used by PowerTutor itself):

```
#10058:
Wake lock window: 5s 71ms window (1 times) realtime
Proc edu.umich.PowerTutor:
  CPU: 11s 750ms usr + 4s 530ms krn
  1 proc starts
Apk edu.umich.PowerTutor:
  Service edu.umich.PowerTutor.service.UMLoggerService:
    Created for: 4m 4s 750ms uptime
    Starts: 1, launches: 1
```

In principle, one might create tools that use this output — or perhaps steal a peek at the data used by the Settings application – to create something a bit more developer-friendly.

# Sources of Power Drain

---

If you can measure power drain well yourself, that is the best way for you to determine precisely where your power consumption is going. Alas, for various reasons, you may not be able to get good power consumption data.

Which means you may have to guess.

We know the general sorts of things that consume power in a device, such as the screen and the CPU. We know that if we use these things less, we will use less power. Eventually, though, we have an app that does nothing, and while this may result in optimal power usage, we are still likely to get poor reviews, because *the app does nothing*.

What we need is some rough idea of how bad certain things are, so we can weigh our use of those system components appropriately.

This chapter will try to give you some “rule of thumb” heuristics of how to estimate power usage of various system components, plus some general recommendations of how to use less of that particular component without necessarily eliminating useful functionality from your app.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate.

Also note that:

- mA = milliamps, where the ampere (or “amp”) is the SI unit of current

- mAh = milliamp-hours, which is how battery capacities are measured (e.g., 2000mAh can power a 200mA draw for 10 hours)

## Screen

Screen size and battery size generally trend together. Tablets have bigger batteries and bigger screens than do phones, which in turn are bigger in both areas than are wearables.

A rough rule of thumb is to expect to consume ~10% of the device's battery for every hour you keep the screen on. Or, to look at it another way, on a phone-sized screen, expect a power draw of ~100-200mA, depending on variations in screen size and display technology (e.g., AMOLED).

Normally, the user is in control over how long your app is in the foreground and therefore is "to blame" for the screen being on. There are a couple of cases where you can make the screen be more of a problem.

The first is if you acquire() a WakeLock (other than a PARTIAL\_WAKE\_LOCK)... and forget to ever release() it. Since the WakeLock will keep the screen on, the screen will stay on, even if your app is in the background, until such time as your process is terminated or the device shuts down due to low battery.

In fact, such WakeLock types have been deprecated, with the last of them being flagged as deprecated in API Level 17. The recommended alternative is to use `android:keepScreenOn` or `setKeepScreenOn()` on some View. This will keep the screen on, so long as the activity hosting that View is in the foreground. That way, just moving to the background releases the underlying WakeLock, allowing the device to return to sleep.

However, in some cases, even that may be insufficient. Suppose that the user is in your activity, and they get distracted, putting down their device for an extended period. Unless you somehow detect the inactivity, and manually turn off the keep-screen-on mode, the screen will stay on indefinitely, until the power is drained. Hence, if you have a decent way of determining if the user is still using your activity, consider using that as a way to determine when the device is inactive (e.g., a `postDelayed()` that gets canceled and rescheduled when the user does something, so if the `postDelayed()` Runnable gets invoked, you know the user has done nothing for the delay period). Then, if you know the device is inactive, call `setKeepScreenOn(false)` to return the screen to its normal operating mode.

The academic paper [“How is Energy Consumed in Smartphone Display Applications?”](#) has a more extended analysis of screen power draw.

### Disk I/O

Disk I/O gets more efficient with bigger operations.

You can see this in something like SQLite, where wrapping a bunch of INSERT statements into a single transaction can have substantial benefits in terms of how long the I/O takes.

Not surprisingly, this has a similar impact on power consumption:

- Writing 1GB of data 1,000 bytes at a time is about twice as expensive as is writing it 10,000,000 bytes at a time
- Writing 1GB of data 100 bytes at a time is about five times as expensive as is writing it 1,000 bytes at a time

Hence, you want to try to batch up your disk I/O, where possible, to do fewer, bigger operations, rather than lots of little ones. This includes:

- Batching database I/O in a transaction, as noted above
- Caching data that you intend to log to disk in memory and only writing when your in-memory buffer reaches a certain size or age (though beware the dangers of your process being terminated before you get a chance to write the data)
- Consider using larger buffer sizes with `BufferedInputStream` and `BufferedOutputStream`, if you can afford the heap space, though the 8KB defaults are not that bad

As a rough model, consider disk I/O to draw ~200mA. The smaller the I/O operations, the more time it takes you to accomplish the work, and hence the less efficient those operations are.

While disk I/O is relatively expensive while it is occurring, most apps are not continuously reading or writing, and therefore the total impact to the battery will not be that bad. Apps that *do* continuously use the disk — such as music or video players — will consume quite a bit of power.

## WiFi and Mobile Data

Internet access via WiFi and mobile data networks is another area that you, the developer, tend to control. Some apps require continuous Internet access and only while in the foreground, like a streaming media player. But many more apps wind up doing Internet access periodically in the background, looking for new information on some server somewhere. Unfortunately, these are the sorts of “vampire” apps that can drain the battery without users necessarily being aware of it. Individually, these apps might not even appear all that bad, but when a device has dozens of them, the combined impact results in poor battery life.

Moreover, we also have the problem of dealing with multiple ways of getting to the Internet. Simple solutions will leave us totally oblivious to the differences in downloading via WiFi versus mobile data, at the potential cost in battery consumption. Slightly less-simple solutions optimize for mobile data, to try to minimize power drain in that model. More-elaborate solutions detect what sort of connection we have (using `ConnectivityManager`) and choose among different strategies as connectivity changes.

Here are some things you can do to try to help manage your Internet power consumption.

### Use Less

The simplest, rough-cut way to consume less power for Internet access is to do less Internet access in the first place. The less time you spend downloading (or uploading) data, the less power you tend to draw while doing so. In a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

And, of course, consuming less bandwidth can have other benefits, particularly for people on metered mobile data plans.

There are chapters [elsewhere in the book](#) that cover ways to deal with bandwidth consumption for bandwidth’s sake.

### Use What You Already Downloaded

For data that is likely to be unchanging, use a disk cache, so you can avoid downloading the same content again. Such a cache can be used at two levels:

## SOURCES OF POWER DRAIN

---

1. Simply by having the file in the cache can be a signal to your app that you already have the data and can avoid any sort of request to fetch it again.
2. For HTTP, by recording some additional details (If-Modified-Since and ETag headers), you can make a request to the server to download the content again, where the server can tell you if you already have the current copy of the content (via a 304 response code).

Many of the Internet libraries discussed [earlier in this book](#) offer disk caching as part of their services.

### Use In Batches

As noted earlier in this section, in a very coarse approximation, battery consumption will be proportional to bandwidth consumption.

Unfortunately, that approximation is pretty coarse.

We as developers tend to think of Internet access as being like a faucet with two states: on and off. In reality, wireless radios tend to have three states: full power, low power, and standby mode. Opening a socket will bring the radio to full power. An idle radio (no packets transferred) will drop to low power after a while, and eventually back to standby mode. Not surprisingly, the power draw for full power is substantially more than low power, which in turn is more than standby.

However, this model introduces some problems:

- There is some latency to move from standby or low power to full power. This slows down data transfer while the radio “warms up”.
- The idle time needed to transition to a lower power state is substantial, with values in the 5-15 second range well within reason. This means that making a request has lingering power cost even *after* our request has completed.

The net is that you want to bring the radio to full power as few times as possible (to minimize the percentage of time we are slowly dropping back to standby and consuming power while we do). And, while we are at full power, we want to do all necessary — or perhaps possibly necessary — data transfers, to avoid having to go back to full power again any time soon.

In other words, you want to batch your network I/O. This is reminiscent of the recommendations to batch disk I/O from earlier in this chapter.

So, for example, if you are going to upload data to a server, use that same pulse of work to download anything that needs downloading, rather than having separate schedules for uploads and downloads. Doing more in a batch and having fewer batches will reduce the cost of the power state changes.

### Use When the Server Wants You To

One common pattern for Internet access is to poll a server. This is fairly easy to code, using something like `AlarmManager` to get control every so often.

However, this approach resembles children in the back seat of a car, frequently pestering their parents with “Are we there yet?”

Just as the parents will tell the children “We will get there when we get there, and we will tell you when we get there”, you can take a similar approach, using [Google Cloud Messaging \(GCM\)](#). Rather than poll the server periodically, have the server contact your app on the device when there is data ready to be downloaded. This works well in cases where polls are likely to result in “yes, we have no data” responses — the pushes can be far less frequent than the polls would be. This can also reduce load on your servers, for not having to respond to poll requests across all your users.

Note, though, that the battery benefits are from using GCM itself. From the standpoint of an app, GCM is “always on”, and the power consumed by GCM is attributed to Android itself, not to the app. Hence, pushes are almost “free” from the standpoint of power cost. This will *not* be the case if you “roll your own” push system (MQTT, WebSockets, etc.). In this case, you are attempting to keep a long-lived socket yourself, *in addition* to the one maintained by GCM. Clearly, there are ways to do this that minimize the power consumption of the long-lived socket connection, but that is not easy to accomplish. Hence, you need to weigh the costs of depending upon the Play Services SDK and routing your communications through Google’s servers with the costs of trying to do your own separate push mechanism in a battery-friendly fashion.

### Use When Android Wants You To

If server push through GCM is impractical (e.g., you do not control the server), you can reduce your power use for Internet access by batching *across apps*, in addition to batching within your app.

What Google wants you to use for synchronizing data with a server is the `SyncManager`. This is an overly-complicated framework that, among other things,

gives you control to sync to the server at the same time that other apps needing to sync get control. That way, we can “warm up” the wireless radio once and handle several apps’ worth of data transfers at once. SyncManager will be covered in this book eventually.

Part of the reason why Android moved to make alarms with AlarmManager more “inexact” in API Level 19+ is for this same sort of batching. While AlarmManager certainly can be used for a variety of purposes, a lot of apps use it for Internet data transfer. Allowing Android to control when those alarms occur allows Android to try to coalesce them, and perhaps even time them to happen when SyncManager-led transfers occur, with the objective of minimizing the number of times we bring the wireless radio out of standby mode.

### Use Additional Reading

The Android developer documentation has [a series of “training” pages](#) on minimizing power consumption for data transfers. This expands upon Reto Meier’s Google I/O presentations that touch upon this topic.

## GPS

In light testing, GPS seems to draw ~35mA. Additional power will be consumed for using those results, though, and so the net effect on the battery will be somewhat higher, depending upon what your app does when it gets a GPS fix.

That figure is corroborated by the academic paper [“An Analysis of Power Consumption in a Smartphone”](#), though that paper tested rather old devices (HTC Dream and Nexus One).

Again, different devices will have different components, and some devices’ GPS modules may be more or less efficient.

Hence, GPS itself is a power drain, but not a massive one... if what you are doing with the GPS fixes itself is efficient. Keeping the GPS on for several hours will certainly take a chunk out of the battery charge, but if you are doing lots of work (e.g., navigation app) in response to those fixes, several hours may be more than the battery can handle.

If you can get by with the dependency on the Play Services SDK, using [LocationClient](#) can help here, particularly in cases where the user may not be

moving much, as Google's fused location provider uses the accelerometer to help determine how much they need to use GPS versus other possible means of determining location.

### Camera

The camera will consume power while it is actively receiving input, whether that is for the preview frames or for taking full-resolution pictures or video. Of course, it will also consume additional power when recording images to disk, whether those be still photos or continuous video.

A rough guide is that a camera preview will draw ~200mA *plus* the power for screen, CPU, etc. That could easily total over 350mA, even if you are not doing much. Normally, though, the camera preview is on for short periods of time, and only under user control.

A corresponding value for recording video, including the disk I/O and camera preview, would be ~600mA (plus the screen). That is the sort of thing you only want to do in short bursts, as a couple of hours of video recording can really take a bite out of battery. However, once again, normally the user is the one controlling when video is recorded.

### Additional Sources

The above sources of power drain are comparatively easy to model and provide a heuristic for determining your possible power usage.

However, there are plenty of other things that can drain the battery, for which this chapter does not provide such a heuristic. In many cases, the usage patterns of the system component will vary so widely that a simple heuristic is unrealistic. In some cases, the power drain from components from different manufacturers will be very different. In some cases, the author of this book simply lacks sufficient expertise with the technology to provide much help (e.g., Bluetooth).

The sections that follow will try to provide some help, though.

### CPU/GPU

Perhaps the biggest source of power drain beyond the components listed above will

## SOURCES OF POWER DRAIN

---

be the processors: the CPU and the GPU. These draw a fair bit of power, which is why processor manufacturers go to great lengths to try to adapt to varying conditions, turning off cores or switching clock speeds, to try to minimize the power drain.

Usually, so long as we are in the foreground, any CPU/GPU usage impact on power will be considered “normal” by the user. Of course, trying to boost performance here can benefit the user, not only in terms of possibly reduced power consumption, but less lag or other forms of sluggishness. Hence, trying to optimize processor utilization is worthwhile.

However, the bigger complaints from the user will come from power drain while your app is in the background. The biggest source of those complaints will come from your use of WakeLocks, preventing the device from going into a low-power sleep state.

There are some apps available on the Play Store that reportedly can give you some idea of how long you may be holding a WakeLock, however they generally require root, particularly for Android 4.4+.

### Sensors

Sensors, more so than many other device components, seem to get sourced from a wide range of manufacturers. They also seem to be tied into the devices differently from device to device. For example, some devices allow sensors to continue collecting data while the device is otherwise in a sleep mode, while many do not.

As such, it is difficult to give much guidance in terms of power drain tied to your use of sensors.

That being said, here are a few notes that may help:

1. Generally speaking, the more you use a sensor, the more likely it is that it will reflect in power drain. However, only some of that power drain will be from the sensor hardware itself. Your application code processing sensor events will bear much of the blame. Reducing the periods of time when you are registered for sensor events, using longer delays between events, and sensor event batching are ways that you can reduce the power drain associated with the sensors and your associated code.
2. Conversely, in some environments, use of a particular sensor may be “free”, insofar as the device uses the sensor itself on a continuous basis. For

example, the accelerometer and/or gyroscope is used by devices to detect orientation changes. Hence, those sensors must be powered on regularly, and therefore you cannot be “blamed” for the fact that the sensors are drawing power. Your use of the sensor data may contribute to power drain, of course.

### Audio Input and Output

Playing audio through the earpiece, speaker, wired headset, or Bluetooth, will consume some amount of power. The amount will vary by how long you are playing the audio and how the audio is played (e.g., Bluetooth may require more power than on-device audio output). However, in both cases, usually the user has control over the audio, particularly if it is to be playing for a lengthy period of time (e.g., music player), and so the power drain associated with audio playback is less likely to be considered to be a problem, as users will get annoyed with *uncontrolled* power drain, more so than power drain that they can manage themselves.

Recording audio via the on-board microphone or Bluetooth should also consume some incremental power. In cases where the user is in control over when recording is happening, the power drain is unlikely to cause the user much distress.

Where both playback and recording of audio may cause a perceived power problem is in places where the user has less control. For example, an alarm clock app should have some sort of timeout to stop playing the ringtone (or whatever) after some period, if the user fails to respond to the alarm. After all, it is possible that the user is not where the device is and is not in position to stop the alarm. In this case, the power drain will be from several components, audio playback being just one, but it is the uncontrolled nature of the power drain that can get you in trouble.

# **Addressing Application Size Issues**

---

Sometimes, our apps are just too big, where “too big” can be defined as:

- Bigger than the 100MB limit imposed by the Play Store
- Bigger than some other limit imposed by some other distribution channel
- Big enough that we worry about bandwidth costs, particularly for users on metered data plans
- Big enough that we hit some internal Dalvik limitations

This chapter will review various techniques for trying to keep the size of your app down to a reasonable level.

## **Prerequisites**

This chapter assumes that you have read the core chapters of the book.

## **The APK Analyzer**

One way to reduce the size of your APK is to see what is inside of it that you can get rid of. This is also useful to see if your attempts to get rid of it actually work and reduce the size of the APK file.

Android Studio, starting with version 2.2, has an APK analyzer that will help you do this.

To analyze an APK, choose Build > Analyze APK... from the Android Studio main menu. Unfortunately, this is not aware of your actual APKs from your project, instead dumping you in a standard file-open dialog. You will need to rummage

## ADDRESSING APPLICATION SIZE ISSUES

around your development machine to try to track down the APK to analyze. Look in your module's build/outputs/apk/ directory, though you may need to specifically build the APK for the build variant that you want to look at.

The analyzer will then generate a tree-table, showing you what things in your app are consuming space:

The screenshot shows the APK Analyzer interface for the file 'demo-playground-release-unsigned.apk'. The application is identified as 'com.commonsware.cwac.cam2.playground (version 1.0)'. The raw file size is 775 KB and the download size is 736.2 KB. A table lists the files and their sizes:

File	Raw File Size	Download Size	% of Total Download...
classes.dex	2.2 MB	690.7 KB	92.6%
res	59.8 KB	47.7 KB	6.4%
resources.arsc	20.9 KB	5.8 KB	0.8%
AndroidManifest.xml	5.1 KB	1.4 KB	0.2%
META-INF	87 B	83 B	0%

Figure 1022: APK Analyzer, As Initially Launched

The screenshot shows the same APK Analyzer interface, but with the 'res' directory expanded. The table now includes detailed information for each resource folder:

File	Raw File Size	Download Size	% of Total Download...
classes.dex	2.2 MB	690.7 KB	92.6%
res	59.8 KB	47.7 KB	6.4%
drawable-xhdpi-v4	13.8 KB	13.8 KB	1.9%
drawable-hdpi-v4	10.4 KB	10.4 KB	1.4%
drawable-xxhdpi-v4	8.1 KB	7.8 KB	1.1%
drawable-mdpi-v4	6.6 KB	6.6 KB	0.9%
xml	5.8 KB	1.8 KB	0.2%
anim	4.6 KB	2.3 KB	0.3%
layout-v17	3.3 KB	1.1 KB	0.1%
layout	3.2 KB	1 KB	0.1%
drawable-ldpi-v4	1.8 KB	1.8 KB	0.2%
menu	1.4 KB	558 B	0.1%
drawable	872 B	387 B	0.1%
resources.arsc	20.9 KB	5.8 KB	0.8%
AndroidManifest.xml	5.1 KB	1.4 KB	0.2%
META-INF	87 B	83 B	0%

Figure 1023: APK Analyzer, Drilling Down Into Resources

## ADDRESSING APPLICATION SIZE ISSUES

If you click on a DEX file, such as `classes.dex`, a bottom panel displays details of the classes inside the file:

Figure 1024: APK Analyzer, Drilling Down Into DEX

The “Defined Methods” column indicates how many methods are defined by the classes in the packages, where those classes are in the DEX file. “Referenced Methods” refers to how many methods that classes in the DEX file reference from the indicated packages, and that ties into what’s known as the “64K DEX method reference limit”, which we will get into [a bit later in this chapter](#).

If you have multiple builds of your APK — such as a debug and a release build, or an old and a new build — you can open one in the APK Analyzer, then click the “Compare with...” button and choose the second APK. This opens up a floating window showing you the size differences between the two APKs:

Figure 1025: APK Analyzer, Comparing Two APKs

## Java Code, and the 64K Method Limit

In ordinary Java development, there are few limits as to how big your applications can get. You tend to run into physical limitations, such as available system RAM, before you run into any limitations of the programming language or runtime environment.

And, normally, in Android applications, you do not worry about how many classes or methods you have. However, “normally” is not “always”, and there is a specific scenario that complex apps need to worry about.

### What Is It?

[Quoting Andy Fadden](#), Android platform engineer:

The issue is not with the Dalvik runtime nor the DEX file format, but with the current set of Dalvik instructions.

You can reference a very large number of methods in a DEX file, but you can only invoke the first 65536, because that’s all the room you have in the method invocation instruction.

I’d like to point out that the limitation is on the number of methods referenced, not the number of methods defined. If your DEX file has only a few methods, but together they call 70,000 different externally-defined methods, you’re going to exceed the limit.

[An externally-defined method is] a method defined in a separate DEX file. For most apps this would just be framework and core library / uses-library stuff.

Specifically, you will crash at compile time, with an error message akin to:

```
Unable to execute dex: method ID not in [0, 0xffff]: 65536
Conversion to Dalvik format failed: Unable to execute dex: method ID not
in [0, 0xffff]: 65536
```

## 64K Seems Like a Lot of Typing...

Well, it is, and it isn't.

First, it is not merely your own methods. You can reach the 64K method limit without implementing 64K methods in your application yourself. You can:

- Call lots of methods defined by the framework
- Absorb lots of methods from libraries, particularly larger libraries that offer many more features than your app uses

This still tends to mean that simpler apps are unlikely to run into this limit, while more complex apps might.

## Where Are The Methods Coming From?

The APK Analyzer can help you determine what methods get referenced in your APK file. Just click on the DEX file and start looking through the package tree, specifically looking for methods that will not be in your DEX file, such as `java.*`, `javax.*`, and non-support classes in `android.*`:

---

## ADDRESSING APPLICATION SIZE ISSUES

---

For example, the app being profiled in the APK Analyzer in these screenshots reportedly references four methods on `RippleDrawable`:

Class	Defined Methods	Referenced Methods
android	9896	12322
support	9896	9898
view	0	782
app	0	251
graphics	0	246
drawable	0	77
Drawable	0	49
RippleDrawable	0	4

*Figure 1027: APK Analyzer, Showing Referenced Methods on `RippleDrawable`*

The developer of this app (who also happened to write this book) does not reference `RippleDrawable` anywhere. Hence, some library that the app is pulling in has code tied to `RippleDrawable`.

### Mitigation Tactics

If you are relatively close to the 64K method limit, you may be able to tweak your project to get back under the limit without having to significantly rework your project.

#### Use Granular Libraries

Some libraries, like Google Play Services, come in two forms: a “kitchen sink” and more granular libraries for individual features. If your need for the library can be met by the granular libraries, use them, and you can remove your dependency on the “kitchen sink”.

In the case of Google Play Services, try *not* to depend upon the `com.google.android.gms:play-services` artifact. Instead, try to depend upon one of the more granular artifacts, such as `com.google.android.gms:play-services-maps` for [Maps V2](#). For services, like [Google Cloud Messaging](#), that have no specific granular artifact, depend instead upon `com.google.android.gms:play-services-base` — while still large, this is far smaller than is `com.google.android.gms:play-services`.

#### Use Better Libraries

One common culprit of hitting the 64K method limit comes from libraries, as their

## ADDRESSING APPLICATION SIZE ISSUES

---

methods count along with yours. Hence, choosing different libraries can perhaps reduce your method count.

One specific case of this comes from the code generated by Google's [Protocol Buffers](#). If you are using Protocol Buffers heavily, your generated classes may each be defining hundreds of unused methods. Switching to an alternative implementation can reduce this significantly. Some such implementations include:

- [micro-protobuf](#)
- Square's [Wire](#)

### Use ProGuard

If your debug builds are failing due to the 64K method limit, try a release build. If that works, the reason is ProGuard and its ability to strip out code that is deemed to be unreachable.

In this case, you can “buy yourself some time” by arranging to build your app in debug mode with ProGuard, but without ProGuard's normal code obfuscation work (e.g., `-dontoptimize -dontobfuscate` switches in the ProGuard configuration). [Quoting Eric Lafortune](#), ProGuard's lead developer:

If you apply ProGuard with shrinking enabled but optimization and obfuscation disabled (`-dontoptimize -dontobfuscate`), the code will already be more compact, and you can still use a debugger. The source files, class names, method names, line numbers, etc remain unchanged and any breakpoints in removed unreachable code are irrelevant.

With Gradle-based builds, it should be possible to set this up using `minifyEnabled true` and a custom ProGuard configuration file:

```
android {
  buildTypes {
    debug {
      minifyEnabled true
      proguardFile 'proguard-no-obfuscate.txt'
    }
  }
}
```

(where `proguard-no-obfuscate.txt` contains the `-dontoptimize -dontobfuscate` switches)

### Mitigation Strategies

If the aforementioned tactics are insufficient — or if they help somewhat, but you are still near the limit with a lot of development yet to be done — you may need to pursue some more strategic ways of resolving your application size.

#### Don't Go Overboard

One source of method explosion comes from too much adherence to server-side Java coding styles.

For example, if you find yourself defining hundreds of interfaces and/or abstract classes, with Factory classes (and perhaps FactoryFactory classes), you are more likely to hit the 64K method limit due to all those separate definitions. Consider whether the flexibility that you believe that you obtain from this coding style is worth the risk.

#### Smaller Apps, Loosely Connected

It may be that you are simply creating an app that is entirely too complicated for the Android environment. Android's Intent system is designed to enable apps to inter-operate, and so you may need to consider splitting your app into pieces, such as:

- A suite of related apps
- A host app and plugin apps that enable additional functionality
- An app and an affiliated Web app, where certain functionality is handled by the Web app in a standard browser

#### Multidex

The 64K method reference limit refers to the number of methods referenced from a given DEX file. One way to address this, in theory, would be to split the app into multiple DEX files, each getting some of the classes from your app and its dependencies. Each DEX file is likely to be below the 64K method reference limit.

Android has native multidex support starting with Android 5.0. There is a quasi-backport of this for older devices, but [it opens the door to security issues](#) and ideally is avoided.

To support native Android 5.0+ multidex, you need to add `multiDexEnabled true` to

the `defaultConfig` closure in your module's `build.gradle` file, alongside where you declare your `minSdkVersion`, `targetSdkVersion`, and so on.

### Native Code

Native code, implemented as NDK-compiled libraries, represent another source of app bloat. This will occur regardless of whether the NDK code is yours or if you are using a third-party library that supplies those binaries (e.g., SQLCipher for Android).

Native code is not intrinsically large. However, in some cases, native code is a port from some other environment (or environments) and may contain a lot of stuff that your app does not need. Worse, ProGuard will not strip out unused native code, as its algorithms only work with Java-style bytecode. Hence, it is not out of the question for apps to devote several MB just to the Linux `.so` files that make up the NDK-compiled libraries.

Fortunately, there are some workarounds.

### Mitigation via Per-CPU APKs

Some distribution channels, like the Play Store, support publishing multiple versions of an APK, with different versions for different CPU architectures. Hence, you could have one APK with x86 binaries and one APK with ARM binaries, as opposed to having one “fat binary” with both.

The Android Gradle Plugin offers [APK splits](#) as a way of implementing this, where you get different APKs based on CPU architecture.

### Mitigation via libhoudini

As is noted in [the chapter on the NDK](#), `libhoudini` is proprietary Intel code that allows ARM-compiled NDK binaries to run on x86 CPUs, using the same sort of opcode translation that is used by the Android emulator. Many, though not all, x86-powered Android devices have `libhoudini`. Those that do could run your app even if you only ship ARM NDK binaries and not x86 ones. This gives you the same sort of space savings as you would get by publishing separate ARM vs. x86 APKs (per the previous section), without having to manage multiple APKs yourself. The cost is speed, as the translation layer adds significant overhead, much as you see with the Android emulator running ARM emulator images instead of x86 ones.

## Mitigation via Ignoring Non-ARM

Of course, what a lot of developers do is simply only worry about ARM.

While Google does not publish percentages of CPU architectures the way they do Android OS versions, it is safe to say that, as of early 2014, ~1% of Android devices are powered by non-ARM CPUs. That percentage may climb, particularly as Intel pushes more x86 chipsets. But the *vast* majority of Android devices are powered by ARM. So, even if some of those x86 environments lack `libhoudini` (e.g., the manufacturer did not license `libhoudini` from Intel), they are so few in number that developers are prone to ignore x86.

Ironically, what drives x86 for developers is the development environment itself, not the production environment. The x86 emulator is nicely responsive, compared to a similarly-configured ARM emulator image. Many developers avoid the ARM emulator entirely, with it being too slow. Hence, developers may be interested in having x86 binaries in the APK to allow the app to run on the x86 emulator (which lacks `libhoudini`). In this case, it may be worthwhile to have a dedicated release build process that strips out the x86 binaries, if the space that those binaries take up is more than you can afford.

## Images

Bitmap images are notorious for taking up lots of heap space. However, they can also swell the size of your APK. While the bitmap PNG or JPEG files will be compressed on disk, if you have enough of them, they can still consume many MB of space in the APK, particularly since the APK cannot compress them further.

## Mitigation via Resource Aliases

You may have multiple copies of the same image.

The example cited in the Android documentation is where you want to have locale-specific drawable images. For example, perhaps you want to show a flag, and you use language resource sets to try to map the right flag to the right language. However, some flags are going to be used in multiple languages, such as the Canadian flag being needed for `en-rCA` and `fr-rCA`. By default, you would place your flag icon in each of those resource sets, duplicating your results. This gets worse if you have a few versions of the same flag icon for different densities.

However, you can elect to use a resource aliases to handle this differently.

Suppose that your code refers to a flag drawable resource (e.g., `@drawable/flag` or `R.drawable.flag`). For many languages, you would have a unique flag in the appropriate resource set. For cases where the same flag is used in multiple situations:

1. Put the flag in a resource set that is not tied to locale (e.g., `res/drawable-hdpi/` instead of `res/drawable-en-rCA-hdpi/`), for as many densities as you choose, but under a different name (e.g., `flag_canada.png` instead of `flag.png`)
2. Create a small XML file, `flag.xml`, in each of the locale-specific directories (e.g., `res/drawable-en-rCA/` and `res/drawable-fr-rCA/`), pointing to your `flag_canada` drawable:

```
<?xml version="1.0" encoding="utf-8"?>
<bitmap
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:src="@drawable/flag_canada" />
```

When you reference `R.drawable.flag` on an `en-rCA` or `fr-rCA` device, Android will read in the XML resource, then turn around and retrieve the `flag_canada` drawable, and use that. Since the two XML files are likely to be smaller than the sum total of the duplicate copies, you save disk space.

### Mitigation via pngquant

In practice, the above technique is just not that commonly used, because it addresses a fairly narrow scenario. A more general-purpose solution is to try to tweak the images to be visually nearly identical, yet take up less disk space.

There are a variety of tools for this, mostly aimed at Web development, where smaller image file sizes means faster-loading Web pages.

One such tool is [pngquant](#). Given a PNG file as input, it generates a smaller PNG file as output, one with an optimized color palette, using mathematical techniques to choose colors that will maintain as much of the original look as possible. Many of the images in this book were optimized using `pngquant`, at a substantial savings in disk size, without materially sacrificing image quality.

## APK Expansion Files

The ultimate solution to disk space concerns, for distribution through the Play Store, is to get stuff out of your app entirely and distribute that stuff by other means. The Play Store offers [APK expansion files](#) with this in mind. You can publish one or two expansion files, each containing up to 2GB of files. While these will not be treated as resources or assets, you do have access to the file contents at runtime. Game developers will use these for sound effects, additional artwork, and so on. The biggest limitation is that these files may not be supported by all distribution channels.

# Crash Reporting Using ACRA

---

When you wrote your app, you intended for it to work.

Alas, [the road to a very warm place is paved with good intentions](#).

Hence, it is fairly likely that your app will crash in the hands of your users. In order to be able to fix the underlying problems, you need to learn about the crashes and the state of the app at the time of the crash.

There are any number of solutions to this problem. This chapter will outline a few of them and focus on one open source solution: Application Crash Reports for Android, better known as ACRA.

Specifically, this chapter covers ACRA 5.1.1. If you used ACRA previously, the configuration API has changed a fair bit, particularly in terms of the annotations that you can use.

## Prerequisites

Understanding this chapter requires that you have read the core chapters and understand how Android apps are set up and operate. Having read [the chapter on notifications](#) is also a good idea, though not absolutely essential.

## What Happens When Things Go “Boom”?

In development, when your app crashes, you get a little dialog box indicating that the app crashed, and you get your Java stack trace in Logcat.

## CRASH REPORTING USING ACRA

---

In production, little of that does you any good. In particular, you have no way of seeing Logcat from end user devices. Instead, you need to have some means of capturing that stack trace, along with perhaps additional data, and collect it somewhere.

App distribution channels may offer this as part of their feature set. The Play Store, in particular, offers its own crash reporting, where crashes “in the field” get reported to you by means of your Developer Console on the Web. However:

- You might not be distributing through the Play Store at all, let alone exclusively, and so the Play Store reporting does not help you for all your users
- The Play Store’s approach makes reporting the crash optional, as the user can elect to not send a report, meaning that you don’t find out about every crash
- You have no control over what data is and is not collected, both for ensuring that you have enough information to have a shot at fixing the bug and for minimizing extraneous data that might have privacy implications
- Google gets a copy of the crash data, which you may or may not find to be appropriate

Various other services offer their own crash reporting as part of a larger suite of features. However, once again, you may not have control over what data is collected, and you certainly have no control over who all gets the data.

For the privacy-minded app developer, you want something along these lines, but where you can control to a fine degree of detail what gets collected and where the data is sent solely to you, not to some third party.

And that’s where ACRA comes in.

## Introducing ACRA

ACRA has been around since 2010, originally on Google Code, and now on [GitHub](#). It comes in the form of a library that you add to your app, with code that will get control when an unhandled exception occurs inside your app. There, ACRA *carefully* will collect information about the crash (e.g., the stack trace) and the environment (e.g., what version of Android the app was running on). ACRA can then deliver that information to you by [any number of means](#), plus optionally provide [feedback to the user](#) about the crash itself.

Since you control what ACRA collects and you control where ACRA sends the data, you can minimize how much information gets into the hands of third parties. The cost is in convenience, as either you have to:

- Fuss with managing your own server for receiving the crashes, or
- Use a third-party service for that server, reducing some of the privacy, or
- Use options that are clunky for everyone involved, such as the user sending emails containing crash reports

## Where ACRA Reports Crashes

In the beginning, ACRA logged crashes to a Google Docs spreadsheet. Eventually, Google grumbled about this, and so that option is now deprecated.

That limitation notwithstanding, ACRA supports a range of possible ways for crash reports to get from the user's device to your eyes, so that you can try to fix whatever problems ail your app.

## An Existing Crash Logging Service

Some crash logging services allow you to use ACRA in your code, rather than rely upon some proprietary library. You simply configure ACRA to send the data to their servers, which then notify you about crashes and give you dashboards and such to visualize how much your app is crashing. [HockeyApp](#), [TracePot](#), and [Splunk Mint](#) are examples of such services.

The advantage here is convenience coupled with control over the client side. However, you are still sharing crash details with third parties, potentially raising privacy or security issues.

## Acralyzer

The official ACRA reporting server is [Acralyzer](#). This, along with its `acra-storage` companion, are CouchApps, powered by Apache CouchDB. You upload the Acralyzer and `acra-storage` CouchApps into your own CouchDB instance, then configure ACRA in your app to talk to those apps.

Acralyzer and `acra-storage` are open source, as is CouchDB. You can either host a CouchDB instance on your own server or use various CouchDB hosting providers.

## CRASH REPORTING USING ACRA

---

This solution offers the best blend of [analysis features](#) and user privacy and security. However, it does require you to learn enough about CouchDB to be able to set up and maintain an instance. Also, Acralyzer has not had many updates recently.

### Email

The easiest solution to set up is the most awkward for everything else: have the user send you an email. In this model, ACRA prepares a report, then uses ACTION\_SENDTO to lead the user to an email app to send the report to an email address that you configure in your app. The user can then just send the prepared email from their email client (e.g., Gmail), and the report shows up in the inbox for this email address.

You do not need to set up some sort of server, let alone maintain it. Your app does not even need the INTERNET permission.

However:

- The user might not send the email, choosing instead to abandon the mail client
- The user might not use their device for email, and therefore have no good means of getting you the report
- While you get the raw crash data, you do not get any of the nifty charts and such that you can get from a full-fledged crash reporting server

### A Host for Testing

The protocol used by ACRA to communicate with a Web server is blissfully simple. Handling ACRA crash reports yourself does not require that much server-side code, in case you wanted to integrate this capability into the rest of your REST-style Web services.

For example, this trivial Ruby script implements an ACRA-compatible endpoint:

```
require 'fileutils'
require 'sinatra'
require 'json'

LOG_ROOT='/tmp/ACRAfier'

put '/reports/:id' do
  acra=JSON.parse(request.body.read)
```

---

## CRASH REPORTING USING ACRA

---

```
FileUtils.mkdir_p(LOG_ROOT) if !File.exist?(LOG_ROOT)

f=File.join(LOG_ROOT, params[:id]+' .json')
File.open(f, 'w') {|io| io.write(JSON.pretty_generate(acra))}
end
```

(from [ACRA/Simple/stub\\_server.rb](#))

As we will see [later in this chapter](#), you can configure ACRA to use a simple HTTP PUT request to submit a crash report to the server. This Ruby script implements a small REST-style Web service using Sinatra, where crash reports are pushed to a `/reports/.../` URL, where `...` is an ACRA-generated unique ID for the report. This script just logs the JSON that we get from ACRA to a file in a designated directory. With a few more lines of code, you could have it generate a human-readable report and email it to you, along with the JSON as an email attachment. Or, you could do whatever you want.

This Ruby script can be found as `stub_server.rb` in [the book's GitHub repo](#). If you have Ruby installed, just install the `sinatra` and `json` gems, then run `ruby stub_server.rb` to fire up the server.

In practice, you would need a bit more smarts on a publicly-visible Web service, to help prevent people from maliciously flooding your crash reporting server with bogus data. However, the minimal requirements for ACRA are very straightforward and could be implemented in any reasonable server-side Web framework.

## ACRA Integration Basics

Given that you have identified how you want to receive the crash reports, the next step is to add ACRA to your project and configure it to send crash reports to your chosen location.

The [ACRA/Simple](#) sample project demonstrates a fairly simple ACRA integration.

### Adding the Dependencies

ACRA is distributed through standard Maven-style artifact repositories and should be automatically picked up when you add the appropriate implementation directives to your dependencies. However, there are several possible dependencies. You add one or more based on:

---

## CRASH REPORTING USING ACRA

---

- How you want to receive the crash report (e.g., via a Web service, via email)
- How you want to alert the user about the crash

In this sample app, we will see one form of report delivery (Web service) and three options for informing the user (dialog, notification, ...and not telling the user about the crash). We have three dependencies to give us all of those options:

```
def acraVersion='5.1.1'

dependencies {
    implementation "ch.acra:acra-http:$acraVersion"
    implementation "ch.acra:acra-dialog:$acraVersion"
    implementation "ch.acra:acra-notification:$acraVersion"
}
```

(from [ACRA/Simple/app/build.gradle](#))

All three have the same version number, so we define that once and use Groovy string interpolation (`$acraVersion`) to inject that version number into the dependency request.

### Java 8

ACRA 5.x also requires you to enable Java 8 compilation in your project, via the `compileOptions` closure in the `android` closure:

```
compileOptions {
    sourceCompatibility JavaVersion.VERSION_1_8
    targetCompatibility JavaVersion.VERSION_1_8
}
```

(from [ACRA/Simple/app/build.gradle](#))

### Build Types, Product Flavors, and ACRA

It is very likely that you will want to have different ACRA configurations based upon build types and/or product flavors:

- Have the debug build not use ACRA, but have the jenkins build by your CI server use ACRA to collect crashes and integrate them into the test results, and have the release build use your production ACRA server
- Skip ACRA for your Play Store distribution (because you decide you would rather just use the Play Store's crash reporting), but use ACRA for your

## CRASH REPORTING USING ACRA

---

amazon product flavor (the version of your app that you distribute through the Amazon AppStore for Android)

- And so on

`buildConfigField` is a great way to manage this. Use your `build.gradle` file to establish values for some constants, then use them in the ACRA configuration code in Java later on.

The sample app defines two such fields for `BuildConfig`:

- `ACRA_INSTALL`, a `boolean` that will be `true` if we should use ACRA, `false` otherwise
- `ACRA_URL`, a `String` that will point to the server to which we wish to push the ACRA-collected crash data

The sample app defines the same values for both fields in both build types (debug and release), simply because you are probably playing around with the sample in a debug build:

```
buildTypes {
    debug {
        buildConfigField "String", "ACRA_URL", "'http://10.0.2.2:4567/reports'"
        buildConfigField "boolean", "ACRA_INSTALL", 'true'
    }

    release {
        buildConfigField "String", "ACRA_URL", "'http://10.0.2.2:4567/reports'"
        buildConfigField "boolean", "ACRA_INSTALL", 'true'
    }
}
```

(from [ACRA/Simple/app/build.gradle](#))

The URL used for `ACRA_URL` points to `10.0.2.2`, the IP address on an Android emulator that refers back to the `localhost` of your developer machine. In particular, this URL is set up for the server Ruby script mentioned previously in this chapter. If you wish to use a different server, not only will you need to consider changing this URL, but you will need to make some other adjustments to the Java code, in all likelihood, as will be seen in the next couple of sections.

## Creating a Custom Application

ACRA needs some one-time initialization, and it is set up to do that by means of a custom `Application` subclass. Most likely, you do not already have one of these, though some libraries will require you to create one, perhaps inheriting from some

## CRASH REPORTING USING ACRA

---

library-supplied Application subclass.

Regardless, you will need a subclass of Application in your project, and you will need to have the `android:name` attribute of your `<application>` element in the manifest point to that Application subclass:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.button"
  xmlns:android="http://schemas.android.com/apk/res/android"
  xmlns:tools="http://schemas.android.com/tools"
  android:versionCode="1"
  android:versionName="1.0">

  <uses-permission android:name="android.permission.INTERNET" />

  <application
    android:name=".ACRAApplication"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".ButtonDemoActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
  </application>
</manifest>
```

(from [ACRA/Simple/app/src/main/AndroidManifest.xml](#))

Here, `android:name` points to an `ACRAApplication` class that we will examine shortly.

Also note that the manifest has a `<uses-permission>` element, asking for the `INTERNET` permission. Unless you use ACRA's support for sending crash reports via the user's email app, you will need the `INTERNET` permission for getting crash reports to some server.

### Implementing the Application

Your custom Application subclass — such as `ACRAApplication` in the sample app — needs a few things to set up ACRA. Mostly, they are in the form of annotations added to the class declaration:

```
package com.commonware.android.button;

import android.app.Application;
import android.content.Context;
import org.acra.ACRA;
import org.acra.annotation.Acracore;
import org.acra.annotation.AcracoreHttpSender;
import org.acra.data.StringFormat;

@Acracore(
    buildConfigClass = BuildConfig.class,
    reportFormat=StringFormat.JSON
)
@AcracoreHttpSender(
    uri=BuildConfig.ACRA_URL,
    httpMethod=org.acra.sender.HttpSender.Method.PUT
)
public class ACRAApplication extends Application {
    @Override
    protected void attachBaseContext(Context base) {
        super.attachBaseContext(base);

        if (BuildConfig.ACRA_INSTALL) {
            ACRA.init(this);
        }
    }
}
```

(from [ACRA/Simple/app/src/main/java/com/commonware/android/button/ACRAApplication.java](#))

### Configuring the Core

The `@Acracore` annotation is used for any ACRA-enabled app, and it has a number of properties to control general behavior of ACRA overall. Here, we configure just two:

- `buildConfigClass`, to teach ACRA where our `BuildConfig` gets generated
- `reportFormat`, specifying that we want the crash data provided to us in JSON format

The `reportFormat` attribute is optional, and JSON happens to be the default format. It is included here for illustration purposes.

### Configuring Report Delivery

The point behind ACRA is to get a crash report to you, by one means or another. If you are using the ACRA-supplied Web service or email sending options, there are annotations that you can use to configure them: `@AcraHttpSender` and `@AcraMailSender`. In the sample app, we have an `@AcraHttpSender` annotation, where we set the `uri` property to indicate the URL where to send the report to, and we set `httpMethod` to indicate that we want an HTTP PUT request to be how we get that report. This will cause ACRA to generate our JSON and do a simple HTTP PUT to our designated URL.

### Configuring User Notification

`ACRAApplication` is set up to not tell the user about any crashes. Hence, it has no configuration for any sort of user notification. In many cases, you may want to let the user know about the crash, and if you use one of the ACRA-supplied notification options, you have annotations for those:

- `@AcraDialog`, to configure a dialog to appear when the app crashes
- `@AcraNotification`, to display a Notification when the app crashes
- `@AcraToast`, to show a Toast when the app crashes

We will see examples of some of those coming up later in this chapter.

### Initializing ACRA

Finally, in `attachBaseContext()` of `Application`, in addition to chaining to the superclass, we need to call `ACRA.init()`, passing in the `Application` itself.

Note that the `ACRA.init()` call is inside a check of the `BuildConfig.ACRA_INSTALL` boolean that we set up in the Gradle build files. If a particular build type or product flavor sets `ACRA_INSTALL` to `false`, ACRA will not be enabled. For simpler projects, rather than defining your own `ACRA_INSTALL`-style flag, you could just use `!BuildConfig.DEBUG`, to only configure ACRA on release builds. While there is nothing stopping you from using ACRA in development, you may find that it interferes somewhat with how you are used to debugging your crashes.

Also, if you have an existing `Application` subclass, you need to consider how [ACRA's error-reporting process](#) will impact your existing logic.

### Reporting Crashes

Good news! You're done!

ACRA does not require you to litter your code with magic `try/catch` blocks to catch and report exceptions. After all, some Android exceptions – even those triggered from bugs in your code — are raised by Android framework code and your code appears nowhere in the stack trace.

Instead, ACRA takes advantage of `Thread` and its `setDefaultUncaughtExceptionHandler()` method, to get control when any unhandled exception occurs. All those crashes that normally would shut down a component or the whole app now go to ACRA and can be reported to your designated server.

Occasionally, you may wish to add some crashes that you *are* handling yourself to ACRA. For example, there may be some edge or corner cases that you are explicitly handling but are uncertain if they ever would happen. You could arrange to pass the `Exception` over to ACRA, which it will treat the same as any other crash that it intercepts.

To do this, call `getErrorReporter()` on the ACRA class, and call either `handleException()` or `handleSilentException()` on the error reporter. The difference is that `handleSilentException()` always reports the error silently, while `handleException()` will process this exception like any other, possibly alerting the user to the crash, as will be seen in the next section.

### What the User Sees

The `Simple` sample app has ACRA configured, but this does us little good if we do not crash. So, the UI for the activity has a `Button`, and tapping that button will trigger a `RuntimeException`:

```
package com.commonware.android.button;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
```

## CRASH REPORTING USING ACRA

---

```
public class ButtonDemoActivity extends Activity {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);
    }

    public void earthShatteringKaboom(View v) {
        throw new RuntimeException(getString(R.string.msg_kaboom));
    }
}
```

(from [ACRA/Simple/app/src/main/java/com/commonsware/android/button/ButtonDemoActivity.java](#))

...whose message is tied to a string resource.

When you click the Button, ACRA will send a crash report to your designated server. What the *user* perceives, though, varies based upon configuration.

### Default: “Silent”

If you do not specify otherwise in your ACRA configuration, the default behavior will be “silent”. In this case, “silent” means “the user is not told that a report is being sent via ACRA”. The app simply goes away.

This works. This is easy. This is not user-friendly. This is not recommended.

### Dialog

Another option is the “dialog” approach, where the user is shown a dialog-themed activity, indicating what happened and allowing the user to provide some additional information.

*Figure 1028: ACRA-Reported Crash, Dialog Mode*

On the plus side, this is more transparent to the user, and the user can provide a bit more detail that might be useful to you. However, the user can also cancel out of the dialog, in which case you do not receive a crash report at all. However, this may be one way of complying with [Google’s directives regarding “Prominent Disclosure” with respect to crash reporting](#).

To set this up, you need to add a few more options to your ACRA configuration. You can see this in `ACRADialogApplication` in the sample project, which is a clone of `ACRAApplication`, set up for dialog-style reporting:

```
package com.commonware.android.button;

import android.app.Application;
import android.content.Context;
import org.acra.ACRA;
```

## CRASH REPORTING USING ACRA

---

```
import org.acra.annotation.AcraCore;
import org.acra.annotation.AcraDialog;
import org.acra.annotation.AcraHttpSender;
import org.acra.data.StringFormat;

@AcraCore(
    buildConfigClass = BuildConfig.class,
    reportFormat=StringFormat.JSON
)
@AcraDialog(
    resText = R.string.msg_acra_dialog,
    resCommentPrompt = R.string.msg_acra_comment_prompt,
    resEmailPrompt = R.string.msg_acra_email_prompt,
    resTheme = R.style.AppTheme_Dialog
)
@AcraHttpSender(
    uri=BuildConfig.ACRA_URL,
    httpMethod=org.acra.sender.HttpSender.Method.PUT
)
public class ACRADialogApplication extends Application {
    @Override
    protected void attachBaseContext(Context base) {
        super.attachBaseContext(base);

        if (BuildConfig.ACRA_INSTALL) {
            ACRA.init(this);
        }
    }
}
```

(from [ACRA/Simple/app/src/main/java/com/commonsware/android/button/ACRADialogApplication.java](#))

What turns on dialog mode is the addition of the `@AcraDialog` annotation. Here, we can configure:

- The message that appears at the top (`resText`)
- The message that appears before the first `EditText` in the dialog (`resCommentPrompt`)
- The message that appears before the second `EditText` in the dialog (`resEmailPrompt`)
- The theme used to style the dialog (`resTheme`)

This sample app only runs on API Level 21+ (as it depends upon `Theme.Material` for the main UI), so we only need to provide one theme definition, here called `AppTheme.Dialog`:

## CRASH REPORTING USING ACRA

---

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

  <style name="AppTheme" parent="android:Theme.Material">
    <item name="android:colorPrimary">@color/primary</item>
    <item name="android:colorPrimaryDark">@color/primary_dark</item>
    <item name="android:colorAccent">@color/accent</item>
  </style>

  <style
    name="AppTheme.Dialog"
    parent="@android:style/Theme.DeviceDefault.Dialog"/>
</resources>
```

(from [ACRA/Simple/app/src/main/res/values/styles.xml](#))

Here, we follow ACRA's advice and have `AppTheme.Dialog` inherit from `Theme.DeviceDefault.Dialog`. `DeviceDefault` is a theme based on the core theme for the Android OS version (`Material` for Android 5.0+), but one that can be tailored by device manufacturers and custom ROM developers. By extending `Theme.DeviceDefault.Dialog`, we are saying that we want our dialog to be styled like other system dialogs.

`Theme.DeviceDefault.Dialog` should be a fine base theme for API Level 11+. If you are supporting older Android devices than that, for those older API levels, use `Theme.Dialog` instead.

Of course, your `android:name` attribute of your `<application>` element in the manifest will need to point to this `Application` subclass. If you wish to try the dialog in the sample app, you will need to modify the sample app's manifest to point to `ACRADialogApplication` instead of `ACRAApplication`.

Note that if the user cancels the dialog, you do *not* get a crash report.

### Notification

While the dialog mode is great, it is unsuitable for crashes that may occur in the background. You do not want to pop up a dialog box unexpectedly, as users may not appreciate the interruption.

The default "silent" mode, for crashes originating in the background, will not show a dialog. This is far more suitable for background work, but it does not let the user know that a crash occurred.

## CRASH REPORTING USING ACRA

---

The Notification mode serves as middle ground. When a crash occurs in the background, ACRA raises a Notification. The user can interact with the Notification to send the report or not:

*Figure 1029: ACRA Notification*

To use this, add the `@AcraNotification` annotation to your custom Application subclass, as seen in the `ACRANotificationApplication` class in the sample app:

```
package com.commonware.android.button;

import android.app.Application;
import org.acra.ACRA;
import org.acra.annotation.AcraCore;
import org.acra.annotation.AcraHttpSender;
import org.acra.annotation.AcraNotification;
import org.acra.data.StringFormat;

@AcraCore(
    buildConfigClass = BuildConfig.class,
    reportFormat=StringFormat.JSON
)
@AcraNotification(
    resText = R.string.msg_acra_notify_text,
    resTitle = R.string.msg_acra_notify_title,
    resChannelName = R.string.channel,
    sendOnClick = true
)
@AcraHttpSender(
    uri=BuildConfig.ACRA_URL,
    httpMethod=org.acra.sender.HttpSender.Method.PUT
)
public class ACRANotificationApplication extends Application {
    @Override
    public void onCreate() {
```

## CRASH REPORTING USING ACRA

---

```
super.onCreate();

if (BuildConfig.ACRA_INSTALL) {
    ACRA.init(this);
}
}
```

(from [ACRA/Simple/app/src/main/java/com/commonsware/android/button/ACRANotificationApplication.java](#))

Here, we configure a bunch of properties, to control the Notification:

- The title (`resTitle`) and text (`resText`) of the Notification
- The channel name to use for this Notification on Android 8.0+ devices (`resChannelName`)
- Whether clicking on the Notification itself should send the report, or only if the user clicks OK (`sendOnClick`)

If you switch the `android:name` of the `<application>` manifest element over to point to `ACRANotificationApplication`, crashing the app will bring up the Notification.

### Limitations

The big limitation is that you get exactly one reporting mode for your app, for automatically-collected crashes. This means that your choice of reporting mode will be dictated by whether or not you are doing work in the background, while you do not have a UI in the foreground (e.g., a `Service`):

- If you are not doing background work, use the dialog or silent modes
- If you are doing background work, use the notification or silent modes

### What You See

The sample app asks ACRA to send the crash data over in a JSON structure. That JSON contains all sorts of information by default, including `USER_COMMENT` and `USER_EMAIL` properties if you chose the dialog or notification modes.

Here is what we get from a crash of the sample app, using the silent notification mode:

```
{
  "REPORT_ID": "eb5a82d3-2a20-4266-a500-43d3498b5d29",
```

(note: some property values were truncated with . . ., as they were much too long to try to display in a book)

Your server can parse this and use it to take appropriate action.

Note that the Java stack trace (STACK\_TRACE property) is formatted with embedded Java-style/C-style control characters (\n for newlines, \t for tabs). Your server can convert that into plain text with appropriate formatting.

## ACRA and Processes

If you crash with an unhandled exception, your existing process is in a state of disarray. To help ensure that ACRA can report your crash successfully, ACRA by default runs its error-reporting Service in a separate ACRA-specific process.

Most of the time, this does not affect you.

One place where it might is if you have a custom Application subclass for things beyond ACRA. Bear in mind that each process gets its own copy of the virtual machine (Dalvik or ART) and each gets its own independent instance of your designated Application class. Work that you do for your main app's process you may wish to skip for the ACRA-specific background process.

## **Trail: Miscellaneous Topics**

---

# In-App Diagnostics

---

Android has many tools to help you make sense of what is going on in your app, from complex tools like [Traceview](#) to simpler things like Logcat. Plus, if you are using an IDE, you have access to a debugger, which can let you step through code, inspect data members and other variables, and so on.

However, they all have one element in common: they are general-purpose tools. They know nothing specifically about your app, just Android apps in general. As a result, there may be information that *you* can gather that would be of immense benefit for debugging and diagnostic purposes, but that the general-purpose tools cannot collect for you.

More importantly, you need some way to see any diagnostic data that you collect. Logging stuff to Logcat can sometimes work, but then you have to worry about accidentally shipping that logging code in production, which would be less than ideal. And there are many cases where Logcat itself will not be a great visualization of the information.

What would be better is if we could add our own diagnostic tools to our app, for use while debugging, while excluding them from our release builds. And it would be great if we could add in these tools without changing much, if anything, of our production code to reference them. This chapter will explore how to implement such tools.

## Prerequisites

In addition to the core chapters, it would be a good idea if you had read:

- the chapter on [Gradle and the new project structure](#), to understand more

- about the debug source set
- the chapter on [manifest merging](#), to understand how the debug source set can contribute to the overall app's manifest

Also, one of the techniques bears some resemblance to [the tapjacking attack](#), though fortunately without the privacy and security ramifications.

One of the sample apps is based on a RecyclerView sample app, and so you may wish to skim [the RecyclerView material](#) to ensure that you understand enough about what is going on with the sample.

## The Diagnostic Activity

Having a “back door” to get at diagnostic information about a program is a time-honored technique. Alas, far too many of those back doors wind up in production code, and too many of those wind up resulting in privacy or security flaws. Yet, the approach is still used to this day.

From a GUI standpoint, these back doors usually required some sort of special key sequence to initiate (e.g., press `Ctrl-Shift-Z` three times in less than a second). The objective was to make them easy enough to get to but not something that would routinely get in the way. And, for those back doors that wound up shipping, eventually word would get out about the magic key sequence, leading to all sorts of trouble.

In Android, we can dispense with the magic key sequence (which is good, since we often are not using keyboards). An app can have as many launcher icons as it needs, so we just need a launcher icon to get into some custom diagnostic activity that we want. However, now we *really* do not want to ship this code in production, as the diagnostic activity is no longer hidden, but rather is in plain view in the user's home screen launcher.

Fortunately, the advent of source sets with the Android Gradle Plugin, plus a reasonably robust manifest merger process, makes setting up this sort of tool fairly easy, yet keeps it out of the production code. Most of the work will be in actually writing the activity to report on whatever it is that you wanted reported on.

The [Diagnostics/Activity](#). sample project will illustrate this process.

This app is a clone of a [previous sample](#) that retrieves Stack Overflow questions in

the android tag via Square's Retrofit library. It also uses Square's Picasso library to load in the avatars of the people asking the questions. Picasso has an API for getting at statistics about the images that were downloaded: how many, how big, how many were already cached, and so on. The revised sample shown in this section will create a diagnostic activity that reports this information, as an illustration of having such an activity supply statistics that may be useful in tuning, debugging, etc.

### The Sourceset

This project has two source sets, main and debug. main is where the production code lies; debug is where the diagnostic activity resides. The debug source set is tied to the debug build type, so only when doing a debug build will our debug code be included in the app. Since your production signing key is (hopefully) only being used by your release build type, this helps ensure that the diagnostic code does not ship with your production app.

### The Manifest

Both source sets have manifests. For debug builds, the debug source set's manifest will be merged with the main source set's manifest to create the combined result.

The objective is to have the debug source set's manifest have the minimum elements and attributes required to have it successfully add what it needs to the app. The more stuff in a source set's manifest, the more likely it is that the stuff will conflict with similar stuff from main or other manifests and cause build problems.

Here, the debug manifest simply declares a new <activity>:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android">

  <application>
    <activity
      android:name="com.commonware.android.debug.util.PicassoDiagnosticActivity"
      android:label="@string/picasso_diagnostics"
      android:taskAffinity="com.commonware.android.debug.activity.PicassoDiagnosticActivity">
      <intent-filter>
        <action android:name="android.intent.action.MAIN"/>

        <category android:name="android.intent.category.LAUNCHER"/>
      </intent-filter>
    </activity>
  </application>
</manifest>
```

(from [Diagnostics/Activity/app/src/debug/AndroidManifest.xml](#))

Note that the class name for the `PicassoDiagnosticActivity` is fully-qualified (`com.commonsware.android.debug.util.PicassoDiagnosticActivity`). For the purposes of this particular diagnostic, the activity does not have to be in the same package as the rest of the app. In fact, this activity could be in a library that could be referenced by many apps, if desired.

Also note the `taskAffinity` for the `<activity>` is set to its fully-qualified class name. This helps ensure that this activity will reside in a different task than does our main UI, so that the diagnostics activity does not artificially alter BACK button processing and the like from the regular task.

Since the main source set will not contain this particular `<activity>` element, there are no collisions, and the manifest merger will turn out clean.

### The Activity

The activity itself is rather boring.

It loads in a layout resource containing a `TableLayout` that will contain our Picasso diagnostic report:

```
<?xml version="1.0" encoding="utf-8"?>
<ScrollView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TableLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_margin="8dp"
        android:shrinkColumns="1"
        android:stretchColumns="1">

        <TableRow>

            <TextView
                android:id="@+id/last_updated"
                style="@style/TableText.Title"
                android:layout_width="wrap_content"
                android:layout_height="wrap_content"
                android:text="Last Updated"/>

            <TextView
```

## IN-APP DIAGNOSTICS

---

```
        android:id="@+id/last_updated_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/avg_download_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Download Size"/>

    <TextView
        android:id="@+id/avg_download_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/avg_orig_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Average Original Bitmap Size"/>

    <TextView
        android:id="@+id/avg_orig_size_value"
        style="@style/TableText.Value"

        android:layout_height="wrap_content"/>
</TableRow>

<TableRow>

    <TextView
        android:id="@+id/total_xform_size"
        style="@style/TableText.Title"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:text="Total Transformed Size"/>

    <TextView
```

## IN-APP DIAGNOSTICS

---

```
        android:id="@+id/total_xform_size_value"
        style="@style/TableText.Value"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content" />
    </TableRow>

    <TableRow>

        <TextView
            android:id="@+id/xform_count"
            style="@style/TableText.Title"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content"
            android:text="Transformed Count" />

        <TextView
            android:id="@+id/xform_count_value"
            style="@style/TableText.Value"
            android:layout_width="wrap_content"
            android:layout_height="wrap_content" />
    </TableRow>
</TableLayout>
</ScrollView>
```

(from [Diagnostics/Activity/app/src/debug/res/layout/main.xml](#))

That layout, in turn, references some custom styles, to avoid having to repeat the configuration of each of the `TextView` widgets quite so much:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <style name="TableText">
        <item name="android:textSize">12sp</item>
        <item name="android:layout_margin">8dp</item>
    </style>

    <style name="TableText.Title">
        <item name="android:textStyle">bold</item>
    </style>

    <style name="TableText.Value">
        <item name="android:typeface">monospace</item>
    </style>
</resources>
```

(from [Diagnostics/Activity/app/src/debug/res/values/styles.xml](#))

The activity loads the layout, gets a `StatsSnapshot` from Picasso containing a

## IN-APP DIAGNOSTICS

---

snapshot of the results of using Picasso, and pours the data into the various TextView widgets:

```
package com.commonware.android.debug.util;

import android.app.Activity;
import android.os.Bundle;
import android.text.format.DateUtils;
import android.widget.TextView;
import com.commonware.android.debug.activity.R;
import com.squareup.picasso.Picasso;
import com.squareup.picasso.StatsSnapshot;

public class PicassoDiagnosticActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        StatsSnapshot ss=Picasso.with(this).getSnapshot();

        TextView tv=findViewById(R.id.last_updated_value);

        tv.setText(DateUtils.formatDateTime(this, ss.timeStamp,
            DateUtils.FORMAT_SHOW_TIME));

        tv=findViewById(R.id.avg_download_size_value);
        tv.setText(Long.toString(ss.averageDownloadSize));

        tv=findViewById(R.id.avg_orig_size_value);
        tv.setText(Long.toString(ss.averageOriginalBitmapSize));

        tv=findViewById(R.id.avg_xform_size_value);
        tv.setText(Long.toString(ss.averageTransformedBitmapSize));

        tv=findViewById(R.id.cache_hits_value);
        tv.setText(Long.toString(ss.cacheHits));

        tv=findViewById(R.id.cache_misses_value);
        tv.setText(Long.toString(ss.cacheMisses));

        tv=findViewById(R.id.download_count_value);
        tv.setText(Long.toString(ss.downloadCount));

        tv=findViewById(R.id.max_size_value);
        tv.setText(Long.toString(ss.maxSize));
    }
}
```

## IN-APP DIAGNOSTICS

---

```
tv=findViewById(R.id.orig_bitmap_count_value);
tv.setText(Long.toString(ss.originalBitmapCount));

tv=findViewById(R.id.size_value);
tv.setText(Long.toString(ss.size));

tv=findViewById(R.id.total_dl_size_value);
tv.setText(Long.toString(ss.totalDownloadSize));

tv=findViewById(R.id.total_orig_size_value);
tv.setText(Long.toString(ss.totalOriginalBitmapSize));

tv=findViewById(R.id.total_xform_size_value);
tv.setText(Long.toString(ss.totalTransformedBitmapSize));

tv=findViewById(R.id.xform_count_value);
tv.setText(Long.toString(ss.transformedBitmapCount));
}
}
```

(from [Diagnostics/Activity/app/src/debug/java/com/commonsware/android/debug/util/PicassoDiagnosticActivity.java](#))

### The Results

If you install the app on a device or emulator from a debug build, you will get two launcher icons. The one labeled “Picasso Diagnostics” will be the `PicassoDiagnosticsActivity`. If you bring up that activity after having run the main activity, you will see some information about the images that Picasso loaded:

*Figure 1030: Picasso Diagnostic Activity*

A release build, on the other hand, does not include the extra activity, its resources, or its manifest entry, since those are all in the debug source set.

Also, nothing from this affected our main source set contents. We did not have to add things to the manifest, or adjust our Java code, or anything of the sort.

### The Limitations

While this sample is fairly trivial, these sorts of diagnostic activities can be as elaborate as is needed. In some cases, as with this sample, the results are reusable — so long as the app has Picasso, this code can add in the diagnostic activity.

However, this is only good for post-mortem sorts of diagnostics, where you do

something in the “real” app, then head over to the diagnostic activity to see what it has to report. In many cases, this is perfectly reasonable. In other cases, the act of switching to the diagnostic activity might affect the diagnostics, if those diagnostics are dependent upon things like activity lifecycle methods. You also cannot learn anything in real time, seeing both the app and the diagnostics simultaneously (or nearly so).

However, there are other options that can improve in these areas, for situations that need such improvement.

### The Diagnostic Overlay

Sometimes, the information that we want needs to be presented to the developer in real time, while the user is looking at the UI of the app.

Take `StrictMode`, for example.

`penaltyDeath()` can be used to totally crash the app when, say, the app detects network I/O on the main application thread. However, this is rather harsh, particularly since Google ships all sorts of code in the framework that does improper things on the main application thread.

`penaltyLog()` is great, in that it gives us the stack trace of where the problem is but does not outright crash the app. However, we might not notice the stack traces, if we are not paying close attention to Logcat.

So, one popular combination is `penaltyFlashScreen()` combined with `penaltyLog()`. `penaltyFlashScreen()` will flash a red border around the edges of the screen, as a hint that “hey, something was detected – please check Logcat for details!” In the absence of this, or some other visual penalty, like `penaltyDialog()`, the developer might not learn what `StrictMode` is trying to tell her.

Another example is `gfxinfo`. As is noted in [the chapter on jank](#), `gfxinfo` can give you some information about how long it takes for frames to be rendered, so you know when you are dropping frames. One option for this is via an overlay that appears on top of the main UI, so you can see in real time a bar chart of frame times, so you can see what user actions can trigger jank.

You can employ the same sorts of techniques yourself, to put an overlay on the screen, whether temporarily (e.g., the `StrictMode` `penaltyFlashScreen()` option) or

more durably (e.g., the `gfxinfo` bar chart). The [Diagnostics/Overlay](#) sample project will demonstrate the former, alerting you of slowdowns in the rendering of your items in a `RecyclerView`.

### The Gradle Setup

For the purposes of demonstration, we need a sample app that can actually perform poorly, so we detect slowdowns and alert the developer via the screen overlay. At the same time, we need a sample app that does *not* perform poorly, so we can determine if the overlay works properly in both cases.

This sample project toggles between the two modes via a custom `BE_STUPID` field added to the `BuildConfig` class, based upon build type:

```
buildTypes {
    debug {
        buildConfigField "boolean", "BE_STUPID", "true"
    }

    release {
        buildConfigField "boolean", "BE_STUPID", "false"
    }
}
```

(from [Diagnostics/Overlay/app/build.gradle](#))

Admittedly, we could have skipped this and used the `BUILD_TYPE` field on `BuildConfig`. That will hold whatever the name of the build type was that built the APK that we installed, so it will be `debug` or `release` in this project. However, in case you wanted to have different rules for when the app should be stupid or not, we pull it out into a separate `BuildConfig` field. For example, you might elect to add two product flavors, so switching between `true` and `false` for `BE_STUPID` is based on product flavor instead of build type.

### Introducing `RVAdapterWrapper`

The wrapper pattern in Java can be fairly powerful, allowing you to extend Java objects without changing inheritance hierarchies. Rather, you wrap the object in a wrapper that implements the same interface (or inherits from the same base class). The wrapper can do some things on its own (the extended behavior) and delegate to the wrapped object for everything else. Plus, *subclasses* of the wrapper can basically override stock wrapper behavior and behavior of the wrapped object.

## IN-APP DIAGNOSTICS

---

Android has a few such wrapper classes, like `CursorWrapper` and `ContextWrapper`. The author of this book published an `AdapterWrapper`, for the `AdapterView` family of classes, as [a tiny open source library](#). And this chapter has `RVAdapterWrapper`, which implements a wrapper for `RecyclerView.Adapter`:

```
package com.commonware.android.debug.videolist;

import android.support.v7.widget.RecyclerView;
import android.view.ViewGroup;

public class RVAdapterWrapper<T extends RecyclerView.ViewHolder> extends RecyclerView.Adapter<T> {
    private final RecyclerView.Adapter<T> wrapped;

    public RVAdapterWrapper(RecyclerView.Adapter<T> wrapped) {
        super();

        this.wrapped=wrapped;
    }

    public RecyclerView.Adapter<T> getWrappedAdapter() {
        return(wrapped);
    }

    @Override
    public T onCreateViewHolder(final ViewGroup parent, final int viewType) {
        return(wrapped.onCreateViewHolder(parent, viewType));
    }

    @Override
    public void onBindViewHolder(final T holder, final int position) {
        wrapped.onBindViewHolder(holder, position);
    }

    @Override
    public long getItemId(int position) {
        return(wrapped.getItemId(position));
    }

    @Override
    public int getItemViewType(int position) {
        return(wrapped.getItemViewType(position));
    }

    @Override
    public void onAttachedToRecyclerView(RecyclerView recyclerView) {
        wrapped.onAttachedToRecyclerView(recyclerView);
    }

    @Override
    public void onDetachedFromRecyclerView(RecyclerView recyclerView) {
        wrapped.onDetachedFromRecyclerView(recyclerView);
    }

    @Override
    public void onViewAttachedToWindow(T holder) {
        wrapped.onViewAttachedToWindow(holder);
    }
}
```

```
@Override
public void onViewDetachedFromWindow(T holder) {
    wrapped.onViewDetachedFromWindow(holder);
}

@Override
public void onViewRecycled(T holder) {
    wrapped.onViewRecycled(holder);
}

@Override
public void registerAdapterDataObserver(RecyclerView.AdapterDataObserver observer) {
    wrapped.registerAdapterDataObserver(observer);
}

@Override
public void setHasStableIds(boolean hasStableIds) {
    wrapped.setHasStableIds(hasStableIds);
}

@Override
public void unregisterAdapterDataObserver(RecyclerView.AdapterDataObserver observer) {
    wrapped.unregisterAdapterDataObserver(observer);
}

@Override
public int getItemCount() {
    return(wrapped.getItemCount());
}
}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/RVAdapterWrapper.java](#))

The constructor takes the `RecyclerView.Adapter` to be wrapped, and `RVAdapterWrapper` offers a `getWrappedAdapter()` to retrieve that object. Everything else is a simple implementation of the wrapper pattern, overriding all methods from `RecyclerView.Adapter` and delegating them to the wrapped adapter.

### TimingWrapper (a.k.a., StrictMode for RecyclerView)

`RVAdapterWrapper` exists mostly to serve as a base class for `TimingWrapper`. `TimingWrapper` arranges to collect the time used by `onCreateViewHolder()` and `onBindViewHolder()`, so we can see if those times exceed some threshold and therefore is worthy of alerting the developer.

Its constructor takes the `RecyclerView.Adapter` to wrap, along with the `Activity` that is hosting this UI. In addition to chaining to the superclass and holding onto that `Activity` (as a data member named `host`), the constructor also retrieves a `WindowManager` system service:

```
public TimingWrapper(RecyclerView.Adapter<T> wrapped, Activity host) {
```

## IN-APP DIAGNOSTICS

---

```
super(wrapped);

this.host=host;
wm=(WindowManager)host.getSystemService(Context.WINDOW_SERVICE);
}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

TimingWrapper overrides onCreateViewHolder() and onBindViewHolder(), tracking the amount of time that those calls take, and calling a private warn() method with the time for the call:

```
@Override
public T onCreateViewHolder(final ViewGroup parent, final int viewType) {
    long start=SystemClock.uptimeMillis();
    T result=super.onCreateViewHolder(parent, viewType);

    warn(SystemClock.uptimeMillis() - start);

    return(result);
}

@Override
public void onBindViewHolder(final T holder, final int position) {
    long start=SystemClock.uptimeMillis();

    super.onBindViewHolder(holder, position);
    warn(SystemClock.uptimeMillis() - start);
}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

Here, T is the RecyclerView.ViewHolder used by the wrapped adapter and declared by the specific use of the TimingAdapter:

```
public class TimingWrapper<T extends RecyclerView.ViewHolder> extends RVAdapterWrapper<T> {
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

warn() sees if the amount of time the call took exceeds some threshold, set here to be 7ms. If it does, we first log a stack trace to Logcat, following the technique used by StrictMode itself of having a private LogStackTrace Exception that is just there to collect a stack trace:

```
private void warn(long delta) {
    if (delta>7) {
        String msg=String.format("RVAdapterWrapper violation: ~duration= %d ms",
```

```
        delta);

    Log.e(TAG, msg, new LogStackTrace());

    if (v==null) {
        WindowManager.LayoutParams params=new WindowManager.LayoutParams(
            WindowManager.LayoutParams.MATCH_PARENT,
            WindowManager.LayoutParams.MATCH_PARENT,
            WindowManager.LayoutParams.TYPE_SYSTEM_OVERLAY,
            WindowManager.LayoutParams.FLAG_NOT_FOCUSABLE
                | WindowManager.LayoutParams.FLAG_NOT_TOUCHABLE,
            PixelFormat.TRANSLUCENT);

        v=new View(host);
        v.setBackgroundResource(R.drawable.border);
        wm.addView(v, params);

        v.postDelayed(new Runnable() {
            @Override
            public void run() {
                wm.removeView(v);
                v=null;
            }
        }, 500);
    }
}

private static class LogStackTrace extends Exception {}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/TimingWrapper.java](#))

Then, if we are not presently showing an overlay (i.e., the `v` data member is not `null`), we:

- create a `WindowManager.LayoutParams` that will fill the screen, using `TYPE_SYSTEM_OVERLAY` as the type, and indicating that it has a translucent background
- create a simple `View` and give it a background defined as the border drawable resource
- use the `WindowManager` to show that view
- use `postDelayed()` to get control in 500ms and remove that view, also setting `v` back to `null`

`border` is defined in `res/drawable-nodpi/` as a `ShapeDrawable`, consisting of a transparent rectangle with a 16dp-wide green border:

```
<?xml version="1.0" encoding="utf-8"?>
<shape xmlns:android="http://schemas.android.com/apk/res/android"
    android:shape="rectangle">
    <stroke android:color="#ff00ff00" android:width="@dimen/border_width"/>
</shape>
```

(from [Diagnostics/Overlay/app/src/main/res/drawable-nodpi/border.xml](#))

The net effect is that the border will flash a 16dp-wide green line around the edge of the screen for 500ms before being removed.

Note that to use the TYPE\_SYSTEM\_OVERLAY, we have to hold the SYSTEM\_ALERT\_WINDOW permission:

```
<uses-permission android:name="android.permission.SYSTEM_ALERT_WINDOW" />
```

(from [Diagnostics/Overlay/app/src/main/AndroidManifest.xml](#))

We will get more into the ramifications of that permission on Android 6.0+ devices [later in this chapter](#).

## The RecyclerViewActivity

You will notice that the RVAdapterWrapper and TimingWrapper code is in the main source set. Hence, those classes will exist on debug and release builds. However, we only *use* them on some builds, courtesy of a tweaked RecyclerViewActivity. The revised activity has getAdapter() and setAdapter() implementations that work with an unwrapped adapter, but hold onto a wrapped adapter, on DEBUG builds:

```
package com.commonware.android.debug.videolist;

import android.os.Build;
import android.provider.Settings;
import android.support.v4.app.FragmentActivity;
import android.support.v7.widget.RecyclerView;

public class RecyclerViewActivity extends FragmentActivity {
    private RecyclerView rv=null;

    public void setAdapter(RecyclerView.Adapter adapter) {
        boolean canDrawOverlays=
            (Build.VERSION.SDK_INT<=Build.VERSION_CODES.LOLLIPOP_MR1);

        if (!canDrawOverlays && Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
            canDrawOverlays=Settings.canDrawOverlays(this);
        }
    }
}
```

```
}

    if (BuildConfig.DEBUG && canDrawOverlays) {
        adapter=new TimingWrapper(adapter, this);
    }

    getRecyclerView().setAdapter(adapter);
}

public RecyclerView.Adapter getAdapter() {
    RecyclerView.Adapter result=getRecyclerView().getAdapter();

    if (result instanceof RVAdapterWrapper) {
        result=((RVAdapterWrapper)result).getWrappedAdapter();
    }

    return(result);
}

public void setLayoutManager(RecyclerView.LayoutManager mgr) {
    getRecyclerView().setLayoutManager(mgr);
}

public RecyclerView getRecyclerView() {
    if (rv==null) {
        rv=new RecyclerView(this);
        setContentView(rv);
    }

    return(rv);
}
}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/RecyclerViewActivity.java](#))

One criterion for whether we will use the `TimingWrapper` is whether or not we are on a debug build. The other criteria take a bit more explanation, which we will get to [later in this chapter](#).

## Being Stupid

The overall sample app is a clone of a `RecyclerView` sample that loads videos from `MediaStore` and shows them in alphabetical order, along with thumbnails of the videos. This version of the sample is augmented with `Advanced Be-Stupid Technology™`, where `RowController` does the thumbnail retrieval on the main application thread when being stupid or uses `Picasso` when not:

---

## IN-APP DIAGNOSTICS

---

```
void bindModel(Cursor row) {
    title.setText(row.getString(row.getColumnIndex(MediaStore.Video.Media.TITLE)));

    int uriColumn=row.getColumnIndex(MediaStore.Video.Media.DATA);
    int mimeTypeColumn=
        row.getColumnIndex(MediaStore.Video.Media.MIME_TYPE);
    int videoId=row.getInt(row.getColumnIndex(MediaStore.Video.Media._ID));

    videoUri=row.getString(uriColumn);
    videoMimeType=row.getString(mimeTypeColumn);

    if (BuildConfig.BE_STUPID) {
        ContentResolver cr=thumbnail.getContext().getContentResolver();
        BitmapFactory.Options options=new BitmapFactory.Options();

        options.inSampleSize = 1;

        Bitmap thumb=MediaStore.Video.Thumbnails.getThumbnail(cr, videoId,
            MediaStore.Video.Thumbnails.MICRO_KIND, options);

        thumbnail.setImageBitmap(thumb);
    }
    else {
        Uri video=
            ContentUris.withAppendedId(MediaStore.Video.Media.EXTERNAL_CONTENT_URI,
                videoId);

        Picasso.with(thumbnail.getContext())
            .load(video.toString())
            .fit().centerCrop()
            .placeholder(R.drawable.ic_media_video_poster)
            .into(thumbnail);
    }
}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/RowController.java](#))

## The Results

The green border will flash if a call to `onCreateViewHolder()` or `onBindViewHolder()` takes more than 7ms. In theory, this should only occur if one of those methods does a non-trivial bit of work on the main application thread.

In practice, this seems to generate a fair number of false positives, presumably due to context-switching between threads on the available device cores.

## Areas for Improvement

Those results point at areas where this technique might be improved:

- Pass the timing value into the `TimingWrapper` constructor, rather than hard-coding it to 7ms

- Rather than worrying about individual calls exceeding a 7ms threshold, point out if a rolling average of recent calls exceeds the threshold, to perhaps smooth out the data a bit and avoid the false positives

### What Changed in Android 6.0

Let's go back to the `setAdapter()` implementation, where we conditionally apply the `TimingAdapter`:

```
public void setAdapter(RecyclerView.Adapter adapter) {
    boolean canDrawOverlays=
        (Build.VERSION.SDK_INT<=Build.VERSION_CODES.LOLLIPOP_MR1);

    if (!canDrawOverlays && Build.VERSION.SDK_INT>=Build.VERSION_CODES.M) {
        canDrawOverlays=Settings.canDrawOverlays(this);
    }

    if (BuildConfig.DEBUG && canDrawOverlays) {
        adapter=new TimingWrapper(adapter, this);
    }

    getRecyclerView().setAdapter(adapter);
}
```

(from [Diagnostics/Overlay/app/src/main/java/com/commonsware/android/debug/videolist/RecyclerViewActivity.java](#))

As noted earlier, we only use `TimingWrapper` on debug builds, not release builds.

We also only use `TimingAdapter` if one of two things is true:

- Either we are on some version of Android prior to 6.0, or
- We are allowed to draw overlays

Historically, the `SYSTEM_ALERT_WINDOW` permission was merely listed as dangerous. Users would be notified about it at install time, but otherwise it was just a standard permission.

Originally, few apps requested this permission. Over time, more and more apps started using this for things like Facebook's "chatheads" UI.

In Android 6.0, `SYSTEM_ALERT_WINDOW` was moved to be a signature-level permission. Ordinarily, the net effect of this change would be that apps could no longer hold the permission, unless they were signed by the signing key that signed the firmware. While that's possible for device manufacturers and custom ROM

## IN-APP DIAGNOSTICS

---

developers, ordinary Android SDK developers would be left out.

However, Android 6.0 provided another means to get the rights to use `TYPE_SYSTEM_OVERLAY` windows, through a double-opt-in mechanism. The user not only has to install the app, but has to go to a particular screen in the Settings app to agree to grant your app the right to draw over top of other apps.

The default way for a user to get to that screen is to go into Settings > App, then click the gear icon in the action bar of the Settings app:

## IN-APP DIAGNOSTICS

---

Tapping that brings up a “Configure apps” screen:

*Figure 1032: Android 6.0 Settings App, Configure Apps Screen*

## IN-APP DIAGNOSTICS

---

There, tapping the “Draw over other apps” entry brings up a list of all of the apps that have requested the `SYSTEM_ALERT_WINDOW` permission:

*Figure 1033: Android 6.0 Settings App, Draw Over Other Apps Screen*

Tapping on any one of those allows the user to toggle on or off this access:

*Figure 1034: Android 6.0 Settings App, Configuring Overlay Permission*

In code, you can find out if the user has enabled this access by calling `canDrawOverlays()` on the `Settings` class, as we did in `setAdapter()` above. However:

- This requires you to have a `compileSdkVersion` of 23 or higher
- You cannot call that method on pre-Android 6.0 devices

On Android 6.0+, if `canDrawOverlays()` returns `false`, you are welcome to lead the user over to the appropriate screen in Settings to try to convince them to allow you to draw over other apps. To do that:

- Create a package: `Uri` that points to your app
- Wrap that in an `ACTION_MANAGE_OVERLAY_PERMISSION` Intent
- Call `startActivity()` to bring up that screen

```
Intent i=new Intent(Settings.ACTION_MANAGE_OVERLAY_PERMISSION,
    Uri.parse("package:" + getPackageName()));

startActivity(intent);
```

## IN-APP DIAGNOSTICS

---

Note that apps with a `targetSdkVersion` of 22 or lower are “grandfathered” into having default access to draw over other apps, simply by having requested the `SYSTEM_ALERT_WINDOW` permission. However, the user can still go into the Settings app and revoke that capability, in which case attempting to draw over another app will result in a `SecurityException`

```
10-22 13:15:14.520 29661-29661/com.commonsware.android.debug.videolist E/

.
.
```

In many cases, there is no good way to recover from this `SecurityException`, in which case you really want to consider switching to `compileSdkVersion` of 23 or higher and calling `canDrawOverlays()` to detect this potential problem before it occurs.

# Anti-Patterns

---

Much of this book has been focused on what you should do. In contrast, this chapter is focused on what you should *not* do.

All platforms have their anti-patterns: things that are technically possible but are not in the best interests of the users of that platform. Android is no exception. Some anti-patterns are simply annoying to users, while other anti-patterns can significantly infringe upon a user's use of their Android device, or even the user's freedom.

Much as the Hippocratic Oath directs doctors to “first, do no harm”, Android application developers owe it to the users of their apps to avoid these anti-patterns to the greatest extent possible.

## Prerequisites

This chapter assumes that you have read much of the book, particularly the core chapters.

## Leak Threads... Or Things Attached to Threads

Leaking a thread means that you start a thread and never cause it to stop. For example, you might start a thread that runs in an infinite loop, doing some work and then sleeping for a while. The problem with infinite loops is that “infinite” is an awfully long time.

All threads should clean up, in a timely fashion, when the component (e.g., activity, service) that started the thread is destroyed — or, in the case of an activity, perhaps

just moved into the background.

*How* you ensure that the thread gets cleaned up is up to you. For threads doing transactional work, such as literally running a database transaction, it may be fine to just let them run to completion and shut down of their own accord. For “infinite” loops, there should be some way to tell the thread that it is no longer needed, such as via an `AtomicBoolean` flag, or using something more structured than a plain timing loop, such as a `ScheduledExecutorService`.

Also, bear in mind that you are responsible for threads that are created, on your behalf, by other things that you do. The most common leak scenario here comes with listeners associated with system services, like `LocationManager` and `SensorManager`. If you register a `LocationListener` via `requestLocationUpdates()` and fail to unregister that listener, you will not only be leaking the listener, but the component associated with that listener, and every system resource tied to that listener, such as any background threads.

### The Costs

Threads are intrinsically static in scope. Hence, any object they can reach, directly or indirectly, cannot be garbage-collected while the thread is still running. Hence, if an activity forks a thread, it might do so using an anonymous inner class:

```
new Thread() {
    public void run() {
        // do something
    }
}.start();
```

Instances of an inner class — anonymous or otherwise — have an implicit reference back to the object that created them. Hence, the `Thread` would hold onto the `Activity` that created the thread, which in turn would hold onto all of its widgets and so forth. None of that can be garbage-collected until after the thread terminates, even if the activity is destroyed.

### The Counter-Arguments

#### **I want the thread to keep running even after the activity is destroyed**

In this case, the thread should be created and managed by a service, not simply leaked. Not only does this give you an opportunity to clean up the thread when

needed, but it also alerts Android that you are still trying to do some work, so Android will not necessarily terminate your process very quickly.

However, be careful about assuming that you can have a thread — even one managed by a service — run forever, as you will see in the next couple of sections.

### **I do not know when the thread is no longer needed**

Then you have a serious design problem.

A common variation on this theme is:

### **The thread is needed so long as I have an activity in the foreground**

This is a bit tricky, as Android does not really expose the concept of *applications* being in the foreground, just activities.

The safest course of action is to have the thread be managed by a service, then keep track of whether or not you have an activity in the foreground. For example, in `onPause()` of each activity, use `postDelayed()` to return control to you after a short delay, and in `onResume()`, update a timestamp of your last return to the foreground (held in a static data member). When the `Runnable` for `postDelayed()` executes, check that timestamp — if it is too old, you know that none of your activities are in the foreground, and you can stop the service, having it stop your thread.

## **Use Large Heap Unnecessarily**

Encountering an `OutOfMemoryError` certainly sucks. These are caused either by a memory leak or by trying to use more memory than is practical given the device. For example, loading up lots of bitmaps can easily chew up your available heap space.

To some, therefore, `android:largeHeap` seems to be the perfect solution.

Added in API Level 11, `android:largeHeap` tells Android to give you a much larger heap size than is normally given to a process. So, instead of having 32MB or 48MB or so of heap, you might have 256MB of heap.

The right solution, in most cases, is to fix the underlying memory problem, not to mask it by requesting an over-sized heap.

### The Costs

To you, having hundreds of megabytes of extra heap may be a blessing. To the user, it may be a curse. That memory has to come from somewhere, and the “somewhere” is from other processes. Your app will force other apps’ processes to be terminated far more quickly than normal, which may slow the user down when she tries to switch between your app and others. Your app may even materially harm the functionality of other apps, who have their processes terminated before they can finish their work, just to satisfy your memory craving.

Bear in mind that Android does not employ swap space (the Linux equivalent of a Windows pagefile). Hence, whereas Windows can allocate lots of memory and slows down as it goes, Android is far more limited, in accordance with its mobile roots.

Furthermore, in many cases, adding more heap space does not eliminate the problem, any more than spraying air freshener gets rid of the dead cat in your living room that is causing the odor. With a memory leak, for example, all the larger heap does is increase the time before you eventually run out of memory.

### The Counter-Arguments

#### **I really need to be able to manipulate large chunks of memory**

There are certainly apps for which `android:largeHeap` is justified, such as complex data editors, such as image editors, video editors, etc.

Hence, in practice, the real anti-pattern is not using `android:largeHeap`, but rather in doing so for apps where the user would not feel that the resulting effects are justified. For example, neither a Twitter client, nor a banking app, should need a large heap, even if the developer is running into memory management issues.

#### **Android makes it too hard to manage memory, so I need a large heap**

There is no question that developing mobile applications is challenging, particularly when it comes to memory management. That is not unique to Android — embedded systems developers are used to writing apps where the heap size is better measured in KB instead of MB, for example.

Outside of bitmaps and massive data sets, though, it is a bit difficult to actually run out of memory. While a `TextView` may take up 1KB of heap space, it takes a *lot* of `TextView` widgets to chew through a 48MB heap.

The reason why bitmaps tend to trip up developers is that Android makes using them *too easy*. For example, it is simple to set a bitmap as a background of some container like a `LinearLayout`, where developers then blindly ignore the fact that if the bitmap is not *precisely* the size of the container, Android will need to scale the image, consuming more heap space.

## Misuse the MENU Button

The MENU button on Android devices is designed to display either the options menu (on Android 1.x/2.x devices that are not using an action bar backport or the action bar overflow menu).

The MENU button is *not* designed for any other purpose. Some developers have taken to using it for arbitrary aims, and that is a mistake.

## The Costs

The MENU button does not exist on many Android devices. In particular, devices designed for Android 3.0 and higher do not *need* a MENU button. Some will have them, but most will not. Hence, anything that requires the MENU button will simply be unavailable on those devices.

And, as of Android 4.4, Google is putting increasing pressure on device manufacturers to dump the MENU button, making it less likely to appear in the future.

## The Counter-Arguments

**Well, if I keep `targetSdkVersion` below 11, I can have a soft MENU button**

This is true, insofar as a menu affordance will be added to the system bar or navigation bar on devices that lack a dedicated MENU button.

Whether the *user* is expecting to use this button is another thing entirely.

As more and more users run Android 3.0+ devices, they will use more and more apps that have `android:targetSdkVersion` set to 11 or higher. The remaining handful of apps that do not will be “weird”. In particular, they may not notice the menu affordance, as they are not looking for one, or they may not know what it does, as they are not used to needing it.

Moreover, eventually, other things will drive you to want an `android:targetSdkVersion` higher than 10, as the menu affordance is not the only feature driven by this value. The sooner you can remove your dependence on a menu affordance, the sooner you can upgrade your `android:targetSdkVersion` to solve other problems that you are encountering.

### **I think the action bar is ugly, a waste of space, or otherwise bad**

That's nice. It does not mean that you need a menu affordance and a tie to a MENU button.

For example, well-written games will have a menu integrated into the game UI itself. This was often done even before Android 3.0, since the options menu UI would not look much like the game's UI, and the developer wanted a consistent look-and-feel.

So long as the user recognizes how to reach the menu (e.g., a three-dots or three-bars icon), the menu does not have to be driven by Android, but instead could be handled by your app directly. You can see this in the Google Navigation app, which avoids an action bar but still displays its own menu from its own on-screen menu affordance.

## **Interfere with Navigation**

Some developers try to take over the device. They attempt to block the use of anything not related to their app: the HOME key, the recent tasks list, the notification drawer, etc.

Android treats such behavior as malware. Android is designed to keep control of the device in the hands of the user and tries very hard to prevent apps from stealing that control.

### **The Costs**

While there are certain cases where blocking navigation outside the app may seem justified (see the counter-arguments, below), there is simply too much opportunity for malfeasance. Users tend to want to use their devices on their terms, not necessarily the terms of some random developer. Malware authors, in particular, love to learn about script-kiddie hacks that allow them to control a device, and by extension, control the users.

## The Counter-Arguments

### I am writing a lock screen

No, you are not. You are writing something that you *think* is a lock screen. Really what you are writing is something that weakens device security... if the app in question is designed to be downloaded and run on arbitrary devices.

Android devices can be rebooted into “safe mode”. Much like the Windows boot option that bears the same name, “safe mode” only runs apps that are part of the system firmware, not any third-party apps.

So, let’s assume that the user installs your “lock screen”. Inevitably, part of the setup of a third-party “lock screen” is to disable any sort of security that is part of the native lock screen, so the user does not have to unlock things twice. Even though your lock screen may implement all sorts of security, all somebody else has to do is reboot the device in safe mode, and they now have complete access to the device, including the ability to uninstall your lock screen. By contrast, the native lock screen is in force even if the device reboots in safe mode.

### I am writing a parental control app

Rebooting in safe mode is within the motor-control skills of your average three-year-old child. Hence, the primary limitation is whether or not the child knows *how* to reboot the device in safe mode, which they can learn from the Internet, friends, etc. And, if the device is really an adult’s device, where the “lock screen” allows access to a subset of child-friendly apps, the real risk is not from the child rebooting the device in safe mode, but from the crook who steals the device rebooting in safe mode.

### I am writing a lock screen designed to run on whole-disk-encrypted devices

While whole disk encryption — available on Android 4.0+ — does solve the issue of rebooting in safe mode, bear in mind that users then cannot disable the required password security on the native lock screen, as that is tied into the whole disk encryption process.

### I am writing a kiosk app

Here, the term “kiosk app” refers to an app that represents the functionality of a single-purpose device. For example, a restaurant might want to distribute menus to

customers in the form of a tablet app; the menu app would be the “kiosk app”.

In this case, the owner of the device is the one trying to lock it down to be single-purpose. That is completely reasonable... except that it runs counter to the behavior of standard consumer builds of Android.

The right solution, in this case, is to create custom firmware for the single-purpose devices. This firmware can set up the kiosk app to be the home screen (thereby blunting the effectiveness of HOME, BACK, etc.), and modifications to the firmware can apply access controls to other aspects of the device (e.g., notifications). Unfortunately, there are few (if any) businesses set up to help create such single-purpose firmware for single-purpose devices.

## Use `android:sharedUserId`

If you are creating more than one application, where those applications should be sharing data, you may be tempted to use `android:sharedUserId`. This attribute, applied to the root `<manifest>` element in your manifest, allows two or more apps to share a Linux user account. That will allow these apps full access to the other apps' files. The limitations are that you must use the same value for `sharedUserId` and that all such apps must be signed with the same signing key.

However, this is a fairly crude and somewhat risky approach to sharing information between apps. In most cases, you will be better served using any of the structured IPC options within Android, such as remote services and content providers.

## The Costs

First, you must make the decision to use `android:sharedUserId` before you ever ship your app in production. Should you change the `sharedUserId` value — or switch from no value to a new value — when your change is installed, the new version of your app will have no rights to access the old version of your app's files. This is unlikely to turn out well.

Second, it will be up to you to maintain data integrity of these files in the face of simultaneous access from multiple apps. SQLite should handle this for you for your databases, as it is set up to use process-level locking — this is why SQLite can be used as the out-of-the-box database solution for Web frameworks like Rails. However, any other sort of file, including `SharedPreferences`, will lack that coordination, unless you somehow arrange to do it yourself. And even the SQLite-

level coordination has its limits, as one app has no way to know about another app's changes to the data, except by re-querying the database.

Third, using `android:sharedUserId` limits your flexibility. You cannot use it with third-party apps. You cannot readily sell one of your apps in your suite, as then it becomes a third-party app and can no longer be signed by the same signing key as are the rest of your apps. Basically, `sharedUserId` causes multiple separate APKs to behave, in some respects, as one larger APK.

### The Counter-Arguments

#### I need to ensure only my apps can share the data, not others

Use a signature-level permission. This gives you the same level of security as does `android:sharedUserId` without most of the risks.

#### Writing IPC code is tedious

So is writing cross-process data integrity code.

### Implement a “Quit” Button

Perhaps the most contentious question and answer on Stack Overflow's `android` tag is [“Quitting an application - is that frowned upon?”](#). This exchange is nearly three years old (as of the time of this writing), yet the answer receives both upvotes (and a few downvotes) with some regularity.

Other Android experts, such as Reto Meier, have weighed in on the issue and have [offered similar recommendations](#) – that is, do not have a “quit” or “exit” button in your app.

(here, “button” is shorthand for any command-style interface, and includes menu options, action bar items, and the like by extension)

The reason is simple: whatever your “quit” or “exit” button does *should be happening in other conditions as well*, and handling those other conditions should eliminate the need for the button.

If the app moves into the background *for any reason*, you need to treat the user and her device with respect. This means stopping background threads that are not

needed, releasing system resources like the GPS radio (immediately or after a modest delay), and the like. The user should not need to “quit” your app to accomplish this, because your app will move to the background for other reasons, such as incoming phone calls, or the user pressing the HOME button.

### The Costs

You might think “well, what’s the harm in having the ‘quit’ button that, say, just calls `finish()`?”

First, rarely is it that simple. Calling `finish()` will return the user to the previous activity, and so for any multi-activity app, there will be scenarios where `finish()` is not really “quit”. The only simple thing you can universally do is have “quit” bring up the home screen, in which case all you have done is waste screen real estate duplicating the HOME button functionality. Worse, the developer might say “oh, well, I will just terminate my process when they press ‘quit’”, and *that* anti-pattern [is coming up next in this chapter](#).

Second, the user will start to think that they *need* to press “quit”, or else bad things might happen. They will see an explicit “quit” option and start to wonder “well, gee, when am I supposed to press that, and what happens if I do not?” This, in turn, will lead to the user going out of their way to make sure to press your “quit” button, even if doing so does not actually change anything about the behavior of your app, courtesy of [the placebo effect](#).

### The Counter-Arguments

#### **I need to let the user log out of the app, so I need a “quit” button**

No, you need a “logout” button that clears your cached authentication credentials (e.g., sets a static data member to `null`), then brings up the login activity using `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to wipe out all other activities in your process. And, probably, you need to have some sort of inactivity-based “timeout” that also logs out the user (e.g., sets that static data member to `null`).

#### **I am running stuff in the background, so I need a “quit” button**

No, you need a “stop that background stuff” button, preferably with a shorter, more specific label. And, you need that to also be available from the Notification that you are using with your foreground service, where applicable.

## Terminate Your Process

Closely related to the above anti-pattern is to forcibly stop your process, such as via `System.exit()`, `Runtime.exit()`, `Process#killProcess()`, and so forth. These are often used in concert with [an in-app “quit” button](#), or sometimes for other reasons (e.g., could not figure out how to handle an exception gracefully).

### The Costs

Simply put, Google has warned, repeatedly, that there may be side effects from terminating your own process, rather than having Android do proper cleanup first.

- “You should really think about not exiting the application. This is not how Android apps usually work.” ([Romain Guy](#))
- “To be clear: using `System.exit()` is strongly recommended against, and can cause some poor interactions with the system. Please don’t design your app to need it.” ([Dianne Hackborn](#))
- “There is no reason or need to call `[exit()]`” ([Dianne Hackborn](#))
- “Nobody has said anything about `Process.kill()` not doing anything. You want to kill your *own* process and cause the user to experience your *own* application having weird behavior at times due to it? Have at it. I just want to be clear that this is not what we recommend doing... and you are likely to cause bad behavior in your app at least at times due to it... There is no API to quit an application, because there is no such concept on Android, and trying to implement such a thing is going to result in fighting against how Android works.” ([Dianne Hackborn](#))

### The Counter-Arguments

#### **I am using a C library that is buggy, so I need to terminate my process**

Fix the bugs in the library. For example, C libraries that rely too heavily on global variables may need to be adjusted to use session handles that get passed around.

#### **Well, it is not my C library, but one from a third party, so I need to terminate my process**

Find a library that is Android-compatible, then. It is likely that you will encounter other problems with this library, if it is not designed to work on Android (e.g., not set up to work properly on ARM CPUs).

### **There is a bug in Android for which I have found no workaround short of terminating my process**

This is one of the few legitimate reasons for terminating a process, but it is so rare that it is difficult to find a citation of a place where such a bug (and workaround) exists.

### **I need to do *something* from my top-level exception handler!**

Set relevant static data members to null, then start up your launcher activity, using `FLAG_ACTIVITY_SINGLE_TOP` and `FLAG_ACTIVITY_CLEAR_TOP` to wipe out all other activities in your task. This should reset you to your original state, as if the user had launched the app.

## **Try to Hide from the User**

Some developers view the user as the enemy. These developers try to insulate their app from the user, to make data inaccessible to the user, to make the app “unkillable” by the user, etc. In many cases, this is at the behest of some enterprise, wanting to exert control over the user’s use of the app or even the device.

Android is a consumer operating system. It is designed to put power in the hands of whoever is holding the device and can authenticate themselves to the device (e.g., via a password on the lock screen). Enterprises and malware authors have much the same interests: they wish to take control away from the user and give the control to somebody else. Android defends against malware; enterprises get caught in the crossfire.

Inevitably, the right solution here will be an enterprise remix of Android, designed to be loaded on enterprise-supplied devices, that put the control in the hands of the enterprise.

## **The Costs**

Simply put, you are wasting your time, which could be better spent on other pursuits.

With respect to data, if your app can access that data, by definition, a sufficiently talented user can get at the data:

- If you put it on internal storage, the user can root the device
- If you further encrypt the data, the user can find the encryption algorithm and key in your app, then decrypt the data
- If you try obfuscation or other techniques to mask the encryption algorithm and key, the user will use cracking tools to find this information anyway, or will transfer your app to a ROM mod that contains a modified version of the Android framework that can collect this information when you go to decrypt the data
- And so on

With respect to the process, the user can force-stop any installed app via the Settings app. And, even if you use script-kiddie tricks to try to prevent access to Settings, the user can nuke your app from orbit via the command line, using the full Android SDK or third-party tools.

### The Counter-Arguments

#### **I am creating an app for an enterprise, and we need to control the app**

Then you further need to control the device, which leads to the “enterprise flavor of Android” solution mentioned earlier in this section.

#### **I am creating a lock screen/parental control app/kiosk app**

Please see the counter-arguments for “Interfering with Navigation” from [earlier in this chapter](#).

### Use Multiple Processes

Some Android professionals recommend the use of `android:process` to have components run in separate processes from the main one for an application. For example, you might have all of your activities in the main process but isolate a service in a separate process. Or, you might have some memory-intensive activity (e.g., an image editor) run in a separate process.

As with most of these anti-patterns, while the `android:process` feature is valid, it is rarely necessary. To some extent, developers get caught up in process isolation from its use on servers and forget that mobile devices typically have fewer resources — RAM and CPU — than do their server counterparts. Few of Google’s apps use `android:process`; even complex apps like Gmail or the original Browser avoid it.

## The Costs

Each process gets its own heap space, cutting into the heap available for other applications. As with the large-heap anti-pattern [discussed above](#), this will tend to force other apps to be ejected from memory sooner than normal, with commensurate impacts on user experience.

Inter-process communication (IPC) is not cheap, compared with normal method invocation within a process. Hence, tightly-coupled processes will chew through more CPU than their single-process counterparts. While it is unlikely that you will see major performance implications (unless you are doing a preposterous amount of IPC), this will consume more battery than is otherwise warranted.

## The Counter-Arguments

**I am using a C library that is buggy, and you told me not to terminate my process**

As noted earlier, fix the bugs in the library.

**Hello? It is not my C library, but one from a third party!**

Find a library that is Android-compatible, then.

**I need more heap space**

On Android 3.0 and higher, `android:largeHeap` is available, though its misuse is [another anti-pattern, discussed above](#). However, prior to Android 3.0, `android:largeHeap` was not an option. One workaround used by some apps is to fork several processes, thereby getting several “small” heap allocations (e.g., 32MB) instead of just one.

In cases where `android:largeHeap` is indeed justified, using multiple processes as a workaround on older Android versions is justified as well. However, bear in mind that IPC overhead is non-trivial, so have a plan to dump the multiple processes and use `android:largeHeap` once you drop support for Android 1.x/2.x.

**I want my UI not to freeze when doing background work**

Use threads, not processes, for this.

## Hog System Resources

Some of these anti-patterns, like the multiple-process one just now, are really concrete sub-types of a more general anti-pattern: assuming yours is the only app running on the device. While your app may be the only one running in the foreground (assuming that you actually *are* in the foreground), there are other apps in the background, and ones that soon will come to the foreground. You need to “play nice” and ensure that these other apps will have their fair share of system resources.

One example is open files on external storage. For some devices — but not all — there is a limit of 1,024 simultaneously open files. In principle, that should be plenty. However, if some app — maybe yours? — opens a whole bunch of files, it is possible that other apps trying to access external storage at that point will crash because the limit was hit.

### The Counter-Arguments

**Um, well, I’m just more important than those other developers**  
:facepalm::

---

## **Trail: Widget Catalog**

---

# Widget Catalog: AdapterViewFlipper

---

A [regular ViewPager](#) shows only one child widget or container at a time. So does an AdapterViewFlipper. The difference is where the children come from. With a regular ViewPager, you add children much like you would any other standard container class, such as defining the children in your layout XML resource. With AdapterViewFlipper, the children come from an Adapter.

While AdapterViewFlipper does not inherit from ViewPager (or vice versa, for that matter), their public API is largely the same:

- You can control which child is visible, either by index or via `showNext()/showPrevious()` methods to rotate between them.
- You can set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.
- You can set up AdapterViewFlipper to automatically flip between children on a specified period.

There are two key advantages for AdapterViewFlipper:

1. Since it uses an Adapter model, it can be more memory efficient for lots of children, through child view recycling
2. It is available for use in an [app widget](#)

However, AdapterViewFlipper is new to API Level 11 and is unavailable on older versions of Android. It is not included in the Android Support package backport.

## Key Usage Tips

All of the usage tips from [ViewPager](#) are relevant for AdapterViewFlipper.

### A Sample Usage

The sample project can be found in [WidgetCatalog/AdapterViewFlipper](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<AdapterViewFlipper xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

(from [WidgetCatalog/AdapterViewFlipper/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.avflip;

import android.app.Activity;
import android.os.Bundle;
import android.widget.AdapterViewFlipper;
import android.widget.ArrayAdapter;

public class FlipperDemo2 extends Activity {
    static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
        "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
        "placerat", "ante", "porttitor", "sodales", "pellentesque",
        "augue", "purus" };
    AdapterViewFlipper flipper;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        flipper=(AdapterViewFlipper)findViewById(R.id.details);
        flipper.setAdapter(new ArrayAdapter<String>(this, R.layout.big_button, items));
        flipper.setFlipInterval(2000);
        flipper.startFlipping();
    }
}
```

(from [WidgetCatalog/AdapterViewFlipper/app/src/main/java/com/commonware/android/avflip/FlipperDemo2.java](#))

### Visual Representation

There is no visual representation of an AdapterViewFlipper itself, as it renders no pixels on its own. Rather, it simply shows the current child.

# Widget Catalog: CalendarView

---

CalendarView, as you might have guessed, displays a calendar to the user, designed to allow the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

Note that this is a small calendar – it is not designed to show details *within* a date, such as appointments and times.

This view is available standalone and also as an optional adjunct to [the DatePicker widget](#).

This view was added in API Level 11 and therefore will not be available on older versions of Android, though [a backport is available](#) that works on Android 2.2 onwards.

## Key Usage Tips

If you do nothing, the CalendarView will start with today's date, though you can call a `setDate()` method to pass in a `Calendar` object to use to change the initially-selected date. You can also call `setOnDateChangeListener()` to supply an `OnDateChangeListener` to learn when the user changes the date in the CalendarView.

CalendarView works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the year/month/day-of-month from the CalendarView (as supplied to the `onSelectedDayChange()` method of your `OnDateChangeListener`) and converting it into something you can use in your code.

### A Sample Usage

The sample project can be found in [WidgetCatalog/CalendarView](#).

Layout:

```
<CalendarView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/calendar"
    android:layout_width="match_parent"
    android:layout_height="match_parent"/>
```

(from [WidgetCatalog/CalendarView/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.wc.calendar;

import android.app.Activity;
import android.os.Bundle;
import android.widget.CalendarView;
import android.widget.CalendarView.OnDateChangeListener;
import android.widget.Toast;
import java.util.Calendar;
import java.util.GregorianCalendar;

public class CalendarDemoActivity extends Activity implements
    OnDateChangeListener {
    CalendarView calendar=null;

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        calendar=(CalendarView)findViewById(R.id.calendar);
        calendar.setOnDateChangeListener(this);
    }

    @Override
    public void onSelectedDayChange(CalendarView view, int year,
        int monthOfYear, int dayOfMonth) {
        Calendar then=new GregorianCalendar(year, monthOfYear, dayOfMonth);

        Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_LONG)
            .show();
    }
}
```

## WIDGET CATALOG: CALENDARVIEW

---

```
}
```

(from [WidgetCatalog/CalendarView/app/src/main/java/com/commonsware/android/wc/calendar/CalendarDemoActivity.java](#))

## Visual Representation

This is what a CalendarView looks like in a few different Android versions and configurations, based upon the sample app shown above.

## WIDGET CATALOG: CALENDARVIEW

---

*Figure 1036: Android 4.1*

*Figure 1037: Android 5.0*

## WIDGET CATALOG: CALENDARVIEW

---

# Widget Catalog: DatePicker

---

`DatePicker`, as the name might suggest, allows the user to pick a date. You supply a starting date, which the user then manipulates, triggering event listeners whenever the date is changed.

## Key Usage Tips

If you do nothing, the `DatePicker` will start with today's date. However, if you want to set up an `OnDateSetListener` to find out when the date changes, you will need to call `init()` to do so, in which you also need to set the date.

`DatePicker` works well with `Calendar` and `GregorianCalendar`, in terms of setting and getting the year/month/day-of-month from the `DatePicker` and converting it into something you can use in your code.

API Level 11 introduced an optional `CalendarView` adjunct to the `DatePicker`, determined via `setCalendarViewShown()` or `android:calendarViewShown`. This works well on `-normal` screens in landscape and on `-large/-xlarge` screens. On `-normal` screens in portrait, the year portion of the picker may be chopped off to save room. Using the `CalendarView` option on `-small` screens is probably not a good idea.

However, on Android 5.0+, the `CalendarView` is *always* shown and cannot be removed, as the “picker” itself does not allow the user to pick a date. The user uses the `CalendarView` to pick a date, or taps on the year in the “picker” to choose a year. This means that `DatePicker` is not a particularly good widget to use, especially on smaller screens.

## A Sample Usage

The sample project can be found in [WidgetCatalog/DatePicker](#).

Layout:

```
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:gravity="center_horizontal">

    <DatePicker
        android:id="@+id/picker"
        android:layout_width="match_parent"
        android:layout_height="0dip"
        android:layout_weight="1"
        android:datePickerMode="spinner"
        android:calendarViewShown="true"/>

    <CheckBox
        android:id="@+id/showCalendar"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:checked="true"
        android:text="@string/calendar"/>

</LinearLayout>
```

(from [WidgetCatalog/DatePicker/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.wc.datepick;

import android.app.Activity;

# Widget Catalog: ExpandableListView

---

Android does not have a “tree” widget, allowing users to navigate an arbitrary hierarchy of stuff. In large part, that is because such trees are difficult to navigate on small touchscreens with comparatively large fingers.

Android *does* have `ExpandableListView`, a subclass of `ListView` that supports a two-layer hierarchy: groups and children. Groups can be expanded to show their children or collapsed to hide them, and you can get control on various events for the groups or the children.

## Key Usage Tips

Android offers an `ExpandableListActivity` as a counterpart to its `ListActivity`. However, it does not offer an `ExpandableListFragment`. This is not a major issue, as you can work with an `ExpandableListView` inside a regular `Fragment` yourself, just as you would for most other widgets not named `ListView`.

Rather than use a `ListAdapter` with `ExpandableListView`, you will use an `ExpandableListAdapter`, where you can control separate details for groups and children. These include:

- `SimpleExpandableListAdapter`, roughly analogous to `ArrayAdapter`, where your data resides in a `List` of `Map` objects for groups, and a `List` of a `List` of `Map` objects for the children
- `CursorTreeAdapter` and `SimpleCursorTreeAdapter`, roughly analogous to `CursorAdapter` and `SimpleCursorAdapter`, for mapping data in a `Cursor` to rows and columns

In many cases, though, the complexity of managing groups and children will steer

you down the path of extending `BaseExpandableListAdapter` and handling all of the view construction yourself. There are many methods that you will need to implement:

- `getGroupCount()`, to return the number of groups
- `getGroup()` and `getGroupId()`, to return an `Object` and unique `int` ID for a group given its position
- `getGroupView()`, to return the `View` that should be used to render the group, perhaps using the built-in `android.R.layout.simple_expandable_list_item_1` that is set up for such groups and handles rendering the expanded and collapsed states
- `getChildrenCount()`, to return the number of children for a given group
- `getChild()` and `getChildId()`, to return an `Object` and unique `int` ID for a child given its position (and its group's position)
- `getChildView()`, to return the `View` that should be used to render the child, given its position and its group's position
- `isChildSelectable()`, to indicate if the user can select a given child, given its position and its group's position
- `hasStableIds()`, to indicate if the ID values you returned from `getGroupId()` and `getChildId()` will remain constant for the life of this adapter

There are four major events that you will be able to respond to with respect to the user's interaction with an `ExpandableListView`:

- Clicks on a child (`setOnChildClickListener()`)
- Clicks on a group (`setOnGroupClickListener()`)
- When groups expand (`setOnGroupExpandListener()`) or collapse (`setOnGroupCollapseListener()`)

If you use `setOnGroupClickListener()` to be notified about clicks on a group, be sure to return `false` from your implementation of the `onGroupClick()` method required by the `OnGroupClickListener` interface. If you return `true`, you consume the click event, which prevents `ExpandableListView` from using that event to expand or collapse the group.

## A Sample Usage

The sample project can be found in [WidgetCatalog/ExpandableListView](#).

## WIDGET CATALOG: EXPANDABLELISTVIEW

                      Toast.LENGTH_SHORT).show();
    }
}
```

(from [WidgetCatalog/ExpandableListView/app/src/main/java/com/commonsware/android/wc/elv/MainActivity.java](#))

This activity loads up a JSON file from a raw resource on the main application thread in `onCreate()`, which is not a good idea. It would be better to do that work in a background thread, perhaps an `AsyncTask` managed by a retained fragment. The implementation shown here is designed to keep the sample small, not to demonstrate the best way to load data from a raw resource.

Adapter:

```
package com.commonsware.android.wc.elv;

    }

    @Override
    public boolean hasStableIds() {
        return(true);
    }

    private JSONArray getChildren(int groupPosition) throws JSONException {
        String key=getGroup(groupPosition).toString();

        return(model.getJSONArray(key));
    }
}
```

(from [WidgetCatalog/ExpandableListView/app/src/main/java/com/commonsware/android/wc/elv/JSONExpandableListAdapter.java](#))

This adapter wraps a `JSONObject` and assumes that the JSON structure is an object, keyed by strings, whose values are arrays of strings. The object returned by `getGroup()` is the key for that group's position; the object returned by `getChild()` is the string at that child's array index for it's group's array. Since the data structure is treated as immutable, and since there are no other better IDs in the data structure itself, the group ID is simply the group's position, and the child's ID is simply a mash-up of the group and child positions.

## Visual Representation

This is what an `ExpandableListView` looks like in a few different Android versions and configurations, based upon the sample app shown above.

*Figure 1045: Android 2.3.3, Portrait*

*Figure 1046: Android 4.0.3, Portrait*

Note that while the data in the JSON file has the groups sorted alphabetically, because `JSONObject` effectively loads its data into a `HashMap`, the sorting gets lost in the data model, which is why the groups appear out of order.

Also note that the visual representation of the “collapsed” and “expanded” states is controlled by the `ExpandableListAdapter` and the view used for the groups. In this sample, we use `android.R.layout.simple_expandable_list_item_1` for the groups, which gives us the caret designation for expanded versus collapsed states in 4.0.3 and the lower-left arrowhead-in-circle icon for 2.3.3. You can create your own rows with your own indicators as you see fit.

# Widget Catalog: SeekBar

---

SeekBar allows the user to choose a value along a continuous range by sliding a “thumb” along a horizontal line. In effect — and in practice, as it turns out — SeekBar is a user-modifiable ProgressBar.

## Key Usage Tips

The value range of a SeekBar runs from 0 to a developer-set maximum value. As with ProgressBar, the default maximum is 100, but that can be changed via an `android:max` attribute or the `setMax()` method. The minimum value is always 0, so if you want a range starting elsewhere, just add your starting value to the actual value (obtained via `getProgress()`) to slide the range as desired.

You can find out about changes in the SeekBar value by attaching an `OnSeekBarChangeListener` implementation. The primary method on that interface is `onProgressChanged()`, where you are notified about changes in the progress value (second parameter) and whether that change was initiated directly by the user interacting with the widget (third parameter). The interface also has `onStartTrackingTouch()` and `onStopTrackingTouch()`, to indicate when the user is attempting to change the position of the thumb via the touchscreen, though these methods are less-commonly used.

## A Sample Usage

The sample project can be found in [WidgetCatalog/SeekBar](#).

Layout:

## WIDGET CATALOG: SEEKBAR

---

```

## WIDGET CATALOG: SEEKBAR

---

# Widget Catalog: SlidingPaneLayout

---

In the master-detail UI pattern, we are showing both the master and the detail fragment, side-by-side, on larger screens, while showing only one at a time on smaller screens. `SlidingPaneLayout` encapsulates that logic.

`SlidingPaneLayout` will detect the screen size. If the screen size is big enough, `SlidingPaneLayout` will display its two children side-by-side. If the screen size is not big enough, `SlidingPaneLayout` will display one child at a time. However, by default, when the “master” child is visible, a thin strip on the right will allow the user to return to the “detail” child. Similarly, a swiping gesture can switch from the “detail” back to the “master” child. These are in addition to any changes in context you might introduce based on UI operations (e.g., tapping on an element in a master `RecyclerView` automatically switching to the detail child).

`SlidingPaneLayout` is in the Support Library, in the `support-core-ui` artifact for 27.1.1 and its own `slidingpanelayout` artifact in 28.0.0 and higher.

## Declaring a SlidingPaneLayout

A `SlidingPaneLayout` can go in your activity’s layout. It works like a horizontal `LinearLayout` and is designed to hold two or more children. The first child is considered to be “the pane” and is the portion that slides over top of everything else in the `SlidingPaneLayout`.

As with a `LinearLayout`, you can use `android:layout_width` to specify minimum widths for your contents, plus `android:layout_weight` to allocate any unused space:

```
<android.support.v4.widget.SlidingPaneLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/panes"
    android:layout_width="match_parent"
```

## WIDGET CATALOG: SLIDINGPANELAYOUT

---

```
android:layout_height="match_parent">

<fragment
    android:id="@+id/sensors"
    android:name="com.commonware.android.sensor.monitor.SensorsFragment"
    android:layout_width="300sp"
    android:layout_height="match_parent" />

<fragment
    android:id="@+id/log"
    android:name="com.commonware.android.sensor.monitor.SensorLogFragment"
    android:layout_width="400dp"
    android:layout_height="match_parent"
    android:layout_weight="1" />

</android.support.v4.widget.SlidingPaneLayout>
```

(from [Sensor/Monitor/app/src/main/res/layout/activity\\_main.xml](#))

Here, we have two fragments inside of the `SlidingPaneLayout`. If the current screen width is `300sp+400dp` or larger, both fragments will be shown side-by-side, with the log fragment taking up all remaining space (courtesy of its `android:layout_weight="1"` attribute). If the current width is smaller than `300sp+400dp`, though, the two fragments will overlap, with the sensors fragment sliding over top of the log fragment.

## Visual Representation

The app that is using the above layout is from [the chapter on sensors](#). The sensors fragment shows a list of all of the sensors on the device, and the log shows a roster of sensor readings from that sensor.

*Figure 1050: SlidingPaneLayout, Showing the Pane*

Figure 1052: SlidingPaneLayout, with Both Panes on a Tablet

## Interacting with a SlidingPaneLayout

Sometimes, just setting up the `SlidingPaneLayout` is sufficient. Sometimes, you want user interactions to affect the pane. For example, the aforementioned sample app closes the pane once the user makes a selection in the list of available sensors.

`SlidingPaneLayout` offers:

- `openPane()` to show the pane
- `closePane()` to hide the pane, if the pane can be hidden (i.e., not when both panes are always showing)
- `isSlideable()` to determine if the pane is always visible or if the pane can truly be closed

# Widget Catalog: StackView

---

StackView is an AdapterView. Whereas ListView uses a horizontal scrolling list as its UI metaphor, StackView uses a stack of cards as its metaphor. Just as ListView shows a handful of rows, StackView shows a handful of cards. These cards can be swiped away via a swipe towards the southwest corner of the screen. The top card is fully visible; the edges of a few other cards can be seen but are otherwise obscured by cards “higher in the stack”.

While certainly usable in activities and fragments, StackView was introduced in support of app widgets. App widgets like bookmarks, Google Books covers, and the like use StackView to show an item and allow users to navigate to the rest of the items by flipping these virtual cards.

## Key Usage Tips

Generally speaking, working with StackView is not significantly different than is working with any other AdapterView. You create an Adapter defining the contents (in this case, defining the cards), you attach the Adapter to the StackView, and put the StackView somewhere on the screen.

As the cards overlap, however, transparency becomes an issue. If the top card is not completely opaque, you will see the card beneath it “peeking through” as its contents are blended in via the alpha channel. In some cases, this is a perfectly desirable outcome. However, if that is not what you want, make sure that the backgrounds of your overall container for the card’s contents (e.g., a RelativeLayout) has an opaque background, such as a color with FF for the alpha value.

Also, since the objective is to have the children be visually stacked, the children

cannot be the size of the StackView itself (e.g., the children cannot use `match_parent` for a dimension). StackView seems to work best with children that have explicit sizes (e.g., values in dp).

## A Sample Usage

The sample project can be found in [WidgetCatalog/StackView](#).

Activity Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<StackView xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/details"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```

(from [WidgetCatalog/StackView/app/src/main/res/layout/main.xml](#))

Item Layout:

```
<TextView xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="200dp"
    android:layout_height="200dp"
    android:background="#FFF000"
    android:gravity="center"
    android:textAppearance="?android:attr/textAppearanceLarge" />
```

(from [WidgetCatalog/StackView/app/src/main/res/layout/item.xml](#))

Activity:

```
package com.commonware.android.wc.stack;

import android.app.Activity;
import android.content.Context;
import android.os.Bundle;
import android.view.View;
import android.view.ViewGroup;
import android.widget.ArrayAdapter;
import android.widget.StackView;

public class MainActivity extends Activity {
    static String[] items= { "lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit", "morbi", "vel", "ligula",
        "vitae", "arcu", "aliquet", "mollis", "etiam", "vel", "erat",
```

## WIDGET CATALOG: STACKVIEW

---

```
        "placerat", "ante", "porttitor", "sodales", "pellentesque",
        "augue", "purus" };
StackView stack;

@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    stack=(StackView)findViewById(R.id.details);
    stack.setAdapter(new ItemAdapter(this, R.layout.item, items));
}

private static class ItemAdapter extends ArrayAdapter<String> {
    public ItemAdapter(Context context, int textViewResourceId,
        String[] objects) {
        super(context, textViewResourceId, objects);
    }

    @Override
    public View getView(int position, View convertView, ViewGroup parent) {
        View result=super.getView(position, convertView, parent);

        result.setBackgroundColor(0xFF330000 + (position * 0x0A0A));

        return(result);
    }
}
}
```

(from [WidgetCatalog/StackView/app/src/main/java/com/commonsware/android/wc/stack/MainActivity.java](#))

## Visual Representation

This is what a StackView looks like in Android 4.0.3, based upon the sample app shown above:

*Figure 1053: Android 4.0.3, As Initially Seen*

## WIDGET CATALOG: STACKVIEW

---

# Widget Catalog: TabHost and TabWidget

---

Before we had the action bar and `ViewPager`, we had `TabHost` and `TabWidget` as our means of displaying tabs. Nowadays, in most cases, using tabs with a `ViewPager` is the preferred option. However, there may be cases where the classic tabs are a better solution, or you may have inherited legacy code that still uses `TabHost`.

## Deprecation Notes

Just as `ListActivity` helps one use a `ListView`, `TabActivity` helps one use a `TabHost`. However, `TabActivity` is marked as deprecated. That is largely because its parent class, `ActivityGroup`, is deprecated. While you can still use `TabActivity`, it is no longer recommended. It also is not necessary, as there are ways to use `TabHost` and `TabWidget` without using `TabActivity`, as will be demonstrated later in this chapter.

## Key Usage Tips

There are a few widgets and containers you need to use in order to set up a tabbed portion of a view:

- `TabHost` is the overarching container for the tab buttons and tab contents
- `TabWidget` implements the row of tab buttons, which contain text labels and optionally contain icons
- `FrameLayout` is the container for the tab contents; each tab content is a child of the `FrameLayout`

You load contents into that `FrameLayout` in one of two ways:

1. You can define the contents simply as child widgets (or containers) of the `FrameLayout` in a layout XML file you are using for the whole tab setup
2. You can define the contents at runtime

Curiously, you do not define what goes in the tabs themselves, or how they tie to the content, in the layout XML file. Instead, you must do that in Java, by creating a series of `TabSpec` objects (obtained via `newTabSpec()` on `TabHost`), configuring them, then adding them in sequence to the `TabHost` via `addTab()`.

The two key methods on `TabSpec` are:

- `setContent()`, where you indicate what goes in the tab content for this tab, typically the `android:id` of the view you want shown when this tab is selected
- `setIndicator()`, where you provide the caption for the tab button and, in some flavors of this method, supply a `Drawable` to represent the icon for the tab

Note that tab “indicators” can actually be views in their own right, if you need more control than a simple label and optional icon.

Also note that you must call `setup()` on the `TabHost` before configuring any of these `TabSpec` objects. The call to `setup()` is not needed if you are using the `TabActivity` base class for your activity.

## A Sample Usage

The sample project can be found in [WidgetCatalog/Tab](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<TabHost xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/tabhost"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <LinearLayout
        android:orientation="vertical"
        android:layout_width="match_parent"
        android:layout_height="match_parent">
```

## WIDGET CATALOG: TABHOST AND TABWIDGET

---

```
<TabWidget android:id="@android:id/tabs"
  android:layout_width="match_parent"
  android:layout_height="wrap_content"
/>
<FrameLayout android:id="@android:id/tabcontent"
  android:layout_width="match_parent"
  android:layout_height="match_parent">
  <AnalogClock android:id="@+id/tab1"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
  />
  <Button android:id="@+id/tab2"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:text="A semi-random button"
  />
</FrameLayout>
</LinearLayout>
</TabHost>
```

(from [WidgetCatalog/Tab/app/src/main/res/layout/main.xml](#))

### Activity:

```
package com.commonware.android.tabhost;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TabHost;

public class TabDemo extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        TabHost tabs=(TabHost)findViewById(R.id.tabhost);

        tabs.setup();

        TabHost.TabSpec spec=tabs.newTabSpec("tag1");

        spec.setContent(R.id.tab1);
        spec.setIndicator("Clock");
        tabs.addTab(spec);

        spec=tabs.newTabSpec("tag2");
        spec.setContent(R.id.tab2);
```

## WIDGET CATALOG: TABHOST AND TABWIDGET

---

```
spec.setIndicator("Button");
tabs.addTab(spec);
}
}
```

(from [WidgetCatalog/Tab/app/src/main/java/com/commonsware/android/tabhost/TabDemo.java](#))

Note that ordinarily you would use icons with your tabs, and so the second parameter to `setIndicator()` would be a reference to a drawable resource. This particular sample skips the icons.

## Visual Representation

This is what a TabHost and TabWidget look like in a few different Android versions and configurations, based upon the sample app shown above.

## WIDGET CATALOG: TABHOST AND TABWIDGET

---

*Figure 1055: Android 4.0.3*

# Widget Catalog: TimePicker

---

Just as [DatePicker](#) allows the user to pick a date, TimePicker allows the user to pick a time. This widget is a bit simpler to use, insofar as you do not have the option of the integrated CalendarView as you do with DatePicker. In other respects, TimePicker follows the patterns established by DatePicker.

Note that TimePicker only supports hours and minutes, not seconds or finer granularity.

## Key Usage Tips

With DatePicker, the act of supplying an `OnDateSetListener` also required you to supply the year/month/day to use as a starting point. TimePicker is more intelligently designed: setting the `OnTimeSetListener` is independent from adjusting the hour or minute.

As with DatePicker, TimePicker works well with Calendar and GregorianCalendar, in terms of setting and getting the hour/minute/second from the TimePicker and converting it into something you can use in your code.

There is [a bug](#) in which your `OnTimeSetListener` is not invoked when the user changes between AM and PM when viewing the TimePicker in 12-hour display mode.

## A Sample Usage

The sample project can be found in [WidgetCatalog/TimePicker](#).

## WIDGET CATALOG: TIMEPICKER

---

### Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:orientation="vertical"
    android:gravity="center_vertical">

    <TimePicker
        android:id="@+id/picker"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

</LinearLayout>
```

(from [WidgetCatalog/TimePicker/app/src/main/res/layout/main.xml](#))

### Activity:

```
package com.commonware.android.wc.timepick;

import android.app.Activity;
import android.os.Bundle;
import android.widget.TimePicker;
import android.widget.TimePicker.OnTimeChangedListener;
import android.widget.Toast;
import java.util.Calendar;

public class TimePickerDemoActivity extends Activity implements
    OnTimeChangedListener {
    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        TimePicker picker=(TimePicker)findViewById(R.id.picker);

        picker.setOnTimeChangedListener(this);
    }

    @Override
    public void onTimeChanged(TimePicker view, int hourOfDay, int minute) {
        Calendar then=Calendar.getInstance();

        then.set(Calendar.HOUR_OF_DAY, hourOfDay);
        then.set(Calendar.MINUTE, minute);
```

## WIDGET CATALOG: TIMEPICKER

---

```
then.set(Calendar.SECOND, 0);

Toast.makeText(this, then.getTime().toString(), Toast.LENGTH_SHORT)
    .show();
}
}
```

(from [WidgetCatalog/TimePicker/app/src/main/java/com/commonsware/android/wc/timepick/TimePickerDemoActivity.java](#))

## Visual Representation

*Figure 1058: Android 5.0*

## WIDGET CATALOG: TIMEPICKER

# Widget Catalog: ViewFlipper

---

A ViewFlipper behaves a bit like a FrameLayout that is set up such that only one child can be visible at a time. You can control which of those children is visible, either by index or via `showNext()/showPrevious()` methods to rotate between them.

You can also set up [animated effects](#) to control how a child leaves and the next one enters, such as applying a sliding effect.

And, you can set up ViewFlipper to automatically flip between children on a specified period, without further developer involvement. This, coupled with the animation, can be used for news tickers, ad banner rotations, or the like where light animations (e.g., fade out and fade in) can be used positively.

## Key Usage Tips

ViewFlipper can have as many children as needed (within memory constraints), though you will want at least two for it to be meaningful.

By default, the transition between children is an immediate “smash cut” — the old one vanishes and the new one appears instantaneously. You can call `setInAnimation()` and/or `setOutAnimation()` to supply [an Animation object or resource](#) to use for the transitions instead.

By default, the ViewFlipper will show its first child and stay there. You can manually flip children via `showNext()`, `showPrevious()`, and `setDisplayChild()`, the latter of which taking a position index of which child to display. You can also have automatic flipping, by one of two means:

1. In your layout, `android:flipInterval` will set up the amount of time to

- display each child before moving to the next, and `android:autoStart` will indicate if the automated flipping should begin immediately or not
2. In Java, `setFlipInterval()` serves the same role as `android:flipInterval`, and you can control when flipping is enabled via `startFlipping()` and `stopFlipping()`

## A Sample Usage

The sample project can be found in [WidgetCatalog/ViewFlipper](#).

Layout:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    >
    <ViewFlipper android:id="@+id/details"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        >
    </ViewFlipper>
</LinearLayout>
```

(from [WidgetCatalog/ViewFlipper/app/src/main/res/layout/main.xml](#))

Activity:

```
package com.commonware.android.flipper2;

import android.app.Activity;
import android.os.Bundle;
import android.view.ViewGroup;
import android.widget.Button;
import android.widget.ViewFlipper;

public class FlipperDemo2 extends Activity {
    static String[] items={"lorem", "ipsum", "dolor", "sit", "amet",
        "consectetuer", "adipiscing", "elit",
        "morbi", "vel", "ligula", "vitae",
        "arcu", "aliquet", "mollis", "etiam",
        "vel", "erat", "placerat", "ante",
        "porttitor", "sodales", "pellentesque",
        "augue", "purus"};
```

## WIDGET CATALOG: VIEWFLIPPER

---

```
ViewFlipper flipper;

@Override
public void onCreate(Bundle state) {
    super.onCreate(state);
    setContentView(R.layout.main);

    flipper=(ViewFlipper)findViewById(R.id.details);

    for (String item : items) {
        Button btn=new Button(this);

        btn.setText(item);

        flipper.addView(btn,
            new ViewGroup.LayoutParams(
                ViewGroup.LayoutParams.FILL_PARENT,
                ViewGroup.LayoutParams.FILL_PARENT));
    }

    flipper.setFlipInterval(2000);
    flipper.startFlipping();
}
}
```

(from [WidgetCatalog/ViewFlipper/app/src/main/java/com/commonsware/android/flipper2/FlipperDemo2.java](#))

## Visual Representation

There is no visual representation of a ViewFlipper itself, as it renders no pixels on its own. Rather, it simply shows the current child.

---

## **Trail: Device Catalog**

---

# Device Catalog: Chrome and Chrome OS

---

Ever since Android and Chrome were moved under the same executive within Google, rumors abounded that Android and Chrome OS would merge in one form or fashion.

In 2015, Google started down that path, offering the ability for developers to start packaging Android apps to run on Chrome OS. And — albeit via a different mechanism — some Chrome OS devices now offer the Play Store and users can install compatible apps from there.

The exact number of Chromebooks that have been sold is subject to some debate. One analyst pegged business (B2B) Chromebook sales in the first half of 2015 at [around 2 million](#), with an upbeat, pro-Chromebook spin. Another analyst indicated that total sales for Chromebooks in 2014 were [6 million](#), a tiny percentage of PC/laptop sales. In mid-2016, IDC estimated that Chromebook sales for the first quarter of 2016 were around 2 million, [exceeding the sales of Apple's line of Mac notebooks](#). But one analyst is [predicting 17 million Chromebooks to be sold in 2023](#), which suggests that growth will be modest.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book.

## How This Works

From the user's standpoint, Android apps appear alongside their Chrome OS counterparts. For example, the Play Store will be in their app launcher:

*Figure 1059: Chrome OS App Launcher/finder, As Initially Launched*

Android apps appear in floating windows, similar to their Chrome OS counterparts:

*Figure 1060: Chrome OS, Showing Amaze File Manager*

## Chrome OS Form Factors

The classic form factor for Chrome OS devices was the “Chromebook”. This is a notebook/netbook-style device, with a keyboard and touchpad. Many Chromebooks support touchscreens, and some Chromebooks have 180-degree hinges, allowing the screen to be folded over such that the Chromebook forms a chunky tablet.

Nowadays, there are other Chrome OS form factors that are getting attention:

- Some Chromebooks have detachable keyboards, where the screen can work on its own as a tablet
- Some Chrome OS tablets are available, basically working like a Chromebook without a supplied keyboard
- A variety of “Chromebox” devices are available, which are miniature desktops, where you provide your own monitor, keyboard, and mouse

As a result, Chrome OS really opens up the range of possible ways that the user can

interact with your app. In particular, not all Chrome OS devices offer touchscreens, as some Chromebooks and all Chromeboxes are limited to keyboard and mouse input. So not only do you need to consider how best to support Chrome OS overall, you need to consider how best to support keyboard/mouse-based user input. While Android can do a reasonable job of that “out of the box”, some amount of additional work may be needed before your app feels natural when the user is clicking with a mouse rather than tapping on a screen.

## Testing Your App on Chrome OS

For lightweight use, Google publishes a [Chrome OS emulator](#) that is integrated into the Android SDK emulator system used by Android Studio. As with the regular SDK emulator images, the Chrome OS emulator attempts to show you what your app will be like on a Chrome OS device. However, it will have a variety of gaps, particularly tied to hardware. Just as a developer should never ship an Android app based solely on testing in an Android emulator, a developer should never ship a Chrome OS Android app based solely on testing in the Chrome OS emulator.

For real testing, you will want to test on hardware, which is the focus of this section.

### Step #1: Get a Compatible Chrome OS Device

All Chrome OS devices shipped in 2017 and beyond are supposed to ship with Android support.

Select older devices will get Android support as well. [This page](#) lists the official status of Chrome OS for various older devices. Any device not listed there is unlikely to get Chrome OS, and even many of the “Planned” ones might drop off.

You will need a Google account to set up your Chrome OS device or the Chrome OS emulator.

### Step #2: Enable Android Apps

If you want to test your app in the Play Store, it may be already enabled for you, in which case you can just install your app and try it out.

If it is not already enabled, but the device is already shipping in production form with Android support, you may need to enable it in Chrome OS’s Settings app. You may also need to do this for the Chrome OS emulator. To do that:

## DEVICE CATALOG: CHROME AND CHROME OS

---

- In the lower-right corner of the Chrome OS desktop, click on the bar that shows the time, battery level, and your account picture:

*Figure 1061: Chrome OS Status Bar*

- You should then see a popup panel with status information and a few controls, akin to elements of the notification shade in Android:

*Figure 1062: Chrome OS Configuration Panel*

The exact look of this panel will vary by device and Chrome OS version.

- In that panel, tap on “Settings”

The exact look of the Settings window will *also* vary by device and Chrome OS version.

Towards the bottom of this Settings page, you should see an “Android Apps” or “Google Play Store” section:

Click the “Enable Android Apps to run on your Chromebook” checkbox or the “Enable Google Play Store on your Chromebook” checkbox, whichever one you have. At this point, you should gain access to the Play Store and be able to install apps from there.

Also, note the “App Settings” or “Manage your Android preferences” link below that checkbox. This will bring up the *Android* Settings application, which is separate and distinct from the Chrome OS Settings page that you are on. There is no icon for the Android Settings app in the regular Chrome OS app launcher; you have to know to come here to adjust the Android settings.

### Step #3: Switch the Device to the Dev Channel

Some of the devices listed on that Chrome OS/Android status page indicate that the status is “Stable Channel”. Such devices either ship with Android support or will get it with a regular Chrome OS update, and so the instructions in the preceding section should be sufficient for you to test a production app. Similarly, the Chrome OS emulator ships with Android support directly.

For devices whose status is “Beta Channel” or “Dev Channel”, you will need to switch your Chrome OS device to that channel. This works much like the “canary channel” for Android Studio releases, or the dev channel for Chrome/Chromium releases. It configures the device to pull from a different update source, one that pushes updates more aggressively than it does to normal users.

To do this:

- In the “Settings” page, click on the “About Chrome OS” link
- In the About dialog, click on “Check for and apply updates”, to make sure

## DEVICE CATALOG: CHROME AND CHROME OS

---

that you are on the latest stuff for your current channel:

*Figure 1064: Chrome OS About Screen*

- Once that is done (and you have returned to the About dialog after a reboot, if updates were needed), click the “Detailed build information” link, which brings up a bunch of details regarding your Chrome OS device:

*Figure 1065: Chrome OS Detailed Build Information Screen*

- Click on the “Change channel...” button in the Channel category, which brings up a dialog showing available channels:

*Figure 1066: Chrome OS Channel Options*

- Click on the radio button for your desired channel and accept the dialog

This should apply a new round of updates, pulled from your chosen channel, then require you to reboot the Chrome OS device.

### **Step #4: Enable Chrome OS Developer Mode**

Those steps are sufficient to allow you to download and run apps from the Play Store. For seeing if your already-shipping app works on Chrome OS, that may be sufficient.

Those steps are also sufficient for getting the Chrome OS emulator working — you should be ready to go from there, with Logcat access and everything else already set up.

However, on hardware, at this point you have no access to Logcat, and you have no means of running debug builds or otherwise testing anything *other* than your already-shipping app. For hardware, to access these things, you need to enable Chrome OS developer mode. There is no direct analogue for this in the Android

world. The closest match is enabling fastboot, perhaps as part of installing an Android developer preview ROM or some other custom ROM.

Unfortunately, the instructions for enabling developer mode are hardware-specific and arcane. Also note that doing this will factory-reset your Chrome OS device, so make sure there is nothing on the device that you need.

### Chromebooks

For Chromebooks, try this:

- Shut down the device normally.
- Then, hold down the **Esc** and **Refresh** keys, and while holding them down, press the power button to turn on the device. The **Refresh** key looks like a circular arrow and may be denoted as **F3** on your keyboard. This brings up a “recovery screen”.
- On the recovery screen, press **Ctrl-D**. This screen should prompt for confirmation, then reboot the device into developer mode.

### Chrome OS Tablets

For Chrome OS tablets — where you will not have a keyboard — do this instead:

- With the device powered on, press the volume-down, volume-up, and power buttons simultaneously
- When the screen turns off, release the buttons
- The screen should turn back on momentarily on its own — otherwise, press the power button
- If you boot back into Chrome OS, try the process again from the start
- In the Chrome OS recovery menu, press the volume-down button once to open a boot menu (e.g., “Show debug info”, “Power off”)
- Press both the volume-up and volume-down buttons simultaneously
- In the revised menu, use the volume buttons to highlight “Confirm Disabling OS Verification”, then press the power button
- Wait a while for Chrome OS to reboot a few times, factory reset your device, and enable developer mode

### Chromeboxes

For a Chromebox (desktop-style Chrome OS device), look for a “reset” or “recovery” pinhole in the case. If you have one:

- Power down the device as normal
- Using a paperclip, press the reset button while simultaneously pressing the power button
- Release the reset button after a second
- When you get to the OS recovery screen, press `Ctrl-D`, which should then take you to a confirmation screen
- When that confirmation screen appears, use the paperclip to again press the reset (“recovery”) button
- After a quick reboot, press `Ctrl-D` at the recovery screen
- Wait a while for Chrome OS to reboot a few times, factory reset your device, and enable developer mode

### Where You Go From Here

From this point forward, your device will be developer mode. However, on subsequent reboots, that recovery screen will always appear. There, you have three choices:

1. Wait 10-30 seconds, in which case the device will continue its boot into developer mode
2. Press `Ctrl-D` to skip the delay, if you have a recognized keyboard at this point (note: USB keyboards work, but probably not Bluetooth ones)
3. Use the volume buttons to navigate the menu and choose “Developer Options” > “Boot from Internal Disk”, on Chrome OS tablets (and possibly other Chrome OS devices)
4. Follow the instructions on the screen to leave developer mode and return to normal operation

### Step #5: Set Up the Android Environment

At this point, you will need to go through some standard steps for doing development in an Android environment, via the Android edition of the Settings app. You get to this via that “App Settings” or “Manage your Android preferences” link in the “Android Apps” (or “Google Play Store”) category of the Chrome OS Settings page.

There, you can:

- Go into “About” and tap seven times on the “Build number” entry to enable developer settings
- Go into “Developer options” and enable USB debugging (and anything else that you typically use)
- Go into “Security” and enable “Unknown sources”

Note that those options may already be enabled, once you enable “Developer options” via the seven-taps technique.

### **Step #6: Side-Load and Install Your App**

At this point, you can try out custom builds of your app, by installing them manually (a.k.a., “side-loading”).

Unfortunately, Chrome OS knows nothing about APK files, so you cannot use the Chrome OS Files app to install an APK file.

The simplest way to side-load apps is to have an Android app do it:

- a cloud storage client (e.g., Dropbox)
- an Android-native Web browser
- a file manager, to load an APK you got onto the device by some other means (e.g., Amaze File Manager)

As mentioned earlier, the Downloads folder in Chrome OS is shared with the same folder on external storage in Android. So, you can also copy an APK over via a USB flash drive, put it in Downloads using Chrome OS, then use a file manager to install it from Downloads.

### **Step #7: Get adb Working**

However, you still do not have access to Logcat, or any ability to use development tools like Android Studio to work on apps on the Chrome OS device (though the emulator will work at this point).

[Some devices support adb over USB](#). Most do not. Setting up adb access is possible but a bit complicated, based on the [official instructions](#).

**NOTE:** You will need a keyboard to complete this process. While most Chrome OS

devices have a keyboard, Chrome OS tablets might not. You will need to use your own keyboard (Bluetooth or USB), and you will want to get that set up and working before continuing.

### Step #7a: Configure the Chrome OS Device

Press `Ctrl-Alt-T` to open `crash`, a quasi-shell provided in Chrome OS. At that command prompt, run the `shell` command to get to `bash`, a full Linux-style shell.

Then, execute the following statements:

```
sudo crossystem dev_boot_signed_only=0
sudo /usr/libexec/debugd/helpers/dev_features_rootfs_verification
sudo reboot
```

This will reboot your Chrome OS device. If you run into errors running the `dev_features_rootfs_verification` command, try rebooting after the `crossystem`, then dropping back into the shell and running the `dev_features_rootfs_verification` command again.

Then, go back into `bash` via `crash`, and execute:

```
sudo /usr/libexec/debugd/helpers/dev_features_ssh
```

This enables an SSH daemon and presumably makes corresponding adjustments to the `iptables`-based firewall.

**NOTE:** You will need to execute this `dev_features_ssh` script after every reboot of your Chrome OS device. Whereas the other portions of this step persist after a reboot, this portion does not. However, after a firmware update, you may need to do all of these steps.

### Step #7b: Find Your Chrome OS IP Address

In the `bash` shell, you can use `ifconfig` to get details of your TCP/IP settings — `wlan0` probably has your IP address. However, this is mostly for people with Linux experience. Everyone else may prefer using the Chrome OS UI to determine the IP address.

Go into Settings (e.g., tap on the time/WiFi/battery/account bar in the lower-right, then tap the gear icon). Towards the top of the Settings page, there will be an

“Internet connection” section.

*Figure 1067: Chrome OS Settings, Internet Connection Section*

If you are using WiFi, tap on the “Wi-Fi network” item, then tap on the WiFi network that you are using. That should bring up a three-tab dialog with details about this network connection.

*Figure 1068: Chrome OS Settings, Internet Connection Dialog*

The middle tab — Network — will show your IP address:

*Figure 1069: Chrome OS Settings, Internet Connection Dialog, Network Tab*

Make note of this address.

### **Step #7c: Connect to Chrome OS for Development**

When you want to develop using the Chrome OS device as the target, execute `adb connect <IP>:22`, where `<IP>` is the same IP address that you used previously. Note that the official docs drop off the `connect` part, which does not work.

This should trigger the standard Android debugging authorization dialog, akin to what you see when you first try USB debugging on a phone or tablet. You will need to accept this dialog before continuing.

At this point, `adb devices` should show your connection, and you should be able to run apps on the Chrome OS device akin to how you do so for locally-connected devices, emulators, etc.

If the Chrome OS device goes to sleep, it will disable its WiFi connection. You will need to wake up the device and run `adb connect` again to be able to work with it from Android Studio.

If you reboot the Chrome OS device, you will need to agree once more to the Play Store terms of service and (try) to sign into the Play Store. The Play Store UI may appear to get stuck, with a never-ending progress bar. However, once you have gotten to that point, you should be able to use `adb connect` to re-connect to the Chrome OS device.

## Be Prepared To Be Wiped Out

Some dev channel updates will wipe out your Android environment, deleting all apps and files. Hence, do not store things on the test devices that you will regret losing. Also, you will need to re-do Step #4, and possibly Step #6, to re-establish a developer environment.

For example, in June 2017, Google started releasing an update to the Android environment that replaced Android 6.0 with Android 7.1.1. This required redoing some of the above steps, such as the seven-taps technique to enable “Developer options”. However, installed apps were unaffected.

## Compatibility and Your App

You may find that you go through Step #1 and Step #2 above — thereby enabling Android apps for the Chrome OS device — and find that your app is not available on the Play Store.

Or, perhaps you go through those steps, and *do* find that your app is on the Play Store... but you would prefer that it not be there.

## Trying to Get Onto Chrome OS

There is [a long list](#) of `<uses-feature>` elements that, if present in your manifest with the wrong values, will cause your app to not be distributed to Chrome OS devices.

For example, if you have a `<uses-feature>` element stating that you require `android.hardware.telephony` — that the device have telephony capability — your app might not be distributed to Chrome OS devices. You would need to relax this requirement.

Conversely, not all Chrome OS devices have touchscreens. Ideally, you test your app using a keyboard and mouse or trackpad and confirm that it works well without a

touchscreen. Then, add this to your manifest:

```
<uses-feature  
  android:name="android.hardware.touchscreen"  
  android:required="false" />
```

This advertises that you are willing to support non-touchscreen environments and therefore can be installed on non-touchscreen Chrome OS devices. The default is that you need a touchscreen; you have to specifically opt out of that requirement to reach the full range of Chrome OS devices.

### Trying to Stay Away From Chrome OS

Perhaps you are not in position to fully support Chrome OS. In that case, you could add one of the proscribed `<uses-feature>` elements to block distribution to Chrome OS devices. However, this approach will also block your app from other devices that happen to lack that hardware feature.

Sometimes, that is really what you want. So, for example, if you need USB host mode, you should have a `<uses-feature>` element for `android.hardware.usb.host`, so that any device that lacks USB host mode support will not install your app.

There is no manifest setting, though, that will block your app from Chrome OS devices and not affect any other device type. Google wants you to support Chrome OS and does not make it easy to opt out without also losing access to other hardware.

### Your App on Chrome OS

On the surface, Android apps will perceive Chrome OS as just another Android device. Other than the manifest entries listed above, there is nothing that you absolutely need to do in your app to run on Chrome OS.

That being said, Chrome OS is going to be somewhat different than a normal Android device. Those differences may be something that you want to try to take into account.

### Environment

Chrome OS is presently running API Level 25 (Android 7.1), though it contains some

elements of Android 8.0's multi-window functionality.

We can tell what the API level is by logging `Build.VERSION.SDK_INT`, along with other values, as seen in the [Introspection/EnvDump](#) sample app. This has a single activity, designed to collect a bunch of device data and dump it to Logcat:

```
package com.commonware.android.envdump;

import android.app.Activity;
import android.app.ActivityManager;
import android.content.pm.FeatureInfo;
import android.content.res.Configuration;
import android.os.Build;
import android.os.Bundle;
import android.util.DisplayMetrics;
import android.util.Log;
import android.widget.TextView;

public class MainActivity extends Activity {
    private static final String TAG="EnvDump";
    private final StringBuilder buf=new StringBuilder();

    @Override
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.main);

        logBuildValues();
        logSystemFeatures();
        logActivityManagerStuff();
        logDisplayMetrics();
        logConfiguration();

        TextView tv=(TextView)findViewById(R.id.text);

        tv.setText(buf.toString());
    }

    private void logBuildValues() {
        log("Build.VERSION.SDK_INT="+Build.VERSION.SDK_INT);

        log("Build.BRAND="+Build.BRAND);
        log("Build.DEVICE="+Build.DEVICE);
        log("Build.DISPLAY="+Build.DISPLAY);
        log("Build.HARDWARE="+Build.HARDWARE);
        log("Build.ID="+Build.ID);
        log("Build.MANUFACTURER="+Build.MANUFACTURER);
    }
}
```

## DEVICE CATALOG: CHROME AND CHROME OS

---

```
log("Build.MODEL="+Build.MODEL);
log("Build.PRODUCT="+Build.PRODUCT);

if (Build.VERSION.SDK_INT>=Build.VERSION_CODES.LOLLIPOP) {
    StringBuilder buf=new StringBuilder();

    for (String abi : Build.SUPPORTED_ABIS) {
        if (buf.length() > 0) {
            buf.append(',');
        }

        buf.append(abi);
    }

    log("Build.SUPPORTED_APIS=" + buf);
}
else {
    log("Build.CPU_API="+Build.CPU_API);
    log("Build.CPU_API2="+Build.CPU_API2);
}
}

private void logSystemFeatures() {
    for (FeatureInfo feature :
        getPackageManager().getSystemAvailableFeatures()) {
        log("System Feature: "+feature.name);
    }
}

private void logActivityManagerStuff() {
    ActivityManager mgr=(ActivityManager) getSystemService(ACTIVITY_SERVICE);

    log("heap limit="+mgr.getMemoryClass());
    log("large-heap limit="+mgr.getLargeMemoryClass());
}

private void logDisplayMetrics() {
    DisplayMetrics dm=new DisplayMetrics();

    getWindowManager().getDefaultDisplay().getMetrics(dm);

    log("DisplayMetrics.densityDpi="+dm.densityDpi);
    log("DisplayMetrics.xdpi="+dm.xdpi);
    log("DisplayMetrics.ydpi="+dm.ydpi);
    log("DisplayMetrics.scaledDensity="+dm.scaledDensity);
    log("DisplayMetrics.widthPixels="+dm.widthPixels);
    log("DisplayMetrics.heightPixels="+dm.heightPixels);
}
```

```
private void logConfiguration() {
    Configuration cfg=getResources().getConfiguration();

    log("Configuration.densityDpi="+cfg.densityDpi);
    log("Configuration.fontScale="+cfg.fontScale);
    log("Configuration.hardKeyboardHidden="+cfg.hardKeyboardHidden);
    log("Configuration.keyboard="+cfg.keyboard);
    log("Configuration.keyboardHidden="+cfg.keyboardHidden);
    log("Configuration.locale="+cfg.locale);
    log("Configuration.mcc="+cfg.mcc);
    log("Configuration.mnc="+cfg.mnc);
    log("Configuration.navigation="+cfg.navigation);
    log("Configuration.navigationHidden="+cfg.navigationHidden);
    log("Configuration.orientation="+cfg.orientation);
    log("Configuration.screenHeightDp="+cfg.screenHeightDp);
    log("Configuration.screenWidthDp="+cfg.screenWidthDp);
    log("Configuration.touchscreen="+cfg.touchscreen);
}

private void log(String msg) {
    Log.d(TAG, msg);
    buf.append(msg);
    buf.append('\n');
}
}
```

(from [Introspection/EnvDump/app/src/main/java/com/commonsware/android/envdump/MainActivity.java](#))

The following sections outline some settings of note to Android developers.

### System Features

Most Chrome OS devices should advertise support for the following system features (e.g., `PackageManager` and `hasSystemFeature()`):

- `android.hardware.audio.output`
- `android.hardware.bluetooth`
- `android.hardware.bluetooth_le`
- `android.hardware.faketouch`
- `android.hardware.location`
- `android.hardware.location.network`
- `android.hardware.screen.landscape`
- `android.hardware.screen.portrait`
- `android.hardware.type.pc`

## DEVICE CATALOG: CHROME AND CHROME OS

---

- `android.hardware.wifi`
- `android.software.backup`
- `android.software.freeform_window_management`
- `android.software.print`
- `android.software.voice_recognizers`
- `android.software.webview`
- `com.google.android.feature.GOOGLE_BUILD`
- `com.google.android.feature.GOOGLE_EXPERIENCE`
- `org.chromium.arc`
- `org.chromium.arc.device_management`

Portable Chrome OS devices (not Chromeboxes) should also support:

- `android.hardware.camera`
- `android.hardware.camera.any`
- `android.hardware.camera.front`
- `android.hardware.microphone`
- `android.hardware.sensor.accelerometer`
- `android.hardware.touchscreen`
- `android.hardware.touchscreen.multitouch`
- `android.hardware.touchscreen.multitouch.distinct`
- `android.hardware.touchscreen.multitouch.jazzhand`

Others will be hit-or-miss:

- `android.hardware.audio.low_latency`
- `android.hardware.audio.pro`
- `android.hardware.opengles.aep`
- `android.hardware.sensor.gyroscope`
- `android.hardware.vulkan.level`
- `android.hardware.vulkan.version`
- `android.software.midi`

### NDK Binaries

The `Build.SUPPORTED_APIS` value indicates what CPU architectures are supported for NDK binaries:

## DEVICE CATALOG: CHROME AND CHROME OS

---

Device	Value
Acer Chromebook R11 C738T	x86,armeabi-v7a,armeabi
Acer Chromebook Tab 10 D651N-K9WT	armeabi-v7a,armeabi
HP Chromebox x2	x86_64,x86,armeabi-v7a,armeabi

If the device has an x86 CPU, that will be listed. All Chrome OS devices appear to support ARM NDK binaries, presumably through libhoudini or similar technology.

### Other Values

The heap limit seems to be generally set to 192MB with the large-heap limit set to 512MB, though they might be lower on very low-end Chrome OS devices.

For devices with their own screens, `DisplayMetrics` and `Configuration` should report appropriate values for screen density, based on the screen size and resolution. Chromeboxes may be less reliable, in large part because they do not know the physical size of the display.

### Screen Size and Orientation

The user can toggle between three different states for your activity's window:

- regular landscape
- regular portrait
- full-screen (akin to pressing the “maximize” button on a desktop OS)

Your activity will undergo configuration changes, as you might expect, when the user switches between these.

### Lifecycle Events

Lifecycle events behave more or less as you might expect:

- While your app's window is the focused window, your app is in the normal running state (i.e., `onResume()` has been called).
- If another window takes over the focus, but your window is still visible, your activity in that window will be paused, then resumed if the window regains

the focus.

- If the user minimizes your window, you will be called with `onPause()` and `onStop()`, as your activity is no longer visible.
- If the user switches between the floating-window and the full-screen sizes, your activity will undergo a configuration change and, by default, be destroyed and recreated. Note that there seems to be a bug, as your activity goes through a spurious extra pause/resume cycle before settling down.

Chrome OS remembers your last window size (floating or full-screen). On the next launch of your app, you will return to that size.

One oddity: if another window takes over the full screen, even though your window is no longer visible, your activity is not stopped. It is paused — that will happen once the window loses the focus. The only time you are stopped is if the window is minimized (or the activity is being destroyed).

### Touchscreen and Keyboard Input

As noted earlier, not all Chrome OS devices have touchscreens. Chromebooks will have trackpads; Chromeboxes will rely on mice. And pretty much all Chrome OS devices will have full keyboards.

For touchscreen-equipped Chromebooks, the full suite of gestures should be available to developers. However, for devices lacking a touchscreen, using Android apps becomes... interesting.

For example, to scroll a `ListView` or `RecyclerView`, you cannot simply drag a scrollbar, because there *is* no scrollbar. Even if you putter around and arrange for scrollbars to become visible, they do not respond to touch input. Instead, users need to know to press a meta key (e.g., `Ctrl`) while “swiping” the list with the mouse to be able to scroll. This is somewhat easier with a trackpad, as a two-finger swipe will scroll the list.

However, you really need to consider [optimizing your app for keyboards and mice](#), rather than assuming touchscreens or trackpads with Chrome OS.

### Storage

Internal and external storage both work fine on Chrome OS. However, outside of debugging tools, you do not have any ability to work with the files themselves as a

developer, much like how you are limited in accessing files that are part of an emulator image.

The exception, as noted earlier in this chapter, is the Downloads directory on external storage. This is also available to Chrome OS users via the Files app.

Note that the Storage Access Framework works, for things like ACTION\_OPEN\_DOCUMENT and ACTION\_CREATE\_DOCUMENT. You do not have access to removable storage, though, even through the Storage Access Framework.

### Notifications

Notifications work... at least to some extent.

Their look and feel gets normalized to Chrome OS styling, so they will not look like standard Android notifications:

*Figure 1070: Android Notification with Two Actions on Chrome OS*

Also, actions seem to automatically cancel the Notification, even if that is not what you intended.

### Internet Access

On the whole, HTTP access “just works”, whether you are using WebView or HttpURLConnection.

SSL also “just works”, subject to the same sorts of limitations that you see in normal Android development, such as what root certificates are available for validating the SSL certificate for a particular `https://` URL.

The author has not tested lower-level socket operations at this time.

## Miscellaneous Oddities

Theme.Translucent.NoTitleBar does not work, insofar as you will still wind up with a window in Chrome OS, one with an all-black background:

Figure 1071: “Invisible” Activity on Chrome OS

[Android apps cannot work with external displays](#) plugged into the Chrome OS device, using Presentation or similar techniques. It is possible that this is because some Chrome OS devices do not have their own built-in displays (e.g., ChromeBoxes) and rely on an external display as their primary display.

## Distribution Options

Obviously, with the right manifest settings, you can distribute your app via the Play Store.

However, at the present time, sideloading is not an option, except for people who have gone through the steps outlined in this chapter to turn their Chrome OS devices into developer machines. Few users will be doing this. Hence, the Play Store is your only practical distribution channel right now.

## Getting Help

The official support point is the #AndroidAppsOnChromeOS hashtag on [the Android developer Google+ community](#). There is an equivalent [tag on Stack Overflow](#), which briefly was an official support point before being replaced by Google+.

If you encounter bugs, you are supposed to be able to file issues [through this link](#) on the Chromium issue tracker.

# Device Catalog: BlackBerry

---

BlackBerry — formerly Research In Motion — has been a long-standing player in mobile devices. Their BlackBerry two-way pagers and early smartphones help set the stage for Android, iOS, and those that followed.

BlackBerry and Android have had an interesting history.

In 2011, BlackBerry leapt into the tablet arena with the Playbook, and the 2.0 version of the Playbook OS supported running carefully repackaged Android applications.

While the Playbook itself had modest success, the ability to distribute Android applications to BlackBerry devices continued with their BlackBerry 10 (BB10) platform, where they offered several phones that could run Android apps. Originally, these had to be specially packaged for BB10, and that is still a common course today. However, in concert with offering the Amazon AppStore for Android on BB10, BlackBerry made it possible to install ordinary APK files as well. Many developers have enjoyed success distributing their app through BlackBerry World (the primary distribution channel for apps to BlackBerry products) and Amazon Appstore for Android.

In 2015, BlackBerry continued their Android push with the BlackBerry Priv, a device designed from the outset to run Android. The Priv comes with a full suite of BlackBerry-related software, including the legendary BlackBerry Messenger (BBM). However, much of that software — including BBM itself — is available on the Play Store for ordinary Android devices. In general, from the standpoint of an Android app developer, the Priv is no different than an Android device from any other major manufacturer. The Priv is even part of the Google Play ecosystem and comes with the Play Store and Google Play Services.

Putting the Priv aside, though, getting your app going on BB10 is a bit more of an

adventure. This chapter will describe a bit about what is involved in getting your Android app to BB10 devices.

## I Thought BlackBerry Had Their Own OS?

They do.

However, current versions of that OS — this chapter was last updated when version 10.3 was the latest shipping version — contain an Android runtime environment. BlackBerry OS can run Android apps alongside apps written natively for BlackBerry OS or running on other runtimes (e.g., Adobe AIR). This gives developers a wide range of ways to get their app onto modern BlackBerry devices. However, it does mean that our apps may have somewhat less direct access to hardware, as there is another layer between us and that hardware.

## What Else Is Different?

At its core, BlackBerry is a device manufacturer, no different than any other manufacturer that you may have dealt with previously. The biggest difference is BlackBerry's ability to run Android applications that you prepare for their devices.

That being said, the world of BlackBerry is a *bit* different than what you may be used to.

### Hardware

BlackBerry makes phones with a variety of capabilities, much as do other manufacturers. You should be writing your apps to support a range of device characteristics, such as screen size and density. That will help you with BlackBerry support, just as it helps you with support for other manufacturers' devices.

Note, though, that BlackBerry has some history which will affect their device designs, and your apps by extension. Notably, BlackBerry has been renowned for their hardware keyboards. While not all BlackBerry devices today have such keyboards, it is likely that BlackBerry will ship keyboard-equipped devices for some time to come.

This has three impacts upon you as a developer:

1. Do not assume that the user is using a soft keyboard. Usually, this is not a

- problem from a programming standpoint, though you may wish to take it into account in documentation.
2. Do not assume that the user always uses the touchscreen to navigate. Some BlackBerry users may use the hardware keyboard for navigation. This is particularly true for users who gravitate towards hardware keyboards for accessibility reasons. Your app should support [proper focus](#) to allow it to be navigated without accessing the touchscreen, to the greatest extent possible.
  3. BlackBerry keyboards often have not been “slider” keyboards (i.e., ones that might slide under the display when not in use). Rather, they are always available, below the screen. This will often result in somewhat smaller screen sizes, and odd aspect ratios, compared to what you are used to. There simply is not enough room for a large touchscreen *and* an always-available physical keyboard without having an excessively large device. The BlackBerry Q10, for example, has a 720x720 resolution screen, and most Android developers do not encounter square screen resolutions. You will need to take this into account, but only in cases where such an aspect ratio might cause you problems (e.g., full-screen image backgrounds).

### BlackBerry OS 10.3

Beyond the hardware, the BlackBerry OS — and the Android runtime environment that executes our Android apps — puts some limits on what we can do in our apps. Of note:

- BlackBerry OS 10.3’s Android environment uses Android 4.3 (API Level 18), so apps that have an `android:minSdkVersion` higher than that will not be eligible to run on 10.2 devices.
- Some classes will be non-functional, particularly those related to telephony capabilities. You cannot use `SmsManager`, for example.
- Some types of apps will not work well, because the Android runtime runs alongside other non-Android apps on the hardware. Replacement home screen implementations, for example, are unlikely to work. Similarly, background apps that display a UI (e.g., Facebook “chatheads”-style popups) using `SYSTEM_ALERT_WINDOW` are unlikely to work.
- App widgets are not supported. So long as the app widget is a non-essential feature of your app, this should not be a problem — after all, the user does not *have* to use your app widget on any Android device. However, if the *sole purpose* of your app is to provide an app widget, such an app will not be useful on BlackBerry.
- Not all connectivity is surfaced in the Android runtime from the underlying

hardware. For example, WiFiDirect and direct USB access are all unavailable.

### Navigation

Like most Android tablets, BlackBerry devices offer little in the way of physical or off-screen navigation buttons. For example, there is no BACK button. However, a navigation bar will contain a BACK soft button for users. If your app takes over the full screen, this bar will not be there all the time, but a swipe down from the top of the screen should expose it.

Similarly, your menu will not be accessed via a MENU key, but rather via a downward swipe to expose the menu. This also means that any special MENU-button logic of yours may not work, if you are using the MENU button for things other than displaying the action bar overflow or other form of options menu.

### Nothing Googly

As with other devices cited in this book, the BlackBerry series of devices lack support for Google's proprietary apps. For app developers, this means that you lack access to Google Play Services and the various APIs exposed by it, such as [Maps V2](#) and [Google Cloud Messaging](#).

BlackBerry does offer its replacement for GCM, in the form of the [BlackBerry Push Service](#). However, for maps, they steer you towards using [geo: Intent structure and startActivity\(\)](#).

If you are dependent upon other APIs offered by Google Play Services (e.g., [LocationClient](#)), you will need to reconsider your use of those APIs if you wish to ship on devices that are outside the Google ecosystem.

### Package Name Length

The BlackBerry Android runtime appears to only support package names of 29 characters or less. The build tools will fail if your package name is longer than 29 characters.

Note that this should only pertain to the “application ID” role of a package name, not the “hey, where does R.java get generated?” role of the package name. Hence, it should be possible to replace the application ID of your app via a [product flavor](#), to give yourself a shorter identifier while not breaking your source code references to

resources.

## What Are We Making?

This might seem like an odd question. After all, the point of this chapter is to make an Android application that can run on BlackBerry devices.

Up until early 2014, that meant you had one option: write a BAR.

A BAR (BlackBerry ARchive, presumably) is a repackaged version of an Android APK, designed to be distributed by BlackBerry and installed on BlackBerry devices. Most of [the tooling supplied by BlackBerry](#) surrounds this process of validating that an APK should abide by BlackBerry's requirements and converting that APK into a BAR.

Starting with BlackBerry OS 10.2.1, though, BlackBerry device users can download and install an APK directly. That APK still needs to work within the confines of the BlackBerry Android runtime and must avoid things that will not work there (e.g., replacement home screens). But the user is no longer reliant upon the developer going ahead and creating a BAR file.

So, what you are creating depends a bit on how you want to distribute the app:

- If you wish to distribute via BlackBerry world, you will need to repackage your APK as a BAR file
- If you wish to distribute through Amazon Appstore for Android, or if you wish to self-distribute, you can still ship an APK, though you may wish to use some of BlackBerry's tools to help ensure that your APK will be compatible

## Getting Your Development Environment Established

By and large, developing an app to run on the BlackBerry OS Android runtime is the same as is developing an app to run on any other Android environment. You have your standard choices of IDEs and other development tools, the ability to use third-party libraries, and so forth.

Where things start to differ is in testing, where BlackBerry OS ships a [Simulator](#) that fills a role similar to that of the Android emulator. To use the Simulator, you will

need to package your app into a BAR file, and BlackBerry provides tools to assist you in that process as well.

## Checking and Repackaging Your App

There are two basic technical steps for preparing your app for distribution through [the BlackBerry World market](#).

The first is to validate that your app does indeed stick to APIs that are supported by the BlackBerry Android runtime. This helps prevent apps from appearing on BlackBerry World that are guaranteed to fail.

The second is to convert the APK into a BAR file. BAR files are used for all of the BlackBerry OS runtimes, including ones like Adobe AIR. Your BAR will contain the same stuff that is in your APK, plus some additional metadata, in a format shared by all of the other runtimes, for interpretation and use by the BlackBerry OS. Again, if you are not planning on distributing through BlackBerry world, you will not need to worry about a BAR file.

## Android Studio Plugin

BlackBerry is distributing [an Android Studio plugin](#) to help with preparing Android apps for BlackBerry. Note, though, that this is an *Android Studio* plugin, not a Gradle plugin. On the plus side, this gives you new BlackBerry-related options in the Android Studio UI. However, since Android Studio evolves frequently, there is a decent chance that the BlackBerry plugin will not work on some newer Android Studio builds, until BlackBerry catches up.

This plugin includes:

- an adb proxy that allows Android Studio to work with BlackBerry devices and running simulators
- a UI for obtaining a “device debug token”, required to allow you to test your apps on BlackBerry devices
- package an APK as a BAR

## Standalone GUIs

You also have the option for doing BlackBerry-related chores from [standalone GUIs](#), independent of any IDE.

Basically, both IDE plugins simply provide menu options and toolbar buttons for launching the standalone GUIs from within the IDE. If you are not using Android Studio, those GUIs are available independently that you can run like any other desktop development tool.

### **BlackBerry 10 Simulator**

BlackBerry distributes VMWare images that embody a BlackBerry 10 Simulator. You can use these with VMWare Player (Windows and Linux) or VMWare Fusion (macOS), versions 3.1 or higher.

The Simulator fills a role similar to that of the standard Android emulator, allowing you to test your apps for BlackBerry OS without necessarily having a Blackberry OS 10 device, or for testing scenarios that are difficult to test with actual hardware.

In particular, the Simulator offers a wide range of simulated input and output, including:

- Simulated sensor input for the accelerometer and ambient light sensor
- Using a development machine's Bluetooth adapter for testing Bluetooth
- Simulated NFC tags

In addition, the Simulator supports some of the same types of simulated input that you see with the Android emulator, such as simulated GPS fixes and simulated incoming phone calls.

The VMWare image will have its own IP address, which you can obtain from the Simulator running in the image. You can then deploy your BAR to it using the `adb` proxy, which you can launch from your IDE or the standalone GUI.

### **Developing on Hardware**

A BlackBerry OS 10 device can run either signed or unsigned BAR files. Unsigned BAR files, though, require a one-time upload of a “debug token”, the creation of which requires the same credentials as you would use to sign the BAR in the first place.

### **How Does Distribution Work?**

As with any environment where the Play Store is not available, developers have to

determine how best to get their apps to the users of BlackBerry devices.

As with most non-Play Store ecosystems, there is the official solution... and then there are the other solutions.

### **BlackBerry World**

BlackBerry's own "market" is BlackBerry World. This supports native BlackBerry apps, plus those for runtimes like the Android runtime. So long as your app is packaged as a BAR, it should be able to be released through BlackBerry World, much like how you distribute an APK through the Play Store.

BlackBerry World is a curated marketplace, meaning that BlackBerry staff will review your app submissions and may reject them if they violate requirements or other terms.

Beyond that, BlackBerry World has most of the standard capabilities that you would expect from an app market, such as paid apps, in-app purchases, multiple billing options (PayPal and carrier billing), control for distribution to various countries and mobile carriers, etc.

### **Amazon Appstore for Android**

However, many Android developers will probably elect to distribute through Amazon Appstore for Android, now that it ships on new BlackBerry devices.

Partly, it is for improved reach: by distributing through Amazon's channel, you reach the Kindle Fire and Fire TV series of devices, plus any other Android devices that happen to have the Amazon Appstore for Android installed.

Partly, you can distribute in the form of an APK, rather than having to mess around with registering for BlackBerry World, creating BAR files, and the like.

### **Alternatives**

Starting with BlackBerry OS 10.2.1, you can distribute APK files through your Web site or similar means, and BlackBerry users can download and install them. However, nothing is done to validate that the apps you download will work on BlackBerry OS's Android runtime, as they may use APIs that are not available.

Also note that the BlackBerry OS settings have an equivalent to the Android "allow

## DEVICE CATALOG: BLACKBERRY

---

apps from other sources” setting that must be enabled for such installation to occur.

As an example, you can install the [F-Droid “market” app](#) to download free and open source Android apps to a BlackBerry OS device. How many of the apps distributed through F-Droid will work on BlackBerry OS, besides F-Droid itself, is unknown.

# Device Catalog: Android TV

---

Google not only offers the Chromecast, but also offers Android TV as a way to get content “into the living room”. Android TV devices — whether they be set-top boxes or are integrated into televisions directly — run Android apps directly, unlike Chromecast. Android TV, therefore, is a competitor to devices like [Amazon’s Fire TV](#).

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Having read the chapter on [“ten-foot” user experiences](#) is also a good idea.

## Hey, Wait a Minute... I Thought the Name Was “Google TV”?

You can be forgiven for any confusion over the names.

Google TV was Google’s initial attempt to get content onto televisions. Debuting in 2011, Google TV has some of the same characteristics as does Android TV:

- It ran Android apps directly (at the time, on Android 3.1)
- It could be a dedicated set-top box, integrated into other sorts of media players (e.g., Blu-Ray), or integrated into televisions

However, Google TV did not prove all that popular.

In 2014, Google announced that they were no longer supporting app development for Google TV, much to the consternation of the ~17 people still using Google TV

devices.

That being said, designing an app for Android TV resembles designing an app for Google TV or for any other [“ten-foot” user experience](#). Hence, design guidance that you may run across for Google TV may have some tips that are still relevant for Android TV and other TV-centric Android environments.

## Some Android TV Hardware

Android TV debuted in 2014. However, as of the end of 2014, there were a total of two Android TV device models... both available from Google. While other manufacturers had announced plans regarding Android TV, none were available at the time of this writing.

### ADT-1

When Google TV was announced, there was a similar lack of hardware. To help ensure that there were TV-capable apps at the time of a wider Google TV rollout, Google offered free developer devices to various firms and solo developers.

## DEVICE CATALOG: ANDROID TV

---

Google did the same thing with Android TV, where they offered a free ADT-1 device to qualified registrants. While deliveries of the ADT-1 were spread out over a few months, they generally arrived significantly in advance of production Android TV hardware.

*Figure 1072: ADT-1 Developer Android TV Device*

## Nexus Player

The first production-grade Android TV device is Google's own Nexus Player. As with the ADT-1, the Nexus Player has an HDMI port for connecting to a TV (or projector, monitor, etc.). It also has its own remote control and power adapter.

Both the ADT-1 and the Nexus Player are presently running Android 5.0.

## What Features and Configurations Does It Use?

Android has built into the SDK a fair bit of device flexibility. Most of this comes in the form of configurations (things that affect resources) and features (other stuff). If your application can handle a range of configurations and features, or can advertise that they need certain configurations or features, they can handle Android TV or arrange to not be available for Android TV on the Play Store.

## Screen Size and Density

Android TV devices are always categorized as xlarge screen size.

Densities, however, are a bit more complicated.

Android TV is for use with HDTV, whether Android TV is integrated into the television or it comes as an external set-top box. There are two predominant HDTV resolutions, known as 720p (1280x720) and 1080p (1920x1080). A 1080p television will be categorized as an xhdpi density device. A 720p television will be categorized as a tvdpi device. tvdpi is for devices around 213dpi, in between mdpi and hdpi. In practice, you might elect to skip tvdpi for your drawable resources, allowing Android to resample your mdpi, hdpi, or xhdpi drawables as needed.

### Input Devices

Android TV will not normally be navigated using a touchscreen. Instead, the normal form of input will be a D-pad remote. Developers will need to ensure that their apps are navigable this way.

### Other Hardware

Android TV has no sensors, no camera, no microphone, and no telephony features. As such, any application requiring such features will not run on Android TV and will not even show up in the Play Store for such devices.

Bear in mind that some of these will be driven by permissions. If you ask for the SEND\_SMS permission, Android will assume you need android.hardware.telephony unless you specifically state otherwise, via a <uses-feature> element for android.hardware.telephony with android:required="false".

## What Is Really Different?

Beyond the features and configurations, there are other things about Android TV that will depart from what you might expect for an Android environment, due to the nature of the TV set-top box platform and the Android implementation upon it.

### Overscan

Since Android TV typically uses a television for its primary output, overscan can be an issue. Addressing overscan is covered as part of [the chapter on the “10 foot UI”](#).

### Ethernet

While Android TV devices will generally be connected to the Internet, it may not be via WiFi. Since Android TV devices generally are not portable, some will have Ethernet jacks, and hence some users will elect to wire in their Android TV as opposed to using WiFi.

The upshot is that you should not assume that `WifiManager` will necessarily give you useful results. Also, `ConnectivityManager` should report wired Ethernet as `TYPE_ETHERNET`, added in API Level 13, when you call methods like `getActiveNetworkInfo()`.

### Location

Generally speaking, Android TV devices will tend not to move, earthquakes and large dogs notwithstanding.

As such, Android TV devices do not have GPS receivers. Rather, location is determined in an approximate fashion via address-based lookups, using a postal code. Hence, asking Android for a GPS fix on a Android TV device will be ineffective.

However, since users of Android TV devices tend not to be moving much at the time, it is a bit more likely than normal that they will want information about some location other than where they are. If your app is exclusively tied to providing information about their current location, you may wish to consider how you could extend your app to help users get information about other places that they may be interested in.

### Media Keys

Android TV devices are usually manipulated by remote controls. Some of these remotes will have lots of buttons, such as media-specific buttons for play, pause, etc.

The `KeyEvent` class has had support for some media buttons since API Level 3, mostly for use with wired headsets. API Level 11 added a bunch more media buttons. Your Android TV application may wish to respond to these, via `onKeyDown()` in a `View` or `Activity`.

In particular, an Android TV application should not be using on-screen controls for play, pause, etc., as they take up screen space that probably could be put to better

use. Rather, use layouts that offer such controls for touchscreen devices (e.g., phones and tablets) but rely on the media buttons for non-touchscreen devices.

## Getting Your Development Environment Established

Android TV emulator images are available in the SDK Manager for Android 5.0 and above:

Figure 1074: Android TV Emulator Images in SDK Manager

## DEVICE CATALOG: ANDROID TV

Your AVD Manager can then help you set up TV emulator images, for rather large theoretical screen sizes:

Figure 1075: Android TV Hardware Profiles in AVD Manager

The rest of the emulator setup is the same as you would have for phone or tablet emulators.

The emulator even has “leanback” UI characteristics, rather than a standard Android emulator home screen:

*Figure 1076: Android TV 1080p Emulator, As Initially Launched*

### Connecting to Physical Devices

The ADT-1 and Nexus Player have micro-USB ports for debugging purposes. This, though, requires that your player and your development machine be within USB cable reach of one another. The author of this book uses [a pico projector](#) to be able to work with TV-native devices (Android TV, Fire TV, etc.) or external displays (HDMI, MHL, etc.).

To enable an Android TV for debugging, you will need to enable developer options, much like you do for a mobile device (click on the build number 7 times in the Setting's About screen). Then, in the “Developer Options” screen, you can go into Debugging and elect to enable “USB debugging”.

### How Does Distribution Work?

Your app probably falls in one of three buckets: you want it on Android TV (along with other devices), it *only* supports Android TV, or it will not work on Android TV. Whichever of those buckets best fits your device will determine the manifest

settings you will want to ensure that the Play Store (and perhaps other third-party markets in the future) will honor your request.

### Getting Your App on Android TV

The first criterion for getting your app visible to Android TV devices on the Play Store is to add a `<uses-feature>` element to your manifest, indicating that you do not require the `android.hardware.touchscreen` feature:

```
<uses-feature android:name="android.hardware.touchscreen" android:required="false"/>
```

By default, Android assumes that you need a touchscreen, and so without this clarification in your manifest, you will not appear in the Play Store.

Also, add similar `<uses-feature>` elements for any hardware that you might like to use where available but do not absolutely need, particularly hardware that Android TV may lack. The [documentation](#) outlines the features that Android TV devices will likely lack.

You need to have an activity that has an `<intent-filter>` for `ACTION_MAIN` and `CATEGORY_LEANBACK_LAUNCHER`. This will be your launcher activity on Android TV devices, instead of your `ACTION_MAIN/CATEGORY_HOME` activity. Of course, you are welcome to have one activity serving as the launcher for both types of devices, if you can come up with one with a solid presentation for both mobile devices and TVs.

In addition, do not have any activities with `android:screenOrientation` set to `portrait`, as Android TV devices always display in landscape

### Supporting Only Android TV

If your app only supports Android TV, in addition to the above requirements, you should also add one more `<uses-feature>` element to your manifest:

```
<uses-feature android:name="android.hardware.type.television"
android:required="true"/>
```

This will filter you out of the Market for all non-TV environments.

### Avoiding Android TV

If your app specifically is untested on Android TV, you need to have something in

## DEVICE CATALOG: ANDROID TV

---

the manifest that will keep you *off* Android TV devices' views of the Play Store. The easiest is to say that you need a touchscreen:

```
<uses-feature android:name="android.hardware.touchscreen" android:required="true"/>
```

Note that `true` is the default setting for this particular feature, though putting it in your manifest to remind you that you do require a touchscreen is a good idea.

# Device Catalog: Amazon Fire TV and Fire TV Stick

---

Amazon has joined the TV set-top box fray with the Fire TV and, more recently, the Fire TV Stick. These devices are powered by FireOS, Amazon's variation of Android. And, as with other Amazon FireOS devices, like the Kindle Fire tablet series, you can write apps that run on Fire TV and the Fire TV Stick.

This chapter will review these devices from a developer's standpoint, to help you create apps for this platform.

## Prerequisites

Understanding this chapter requires that you have read the core chapters of this book. Reading [the chapter on the ten-foot user interface](#) is also recommended, either before or after this chapter.

Also, some sections will make reference to [Android TV](#) as a point of reference.

## Introducing the Fire TV Devices

As of August 2017, there were two major flavors of Fire TV device: the original Fire TV, and the Fire TV Stick. Both run FireOS, Amazon's name for their derivative of Android.

### Fire TV

As with most Android-powered set-top boxes, the original Fire TV is small and is

## DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

---

designed to connect with your television (or monitor, or projector, or whatever) via HDMI:

## DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

---

It comes with a small wireless remote designed for basic controls, akin to what you might find on other streaming boxes or similar entertainment devices:

*Figure 1078: Fire TV Remote*

## DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

---

Optionally, you can get a gaming controller that works with the Fire TV. While the regular controller is fine for navigating the Fire TV UI, the gaming controller will be more suitable for more serious game play:

*Figure 1079: Fire TV Gaming Controller*

## DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

---

While the Fire TV is powered by Android, the on-device UI is definitely targeting a set-top box environment. The home screen is dominated by media, coming from whatever supported streaming content providers you have set up with the Fire TV (e.g., Amazon Prime):

Figure 1080: Fire TV Home Screen

## DEVICE CATALOG: AMAZON FIRE TV AND FIRE TV STICK

---

The “Apps” section shows a mix of what is installed and what is available for you to download, with “cloud” icons indicating apps that are available but are not presently installed:

*Figure 1081: Fire TV “Your Apps Library”*

## Fire TV Stick

The Fire TV Stick is physically substantially smaller than is the Fire TV, designed to more closely resemble the Chromecast:

*Figure 1082: Fire TV Stick, with Remote, AC Adapter, and HDMI Extension Cable*

The user experience of a Fire TV Stick, though, is largely the same as with a regular Fire TV. Both run the same FireOS environment, with the same sort of browsing metaphor.

The biggest difference is that the Fire TV Stick is less powerful (less RAM, weaker CPU and GPU). For conventional apps, this is unlikely to be a problem, as the Fire TV Stick is as powerful as many standard Android phones and tablets. Games, however, are more likely to stress the hardware.

From the user's standpoint, the Fire TV Stick's big selling point is its low price, about a third of what the Fire TV costs.

## What Features and Configurations Do They Use?

The Fire TV device family behaves a bit like a “mashup” of other TV-centric devices (Android TV, OUYA, etc.) and the Kindle Fire series of tablets.

### Screen Size, Density, and Orientation

One area where the Fire TV series differs from pretty much anything that came before it comes with the behavior of the screen. As with other TV-centric devices like Android TV, the assumption is that the screen is locked to landscape. However, beyond that, Amazon has struck out on its own in terms of screen characteristics.

With Android TV, the screen size and density are based on the type of display that the Android TV box is plugged into.

With the Fire TV devices, your code deals with a rendering surface of 1920x1080 pixels, regardless of whether the device is plugged into a 1080p screen or something else (720p, 4K, etc.). The density is always treated as `-xhdpi`, giving you a resolution of 960dp by 540dp, and a `-large` screen size. The hardware will handle scaling the output down (or, in theory, up for 4K) as needed.

On the plus side, this simplifies app development, as you do not need to deal with different screen capabilities yourself. However, it remains to be seen how well the Fire TV will scale the output.

Also, note that Fire TV devices do not address [overscan](#) when they apply this scaling. Hence, you will want to keep your content away from the edges of the available space, only showing your background there, in case those edges are not visible on some televisions.

As with any TV-centric device, since the screen is locked to landscape, activities that are locked to portrait (e.g., `android:screenOrientation="portrait"` in the manifest for the activity) will behave oddly. If you are targeting devices like the Fire TV series, be sure to allow your activities to work in portrait *or* landscape, not just portrait.

### Input Devices

As noted earlier, Fire TV devices ship with a simple remote control, designed for media management (play, pause, etc.) and basic D-pad navigation. Some users may also elect to pick up a Fire TV game controller or use other Bluetooth game

controllers. Technical details for working with these input devices can be found [later in this chapter](#).

Conversely, Fire TV devices do not have touchscreens. You cannot assume that the user can tap on random portions of the screen. Instead, you need to make sure that your app is completely reachable via a D-pad. This is described in greater detail in [the chapter on the “ten-foot UI”](#).

### Hardware Features

As a set-top box, Fire TV devices lack a lot of hardware that you normally associate with phones and tablets, such as:

- GPS
- camera
- microphone
- sensors
- telephony

The microphone is actually a bit complicated. The Fire TV remote has a microphone and a button to activate it. The Fire TV Stick remote does not have a microphone. There is a Fire TV Remote app available on [the Play Store](#) and Amazon Appstore for Android that offers microphone input as well. However, all these microphones are just for Fire TV voice search. There is no means for developers to use these for arbitrary audio input, the way that a microphone on a phone or a tablet can.

### What Is Really Different?

Some things are “really different” simply because the output screen is TV-sized, not phone-sized or tablet-sized. See [the chapter on the “ten-foot UI”](#) for more about this.

Some things are “really different” in the same way that they are “really different” for the Kindle Fire series, such as having nothing “Googly”, like Maps V2 or anything else from Play Services.

The biggest additional “really different” item is the limitation on where apps can come from, which is discussed [later in this chapter](#) as part of the overall app distribution options for Fire TV devices.

Note that Fire TV devices have their own way of representing notifications. A standard Android Notification will not appear anywhere on a Fire TV device. Instead, you will need to support the Fire TV series' own [notifications API](#). While their API is modeled after Android's Notification and NotificationManager, they do have their own classes, and the results are more reminiscent of Toasts and Dialogs.

Also note that Fire TV devices do not display an Android action bar, representing those items in a pop-up menu triggered by the MENU button of the Fire TV remote control.

## Casting and Fire TV

The success of Chromecast means that TV-connected Android devices will tend to be compared to Chromecast, particularly in terms of how apps on phones and tablets can work with the TV-connected device.

At the time of this writing, Amazon has not shipped anything for Fire TV that would enable apps [using `MediaRouteActionProvider` and `RemotePlaybackClient`](#) to work with Fire TV. In principle, Amazon or somebody else could implement a `MediaRouteProvider` and distribute that as an app that goes on ordinary Android phones and tablets, where that `MediaRouteProvider` enables media routes pointing to a connected Fire TV. The `MediaRouteProvider` would forward requests from the phone or tablet to the Fire TV, which would be displayed by some app on the Fire TV.

Amazon more formally supports [the “Discovery and Launch” \(DIAL\) protocol](#) with Fire TV. DIAL allows an app on a phone or tablet to launch apps on Fire TV. Unfortunately, documentation for this is lacking at the present time.

Also, the Fire TV series can serve as a Miracast endpoint. In Settings > Display & Sounds, you will find an option to “enable display mirroring”. This turns on Miracast support, allowing mobile devices to mirror their screen content via the Fire TV to the connected television, projector, or monitor. This also works with Android's [Presentation support](#), allowing you to direct separate content to the Fire TV's “mirror” than what you show on the device's own screen.

## Getting Your Development Environment Established

Developing for the Fire TV series, as with developing for the Kindle Fire series, is accomplished using an actual Fire TV or Fire TV Stick device.

The primary thing notably different about testing your app on a Fire TV device is that it does not use a micro USB cable for the `adb` connection, the way that you may be used to from testing with most Android hardware. If you can find a suitable USB cable to bridge between your development machine and the Fire TV, reportedly you [can use USB debugging](#). Otherwise, you can use `adb` over the network.

To set this up, you must first enable ADB debugging, much like you do with other Android devices. On a Fire TV device, this is in Settings > System > Developer Options:

*Figure 1083: Fire TV Developer Settings*

You will then need the IP address of your Fire TV device. Most likely the easiest way for you to find that is via the Settings > System > About > Network screen:

*Figure 1084: Fire TV Network Settings*

You can then run `adb connect` (followed by the IP address) at a command prompt to make the connection. You may need to stop and restart `adb` before doing this, via `adb kill-server` and `adb start-server`.

At this point, if all is set up properly, `adb devices` will list the Fire TV device's IP address, and the Fire TV device will be accessible from your IDEs and other development tools.

Note that this `adb` setup will persist until `adb` is next restarted, even if the Fire TV device is powered down. You can use `adb disconnect` (followed by the IP address) to break the connection if you no longer need it.

## Working with the Remote and Controller

Your Fire TV users will be interacting with their Fire TV using the supplied remote, the Fire TV gaming controller, or other controllers.

## Wireless Remote

Mostly, the wireless remote offers buttons that you should be handling already, assuming you are [implementing a ten-foot UI](#) or are otherwise correctly handling [focus management and accessibility](#). BACK and the D-pad buttons will work on the Fire TV much as you would expect.

The Fire TV device remote has a MENU button, which will bring up an old-style Android options menu. Your simple action bar items, particularly those in the overflow, will appear in this menu without issue. Most likely you will want to skip the action bar on your Fire TV apps, though, which means that action views, action providers, and the like will need to be replaced with alternatives.

The remote also offers play/pause, rewind, and fast-forward buttons that map to their corresponding Android KeyEvent types (e.g., KEYCODE\_MEDIA\_PLAY\_PAUSE). You can watch for these events in `onKeyDown()` of your activity to be able to respond to them.

Note that you do not have the ability to intercept home or voice search button presses on the wireless remote. And, the Fire TV Stick's remote does not offer the voice search button.

## Gaming Controller

The wireless remote's input options are purely buttons. The Fire TV series gaming controller, like most such controllers, are designed for more “analog” input, where the force you apply to a stick might trigger slightly different behavior in a game.

As such, the gaming controller support in Android and FireOS takes a two-tier approach, with primary and secondary ways of handling events. If your code consumes the primary event, the secondary event is not triggered. The idea is that fairly “vanilla” apps might pay attention to the secondary events, as they tend to be more in common with the events you might get from the wireless remote or non-Fire TV devices. But apps that are more game-centric might pay attention to the primary events instead.

For analog inputs — the left and right sticks and the D-pad — the primary event input is supplied as `MotionEvent` objects, which you can pick up in methods like `onGenericMotionEvent()` in a `View`. Secondary event input comes in the form of standard D-pad events. So, an ordinary app will automatically support the sticks and D-pad, simply by accepting D-pad input.

Some buttons also take the two-tier approach. The A button (bottom one in the button cluster on the upper-right side of the controller) can be picked up either as a `KEYCODE_BUTTON_A` KeyEvent (primary) or a `KEYCODE_DPAD_CENTER` KeyEvent (secondary). The B button (right one) maps to `KEYCODE_BUTTON_B` (primary) and `KEYCODE_BACK` (secondary).

Other buttons just fire simple KeyEvents (e.g., left shoulder is `KEYCODE_BUTTON_L1`), while the two triggers just use MotionEvents (`AXIS_BRAKE` on the left, `AXIS_GAS` on the right).

Amazon's Fire TV site has [full details of the options and how to use them](#).

## How Does Distribution Work?

Like the Kindle Fire, Fire TV devices lack the Play Store. If you want your app to be available to Fire TV device users, you will need to explore other ways of promoting and delivering the app.

The principal — and nearly exclusive — way to get apps onto a Fire TV device is by listing them in the Amazon AppStore for Android.

However, for ordinary users, that is the *only* option. Most Android devices — including the Kindle Fire series — allow the user to download apps from Web sites, if they have the appropriate option checked in Settings. The Fire TV lacks this setting, and therefore ordinary users cannot download an app to the Fire TV from third-party app stores.

“Sideloading” an app using `adb` works, though this is usually only viable for developers or serious power users. Such apps will not appear in the home screen launcher and must be launched instead via Settings > Applications.

## Getting Help

Amazon maintains [a set of documentation](#) related to Fire TV device development, along with [a set of forums](#) for asking Amazon-specific development questions regarding the Fire TV device series or their various SDKs.

# Device Catalog: Samsung DeX

---

There has been a long-standing goal in some circles to allow Android devices to serve as desktop or notebook replacements, through the use of accessories. One of the first forays in this area was [2011's Motorola Atrix](#), which offered a notebook-style docking station that allowed the Android device to be used with the dock's keyboard and 11.5" display.

In recent years, Samsung has made a renewed push in this area, in the form of Samsung DeX.

## DEVICE CATALOG: SAMSUNG DEX

---

The original 2017 DeX was a desktop docking station for the Galaxy S8/S8+ that provided power, an Ethernet jack, USB ports, and an HDMI port.

*Figure 1085: Samsung DeX, Front Top Showing Device Connector*

*Figure 1086: Samsung DeX, Rear Showing Ports*

## DEVICE CATALOG: SAMSUNG DEX

When docked, the Samsung phone would switch into a “DeX” mode that offers a freeform multiwindow experience. In this mode, the touchscreen is turned off, and the user navigates the windows using a keyboard and mouse (USB or Bluetooth), as with a traditional desktop OS.

*Figure 1087: DeX Mode, Showing Freeform-Style Windows*

---

## DEVICE CATALOG: SAMSUNG DEX

---

In 2018, Samsung introduced the DeX Pad, which not only offers power, USB ports, and an HDMI port, but also allows the Samsung phone to serve as a touchpad for navigating the DeX environment:

*Figure 1088: DeX Pad, Connected to an LCD Panel*

The DeX Pad and original DeX dock now work with a variety of high-end Samsung devices, including:

- Galaxy S8 and S8+
- Galaxy S9 and S9+
- Galaxy Note 8

On the whole, developers do not seem to be concerning themselves too much with DeX — for example, as of early August 2018, there were exactly [two questions on Stack Overflow in the samsung-dex tag](#). That being said, the DeX is an interesting demonstration of Android’s freeform multi-window mode. Plus, it is yet another environment that puts [keyboards and mice](#) “front and center” for users and, by extension, app developers.

## DeX Screen Modes

The user has two choices when docking their device in the DeX: screen mirroring mode and DeX mode.

### Screen Mirroring

What Samsung describes as “screen mirroring” mode is pretty much what you would expect from an Android device connected to an HDMI display. By default, the contents of the touchscreen are mirrored on the HDMI display. And, if you use things [like Presentation](#), you can display separate content on the HDMI display from what is shown on the touchscreen.

However, this mode may not be very popular, for one simple reason: the device is docked in the DeX in portrait mode. This means that the content shown on the HDMI device, by default, is in portrait mode. While you could lock your activity to landscape mode, so its [Presentation](#) appears in landscape, then the activity is in the wrong orientation on the touchscreen.

Also, screen mirroring mode does not seem to be available with the DeX Pad.

### DeX Mode

More often than not, if people are bothering to put their devices in a DeX, it is to use Dex mode, with freeform-style windows.

This uses Android’s official freeform [multi-window support](#). In theory, the experience should be somewhat reminiscent of how Android apps behave on [Chrome OS](#), which also uses freeform multi-window.

Activities that are not resizable will appear in portrait mode by default:

*Figure 1089: Non-Resizable Activity on DeX in Portrait*

There is an icon in the title bar that allows the user to rotate the window to landscape:

*Figure 1090: Non-Resizable Activity on DeX in Landscape*

Activities that are resizable — the `<activity>` or `<application>` explicitly has `android:resizeableActivity="true"` — can be resized by using a mouse and dragging the window edges, as with a traditional desktop operating system.

All windows, resizable or not, can be minimized, putting them in an application dock at the bottom of the DeX screen.

## Other App Impacts

While the screen, keyboard, and mouse are the primary changes that app developers will face when thinking about the DeX, there are other issues to take into account and opportunities to consider.

## Configuration and State Changes

The strangest part of life in a DeX dock comes in the various state changes that your app can undergo. Sometimes, these are part of standard Android configuration changes. Sometimes, these are more distinctive to the DeX.

### Moving In and Out of DeX

Here, we have many scenarios:

- A device is placed into the dock, and the device goes into DeX mode
- A device is placed into the dock, and the device goes into screen-mirroring mode
- A docked device is switched from DeX mode to screen-mirroring mode
- A device in DeX mode is removed from the dock
- A device in screen-mirroring mode is removed from the dock

(in theory, there should also be “a docked device is switched from screen-mirroring mode to DeX mode”, but there does not appear to be an option for this)

The default behavior in all of these is:

- If your app is in the foreground at the time of the state change, your app will be killed and restarted
- If your app is in the background at the time of the state change, your app is killed and not restarted

Going into Dex mode will have your foreground app appear in the “system tray”, which serves the same role in desktop mode as the overview screen does in standard Android. Clicking your app’s icon will bring up your window... starting your app along the way.

The reason why Samsung does this by default is that switching to and from DeX mode is a fairly major change to your environment, specifically amounting to these configuration changes:

- density
- orientation
- screenLayout
- screenSize
- smallestScreenSize
- uiMode

In addition, there is a fairly substantial resolution change (e.g., 2960x1440 to whatever the HDMI display supports).

If you can handle all of those changes without harming the user experience, add this

<meta-data> element as a child of the <application> element in your manifest:

```
<meta-data android:name="com.samsung.android.keepalive.density" android:value="true"/>
```

With that element in place, when the user enters or exits DeX mode (e.g., puts the device into or removes it from the dock), your app is supposed to be left alone. In practice, this does not appear to work.

### Resource Set Qualifiers

DeX honors the `-desk` UI mode resource set qualifier. If you want a different layout for a desktop-style UI compared to a mobile-style UI, you could have dedicated layout resources in `res/layout-desk/` or related resource sets.

### Networking

If the DeX dock is plugged into Ethernet, the device will switch to Ethernet connectivity when it is placed into the dock by default, though the user can configure this behavior.

If your app assumes that the Internet connection is via WiFi or mobile data, this is yet another scenario in which it might not be, to go along with [Android TV](#), Android Things, and various miscellaneous Android devices offering Ethernet ports (e.g., Jide's Remix Mini PC).

Also, this means that your connectivity may change when the device is put into or removed from the dock... but, as noted above, your app may be killed anyway.

Note that the DeX Pad does not offer an Ethernet port.

### USB

In addition to working with keyboards and mice, the USB ports on the DeX dock are standard USB hosts. So, for example, the user can plug in a flash drive and browse that drive's contents.

In principle, the user can plug in any sort of USB device, and so long as the Samsung device has the appropriate drivers (or your app uses the USB APIs), the device should work.

Note that the USB ports are USB 2.0, not 3.0 or higher. Also note that they are classic

Type A connectors, even though the power supply input comes from a Type C connector.

### Debugging Interface

The DeX dock requires that you power it through a high-power USB port. A standard 500mA USB port will be insufficient. The problem is that most high-power USB ports do not also support data, and in those situations you cannot use the USB cable for debugging.

Fortunately, what is often called “WiFi debugging” works, though technically it may be occurring over Ethernet, if the DeX dock has an Ethernet cable plugged in and the device is using it.

To use this style of debugging:

- With the Samsung device out of the DeX dock, plug it into your development machine as normal
- Run `adb tcpip 5555` from the command line, to turn on WiFi debugging
- Unplug the device from the USB cable and place it into the DeX dock
- Use Settings > About device > Status or some other means to identify the IP address of the device, bearing in mind that this might be either Ethernet or WiFi
- On your development machine, run `adb connect ...`, where ... is the IP address of the device

You should get a message showing that you are connected, `adb` devices should show the connection, and Android Studio should be able to work with the Samsung device.

Use `adb disconnect ...`, where ... is the IP address of the device, to drop this debugging connection.

### Screenshots

When the docked device is in DeX mode, you cannot take screenshots through normal means (e.g., Android Studio, `adb shell screencap`). As with Android Things, you *can* record screencasts. And, given a short screencast, you can extract a frame to use as a screenshot, such as via the command-line `ffmpeg` utility.

However, the screencast (and any resulting screenshot) may be off, depending on

the screen resolution of whatever HDMI display you have plugged the DeX dock into. The screencast will record at 2960x1440 resolution, which is the resolution of the touchscreen. However, it is very likely that your HDMI display cannot show that, and so the DeX dock will display at something like 1080p (1920x1080). The screencast will be at 2960x1440 resolution, with the external display's content shown in the upper-left corner, and black pixels filling the rest of the 2960x1440 frame.

For screenshots, you can crop the raw screenshot to get the portion that you need, dropping out the extraneous black bands:

```
adb shell screenrecord --verbose /sdcard/screen.mp4 --time-limit 1
adb pull /sdcard/screen.mp4
adb shell rm /sdcard/screen.mp4
ffmpeg -ss 0 -i screen.mp4 -t 1 -s 2960x1440 -f image2 temp.png
convert temp.png -crop 1920x1080+0+0 +repage result.png
```

Here, we use `adb`, `ffmpeg`, and ImageMagick's `convert` tools to record a one-second screencast, clip a 2960x1440 frame from it (to `temp.png`), then crop the upper-left 1920x1080 pixels to form the final screenshot (`result.png`).

For screencasts, there should be an equivalent way of having `ffmpeg` crop all of the frames to the desired resolution. The proof of this is left as an exercise for the reader.

## Detecting DeX

Ideally, your app does not care whether it is running on a device in a DeX dock or not. In theory, if you do everything correctly in general (particularly [multi-window support](#)), then “it just works”.

If you run into some DeX-specific quirk that you need to work around, you cannot use traditional `Build` values like `Build.PRODUCT`, because those reflect the *device*, not the dock.

Instead, Samsung apparently extended the `android.content.res.Configuration` class to have a DeX-specific field on DeX-capable devices:

```
private boolean iCanHazDeX() {
    boolean result=false;
    Configuration config=getResources().getConfiguration();

    try {
        Class clsConfig=config.getClass();
```

```
    if (clsConfig.getField("SEM_DESKTOP_MODE_ENABLED").getInt(clsConfig)
        ==clsConfig.getField("semDesktopModeEnabled").getInt(config)) {
        result=true;
    }
}
catch(Exception e) {
    // guess not!
}

return(result);
}
```

### Drag-and-Drop

The Samsung DeX environment supports cross-window [drag-and-drop](#) within one app. It also supports cross-app drag-and-drop, so one app can advertise as a drop target and other apps can allow drag-and-drop to the first app.

### For More Information

Samsung has several pages devoted to developer documentation for the DeX, including:

- Instructions for [modifying your app](#) to be more DeX-friendly
- Information for [testing your app without a DeX](#)
- A [FAQ](#)

---

## **Trail: Appendices**

---

# Appendix A: CWAC Libraries

---

CommonsWare — the publisher of this book — has also published a series of open source libraries, collectively named the CommonsWare Android Components (CWAC). If you have read through the book, you will have seen many of these libraries.

This appendix lists all of the CWAC libraries. If the library is covered elsewhere in the book, the appendix links you to that coverage. Those that are not covered elsewhere will be described in this appendix, to accompany the online documentation found at the library's GitHub repository.

## cwac-document

[The cwac-document repository](#) holds a fork of `DocumentFile` that:

- Supports non-document `Uri` values
- Supports `Uri` values on older devices
- Offers convenience methods for working with the content (e.g., `copyTo()`, `copyFrom()`, `openInputStream()`, `openOutputStream()`)

## cwac-layouts

[The cwac-layouts repository](#) contains a series of custom containers and related views.

The current contents of this library — `AspectLockedFrameLayout`, `MirroringFrameLayout`, and `kin` — are covered in [the chapter on custom views](#).

## cwac-netsecurity

The [cwac-netsecurity repository](#) contains a backport of Android 7.0's network security configuration subsystem, to make it easier for you to work with SSL-enabled Web sites. This is covered in greater detail in [the chapter on SSL](#).

## cwac-presentation

The [cwac-presentation repository](#) contains code in support of the Presentation system, for sending alternative content to an external display, independent of the device's primary screen.

All of the classes in this repository are covered in [the chapter on the Presentation system](#).

## cwac-provider

The [cwac-provider repository](#) contains StreamProvider, a riff on Google's FileProvider, offering a “canned” implementation of a ContentProvider that can serve files from a variety of sources, such as assets and raw resources from your project.

This is discussed briefly in [the chapter on ContentProvider implementations](#).

## cwac-saferoom

The [cwac-saferoom repository](#) contains code that bridges the gap between SQLCipher for Android and the Room database layer from the Architecture Components. This library is covered in depth in [“Android's Architecture Components”](#).

## cwac-security

The [cwac-security repository](#) contains code to help app developers help their users defend against attacks. At the moment, this contains the PermissionUtils class, used to help determine if a custom permission was defined by another app before yours was installed. This is discussed in [the chapter on advanced permission techniques](#).

# Appendix B: Android 8.0

---

In 2017, Google released Android 8.0, code-named “Oreo”, followed shortly by Android 8.1. Android 8.1 changed very little in the Android SDK for most developers, but Android 8.0 had some significant changes.

This appendix outlines those changes. In some cases, it serves as pointers to where this material is covered elsewhere in the book. For smaller topics, details of the change appear directly in the appendix.

## The War on Background Processing, Continued

Starting with Android 6.0, Google has been trying to limit the impacts of background processing on the device, particularly with respect to battery usage and RAM consumption. Since most background work tends to be invisible to the user, users therefore will tend to blame Android for problems that stem from the users’ chosen apps as much, if not more than, from Android itself. As a result, in Android 6.0, Doze mode and app standby were added to curtail periodic work, and Android 7.0 started putting limitations on some types of system broadcasts.

Android 8.0 is furthering Google’s objectives in this area, eliminating significant types of background processing.

### Background Service Limitations

For apps that have a `targetSdkVersion` over 25 and are running on Android 8.0, background services are limited. After a short period of time — as low as one minute — any such services will be stopped and you will be unable to start new ones.

Also, even if your `targetSdkVersion` is 25 or lower, you might *still* have these

limitations applied to your app. If your app appears on the Battery screen in Settings — indicating that it is using above-average power — the user will have the ability to apply these limitations to your app from there.

This is explored in greater detail in [the chapter on services](#).

### WakeLock Limitations

If your service holds a WakeLock, and that WakeLock is not released when the service is stopped, Android will forcibly release the WakeLock.

Leaking an acquired WakeLock was a bad practice, and since your process can be terminated quickly at any point once you no longer have a running service, developers should have been assuming all along that a WakeLock should be released when a service is stopped. Android 8.0 is merely being a bit more aggressive about dealing with these leaks.

### Manifest-Registered Broadcast Limitations

For apps that have a `targetSdkVersion` over 25, another limitation comes into play: you cannot receive implicit broadcasts via a manifest-registered receiver.

In other words, if you have a receiver in the manifest that has an `<intent-filter>`, there is a very good chance that it will no longer receive broadcasts.

### What Is Affected

Implicit broadcasts are broadcasts using an implicit Intent, one that just has an action string (and possibly a `Uri`, categories, or MIME type), but does not identify a specific `BroadcastReceiver`. Explicit broadcasts use an explicit Intent, one that does identify a specific `BroadcastReceiver`.

The Android 8.0 limitation affects:

- Implicit broadcasts sent by the system, except for [a handful of whitelisted ones](#)
- Implicit broadcasts sent by apps, intended to be delivered to other apps
- Implicit broadcasts sent by apps, intended to be delivered only to themselves, based off of old programming patterns that used system broadcasts instead of an in-process [event bus](#) (e.g., `LocalBroadcastManager`,

greenrobot's EventBus)

If your `targetSdkVersion` is 25 or lower, though, your app will not be affected. Also, if you happen to be the one sending the broadcast, and you are requiring a signature-level permission for that broadcast, [your app will not be affected, apparently](#).

Also note that various Intent actions documented on the Intent class are actually used with explicit broadcasts, not implicit ones. For example, the `ACTION_PACKAGE_REPLACED` broadcast is an implicit one, but `ACTION_MY_PACKAGE_REPLACED` is an explicit one, as that one is only sent to the app that was just upgraded.

The [Intents/PackageLogger](#) sample project is a very simple app, dominated by an `OnPackageChangeReceiver` that registers for a few Intent actions in the manifest:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonware.android.sysevents.pkg"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <application
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:allowBackup="false">
    <receiver android:name=".OnPackageChangeReceiver">
      <intent-filter>
        <action android:name="android.intent.action.PACKAGE_ADDED" />
        <action android:name="android.intent.action.PACKAGE_REPLACED" />
        <action android:name="android.intent.action.PACKAGE_REMOVED" />

        <data android:scheme="package" />
      </intent-filter>
    </receiver>

    <activity
      android:name="BootstrapActivity"
      android:theme="@android:style/Theme.Translucent.NoTitleBar">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>
```

## APPENDIX B: ANDROID 8.0

---

```
</application>
</manifest>
```

(from [Intents/PackageLogger/app/src/main/AndroidManifest.xml](#))

...and logs their occurrences to Logcat:

```
package com.commonware.android.sysevents.pkg;

import android.content.BroadcastReceiver;
import android.content.Context;
import android.content.Intent;
import android.util.Log;

public class OnPackageChangeReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Log.d(getClass().getSimpleName(),
            intent.getAction()+" for "+intent.getData().toString());
    }
}
```

(from [Intents/PackageLogger/app/src/main/java/com/commonware/android/sysevents/pkg/OnPackageChangeReceiver.java](#))

On Android 7.1 and lower devices, this app dutifully logs those events (e.g., when the user installs an app). On Android 8.0, instead, the receiver does not get control, and the following message is recorded to Logcat:

```
W/BroadcastQueue: Background execution not allowed: receiving Intent {
act=android.intent.action.PACKAGE_REMOVED dat=package:com.commonware.cwac.cam2.demo
flg=0x4000010 (has extras) } to
com.commonware.android.sysevents.pkg/.OnPackageChangeReceiver
```

### Why This Ban Was Added

You might think that the concern was tied to the battery, as this seems like another front in the ongoing “war on background processing” that has been going on since Doze mode was introduced in Android 6.0.

As it turns out, battery is of secondary importance. The real reason is process churn.

Quoting [a Google engineer](#):

To help understand what is going on, I need to clarify that the purpose of

this change is *not* directly related to battery use, but rather to address long-standing issues we have had in the platform where devices that are under memory pressure can get in to bad thrashing states. Very often these states are due to broadcasts: some broadcast or broadcasts are being sent relatively frequently, which a lot of applications are listening to through their manifest (so need to be launched to receive it), but there is not enough RAM to keep all of those app processes *<sic>* in cache, so the system ends up continually thrashing through processes each time the broadcast is sent.

This is an issue regardless of whether the device is currently plugged in to power. In fact, this can more frequently be an issue on Android TV devices (which are always plugged in to power) because they tend to be fairly tight on RAM!

### Workarounds for Senders

If you are using broadcasts for communicating between app components within a single process, switch to using `LocalBroadcastManager`.

If you are using broadcasts for communicating between app components within multiple processes of your own, switch to using explicit broadcasts.

Beyond that, if you are sending implicit broadcasts, you can break through the ban by finding the receivers and sending individual explicit broadcasts instead.

This, and the overall ban, is illustrated in the [Intents/Fanout](#) sample project. As with some of the event bus samples, this app has a UI that consists of a transcript-mode `ListView`, to which we will append events as they arrive. In this case, the events are broadcasts that we are sending, using different approaches for sending them based on an overflow menu item.

If the user taps the “Explicit” overflow menu item, we create an explicit `Intent` identifying our `TestReceiver` and send that using `sendBroadcast()`. This works, even for an app like this one that has `targetSdkVersion '0'`, and the broadcast shows up in the list.

If the user taps the “Implicit” overflow menu item, we create an implicit `Intent` tied to the action string used by the `<intent-filter>` of the `TestReceiver`:

```
<?xml version="1.0" encoding="utf-8"?>
```

## APPENDIX B: ANDROID 8.0

---

```
<manifest package="com.commonware.android.broadcast.fanout"
  xmlns:android="http://schemas.android.com/apk/res/android"
  android:versionCode="1"
  android:versionName="1.0">

  <application
    android:allowBackup="false"
    android:icon="@drawable/ic_launcher"
    android:label="@string/app_name"
    android:theme="@style/AppTheme">
    <activity
      android:name=".MainActivity"
      android:label="@string/app_name">
      <intent-filter>
        <action android:name="android.intent.action.MAIN" />

        <category android:name="android.intent.category.LAUNCHER" />
      </intent-filter>
    </activity>

    <receiver android:name=".TestReceiver">
      <intent-filter>
        <action android:name="${applicationId}.TEST" />
      </intent-filter>
    </receiver>
  </application>
</manifest>
```

(from [Intents/Fanout/app/src/main/AndroidManifest.xml](#))

However, sending that implicit Intent fails, with this warning message showing up in Logcat:

```
W/BroadcastQueue: Background execution not allowed: receiving Intent {
  act=com.commonware.android.broadcast.fanout.TEST flg=0x10 (has extras) } to
  com.commonware.android.broadcast.fanout/.TestReceiver
```

If the user taps the “Fanout” overflow menu item, we create the same implicit Intent as before (though we tuck an extra onto it to identify it as the “fanout” case instead of the regular implicit case). And this time, it works. The reason why it works is that rather than sending one implicit broadcast, we send N explicit broadcasts, one for each registered receiver:

```
private static void sendImplicitBroadcast(Context ctxt, Intent i) {
  PackageManager pm=ctxt.getPackageManager();
```

## APPENDIX B: ANDROID 8.0

---

```
List<ResolveInfo> matches=pm.queryBroadcastReceivers(i, 0);

for (ResolveInfo resolveInfo : matches) {
    Intent explicit=new Intent(i);
    ComponentName cn=
        new ComponentName(resolveInfo.activityInfo.applicationInfo.packageName,
            resolveInfo.activityInfo.name);

    explicit.setComponent(cn);
    ctxt.sendBroadcast(explicit);
}
}
```

(from [Intents/Fanout/app/src/main/java/com/commonsware/android/broadcast/fanout/MainActivity.java](#))

Unfortunately, this brings back the process churn, and if lots of developers do this, there may be reprisals from Google. You might try introducing some delay between the broadcasts, inside the loop, to spread out the impact. However, this starts to get tricky if you spread it out over more than a few seconds (e.g., do you now need an `IntentService` and a `WakeLock`? what if your process is terminated before the broadcast loop is completed?).

Google [recommends](#) that you have the user agree to which of these components should receive the broadcast, perhaps through some sort of `MultiSelectListPreference`. Then, instead of broadcasting to all that match your implicit broadcast, you only broadcast to those that the user has chosen. How practical this is will depend on the app and the desired user experience.

### Workarounds for Receivers

If you are receiving system-sent implicit broadcasts (e.g., `ACTION_PACKAGE_ADDED`), keep your `targetSdkVersion` at 25 or lower, until we figure out better workarounds that (hopefully) do not involve polling.

If you are receiving implicit broadcasts from another app, ask the developer of that app what the plan is for Android 8.0. Perhaps they will use the above technique, or perhaps they will switch to some alternative communications pattern.

### Background Location Limitations

Background apps — principally, those that do not have the foreground UI and are not a foreground service — will receive fewer location updates than before, whether using `LocationManager` or the Play Services fused location API. The documentation

says that background apps will receive location information “only a few times each hour”.

Note that this affects *all apps*, not just those with a `targetSdkVersion` over 25.

Besides putting your app in the foreground, you can:

- Use the Play Services geofencing API (detecting when the device enters or leaves a designated area), as these events may not be affected by the limit
- Use the “passive provider” with `LocationManager` (basically asking to get a copy of locations sent to other apps but not otherwise attempting to get locations), as if other apps happen to be in the foreground and requesting locations, you may get those updates as well, despite being in the background

## JobScheduler Enhancements

A minor improvement to `JobScheduler` comes in the form of new constraint methods on `JobInfo.Builder`: `setRequiresBatteryNotLow()` and `setRequiresStorageNotLow()`. If you use these, your jobs will not run when the battery is low or when storage is low, respectively.

However, the bigger change really comes in the roles that `JobScheduler` plays:

- The original role was for classic periodic work. You would request to get control every so often (in addition to constraints like the ones cited above). When you got control, you would do some chunk of work, then indicate that the job was finished.
- The role added in Android 7.0: monitoring content for changes. You could add a “trigger content Uri” to a `JobInfo.Builder`, indicating that rather than getting control every so often, you want to get control when the content at that Uri changes. The net result is the equivalent of a `ContentObserver`, without your app having to have a process running all of the time.
- One role added in Android 8.0 is a work queue. The idea here is that your periodic job is spending a period of time processing any enqueued work, where the job ends either when there is no more work to be done or when your allotment of time for the job elapses.
- That role is in support of yet another role, as a replacement for `IntentService` for performing background work, by means of a `JobIntentService` offered in the Android Support Library.

### JobIntentService

IntentService still works on Android 8.0, but unless you make it be a foreground service, you will be limited to ~1 minute of runtime before your service is stopped abruptly. JobIntentService is a wrapper around a JobService that offers IntentService-style semantics. On Android 8.0 and higher, when you tell a JobIntentService to do some work, it enqueues that work via JobScheduler. On Android 7.1 and earlier, the JobIntentService behaves more like a regular IntentService, though one that supplies a WakeLock for you (akin to the author's WakefulIntentService).

JobIntentService is examined in greater detail in [the chapter on services](#).

### JobScheduler as Work Queue

Under the covers, JobIntentService is taking advantage of a new capability in JobScheduler on Android 8.0: a work queue. IntentService had such a queue, after a fashion, in that it would process one Intent at a time through onHandleIntent(), queuing up other Intent objects that arrive while onHandleIntent() is busy. JobScheduler now offers a similar capability for your JobService, where you can post jobs and have your JobService end when the work is completed.

This is covered in detail in [the chapter on JobScheduler](#).

### Auto-Fill

Many Web browsers, such as Chrome, offer “auto-fill”. The browser remembers things that you have typed into certain fields, like addresses, and offers to fill those back in when you go to fill in the same form again... or even a different form with similar fields.

Android 8.0 adds auto-fill capability to Android. However, as with [the Assist API](#), Android itself is merely a conduit for form information. The actual implementations of auto-fill, in terms of storing and restoring values, is handled by an auto-fill service, which the user can enable in Settings. Presumably, when Android 8.0 ships in final form, a Google-supplied auto-fill service will come pre-installed, but users can switch to alternative implementations.

While the documentation suggests that no code changes are required to participate in auto-fill, that is not strictly accurate. Auto-fill relies at least in part upon widget

IDs to determine the roles of the widgets, and as a result you may need to consider revising your widget IDs to follow some conventions. Also, you will need to consider whether some or all of your activities really should be participating in auto-fill, for privacy or security reasons.

Auto-fill is covered in detail in [a separate chapter](#).

## Notification Channels

Through Android 7.1, all notifications were created equal. In other words, the user could apply a single set of rules for configuring how those notifications were delivered from your app. How *much* configuration was even available varied by Android OS version, but on newer devices users could control whether to block those notifications, show them without any sound or vibration, what amount of information should be shown on the lockscreen, and so on.

In Android 8.0, all notifications go into channels that you initially define. The user then has the ability to control the behavior of notifications on a per-channel basis. This offers finer granularity of control over the breadth of notifications that your app might deliver. Android 8.0 also extends the depth of control, with more options for the user to decide how a channel's notifications should work.

These are covered briefly in [the chapter on notifications](#) and in greater detail in [the chapter on advanced Notification techniques](#).

## Other Changes with Notifications

Android 8.0 offers a few additional features of note for notifications, features that are independent of — or only partially tied into — the new notification channels: auto-timeout, colored notifications, and launcher icon badges. These are covered in [the chapter on advanced Notification techniques](#).

## Multi-Window Changes

Android 7.0 introduced a native implementation of multi-window, with a particular emphasis on split-screen presentations on phones and tablets.

Android 8.0 extends this, particularly adding picture-in-picture support for mobile devices, and extending multi-window to also work on external displays, such as TVs

and monitors. These changes are covered in [the chapter on multi-window support](#).

### WebView Changes

WebView, as Android developers use it, is really a facade API, as of Android 5.0. Previously, the WebView implementation was part of the Android framework. Nowadays, the implementation is delegated to the Android System WebView, which allows Google to update the WebView implementation without relying upon manufacturers to distribute firmware updates.

Hence, to some extent, WebView continuously changes, as the Android System WebView app gets updated a few times per year.

However, it is only in a new version of Android that Google changes the API or the general approach taken by a WebView implementation. In Android 8.0, two significant changes were made: multi-process mode and support for banning of cleartext traffic. These are covered in [the chapter on advanced WebView usage](#).

### ContentProvider Changes

ContentProvider got a few new features in Android 8.0 as well, related to paged queries and requesting data refreshes. Unfortunately, these changes are completely undocumented.

These changes will be examined in a future edition of this book.

### Storage Access Framework Changes

The [Storage Access Framework](#) underlies ACTION\_OPEN\_DOCUMENT, ACTION\_CREATE\_DOCUMENT, and related actions, providing you with the equivalent of the “file open” and “save as” dialogs you may be used to in other programming environments. This framework received a few extensions in Android 8.0, which are outlined in [the chapter on consuming documents](#).

### Package Management

Apps that install or delete other apps will experience some changes in Android 8.0, as well apps that have used broadcasts like ACTION\_PACKAGE\_ADDED to find out about

changes in the mix of installed apps. These changes are covered in detail in [the chapter on miscellaneous integration techniques](#).

## Fonts as Resources

While Android has long had a `Typeface` class, using it was a pain. There was no way in layout resources to reference a custom `Typeface`, and so you had to apply the `Typeface` directly in Java code. At best, you could use a library like [Calligraphy](#) to try to simplify this.

Android 8.0, for the first time, makes fonts a first-class type of resource.

You can put OTF and TTF fonts into `res/font/` directories, or in other directories based upon resource set qualifiers (e.g., `res/font-v26/`). The font resource directories can also hold `<font-family>` XML files that tie multiple OTF/TTF fonts together into a single font family, for cases where different styles or weights are stored as separate font files.

Then, in layouts and style resources, you can use `android:fontFamily` on `TextView` and its subclasses, to indicate that the `TextView` should use fonts from your chosen family. Then, attributes like `android:textStyle` will pull fonts from the font family, and those fonts will be applied to the text in the `TextView`.

Also:

- The `Resources` object (obtained via `getResources()` on a suitable `Context`) has a `getFont()` method to retrieve a `Typeface` for a given font resource, given its `R.font` resource ID (e.g., `R.font.hack`)
- Information about system-supplied fonts can be obtained via a `FontManager` system service and its `getSystemFonts()` method

## Other Major Changes in Android 8.0

While Android 8.0 does not have very many user-facing changes, it does have quite a few that affect developers, beyond those already listed.

### Cache Quotas

Historically, `getCacheDir()` and `getExternalCacheDir()` represented “cache” directories. There were no limits as to what we could store there, in terms of

available space. However, we had to recognize that Android — and select third-party apps — might clear our cache at any point.

Android 8.0 introduces a “cache quota”. The name brings to mind a hard quota, where we crash or something if we exceed the limit. In truth, this appears to be a soft quota: apps exceeding the quota are likely to have their caches cleared, if and when Android needs to free up disk space.

The `StorageManager` system service has two methods related to this:

- `getCacheQuotaBytes()` tells you what your quota is
- `getCacheSizeBytes()` tells you how much cache space you are using

Both methods take a `File` object and return the corresponding values for cache stored on the filesystem on which that `File` is stored. For most Android devices, internal and external storage are on the same partition with the same filesystem, but that is not the case for *every* device. Hence, you will want to check both internal and external storage, using appropriate `File` objects, if you are storing data in both places.

You might use these methods as part of your own manual cache trim operation. For example, you might set up an idle-time once-a-day job with `JobScheduler` to examine what is in cache and delete a few things to get you under the cache quota. This would reduce the likelihood that Android will wipe out all of your cache, because you exceeded the quota and Android needed to free up the disk space for the user.

### Content Annotations

Usually, when we want a chooser for some activity `Intent` that we want to start, we use `Intent.createChooser()` to wrap our `Intent` in another `Intent`. That “outer” `Intent` will be an `ACTION_CHOOSER` `Intent`, and that `Intent` can itself be configured via extras.

One new `ACTION_CHOOSER` extra is `EXTRA_CONTENT_ANNOTATIONS`. You can put an `ArrayList` of up to three strings into this extra. Those will be used to help rank the apps that appear in the chooser.

This appears to be based on a learning algorithm; activities that are among the candidates do not somehow advertise what “content annotations” they are good at. Rather, the idea appears to be that Android will learn over time which apps the user

wants to use for which types of content, based on these annotations.

The [documentation for EXTRA\\_CONTENT\\_ANNOTATIONS](#) provides a list of nouns to choose from for these annotations. Exactly how your app is supposed to determine which of those nouns is relevant for any particular chooser is unclear.

### Seekable Streams

A major headache with the migration of Android away from sharing files to sharing streams from ContentProviders is the issue of seekability. Many apps want to be able to use methods like `mark()` and `reset()` on an `InputStream` as they are processing content. However, that implies a “seekable” stream, one where we can rewind and re-read bytes seen (or skipped) previously. In general:

- Streams created directly from files (e.g., `ParcelFileDescriptor.openFile()`) were seekable
- Streams created via pipes (e.g. `ParcelFileDescriptor.createPipe()`) were not seekable

For content that already exists as an ordinary file, this was not much of a limitation, as using file-based streams was already the easy solution. However, not all content is available as ordinary files, such as:

- Content stored as files, but in an encrypted or otherwise encoded format that needs to be decoded as part of serving it to other apps
- Content stored in BLOB columns of a SQLite database
- Content that is in “the cloud” and has not yet been downloaded to the device

The net effect was that many apps, for maximum compatibility with *other* apps, would need to create a file with all of the content, wasting disk space and possibly harming privacy and security.

In Android 8.0, `StorageManager` offers support for “proxy file descriptors”, via methods like `openProxyFileDescriptor()`. These give you a `ParcelFileDescriptor`, for use in methods like `openFile()` on a `ContentProvider`. However, rather than assuming a particular file or a particular pipe, a `ProxyFileDescriptorCallback` is used to ask you to provide access to the data, based on offsets and sizes. How you implement that is up to you. For example, for content backed by a BLOB column, you might cache the content as a byte array, then return segments of that byte array as needed by the `ProxyFileDescriptorCallback`.

However, ProxyFileDescriptorCallback leaves *much* to be desired, to the point where it is useless for most clients and providers.

Back in [the chapter on ContentProvider patterns](#), we had a demo of using a ParcelFileDescriptor pipe, via createPipe(), as a way of returning custom data from a ContentProvider. The [ContentProvider/ProxyPipe](#) sample project is an updated version of the original Pipe example, adjusted to build using Android 8.0 and to use ProxyFileDescriptorCallback.

### Implementing a ProxyFileDescriptorCallback

Our ProxyFileDescriptorCallback implementation is called BufferProxyCallback, so named as it will stream back the contents of an in-memory buffer. This is not particularly realistic, but it does simplify the example a fair bit, focusing on the ProxyFileDescriptorCallback API:

```
package com.commonware.android.cp.pipe;

import android.os.ProxyFileDescriptorCallback;
import android.system.ErrnoException;
import android.system.OsConstants;
import hugo.weaving.DebugLog;

class BufferProxyCallback extends ProxyFileDescriptorCallback {
    private final byte[] buffer;

    @DebugLog
    BufferProxyCallback(byte[] buffer) {
        this.buffer=buffer;
    }

    @DebugLog
    @Override
    public void onRelease() {
        // not needed here
    }

    @DebugLog
    @Override
    public long onGetSize() throws ErrnoException {
        return(buffer.length);
    }

    @DebugLog
    @Override
    public int onRead(long offset, int size, byte[] data) throws ErrnoException {
        int toRead=(offset+size<=buffer.length) ? size : (int)(buffer.length-offset);

        System.arraycopy(buffer, (int)offset, data, 0, toRead);

        return(toRead);
    }
}
```

## APPENDIX B: ANDROID 8.0

---

```
@DebugLog
@Override
public int onWrite(long offset, int size, byte[] data) throws ErrnoException {
    throw new ErrnoException("onWrite", OsConstants.EOPNOTSUPP);
}

@DebugLog
@Override
public void onFsync() throws ErrnoException {
    // not needed here
}
}
```

(from [ContentProvider/ProxyPipe/app/src/main/java/com/commonsware/android/cp/pipe/BufferProxyCallback.java](#))

ProxyFileDescriptorCallback is an abstract class, and there are five methods that you need to override to fulfill the contract:

- `onGetSize()`, which returns the number of bytes in the content, which in this case is the length of the buffer.
- `onRead()`, which needs to copy a specified sequence of bytes, based on an offset from the front of the content and a length, to a supplied byte array. Here, `onRead()` uses `System.arraycopy()` to copy from buffer to buffer, either to the requested length (`size`) or the remaining bytes (the length of the buffer, minus the offset). It needs to return the number of bytes that are read.
- `onWrite()`, which needs to take the bytes from a supplied byte array and update a region of the content to match. Here, we are implementing a read-only proxy, and so we raise an `ErrnoException`, indicating that this particular operation is not supported. If this method were implemented “for real”, `onWrite()` needs to return the number of bytes actually written.
- `onFsync()` needs to ensure that any writes created by `onWrite()` are fully committed to disk (or the equivalent if disk is not the backing store for the data). Here, there is nothing to “sync”, so this method is ignored.
- `onRelease()`, which is called when this particular proxy is no longer needed, so you can release any resources that you might be holding.

`onRead()` is particularly tricky to implement for things other than an in-memory buffer. The documentation states that “It needs to return exact requested size of bytes unless it reaches file end”. Many I/O options do not have a read operation that guarantee an exact number of bytes to be read. As a result, the proxy may need to do some caching of bytes from a previous read operation, to use on the next one, when the number of requested bytes does not match the number of bytes that were read off of whatever I/O channel is being used.

## APPENDIX B: ANDROID 8.0

---

These methods all are capable of throwing an `ErrnoException`. That is a rather new and obscure exception, and it actually points to a problem that most developers will encounter with `ProxyFileDescriptorCallback...` which we will see in a bit.

### Using a `ProxyFileDescriptorCallback`

A `ContentProvider` can then use a `ProxyFileDescriptorCallback` in concert with `StorageManager` and `openProxyFileDescriptor()`, in places like `openFile()`:

```
@Override
public ParcelFileDescriptor openFile(Uri uri, String mode)
    throws FileNotFoundException {
    AssetManager assets=getContext().getAssets();

    try {
        InputStream in=
            assets.open(uri.getLastPathSegment(), AssetManager.ACCESS_STREAMING);
        byte[] content=readAll(in);

        StorageManager sm=getContext().getSystemService(StorageManager.class);

        return(sm.openProxyFileDescriptor(ParcelFileDescriptor.MODE_READ_ONLY,
            new BufferProxyCallback(content)));
    }
    catch (IOException e) {
        Log.e(getClass().getSimpleName(), "Exception opening pipe", e);

        throw new FileNotFoundException("Could not open pipe for: "
            +uri.toString());
    }
}
```

(from [ContentProvider/ProxyPipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java](https://github.com/CommonsWare/android-cp-pipe/blob/master/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java))

Here, we first open an `InputStream` on a PDF file stored in `assets/`, then pass that stream to a `readAll()` method that reads in the entire PDF into a buffer:

```
// inspired by http://stackoverflow.com/a/17861016/115145

public static byte[] readAll(InputStream is) throws IOException {
    try (ByteArrayOutputStream baos=new ByteArrayOutputStream()) {
        byte[] buf=new byte[16384];

        for (int len; (len = is.read(buf)) != -1; ) {
            baos.write(buf, 0, len);
        }
    }
}
```

```
    baos.flush();
    is.close();

    return(baos.toByteArray());
}
}
```

(from [ContentProvider/ProxyPipe/app/src/main/java/com/commonsware/android/cp/pipe/PipeProvider.java](#))

Then, we obtain a `StorageManager` via `getSystemService()` and call `openProxyFileDescriptor()`, passing in the read/write mode that we want (in this case, hard-wiring it to `MODE_READ_ONLY`) and the `ProxyFileDescriptorCallback` that we want to use (here, a `BufferProxyCallback` wrapped around that buffer).

### The Woes of `ProxyFileDescriptorCallback`

`ProxyFileDescriptorCallback` is intrinsically incompatible with Java I/O. Java I/O classes and methods are a (relatively) high-level interface to the low-level sorts of functions that C/C++ developers use, like `fread()`. As a result, [it is unlikely that you will find `ProxyFileDescriptorCallback` to be easy to use](#).

Also, the results add no real value over just using a pipe... unless the client jettisons all Java I/O (including anything layered on top of it) and [uses that same low-level I/O API](#).

### Foreground Heap Compaction

When Android first shipped, the runtime environment that ran our apps — Dalvik — offered no heap compaction in its garbage collection. As a result, our heap would become fragmented, looking like a block of Swiss cheese, with lots of smaller free blocks of memory. This was in contrast to the way garbage collection worked on the Java VM, where the heap was compacted regularly. As a result, we would get an `OutOfMemoryError` very frequently. We were not out of heap space, but there was no single block of memory big enough for whatever we were trying to allocate. All we had were lots of smaller blocks.

Android 5.0 introduced ART as a new runtime environment. ART's garbage collector *would* compact the heap, moving objects around in memory to coalesce all those smaller blocks of free memory into one large block. However, it would only compact the heap when the app was in the background, as otherwise the heap compaction work might slow the app down too much at points in time when the user might

notice.

Android 8.0's update to ART brings a new garbage collection algorithm, one that attempts to compact the heap while our app is in the foreground, as well as when it is in the background. This should further reduce spurious `OutOfMemoryErrors`, limiting those to cases when we are truly running out of heap space or are trying to allocate some ridiculously large block.

### Shortcuts, App Widgets, and Pinning

Home screen implementations in Android have long had support for shortcuts. However, from an Android SDK standpoint, shortcuts did not exist, by and large. You could use `ACTION_CREATE_SHORTCUT` to allow the user and an app to define the Intent to be used as a shortcut... and that was about it. Some apps relied upon an undocumented, unsupported `com.android.launcher.action.INSTALL_SHORTCUT` means of asking a home screen to create a shortcut, though home screen implementations were never required to support it.

Android 7.1 added a more formal definition of shortcuts, initially aimed at providing them as options when the user long-pressed on a launcher icon in the home screen. This also introduced `ShortcutManager` as a way for an app to define available shortcuts dynamically.

Android 8.0 steers developers away from `com.android.launcher.action.INSTALL_SHORTCUT` and to `requestPinShortcut()` on `ShortcutManager` as a way to ask the launcher (and the user) to set up a shortcut.

Android 8.0 also offers a similar way to prompt the user to set up an app widget. For launchers that have support for this (reported by `isRequestPinAppWidgetSupported()` on `AppWidgetManager`), you can call `requestPinAppWidget()` on `AppWidgetManager` to try to convince the user to set up an app widget.

These capabilities will be examined in greater detail in an upcoming edition of this book.

### Auto-Sizing TextView

Android 8.0 added the ability to automatically change the font size in a `TextView` based upon the length of the text, something that previously we obtained from third-party libraries. This is covered in [the chapter on fonts and text](#).

### SMS Tokens

In Android 4.4, Google significantly changed the behavior of SMS messages. In particular, all messages would wind up in the user's SMS client. Previously, it was possible for apps to monitor and intercept messages, and some developers used this for a communications channel. For example, to validate a user's phone number, the server might send an SMS message to that number, which the app would intercept and process, bypassing the user's SMS client. On Android 4.4, that flow did not work as well, as the message would still wind up in the SMS client, whether the app responsible for the message wanted that or not.

Android 8.0 provides “app-specific SMS tokens”, via a `createAppSpecificSmsToken()` method on `SmsManager` as a way of accomplishing this flow. This is covered in detail in [the chapter on SMS](#).

### Custom Preference Storage

Android 8.0 adds `PreferenceDataStore`. In theory, this allows for pluggable ways to persist `SharedPreferences`, such as storing them in an encrypted container. In practice, it does not work especially well. The details of `PreferenceDataStore` – and its problems — are found in [the chapter on advanced preferences](#).

### FragmentManagerCallbacks

In API Level 14, we were given `ActivityLifecycleCallbacks`. We can register an instance of this interface on an `Application` object, and then receive callbacks for every lifecycle method for every one of our app's activities. This allows us to implement cross-cutting concerns (e.g., lifecycle method logging) without having to implement those concerns on each and every activity class.

Android 8.0 gives us `FragmentManagerCallbacks`. We can register an instance of this interface with a `FragmentManager`, and then receive callbacks for every lifecycle method for every one of the fragments managed by that `FragmentManager`. This should allow us to implement cross-cutting concerns (e.g., lifecycle method logging) without having to implement those concerns on each and every fragment class.

As with everything involving fragments, there are two implementations: one for the native fragments and one for the fragments backport in the `support-fragment` artifact. This is another situation where you might elect to use the fragments backport, even on an app with a `minSdkVersion` over 11, so you can use this new

capability even on older devices.

## Other Minor Changes in Android 8.0

And, of course, there are lots of other smaller changes floating around Android 8.0, including those outlined here.

### Permission Granularity

With the runtime permission system introduced in Android 6.0, we request *permissions*. However, the UI presented to the user allows them to grant *permission groups*. Presumably, this is to simplify the user experience.

However, in Android 6.0 through 7.1, even though you might request only one permission out of the group, you would actually be granted all the permissions in the group. So, for example, requesting `READ_EXTERNAL_STORAGE` would also allow you to write to external storage, without having specifically requested this via `requestPermissions()`.

This bug is fixed in Android 8.0, for apps with a `targetSdkVersion` over 25. Now, you are only granted the permissions that you request.

This is not supposed to change the user flow, though. Suppose that you call `requestPermissions()` and ask for `READ_EXTERNAL_STORAGE`. The user is prompted whether to give your app the rights associated with the storage permission group. If the user agrees, you get `READ_EXTERNAL_STORAGE`, and only `READ_EXTERNAL_STORAGE`. However, if later you call `requestPermissions()` for `WRITE_EXTERNAL_STORAGE`, in theory, the user will not be prompted regarding this new permission, since the user already granted you all the rights for the storage permission group. Your `onRequestPermissionsResult()` method should be invoked immediately, indicating that you now have access.

This supposed flow, though, never worked. The user was always prompted for all permissions listed in `requestPermissions()`, even if the permission group had already been granted. This is why various sample apps in this book employ a `netPermissions()` method, so that we only ask for the permissions that we need that we do not already have.

## Tooltips

Mouse-centric environments — like classic desktop operating systems — have long had tooltips, where an information bubble appears when you hover over a widget. Android has had the occasional tooltip-like feature, such as the tooltip that you get on action bar items when long-pressing them. Android 8.0 extends this to all widgets. Simply provide the desired text via `android:tooltipText` or `setTooltipText()`. A tooltip will then appear when either the user long-presses the widget or if the user hovers over the widget. In both cases, though, if the long-press or hover event is consumed by something else, the tooltip is not shown.

This is covered in greater detail in [the chapter on keyboards and mice](#).

## ZoomButton Deprecated

The ill-used `ZoomButton` widget is now formally deprecated. Most likely, if you are still using it, you should move to something else, such as:

- zoom gestures (e.g., pinch-to-zoom)
- a pair of `ImageButton` widgets

Alternatively, you might consider forking the source code to `ZoomButton` and maintaining your own copy.

## App Categories

Apps can use `android:appCategory` in the `<application>` element to suggest a category to use for grouping this app with other similar apps on the device.

There is [a short list of available categories](#). Some are fairly obvious (e.g., game, maps), while others are somewhat vague (productivity).

## Changes in ANDROID\_ID Scope

`ANDROID_ID` has been a long-troubled identifier for Android devices. In the early days, it might be missing or set to some hard-coded value, rather than being a unique identifier. Separate users on a shared Android device get separate `ANDROID_ID` values, so it is not a per-device identifier anyway. On the whole, Google does not recommend the use of `ANDROID_ID`, as seen by its conspicuous absence from [their identifier guidelines](#).

---

## APPENDIX B: ANDROID 8.0

---

In Android 8.0, `ANDROID_ID` changes yet again, to now be a per-app/per-user identifier. Each app, for each user on a device, gets its own `ANDROID_ID` value. However, Google does guarantee that the value will remain consistent for that app/user combination, surviving even an uninstall and reinstall. However, because the value differs by apps, apps in a suite (or apps sharing a common advertising library) cannot correlate actions, as they will each get their own `ANDROID_ID` value.

For the record, you get the `ANDROID_ID` value via:

```
Settings.Secure.getString(getContext().getContentResolver(),  
Settings.Secure.ANDROID_ID);
```

### Alert Windows

The “chat heads” offered by Facebook’s Android app kicked off a spur of interest in how to create windows that can float over arbitrary apps. This facility was never intended for widespread use, and presumably it adds challenges to future multi-window scenarios.

The technique to create these windows involves using `WindowManager` to create a new window with particular types, like `TYPE_PHONE` or `TYPE_SYSTEM_ALERT`.

On Android 8.0, apps with a `targetSdkVersion` over 25 cannot use these window types anymore. Instead, a new type, called `TYPE_APPLICATION_OVERLAY`, has been added, which apps can use, subject to some limitations:

- These overlay windows do not float over system UI elements, such as the navigation bar or soft keyboards
- Your requested window size and position may be changed by Android as needed “to improve screen presentation”
- The user can block your app from showing these windows

### Build.SERIAL Versus Build.getSerial()

One of the values that has appeared on the `Build` class is `SERIAL`, advertised as being a serial number for the device. Whether or not it actually *is* a serial number has been up to device manufacturers.

On Android 8.0, `Build.SERIAL` is deprecated. More importantly, if your `targetSdkVersion` is over 25, `Build.SERIAL` will be set to the string “unknown”.

Instead, you need to start using a new `getSerial()` method on the `Build` class. However, this requires the `READ_PHONE_STATE` permission, which, as a dangerous permission, requires you to request it at runtime.

### StorageStatsManager

`UsageStatsManager` was added in API Level 21, to provide access to historical app usage data.

A similar class, `StorageStatsManager`, is part of Android 8.0, to provide information about storage usage, for things beyond what `StatFs` has provided developers for years. In particular, you can get:

- the “marketing” explanation of the data storage on some volume, which tends to be higher than the actual amount of storage on that volume
- the amount of free space taking into account the amount of used cache that could be freed up by the system
- the storage usage by particular user accounts
- the storage usage by particular apps

As with `UsageStatsManager`, `StorageStatsManager` requires that you request the `PACKAGE_USAGE_STATS` permission. The user cannot grant you this permission directly (e.g., via runtime permissions), but this will cause your app to appear in Settings in a place where the user can grant you this permission.

Also, `setCacheBehaviorAtomic()` allows you to control whether deleting the cache always happens “atomically” (i.e., deleting everything) or whether Android can delete individual cached files. You would specifically want to opt into atomic behavior if you cannot deal with Android deleting some cache files but not others.

### TextClassificationManager

If you have ever used [Google Translate](#), and watched it guess what language your pasted-in text was written in, `TextClassificationManager` offers that same “guess the language” feature. Given an instance of the `TextClassificationManager` system service, calling `detectLanguages()` on it will return details of what language(s) were detected, in the form of a `List` of `TextLanguage` objects. From there, you can find confidence scores and the like, to understand how confident Android is in its guess.

Also, given a `TextClassificationManager`, you can obtain a `TextClassifier`. This appears to be an updated edition of `Linkify`: a scanner that can find linkable

## APPENDIX B: ANDROID 8.0

---

entities (e.g., email addresses, physical addresses, URLs, phone numbers) and provide information to you about them for the purposes of applying markup.

# Appendix C: Android 9.0

---

Another year, another major Android release!

2018 has given us Android 9.0 (formerly Android P). This chapter outlines some of the changes that we got in this new pie-flavored version.

## Major Breaking Changes

There are a number of changes made in Android 9.0 which have the ability to break your builds (right away) or break your app (once you raise your `targetSdkVersion` to 28 or higher).

### Native Fragment Deprecation

If you have been using native fragments — `android.app.Fragment` and `kin` — you will get a lot of deprecation warnings as soon as you set your `compileSdkVersion` to 28. That is because native fragments and the native implementation of `Loader` are deprecated.

As usual, “deprecated” here means “we have an alternative that we would prefer that you use”. In this case, the alternative is the fragment/loader implementation from `support-fragment` in the Support Libraries (`android.support.v4.app.Fragment`, `android.support.v4.app.FragmentActivity`, etc.). The benefit of using the `support-fragment` implementation is that it comes from a library, so the implementation is baked into your APK and should be fairly stable across Android OS versions and devices. The native fragments and loaders, on the other hand, have implementations that vary by Android OS version, and so you may be subject to bugs on older devices that are fixed in the library.

The cost is a slightly larger APK. However, support-fragment is not very large, and you may already be pulling in this library via transitive dependencies.

### HTTPS Required By Default

The Android 9.0 documentation indicates that, by default, plain HTTP traffic (“cleartext traffic”) is no longer allowed to any domain. This is supposed to be implemented via a change to [network security configuration](#), where `cleartextTrafficPermitted` would be set to `false` by default. This change takes effect if you have `targetSdkVersion` set to 28 or higher.

Ideally, you use HTTPS everywhere.

The workaround is to establish a network security configuration in your app and either:

- Whitelist those domains for which you still need plain HTTP, or
- Set a `<base-config>` to allow cleartext traffic by default for all domains

### No Hidden API Access

Starting with Android 9.0, Google is going to start [blocking your ability to access classes and members marked with the @hide pseudo-annotation](#), plus private and package-private members. Simply put, if it is not documented in the Android SDK, you may not be able to refer to it at compile time by using Java reflection or similar techniques.

They indicate that this will be a phased rollout, stating that “Initially, this restriction will impact interfaces with low or no usage”. So, right now, we do not know exactly what will and will not be blocked.

If you pay close attention to LogCat, you will find warnings when code in your process accesses things that will be blocked:

```
W/dex2oat: Accessing hidden field Ljava/lang/Throwable;-->detailMessage:Ljava/lang/String; (light greylist, JNI)
W/zygote64: Accessing hidden method Landroid/app/ActivityThread;->currentActivityThread()Landroid/app/ActivityThread; (light greylist, reflection)
```

The first warning message comes from some JNI code attempting to access a field inside of `Throwable`. We know from the message that this is from JNI because the

## APPENDIX C: ANDROID 9.0

---

warning indicates as such in the parenthetical expression at the end. That same message indicates that this is on the “light greylist”, which should still work in Android 9.0, but may not work in future versions of Android.

The second warning comes from Java code using reflection, accessing a static method on a hidden class. That too is on the “light greylist”.

According to [the documentation](#), there is also a “dark greylist” that represents things that will fail outright in Android 9.0. However, while the docs show that `currentActivityThread()` is on the “dark greylist”, actually trying it results in a “light greylist” message, as is shown above.

Developers should examine their code bases for any signs of using reflection to access hidden members: `Class.forName()`, `getConstructor()`, `getField()`, and so on. This is particularly important for library authors, as issues with a library get amplified by the number of library users.

The big reason is that Google has set up [a dedicated issue tracker component](#) for requests to make formerly-private APIs public. The results of filing issues on the issue tracker can be generously described as “mixed”. However, what has become clear is that Google does not make changes to a release once the first developer preview has shipped, outside of egregious problems. So, if you want some APIs to be made public *for 2019’s new version of Android*, you had best [get those requests filed](#) quickly, so that they can get in the pipeline.

Note that not all uses of reflection will need to result in changes in Android 9.0. Of note:

- Using reflection for accessing your own code is fine, if perhaps heavyweight
- Using reflection for accessing things on older devices, where newer devices have some official solution, will not change based on Android 9.0’s release — while this is still risky, the risk is not any greater now than before
- Using reflection for accessing manufacturer-supplied libraries — the kind that you need to use `<uses-library>` for in the manifest — should be unaffected by this change

One challenge in detecting these problems is that the warning does not indicate where the invalid access is coming from. It will difficult to identify the library that is the culprit, for cases where your own code is not the source of the violation.

However, `StrictMode` not only offers [callbacks to find out when violations occur](#), but

it also now treats these violations as part of the VM policy. So, you could arrange to have `StrictMode` report these violations to you, where you then log the stack trace somewhere. For example, you might modify your test suites to enable `StrictMode` to collect this information, then write the output somewhere that your tests can pick up and incorporate into their results. We will see an example of this [later in the chapter](#).

## A Minimum `targetSdkVersion`

As [Android Police reported](#), if your app has a `targetSdkVersion` below 17, and the user installs and attempts to run it on Android 9.0, the user is greeted with a warning dialog:

*Figure 1091: Android 9.0 Low `targetSdkVersion` Warning Dialog*

(here, the app’s name is “My Old App”)

This only appears on the first run of the app. If the user clicks the “Check for updates” button, they are taken to the Play Store... even if the app was not from there.

This is a fairly awkward introduction for your app.

This, coupled with the Play Store’s already-scheduled [ban on new apps and updated apps that use older `targetSdkVersion` values](#), puts pressure on you to keep your

`targetSdkVersion` up to date. And, if the `targetSdkVersion` threshold turns into a ban, developers will need to consider whether they are in position to invest time in the app whenever Google decides to raise this threshold.

### Foreground Service Permission

Your app needs to request the `FOREGROUND_SERVICE` permission if it will start a foreground service. This is a normal permission and does not require runtime permissions, but if you fail to have the `<uses-permission>` element for `FOREGROUND_SERVICE` in the manifest, your app will crash with a `SecurityException`. This change should take effect if you have `targetSdkVersion` set to 28 or higher.

### Background Apps and Privacy

Background apps — those with no foreground UI and no foreground service — will be blocked from accessing the microphone, camera, and many sensors. While there are plenty of legitimate reasons for wanting to use those data sources in the background, there are privacy issues, as the user is not aware that, say, the microphone is capturing what the user says. There can also be power considerations as well.

Most apps should be unaffected by these changes, but if you use any of those hardware features, make sure that you test your app thoroughly on Android 9.0. For example, it is unclear how quickly these restrictions are applied — if the user presses HOME, ideally you have a grace period of a few seconds to clean up your use of this hardware. It is also unclear what the real-world effects are (e.g., are exceptions thrown?).

### “The War on Background Processing”, Continued

Android 9.0 introduced [“app standby buckets”](#). In Android 6.0-8.1, your app would move into an “app standby” category if the user had not visited the app’s UI recently, and while in “app standby”, it was pretty much as if Doze mode was on all the time for your app. Now, there are four major “buckets”: active, working set, frequent, and rare, with progressively stronger restrictions placed on app operation. In particular:

- FCM high-priority messages — formerly Google’s recommended approach for getting your app to react to external data changes — will be capped in the “frequent” and “rare” buckets
- Device manufacturers can decide for themselves when and how to categorize

apps into these buckets

The user can also elect to manually restrict background operations for your app. If the user does, basically nothing works: no jobs, no alarms, no network. There are no “idle maintenance windows” or anything of the sort. The only thing that works when you are restricted this way are FCM high-priority messages, and app standby means that they might not work either. The user can enable background restrictions on their own by visiting Settings > Apps > (your app) > Advanced > Battery > Background Restriction. In theory, users would be unlikely to do this. However, [the documentation](#) indicates that the OS will alert the user to apps that:

- Hold a partial `WakeLock` for more than an hour while the screen is off, and
- If the app’s `targetSdkVersion` is below 26 and it has “excessive background services” (which is undefined)

There is a [new `isBackgroundRestricted\(\)` method on `ActivityManager`](#). Based on the documentation, it appears that this will return `true` if the user goes and elects to restrict your background operation manually.

There is [a table of what the effects are for different types of scenarios](#), such as the four app standby buckets.

[The power change documentation](#) also has:

Android 9.0 makes a number of improvements to battery saver mode. The device manufacturer determines the precise restrictions imposed.

Apparently, “random behavior based on device manufacturer whim” is an “improvement”.

In general, do not write apps that require periodic background work.

### Device Administration Deprecations

Four device admin policies that you might be requesting for use from your device admin app are marked as deprecated in Android 9.0 and are slated to throw a `SecurityException` in Android Q:

- Blocking camera access (`USES_POLICY_DISABLE_CAMERA`)
- Disabling certain unspecified keyguard features (`USES_POLICY_DISABLE_KEYGUARD_FEATURES`)

- Forcing the user to reset their password after an admin-defined time period (USES\_POLICY\_EXPIRE\_PASSWORD)
- Forcing the user to use passwords meeting certain quality guidelines, such as minimum length (USES\_POLICY\_LIMIT\_PASSWORD)

These policies will be limited to device owners and profile owners in the future.

### Missing Stuff Returns

Historically, to start an activity from a non-activity Context, you needed to add FLAG\_ACTIVITY\_NEW\_TASK to the Intent. Otherwise, you would crash with an exception pointing out the need for this flag. However, starting with Android 7.0, this flag was no longer needed, inexplicably. That flag is required again as of Android 9.0. The safest thing to do is to use it on all versions, as having the flag did not seem to cause any ill effects on Android 7.0-8.1.

Similarly, the documentation for Android 8.0 claimed that to be able to delete installed apps using ACTION\_UNINSTALL\_PACKAGE, an app needed to hold the REQUEST\_DELETE\_PACKAGES permission. That was not the case, but now it *is* required for Android 9.0.

### Removal of Deprecated Testing Classes

The original generation of JUnit-based test classes, such as ActivityInstrumentationTestCase2, have been removed from the SDK. However, you can opt into having those in your project via some useLibrary directives in your android closure in your module's build.gradle file. Ideally, you have long since moved on from those original test classes, but if you have legacy code that has legacy test code, you have access to [legacy testing libraries](#) to allow all of that to (hopefully) keep working.

### Signature Changes and Deprecations

Android apps can examine the “signatures” of apps. In reality, these are X.509 certificates representing the public key of the code that signed the APK.

Historically, apps were only signed by one certificate. Technically, apps could be signed by multiple certificates, but this was *very* infrequent. And, in that scenario, all keys needed to match: if the app was signed by certificates K<sub>1</sub> and K<sub>2</sub>, any upgrade to that app also had to be signed by K<sub>1</sub> and K<sub>2</sub>.

Android 9.0 debuts APK Signature Scheme v3, the next generation of APK signing algorithms. It adds the possibility of key rotation: allowing an APK to be signed by a different certificate than what was used to originally sign it. The new signature scheme allows for the APK to show an entire history of certificates, to prove that the new certificate is allowed by the holder of the previous certificate.

A side effect of this change is that the APIs used to examine signatures now need to address this signature history. To that end, Android 9.0 deprecates the `GET_SIGNATURES` flag used in `PackageManager` and the resulting `signatures` field in `PackageInfo`. They are replaced by `GET_SIGNING_CERTIFICATES` and `signingCertificateHistory`, respectively. For most apps, at least at the time being, `signingCertificateHistory` will have just the one-and-only certificate. But, in the future, if the Play Store or other tools enable key rotation, APKs may have a deeper history accessible via `signingCertificateHistory`.

APKs signed with prior generations of the APK Signature Scheme still work on Android 9.0, and it remains to be seen when the tools will catch up and offer this new signing option (and how those tools work).

## Major Features

Beyond the stuff that might break your app, Android 9.0 debuts a number of new features that may be of interest to you and your users.

### Slices

Partly, slices represent a next-generation implementation of the `RemoteViews` system. `RemoteViews` is used mostly for [app widgets](#) and [custom notifications](#). It is a data structure that describes a UI, designed to be passed between apps (or from an app to a system process). One app creates the `RemoteViews`, the other app or process displays the View hierarchy defined by those `RemoteViews`. However, `RemoteViews` are not magic. So long as both sides agree on the rules, you can create your own serialization of UI-construction instructions and pass them between processes. That is what slices do: create a new convention for passing this sort of information between apps.

Partly, slices provide a framework for requesting and receiving these UI structures. In that sense, it is a bit reminiscent of app widgets, where you have providers and hosts. Ordinary apps are app widget providers; home screens are typically app widget hosts. Similarly, apps can be slice providers or slice hosts. In this fashion, one

app can embed UI defined by another app.

This book contains [a dedicated chapter on publishing slices](#).

### Notification Improvements

Notifications have been steadily altered in many of the past several Android major releases. Android 9.0 is no different, though its changes are somewhat more modest than what we saw previously.

A continued focus is on in-notification messaging:

- The native APIs have been adjusted to use a `Person` class to identify messaging participants, including their chat handle, avatar, etc.
- `MessagingStyle` now supports inline images via `setData()`
- `RemoteInput` for inline replies now supports `setChoices()` on phones and tablets the way that it does on Wear OS devices, where you can supply some suggested responses, to save the user from having to type something in directly

Also, actions can have a “semantic action” associated with them, where you indicate what general role the action has (e.g., delete, reply, mark as read). It is unclear what impact this has on anything.

None of these are supported by `NotificationCompat` at this time.

In addition, Android 9.0 will send broadcasts when users block or unblock a notification channel or channel group. You can listen for such broadcasts if desired — the action strings are defined as constants on `NotificationManager` (e.g., `ACTION_NOTIFICATION_CHANNEL_BLOCK_STATE_CHANGED`).

### Fingerprint Improvements

Android 9.0 brings with it some improvements to how you can work with the fingerprint sensor on the device for authentication purposes.

#### BiometricPrompt

The `FingerprintManager` API has been deprecated and replaced with `BiometricPrompt`. It remains to be seen if an implementation of `BiometricPrompt`

will be added to the Support Library; there is no sign of one at present.

`BiometricPrompt` provides a stock UI around fingerprint scanning. You simply get the results when the user's attempt to scan a fingerprint completes, in one form or fashion.

In principle, `BiometricPrompt` can handle other forms of biometric authentication, such as face scanning or iris scanning. It is unclear to what extent Android 9.0 – or any Android 9.0 hardware — will support this.

The [DeviceAuth/FingerDialog](#) sample application is a clone of the `FingerCheck` sample application shown in [the chapter on device authentication](#). There, we used `RxFingerprint` as a reactive wrapper around the `FingerprintManager` API to scan a fingerprint and indicate the outcome. `FingerDialog` replaces `RxFingerprint` with `BiometricPrompt`.

We use a `BiometricPrompt.Builder` to create an instance of `BiometricPrompt`:

```
prompt=new BiometricPrompt.Builder(this)
    .setTitle("This is the title")
    .setDescription("This is the description")
    .setNegativeButton("Ick!", getMainExecutor(),
        (dialogInterface, i) -> button.setImageDrawable(off))
    .setSubtitle("This is the subtitle")
    .build();
```

(from [DeviceAuth/FingerDialog/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

You get to provide three pieces of descriptive text: a title, a subtitle, and a “description”. No particular guidance is supplied for what the roles are for these bits of text, but only the title is required.

You also need to provide information that goes on the “negative button”, which the user can click to bail out of the fingerprint scan. This includes the caption of the button, an `Executor` to use to invoke your callback, and the callback itself. Here, we use the new `getMainExecutor()` method on Android 9.0 to get an `Executor` that executes code on the main application thread. Our callback, in the form of a lambda expression, simply toggles the state of an image to show an “off” color.

`BiometricPrompt` does not have an up-front way of telling you whether it will work, strictly speaking. The documentation recommends that you call `hasSystemFeature(PackageManager.FEATURE_FINGERPRINT)` on a `PackageManager`, to at least filter out devices that have no fingerprint hardware, before trying to use

## APPENDIX C: ANDROID 9.0

---

BiometricPrompt. Everything else is handled via callbacks. Also note that there may be other checks that will be required in the future for other forms of biometrics.

So, whereas `authenticate()` originally started using `RxFingerprint` to confirm that fingerprints were available and then request a scan, we now start with the `FEATURE_FINGERPRINT` check:

```
private void authenticate() {
    if (getPackageManager().hasSystemFeature(PackageManager.FEATURE_FINGERPRINT)) {
        button.setImageDrawable(on);
        prompt.authenticate(signal, getMainExecutor(), authCallback);
    }
    else {
        Toast.makeText(this, R.string.msg_not_available, Toast.LENGTH_LONG).show();
    }
}
```

(from [DeviceAuth/FingerDialog/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

If we have that feature, we call `authenticate()` on the `BiometricPrompt` that we built (and saved to a prompt field in the `MainActivity`). `authenticate()` takes:

- A `CancellationSignal` object, which you can use to cancel the scan yourself, should that prove necessary
- An `Executor` on which to invoke your callback
- An `AuthenticationCallback`, here implemented as a nested class:

```
private final BiometricPrompt.AuthenticationCallback authCallback=
    new BiometricPrompt.AuthenticationCallback() {
        @Override
        public void onAuthenticationError(int errorCode, CharSequence errString) {
            button.setImageDrawable(off);

            if (errorCode==BiometricPrompt.BIOMETRIC_ERROR_NO_BIOMETRICS) {
                startActivity(new Intent(Settings.ACTION_FINGERPRINT_ENROLL));
            }
            else {
                Toast.makeText(MainActivity.this, errString, Toast.LENGTH_LONG).show();
            }
        }

        @Override
        public void onAuthenticationHelp(int helpCode, CharSequence helpString) {
            // unused
        }

        @Override
        public void onAuthenticationSucceeded(BiometricPrompt.AuthenticationResult result) {
            Toast.makeText(MainActivity.this, R.string.msg_authenticated, Toast.LENGTH_LONG).show();
            button.setImageDrawable(off);
        }

        @Override
```

## APPENDIX C: ANDROID 9.0

---

```
public void onAuthenticationFailed() {  
    // unused  
}  
};
```

(from [DeviceAuth/FingerDialog/app/src/main/java/com/commonsware/android/auth/finger/MainActivity.java](#))

The callback has four methods that you need to implement. The one that you want to have called is `onAuthenticationSucceeded()`, meaning that the user has successfully scanned a fingerprint. `onAuthenticationError()` will be called if there is some specific problem, such as too many failed attempts or if there are no fingerprints enrolled. Both of these appear to work, and we will see more about `onAuthenticationError()` in the next section. The remaining two methods — `onAuthenticationHelp()` and `onAuthenticationFailed()` — will be called with the fingerprint dialog still visible, and the dialog itself seems to provide feedback to the user about the issues it is encountering. Hence, it is unclear whether these callbacks are useful in this scenario.

The dialog itself will show your icon, along with your supplied messages:

*Figure 1092: BiometricPrompt UI*

If there is a recoverable problem, the dialog will inform the user:

*Figure 1093: BiometricPrompt UI, Showing Recoverable Error*

### **ACTION\_FINGERPRINT\_ENROLL**

If you get called with `onAuthenticationError()`, and the supplied error code is `FINGERPRINT_ERROR_NO_FINGERPRINTS`, this means that the device does not have a scanned fingerprint to use for comparison purposes. At this point, you have two options:

- Back away slowly, as you have no idea who is holding the device and whether it is really the user or not
- Offer to help the user set up fingerprints, including setting up a secure lockscreen (if that part is not already done)

To do the latter, you can start the `ACTION_FINGERPRINT_ENROLL` activity, as shown above. This leads the user into a several-pane wizard UI to set up the secure lockscreen and enroll a fingerprint. This is the same wizard that they would get if they went into Settings and elected to add a fingerprint through its UI.

## Other Notable Changes

Many other changes are coming in Android 9.0, with varying impacts on app developers.

### Display Cutouts

2017 was The Year of the Notch.

Not only did [Essential's first Android phone](#) have their front-facing camera intrude on the display, but so did a phone from Apple.

Apple, being a trend-setter in phone design, resulted in a variety of Android device manufacturers debuting notch display designs at events such as Mobile World Congress 2018. To help accommodate that, Android 9.0 is standardizing the concept of “display cutouts”, so that the OS can help “route around the damage” caused by these inaccessible screen coordinates.

---

## APPENDIX C: ANDROID 9.0

---

Android 9.0 devices and emulators can simulate a device with a display notch, even if the device itself does not have one. In Settings > Developer Options > Drawing, you will find a "Simulate a display with a cutout preference, with a handful of options:

*Figure 1094: Android 9.0 Notch Simulation Option*

Due to some bugs with the simulation, it is a bit difficult to determine exactly how Android will react to display notches. It is even more difficult to document them, since [portrait screenshots do not show the simulated display cutout](#).

In portrait mode, the status bar becomes taller. With the simulated behavior, the status bar toggles between normal height (when there is no simulated display cutout) and a taller state. That taller state is tall enough to accommodate the tall form of the simulate display cutout, even if the cutout that you choose is not that tall. It is unclear whether production devices with notches will have the status bar match the notch or whether the status bar will be a consistent height regardless of notch height.

In landscape mode, it appears that the entire display will be truncated to accommodate the notch.

For most apps, none of this will matter. Apps that operate in full-screen mode will require testing, as will apps that try to work with the actual display size rather than the size of widgets inside of their UI. A new `DisplayCutout` class can give you details of where the cutout is (if there is one). `WindowManager.LayoutParams` now offers a `layoutInDisplayCutoutMode` field, where you can specify whether your window should extend into the cutout area or not, when your app is full-screen.

## ImageDecoder

If you are using `BitmapFactory` directly, that may not be the best option for you. Consider using an image-loading library, such as Picasso or Glide. Such libraries handle more of the overall image-loading process, such as dealing with background threads and image caches.

If you maintain such a library, or you have a clear reason to use `BitmapFactory` directly, you have a new option in Android 9.0, called `ImageDecoder`. `ImageDecoder` is billed as being a replacement for `BitmapFactory`, though in truth the two classes' functionalities do not completely overlap. At its core, though, `ImageDecoder` does fill the same role as does `BitmapFactory`: load a `Bitmap` from some representation of the image.

One key difference between the two is where the image can come from:

Representation	Supported by <code>BitmapFactory</code>	Supported by <code>ImageDecoder</code>
assets	yes (via <code>InputStream</code> )	yes
byte array	yes	yes (via <code>ByteBuffer</code> )
<code>InputStream</code>	yes	no
File	yes	yes
<code>FileDescriptor</code>	yes	no
resource	yes	yes
Uri	yes (via <code>InputStream</code> )	yes

With `BitmapFactory`, there are dedicated methods for the different data sources, such as `decodeStream()` and `decodeByteArray()`. With `ImageDecoder`, it is a two-

step process: you call a `createSource()` method to create a `Source`, then pass that to `decodeBitmap()`.

`BitmapFactory` can take a `BitmapFactory.Options` to configure the decoding process. `ImageDecoder` replaces most of those with setters on the `ImageDecoder` itself, such as `setMutable()` or `setResize()`.

Often, we need to know the size of the image before we are ready to actually load it, such as for calculating the scaling factor to apply to it (i.e., `inSampleSize` in `BitmapFactory.Options`). With `BitmapFactory`, that required two `decode...()` calls: one to get the size and a second to do the real decoding. This was a pain for some data sources, such as `InputStream`, that are designed to be used once. `ImageDecoder` replaces that with an optional `OnHeaderDecodedListener` where you can get the size data. That listener gets the `ImageDecoder` itself as a parameter to its `onHeaderDecoded()` method, so you can further configure the decode operation based on the header data.

`ImageDecoder` not only allows you to get a `Bitmap` back, but it also supports returning a `Drawable`, via `decodeDrawable()`. In particular, this should support decoding animated GIF and WebP images to an `AnimatedImageDrawable`.

### AppComponentFactory

Android now allows apps to more directly control the instantiation of activities, services, content providers, and broadcast receivers, by means of an `AppComponentFactory`.

You can define a subclass of `AppComponentFactory` and register it in the manifest in the `<application>` element via an `android:appComponentFactory` attribute. Then, whenever the framework needs to create an instance of an `Activity`, `Application`, `ContentProvider`, `BroadcastReceiver`, or `Service`, your `AppComponentFactory` will be asked to do that work. You are given a `ClassLoader`, the `String` of the component name that appeared in the manifest, and an `Intent` (for `Activity`, `Service`, and `BroadcastReceiver`). Your job is to return the desired object. It would appear that you could chain to the superclass for those components that you do not want to handle differently, allowing you to focus on the scenarios where you want to do something different than what the framework normally does.

Let's use an `Activity` as an example. Normally, when the user taps the home screen launcher icon, Android creates an instance of the designated `Activity` subclass using the zero-argument public constructor. However, if the app has registered an

## APPENDIX C: ANDROID 9.0

---

`AppComponentFactory` and overrides the `instantiateActivity()` method, that will be called, and it needs to return the `Activity`.

For example, `instantiateActivity()` could:

- Use some other sort of constructor, perhaps involving dependency injection
- Have a generic placeholder `<activity>` element, and decide in Java code what the actual `Activity` will be, by using other information in the `Intent` and perhaps other state information in the app (e.g., splash screen in some scenarios)
- Create some sort of `ActivityWrapper` that wraps the real `Activity` subclass, where the wrapper can do logging and such, forwarding all calls onto the wrapped `Activity`

And so on. Hence, this capability could be useful for a variety of scenarios. Unfortunately, some of those scenarios involve malware, particularly in the form of app repackagers. These are tools that take an app, inject some malware, and repackage the app with that malware. The repackaged app can then be distributed by whatever means the malware author desires. It used to be that the “inject some malware” step was relatively manual. With `AppComponentFactory`, all that the repackager needs to do is:

- Create and register an `AppComponentFactory` that overrides `instantiateActivity()` (or whatever) to put a wrapper around the app’s real component
- Ship the altered app by whatever a preferred distribution channel is
- Get results from the wrappers (e.g., report everything the user types in, slap ad banners over the UI, replace the app’s own ad banners with my own)

The [Introspection/ActivityMill](#) sample application demonstrate the use of `AppComponentFactory`.

Our activity — `MainActivity` — is unusual. It has a private constructor and a factory method for creating instances of the activity:

```
package com.commonware.android.activitymill;

import android.app.Activity;
import android.os.Bundle;

public class MainActivity extends Activity {
    private final String revisedTitle;
```

## APPENDIX C: ANDROID 9.0

---

```
static MainActivity sockItToMe(String revisedTitle) {
    return new MainActivity(revisedTitle);
}

private MainActivity(String revisedTitle) {
    this.revisedTitle=revisedTitle;
}

@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_main);
    setTitle(revisedTitle);
}
}
```

(from [Introspection/ActivityMill/app/src/main/java/com/commonsware/android/activitymill/MainActivity.java](#))

Normally, this would not work. Android would crash when trying to start the activity, because it would not find a public zero-argument constructor.

However, in our case, we are using `AppComponentFactory` to create our `MainActivity` instances:

```
package com.commonsware.android.activitymill;

import android.app.Activity;
import android.app.AppComponentFactory;
import android.content.Intent;

public class ActivityMill extends AppComponentFactory {
    @Override
    public Activity instantiateActivity(ClassLoader cl, String className,
                                      Intent intent) {
        return MainActivity.sockItToMe("This is not the regular title");
    }
}
```

(from [Introspection/ActivityMill/app/src/main/java/com/commonsware/android/activitymill/ActivityMill.java](#))

This class is registered in the manifest via `android:appComponentFactory`:

```
<?xml version="1.0" encoding="utf-8"?>
<manifest package="com.commonsware.android.activitymill"
    xmlns:android="http://schemas.android.com/apk/res/android">
```

## APPENDIX C: ANDROID 9.0

---

```
<application
  android:appComponentFactory=".ActivityMill"
  android:allowBackup="true"
  android:icon="@mipmap/ic_launcher"
  android:label="@string/app_name"
  android:roundIcon="@mipmap/ic_launcher_round"
  android:supportsRtl="true"
  android:theme="@style/AppTheme">
  <activity android:name=".MainActivity">
    <intent-filter>
      <action android:name="android.intent.action.MAIN" />

      <category android:name="android.intent.category.LAUNCHER" />
    </intent-filter>
  </activity>
</application>

</manifest>
```

(from [Introspection/ActivityMill/app/src/main/AndroidManifest.xml](#))

By overriding `instantiateActivity()`, we get control when the framework wants to instantiate `MainActivity`. If we chain to the superclass, normal instantiation occurs, and we crash with an `InstantiationException`. Instead, we call the `sockItToMe()` factory method and create the `MainActivity` instance that way, returning it. Then, it all works... on Android 9.0 and higher.

However, there are limitations and issues:

- This does not work on Android 8.1 and lower. So, either your `minSdkVersion` has to be 28 or higher, or you need to be able to support both cases where your `AppComponentFactory` creates the instance and cases where it does not.
- You cannot do a lot with the activity when you create it. For example, the sample app changes the title of the activity, which you can see in the action bar if you run the sample app. However, to make that work, we have to hold onto the title and apply it in `onCreate()`. If you try calling `setTitle()` before `onCreate()` — such as from the constructor — while nothing crashes, your change does not take effect. Similarly, any methods on `Activity` that require it to be fully configured as a `Context` (e.g., `getString()`) may not work reliably at this point.
- Depending on the nature of your changes, you may get superfluous complaints elsewhere. For example, in the sample app, Android Studio highlights the `.MainActivity` value of the `android:name` in `<activity>`, complaining that this class has no public zero-argument constructor. While

this is true, that is not a problem, as we are using an `AppComponentFactory`. Android Studio [does not know this](#) and so it complains.

### Indoor Positioning

Android 9.0 offers new classes, in the `android.net.wifi.rtt` package, for helping you determine the location of the device within a building, by estimating the distance from the device to a WiFi access point (AP). If you can get distance estimates from 3+ APs, you can use triangulation to come up with a position estimate relative to those APs.

This is designed for use by indoor mapping applications for large (typically public) buildings. Such buildings already have a number of APs to provide adequate WiFi coverage. APs rarely move, and so if you know where the device is relative to the APs, you can show the user on a map where they are within the building.

This feature requires compatible hardware. The Google Pixel, for example, supports this. However, it remains to be seen how many Android 9.0 models will support this feature. There is a new system feature — also called `android.hardware.wifi.rtt` — that you can use with `<uses-feature>` to filter out devices that lack support for it. Or, you can use `getPackageManager().hasSystemFeature(PackageManager.FEATURE_WIFI_RTT)` to determine at runtime whether these APIs should work.

### JobScheduler Additions

`JobInfo.Builder` has a few new options:

- `setEstimatedNetworkBytes()` provides a hint for how much bandwidth should be needed to execute this job. The idea is that jobs needing a lot of bandwidth may be postponed when the device has a lousy network connection, as excessive retries may chew up the battery.
- `setImportantWhileForeground()` is strange. Based on the docs, it appears as though it will relax some of the restrictions imposed by Doze mode, if your app happens to be in the foreground at the time of the job. Presumably this includes cases where the screen is off and your app was the last one to be in the foreground. Otherwise, if the screen is on and you are in the foreground, there should be no Doze restrictions in the first place.
- `setIsPrefetch()` indicates that this job is pre-fetching some data for the user. `JobScheduler` may adjust your job's timing as a result, either to invoke

it as part of launching your UI (e.g., if the user clicks on your launcher icon) or if there is a lot of spare bandwidth (even if that bandwidth is metered and you ordinarily try to avoid metered data).

- `setRequiredNetwork()` allows you to spell out the details of what sort of network connection that you need, based on capabilities and transport types, as defined by a `NetworkRequest`.

### StrictMode Callbacks

`StrictMode` has been around for years, and it serves as a useful tool for identifying bad behavior. In particular, it excels at pointing out I/O performed on the main application thread. `StrictMode` combines a set of detection rules (e.g., detect network I/O) and penalties (e.g., flash a red border on the screen). By default on API Level 11+, `StrictMode` is configured to check for network I/O on the main application thread and crash the app if such I/O is encountered. But, we can reconfigure this, and we often do, with different configurations for different scenarios. For example, crashing the app may be OK in a debug build, but it would be unwise in a release build.

Android 9.0 adds a new form of penalty: invoking a listener that you provide. In the absence of any other penalty, invoking your listener is all that happens when a `StrictMode` violation is encountered. You get a `Violation` object that identifies the problem, and you can handle it yourself, by whatever means you deem to be appropriate. Your app keeps running, so these `StrictMode` reports are advisories of bad behavior.

This has a few interesting use cases.

For testing, you might try to craft a listener that can match your violations with the test case. `penaltyLog()` logs the violations to LogCat, but it may be difficult to determine what test case triggered the violation. Your own code may be able to do this better. Plus, you might arrange to integrate this information into your test reporting framework.

Historically, we have been advised not to use `StrictMode` in production. Mostly, that is because all of the available penalties either harm the user (e.g., crashing the app) or have limited use (e.g., logging to LogCat, where we cannot then access the log). However, you might consider experimenting with using this new `penaltyListener()` approach to collect `StrictMode` violations in production and include them in your existing crash logging or analytics solution.

### Example: ACRA Reporting

For example, the [ACRA/StrictMode](#) sample application is based on the ACRA sample shown in [the chapter on ACRA](#). ACRA is a client-side library for collecting crash data, to send to the backend of your choice. The app's UI consists of a single Button, which, when clicked, will do something awful. In the original sample, it just threw a RuntimeException. In this sample, it attempts to get some information from the Internet on the main application thread, which is bad.

In our custom Application subclass — ACRAApplication — we not only configure ACRA, but we configure StrictMode as well:

```
package com.commonware.android.button;

@AcraCore(
    buildConfigClass = BuildConfig.class,
    reportFormat=StringFormat.JSON
)
@AcraHttpSender(
    uri=BuildConfig.ACRA_URL,
    httpMethod=org.acra.sender.HttpSender.Method.PUT
)
public class ACRAApplication extends Application {
    @Override
    protected void attachBaseContext(Context base) {
        super.attachBaseContext(base);

        if (BuildConfig.ACRA_INSTALL) {
            ACRA.init(this);
        }
    }

    @Override
    public void onCreate() {
        super.onCreate();

        new Handler().postAtFrontOfQueue(this::enableStrictMode);
    }

    private void enableStrictMode() {
        StrictMode.ThreadPolicy.Builder b=new StrictMode.ThreadPolicy.Builder()
            .detectNetwork()
            .penaltyListener(this::onThreadViolation, AsyncTask.THREAD_POOL_EXECUTOR);
```

## APPENDIX C: ANDROID 9.0

---

```
StrictMode.setThreadPolicy(b.build());
}

private void onThreadViolation(Violation violation) {
    ACRA.getErrorReporter().handleSilentException(violation);
}
}
```

(from [ACRA/StrictMode/app/src/main/java/com/commonsware/android/button/ACRAApplication.java](#))

In the `enableStrictMode()` method, we call `penaltyListener()`, which takes our `OnThreadViolationListener` (here in the form of a Java 8 method reference) and an `Executor`. The `Executor` will control what thread is used for invoking our listener. In this case, we are using the `THREAD_POOL_EXECUTOR` from `AsyncTask`, as that is already configured.

The listener gets a `Violation` object. That is a subclass of `Throwable`, and so you can treat it similarly to how you might treat an `Exception` object. In this case, we use `ACRA` to log this violation, via its `handleSilentException()` method.

We could use `penaltyDeath()`, and `ACRA` would pick up the violation there as well. However, that breaks the app, and a thrown `Exception` leaves your app in a somewhat precarious position. Instead, by using `penaltyListener()`, we can still record these violations, while the app continues to run (albeit perhaps with problems due to whatever bugs we have that are triggering the violations).

The downside of this approach is the potential of flooding. `penaltyListener()` reports each individual violation. Since the app is continuing to run, it may result in lots of violations in short order. The sample app's `Button` uses `URLConnection` on the main application thread:

```
public void earthShatteringKaboom(View v) {
    try {
        URL url=new URL("https://commonsware.com/Android/excerpt.pdf");
        HttpURLConnection c=(HttpURLConnection)url.openConnection();
        String mimeType=c.getHeaderField("Content-type");

        c.disconnect();

        Toast.makeText(this, "MIME type: "+mimeType, Toast.LENGTH_LONG).show();
    }
    catch (MalformedURLException e) {
        Log.e(getClass().getSimpleName(), "Who are you calling malformed?", e);
    }
    catch (IOException e) {
```

## APPENDIX C: ANDROID 9.0

---

```
Log.e(getClass().getSimpleName(), "Well, that's disappointing.", e);
}
```

(from [ACRA/StrictMode/app/src/main/java/com/commonsware/android/button/ButtonDemoActivity.java](#))

(where `earthShatteringKaboom()` is called when the Button is clicked, by means of an `android:onClick` attribute in the layout)

This little code snippet will result in several violations all being passed to the listener, for different phases of the HTTP request (e.g., DNS lookup, opening a socket connection to the HTTP server). Your listener — or other code that uses the resulting `Violation` objects — will need to take steps to ensure that you do not get overwhelmed with data. For example, you might come up with an algorithm that uses the stack trace (in the form of the `StackTraceElement` array in the `Violation`) to report unique violations, based on the first occurrence of your code in the stack trace.

### Example: Greylist Violation Reporting

As mentioned previously in this chapter, the use of hidden APIs is starting to be banned. You can find messages in LogCat about your use of such hidden APIs, whether directly or from libraries. However, those messages are merely simple LogCat entries, and they are easily missed. It would be nice to raise awareness of these things, but not to the point of crashing the app.

Another problem with the greylist LogCat entries is that they do not provide a full stack trace. They just say that a particular hidden API was invoked, not *where* it was invoked. This makes debugging such violations difficult.

By using the callback option with `StrictMode`, you can find out about the greylist violations and take your own steps. For example, as part of a test suite, you can collect the stack traces and log them someplace for later inspection. That is what the [StrictMode/GreyMarker](#) sample application does.

In the main source set, we have a class, named `BadHorse`, with some evil code:

```
package com.commonsware.android.strictmode.greymarker;

import java.lang.reflect.Field;

class BadHorse {
    static int getCloseButtonId() throws ClassNotFoundException,
        NoSuchFieldException, IllegalAccessException {
```

## APPENDIX C: ANDROID 9.0

---

```
Class<?> androidIdClass = Class.forName("com.android.internal.R$id");
Field closeButtonField = androidIdClass.getField("closeButton");

return closeButtonField.getInt(null);
}
}
```

(from [StrictMode/GreyMarker/app/src/main/java/com/commonsware/android/strictmode/greymarker/BadHorse.java](#))

We are looking up the value of an internal widget ID: the one used to identify the close button on toolbars.

This class is tested by the associated `BadHorseTest`:

```
}
```

(from [StrictMode/GreyMarker/app/src/androidTest/java/com/commonsware/android/strictmode/greymarker/BadHorseTest.java](#))

If you run that test individually and check LogCat, you will find a debug message about the greylist violation:

```
07-29 10:29:55.818 12481-12497/com.commonsware.android.strictmode.greymarker W/
mode.greymarke: Accessing hidden field Lcom/android/internal/R$id;->closeButton:I
(light greylist, reflection)
```

If, instead, you run the `GreylistSuite` in the instrumented tests, you will get a file written to `Android/data/com.commonsware.android.strictmode.greymarker/cache/__greylist/` on external storage, with a semi-random filename. If you copy that file (e.g., via Android Studio's Device File Explorer) and examine it, you will find that it contains a full stack trace showing where the greylist violation occurred:

```
android.os.strictmode.NonSdkApiUsedViolation: Lcom/android/internal/R$id;-
>closeButton:I
    at android.os.StrictMode.lambda$static$1(StrictMode.java:428)

at
android.support.test.runner.AndroidJUnitRunner.onStart(AndroidJUnitRunner.java:384)
at android.app.Instrumentation$InstrumentationThread.run(Instrumentation.java:2145)
```

This is much more useful than the one-line LogCat warning that we normally get. Plus, you could arrange to have your test Gradle tasks look for this file and take it into account with your test results.

GreylistSuite is a JUnit4 test suite, identifying the test classes that are part of the suite:

```
@RunWith(Suite.class)
```

## APPENDIX C: ANDROID 9.0

---

```
@Suite.SuiteClasses({BadHorseTest.class})
public class GreylistSuite {
```

(from [StrictMode/GreyMarker/app/src/androidTest/java/com/commonsware/android/strictmode/greymarker/GreylisSuite.java](#))

It has a `@BeforeClass` method that configures `StrictMode` to look for greylist violations and pass them to an `OnVmViolationListener` named `GREYLISTENER`:

```
@BeforeClass
public static void init() {
    if (Build.VERSION.SDK_INT >= Build.VERSION_CODES.P) {
        if (LOG_DIR.listFiles() != null) {
            for (File file : LOG_DIR.listFiles()) {
                if (!file.isDirectory()) {
                    file.delete();
                }
            }
        }
    }

    StrictMode.setVmPolicy(new StrictMode.VmPolicy.Builder()
        .detectNonSdkApiUsage()
        .penaltyListener(LISTENER_EXECUTOR, GREYLISTENER)
        .build());
}
}
```

(from [StrictMode/GreyMarker/app/src/androidTest/java/com/commonsware/android/strictmode/greymarker/GreylisSuite.java](#))

Here, `LOG_DIR` points to that directory on external storage, while `LISTENER_EXECUTOR` is just a single-thread thread pool:

```
private static final ExecutorService LISTENER_EXECUTOR = Executors.newSingleThreadExecutor();
private static File LOG_DIR =
    new File(InstrumentationRegistry.getTargetContext().getExternalCacheDir(), "__greylis");
```

(from [StrictMode/GreyMarker/app/src/androidTest/java/com/commonsware/android/strictmode/greymarker/GreylisSuite.java](#))

`GREYLISTENER` writes a file for each violation, using `SystemClock.uptimeMillis()` for the base of the filename:

```
private final static StrictMode.OnVmViolationListener GREYLISTENER =
    new StrictMode.OnVmViolationListener() {
        @Override
        public void onVmViolation(Violation violation) {
            LOG_DIR.mkdirs();

            String name = Long.toString(SystemClock.uptimeMillis()) + ".txt";
            File trace = new File(LOG_DIR, name);
```

## APPENDIX C: ANDROID 9.0

---

```
try {
    FileOutputStream fos=new FileOutputStream(trace);
    OutputStreamWriter osw=new OutputStreamWriter(fos);
    PrintWriter out=new PrintWriter(osw);

    violation.printStackTrace(out);
    out.flush();
    fos.getFD().sync();
    out.close();
}
catch (IOException e) {
    Log.e(TAG, "Exception writing trace", e);
}
}
};
```

(from [StrictMode/GreyMarker/app/src/androidTest/java/com/commonsware/android/strictmode/greymarker/GreylisSuite.java](#))

(this is a sloppy way to generate unique filenames, but it will suffice for the purposes of this sample)

There is a corresponding `@AfterClass` method that shuts down the thread pool:

```
@AfterClass
public static void term() {
    LISTENER_EXECUTOR.shutdown();

    try {
        LISTENER_EXECUTOR.awaitTermination(5, TimeUnit.SECONDS);
    }
    catch (InterruptedException e) {
        Log.e(TAG, "Saving stack traces took too long!", e);
    }
}
```

(from [StrictMode/GreyMarker/app/src/androidTest/java/com/commonsware/android/strictmode/greymarker/GreylisSuite.java](#))

Note that there is no good way to fail a test here. Even if you throw an exception from `onVmViolation()`, that does not fail a specific test, because `onVmViolation()` is not called synchronously from the test code. Instead, it is called using that thread pool, and so it is decoupled from the test execution itself.

Also note that this approach might collide with whatever `StrictMode VM` configuration that you might have in your actual app.

### WebView Improvements

WebView gains a couple of features in Android 9.0.

#### Disabling It

Using WebView consumes a fair amount of RAM. Unfortunately, particularly if you are using third-party libraries, it may be difficult to determine if you are using WebView and, more importantly, *what* is triggering WebView to be loaded into your process.

To that end, Android 9.0 offers a static `disableWebView()` method on `WebView`. As the British like to say, `disableWebView()` “does what it says on the tin”: it disables access to `WebView` in this process. If you try using `WebView`, you will crash with an `IllegalStateException`:

```
Caused by: java.lang.IllegalStateException: WebView.disableWebView() was called:
WebView is disabled
```

```
    at android.webkit.WebViewFactory.getProvider(WebViewFactory.java:249)
    at android.webkit.WebView.getFactory(WebView.java:2648)
    at android.webkit.WebView.ensureProviderCreated(WebView.java:2643)
    at android.webkit.WebView.setOverScrollMode(WebView.java:2708)
    at android.view.View.<init>(View.java:4792)
    at android.view.View.<init>(View.java:4932)
    at android.view.ViewGroup.<init>(ViewGroup.java:654)
    at android.widget.AbsoluteLayout.<init>(AbsoluteLayout.java:55)
    at android.webkit.WebView.<init>(WebView.java:659)
    at android.webkit.WebView.<init>(WebView.java:604)
    at android.webkit.WebView.<init>(WebView.java:587)
    at android.webkit.WebView.<init>(WebView.java:574)
```

For a debug build, crashing the app is a very obvious sign that you are using `WebView` somewhere that you should not be. For a release build, though, crashing your code is fairly user-hostile — the user is often better served by your app just using more memory. Hence, `disableWebView()` is the sort of thing that you may want to use only in debug builds, perhaps in tandem with a `penaltyDeath()` `StrictMode` configuration.

#### Tracing It

Android 9.0 offers `TracingController`. This allows you to enable you to collect tracing data about what is going on in the `WebView` instances in your process. That

## APPENDIX C: ANDROID 9.0

---

trace can be written to a file and examined in Chrome Dev Tools.

For ordinary Android developers, this is not especially useful. For seasoned Web developers — those for whom navigating `chrome://tracing/` is perfectly normal — this tracing might be very useful for identifying specific performance issues with WebView-enabled apps. In particular, developers of hybrid apps (or maintainers of hybrid app frameworks) might relish the ability to get this data.

The [WebKit/Tracing](#) sample application is a trivial WebView-based app that just loads [the CommonsWare home page](#), but also enables tracing:

```
package com.commonware.android.browser1;

import android.app.Activity;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.Handler;
import android.webkit.TracingConfig;
import android.webkit.TracingController;
import android.webkit.WebView;
import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.util.concurrent.Executors;
import static android.webkit.TracingConfig.CATEGORIES_WEB_DEVELOPER;

public class BrowserDemo1 extends Activity {
    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
        setContentView(R.layout.main);

        TracingController.getInstance()
            .start(new TracingConfig.Builder()
                .addCategories(CATEGORIES_WEB_DEVELOPER)
                .build());

        ((WebView)findViewById(R.id.webkit)).loadUrl("https://commonsware.com");
    }

    @Override
    protected void onDestroy() {
        File out=new File(getExternalFilesDir(null), "trace.json");

        try {
            TracingController.getInstance().stop(new FileOutputStream(out),
```

## APPENDIX C: ANDROID 9.0

---

```
        AsyncTask.THREAD_POOL_EXECUTOR);
    }
    catch (FileNotFoundException e) {
        e.printStackTrace();
    }

    super.onDestroy();
}
}
```

(from [WebKit/Tracing/app/src/main/java/com/commonsware/android/browser/BrowserDemo.java](#))

In `onCreate()` of our activity, before we do anything with the `WebView`, we set up tracing. To do that, call `TracingController.getInstance()` to get the singleton instance of `TracingController`. Then, call `start()` on the controller, passing in a `TracingConfig` to describe the tracing that you want.

A `TracingConfig` instance is created through a `TracingConfig.Builder`, following the typical builder pattern: call a series of configuration methods on the builder, then call `build()` to build the result. There are two methods of note on `TracingConfig.Builder` that you can use to tailor the behavior of the tracing:

- `addCategories()` controls the particular events that are recorded. The sample app uses `CATEGORIES_WEB_DEVELOPER` for a general-purpose set of events, but there are more fine-grained categories that you can choose from.
- `setTracingMode()` controls how much data is recorded. The default is `RECORD_CONTINUOUSLY`, which uses a ring buffer to cap the amount of memory that is used. This will allow you to collect around 64K events. If you need more than that, you can use `RECORD_UNTIL_FULL`, which will record until you run out of system RAM... but running out of system RAM is not a good thing.

At this point, all `WebView` instances should record tracing data. This is buffered in system RAM until you are done tracing, at which point you call `stop()` on the `TracingController` singleton. `stop()` takes two parameters:

- An `OutputStream` to use for writing the results. The sample app writes a file to external storage, but so long as you can create a valid `OutputStream`, in principle the exact output location is up to you.
- An `Executor` to supply the thread for this I/O. Here, the sample app uses the existing `ThreadPoolExecutor` used by `AsyncTask`, so we do not add more threads to our app.

## APPENDIX C: ANDROID 9.0

You can then get the resulting trace file off the device or emulator, such as by using the Device File Explorer in Android Studio. In a copy of Chrome or Chromium, visit `chrome://tracing/`, click the “Load” button, and choose the trace file. At that point, you will get... something that an expert Web developer might be able to use:

Figure 1095: Chrome Dev Tools, Showing Tracing Results

### Autofill Service Detection

Apps can now find out what autofill service the user has chosen, if any, via [getAutofillServiceComponentName\(\) on AutofillManager](#). This would be useful if your app wants to have a whitelist of trusted autofill services that you are willing to use, blocking autofill if the user chose one that you do not recognize.

For example, if you have the default Google-supplied autofill service enabled, `getAutofillServiceComponentName()` will return a `ComponentName` that identifies the service as `com.google.android.gms/com.google.android.gms.autofill.service.AutofillService`.

### Storage Volume Action

The Settings app now has an area where users can control whether apps have access to removable storage volumes, such as access requested by `createAccessIntent()` on `StorageVolume`. As a developer, you can lead the user to this screen by starting an activity for the `Settings.ACTION_STORAGE_VOLUME_ACCESS_SETTINGS` Intent action.

## KeyEvent Fallback Processing

There are now two tiers of `KeyEvent` processing available to `View`. The original set of options include:

- The `onKey...()` family of methods that `View` subclasses can override, such as `onKeyDown()`
- `setOnKeyListener()`, for an outside party to find out about `KeyEvents` delivered to the `View`

Android 9.0 adds an `addOnUnhandledKeyListener()`, for an outside party to register a “fallback”-grade listener.

The `OnUnhandledKeyListener` that you supply to `addOnUnhandledKeyListener()` will receive any key events that are not consumed by `onKey...()` or a registered `OnKeyListener`. The `OnUnhandledKeyListener` is supposed get a chance at the events before the `Activity` does (e.g., via its `onKeyDown()` method).

It is unclear what the use case will be for this.

## Magnifier

There is a `Magnifier` class, tersely described as “Android magnifier widget”. From the name, it would appear that the point is for it to magnify something.

The [Basic/Magnifier](#) sample application is a clone of the `Basic/Image` sample shown in [the chapter on basic widgets](#). However, this time, we attach a `Magnifier` to the `ImageView` when the user clicks on it:

```
package com.commonware.android.image;

import android.app.Activity;
import android.os.Bundle;
import android.widget.ImageView;
import android.widget.Magnifier;

public class ImageViewDemo extends Activity {
    ImageView icon;

    @Override
    public void onCreate(Bundle state) {
        super.onCreate(state);
    }
}
```

## APPENDIX C: ANDROID 9.0

---

```
setContentView(R.layout.main);

icon=findViewById(R.id.icon);

icon.setOnClickListener(view -> {
    Magnifier mag=new Magnifier(icon);

    mag.show(icon.getWidth()/2, icon.getHeight()/2);
});
}
```

(from [Basic/Magnifier/app/src/main/java/com/commonsware/android/image/ImageViewDemo.java](#))

Note that you cannot set up the `Magnifier` right away in `onCreate()`. At that point, while the Java object for a widget has been set up, the widget has not been attached to the activity's window. Your attempt to create the `Magnifier` will crash. Instead, either wait for user input or use a `ViewTreeObserver` to find out when the widget has been attached.

There is very little one can do with a `Magnifier`, at least at present:

- You create one by passing in the widget that (presumably) is supposed to be magnified
- You call `show()` on the `Magnifier`, passing a location within the bounds of the widget where the magnified area is to be shown
- You call `dismiss()` to get rid of the `Magnifier`
- You can call `update()` on the `Magnifier` to have it grab fresh content from the widget

However, you have no means of controlling the size, the magnified area, or anything else about the `Magnifier`. Worse, the `Magnifier` itself does not respond to user input: the user cannot move, pan, or otherwise manipulate it. It just sits there.

And, it does not magnify much:

*Figure 1096: A Magnifier, Magnifying... Not Much*

## Notes About the Support Library

As with every Android platform release, there is an accompanying release of the Android Support Library. Some of this simply updates those artifacts to be compatible with changes in the new platform release. Some of the new platform features might be available as a backport. And, usually, there are other changes as well, as the Library evolves.

### Package Names

For new classes, Google is adopting `androidx` as the top-level package identifier, as opposed to `android.support`. So, for example, while `RecyclerView` is in the `android.support.v7.widget` package, new classes related to `RecyclerView` may wind up in the `androidx.recyclerview` package (or sub-packages).

### Further Library Subdivision

Ideally, you use focused dependencies in your project, rather than larger ones like `support-v4`, `support-v13`, etc. While ProGuard and similar tools can remove excess stuff from your project, it cannot do a perfect job of that. All else being equal, it is better to have smaller dependencies to start with, rather than assuming that tools can remove everything that you are not using.

The Support Library started offering smaller dependencies a few years ago, with `support-core-utils`, `support-core-ui`, `support-compat`, `support-fragment`, and others being split out from the original `support-v4` artifact. While you can continue referring to `support-v4`, it just pulls in a lot of other smaller artifacts via transitive dependencies. Ideally, you just use the subset of those other dependencies that you really need.

The next major release of the Support Library will further subdivide `support-core-utils`, `support-core-ui`, `support-compat`, and `design` into yet smaller artifacts. In this case, it appears that some classes will remain in their original artifacts, while others get moved into smaller transitive dependencies. Once again, ideally, you use the most-focused dependencies that support what you need, to reduce your APK size.

### RecyclerView Selection

Major classes in the `AdapterView` hierarchy had the notion of item selection. For example, you could have `single-select` or `multiple-select` `ListView` widgets. `RecyclerView` did not offer anything for this, dumping it on developers' laps to come up with a way to implement it. This book has a few examples of how to do this... and those examples will be obsolete by late 2018.

That is because the Support Library *finally* is offering classes to help with item selection in `RecyclerView`. It will assist with multiple modes of user input (touch, mouse, keyboard), including “rubber-band” selection with mice. However, since `RecyclerView` itself does not know how to render item selection, that part will be up to you.

Once the 28.x.x edition of the Support Library ships in final form, this book will switch to coverage of this new `recyclerview-selection` artifact and its classes, in lieu of the book's “home grown” selection examples.

### New Design Widgets

The design library is adding a new wave of widgets, including an official Google implementation of the “chips” pattern. Unfortunately, these are undocumented at this time.

### Getting Help with 9.0

If you have issues with the Android 9.0, you can:

- Turn to [Stack Overflow](#)
- Use the [issue tracker](#)

# Appendix D: Community Theater and the Appinars

---

In addition to the book chapters themselves and [the related source code for the sample apps](#), you also have access to “appinars”. Appinars are app-based training, blending video, slides with voiceovers, source code samples, and more.

The APK edition of the book has an embedded appinar player, called Community Theater, along with an embedded roster of available appinars. You can browse through those appinars, download the ones of interest, and play them through Community Theater.

Note that this feature is only available if you are using the APK edition on Android 4.4 or higher.

## Viewing the Appinar Roster

In the main book reader, the action bar overflow has a “Community Theater” option:

*Figure 1097: Book Reader, Showing Overflow*

## APPENDIX D: COMMUNITY THEATER AND THE APPINARS

---

Tapping that will bring up a roster of available appinars, broken down into categories:

*Figure 1098: Appinar Roster, Showing Categories and Appinars*

Tapping an appinar brings up details for that appinar:

*Figure 1099: Appinar Roster, Showing Appinar Details*

New appinars will be added with each book update. Existing appinars might be updated to reflect new content or to fix egregious bugs.

## Managing Appinars

Tapping the “download” action bar item will download the appinar to your machine. The approximate amount of data to be downloaded, in the form of a ZIP file, is shown above the button.

## APPENDIX D: COMMUNITY THEATER AND THE APPINARS

---

While the download is going on, a progress bar will be visible in the appinar detail screen, as well as in a notification:

*Figure 1100: Appinar Roster, While Appinar is Downloading*

## APPENDIX D: COMMUNITY THEATER AND THE APPINARS

---

Once the appinar is downloaded, the action bar will have options to play or delete the appinar:

*Figure 1101: Appinar Roster, Showing Downloaded Appinar*

## APPENDIX D: COMMUNITY THEATER AND THE APPINARS

---

Tapping the delete action bar item will bring up a confirmation panel:

*Figure 1102: Appinar Roster, Showing Delete Confirmation*

If you confirm the request, the appinar will be deleted.

## Viewing an Appinar

Viewing an appinar is merely a matter of downloading it, then tapping the play button in the action bar. Playback should begin immediately, usually with a title slide followed by a brief opening video:

*Figure 1103: Player Screen, Showing a Balding Guy*

Eventually, when the appinar ends, you will be taken back to the roster of available appinars, where you were when you tapped the play button originally.

Note that while you can view the roster in portrait or landscape mode, playback is locked to landscape, due to the aspect ratio of the videos.

## Pausing Playback

If you double-tap the screen while an appinar is playing, playback will be paused. The action bar will appear at the top of the screen, allowing you to [navigate through the appinar](#) and so on.

To resume playback, press the BACK button, or double-tap the screen again.

## Navigating the Appinar

When playback is paused via a double-tap, and the action bar is visible, you can open a navigation drawer, via the “hamburger” icon in the action bar:

*Figure 1104: Player Screen, Paused, Showing the Navigation Drawer*

This contains a list of the different “scenes” of the appinar. Tapping on a scene will resume playback, jumping to that particular scene.

The action bar also has “fast-forward” and “rewind” buttons. The fast-forward button jumps to the next scene. The rewind button will start the current scene over from the beginning, if you are well into playback of the scene. If you are close to the start of the scene, the rewind button will take you to the previous scene.

## Manipulating the Content

Parts of the appinar may show full source code listings. You can use pinch-zoom gestures to change the font size, if the size is too small for your current display. Pinch-zoom gestures also work on some full-screen images, if the image is significantly larger than your display.

Most of the source code scenes, and a few others noted in the voiceovers, will have

“share” action bar items.

*Figure 1105: Player Screen, Paused, Showing Action Bar with Share Item*

When playback is paused and the action bar is visible, you can tap that share icon to view the source code (or Web page or other resource) in a separate app, or send the URL to the resource through some other app to another person or Web service (e.g., forward a URL via email or SMS).
